MAGNUS, HEINRICH GUSTAV (1802–1870), German chemist and physicist, was born at Berlin on May 2, 1802. His father was a wealthy merchant; and of his five brothers one, Eduard (1799–1872), became a celebrated painter. After studying at Berlin, he went to Stockholm to work under Berzelius, and later to Paris, where he studied for a while under Gay-Lussac and Thénard. In 1831 he returned to Berlin as lecturer on technology and physics at the university. As a teacher his success was rapid and extraordinary. His lucid style and the perfection of his experimental demonstrations drew to his lectures a crowd of enthusiastic scholars, on whom he impressed the importance of applied science by conducting them through the factories and workshops of the city; and he further found time to hold weekly "colloquies" on physical questions at his house with a small circle of young students. From 1827 to 1833 he was occupied mainly with chemical researches, which resulted in the discovery of the first of the platino-ammonum compounds ("Magnus's green salt" is $Pt(NH_3)_2Cl_2$) of "sulphovinic," "ethionic" and "isethionic" acids and their salts, and, in conjunction with C. F. Ammermueller, of periodic acid. Among other subjects at which he subsequently worked were the absorption of gases in blood (1837–1845), the expansion of gases by heat (1841–1844), the vapour pressures of water and various solutions (1844–1854), thermo electricity (1851), electrolysis (1856), induction of currents (1858–1861), conduction of heat in gases (1860), and polarization of heat (1866–1868). From 1861 onwards he devoted much attention to the question of diathermancy in gases and vapours, especially to the behavior in this respect of dry and moist air, and to the thermal effects produced by the condensation of moisture on solid surfaces.

In 1834 Magnus was elected extraordinary, and in 1845 ordinary professor at Berlin. He was three times elected dean of the faculty, in 1847, 1858 and 1863; and in 1861, rector magnificus. His great reputation led to his being entrusted by the government with several missions; in 1865 he represented Prussia in the conference called at Frankfort to introduce a uniform metric system of weights and measures into Germany. For forty-five years his labour was incessant; his first memoir was published in 1825 when he was yet a student; his last appeared shortly after his death on April 4, 1870. In 1840 he married Bertha Humblot by whom he left a son and two daughters.

See *Allgemeine deutsche Biog.* The Royal Society's *Catalogue* enumerates 84 papers by Magnus, most of which originally appeared in *Poggendorff's Annalen.*

MAGNUS, SIR PHILIP (1842–1933), English educator, was born in London on Oct. 7, 1842. He was educated at University college, London, from which institution he graduated with first class honours in arts and science. After lecturing on applied mathematics at various institutions he served the London institute from 1880 to 1915 as organizing director and secretary of city and guilds and after 1888 as superintendent and secretary of the institute's technology department. He was president of the Council of College Preceptors and from 1881 to 1884 a member of the Royal Commission on Technical Instruction. He was knighted in 1886. He died on Aug. 29, 1933. His published works include *Hydrostatics and Pneumatics; Industrial Education; Educational Aims and Efforts.* He was editor of *Education Library* and joint-editor of *London Science Class-books.*

MAGNUSSON, ARNI (1663–1730), Icelandic historian and antiquarian, was born in Vestland, Iceland, on Nov. 13, 1663, and died at Copenhagen on Jan. 6, 1730. He studied theology at Copenhagen, and in 1696, on his return from a visit to Germany, was appointed to the post of secretary of the secret archives. In

1701 he was elected professor of Danish antiquities and the next year was sent on a royal mission to Iceland, where he stayed ten years, collecting documents relative to the history of that country which he bequeathed to the university of Copenhagen.

Magnusson's most important works are *Incerti auctoris Chronica Danorum, et praecipue Islandiae* (Leipzig, 1695); and *Testamentum Magni regis Norvegiae* (Copenhagen, 1719). *See* also his letters, *Arne Magnusson's Private Brevveksling* (Copenhagen, 1920).

MAGNY, CLAUDE DRIGON, Marquis De (1797–1879), French heraldic writer, was born in Paris. After being employed for some time in the postal service, he devoted himself to the study of heraldry and genealogy, his work in this direction being rewarded by Pope Gregory XVI with a marquisate. He founded a French college of heraldry, and wrote several works on heraldry and genealogy, of which the most important were *Archives nobiliaires universelles* (1843) and *Livre d'or de la noblesse de France* (1844–52). His two sons, Edouard Drigon and Achille Ludovice Drigon, respectively comte and vicomte de Magny, also wrote several works on heraldry.

MAGO, the name of several Carthaginians. (1) The reputed founder of the military power of Carthage, *fl.* 550–500 B.C. (Justin xviii. 7, xix. 1). (2) The youngest of the three sons of Hamilcar Barca. He accompanied Hannibal into Italy, and held important commands in the great victories of the first three years. After the battle of Cannae (216 B.C.) he sailed to Carthage to report the successes gained. He was about to return to Italy with strong reinforcements for Hannibal, when the government ordered him to go to the aid of his other brother, Hasdrubal, who was hard pressed in Spain. He carried on the war there with varying success in concert with the two Hasdrubals until, in 209, his brother marched into Italy to help Hannibal. Mago remained in Spain with Hasdrubal, the son of Gisco. In 207 he was defeated by M. Iunius Silanus, and in 206 the combined forces of Mago and Hasdrubal were scattered by Scipio Africanus in the decisive battle of Silpia. Mago maintained himself for some time in Gades, but afterwards received orders to carry the war into Liguria. He wintered in the Balearic isles, where the harbour Portus Magonis (Port Mahon) still bears his name. Early in 204 he landed in Liguria, where he maintained a desultory warfare till in 203 he was defeated in Cisalpine Gaul by the Roman forces. Shortly afterwards he was ordered to return to Carthage, but on the voyage home he died of wounds received in battle.

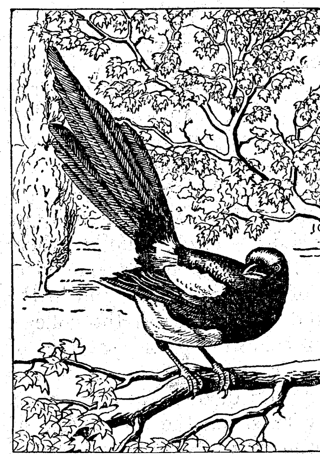
See Polybius iii.; Livy xxi.–xxiii.; xxviii.; chs. 23–37; xxix., xxx.; Appian, *Hispanica,* 25–37; T. Friedrich, *Biographie des Barkiden Mago;* H. Lehmann, *Der Angriff der drei Barkiden auf Italien* (Leipzig, 1905); and further J. P. Mahaffy, in *Hermathena,* vii. 29–36 (1890).

(3) The name of Mago is also attached to a great work on agriculture which was brought to Rome and translated by order of the senate after the destruction of Carthage. The book was regarded as a standard authority, and is often referred to by later writers.

See Pliny, *Nat. Hist.* xviii. 5; Columella, i. 1; Cicero, *De oratore,* i. 58.

MAGPIE or **PIE,** a bird once abundant throughout Great Britain, but now much scarcer, though since the World War its numbers have increased. It did not reach Ireland until the 17th century, but is now common enough in that country. This species is extending its range where not molested.

In Norway, the magpie is very tame, nesting in the gardens even of town houses, but in Britain persecution has made it shy, and most people know it only as a captive in a wicker cage, where its vivacity and natural beauty are lessened or lost. At large, few European birds possess greater beauty, the pure white of its scapulars and inner web of the flight-feathers contrasting vividly with the deep glossy black on the rest of its body and wings, while its long tail is lustrous with green, bronze, and purple reflections. The pie's nest is a wonderful structure, placed either in trees or bushes, and massively built. Its foundation consists of stout sticks, turf and clay, wrought into a deep, hollow cup, plastered with earth, and lined with fibres; but around this is erected a basket-like outwork of thorny sticks, forming a dome over the nest, and leaving a hole in the side for entrance and exit. Herein are laid from six to nine eggs, of a pale bluish-green freckled with brown and blotched with ash-colour. The magpie, in common with the raven, the jay, and many birds of prey, has a remarkable capacity, when its mate is killed, for obtaining a new mate within a day or two. In the case of the pie and the jay, a large gathering of birds of the species is said to appear on the scene, and apparently the new mate is selected from these.



BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY
THE MAGPIE (PICA PICA OR PICA RUSTICA)

The pie belongs to the crow family and is scientifically termed *Pica pica.* It inhabits Europe, North-west Africa and Asia, and is replaced in western North America by a sub-species. In California *P. nuttalli* is distinguishable by its yellow bill and the bare yellow skin round its eyes.

MAGWE, a district and division of Burma. In 1941 the division included the district of Thayetmyo, Minbu, Magwe, Pakôkku and Pakôkku hill tract and the Chin hills district. The district has an area of 3,724 sq.mi.; pop. (1941) 559,926. Magwe may be divided into two portions: the low, flat country in the west, forming part of the surrounding valley, and the undulating high forested ground in the east forming part of the Pegu Yomas, which at some parts reaches a height of 1,500 feet. In the heart of the district there is a low fertile plain which is about 45 mi. from north to south and as much as 30 mi. wide in places. The railway from Pyinmana runs through this plain and beyond. The chief streams are the Yin and the Pin, which form the northern boundary. The only perennial stream is the Yanpè. The annual rainfall averages about 27 inches. The maximum temperature rises to a little over 100° F. in the hot season, and falls to an average minimum of 53° F. and 54° F. in the cold season. Rice is the staple product, and considerable quantities are exported. Sesamum, maize, and millet are also cultivated, as well as cotton, while an important crop in the sandy soil is ground nuts (peanuts).

In this district are included the well-known Yenangyaung and Chauk oilfields. A block of 80 sq.mi. was demarcated by the government as the area of the Yenangyaung oilfields but only about 2 or 3 sq.mi. are occupied by the actual field and the bulk of the production has been from an area of only 1¼ sq.mi. The state lands were leased to the Burmah Oil company but two large blocks in the richest part (the Beme and Twingôn reserves) were reserved for the hereditary Burmese owners called twinsa. Although there are still some primitive hand-dug wells nearly all the native owners have sold their rights to companies operating with modern plant. Hence it is in these reserves that competition between the competing companies has been extraordinarily keen, though methods of working have been carefully and wisely supervised by government agents. There is now scarcely a well site of value left. The town of Yenangyaung had a pop. (1931) of 11,098. A great advance has been made in recent years by electrifying the field. The oil is sent by pipe line to the refineries at Syriam near Rangoon.

The town of MAGWE, on the Irrawaddy, is the headquarters of the district and of the division; pop. (1931) 8,209.

MAGYARS, the name of the people called in English, Hungarians. Though they have become physically assimilated to the western peoples, they belong in origin and language to the Finno-Ugrian (*q.v.*) division of the Alpo-Carpathian stock. Before World War I they formed barely half of the population of Hungary, but were by far the largest and most compact of all its racial groups. Magyar was the official language of Hungary, the official name of which (*Magyarország,* or "country of the Magyars") enshrined the Magyar claim to predominance. The Magyars themselves sometimes applied the name *Magyarország* to Hungary "proper," excluding Croatia-Slavonia, the whole kingdom being called *Magyarbirodalom,* the Magyar monarchy or realm.

Hungary, as constituted now, does not include the whole of the *Magyarország.* (W. A. P.)

MAHABALESHWAR or MALCOLMPETH, a hill station in Satara district, and the principal sanatorium in the Bombay presidency, India. Pop. (1941) 5,090. It is reached from Wathar railway station (39 m.) by motor from Poona (75 m.). Mahabaleshwar occupies the summit of a ridge of the Western Ghats, about 4,500 ft. above sea-level. It was established in 1828 by Sir John Malcolm, governor of Bombay, who obtained the site from the raja of Satara in exchange for another patch of territory. It lies higher and is therefore cooler than Matheran, but the rainfall (from 150 to 409 in. a year) is very heavy. The climate is pleasant, particularly from October to March.

MAHAFFY, SIR JOHN PENTLAND (1839–1919), Irish classical scholar, was born in Switzerland on Feb. 26, 1839, and was educated abroad and at Trinity college, Dublin, where he was professor of ancient history. In 1913 he became vice-provost, and in Nov. 1914, provost of Trinity college, and in the Irish rebellion (Easter 1916) directed the defence of the college. He was made a G.B.E. in 1918 in recognition of the services of the college during the World War. From 1911 to 1916 he was president of the Royal Irish Academy. He died on April 30, 1919. Some of his many works, especially those on the Silver Age of Greece, have become standard authorities. He also translated Fischer's *Commentary on Kant* (1866) and edited the Petrie Papyri in the *Cunningham Memoirs* (3 vols. 1891–1905).

BIBLIOGRAPHY.—His works include, besides those mentioned above; *History of Classical Greek Literature* (4th ed., 1903 *seq.*); *Social Life in Greece from Homer to Menander* (4th ed., 1903); *The Silver Age of the Greek World* (1906); *The Empire of the Ptolemies* (1896); *Greek Life and Thought from Alexander to the Roman Conquest* (2nd ed., 1896); *The Greek World under Roman Sway from Polybius to Plutarch* (1890); *An Epoch in Irish History, 1591–1660* (1904); *The Particular Book of Trinity College* (1904); *Plate in Trinity College* (1918). *See* obituary notices in *The Times* and in *Hermathena,* XLII. (1920), which contains a bibliography.

MAHAN, ALFRED THAYER (1840–1914), Rear-Admiral, American naval historian was born on Sept. 27, 1840 at West Point on the Hudson where his father was professor of military engineering. The boy's fancy was for the sea. He revelled in Marryat. Columbia college and the Naval academy at Annapolis qualified him for the United States navy in which he served forty years. He saw active service in the Civil war and when 21 designed a "mystery ship" and volunteered to command it. After being lecturer on naval history and strategy at the naval war college in 1885 he became its president. An indefatigable student with a prodigious memory, he steeped himself in the strategy of Jomini, Napoleon and Nelson and made critical analyses of the conclusive battles of the world on land and sea. *The Influence of Sea Power upon History, 1660–1783,* published in 1890 was inspired by a conviction that the historic significance of the control of the sea had never been fully revealed. It was followed in 1892 by *The Influence of Sea Power upon the French Revolution and Empire, 1793–1812.* These masterly works captured the imagination of naval men, statesmen and scholars and profoundly influenced the naval policy of the great powers. In breadth of vision and originality of treatment they were unrivalled. No previous writer had so convincingly established the dominating influence of sea power upon the destinies of nations. The famous trilogy was completed by *The Life of Nelson* in 1897. Mahan was acclaimed an authority upon naval strategy especially in Great Britain where his genius was first recognized. His doctrines may be said to have governed the naval political thought of the world. Degrees were conferred upon him by Oxford and Cambridge in 1894 and later by leading American Universities. He commanded the cruiser "Chicago" in European waters 1893–1895 and was accorded a notable reception in England and elsewhere. Mahan served on the naval War Board during the Spanish-American War of 1898 and as delegate to the Hague Peace conference 1899. President Roosevelt declared "There is no question you stand head and shoulders above the rest of us." He was in 1900 awarded the Chesney Gold Medal for his three masterpieces, which were translated into several foreign languages. He was president of the American Historical Association in 1902 and chairman of a commission on naval affairs in 1908. Mahan possessed historic insight and the mind of a statesman. Calm impartiality governed his conclusions. He excelled as a strategist rather than as a tactician. His chief aim was to make clear the paramount importance of the sea as a decisive factor in history. He analysed the elements of sea power in all its bearings, military, national, territorial and commercial. With masterly touch he dissected the strategic features of the Caribbean. He stressed the interdependence of the military and commercial control of the sea and confirmed the doctrine that commerce dominates war. In *The Interests of America in Sea Power* 1897 and in most of his twenty volumes he sought to arouse his countrymen to a realisation of their maritime responsibilities. His doctrines stimulated the growth of navies between 1900 and 1914. The extreme views of the "Fleet in Being" School he considered unsound. He doubted the infallibility of arbitration in international disputes. He consistently advocated a solid understanding between Great Britain and America. In Anglo-American naval supremacy he saw the surest hope of peace. His writings abound in appreciations of the British navy. He foresaw the menace to the United States in the attempt to cripple Britain's naval power by the proposal to grant immunity from capture to sea-borne belligerent commerce in time of war. With steadfast courage against powerful political opposition he persistently condemned this proposal. In timely warnings to Britain in 1910 he foreshadowed the events of 1914–1918. Discussion of sea power compels recourse to his works which are invaluable to students of international affairs. (*See* SEA POWER.) Mahan married in 1872 Ellen Lyle Evans. He died on Dec. 1, 1914, having foretold the defeat of the Central powers and the surrender of the German navy. He was a deeply religious man, high-minded, chivalrous and unassuming. As an exponent of sea power he had no peer in the annals of literature.

For complete list of works and bibliography *see* Charles Carlisle Taylor *The Life of Admiral Mahan* (1920). (C. C. TAY.)

MAHANADI ("The Great River"), river, India. It rises in 20° 10′ N., 82° E., 25 m. S. of Raipur town, in the wild mountains of Bastar in the Central Provinces. At first an insignificant stream, taking a northerly direction, it drains the eastern portion of the Chhattisgarh plain, then a little above Seorinarayan it receives its first great affluent, the Seonath; thence flowing for some distance due E., its stream is augmented by the drainage of the hills of Uprora, Korba, and the ranges that separate Sambalpur from Chota Nagpur. At Padampur it turns towards the south, and struggling through masses of rock, flows past the town of Sambalpur to Sonpur. From Sonpur it pursues a tortuous course among ridges and rocky crags towards the range of the Eastern Ghats, which it pierces by a gorge overlooked by forest-clad hills. Since the opening of the Bengal-Nagpur railway, the Mahanadi is little used for navigation. It reaches the Orissa delta at Naraj, about 7 m. west of Cuttack town; and after traversing Cuttack district from west to east, and throwing off numerous branches, it falls into the Bay of Bengal at False point by several channels.

The Mahanadi has an estimated drainage area of 50,000 sq.m., and its rapid flow renders its maximum discharge in time of flood second to that of no other river in India. During high floods over 1,500,000 cu.ft. of water pour every second through the Naraj gorge. In the dry weather the discharge dwindles to 500 cu.ft. per second in a normal year. Efforts have been made to husband and utilize the vast water supply thrown upon the Orissa delta during seasons of flood. Each of the three branches into which the parent stream splits at the delta head is regulated by a weir. The four canals which form the Orissa irrigation system irrigate 292,000 acres. Two take off from the Biropa weir, and one, with its branch, from the Mahanadi weir. A new canal to protect the Raipur district, with headworks at Rudri on the Mahanadi, which was in course of construction in 1926, will irrigate a further 300,000 ac. when completed.

MAHANOY CITY, a borough of Schuylkill county, Pennsylvania, U.S.A., 35 m. S.S.W. of Wilkes-Barre, in the shadow of Broad mountain, at an altitude of 1,240 feet. It is served by the Lehigh Valley and the Reading railways. The population in 1940 was 13,442 (12% foreign-born white). Anthracite-mining is the dominant industry. There are iron works and shirt factories. The borough was incorporated in 1863.

MAHAR, the name of a servile caste in the Deccan, India. Their special function, apart from that of scavenger, is to act as village watchman, as guardian of the village boundaries, and as public messenger. In some parts they are also weavers of coarse cotton cloth.

MAHARAJPUR, a village in Gwalior state, Central India. Population 366. It was the scene of a battle (Dec. 29, 1843) in which Sir Hugh Gough, accompanied by the governor-general, Lord Ellenborough, defeated the insurgent army of Gwalior.

MAHAS: *see* BARABRA.

MAHĀVAṂSA, the *Great Chronicle,* a history of Ceylon from the 5th century B.C. to the middle of the 5th century A.D., written (6th cent.) in Pali verse by Mahānāma of the Dīghasanda Hermitage. In historical value it compares well with early European chronicles. In India proper the decipherment of early Indian inscriptions was greatly facilitated by data found in the Mahāvaṃsa. It was composed on the basis of earlier Sinhalese works, now lost, particularly one, also called the Mahāvaṃsa, written in Sinhalese prose with Pali memorial verse interspersed. The extant Pali work gives legends and the genealogy of the Buddha; a sketch of Indian history and an account of Indian Buddhism down to Asoka; a description of the sending out of missionaries after Asoka's council, especially of Mahinda to Ceylon; a sketch of the previous history of Ceylon; a long account of the reign of Devānam-piya Tissa, who received Mahinda, and established Buddhism in the island; short accounts of his successors down to Duṭṭha Gāmīin (Dadagamana or Dutegemunu); then a long account, amounting to an epic poem, of the career of that prince, who drove out the Tamil invaders; and notices of later kings. The Mahāvaṃsa was the first Pali book made known to Europe.

See *The Mahāvamsa,* ed. by Geo. Turnour (Colombo, 1837); ed. by W. Geiger (London, 1908); H. Oldenberg, introduction to his edition of the *Dīpavaṃsa* (London, 1879); O. Franke, in *Wiener Zeitschrift für die Kunde des Morgenlandes* (1907); W. Geiger, *Dīpavaṃsa und Mahāvaṃsa* (Leipzig, 1905, trans. by Ethel M. Coomaraswamy, Colombo, 1908), and *The Mahāvaṃsa* (Pali Text Society, 1912).

MAHĀYĀNA, the name of a development in the later schools of Buddhism, which taught special doctrines about the Buddhas and new metaphysical theories. It originated between the age of Asoka and the Christian era, but nothing of its rise or its authors is certainly known, as this period is one of the darkest of Indian history. The earliest indication of Mahāyāna as a school is found in the Gandhāra sculptures of the 1st century B.C., in which the bodhisattva ideal is prominent. Our actual knowledge is derived from the Mahāyāna sūtras themselves (some of them perhaps as early as the 1st century A.D.), and also from independent expositions by Mahāyāna teachers, the reports of Chinese pilgrims, and the polemical works of Hindu authors. *Yāna* means "career," but *mahāyāna* is usually translated "great vehicle," as the *Lotus* (ch. 3), one of the chief Mahāyāna sūtras, describes the careers taught by the different schools under the parable of the chariots, Mahāyāna being compared to a great bullock chariot, while the older schools are goat and deer chariots.

The older schools, the best known of which are the Theravādins (represented by the Pāli Canon) and the Sarvāstivādins, taught that all that the individual had to do was to follow out the teaching of Buddha and seek Nirvāna. Those who made this their immediate goal were the monks, the disciples (*śrāvaka*) who aimed at the state of arhat each for himself, hence the name of this teaching as *śrāvaka-yāna,* "vehicle of disciples." These old schools recognized also the possibility of attaining buddhahood, though it was not set forth as a practical aim. One who became a private buddha without publicly preaching was a pratyekabuddha and his career was the *pratyekabuddha-yāna.* Both these vehicles are mentioned together as *hīnayāna,* "low vehicle," but this term is extremely rare in the texts. It has become common among western writers owing to its use by the Chinese pilgrims.

Effect of New Doctrine.—The new doctrines did not contradict the older ideals, but supplemented them by teaching that each individual was potentially a Buddha. He should aim both at attaining Nirvāna for himself, and at becoming a Buddha, whereby he can preach to others and serve the welfare of all. One who makes this his goal is a bodhisattva, and sets out on a course of training by which through many rebirths he acquires great merit, and in the stages of his career attains in perfection six virtues known as *pāramitās.* Hence the Mahāyāna is also called the *bodhisattva-yāna.* The actual result of this teaching was not to transform all disciples into saviours, but to make the ordinary man look for salvation to certain great bodhisattvas, who by their accumulated merit save beings from hell, and assure rebirth in heaven to all those who devoutly repeat the name of their favourite bodhisattva. The success of the movement was in fact largely due to the scope it gave to the instincts of worship and religious devotion. These developments were doubtless due to contact with the popular Hindu religions. There was no longer any question as to whether the Buddha who has attained Nirvāna can be said to exist. He abides with other Buddhas in heavens at the ten points of space. This is an approach to the current Hindu polytheism. An approach to monotheism is found in some very late schools in the belief in one universal Buddha, but it is not the predominant doctrine. In the *Lotus* (ch. 15) Buddha declares that when the world becomes bad and unbelieving he manifests himself again. This is exactly the claim that Krishna makes in the *Bhagavadgītā.* But the leading Mahāyāna doctrine concerns bodhisattvas. The bodhisattvas, whatever their origin, are assimilated to current Hindu gods. Avalokiteśvara, one of the most popular of them, is said in the *Kāraṇḍavyūha* to take the form of Śiva, Vishnu, etc., in order to teach the doctrine to the worshippers of these gods. Another hinduizing feature is that of magic and magic formulas (*dhāraṇīs*) and the religious use of sexual symbolism in which each bodhisattva is provided with a female counterpart. The works dealing with this aspect are classed as Tantra. The use of magic is found in the earliest Buddhism, but it is not treated as part of the doctrine. In Tantrism the repetition of meaningless syllables is a means of acquiring merit, and the continuous repetition of Avalokiteśvara's name is enough to assure rebirth in heaven.

Metaphysical Teaching.—The metaphysical teaching of Mahāyāna is known as the doctrine of the void (*śūnyatā*). It is found chiefly in the class of sūtras known as *Prajñāpāramitā,* and is usually termed negativism or nihilism. There is no expounding or discussion in these works, and the method consists in dogmatically stating certain principles or individual facts and then dogmatically denying them or asserting the contrary. The statements are represented as being uttered by Buddha and assented to or expanded by one of the great bodhisattvas, and hence as needing no justification. Whether a coherent metaphysical system lay behind them is not clear. The real metaphysic of Mahāyāna lies in the systems based on the doctrine of the void by Mahāyāna teachers. They sought to find an absolute not merely as ultimate goal, but as a cosmical principle. For Aśvaghosha (1st century A.D.) this was *tathatā* "suchness." His chief philosophical work, *The Awakening of Faith,* is known only through a Chinese translation. The most developed system is that of Nāgārjuna, who is usually placed in the 2nd century A.D. In his system the doctrine of the void becomes a doctrine of relativity. The truth of no individual fact can be asserted because nothing is real apart from the whole. The system is known as Śūnyavāda or Mādhyamika. The system of Asanga and Vasubandhu (5th century A.D.) is known as Yogāchāra or Vijñānavāda, in which everything is denied except consciousness (*vijñāna*). It is thus a system of subjective idealism. These two latter systems are important for the history of Indian philosophy, as they receive elaborate refutations in the commentaries on the orthodox philosophical sūtras, and the vedānta doctrine of māyā, cosmical illusion, has evidently adopted some of the principles of vijñānavāda.

BIBLIOGRAPHY.—The most representative of the Mahāyāna sūtras is the *Saddharmapuṇḍarīka* (St. Petersburg [Leningrad], 1912; trans. by

Kern, Oxford, 1884, in French by Burnouf as *Le Lotus de la bonne loi,* Paris, 1852); *Mahāyāna Texts* contains translations of *Vajracchedikā Prajñāpāramitā* and of several sūtras by Max Müller and others illustrating the worship of bodhisattvas. The most important work on Nāgārjuna's system is T. Stcherbatsky, *The Conception of Buddhist Nirvāna* (Leningrad, 1927); *cf.* A. B. Keith, *Buddhist philosophy* (1923); and D. T. Suzuki, *Outlines of Mahāyāna Buddhism* (1907). Later schools have developed in China and Japan. *See* Yamakami Sōgen, *Systems of Buddhistic Thought* (Calcutta, 1912).

(E. J. T.)

MAHDI (Arab. "he who is guided aright"), a title assumed by the third Abbasid caliph (*see* CALIPHATE). According to Moslem traditionists Mohammed declared that one of his descendants, the Imam of God, who would fill the earth with equity and justice, would bear the name of al-mahdi. The Sunnis hold that this mahdi has not yet appeared. The name of mahdi is also given by the Shiites to the last of the Imams of the house of Ali, who disappeared mysteriously about 874. It was under the name of al-mahdi that Mokhtar proclaimed Ali's son Mohammed as the opponent of the caliph Abdalmalik and, according to Shahrastani, the doctrine of the mahdi, the hidden deliverer who is one day to appear and fill the oppressed world with righteousness, first arose in connection with a belief that this Mohammed had not died but lived concealed at Mount Radwā, near Mecca, guarded by a lion and a panther. The belief in the appearance of the mahdi readily lent itself to imposture. Of the many pretenders to this dignity known in all periods of Moslem history the most famous was the first caliph of the Fatimite dynasty in North Africa, Obaidallah al-Mahdi, who reigned from 909 to 933. After him was named the first capital of the dynasty, the once important city of Mahdia (*q.v.*). Another great historical movement, headed by a leader who proclaimed himself the mahdi (Mohammed Ibn Abdallah Ibn Tumart), was that of the Almohades (*q.v.*).

In 1881 Mohammed Ahmed Ibn Seyyid Abdullah (*q.v.*), a Dongolese, proclaimed himself al-mahdi and founded in the eastern Sudan the short-lived empire which was overthrown by an Anglo-Egyptian force at the battle of Omdurman in 1898. Concurrently with the claim of Mohammed Ahmed to be the mahdi the same title was claimed by, or for, the head of the Senussi, a confraternity powerful in many regions of North Africa.

BIBLIOGRAPHY.—J. Darmesteter, *The Mahdī* (1885); D. S. Margoliouth, *On Mahdis and Mahdiism* (Proceedings of the British Academy, vol. VII, 1916); I. Goldziher, *Vorlesungen über den Islam* (1925).

MAHDIA (also spelt *Mehdia, Mehedia,* etc.), a port of Tunisia, on the coast between the gulfs of Hammamet and Gabes, 47 mi. by rail S.S.E. of Susa. Pop. (1936) 8,488, of whom 511 were Europeans. Mahdia is built on a rocky peninsula which projects eastward about a mile beyond the normal coast line, and is not more than a quarter of a mile wide. The extremity of the peninsula is called Ras Mahdia or Cape Africa—Africa being the name by which Mahdia was designated by Froissart and other European historians during the middle ages and the Renaissance. In the centre of the peninsula and occupying its highest point is a citadel (16th century); another castle farther west is now used as a prison and is in the centre of the native town.

The European quarter and the new port are on the southwest side of the peninsula. The small artificial harbour is available for small boats only; steamers anchor in the roadstead about a quarter of a mile from the shore. On the southeast, cut out of the rock, is the ancient harbour, or *cothon.* There are manufactories of olive oil.

Mahdia occupies the site of a Phoenician settlement on which grew a Roman centre, name unknown. After the Arab conquest of North Africa the town fell into decay. It was refounded in 912 by the first Fatimite caliph, Obaidallah al-Mahdi, after whom it was named. It became the port for Kairawan and was for centuries a city of considerable importance, largely owing to its great natural strength and its position on the Mediterranean. It carried on an active trade with Egypt, Syria and Spain. The town was occupied by the Normans of Sicily in the 12th century, but after holding it for about 12 years they were driven out in 1159 by the Almohades. In 1390 a joint English and French force vainly besieged Mahdia for 61 days. In the early part of the 16th century the corsair Dragut seized the town and made it his capital, but in 1550 the place was captured by the Spaniards, who held it until 1574. Before evacuating the town the Spaniards dismantled the fortifications. Near to Mahdia, about 3 mi. to the northeast of the lighthouse, were found in the sea, in 1908, at a depth of 528 ft., the remains of an ancient galley, of Athenian construction, laden with objects of art, and sunk in the first century A.D. Beautiful statues of bronze and many fragments found by divers are gathered together in the Alaoui museum at Tunis.

MAHÉ, a French settlement in the Malabar district of Madras, India, situated in 11° 43′ N. and 75° 33′ E., at the mouth of a river of the same name. Area, 26 sq.mi.; pop. (1941) 14,092. It is the only French possession on the west coast of India, and is in charge of an administrator, subordinate to the governor-general at Pondicherry. It is now a decaying place, with no foreign trade, but has municipal and local councils, and representation in the general council at Pondicherry and the French *Chambre des députés,* etc.

MAHESHWAR, a town in Indore state, Central India, on the north bank of the Narbada (Nerbudda). Pop. (1931), 6,399. Though of great antiquity, and also of religious sanctity, it is chiefly noted as having been the residence of Ahalyā Bāī, the famous queen of the Holkar dynasty during the last half of the 18th century.

MAHI, a river of western India, which rises in central India and, after flowing through south Rajputana, enters Gujarat and falls into the sea by a wide estuary near Cambay; total length, 300 mi.; estimated drainage area, 16,000 sq.mi. It gave its name to the former Mahi Kantha agency of Bombay.

MAHI KANTHA, former agency, India: *see* SABAR KANTHA.

MAHILLON, VICTOR (1841–1924), Belgian musical scholar, was born at Brussels on March 10, 1841, the son of Charles Mahillon (1813–1877), the founder of the famous firm of wind instrument makers. As honorary curator of the museum of the Brussels conservatoire he got together a magnificent collection of old musical instruments, and had reproductions made of many more. His most important literary work, embodying the results of life-long research, is contained in the catalogues of the museum which he began in 1877.

MAH JONGG, a name given to a Chinese game which enjoyed great popularity in the United States, England and Australia 1922–26, and again in the United States after 1935. The game is played with bone- or ivory-faced tiles similar in construction to dominoes but bearing on their faces Chinese characters together with English index letters and numerals. These tiles were an important export item to China for several years. In 1923 Mah Jongg sets, mostly of Chinese manufacture, outsold radios in the United States, though the two items sold in the same price range.

No game closely resembling Mah Jongg appears in the records of early Chinese games, though cards or dominoes similarly marked were used in other games. The game which came to be known as Mah Jongg was probably of 19th-century origin. It was known by different names in China and each name was differently pronounced in the several Chinese dialects, so that any number of transliterations have been advanced—principally *ma tsiang, ma cheuk, ma tseuk* (hempen birds, or sparrows). W. H. Wilkinson of her majesty's consular service observed the game in China in the last quarter of the 19th century and caused a card game of like nature to be published in London in 1894, calling it Khanhoo; it was unsuccessful. Joseph P. Babcock, a U.S. resident in Shanghai, was another who observed the Chinese game and, in 1919, conceived a plan for its introduction to the United States. He modified the rules somewhat and added to the tiles index letters and numerals such as the ones to which western card players were accustomed. He coined and trademarked the term *mah jongg* as the announcement of the winner. He formed a company which bought sets manufactured to this design in China and exported them to the United States. However, so many other Chinese manufacturers exported sets under names devised to evade the trade-mark (including the simple change to *mah jong*) that Babcock's original company made only a small portion of the sets which were sold before the fad ended.

The extensive literature which grew out of the mah jongg fad engendered dozens of fantastic legends as to the origin and romantic history of the game. None of these stories was documented and apparently none was authentic. The striking feature of mah jongg is its resemblance to coon-can and rummy (*qq.v.*), which appeared contemporaneously with Khanhoo. There is some reason for thinking that the Chinese domino game inspired the occidental card games, but it could have been the other way around.

Pieces.—Modern mah jongg sets are usually made of synthetic resins ("plastics") instead of bone. A full mah jongg set contains 136 or 144 tiles. These are named and numbered as follows:

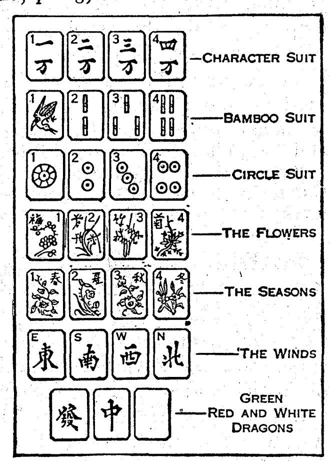
1. *Bamboos*, numbered 1 to 9, four of each number	36 tiles.
2. *Circles*, numbered 1 to 9, four of each number	36 tiles.
3. *Characters*, numbered 1 to 9, four of each number	36 tiles.
4. *Honours*, 4 red dragons, 4 green, 4 white dragons	12 tiles.
5. *Winds*, 4 east winds, 4 south winds, 4 west winds, 4 north winds	16 tiles.
	136 tiles.
In addition:—	
6. *Flowers and Seasons*, 4 of each or 8 of either	8 tiles.
	144 tiles.

The bamboos are often called *sticks*, the circles *dots*, the characters *cracks*. The set also includes two dice, a quantity of tokens used for scorekeeping and a rack for each player whereon he can place 14 tiles so that their faces will be visible only to himself.

Method of Play.—The usual game is for four, though variants have been devised for smaller and larger groups. The dice are thrown to assign one of the four "winds" or compass positions to each player. The tiles are shuffled face down, and a wall is built as a hollow square, two tiles high and 17 or 18 wide on each side (depending on whether the flowers are used).

East wind takes 14 tiles from the walls, and each other player 13; the order in which the tiles are taken is determined by throwing the dice. If the flowers are used, a flower in the hand is immediately *grounded* face up and another tile drawn to replace it.

The object is to form sets: *chow*, a sequence of three tiles in numerical order in the same suit; *pung*, three tiles of the same suit and rank, or three dragons of the same colour or three winds of the same direction; *kong*, a pung plus the fourth matching tile. The first player to hold four sets and a pair calls mah jongg and wins.



TILES OF COMMON SUITS AND HONOURS USED IN MAH JONGG

A full set contains 144 tiles, divided into 6 suits, but sometimes only 5 are used

East wind begins the play by discarding one tile, face up. Thereafter each player in rotation (which is counter-clockwise) draws either the last discard or a tile from the wall, then discards any one tile. Any player may claim the previous discard if it gives him a set; if two or more claim it, order of the precedence is: *woo* (ability to complete the hand with that tile); pung, kong, chow. As between equal claims, the player next in turn to play has precedence. A discard may be used only if it can at once be *grounded* (exposed face up on the table) as part of a set.

When a player wins, settlement is made on a schedule which assigns different values to different sets and combinations of sets. East wind always pays or collects double. Each player settles not only with the winner but also with each other player individually.

The style of play which became popular in the United States in the 1930s greatly complicated the schedule of values and made the play largely a matter of trying for the higher-scoring combinations.

There is a considerable element of skill to the play of mah jongg.

See J. P. Babcock, *Mah Jongg* (1920); Lee Foster Hartman, *Standardized Mah Jong*, (1924); E. S. Winters, *Ma Cheuk, as played by the Chinese* (1923); and on the later development of the game, Viola L. Cecil, *The New Mah Jongg* (1945).

MAHLER, GUSTAV (1860–1911), Austrian composer and conductor, was born at Kalischt, Bohemia, July 7, 1860. From 1885 onwards he conducted in Prague, Budapest, Hamburg and London, becoming director of the Vienna Opera in 1897. By unremitting zeal and tireless enthusiasm he brought the Viennese opera to a high state of perfection, but the strenuous work which he exacted from all earned him the name of "the tyrant" and made him many enemies, and in 1907 he was obliged to resign his post. He immediately received the offer of a conductorship in America, which he visited for three seasons, returning to Vienna in 1911, where he died on May 18. Mahler reflected to some extent in his works the classical tradition inherited from Schubert and Bruckner. In addition to his songs and chamber music, he wrote no fewer than nine symphonies, planned on a gigantic scale for an orchestra nearly doubled in strength.

See R. Specht, *Gustav Mahler*, etc. (1913); P. Stefan, *Gustav Mahler, a Study of his Personality and Work* (1913); G. Adler, *Gustav Mahler* (Vienna, 1916); P. Bekker, *Gustav Mahler's Sinfonien* (1921); R. Mengelberg, *Gustav Mahler* (Leipzig, 1923).

MAHLSTICK, a stick with a soft leather or padded head, used by painters to support the hand that holds the brush. The word is an adaptation of the Dutch *maalstok*, *i.e.*, the painter's stick, from *malen*, to paint.

MAHMUD I (1696–1754), sultan of Turkey, the son of Mustafa II, succeeded his uncle Ahmed III in 1730. After the suppression of a military revolt the war with Persia was continued with varying success, and terminated in 1736 by a treaty of peace restoring the *status quo ante bellum*. Turkey had next to face Russia, later joined by Austria. War went on for four years; the successes gained by Russia were outweighed by Austria's various reverses, terminating by the defeat of Wallis at Krotzka, and the peace concluded at Belgrade was a triumph for Turkish diplomacy. The sultan, throughout desirous of peace, is said to have been much under the influence of the chief eunuch, Haji Beshir Aga. In 1754 Mahmud died of heart-disease. He built numberless kiosques, where nocturnal orgies were carried on by him and his boon companions. In this reign the system of appointing Phanariote Greeks to the principalities of Moldavia and Walachia was instituted. (*See* PHANARIOTES.)

MAHMUD II (1785–1839), sultan of Turkey, was the son of Abdul-Hamid I, and succeeded his brother, Mustafa IV, in 1808. He had shared the captivity of his ill-fated cousin, the ex-sultan, Selim III, whose efforts at reform had ended in his deposition by the janissaries. The reforming efforts of the grand vizier Bairakdar, to whom he had owed his life and his accession, broke down on the opposition of the janissaries; and Mahmud had to wait for more favourable times. Meanwhile the empire seemed in danger of breaking up. In 1812 the war with Russia was closed by the Treaty of Bucharest, which restored Moldavia and the greater part of Wallachia to the Ottoman Government. But the terms of the treaty left a number of burning questions, both internal and external, unsettled; notably in the case of the claim of Russia to Poti and the valley of the Rion (Phasis), which was still outstanding at the time of the congress of Vienna (1814–15) and prevented the question of a European guarantee of the integrity of Turkey from being considered.

Meanwhile, within the empire, ambitious valis were one by one attempting to carve out dominions for themselves at the expense of the central power. The ambitions of Mehemet Ali of Egypt were not yet fully revealed; but Ali (*q.v.*) of Jannina, who had marched to the aid of the sultan against the rebellious pasha Pasvan Oglu of Widdin, soon began to show his hand, and it needed the concentration of all the forces of the Turkish empire to effect his overthrow and death (1822). The preoccupation of the sultan with Ali gave their opportunity to the Greeks whose disaffection had long been organized in the great secret society of the *Hetaeria Philike,* against which Metternich had in vain warned the Ottoman Government. In 1821 occurred the abortive raid of Alexander Ypsilanti into the Danubian principalities, and in May of the same year the revolt of the Greeks of the Morea began the war of Greek Independence. (*See* GREECE: *Modern History.*) The rising in the north was easily crushed; but in the south the Ottoman power was hampered by the defection of the sea-faring Greeks, by whom the Turkish navy had hitherto been manned.

After three abortive campaigns Mahmud was compelled, infinitely against his will, to summon to his assistance the already too powerful pasha of Egypt, Mehemet Ali, whom he had already employed to suppress the rebellious Wahhabis in Arabia. The disciplined Egyptian army, supported by a well organized fleet, rapidly accomplished what the Turks had failed to do; and by 1826 the Greeks were practically subdued on land, and Ibrahim was preparing to turn his attention to the islands. But for the intervention of the Powers and the battle of Navarino Mahmud's authority would have been restored in Greece. The news of Navarino betrayed Mahmud into one of those paroxysms of rage to which he was liable, and which on critical occasions were apt fatally to cloud his usual good sense. After in vain attempting to obtain an apology for "the unparalleled outrage against a friendly power" he issued on Dec. 20 a solemn *hatti sheriff* summoning the faithful to a holy war. This, together with certain outstanding grievances and the pretext of enforcing the settlement of the Greek Question approved by the Powers, gave Russia the excuse for declaring war against Turkey. After two hardly fought campaigns (1828, 1829) Mahmud was at length, on Sept. 14, 1829, compelled to sign the Peace of Adrianople.

From this moment until his death Mahmud was, to all intents and purposes, the "vassal of Russia," though not without occasional desperate efforts to break his chains. (For the political events of the period between the first revolt of Mehemet Ali [Sept. 1832] and the death of Mahmud *see* MOHAMMED ALI.) The personal attitude of the sultan, which alone concerns us here, was determined throughout by his overmastering hatred of the upstart pasha, of whom he had stooped to ask aid, and who now defied his will; and the importance of this attitude lies in the fact that, as the result of the success of his centralizing policy, and notably of the destruction of the janissaries (*q.v.*), the supreme authority, hitherto limited by the practical power of the ministers of the Porte and by the turbulence of the privileged military caste, had become concentrated in his own person.

This omnipotence of the sultan in deciding the policy of the Government was in striking contrast with his impotence in enforcing his views on his subjects and in his relations with foreign powers. Mahmud, in spite of—or rather because of—his well-meant efforts at reform, was hated by his Mussulman subjects and stigmatized as an "infidel" and a traitor to Islam. Mahmud's policy was the converse of that recommended by Machiavelli, viz., in making a revolution to change the substance while preserving the semblance of the old order. Metternich's advice to Mahmud to "remain a Turk" was sound enough. His failure to do so—in externals—left him isolated in his empire: *rayahs* and true believers alike distrusted and hated him. Of this hatred he was fully conscious; he knew that his subjects, even many of his own ministers, regarded Mehemet Ali as the champion of Islam against the "infidel sultan"; he suspected the pasha, already master of the sacred cities, of an intention to proclaim himself caliph in his stead. This, together with the weakness due to military reforms but recently begun, drove him to rely on the aid of Russia. The long tradition of French friendship for Turkey had been broken, in 1830, by the conquest of Algiers. Austria was, for the time, but the faithful ally of the tsar.

On Aug. 9, 1832, Mahmud made, through Stratford Canning, a formal proposal for an alliance with Great Britain, which Palmerston refused to consider for fear of offending France. Mahmud bitterly contrasted the fair professions of England with the offers of effective help from Russia. His old ally having deserted him, he accepted the aid of his hereditary foe. The Russian expedition to the Bosporus, the convention of Kutaiah, and the Treaty of Unkiar Skelessi (July 8, 1833) followed. Mahmud was under no illusion as to the position in which the latter placed him towards Russia; but his fear of Mehemet Ali and his desire to be revenged upon him out-weighed all other considerations. With his single aim in view he busied himself with the creation of a national militia, with the aid of Moltke and other German officers. In 1834 the revolt of Syria against Ibrahim seemed to give him his opportunity. He pleaded the duty of a sultan to go to the aid of his subjects when oppressed by one of his servants; but the Powers were obdurate, even Russia, much occupied in affairs nearer home, leaving him in the lurch.

Mahmud was astute enough to take advantage of the offence given to the Powers by Mehemet Ali's system of monopolies, and in 1838 signed with Great Britain, and afterwards with others, a commercial treaty which cut at the root of the pasha's system. A few months later his passionate impatience overcame his policy and his fears. The hand of death was upon him, and he felt that he must strike now or never. In vain the Powers, now united in their views, warned him of the probable consequences of any aggressive action on his part. On his sole initiative he sent instructions to Hafiz Pasha, commanding the Ottoman troops concentrated at Bir on the Euphrates, to advance into Syria. The fatal outcome of the campaign that followed he did not live to hear. When the news of Ibrahim's overwhelming victory at Nessib (June 24, 1839) reached Constantinople, Mahmud lay unconscious. He died early in the morning of July 1.

Mahmud II. cannot be reckoned among the great sultans, neither had he any of the calculating statecraft which characterized Abd-ul-Hamid II.; but his qualities of mind and heart, none the less, raised him far above the mass of his predecessors and successors. He was well versed in State affairs and loyal to those who advised and served him, personally brave, humane and kindly when not maddened by passion, active and energetic, and always a man of his word. Unhappily, however, the taint of the immemorial corruption of Byzantium had fallen upon him too, and the avenue to his favour and to political power lay too often through unspeakable paths. When he came to the throne the empire was breaking up from within; one by one he freed the provinces from the tyrannical rulers who, like Ali of Jannina, were carving out independent, or quasi-independent, empires within the empire. If he failed in his wider schemes of reform, it was because it is impossible to impose any system, however admirable, from above on a people whose deepest convictions and prejudices it offends.

There is a great deal of valuable material for the history of Mahmud and his policy in the unpublished Foreign Office records (1832–39), volumes of correspondence marked *Turkey.—From Sir Stratford Canning.—From Mr. Mandeville.—From Lord Ponsonby. See* further works mentioned under TURKEY: *History;* and MEHEMET ALI.

(W. A. P.; X.)

MAHMUD NEDIM PASHA (*c.* 1818–1883), Turkish statesman, was the son of Nejib Pasha, ex-governor-general of Baghdad. He was successively under-secretary of State for foreign affairs, governor-general of Syria and Smyrna, minister of commerce, and governor-general of Tripoli; minister successively of justice and of marine (1869); grand vizier in 1871 and 1872 and in 1875 and 1876. He was high in favour with Sultan Abd-ul Aziz and fell much under the influence of General Ignatiev, the forceful Russian ambassador, before the war of 1877–78, his subserviency to Russia earning for him in the nickname of "Mahmudoff." His administration was most unsuccessful, and he was largely responsible for the issue of the decree suspending the interest on the Turkish funds. He was minister of the interior from 1879 to 1883.

MAHMUD[1] OF GHAZNI (971–1030), son of Sabuktagīn, Afghan conqueror, was born on Oct. 2, 971. His fame rests on

[1]The name is strictly Maḥmūd.

his repeated invasions of India. His military capacity, inherited from his father, Nasir-ud-din Sabuktagīn, was strengthened by youthful experience in the field. Sabuktagīn, a Turki slave of Alptagīn, governor of Khurasan under Abdalmalik I. b. Nuḥ of the Samanid dynasty of Bukhara, early brought himself to notice. (*See* SAMANIDS.) He was raised to high office in the state by Alptagīn's successor, Abū Ishāk, and in A.H. 366 (A.D. 977), by the choice of the nobles of Ghazni, he became their ruler. He soon began to make conquests in the neighbouring countries, and in these wars he was accompanied by his young son Mahmud.

In 994 Mahmud was made governor of Khurasan, with the title of Saif addaula (ud-daula) ("Sword of the State") by the Sāmānīd Nūh II. Two years later, his father Sabuktagīn died in the neighbourhood of Balkh, having declared his second son, Ismail, who was then with him, to be his successor. As soon as Ismail had assumed the sovereignty at Balkh, Mahmud, who was at Nishapur, addressed him in friendly terms, proposing a division of the territories held by their father at his death. Ismail rejected the proposal, and was immediately attacked by Mahmud and defeated. Retreating to Ghazni, he there yielded, and was imprisoned, and Mahmud obtained undisputed power as sovereign of Khurasan and Ghazni (997).

The Ghaznevid dynasty is sometimes reckoned by native historians to commence with Sabuktagīn's conquest of Bost and Kosdār (978). But Sabuktagīn, throughout his reign at Ghazni, continued to acknowledge the Sāmānid suzerainty, as did Mahmud also, until the time, soon after succeeding to his father's dominions, when he received from Qādir, caliph of Baghdad (*see* CALIPHATE, C. § 25), a *khilat* (robe of honour), with a letter recognizing his sovereignty, and conferring on him the titles *Yamīn-addaula* ("Right hand of the State"), and *Amīn-ul-Millat* ("Guardian of the Faith"). From this time it is the name of the caliph that is inscribed on Mahmud's coins, together with his own new titles.

The new honours received from the caliph gave fresh impulse to Mahmud's zeal on behalf of Islam, and he resolved on an annual expedition against the idolaters of India. He could not quite carry out this intention, but a great part of his reign was occupied with his Indian campaigns. In 1000 he started on the first of these expeditions, but he went no farther than the hill country near Peshawar. Mahmud's army first crossed the Indus in 1001, opposed by Jaipāl, raja of Lahore. Jaipāl was defeated, and Mahmud, after his return from this expedition, is said to have taken the distinctive appellation of *Ghāzi* ("Valiant for the Faith"), but he is rarely so-called. On the next occasion (1005) Mahmud advanced, as far as Bhera on the Jhelum, when his adversary Anang-pāl, son and successor of Jaipāl, fled to Kashmir. The following year saw Mahmud at Multan. When he was in the Punjab at this time, he heard of the invasion of Khurasan by the Ilek Khan Nasr I. ruler of Transoxiana whose daughter Mahmud had married. After a rapid march back from India, Mahmud repelled the invaders. The Ilek Khan, having retreated across the Oxus, returned with reinforcements, and took up a position a few miles from Balkh, but was defeated by Mahmud.

Mahmud again entered the Punjab in 1008, this time for the express purpose of chastising Sēwah Pāl, who, having become a Mussulman, and been left by Mahmud in charge of Multan, had relapsed to Hinduism. The Indian campaign of 1009 was notable. Near the Indus Mahmud was opposed again by Anang-pāl, supported by powerful rajas from other parts of India. After a severe fight, Anang-pāl's elephants were so terror-struck by the fire-missiles flung amongst them by the invaders that they turned and fled, the whole army retreating in confusion and leaving Mahmud master of the field. Mahmud, after this victory, pushed on through the Punjab to Nagar-kōt (Kangra), and carried off much spoil from the Hindu temples to enrich his treasury at Ghazni. In 1011 Mahmud, after a short campaign against the Afghans under Mohammed ibn Sūr in the hill country of Ghur, marched again into the Punjab. The next time (1014) he advanced to Thanēsar between the Sutlej and the Jumna.

Before beginning his inroad into Hindustan he had to march north into Khwārizm (Khiva) against his brother-in-law Mamūn, who had refused to acknowledge Mahmud's supremacy. The result was as usual, and Mahmud, having committed Khwārizm to a new ruler, one of Mamūn's chief officers, returned to his capital. Then in 1018, with a very large force, he proceeded to India again, extending his inroad this time to the great Hindu cities of Mathra on the Jumna and Kanauj on the Ganges. He reduced the one, received the submission of the other, and carried back great stores of plunder. Three years later he went into India again, marching over nearly the same ground, to the support, this time, of the raja of Kanauj, who, having made friendship with the Mohammedan invader on his last visit, had been attacked by the raja of Kalinjar. But Mahmud found he had not yet sufficiently subdued the idolaters nearer his own border, between Kabul and the Indus, and the campaign of 1022 was directed against them, and reached no farther than Peshawar. Another march into India the following year was made direct to Gwalior.

The next expedition (1025) is the most famous of all. The point to which it was directed was the temple of Somnath on the coast of the Gujarāt peninsula. After an arduous journey by Multan, and through part of Rajputana, he reached Somnath, and met with a very vigorous but fruitless resistance on the part of the Hindus of Gujarāt. Moslem feet soon trod the courts of the great temple. The chief object of worship it contained was broken up, and the fragments kept to be carried off to Ghazni. For the more recent story of the Somnath gates *see* SOMNATH.

After the successes at Somnath, Mahmud remained some months in India before returning to Ghazni. Then in 1026 he crossed the Indus once more into the Punjab. His brilliant military career closed with an expedition to Persia, in the third year after this, his last, visit to India. The Indian campaigns of Mahmud and his father were almost, but not altogether, unvarying successes. The Moslem historians touch lightly on reverses. And, although the annals of Rajputana tell how Sabuktagīn was defeated by one raja of Ajmere and Mahmud by his successor, the course of events which followed shows how little these and other reverses affected the invader's progress. Mahmud's failure at Ajmere, when the brave raja Bisal-deo obliged him to raise the siege but was himself slain, was when the Moslem army was on its way to Somnath. Yet Mahmud's Indian conquests, striking and important in themselves, were, after all, in great measure barren, except to the Ghazni treasury. Mahmud retained no possessions in India under his own direct rule. But after the repeated defeats, by his father and himself, of two successive rajas of Lahore, the conqueror assumed the right of nominating the governors of the Punjab as a dependency of Ghazni, a right which continued to be exercised by seven of his successors. And for a time, in the reign of Masa'ud II. (1098–1114), Lahore was used as the residence of the reigning Ghaznevid sovereign.

Mahmud died at Ghazni in 1030, the year following his expedition to Persia. He is conspicuous for his military ardour, his ambition, strong will, perseverance, watchfulness and energy, combined with great courage and unbounded self-reliance. But his tastes were not exclusively military. His love of literature brought men of learning to Ghazni, and his acquaintance with Moslem theology was recognized by the learned doctors.

The principal histories of Mahmud's reign are—*Kitāb-i-Yamīnī* (Utbi); *Tarīkh-us-Subuktigīn* (Baihaki); *Tabakāt i Nasiri* (Minhāj el-Sirāj); *Rauzat-us-Safa* (Mir Khond); *Habīb-us-Sivar* (Khondamir). *See* Elliot, *History of India;* Elphinstone, *History of India;* and Roos-Keppel's translation of the *Tarīkh-i-Sultan Mahmūd-i-Ghaznavi* (1901).

MAHOBA, an ancient town in India, in Hamirpur district of the United Provinces. Pop. (1941) 17,224. As the capital of the Chandel dynasty, who ruled over Bundelkhand from the 9th to the 13th century, the neighbourhood is covered with architectural antiquities, prominent among which are artificial lakes, formed by banking up valleys with masonry dams. The largest of these is more than 4 m. in circuit.

MAHOGANY, a dark-coloured wood largely used for household furniture, the product of large trees of the genus *Swietenia* (Meliaceae), indigenous to Central America, northern South America and the West Indies. It was originally received from Jamaica; 521,300 ft. were exported from that island in 1753. The important commercial species of Central America is *S. macrophylla* while that of the West Indies is *S. mahagoni.* They bear compound leaves, resembling those of the ash, and clusters of small flowers, with five sepals and petals and ten stamens which are united into a tube. The fruit is a pear-shaped woody capsule, and contains many winged seeds. The most valuable product is the timber, first noticed by the carpenter on board Sir Walter Raleigh's ship in 1595 for its great beauty, hardness and durability. Dr. Gibbons brought it into notice as well adapted for furniture in the early part of the 18th century, and its use as a cabinet wood was first practically established by the cabinet-maker Wollaston, who was employed by Gibbons to work up some mahogany brought to England by his brother. It was introduced into India in 1795, and is now cultivated in Bengal and as far north as Saharanpur.

The timber of species of *Cedrela* and *Melia,* other members of the family Meliaceae, are used as mahogany, and the product of the West African *Khaya senegalensis* is known as African mahogany. There is much confusion between the product of these various trees. *Kiggelaria dregeana* (family Bixaceae), a native of South Africa, is known as Natal mahogany.

In North America several small trees of the genus *Cercocarpus* (fam. Rosaceae, *q.v.*), with very hard, fine-grained, reddish wood, are called mountain mahogany. The curl-leaf mountain mahogany (*C. ledifolius*), sometimes 40 ft. high, is found from Colorado and Wyoming to California and Washington. The hairy mountain mahogany (*C. paucidentatus*) occurs from western Texas to Arizona. The birch-leaf mountain mahogany (*C. betuloides*), the alder-leaf mountain mahogany (*C. alnifolius*) and the Trask mountain mahogany (*C. Traskiae*) are confined to southern California. The last mentioned, named for its discoverer, Mrs. Blanche Trask, and known only from Santa Catalina (*q.v.*) island, is one of the rarest of American trees. The small-leaf mountain mahogany (*C. parviflorus*) is a common shrub of the chaparral (*q.v.*) throughout the Sierra Nevada and Coast ranges of California. The dry wood of the trunk is so extremely dense that it is difficult to drive ordinary nails into it, whence the name hard tack given to this shrub by mountaineers. The mahogany sumach (*Rhus integrifolia*), a handsome evergreen shrub or small tree of southern California and adjacent Mexico, is sometimes called California mahogany.

MAHONE, WILLIAM (1826–1895), American soldier and senator, was born near Monroe, Va., on Dec. 1, 1826. In 1847 he graduated at the Virginia Military Academy and, having studied civil engineering, became chief engineer of the Norfolk and Petersburg railway. At the outbreak of the Civil War he became lieutenant-colonel of Virginia volunteers in the Confederate army, and soon after colonel of the Sixth Virginia Infantry. He participated in most of the battles of the peninsula and those around Petersburg, winning a reputation for his hardy campaigning. He was commissioned brigadier-general in March and major-general in August 1864 He afterwards commanded a division in Ambrose B. Hill's Corp. After the war he again turned to railway affairs and became president of the Norfolk and Tennessee. He became the leader of the readjuster party in Virginia, was an unsuccessful candidate for governor in 1878, but in 1880 was elected U.S. senator, which position he held until his defeat in 1887. He died at Washington, D.C., on Oct. 8, 1895.

MAHONIA, a genus of unarmed evergreen shrubs (family Berberidaceae), closely allied to the barberry (*q.v.*) and considered by some as a section of *Berberis.* The mahonias differ from the true barberries mainly in having compound leaves and a calyx of 9 sepals. There are about 50 species of *Mahonia,* found chiefly in Asia, western North America and Central America. Several are cultivated for their ornamental foliage, flowers and fruit, including the Oregon-grape (*q.v.*); the Japanese mahonia (*M. japonica*), native to China; and *M. fortunei,* also native to China and named after the English traveller, Robert Fortune.

MAHONY, FRANCIS SYLVESTER (1804–1866), known as "Father Prout," Irish priest and author, son of a woollen manufacturer, was born in Cork in 1804. His classical education was chiefly obtained at a Jesuit College at Amiens, and after studying in Paris he entered the Jesuit College at Rome and was admitted into the Society of Jesus. He served in Switzerland and at Clongoweswood, Ireland, where he was prefect of studies and subsequently master of rhetoric. Here he was involved in scandals that led to his resignation. On going to Italy he was told at Florence that he was expelled from the society. He obtained priest's orders at Rome in 1832, and returned to Ireland, later officiating in the chapel of the Bavarian Legation in London. He fell in with William Maginn, and about 1834 began to contribute his celebrated "Prout Papers" to *Fraser's Magazine.* These consist of episodes in the life of the parish priest "Father Prout," and dialogues after the model of "Christopher North." Of his poetic writings, his "Bells of Shandon" has always been greatly admired. His verse tends to show that with all his sarcastic and cynical wit his genius had also its tender, serious and sentimental side. In 1846 Mahony became correspondent at Rome to the *Daily News,* and his letters from that capital give very vivid pictures of the first years of the reign of Pius IX. He died in Paris on May 18, 1866.

An edition of his works, by Charles Kent, was published in 1881.

MAHOUT, an elephant-driver. The mahout sits on the elephant's neck and directs him by voice and by the use of a goad called *ankus.*

MAHRATTAS. The Mahrattas are a mixed people inhabiting Central India from Gwalior to Goa. Their religion is Hinduism and their language is Marathi. Their origin is obscure, but they seem to have entered India before Mahmud of Ghazni with his Mohammedan horde conquered Indian states in the early 11th century. The real founder of the Mahrattas as a power was Sivaji Bhonsla (1627–80). He gradually succeeded in compelling the independent chiefs to acknowledge his suzerainty, and drawing upon their military resources he subdued much of the territory of the emperor of Delhi. In 1674 he was proclaimed maharajah of the Konkan, and he instituted a levy of a fourth of the land revenues. Sivaji was succeeded by his son, Sambaji, in 1680, and in 1689 the latter was captured and put to death by Aurangzeb (*q.v.*). Thereafter, there being no stable rule in existence, the *peshwas* or chief ministers indulged their ambitions to the full and the Mahrattas began to decline, being divided among themselves.

Sivaji's successor was merely a titular monarch, the *peshwa* becoming the hereditary ruler. These *peshwas* were Brahman by faith and gradually the struggle became one between the military and religious powers. In the early 18th century the five Mahratta states of Baroda, Gwalior, Indore, Nagpur and the "dominions of the Peshwa" were constituted. Owing to internal strife the East India company was forced to intervene. When, in 1739, Nadir Shah invaded the empire of Delhi the *peshwas* saw an opportunity of seizing further territory from the mogul emperor. In 1761 their power was almost irretrievably destroyed in their defeat by Ahmad Shah, ruler of Afghanistan, at the battle of Panipat. In 1779 began a series of wars between the Mahrattas and the British and the names of Wellesley and Lake are famous in connection with the brilliant victories over the soldiers of Indore, Nagpur and Gwalior in the third Mahratta War (1803–05). The efforts of these officers resulted in the accession of much territory to the British flag. In 1817 the Mahratta *peshwa* united with Nagpur and Indore in attacking the British forces, and the result was the annexation of the *peshwa's* territories to the presidency of Bombay. Later, Indore and Nagpur were annexed by the British and the state of Gwalior was brought under British control in the middle of the 19th century. At the present day there are special titles for the rulers of the Mahratta states, the ruler of Indore being known as Holkar of Indore, Sindia of Gwalior, and Gaikwar of Baroda. These are family names.

See J. Grant Duff, *History of the Mahrattas* (3 vols., 1826); T. D. Broughton, *Letters Written in a Mahratta Camp* (1813); M. G. Ranade, *Rise of the Maratha Power* (Bombay, 1900); Index to the *Imperial Gazetteer of India* (1909).

MAHSEER (*Barbus mosal*), a large-scaled barbel of the rivers of India, attaining a weight of over 100 lb. and celebrated as a sporting-fish.

MAI, ANGELO (1782–1854), Italian cardinal and philologist, was born of humble parents at Schilpario in the province of Bergamo, Lombardy, on March 7, 1782, was made a cardinal in 1838, and died at Castelgandolfo on Sept. 8, 1854. He was educated at the Collegium Romanum, and after teaching at Orvieto and elsewhere was made custodian of the Ambrosian library at Milan in 1813. He went to Rome in 1819 as chief keeper of the Vatican library.

It is on his skill as a reader of palimpsests that Mai's fame chiefly rests. To the period of his residence at Milan belong: Fragments of Cicero's *Pro Scauro, Pro Tullio, Pro Flacco, In Clodium et Curionem, De aere alieno Milonis, De rege Alexandrino* (1814); *M. Corn. Frontonis opera inedita, cum epistolis item ineditis, Antonini Pii, Marci Aurelii, Lucii Veri et Appiani* (1815; new ed., 1823, with more than 100 additional letters found in the Vatican library); portions of eight speeches of Quintus Aurelius Symmachus; fragments of Plautus; the oration of Isaeus *De hereditate Cleonymi;* the last nine books of the *Antiquities* of Dionysius of Halicarnassus, and a number of other works. *M. Tullii Ciceronis de republica quae supersunt* appeared at Rome in 1822; *Scriptorum veterum nova collectio, e vaticanis codicibus edita* in 1825–38; *Classici scriptores e vaticanis codicibus editi* in 1828–38; *Spicilegium romanum* in 1839–44; and *Patrum nova bibliotheca* in 1845–53.

See B. Prina, *Biografia del cardinale Angelo Mai* (Bergamo, 1882), a scientific work, which gives a full and, at the same time, a just appreciation of his work; Cozza-Luzi, *Epistolario del card. Angelo Mai* (Bergamo, 1883); life by G. Poletto (Siena, 1887).

MAIA (mī'yạ). (1) In Greek mythology, the eldest of the Pleiades, the seven daughters of Atlas and the Oceanid Pleïone, mother of Hermes (*q.v.*). (2) An obscure Roman goddess, also called Maiesta, the cult-partner of Volcanus; commonly confused with (1) in poetry and later cult.

MAIDAN, a term used in Morocco and other parts of the Arabic-speaking East for an open space, usually in front of a palace. It is used generally in the Middle East to signify an open plain, *e.g.,* Maidan park, Calcutta. It is a common part of place-names in Afghanistan and Persia.

MAIDEN or **MAID,** a young unmarried girl. "Maid" is a shortened form of "maiden," O. Eng. *maegden,* which represents a diminutive of a Teutonic word meaning "young person," of either sex. An old English word "may," meaning a kinsman or kinswoman, and also a virgin or girl, represents the original. In early usage "maiden" as meaning "virgin" is frequently applied to the male sex, thus, in Malory's *Morte d' Arthur,* Sir Percyvale is called a "parfyte clene megden."

The title of "Maid of Honour" is given to an unmarried lady attached to the personal suite of a queen. The custom of sending young girls of noble or good birth to the court of a prince or feudal superior, for the purpose, primarily, of education, goes back to early feudal times, and is parallel with the sending of boys to act as pages and squires to the feudal castles. The regular establishment of maids of honour (*filles d'honneur*) appears first in the French court. As an institution they were suppressed in the reign of Louis XIV., at the instigation of Mme. de Montespan—who had been one of them—and their place was taken by the *dames de palais.* In the English court, this custom of attaching "maids of honour" to the queen's person was no doubt adopted from France. At the present day a queen regnant has eight maids of honour, a queen consort four. They take precedence next after the daughters of barons, and where they have not by right or courtesy a title of their own, they are styled "Honourable."

The Scottish Maiden was an instrument of capital punishment formerly in use in Scotland. It is said to have been invented by the earl of Morton, who is also said to have been its first victim. But the maiden was first used at the execution of the inferior agents in the assassination of Rizzio (1561) and Morton was not beheaded till 1581. The maiden was practically an early form of guillotine. A loaded blade or axe moving in grooves was fixed in a frame about 10 ft. high. The axe was raised to the full height of the frame and then released, severing the victim's head from his body. At least 120 suffered death by the maiden, including the regent Morton, Sir John Gordon of Haddo, President Spottiswood, the marquis and earl of Argyll. In 1710 it ceased to be used; it is now preserved in the museum of the Society of Antiquaries of Scotland, in Edinburgh.

MAIDENHAIR, in botany, the common name for a fern, *Adiantum Capillus-Veneris,* characterized by the spreading hair-like branches of the frond, the ultimate pinnules of which are ½ to 1 in. long with a rounded crenate outer edge and repeatedly forked veins; the sori (or masses of spore-capsules) are in the crenatures of the pinnules, and are protected by kidney-shaped indusia. The plant is widely distributed in temperate and tropical regions and is occasionally found in the western counties of England, the Isle of Man and west Ireland, growing on damp rocks or walls especially near the sea. In the United States it occurs from Virginia to Florida and west to Missouri, southern British Columbia and California. The more northern American maidenhair (*A. pedatum*), a larger and very beautiful fern, grows in woods from Nova Scotia to Alaska, south to Georgia and Arkansas, in the Rocky mountains to Utah and to California. The genus *Adiantum* is a large one containing many handsome species both tropical and temperate, well known in greenhouse and hothouse cultivation.

Maidenhair-tree is a popular name for *Ginkgo biloba,* a remarkable and handsome gymnospermous tree, the fan-shaped leaves of which with their forked veins recall those of the maidenhair. (*See* Ginkgo; Gymnosperms.)

MAIDENHEAD, a municipal borough of Berkshire, England; 24½ mi. W. of London by rail. Pop. (est. 1938) 23,070. Edward I. (1297) gave a grant of pontage in aid of Maidenhead bridge, which was almost broken down; similar grants were made later. In 1451 Henry VI. incorporated the guild of the Brethren and Sisters of Maydenhith to keep the bridge in order: the guild, dissolved at the Reformation, was revived by Elizabeth, who, in 1581 substituted for it a corporation. The governing charter until the 19th century was that of James I. (1685). In the 18th century a considerable river trade was done in malt, meal and timber. The Wednesday market is held under a charter of Elizabeth. Maidenhead is a residential town and a boating centre. A timbered house of the 15th century survives in Ockwells. The present stone bridge carrying the London road over the Thames dates from 1772. Trade is in malt and grain. Area 7.8 sq.mi.

MAID MARIAN, a personage incorporated in the English legend of Robin Hood (*q.v.*). She seems to have been an essential feature of the morris dance, and in the may-game was paired sometimes with Robin Hood, but oftener with Friar Tuck. The well-known pastoral play of Adam de la Hale, *Jeu de Robin et Marion,* and the many French songs on the subject, account for the association of the names. In the ballads on Robin Hood her name is only twice mentioned, but there is a late ballad, by a certain S. G. (F. J. Child, *English and Scottish Ballads,* i. 219), which tells how Maid Marian sought Robin in the forest disguised as a page, and fought with him for an hour before she recognized him by his voice. S. G. was perhaps acquainted with the two plays, written in 1598, of *The Downfall* and *The Death of Robert Earl of Huntingdon,* by Anthony Munday and Harry Chettle. In *The Downfall* Matilda Fitz Walter escapes from the persecution of King John by following her lover to Sherwood forest, where they take the names of Robin Hood and Maid Marian. Perhaps this tale has some connection with the romance of the outlaw, Fulk Fitz Warin. Matilda or Mahaud, widow of Theobald Walter, escaped from John's solicitations by marrying the outlawed Fulk and following him to the forest. There were in semi-historical legends three Matildas pursued by King John, of whom particulars are given by H. L. D. Ward in his *Catalogue of Romances* (i. 502). Their several histories were fused by the Elizabethan dramatists, and associated with the Maid Marian of the morris dance who up to that time had probably only a vague connection with Robin Hood.

MAIDSTONE, market town, municipal borough and county town of Kent, England, in the Maidstone parliamentary division, 41 mi. E.S.E. of London by the Southern railway. Pop. (est. 1938) 47,630. Area 9.3 sq.mi. There is evidence of a Roman settlement, but the name Maidstone (Medwegestun, Meddestane, Maydestan), probably meaning Medway town, is presumably Saxon. At the time of the Domesday survey the town belonged to the archbishop of Canterbury, and from the reign of John to the Reformation the archbishops had a residence there. The shire-moot was held on Penenden heath in the 11th century, and Maidstone was an assize town in the reign of Edward I. Wat Tyler, leader of the peasants' revolt of 1381, was a native of Maidstone. In 1537 Cranmer exchanged the manor of Maidstone with the king, and it was granted by Edward VI to Sir Thomas Wyatt. Edward also incorporated the town but this charter was forfeited through Wyatt's rebellion; a second charter was granted by Elizabeth in 1559 and a new one by George II in 1747. This remained the governing charter until 1835. Four fairs, still held, were granted by the charter of 1559. A Thursday market was granted by Henry III to Archbishop Boniface, and a market every second Tuesday in the month by charter of George II. A corn market on Thursday and a cattle market on Tuesday are still held.

The manufacture of linen and woollen goods was introduced by Walloons, who settled there in 1567. This was succeeded by paper-making, now the chief industry of the town, which is also the principal grain centre in the county. The cultivation of hops has been carried on since the 17th century, and there are large breweries and maltings. Other industries are quarrying for Kentish rag, agricultural implement making, iron founding, and manufacturing hop bags, matting, sacking, etc., besides cement and lime works. The water traffic on the Medway is now comparatively small.

Archbishop Boniface in 1260 established a hospital there (Newark hospital) for poor pilgrims, the chapel of which, with modern additions, is now St. Peter's church. The parish church of St. Mary, which had existed from Norman times, was demolished in 1395 by Archbishop Courtenay, who erected on the site the present Church of All Saints. The ruins of Courtenay's college of secular canons are interesting 14th-century architecture. A Perpendicular building, with an Elizabethan east front, now houses the school of science and art. The grammar school was founded in 1549 and endowed with the estates of the local Corpus Christi fraternity, then dissolved; the gild hall remains, but the school is in modern buildings on a new site. A museum, with public library, was opened in 1858, in an early 16th-century building, which is the headquarters of the Kent Archaeological society. From Saxon times down to 1830 executions and all the great county meetings took place on Penenden heath, a common enclosed as a public recreation ground. In 1929 the corporation bought the Mote estate of 558 ac. and converted it into a public park and housing estate. A new courthouse was opened in 1937.

MAIDU. This Indian group, of Penutian (*q.v.*) stock, lived in California east of Sacramento river. Dialectically it comprises three divisions, north-western, north-eastern and southern or Nisinan; but a physiographically founded cultural cleavage into Maidu of the valley, foot-hills, and mountains is more significant. The valley division was wealthiest and most advanced, and together with the Patwin west of the Sacramento had developed the Hesi form of the Kuksu cult, a spirit-impersonating religion with initiating societies, which appears to mark the culminating point of central Californian culture. The name Maidu, pronounced My-doo, means "people." The population, originally 8–10,000, was 1,100 in 1910, including mixed bloods.

See R. B. Dixon, *Bull. Am. Mus. Nat. Hist.*, vol. xvii. (1905).

MAIHAR, a state in the Central India agency. Area, 412 sq.mi.; pop. (1941) 79,558. The state, which is watered by the Tons river, consists mainly of alluvial soil covering sandstone, and is fertile except in the hilly district of the south. A large area is under forest. The ruler, whose title is raja, claims descent from the Kachwaha Rajput clan. His salute is nine guns. The town of Maihar (pop. 7,678) is on the East Indian railway, 97 mi. N. of Jubbulpore. Ruins nearby indicate that the place was formerly much more extensively occupied.

MAILLOL, ARISTIDE (1861–1944), French sculptor, was born at Banyuls sur Mer, Rousillon. After studying at Perpignan he entered the studio of Cabanel in Paris, at the age of 21, as a student of painting. He belonged to a group of young artists who, inspired by Gauguin, abandoned impressionism for a more decorative form of art. In order to realize his aspirations, he worked on tapestry design; he built majolica vases and experimented with glazes; he modelled wall fountains with figures in relief; and finally he tried his hand very successfully at small figures in clay. He then began his great statues in stone and bronze, which established his reputation as the greatest French sculptor of his time. He found in the early 5th-century art of Greece the confirmation of his artistic aspirations. The sense of proportion and feeling for unity, the harmony of the masses which Greek art displays, became the guiding principles on which he modelled his figures. In 1909 he visited Greece in company of Count Kessler, his enthusiastic admirer and friend, for whose Cranach Press he executed a series of wood engravings to illustrate the Eclogues of Virgil. Maillol was a member of the Salon d'Automne and a regular exhibitor at the Salon des Independants. He worked in close contact with nature in his native fishing village on the shores of the Mediterranean, and spent some months of the year at Marly, near Paris.

Among his monumental works are the standing figures of Flora (1911) and Pomona (1912) in the Morrozoff collection at Winterthur; the two "Crouching Women" of Osthaus, in Hagen, and of Count Kessler's collection, Berlin; the war monuments at Elne, Céret and Port Vendres; the reclining goddess of "Fame" for the monument to Cézanne, on which he worked during ten years, and which he completed in 1925. His little terra-cotta statuettes are among his most attractive work. Maillol died in Oct. 1944.

See Octave Mirbeau, *Aristide Maillol* (1922); Marc Lafargue, *Aristide Maillol* (1925).

MAIL-ORDER BUSINESS, a retail commercial enterprise carried on entirely or almost entirely by mail. Its customers, from illustrated catalogues which are sent to them by mail, order general merchandise of every description and receive their merchandise by parcel post, express or freight from either central storage or shipping points or direct from the factory, permitting in many instances appreciable savings through reduction in transportation and handling costs, which, in turn, are passed along to the benefit of the customers in the form of lower prices.

American mail-order business received its initial impulse from a natural desire on the part of the average individual to buy dependable merchandise at below prevailing retail prices. It took concrete form about 1872 in the organization of farmer grange alliances and similar associations for the purpose of collective buying. The movement was promptly capitalized by the pioneers in the industry, who sought to attract sales from printed lists of merchandise instead of selling over the counter. The complete success of the mail-order business is due to the fact that it not only maintains as its creed lower prices and better quality, but strictly honest dealing and a broad guarantee of satisfaction.

In early days distribution of merchandise was uncertain and was accomplished almost entirely through jobbing houses or manufacturers' representatives, who sold to the retail dealer, who, in turn, sold to the user. The mail-order business cut through those slow and expensive methods of distribution. It eliminated the middleman, with his added profit and expense; saved that amount, and thus materially lowered the cost of merchandise to its customers.

As time went on, improved manufacturing methods produced better goods at steadily lowering costs; transportation facilities grew more efficient; the parcel post was established; and scientifically worked out systems made it easier every year to handle, pack and ship vast quantities of merchandise with precision and dispatch and at a minimum of expenditure. Every advance of this nature lowered retail selling prices still more. Then the mail-order business began to come into its own, its pronounced growth dating from about the beginning of the 20th century.

The early years of the business were not marked by that fine regard for the ethics of the successful commercial enterprise of to-day. Not infrequently overstatement and exaggeration, if not downright misrepresentation, characterized the descriptions in the catalogue. But the conviction gradually grew that misrepresentation was not only immoral, but unprofitable. The mail-order house began to censor its catalogue descriptions with more care and with a keener eye for the truth. To that fact; to the outstanding advantages of this method of shopping, especially to people in rural districts; to its guarantee of satisfaction strictly adhered to; and to the low prices and complete assortments offered, the mail-order house may attribute its remarkable growth.

Reasons for Success.—The mail-order business has materially reduced the cost of living for millions of people; has been one of the biggest factors in establishing the now generally accepted principle of one price to all; has become so thoroughly stabilized that the catalogues of the larger houses of to-day are to a great extent the merchandise price standards of the country. Not only do the successful mail-order houses strive for truth in their advertising and cataloguing, but they exert themselves to a considerable extent to safeguard their customers even against themselves. They refuse to catalogue and sell merchandise which is harmful or against public interest. For instance patent medicines, many of which are injurious, are no longer advertised, only those medicines being offered which are officially approved by leading drug and medical associations. Furthermore, late years have seen a marked increase in laboratory tests to assure serviceability and at least minimum standards of quality in merchandise advertised.

Cutting Costs in Buying.—The first great economy effected by the mail-order houses, is the elimination of the middleman. Almost without exception, they buy from the factory and sell to the user. The big houses buy in vast quantities, and for cash. They not infrequently take over the entire product of a factory. They place huge orders with factories during their otherwise slack seasons, cutting costs still more. Where they find that they can more advantageously manufacture the article themselves, they are prepared to do so. The smaller houses, of course, cannot avail themselves of all these ways of reducing costs; but they all, to a certain extent, employ the same means to the same end.

Operating Economies Developed.—In the operating methods also great economies are brought about, especially in the larger mail-order houses, in the handling, packing and shipping of merchandise. Orders to the mail-order house correspond to customers in the retail store, but the mail-order house has a great economic advantage in that the number of orders (or customers) at any given time of the day can be controlled. Under the schedule system which was originated by Sears, Roebuck and Company of Chicago, the largest of all mail-order houses, and which moves with the smoothness and exactness of a precision instrument, orders are scheduled every ten minutes, the quantity, which varies greatly with the seasons, depending upon the number received during the day. Thus, they have an uninterrupted flow of business which is the same at 8 o'clock in the morning as it is at any other period of the day, and the rush hours and slack periods experienced by retail stores are eliminated. Orders move through the various departments of the house all day long, and in rush seasons far into the night, on this ten minute schedule. An order which is received at, say, 8 o'clock in the morning may be scheduled to be shipped at ten minutes after 1 o'clock that afternoon. At precisely 1.10 P.M. that merchandise is in the shipping room being packed. A few minutes later it is on its way to the customer along with thousands of other orders scheduled for the same hour and minute. The 1.10 shipments out of the way, the packing room occupies itself with those scheduled for 1.20, but not a 1.20 order is touched until every 1.10 order is disposed of. This schedule is feasible only because it is possible to determine at the beginning of the day just how many orders the various merchandise departments will be called upon to handle. And its perfect operation makes possible the 24-hour service which fills and ships 99 out of every 100 orders within 24 hours after they are received. The even, uninterrupted flow of orders to the merchandise departments prevents an overload one hour and a slack time the next. The distribution of these orders is based on the averages which, in this instance, are determined by years of experience.

One single mail-order house, Sears, Roebuck and Company, for example, receives in an average day approximately 4,400lb. of first class mail at all its branches. This more than two tons of mail per day represents a total of 242,000 letters. Before the mail is taken out of the sacks, it is weighed, and by its weight the company is able to determine with sufficient accuracy for all purposes how many orders have been received. A thousand pounds of mail averages 55,000 letters; out of the 55,000 letters a certain percentage contains orders; the balance is given up to miscellaneous correspondence. Experience tells also what the percentage of orders received at 9 o'clock is as compared to the total orders that will be received that day. Therefore, by weighing the mail received and deducting miscellaneous correspondence, how many orders will be received that day can very easily be determined. With this knowledge at the beginning of the day and at intervals throughout the day, it is possible to fix shipping times and pass orders along to the various merchandise departments at a rate which will keep them running easily and steadily without hitch or break.

The average value of the orders varies with the season, but past experience has given the mail-order house an accurate chart of what this seasonable variation is; so that not only is the number of orders approximately determined by this process of calculation, but their gross value as well, and the day's total sales can be computed with amazing accuracy before the day is well begun.

Machines and mechanical aids of every possible sort are employed. Man power is eliminated wherever a machine will do the work better and quicker—particularly quicker. Machines open the mail at the rate of 450 letters a minute, at the same time stamping the date on the envelope. Pneumatic tubes, endless belt conveyors, chutes, electric trucks do their part in the distribution of orders to the merchandise departments and in the handling of the merchandise thereafter. Supplementing all this is the high specialization of head and hand work. One corps of employees does nothing but remove letters and orders from envelopes. They pin the cheques and money orders to the order sheets and letters which they accompany. Another group tallies the amounts sent with the orders, notes the amounts on the orders, detaches the remittances to be sent to the cashier's office, and passes the orders to another division. Here the orders are sorted by still other highly expert persons, recorded and finally distributed to the merchandise departments. All work with great rapidity. A mail-order house is divided into many distinct merchandise departments, such as furniture, piece goods, hardware, phonographs and pianos, hosiery, stoves, etc. These are scattered over many acres of floor space. A single order from a customer may call for merchandise from one or perhaps 20 or more of these departments. The problem then is to bring the merchandise from each of these departments into a certain section of the shipping room at a certain hour and minute in order that they may be packed together, or at least shipped simultaneously.

Let us suppose there is an order on 20 different departments scheduled for shipment at 10 A.M. Expert typists have drawn off on 20 separate sheets the orders for each of the 20 departments involved. These sheets are sent by pneumatic tubes to the departments, where trained stock men and order fillers take them in hand. Carefully checked and rechecked to avoid mistakes, the merchandise goes by chutes, endless belt conveyors and other mechanical devices to that part of the shipping room designated. From all 20 departments it arrives there by 10 A.M.—not more than 20 minutes before—not one minute after. Everywhere is system, precision, intelligently applied energy. There is little room for lost motion anywhere. There are no idle clerks waiting for customers, nor taking time to explain, describe or sell. Thus, throughout the entire system—buying, handling, shipping—substantial savings are made of time and money. And these are reflected in the low retail prices found in the catalogue.

A General Survey.—It is impossible to estimate accurately the number of mail-order houses in America to-day. Besides those carrying a general merchandise line, with business running into hundreds of millions of dollars a year, such as Sears, Roebuck and Company, or Montgomery Ward and Company, there are hundreds of individuals and organizations doing business by mail, selling limited lines of merchandise or specialties only. No authoritative figures as to the aggregate amount of business done by mail in the United States is available, but the magnitude of the business may be seen in some degree from the fact that one mail-order house alone, Sears, Roebuck and Company, for the year 1937 served approximately 11,000,000 families who purchased nearly 48,000,000 separate orders. This volume, handled swiftly and smoothly by the company's efficient schedule system, was moved through large plants located in 10 metropolitan centres of the United States. Making proper allowance for duplications in names (two or more customers in one family), which it is not always possible to avoid, a conservative estimate places the number of people in the United States buying from this one organization alone at probably one-third the entire population.

From the magnitude of the industry and its steady growth, it is evident that the mail-order business is a vital factor in the commercial life of the nation and one which is each year playing a more important part.

MAIMANA, a town and khanate of Afghan Turkistan. The town is situated 100 m. S.W. of Balkh, and only some 25 m. from the frontier of Russian Turkistan. It is about two-thirds the size of Herat, square built and surrounded by a ruined wall and moat. The khanate was for long in dispute between Bukhara and Kabul, but in 1868 Abdur Rahman laid siege to the town, and it was compelled to come to terms. Its political status as an Afghan province was definitely fixed by the Russo-Afghan boundary commission of 1885. The inhabitants are chiefly Uzbegs.

MAIMBOURG, LOUIS (1610–1686), French Jesuit and historian, was born at Nancy on Jan. 10, 1610. He entered the Society of Jesus at the age of sixteen. After having taken some part in minor controversies he threw himself with energy into the dispute on the Gallican Liberties; for his *Traité historique sur les prérogatives de l'Église de Rome* (4 vols., 1685; mod. ed., 1831) he was by command of Innocent XI. expelled from the Society, but rewarded by Louis XIV. with a residence at the abbey of St. Victor, Paris, and a pension. He died on Aug. 13, 1686. His *Oeuvres complètes* were published in 14 vols. (1686–87); *Oeuvres choisies,* ed. J. P. Migne (1846).

MAIMING, mutilation, a physical injury which involves the loss of, or incapacity to use, a bodily member. Maiming or mutilation is and has been practised by many races with various ethnical and religious significances, and was a customary form of punishment on the principle of an "eye for an eye" (*see* Mutilations and Deformations). In law "maiming" is a criminal offence; the old law term employed for a special case of maiming of persons was "mayhem" (*q.v.*), an Anglo-French variant form of the word. The punishment incurred for maiming of cattle in Great Britain is 13 to 14 years' penal servitude. Malicious injury to other animals is a misdemeanour punishable on summary conviction. For a second offence the penalty is imprisonment with hard labour for over 12 months. (Malicious Damage Act 1861.) Maiming means the permanent injury of the animal but the Statute of 1861 also makes wounding an animal an offence. Maiming of animals by their owner falls under the Cruelty to Animals acts, and the Protection of Animals acts 1911 and 1912.

MAIMON, SALOMON (1754–1800), German philosopher, was born of Jewish parentage in Polish Lithuania, and died at Nieder-Siegersdorf on Nov. 22, 1800. He married at the age of 12, and studied medicine in Berlin. In 1770 he severed his connection with his orthodox co-religionists by his critical commentary on the *Moreh Nebuhim* of Maimonides, and devoted himself to the study of philosophy on the lines of Wolff and Moses Mendelssohn. After many vicissitudes he found a quiet home with Count Kalkreuth at Nieder-Siegersdorf in 1790, and began to publish the works which have made his reputation as a critical philosopher. In 1788 he made the acquaintance of the Kantian philosophy, which was to form the basis of his lifework, and in 1790 he published the *Versuch über die Transcendental-philosophie,* in which he formulates his objections to the system. Maimon takes a view intermediate between Kant and Hume. Hume's attitude to the empirical is entirely supported by Maimon. The casual concept, as given by experience, expresses not a necessary objective order of things, but an ordered scheme of perception; it is subjective and cannot be postulated as a concrete law apart from consciousness. The main argument of the *Transcendentalphilosophie* not only drew from Kant, who saw it in ms., the remark that Maimon alone of all his critics had mastered the true meaning of his philosophy, but also directed the path of most subsequent criticism.

Maimon's other principal works are: *Philos. Wörterbuch* (1791); *Streifereien im Gebiete der Philos.* (1793); *Über die Progresse der Philos.* (1793); *Die Kategorien des Aristoteles mit Anmerkungen erläutert* (1794); *Versuch einer neuen Logik* (1794 and 1798; new ed. by the Kant-Gesellschaft, ed. B.C. Engel, 1912); *Kritische Untersuchungen über den menschl. Geist* (1797).

See *S. Maimons Lebensgeschichte von ihm selbst beschrieben* (1792, ed. K. P. Moritz; Eng. trans. by J. C. Murray, 1888); Wolff, *Maimoniana* (1813); Witte, *S. Maimon* (1876).

MAIMONIDES (Rabbi Moses Ben Maimon) (1135–1204), also known from the initials of these last words as Rambam, Jewish philosopher and master of Rabbinic literature, was born in Cordova on March 30, 1135, and educated by his father and by Arabic masters. When Cordova was taken by the victorious Almohades in 1148 the position of the Jews became intolerable, and Maimonides, after ten years of wandering, decided to settle in Fez. Five years later he moved to Cairo where he became recognized as the greatest Rabbinic authority of his time. He was appointed body physician to Saladin, and married the sister of Ibn al Māli, one of the royal secretaries. Maimonides died on Dec. 13, 1204.

In his important philosophical treatise, *The Guide for the Perplexed,* a work which strongly influenced his Arabian, Jewish and Christian successors, Maimonides seeks to harmonize Biblical and Rabbinic teaching with philosophy, and especially with the philosophy of Aristotle. At the same time, he recognizes that reason is limited and requires to be supplemented by revelation. The first book, which is concerned with the establishment of the spirituality of God, discusses the figurative meaning of anthropomorphic expressions applied to God in the Scriptures, the impropriety of assigning to Him any attributes other than negative ones, and, lastly, the Mutakallmun doctrines of God and their scientific basis. Book II. proves the existence of God by the argument of the unmoved mover, and by the distinction between the necessary and the possible and between the necessary and the contingent. Aristotle's cosmology is then accepted in outline and his separate intelligences moving the celestial spheres are identified with the angels of Scripture. Aristotle's doctrine of the eternity of the world Maimonides finds less acceptable because it obviously clashes with Scripture. He suggests that the account of creation in Genesis must be interpreted allegorically, and seeks to show that while reason cannot prove the *productio ex nihilo* of the world, such a *productio* is not contrary to reason; in fact, it is more acceptable than the theory of Aristotle because it substitutes for the idea of mechanical necessity the conception of an intelligent being acting purposively. On the other hand, Maimonides contends that the objections raised against the eternity of the world are unsatisfactory and that Aristotle's view may have been merely tentative. The second book ends with a discussion of the requisites of prophecy. Book III. treats of evil as the privation of good and as originating in free-will, of the Divine knowledge of singulars and of Providence, of design in nature, in the law and in Biblical narrative, and, lastly, of moral precepts.

The *Guide* was published by S. Munk (3 volumes, Paris, 1856–66), English translation by M. Friedländer (3 volumes, 1881–85), reissued in one volume, of which the last edition appeared in 1925. Of the numerous other works of Maimonides the chief are the commentary on the *Mishnah* (Hebrew translation, Naples, 1492). The eight chapters prefaced to the commentary on tractate Aboth were translated into English by J. I. Gorfinkle (New York, 1912); the *Mishnah Torah* (last edition, Leipzig, 1862, partial English translation by E. Soloweyczik, 1863); *Kitab al-Fara'id* (Hebrew translation, Lisbon, 1497; French translation by M.

Bloch, 1888); *Responsa* (edition 1859); a work on the terminology of logic (Latin translation, Venice, 1552; German translation, Breslau, 1828) and a treatise on poisons (French translation, Paris, 1865).

MAIN, a river of Germany, 310 m. long and the most important right-bank tributary of the Rhine. It has two sources, the Weisse Main (White Main) which rises in the granitic rocks of the Fichtelgebirge, and the Rote Main (Red Main), which, rising on the eastern slope of the Jurassic rocks of the Frankish Jura, flows past Bayreuth. They unite near Kulmbach after which the river, flowing north-west keeps to the Trias, and flows round the north end of the Frankish Jura to Bamberg. Here it receives its chief tributary, the Regnitz (left), and enters upon its middle course. Flowing amid vine-clad hills it passes Würzburg, and thence, dividing the forest-clad ranges of the Spessart and the Odenwald, reaches Gemünden. Here it is joined by the Frankish Saale (right) and turning abruptly south, receives at Wertheim the beautiful Tauber (left). From the latter it proceeds due north to Aschaffenburg, whence passing Frankfort it joins the Rhine just above Mainz. It is navigable from the confluence of the Regnitz for barges and other small craft, and through the Ludwigs canal is connected with the Danube. (*See* RHINE.)

MAIN, power or strength; *e.g.,* the expression "with might and main" (Lat. *magnus,* great). "The main," the high open sea, is for "main sea," *cf.* "mainland," the principal part of a territory excluding islands and sometimes far-projecting peninsulas. The "Spanish main" was the mainland of the north-east coast of South America, stretching from the Orinoco to the Isthmus of Panama, and the former Spanish possessions in Central America bordering on the Caribbean Sea, or more loosely, the Caribbean Sea itself. The principal pipe or cable for gas, water, electricity, etc., is called the "main." In cockfighting, "main" has signified both the match and the birds. In hazard it is the number called by the "caster" before the dice are thrown; this may be any number from five to nine inclusive; hence the expression "main chance." "Main," a shortened form of domain or demesne, survives in Scotland, usually in the plural "mains" for a home farm.

MAINA (or MANI) and **MAINOTES,** a district and people of the Peloponnesus, the modern Morea. Maina is the country occupied by the mountain range of Taygetus from Sparta to Cape Matapan, the ancient Taenarum. It is now divided between the modern districts Oetylos and Gythion. It contained over a hundred villages. The Mainotes claim to descend from the Spartans, and probably represent the Eleuthero Laconians delivered by Rome from the power of Sparta, as is suggested by traces of ancient Greek in their dialect and by their physical type. They did not become Christians till the 9th century.

Their country being a natural fortress, they were able to defend themselves against the Byzantine emperors, the barbarian invaders, the Latin princes of Achaea of the house of Villehardouin, and the Turks. As their country is also poor and maritime, they were early tempted to piratical adventure. Gibbon has referred to "the inhuman pillage of all that is shipwrecked on their rocky shore." Their neighbours gave their country the name of "Kakoboulia" —the land of wicked counsels. The passes of their mountains and their villages were fortified, so leading to their favourite epithet, Maina Polypyrgos—"many-towered." On the western side are the remains of feudal keeps, erected by William II. de Villehardouin (1245–1278) and other Latin princes of Achaea. From the 15th till the 17th century they recognized as head chiefs a family which claimed to belong to the Comneni of Trebizond. But the real power was in the hands of chiefs, a turbulent and martial aristocracy. Feuds were enduring and ferocious.

In the 18th century the family of Mavromicheli (Black Michael), in lower Maina, established a general headship after much strife and many murders. The Mainotes rose against the Turks at Russian instigation in 1770 and managed to gain virtual independence in 1777. During the Greek war of independence the Mainotes were led by Petros (Petro Bey) Mavromicheli, "the king of Maina," who undoubtedly cherished the hope of establishing a principality for himself. The freedom of Greece, for which he had fought in his own way, was the ruin of his ambition. He found the new order less compatible with his schemes than the Turkish dominion, and was imprisoned by the Greek president Capodistrias (*see* CAPO D'ISTRIA, COUNT), who was in revenge murdered by the Mavromichelis. The family were finally content to become courtiers and officials in the reign of King Otho I. In the 19th century Maina was but little affected by civilization, except so far as navies prevented piracy.

See W. Martin Leake, *Travels in the Morea* (1830); M. E. Yemeniz, "La Maina," in *Revue des deux mondes* (March 1, 1865); and Philipson, "Zur Ethnographie des Peloponnes," in *Petermanns Mittheilungen,* vol. 36 (Gotha).

MAINAN, an independent linguistic stock of South American Indians, so called from the Mainas, one of its important tribes. This stock occupies a considerable area in north-eastern Peru, on the north side of the Marañon between the lower Pastaza and Tigre rivers, and south of it on the Samiria and lower Huallaga rivers, extending to the Mayo, and westward to the Potro. The Jeberos (Xeberos), often confounded with the Jivaran (*q.v.*), are members of this group. The tribes of this stock were sedentary agriculturists, pottery and textile makers, and greatly given to taking enemy heads, shrinking and preserving them as do the Jivaros. They now retain little of their original culture.

See F. de Figueroa, "Relación de las Misiones . . . *en el Pais de los Maynas,*" Col. de Libros y Documentos referentes a la Historia de America, vol. i. (Madrid, 1904).

MAINE, SIR HENRY JAMES SUMNER (1822–1888), English comparative jurist and historian, son of Dr. James Maine, of Kelso, Roxburghshire, was born on Aug. 15, 1822. He was educated at Christ's Hospital and Pembroke college, Cambridge. In 1847 he was appointed regius professor of civil law, and he was called to the bar three years later; he held this chair till 1854. Even the rudiments of Roman law were not then included in the ordinary training of English lawyers. Maine's lectures as reader to the Inns of Court were the groundwork of *Ancient Law* (1861), the book which made his reputation at one stroke. Its object was "to indicate some of the earliest ideas of mankind, as they are reflected in ancient law, and to point out the relation of those ideas to modern thought."

From 1863 to 1869 Maine was legal member of council in India. Plans of codification of Indian law were prepared, and largely shaped, under the direction of Maine, and they were carried into effect by his successors, Sir J. Fitzjames Stephen and Dr. Whitley Stokes. The results are open to criticism in details, but form on the whole a remarkable achievement in the conversion of unwritten and highly technical law into a body of written law sufficiently clear to be administered by officers to many of whom its ideas and language are foreign. All this was in addition to the routine of legislative and consulting work and the establishment of the legislative department of the Government of India on substantially its present footing.

Maine brought back from his Indian office a store of knowledge which enriched all his later writings, though he took India by name for his theme only once. Three of his addresses as vice-chancellor of Calcutta university were published, wholly or in part, in the later editions of *Village Communities;* the substance of others is understood to be embodied in the Cambridge Rede lecture of 1875, which is to be found in the same volume. The practical side of Maine's experience was not long lost to India; he became a member of the secretary of State's council in 1871, and remained so for the rest of his life. In 1869, Maine was appointed to the new chair of historical and comparative jurisprudence at Oxford. During the succeeding years he published the principal matters of his lectures in a carefully revised literary form: *Village Communities in the East and the West* (1871); *Early History of Institutions* (1875); *Early Law and Custom* (1883). In all these works the phenomena of societies in an archaic stage, whether still capable of observation or surviving in a fragmentary manner among more modern surroundings or preserved in contemporary records, are brought into line, often with singular felicity, to establish and illustrate the normal process of development in legal and political ideas.

In 1877 Maine became master of Trinity Hall, Cambridge, and in 1887 Whewell professor of international law. This branch of his work is represented by a posthumous volume which had not received his own final revision, *International Law* (1888). Meanwhile he had published in 1885 his one work of speculative politics, a volume of essays on *Popular Government,* designed to show that democracy is not in itself more stable than any other form of government, and that there is no necessary connection between democracy and progress. The book was deliberately unpopular in tone; it excited much controversial comment and some serious and useful discussion.

Maine's health, which had never been strong, gave way towards the end of 1887. He went to the Riviera under medical advice, and died at Cannes on Feb. 3, 1888. His work was promptly and fully appreciated on the Continent, where it has perhaps been understood better than in England that it is as the pioneer of a method that he must be estimated. But his basic conception of the development of law is disputable. A Hegelian in philosophy, he regards law as developing "from status to contract," from a state in which legal relations are independent of the will to one in which they flow from it. But was this conception a part of Roman law at all, or imported into it by the school of Savigny? Is the movement anything more than from the group to the individual, and was the growing importance of contract not due rather to Stoic conceptions of duty than to 19th century conceptions of the value of the will? The tendency he postulated was certainly that of his time; the tendency to-day seems to be the other way.

See Sir A. Lyall and others, in *Law Quart. Rev. iv.* 129 *seq.* (1888); Sir F. Pollock, "Sir Henry Maine and his Work," in *Oxford Lectures,* etc. (1890); "Sir H. Maine as a Jurist," *Edin. Rev.* (July 1893); Introduction and Notes to new ed. of *Ancient Law* (1906); Sir M. E. Grant Duff, *Sir Henry Maine: a brief Memoir of his Life,* etc. (1892); L. Stephen, "Maine" in *Dict. Nat. Biog.* (1893); P. Vinogradoff, *The Teaching of Sir Henry Maine* (1904).

MAINE, an old French province, bounded on the north by Normandy, east by Orléanais, south by Touraine and Anjou, and west by Brittany. Under the Roman empire it consisted of two *civitates* comprised in the Provincia Lugdunensis Tertia—the Civitas Cenomannorum and the Civitas Diablintum, whose chief towns were Le Mans and Jublains. These two *civitates* were united during the barbarian period and formed a single bishopric, that of Le Mans, suffragan to the metropolitan see of Tours. Under the Merovingians and Carolingians the diocese of Le Mans corresponded to the Pagus Cenomanensis, and in the feudal period to the county of Maine. In the 16th century the county of Maine, with the addition of Perche, formed a military government—the province of Maine. Since 1790 this province has been represented approximately by the departments of Sarthe and Mayenne, the respective capitals of which are Le Mans and Laval. In 1855 the bishopric of Laval was separated from that of Le Mans. Roger (*c.* 892–*c.* 898) was perhaps the first hereditary count of Maine. In the 12th century, Maine was attached to Anjou (*q.v.*) till 1204, when it was united to the royal domain. In 1246 it was given by Louis IX. to his brother Charles, count of Provence. Again united to France in 1328, it was given in 1356 as an apanage to Louis, second son of King John II., and did not definitely return to the French crown until 1481, after the death of Charles II., count of Maine. During the Hundred Years' War Maine was taken in 1425 by the English, who lost it in 1448.

MAINE, is the most northeasterly State of the United States of America and the largest State in New England. It lies between 43° 4′ and 47° 27′ 33″ N. and between 66° 56′ 48″ and 71° 6′ 41″ W. and is bounded on the north-west by Quebec; north and east by New Brunswick; south-south-east by the Atlantic ocean; and west by New Hampshire. It has an area of 33,215 sq.mi., 2,175 sq.mi. being water surface. Owing to its forest, it is known as the "Pine Tree State."

Physical Features.—Considering the area as a whole, the surface of Maine is a gently rolling upland, above which rise mountain peaks, isolated and in clusters and below which are numerous river valleys. The highest peak is Mt. Katahdin (5,200ft.) others being: Saddleback mountain (4,000ft.), Mt. Abraham (3,388ft.), Mt. Bigelow (3,600ft.), and Mt. Blue (3,200ft.). A little north of this line of mountain peaks is the water-parting which divides the State into a north slope and a south slope. The north slope though quite hilly in the middle and west is so poorly drained that swamps abound in all sections. The south slope, which contains nearly all the mountains and is generally more hilly, has a mean descent toward the sea of about 7ft. to the mile.

After the uplift, which caused the rivers to cut below the general "uplands" and develop well-marked valleys for themselves, came the period of the great continental glaciation. The glacier or ice sheet overran all Maine, irregularly scouring out the bed rock to produce rock basins, damming up many river valleys with glacial deposits, and completely disarranging the drainage lines. When the ice melted the rock basins and the dammed-up valleys filled with water and became lakes. These lakes are more than 1,600 in number, are scattered in all parts of the State, are especially numerous at high elevations, and have an aggregate area in excess of 2,000 sq. miles. Few other regions have so many large lakes so variously situated and with such beauty of aspect and surroundings. They contribute largely to a constant supply of water-power, for which the rivers of south-west Maine are exceptionally well adapted. Moosehead lake (about 120 sq.m.; 35m. long and from 2m. to 10m. wide), on the boundary between Piscataquis and Somerset counties, is the largest in Maine and the largest inland body of water wholly in New England; the Kennebec river is its principal outlet. Mt. Kineo rises abruptly to about 1,760ft. above the sea and about 700ft. above the lake on its eastern shore. Other lakes, such as the Rangeley lakes, Chesuncook and Twin lakes on the Penobscot, and the Grand or Schoodic lakes, on the eastern boundary at the head waters of the St. Croix river, equal or surpass Moosehead in picturesqueness. Glaciation is responsible for the poor soil of most of the State; for, although the rocks are the same crystallines that give good soils farther south in unglaciated regions, glacial erosion has removed decayed portions of the Maine rocks, revealing fresh, barren rock over great areas, and in other places hardpan or boulder clay has been deposited as a thin coating.

After the uplift came a period of subsidence, during which this region sank one or more thousand feet, allowing the sea to encroach on the land and run far inland into the previously made river valleys. This depression probably occurred during the glacial period, perhaps toward its close, and is responsible for the second most important feature of Maine physiography, the embayed coast. To this subsidence are due the picturesque coastal scenery, the numerous islands and bays, the good harbours and the peculiar coast line. The shortest distance between the north-east and south-west extremities of the coast is only 225m., but, on account of projections and indentations, the coast line measures not less than 2,500 miles. The headlands, the deep indentations and the numerous islands in the bays and beyond produce a beautiful mingling of land and sea, and give to the whole ocean front the appearance of a fringed and tasselled border. West of the mouth of the Kennebec river are a marshy shore and many low grassy islands; but east of this river the shore becomes more and more bold, rising in the precipitous cliffs and rounded summits of Mt. Desert and Quoddy Head, 1,532 and 180ft. high, respectively. All along the coast-line there are capacious and well-protected harbours, Casco, Penobscot, Frenchman's, Machias and Passamaquoddy bays being especially noteworthy. After the subsidence came another period of uplift, possibly still in progress. This uplift has brought up submarine deposits of sand, etc., to form little coastal plains at some points along the coast, providing good land for settlement and clay for brick and pottery. Evidence of this uplift is found in old beach lines now above sea-level.

The principal river systems of Maine are the St. John on the north slope, and the Penobscot, the Kennebec, the Androscoggin and the Saco on the south slope. The Penobscot, Kennebec, Androscoggin and Saco have numerous falls and rapids.

The climate of the state is moist and, for the latitude, cold. The precipitation is about 42·5 in. annually and is distributed very evenly throughout the year, 10 to 11 in. of rain or its equivalent in snow falling each season. The snowfall varies from about 60 in. on the coast to more than 100 in. on the north slope, the average for the state being about 83 in. The summers are short, there being only about four and a half months between frosts, even in the southern section. The heat of summer is tempered by the sea and cool north winds, the mean summer temperature being about 62° F. The mean winter temperature is approximately 20° F., and the mean annual temperature for the entire state is 42° F., that for the north slope being about 5° lower than that for the south slope. Although the temperature remains rather steadily below the freezing point for at least three months of the year, many of the harbours remain unobstructed for the tides and the prevailing off-shore winds break up and drive off the ice.

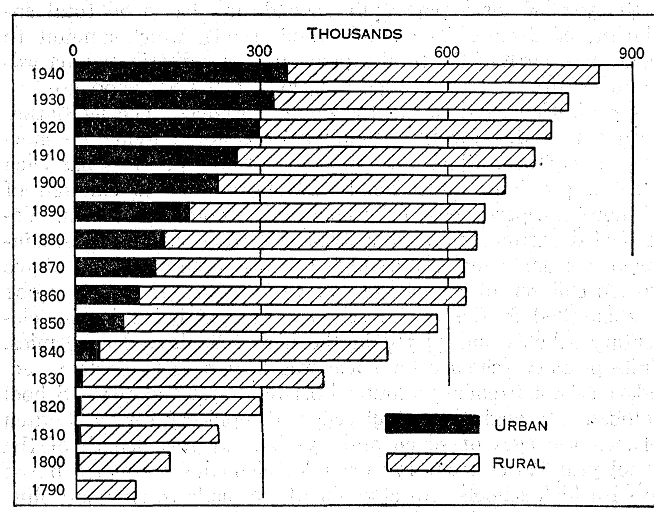
Government.—Maine is the only state in the union in which state elections are not held in November; they are held in September in even-numbered years. The state has had but one constitution; this was ratified in Dec. 1819, about three months before the admission of the state into the union. It admits of amendment by a two-thirds vote of both houses of the legislature, followed by a majority vote of the electorate at the next September election; or, as provided by an amendment adopted in 1875, the legislature may by a two-thirds vote of each house summon a Constitutional Convention. From 1819 to 1875 12 amendments were adopted; in 1875, after nine more were added, the 21 were incorporated in the text; and between 1875 and 1941, 40 more were adopted. The governor is the only executive officer of the state elected by popular vote. There is no lieutenant governor, the president of the senate succeeding to the office of governor in case of a vacancy; but there is a council of seven members elected by the legislature (not more than one from any one senatorial district), whose sole function is to advise the governor. His power of appointment is unusually extensive, and the advice and consent of the council (instead of that of the senate as in other states) are required for his appointments. He appoints all judges, medical examiners and notaries public, besides all other civil and military officers for whose appointment neither the constitution nor the laws provide otherwise. His removal power extends even to the locally elected sheriffs and county attorneys. The seven members of the council, the secretary of state, the treasurer, the attorney-general and auditor are elected biennially by a joint ballot of the two houses of the legislature.

The legislature meets on the first Wednesday in January in odd-numbered years, at Augusta, the capital. It is composed of a senate of 33 members and a house of representatives of 151 members. Members of each house are elected for a term of two years: senators by counties on the basis of one for each 30,000 inhabitants and each fraction additional, and representatives according to the population of towns of 1,500 and over, townships and plantations having less than 1,500 being grouped together to select a representative. There is a new reapportionment for the senate and the house every ten years. In September 1908 a constitutional amendment was adopted providing for referendum and initiative by the people. Any bill passed by the legislature, unless designated an emergency measure, must be referred to popular vote before becoming law, if there is a referendum petition therefor signed by 10,000 voters; and a petition signed by 12,000 voters initiates new legislation.

At the head of the department of justice is the supreme judicial court, which consists of a chief justice and five associate justices appointed by the governor and council for a term of seven years. The court holds eight sessions annually, four each at Augusta and Portland. A superior court of seven justices is also statewide, holding sessions in each county either two or three times a year. In each county there is a probate court for the settlement of the estates of deceased persons, which is presided over by a single judge and which holds monthly or bimonthly sessions. Three county commissioners (two in Waldo county) hold court from two to six times annually in each county according to the volume of business handled. Judgeships on the county probate and county commissioners' courts are elective, unlike those on state courts, the judges and registers of probate courts being chosen every four years and one county commissioner being selected for a six-year term biennially.

The principal units of local government are the town (or township), the plantation, the county and the city. As in other parts of New England, the town or city is the most important of these. At the regular town meeting, ordinarily held in March, the electorate of the town assembles, decides what shall be done for the town during the ensuing year, elects officers to execute its decisions with limited discretion, and votes money to meet the expenses. The principal officers are the selectmen (usually three), town clerk, assessors, collector, treasurer, school committee and road commissioner. Maine is the only state in the union that retains what is known as the organized plantation. This is a governmental unit organized from an unincorporated township having at least 200 inhabitants, and its principal officers are the moderator, clerk, three assessors, treasurer, collector, constable and school committee. The county is an intermediate organization between the state and the towns, to assist chiefly in the administration of justice, especially in the custody of offenders. Its officers are three commissioners, a treasurer, a register of deeds, a judge of probate, a register of probate and a sheriff.

Population.—The population of Maine in 1790 was 96,540; in 1820 it was 298,335; in 1850, 583,169; in 1880, 648,936; in 1910, 742,371; and in 1940, 847,226. This last figure represents an increase of 6·2% over the population in 1930. The population per square mile was 27·3, as compared with 44·2 for the United States as a whole. Of the 1940 population, 343,057, or 40·5%, lived in urban places; that is, in cities and villages of 2,500 or more. The number of occupied dwelling units returned in the housing census of 1940 was 218,999, which is approximately the same as the number of families.



BY COURTESY OF THE U. S. BUREAU OF THE CENSUS

URBAN AND RURAL POPULATION OF MAINE, 1790–1940

The average population per family (occupied dwelling unit) declined from 4·0 in 1930 to 3·9 in 1940. The number of males per 100 females in the entire population of the state was 101·8. The population of the state and of its principal cities is:

Area	Population			Per cent of increase	
	1940	1930	1920	1930–40	1920–30
The State	847,226	797,423	768,014	6·2	3·8
Urban	343,057	321,506	299,569	6·7	7·3
Rural	504,169	475,917	468,445	5·9	1·6
Per cent urban	40·5	40·3	39·0	..	..
Principal cities:					
Portland	73,643	70,810	69,272	4·0	2·2
Lewiston	38,598	34,948	31,791	10·4	9·9
Bangor	29,822	28,749	25,978	3·7	10·7
Augusta	19,360	17,198	14,114	12·6	21·9

Finance.—Before 1912 the state constitution forbad the borrowing of money in excess of $300,000, except for the suppression of a rebellion, for war purposes, or for repelling an invasion. In that year an amendment to the constitution was adopted allowing the state to incur a debt not exceeding $2,000,000 for state highway purposes. Since 1912 several other amendments were adopted, extending the state's borrowing power to a total of about $36,000,000. The chief sources of the state's revenue are a general property tax; excise and franchise taxes of corporations, especially those of railway and insurance companies and savings banks; motor licence fees; a tax on internal combustion engine fuel; and a tax on collateral inheritances. The general property tax for state and local purposes is assessed by local assessors, but their work is reviewed for the purpose of equalization among the several towns and counties by the state assessor who also assesses the corporations. The chief expenditures of the state in 1940 were for highways, old-age assistance, education and charitable and benevolent institutions. The budget report for the fiscal year ending June 30, 1940, showed a cash balance on hand June 30, 1939, of $4,386,551; total receipts for the year, $44,179,595; total expenditures for the period, $43,822,761; and cash balance on hand June 30, 1940, $4,743,385.

Education.—The public-school system of Maine compares favourably with those of states of greater wealth. A well-arranged program providing for school buildings of modern construction has been followed in cities and towns; and in rural communities single-room school buildings have been giving way to consolidated schools, transportation being furnished to pupils from remote homes. In 1939 the total educational expenditures amounted to $11,504,888, or a per caput expenditure, based on total enrolment, of $58.90. The state school funds, which amount to about one-fourth of the total expenditures, are distributed according to children of school age, etc., except for $325,000 used as an equalization fund to aid the poorer districts. The legislature in 1919 provided for the schooling of children living in unorganized territory. Since that time remarkable progress has been made in providing educational advantages for the children of lighthouse keepers, coast fishermen and remote lumbermen. Vocational departments and industrial and trade courses are maintained in a large number of high schools. The state had above 250,000 children of school age (5–21) in 1939. Of these 170,001 were enrolled in the public schools, 125,422 being in the elementary schools and 44,579 in the high schools and academies. While primary school attendance was beginning to decline, secondary school attendance doubled between 1920 and 1940. School attendance through the school year is compulsory for all children between the ages of seven and 15. The average length of the school year varies from 177 days for elementary schools to 181 days for high schools. An effort has been made to eliminate illiteracy through evening schools and adult classes. Maine provides for the training of teachers in six normal schools, which in 1939–40 had an enrolment of 1,122 students. Two normal schools offer four-year courses leading to B.S. degrees. Commercial teacher-training is given by accredited commercial schools, several of which are affiliated with the University of Maine school of education. The University of Maine is at Orono, to which is attached an agricultural experiment station. Among the important institutions of learning which have no official connection with the state are Bowdoin college, at Brunswick; Colby college, at Waterville; Bates college, at Lewiston and Bangor Theological seminary (Congregational), at Bangor.

Charities and Corrections.—The state's welfare activities were co-ordinated in 1931 by an act establishing the department of health and welfare. The department was composed of three bureaus: health, welfare and institutional service, having authority over the state's welfare program. In 1939 the legislature removed control of state institutions from health and welfare to a new department of institutional service. The penal and reformatory institutions consist of the state prison, at Thomaston; the reformatory for men, at South Windham; the reformatory for women, at Skowhegan; the state (reform) school for boys, at South Portland; and the state (reform) school for girls, at Hallowell. The schools are not places of punishment, but reformatories for delinquent boys from eight to 16 years of age and girls from six to 16 years of age who have been committed by the courts for violations of law, or, in the case of girls, who, by force of circumstances or association, are "in manifest danger of becoming outcasts of society." The inmates in the state schools get instruction in various trades and occupations so as to be able to earn a living when discharged. Paupers were formerly cared for chiefly by towns and cities, those wholly dependent being placed in almshouses and those only partially dependent receiving aid in their homes. Federal-state old-age assistance funds are administered by the department of health and welfare. The charitable institutions maintained by the state are: the Augusta State hospital, at Augusta; Bangor State hospital, at Bangor; Central Maine sanatorium, at Fairfield; Northern Maine sanatorium, at Presque Isle; Western Maine sanatorium, at Greenwood Mountain; Pownal State school for the feeble-minded, at West Pownal; Bath Military and Naval Orphan asylum, at Bath, and the Maine school for the deaf, at Portland.

Agriculture, Forests and Fisheries.—It is estimated that about one-third of the people living in Maine are engaged in, or are supported by agriculture, but over one-half of the foodstuffs come from outside the borders of the state. The total number of farms declined from 60,016 in 1910 to 41,907 in 1935. The number of acres in farms showed a corresponding drop, decreasing from 6,296,859 ac. in 1910 to 4,721,842 ac. in 1935. The total value of farm property increased, between 1910 and 1930, from $199,271,998 to $248,696,000. Approximately 93% of the total number of farms are operated by their owners. Numerous co-operative associations have been organized in the interest of specialized producers, but they have not met with complete success, one notable failure being the collapse of the Maine potato growers' exchange in 1925. The total value of all farm products, in 1935, was estimated at $59,100,000. The state ranks first in the union in the production of potatoes. In 1940, the 165,000 ac. planted in potatoes produced 44,000,000 bu., worth more than one-half the total value of all farm crops. The agricultural product second in value was hay, with a production, in 1939, of 918,000 tons and an estimated value of $7,362,360. The only cereal produced on an economic scale was oats. Other crops of economic value are sweet corn for canning, apples, blueberries, dry beans and buckwheat. In 1938 there were 1,615,000 hens on the farms of Maine, and poultry products aggregating $7,008,000 were sold from them. By 1940 the number of hens was 1,873,000. During 1934 66,791,000 gal. of milk and 6,720,000 lb. of butter were produced. The livestock raised on Maine farms, in 1935, included 52,000 horses, worth $4,005,560; 245,000 cattle, worth $4,780,850; 59,000 sheep, worth $254,880; and 44,000 swine, worth $260,480.

The total land area of Maine is given as 19,865,000 ac., of which 16,269,464 ac. is forest land. From this forest land is cut annually 225,000,000 bd.ft. of lumber, 700,000 cords of pulpwood, and 500,000 cords of fuel wood. The men employed in these three industries alone receive $7,000,000 yearly in wages, and over 40% of the total railroad freight tonnage originating in Maine is composed of forest products.

Fishing is still an important industry along the coast of Maine. The catching and canning of young herring under the trade name of "sardines" is the chief product of the fisheries. The sardine production in 1937 was 1,680,241 standard cases, worth $4,998,373, this production being exceeded only by California. In 1938 the pack dropped to 659,584 cases, rising to 2,171,667 cases in 1939. The lobster catch is second in importance to the sardine industry, its value being between $1,000,000 and $2,000,000 per year. Other fishery products are: Cod, herring, haddock, clams, smelts, hake, sword-fish and mackerel.

Minerals and Manufactures.—In 1938 stone, sand, cement, clay products and slate led. Maine formerly ranked high as a producer of lime, building granite and slate, but production in these fields has fallen far below previous records. Granite and slate production have partly revived. Granite abounds all along the coast east of the Kennebec and on the adjacent islands, and is found farther inland, especially about the Rangeley lakes in Franklin and Oxford counties, and near Mt. Katahdin in Penobscot and Piscataquis counties. The huge monolithic columns 51.5 to 54 ft. long and 6 ft. in diameter for the cathedral of St. John the Divine in New York city were quarried on Vinalhaven island. Mineral products with their value in 1938 were: clay products worth $210,814; feldspar, 13,764 long tons, worth $68,047; and sand

and gravel, 3,802,704 short tons, worth $968,766. The total mineral production of the state in 1938 was valued at $3,548,638. Maine has no coal and has only a small amount of iron ore within her borders for the encouragement of manufacturing, yet the abundance of timber, the numerous coves, bays, navigable streams and water-power sites have helped to overcome the handicap. Shipbuilding was the leading industry until about the middle of the 19th century, when wooden ships began to be supplanted by ships of iron and steel. The first cotton mill was built at Brunswick, on the Androscoggin, about 1809; woollen mills followed; and late in the century some of the largest paper and pulp mills in the Union were erected, which are run by water power from the rivers. Maine had, in 1935, according to the census of manufactures, 1,223 industrial establishments, which gave employment to 69,764 wage earners, and had a product worth $371,-849,483. The seven leading industries were as follows: Paper, $53,499,-799; woollen and worsted goods, $41,554,605; boots and shoes, $39,227,671; wood pulp, $22,759,007; cotton goods, $20,152,963; canned vegetables, $8,061,257; and lumber products, $6,165,544. There is still much undeveloped water power; the Public Utilities Commission credits Maine with a potential maximum of 1,383,000 h.p. of which 702,000 are undeveloped.

Transportation.—The S.W. part of the state, with the manufacturing, the quarrying and much of the older agricultural district, always has had fairly satisfactory means of transportation, either by water or by rail. The coast has many excellent harbours, the Kennebec river is navigable for coast vessels to Augusta, and the Penobscot to Bangor. It was not until the last decade of the 19th century that the forests, the farming lands and the summer resorts of Aroostook county were reached by a railway, the Bangor and Aroostook. The total railway mileage in 1938 was 1,932. This shows a decrease of 381 mi. since 1920. The principal railway systems are the Maine Central, which enters every county but one, the Boston and Maine, the Bangor and Aroostook, the Canadian Pacific and the Canadian National. Steamboat lines formerly ran between Maine ports and several Canadian and American ports, but by 1941 most of the steamboats had disappeared. Several air lines connect the state with other states. Plane and auto transport have largely replaced ships and reduced electric and steam railroad traffic. The state highway system at the end of 1935 consisted of 8,060 mi., 6,639 of the total being surfaced. During the year 1936, 48.2 mi. of new surfacing were placed.

History.—Historical scholars are not agreed upon the date at which a history of Maine should begin. If the accounts of explorations by Norsemen be taken into consideration, it is possible that Maine was first sighted by these hardy seamen and explorers about A.D. 1000, when, it is supposed, Leif Ericsson discovered Vinland. The lack of any definite evidence of their explorations passes the credit of discovering Maine to others. John Cabot, while on his second voyage to the New World in 1498, probably saw the rugged coast of Maine. During the 16th century and the early part of the 17th the coast of Maine attracted various explorers, among them Giovanni da Verrazano (1524); Estéban Gomez (1525); Simon Ferdinando (1597); John Walker (1598); Bartholomew Gosnold and Bartholomew Gilbert (1602); Martin Pring (1603); Pierre du Guast, Sieur de Monts (1604); George Weymouth (1605); and John Smith (1614), who explored and mapped the coast and gave to the country the name New England. Gosnold and Gilbert had brought a small band of colonists with them in 1602 but made no attempt at colonization, because of the many savages seen along the shore. In 1603 De Monts received from Henry IV. of France a charter for all the region between 40° and 46° N., or a territory extending from about the present city of Philadelphia to Newfoundland, under the name of Acadie or Acadia, and in 1604 he built a fort on Neutral or St. Croix island at the mouth of the St. Croix river. A severe winter and scurvy reduced the colony by almost half before spring; when relief came it was decided to remove to Port Royal. In 1605 George Weymouth explored the south-west coast, kidnapped five Indians and carried them to England, where three of them lived for a time in the family of Sir Ferdinando Gorges, who soon became the leader in founding Maine. In 1607 the Plymouth company, of which he was an influential member, and which had received a grant of this region from James I. of England in the preceding year, sent out a colony numbering 120 under George Popham (*c.* 1550–1608), brother of Sir John Popham, and Raleigh Gilbert, son of Sir Humphrey Gilbert. The colony established itself at the mouth of the Kennebec river in August, but, finding its supplies insufficient, about three-fifths of its number returned to England in December. Popham died during the winter and Gilbert presided over the council.

The next spring James Davis arrived, bringing with him news of the death of Chief Justice Popham and of Sir John Gilbert, Raleigh Gilbert's brother. The death of two of the colony's chief sponsors and the hardships of the past winter caused the colonists to abandon the settlement and return to England. In 1609 the French Jesuits, Biard and Massé, established a fortified mission station on the island of Mount Desert; and although this, as well as the remnant of De Monts' settlement at the mouth of the St. Croix, was taken in 1613 by Sir Samuel Argall (d. 1626), acting under the instructions of the English at Jamestown, Va., some of these colonists returned later. In 1620 the Council for New England, the successor of the Plymouth company, obtained a grant of the country between 40° and 48° N., extending from sea to sea; and two years later Gorges and John Mason (1586–1635) received from the council a grant of the territory between the Merrimac and the Kennebec rivers for 60m. inland, under the name of the "Province of Maine." In 1629 they divided their possession, Gorges taking the portion between the Piscataqua and the Kennebec. Numerous grants of land in this vicinity followed within a few years; and permanent settlements at York, Saco, Biddeford, Cape Elizabeth, Falmouth (now Portland) and Scarborough were established in rapid succession. The Council for New England surrendered its charter in 1635. In the division of its territory Gorges retained the portion previously granted to him. The region between the Kennebec and the St. Croix north to the St. Lawrence, though still claimed by the French as part of Acadia, was conveyed to Sir William Alexander (1567?–1640); and in 1664, to the Duke of York, afterwards King James II.

Gorges named his tract the "County of New Somersetshire," and immediately began the administration of government, setting up in 1635 or 1636 a court at Saco under the direction of his kinsman, William Gorges. In 1639 he procured for his province a royal charter modelled on that of Maryland, which invested him with the feudal tenure of a county palatine and vice-regal powers of government. But east of the Piscataqua his charter was in conflict with the other (mutually conflicting) grants of the Council for New England; and Gorges and his agents met with a determined opposition, led by George Cleeve, the deputy-president of the Lygonia or "Plough" patent. This patent extended along the coast from Cape Porpoise to Casco and had been granted governmental as well as territorial rights. Moreover, Puritan Massachusetts, which was naturally hostile to the Anglicanism of Gorges and his followers, interpreted her charter so as to make her northern boundary run east and west from a point 3m. north of the source of the Merrimac river, and on this basis laid claim to practically the whole of Maine then settled. The factional quarrels there and with the Commonwealth Government in England made it easy for Massachusetts to enforce this claim at the time, and between 1652 and 1658 Maine was gradually annexed to Massachusetts. In 1672 Massachusetts extended her boundary eastward as far as Penobscot bay. Ferdinando Gorges, a grandson of the original proprietor, brought before parliament his claim to Maine, and in 1664 a committee of that body decided in his favour; but Massachusetts successfully resisted until 1677, when the king in council decided against her. She then quietly purchased the Gorges claim for £1,250 and held the province as a proprietor until 1691, when, by the new Massachusetts charter, Maine was extended to the Saint Croix river and was made an integral part of Massachusetts.

The French still claimed all territory east of the Penobscot, and so Maine was not only an exposed frontier but a battleground during the long struggle of the English against the Indians and the French. Its citizens also bore a conspicuous part in the expeditions beyond its borders. Port Royal was taken in May 1690 by Sir William Phipps, and Louisburg in June 1745 by Sir William Pepperell, both these commanders being from Maine. These expeditions were such a drain on Maine's population that Massachusetts was called upon to send men to garrison the little forts that protected the homes left defenceless by men who had gone to the front. During the War of Independence the town of Falmouth (now Portland), which had ardently resisted the claims of the British, was bombarded and burned, in 1775.

In the same year Benedict Arnold followed the course of the Kennebec and Dead rivers on his expedition to Quebec; and from 1779 to 1783 a British force was established at Castine. The embargo and non-intercourse laws from 1807 to 1812 were a severe blow to Maine's shipping, and in the war of 1812, Eastport, Castine, Hampden, Bangor and Machias fell to the British.

Maine, as a part of Massachusetts, was in general well governed, but a geographical separation, a desire to be rid of the burden of a large State debt, and a difference of economic interests as well as of politics (Maine was largely Democratic and Massachusetts was largely Federalist) created a desire for an independent commonwealth. This was felt before the close of the War of Independence, and in 1785–87 conventions were held at Falmouth (Portland) to consider the matter, but the opposition prevailed. The want of protection during the war of 1812 revived the question, and in 1816 the general court, in response to a great number of petitions, submitted to a vote in the towns and plantations of the district the question: "Shall the legislature be requested to give its consent to the separation of the District of Maine from Massachusetts, and the erection of said District into a separate State?" The returns showed 10,393 yeas to 6,501 nays, but they also showed that less than one-half the full vote had been cast. Acting upon these returns the legislature passed a bill prescribing the terms of separation, and directed another vote of the towns and plantations upon the question of separation and the election of delegates to a convention at Brunswick which should proceed to frame a Constitution, in case the second popular vote gave a majority of five to four for separation; but as that vote was only 11,969 yeas to 10,347 nays, the advocates of separation were unsuccessful. A large source of opposition to separation was removed in 1819 when Congress rearranged the customs districts so that coasting vessels from Maine, as a separate State, would not have to enter and clear on every trip to or from Boston. As a consequence, the separation measures were carried by large majorities that year, a Constitution was framed by a convention which met at Portland in October, and ratified by town meetings in December, and Maine applied for admission into the Union. Owing to the peculiar situation in Congress at the time, arising from the contest over the admission of Missouri, the question of the admission of Maine became an important one in national politics. By an act of March 3, 1820, Maine was finally admitted into the Union as a separate State, her admission being a part of the Missouri Compromise (*q.v.*).

The boundary on the north had not yet been ascertained and had long been a subject of dispute between the United States and Great Britain. The treaty of 1783 (Article II.) had defined the north-east boundary of the United States as extending along the middle of the river St. Croix "from its mouth in the Bay of Fundy to its source" and "due north from the source of St. Croix river to the highlands; along the said highlands which divide those rivers that empty themselves into the river St. Lawrence from those which fall into the Atlantic ocean, to the north-westernmost head of Connecticut river, thence down along the middle of that river to the forty-fifth degree of north latitude." Great Britain claimed that the due north line was 40m. long and ran to Mars Hill in Aroostook county, and that the highlands ran thence westerly 115m. to the source of the Chaudière. The United States, on the other hand, claimed that the northerly line was 140m. long, running to the highlands dividing the Restigouche and the tributaries of the Metis; and there was a further disagreement with regard to the side of the highlands on which the boundary should be, and as to what stream was the "north-westernmost head of Connecticut river." The 5th Article of the Jay treaty of 1794 provided for a commission to decide what the St. Croix river actually was, and this commission in 1798 defined the St. Croix, saying that its mouth was in Passamaquoddy bay and that the boundary ran up this river and the Cheputratecook to a marked monument. The Treaty of Ghent in 1814 (Article IV.) referred the question of the ownership of the islands in Passamaquoddy bay to a commission, which gave Moose, Dudley and Frederick islands to the United States, and (Article V.) provided for the survey (which was made in 1817–18) of a part of the disputed territory, and for a general commission. The general commissioners met at St. Andrews, N.B., in 1816, and in New York city in 1822, only to disagree; and when the king of the Netherlands, chosen as arbitrator in 1829 (under the convention of 1827), rendered in 1831 a decision against which the State of Maine protested, the Federal senate withheld its assent to his decision. In 1838–39 the territory in dispute between New Brunswick and Maine became the scene of a border disturbance, known as the "Aroostook War"; Maine erected forts along the line she claimed, Congress authorized the president to resist any attempt of Great Britain to enforce exclusive jurisdiction over the disputed territory, and an armed conflict seemed imminent. Gen. Winfield Scott was sent to take command on the Maine frontier, and on March 21, 1839, he arranged a truce and a joint occupancy of the territory in dispute until a satisfactory settlement should be reached by the United States and Great Britain. The Webster-Ashburton treaty of 1842 was a compromise which allowed Maine about 5,500 sq.m. less than she had claimed, and allowed Great Britain about as much less than her claim. All grants of land previously made by either party within the limits of the territory which by this treaty fell within the dominions of the other party were to be "held valid, ratified and confirmed to the persons in possession under such grants, to the same extent as if such territory . . . fallen within the dominions of the party by whom such grants were made." The government of the United States agreed to pay to Maine and Massachusetts "in equal moieties" the sum of $300,000 as compensation for the lands which they had claimed, and which under the treaty they were called upon to surrender. In 1853 Maine acquired from Massachusetts for $362,500 the latter's claim to all land in the disputed area. The "North-East Boundary Dispute," was settled in 1910.

The Democratic majority in the district of Maine effected the separation from Massachusetts, and from the date of that separation until 1853 Maine was classed as a Democratic State, although it elected a Whig governor in 1838 and in 1840, and cast its electoral vote for John Quincy Adams in 1824 and in 1828, and for W. H. Harrison in 1840. Maine was a pioneer in laws regulating the liquor business. In 1846 the first prohibitory law was passed; but, owing to its many weaknesses, a new and stricter law became effective in 1851. As a result of the prohibition and slavery questions, there was a party disintegration between 1850 and 1855, followed by the supremacy of the Republican Party from 1856 to 1878. In 1878 the electorate failed to select a governor, as no candidate received a majority of the votes as required by the Constitution. A Democratic-National fusion in the legislature resulted in the election of Alonzo Garcelon (1813–1906), the Democratic candidate. Again there was no election by popular vote in 1879, and Garcelon and his council secured a fusion majority in the legislature. On Jan. 3, 1880, the Supreme Court declared the governor and council in error in counting in a fusion majority, but on Jan. 7 the governor swore in a legislature with 78 fusion and only two Republican members, and, the governor's term having expired, the president of the senate, James D. Lamson, became governor ex officio. On Jan. 12 the Republicans, whose organized legislature was declared legal by the Supreme Court, seized the legislative chambers and chose as governor Daniel Franklin Davis (1843–97). On Jan. 17, Joshua L. Chamberlain, to whom the peaceful solution of the difficulty had largely been due, retired from the task assigned him by Garcelon on Jan. 5 "to protect the public property and institutions of the State" until Garcelon's successor should be duly qualified. In 1880 the Democrats and Greenbackers united and elected their candidate, but after 1883 Maine was strongly Republican until 1910.

Maine's position as a favourite resort for summer vacationists dates from about 1870, when camps, summer hotels and boarding houses began to multiply throughout the State. The needs of this summer population gave a new turn to certain types of agriculture, and the demand for souvenirs revived among the Indians basket-weaving, moccasin-making and such crafts. In 1875 a compulsory education act was passed. The law prohibiting the manufacture or sale of intoxicating liquor was made a part of the Constitution in 1884 by an overwhelming majority of the votes cast. In 1914 the Public Utilities commission was created by an act of the legislature; in the year following, a workmen's compensation law was adopted. Some of the administrative functions of the state were reorganized in 1931 into five departments.

The Republicans have generally controlled Maine since the early eighties, although the Democrats elected a governor in 1910 and won the state's vote for Wilson in 1912. Two decades later the Democrats again elected a governor, Louis J. Brann, thus providing a good omen for the party's national triumph two months later. Roosevelt failed to carry Maine at that time, but Brann was reëlected in 1934. The state's vote for repeal of the 18th amendment in 1933 and for the repeal of its own constitutional provision for prohibition in 1934 further revealed its break from historic traditions. The long contemplated Passamaquoddy Bay hydro-electric project was endorsed in 1934 as a New Deal public works project in order to relieve unemployment and to harness the natural energy of the tides, but was discontinued in June 1936 with the failure of congress to appropriate funds. The Republican party carried Maine in state and national elections in 1936, 1938 and 1940. National defence in Maine in 1941 began with an army air base under construction, airports projected, and a shipbuilding boom under way.

BIBLIOGRAPHY.—There is no satisfactory complete history of Maine. *Maine, A History* (5 vol., 1919), edit. by Louis C. Hatch, treats the state's history to the date of its publication. Bibliographical aids are: Joseph Williamson, *Bibliography of the State of Maine from the Earliest Period to 1891* (1896); H. W. Bryant, *Check List of Maine Town Histories* (1902–04); A. J. Huston, *Check List of Maine Local Histories* (1915); and Elizabeth Ring, *A Reference List of Manuscripts Relating to the History of Maine*, 3 vol. (1938–41). For early history, *see* Henry S. Burrage, *The Beginnings of Colonial Maine, 1602–58* (1914) and *Gorges and the Grant of the Province of Maine, 1622* (1923); H. M. Sylvester, *Maine Pioneer Settlements* (5 vol., 1909); J. P. Baxter, *Sir Ferdinando Gorges and his Province of Maine* (1890); W. D. Williamson, *History of the State of Maine* (Hallowell, 1832); and J. L. Chamberlain, *Maine, Her Place in History* (Augusta, 1877). *See* also W. K. Moorehead, *A Report on the Archaeology of Maine* (1922); *Maine Historical Society Collections* (in 3 series, 1831, *et seq.*); *Gorges Society Publications* (1884, *et seq.*); *Documentary History of the State of Maine*, published by the Maine Historical Society (24 vol., 1896–1916); and George Folsom, *A Catalogue of Original Documents in the English Archives Relating to . . . Maine* (1858). For administration, *see* the *Maine Register; Maine Statutes;* and the *Reports* of the various state departments, boards, and commissions. Emerson, *When North Winds Blow* (1922). (K. C. M. S.; E. F. D.)

MAINE DE BIRAN, FRANÇOIS-PIERRE-GONTHIER (1766–1824), French philosopher, was born at Bergerac, on Nov. 29, 1766. The name Maine he assumed (some time before 1787) from an estate called Le Maine, near Mouleydier. After studying under the *doctrinaires* of Périgueux, he entered the king's life-guards, and was present at Versailles on the memorable Oct. 5 and 6, 1789. He then retired to his estate at Grateloup, near Bergerac, where his retired life preserved him from the horrors of the Revolution. It was at this period that, to use his own words, he "passed *per saltum* from frivolity to philosophy." After the Reign of Terror Maine de Biran took part in political affairs. He was excluded from the council of the Five Hundred on suspicion of royalism, but took part with his friend Lainé in the commission of 1813, which expressed for the first time direct opposition to Napoleon. After the Restoration he was treasurer to the chamber of deputies. He died in July 1824.

Maine de Biran's most important works were not published during his lifetime. An incomplete collection, by Victor Cousin, appeared in 1834 and 1841. But the publication (in 1859) by E. Naville (from mss. placed at his father's disposal by Biran's son) of the *Oeuvres inédites de Maine de Biran*, in three volumes first rendered possible a connected view of his philosophical development. At first a sensualist, like Condillac and Locke, next an intellectualist, he finally shows himself a mystical theosophist. The *Essai sur les fondements de la psychologie* represents the second or completest stage of his philosophy, the fragments of the *Nouveaux essais d'anthropologie* the third.

Biran's work presents a very remarkable specimen of deep metaphysical thinking directed by preference to the psychological aspect of experience.

The *Oeuvres inédites* of Maine de Biran by E. Naville contain an introductory study; in 1887 appeared *Science et psychologie: nouvelles oeuvres inédites*, with introduction by A. Bertrand. *See* also O. Merton, *Etude critique sur Maine de Biran* (1865); E. Naville, *Maine de Biran, sa vie et ses pensées* (1874); J. Gérard, *Maine de Biran, essai sur sa philosophie* (1876); Mayonade, *Pensées et pages inédites de Maine de Biran* (Périgueux, 1896); G. Allievo, "Maine de Biran e la sua dottrina antropologica" (Turin, 1896, in *Memorie dell' accademia delle scienze*, 2nd ser., xlv., pt. 2); A. Lang, *Maine de Biran und die neuere Philosophie* (Cologne, 1901); monographs by A. Kühtmann (Bremen, 1901) and M. Couailhac (1905); N. E. Truman in *Cornell Studies in Philosophy*, No. 5 (1904) on Maine de Biran's Philosophy of Will.

MAINE-ET-LOIRE, a department of western France, formed in 1790 for the most part out of the southern portion of the former province of Anjou, and bounded N. by the departments of Mayenne and Sarthe, E. by Indre-et-Loire, S.E. by Vienne, S. by Deux-Sèvres and Vendée, W. by Loire-Inférieure, and N.W. by Ille-et-Vilaine. Area, 2,787 sq. miles. Pop. (1936) 477,690. The department includes the course of the Authion and the lower course of the Maine, with its feeders, the Loir, Sarthe, Mayenne and Oudon, on the right bank of the Loire; as well as those of the Layon, Evre and Divatte on the left. The Val d'Anjou, followed by the Loire, forms a zone of rich meadows, market gardens and orchards from east to west. The west of the department is floored by Palaeozoic rocks and granites of the Armorican system, but east of the line of the Sarthe the rocks are chiefly cretaceous, with tertiary capping on the somewhat higher ground between the rivers. The name Val d'Anjou belongs strictly to the eastern part of the Loire valley in the department. The climate is very mild. The mean annual temperature of Angers is about 54°; the rainfall is between 23 and 24 in. annually. The frequent fogs, combined with the peculiar nature of the soil in the south-east of the department, are highly favourable to meadow growths. The winter colds are never severe, and readily permit the cultivation of certain trees which cannot be reared in the adjoining departments.

The chief cereals grown are wheat, oats and barley, and potatoes and mangels also give good returns. Much hemp is grown in the valley of the Loire, and the vegetables, melons and other fruits of that region are of the finest quality. Good wine is produced at Serrant and other places near Angers, and on the right bank of the Layon and near Saumur, famous for its sparkling white wine. Cider apples, and fruit generally, are produced. Woodland, chiefly of oak and beech, covers large tracts. The fattening of cattle is an important industry round Cholet, and horses are reared. There are important slate quarries near Angers, tufa is worked in the river valleys, and freestone and other stone, iron and coal are also found. The manufactures are linen and woollen stuffs, ticking, gingham, etc., umbrellas, calicoes, handkerchiefs, etc. The department is served by the railways of the State and of the Orléans company. The Mayenne, the Sarthe and the Loire, together with some of the lesser rivers, provide about 130 m. of navigable waterway. In the south-east the canal of the Dive covers some 10 m. in the department.

There are four arrondissements—Angers, Cholet, Saumur and Segré, with 34 cantons and 381 communes. Maine-et-Loire belongs to the académie (educational division) of Rennes, to the region of the IX. army corps (Tours) and to the ecclesiastical province of Tours. Angers (*q.v.*), the capital, is the seat of a bishopric and of a court of appeal. Other important places are Cholet, Saumur and Fontevrault. For architectural interest there may also be mentioned the châteaux of Brissac (17th century), Serrant (15th and 16th centuries), Montreuil-Bellay (14th and 15th centuries), and Ecueillé (15th century), and the churches of Puy-Notre-Dame (13th century) and St. Florent-le-Vieil (13th, 17th and 19th centuries), the last containing the fine monument to Charles Bonchamps, the Vendean leader, by David d'Angers. Gennes has remains of a theatre and other Roman remains, as well as two churches dating in part from the 10th century. Ponts-de-Cé, an interesting old town built partly on islands in the Loire, is important, because till the Revolution its bridges formed the only way across the Loire between Saumur and Nantes.

MAINPURI, a town and district of British India, in the Agra division of the United Provinces. The town (pop. [1941], 19,261) consists of two separate portions, Mainpuri proper and Mukhamganj. Holkar plundered and burned part of the town in 1804, but was repulsed by the local militia. Since the British occupation the population has rapidly increased and many improvements have been carried out. The Agra branch of the Grand Trunk road runs through the town, forming a wide street lined on both sides by shops, which constitute the principal bazaar. Mainpuri has a speciality in the production of carved wooden articles inlaid with brass wire. The American Presbyterian mission manages a high school.

The District of Mainpuri lies in the central Doab. Area, 1,679 sq.mi. Pop. (1941) 872,601. It consists of an almost unbroken plain wooded throughout with mango groves, and isolated clumps of *bábul* trees occasionally relieve the bareness of its saline *usar* plains. On the south-western boundary the Jumna flows in a deep alluvial bed, sometimes sweeping close to the high banks which overhang its valley, and elsewhere leaving room for a narrow strip of fertile soil between the river and the upland plain. The district is watered by two branches of the Ganges canal.

Mainpuri anciently formed part of the great kingdom of Kanauj, and after the fall of that famous state it was divided into a number of petty principalities, of which Rapri and Bhongaon were the chief. In 1194 Rapri was made the seat of a Muslim governor. Mainpuri fell to the Moguls on Baber's invasion in 1526, passed, towards the end of the 18th century, into the power of the Mahrattas, and finally became a portion of the province of Oudh. When this part of the country was ceded to the British, in 1801, Mainpuri town became the headquarters of the extensive district of Etawah, which was in 1856 reduced by the formation of Etah and Mainpuri into separate collectorates.

MAINTAINED PRICE: *see* Price Maintenance.

MAINTENANCE AND CHAMPERTY. In English law maintenance is the maintaining or assisting a party, with money or otherwise, to prosecute or defend an action in which the maintainer has no legitimate interest. The law allows a master to assist his servant, near relations to support each other, the charitable to assist the poor, and persons having an interest even contingent in the subject matter or principle involved in a suit to assist a party to it. Other maintenance is a criminal offence and a civil cause of action. In theory, even if the maintained action succeeds so that a party is assisted only to secure his legal due, the unsuccessful party can sue the maintainer if he can prove that he has suffered damage (*Neville* v. *London Express Newspaper Ltd.*, 1919, A.C. 368), but this is seldom if ever possible since the damages and costs which he is compelled to pay flow from his own wrong and not from the maintenance. If the maintainer is to be rewarded by receiving some part of the subject matter of or some profit from the suit the bargain is the criminal offence of Champerty. (X.)

United States.—Maintenance and champerty as defined by the common law are still generally criminal in the United States. The criminal aspect of maintenance and champerty has now little significance, but the concepts retain their vigour in rendering unethical the conduct of a particular attorney or illegal contracts between attorneys and clients concerning remuneration for services rendered in the prosecuting of a suit. The charging of legal fees contingent upon success is technically champerty, but the strict definition has relaxed as the social necessity of such a practice has become increasingly apparent. The common law doctrines that made illegal all champertous agreements have consequently been greatly modified by judicial decision. A few States follow the so-called Massachusetts rule which makes illegal an agreement by an attorney that he shall receive a specific share in the proceeds of the suit but considers an agreement legal which merely provides for a larger fee in the event of success. The majority of States follow the rule that champerty of itself does not make the agreement illegal unless it is accompanied either by maintenance in the form of an agreement that the attorney will bear the expenses of the suit, or by a provision binding the client not to compromise or release the claim without the consent of the attorney. The fact that such rules consider the form and not the substance of the agreement has led to the modern view held by a few States, namely that neither technical champerty nor maintenance invalidates the contract but its validity is to be determined by a consideration of whether the particular agreement induced the litigation and revealed an overreaching of the client by the attorney. Many States unfortunately have allowed an attorney whose agreement for fees is invalid because of champerty or maintenance to recover reasonable fees from his client, thus permitting him to charge any fees that he may desire in the first instance and in the unusual event of litigation assuring him no matter what the final outcome a reasonable compensation. The champertous character of an agreement between attorney and client can be availed of only by the parties to it, and no defendant can successfully defend the claim against him by proving that the plaintiff is prosecuting it under a champertous agreement.

The ease with which the practices of champerty, maintenance and barratry or the stirring up of vexatious litigation have eluded both the criminal law and the restraining influence of doctrines rendering contracts between lawyers and clients illegal, has led in the large American cities to the practice of "ambulance chasing." Unscrupulous attorneys eager to solicit business in negligence cases employ runners who keep track of accidents with the aid of police, newspaper reporters, doctors, etc., and by appearing on the scene shortly after the accident manage to inveigle the victims into engaging them to prosecute their claims. Needless litigation over minor and often spurious injuries is thus aroused. In Minnesota by virtue of a statute which has since been declared unconstitutional (*Davis* v. *Farmers' Co-op. Equity Co.*, 262 U.S. 312 [1923]), attorneys sought to bring within the jurisdiction of Minnesota courts claims for injuries arising out of railroad transportation which may have occurred a thousand or more miles from the place of trial merely on the ground that the railroad maintained a freight and passenger agent in the State although it operated no trackage within the State, nor was the plaintiff a resident of the State. Similar attempts have been made by other States to facilitate the trial of accident cases remote from the place of their occurrence so as to harass the defendent into a settlement irrespective of the merits of the plaintiff's claim by the prospect of the costs that he would incur in bringing his witnesses to the place of trial. The seriousness of the evil of ambulance chasing is also attested to by recent investigations initiated by the bar and conducted by the courts of New York, Ohio and Wisconsin into the practice in the hope of devising means for its correction. As a result of the investigation conducted by the supreme court of New York in 1928 in the city of New York disbarment proceedings and criminal prosecutions were begun against more than 70 New York lawyers. Though ambulance-chasing is in part the reaction of some of the legal profession to the unscrupulous methods of claim agents for defendant corporations in securing releases from injured parties for nominal sums before the consequences of the injury could be rationally ascertained, its sway can be attributed to the want of sufficiently high moral and intellectual standards for admission to the practice of law.

(J. M. La.)

MAINTENON, FRANÇOISE D'AUBIGNÉ, Marquise de (1635–1719), the second wife of Louis XIV., was born in a prison at Niort, on Nov. 27, 1635. Her father, Constant d'Aubigné, was the son of Agrippa d'Aubigné, the friend and general of Henry IV., and had been imprisoned as a Huguenot malcontent, but her mother had the child christened a Catholic. After the release of d'Aubigné the family went to Martinique. There the father died. Mother and child returned to France, where Françoise was surrendered to a Protestant relative who is said to have converted her to Protestantism. She was removed by an order of state to Catholic guardianship, and reconverted. She and her mother were penniless, and the girl married (1652) Scarron, the famous wit, to whom she was more nurse than wife. He died in 1660. Anne of Austria continued his pension to his widow, and even increased it to 2,000 livres a year, which enabled her to entertain and frequent literary society. After Anne's death the pension was continued by the king on the intercession of his mistress, Madame de Montespan, who put her in charge of the children whom she bore to Louis. In 1674 the king determined to have his children at court, and their governess who had now made sufficient fortune to buy the estate of Maintenon, accompanied them. In 1678 her estate at Maintenon was raised to a marquisate. Mme. de Montespan's jealousy was aroused by these favours, and Mme. de Maintenon's position was almost unendurable until Mme. de Montespan left the court. Madame de Maintenon now became the king's mistress "en titre." The queen declared she had never been so well treated as at this time, and eventually died in Mme. de Maintenon's arms in 1683. In 1684 Mme. de Maintenon was made first lady in waiting to the dauphiness, and in the winter of 1685–1686 she was privately married to the king by Harlay, archbishop of Paris, in the presence, it is believed, of Père la Chaise, the king's confessor, the marquis de Montchevreuil, the chevalier de Forbin, the marquis de Louvois and the valet, Bontemps. No written proof of the marriage is extant, but that it took place is nevertheless certain. Her life during the next 30 years can be fully studied in her letters.

Her political influence has probably been exaggerated, but it was supreme in matters of detail. The ministers of the day used to discuss and arrange all the business to be done with the king beforehand with her, and it was all done in her cabinet and in her presence, but the king in more important matters often chose not to consult her. Such mistakes as, for instance, the replacing of Catinet by Villeroi may be attributed to her, but not whole policies—notably, according to Saint-Simon, not the policy with regard to the Spanish succession. Even the revocation of the edict of Nantes and the dragonnades have been unjustly laid to her charge. Her influence was on the whole a moderating and prudent force. Her social influence was always exercised on the side of decency and morality. Side by side with this public life, she passed a happier existence as the foundress of St. Cyr. Mme. de Maintenon was a born teacher; and she had always wished to establish a home for poor girls of good family placed in such straits as she herself had experienced.

As soon as her fortunes began to mend she started a small home for poor girls at Ruil, which she afterwards moved to Noisy, and which was the nucleus of the splendid institution of St. Cyr, which the king endowed in 1686, out of the funds of the abbey of St. Denis. For her "little sisters" at St. Cyr Racine wrote his *Esther* and his *Athalie*.

The later years of her power were marked by the promotion of her old pupils, the children of the king and Mme. de Montespan, to high dignity between the blood royal and the peers of the realm, and it was doubtless under the influence of her dislike for the duke of Orleans that the king drew up his will, leaving the personal care of his successor to the duke of Maine, and hampering the duke of Orleans by a council of regency, an arrangement which was overthrown by the parlement after the king's death. The regent Orleans visited her at St. Cyr and continued her pension of 48,000 livres. On April 15, 1719, she died, and was buried in the choir at St. Cyr.

Her *Lettres historiques et édifiantes* (7 vols.) and her *Correspondance générale* (4 vols., 1888), were edited by Th. Lavallée. Saint-Simon's account of the court in her day is contained in vol. xii of his *Mémoires*. *See* also Mademoiselle d'Aumale's *Souvenirs sur Madame de Maintenon,* ed. Comte d'Haussonville and G. Hanotaux (3 vols., 1902–04); A. MAINZ (Fr. Mayence), a city and episcopal see of Germany, on the left bank of the Rhine, almost opposite the influx of the Main, in the *Land* of Hesse, and at the junction of the important main lines of railway from Cologne to Mannheim and Frankfort-on-Main, 25 mi. W. of the latter. Pop. (1933) 142,428; (1939) 158,971, of whom two-thirds are Roman Catholic.

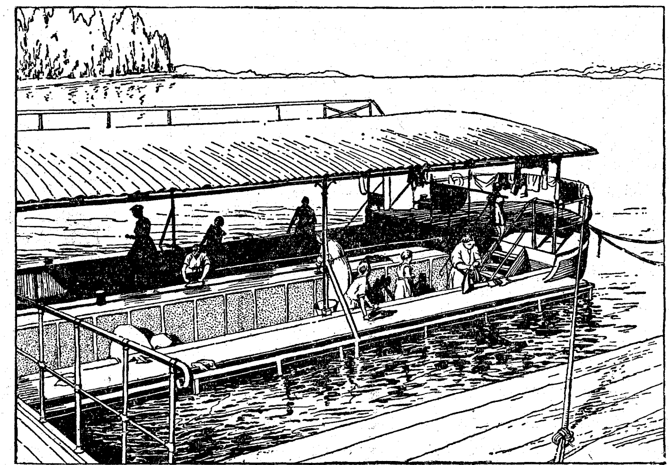
History.—Mainz was a pre-Roman settlement, at which, about 13 B.C. Drusus, the step-son of Augustus, erected a fortified camp; the *castellum Mattiacorum* (the modern Castel) on the opposite bank was afterwards added to it, the two being connected with a bridge at the opening of the Christian era. The earlier name became latinized as *Maguntiacum,* or *Moguntiacum,* and a town gradually arose around the camp, which became the capital



BY COURTESY OF H. A. FRANCKS

A FLOATING LAUNDRY ON THE RHINE, JUST BELOW WHERE THE MAIN JOINS IT

of Germania Superior. During the Völkerwanderung Mainz suffered severely, being destroyed on different occasions by the Alamanni, the Vandals and the Huns. Christianity seems to have been introduced into the town at a very early period, and in the 6th century a new Mainz was founded by Bishop Sidonius. In the middle of the 8th century under Boniface it became an archbishopric, and to this the primacy of Germany was soon annexed. Charlemagne, who had a palace in the neighbourhood, gave privileges to Mainz, which rose rapidly in wealth and importance, becoming a free city in 1118. In 1160 the citizens revolted against Archbishop Arnold, and in 1163 the walls of the city were pulled down by order of the emperor Frederick I.

In 1244 certain rights of self-government were given to the citizens; and in 1254 Mainz was the centre and mainspring of a powerful league of Rhenish towns. In 1462 there was warfare between two rival archbishops. The citizens espoused the losing cause and were deprived of their privileges. Many of the inhabitants were driven into exile, and these carried into other lands a knowledge of the art of printing, which had been invented at Mainz by Johann Gutenberg in 1450. During the Thirty Years' War Mainz was occupied by the Swedes and by the French. In 1792 the citizens welcomed the ideas of the French Revolution; they expelled their archbishop, and opened their gates to the French troops. Mainz was ceded to France by the treaty of Campo Formio in 1797, and again by the Treaty of Lunéville in 1801. In 1814 it was restored to Germany and in 1816 it was handed over to the grand duke of Hesse. After World War I it was occupied by Allied troops. During World War II it was bombed by the British.

Architecture and Trade.—The cathedral is a Romanesque edifice with numerous Gothic additions and details. It was originally erected between 975 and 1009, but has since been repeatedly burned down and rebuilt, and in its present form dates chiefly from the 12th, 13th and 14th centuries. The whole building was restored by order of Napoleon in 1814, and another thorough renovation was made more recently. The most noteworthy of the other churches are those of St. Ignatius, with a finely painted ceiling, of St. Stephen, built 1257–1328, and restored after an explosion in 1857, and of St. Peter. The old electoral palace (1627–1678), a large building of red sandstone, now contains a valuable collection of Roman and Germanic antiquities. Among the other principal buildings are the former palace of the grand duke of Hesse, built in 1731–1739 as a lodge of the Teutonic order, and the government buildings. A statue of Gutenberg, by Thorwaldsen, was erected at Mainz in 1837. Mainz still retains many relics of the Roman period, the most important of which is the Eigelstein, a monument believed to have been erected by the Roman legions in honour of Drusus. It stands within the citadel, which occupies the site of the Roman castrum. A little to the south-west of the town are the remains of a large Roman aqueduct, of which upwards of sixty pillars are still standing. The university of Mainz, founded in 1477, was suppressed by the French in 1798.

The site of Mainz would seem to mark it out naturally as a great centre of trade, but the illiberal rule of the archbishops and its military importance seriously hampered its commercial and industrial development, and prevented it from rivalling its neighbour Frankfort. It is now, however, the chief emporium of the Rhenish wine traffic, and also carries on an extensive transit trade in grain, timber, flour, petroleum, paper and vegetables. The principal manufactures are leather goods, furniture, carriages, chemicals, musical instruments, cement and boots. Other industries include brewing, ship-building and printing. Mainz is the administrative and judicial capital of the province of Rhein-Hessen.

The Archbishopric of Mainz, dating from 747, was one of the seven electorates of the Holy Roman Empire, and became a powerful state during the middle ages, retaining some of its importance until the dissolution of the empire in 1806. Its archbishop was president of the electoral college, arch-chancellor of the empire and primate of Germany. The lands of the electorate lay around Mainz, and were on both banks of the Rhine; their area at the time of the French Revolution was about 3,200 sq.m. The archbishopric was secularized in 1803, two years after the lands on the left bank of the Rhine had been seized by France. Some of those on the right bank of the river were given to Prussia and to Hesse; others were formed into a grand duchy for Dalberg. The archbishopric itself was transferred to Regensburg.

MAIR, ALEXANDER WILLIAM (1875–1928), Scottish classical scholar, was born on June 9, 1875, at Deerhill, Banff. After a distinguished career at Aberdeen and Cambridge he was appointed (1899) assistant professor and (1903) professor of Greek at Edinburgh university. He was an unusually able and meticulous scholar of the Cambridge school, and a highly successful teacher. His chief works were his editions and translations of Hesiod, Callimachus, Lycophron and Oppian (the last-named being unpublished at his death). He also wrote the biographies of PLINY, LUCIAN, EPICURUS and several other articles for the present edition of this *Encyclopædia.* He was burned to death by an accident in his study on Nov. 12, 1928.

MAIRET, JEAN DE (1604–1686), French dramatist, was born at Besançon, and died there on Jan. 31, 1686. His own statement that he was born in 1610 has been disproved. He went to Paris to study at the Collège des Grassins about 1625, in which year he produced his first piece *Chriséide et Arimand,* followed in 1626 by *Sylvie,* a "pastoral tragi-comedy." In 1634 appeared his masterpiece, *Sophonisbe,* which marks, in its observance of the rules, the beginning of the "regular" tragedies. Mairet was one of the bitterest assailants of Corneille in the controversy over *The Cid.* It was perhaps his jealousy of Corneille that made him give up writing for the stage. He was appointed in 1648 official representative of the Franche-Comté in Paris, but in 1653 he was exiled for a short time by Mazarin. His other plays include *Silvanire ou la Morte-vive,* published in 1631 with a preface on the observance of the unities, *Les Galanteries du duc d'Orsonne* (1632), *Virginie* (1633), *Marc-Antoine* (1635) and *Le Grand et dernier Solyman* (1637).

See G. Bizos, *Etude sur la vie et les oeuvres de Jean de Mairet* (1877). *Sophonisbe* was edited by K. Vollmöller (Heilbronn, 1888), and *Silvanire* by R. Otto (Bamberg, 1890).

MAIRONIS (1862–1932), Lithuanian poet, whose real name is Jonas Mačiulis, was born at Pasandvaris, in the Kaunas (Kovno) district. In 1909, Maironis was appointed rector of the Kaunas seminary and in 1922 became a professor and deacon of the theological faculty of the Kaunas University which he helped to found. His songs are sung all over Lithuania. His famous poem *Young Lithuania* describes the national rebirth; *Our Sufferings* is a poem descriptive of the Lithuanian national ripening and conquest of independence; his *Magdalen of Raseiniai* castigates the national vices, while his Polish poem *Znad Biruty* appeals to the Polonised Lithuanian nobility. His dramatic works include *Where is Salvation? The Death of Kestutis,* and *Vytautas with the Crusaders,* the two last being historical plays of the 14th century. Maironis also translated the *Rigveda* into Lithuanian.

MAISTRE, JOSEPH DE (1754–1821), French diplomatist and polemical writer, was born at Chambéry on April 1, 1754. His family was an ancient and noble one, and is said to have been of Languedocian extraction. The father of Joseph was president of the senate of Savoy, and held other important offices. Joseph himself, after studying at Turin, entered the civil service of Savoy, finally becoming a member of the senate. In 1786 he married Françoise de Morand. The invasion and annexation of Savoy by the French Republicans made him an exile. He betook himself to the neutral territory of Lausanne. There, in 1796, he published his *Considérations sur la France.* In this he developed his Legitimist views, based on his religious convictions. The philosophism of his day was his lifelong aversion.

Charles Emmanuel now summoned de Maistre to Turin; he followed the king to Sardinia, and in 1802 he was appointed envoy extraordinary and minister plenipotentiary at St. Petersburg. During these years he only published a single treatise, on the *Principe générateur des Constitutions;* but he wrote his best and most famous works, *Du Pape* (written in 1817) and its continuation, *De L'église gallicane* and the *Soirées de St. Pétersbourg,* the last of which was never finished. *Du Pape,* written from the standpoint of papal absolutism, is a treatise on the relations of the sovereign pontiff to the Church, to temporal sovereigns, to civilization generally, and to schismatics, especially Anglicans and the Greek Church. The *Soirées de St. Pétersbourg* deals with the fortunes of virtue and vice in this world. It contains two of De Maistre's most famous pieces, his panegyric on the executioner as the foundation of social order, and his acrimonious, and in part unfair, but also in part very damaging, attack on Locke. Besides these works he wrote an examination of the philosophy of Bacon, some letters on the Inquisition, and, earlier than any of these, a translation of Plutarch's "Essay on the Delay of Divine Justice," with somewhat copious notes. After 1815 he returned to Savoy, and was appointed to high office. He died on Feb. 26, 1821, at Turin. Most of the works mentioned were posthumous, and it was not till 1851 that a collection of *Lettres et opuscules* appeared.

Joseph de Maistre was one of the most powerful, and by far the ablest, of the leaders of the neo-Catholic and anti-revolutionary movement. He regarded the temporal monarchy as an institution of altogether inferior importance to the spiritual primacy of the pope. He was by no means a political absolutist, except in so far as he regarded obedience as the first of political virtues, and he seldom loses an opportunity of stipulating for a tempered monarchy. But the pope's power is not to be tempered at all, either by councils or by the temporal power or by national churches, least of all by private judgment. The absolute necessity of order was, doubtless, the first principle of this thinker, who will invite comparison with Hobbes. The anarchic tendencies of the Revolution in politics and religion offended him. Moreover, he was profoundly and accurately learned in history and philosophy and the superficial blunders of the *philosophes* irritated him as much as their doctrines. To Voltaire he shows no mercy.

Of the two works named as his masterpieces, *Du Pape* and the *Soirées de St. Pétersbourg,* editions are extremely numerous. No complete edition of his works appeared till 1884–87, when one was published at Lyons in 14 volumes. This had been preceded, and has been followed, by numerous biographies and discussions: C. Barthélemy, *L'Ésprit de Joseph de Maistre* (1859); R. de Sézeval, *Joseph de Maistre* (1865); L. I. Moreau, *Joseph de Maistre* (1879); F. Paulhan, *Joseph de Maistre et sa philosophie* (1893); L. Cogordan, "Joseph de Maistre" in the *Grands écrivains français* (1894); F. Descostes, *Joseph de Maistre avant la révolution* (1896), and other works by the same writer; J. Mandoul, *Un Homme d'état italien: Joseph de Maistre et la politique de la maison de Savoie* (1900); E. Grasset, *Joseph de Maistre* (1901); L. Arnould, *La Providence et le Bonheur d'après Bossuet et Joseph de Maistre* (1916); C. Besse, *Le paradox celebre de J. de Maistre sur la guerre* (1916); M. Jugie, *J. de Maistre et l'église Gréco-Russe* (1922); and F. Vermale, *Notes sur J. de Maistre inconnu* (Chambéry, 1921).

MAISTRE, XAVIER DE (1763–1852), younger brother of Joseph de Maistre, was born at Chambéry on Nov. 8, 1763. He served in the Piedmontese army, and wrote his delightful fantasy, *Voyage autour de ma chambre* (published 1794) when he was under arrest at Turin in consequence of a duel. On the annexation of Savoy to France, he left the service, and took a commission in the Russian army. He served under Suvarov in his victorious Austro-Russian campaign and accompanied the marshal to Russia. He shared the disgrace of his general, and supported himself for some time in St. Petersburg by miniature painting. But on his brother's arrival in St. Petersburg he was introduced to the minister of marine. He was appointed to several posts in the capital, but also saw active service, was wounded in the Caucasus, and attained the rank of major-general. He died at St. Petersburg on June 12, 1852. Besides the *Voyage* already mentioned, Xavier de Maistre's works (all of which are of very modest dimensions) are *Le Lépreux de la cité d'Aoste* (1811); *Les Prisonniers du Caucase* (1825), *La Jeune Sibérienne* (1825) and the *Expédition nocturne*, a sequel to the *Voyage autour de ma chambre* (1825).

His works, with the exception of some brief chemical tractates, are included in the collections of Charpentier, Garnier, etc. and his *Oeuvres inédites* (2 vols., 1877). *See* Sainte-Beuve's *Portraits contemporains*, vol. iii. A. Berthier, *Xavier de Maistre* (Lyon, 1920) C. de Bultet, *Aperçu de la vie de Xavier de Maistre* (Grenoble, 1919).

MAITLAND, EDWARD (1824–1897), English humanitarian writer, was born at Ipswich on Oct. 27, 1824, and was educated at Caius college, Cambridge. With Anna Kingsford (1846–88), the supporter of vegetarianism and anti-vivisectionism, he brought out *Keys of the Creeds* (1875), *The Perfect Way: or the Finding of Christ* (1882), and founded the Hermetic Society in 1884. After her death he founded the Esoteric Christian Union in 1891, and wrote her *Life and Letters*. He died on Oct 2, 1897.

MAITLAND, FREDERIC WILLIAM (1850–1906), English jurist and historian, son of John Gorham Maitland, was born on May 28, 1850, and educated at Eton and Trinity, Cambridge. He was called to the bar (Lincoln's Inn) in 1876, and made himself a thoroughly competent equity lawyer and conveyancer, but finally devoted himself to comparative jurisprudence and especially the history of English law. In 1884 he was appointed reader in English law at Cambridge, and in 1888 became Downing professor of the laws of England. Though handicapped in his later years by delicate health, his intellectual grasp and wide knowledge and research gradually made him famous as a jurist and historian. He edited numerous volumes for the Selden Society, including *Select Pleas for the Crown, 1200–1225*, *Select Pleas in Manorial Courts* and *The Court Baron*; and among his principal works were *Gloucester Pleas* (1884), *Justice and Police* (1885), *Bracton's Note-Book* (1887), *History of English Law* (with Sir F. Pollock, 1895; new ed. 1898); *Domesday Book and Beyond* (1897), *Township and Borough* (1898), *Canon Law in England* (1898), *English Law and the Renaissance* (1901), the *Life of Leslie Stephen* (1906). His writings are marked by vigour and vitality of style, as well as by the highest qualities of the historian who recreates the past from the original sources; he had no sympathy with either legal or historical pedantry. He died at Grand Canary on Dec. 19, 1906.

See P. Vinogradoff's article on Maitland in the *English Historical Review* (1907); Sir F. Pollock's in the *Quarterly Review* (1907); G. T. Lapsley's in *The Green Bag* (Boston, Mass., 1907); A. L. Smith, *F. W. Maitland* (1908); H. A. L. Fisher, *F. W. Maitland* (1910).

MAITLAND, SIR RICHARD (LORD LETHINGTON) (1496–1586), Scottish lawyer, poet and collector of Scottish verse, son of Sir William Maitland of Lethington and Thirlestane, who fell at Flodden, studied law at the university of St. Andrews, and afterwards in Paris. His castle at Lethington was burnt by the English in 1549. He was in 1552 one of the commissioners to settle matters with the English about the debatable lands. About 1561 he seems to have lost his sight, but he continued to attend to public business, and was the same year admitted an ordinary lord of session with the title of Lord Lethington, and a member of the privy council. In 1562 he was appointed keeper of the Great Seal, resigning in 1567, in favour of John, prior of Coldingham, his second son. He sat on the bench until his eighty-eighth year. He died on March 20, 1586.

The poems of Sir Richard Maitland are for the most part satirical, and are principally directed against the social and political abuses of his time. He collected and preserved many pieces of Scots poetry. These were copied into two large volumes, one in folio, written by himself, and another in quarto, written by his daughter. These volumes were purchased at the sale of the Lauderdale library by Samuel Pepys, and have since been preserved in the Pepysian library, Magdalene college, Cambridge. They lay there unnoticed for many years till Bishop Percy published one of the poems in his *Reliques of English Poetry*. Several were included by John Pinkerton, in *Ancient Scottish Poems* (2 vols., 1786).

For an account of the Maitland Folio MS. *see* Gregory Smith's *Specimens of Middle Scots*, 1902 (p. lxxiii.). Maitland's own poems were reprinted by Sibbald in his *Chronicle of Scottish Poetry* (1802), and in 1830 by the Maitland Club, named after him, and founded for the purpose of continuing his efforts to preserve the remains of early Scots literature. Sir Richard left in manuscript a history of the family of Seton, and a volume of legal decisions collected by him between the years 1550 and 1565. Both are preserved in the Advocates' Library, Edinburgh; the former was published by the Maitland Club, in 1829. The Scottish Text Society published *The Maitland Folio Manuscript* (ed. W. A. Craigie, 1919, etc.) and the *Maitland Quarto Manuscript* (ed. W. A. Craigie, 1920, etc.).

MAITLAND (MAITLAND OF LETHINGTON), **WILLIAM** (*c.* 1528–1573), Scottish statesman, eldest son of Sir Richard Maitland (1496–1586) (*q.v.*) was educated at St. Andrews, and in 1558 became secretary of State to the regent, Mary of Lorraine. In 1559, however, he threw in his lot with the lords of the congregation. He was sent to Elizabeth for assistance and worked consistently for a union between the two crowns. In 1561 he was appointed secretary of State, and for about six years he directed the policy of Scotland and enjoyed the confidence of Mary Queen of Scots. John Knox was consistently antagonistic to him, and their encounter in the general assembly of 1564 is famous. Maitland was doubtless concerned in the conspiracy against David Rizzio, and after Rizzio's murder was obliged to leave the court and was himself in danger of assassination. In 1567 he was again at Mary's side. He was a consenting party to the murder of Darnley, although he had favoured his marriage with Mary, but the enmity between Bothwell and himself was one of the reasons which drove him into the arms of the queen's enemies, among whom he figured at Langside.

He was one of the Scots who met Elizabeth's representatives at York at 1568; here he showed a desire to exculpate Mary and to marry her to the duke of Norfolk, but he was arrested in Sept. 1569 on account of his share in the Darnley murder. He was delivered from his captors by a ruse on the part of his friend, Sir William Kirkcaldy of Grange. Maitland now became the leader of the remnant which stood by the cause of the imprisoned queen, and with Kirkcaldy held Edinburgh castle against the regent Morton. The castle surrendered in May 1573 and on June 7 or 9 1573 Maitland died at Leith.

"Secretary Maitland" was a man of great learning with a ready wit and a caustic tongue. He placed his country above the claims of either the Roman Catholic or the Protestant religions. Among the testimonies to his abilities are those of Queen Elizabeth, of William Cecil and of Knox.

See J. Skelton, *Maitland of Lethington* (1894); A. Lang, *History of Scotland*, vol. ii. (1902).

MAITLAND, WEST AND EAST (with **CESSNOCK**), adjoining towns of New South Wales, Australia, situated in the lower valley of the Hunter River, 20 miles N.W. of Newcastle. Maitland West lies on low ground and was subject to disastrous floods until strong embankments were built. East Maitland lies higher and is mainly residential. In the rich areas adjoining, mixed farming is practised intensively—lucerne largely on the river flats (6–9 crops a year), maize and vegetables—but dairying (fresh milk and butter), along with bee-keeping, is increasingly replacing other forms. (Av. ann. temps., 75°–53° F; av. ann. rainfall, 33 in.) The Maitlands were formerly market and business centres for extensive agricultural areas reaching up the Hunter River and West Maitland is noted still for its great horse and cattle market. They are well-built towns, and West Maitland has a certain amount of industrial activity. Pop. (1933) East Maitland 4,138; West Maitland 8,191; Cessnock 14,385. Cessnock (17 mi. S.W.) has recently curtailed Maitland's sphere and is superseding it as a market centre. The South Maitland coalfield (*c.* 100 sq.mi.; *c.* 1,400,000 tons reserves) extends some 23 mi. southwards from Maitland and is now the leading coal-producing area in Australia. The coal is that of the "Greta" seam and is of good all-round quality (gas-making, railways, export); the normal annual output is about 10,000,000 tons. Cessnock, the centre for a dairying and agricultural district, is now a substantial town with excellent buildings and has mainly a mining population of about 14,000. (*See* also SINGLETON.)

MAITREYA, the name of the bodhisattva who is to be the next future Buddha. In accordance with the Hindu theory of recurrent cycles of the universe, Buddhism held that its truths have been repeatedly taught by Buddhas, who arise in succession, and that the doctrine after its decay and disappearance will be again realized and taught by other Buddhas in the future. A cycle in which no Buddha appears is called empty, but in this cycle there are to be five, or according to some schools 1,000. Four have already appeared, and the fifth is to be Maitreya (Pāli, *Metteyya*).

The theory of recurrent Buddhas may not be primitive, but it certainly arose before the close of the Pāli Canon, as Metteyya is twice mentioned there (*Dīgha-nikāya,* No. 26, *Buddhavamsa,* ch. 27), and the belief became established in all schools. According to the *Lalita-vistara* Maitreya was appointed vicegerent in the Tushita heaven when Gotama left it to become Buddha. He is sometimes represented in Mahāyāna sūtras as being present as a bodhisattva at the Buddha's discourses.

MAITTAIRE, MICHEL (1668–1747), English bibliographer, was born in France but went to England with his parents, who were Huguenots, after the revocation of the Edict of Nantes in 1685. He was educated at Westminster school and at Christ Church college, Oxford, after which he taught at Westminster (1695–99) and at a school of his own. For a time he was also tutor to Philip Stanhope, Lord Chesterfield's natural son.

His chief work is *Annales Typographici ab Artis inventae origine ad annum* 1557 *cum appendice ad annum* 1664 (1719–41), a list of all books published before the year 1664, which is still consulted by bibliographers and scholars. He was also responsible for a number of works important to classical scholars, including *Graecae Linguae Dialecti* (1706) and *Latin Classics,* and for a history of typography (1717). He died in London, Sept. 7, 1747.

MAITZ-DE-GOIMPY, LOUIS EDMÉ GABRIEL, COMTE DU (1729–*c.* 1790), French naval officer, was born Feb. 8, 1729, near St. Léger, Eure-et-Loir. He joined the French navy in 1746 and remained in it until his retirement in 1785, by which time he had risen to the rank of commodore. During the American Revolutionary war, he commanded the ship "Destin" and participated in three important naval actions off the American coast, one under de Guichen and two under de Grasse, in the first of which he was wounded.

In addition to his achievements as a naval officer, Maitz-de-Goimpy helped to found the Académie de Marine (1752) and was the author of books on astronomy and on naval matters. He died at Billancourt.

MAIWAND, a village of Afghanistan, 50 mi. northwest of Kandahar. It is chiefly notable for the defeat inflicted on a British brigade under General Burrows by Ayub Khan on July 27, 1880, during the second Afghan War (*see* AFGHANISTAN). Ayub Khan, Shere Ali's younger son, who had been holding Herat during the British operations at Kabul and Kandahar, set out towards Kandahar with a small army in June 1880, and a brigade under General Burrows was detached from Kandahar to oppose him. Burrows advanced to the Helmund, opposite Girishk, but was there deserted by Shere Ali, the wali of Kandahar, and had to retreat to Kushk-i-Nakhud. In order to prevent Ayub passing to Ghazni, Burrows advanced to Maiwand on July 27 and attacked Ayub, who had already seized that place. The Afghans, who numbered 25,000, out-flanked the British, the artillery expended their ammunition, and the native portion of the brigade got out of hand and pressed back on the British battalion. The brigade was completely routed and had to thank the apathy of the Afghans for escaping total annihilation. Of the 2,476 British troops engaged, 934 were killed and 175 wounded or missing. This defeat necessitated Sir Frederick Roberts' famous march from Kabul to Kandahar.

See Lord Roberts, *Forty-one Years in India* (1896).

MAIZE or INDIAN CORN, *Zea Mays,* a plant of the tribe Maydeae of the grass family (Gramineae). The word "maize," derived from the Arawak *má-hiz,* is preferred in international usage since "corn," the term by which the plant is known in the United States, is in many countries synonymous with "grain" and may be applied to any cereal.

Origin and History.—Maize is undoubtedly a plant of American origin, since it was unknown in other parts of the world before the discovery of America. Its modern history begins Nov. 5, 1492, when two Spaniards whom Columbus had delegated to explore the interior of Cuba returned with a report of "a sort of grain they call maiz which was well tasted, bak'd, dry'd and made into flour." Later explorers to the new world found maize being grown by the Indians in all parts of America where agriculture was practised, from Canada to Chile. There is little question that maize had been, for many centuries before the discovery of America, the chief cereal and the basic food plant of the pre-Columbian American civilizations and advanced cultures including the Inca of Peru, the Maya and Aztec of middle America and the cliff-dweller of the southwest. Well-preserved ears of maize and funeral vases ornamented with figures of maize are among the objects frequently encountered in prehistoric graves of Peru, Bolivia and Ecuador. Stone carvings of the maize deity are numerous among the archaeological remains of middle America.

Maize was, in a sense, the bridge over which European civilization travelled to a foothold in the new world. To many of the early colonists, who learned its culture from the Indians, it became the daily bread by which they were nourished. Modern American agriculture is founded to a large extent upon an elaborate cultural complex taken from the American Indians, for not only did the European colonist adopt the maize plant; he also embraced the methods of culture, harvesting and utilization which the Indian had developed through generations of trial and error. The planting of maize in hills, its interplanting with beans and squashes, the use of husking pins in harvesting, the storing of the ears in ventilated cribs, the use of green corn for roasting ears, the removal of the hull with lye to make hominy are but a part of the Indian inventions adopted with only slight changes by the white man.

Introduced into Europe by Columbus and into Africa by the Portuguese, maize spread rapidly throughout the old world. Within one generation after the discovery of America it was known over most of Europe. Within two generations it had spread through Africa, India, Tibet and China, and when European ships began to reach the Chinese coast, maize was already being extensively grown there and was being taxed by the emperor. The first references to maize in literature appear early in the 16th century. The first botanical illustration of the plant occurs in the herbal of Leonard Fuchs, in 1542. The earliest Chinese illustration is found in the *Pên ts'ao kang mu* of Li Shih-Chên, which is dated at 1573. Of all of the manifold products of the new world, maize spread the most rapidly, even more rapidly than tobacco.

The botanical origin of maize is less clear than its geographical origin. Earlier botanists were virtually unanimous in the opinion that maize had originated from pod corn, a primitive type in which the grains are enclosed individually in glumes (Fig. 2). In 1875, however, Ascherson showed that teosinte (*Euchlaena mexicana*), a plant growing in the wild in Guatemala, and as a weed in the cornfields in parts of Mexico, is closely related to maize. Harshberger in 1896 gave final proof of this relationship by demonstrating that maize and teosinte can be hybridized to produce highly-fertile hybrids. For the next half-century, the majority of botanists held the opinion that maize had been derived in some manner from teosinte, either by mutation or by hybridization, and that its centre of origin was in Mexico or Guatemala. In 1939, Mangelsdorf and Reeves, as the result of historical research and extensive hybridization experiments with maize, teosinte and Tripsacum, a third American genus of the tribe Maydeae, concluded: (1) that maize originated from a wild form of pod corn which was once, and perhaps still is, indigenous to the lowlands of South America; (2) that teosinte, the closest relative of maize, is a recent product of the natural hybridization of maize and Tripsacum, which occurred after cultivated maize had been introduced by man into Central America; (3) that the great diversity now displayed by maize is due in part to the inevitable development of numerous new varieties following such hybridization.

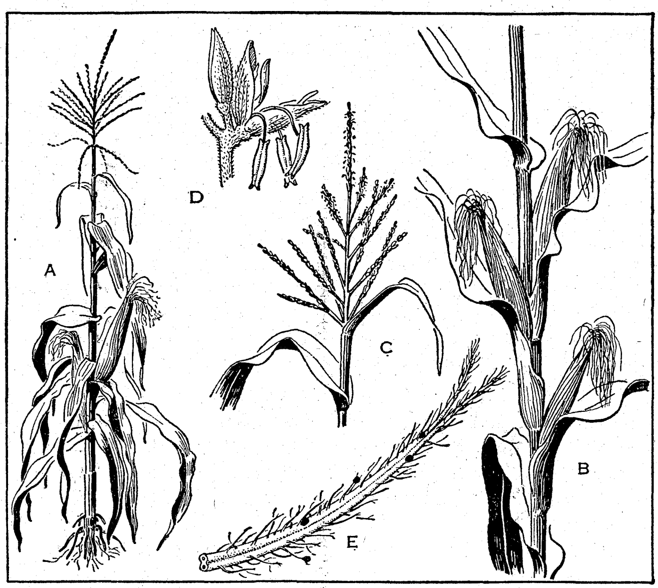

FIG. 1.—A. ENTIRE MAIZE PLANT; B. STALK SHOWING FEMALE OR PISTILLATE INFLORESCENCES; C. THE MALE OR STAMINATE INFLORESCENCE; D. STAMINATE SPIKELET, SHOWING ANTHERS; E. PORTION OF STYLE OR "SILK" MAGNIFIED SHOWING BIFID END AND POLLEN GRAINS CAUGHT IN HAIRS

Botanical Characteristics.—The maize plant is a tall, annual, monoecious grass with a stout, erect, solid stem, a fibrous root system and large narrow leaves with wavy margins, spaced alternately on opposite sides of the stem (Fig. 1A).

The male or staminate flowers are borne on the tassel, a panicle which terminates the main axis of the stem (Fig. 1C). As in all grasses, the flowers occur in spikelets, usually arranged in pairs, one sessile, the other pediceled (Fig. 1D). Each floret contains three anthers (Fig. 1D); each anther, approximately 2500 pollen grains. A single tassel may shed several million pollen grains. These are barely visible to the naked eye, approximately 1/250 inch in length and are ovoid in shape. They are light and easily carried by the wind and this accounts for the fact that maize is naturally cross-pollinated.

The female or pistillate inflorescence, the forerunner of the "ear," is a unique structure among the grasses. Botanically, it is a spike on whose thickened axis, the "cob," the paired spikelets are borne in longitudinal rows. Each row of paired spikelets normally gives rise to two rows of grain; hence the number of rows of grain on the ear is always an even number: 8, 10, 12 and higher even numbers up to 36.

The pistillate inflorescence is enclosed by "shucks" or "husks" which are modified leaves (Fig. 1B). The familiar "silks" which emerge in a pendulous mass from the end of the ear shoot are the styles attached to the ovaries (Fig. 1E). There is a single silk for each potential seed, and the number of seeds on the ear may equal but can never exceed the number of silks which have emerged. Pollination occurs when wind-borne pollen falling upon the fine hairs of the silks germinates and sends its pollen tube down the tissues of the long styles.

Principal Types.—The diversity in maize is enormous and probably exceeds that of any other cultivated plant. There are early maturing varieties, Gaspé Flint from the Gaspé peninsula of Canada and Cinquantino from the Pyrenees mountains of Spain, which mature in 60–70 days; there are very late varieties in Colombia which require 11 months to reach maturity. The number of leaves on a single plant varies from 8 to 48; the number of tillers or suckers from none to 12. Height of stalk may vary from less than 2 ft. to more than 20. The number of rows of grain on the ear may range from 4 to 36, and the size of the ear varies from the diminutive ears of popcorn varieties, some of which are smaller than a man's thumb, to the gigantic corn grown in the Jala valley of Mexico which produces ears up to 2 ft. in length.

Accompanying the variation in vegetative characteristics is a corresponding array of distinct colours. Stalks, leaves and shucks may be green, red, purple, brown, golden or striped. The silks may be green, salmon or various shades of red. The grain may be yellow, white, various shades of red, blue, and brown or variegated.

Superimposed upon the diversity in form and colour is a variation in the texture or the covering of the kernel which serves as the basis for classifying the varieties of maize into the six principal types usually recognized (Fig. 2):

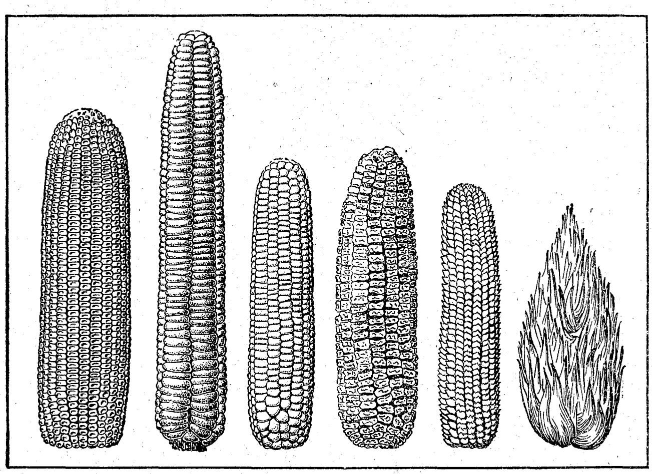

FIG. 2.—THE PRINCIPAL TYPES OF MAIZE FROM LEFT TO RIGHT: DENT, FLINT, FLOUR, SWEET, POP AND POD

1. *Dent corn* is characterized by a depression or indentation in the crown of the kernel, which may vary from a dimple to a rough crease, and which is caused by the unequal drying of the hard and soft starch of which the kernel is composed. Dent corn is the principal type grown commercially in the United States, especially in the corn belt. Although dent corn may occur in any of the known grain colours, the majority of commercial varieties are either yellow or white. Before 1920, yellow corn was preferred in the north, white corn in the south, but with the discovery that yellow corn is richer than white in carotene, a precursor of Vitamin A, and hence frequently more valuable as a feed, there was a decided trend toward yellow varieties. White dent is still preferred for many industrial purposes, especially the manufacture of hominy.

2. *Flint corn* differs from dent corn in containing little soft starch, hence it does not become indented upon drying. The early-maturing flints are extensively grown in the northern United States and Canada, since they germinate more readily in cold soils than dent corn. The tropical flints, because of their resistance to damage by weevils, are the preferred type in tropical lowlands.

3. *Flour corn,* also known as "soft" or "squaw" corn, is usually similar to flint corn in vegetative characteristics, but differs

from it in the texture of the kernels, which are composed largely of soft starch. Because of its soft and mealy kernels, which are easily ground or chewed, flour corn is preferred by Indian tribes wherever it can be grown. It is of little commercial importance in the United States, but is the predominating type in the Andean region of Peru, Bolivia and Ecuador, where many large-seeded varieties, some with kernels an inch in length and almost equally broad, are known.

4. *Sweet corn* is distinguished by its wrinkled, translucent seeds, a condition resulting from the fact that the sugar manufactured by the plant is not converted to starch as it is in other types. Sweet corn is used almost exclusively for human consumption as green corn or roasting ears and as canned or frozen corn.

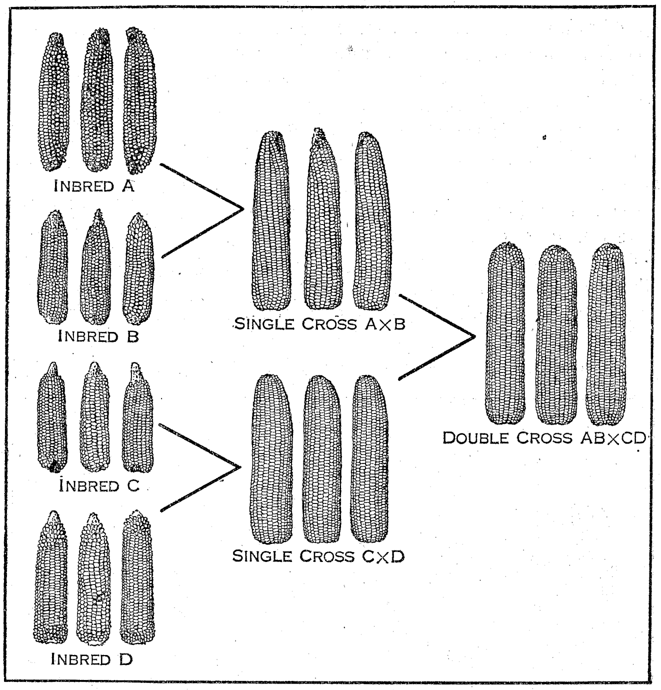

FIG. 3.—HYBRID CORN: INBRED STRAINS A AND B ARE CROSSED TO PRODUCE A SINGLE-CROSS, INBREDS C AND D ARE CROSSED TO PRODUCE A SECOND SINGLE-CROSS. SINGLE-CROSSES AB AND CD ARE CROSSED TO PRODUCE THE COMMERCIAL DOUBLE-CROSS

5. *Popcorn* is actually an extreme type of flint corn, and is included with the latter by some authorities. It is characterized by small hard kernels, completely devoid of soft starch. When heated, the moisture in the cells expands, finally causing the kernels to explode or pop. Popcorn is used extensively in the U.S. confectionery industry. Most of the commercial crop is grown in several counties in Iowa and Nebraska.

6. *Pod corn* is a peculiar type in which each kernel is individually enclosed in husk-like structures, the glumes. It has no commercial importance, but is sometimes grown as a horticultural novelty. It is of considerable botanical interest in representing a primitive condition, probably characteristic of the original wild corn.

Hybrid Maize.—Numerous attempts have been made to improve the uniformity, productiveness and other characteristics of maize through breeding. Earlier attempts to accomplish this met with little success, but beginning about 1920, a new method of corn improvement involving the production of hybrid corn (Fig. 3) was widely adopted and became extremely effective. The method is based upon discoveries in genetics made by E. M. East and D. F. Jones of the Connecticut Agricultural Experiment station and by G. H. Shull of Princeton university.

The first step in the production of hybrid corn is the isolation of superior inbred strains. This is accomplished by artificial self-pollination under bags, which represents a form of inbreeding approximately three times as intense as brother and sister mating in livestock. Inbreeding reduces vigour and productiveness, but results in great uniformity within the strain. The second step involves the crossing of inbred strains by pairs (A x B, C x D, etc.) to produce single-crosses. Single-crosses are exactly as uniform as the parental inbred strains, but because of the phenomenon of hybrid vigour, much more productive. Single-crossed seed of sweet corn is extensively used in the production of green corn for commercial canneries where uniformity in size and shape of the ears is important. Single-crossed seed is usually too expensive, however, for general farm use. A third step is necessary to reduce seed costs. This third step, the production of double-crossed seed, involves the crossing of two single crosses (AB x CD). Double-crosses are slightly less uniform than single-crosses, but almost equally productive.

Hybrid corn does not breed true; but once a satisfactory combination of inbred strains has been identified, the hybrid seed can be produced anew each year from the true-breeding parental inbred strains. Crossing is readily accomplished by growing two stocks in alternate strips in the same field and removing all tassels from the plants of one before pollen is shed. Hybrid corn has proved so productive that by 1943, in spite of the expense involved in producing the seed, more than 50,000,000 ac. were being planted annually to hybrid corn, and an extensive industry devoted to the production of hybrid seed had developed.

World Distribution.—Although pre-eminently an American crop, maize is one of the most widely distributed of the world's food plants. It is grown from 58° N. lat. in Canada and Russia to 40° S. lat. in South America. It is cultivated below sea level in the Caspian plain, and at altitudes exceeding 12,000 ft. in the Peruvian Andes. It thrives almost equally well in the short summer of Canada and the perpetual summer of tropical Colombia. A crop of maize matures somewhere in the world every month of the year.

From the standpoint of acreage planted, maize ranks second among the world's crop plants, being exceeded only by wheat. In the United States, which produces more than half the world's crop, it is by all odds the most important crop, being grown in every state and on approximately three-fourths of all farms. It reaches its maximum importance in the corn belt, a region of fertile, well-drained soils comprising Iowa and parts of Illinois, Indiana, Ohio, Missouri, Kansas, Nebraska, South Dakota and Minnesota. In this region, maize occupies approximately one-half the cultivated land.

Argentina ranks second to the United States in maize production, and is the chief exporting country. In Europe, maize is of greatest importance in the Danube basin and of considerable secondary importance in Italy, Spain and southern France. Both India and south Africa produce considerable quantities of maize, largely for domestic consumption.

Utilization of Maize.—Maize is utilized in three principal ways: (1) as a feed for livestock; (2) as a human food; (3) as a raw material in industry.

In the United States, almost 90% of the maize produced is fed to livestock; approximately half of this amount to hogs, the remainder to beef and dairy cattle, horses and mules and poultry. It requires 10–12 lbs. of corn to produce 1 lb. of beef, 6–8 lbs. to produce 1 lb. of pork. For feeding cattle, the entire plant is frequently harvested and used as ensilage.

As a human food, maize is inferior to other cereals. It contains no gluten and makes a heavy, crumbly bread. It is deficient in niacin, and diets containing excessive amounts of maize usually result in pellagra. Nevertheless, maize was used exclusively for human food in prehistoric times, and is still used extensively for this purpose in Latin-American countries, in parts of Europe and the United States and in south Africa and India. The *tortilla,* a thin flat cake of maize, is the daily bread of Mexico, and maize constitutes 75% to 85% of the diet of the Maya Indians of Guatemala. In the United States, maize is of greatest importance as a human food in the south, but is used to some extent in all parts of the country in the form of corn bread, hominy, mush or polenta, griddle-cakes, scrapple, popcorn, confections and numerous manufactured cereal preparations. Sweet corn, harvested when the grain is in the "milk" stage, is an important American vegetable, consumed fresh, canned or frozen.

Chief among the industrial uses of maize is the manufacture of corn starch and its derivatives and by-products, corn sugar or dextrose, corn syrup, dextrins, corn oil and industrial alcohol. The grain is used in making various alcoholic beverages. The stalk is manufactured into paper and wallboard. Husks are used as filling material. Cobs are used for fuel, for the making of charcoal and the preparation of industrial solvents. Corncob pipes are manufactured from a large-cobbed variety grown in Missouri. During World War II, considerable quantities of maize, converted into alcohol, were used in the manufacture of synthetic rubber. A special type of corn with waxy endosperm has been employed as a substitute for imported cassava starch in the manufacture of tapioca and adhesives.

Production Statistics.—World production of maize in 1940 was slightly more than 5,000,000,000 bu., distributed as follows: United States, 2,500,000,000; Europe, 770,000,000; South America, 712,000,000; Asia, 590,000,000; Africa, 249,000,000. The principal exporting countries for the five-year period, 1930–34, were Argentina, 252,000,000 bu.; Rumania, 44,000,000; Yugoslavia, 17,000,000; Union of South Africa, 13,000,000; United States, 6,000,000. Principal importing countries for the same period were the United Kingdom, 102,000,000 bu.; the Netherlands, 52,000,000; France, 35,000,000; Belgium, 30,000,000; Denmark, 21,000,000.

The acreage of maize harvested in the United States in 1940 was approximately 86,738,000 ac., of which 76,796,000 ac. were harvested as grain, 4,671,000 ac. harvested as silage and 5,271,000 ac. harvested as forage or used for hogging down. The consumption of maize in the United States in 1940 was 2,509,680,000 bu., distributed approximately as follows: starch and derivative products, 141,000,000; alcoholic beverages, 34,000,000; breakfast foods, 9,000,000; farm household use, 31,000,000; seed, 16,000,000; feed and waste, 2,250,000,000; exports, 14,000,000.

MAJANO (or MAIANO), **BENEDETTO DA** (1442–1497), Italian sculptor and architect, was born at Majano, Venetia. Little is known of his early life except that it is likely that he studied under his brother, Giuliano, and that he learned stonemasonry in his youth. For a time inlaid wood was his favourite medium, but he gave up this technique when some of his carefully worked pieces were warped by moisture and ruined. He decided to devote himself to a medium less susceptible to damage and turned to marble. The first piece of sculpture which can definitely be attributed to him is a bust of Pietro Mellini (1474).

Mellini then commissioned him to execute a pulpit for Santa Croce in Florence, and this work is generally regarded as his masterpiece. In five panels, it shows bas-relief scenes from the history of the Franciscan order. It has been said of Benedetto's work on it that "he painted in marble as Ghiberti painted in bronze."

His next important patron was Filippo Strozzi, for whom he built a palace at Florence and of whom he sculptured one of his best busts. Other important works of Benedetto's include the altar in San Savino in Faenza and the ciborium in San Domenico in Siena.

During the last years of his life, he lived in San Gimignano. He died May 27, 1497. Majano is generally considered to be one of the great sculptors of his century.

MAJESTY, dignity, greatness, a term especially used to express the dignity and power of a sovereign. This application is to be traced to the use of *maiestas* in Latin to express the supreme sovereign dignity of the Roman state, the *maiestas republicae* or *populi Romani*, hence *maiestatem laedere* or *minuere*, was to commit high treason, *crimen maiestatis*. (For the modern law and usage of *laesa maiestas see* TREASON.) From the republic *maiestas* was transferred to the emperors, and the *maiestas populi Romani* became the *maiestas imperii*, and *augustalis maiestas* is used as a term to express the sovereign person of the emperor. Honorius and Theodosius speak of themselves in the first person as *nostra maiestas*. The term "majesty" was strictly confined in the middle ages to the successors of the Roman emperors in the west, and at the treaty of Cambrai (1529) it is reserved for the emperor Charles V. Later the word is used of kings also, and the distinction is made between imperial majesty (*caesareana maiestas*) and kingly or royal majesty.

From the 16th century dates the application of "Most Christian and Catholic Majesty" to the kings of France, of "Catholic Majesty" to the kings of Spain, of "Most Faithful Majesty" to the kings of Portugal, and "Apostolic Majesty" to the kings of Hungary. In England the use is generally assigned to the reign of Henry VIII, but it is found, though not in general usage, earlier; thus the *New English Dictionary* quotes from an *Address of the Kings Clerks to Henry II* in 1171, where the king is styled *vestra majestas*, and Selden finds many early uses in letters to Edward I, etc.

The fullest form in English usage is "His Most Gracious Majesty"; another form is "The King's Most Excellent Majesty," as in the English Prayer-book. "His Sacred Majesty" was common in the 17th century; and of this form Selden says: "It is true, I think, that in our memory or the memory of our fathers, the use of it first began in England." "His Majesty," abbreviated H.M., is now the universal European use in speaking of any reigning king, and "His Imperial Majesty," H.I.M., of any reigning emperor. From early times, the word has been applied to the Deity.

MAJLÁTH, JÁNOS or JOHN, COUNT (1786–1855), Hungarian historian and poet, was born at Budapest on Oct. 5, 1786. First educated at home, he subsequently studied philosophy at Eger (Erlau) and law at Györ (Raab), his father, Count Joseph Majláth, an Austrian minister of state, eventually obtaining for him an appointment in the public service. Majláth devoted himself to historical research and the translation into German of Magyar folk-tales and of selections from the works of the best of his country's native poets. Moreover, as an original lyrical writer and as an editor and adapter of old German poems, Majláth showed considerable talent. During the greater part of his life he resided either at Budapest or Vienna, but a few years before his death he moved to Munich, where he fell into a state of destitution and extreme despondency. Seized at last by a terrible infatuation, he and his daughter, Henriette, who had long been his constant companion and amanuensis, drowned themselves in the Lake of Starnberg, a few miles southwest of Munich, Jan. 3, 1855.

Of his historical works the most important are the *Geschichte der Magyaren* (Vienna, 1828–31, 5 vols.; 2nd ed., Ratisbon, 1852–53) and his *Geschichte des österreichischen Kaiserstaats* (Hamburg, 1834–50, 5 vols.). Specially noteworthy among his metrical translations from the Hungarian are the *Magyarische Gedichte* (Stuttgart and Tübingen, 1825) and *Himfy's auserlesene Liebeslieder* (Budapest, 1829; 2nd ed., 1831). A valuable contribution to folk-lore appeared in the *Magyarische Sagen, Märchen und Erzählungen* (Brünn, 1825; 2nd ed., Stuttgart and Tübingen, 1837, 2 vols.).

MAJOLICA, a name properly applied to a species of Italian ware in which the body is coated with a tin-enamel, on which is laid and fired a painted decoration. It is also applied to similar wares made in imitation of the Italian ware in other countries. The word in Italian is *maiolica*. Du Cange quotes from a chronicle of Verona of 1368, in which the form *majolica* occurs for the more usual Latin form, *majorica*.

It has usually been supposed that this type of pottery was first made in the island of Majorca, but it is more probable that the name was given by the Italians to the lustred Spanish ware imported by ships hailing from the Balearic Islands. (*See* POTTERY AND PORCELAIN.)

MAJOR (or MAIR), **JOHN** (1470–1550), Scottish theological and historical writer, was born at Gleghornie, near North Berwick. He was educated at the school of Haddington, where John Knox was later a pupil. After a short period spent at Cambridge (at God's house, afterward Christ's college) he entered the University of Paris in 1493, studying successively at the colleges of St. Barbe, Montaigu and Navarre, and graduating as master of arts in 1496. Promoted to the doctorate in 1505, he lectured on philosophy at Montaigu college and on theology at Navarre.

He visited Scotland in 1515 and returned in 1518, when he was appointed principal regent in the University of Glasgow, John Knox being one of those who attended his lectures there. In 1522 he removed to St. Andrew's university, where in 1525 George Buchanan was one of his pupils. He returned to the college of Montaigu in 1525 but was once more at St. Andrew's in 1531, where he was head of St. Salvator's college from 1534 until his death in 1550.

Major's voluminous writings may be grouped under (*a*) logic and philosophy, (*b*) Scripture commentary and (*c*) history. All are in Latin, all appeared between 1503 and 1530 and all were printed at Paris. The first group includes his *Exponabilia* (1503), his commentary on Petrus Hispanus (1505–1506), his *Inclitarum artium libri* (1506, etc.), his commentary on Joannes Dorp (1504, etc.), his *Insolubilia* (1516, etc.), his introduction to Aristotle's logic (1521, etc.), his commentary on the ethics (1530) and, chief of all, his commentary on Peter Lombard's *Sentences* (1509, etc.); the second consists of a commentary on Matthew (1518) and another on the Four Gospels (1529); the last is represented by his famous *Historia Majoris Britanniae tam Angliae quam Scotiae per J.M.* (1521). In political philosophy he maintained the Scotist position that civil authority was derived from the popular will, but in theology he was a scholastic conservative, though he never failed to show his approbation of Gallicanism and its plea for the reform of ecclesiastical abuses. He hoped to reconcile realism and nominalism in the interests of theological peace. He claimed that the historian's chief duty is to write truthfully, and he was careful to show that a theologian might fulfil this condition.

The *History,* on which his fame now rests, was reprinted by Freebairn (Edinburgh, 1740) and was translated in 1892 by Archibald Constable for the Scottish History society. The latter volume contains a full account of the author by Aeneas J. G. Mackay and a bibliography by Thomas Graves Law.

MAJOR, RICHARD HENRY (1818–1891), English historian and geographer, was born in London, Oct. 3, 1818. He held several positions with the British museum, including that of curator of the department of printed maps and plans, which position he was the first to occupy. He also served the Hakluyt society and the Royal Geographical society in a number of executive capacities. He was particularly interested in the explorations of the Italians and the Portuguese in the 15th and 16th centuries, and for his work in this field he was decorated by the Brazilian, Italian and Portuguese governments.

Major's best-known work is a *Life of Prince Henry of Portugal, surnamed the Navigator* (1868), to which he later published a sequel, *The Discoveries of Prince Henry the Navigator and their Results* (1877).

He died in Kensington, June 25, 1891.

MAJOR (Lat. for "greater"), a word used, both as a substantive and adjective, for that which is greater than another in size, quality, degree, importance, etc.; often opposed correlatively to that which is "minor" in the same connotation. In the categorical syllogism in logic, the "major term" is the term which forms the predicate of the conclusion, the "major premise" is that which contains the major term. *Major* as part of an official title in mediaeval Latin has given the Spanish *mayor,* French *maire* and English mayor (*q.v.*). In English the unadapted form "major" is the title of a military officer now ranking between a captain and a lieutenant-colonel.

Originally, the military term was used adjectivally in the title sergeant-major, the "third principal officer in a regiment" (Ward 1639), now the major. In the 16th and 17th centuries there was a similarity between the duties of the sergeant, sergeant-major and sergeant-major-general, in that they attended to the drill and administration of a company, a regiment and an army, respectively. In conversation sergeant-major was abbreviated to major and sergeant-major-general to major-general, whence the modern titles of major and major-general derive. In the case of sergeant-major the "sergeant" was dropped generally about 1660, although in some quarters it lingered for some years later.

Up to about the beginning of the 18th century majors, in common with other field-officers, had companies, the executive command being in the hands of a lieutenant. Majors have now displaced lieutenant-colonels as seconds-in-command of units, though junior majors now command companies, squadrons and batteries. In those armies where the regiment corresponds to a brigade (of three or four battalions), majors command battalions, while the regiment is commanded by a colonel. In the 17th century the duties of a major were a combination of those now performed by the major (second-in-command) and sergeant-major, but on the introduction of adjutants he was relieved of much of the routine work and assumed the more important duties of second-in-command.

The brigade-major corresponds in a higher sphere to the adjutant of a battalion. Such expressions as "town-major" and "fort-major" indicate the purpose of the appointment.

Drum-major was an ancient title in the British service, until it was abolished in 1881 to be substituted by sergeant-drummer, which in turn was abolished in 1928 on the re-introduction of drum-major. The title sergeant-major was introduced as a non-commissioned rank in the British service early in the 18th century and was elevated to warrant rank in 1881. The equivalent term in the Household cavalry is corporal-major.

In music, the term major (*i.e.,* greater) is opposed to minor (*i.e.,* smaller) as defining the size of intervals, a minor interval containing a semitone less than a major. Thus a major third (*e.g.,* C to E) contains four semitones; and a minor third (C to E flat), three. A major scale in turn is one with a major third, as distinguished from a minor scale in which the third is minor, these two different scales constituting the major and minor modes respectively. (*See* HARMONY.)

MAJORCA, the largest of the group of Spanish islands in the Mediterranean sea known as the Balearic Islands (*q.v.*). Pop. (1940) 327,120; area, 1,405 sq.mi. On the northwest the coast is precipitous, but on the other sides it is low and sloping. On the northeast the chief bays are those of Alcudia and Pollensa; while on the southwest is the still more important bay of Palma. In the northwest a chain of mountains runs parallel with the coast and attains its highest elevation in Silla de Torrellas (5,154 ft.). Majorca has typical limestone scenery. Some of the valleys, such as those of Valldemosa and Sóller, have luxuriant vegetation. There are marble quarries, those near Santañy being celebrated; while lead, iron and cinnabar have also been obtained. Coal is found at Benisalem, Selva, Santa Maria and elsewhere.

The inhabitants are principally engaged in agriculture. Old pine woods have in many places given way to the olive, the vine and the almond tree, to fields of wheat and flax or to orchards of figs and oranges.

Inca is the centre of the oil district. The wines are light but excellent, especially the Muscatel and Montona. Brandy is made and exported; woollen and linen cloths are woven; the silkworm is reared and its produce manufactured; and canvas, rope and cord are largely made.

The four principal roads are those from Alcudia, Manacor, Sóller and Andraitx to Palma, the capital. The main railway line runs from Palma to Manacor and Alcudia. There is regular communication with Barcelona and Alicante.

The principal towns include—besides Palma (97,009), Felanitx (7,403) and Manacor (13,585), which are described in separate articles—Andraitx (3,301), Inca (10,799), Lluchmayor (9,347), Pollensa (5,722), Santañy (3,757), Sóller (7,146) and La Puebla (10,080).

MAJORIAN (IULIUS VALERIUS MAIORIANUS), emperor of the west from 457 to 461. After the deposition of Avitus Majorian was declared emperor by the regent, Ricimer. After repelling an attack by the Vandals upon Campania (458), he prepared a large force to invade Africa. Having defeated and concluded an alliance with Theodoric the Visigoth, at the beginning of 460 he crossed the Pyrenees for the purpose of joining the powerful fleet which he had collected at Carthagena. The Vandal king Gaiseric, however, succeeded through the treachery of certain officers in destroying the Roman fleet. Majorian thereupon made peace. But his ill-success had destroyed his military reputation. A mutiny inspired by Ricimer broke out in Lombardy, and on the 2nd of August 461 Majorian was forced to resign. He died five days afterwards, either of dysentery or by violence. Majorian was the author of a number of laws, appended to the Theodosian Code. Of these the most interesting is that forbidding the use of ancient monuments as quarries for building material.

See Sidonius Apollinaris, *Panegyric of Majorian* (*Chronica Minora*, ed. Mommsen, vols. 1, 2 and 3); Gibbon, *Decline and Fall*, ch. xxxvi. (where an outline of the "novels" of Majorian is given); J. B. Bury, *Later Roman Empire*, ch. iii.

MAJORITY: *see* INFANT; AGE.

MAJUBA (properly AMAJUBA, Zulu for "the hill of doves"), a mountain in the Drakenberg, of northern Natal, rising about 7,000 ft. above the sea and over 2,000 ft. above the level of the surrounding country. It overlooks the pass over the Drakenberg known as Laing's Nek, is 8 m. S. of the Transvaal border and 18 m. N. of the town of Newcastle. The railway from Durban to Johannesburg skirts the base of the mountain. During the Boer War of 1880–81 Majuba was occupied on the night of the 26th of February 1881 by some 600 British troops under Sir George Pomeroy Colley. On the following morning the hill was stormed by the Boers under Piet Joubert and the British routed, Colley being among the slain.

MAKAH, the Indians of Cape Flattery, Washington, the only group of Nutka affiliation in the United States. Bold canoemen, they paddle far out on the ocean to harpoon whales. Their culture, of general North Pacific coast type, has closest resemblance to that of the Quileute and Nutka. Of an original 2,000, some 400 remain.

See J. G. Swan, *Indians of Cape Flattery* (1870).

MAKALAKA, a general designation used by the Bechuana, Matabele and kindred peoples, for conquered or slave tribes. The name is more frequently used to designate the Makalanga, one of the tribes now classed as Mashonas conquered by the Matabele.

MAKARAKA ("Cannibals"), a negroid people of Central Africa, related to the powerful Azande or Niam-Niam race, occupying the Bahr-el-Ghazal west of Lado. They came originally from the country of the Kibas, north of the Welle. They are a reddish-black, with nose less flat and cheek-bones less prominent than the ordinary negroes, and they do not extract the incisors. Their long silky hair is built up in the most fantastic form by means of vegetable substances. They are well-known for strength and staying power.

See W. Junker, *Travels in Africa* (1890–92).

MAKARSKA (Ital. *Macarsca*), the chief town of an administrative district in Dalmatia, Yugoslavia. Pop. (1931) 11,685, chiefly Serbo-Croatian. Makarska is a steamship station and has a brisk trade in wine, grain and fruit. Under the name of Mocrum, Makarska was a thriving Roman city, and a bishopric until 639, when the town was destroyed by the Avars. Its bishopric was revived in 1320, but merged in that of Split (Spalato) in 1830.

MAKART, HANS (1840–1884), Austrian painter, born at Salzburg on May 27, 1840, was the son of an inspector of the imperial castle. He has been aptly called the first German *painter* of the 19th century. When he entered the Vienna Academy, German art was under the rule of Cornelius's cold classicism and was entirely intellectual and academic. Makart, poor draughtsman to the very last, with a passionate and sensual love of colour was forced to leave the Vienna Academy. He went to Munich, and after two years of independent study attracted the attention of Piloty, under whom he made astonishing progress. Gradually he came to sacrifice everything to the decorative quality of his work. His "Romeo and Juliet" was bought by the Austrian emperor for the Vienna Museum, and Makart was invited to come to Vienna, where a large studio was placed at his disposal. In Vienna he became the acknowledged leader of the artistic life of the city. The obvious appeal of his huge compositions in their glowing richness of colour, in which he tried to emulate Rubens, made him appear a very giant to his contemporaries in Vienna, and indeed in all Austria and Germany. He reached the zenith of his fame when, in 1879, he designed, single-handed, the costumes, scenic setting, and triumphal cars of the grand pageant with which the citizens of Vienna celebrated the silver wedding of their rulers, all dressed in the costumes of the Rubens and Rembrandt period.

Unfortunately Makart used such villainous pigments and mediums that the majority of his large paintings have practically perished. The paint has cracked, and in some instances crumbled away, and this loss of their chief quality has accentuated their weakness of drawing and execution, and the prevalence of glaring anachronism in his work. He died in Vienna on Oct. 3, 1884.

Important examples of his work are to be found at the galleries of Vienna, Berlin, Hamburg and Stuttgart. For the Vienna Museum he also executed a series of decorative lunettes. His great historical pictures include "Catherina Cornaro," "Diana's Hunt," "The Entry of Charles V. into Antwerp," "Abundantia," "Spring," "Summer," "The Death of Cleopatra," and the "Five Senses."

MAKE-UP. As long as dramatic exposition has existed it has presumably been accompanied by some form of masquerade for the purpose of transforming the actor into the part he portrays. History reveals its employment far into antiquity.

Primitive Make-up.—A suggestion of the simplicity and crudeness of the earliest devices of make-up may be found in the religious rites of primitive races in modern times. The Patagonians, whose only form of dramatic movement was the swaying of their bodies and a monotonous mumbling of incantations, made up for the occasion by smearing their faces with chalk. Among the Australian aborigines, who rank somewhat higher in the ethnological scale, ritual ceremonies are enhanced by bodily adornments of wreaths, flowers and feathers worn over greased bodies and faces daubed with white clay.

The Aleutian Indians use painted wooden masks representing demons and sea animals for their mystic rites, while the natives of the South Sea islands dress their heads with helmet-like structures, into which are built masks of wood, reeds, tortoise shell and human skulls, sometimes decorated with vegetable substances to represent hair. Some of these islanders, like the Areoi, discard the mask and impress their spectators by painting their faces red and their bodies black. The Red Indians of North America, besides decorating their bodies and faces with variously hued war paints, were accustomed to behold their medicine man dressed for their rituals in the complete skin and head of elk, bear, wolf or panther.

The Chinese and Siamese theatre of to-day not only hands down its old tradition of masks, but makes use of grotesquely painted faces of blue, green, ochre, vermillion and ghastly white for demons and spirits. For the official ceremonies of the ancient Egyptians wigs were worn by kings and priests. Persian warriors wove strands of jute into their marcelled beards.

In the procession of Dionysus, out of which grew the Greek drama, the god was represented with long hair and beard, two small horns projecting from his forehead, while the reeling Bacchantes appeared with faces smeared with wine dregs or mulberry juice. Some of the followers in the train portrayed dead souls clad in shrouds with their faces covered in white lead.

Development.—For the miracle plays of the 14th century and onward actors made up with startling realism for animals, devils, saints and angels. Much ingenuity in facial disguise was used in a mediaeval play called *The Acts of the Apostles,* wherein the spectators saw the eyes of St. Matthew drawn out of his head and Simon Magus change his face several times. In an early English Passion play, Christ and the Apostles wore gilt wigs and the evil spirits appeared with bodies painted a reptile-like green, huge horns of oxen and rams ornamenting their heads.

The stage directions of a French morality play, *Bien Avisé et Mal Avisé,* call for a double face for Fortune—one smiling and the other terrible. In a modern production of an old secular play, *Noah's Flood,* at the New Theatre, New York, God was supplied with a gilded face.

A favourite farce actor in Paris during the reign of Henry IV. was known as Gros Guillaume. His face make-up consisted of a thick coating of flour which, at comic moments, he sent flying into the eyes of his fellow actors by puffing out his fat cheeks; on his chin he wore a piece of white lamb's skin, representing a beard. The popular *Commedia dell' Arte* (*q.v.*) of the Italian theatre of the 16th and 17th centuries was performed by actors masked always in the typical grotesquerie of Pierrot, Harlequin, Pantaloon, Scaramouche, Capitano, etc. The white face of the modern circus clown is a direct inheritance from the Pierrot, who in the 18th century discarded the mask and powdered his face with flour. The Italian Pulcinello and the French Polichinelle were represented as deformed old men with white hair and moustaches and huge hooked red noses.

The English stage of Elizabeth did away with the mask as a means of facial make-up. Instead of the set expressions of the disguised Harlequins and Pantaloons, actors were seen as human beings with their natural faces or appropriately painted, bearded and wigged as the character called for. Cosmetics were applied simply and obviously as there was no artificial lighting to soften disguise deficiencies. The theatre of Molière encountered few make-up difficulties. The customary long ringlets of the Court were worn whatever the period of the play, whether Roman or Contemporary and the only beard necessary was the partly shaved moustache of the prevailing mode.

The ignoring of archaeological verity in make-up was characteristic of the English stage until after the time of David Garrick who, for nearly every character, wore the white court wig of George III. and as Romeo appeared as a British gentleman of his day. The art of make-up was but little studied before the beginning of the 19th century. Costume was clumsy and incorrect, wigs and beards for character parts of crude material and the faces of old men, villains and clowns inartistically painted. The early method of acting Shylock was as a comedy part that roused audiences to laughter. Doggett, a celebrated Shylock, wore a ridiculous red wig and beard for the part. The first actor to redeem the character from buffoonery was Macklin, who presented him sinister and black-bearded. Since Macklin, actors have varied the aspect of Shylock according to their fancy. A well-remembered portrait was that of Henry Irving whose Jew was the picture of an elderly aristocrat.

The stage lighting of the period was dim and ineffectual, first by candles, later by smoking oil lamps, and in its twilight crudity passed unnoticed. As illuminating gas and calcium lights were introduced the necessity arose for greater circumspection in appearance. Make-up material, however, was still somewhat elemental and natural appearing heads and complexions a rarity. The electrical lighting in theatres today would make sorry work of some of these old stagers. Wigs were constructed of any workable material resembling human hair, sheep and goat fleeces, yak and horse hair. Sometimes for rough and tousled heads jute was used. Human hair, nevertheless, was employed when available and gradually superseded the coarser material. Llama hair is often used in white wigs.

Modern Make-up.—The art of the wig-maker has kept pace with the general perfection of theatrical devices. The old man's bald or semi-bald pates were formerly constructed of light felt or soft buckskin and coloured with dry chalk, ochre and vermillion until a flesh-like hue was obtained. The up-to-date peruquier builds his bald wigs on blocks that shape the article to the real proportions of the head and with hard, shell-like pates. Wax and papier mâché were used at first, later celluloid of a natural flesh colour. Through this the hair is sewn shred by shred with a needle formed like a fish hook. In the case of full wigs for younger characters a soft flexible cap of silk gauze or bolting cloth is fitted to the head and the hair sewn through. For the purpose of quick disguise a composite wig consisting of pate, forehead, eyebrows, nose and moustache is a device that has been found effective but the disadvantage it possesses is that it takes away all expression of the face. It resembles the mask of the *Commedia dell' arte*. There have been odd experiments in make-up such as in Granville Barker's production of *Midsummer Night's Dream* (London, 1914) wherein the fairies' faces and wigs were bright gold.

Beards made on wire frames and hung over the ears, and moustaches pinched into the nostrils by wire have been replaced by natural looking appendages sewn on gauze and attached to the face by spirit gum—a compound of rosin, mastic and alcohol. The most artistic result, however, is accomplished by the use of crêpe hair, a vegetable fibre that is braided into long ropes and cut off, combed out and pasted to the face piecemeal. Sheep wool dyed was formerly used.

Grease paint, a valuable invention of over a half-century ago, is a composition of oil, spermaceti and wax, suited to any complexion, ruddy, sallow, Moorish or fair, and runs in colour scheme from white to black. (*See* COSMETICS.) Mascara for tinting the hair is made in various hues of pressed gum and colour and applied with a wet brush. Face powder is of talc tinted with lake colours. Minstrel black is a compound of burnt cork and glycerine. This was used for the stage negro until brown grease paint showed the wiser way. Even Othello was at one time blackened with charred cork. Clown white has a basis of zinc oxide. Formerly white lead was employed but this was found to possess dangerous qualities. Its use caused the death of the most famous of American clowns, George L. Fox. Rice starch is the usual material for whitening the hair. There is little difference between the preparation of the face for the stage and for the screen. The latter requires a more minute method and must allow for the colour prohibitions of the camera. (*See* MOTION PICTURES: *Make-up.*)

With the newer possibilities of make-up the actor should be chary of its use in the theatre. It is often quite unnecessary. Too great an overlay of paint hides expression and inhibits the play of facial muscles. The subtle changes of emotion are often hidden and lessen the effect of the actor's work upon his audience. Many artists of the theatre use practically none at all. The Italian actress, Eleanora Duse, discarded it entirely. Modern stage lighting which strikes the actor's features from many angles is so searching that it reveals paint instead of complexion unless colour is sparingly put on. It must not be forgotten that a great part of an actor's charm lies in his unconcealed personality. The deadly white skin, the over-rouged cheek, the flaming mouth and the heavily lined eyelid all make for unappealing grotesquerie.

(O. SK.)

MAKING-UP PRICE. A term used in the London and other British stock exchanges to denote the price at which speculative bargains are carried over from one account to the next. The carrying over of a "bull" position in Eries, for example, implies a sale for cash and a simultaneous repurchase for the new account, both bargains being done at the making-up price. This is fixed at noon on carry-over day, in accordance with the market price then current (*see* STOCK EXCHANGE). The term is also used in New York, where the making-up prices are fixed at the end of a day's business, in accordance with the American system of daily settlements.

MAKÓ, the capital of Csanád county, Hungary, a typical market town of the Hungarian plain situated near the right bank of the Maros. Cereal cultivation and stock raising are important activities on its fertile communal lands and there are several flour mills in the town, but its chief specialisation is the growth of vegetables, particularly onions for which it is famous. Pop. (1930) 35,824.

MAKONNEN, RAS TAFARI (1891–), king of Abyssinia, "King of the Kings of Ethiopia, Lion of Judah, the Elect of God," born July 17, 1891, was great-grandson of Haile Melekot, King of Shoa, and son of a distinguished soldier and diplomat. He was educated by the French mission at Harrar. In 1912 he married Waizero Manin, granddaughter of Ras Michael, his eldest son being born July 27, 1916. When on Sept. 27, 1916, the dissolute Lej Yasu was dethroned and his aunt, Zauditu, proclaimed empress, Tafari, her cousin, was appointed regent, heir to the throne, and Ras (prince) of Rases. Ras Michael, Yasu's father, was defeated on Oct. 27. Yasu rallied his father's army, but it surrendered at Magdala in Dec. 1917. Yasu was incarcerated in 1921. An indefatigable worker, widely read, possessing personality, ability and enthusiasm for reform, Tafari

OTIS SKINNER (1858–1942) IN VARIOUS RÔLES ILLUSTRATING CONTRASTS IN MAKE-UP

1. As Charles Surface in "The School for Scandal"
2. Portraying Hajj in "Kismet"
3. As Sancho Panza in Cervantes' "Don Quixote"
4. As Falstaff in "Henry IV."
5. Otis Skinner without make-up
6. As he appeared in "Mister Antonio"
7. As Denis Roulette in "Sire"
8. As Falstaff in "Merry Wives of Windsor"
9. As Philippe Bridau in "The Honor of the Family"

gradually increased his power. In order to gain authority independently of the Empress Zauditu, Ras had himself proclaimed king, Nov. 7, 1928. After Zauditu's death he formally mounted the throne on Nov. 2, 1930, as Emperor Haile Selassie I. He continued his work of modernization, secured the admission of Abyssinia to the League of Nations in 1923, and made a dramatic tour of European capitals in 1924. Difficulties with England over control of the Nile waters were soon overshadowed by disputes with Italy. In spite of the arbitration agreement of 1928 and the action of the League of Nations, hostilities broke out late in 1935 with Italy, ending in the flight of the emperor from Addis Ababa, May 1, 1936, occupation of the capital by the Italians, May 5, and the proclaiming of King Victor Emmanuel as emperor of Abyssinia. In May 1941 Haile Selassie returned to Addis Ababa. (J. Sw.)

MAKRAN or **MEKRAN,** a province of Baluchistan, India, fringing the Arabian sea from Persia almost to Sind for 200 mi. It is subject to the khan of Kalat under British supervision. Total area, 23,269 sq.mi.; pop. (1941), 86,651. The lateral valley of Kej is associated with Makran in early geographical records. The Kej-Macoran of Marco Polo is the Makran of today.

The long stretch of sandy foreshore is broken on the coast-line by the magnificent cliffs of Malan, the headlands of Ormarah and Gwadar, and the precipitous cliffs of Jebel Zarain, near Pasni. Within them lies the usual frontier band of parallel ridges, alternating with narrow valleys. The normal conformation of the Baluchistan frontier is somewhat emphasized in Makran. Here the volcanic action, which preceded the general upheaval of recent strata and the folding of the edges of the interior highlands, is still in evidence in occasional boiling mud volcanoes on the coast-line. Evidence of extinct mud volcanoes exists through a very wide area in Baluchistan and Seistan. The coast is indented by several harbours. Ormarah, Khor Kalmat, Pasni and Gwadar are all somewhat difficult of approach by reason of a sand-bar which appears to extend along the whole coast-line, and which is very possibly the last evidence of a submerged ridge; and they are all subject to a very lively surf under certain conditions of wind. Of these the port of Gwadar (which belongs to Muscat) is the most important. They all are stations of the Indo-Persian telegraph system which unites Karachi with Bushire. With the exception of the Kej valley, and that of the Bolida, which is an affluent of the Kej, there are no considerable spaces of cultivation in Makran. These two valleys seem to concentrate the whole agricultural wealth of the country. They are picturesque, with thick groves of date palms at intervals, and are filled with crops and orchards, yet the surrounding waste of hills is chiefly a barren repetition of sun-cracked crags and ridges with parched and withered valleys intersecting them. Makran is the home of remnants of an innumerable company of mixed people gathered from the four corners of Asia and eastern Africa. The ancient Dravidians, of whom the Brahui is typical, still exist in many of the districts which are assigned to them in Herodotus. Amongst them there is always a prominent Arab element, for the Arabs held Makran even before they conquered Sind. There are negroes on the coast, bred from imported slaves. The Meds of the Indus valley still form the greater part of the fishing population, representing the Ichthyophagi of Arrian. The old Tajik element of Persia is not so evident in Makran as it is farther north; and the Karak pirates whose depredations led to the invasion of India and the conquest of Sind, seem to have disappeared altogether. The fourth section includes the valleys formed by the Rakshān and Mashkel, which, sweeping downwards from the Kalat highlands and the Persian border east and west, unite to break through the intervening chain of hills northward to form the Mashkel swamps, and define the northern limits of Makran. In these valleys are narrow strips of very advanced cultivation, especially dates. The great Mashkel swamp and the Kharan desert to the east of it, mark the flat phase of southern Baluchistan topography. It is geologically part of an ancient inland lake or sea which included the present swamp regions of the Helmund. The latter is separated from the higher central depression of the Lora by a long transverse band of serrated hills. Here and there these jagged peaks appear as if half overwhelmed by an advancing sea of sand. They are treeless and barren, with occasional water at the edges of their foot-hills. The Koh-i-Sultan, at the western extremity of the northern group of these hills, is over 6,000 ft. above sea-level, but the general level of the surrounding deserts is only about 2,000 ft., sinking to 1,500 ft. in the Mashkel Hamun and the Gaod-i-Zirreh.

The whole of this country has been surveyed and the boundary between Persian and British Baluchistan demarcated by a commission in 1895–1896. In 1898 a British force was sent to Makran by sea, owing to a rebellion against the authority of the khan of Kalat, and an attack made by some Makran chiefs on a British survey party. A brief campaign terminated with the capture of the Kej citadel. Another similar expedition was required in 1901 to storm the fort at Nodiz.

See *Baluchistan District Gazetteer*.

MAKSOORA, in Mohammedan architecture, the sanctuary or praying-chamber in a mosque, sometimes enclosed with a lattice screen; the word is occasionally used for a similar enclosure round a tomb.

MAKUAN, a group of little-known tribes of South American Indians, constituting an independent linguistic stock. The Maku tribes are scattered over a considerable area in the region about the equator between the Rio Negro and Yapura rivers. They are a short, rather ugly and light-skinned folk, shy and usually of quite primitive culture. Many of them are slaves of the adjacent Arawakan and other tribes. They are regarded as the shattered remnants of a once widely spread primitive population, which has been in large measure destroyed or absorbed by the Arawakan and other tribes who have penetrated and overrun the region. The wilder tribes have no agriculture, pottery or textiles, and live as nomad hunters with flimsy temporary shelters.

See T. Koch-Gruneberg, *Die Maku* (Anthropos, vol. i. pp. 877–906); *Zwei Jahre unter den Indianern* (Berlin, 1909).

MALABAR, a district of British India, in the Madras Presidency. Geographically the name is sometimes extended to the entire western coast of the peninsula. Properly it should apply to the strip below the Ghats, which is inhabited by people speaking the Malayalam language, a branch of the Dravidian stock, who form a peculiar race, with castes, customs and traditions of their own. It would thus be coextensive with the old kingdom of Chera, including the modern states of Travancore and Cochin, and part of Kanara. In 1931 the total number of persons speaking Malayalam in the Presidency was 3,727,254.

The district of Malabar extends for 145 mi. along the coast, running inland to the Ghats with a breadth varying from 70 to 25 mi. The administrative headquarters are at Calicut. Area, 5,790 sq.mi. Malabar is much diversified in its configuration; from the eastward, the great range of the Western Ghats, only interrupted by the Palghat gap, looks down on a country broken by spurs, ravines, forests and jungle. To the westward, gentler slopes and downs, and gradually widening valleys, closely cultivated, succeed the forest uplands, till, nearer the seaboard, the low laterite tablelands shelve into rice plains and backwaters fringed with coco-nut palms. The coast runs in a south-easterly direction, and forms a few headlands and small bays, with a natural harbour in the south at Cochin. In the south there is considerable extent of table-land. The mountains of the Western Ghats, from 3,000 to 7,000 ft. high, run almost parallel to the coast, and along the coast is an almost continuous chain of lagoons or backwaters which have been formed by the action of the waves and shore currents in obstructing the waters of the rivers. Connected by artificial canals, they form a cheap means of transit for a large local trade. Fishing and fishcuring is an important industry, coir is manufactured, and there are saw-mills, soap and tile works. The forests are extensive and of great value. The population in 1941 was 3,929,425.

The staple crop is rice, the next most important products being coco-nuts, fruits, and pepper. Coffee is grown chiefly in the upland tract known as the Wynaad. The Madras railway crosses the district and runs along the coast from Calicut to Mangalore. The principal seaports are Calicut, Tellicherry, Cannanore and Cochin. The principal exports are coffee, coco-nut products and pepper.

MALABARI, BEHRAMJI (1853–1912), Indian journalist and social reformer, was born in 1853 at Baroda, the son of a poor Parsi in the employment of the state. He was educated in a mission school, but he never obtained an academical degree. Coming to Bombay, he fell under the influence of Dr. John Wilson, principal of the Scottish College. He published a volume of poems in Gujarati (1875), and *The Indian Muse in English Garb* (1877), which attracted attention in England. In 1880 he acquired the *Indian Spectator,* which he edited for twenty years until it was merged in the *Voice of India.* In 1901 he became editor of *East and West.* He was an ardent and indefatigable advocate of social reform in India, especially as regards child marriage and the remarriage of widows. It was largely by his efforts, in the press and in tours through the country, that the Age of Consent Act was passed in 1891. He died at Bandora, near Bombay, on July 12, 1912.

He also wrote *Gujarat and the Gujarati's* (1883), and *The Indian Eye on English Life* (1893).

See R. P. Karkaria, *India, Forty Years of Progress and Reform* (London, 1896).

MALABON, a municipality (with 21 *barrios* or districts) of the province of Rizal, Luzon, Philippine Islands, one mile inland from Manila bay and three miles north of Manila, with which it is connected by a street-car line. Pop. (1939) 33,285; 22 whites. Malabon is noted for its fish ponds and fisheries and for the manufacture of perfume from the flowers of ilang-ilang trees (*Cananga odorata*). Other leading industries are sugar refining, cigar making and the weaving of jusi cloth. Tagalog is the vernacular. Of the inhabitants aged 6 to 19 inclusive, 39·6% were reported in 1939 as attending school, while 75·2% of the population 10 years old and over was reported as literate. Malabon was formerly known as Tambóbong.

MALACCA, a town on the west coast of the Malay peninsula, which with the adjoining territory forms one of the Straits Settlements, and gives its name to the straits that divide Sumatra from the Malay peninsula. Malacca was administered by a resident councillor, responsible to the governor of the Straits Settlements, and by district officers and other officials under his direction. The population of the town of Malacca in 1939 was about 44,000. In 1941 the population of the territory was estimated at 233,930, of whom Malays numbered 110,673, Chinese 91,099, Indians 28,416 and Europeans 588 (*see* also STRAITS SETTLEMENTS). The trade of this once flourishing port has declined, most of the vessels being coasting craft. This is due to the shallowness of the harbour, and to the fact that Penang and Singapore, at either entrance to the straits, draw all the trade and shipping. The area of the territory is 637 sq.mi. The settlement is wholly agricultural. Much of the land has been in the hands of natives, but there is ordinarily a large acreage under rubber (*hevea*). The settlement is well opened up by roads; and a railway, which is part of the Federated Malay States railway system, was constructed from the town of Malacca to Tampin in the Negri Sembilan. There is a good rest-house at Malacca and a comfortable seaside bungalow at Tanjong Kling, seven miles from the town. Malacca is 118 mi. by sea from Singapore and 50 mi. by rail from Seremban, the capital of the Negri Sembilan. In World War II it was occupied by Japan.

History.—Malacca, visited by few ships, was the least important of the three British settlements on the Straits which gave their name to the colony. It has, however, a remarkable history (*see* MALAY PENINSULA: *History*). The precise date of its foundation cannot be ascertained, but there is reason to believe that this event took place in the 14th century. The Roman youth Ludovigo Barthema is thought to have been the first European to visit it, some time before 1503; and in 1508 Diogo Lopez de Siqueira sailed from Portugal for the purpose of exploiting Malacca. He was hospitably received, but disagreements with the natives ensued and word was brought to Siqueira that a treacherous attack was about to be made upon his ships. Siqueira sent a native man and woman ashore "with an arrow passed through their skulls" to the sultan, "who was thus informed," says de Barros, "through his subjects that unless he kept a good watch the treason which he had perpetrated would be punished with fire and sword." The sultan retaliated by arresting Ruy de Araujo, the factor, and twenty other men who were ashore collecting cargo. Siqueira immediately burned one of his vessels and sailed for Portugal. In 1511 d'Albuquerque captured the town. Malacca became a Portuguese possession for 130 years, and was the base of their commercial explorations in south-eastern Asia while they enjoyed, and later while they sought to hold, their monopoly in the East. It was from Malacca, immediately after its conquest, that d'Albuquerque sent d'Abreu on his voyage of discovery to the Moluccas, or Spice islands, which later were the objective of Magellan's voyage of circumnavigation. Under the Portuguese government St. Francis Xavier started a mission in Malacca, the first Christian mission in Malayan lands.

The Dutch held Malacca from 1641 till 1795, when it was taken from them by Great Britain, and the Dutch system of monopoly in the straits was abolished. The colony was restored to the Dutch in 1818, but six years later it came finally into the hands of Great Britain, being exchanged by a treaty with Holland for the East India Company's settlement of Bengkulen and a few other unimportant places on the west of Sumatra. By this treaty the Dutch were precluded from interference in the affairs of the Malay peninsula, and Great Britain from similar action in regard to the States of Sumatra, with the exception of Achin, the right to protect that state being maintained by Great Britain until in 1872 it was finally abandoned by a treaty concluded with Holland. It was not until 1833 that the whole territory was brought under British control. It fell to the Japanese in Jan. 1942.

MALACHI, the name assigned to the last book of the Old Testament in English (the last of the "prophets" in the Hebrew Bible), which according to the title (Mal. i. 1) contains the "word of Yahweh to Israel by the hand of Malachi." In form the word means "my messenger." It could be explained as a contraction of Malachiah, "messenger of Yahweh"; but the Septuagint is probably right in not regarding it as a proper name ("by the hand of His messenger"). Not only do we know nothing from internal or external evidence of the existence of a prophet of this name, but the occurrence of the word in the title is naturally explained as derived from iii. 1: "Behold, I send my messenger" (*cf.* ii. 7). The prophecy must, therefore, be regarded as anonymous; the title was added by the compiler who wrote similar editorial titles to the anonymous prophecies beginning Zech. ix. 1, xii. 1. (Note the use of "burden").

The contents of the prophecy fall into a series of clearly marked sections, as in the paragraph division of the Revised Version. These apply, in various ways, the truth emphasized at the outset: Yahweh's love for Israel in contrast with his treatment of Edom (i. 2–5). Israel's response should be a proper regard for the ritual of His worship; yet any offering, however imperfect, is thought good enough for Yahweh's altar (i. 6–14). Let the priests, who are responsible, take warning, and return to their ancient ideals (ii. 1–9). Again, the common Fatherhood of God should inspire a right relation among fellow Israelites, not such conduct as the divorce of Israelite wives in order to marry non-Israelite women (ii. 10–16). The prevalence of wrong-doing has provoked scepticism as to righteous judgment; but the messenger of Yahweh is at hand to purge away indifferentism from worship and immorality from conduct (ii. 17–iii. 6). The payment of tithes now withheld will be followed by the return of prosperity (iii. 7–12). Religion may seem useless, but Yahweh remembers His own, and will soon in open judgment distinguish them from the irreligious (iii. 13–iv. 3). The book closes with an appeal to observe the law of Moses, and with a promise that Elijah shall come before the threatened judgment—probably a later addition.

The topics noticed clearly relate the prophecy to the period of Ezra and Nehemiah, when the Temple had been rebuilt (i. 10; iii. 1, 10), the province of Judah was under a Persian governor (i. 8), and there had been time enough for the loss of earlier enthusiasm. The majority of modern scholars are agreed that the prophet prepares for the work of those reformers (Ezra, 458 *c.;* Nehemiah, 444, 432 B.C.). The priests have fallen into contempt (ii. 9) and have neglected what is still one of their chief trusts, the oral law (ii. 6 *seq.*). The priestly code of written law, in its present form, was not promulgated until 444 B.C. (Neh. viii.–x.) and it is not presupposed by "Malachi" who writes under the influence of the earlier Code of Deuteronomy only, and must therefore belong to a date prior to 444. The independent character of the attack on current abuses (marriage with foreign women, ii. 11; non-payment of sacred dues, iii. 8) suggests priority to the work of Ezra. The prophecy affords an interesting and valuable glimpse of the post-exilic community, with its various currents of thought and life. The completion of the second Temple (516 B.C.) has been followed by disillusionment as to the anticipated prosperity, by indifference to worship, scepticism as to providence, and moral laxity. In view of these conditions, the prophet's message is to reassert the true relation of Israel to Yahweh, and to call for a corresponding holiness, especially in regard to questions of ritual and of marriage.

The book is a significant landmark in the religious history of Israel. Its emphasis on the observance of ritual finds fullest development in the Priestly Code, subsequently promulgated; its protest against foreign marriages is made effective through the reforms of Ezra and Nehemiah; the influence of its closing words on later expectation is familiar to every reader of the new Testament (Matt. xvii. 3, 4, 10–13; xxvii. 47, 49; John i. 21, 25).

BIBLIOGRAPHY.—The chief commentaries in German are those by Nowack (1897, 1904), Wellhausen (1898), Marti (1904), Sellin (1922); there is one in French by A. van Hoonacker (1908). Those recommended in English are by G. A. Smith (1898, 1927), S. R. Driver (*Century Bible,* 1906), J. M. P. Smith (*International Critical Commentary,* 1912, W. E. Barnes (*Cambridge Bible,* 1917).

(H. W. R.)

MALACHITE, a bright green mineral, consisting of a basic copper carbonate, $CuCO_3Cu(OH)_2$. It belongs to the monoclinic system, but rarely forms good crystals, occurring mostly as nodular, botryoidal or reniform masses, with pronounced radial and concentric structure, successive layers often varying much in colour. It may also be quite compact or earthy and often forms thin films or mere stains on rocks. It is very commonly associated with the deep blue azurite (*q.v.*). The density is about 4 and the hardness 3·5–4·0. It is soluble in acids with effervescence.

Malachite is one of the commonest ores of copper and perhaps the most conspicuous, being a useful guide in prospecting. It is found in the upper oxidized portions of copper deposits, and is formed by the action of water, air and carbon dioxide on primary copper sulphides, especially where calcium carbonate is present. The soluble copper salts set free by oxidation of the sulphides react with limestone or other carbonates and precipitate the insoluble malachite. The mineral is found in nearly all copper-mining districts: specially fine specimens have come from various mines in Russia, where it has often been used as a polished ornamental stone, though the colour is rather crude. Other well-known localities for good specimens are the Copper Queen mine, Bisbee, Arizona, and the old Burra Burra mines, Kooringa, South Australia. (*See* also DYES, SYNTHETIC.) (R. H. RA.)

MALACHOWSKI, STANISLAW (1736–1809), Polish statesman, the younger son of Stanislaw Malachowski, palatine of Posen. He was first elected a deputy to the Diet of 1764, and the Four Years' Diet unanimously elected him its speaker (1788). Malachowski worked tirelessly for reform and to save the republic. He was one of the framers of the constitution of May 3, 1791, exceeding in liberality all his colleagues and advocating the extension of the franchise to the towns and the emancipation of the serfs. In 1807 Malachowski was placed at the head of the executive committee appointed at Warsaw after its evacuation by the Prussians, and when the grand duchy of Warsaw was created Malachowski became president of the senate. In the negotiations with the Austrian government concerning the Galician salt-mines Malachowski assisted the treasury by hypothecating all his estates as an additional guarantee. In 1809 he died at Warsaw.

MALACHY, ST. (*c.* 1094–1148), otherwise known as Maol-Maodhog (or Maelmaedhog) Ua Morgair, archbishop of Armagh and papal legate in Ireland, was born at Armagh. His father, an Irish clergyman, the *Fearleighlinn,* or *lector,* at the university, was said to have been of noble family. He was vicar of Archbishop Celsus or Ceallach of Armagh, and carried out many reforms ending to increase conformity with the usage of the Church of Rome. He spent four years with Malchus, bishop of Lismore (in Munster), a strong advocate of Romanism. On his return from Lismore, Malachy undertook the government of the decayed monastery of Bangor (in Co. Down), but very soon afterwards he was elected bishop of Connor (now a small village near Ballymena). After the sack of that place by the king of Ulster he withdrew into Munster; here he was kindly received by Cormac MacCarthy, with whose assistance he built the monastery of Ibrach (in Kerry). Meanwhile he had been designated by Celsus to succeed him in the archbishopric but eventually returned, at his own desire, to the smaller and poorer portion of it, the bishopric of Down. In 1139, Malachy set out from Ireland with the purpose of soliciting from the pope the pallium for the archbishop of Armagh. On his way to Rome he visited Clairvaux, and thus began his friendship with St. Bernard. Malachy was received by Innocent II with great honour, and made papal legate in Ireland, though the pope refused to grant the pallium until it had been unanimously applied for "by a general council of the bishops, clergy and nobles." Nine years later (1148), at a synod of bishops and clergy held at Inis-Patrick (St. Patrick's island, near Skerries, Co. Dublin), Malachy was commissioned to return to Rome and make fresh application for the pallium; he did not, however, get beyond Clairvaux, where he died in the arms of St. Bernard, on Nov. 2, 1148. The object of his life was realized four years afterwards, in 1152, during the legateship of his successor. Malachy was canonized by Clement III in 1190. Malachy reformed and reorganized the Irish Church and brought it into subjection to Rome; like Boniface, he was a zealous reformer and a promoter of monasticism. He opened the first Cistercian monastery in Ireland, five more being soon afterwards established. Several works are attributed to him, but are all probably spurious.

St. Bernard's *Life* of Malachy, and two sermons on his death will be found in J. P. Migne, *Patrologia Latina,* clxxxii, clxxxiii; *see* also the ecclesiastical histories of Ireland by J. Lanigan (1829) and W. D. Killen (1875); A. Bellesheim, *Geschichte der katholischen Kirche in Irland,* Bd. I. (Mainz, 1890); G. T. Stokes, *Ireland and the Celtic Church* (6th ed., 1907); J. O'Hanlon, *Life of Saint Malachy* (Dublin, 1859); articles in *Dict. Nat. Biog.* and Herzog-Hauck's *Realencyklopädie für protestantische Theologie.*

MALACOSTRACA, the largest subclass of the Crustacea (*q.v.*), including the lobsters, crawfish, crabs, shrimps, prawns, beach fleas, sow bugs and various other crustaceans. They may be briefly defined as Crustacea having the body composed of nineteen somites, all, typically, bearing appendages, the trunk-limbs differentiated into two series, a thoracic of eight and an abdominal of six pairs; and the genital openings of the female on the sixth, those of the male on the eighth thoracic somite. A study of the comparative morphology of the Malacostraca permits us to draw up a scheme for the probable course of evolution of the group which is, at least, not contradicted by our scanty knowledge of its fossil representatives. According to this scheme, the earliest Malacostraca exhibited what has been called the "caridoid facies"; that is to say, they were shrimplike in general form, with a carapace enveloping, but not coalesced with, the thoracic somites, with stalked eyes, biramous antennules, and a scale-like exopodite on the antenna, with the thoracic limbs forming walking-legs with swimming exopodites and branchial epipodites and with a tendency for one or more of the anterior pairs to be assimilated to the mouth-parts as maxillipeds; with the abdominal appendages forming biramous swimmerets, except the last pair which are large, lamellar, and form with the telson a "tail-fan."

The earliest fossils that can be definitely referred to the Malacostraca occur in the Carboniferous rocks and present, with little modification, the caridoid facies described above. Some of them (*Pygocephalus*) have a brood-pouch formed by overlapping plates (*oostegites*) from the bases of the thoracic legs and appear, therefore, to be referable, to the Mysidacea. From the caridoid Mysidacea a series can be traced in which the carapace is progressively reduced, the thoracic exopodites are lost and the eyes become sessile. Although palaeontology gives no help, the steps of this series are indicated by the specialized offshoots which have given the Cumacea, Thermosbaenacea, Tanaidacea and Isopoda. The Amphipoda belong to the same series but their precise place in it is less clear. The other orders of Malacostraca have no brood-pouch and appear to have diverged very early from the primitive stock. Already in Carboniferous times the Syncarida had lost the carapace and had much the same general structure as the recent *Anaspides* and its allies. Another series in which the carapace coalesced with the thoracic somites gave rise to the great group of the Decapoda, from which the Euphausiacea are perhaps an offshoot. The Decapoda, beginning with caridoid forms, have, in several independent lines, assumed the crablike or "carcinoid facies" by reduction of the abdominal region (Brachyura or true crabs, and crablike Anomura). The Stomatopoda had assumed nearly their typical structure in Jurassic times but their earlier history is unknown.

In the scheme of phylogeny thus outlined no mention has been made of the Phyllocarida, which, in most systems of classification, are ranked as the most primitive Malacostraca, forming a link with the Branchiopoda. They differ from the other Malacostraca in having an additional somite in the abdomen, the telson terminating in a "caudal fork," and a bivalve carapace provided with an adductor muscle. The thoracic limbs are more or less flattened and leaflike and have a general resemblance to the trunk-limbs of the Branchiopoda though a close comparison is difficult. The existing genera, *Nebalia* and its allies, are believed to show affinity with the fossil *Ceratiocaridae,* the earliest of which appear in Cambrian rocks and are thus vastly more ancient than any other Malacostraca. Recent work, however, tends to diminish the significance of the differences between Phyllocarida and other Malacostraca, and, in particular, the recognition of a vestigial seventh abdominal somite in certain primitive Mysidacea suggests that the Phyllocarida may, after all, be mose closely related to the Peracaridan series than has been supposed.

The orders composing the Malacostraca may be grouped in the following five divisions, briefly characterized below:

1. *Peracarida.* A carapace, if present, not fused with more than four thoracic somites; eyes, when present, stalked (Mysidacea, stalks movable; Tanaidacea, stalks fixed) or sessile (Cumacea, Isopoda, Amphipoda). The Mysidacea comprise generally small shrimplike swimming forms, nearly all marine. They are called "opossum" shrimps because of the brood pouch formed of oöstegites or plates attached to the coxae of the thoracic legs, in which the young undergo their entire metamorphosis after hatching out as nauplii. Their size range is considerable, running from the tiny *Anchialus pusillus,* $\frac{1}{8}$ in. long, to *Gnathophausia ingens,* which exceeds 6 in. in length. Probably all serve as the food of other animals. Several species occur in fresh-water. One of these is *Mysis relicta,* a widely distributed lacustrine form in the northern hemisphere. Thermosbaenacea includes only the minute, blind, creeping *Thermosbaena,* found in a hot spring in Tunis. Cumacea are marine mud-burrowers but the males are, to some extent, free swimming. Tanaidacea are also part of the micro-fauna of the sea bottom, less natatory than the Cumacea. Isopoda are a very varied and successful group, creeping, mud-burrowing and sometimes actively swimming in the sea and a few in fresh water. The destructive wood-boring crustaceans are principally isopods. The most widely distributed of them in both Atlantic and Pacific oceans, *Limnoria lignorum,* the "Gribble," is often accompanied by a boring amphipod, *Chelura terebrans.* Next to the molluscan shipworms, the tiny Gribble ($\frac{1}{8}$ to $\frac{1}{6}$ in. long) is the worst known destroyer of submerged timbers. Infested piling may carry 300–400 individuals to the square inch of surface in favoured localities. An untreated test piece of Oregon fir 5 ft. long by 3 in. square, set in Port Jackson, Australia, was 60% destroyed in six months by a combined attack by *Limnoria* and *Chelura.* By the time nine months had elapsed, it was so utterly riddled with the assistance of shipworms, which had by this time invaded the timber, that insufficient material remained to support further ravages by the borers present. Several species of *Sphaeroma,* though larger ($\frac{3}{8}$ in. long, more or less), also attack wood, but not so generally as *Limnoria,* and less in American than in Australian waters. *Sphaeroma quoyana* is reported to have honeycombed claystone or "papa rock" used in harbour works in New Zealand to such an extent that blocks of concrete overlaying it sank several feet. Parasitism appears in many different families and leads to extremes of specialization and degeneration. One suborder, Oniscoidea, consists of the terrestrial, air-breathing wood lice. Creeping and swimming forms of Amphipoda, another varied and successful group, abound in fresh water and in the sea. A few sand-hoppers or "beach fleas" may become wholly terrestrial. The vast majority of amphipods belong to one suborder (Gammaridea), which includes both free-living and parasitic forms; members of a smaller suborder (Hyperiidea) are planktonic, occur at times in vast swarms, and are consumed in great quantities by seals, cetaceans and other marine animals; a third suborder (Caprellidea) contains the exclusively parasitic family *Cyamidae* or whale lice.

2. *Phyllocarida.* Sometimes referred to as *Leptostraca,* this order is characterized in part by a large carapace which is not fused with any of the thoracic somites, stalked eyes and abdomen of seven segments (six in all other Malacostraca). The single order, Nebaliacea, includes only three or four living genera, all marine mud-burrowers, in part scavengers. They are widely distributed in all seas, usually occurring at moderate depths. Some, such as the large *Nebaliopsis typica,* which attains a length of more than $1\frac{1}{2}$ in., live at depths exceeding 1,000 fathoms. The doubtful affinities of the Phyllocarida are mentioned above.

3. *Syncarida.* This group possesses stalked eyes but no carapace. A small fresh-water group of limited distribution, to which belong the mountain shrimp (*Anaspides*) of Tasmania and a few allies in the Australian region, and also the Bathynellidae of central Europe, minute, blind, degenerate, subterranean forms. They appear to be survivors of a group widely distributed in Carboniferous and Permian times.

4. *Eucarida.* This group is recognized by its stalked eyes and carapace fused dorsally with all thoracic somites. The Euphausiacea are a small group of planktonic, phosphorescent shrimps except for a few living in the deep sea at 1,000 fathoms or more. The pelagic species are of importance as food of whalebone whales. The Decapoda, on the other hand, form the most extensive and diversified of all the orders of Crustacea. It includes the largest representatives of the class and, indeed, of living Arthropoda, and, since many of them are used for food, they are more generally familiar and more thoroughly studied than any other Crustacea. They are classified into two suborders: —Natantia, comprising the shrimps and prawns; and Reptantia, subdivided into four sections, spiny lobsters and their relatives, (Palinura), true lobsters and crayfish (Astacura), hermit and lithodid crabs and their allies (Anomura) and the true crabs (Brachyura). The headquarters of the group is in the sea but many of its members have invaded fresh waters (river prawns and river crabs in the tropics and crayfishes in temperate regions) and although a few are so far terrestrial as to deserve the name of land crabs, and may even climb lofty trees like the Coconut Crab, they pass their young stages in salt or fresh water.

5. *Hoplocarida.* These differ from all other Malacostraca in having the first antennae and the stalked eyes attached to movably articulated segments of the head. The carapace is small and shallow, fused with two or three thoracic somites, leaving four well-developed somites free. The members of the single order Stomatopoda are sometimes known as "mantis shrimps" from the resemblance of their large prehensile claws to those of the mantis insect. They are exclusively marine, burrowing in sand or lurking

VARIOUS CRUSTACEA MALACOSTRACA

1, 2, 3, 4, 6, 10. Coral gall crab, *Hapalocarcinus marsupialis* (Eucarida, Order Decapoda, Section Brachyura) and "house" formed by coral, *Pocillopora* species. This crab occurs in the Indo-Pacific and in South America, on the west coast of Colombia and in the Secas Islands, Panama; specimens photographed are from Port Utria, Colombia. 1. Shows the breathing holes kept open by respiratory streams of water. 3. Opened gall with female. Figs. 1-4 about x 2. 5. Young, partially formed gall. 6. Female x 4 showing egg mass and abdominal "pouch" from which the crab derives its specific name

5. *Phronima* (Peracarida, Order Amphipoda, Suborder Hyperiidea) by reflected light, compare with Plate fig. 2, Crustacea. Natural size

7. *Arcturus baffini* (Peracarida, Order Isopoda), a North American Arctic species. The female usually carries her young around on her long antennae. The figured specimen is an old "granny" which has not moulted for a long time, as it carries several barnacles, *Balanus* species (Cirripedia, Order Thoracica), attached to its back. Natural size

8, 9. Land hermits, *Coenobita clypeatus* (Eucarida, Order Decapoda, Reptantia, Section Anomura), common in Florida and the Caribbean region; under favourable circumstances grow to be three or four times the size of the specimens shown here. About x ½

CLAUS, "LEHRBUCH" (JULIUS SPRINGER), (3) FROM SARS, "CRUSTACEA OF NORWAY" (BERGEN MUSEUM), (4-5) FROM MAYER, "CAPRELLIDEN," (6-7, 10-11) FROM CALMAN, IN "A TREATISE ON ZOOLOGY" (A. & C. BLACK)

VARIOUS CRUSTACEA MALACOSTRACA

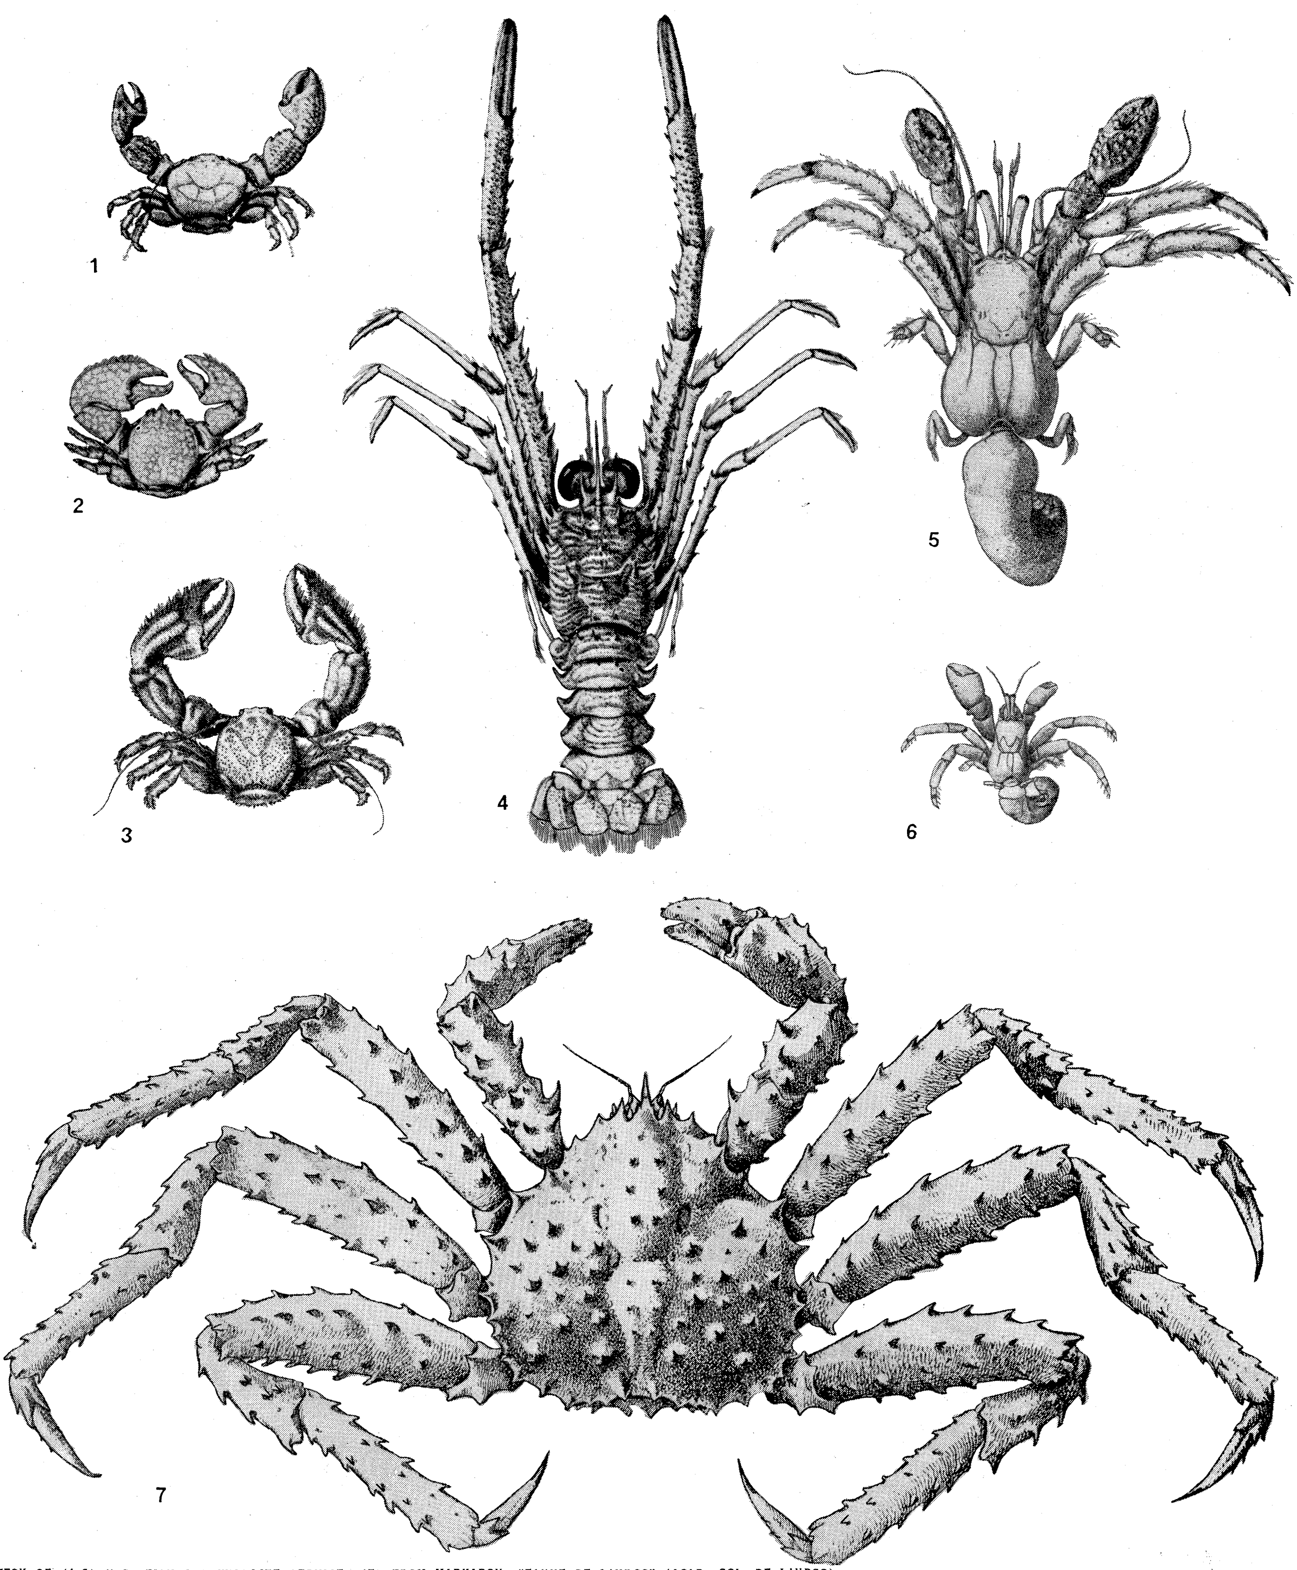
1. Diagram of a generalized malacostracan, showing the "caridoid facies"
2. *Nebalia bipes* (Phyllocarida, Order Nebaliacea). Appendages show through the transparent shell or carapace. *Nebalia* is widely distributed in both the Atlantic and Pacific oceans. About x 12
3. Freshwater amphipod, *Gammarus pulex* (Peracarida, Order Amphipoda, Suborder Gammaridea), by some called freshwater "shrimp." A widely distributed Palaearctic species ranging from England to Japan and found in some parts of North Africa; does not occur in North America

4, 5. "Skeleton shrimp," *Caprella eximia* (Peracarida, Order Amphipoda, Suborder Caprellidea); female (fig. 4) and male (fig. 5) from the Pacific shores of Asia. Enlarged x 3

6. *Anaspides tasmaniae* (Syncarida, Order Anaspidacea), found only in rocky pools at high elevations in the mountains of Tasmania the figure here given
7. *Apseudes spinosus* (Peracarida, Order Tanaidacea), female with eggs in "brood pouch" or marsupium. Primarily a Norwegian species, it has been taken off the Irish coast in 725 fathoms

8, 9. *Diastylus planifrons* (Peracarida, Order Cumacea). 8. Female with eggs in "brood pouch" from the Straits of Magellan. About x 7. 9. Same, dorsal view of cephalothorax

10. *Meganyctiphanes norvegica* (Eucarida, Order Euphausiacea), male, common in the cooler parts of the north Atlantic; in immense swarms or schools, called "krill" by Norwegian fishermen and whalers, serves as food of whales. About x 2
11. Opossum shrimp, *Mysis relicta* (Peracarida, Order Mysidacea), female with brood pouch. A circumpolar species found in the larger freshwater lakes of North America, Europe and Asia



COURTESY OF (1-6) U.S. FISH AND WILDLIFE SERVICE, (7) FROM MARKAROV, "FAUNE DE L'URSS" (ACAD. SCI. DE L'URSS)

VARIOUS CRUSTACEA MALACOSTRACA
(EUCARIDA, ORDER DECAPODA, REPTANTIA, SECTION ANOMURA)

1, 2, 3. Porcellanid "crabs." **1.** *Pachycheles rugimanus,* ranging from North Carolina through the West Indies. About x 2. **2.** *Porcellana sayana,* ranging from North Carolina through the Caribbean area to Panamá; generally found commensal with hermit crabs in gastropod mollusk shells. About natural size. **3.** *Megalobrachium poeyi,* ranging from the Bahamas through the West Indies to Colombia. About x 2

4. "Munida" or squat lobster, *Munida evermanni,* known only from deep water (220-225 fathoms) off Puerto Rico. About x 1½

5, 6. Hermit crabs without their usually carried gastropod shells. 5. *Clibanarius tricolor,* found in Bermuda and ranging from Florida through the West Indies to Barbados, a common species. About x 6. 6. *Calcinus tibicen,* more widely distributed than the preceding species, ranging from Florida to Brazil. About natural size

7. *Paralithodes camtschatica,* Alaskan king crab. Related species are called rock crabs in Europe. Occurring in the north Pacific ocean and the Bering sea, from the shores of Japan and Kamtschatka northward to Bering strait and south to southeastern Alaska. Males are larger than the females, attaining an over-all spread of 4 or 5 ft., with shell or carapace measuring nearly 12 in. in length; weight up to 22 lb.

It is to be noticed in the Anomura that the fifth pair of legs, counting the pincer legs or chelipeds, are much reduced in size and are often hidden under the shell or carapace, as in the king crab, fig. 7. In the hermit crabs the fourth pair of legs, as well, are reduced in size

MALACOSTRACA

CRUSTACEA MALACOSTRACA

1. Spiny or rock lobster of the Pacific coast of North America, *Panulirus interruptus* (Eucarida, Order Decapoda, Reptantia, Section Palinura). The Florida counterpart, *Panulirus argus,* as well as the South African spiny lobster, attains a body length of 18 in. A California spiny lobster weighing 17 lb. has been recorded. About one-fifth natural size
2. Mantis shrimp, *Squilla empusa* (Hoplocarida, Order Stomatopoda) from Woods Hole, Mass. Not quite one-half natural size
3. River crayfish, *Cambarus affinis* (Eucarida, Order Decapoda, Reptantia, Section Astacura), from Havre de Grace, Md. About one-half natural size
4. Blue crab of the east coast of the United States, *Callinectes sapidus* (Eucarida, Order Decapoda, Reptantia, Section Brachyura), about three-tenths natural size; fully grown males may attain a shell width of as much as 8¾ in.
5. Edible crab of Pacific coast of North America, also known as the Dungeness crab, *Cancer magister* (Eucarida, Order Decapoda, Reptantia, Section Brachyura); attains a shell or carapace width of approximately 8 in.
6. Green crab, or "Joe Rocker," common shore crab of Europe, *Carcinides maenas* (Eucarida, Order Decapoda, Reptantia, Section Brachyura), occurring on north Atlantic coast of the United States, Pernambuco, Brazil, Bay of Panama, coasts of Europe and North Africa, Suez Canal, Red Sea, Ceylon, Australia and Hawaiian Islands. About one-third natural size.
7. Stone crab, *Menippe mercenaria* (Eucarida, Order Decapoda, Reptantia, Section Brachyura); southern Atlantic and Gulf coasts of United States and Mexico. Attains a width of shell or carapace of 5 in. Like the blue crab, the stone crab is much relished for food in the eastern and southern U.S.

in crevices in the shallow waters of all the warmer seas. A few go into brackish water. Many species are rare, known only from a few specimens, yet others are found in greater abundance, such as *Squilla investigatoris,* of which 500 were taken in a single haul from 110 fathoms in the Indian ocean. Despite their vicious claws, they have numerous enemies among the fish and octopuses. They are much used fresh or fried for food in the Mediterranean region, in the Philippines, Malaya and elsewhere. In Japan they are cheaper than other edible crustacea. One of the largest stomatopods on record is a Philippine specimen of *Lysiosquilla maculata,* whose body measured slightly more than 15 in. in length.

See CRAB; CRAYFISH; HERMIT CRAB; LOBSTER; SHRIMP; WOOD LOUSE. For terminology, *see* ZOOLOGY. (W. T. C.; W. L. ST.)

MÁLAGA, a maritime province of Spain, one of the eight modern subdivisions of Andalusia; bounded on the west by Cadiz, north by Seville and Cordova, east by Granada, and south by the Mediterranean sea. Pop. (1940), 677,474; area, 2,813 square miles. The northern half of Málaga belongs to the Andalusian plain watered by the Guadalquivir, the southern is mountainous, and rises steeply from the coast. Of the numerous sierras is that of Alhama, separating the province from Granada, rising above 7,000 ft.; its westward continuation in the Sierra de Abdalajis and the Axarquia between Antequera and Málaga; and not far from the Cadiz boundary the Sierras de Ronda, de Mijas, de Tolox and Bermeja, converging and culminating in a summit of nearly 6,500 ft. The principal river is the Guadalhorce, which rises in the Sierra de Alhama. After a westerly course past Antequera it bends through the defile of Peñarrubia and the *Vega* or Vale of Málaga, falling into the sea near that city. The only other considerable stream is the Guadiaro or Guadalevín, which has the greater part of its course within the province and flows past Ronda. There is an extensive salt lagoon near the northern boundary. The mountains are rich in lead and iron. There are warm sulphurous springs and baths at Carratraca. Large quantities of grapes and raisins, oranges and lemons, figs and almonds, are exported. The oil and wines of Málaga are also esteemed. After 1870 the manufacture of beet and cane sugar developed into an important industry. The fisheries are important. The province is traversed by the Cordova-Málaga railway. The nationalists occupied the province during the civil war of 1936–39.

Málaga, the capital (pop. 1940, 208,344), Antequera (23,218), Vélez-Málaga (10,813), Ronda (15,813), Coín (9,631) and Alora (5,614), are described in separate articles.

MÁLAGA, capital of Málaga province, an episcopal see, and, next to Barcelona, the most important seaport of Spain, situated on the Mediterranean coast, at the southern base of the Axarquia hills and at the eastern extremity of the fertile Málaga plain in 36° 43′ N. and 4° 25′ W. Pop. (1940), 208,344 (mun., 238,085). The climate is mild and equable, the mean annual temperature being 66.7°. The principal railway inland gives access through Bobadilla to all parts of Spain, with a branch line along the coast to Vélez-Málaga. Málaga is the Μάλακα of Strabo (iii. 156) and Ptolemy (ii. 4, 7) and the *Malaca foederatorum* of Pliny (iii. 3). The place seems to have been of some importance even during the Carthaginian period; under the Romans it became a municipium, and under the Visigoths an episcopal see. In 711 it passed into the possession of the Moors, and soon came to be regarded as one of the most important cities of Andalusia. It was attached to the caliphate of Cordova, but on the fall of the Omayyad dynasty it became for a short time the capital of an independent kingdom; afterwards it was dependent on Granada. In 1487 it was taken by Ferdinand and Isabella after a protracted siege. In 1810 it was sacked by the French. It was captured Feb. 8, 1937 by the nationalist general Queipo de Llano. Málaga lies principally on the left bank of the Guadalmedina ("river of the city"); the streets near the sea are comparatively modern, and well-built suburbs have spread into the rich and pleasant country which surrounds the city. The Plaza de Riego, the Plaza de la Constitucion, and the Paseo de la Alameda are important. The cathedral, on the site of an ancient mosque, was begun about 1528; after its construction had been twice interrupted, it was completed to its present state in the 18th century. The castle of Gibralfaro, on a rock to the N.E., dates from the 13th century.

New harbour works were undertaken in 1880, and all vessels can load or discharge at the quays, which are connected with the main railway system by a branch line. Iron, lead, wine, olive oil, brandy, almonds, fresh and dried fruit, hats and canary seed are exported in large quantities. Imports include petroleum, grain, codfish, fuel, chemicals, iron and steel, machinery and manures. There are large cotton mills, iron foundries, smelting works and engineering works. The industries include tanning, distilling and the manufacture of sugar, chocolate, soap, candles, artificial ice, chemical products, white lead and pianos.

MALAKAND PASS, a mountain pass in the North-West Province of India connecting the British district of Peshawar with the Swat valley. It is now a military post and the headquarters of a political agency. It came into prominence for the first time in 1895 during the Chitral campaign, when 7,000 Pathans held it against Sir Robert Low's advance but were easily routed. After the campaign was over a fortified camp was formed on the Malakand to guard the road to Chitral. During the frontier risings of 1897 the Swatis made a determined attack on the Malakand, where 700 were killed, and on the adjacent post of Chakdara, where 2,000 were killed. A military force was hurried to the relief and took part in the prolonged frontier operations of 1897–98. (*See* SWAT.)

MALALAS (or MALELAS) (Syriac for "orator"), **JOHN** (*c.* 491–578), Byzantine chronicler, was born at Antioch. He wrote a chronicle beginning with the creation and ending with the death of Justinian (565). It possesses little historical value; it is, however, important as the first specimen of a chronicle written not for the learned but for the instruction of the monks and the common people, in the language of the vulgar, with an admixture of Latin and Oriental words. It is preserved in an abridged form in a single ms. now at Oxford.

For a full discussion *see* Krumbacher, *Geschichte der byzantinischen Litteratur* (1897), p. 332–334, and the *editio princeps,* by E. Chilmead (Oxford 1691), containing Bentley's well-known letter to Mill.

MALAN, SOLOMON CAESAR (1812–1894), British divine and orientalist, was born at Geneva on April 22, 1812. His father, Dr. H. A. C. Malan, a Protestant divine, came of an exiled French family. In 1830 he became tutor in the marquis of Tweeddale's family, in Scotland, and in 1833 he matriculated at St. Edmund hall, Oxford, where he gained several scholarships. From 1837 to 1840 he held the post of classical lecturer at Bishop's college, Calcutta. After serving various curacies, he was presented to the living of Broadwindsor, Dorset, which he held from 1845 until 1886. In addition to many European languages, he was familiar with Tibetan, Chinese, Armenian and Georgian, and his translations were numerous. He opposed Westcott and Hort's text of the New Testament, and the transliteration of oriental languages. He died at Bournemouth on Nov. 25, 1894. His life was written by his son.

MALANGE: *see* ANGOLA.

MÄLAR, a lake of Sweden, extending 73 m. westward from Stockholm, which lies at its junction with the Saltsjö, an arm of the Baltic Sea. The height of the lake normally only reaches 2 ft. above sea-level, and its outflow is sometimes reversed. The area is 449 sq.m., and the deepest sounding is 210 feet. It contains numerous islands and its outline is very irregular, the mean breadth being about 15 m. but an arm extends northward for 30 m. nearly to the city of Uppsala. The lake is connected by navigable channels with lake Hjelmar, to the south-west, and the Baltic to the south, by the Södertelge canal and by two channels at Stockholm. The more important towns, besides Stockholm, are Vesterås on the north, Södertelge and Eskilstuna near the south shore. Many of the business men of Stockholm have residences on the shores of the lake. On Drottningholm is a palace built by Nicodemus Tessin in the 17th century on the site of one built by John III. in the 16th century. At Mariefred on the south shore there is the castle of Gripsholm (1537), with four towers built by Gustavus Vasa, containing a large collection of portraits. On the northward arm of the lake is the palace of Rosenberg, now a school of gunnery. On the same arm is Sigtuna, whose ruined churches are a memorial of its former rank among the principal towns of Sweden. On Björkö, an island in the eastern part of the lake, there was a large settlement of earlier importance than Sigtuna. Here a cross commemorates the preaching of Christianity by St. Ansgar in 829. On the northern arm about 10 m. south of Uppsala, there is the château of Skokloster, occupying the site of a monastery.

MALARIA (syn. ague, intermittent [and remittent] fever, marsh fever, jungle fever, hill fever), a disease caused by the presence of special micro-parasites in the blood, conveyed to man by anopheline mosquitoes and characterized by exacerbations at regular intervals, the so-called "ague fit." The ague fit begins with chilliness, increasing until the whole body shivers and the teeth chatter with cold; the face is pale or livid, the fingers dead white, the nails blue. During this stage the cutaneous vessels are constricted and the surface is cold to touch, but rectal temperature rises. There is a copious flow of clear, watery urine. The second stage is that of dry heat, the skin is burning and flushed. The urine now is scanty and high coloured. The third stage is that of sweating, which is profuse, and may be drenching. The urine is scanty and deposits a thick brick-red sediment of urates on cooling. The three stages together will probably last six to 12 hours and after a period of 24 hours (quotidian), 48 hours (tertian) or 72 hours (quartan) from the commencement of the ague fit, according to the type of infecting parasite, the cycle of symptoms will be repeated. Between attacks the patient is generally in fair health except for that general undermining which the repetition of attacks brings about in time.

Malaria had long been recognized as a disease of world-wide incidence and the cause of a higher sickness and death-rate than any other disease. The finding of malarial parasites in the blood cell by Laveran at Constantine in 1880, the demonstration of the life cycles of the quartan and tertian species of parasite by Golgi in 1885, and of the subtertian fever species by Marchiafava and Celli, and the discovery that the disease is transmitted through the agency of mosquitoes first from bird to bird, by Ronald Ross in India 1897–99, and later from man to man, in conjunction with the investigations and teachings of Patrick Manson and other pioneers, were important factors in a great stimulus to the study of tropical diseases, both of men and of animals in general, and the whole of tropical sanitation was powerfully affected.

Parasites.—Malaria is due to small Protozoa (*q.v.*) or animal parasites which pass an asexual stage in man, living and developing in the red blood cells, dividing into young forms or fresh broods in two or three days' time and producing some male and female forms (gametocytes), which are drawn with the blood into the stomach of the female mosquito, and there conjugate and complete a sexual cycle. An oöcyst forms from the female gamete and in this a swarm of young sporozoites develop and, becoming free in the body cavity, pass to the salivary glands, whence they are injected at the bite of the mosquito and begin again the asexual stage in man. (*See* PARASITIC DISEASES.)

Malaria parasites are of three species: *Plasmodium falciparum, P. vivax* and *P. malariae,* the causal organisms of "subtertian," tertian and quartan fevers respectively. Following the teaching of Laveran, a small body of workers believed that there was but one species, a theory of unity, and on the other hand certain investigators, because of minute differences between examples of the same species, concluded there were even further species and gave names to them. However, as Prof. Marchoux pointed out in a thorough review of the question at the First International Malaria Congress held at Rome in Oct. 1924, experimental research tended to support the idea of plurality and existence of the three species above named. This was supported by the difference and practically constant periods of evolution of each, the transmission of the same species to healthy subjects, the specificity of culture of the parasites of each of the three species *in vitro,* and by epidemiological studies.

In malaria symptomology nothing of fundamental importance has been discovered in recent years. There has been advance on our knowledge of the cause and treatment of blackwater fever (*q.v.*) or haemoglobinuria, the serious nature of which has called forth many investigations, especially in the particular and heavily infected regions where it occurs. Some investigators hold that this condition may arise not only in infections with *P. falciparum,* but occasionally with *P. vivax* and exceptionally with *P. malariae.* The association of an unknown virus with the malarial parasite has been considered as the cause. J. Thomson's work in Rhodesia in 1923–24 gave strong evidence in favour of *P. falciparum* as the causal organism of all local cases and possibly elsewhere. He showed that *P. falciparum* can almost always be found in the blood; and that cases had been living in a district heavily infected by *P. falciparum.* He found one case after five months and another after 40 years' residence; he noted its occurrence only in people who had had attacks of malaria, though possibly unrecognized as such at the time, and had taken their quinine inadequately in amount and over an insufficient period of time. A similar observation was made in the cases which developed blackwater fever on their way home, or after they had left an endemic area even for some time. The finding of the other species of parasite, both of which tend more to chronicity and are readily found in the blood stream, may, when present, be, in Thomson's view, but an indication of a mixed infection.

Diagnosis.—In the diagnosis of malaria in endemic localities the estimate of inhabitants infected is based on the percentage rate of an enlarged spleen or of a positive blood finding amongst a proportion of the population. For the latter, the examinations of a thick and a thin film of blood are made. In the absence of the parasite an estimate of the relative number of large mononuclear (endothelial) cells to other white cells in the blood may be made in certain cases, but the evidence obtained is not conclusive. An increase above the basic figure of 15% endothelial cells of the total white cells was taken by Stevens and Christopher as indicative of actual or recent malaria in Europeans living in the tropics. Blood cell counts made at some time prior and subsequent to the finding of the malarial parasite did not show the presence of a constant relative increase of endothelial cells, nor was this a constant factor in latent malaria, even when the clinical diagnosis was obvious and the most reliable factor, an enlarged spleen, present. With regard to the finding of the parasite in the blood in these cases of "latent malaria in England" it must be remembered that but a small drop is taken and that parasites are not easily found except at the period of a relapse. The clinical signs of latent malaria most commonly found are, in order of frequency, an enlarged spleen, anaemia, functional disorders of the heart and enlargement of the liver. The tendency to chronicity and febrile relapses in malarial infections is very marked.

Distribution.—Malaria is a world-wide disease with endemic foci in all countries. It is most prevalent and extremely common in the tropics with the native population and high infection rate, constant heat, moisture and water for the breeding of the anopheline mosquito and requisite temperature for the development of the sexual stage of the parasite therein. As the poles are approached, the foci of endemicity gradually become less. For the development of the parasite in the mosquito an adequate temperature is necessary. On an average the three forms, *P. malariae, P. vivax* and *P. falciparum,* take 14, 11 and six days, respectively, the time varying with the temperature. In subtropical countries, malarial outbreaks follow the rainy seasons, when opportunities arise for the breeding of the mosquitoes. Norway and Sweden are examples of countries wherein *Anopheles* are present but malaria absent.

In Great Britain malaria was formerly not uncommon, but became rare until the return of many infected troops. Related to the presence of these carriers there were 235 indigenous cases in England in 1917, the number falling to four in 1924, thus corresponding with the cure of the malarial carriers. There exist in England three species of *Anophelinae* in which the parasites may develop and be transmitted from man to man, but with treatment of infected cases from abroad there is now practically an absence of the human carrier of the parasites, or at least of parasites with sufficiently numerous sexual forms in the blood, a minimum of 12 per cu.mm. of blood being considered necessary for development in the mosquito. Climatic conditions, particularly temperature and humidity, influence the endemic prevalence of malaria. A mean daily temperature exceeding 60° F is necessary for its propagation for the full development of the parasite in the mosquito, *P. falciparum* requiring a very high temperature; *P. malariae* completing its cycle at a low one, and *P. vivax* over a wide range of low to high. This explains the seasonal incidence of the three types of malaria, the relatively high incidence of *P. falciparum,* the most malignant parasite, and the large number of infected inhabitants and high death-rate in the tropics and subtropics, and its rarity in indigenous cases in temperate climes, the presence of the endemic foci of *P. malariae* in the cooler hill country in the tropics and subtropics and the universal distribution of *P. vivax.*

Though *P. falciparum* is the most malignant and spreads most rapidly when anophelism is intense, because of its greater output of gametes in the blood, it does not tend to such chronicity in the absence of reinfection as do the other two forms. In the absence of reinfection *P. malariae,* by far the rarest form, is, however, the most resistant and *P. vivax* holds an intermediate place. Of 28,270 blood examinations made in England at one laboratory on cases of malaria contracted during the World War, 777 were found positive, and of these *P. vivax* numbered 759, *P. falciparum* 14, *P. malariae* four. There was a marked falling off as the time in England lengthened, and it was rare to find the parasite after the quarterly period of 12 to 15 months. Seven cases were found after 30 months all with *P. vivax,* one in a double infection with *P. malariae* after 39 months, and one case after 51, and another after 59 months; *P. falciparum* was found after three months in a double infection with *P. vivax* at the 11th month, once alone at the 12th month, and once in a triple infection at the 14th month. The third of the four cases of *P. malariae* had also been home a long time, namely, 16 months. In none of this extensive series was the parasite ever found after five years at home. It is not uncommon to hear a person settled in a non-infective country for many years accusing a temporary febrile attack or period of lassitude as a return of malaria which he once contracted abroad. Proof of this seems wanting. Though malaria has been transferred directly from man to man, the parasites infecting man have not been made to infect any animal. Entomologists have furthered their investigations into the bionomics and classification of mosquitoes and the determination of the species of anopheles that carry malarial parasites.

S. P. James and Dale have reported that quinine, quinidine and cinchonine possess the same curative properties for all forms of malaria, and without difference in their toxicity save for the greater cardiac depressant action of quinidine. Fletcher at Kuala Lumpur has made a careful series of observations on this point.

Prophylaxis and Treatment.—The treatment of malaria is intimately bound up with prophylaxis. Particular reference may, however, be made to the recent therapeutic use of horse serum in the treatment of that severe form of malaria, blackwater fever, wherein this serum appears to inhibit the action of an auto-haemolysin and its destruction of red blood cells in the body.

Many clinicians strongly advocate in tropical regions intramuscular and intravenous injections of the bihydrochloride of quinine in serious cases, and injections do act quickly in severe, malignant, remittent and comatose cases, but in ordinary cases oral administration of the sulphate has been satisfactory. In acute attacks it must be borne in mind that 24 hours or more may elapse before the good effects of quinine become manifest.

The classical successes in the reduction of malaria at Ismailia, Hongkong, Havana and elsewhere have encouraged similar work in other localities, but there are few such examples as the long continued labours of M. Watson in the Federated Malay States and the brilliant sanitary victory of Gen. Gorgas and the Americans over both malaria and yellow fever at Panama. The work of Darling, Bass and others in southern United States and in the islands must also be mentioned. The method of mosquito reduction against malaria, first suggested and tried under Ross in Freetown, Sierra Leone, in 1899, has not been followed as widely as anticipated, and local authorities too often dislike spending money on sanitation and hamper practical efforts of sanitarians by the attitude that it is better to prevent malaria by quinine or by the use of mosquito-nets, measures impractical in an uneducated native community. Local conditions must always determine the most suitable mode of prophylaxis, and it is important, as É. Sergent points out, to have several methods of control which may well be combined and include with specific measures an educational propaganda. Obviously there must be action to eliminate infection from all carriers of the parasite; in other words, to prevent the mosquito becoming infected, to destroy the species of Anopheles in which the parasite may develop, and to prevent their biting and inoculating the parasite into the blood of man. Good results have attended well-applied efforts of this kind. Better health results and there are real economic returns for expenditure. The native must be looked after and enjoined to adopt some sanitary methods until he is taught to share in systematized efforts to protect and cure himself of malaria as of other endemic diseases.

Measures to rid carriers of the parasite are most difficult to put into practice. There is no settled or fixed dosage, or time of administration, of the specific remedy, quinine or other of the cinchona bark extracts. Acute attacks respond readily to quinine; each dose makes a reduction in the number of parasites, and this reduction occurs every day, until finally none of the parasites is left. Treatment must be continued for a long time. Empirically three months appear to be enough, but there are obstinate cases.

Standard Treatment.—For some years a standard line of treatment to procure disinfestation has been adopted by Bass in America and by Ronald Ross and his colleagues in Great Britain, and the former has been recently introduced by J. Thomson in Rhodesia. The two former vary slightly. Ross gives 30 grains of quinine daily during the attack and for three days after, followed by ten grains daily, just before or after breakfast, for three months; Bass ceases after two months. Success has attended these standard treatments, and it is well for administrative purposes that a standard be adopted in each country. It will not cure all cases, but the exceptions appear rare and when detected can be specially treated. Stevens found arsenic, after initial doses of quinine, of great value in helping to eradicate the parasite. Together with quinine or other drug therapy, the important factor of building up and maintaining the general health, so as to assist the natural forces of the body to eliminate the malarial parasite, must not be forgotten.

Regarding the value of quinine prophylaxis amongst carriers, the results obtained at the malaria centres and camps during the war showed that any dosage under a total of 60 grains weekly proved insufficient for an adult male. Other salts of quinine, of hydrochloride and bihydrochloride, affect the digestion less and seem to be as satisfactory. The tannate has been much used in Italy, especially for prophylaxis among children. The daily small dose is more easily, and therefore more certainly, taken by patients (out of hospital) than larger occasional doses which cause some dyspepsia and headache and are therefore frequently postponed. Children can be given a larger proportion by body-weight than adults, say, twice as much. Ross has always felt that, to be effective, quinine should be continued in ten-grain doses daily for three months after a subject has left a malarial country.

Quinine prophylaxis has been of value on particular occasions, such as in tiding a body of troops over a critical period of fighting or passing through a heavily infected area, in that it has kept off attacks of malaria during that time. Bodies of troops in Salonika who were given quinine daily remained free as long as they were taking it, but went down with malaria as soon as they stopped it, showing they were infected in spite of it.

Not all people bear quinine continued over a long period well, and they may show symptoms of quininism. Occasionally an individual is hypersensitive to quinine and may show symptoms even following an initial dose. On the first appearance of quininism the drug should be stopped for a time, or arsenical treatment substituted. In the hypersensitive case some begin with very small doses to desensitise the patient. Certain investigators in the Tropics consider that it is more difficult to eliminate the parasite by quinine therapy in cases that have been taking quinine consistently and have become infected in spite of it. The cost of quinine and of its supervised administration has frequently rendered quinine prophylaxis impracticable in certain endemic areas.

Quinine prophylaxis should be supported by measures to prevent mosquito bites as far as practicable. In endemic areas and where there are many carriers the infection rate of the mosquito may be very high and frequent reinfection may occur.

The second measure of prophylaxis, *i.e.,* the reduction of anopheline mosquitoes and the prevention of bites, has received more general application. This is difficult and costly, but it results in a lessened sickness and death-rate from malaria, and in profit from the expenditure incurred.

In subtropical regions or where mosquitoes hibernate in dark places in rooms of homes, cellars, stables, outhouses and such places, often attaching themselves to cobwebs, they should systematically be killed directly or by fumigation. The breeding place of the mosquitoes is any still water on which they lay their eggs, and to kill the larvae and pupal forms through which they pass in development is the object in view. Much can be done by the filling in of small pools, cattle foot-marks, draining of marshes, clearing out of long grass and reeds from the sides of streams, the conversion of still to running water when in large masses, the clearing away of all cans and unnecessary water containers and the covering by gauze of cisterns and tanks and the like around the homes. A female mosquito lays about 250 eggs at one time and seven to ten days bring them to maturity. The young aquatic forms may be destroyed by larvicides such as kerosene, waste oil, cresol or "paris green," which, when mixed with 100 parts of dust (1 c.c. of the mixture to 10sq. metres of water) and blown on to the water, distributed by the winds or dropped from aeroplanes, kills the anopheline larva forms and does not injure the fish or the animals that drink therefrom. Valuable agents against larvae and pupae are the surface-feeding minnows, gambusia, stickleback and perch.

Anopheline mosquitoes do not attack until sunset, when one may remain as far as possible indoors in houses, bungalows and huts protected by close-mesh wire or netted windows and double doors; a bed or head net should cover any exposed part of the body during sleep. In the early evening the wearing of puttees by men and a paper lining under the stockings of women prevents bites on the legs. Coolie lines should be placed, when possible, a mile from the breeding places of Anopheles, though this does not mean that the mosquitoes cannot fly much farther. There is little danger to be anticipated from breeding places over a mile distant, if the mosquitoes have opportunities of feeding close at hand (*i.e.,* from other mammals), and if the intervening space be raised, wind-swept and clear of all shrubs and trees. The knowledge that the mosquito will attack man or animal in its thirst for blood has raised certain questions regarding the preservation of game, but up to the present no practical studies on any extensive scale have been made.

Use in Psychiatry.—Following the observation of W. Jauregg in Vienna in 1917, that certain chronic conditions showed improvement after malarial attacks, the therapeutic use of malaria in psychiatry has been extensively applied in many countries. Many cases of general paralysis have benefited, some sufficiently to be able to return to family and social life. Time must be given to determine the permanency or otherwise of the amelioration. Its use in other cases of cerebrospinal syphilis and also in such mental diseases as *dementia praecox,* confusional insanity and *encephalitis lethargica* is under consideration. The parasite used is *P. vivax* and it appears more satisfactory to inoculate the patient by an experimentally infected mosquito than by infection with blood from a case of malaria. Thereby all risks of other infection are avoided, a wise precaution, especially in an endemic region where other species of the parasite occur. Infected cases are allowed to have six to ten febrile attacks of malaria and are then given quinine which in these experimental cases readily cures the attacks.

War Malaria.—The following were the British War Office figures of the number of cases admitted to hospital in four of the fighting areas during the war: Mesopotamia, 1916, 680; 1917, 744; 1918, 10,202. Salonika, 1916, 31,059; 1917, 71,413; 1918, 59,087. East Africa, 1917, 58,236; 1918, 20,015. Egypt, 1916, 1,423, 1917, 8,480; 1918, 30,241.

Until the war spread to the Eastern fronts British armies suffered little from tropical diseases. In the summer of 1916 an epidemic of malaria occurred among the troops on the Salonika front, and continued until the end of the war.

Following the outbreak of malaria at Salonika, Sir Alfred Keogh, the director-general, Army Medical Services, early in 1917 appointed a special malaria hospital in each command in the United Kingdom, for the express purpose of finding a permanent cure if possible, and of treating the thousands of men who were being returned home sick with malaria from the Eastern fronts, Sir Ronald Ross being also appointed consultant in malaria at the War Office. The fact that moderate doses of quinine will control actual attacks within a few days was fully verified, with very few exceptions. Almost every form of treatment that had ever been suggested—enormous doses of quinine reaching 100 grains *per diem,* smaller doses continued for three weeks or more, additional medication with arsenic and other drugs, continuous doses lasting for a month, and various kinds of interrupted dosage—all proved uncertain. Thirty gains of quinine, continued every day for three weeks, proved a failure. Intramuscular injections and even intravenous injections did no better. Men who were presumed to be cured relapsed again after returning to duty; a large proportion of those infected with malaria became almost useless for further service. Numerous nostrums advocated for malaria proved valueless, the only exceptions being one or two arsenical preparations, which, however, were *no better* than ordinary quinine.

In all these attempts, treatment had seldom been continued for more than one month and rarely or never for more than two months—owing, of course, to military exigencies. It was decided to deal with the large numbers of discharged soldiers by a longer period of treatment. In 1918 two whole divisions, full of malaria, had been brought from Salonika to France and were there subjected to a longer course of treatment preparatory to their being sent again into the firing-line. The regiments arrived in an extremely bad condition, were all placed in camps in the Dieppe region, and the men were given 15 grains of quinine in solution once daily for a fortnight, followed by ten grains of quinine in solution daily for two and one-half months more. The course, designed and carried out by Col. J. Dalrymple, had marvellous results, almost the whole of the two divisions being found fit for the front at the end of three months. About the same time large malaria concentration-camps were established in England, where cases were given similar treatment, but for shorter periods; and it was found generally that (1) doses of less than ten grains daily did not suffice to prevent relapses even while they were being taken; (2) doses of ten grains daily did so suffice, except in about 6% of the cases, most of whom, however, relapsed during the first days of the treatment; (3) 15 grains a day reduced the relapses still further, but only to about 4% or 5%.

The long-continued treatment of malaria was now proved to be satisfactory, and was extended to pensioners also. In one London clinic alone nearly 30,000 pensioners have been treated in this way. The results have been admirable, and probably few who have taken the treatment properly have returned. But the ten grains of quinine must be taken religiously every day, and it is well to associate this with or follow it by a course of arsenic. Quinidine replaced the quinine in a small number of these cases. Empirically, three months appear to be enough, but in obstinate cases four months might be better. Even long courses of treatment will not necessarily cure people who are subject to reinfection during treatment; and it is even possible that they are not so effective during the first six months or the first year of infection as they are later. The results described above were obtained among returned cases in Britain.

The prevention of malaria on the battle-front was always difficult and sometime impossible. Mosquito-reduction in the face of enemy fire is impracticable; quinine prophylaxis was under such conditions disappointing; and the armies were obliged to fall back upon mosquito-nets and mosquito-proof tents and bivouac shelters, carefully designed by the British War Office. Better results were obtained at the bases of operations, especially in Palestine; and a very successful campaign of mosquito reduction was carried out by Col. J. C. Robertson at Taranto in southern Italy.

MALATYA (MALATIEH or ASPUZU), the chief town of a vilayet in Turkey, on the Samsun-Sivas-Diarbekr road, altitude 2,900 ft., situated about 10 mi. S.W. of the junction of the Tokhma Su (med. Kubakīb) with the Euphrates, near the south end of a fertile plain, and at the northern foot of the Taurus. Pop. (1940) 36,292. It was rebuilt after the earthquake of 1893, and is noted for its fruit orchards. Eskishehr or Old Malatya (*Melitene*), 5 mi. N.E. and 3 mi. from the mediaeval bridge (Kirkgeuz) over the Tokhma Su, has large gardens and many ruined mosques, baths, etc., relics of Mansur's city. The earliest site was possibly Arslan Tepe about 2 mi. south of Eskishehr where two "Hittite" stelae, representing hunting scenes, were found.

Under Titus, Melitene was the seat of the 12th legion; Trajan raised it to a city. Lying in a very fertile country at the focus of important routes, it grew in size and importance, and was the capital of Armenia Minor or Secunda. Justinian, who completed the walls commenced by Anastasius, made it the capital of Armenia Tertia; it was then a great place (Procop., *De aed.*, iii. 4). The town was burned by Chosroes after his defeat there in 577. Taken by the Saracens, retaken and destroyed by Constantine Copronymus, it was recovered to Islam, and rebuilt under Mansur (A.D. 756). It again changed hands more than once, being reckoned among the frontier towns of Syria (Iṣtakhry, pp. 55, 62). At length the Greeks recovered it in 934, and Nicephorus II., finding the district much wasted, encouraged the Jacobites to settle in it. A convent of the Virgin, and the church which bears his name, were erected by bishop Ignatius. Malatya became a great seat of the Jacobites, and was the birthplace of their famous maphrian Barhebraeus (or Abulfaragius). At the time of the first crusade, the city, being hard pressed by the Turks, was relieved by Baldwin. The city returned to the Turks in 1102 and subsequently became part of the realm of Kilij Arslan, sultan of Iconium.

MALAYALAM, a language of the Dravidian family, spoken on the west coast of southern India. It is believed to have developed out of Tamil as recently as the 9th century. It possesses a large literature, in which words borrowed from Sanskrit are conspicuous. The literary language is closely connected with Tamil. In general it differs from Tamil in the absence of personal terminations to verbs.

See Bibliography in *Linguistic Survey of India*, vol. iv. (1906).

MALAY ARCHIPELAGO, the largest group of islands in the world, lying southeast of Asia and north and northwest of Australia. It includes the Sunda Islands, the Moluccas, New Guinea and the Philippine Islands, but excludes the Andaman-Nicobar group. The equator passes through the middle of the archipelago; it successively cuts Sumatra, Borneo, Celebes and Halmahera, four of the most important islands.

	Area	Estimated population
	Sq.mi.	
Sunda Islands	646,385	61,127,108
Moluccas	30,168	543,030
New Guinea	312,329	1,312,013
Philippine Islands	115,600	16,000,303

The islands of the archipelago nearly all present bold and picturesque profiles against the horizon, and at the same time the character of the scenery varies from island to island and even from district to district. Volcanoes running southeast through Sumatra, east through Java and the southern islands to Timor, curving north through the Moluccas, and again north, from the end of Celebes through the whole line of the Philippines, follow a line roughly resembling a horseshoe narrowed toward the point. A disastrous eruption occurred in Aug. 1928 from Mt. Rokatinda, in the island of Palu Wai, north of Flores. The loftiest mountain in the archipelago would appear to be Kinabalu in Borneo (13,451 ft.). An important fact in the physical geography of the archipelago is that Java, Bali, Sumatra and Borneo, and the lesser islands between them and the Asiatic mainland, all rest on a great submerged bank, nowhere more than 100 fathoms below sea level and seldom exceeding 50 fathoms, which may be considered a continuation of the continent; while to the east the depth of the sea has been found at various places to be from 1,000 to 3,557 fathoms. As the value of this fact was particularly emphasized by Wallace, the limit of the shallow water, which is found in the narrow but deep channel between Bali and Lombok, and strikes north to the east of Borneo, has received the name of "Wallace's Line." The Philippines on the other hand, "are almost surrounded by deep sea, but are connected with Borneo by means of two narrow submarine banks" (A. R. Wallace, *Island Life*). The archipelago, in effect, is divided between two great regions, the Asiatic and the Australian, and the fact is evident in various branches of its geography—zoological, botanical, and even human. It is believed that there was a land connection between Asia and Australia in the later part of the Secondary epoch, and that the Australian continent, when separated, became divided into islands before the southeastern part of the Asiatic.

The most notable fact in the geological history of the archipelago was the discovery in Java of the fossil remains of *Pithecanthropus erectus* and *Homo Modjokertensis*. The strata in which they were found belong to the middle Pleistocene. Among the rocks of economic importance may be mentioned granite of numerous kinds, syenite, serpentine, porphyry, marble, sandstones and marls. Coal is worked in Sumatra and Borneo; china clay in Java. Diamonds are obtained in Borneo, garnets in Sumatra, Bachian and Timor, and topazes in Bachian, antimony in Borneo and the Philippines; lead in Sumatra, Borneo, Celebes and the Philippines; copper and malachite in the Philippines, Celebes, Timor, Borneo and Sumatra; nickel in Celebes and, most important of all, tin in Banka, Billiton and Singkep. Iron is pretty frequent in various forms, occurring in Celebes and particularly in southeast Borneo. Wolframite is known, and manganese is mined in Java. Chromium, manganese and gold are mined in the Philippines. Gold exists in Sumatra and other islands; silver is found in Java and Sumatra. Platinum and quicksilver are found in Borneo. Petroleum is a valuable product of Sumatra and many parts of British and Dutch Borneo. Saltpetre is found in Sumatra and Flores, and sulphur, naphtha, alum, lignite and magnetite in Sumatra, and asphalt in Buton (Celebes).

Climate, Flora, Fauna.—The most striking general fact as regards climate in the archipelago is that wherever that part of the southeast monsoon which has passed over Australia strikes, the climate is comparatively dry, and the vegetation is less luxuriant. The east end of Java has less rainfall than the west; the distribution of the rain on the north coast is quite different from that on the south, and a similar difference is observed between the east and west of Celebes. The northwest monsoon, beginning in October and lasting till March, brings the principal rainy season in the archipelago.

Most of the islands of the archipelago belong to the great equatorial forest belt. In its economical aspect the vegetation, whether natural or cultivated, is of prime interest. The list of fruits is very extensive, though few of them are widely known. These, however, include the orange, mango, mangosteen, shaddock, guava and the durian. The variety of food plants is equally notable. Not only are rice and maize, sugar and coffee, among the widely cultivated crops, but the coconut, the bread-fruit, the banana and plantain, the sugar palm, the tea plant, the sago palm, the cacao tree, the ground-nut, the yam, the cassava and others besides are of practical importance. The cultivation of sugar, rubber, kapok, palm oil and coffee owed its development mainly to the Dutch; and to them also was due the introduction of tea and cinchona (quinine). They greatly encouraged the cultivation of the coconut among the natives, and it flourishes, especially in the coast districts, in almost every island in their territory. The oil is largely employed in native cookery. Pepper, nutmegs and cloves were long the objects of the most important branch of Dutch commerce; and gutta percha, camphor, dammar, benzoin and other forest products have a place among the exports. (For details concerning flora and fauna, *see* separate articles, especially JAVA.)

Inhabitants.—The majority of the native inhabitants of the Malay archipelago belong to two races, the Malays and the Melanesians (Papuans). As regards the present racial distribution, the view accepted by many anthropologists, following A. H. Keane, is that the Negritos, still found in the Philippines, are the true aborigines of Indo-China and western Malaysia, while the Melanesians, probably their kinsmen, were the earliest occupants of eastern Malaysia and western Polynesia. At some date long anterior to history it is supposed that Indo-China was occupied first by a fair Caucasian people and later by a yellow Mongolian race. From these two have come all the peoples—other than Negrito or Papuan—found today from the Malay peninsula to the farthest islands of Polynesia. A rather recent Hindu strain is evident in Java, strongly in parts of Bali, in some districts in Sumatra, and others of the western islands. There are many Arab and Indian settlers, and slight intermarriage exists between these and the Malayans. The Chinese form, from an economical point of view, one of the most important sections of the community in many of the more civilized districts. Chinese have been established in the archipelago from a very early date: the first Dutch invaders found them settled at Jacatra; and many of them, as, for instance, the colony of Ternate, have taken so kindly to their new home that they have acquired Malay to the disuse of their native tongue.

There is a vast field for philological explorations in the archipelago. Of the great number of distinct languages known to exist, few have been studied scientifically. The most widely distributed is the Malay, which has not only been diffused by the Malays themselves throughout the coast regions of the various islands, but has also been adopted by the government of the Dutch East Indies as a *lingua fianca.* The most cultivated of the native tongues is the Javanese, and it is spoken by a greater number of people than any of the others. Among the other languages which have been reduced to writing and grammatically analyzed are the Balinese, closely connected with the Javanese, the Sasak (Lombok) and allied Sumbawanese, Sumbanese, Rottinese and Timorese languages. The commercial activity of the Buginese causes their language to be fairly widely spoken. (K.G.J.; E.E.L.; X.)

HISTORY

The Hindu and Moslem Periods.—Indians, both merchants and political refugees, arrived in the East Indies early in the Christian era. The immigration continued for seven centuries; but the number that came was never large. The new arrivals intermarried with the Indonesian aristocracy, and their descendants formed the governing class. The immigrants deeply affected government and religion, although the lower class remained purely Indonesian. The Indians exerted their greatest influence in Java and Sumatra, and from there the new culture spread to Bali and the Moluccas. Traces of Indian civilization have also been found in Borneo and Celebes. While the majority of the immigrants were Hindus, there were also some Buddhists; and the two religions co-existed without persecution. India likewise provided the models for architecture and sculpture. Chinese traders arrived in the Malay archipelago about the same time as the Indians; but the Indonesians were not influenced by their civilization.

The two most powerful kingdoms between the 5th and 9th centuries were Shrivijaya and Shailendra. The former, with its capital at Palembang in Sumatra, included part of Sumatra and the Malay peninsula, and was a commercial and naval power. The Shailendra dynasty ruled in central Java during the 8th and 9th centuries, and under it Indian art reached its highest development, *e.g.,* the Buddhist temple at Borobudur. The kingdom of Shailendra came under the control of eastern Java about A.D. 870. About 1025 the kingdom of Shrivijaya was greatly weakened by an Indian invasion, although it survived until the latter part of the 13th century. Eastern Java became the most powerful kingdom, and in the late 13th century, King Kertanagara conquered part of Sumatra and Borneo as well as Bali and several islands of the Moluccas. After a brief interlude of civil war and the ephemeral intervention of a Chinese fleet and army sent by Kublai Khan, Vijaya became king in 1294. He greatly extended Kertanagara's conquests and founded the empire of Madjapahit. Its strength rested upon sea power and control of the spice trade; and the petty kings in the islands became tributary vassals. The empire began to decline about 1389, and finally collapsed in the late 15th or early 16th century.

The decay of the Hindu empire of Madjapahit was hastened by the spread of the Moslem religion, which was brought to the East Indies by traders. In 1292 Marco Polo visited the islands, and noted that the inhabitants of the little town of Perlak on the northern tip of Sumatra had been converted to Islam. From here it spread gradually through the islands and the Malay peninsula, until Hinduism survived only in Bali. The process of conversion was still in progress when the Portuguese arrived, and their efforts to substitute Christianity for Islam had little effect. They were more successful in conquering or weakening the new Moslem kingdoms which were beginning to arise out of the ruins of Madjapahit.

The Portuguese and Spanish.—In 1511 Alphonso d'Albuquerque occupied Malacca, and in November of that year an expedition under Antonio d'Abreu was despatched to find a route to the Moluccas and Banda Islands, then famous for their cloves and nutmegs. The explorers reached Amboina and Ternate, after gaining some knowledge of Java, Madura, Sumbawa and other islands, possibly including New Guinea. In 1514 a second Portuguese fleet arrived at Ternate, which during the next five years became the centre of Portuguese enterprise in the archipelago.

Spain sought to secure the Moluccas and in Aug. 1519 an expedition commanded by Ferdinand Magellan (*q.v.*) sailed from Seville to seek a westward passage to the archipelago. After losing the commander in the Philippines and discovering Borneo, the two surviving ships reached the Moluccas late in 1520. One vessel returned to Seville by the cape route, thus completing the first voyage round the world. Reinforcements from Spain arrived in 1525 and 1528; but in 1529 a treaty was concluded between the emperor Charles V and John III of Portugal by which, in return for 350,000 gold ducats, the Spanish claim to the Moluccas was withdrawn. The boundary between the Spanish and Portuguese spheres was fixed at 17° E. of the Moluccas, but the Philippines were included within the Spanish sphere.

Though the Portuguese traders frequented the coast of Java and Sumatra and established a trading post in Sumatra, they annexed no territory in either; but farther east they founded numerous forts and factories, notably in Amboina, the Banda Islands, Celebes and Halmahera. Ternate remained the seat of the governor of the Moluccas, who was the highest official in the archipelago, though subordinate to the viceroy or governor of Portuguese India. The first attempt to enter into relations with the states of Borneo was made by D. Jorge de Menezes, who visited Brunei in 1526, and in 1528 sent an unsuccessful envoy to its rajah.

In 1536, after a period of war and anarchy caused by the tyrannical rule of Menezes, Antonio Galvão, the historian, was appointed governor of the Moluccas. He crushed the rebellion and won the affection of the natives by his just and enlightened administration, which had no parallel in the annals of Portuguese rule in the archipelago. He returned to Europe in 1540 (*see* PORTUGUESE LITERATURE), after inaugurating an active missionary movement, which was revived in 1546–1547 by Francisco de Xavier (*q.v.*). At this period the Portuguese power in the east was already beginning to wane; in the archipelago it was weakened by administrative corruption and by incessant war with native states, notably Bintang and Achin; bitter hostility was aroused by the attempts of Portuguese to establish a commercial monopoly and to convert their subjects and allies (*see* PORTUGAL: *History*).

visited the archipelago between 1527 and 1539. It is possible that they reached Australia; but their cruise had no political significance, and the Spaniards and Portuguese remained without European competitors until the appearance of Sir Francis Drake in 1579. Sir James Lancaster was active in these seas at the end of the century and visited Achin in 1602. An expedition under Sir Henry Middleton traded in the archipelago in 1604. The English were simple traders or explorers; far more formidable were the Dutch, who came to the east partly to avenge the injuries inflicted on their country by the Spaniards, partly to break the commercial monopoly of the peninsula states. As middlemen they already possessed a large interest in the spice trade, for the Portuguese, having no direct access to the principal European markets, had made a practice of sending cargo to the Netherlands for distribution by way of the Scheldt and Rhine. The Dutch now sought to monopolize not only the distribution but the production of spices—an enterprise facilitated by the co-operation of many exiled Portuguese Jews who had settled in Holland.

The first Dutch fleet sailed from Texel, under the command of Cornelius Houtman, on April 2, 1595, and reached Sumatra on Jan. 1, 1596. It visited Madura, and though not a commercial success, demonstrated the weakness of the Portuguese. In 1602 the Dutch East India company (*q.v.*) was incorporated, and for nearly two centuries this organization played the chief part in the history of the archipelago. By 1604 the Dutch could already claim to be the stronger power at sea. They had attacked the Portuguese in Ceylon (1601), established friendly relations with Achin (1602), and defeated a powerful fleet off Banda (1602). In 1606 they concluded a treaty of alliance with the sultan of Johor, and in 1608 they forced the Portuguese to assent to an armistice for 12 years. On Nov. 29, 1609, Pieter Both was chosen by the states-general, on the nomination of the Dutch East India company, as first governor-general of Netherlands India. In 1611, the headquarters of the Dutch was changed from Bantam to Jakatra, which in 1619 was renamed Batavia and was thenceforward the Dutch capital. Meanwhile the English East India company, chartered in 1600, had also extended its operations to the archipelago. After 1611 the commercial rivalry between the Dutch and British became acute, and in 1613, 1615 and 1618 commissioners met in London to discuss the matters in dispute. The result of their deliberations was the treaty of defense, signed on June 2, 1619 and modified on Jan. 24, 1620, which arranged for co-operation between the Dutch and British companies, and especially for the maintenance of a joint fleet. But neither company could restrain its agents in the east from aggressive action, and many fresh causes of dispute arose, the chief being the failure of the British to provide the naval forces required for service against the Portuguese, and the so-called massacre of Amboina (*q.v.*) in 1623. The treaty of defense lapsed in 1637. The Dutch company opened up trade with Japan and China, and prosecuted the war against Portugal with great vigour, invading Portuguese India and capturing Point de Galle in 1640, Malacca in 1641, Cochin and Cannanore in 1663.

Rebellions in Java (1629) and the Moluccas (1650) were suppressed with great severity, but in 1662 the company suffered a heavy reverse in Formosa, all its colonists being expelled from the island. A new war between Great Britain and Holland broke out in 1672 and was terminated by the treaty of Westminster (Feb. 17, 1674). Thenceforward the British company devoted its energies chiefly to the development of its Indian possessions, while the Dutch were left supreme in the archipelago.

Dutch Ascendancy, 1674–1749.—The weakness of Spain and Portugal and the withdrawal of the British left the Dutch company free to develop its vast colonial and commercial interests. In 1627 the so-called Dutch colonial system had been inaugurated by the fourth governor-general, Jan Pieterszoon Coen (*q.v.*). Under this system, which was intended to provide Netherlands India with a fixed population of European descent, Dutch girls were sent to the archipelago to be married to white settlers, and subsequently marriages between Dutchmen and captive native women were encouraged. As early as 1624 vast fortunes had been acquired by traders. The system of practical slavery enforced on the native races provoked an insurrection throughout Java, in which the Chinese settlers participated; but the Dutch maintained naval and military forces strong enough to crush all resistance, and a treaty between the company and the Susuhunan in Nov. 1749 made them practically supreme in Java.

Decline of Dutch Power, 1749–1811.—In the second half of the 18th century there was a rapid decline in the revenue from sugar, coffee and opium, while the competition of the British East India company, which now exported spices, indigo, etc., from India to Europe, was severely felt. The administration was corrupt, largely because of the vast powers given to officials, who were invariably underpaid; and the financial methods of the company precipitated its ruin, large dividends being paid out of borrowed money. The burden of defense could no longer be sustained; piracy and smuggling became so common that the company was compelled to appeal to the states-general for aid. In 1798 it was abolished and its authority vested in a Council of the Asiatic Possessions. In 1803 a commission met to consider the state of the Dutch colonies, and advocated drastic administrative and commercial reforms, notably freedom of trade in all commodities except firearms, opium, rice and wood—with coffee, pepper and spices, which were state monopolies. Some of these reforms were carried out by H. W. Daendels (1808–1811), who was sent out as governor-general by Louis Bonaparte, after the French conquest of Holland. In 1811 Daendels was recalled and J. W. Janssens became governor-general.

British Occupation, 1811–1816.—Netherlands India was at this time regarded as a part of the Napoleonic empire, with which Great Britain was at war. A British naval squadron arrived in Moluccas in February 1810 and captured Amboina, Banda, Ternate and other islands. In 1811 a strong fleet equipped by Lord Minto, then governor-general of India, captured Java. Raffles (*q.v.*) was appointed lieutenant-governor and he introduced many important changes in the departments of revenue, commerce and judicature. He was succeeded by John Fendal, who in 1816 carried out the retrocession of Netherlands India to the Dutch, in accordance with the treaty of Vienna (1814).

Restoration and Reform of Dutch Power, 1816–1910.—The whole history of the archipelago was changed by Raffles' occupation of Singapore in 1819, as a means of preventing the Dutch from acquiring a monopoly of trade throughout Malaya and with China. Questions at issue between Great Britain and the Netherlands were settled by treaty in 1824. The Dutch were given almost entire freedom of action in Sumatra, while the Malay peninsula was recognized as within the British sphere of influence.

The reform movement inaugurated by the commission of 1803 was resumed in 1830, when Johannes van den Bosch was appointed governor-general (*see* JAVA). The reform movement was aided by the publication in 1860 of *Max Havelaar,* a romance by E. Douwes Dekker (*q.v.*), which contained a scathing indictment of the colonial system.

The extension of Dutch political power—notably in Java, Sumatra, Celebes, the Moluccas, Borneo, the Lesser Sunda Islands and New Guinea—proceeded simultaneously with the reform movement, and from time to time involved war with various native states. A large expedition was sent to Lombok in 1894, and almost the whole of that island was incorporated in the Dutch dominions. A 30-years' war with Achin (*see* SUMATRA) began in 1873.

While the Dutch were consolidating their authority, other countries were acquiring new commercial or colonial interests in the archipelago. Immigration from China and Japan steadily increased, especially toward the end of the period 1816–1910. The enterprise of Sir James Brooke (*q.v.*) led, after 1838, to the establishment of British sovereignty in northwest Borneo; in 1895 New Guinea was divided between Great Britain, Germany and the Netherlands; the Spanish-American War of 1898 resulted in the cession of the Philippines, Sulu Island and the largest of the Mariana Islands to the United States, and the sale of the Caroline group to Germany. Australian and Japanese trade in the archipelago was stimulated by the establishment of the Australian commonwealth (1901) and the Russo-Japanese War (1904–05).

The effect of World War I was to deprive Germany of the Caroline Islands and the northern part of New Guinea, which is now administered under mandate by the Commonwealth of Australia. The division of Timor (the Portuguese portion of which was formerly joined up with Macao for administrative purposes but is now independent of that island) between Portugal and Holland was reminiscent of the struggles of past centuries. The Dutch Portuguese treaty of 1859, modified by the convention of 1908, settled all outstanding questions.

Apart from the Philippines, the Malay archipelago was before World War II almost wholly in the hands of the British and the Dutch. (*See* also EAST INDIES.)

BIBLIOGRAPHY.—For the period 1511–95, the chief Portuguese authorities are the chronicles of Barros, Corrêa, Castanheda and Couto (*see* PORTUGAL, *History*), with the letters of Xavier (*q.v.*) and the *Tratado* of A. Galvão (Lisbon 1563 and 1731), of which a translation entitled *Discoveries of the World* was made for Richard Hakluyt and reprinted by the Hakluyt society (1862). *See* also M. F. de Navarette, *Colección de los viages* (vols. 4 and 5, Madrid 1837). For later history *see* John Crawfurd *Descriptive Dictionary of the Indian Islands* (Edinburgh, 1820), and *Twentieth Century Impressions of Netherlands India* (ed. A. Wright, 1910) which gives references to the principal English and Dutch authorities. A. Cabaton, *Les Indes Neerlandaises.* Further bibliography will be found in J. A. Van der Chijs, *Proeve eener nederlandsch-indische Bibliografie, 1659–1870* (Batavia, 1875).

MALAY LANGUAGE. Having been the common medium of intercourse in the Malay archipelago for more than four centuries past, Malay is for practical purposes the most important of the Indonesian languages. But it is not the most typical one, for its morphological system has been much simplified, making it serve as an easy *lingua franca*.

We must distinguish between (1) the Malay of the Malays themselves, including (*a*) the language of literature, which is fairly uniform everywhere, having undergone but little change since the 16th century, and the more modernized styles of journalism and letter writing; (*b*) the speech of educated Malays, based on the common colloquial of the south of the peninsula, the islands of the Riau-Lingga groups and part of the east coast of Sumatra; a special variety of it, the court language, only differing by adding a few terms exclusively appropriate to princely personages; (*c*) the local peasant dialects, which in the north of the peninsula differ very much, especially in pronunciation, from (*b*) and (2) the various versions of Malay, often mere jargons, spoken by all sorts of foreigners. In this last class fall the Malay of the Straits-born Chinese and the Malay current in Java, adopted by the Dutch throughout their eastern possessions.

Scripts.—Since the 14th century Malay has been written in the Arabic alphabet augmented by five letters. Thus written, it is sometimes styled Jawi, an Arabic term derived from "Java the Less," an old name for Sumatra. The oldest surviving Malay manuscripts date from about A.D. 1600. Till the 14th century the language was written in Sumatra in an alphabet of south Indian origin; but old inscriptions are rare and full of Sanskrit words. In some parts of southern Sumatra Malay is still written in a modernized form of this script. The Arabic character, being deficient in vowel symbols and sparing in their use, is ill adapted to Malay, which has many unrelated words differentiated only by vowels. The Dutch and British have transcribed it into the Roman alphabet, the Dutch with Dutch values, the British on the Hunterian system, with (roughly) Italian values for the vowels and English ones for the consonants.

Sounds and Words.—Neglecting the specially Semitic sounds found in Arabic loanwords and often assimilated in speech to the nearest Malay sound, the English Romanized Malay has the following vowels *a, e, i, o, u,* and a neutral vowel written *ĕ;* diphthongs, *ai, au,* consonants, *k, g, ng, ch, j, ny, t, d, n, p, b, m, y, r, l, w, s, h.* The glottal stop is symbolized at the end of a word after a vowel by *k* when the Arabic script has *kof* or *kaf,* by an apostrophe when it has *hamzah.* In some parts of the Malay region (*e.g.* Borneo) final *k* is still a *k.* Normally, vowels in closed syllables are short, in open ones short or long (except *ĕ,* which is always short and often suppressed entirely). Two consonants cannot begin or end a word.

Words are simple, compound or derivative. Simple words, which are mostly of two syllables, are the shortest forms occurring in actual use, compound ones are made by reduplication (complete, partial or with variation of one or more sounds) or by junction, of simple words; derivatives by adding to a simple or compound word one or more syllables, incapable of separate existence, which are prefixed, suffixed or infixed after the initial consonant. Syllabic stress, which is weak, is normally on the penultimate, unless this contains the neutral vowel followed by one consonant only, in which case the stress is on the final.

Morphology.—The infixes, *ĕm, ĕr, ĕl,* are mere survivals. The prefixes and suffixes are living formative factors. The chief prefixes are: *mĕng* (with variants *mĕny, mĕn, mĕm, mĕ,* according to the initial of the simple word), prefixed in certain syntactical relations and forming verbs of action, mostly transitive, *pĕng* (with similar changes), nouns denoting agent or instrument, *bĕr,* verbs middle and reflexive, denoting action of the subject on or for itself (or, with a plural subject, reciprocal), intransitive action, state and, in particular, use, production or possession, and adjectives of similar import; *tĕr,* the accomplished event and, in negative or interrogative phrases, possibility, *di,* the passive. The suffixes *i* and *kan* make transitive, *kan* also causative, verbs; *an,* nouns, both by itself and when accompanied by one of the prefixes *pĕng, pĕr,* and *kĕ;* the last combination is also a passive. Number, gender, case, person, tense, mood and degrees of comparison can be indicated by the addition of separate words; but the language is terse and prefers an impersonal form of expression and tolerates indeterminateness. Reduplication is often used to express indefinite variety, plurality, degree of quality, frequency and reciprocity.

Syntax.—The leading idea comes first and anything in intimate relation to and qualifying it comes next. Thus the genitive, attributive adjective and demonstrative follow the substantive. There is no copula, and in simple sentences either predicate or subject may come first. Where subject, verb and object appear, they occur normally in that order; but an emphatic object can precede the subject. With a passive verb the order subject, verb, agent, can be varied if the agent is the enclitic third personal pronoun *nya,* or if a preposition is used before the subject, agent or both. In speech, sentences are usually shorter than in the written language.

Numerals.—The elements of the system are the integers 1 to 9 (of which 1 has two forms, *satu,* the normal, and *sa,* proclitic before certain words), *puloh,* which by prefixing *sa* and the other integers to it forms 10 and its multiples to 90, *bĕlas,* similarly forming 11 to 19, *ratus,* hundreds, *ribu,* thousands and likewise three words of Sanskrit origin for 10,000, 100,000 and 1,000,000. In enumerating concrete units it is usual to add to the numeral an auxiliary word (like "head" in "three head of cattle," for which Malay substitutes "tail").

Vocabulary.—The language is rich in specific expressions for minutely differentiated kinds of objects and actions (*e.g.,* various modes of carrying, striking, etc.). The vocabulary is very mixed, but native Malay words largely preponderate. The loanwords are mostly terms denoting abstract ideas or else things of foreign origin. In the middle ages many were borrowed from Sanskrit and since the 14th century many more from Arabic. A fair number of Tamil, Persian, Hindustani, Javanese, Chinese, Portuguese, Dutch and English words have also been adopted; and the last two classes (like the Arabic) are still growing. The influx of Dutch (and also Javanese) words into the Malay of the Dutch possessions is widening the gap between it and the language of British Malaya. (C. O. B.)

Literature.—Their most characteristic literature is to be found, not in their writings, but in the folk-tales which are transmitted orally from generation to generation and repeated by the wandering minstrels called by the people *Pĕng-līpor Lāra, i.e.* "Soothers of Care." Some specimens of these are to be found in the *Journal of the Straits Branch of the Asiatic Society* (Singapore). The collections of *Malay Proverbs* made by Klinkert, Maxwell and Clifford also give a good idea of the literary methods of the Malays. Their verse is of a very primitive description. There are rhymed fairy tales. The best Malay books are the *Hikāyat Hang Tūak, Bĕstāmam* and the *Hikāyat Abdullah.* The latter is a diary of events kept during Sir Stamford Raffles' administration by his Malay scribe.

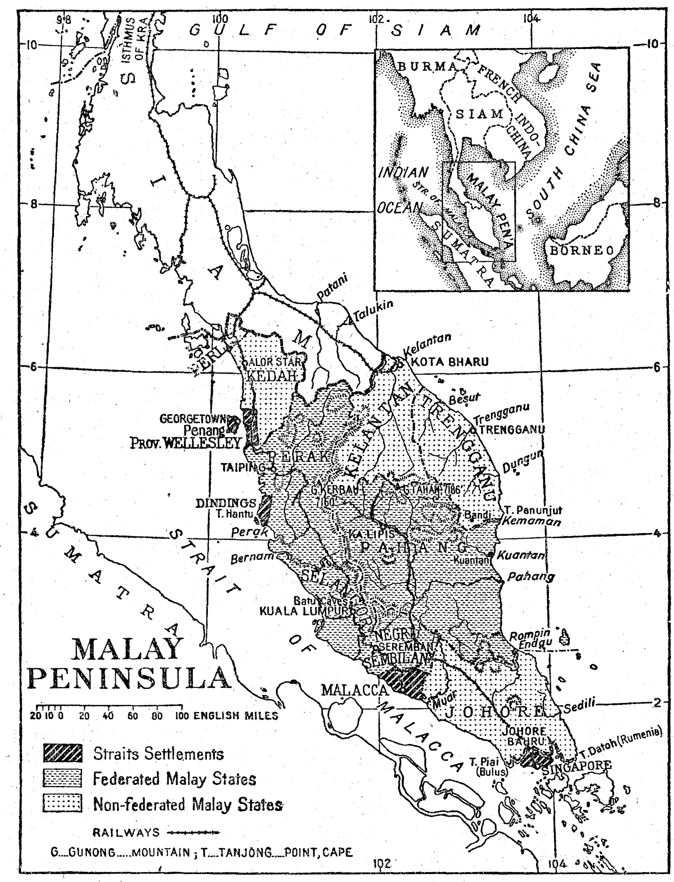
MALAY PENINSULA (called by Malays *Tanah Malayu, i.e.,* Malay Land), projects into the China sea, and forms the most southerly portion of the continent of Asia. Geographically, it begins at the isthmus of Kra, 10° N., at which point it is only between 60 and 70 m. wide, and the distance from sea to sea is further diminished by a large irregular salt-water inlet. Politically and anthropologically, this upper portion must be regarded as a



continuation of Thailand rather than a section of Malaya. From the isthmus of Kra the peninsula extends south with a general inclination towards the east, the most southerly point being Tanjong Bulus in 1° 16½′ N. A line drawn diagonally down the centre from the isthmus of Kra to Cape Rumenia (E. of Singapore) gives the length at about 750 miles. The breadth at the widest point, from Tanjong Penunjut in Trengganu to Tanjong Hantu in the Dindings, is about 200 miles. Area under British influence was about 52,500 sq.mi. The peninsula is bounded on the north by Thailand, on the south by the island and strait of Singapore, on the east by the China sea, and on the west by the Strait of Malacca.

Physical Characteristics.—A range of granite mountains forms a backbone which divides the peninsula into two unequal portions, the larger of which lies to the east and the smaller to the west. Smaller ranges run parallel to the main chain in many places, and there are numerous isolated spurs. A characteristic feature is limestone bluffs that stand up in the plains both on the eastern and the western slopes. The descent from the summits of the range into the plain is somewhat less abrupt on the west than it is on the east, and between the foot of the mountains and the Strait of Malacca the largest alluvial deposits of tin are situated. On the eastern side of the range, after a steep descent, the granite formation gives place to a broad quartzite outcrop, to the east of which there is evidence of tin-bearing granite intrusions. The highest known peak in the main range is Gunong Kerbau (7,160 ft.). The highest mountain is Gunong Tahan (7,186 ft.), which forms part of a quartzite range on the eastern side, between Pahang and Kelantan. The west coast is covered to a depth of some miles with mangrove swamps, with only a few isolated stretches of sandy beach. On the east coast the force of the north-east monsoon, which beats upon the shores of the China sea from November to February, has kept the land for the most part free from mangroves, and the sands, broken here and there by rocky headlands thickly wooded, and fringed by *casuarina* trees, stretch for miles. On both coasts islands are numerous. The peninsula may be described as one vast forest, intersected by countless streams and rivers which form the most lavish water-system in the world; 72% of Malaya is still forest. Only a fraction of these forests has been visited by human beings, the Malays and even some of the aboriginal tribes having their homes on the banks of the rivers, and never, until the first modern road-system was started, leaving the banks of a stream except for a short time when passing from one river-system to another.

The principal rivers on the west are the Perak, the Bernam and the Muar. The first is far finer than its fellows, and is navigable for steamers for about 40 m. from its mouth, and for native craft for over 250 miles. It is shallow and not of much importance as a waterway. The Bernam runs through swampy country for the greater part of its course, and steam-launches can penetrate over 100 m. from its mouth; it is therefore probably the deepest river. The Muar waters a fertile valley, and is navigable for native boats for over 150 miles. On the east coast the principal streams are the Patani, Talukin, Kelantan, Besut, Trengganu, Dungun, Kemaman, Kuantan, Pahang, Rompin, Endau and Sedili, all guarded by difficult bars at their mouths, and dangerous during the north-east monsoon. The deepest rivers are the Kuantan and Rompin; the largest are the Kelantan and the Pahang, both of which are navigable for native boats for over 250 miles. The Trengganu river is obstructed by impassable rapids about 30 m. from its mouth. The rivers on the east coast are still practically the only highways, the Malays travelling by boat in preference to walking, but they serve their purpose indifferently, and beauty is their chief claim to distinction. Magnificent limestone caves are found on both slopes of the peninsula, those at Batu in Selangor being the finest on the west coast, while those of Chadu and Kota Glanggi in Pahang are the most extensive on the east. So far as is known, the Malay peninsula consists of an axial zone of crystalline rocks, flanked on each side by an incomplete band of sedimentary deposits. Granite is the most widely spread of the crystalline rocks; but dykes of various kinds occur, and gneiss, schist and marble are met. These rocks form the greater part of the central range, and they are often—especially the granite—decomposed and rotten to a considerable depth The sedimentary deposits include slate, limestone and sandstone. Coal is mined at Rawang in Selangor. The limestone has yielded *Proetus, Chonetes* and other fossils, and is believed to be of Carboniferous age. In the sandstone Myophoria and other Triassic fossils have been found, and it appears to belong to the Rhaetic or Upper Trias. The minerals produced are tin, gold, iron, galena and others, in insignificant quantities

Tin occurs in the form of cassiterite, and is found always close to granite. In limestone it occurs in pipes and veins. Particularly in clays over the limestone very rich deposits are found. The most important lode-mines in the peninsula are at Sungai Lembing near Kuantan: they are among the world's greatest deep tin-mines. The Malay states produce 30% of the world's output of tin. Gold is worked in Pahang, and has been exploited from time immemorial by the natives of that State and of Kelantan. Small quantities have been found in Perak.

It was formerly the custom to speak of the Malay peninsula as unhealthy, and even to compare it with the west coast of Africa. It is now generally admitted that, though hot, it compares favourably with Burma. The chief complaint which Europeans make is of the extreme humidity, which causes the heat to be more oppressive than where the air is dry. The thermometer, even at Singapore on the southern coast, which is the hottest portion of the peninsula, seldom rises above 93° in the shade, while the mean for the year at that place is generally below 80°. On the mainland, and especially on the eastern slope, the temperature is cooler, the thermometer falling at night below 70°. On an average day in this part of the peninsula the temperature in a European house ranges from 88° to 68°. The number of rainy days throughout the Malay peninsula varies from 160 to over 200 in each year. Violent gusts of wind, called "Sumatras," accompanied by a heavy downpour of short duration are common between the monsoons.

The rainfall on the west coast varies from 64 to 115 in. per annum, and that of the east coast, where the northeast monsoon breaks with all its fury, is usually about 122 inches. The development of health stations at Fraser Hill and Cameron Highlands did much to improve the health of Europeans. In parts of the country malaria is rife, but much has been done to combat the conditions that produce the malaria-carrying mosquito. The Malays formerly suffered severely from smallpox epidemics, but under British rule vaccination was introduced, and the ravages of the disease no longer assume serious dimensions. Occasional small outbreaks of cholera occur in a few localities. After 1925 Singapore was the health hub of the far east, when it became the centre of the Far Eastern Health bureau of the League of Nations. As a whole, the Malays are a remarkably healthy people, and deformity and hereditary diseases are rare. There is little leprosy, but there is a leper hospital near Penang on Pulau Jerjak and another at Pangkor for lepers from the Federated Malay States.

Flora and Fauna.—The soil of the peninsula is fertile. In the vast forests the decay of vegetable matter during countless ages has enriched the soil to the depth of many feet, and from it springs the most marvellous tangle of huge trees, shrubs, bushes, underwood, creepers, climbing plants and trailing vines, the whole hung with ferns, mosses and parasitic growths, and bound together by rattans and huge rope-like trailers. In most places the jungle is so dense that it is impossible to force a way through it without a woodknife, and even the wild beasts use well-worn game tracks through the forest. In the interior brakes of bamboos are found, many of which spread for miles along the river banks. Some good hardwood timber is found, the best being *merbau, rĕsak* and *chĕngal*. Orchids abound. The principal fruit trees are the *durian,* mangosteen, custard apple, pomegranate, *rambutan, pulasan, langsat, rambai,* jack fruit, coconut, areca-nut, sugar palm, and banana. Coffee, sugar cane, rice, pepper, gambier, cotton and sago are grown with success. Rubber is the most important form of cultivation. The principal jungle products are gutta and rubber of several varieties, and many kinds of rattan. The mangrove grows on the west coast in profusion. Agilawood, the camphor tree and ebony are found in small quantities.

The fauna of the peninsula is varied and no less profuse than the vegetable life. The Asiatic elephant; the *seladang,* a bison of a larger type than the Indian gaur; two varieties of rhinoceros; the honey bear (*bruang*), the tapir, the sambhur (*rusa*); the speckled deer (*kijang*), two species of mouse deer (*napoh plandok* or *kanchil*); the gibbon (*ungka* or *wawa'*), the *siamang,* another species of anthropoid ape, the crab-eating macaque (*kra*), the *brok* or coconut monkey, so called because it is trained by the Malays to gather nuts from the coconut trees, and four species of leaf monkey (*lotong*); the bear cat (*arctictis binturong*), the lemur; the Asiatic tiger, the black panther, the leopard, the clouded leopard, several varieties of jungle cat; the wild boar, the wild dog; the flying squirrel, the flying fox; the python, the cobra, and many other varieties of snake, including the hamadryad; the crocodile, the otter and the gavial, as well as many kinds of squirrel, rat, etc., are found throughout the jungles. On the east coast peafowl are found. The argus pheasant, the fire-backed pheasant, the blue partridge, the adjutant bird, several kinds of heron and crane, snipe, wood pigeon, green pigeon, swifts, swallows, pied robins, hornbills, parakeets, flycatchers, nightjars, and many other kinds of bird are met with frequently. Members of the duck tribe are rare: only the tree duck and cotton teal are likely to be met. The forests swarm with insects, from *cicadae* to beautiful butterflies, and from stick and leaf insects to endless varieties of ants. The scorpion and the centipede are common. The profusion and variety of insects probably surpass those to be met with anywhere else in the world.

Political Divisions and Population.—The Malay Peninsula in 1941 was divided into three sections: the colony of the Straits Settlements, and the Federated and Unfederated Malay States. The colony of the Straits Settlements consisted of the islands of Singapore and Penang, the territory of Province Wellesley on the mainland opposite to Penang, and the town and territory of Malacca. The Federated Malay States under British protection consisted of the sultanates of Perak, Selangor and the Negri Sembilan on the west coast, and the sultanate of Pahang on the east coast. The Unfederated States under British protection: Johore, Kelantan, Trengganu, Kedah and Perlis. The population of the peninsula numbers about 5,504,000, of whom 1,420,841 inhabit the colony of the Straits Settlements, 2,193,605 the Federated Malay States and 1,889,648 the Unfederated States.

The population of the peninsula includes 2,358,335 Chinese, mostly immigrants or descendants of immigrants from the southern provinces of China, of whom 915,384 reside in the colony of the Straits Settlements, 978,208 in the Federated, and the remainder in the Unfederated Malay States. The Malay population of the peninsula, including immigrants from the eastern archipelago, number 2,286,459, while Tamils and other natives of India number about 748,829, the aboriginal natives of the peninsula about 33,000, Europeans and Americans 31,197 and Eurasians 19,204.

Excluding the Thai, or Siamese, who are recent arrivals from the north, there are three races which for an extended period of time have had their home in the Malay peninsula. These are the Semang or Pangan, the Sakai and the proto- and civilized Malays. The Semang, as they are most usually called by the Malays, are Negritos—a small, very dark people, with features of the negroid type, prognathous, and with short, woolly hair clinging to the scalp in tiny crisp curls. These people belong to the race which would seem to be the aboriginal stock of southern Asia. They appear to be related to the Aetas of the Philippines and the Andamanese. (*See* ANDAMANESE and NEGRITOS.) The state of civilization to which they have attained is very low. They neither plant nor have they any manufactures except their rude bamboo and rattan vessels, the fish and game traps which they set with much skill, and the bows, blowpipes and bamboo spears with which they are armed. They are skilful hunters, catch fish by ingeniously constructed traps, and live almost entirely on jungle-roots and the produce of their hunting and fishing. The most civilized element of these people is found in Upper Perak, and the members of this clan have some knowledge of the art of planting. To include the Sakai in the category of Malayan races is also incorrect. The Sakai still inhabit in greatest numbers the country which forms the interior of Pahang, the Plus and Kinta districts of Perak, and the valley of Nenggiri in Kelantan. Representatives of their race are scattered among Malay villages throughout the country, and also along the coast, but these have mixed with Malays, and acquired so many customs, etc., from their more civilized neighbours, that they can no longer be regarded as typical of the race to which they belong. The pure Sakai in the interior have a good knowledge of planting rice, tapioca, etc., fashion vessels from bamboos, which they decorate with patterns traced by the aid of fire, make loincloths (their only garment) from the bark of the *trap* and *ipoh* trees; are musical, using a rude lute of bamboo, and a nose-flute, and singing in chorus melodiously; and altogether have attained to a higher degree of civilization than have the Semang. They are about as tall as the average Malay, are slimly built, light of colour, and have wavy fine hair. In their own language they usually have only three numerals, viz., *na-nun,* one; *nar,* two; and *ne',* three, or variants of these; all higher arithmetical ideas being expressed by the word *kerpn,* which means "many." A few cases have been recorded, however, of tribes who can count in their own tongue up to four and five. Among the more civilized, the Malay numerals up to ten are adopted. An examination of their language seems to indicate that it belongs to the Mon-Khmer group of languages, and anthropological information points to the conclusion that they may be related to the Veddas of Ceylon. Though they now use metal tools imported by the Malays, the names they give to those weapons which most closely resemble the stone implements found all over the peninsula are native names wholly unconnected with their Malay equivalents. It has been suggested that in a forgotten past the Sakai were the fashioners or importers of the stone implements. The presence of the Sakai in the interior of the peninsula has been considered as one of many proofs that the Malays intruded from the south and approached the peninsula by means of a sea route, since had they swept down from the north, driven thence by the people of a stronger breed, it might be expected that the fringe of country dividing the two contending races would be inhabited by men of the more feeble stock. Instead, we find the Sakai occupying this position. It is remarkable that the Negritos never pierced the Sakai belt: though more primitive, they may have come to Malaya later, thus indicating that they have been driven northward by the Malays (*q.v.*).

Archaeology.—Stone celts of various types have been unearthed in caves, mines and rice fields, throughout the Federated Malay States. Cord-marked and other pottery occurs in the upper layers of palaeo-protoneolithic culture and with late neoliths. In Batang Padang, Perak, have been found graves, built of large granite slabs; cists, closely related to the dolmen. Rough pottery, iron tools with small sockets for handles, cornelian beads, cross-hatched stone-pounders, and bronze implements of various types reveal the culture of the people who built these graves. At Kenaboi, in Negri Sembilan, stone quoits, stone bark-pounders and tiny socketed bronze celts were found associated. These may be relics of the Mon-Khmers. It may have been they, who at Selinsing, Pahang, and elsewhere sunk circular pits (termed "Siamese mines" by the Malays) as deep as 120 ft. and sometimes no more than 2 ft. apart and connected at the base by galleries.

In Province Wellesley and Kedah Buddhist remains with the script of southern India *c.* A.D. 400 have been found. Clay tablets in the Nagari script of North India of the 10th or perhaps 7th century A.D. were dug up in a Kedah cave. A granite statue of Devi, the wife of Shiva, and other Hindu remains were also discovered recently in Kedah. In Malacca, a stone *Makara* (or fabulous sea-animal) of a type found in Java, may be a relic of Hindu days or a later import. A stone with a 14th century Javanese inscription existed formerly at Singapore.

The most interesting Muslim relic is a stele from Trengganu, now in Raffles' museum, Singapore, erected by a Sri Paduka Tuan, bearing the oldest (14th century A.D.) Malay text in Arabic script known, and exhorting rulers, styled Mandalika, to uphold Islam. At Pengkalan Kempas, in Negri Sembilan, there are a Muslim tombstone of the 15th century and carved monoliths, one of which is of Sumatran type, resembling the gravestone of prince Aditiawarman at Kubor Raja (A.D. 1378). In Malacca are some Muslim, Portuguese and Dutch remains.

History.—As early as the 9th century A.D. Ibn Khordadzbeh and other Arab writers speak of the great Buddhist Palembang kingdom, Soi Vijaya, and references have perhaps been identified in their works to Kedah and Singapore. Lately in Trengganu a stone has been discovered showing that Islam reached the peninsula in the 14th century. Islam destroyed the Hindu and Buddhist kingdoms of Java and Sumatra. In 1292 Marco Polo found it in the little Sumatran port of Perlak. Ibn Batuta also visited Sumatra. Until the rise of Malacca the more frequent ports of call in the Straits of Malacca were in Sumatra.

The importance of the Malay peninsula consisted in its fitness to be the distributing centre of the spices brought from the Moluccas *en route* for India and Europe. As early as the 3rd century B.C. Megasthenes mentions spices brought to the Ganges from "the southern parts of India," and the trade was probably one of the most ancient in the world. So long as India held the monopoly of the clove, the Malay peninsula was ignored, the Hindus spreading their influence through the archipelago and leaving traces thereof even to this day. Mohammedan traders from Coromandel and Malabar, following the routes which had been prepared for them by their forebears, broke down the Hindu monopoly and ousted the earlier exploiters so that by the beginning of the 16th century the spice trade was almost exclusively in their hands. These traders were also missionaries of their religion, as is every Muslim, and to them is due the conversion of the Malays from animism, tinctured by Hindu and Buddhist beliefs, to the Mohammedan creed. The desire to obtain the monopoly of the spice trade has been a potent force in the fashioning of Asiatic history. The Moluccas were, from the first, the objective of the Portuguese, and no sooner had they found their way round the Cape of Good Hope and established themselves successively upon the coast of East Africa, in the neighbourhood of the Gulf of Aden and the Malabar coast, than Malacca, then the chief trading centre of the Malayan archipelago, became the object of their desire.

The first Portuguese expedition sent to capture it was under Diogo Lopez de Siqueira and sailed from Portugal in 1508. At Cochin Siqueira took on board certain adherents of Alffonso d' Alboquerque who were in bad odour with his rival d'Almeida, among them being Magellan, the future circumnavigator of the world, and Francisco Serrão, the first European who ever lived in the Spice islands. Siqueira's expedition ended in failure, owing partly to the aggressive attitude of the Portuguese, partly to the justifiable suspicions of the Malays, and he was forced to destroy one of his vessels, leave a number of his men in captivity, and sail direct for Portugal. In 1510 a second expedition was sent from Portugal under Diogo Mendez de Vasconcellos, but d'Alboquerque retained it at Cochin to aid him in the retaking of Goa, and it was not until 1511 that the great viceroy could spare time to turn his attention to the scene of Siqueira's failure. After futile negotiations for the recovery of the Portuguese captives, the Portuguese made a successful assault upon Malacca.

The Portuguese were satisfied with the possession of Malacca and did not seek to extend their empire in Malaya. Instead they used every endeavour to establish friendly relations with the rulers of neighbouring kingdoms, and before d'Alboquerque returned to India he despatched embassies to China, Siam and several kingdoms of Sumatra, and sent a small fleet, with orders to assume a conciliatory attitude toward all natives, in search of the Moluccas. Very soon the spice trade had become a Portuguese monopoly, and Malacca was the headquarters of the trade. Magellan's famous expedition had for its object not the barren feat of circumnavigation but the breaking down of this monopoly, without violating the papal bull which gave to Spain the conquest of the west, to Portugal the possession of the east. In 1528 a French expedition sailed from Dieppe, penetrated as far as Achin in Sumatra, but returned without reaching the Malay peninsula. It was the first attempt made to defy the papal bull. In 1591, three years after the defeat of the Armada, Raymond and Lancaster rounded the cape, and after cruising off Penang, decided to winter in Achin. They hid among the Pulau Sembilan near the mouth of the Perak river, and captured a large Portuguese vessel which was sailing from Malacca in company with two Burmese ships. In 1595 a Dutch expedition confined its operations to Java and the neighbouring islands.

During this period Achin developed a determined enmity to the Portuguese, and more than one attempt was made to drive the strangers from Malacca. Eventually, in 1641, a joint attack was made by the Achinese and the Dutch, and the latter became the owners of the coveted port. Malacca was taken from the Dutch by the British in 1795; was restored to the latter in 1818; but in 1824 was exchanged for Benkulen and a few more unimportant places in Sumatra. The first British factory in the peninsula was established in the native state of Patani on the east coast in 1613, the place having been used by the Portuguese in the 16th century for a similar purpose; but the enterprise came to an untimely end in 1620 when Captain Jourdain, the first president, was killed in a naval engagement in Patani Roads by the Dutch. Penang was purchased from Kedah in 1786, and Singapore from Johore in 1819. The Straits Settlements—Singapore, Malacca and Penang—were ruled from India until 1867, when they were erected into a crown colony under the charge of the colonial office. In 1874 the Malay state of Perak was placed under British protection by a treaty entered into with its sultan; and this led to the inclusion in a British protectorate of the neighbouring states of Selangor, Negri Sembilan and Pahang, which later formed the Federated Malay States. In 1902 the northern Malay states of the peninsula were admitted to lie within the Siamese sphere of influence, but in 1909 Siam ceded her suzerain rights over Kelantan, Trengganu, Kedah and Perlis to Britain.

During World War II, the Japanese effected a landing in Kelantan on Dec. 8, 1941, and proceeded down both sides of the peninsula. By Jan. 31, 1942 they had completed the conquest of the peninsula, and on Feb. 15 Singapore fell after a two weeks' siege. The British were not prepared for an overland invasion of the supposedly impenetrable peninsula or an attack from the north on the naval base on which 20 years of labour and $400,000,000 had been expended.

(H. Cl.; X.)

MALAYS, the name given by Europeans to the people calling themselves *Orang Malayu, i.e.,* Malayan folk, who are the dominant race of the Malay Peninsula and the Malay Archipelago, and to the brown races which inhabit the portion of Asia south of Siam and Indo-China, and the islands from the Philippines to Java, and from Sumatra to Timor, except the Sakai and Semang in the Malay Peninsula, the Bataks in Sumatra, and the Muruts in Borneo. The name of Orang Malayu is given to those who speak the Malayan language, and represent the dominant people of the area. The Proto-Malays originated from Sumatra in the 12th century. They were generally short in stature, round headed, with broad faces, short noses with broadish nostrils, slightly prominent jaws and cheekbones. The eyes are often oblique with epicentric fold. They belong to the Southern Mongoloid group. (*See* A. C. Haddon, *Races of Man,* and L. H. Dudley Buxton, *Peoples of Asia.*)

The Malays had attained to a certain stage of civilization before they set foot in Malaya. The semi-wild tribes, ethnologically Malayan and distinct from the aboriginal Semang and Sakai, are met with almost invariably in the neighbourhood of the coast and must have reached the peninsula by a sea route, a fact which explains their amphibian habits. Many tribes hold to a pristine paganism. There were possibly several streams of movement for in some instances the earlier Malay immigrants were driven by the later invaders back down the coast and sought refuge in the far interior.

Social and Political Structure.—The Menangkabau Malays of Sumatra are divided into matrilineal, matrilocal clans. The patrilineal patrilocal clan is found elsewhere, but generally the Malays have advanced to a social order from which the clan system is absent. Their political organisation into aristocratic and lower classes—with hereditary rulers, has attained a high level. There are customs, here and there in this extensive area, relating to succession and inheritance which are clearly related to the matrilineal system found in Sumatra. (*See* Dr. G. A. Wilken and C. O. Blagden, *Malayan Sociology,* 1921.)

Religion and Superstitions.—Most Malays to-day are Sunni Mohammedans of the school of Shafi'i, and use the terms *Orang Malayu, i.e.,* a Malay, and *Orang Islam, i.e.,* a Mohammedan, as synonymous expressions. Their conversion from paganism took place between the 13th and 15th centuries, A.D. The raja of Achin, in northern Sumatra, is said to have been converted as early as 1206, while the Bugis in Celebes did not become Mohammedans until 1495. Their conversion was slow, gradual, and is even now in some respects imperfect. Upon the bulk of the Malayan peoples their religion sits but lightly. Prior to their conversion to Islam the Malays were subjected to a considerable Hindu influence, from traders who visited the archipelago from India. In Bali and Lombok the people still profess a form of Hinduism, and Hindu remains are found in many other parts of the archipelago. Throughout, the superstitions of the Malays show this Hindu influence, and many of the demons whom their medicine-men invoke in their magic practices are borrowed from the pantheon of India. A substratum of superstitious beliefs, from the days when the Malays professed only their natural religion, is firmly rooted in the minds of the people. (*See* W. W. Skeat, *Malay Magic,* 1900.)

Mode of Life.—The Malays of the coast are a maritime people, and were long famous for their piracy. They are now peaceable fisher-folk. Inland the Malays live by preference on the banks of rivers, build houses on piles some feet from the ground, and plant groves of coco-nut, betel-nut, sugar-palm and fruit-trees around their dwellings. Rice, the staple food of the people, is the principal article of agriculture among them. Sugar-cane, maize, tapioca and other similar products are grown in smaller quantities. In planting rice three methods are in use: the cultivation of swamp-rice in irrigated fields; the planting of ploughed areas; and the planting of hill-rice by sowing each grain separately in holes bored for the purpose. In the irrigated fields the rice plants are first grown in nurseries and are subsequently transplanted when they have reached a certain stage of development. The Malays also work jungle produce such as gutta, rattans, agila wood, camphor wood, and the beautiful *kamuning* wood which is used by the natives for the hilts of their weapons. The principal manufactures of the Malays are cotton and silk cloths, earthenware and silver vessels, mats and native weapons. The best cotton cloths are those manufactured by the Bugis people in Celebes, and the *batek* cloths which come from Java and are stamped with patterns. The best silks are produced by the natives of Pahang, Kĕlantan and Johor in the Malay Peninsula. The silver ware from Malaya was pronounced the most artistic of any exhibited at the Colonial Exhibition in London in 1886. The pottery of the Malays is rude. The Malays made gunpowder and forged cannon before Europeans arrived. For the writing of Malay itself the Arabic character has been adopted for some hundreds of years. At an earlier time the script used was based upon forms borrowed from Indian sources. The Malays are excellent boat-builders.

Disposition.—In ordinary circumstances, the Malay is not treacherous, and in many instances men of this race have risked their own lives on behalf of Europeans who chanced to be their friends. They are courteous and self-respecting. Their code of manners is minute and strict, and they observe its provisions faithfully. The Malays are indolent, pleasure-loving, improvident, fond of bright clothing, of comfort, of ease, and dislike toil exceedingly. They have no idea of the value of money, and little notion of honesty where money is concerned. They borrow rather than earn money. They frequently refuse to work for a wage though in sore need of cash, and yet at the invitation of one who is their friend they will toil unremittingly without any thought of reward. They are addicted to gambling, and formerly were much given to fighting, but their courage on the whole is not high if judged by European standards. The sexual morality of the Malays is very lax, but prostitution is not common. Polygamy, though allowed by their religion, is practised for the most part among the wealthy classes only. The Malays show a marvellous loyalty to their rajas and chiefs.

Acts of homicidal mania called amuck (*amok*), which word in the vernacular means to attack, can in some cases certainly be traced to madness *pur et simple,* but the typical *amok* is usually the result of circumstances which render a Malay desperate. The motive is often inadequate from the point of view of a European, but to the Malay it is sufficient to make him weary of life and anxious to court death. Briefly, where a man of another race might not improbably commit suicide, a Malay runs *amok,* killing all whom he may meet until he himself is slain.

The nervous affliction called *latah,* to which many Malays are subject, is also a curious trait. The victims lose for the time all self-control and all sense of their own identity, imitating the actions of any person who chances to rivet their attention.

Costume and Weapons.—The Malays wear a loose coat and trousers, and a cap or head-kerchief, but the characteristic item of their costume is the *sarong,* a silk or cotton cloth about two yards long by a yard and a quarter wide, the ends of which are sewn together, forming a kind of skirt. This is worn round the waist folded in a knot, the women allowing it to fall to the ankle, the men, when properly dressed in accordance with ancient custom, folding it over the hilt of their waist-weapon, and draping it around them so that it reaches nearly to the knee. In the hall of a raja on state occasions a head-kerchief twisted into a peak is worn, and the coat is furnished with a high collar extending round the back of the neck only. This coat is open in front, leaving the chest bare. The trousers are short and of a peculiar cut and material, being coloured many hues in parallel horizontal lines. The *sarong* is of Celebes manufacture and made of cotton, to the surface of which a high polish is imparted by friction with a shell. The typical fighting costume of the Malay is a sleeveless jacket with texts from the Koran written upon it, short tight drawers reaching to the middle of the thigh, and the *sarong* is then bound tightly around the waist, leaving the hilt of the dagger worn in the girdle exposed to view.

The principal weapon of the Malays is the *kris,* a short dagger with a small wooden or ivory handle, of which there are many varieties. The blade of a *kris* may either be wavy or straight, but if wavy the number of waves must always be uneven in number. The *kris* most prized by the Malays are those of Bugis (Celebes) manufacture, and of these the kind called *tuasek* are of the greatest value. Besides the short *kris,* the Malays use long straight *kris* with very narrow blades, shorter straight *kris* of the same form, short broad swords called *sundang,* long swords of ordinary pattern called *pedang,* somewhat shorter swords curved like scimitars with curiously carved handles called *chenangkas,* and short stabbing daggers called *tumbok lada.* The principal tools of the Malays are the *parang* or *gôlok,* a heavy knife used in the jungle, without which no peasant ever stirs abroad from his house, the *beliong* or native axe, and the *pisau raut,* which is used for scraping rattan. Their implements consist of a plough fashioned from a fork of a tree, and a rude harrow. Reaping is usually performed by the aid of a curious little knife which severs each ear of grain separately. The fisherfolk use many kinds of nets, which they manufacture themselves. Sails, paddles, oars and punting-poles are all in use. (H. Cl.)

MALAY STATES (British). The native states of the Malay peninsula under British protection, divided into two groups: (1) federated, and (2) unfederated. (For information concerning the botany, geology, etc., of the Malay states, *see* Malay Peninsula. For the ethnology *see* Malays.)

I. FEDERATED STATES

The federated states (area 27,506 sq.mi.), under the protection of Great Britain until Jan. 1942, but not British possessions, were Perak, Selangor, and the confederation of small states known as the Negri Sembilan (*i.e.,* Nine States) on the west coast, and Pahang on the east coast. Each state was under the rule of a sultan, assisted by a state council, upon which the resident, and in some cases the secretary to the resident, had a seat, and which was composed of native chiefs and of representatives of the European, Chinese and sometimes Indian communities, nominated by the sultan with the advice and consent of the resident. The council, in addition to dealing with the appointment of headmen and religious matters revised all sentences of capital punishment. The administrative work of each state was carried on by the resident and his staff of European officials. The sultan of each state was bound by treaty with the British government to accept the advice of the resident; British officials were pledged not to interfere with the religious affairs of the Mohammedan community. In the administration of the Malay population use was made of the native aristocratic system, the peasants being governed largely by their own chiefs, headmen and village elders, under the supervision of British district officers. To the work of development of their country the Malays contributed little, sound administration having been secured by the British officials, enterprise and capital having been supplied mainly by the Chinese, and the labour employed being almost entirely Chinese or Tamil. Meanwhile the Malays lived principally on reservations, raising just enough food for themselves and having virtually no contact with the Chinese and Indian immigrants. Only during the decade prior to the Japanese invasion had a handful of Malay nationalists claimed for their compatriots a share in the tin and rubber industries, in whose development and prosperity they had had very little part. They also asked for more participation in the administration, previously confined to the raja class, and for the restriction of Indian and Chinese immigration.

Each principal department of the administration had its federal head, and all the residents corresponded with and were controlled by the chief secretary, who, in his turn, was responsible to the high commissioner, the governor of the Straits Settlements.

All matters of administrative interest to the federation were settled by the federal council, a body created in 1909. The council consisted of the high commissioner (president), the chief secretary to the government, the four British residents, the legal adviser, the treasurer, the heads of the medical, education and public works departments, the controller of labour and certain nominated unofficial members, European, Malay, Chinese and Indian; it met generally three times a year and all federal legislation was passed by it.

A centralized bureaucracy developed at Kuala Lumpur (the federal capital), which administered the federation efficiently in the interests of the British and Chinese mine-owners and rubber planters. The Malay sultans were so completely relegated, albeit politely, to the background that their colleagues in the unfederated states perennially refused to be assimilated to the federation. The later politico-economic issues of Malay included preference of natives (to Chinese and Indians) for administrative posts, an all-Malayan Customs union, and the struggle for power between Singapore and Kuala Lumpur. These issues respected the treaty rights of the sultans but left the bulk of the peninsula's inhabitants uninterested and untouched in their fairly water-tight social and economic compartments.

Population.—The growth of the population was the yardstick of the states' prosperity. According to the census of 1921, the population was 1,324,890, having increased since 1911 by 27·7%; it continued to rise rapidly, and was estimated at the end of June 1932 to be 1,622,903. In March 1941 there were estimated to be 713,679 Malays; 978,208 Chinese; 468,029 Indians and 11,019 Europeans. The increase among Malays, especially in Selangor, was largely due to the influx of foreign Malays who settled in the coast districts to plant rubber; the increase in the Indian population also synchronized with the development of the rubber industry. Total population (1941) 2,193,605.

Commerce and Industry.—The 19th century trade of the Malay peninsula was so long hampered by the anarchy growing in the sultanates that Singapore successfully agitated for the extension of British sovereignty there. The 20th century brought such a phenomenal development of the peninsula's tin and rubber industries that food crops were neglected and Malaya came to import approximately two-thirds of its food requirements. The depression of 1930–32 proved that over-concentration on tin and rubber had made Malaya's commercial history a fever-chart of prosperity alternating with poverty. The fluctuations were caused by world market conditions (notably in the United States, the best customer) and were almost wholly beyond local control. Wages declined, the immigrant labourers left Malaya, and state revenues—dependent as they were on the two major industries—declined seriously for the second time (the first crisis occurred in 1921) in the country's generally prosperous history. Thanks to international restriction agreements for tin and rubber, prosperity began returning to the peninsula in 1934. Quotas were imposed on Japanese imports, which had been flooding the country, and tariffs were generally raised in accordance with the London-inspired policy of imperial preference, accepted with varying degrees of reluctance by the Malay states. World War II gave a tremendous fillip to tin and rubber exports until 1942 but virtually ruined the younger (and almost wholly Asiatic-controlled) copra and pineapple industries.

In the 1920s, dredging revolutionized the tin industry technically and also altered the nationality of its control. In the late 1930s about 40 British companies, with a capital of £8,000,000–9,000,000, were engaged in tin dredging in the federation: at this period Chinese output accounted for only about 36% of the ore produced, exactly reversing the position in 1920, when they controlled about 63% of the industry. In 1940 Malaya's tin producers established a record export of 85,384 tons, valued at over £21,000,000, despite curtailed prospecting of new lands, increased freight and insurance charges, inequitable assessment of mines, and the failure of some London-registered companies to produce at capacity because of what they termed excessive taxation. That same year Malaya shipped 549,327 tons of rubber at a value of $(Str.)449,780,904—almost double the value of exports for the preceding year. This was accomplished in the face of such obstacles as increased production costs, higher taxation, the withdrawal of some of the European estate staff, and above all, labour strikes and shortages.

Ores other than tin include gold, coal, iron and bauxite. The Raub gold mine in Pahang was the only gold mine working in these states in the years prior to 1942, but alluvial gold was recovered in various places. Coal was mined by the Malayan collieries in Selangor; the output (averaging 350,000–400,000 tons annually) was absorbed wholly by local industries. The iron ores of the east coast states were prospected and exploited by the Japanese, and were shipped in a crude state to Japan, where they were of great importance to the steel industry. One of the Japanese iron mines of Trengganu was also an important producer of low-grade manganese with an average export, during the 1934–38 period, of about 30,000 tons annually. The existence of bauxite in Johore was discovered in 1936; almost all the deposits were prospected and worked by the Japanese. In 1939, 66,700 tons were exported to Japan.

Agriculture.—*Rice.*—The depression of 1930 and the start of World War II aroused the federal government to the danger of continued disparity between the production and consumption of rice—the main food item for 99% of the population. By 1940, a threat to permit the Chinese to break the monopoly of rice-growing traditionally exercised by the Malays, the Malay colonization of newly irrigated lands, and finally an indirect official subsidy to paddy farmers had succeeded in increasing rice cultivation in the peninsula by 27%. But even then the acreage under rice totalled only 740,000; the federated states were producing only a fourth of their rice requirements (more than half of which was grown in Kedah and Kelantan), and the country was still importing about one-half million tons of rice, chiefly from Thailand. Emergency stocks had been built up by the government on the eve of the war; and as hostilities progressed, rice imports were first licensed, then monopolized, and a rice pool for distribution was formed.

Other food crops were officially encouraged during both world wars and the depression. The agriculture department, notably at its experimental farm in Serdang, was deflected from rubber research to crop studies, after the Rubber institute was founded in 1924. Little permanent increase in food production, however, was registered until 1939–40, because rubber and tin production were more remunerative. Transport and marketing facilities were lacking particularly in Pahang, which had the largest available cultivable areas. But by the end of 1940 the area under food crops other than rice (chiefly maize, colocasia, sweet potatoes, tapioca and yams) was 117,883 ac., as compared with 91,782 ac. in 1939. Despite this rise in production, accompanied by far larger returns to the cultivator, vegetables were increasingly imported into Malaya. In 1940 such imports amounted to 69,012 tons, marking an increase over 1939, itself a record year.

Tobacco production was greatly stimulated by World War II, and the Chinese in 1940 opened 13 new factories in the peninsula. Tobacco imports in that year amounted to the usual annual average of 12,500,000 lbs. The area under coffee was only 16,522 ac. in 1940; interest was taken in its cultivation only during rubber slumps. Sugar, formerly important, had almost disappeared by 1938, when there were only 330 acres under cane in the peninsula. In spite of sporadic attempts to stimulate local fruit production and the large acreage under fruit trees (approximately 190,000), this industry experienced only a mild commercial development, owing to inadequate marketing arrangements and the existence of only one canning factory in Penang. Pineapples were the only fruit crop developed for the export market, chiefly Great Britain and Canada. In 1939, more than 50,000 of the 61,280 ac. planted to pineapples as a sole crop were located in Johore; there were 20 canning factories, principally in Singapore. This industry was a Chinese enterprise but was under government organization and supervision. Pineapple growers and coconut producers were especially hard hit by the war's closure of markets after 1939. Even the large vegetable oil producers, owning about 100,000 ac. and £3,000,000 in capital, were producing at a loss. Tea, areca nuts, and derris root were cultivated in the federation, partly for the domestic market and partly for export. At the end of 1940, Malaya had almost 9,000 ac. under tea, of which about half were in Pahang. Areca nuts were exported chiefly to India. Their production expanded both during the depression and World War II. Derris exports, about half of which were sold to the American market, were well maintained in 1940; at that time there were about 10,000 ac. under this crop.

Natural Resources.—*Livestock.*—Improved pig-breeding and cattle-raising figured heavily on the official war program after 1939, but too late to remedy appreciably the peninsula's chronic shortage of livestock.

Fisheries.—Malay fishermen enjoyed a major share of the east coast production, but the financing and marketing of fish were wholly in non-Malay hands. No regulations governed the catch of Malaya's diminishing supply of river fish. In spite of the undeveloped state of this industry, Malaya's fish resources provided considerable revenues to the poorer peninsular states, and also the most important protein element in the local diet. In 1939 total production was estimated at 89,902 tons.

Forests.—Nearly 77% of Malaya's total area was classified as forest land, chiefly on the east coast. About one-fifth of this area was in reserved forests. The more accessible lowland timber suffered severely from agricultural and mining enterprises. Malaya's annual timber consumption, some 40,000,000 cu.ft., ran about 44% over current production. The forestry department fostered a nascent sawmill industry by means of a license system and by developing an export trade to Great Britain. Exports of Malaya's hardwoods were reported to be dangerously stimulated by war demands.

Revenues.—The principal sources were export duties on tin and rubber and, far behind, railway receipts, land and forest revenue, excise, import duties, and the opium monopoly. During 1939–42, tin and rubber exports were subjected to special taxation, and a nominal income tax was levied despite strong local opposition. From 1909 to 1914 the federation's revenues almost doubled; the two world depressions forced retrenchments in the public works program and official emoluments; and prosperous budgets did not reappear until the mid-1930s. Expenditures likewise rose rapidly, so while the tin and rubber booms brought revenues to $(Str.)70,200,000 in 1939, expenditures came to $77,100,000. The following year the position was reversed: revenues soared to $98,500,000 while expenditures totalled $78,500,000, including a gift of $10,000,000 to the imperial government. The chief revenue items were the export taxes on tin ($23,300,000) and on rubber ($7,300,000).

Railways.—Communications in the Federated Malay States kept pace with the growing requirements of the tin and rubber industries. There were in 1940 3,108 mi. of metalled and 198 mi. of unmetalled roads. The total length of line open to traffic under the Federated Malay States railway administration was 1,068 mi. in 1931, after which time there was virtually no new construction.

This includes the Johore state railway, which at Gemas branches into the west coast line to Prai and to the Siamese frontier; and the east coast line, which runs northward toward Tumpat. The Kelantan section was extended southward to the east coast line (total length 328 mi.) to provide direct communication between Kelantan and Singapore. Through traffic, over the west coast line, with the Siamese state railways was opened in 1918, and between the Federated Malay States and Kelantan via the Siamese railway in 1921. The Johore causeway, connecting Singapore with the peninsula, was opened in 1924 and destroyed by the British in 1942. The causeway carried two lines of rails and a roadway; total length, 3,465 ft.; average headway at low tide, 47 ft.

Education.—Important movements for the extension of education were set on foot after World War I, despite difficulties encountered in increasing the number of teachers and the improvement of the teaching staff. A few scholarships were given to Raffles college. The Malay college at Kuala Kangsar for Malays of good birth had an enrolment of 149 boys in 1939. Malay vernacular teachers were trained at the Sultan Idris college. There were trade schools at Kuala Lumpur, Ipoh and Bagan Serai, and a central technical institute in the federal capital. In 1940 the federation spent £437,796 on the education provided in 49 English schools with 19,505 pupils; 582 Malay schools with 63,638 pupils; 572 registered Chinese schools with 58,227 pupils; 17 official and 463 aided Tamil schools. There were, in addition, 100 non-aided schools with 23,527 pupils.

Although increasing allocations of funds were made, free education was dispensed exclusively to Malays, and only grants-in-aid were given to private schools run by Chinese, Indians and missionaries. Higher education was, with the exception of some scholarships, restricted to the few who could pay for it. The government required rubber estate managers to open schools for their coolies' children, but the quality of such education was admittedly low. The education department was trying, prior to 1942, to introduce a more practical vocational program in its curriculum, and to decrease the white-collar unemployment especially conspicuous during the depression, as well as to foster agricultural training in Malay schools. The McLean Commission report, published at the end of 1939, outlined important departures in policy which, however, the war did not permit to materialize.

Perak.—Perak is situated between the parallels of 3° 37′ and 6° 5′ N. and 100° 3′ to 101° 51′ E. on the western side of the Malay peninsula. It is bounded on the north by Province Wellesley and the Malay state of Kedah; on the south by Selangor; on the east by Pahang, Kelantan and the Thai state, Patani; and on the west by the Straits of Malacca. The coast-line is about 90 mi. in length. The extreme distance from the most northerly to the most southerly portions of the state is about 172 mi., and the greatest breadth from east to west is about 100 mi. The total area of the country is estimated at 7,800 sq.mi.

The Perak river runs in a southerly direction, almost parallel with the coast for nearly 150 mi. of its course. The Plus, Batang, Padang and Kinta rivers are its principal tributaries, all of them falling into the Perak on its left bank. The other principal rivers of the state are the Krian, Kurau, Larut and Bruas to the north of the mouth of the Perak, and the Bernam to the south. None of these rivers is of importance as a waterway. The mountain ranges, which cover a considerable area, run from the northeast to the southwest. They are all thickly covered with jungle. The ranges are two, the main range and the Bintang range, with the valley of the Perak between them. There are several hill sanatoria at heights which vary from 2,500 to 4,700 ft. above sea-level.

History.—The early history of Perak is obscure. According to Malay accounts a settlement was first made by Malays in Perak at Bruas, and the capital was later moved to the banks of the Perak river. It would appear as if members of the great Bendaharas of Malacca married into the Bruas family and were concerned in the early settlements. When the Malacca sultanate fell, owing to the invasion of the Portuguese in 1511, a member of that royal house is said to have migrated to Perak, and the present dynasty claims descent from him. What is certain is that Perak was twice invaded by the Achinese, and its rulers carried off into captivity, one of them, Sultan Mansur Shah, becoming ruler of Achin. The first European settlement in Perak was made by the Dutch in 1650, under a treaty entered into with the Achinese; but the natives rose against the Dutch again and again, and it was abandoned in 1783, though it was afterwards reoccupied, the Dutch being finally supplanted by the British in 1795. In 1818 the Siamese conquered Perak, but its independence was secured by a treaty between the British and Siamese governments in 1824. From that date until 1874 Perak was ruled by its own sultans, but in that year, owing to internal strife, Sultan Abdullah applied to the then governor of the Straits Settlements, Sir Andrew Clarke, for a British resident. The treaty of Pangkor was concluded on Jan. 20, 1874. The first resident, J. W. W. Birch, however, was murdered on Nov. 2, 1875, and a punitive expedition became necessary; Sultan Abdullah and the other chiefs concerned in the murder were banished; the actual murderers were hanged; Raja Muda Yusuf was declared regent. He died in 1888, and was succeeded by the sultan Idris, G.C.M.G., a most enlightened ruler, who was from the first a strong and intelligent advocate of British methods of administration. Sir Hugh Low was appointed resident, a position which he held until 1889, when he was succeeded by Sir Frank Swettenham. Until the Japanese conquest, the history of Perak was one of peace, prosperity and wealth. Although the federal capital was Kuala Lumpur in Selangor, Perak enjoyed the honour of being the senior and leading state of the federation.

The population in 1941 was estimated at 984,464, of whom 331,209 were Malays, 445,266 Chinese, 196,945 Indians, 4,069 Europeans, 1,570 Eurasians.

In 1940 imports were valued at £3,310,333, and exports at £6,925,188. Exports were chiefly tin and rubber.

A line of railway connects the port of Teluk Anson with the great mining district of Kinta, whence the line runs, crossing the Perak river at Enggor, to Kuala Kangsar, the residence of the sultan, thence to Taiping, and via Krian to a point opposite the island of Penang. A second line runs south from Perak to Singapore. Perak also possesses some 880 mi. of excellent metalled cart-road.

For administrative purposes the state was divided into six districts: Upper Perak, Kuala Kangsar and Lower Perak, on the Perak River; Kinta; Batang Padang, Larut and Krian. Of these, Larut and Kinta are the principal mining centres, while Krian is a rice-growing district. The districts on the Perak river are mostly peopled by Malays. The administrative capital was Ipoh.

Selangor.—Selangor is situated between the parallels 2° 32′ and 3° 37′ N. and 100° 38′ and 102° E., on the western side of the Malay peninsula. It is bounded on the north by Perak, on the south by Negri Sembilan, on the east by Pahang and Negri Sembilan, and on the west by the Straits of Malacca. The coast-line is about 100 mi. in length, greatest length about 104 mi., and greatest breadth about 48 mi., total area estimated at about 3,000 sq.mi.

The state consists of a narrow strip of land between the mountain range which forms the backbone of the peninsula and the Straits of Malacca. Compared with other states in the peninsula, Selangor is poorly watered. The principal rivers are the Selangor, the Klang and the Langat. The principal port is Port Swettenham, situated at the mouth of the Klang river, and is connected with Kuala Lumpur by a railway. The state has valuable deposits of alluvial tin; mining and rubber-planting are chief industries. Kuala Lumpur was the federal capital of the Malay states.

According to native tradition, the ruling house of Selangor is descended from a Bugis raja, who, with two of his brothers, settled in the state in 1718, the son of the youngest brother by a Johore princess becoming ruler of the country. In 1783 the then sultan of Selangor joined with the Yang-di-per-Tuan Muda of Riau in an unsuccessful attack upon the Dutch who then held Malacca. In retaliation the Dutch, under Admiral Van Braam, invaded Selangor and drove the sultan out of his country. In 1785, aided by the Bendahara of Pahang, Sultan Ibrahim of Selangor reconquered his state; but the Dutch blockaded his ports, and eventually forced him to enter into a treaty whereby he consented to acknowledge their sovereignty. The earliest British political communication with Selangor began in 1818, when a commercial treaty was concluded with the governor of Penang. From 1867 till 1873 there was civil war in the state. In 1874 an atrocious act of piracy off the mouth of the Langat river led to the governor, Sir Andrew Clarke, appointing, at the request of the sultan, a British resident.

In 1941 the total population was estimated at 696,173, of whom 150,604 were Malays, 335,661 Chinese, 194,291 Indians, 4,913 Europeans and 2,625 Eurasians. In 1940 the value of imports was £10,194,343 and of exports £18,580,338.

The main trunk line of the Federated Malay States railways passes through Selangor. It enters the state at Tanjong Malim on the Perak boundary, runs southward through Kuala Lumpur and so into the Negri Sembilan. It runs for 81 mi. in Selangor territory. A branch line 27 mi. long connects Kuala Lumpur with Port Swettenham on the Klang straits where there are extensive wharves, capable of accommodating ocean-going vessels. A second branch line, measuring rather more than 4 mi. in length, connects the caves at Batu with Kuala Lumpur. Frequent communication has been maintained by steamer between Port Swettenham and Singapore, and by coasting vessels between the former port and those on the shores of the Straits of Malacca. All the principal places in the state are connected with one another by telegraph and telephone.

For administrative purposes Selangor was divided into six districts: Kuala Lumpur, in which the capital was situated; Ulu Selangor, which is a prosperous mining district; Kuala Selangor, which is agricultural, and poorly populated by Malays; Ulu Langat, mining and agricultural; Kuala Langat, agricultural; and Klang, the only port of the state. Much money has been expended upon Kuala Lumpur, which possessed large public buildings, waterworks, etc., and where a house for the high commissioner and the residence of the chief secretary was situated. In some sort Kuala Lumpur was the capital not only of Selangor, but also of the whole federation. Its scenery is attractive.

Negri Sembilan.—Negri Sembilan (the Nine States) is a federation of small native states which is now treated as a single entity, being under the control of a British resident, and is situated between parallels 2° 28′ and 3° 18′ N. and 101° 45′ and 102° 45′ E., on the western side of the Malay peninsula. It is bounded on the north by Pahang, on the south by Malacca, on the east by Pahang and Johore, and on the west by the Straits of Malacca. The coast-line is about 28 mi. in length, and the extreme distance from north to south is 55 mi., and that from east to west about 65 mi. The estimated area is about 3,000 sq.mi. Port Dickson, or Arang-Arang, is the only port. It is connected with the capital, Seremban, by a railway 24 mi. in length. Most of the state depends for its prosperity upon agriculture, but in some of the districts tin has been worked with good results.

In the 14th century A.D. Sungai Ujong is mentioned as tributary to the Javanese kingdom, Majapahit; in the 15th it was ruled by the Bendaharas of Malacca; in the 16th came Minangkabau immigrants with matriarchal notions that made their descendants claim aboriginal ancestresses. In the 18th century a raja from Minangkabau was brought from Sumatra to arbitrate between the small states, each of which continued to be governed in all local affairs by its own chief and by the village and tribal councils sanctioned by ancient custom. The Sumatran raja took the title of Yang-di-per-Tuan of Sri Menanti. Apparently the nine states were originally Klang, Jelebu, Sungai Ujong, Segamat and Pasir Besar (both now in Johore), Rembau, Naning (now in Malacca), Jelai (now Inas) and Ulu Pahang (the region between Ulu Serting and Temerlop). During the last years of the 18th century a Yang-di-per-Tuan Muda ruled Rembau, and the state of Tampin was created to provide for the family of the new chief. In 1887 the governor of the Straits Settlements sent Martin Lister to the Negri Sembilan, which had become disintegrated, and by his influence the ancient federal system was revived under the control of a resident appointed by the governor. Prior to this, in 1873, owing to civil war in Sungai Ujong, Sir Andrew Clarke sent a military force to that state, put an end to the disturbances, and placed the country under the control of a British resident. Jelebu was taken under British protection in 1886, and managed by a magistrate under the orders of the resident of Sungai Ujong. In 1896, when the federation of all the Malay states under British control was effected, Sungai Ujong and Jelebu were reunited to the confederation of small states from which they had so long been separated and the whole, under the old name of the Negri Sembilan, or Nine States, was placed under one resident. Later the federation consisted of Sungai Ujong, Jelebu, Johol and Rembau and the smaller states of Ulu Nuar, Jempul, Terachi, Gunong Pasir and Inas.

In 1941 the total population was estimated at 293,510, of whom 104,701 were Malays, 124,418 Chinese, 59,472 Indians, 1,416 Europeans and 855 Eurasians. In 1940 exports were valued at £6,152,723 and imports at £1,305,978, with rubber the leading item of export.

Seremban, the administrative capital of Negri Sembilan, is connected with Port Dickson by a railway 24½ mi. in length. It is situated on the trunk line of the Federated Malay States, and is thus joined by rail to Selangor on the north and to Malacca and Singapore on the south. Frequent steam communication has been maintained between Port Dickson and the ports on the Straits of Malacca and with Singapore.

For administrative purposes Negri Sembilan was divided into five districts, viz., the Seremban district, the Coast district, Jelebu, Kuala Pilah and Tampin. Each of these was under the charge of a European district officer responsible to the resident. The Yang-di-per-Tuan lives at Kuala Pilah. The hereditary chiefs of the various states aided in the government of their districts, and had seats upon the state council over which the Yang-di-per-Tuan presided. Port Dickson was a favourite pleasure resort.

Pahang.—Pahang, on the east coast of the peninsula, is situated between parallels 2° 28′ and 3° 45′ N. and 101° 30′ and 103° 30′ E. It is bounded on the north by Kelantan and Trengganu; on the south by Negri Sembilan and Johore; on the east by the China sea; and on the west by Perak and Selangor. The coast-line is about 112 mi. in length; the greatest length is about 210 mi., and greatest breadth about 130 mi. The state is the largest in the peninsula, its area being estimated at 14,000 sq.mi. The ports on the coast are the mouths of the Endau, Rompin, Pahang and Kuantan rivers, but during the northeast monsoon the coast is not easy of approach, and the rivers, all of which are guarded by difficult bars, are impossible of access except at high tides. Kuantan is the principal port, always accessible at high water, but hampered by monsoon influences which cause the river to silt up.

The principal river of the state is the Pahang; 180 mi. from the coast this river is formed by two others named the Jelai and the Tembeling. The former is joined 20 mi. farther upstream by the Lipis, which has its rise in the mountains that form the boundary with Perak. The Jelai has its rise in a more northerly portion of this range, while its two principal tributaries above the mouth of the Lipis, the Telom and the Serau, rise, the one in the plateau which divides Perak from Pahang, the other in the hills which separate Pahang from Kelantan. The Tembeling has its rise in the hills which divide Pahang from Kelantan, but some of its tributaries rise on the Trengganu frontier, while the largest of its confluents comes from the hills in which the Kuantan river takes its rise. The Pahang is navigable for large boats as far as Kuala Lipis, 200 mi. from the mouth, and light-draught launches can get up to that point. Smaller boats can be taken some 80 mi. higher up the Jelai and Telom. The river, however, as a waterway is of little use, since it is uniformly shallow. The Rompin and Kuantan rivers are somewhat more easily navigated for the first 30 mi. of their course. But the waterways of Pahang are of little value. Gunong Tahan (7,184 ft.) is situated on the boundary between Pahang and Kelantan. Pahang is covered almost entirely by forest, but in the Lipis valley, which formerly was thickly populated, there is an expanse of open grass plain unlike anything to be seen on the western seaboard. The coast is a sandy beach fringed with *casuarina* trees and there are only a few patches of mangrove-swamp.

In the 13th century Pahang was claimed as subject to Buddhist Palembang, in the 14th it (and Tiomen) as subject to Majapahit. Later came the modern Tai or Siamese influence. In the 15th century a sultan of Malacca captured its ruler and married his daughter. The captives could not speak Malay. After the capture of Malacca by the Portuguese its royal house provided rulers for Pahang until its last member was murdered in 1699. Thereafter Pahang fell under the suzerainty of the later rulers of Johore, who left a Dato' Bendahara in charge. An old court name for its capital was Indrapura. The title of the ruler of Pahang was Bendahara until 1882, when Wan Ahmad assumed the title of sultan. Up to that time the Bendahara had been installed by the sultan of Riau, and held office by virtue of that chief's authority. About 1855 the father of Wan Ahmad died at Pekan, and his elder son Bendahara Korish, who succeeded him, drove Wan Ahmad from the country. After making three unsuccessful attempts to dethrone his brother, Wan Ahmad succeeded in 1865 in invading the state and wresting the throne from his nephew, who had succeeded Bendahara Korish some years earlier. In spite of two attempts to shake his power by invasions from Selangor which were undertaken by his nephews Wan Aman and Wan Da, Bendahara Ahmad ruled with a rod of iron. In 1887 he consented to enter into a treaty with the governor of the Straits by which he accepted a consular agent at his court. This treaty was signed on Oct. 8, 1887. In the following year a Chinese British subject was murdered at Pekan in circumstances which pointed to the responsibility of the sultan, and in Oct. 1888 a resident was appointed to assist the sultan in the administration of his country, that being, in the opinion of the British government, the only guarantee for the life and property of British subjects which it could accept. In Dec. 1891 disturbances broke out, the nominal leaders of which were certain of the sultan's trusted chiefs. The sultan took no part in the outbreak, but undoubtedly it had his sympathy. The rebels were driven to seek safety in flight in Nov. 1892, but in June 1894 they gathered strength for a second disturbance, and raided Pahang from Kelantan, in which state they had been given shelter. This event, added to other raids from across the border, led to an irregular expedition into Trengganu and Kelantan by the resident of Pahang (Mr.—later Sir—Hugh Clifford) in 1895, and this had the desired result. The rebel chiefs were banished to Siam. Pahang joined the Federated Malay States by a treaty signed in 1895, and the sultan and his principal chiefs were present at the federal durbar held at Kuala Kangsar in Perak in 1897.

The long succession of civil wars which racked the land after the death of Bendahara Ali caused thousands of Pahang Malays to fly the country. Today the valley of the Lebir river in Kelantan and the upper portions of several rivers near the Perak and Selangor boundaries are inhabited by Pahang Malays, the descendants of these fugitives. The Pahang natives are almost all engaged in agriculture. The work of the mines, etc., has been performed by foreign labour. In the Lipis valley the descendants of the Rawa Malays (from Sumatra) who at one time possessed the interior in defiance of the Pahang rajahs, still outnumber the people of the land. Total population estimate of 1941 was 219,458, of whom 127,165 were Malays, 72,863 Chinese, 17,321 Indians, 621 Europeans and 176 Eurasians. In 1940 exports were valued at £1,915,474 and imports at £577,565; the chief exports were rubber and tin.

A road over the mountains, 82 mi. long, joins Kuala Lipis, the administrative capital of Pahang, to Kuala Kubu, the nearest railway station in Selangor. Another joins Bentong to Kuala Lumpur and a third, Bentong to Negri Sembilan. Pekan, where the sultan resides, was the capital of Pahang until 1898, when headquarters were transferred to the interior as being more central. None of these towns is of any size. In the Kuantan valley, which lies parallel to the Pahang river, a European company worked one of the world's greatest lode tin-mines. Pahang is fertile and well suited for agriculture. The rainfall is heavy and regular. The climate is cooler than that of the west coast, and the full force of the monsoon is felt from October to February. The state was divided into four districts—Ulu Pahang, in which the capital is situated; Temerloh, which includes 80 odd miles of the Pahang valley and the Semantan river; Pekan, which includes the coast rivers down to Endau; and Kuantan. Each of these was under the charge of a district officer. The boundary with Johore and the Negri Sembilan was rectified by a commission which sat in London in 1897–1898.

II. UNFEDERATED STATES

By a treaty in 1909, Siam ceded to Great Britain suzerain rights over the four Siamese Malay states: Kelantan, Trengganu, Kedah and Perlis, which for centuries had been more or less nominal dependencies of Siam and all of which, except Trengganu, had been administered by British officers in the service of Siam for some years before the transfer, which was effected without disturbance. The British government put an adviser at the court of each raja and guaranteed administration on the lines laid down by Siam so far as might be compatible with justice and fair treatment for all. The four states lie to the north of the Federated Malay States, two on the east and two on the west side of the peninsula. In 1914 the southern state Johore accepted an adviser. Total pop. of Unfederated States is 1,889,648.

Johore.—The richest and most highly organized of the Unfederated States of British Malaya, situated at the southern end of the peninsula, stretching from 2° 40′ S. to Cape Romania, the most southerly point on the mainland of Asia, and including all small islands adjacent to the coast which lie to the south of parallel 2° 40′ S. It is bounded north and northwest, respectively, by the federated state of Pahang, Negri Sembilan and the territory of Malacca, south by the strait which divides Singapore island from the mainland, east by the China sea, and west by the Straits of Malacca. The district of Muar was placed under Johore by the British as a temporary measure in 1877, and is now an integral part of it. The coast-line measures about 250 mi. The greatest length from N.W. to S.E. is 165 mi., the greatest breadth from E. to W. 100 mi. The area is estimated at 7,500 sq.mi. The principal rivers are the Muar, the most important waterway in the south of the peninsula; the Johore, up which the old capital of the state was situated; the Endau, which marks the boundary with Pahang; and the Batu Pahat and Sedeli, of comparative unimportance. Johore is less mountainous than any other state in the peninsula. The highest peak (4,187 ft.) is Gunong Ledang, called Mt. Ophir by Europeans. The capital is Johore Bharu, situated at the nearest point on the mainland to the island of Singapore. The palace built by the late sultan Abubakar is a feature of the town. The capital of the province of Muar is Bandar Maharani, named after the wife of the late sultan before he had assumed his final title. Other towns are Batu Pahat, Segamat, Kota Tuiggi, Mersing and Jemaluang. The climate is healthy and equable for a country so near the equator; it is cooler than that of Singapore. The shade temperature varies from 98.5° F to 65° F. The rainfall averages 97 in. per annum.

In 1940 there were 929 mi. of metalled road in the state. In 1941 the total population was estimated at 664,472, of whom 296,727 were Malays, 303,338 Chinese, 58,622 Indians, 1,249 Europeans and 349 Eurasians. The revenues in 1940 came to $(Str.)24,737,983. Imports were valued at $57,275,959, foodstuffs, animals and tobacco accounting for almost half of the total. Exports were valued at $138,214,062, of which rubber accounted for $117,424,870 (205,211 tons). Other exports were iron and tin ores, pineapples, copra, tapioca and betel nuts. In 1938 there were 7 English schools with an average enrolment of 1,993 pupils; 134 Malay vernacular boys' schools with 15,907 pupils and 21 girls' schools with 2,236 pupils. Tamil schools, with 8 exceptions, were all estate schools with an average enrolment of 3,632.

History.—The Mohammedan empire of Johore was founded by the sultan of Malacca after his expulsion from his kingdom by the Portuguese in 1511. Like Achin, Johore took an active part in the protracted war between the Portuguese and the Dutch for the possession of Malacca. In 1699 the last of the Malacca royal line was murdered at Kota Tuiggi and the throne passed to the line of the great Malacca chiefs, the Bendaharas. Later we find Johore ruled by an officer of the Bugis rulers of Riouw, bearing the title of Temenggong, and owing feudal allegiance to his master in common with the Bendahara of Pahang. In 1812, the Dutch had driven the Bugis out of Rian and recognized as sultan of Johore a descendant of the Bendahara chiefs of old Malacca. His son, Sultan Husain, ceded the island of Singapore to the East India company in 1819. In 1855 the then sultan, Ali, was deposed, and his principal chief, the Temenggong, was given the supreme rule by the British. His son, Temenggong Abubakar, proved to be a man of exceptional intelligence. He made numerous visits to Europe, took considerable interest in the government and development of his country, and was given by Queen Victoria the title of Maharaja in 1879. In 1885 he entered into a new agreement with the British government, and was allowed to assume the title of Sultan of the State and Territory of Johore. He was succeeded in 1895 by his son, Sultan Ibrahīm. In 1914 an agreement was concluded whereby a general adviser was appointed with powers similar to those exercised by British residents in the Federated Malay States.

Kelantan.—This state on the east coast, bounded north and northeast by the China sea, east by Trengganu, south by Pahang and west by Perak and Ra-nge, lies between 4° 48′ and 6° 20′ N. and 101° 33′ and 102° 45′ E. The greatest length from north to south is 115 mi. and the greatest breadth from east to west 60 mi. The area is 5,870 sq.mi. The northern part of the state is flat and fertile, but the southern district, which comprises more than half the total area, is hilly and broken.

Next to the Pahang, the Kelantan river is the largest on the east coast. It is 120 mi. long and is navigable for shallow-draft launches and big country boats for about 80 mi., and for vessels of 8 ft. draft for about 6 mi. Its principal tributaries are the Galas, Pergau and Lebir. The Golok and Semarak rivers water the west and east parts of the state, falling into the sea a few miles on either side of the mouth of the Kelantan river. The climate of Kelantan is mild and singularly healthy in the open cultivated regions. The population was estimated in 1941 at 404,470, of whom 365,783 were Malays, 23,188 Chinese, 7,680 Indians, 206 Europeans and 40 Eurasians. The Chinese are increasing and natives of different parts of India are resorting to the state for purposes of trade. Kota Bharu (pop. 14,843) is the only town in the state. It lies on the right bank of the river, about six miles from the sea. Since 1904 it has been laid out with metalled roads and many public and private buildings have been erected. The town is the commercial as well as the administrative centre of the state. Tumpat on the coast (pop. 2,406) is the place next in importance after Kota Bharu. A network of creeks renders communication easy in the northern districts, the river and its tributaries afford means of access to all parts of the south; 336 mi. of road have been made. Kelantan has been connected by telegraph with Bangkok and Singapore, and maintains regular postal communication with those places. Rice cultivation has been the principal industry. Rubber, coconuts and betel-nuts rank next. Much livestock is raised. At present there is no mining. Gold, tin and galena have been found in several localities. The Kelantanese are expert fishermen, some 10,000 finding employment in fishing and fish-drying. Silk-weaving is an industry. Revenues came to £455,948 in 1940. Total exports were valued at £1,639,786; imports at £1,037,386. The chief exports were rubber, iron ore, copra, cattle and areca nuts.

By virtue of a mutual agreement made in 1902 Siam appointed a resident commissioner to Kelantan and consented, so long as the advice of that officer should be followed, to leave internal affairs to be conducted locally. Under this arrangement a council of state was appointed, departments of government were organized, penal, civil and revenue laws were passed and enforced, courts were established and a police force was raised. Though formerly of an evil reputation, the people are peaceful and law-abiding, and serious crime is rare. The state was divided into *mukim* or parishes, but the *imam* no longer exercise temporal authority. There were in 1938 62 Malay vernacular boys' schools with an average enrolment of 5,750 pupils. The Ismail English Boys' school had 104 pupils.

Like Trengganu, Kelantan is said to have been subject to Palembang (the great Buddhist kingdom Sri Vijaya) in the 13th and under the Javanese Majapahit in the 14th century. The rulers of old Malacca conquered it, carrying off princesses with non-Malayan titles. Kelantan is found on Portuguese maps and on Dutch. The sites of ancient towns and the remains of gold diggings are visible here and there, but all knowledge of the men who made these marks has been lost. The present ruling family dates from about 1790. Siam was frequently called upon to maintain internal peace and in 1892 a royal prince was sent to reside in Kelantan as commissioner. Complications brought about by the incapacity of the ruler led to the making of the agreement of 1902, to the fixing of a regular tribute in money to Siam, and ultimately to the lifting of the state from chaotic lawlessness into the path of reform. On July 15, 1909 the state came under British suzerainty and the commissioner of Siam was replaced by a British adviser.

The history of Kelantan has been dominated by the economic and political repercussions from litigation with the Duff Development company, which had been granted a vast concession. In consequence the state's debt came to about $5,500,000.

During World War I the sultans of Trengganu and Kelantan joined forces in a brief revolt against British rule.

Trengganu.—This state on the east coast bounded north and northeast by the China sea, south by Pahang and west by Pahang and Kelantan, lies between parallels 4° 4′ and 4° 46′ N. and 102° 30′ and 103° 26′ E. The greatest length from north to south is 120 mi., and the greatest breadth from east to west 50 mi. It has a coast-line of 130 mi. and an estimated area of about 6,000 sq.mi. There are several islands off the coast, some of which are inhabited. The surface is generally mountainous.

Principal rivers are the Besut, Stiu, Trengganu, Dungun and Kemaman, none of which is navigable for any distance. The climate is mild and fairly healthful. In 1941 the population was estimated at 203,253, of whom 184,286 were Malays, 16,750 Chinese, 421 Indians, 53 Europeans and 15 Eurasians. The Malays are concentrated round the mouths and lower reaches of the rivers. The capital is situated at the mouth of the Trengganu river. Difficulty of access by river and by land renders the interior almost uninhabitable. Communication is maintained by boat along the coast. In 1938 the state possessed 218 mi. of main roads and 150 mi. of subsidiary roads. There were six post offices and four telephone exchanges. The telegraph line was used for telephonic communication from Kuala Trengganu to Besut, Dungun and Kemaman. In 1941 a telegraphic service between Kelantan and northern Trengganu was opened.

Most of the people are rice-planters, nearly 10,000 are fishermen. The chief exports are iron, rubber, tin, dried fish, copra, silk sarongs, haematite, wolfram, gambier and areca-nuts. Silk-weaving, carried on by the women, is a considerable industry. The silk is imported raw and is re-exported in the form of Malay clothing (*sarongs*) of patterns and quality which are widely celebrated. The manufacture of native weapons and of brassware was at one time brisk but is declining. Revenues in 1940 came to $(Str.)3,303,006, of which exports were valued at $13,210,895 and imports at $8,378,136. Rice took first place among imports. The more important imports from Singapore are rice, cotton and silk fabrics, tobacco and cigarettes, sugar, tinned milk, petroleum and machinery.

The Buddhist monk, Chao Ju Kua, writing about A.D. 1225 says that like Kedah, Kelantan and Pahang, Trengganu was subject to the Sumatran Buddhist kingdom, Palembang; Javanese records of the 14th century A.D. mention it as conquered by Majapahit. In later centuries Malacca and Siam disputed its possession. An inscribed stone now in Raffles museum, Singapore, shows that Islam had penetrated the state early in the 14th century. The royal house is descended from the father of the non-royal Bendahara who became sultan of Johore after the murder of the last descendant of the old Malacca royal family in 1699. In 1720 the Bugis sacked the capital. Until the acquisition of the state by Great Britain a triennial tribute of gold flowers was irregularly paid to Siam, and this with occasional letters of instructions and advice constituted almost the only evidence of Siamese suzerainty. Of government there was practically none. The revenues were devoured by the rajas. There were no written laws, no courts and no police. Crime was rampant, the peasantry was mercilessly downtrodden, but the land was full of holy men and the cries of the miserable were drowned in the noise of ostentatious prayer. Trengganu presented in 1909 the type of untrammelled Malay rule which had disappeared from every other state in the peninsula. In that year, however, the first British agent arrived in the state, which was shortly afterwards visited by the governor of the Straits Settlements, who discussed with the sultan the changed conditions consequent upon the Anglo-Siamese treaty and laid the foundations of future reform. In 1919 the agent was replaced by an adviser whose advice must be followed in all questions other than those touching the Mohammedan religion. While revenue came chiefly from opium and land taxes, and there was no poll or income tax, imposts were sufficient to be bitterly resented by the natives.

Kedah.—This state, on the west coast of the peninsula, lies between parallels 5° 20′ and 6° 42′ N., and is bounded, north by Palit and Songkla, east by Songkla and Raman, south by Province Wellesley and Perak, and west by the sea. The coast-line is 65 mi. long, the greatest distance from north to south is 115 mi. and the greatest breadth 46 mi. Off the coast lies a group of islands, the largest of which is Langkawi, well peopled and forming a district of the state.

The total area of Kedah is about 4,000 sq.mi. The land is lowlying and swampy near the coast except towards the south where the height known as Kedah peak rises from the shore opposite Penang, flat and fertile farther inland, and mountainous towards the eastern border. The rivers are small, the Sungai Kedah, navigable for a few miles for vessels of 50 tons, and the S. Muda, which forms the boundary with Province Wellesley, being the only streams worthy of notice. The plains are formed of marine deposit, and in the mountains limestone and granite preponderate. In 1941 the population was estimated at 520,719, of whom 337,456 were Malays, 107,223 Chinese, 61,161 Indians, 664 Europeans and 140 Eurasians. There are three towns of importance. Alor Star, the capital, on the Kedah river, 10 miles from the sea, in a flat, fertile locality, is a well laid out town with good streets, many handsome public and private buildings, and good wharfage for small vessels. Only three urban areas had a population of more than 5,000. Of these Alor Star might be classed as a Malay town and Sungai Patani and Kulim as Chinese centres of population. The bulk of the population is scattered over the plains in small villages. A good road runs from Alor Star to Penang and another south to Taiping in Perak. Bangkok and Singapore are now linked up by a railway system through Perlis. There is a good postal service. In 1938 there were 15 post and telegraph offices, and 588 mi. of road, of which 415 mi. were metalled. In addition, 225 mi. of canals were maintained by the administration. The chief industries are rice and rubber cultivation. In north Kedah rice is the main crop, in the south, rubber, coconuts and tapioca. There are many coconut, betel-nut and fruit plantations. The principal exports have been rubber, rice, tapioca and tin-ore. The chief imports have been cotton goods, tobacco and cigarettes, sugar and petroleum. The ruler held the rank of sultan and was assisted in the government by a council and by the British adviser who after the state passed from Siamese to British protection in 1909 replaced the officer formerly appointed by Siam. In 1905 the Siamese government advanced $2,500,000 to Kedah, to pay the debts of the state, which sum was refunded by the British government on assuming the position of protector. The revenue in 1940–41 was £1,124,108. The chief sources were customs, land revenue, the opium monopoly and excise taxes. The state was divided into a number of administrative districts under European and Malay officials. There were English schools at Alor Star and Sungai Patani, and 82 government boys' schools with an average enrolment of 11,733 pupils. There were also 24 royal boys' schools with 1,742 pupils. Secondary education was given at the Sultan Abdul Hamid college (438 enrolment).

In Kedah there have been found Sanskrit inscriptions going back to A.D. 400. An old name for the country was Langkasuka. There are references in Arab voyagers and in inscriptions at Negapatam and Tanjore to Kedah in the 10th and 11th centuries A.D. It seems clear that it was tributary to Buddhist Palembang and was ravaged by her enemies, the Chola kings. When the rise of Malacca shook Siamese authority in the peninsula, Kedah oscillated between them, and on the conquest of Malacca by the Portuguese, fell to Siam, though the capital was raided and burned by the Europeans. The ruler and his people were converted to Islam in the 15th century. In 1619 the king of Achin led into captivity the rulers of Kedah and Perak. In 1768, the

Siamese kingdom being disorganized, the sultan of Kedah entered into political relations with the East India company, leasing Penang to the latter. Further treaties followed in 1791 and 1802, but in 1821 Siam reasserted her control, expelling the rebellious sultan after a sanguinary war. The sultan made several fruitless efforts to recover the state, and at length made full submission, when he was reinstated. In 1868 an agreement between Great Britain and Siam was substituted for the treaties of the East India company with the sultan. In 1905 the Siamese government had to intervene to avert a condition of bankruptcy, adjusting the finances and reorganizing the general administration. Four years later, the state became a British dependency.

Perlis.—This small state, consisting of the left bank drainage area of the Perlis river, lies between Setul and Kedah, which bound it on the north and west and on the east respectively. It touches the sea only round the mouth of the river. Its area is about 316 sq.mi. In 1941 the total population was estimated at 57,289, of whom 45,959 were Malays, 8,147 Chinese, 1,126 Indians, 3 Europeans and 10 Eurasians. Kangar is the administrative headquarters of the state. A good deal of tin is worked; and rice, fish, eggs and poultry, rubber, cattle, copra, guano, betel-nuts and hides are exported. Rice is the main occupation, with 45,000 ac. under paddy as compared with 5,000 ac. under rubber and 3,800 planted to coconuts. In the early part of the 19th century Perlis was a district of Kedah, but during a period of disturbance in the latter state it established itself as a separate chiefdom. In 1897 Siam restored the nominal authority of Kedah. In 1905 the Siamese government advanced a loan of $200,000 to Perlis and appointed an English adviser to assist in the general administration. This money was refunded to Siam and the adviser relieved by a British officer when the state became British in July 1909. In 1940–41 the revenue was $480,000 (U.S.), of which customs provided more than half. At the end of 1940 there was an enrolment in the schools of 2,703 boys and 754 girls. The state had 35 mi. of metalled roads and 89 mi. of canals and rivers. There were two post offices (at Kangar and at Padang-Besar) and telephonic connection with the federation, Johore and Singapore.

Defense.—As a result of a wish frequently expressed by the Malays to have their own regiment replace the Indian battalion stationed at Taiping, an all-Malay unit of 700 men was garrisoned at Fort Dixon in 1932. Six years later a Malay sapper force was formed. In March 1939, the Malay sappers were increased by 1,000 men, so as to release units of the regular British army. Malays were also accepted in the Naval Volunteer reserve formed in September 1939; in 1941, 100 additional volunteers were recruited. While there were about four times as many Malays in the fighting forces in 1941 as there had ever been before, the strength of the Malay navy when war broke out in the Pacific was only about 800 men. A big step forward, however, was marked by the fact that most of their training was carried out by senior Malay ratings.

The Registration Enactment of 1921 theoretically ensured the registration of British manpower in the federal states. Yet in 1938, at the time when the F.M.S. Volunteer forces plan was completed, only a small percentage among the 12,000 European residents had registered. Deficiencies were officially noted in almost all the volunteer units. Two bills of June 7, 1940, were designed to call up batches of European British for intensive training, but they were incompletely carried out. Passive defense likewise suffered from the lack of a central organization and coherent policy.

In the period 1918–39, the federation contributed £2,300,000 towards imperial defense, and during World War II financed 40% of the local defense expenditures. In August 1940 the federal states raised a war loan of $20,000,000. A year later the federal council authorized the raising of an additional $10,000,000. (*See* World War II.)

(H. Cl.; V. Tn.)

MALAY STATES (Thai or Siamese). After 1909 the border between Malaya and Thailand (Siam) was at about 6° 30′ N. The 20,000 sq.mi. of territory between the border and the isthmus of Kra was inhabited chiefly by Malays and Thai. During the first part of the 20th century these states were semi-autonomous, under their own chieftains. By 1920 the northern states were incorporated into the administrative divisions of Chumpon, Nakhon Srithamarat and Puket. The states of the southern group retained their chieftains, chiefly Malay, till about the time of the 1932 revolution when they too were brought into a unified administration. Palawan, Satun (*q.v.*) and Patani (*q.v.*) were the chief southern states. The whole area was occupied by Japan in Dec. 1941. (*See* World War II.)

This area contains most of Thailand's tin and rubber production. The trend, therefore, similar to that in Malaya, was for the Chinese population to increase at the expense of the Malays. The area has been only partially developed agriculturally.

MALCOLM, the name of four kings of the Scots, two of whom, Malcolm I, king from 943 to 954, and Malcolm II, king from 1005 to 1034, are shadowy personages.

Malcolm III (d. 1093), called Canmore or the "large-headed," was a son of Duncan I, and became king after the defeat of the usurper Macbeth in 1054, being crowned at Scone in 1057. Having married as his second wife (St.) Margaret (*q.v.*), a sister of Edgar Aetheling, who was a fugitive at his court, he invaded England in 1070 to support the claim of Edgar to the English throne, returning to Scotland with many captives after harrying Northumbria. William the Conqueror answered this attack by marching into Scotland in 1072, whereupon Malcolm made peace at Abernathy. However, he ravaged the north of England again and again, until in 1091 William Rufus invaded Scotland and received his submission. Then in 1092 a fresh dispute arose and William summoned Malcolm to his court at Gloucester. The Scot obeyed, and calling at Durham on his southward journey was present at the foundation of Durham cathedral. When he reached Gloucester Rufus refused to receive him unless he did homage for his kingdom. Malcolm declined and almost at once invaded Northumbria. He was killed at a place afterwards called Malcolm's Cross, near Alnwick, Nov. 13, 1093. Four of Malcolm's sons, Duncan II, Edgar, Alexander I and David I, became kings of Scotland, and one of his daughters, Matilda, became the wife of Henry I of England, a marriage which united the Saxon and the Norman royal houses.

Malcolm IV (*c.* 1141–65) was the eldest son of Henry, earl of Huntingdon (d. 1152), son of King David I, and succeeded his grandfather, David, as king of Scotland in 1153. He died unmarried on Dec. 9, 1165.

See E. A. Freeman, *The Norman Conquest*, vols. iv and v (1867–79), and *The Reign of William Rufus* (1882); W. F. Skene, *Celtic Scotland* (1876–80); E. W. Robertson, *Scotland under Her Early Kings* (1862); and A. Lang, *History of Scotland,* vol. i (1900).

MALCOLM, SIR JOHN (1769–1833), Anglo-Indian soldier, diplomatist, administrator and author, was born in Dumfriesshire, Scotland, on May 2, 1769, the son of a farmer. He received a cadetship in the Indian army at the age of 12, and in April 1783 he landed at Madras, shortly afterwards joining his regiment at Vellore. He held various important appointments in India from 1792. In 1799 he became a friend of Lord Wellesley, who sent him as envoy to the Persian court to arrange an alliance with Great Britain. He negotiated favourable treaties at Tehran and returned to Bombay by way of Baghdad in May 1801. He then acted as private secretary to Lord Wellesley and in 1803 was appointed to the Mysore residency. At the close of the Mahratta War, in 1804, and again in 1805, he negotiated important treaties with Sindhia and Holkar, and in 1806, besides seeing the arrangements arising out of these alliances carried out, he directed the difficult work of reducing the immense body of irregular native troops.

In 1808 Malcolm was again sent on a mission to Persia. After his return to England he wrote his *History of Persia* (2 vols., 1815). On his return to India in 1817 he was appointed by Lord Moira his political agent in the Deccan; as brigadier-general under Sir T. Hislop he took a distinguished part in the victory of Mehidpur (Dec. 21, 1817), as also in the subsequent work of settling the country. In 1821 he returned once more to England, where he remained until 1827, when he was appointed governor of Bombay. His influence in this office was directed to the promotion of various economical reforms and useful administrative measures. Leaving India for the last time in 1830, shortly after his arrival in England he entered parliament as member for Launceston and opposed the Reform bill. He died on May 30, 1833.

Besides the work mentioned above, Sir John Malcolm published

Sketch of the Political History of India since . . . 1784 (in 1811 and 1826); *Sketch of the Sikhs* (1812); *Observations on the Disturbances in the Madras Army in 1809* (1812); *Persia, a Poem,* anonymous (1814); *A Memoir of Central India* (2 vol., 1823); and *Sketches of Persia,* anonymous (1827). A posthumous work, *Life of Robert, Lord Clive,* appeared in 1836. See *Life and Correspondence of Sir John Malcolm,* by J. W. Kaye (2 vol., 1856).

MALDA, a district of British India, in the Rajshahi division of Bengal. Area, 2,004 sq.mi.; pop. (1941), 1,232,618. The administrative headquarters are at English Bazar (pop. in 1941, 23,333) near the town of Old Malda. The district is divided into two almost equal parts by the Mahananda river, flowing from north to south. The western tract between the Mahananda and the main stream of the Ganges is an alluvial plain of sandy soil and great fertility. The eastern half is a slightly elevated region, called the Barind. The soil here is a hard red clay; and the whole is sparsely populated. Agricultural prosperity centres on the Mahananda, where mango orchards extend continuously along both banks; the mangoes of Malda have a wide reputation and demand. The principal industry is the production of silk. The weaving of piece goods has declined, but the rearing of silkworms and the export of raw silk and silk thread are carried on upon a large scale. The Godagari-Katihar section of the Eastern Bengal state railway traverses the district and has done much to develop it.

Malda supplied three capitals to the early Mohammedan kings of Bengal. The sites of Gaur and Pandua exhibit the most interesting remains to be found in the lower valley of the Ganges; the site of Tanda, the capital from about 1564 to 1595, was washed away by floods in 1826 and no trace of it remains. (*See* GAUR.) The connection of the East India company with Malda dates from an early period. As early as 1676 there was a factory there, and in 1770 English Bazar was fixed upon for a commercial residency.

MALDEN, a city of Middlesex county, Massachusetts, U.S.A., on the Malden river, 5 mi. N. of Boston. It is served by the Boston and Maine railroad. The population was 58,036 in 1930 (29% foreign-born white, largely from Russia, Canada, Ireland and Italy) and was 58,010 in 1940 by the federal census. It has an area of 4.8 sq.mi., and is almost surrounded by the cities of Melrose, Revere, Everett and Medford, with the Middlesex Fells (a state reservation) closing its boundary on the northwest. Malden is a residential suburb of Boston, with which it is connected by the Boston surface and elevated street railway system; and it has 175 highly diversified manufacturing industries, with an output in 1940 valued at $32,000,000. The city's assessed valuation for 1940 was $68,723,775. When first settled, in 1640, Malden was part of Charlestown and was known as Mystic Side. It was incorporated as the town of Mauldon (named after Maldon, England, the home of some of its founders) in 1649 and was chartered as a city in 1881. Melrose was set off from it in 1850; Everett in 1870. Malden was the birthplace of Adoniram Judson, and Michael Wigglesworth was its minister from 1656 to 1705. It was the first town to petition the colonial government to withdraw allegiance from King George.

MALDEN and COOMBE, a municipal borough in the parliamentary borough of Kingston, Surrey, England, 10 mi. from London on the Southern railway. Pop. (est. 1938) 38,820. Area, 4.94 sq.mi. Walter de Merton, lord chancellor of England, founded a college here in 1264 for the maintenance of 20 scholars at Oxford, where Merton college was founded about two years later. From 1894 to 1936, when they were incorporated as a borough, Malden and Coombe were governed by an urban district council. The district is mainly residential. A borough planning scheme is in force and building is rigidly regulated.

MALDIVE ISLANDS, an archipelago of coral islets in the Indian ocean, forming a chain between 7° 6′ N. and 0° 42′ S. It lies 400 mi. S.W. of Ceylon, and some 300 of the numerous islands in the 17 Maldivian atolls are inhabited. In the extreme south are the isolated atolls of Addu and Fua-Mulaku, separated from Suvadiva by the Equatorial channel, which is itself separated from the main chain of atolls by One-and-a-half-degree channel. Thence the chain continues northward to the Eight-degree channel, beyond which lies Minikoi, 71 mi. from the nearest point of the Maldives and 110 mi. from that of the Laccadives to the north. The main part, north of One-and-a-half-degree channel, consists of a series of banks either surrounded or studded all over with reefs.

After the Portuguese, from about 1518 onward, had attempted many times to establish themselves on the islands by force, and after the Maldivians had endured frequent raids by the Mopla pirates of the Malabar coast, they began to send tokens of homage and claims of protection (the first recorded being in 1645) to the rulers of Ceylon. The Maldive Islands are a dependency of the British colony of Ceylon. The hereditary sultan of the archipelago resides on the island of Malé, 3 mi. in circumference, which is the capital. The entire population of the Maldives (80,000 in 1939) is Mohammedan. The people have been classed in four ethnological divisions. (1) Those of the atolls north of the Kardiva channel. Here the people are more vigorous than their less warlike southern neighbours. They annually visited the coasts of India or Ceylon, and often married Indian wives, thus acquiring distinct racial characters of an approximately Dravidian type. (2) Those of the central division, under the direct rule of the sultan, and more exposed to Arab influences. They formerly traded with Arabia and Malaysia, and many Arabs settled among them, so that they betray a strong strain of Semitic blood in their features. (3 and 4) The natives of the southern clusters, who have had little communication with the Central Malé people, and probably preserve more of the primitive type, approximating in appearance to the Sinhalese villagers of Ceylon. The language is a dialect of Sinhalese, but indicating a separation of ancient date, and many of the Maldivians read Arabic with considerable fluency. They are an intelligent and industrious people. More than half of the men earn their livelihood as fishermen, going to sea in boats of their own building. Coir making is the industry second in importance. The finest quality of coir is found in the Tiladummati atoll. A large number of the people are also engaged in the manufacture of lace. The chief exports of the islands, besides coir, are coco-nuts, copra, millet and fruit.

Minikoi atoll, with the numerous wrecks on its reefs, and its lighthouse, is a familiar sight to seafarers in these waters. The atoll is growing outward on every side, and at one place it rises 19 ft. above sea level. The population, which numbers about 3,000, is divided into five castes, of which the three highest are pure Maldivians, the lower two the same as in the Laccadives. All are centred in a village opposite Mou Rambu Point, on the west or lagoon side; but most of the men are employed with the Lascar crews on large vessels plying in the eastern seas.

See F. W. Hockley, *A Short Account of the People, History and Customs of the Maldive Archipelago* (1935).

MALDON, a market town, municipal borough and port, in the Maldon parliamentary division of Essex, England, on the south side of the Blackwater, 43 mi. E.N.E. from London by the L.N.E.R. Pop. (1938) 9,012. Area 10.4 sq.mi. At Maldon (*Maelduna, Melduna, Mealdon* or *Meaudon*), finds of prehistoric objects indicate early settlement. An earthwork, of which traces exist, may be Saxon or Danish. The Anglo-Saxon Chronicle relates that Edward the Elder established a "burh" there about 921. Maldon was more remarkable for its fortress than for its commercial importance. It remained a royal town up to the reign of Henry I and thus is entered as being on *terra regis* in Domesday. Henry II granted the burgesses their first charter. In 1403 the bishop of London granted further judicial and financial rights. Maldon was incorporated by Philip and Mary in 1554, and in 1768 the incorporation charter was regranted, with modifications in 1810. The church of All Saints dates from 1056. Other public buildings are the grammar school, founded *c.* 1407; the town hall, formerly D'Arcy's tower, built in the reign of Henry VI; and the public hall. There are foundries, an oyster fishery and some shipping. On Osea island there is a farm colony for unemployed. Beeleigh abbey, 1 mi. W., a Premonstratensian house founded in 1180, is a residence in which the beautiful Early English chapter house, the warming house and dormitory are incorporated.

MALEBRANCHE, NICOLAS (1638–1715), French philosopher of the Cartesian school, the youngest child of Nicolas Malebranche, secretary to Louis XIII, and Catherine de Lauzon, sister of a viceroy of Canada, was born at Paris on Aug. 6, 1638.

Deformed and constitutionally feeble, he studied theology at the Sorbonne, and in 1660 he joined the congregation of the Oratory. In 1664 he read Descartes's *Traité de l'homme* (*de homine*). After ten years' study of the works of Descartes he produced the famous *De la recherche de la vérité où l'on traite de la nature, de l'esprit de l'homme et de l'usage qu'il doit faire pour éviter l'erreur dans la science* (1674), followed at intervals by other works, both speculative and controversial. Like most of the great metaphysicians of the 17th century, Malebranche interested himself also in questions of mathematics and natural philosophy, and in 1699 was admitted an honorary member of the Academy of Sciences. During his later years his society was much courted, and he received many visits from foreigners of distinction. He died on Oct. 13, 1715; his end was said to have been hastened by a metaphysical argument into which he had been drawn in the course of an interview with Bishop Berkeley. For a critical account of Malebranche's place in the history of philosophy, *see* CARTESIANISM. His other works include *Conversations métaphysiques et chrétiennes* (1677; Eng. trans., 1695); *Traité de la nature et de la grâce* (Amsterdam, 1680; Eng. trans., 1695); *Méditations chrétiennes et métaphysiques* (1683); *Traité de morale* (Rotterdam, 1684; Eng. trans. by Sir J. Shipton 1699); several polemical works against Arnauld from 1684 to 1688; *Entretiens sur la métaphysique et sur la religion* (1688); *Traité de l'amour de Dieu* (1697); *Entretiens d'un philosophe chrétien et d'un philosophe chinois sur l'existence et la nature de Dieu* (1708); *Réflexions sur la prémotion physique* (1715).

A critical edition of his *Oeuvres* was edited by Jules Simon (4 vols., 1871). This edition omits the *Traité de morale* (ed. H. Joly, 1882). *See* also Mrs. Norman Smith in the *British Journal of Psychology* (Jan. 1905); H. Joly, in the series *Les Grands philosophes* (1901); L. Ollé-Laprune, *La Philosophie de Malebranche* (2 vols., 1870); M. Novaro, *Die Philosophie des Nicolaus Malebranche* (1893); F. Pillon, articles on Malebranche's critics, and his correspondence with Mairan, in *L'Année philosophique* (1894).

MALER KOTLA, an Indian state, within the Punjab, one of the Cis-Sutlej states, under British influence since 1809. The territory lies south of Ludhiana. Area 165 sq.mi. Pop. (1941) 88,109. Estimated gross revenue, £64,875. The town Maler Kotla is 30 mi. S. of Ludhiana; pop. (1941) 29,321. The nawab or chief, is of Afghan descent; his family came from Kabul, and occupied positions of trust in Sirhind under the Mogul emperors. They gradually became independent as the empire decayed in the 18th century. In General Lake's campaign against Holkar in 1805 the nawab of Maler Kotla sided with the British. After the subjugation and flight of Holkar, the English government succeeded to the power of the Mahrattas in the districts between the Sutlej and Jumna; and in 1809 its protection was formally extended to Maler Kotla and other Cis-Sutlej states, against the formidable encroachments of Ranjit Singh. The state contributed handsomely to World War I; its sappers served with distinction in France and Mesopotamia then and in World War II also.

MALESHERBES, CHRETIEN GUILLAUME DE LAMOIGNON DE (1721–1794), known as Lamoignon-Malesherbes, French statesman, was born at Paris on Dec. 6, 1721, of a famous legal family. He studied law, and proved his capabilities as president of the *cour des aides* in the parlement of Paris in 1750, in succession to his father who was made chancellor. The chancellor's duty of controlling the press was entrusted to Malesherbes by his father, and made him known to the public. In 1771 the parlements of France were dissolved, and Maupeou's new method of administering justice substituted. Malesherbes remonstrated against the system, and was banished to his country seat at St. Lucie. He was recalled with the old parlement on the accession of Louis XVI. and made minister of the *maison du roi* in 1775. During his nine months of office he did much to check the practice of issuing *lettres de cachet*. On retiring from the ministry with Turgot in 1776 he travelled through Switzerland, Germany and Holland. In 1787 his essay on Protestant marriages helped to procure their civil recognition in France. He was elected a member of the Académie Française, and turned to scientific and literary pursuits, but the king summoned him back to the ministry in 1787. After a short term of office, he retired again into private life, and, as the troubles increased, went to Switzerland. In Dec. 1792, in spite of his old age and long retirement, he voluntarily undertook, with Tronchet and Desèze, the defence of the king before the Convention, and was required to break the news of his condemnation to the king. He then returned once more to the country, but in Dec. 1793 he was arrested and on April 23, 1794 guillotined, after seeing his daughter, his son-in-law, de Rosambo, and his grand-children executed for their relationship to him.

See *Oeuvres choisies de Malesherbes* (1809); F. A. de Boissy d'Anglas, *Essai sur la vie, les écrits et les opinions de M. de Malesherbes* (2 vols., 1818); de Beaucourt, *Captivité et derniers moments de Louis XVI.* (2 vols., 1892).

MALET, SIR EDWARD BALDWIN, 4th baronet (1837–1908), British diplomatist, 2nd son of Sir Alexander Malet, 2nd baronet, was born at The Hague on Oct. 10, 1837. He was educated at Eton, and entered the diplomatic service in 1854 at the age of 17. He served as attaché to his father at Frankfurt, returning to England to take his degree at Corpus Christi college, Oxford, in 1856. He then held various diplomatic posts at Brussels (1858), Paraná, Argentina (1860), Rio de Janeiro (1861), Washington (1861) and Lisbon (1865). Malet rejoined Lord Lyons, with whom he had worked in Washington, on the latter's transfer to Constantinople (1865). In 1867 he went to Paris, also with Lord Lyons, who sent him, after the battle of Sedan, on a mission to Count Bismarck, which resulted in Jules Favre's interview with Bismarck. For his services from March 19 to June 6, 1871, in charge of the Paris embassy while Lord Lyons was with the French Government at Versailles, Malet was awarded the C.B. He then held appointments as secretary of legation at Peking (1871), Athens, Rome (1875, becoming secretary to embassy in 1876), and Constantinople (1878). Owing to the ill-health of Sir A. H. Layard, Malet was given provisional rank as minister plenipotentiary.

In 1879 Malet became British agent and consul-general in Egypt. He held this post in 1881 during the revolt of the Egyptian army, and recommended intervention by Turkey under European control, or by France and Great Britain. When European diplomatic representatives moved to Alexandria, Malet did his utmost to reassure the Europeans. While engaged on plans for their protection, he was obliged by a sudden illness to return to England. He returned to Egypt on Aug. 10, and after the battle of Tal-el-Kebir (Sept. 13, 1882) obtained the commutation of the death sentence on the defeated Arabi to one of perpetual banishment. After helping Lord Dufferin to draw up and carry out his scheme of reorganization, he was promoted (Sept. 1883) to the post of British envoy at Brussels. In 1884 he was transferred as ambassador to Berlin, where he took part in many important negotiations during his 11 years in office. He was made G.C.M.G. in 1885, and G.C.B. in 1886. After his retirement in 1895 he was appointed (1899) a member of the international court of arbitration at The Hague. He succeeded his brother, Henry Charles Eden, in the baronetcy in 1904. He died at Chorley Wood, Hertfordshire, on June 29, 1908.

Malet published *Shifting Scenes* (1901). The memoir of his service in Egypt was completed from his correspondence after his death and privately circulated in 1909.

MALET, LUCAS, the pen-name of Mary St. Leger Harrison (1852–1931), English novelist, daughter of Charles Kingsley, born at Eversley on June 4, 1852. She studied at the Slade school and at University College, London, and married in 1876 William Harrison, rector of Clovelly. After her husband's death in 1897 she eventually settled in London. Her powerful story, *The Wages of Sin* (1891), attracted great attention, and her *History of Sir Richard Calmady* (1901) had an even greater success.

Her other novels include *Mrs. Lorimer* (1882); *Colonel Enderby's Wife* (1885); *A Counsel of Perfection* (1888); *The Carissima* (1896); *The Gateless Barrier* (1900); *On the Far Horizon* (1906); *Adrian Savage* (1911); *The Tall Villa* (1920); *The Survivors* (1923); *The Days of Want* (1926).

MALHERBE, FRANÇOIS DE (1555–1628), French poet, critic and translator, was born at Caen, the eldest son of another François de Malherbe, *conseiller du roi* in the magistracy of Caen.

He himself was educated at Caen, at Paris, at Heidelberg and at Basle. At the age of 21 he entered the household of Henri d'Angoulême, grand prior of France, the natural son of Henry II. He served this prince as secretary in Provence, and married there in 1581 Madelaine de Coriolis. After his patron's death he lived partly in Provence and partly in Normandy for many years, but very little is known of his life during this period. He was presented by his countryman, the Cardinal Du Perron, to Henry IV., and was at last summoned to court and endowed after one fashion or another. It is said that the pension promised him was not paid till the next reign. His father died in 1606, and he came into his inheritance. From this time forward he lived at court, corresponding affectionately with his wife, but seeing her only twice in some 20 years. His old age was saddened by a great misfortune. His son, Marc Antoine, a young man of promise, fell in a duel in 1626. His father used his utmost influence to have the guilty parties brought to justice, but he died before the suit was decided (it is said in consequence of disease caught at the camp of La Rochelle, whither he had gone to petition the king). Malherbe's first poem *Les Larmes de Saint Pierre* appeared in 1587. His poetical work is scanty in amount. The beautiful *Consolation à Duperier* (*c.* 1599), in which occurs the famous line—

"Et rose, elle a vécu ce que vivent les roses—"

the odes to Marie de' Medici and to Louis XIII., and a few other pieces comprise all that is really worth remembering of him. His prose work is much more abundant, not less remarkable for care as to style and expression, and of greater positive value. It consists of some translations of Livy and Seneca, and of a very large number of interesting and admirably written letters, many of which are addressed to Peiresc, the man of science of whom Gassendi has left a delightful Latin *Life*. It contains also the *Commentaire sur Desportes,* in which Malherbe's minute and carping style of verbal criticism is displayed on the great scale.

The personal character of Malherbe was far from amiable, but he exercised, or at least indicated the exercise of, a great and enduring effect upon French literature, though by no means a wholly beneficial one. The lines of Boileau beginning *Enfin Malherbe vint* are rendered only partially applicable by the extraordinary ignorance of older French poetry which distinguished that peremptory critic. But the good as well as bad side of Malherbe's theory and practice is excellently described by his contemporary and superior Regnier, who was animated against him, not merely by reason of his own devotion to Ronsard but because of Malherbe's discourtesy towards Regnier's uncle P. Desportes, whom the Norman poet had at first distinctly copied. These are the lines:—

Cependant leur savoir ne s'étend nullement
Qu'à régratter un mot douteux au jugement,
Prendre garde qu'un *qui* ne heurte une diphthongue,
Epier si des vers la rime est brève ou longue,
Ou bien si la voyelle à l'autre s'unissant
Ne rend point à l'oreille un vers trop languissant.
. . . .
C'est proser de la rime et rimer de la prose.

This is perfectly true, and from the time of Malherbe dates that great and deplorable falling off of French poetry in its more poetic qualities, which was not made good till 1830. Nevertheless the critical and restraining tendency of Malherbe was not ill in place after the luxuriant importation and innovation of the *Pléiade;* and if he had confined himself to preaching greater technical perfection, and especially greater simplicity and purity in vocabulary and versification, instead of superciliously striking his pen through the great works of his predecessors, he would have deserved wholly well. As it was, his reforms helped to elaborate the kind of verse necessary for the classical tragedy, and that is the most that can be said for him.

Malherbe's works were published two years after his death. He left behind him an unenviable reputation for acerbity in his relations with his contemporaries, but his influence as a critic was great and far reaching. He represents the reaction against the innovations of the Pléiade and the beginning of the strict French classical school.

The chief authorities for the biography of Malherbe are the *Vie de Malherbe* by his friend and pupil Racan, and the long *Historiette* which Tallemant des Réaux has devoted to him. The standard edition is that of Ludovic Lalanne (5 vols., 1862–69).

See A. Gasté, *La Jeunesse de Malherbe* (1890); G. Brunot, *La Doctrine de Malherbe* (1891); V. Bourrienne, *Points obscurs dans la vie normande de Malherbe* (1895); and the duc de Broglie's "Malherbe" in *Les Grands écrivains français.*

MALIBRAN, MARIE FÉLICITÉ (1808–1836), operatic singer, daughter of Manoel Garcia (*q.v.*), was born in Paris on March 24, 1808. Her father was then a member of the company of the Théâtre des Italiens, and she accompanied him to Italy and London. She possessed a soprano voice of unusual beauty and phenomenal compass, which was carefully cultivated by her father. She was only seventeen when she was suddenly asked to take Pasta's place in *The Barber of Seville* at Covent Garden. She was engaged for the remaining six weeks of the season, and then appeared in New York in *Othello, The Barber of Seville, Don Juan, Romeo and Juliet, Tancred.* Her gifts as an actress were on a par with her magnificent voice, and her gaiety made her irresistible in light opera, although her greatest triumphs were obtained in tragic parts. She married a French banker of New York, named Malibran, who was much older than herself. The marriage was an unhappy one, and Mme. Malibran returned alone to Europe in 1828, when she began the series of representations at the Théâtre des Italiens, which excited an enthusiasm in Paris only exceeded by the reception she received in the principal towns of Italy. She was formally divorced from Malibran in 1835, and married the Belgian violinist, Charles de Beriot. She died on Sept. 23, 1836.

See *Memoirs of Mme. Malibran by the comtesse de Merlin and other intimate friends, with a selection from her correspondence* (2 vols., 1840); M. Teneo, *La Malibran, d'après des documents inédits,* in *Sammelbände der internationalen Musik-Gesellschaft* (Leipzig, 1906); L. Héritte de la Tour, *Une famille de grands musiciens mémoires de Louise Héritte Viardot* (1923).

MALIC ACID, widely distributed in the vegetable kingdom in unripe apples (whence its name), in barberries, grapes, mountain ash berries, quinces and sorbapples. Its acid potassium salt is found in rhubarb. It is known in the form of colourless deliquescent needles readily soluble in water or alcohol, and is a hydroxysuccinic acid, $CO_2H{\cdot}CH(OH){\cdot}CH_2{\cdot}CO_2H$; it melts at 100° C and when maintained at 130° C it furnishes fumaric acid alone, but on rapid heating at 180° C maleic anhydride distils away leaving a residue of fumaric acid (*q.v.*).

Since malic acid contains one asymmetric carbon atom (*see* STEREOCHEMISTRY) it should exist in two optically active forms and one inactive racemoid modification. The acid from natural sources is *laevo*-malic acid; the racemoid acid arising in organic syntheses has been resolved into both *laevo-* and *dextro*-forms through the cinchonine salts. Among the simpler syntheses of inactive malic acid are (1) the action of hydrous silver oxide on bromosuccinic acid, (2) the reduction of racemic or tartaric acid (*q.v.*) with hydriodic acid, (3) the hydration of fumaric or malic acid.

MALIGNANT, wicked, of a malicious or wilfully evil disposition. The word was early applied by the Protestants to the Romanists, with an allusion to the "congregation of evil-doers" (Vulgate, *Ecclesiam malignantium*) of Psalm xxvi. 5. In English history, during the Great Rebellion, the name was given to the Royalists by the Parliamentary party. In the Great Remonstrance of 1641 occur the words "the malignant partie, whereof the archbishop (Laud) and the earl of Strafford being heads." The name throughout the period had special reference to the religious differences between the two parties. In medical science, the term "malignant" is applied to a particularly virulent or dangerous form which a disease may take, or to a tumour or growth of rapid growth, extension to the lymphatic glands, and recurrence after operation.

MALIGNITE, a phaneric igneous rock composed principally of orthoclase, aegerine-augite, and biotite, with melanite, nephalite, sphene, etc. It resembles basalts, and was named by Lawson (1896) from the Maligne river, Canada.

MALINES (Flemish, *Mechlin*), an ancient and important city, and the seat since 1559 of the only Belgian archbishopric. Pop. (est. 1939) 62,339. It is on the Dyle in the province of Antwerp, about half-way between Antwerp and Brussels. The archbishop is the primate of the country The archbishop's palace is in a picturesque situation, and dates from the creation of the see. The fine cathedral dedicated to St. Rombaut was begun in the 12th and finished early in the 14th century, and modified in the 15th after a fire. The massive tower of over 300 ft., which is described as unfinished because the original intention was to carry it to 500 ft., is its most striking external feature. The cathedral contains a fine altar-piece by Van Dyck. The old palace of Margaret of Austria, regent for Charles V, has been preserved and is now a court of justice. In the church of Our Lady (16th century) is Rubens' masterpiece "the Miraculous Draught of Fishes," and in that of St. John is a fine triptych by the same master. Malines, although no longer famous for its lace, carries on a large trade in linen, needles, furniture and oil; it is a great junction for the lines Ghent-Liége and Antwerp-Brussels and has large state railway-works.

The lordship of Malines was conferred as a separate fief by Pippin the Short on his kinsman Count Adon in 754. In the 9th century Charles the Bald bestowed the fief on the bishop of Liége, and it passed to Philip the Bold, of Burgundy, in 1384. During the religious troubles of the 16th century Malines suffered greatly, and in 1572 it was sacked by Alva's troops during three days. In the wars of the 17th and 18th centuries it was besieged many times and captured by the French, Dutch and English on several occasions. The French finally removed the fortifications in 1804, since which year it has been an open town.

Malines was bombarded three times during World War I and seriously damaged. The law courts, restored shortly before the war, the school of music, and the picturesque houses round the Yzeren Leeh were ruined, and the south side of the cathedral of St. Rombaut and the chimes badly damaged. The Cloth Hall, also restored before the war, was, afterwards, used as the Town hall. Conferences were held there, 1921–25, between Cardinal Mercier, Archbishop of Malines, and some dignitaries of the Church of England, to further a reunion of the churches.

In World War II, the British expeditionary forces first met the Germans in the vicinity of Malines. The fall of Malines led to the speedy capture of Antwerp and Brussels.

MALINKÉ, the name of a tribe, formerly commonly called Negroid, of west Sudan. Malinké is a general term covering many individual divisions of speech and tribe. The languages spoken are divided into (*a*) Malinké proper (Eastern Malinké), used throughout the length of the Upper Niger above Bamako and between Niger and Bafing; (*b*) Xasonké, usually called Northern Malinké in the Kayes region; (*c*) Western Malinké on the Gambia and (*d*) Southern Malinké on the edge of the dense forests. These languages belong to the Nigero-Senegalese group of tongues, as does the *lingua franca* of the region *Kăgbe* or "white language" (*cf.* Chinese 白話, "white speech," for vernacular). The people and their language are mentioned by El Bakri (11th century), Ibn Batuta (14th century) and by Ibn Khaldun (17th century). For the physical and other characteristics of the Malinké, *see* AFRICA: *Anthropology and Ethnology.*

MALIPIERO, G. FRANCESCO (1882–), Italian composer, was born in Venice on March 18, 1882. He studied under Bossi in Venice, and in 1902 followed him to Bologna. Later he went to Paris, but his strong individuality prevented him from attaching himself to any school. Since 1921 he has been professor of composition at Parma conservatoire. Malipiero is one of the most advanced of Italian composers. One of his aims is to achieve the perfect fusion of music and drama, and his experiments in this direction have aroused great interest and much criticism. In *Pantea,* a symphonic drama for a dancer with invisible chorus and orchestra, the dancer's movements represent, it is claimed, the "moods of the soul." *Sette Canzoni,* perhaps his best achievement so far, is now included with the two dramas *La morte delle maschere* and *Orfeo* in a trilogy under the title *L'Orfeide.* It is divided into episodes, each with a *canzone* as its central feature and mimic action for the setting. But this *canzone* is not a song created for stage requirements but one which has a natural place in scenes of real life. Other dramatic works are: *Ellen e Fuldano, San Francesco d'Assisi, Sogno d'un tramonto d'autunno, Canossa,* and *La mascherata delle principesse.* He has also written four symphonies, *Impressione dal vero* (2 sets, 1911, 1914), *Ditirambo tragico* (1917), *Armenie* (1917), *Per una favola cavalleresca* (1921), *Oriente immaginario,* and *Grottesco* for orchestra; a string quartet: *Rispetti e strambotti* (Coolidge prize 1920); songs, and piano pieces; as well as a number of literary works including the texts of his four operas, a monograph on the Orchestra, and articles on musical subjects in the *Rivista musicale italiana.*

MALLARMÉ, FRANÇOIS RENÉ AUGUSTE (1755–1835), French revolutionary, was born at Nancy on Feb. 25, 1755. He was brought up in his father's profession as a lawyer, and was appointed *procureur-syndic* of the district of Pont-à-Mousson. During the Revolution, he was elected by the department of Meurthe deputy to the Legislative Assembly and the Convention, where he joined the Mountain and voted for the death of Louis XVI. He was made president of the Convention on May 30, 1793, and by his weakness contributed to the fall of the Girondins. In November he was sent to establish the revolutionary government in the departments of Meuse and Moselle. After Robespierre's fall he joined the "Thermidorians," and was sent on a mission to the south of France, where he set free a number of "suspects." On June 1, 1795 he was arrested, but soon set free. He held office both under the directory and the empire. Appointed sub-prefect of Avesnes during the Hundred Days he was imprisoned by the Prussians in revenge for the sentence of death carried out by his orders on some young girls at Verdun who had offered flowers to the Prussians when they entered the town (1793). He lived in exile during the Restoration, returned to France after 1830, and died at Richemont (Seine-Inférieure) on July 25, 1835.

MALLARMÉ, STÉPHANE (1842–1898), French poet and theorist, was born at Paris, on March 18, 1842. His life was simple and without event. His small income as professor of English in a French college was sufficient for his needs, and, with his wife and daughter, he divided the year between a fourth-floor flat in Paris and a cottage on the banks of the Seine. His Tuesday evening receptions, which did so much to form the thought of the more interesting of the younger French men of letters, were almost as important a part of his career as the few carefully elaborated books which he produced at long intervals. *L'Après-midi d'un faune* (1876) and other fragments of his verse and prose had been known to a few people long before the publication of the *Poésies complètes* of 1887, in a facsimile of his clear and elegant handwriting, and of the *Pages* of 1891 and the *Vers et prose* of 1893. His remarkable translation of poems of Poe appeared in 1888, "The Raven" having been published as early as 1875, with illustrations by Manet. *Divagations,* his own final edition of his prose, was published in 1897, and a more or less complete edition of the *Poésies,* posthumously, in 1899. He died at Valvins, Fontainebleau, on Sept. 9, 1898. All his life Mallarmé was in search of a new aesthetic, and his discoveries by the way were often admirable. But he was too critical ever to create freely, and too limited ever to create abundantly. His great achievement remains unfinished, and all that he left towards it is not of equal value. There are a few poems and a few pieces of imaginative prose which have the haunting quality of Gustave Moreau's pictures, with the same jewelled magnificence, mysterious and yet definite. His later work became more and more obscure, as he seemed to himself to have abolished limit after limit which holds back speech from the expression of the absolute. Finally, he abandoned punctuation in verse, and invented a new punctuation, along with a new construction, for prose. Patience in the study of so difficult an author has its reward. No one in our time has vindicated with more pride the self-sufficiency of the artist in his struggle with the material world. To those who knew him only by his writings his conversation was startling in its clearness; it was always, like all his work, at the service of a few dignified and misunderstood ideas. (A. Sy.)

Gosse, *French Profiles* (1905) and A. Symons, *The Symbolist Movement in Literature* (1900); A. Ellis, *Stéphane Mallarmé in English Verse,* introd. by G. Turquet-Milnes (1927). A bibliography is given in the *Poètes d'aujourd'hui* (1880–1900, 11th ed., 1905) of MM. A. van Bever and P. Léautaud.

MALLAWAN, a town in Hardoi district, the United Provinces, India. Pop. (1941) 11,084. Under native rule the town possessed considerable political importance, and upon the British annexation of Oudh in 1856 it was selected as the headquarters of the district. After the Mutiny, however, it was abandoned in favour of Hardoi, and in recent times its population has shown a steady decrease. Saltpetre and brass utensils are manufactured, and in the town is to be found a branch of the Board of Foreign Missions of the Methodist Episcopal Church of the United States.

MALLEABLE CAST IRON: *see* CAST-IRON.

MALLECO, an inland province of southern Chile, lying between the provinces of Bío-Bío and Cautín. Area 5,512 sq.mi.; pop. (1940) 154,174. It is in the rainy, forested region of southern Chile, inhabited to a considerable extent by Araucanian Indians. Gold placer mining has attracted some attention, but the output is small. Principal industries are cattle and wheat raising and timber-cutting. The State central railway crosses the province, and the capital (Angol) is served by a branch line.

MALLESON, GEORGE BRUCE (1825–1898), Indian officer and author, born at Wimbledon, on May 8, 1825. He obtained a cadetship in the Bengal infantry in 1842, and served through the second Burmese War. He attracted attention by his "Red Pamphlet" (1857), before the outbreak of the mutiny. He retired with the rank of colonel in 1877. He died at Kensington, on March 1, 1898. He continued, and considerably rewrote the *History of the Indian Mutiny* (6 vols., 1878–80), left unfinished by Sir John Kaye. He also wrote: *History of the French in India* (2nd ed., 1893) and *The Decisive Battles of India* (3rd ed., 1888).

MALLET or **MALLOCH, DAVID** (?1705–1765), Scottish poet and dramatist, the son of a farmer, was born in Perthshire, probably in 1705. He went to school in Edinburgh, and in 1720, to Edinburgh university, where he made the friendship of James Thomson, author of *The Seasons.* Short poems by Mallet appeared in the *Edinburgh Miscellany,* and in Allan Ramsay's *Tea Table Miscellany,* in which his ballad "William and Margaret" was published in 1724. In this year he changed his name from Malloch to Mallet. He travelled for some years as private tutor to the duke of Montrose's sons, and in 1742 through Pope's influence was appointed secretary to the prince of Wales. For his services as a pamphleteer for the Tory party, Lord Bute gave him a lucrative sinecure in 1760. He died on April 21, 1765. In 1740, in collaboration with Thomson, Mallet produced the masque *Alfred* (containing the patriotic song "Rule, Britannia"); in 1751 after Thomson's death, he published a new version, claiming that it was almost entirely his own work.

A collection of his *Works* appeared in 1759 (3 vols.). His *Ballads and Songs* were edited by F. Dinsdale, with notes and a biographical memoir, in 1857.

MALLET DU PAN, JACQUES (1749–1800), French journalist, was born near Geneva. Voltaire obtained him a professorship at Cassel, which, however, he soon resigned. He joined Linguet (*q.v.*) in London, in the production of his *Annales politiques* (1778–1780), and during Linguet's imprisonment in the Bastille (1781–83) continued them himself. Linguet resented this, and Mallet du Pan changed the title of his publication to *Mémoires historiques* (1783), which he incorporated with the *Mercure de France* in Paris from 1783. He sided with the Royalists at the Revolution, and was sent by Louis XVI on a mission to the German princes (1791–2). His anti-revolutionary pamphlets, and a violent attack on Bonaparte and the Directory resulted in his exile in Berne (1797). In 1798 he came to London and founded the *Mercure britannique.* He died at Richmond, Surrey, on May 10, 1800. Mallet du Pan was a pioneer of modern political journalism.

Mallet du Pan's *Mémoires et correspondance* was edited by A. Sayous (1851). *See* also B. Mallet, *Mallet du Pan and the French Revolution* (1902).

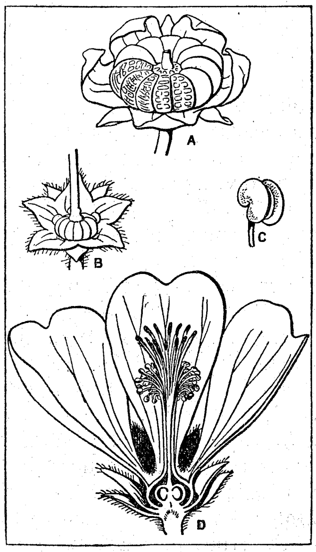
MALLING, EAST and **WEST,** two villages of Kent, England, respectively 5 and 6 mi. W. by N. of Maidstone. Pop. (1931) East Malling, 2,305; West Malling, 2,373. East Malling has large paper mills and there is an important horticultural research station. At West Malling are remains of Malling abbey, a Benedictine nunnery founded in 1090 by Gundulf, bishop of Rochester. The remains, partly incorporated in a modern building, include the Norman west front of the church, the Early English cloisters, the chapter-house and gate-house (the chapel of which is restored to use). About Addington, near West Malling, are considerable prehistoric remains, including mounds, single stones, stone circles and pits in the chalk hills; while at Leybourne are the gateway and other fragments of a mediaeval castle.

MALLOCK, WILLIAM HURRELL (1849–1923), English author, was born at Cockington Court, Devonshire. He was educated privately, and at Balliol college, Oxford. He attracted considerable attention by his satirical story *The New Republic* (2 vols., 1877), in which he introduced characters easily recognized as prominent living men, Mark Pattison, Matthew Arnold, W. K. Clifford and others. In a series of books dealing with religious questions he insisted on dogma as the basis of religion and on the impossibility of founding religion on purely scientific data. In *Is Life Worth Living?* (1879) and *The New Paul and Virginia* (1878) he attacked Positivist theories, and in *Doctrine and Doctrinal Disruption* (1900) he advocated the necessity of a strictly defined creed. Later volumes on similar topics were *Religion as a Credible Doctrine* (1903) and *The Reconstruction of Belief* (1905). Among his anti-socialist works there should be classed his novel, *The Old Order Changes* (1886). His other novels include *A Romance of the Nineteenth Century* (1881), *A Human Document* (1892), *The Heart of Life* (1895) and *The Veil of the Temple* (1904). He published a volume of *Poems* in 1880, and in 1900 *Lucretius on Life and Death* in verse. Mallock died at Wincanton, Somerset, on April 2, 1923.

MALLOW, a town and watering place of co. Cork, Eire, on the Blackwater, 144½ mi. S.W. from Dublin, and 21 N. from Cork by the Great Southern railway. Pop. (1936) 4,948. The town possesses a tepid mineral spring and a spa-house. There are manufactures of mineral water and condensed milk, corn-mills and tanneries. Mallow received a charter of incorporation from James I. Its name was originally Magh Allo, that is, Plain of the Allo (the old name used by Spenser for this part of the river), and the ford was defended by a castle, built by the Desmonds, the ruins of which remain. A bridge connects the town with the suburb of Ballydaheen. Mallow is a centre for salmon fishing on the Blackwater.

MALLOW, any plant of the family Malvaceae, especially of the genera *Hibiscus* (*q.v.*) and *Malva,* the latter embracing about 30 species of annual and perennial herbs, widely distributed throughout the northern hemisphere. The mallows possess the reniform one-celled anthers which specially characterize the Malvaceae (*q.v.*). The petals also are united by their base to the tube formed by the coalesced filaments of the stamens. The special characters which separate the genus *Malva* from others most nearly allied to it are the involucre, consisting of a row of three separate bracts attached to the lower part of the true calyx, and the numerous single-seeded carpels disposed in a circle around a central axis, from which they become detached when ripe. The flowers are mostly white or pinkish, never yellow, the leaves radiate-veined and more or less lobed or cut. Three species are found in Britain. The musk mallow (*Malva moschata*) is a perennial herb with five-partite, deeply cut leaves and large rose-coloured flowers clustered together at the ends of the branched stems and is found growing along hedges and borders of fields, blossoming in July and August. It owes its name to a slight musky odour diffused by the plant in warm dry weather when it is kept in a confined situation. The round-leaved dwarf mallow (*Malva neglecta*) is a creeping perennial growing in waste sandy places, with roundish serrate leaves and small pinkish-white flowers produced in the axils of the leaves from June to September. It is common throughout Europe and the north of Africa, extending to western and northern Asia. The common mallow (*Malva sylvestris*), the *mauve* of the French, is an erect biennial or perennial plant with long-stalked roundish-angular serrate leaves, and conspicuously axillary reddish-purple flowers, blossoming from May to September. Like most plants of the order it abounds in mucilage, and hence forms a favourite domestic remedy for colds and sore throats. The aniline dye called mauve derives its name from its resemblance to the colour of this plant. Besides the foregoing three other species have become naturalized in various parts of North America.

The marsh mallow (*Althaea officinalis*), the *guimauve* of the French, belongs to the same genus as the hollyhock (*q.v.*). (For rose mallow, *see* HIBISCUS.) The mallow of Scripture, Job xxx 4, has sometimes been identified with Jew's mallow (*Corchorus olitorius*), a member of the allied family Tiliaceae, but more plausibly with *Atriplex halimus,* the sea orache of Europe. Once widely used in medicine, mallows are no longer considered of value.



FROM GROOM, "ELEMENTARY BOTANY" (G. BELL & SONS)

MALLOW (MALVA SYLVESTRIS)

A. Fruit. B. Portion of the flower showing calyx, epicalyx and part of style. C. Upper part of stamen, showing opening of anther. D. Vertical section of flower

MALMÉDY, a small town acquired by Belgium from Germany through the treaties after 1918, lying in a wild and deep basin, on the Warche, 20 mi. S. of Aix-la-Chapelle by rail via Eupen. Pop. (est. 1939) 5,913. (*See* EUPEN AND MALMÉDY.)

MALMESBURY, JAMES HARRIS, 1ST EARL OF (1746–1820), English diplomatist, was born at Salisbury on April 21, 1746, who was the son of James Harris, the author of *Hermes.* Educated at Winchester, Oxford and Leyden, he became secretary in 1768 to the British embassy at Madrid, then minister *ad interim,* and in 1772 minister plenipotentiary to the court of Prussia. In 1777 he was transferred to the court of Russia, where he made his reputation, for he managed to get on with Catherine in spite of her predilections for France, and steered adroitly through the accumulated difficulties of the first Armed Neutrality. He was made a knight of the Bath in 1778, but in 1782 returned home owing to ill-health, and was appointed by his friend Fox to be minister at The Hague. He furthered Pitt's policy of maintaining England's influence on the Continent by the arms of her allies, and held the threads of the diplomacy which ended in the king of Prussia's overthrowing the republican party in Holland, which was inclined to France, and re-establishing the prince of Orange. He was created Baron Malmesbury of Malmesbury (Sept. 1788), and permitted by the king of Prussia to bear the Prussian eagle on his arms, and by the prince of Orange to use his motto "Je maintiendrai." He returned to England, and seceded from the Whig party with the duke of Portland in 1793; and in that year he was sent by Pitt, but in vain, to try to keep Prussia true to the first coalition against France. In 1794 he was sent to Brunswick to solicit the hand of the unfortunate Princess Caroline for the prince of Wales. In 1796 and 1797 he was at Paris and Lille vainly negotiating with the French Directory. In 1800 he was created earl of Malmesbury, and Viscount Fitzharris, of Heron Court in the county of Hants. He was now consulted by successive foreign ministers, trusted by men of the most different ideas in political crises, and was above all the confidant, and for a short time after Pitt's death almost the political director, of Canning. Lord Palmerston, who was his ward, derived many of his ideas on foreign policy from him. Malmesbury died on Nov. 21, 1820, and was succeeded as 2nd earl by his son James Edward (1778–1841), under-secretary for foreign affairs under Canning. Malmesbury only published an account of the Dutch revolution, and an edition of his father's works, but his important *Diaries* (1844) and *Letters* (1870) were edited by his grandson.

MALMESBURY, JAMES HOWARD HARRIS, 3RD EARL OF (1807–1889), English statesman, son of the 2nd earl, was born on March 25, 1807, and educated at Eton and Oriel college, Oxford. In 1841 he had only just been elected to the House of Commons as a Conservative when he succeeded to the peerage. His political career attracted a good deal of attention, partly from his being foreign secretary in 1852 and again in 1858–59 (he was also lord privy seal in 1866–68 and in 1874–76), and partly from his influential position as an active Tory of the old school in the House of Lords at a time when Lord Derby and Disraeli were, in their different ways, moulding Conservatism. His *Memoirs of an Ex-Minister,* published in 1884, remain his chief title to remembrance.

MALMESBURY, a market town and municipal borough in the Chippenham parliamentary division of Wiltshire, England, 94½ mi. W. of London by the Great Western railway. Pop. (est. 1938) 2,272. Area, 178 ac. Maildulphus, a Scottish or Irish monk, built a hermitage near the site of the modern Malmesbury (Maildulphi-urbs, Maldelmesburh, Malmesbiri) about 635, and formed the nucleus of the later abbey of which Aldhelm, his pupil, became the first abbot. Aethelstan, who was buried there, rebuilt and endowed the monastery. Round the abbey the town of Malmesbury grew up, and by the time of the Domesday survey it had become one of the only two Wiltshire boroughs. The first charter purports to have been given by Aethelstan. It granted to the burgesses all privileges and free customs such as they held in the time of Edward the Elder, with additional exemptions, in return for help against the Danes. The castle of Henry I gave a further impetus to the growth of the town. In 1645 it was made a free borough under the title of "aldermen and burgesses of the borough of Malmesbury, County Wilts." By this charter it was governed until 1885. The borough returned two members to parliament from 1295 to 1832 and one member from then until 1885. In the middle ages the town possessed a considerable cloth manufacture, and at the Dissolution the abbey was bought by a rich clothier and fitted with looms for weaving. The trade in wool still flourished in 1751.

It lies on a ridge surrounded on all sides except the north-west by the river Avon and a small tributary. The church of St. Peter and St. Paul consists of the greater part of the nave (with aisles) of a Benedictine abbey church. The ruins of the great tower arches now terminate the building eastward. The nave is transitional Norman, with a Decorated superstructure including the clerestory. The south porch is Norman. With the exception of a crypt, the monastic buildings have disappeared. In the market square stands a fine market cross of the 16th century, borne upon an octagonal battlemented basement. Early English fragments of a hospital of St. John of Jerusalem appear in the corporation almshouse. Malmesbury has an agricultural trade, and small manufactures of silk and pillow lace.

MALMGREN, FINN (1895–1928), Swedish meteorologist, was born at Falun. He matriculated at Stockholm at the age of 16, and went to Uppsala university, afterwards becoming assistant to Professor Hamberg at his observatory at Portetjäkko. After a short period at the meteorological institute at Uppsala, Malmgren was appointed assistant professor at Pettersson's hydrographic institute for oceanic studies at Bornö. In 1922 he joined Amundsen in the second stage of his voyage in the North Polar Basin, and acted for three years as meteorologist to the expedition under Dr. H. U. Sverdrup. As a result of his studies during the voyage he took his degrees of Master, and later Doctor, of Science on his return. In 1926 he flew across the North Polar Basin in the airship Norge, and Amundsen's official account of the expedition contains a chapter by him on "Weather and Weather Warnings during the Polar flight." He gave up a post as lecturer and curator at Vastmanlands Dala College to become meteorologist of the Expedition under General Nobile, which sailed in the airship Italia for the North Pole.

After passing over the North Pole on May 24, 1928, the following day the Italia crashed on to the ice, and Malmgren was severely injured. Ten of the party were thrown out on to the ice, and the remainder were carried away in the airship. On May 30, realizing that the injuries of Nobile and Ceccioni made it impossible for them to walk, and believing that a small party would have some chance of reaching Cape North, Malmgren set out with Mariano and Zappi. When they reached Brock island about June 15, Malmgren's legs were frostbitten and he was unable to walk any further. Mariano and Zappi stayed with him for some time, and then, at his own request, dug a trench and left him. He gave his life in order that his two companions might reach Cape North and so obtain provisions for the rest of the expedition. They were picked up by an aeroplane on July 13. A professorship at the university of Uppsala was founded as a memorial to Malmgren.

MALMÖ, a seaport of Sweden, chief town of the district (*län*) of Malmöhus, on a small bay of the Sound, 384 m. S.S.W. of Stockholm by rail. Pop. (1800), 38,054; (1943), 159,708.

Malmö (Malmhauge, Malmey, Malmöye, Malmoughe), sometimes called *Ancona Scanorum* or *Ellenbogen,* first appears in history about the middle of the 13th century. During the Hanseatic period it was the most important commercial town on the Sound, but in the 16th and 17th centuries greatly lost ground owing to the decay of its herring fisheries and the rise of its rival, Copenhagen. It began to revive in the late 18th century.

It is connected with Copenhagen, 17¼ m. W. by N., by steam-ferry, the Sound being kept open in winter by an ice-breaker. It is also the first important station in Sweden on the Berlin–Stockholm route, which crosses the sea between Sassnitz in Rügen and Trelleborg 20 m. S.E. of Malmö. The town formerly had strong fortifications, of which only the citadel (Malmöhus) remains; in it the earl of Bothwell was imprisoned by Frederick II. of Denmark for some time after his departure from Scotland in 1567. The town-hall (1546, largely restored in 1864) contains a handsome chamber, the Knutssal, formerly used by the council of the gild of Canute. The church of St. Peter (*Peterkyrka*) dates in part from 1319. Malmö is second to Stockholm as an industrial centre. There are breweries and large works for the manufacture of machinery, among which are the Kockum mechanical works, with yards for the construction of vessels of war, and others; of cotton and woollen goods, rubber factories, sugar factories, gloves, chocolate, sweetmeats and tobacco. Malmö is a free port. It has a large export trade in grain, timber, cattle, flour, butter, cheese, matches, wood-pulp, etc. The imports are coal, manufactures, cotton, chemicals, iron, herring, manures, grain, etc. The harbourage includes an outer harbour of 22 ft. depth, and two inner basins admitting vessels of 21 ft. draught, with dry dock and patent slip. Malmö returns four members to the second chamber of the Riksdag (parliament).

MALMSEY (mahm'zĭ), a strong sweet wine, originally made at Monemvasia, Napoli di Malvasia, in Greece. The name of the place was corrupted in Med. Lat. into *malmasia,* whence the English form of the word. The corruption malvasia gives the O. Fr. *malvesie,* from which comes the alternative English form "malvoisie." The wine is now made more in Spain and Madeira than in Greece.

MALOCELLO, LANCILOTO ("LANZAROTE, the 'Lancelot Maloisiel' of the French"), leader of the first of modern European oceanic enterprises. This was a Genoese expedition, which about 1270 seems to have sailed into the Atlantic, re-discovered the "Fortunate Islands" or Canaries, and made a settlement in one of the most northerly isles of this archipelago, still known (after the Italian captain) as Lanzarote. "Lancarote" is said to have been killed by the Canarian natives; but the castle built by him was standing in 1402–1404, when it was utilized for the storage of grain by the French conquerors under Gadifer de la Salle. Malocello's enterprise is probably not unconnected with the great Genoese venture of 1291 in search of a waterway to India.

See the *Conosçimiento,* p. 100, as edited by Marcos Jimenez de la Espada in the *Boletin de la sociedad geográfica de Madrid* (February 1877); *Le Canarien* in P. Margry, *Conquête des . . . Canaries,* p. 177; M. A. P. d'Avezac in vol. vi., part ii., of *L'Univers,* pp. 1–41 (*Iles africaines de l'océan atlantique*); C. R. Beazley, *Dawn of Modern Geography,* iii. 411–413, 449, 451.

MALOLOS, a municipality (with administrative centre and 45 *barrios* or districts) and capital of the province of Bulacan, Luzon, Philippine islands, on a branch of the Pampanga river and on the Manila-Dagupan railway. Pop. (1939) 33,384; six whites. During the revolution against the U.S., the insurgent congress met there and framed and proclaimed the "Malolos Constitution." In March 1899 the town was captured by the United States forces. It is a commercial centre of some importance, and palay (rice) is cultivated extensively in the surrounding region. Tagalog is the vernacular. Of the inhabitants aged 6 to 19 inclusive, 46·9% were reported in 1939 as attending school; while 67·4% of the population 10 years old and over was reported as literate.

MALONE, EDMUND (1741–1812), Irish Shakespearian scholar and editor, was born in Dublin, on Oct. 4, 1741, the son of a barrister and a member of the Irish House of Commons. He was educated at Trinity college, Dublin, and was called to the Irish bar in 1767. On the death of his father in 1774 he went to London, where he frequented literary and artistic circles. He frequently visited Dr. Johnson and was of great assistance to Boswell in revising and proof-reading his *Life,* four of the later editions of which he annotated. He was one of Sir Joshua Reynolds's executors, and published a posthumous collection of his works (1798) with a memoir. Horace Walpole, Burke, Canning, Lord Charlemont, and, for a time, George Steevens, were among Malone's friends. Encouraged by the two last he devoted himself to the study of Shakespearian chronology, and the results of his "Attempt to ascertain the Order in which the Plays of Shakespeare were written" (1778) are still largely accepted. This was followed in 1780 by two supplementary volumes to Steevens's version of Dr. Johnson's *Shakespeare;* and this again, in 1783, by an appendix volume. The seven years (1785–92) were devoted to Malone's own edition of Shakespeare in 11 volumes.

Malone published a denial of the claim to antiquity of the Rowley poems (*see* CHATTERTON, THOMAS), and in this (1782) as in his branding (1796) of the Ireland mss. (*see* IRELAND, WILLIAM HENRY) as forgeries, he was among the first to guess and state the truth. His elaborate edition of Dryden's works (1800), with a memoir, was another monument to his industry, accuracy and scholarly care. At the time of his death, on April 25, 1812. Malone was at work on a new octavo edition of Shakespeare, and he left his material to James Boswell the younger; the result was the edition of 1821—generally known as the Third Variorum edition—in 21 volumes.

A memoir of Malone by James Boswell is included in the *Prolegomena* to the edition of 1821. *See* also Sir J. Prior, *Life of Edmond Malone* (1860).

MALONE, a village of northeastern New York, U.S.A., the county seat of Franklin county; on the Salmon river, 10 mi. from the Canadian border, and served by the New York Central and the Rutland railways. Pop. (1920), 7,556 (91% native white); 8,743 in 1940, federal census. It is in the northern foothills of the Adirondacks, at an altitude of 780 ft., and is a centre for excursions into the Great North woods. It has paper, pulp and lumber mills, and other important manufacturing industries. The village (settled about 1805) was at first called Harison and then Ezraville, before adopting its present name in 1812. It was incorporated in 1833. During the War of 1812 it was a point of strategic importance, as it was on the line of communication between Lakes Champlain and Ontario, and later it was twice the rendezvous of Fenians for attacks on Canada.

MALONIC ACID crystallizes in large colourless plates, dissolving readily in water, alcohol or ether, and melts at 135·6° C. Although the sparingly soluble calcium malonate occurs in beetroot, the acid itself, $HO_2C{\cdot}CH_2{\cdot}CO_2H$, is generally produced by laboratory methods, such as the oxidation of malic acid (*q.v.*) or the hydrolysis of cyanoacetic acid, $CN{\cdot}CH_2{\cdot}CO_2H$. When carefully heated at 140–150° C, malonic acid partly decomposes into acetic acid and water, but 10–12% undergoes dehydration with formation of carbon suboxide, C_3O_2.

The outstanding importance of malonic acid in systematic chemistry arises from the varied syntheses which can be effected with its ethyl ester, *diethyl malonate,* or "malonic ester," $CH_2(CO_2C_2H_5)_2$. This ester, usually prepared by passing hydrogen chloride into a solution of cyanoacetic acid (obtained from chloroacetic acid) in absolute alcohol, is a colourless fragrant liquid boiling at 198° C. Its very reactive methylene group, CH_2, is instrumental in effecting syntheses of higher mono- and di-basic acids. (*See* CHEMISTRY: *Organic.*) The replacement of one hydrogen of this methylene group by sodium gives sodiomalonic ester; this on treatment with an alkyl iodide gives the ester of the corresponding alkyl malonic acid. In the presence of sodium ethoxide the esters of malonic acid and diethylmalonic acid undergo condensation with urea to furnish respectively barbituric and diethyl-barbituric acids, the latter being the well-known soporific drug, veronal (*q.v.*). By a similar condensation with urea ethylphenylmalonic ester yields the drug phenobarbital.

MALORY, SIR THOMAS (d. 1471), translator and compiler of the famous English classic, the *Morte d'Arthur.* Previous to the publication of Professor Kittredge's monograph, *Who was Sir Thomas Malory?* the identity of this writer remained an unsolved problem. Of direct evidence we have very little; in the concluding passage of the book the author asks the prayers of the reader for "Syr Thomas Maleore knyght," and states that the book was ended "the ix. yere of the reygne of Kyng Edward the fourth." Caxton, who printed *Morte d'Arthur* after Malory's death, in his preface (1485) says that he printed the book "after a copye unto me delivered whyche copye Syr Thomas Malorye dyd take oute of certeyn bookes of frensshe and reduced it in to Englysshe."

Kittredge identifies Caxton's Malory with Sir Thomas Malory, knight, of Newbold Revell (or Fenny Newbold), M.P. for Warwickshire in 1445. He had served in France, in the retinue of the earl of Warwick. He is almost certainly the "Thomas Malorie, miles," who, on account of his part in the Wars of the Roses was excluded with several others from the operation of a pardon issued by Edward IV. When Sir Thomas Malory's widow died in 1479 she was in possession of his hereditary estates in Northamptonshire and Warwick, so that it seems clear that Sir Thomas must have conveyed them to her in his life-time probably for fear of confiscation.

On two occasions, in 1451 and 1452, Humphrey, duke of Buckingham was commissioned to arrest Thomas Malory, knight, and bring him before the king and council "to answer certain charges," in the first case with respect to the rights of the monks of Axiholme in Kirby Monachorum, the parish which contained Malory's estate of Newbold Revell. (*See* Calendar of Patent Rolls, 1446–52, p. 476, and 1452–61, p. 61.)

Malory's *Morte d'Arthur* is an abridged compilation of the great body of Arthurian romance in its latest form. The *Merlin, Tristan, Lancelot, Queste* and *Mort Artus* are all represented, the only branch omitted is that dealing with the "early history" of the Grail, the *Joseph of Arimathea* and *Grand S. Graal.* But we do not yet know whether Malory himself was responsible for this selection, or whether he found it ready to hand in a ms., the "Frensshe Booke" to which he often refers. Mediaeval copyists, at the instance of their patrons, did make compilations from the various romances within their reach, such as *e.g.,* the enormous codex 112 (*fonds Franç.*) of the Bibliothèque Nationale, which includes large sections of the *Tristan,* the *Lancelot,* and the *Merlin* Suite. Taking into consideration alike what Malory retains and what he omits, it seems most probable that he was in possession, not of complete copies of the romances, but of one or more volumes of compilations from these sources.

The *Morte d'Arthur* represents the Arthurian cycle in the period of its decadence; nor does Malory in any way endeavour to overcome the difficulties caused by the juxtaposition of a number of independent (and often contradictory) versions; but the diversity of sources is harmonized and wrought into a whole by the great charm of Malory's style; simple, direct, idiomatic, yet musical and dignified, it has lent to the relations between Lancelot and Guenevere a character of truth and vitality lacking in his predecessors. Malory took the Arthurian story in its worst and weakest form, and he imparted to it a moral force and elevation which the cycle, even in its earlier and finer stage, had, save in the unique case of Von Eschenbach's *Parzival,* never possessed. *Morte d'Arthur* was the first English prose epic, and formed one of the chief foundations of English prose.

See G. L. Kittredge, "Who was Sir Thomas Malory?" (*Harvard Studies and Notes in Philology and Literature,* vol. v., 1897); and *Sir Thomas Malory* (Barnstable 1925); *Morte d'Arthur,* ed. by Dr. Oskar Sommer (an exact reproduction of the original text in 2 vols.)—vol. iii. a study on *The Sources of Malory.* The sections on *Lancelot* and *Queste* are unfortunately very inadequate; for these cf. *The Legend of Sir Lancelot,* Grimm Library, vol. xii. (J. L. W.; X.)

MALOU, JULES EDOUARD XAVIER (1810–1886), Belgian statesman, one of the leaders of the clerical party, was born at Ypres on Oct. 19, 1810. He was minister of finance in the coalition ministry of J. B. Nothomb in 1844, and formed with B. T. de Theux a Catholic cabinet in 1846, which was overthrown in the Liberal victory of 1847. Malou then became a member of the senate, and his party only regained ascendancy in 1870. The extreme clerical ministry of Baron d'Anethan retired in December 1871 after serious rioting in Brussels, and Malou was the real, though not the nominal, head of the more moderate clerical administrations of de Theux and Aspremont-Lynden (1870–78). After the fall of the ministry in 1878 he adopted a frankly clerical policy, and when he became chief of a new government in June 1884 he proceeded to undo the educational compromise of his predecessors in the Frère-Orban ministry. His legislation in favour of the Catholic schools caused rioting in Brussels, and in October the king demanded the retirement of MM. Jacobs and Woeste, the members of the cabinet against whom popular indignation was chiefly directed. Malou retired, and died at Woluwe Saint Lambert, in Brabant, on July 11, 1886. He was a financier of great experience. A list of his works is given in Koninck's *Bibliographie nationale de Belgique.*

MALOUET, PIERRE VICTOR, BARON (1740–1814), French publicist and politician, was born at Riom (Puy-de-Dôme) on Feb. 11, 1740. He entered the civil service and was employed successively at the French embassy in Lisbon, in the administrative department of the duc de Broglie's army, as commissary in San Domingo (1767–1774), and after his return to France, as commissary-general of the marine. He was sent to carry out plans of colonization in French Guiana in 1776, but superseded in 1779. He became intendant of Toulon, and in 1789 was returned to the states-general. He emigrated to England in Sept. 1792, but later tried and failed to obtain permission to assist in the defence of Louis XVI. In 1801 Napoleon restored him to his position in the civil service, and sent him to Antwerp as commissioner-general and maritime prefect. He entered the council of state in 1810, but offended the emperor by his plain speech, and was disgraced in 1812. Louis XVIII. made him minister of marine at the Restoration, and he died on Sept. 7, 1814.

For accounts of his domestic and colonial policy see *Collection de ses opinions a l'Assemblée Nationale* (3 vols., 1791–92); and *Collection de mémoires et correspondances officielles sur l'administration et notamment sur la Guiane française et hollandaise* (5 vols., 1802).

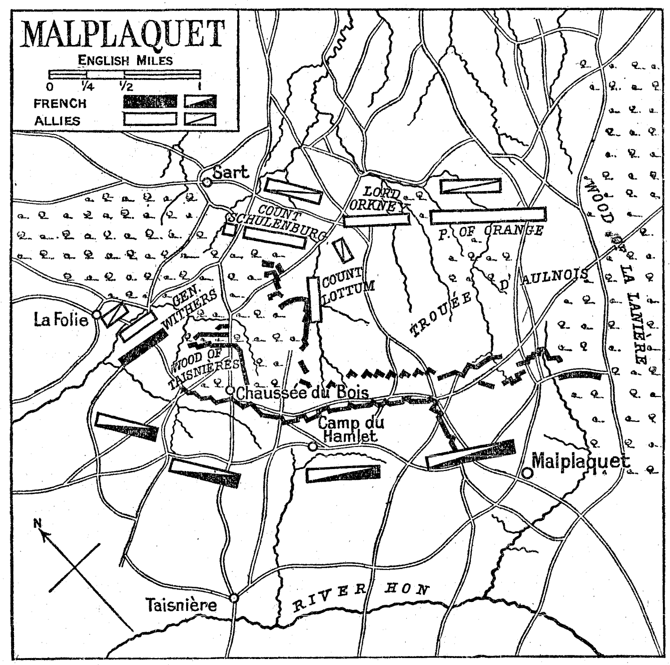
MALPIGHI, MARCELLO (1628–1694), Italian physiologist, was born on March 10, 1628, at Crevalcuore near Bologna, where he graduated in medicine in 1653 and where he became lecturer in 1656. A few months later he was appointed to the chair of theoretical medicine at Pisa, but after four years he returned to Bologna. In 1662 his friend, Borelli, secured his appointment as professor primarius at Messina. After a further four years he again returned to his native university, and spent the next twenty-five years there. In 1691 he removed to Rome as private physician to Innocent XII., and he died there of apoplexy on Nov. 30, 1694. Shortly before his death, he drew up a long account of his academical and scientific labours, correspondence and controversies, and committed it to the charge of the Royal Society of London, which published his autobiography in 1696.

Malpighi was one of the first to apply the microscope to the study of animal and vegetable structure; and his discoveries were so important that he may be considered to be the founder of microscopic anatomy. Although Harvey had correctly inferred the existence of the capillary circulation, he had never seen it; it was reserved for Malpighi in 1661 (four years after Harvey's death) to see for the first time the blood coursing through a network of small tubes on the surface of the lung and of the distended urinary bladder of the frog. This discovery was given to the world in two letters *De Pulmonibus,* addressed to Borelli, published at Bologna in 1661 (often reprinted). These letters contained also the first account of the vesicular structure of the human lung, and they made a theory of respiration for the first time possible. Malpighi's next achievement was a demonstration of the plan of structure of secreting glands. He maintained that the secretion was formed in terminal acini standing in open communication with the ducts. The name of Malpighi is still associated with his discovery of the mucous character of the lower stratum of the epidermis, of the vascular coils in the cortex of the kidney, and of the follicular bodies in the spleen. He was the first to attempt the finer anatomy of the brain, and described the distribution of grey matter and of the fibre-tracts in the cord, with their extensions to the cerebrum and cerebellum with great accuracy; but from his microscopic study of the grey matter he concluded that it was of glandular structure and that it secreted the "vital spirits." At an early period he applied himself to vegetable histology, and became acquainted with the spiral vessels of plants in 1662. His *Anatomia plantarum* published in 1672 included the *Observationes de ovo incubato,* which gave one of the best accounts (with good plates) of the development of the chick. His *Diss. epist. de bombyce* (1669) elaborately described the structure and metamorphosis of the silk-worm.

Malpighi also wrote *Epistolae anatomicae Marc. Malpighii et Car. Fracassati* (Amsterdam, 1662) (on the tongue, brain, skin, omentum, etc.); *De viscerum structura: exercitatio anatomica* (London, 1669); *De structura glandularum conglobatarum* (London, 1689); *Opera posthuma, et vita a seipso scripta* (London, 1697) with preface and additions, was published at Amsterdam in 1700. An edition containing all his works except the last two was published in London in 1686.

MALPLAQUET, a village of France in the department of the Nord, close to the Belgian frontier and about 10 m. S. by E. of Mons, famous as the scene of the battle, September 1709, between the Allies under the duke of Marlborough and Prince Eugène and the French commanded by Marshal Villars, in which the former were victorious. The country to the west and south of Mons is enclosed by a semicircular wall of woods and broken ground, through which there are only two important gaps—that of Jemappes (*q.v.*) (famous in 1792) to the west, and that of Aulnois, in which stands the village of Malplaquet, to the south. In the latter gap and the woods on either side Villars took up his position facing north-eastwards, on August 29/September 9. The forces present, over 90,000 on each side, were exceptionally large, and the French army in particular represented the spirit of its nation to a degree unusual in the armies of that time. Villars was the best general in the service of Louis XIV. and the veteran Marshal Boufflers, though senior to him, had volunteered to serve as his second in command. Marlborough and Eugène lay with their army between Mons and the French camps, which were almost within cannon shot. Marlborough's own wish was for an immediate battle, but he was opposed by the Dutch deputies at his headquarters, and even by Eugène, so that it was only on August 31/September 11 that the attack actually took place. Villars had made full use of his respite. The French right stood at the fringe of the wood of Lanière, the left was strongly posted in the midst of the wood of Taisnière, and across the two and a half miles of open ground between the woods the position was entrenched with several successive lines of works. The troops were almost equally distributed along the whole line as usual, and the cavalry was massed in rear of the infantry. In the Allied army the mounted troops were also kept back, but for the most part distributed to the various infantry commands.

The intention of Marlborough and Eugène, when on the morning of the battle they examined this formidable position, was to deliver the main attack upon the French left wing, combining the assaults of several columns on its front and flanks. In this quarter the French not only held the interior of the wood but also were thrown forward so as to occupy the edges of its north eastern salient, and upon the two faces of this salient Count Lottum with the Prussians, and Count von der Schulenburg with the Austrian infantry were to deliver a convergent attack, while farther to the Allied right a column under the English General Withers was detached to make a wide turning movement through the woods. Marlborough took command on the right, Eugène on



FROM FORTESCUE, "HISTORY OF THE BRITISH ARMY" (MACMILLAN)

PLAN OF THE BATTLE OF MALPLAQUET, SEPTEMBER 9–10, 1709

the left. The centre, which was intended only to observe the enemy until the decision had been forced at the wood of Taisnière, consisted of Lord Orkney's British corps and the prince of Orange's Dutch contingent. The salient of the Taisnière wood was duly attacked, after a heavy cannonade, on its two faces by the Prussians and Austrians about 9 A.M. They encountered a sterner resistance than in any of the battles and combats of the past seven campaigns, for on this field the defenders were fighting, not as hitherto for the interests of their king, but to defend their country, and the regiments of Picardie and Champagne which held the salient were the oldest and most famous of the French line. Lottum attacked again and again without success, until three British battalions had to be sent to reinforce him, and Marlborough placed himself with a corps of cavalry in close support. At last the entrenchments were stormed. Schulenburg had by this time fought his way through the woods and undergrowth, and the united force pressed back the French. Still, so stubborn was the defence and so dense the wood that the impetus of the assault died away and the troops on both sides broke up into small disconnected bodies, fighting too fiercely to be amenable to superior control.

But the French were not reinforced from their right wing as Villars expected. The prince of Orange, far from merely observing the hostile right as he had been ordered to do, committed his corps, very early in the battle, to a serious assault upon it, which Boufflers repulsed with enormous loss. The Dutch infantry never recovered from its casualties on this day, and the memory of Malplaquet was strong even at Fontenoy nearly forty years afterwards. The only advantage to the Allies was that Boufflers did not dare send reinforcements to the hard-pressed left wing. Thanks to this the attackers made steady progress in the wood of Taisnière. Villars launched the "Irish brigade" to check the advance of the Allies, and this famous corps charged into the forest. Villars, Eugène and Marlborough personally led their troops in the encounter which followed. Eugène was wounded, but refused to quit the field. Villars was more seriously hurt, and after trying in vain to direct the fighting from a chair was carried insensible from the field. At this crisis General Withers, who commanded the force that had been ordered to turn the French extreme left, appeared on the scene. The British 18th regiment (Royal Irish), encountering the French *Royal Irlandais,* put them to the rout, and Villars' counterstroke was at an end. The French maintained themselves on this side only by the aid of troops drawn from the centre and right, and this gave the Allied centre the opportunity which the prince of Orange had so rashly anticipated. The great attack over the open was carried out, in spite of the previous repulse, with the greatest determination. Preceded by forty guns, the corps of the prince of Orange and Lord Orkney swiftly carried the first line of works. The Allied cavalry then pushed out to the front, and horse, foot and artillery were combined in the last advance. Boufflers's cavalry masses, coming into play for the first time, fought hard, and the struggle fluctuated with the arrival of successive reserves on either side, but in the end, shortly before 3 P.M., Boufflers (who had been in command since Villars's fall) decided to retreat. The Allies had no troops left intact for the pursuit, and those engaged had expended their last efforts. Moreover Boufflers, experienced soldier as he was, drew off his men before they had lost their order and discipline.

Thus this "very murdering battle" as Marlborough called it—the last and greatest pitched battle of the war—was almost barren of results. The Allies lost not less than twenty thousand men, or nearly a quarter of the whole force, the thirty battalions of the Dutch infantry losing half their numbers. On the French side there were some twelve thousand casualties.

MALSTATT-BURBACH, former German town, in the Saar Territory on the right bank of the Saar (Sarre), which separates it from Saarbrücken, with which it is now incorporated. Malstatt in 1321 received municipal rights which were afterwards resigned to the newer town of Saarbrücken, and in 1818 Malstatt and Burbach were only two small villages. About the middle of the century the population began to increase rapidly, in consequence of the development of industry and the extension of the railway system, and in 1874 the two villages were united to form a town. It lies in the midst of an important coal-mining and industrial district, and produces iron, steel and cement. In 1909 it was incorporated with other towns into the larger industrial centre of Saarbrücken (*q.v.*).

MALT, the name given to grain in which germination has been caused to proceed to a certain stage and has then been arrested by the removal of water and the application of heat. During this limited germination enzymes are developed (*see* FERMENTATION), and the constituents of the grain modified so that the finished malt, when ground and submitted to the mashing process (*see* BREWING), differs from the original raw grain in that the greater portion dissolves. This solubility is due for the most part to the action of the malt enzymes, diastase, etc., on the constituents of the grain. Thus starch, the main constituent of all graminaceous seeds, probably exists in much the same condition in raw grain and in malt. When, however, the malt is mashed, the starch is attacked by the enzyme diastase, and converted by the process of hydrolysis into a mixture of soluble compounds, *e.g.,* the crystalline sugar, maltose, together with isomaltose and glucose and a number of gummy substances known as maltodextrins. It is now known that proteolytic enzymes exist in finished malt, and that, when the mashing process is conducted under certain conditions, these are able to degrade and render more permanently soluble some of the higher proteins present. By the limited germination which constitutes the malting process, the soluble compounds left in the finished malt is from 15 to 25% of total weight of the corn.

Barley for Malt.—Barley belongs to the genus Hordeum, of which there are numerous species and varieties. Linnaeus and the earlier botanists recognized six species of cultivated barleys, but modern botanists usually consider all cultivated barleys as belonging to one species to which the name *H. sativum* has been given. Körnicke regards *H. spontaneum,* a very long thin-grained two-rowed barley (*see* below) which grows in the East as being the parent form; but E. S. Beaven inclines to the view that wild species of more than one form were originally used as food and subsequently cultivated.

Two-rowed barleys are favoured for malting purposes in Europe and are also grown to a certain extent on the Pacific coast of the United States.

Chevallier, a narrow-eared variety named for the original cultivator Rev. John Chevallier, and a wide-eared selection from this variety called Goldthorpe are widely grown although they have been replaced largely by hybrids in recent years.

In America, the six-row barleys are favoured, the principal plantings being of hybrid varieties of the former Manchurian types.

Much was gained through Wahl's study of the Oderbrucker variety although very little is grown today.

O.A.C. 21, a blue strain of Manchurian developed by the Ontario Agricultural college, and Wisconsin 38, a cross between Oderbrucker and a black smooth-awned barley, have been quite popular recently throughout the middle western sections of the United States and Canada.

In the common six-rowed English barley or Scottish bere the two lateral rows of spikelets springing from one side of the rachis either partially or entirely intersect and overlap the alternate lateral spikelets from the opposite side of the rachis. This has given rise to the term "four-rowed barley."

Barleys were formerly developed through "selection" methods but cross-fertilization has enabled the agronomist to combine the good qualities of certain strains in such a manner that both are improved.

Constitution of Barley.—A grain of barley is shuttle-shaped; the end containing the germ which was originally attached to the rachis is known as the proximal end, whilst the opposite end of the corn is called the distal end. A deep furrow runs down the more convex side, which is accordingly denoted the ventral side, the opposite side being distinguished as the dorsal side. Within the ventral furrow at the proximal end is the rachilla already referred to. The skin or husk of a barleycorn consists of two paleae, one adhering to the dorsal side (the palea inferior) and the other to the ventral side (the palea superior); the former overlaps the edges of the latter. The awn or beard is merely an elongation of the palea inferior. If the two paleae are removed from a barleycorn after soaking it in water, it will be seen that there are other skins completely enveloping the embryo and endosperm. These are the true skins, and are known as the pericarp and the testa respectively. Next to these skins will be seen the triple layer of thick-walled square-shaped aleurone cells.

The histology of the barleycorn is best studied by the examination of sections under the microscope. The grain consists of two main portions, the embryo or germ, and the endosperm, the storehouse of reserve materials for the growing plant.

Germination.—The barleycorn in its resting stage is in a state which may be described as one of dormant vitality; it respires very slowly and thus loses weight during storage. The best and driest barleys are said to lose 1·3% of their weight in the first year, 0·9% in the second, and 0·5% in the third. The loss is considerably more with coarse and damp samples. When the grain is steeped this dormant vitality gives place to that complicated series of processes comprised under the general term germination. When germination begins enzymes are secreted, and these act on the reserve materials, starch and proteins of the endosperm, converting them into simpler compounds, capable of diffusing to various parts of the growing germ. Following this, starch and proteins are reformed, the former being deposited in the tissues of the germ and in the cells of the scutellum, which previously were almost free from starch; the protein matter deposited in the latter disappears to a considerable extent, and the protoplasmic content of the cells assumes a very granular appearance. The pointed mass of cells constituting the root-sheath is pushed forward by the root which protrudes through the base of the grain. It is at this stage that the barley is said by the maltster to "chit." After the first rootlet has broken through the ends of the sheath, it is followed by others. The cotyledonary sheath begins to elongate on the third or fourth day of germination and ruptures the true covering of the seed; it then grows upwards between this and the husk and forms the acrospire or "spire" of the maltster.

Condition.—Barley is bought in the open market solely on the evidence of certain external signs, and judgment can only be acquired by very long experience. Immature barley feels cold to the hand, has a greenish-yellow colour, and, when dry, a starved wrinkled appearance. Over-ripeness in barley is distinguished by a white dead appearance of the corn. Mature or dry grains slip through the fingers more readily than unripe or damp ones. The contents of the endosperm should present a white friable or mealy appearance when the corns are bitten or cut in two with a penknife. The condition of the grain may be determined by an apparatus known as the diaphanoscope, which consists of a box fitted with a sliding tray, furnished with a certain number of shuttle-shaped holes (usually 500), each of such a size as just to hold a barleycorn longitudinally. Into the portion of the box below this tray an electric lamp is placed, and the corns are looked at from above. Thoroughly mealy corns are opaque, whilst steely corns are transparent. When certain portions of a corn are steely, these present the appearance of lakes. By this means the percentage of mealy, steely or half steely corns in a sample may readily be estimated.

E. Prior points out that steeliness of barley is of two kinds, one of which disappears after the grain has been steeped and dried, and therefore does not necessarily influence the malting value of the sample, and the other which is permanent, and therefore retards the modification of the corn. He proposed to determine what he called the coefficient of mealiness of a sample of barley by means of the formula:—

$$A = \frac{(M_1 - M)100}{100 - M} + M,$$

in which A is the degree of mealiness, M is the percentage of mealy corns in the original barley, and M_1 is the percentage of mealy corns after steeping and drying the barley. Prior points out that, generally speaking, the degree of mealiness varies inversely as the protein content.

Munro and Beaven confirming Johansen point out that "Mealy grains have a lower specific gravity than steely grains, and contain a larger amount of interstitial air. The total nitrogen content of mealy grains is less than that of steely grains. Steely grains contain a relatively high proportion of nitrogenous substances soluble (*a*) in 5% salt solution, and (*b*) in alcohol of specific gravity 0·9. Mealy barley modifies better than steely during germination. The process of drying damp and under-matured barley intact at 100° F produced an apparent mellowing or maturation. Other things being equal, maturation, which is physiologically a post-ripening process, is correlated with the mealy appearance of the endosperm." H. T. Brown and his collaborators state that thin sections of steely corns when examined under the microscope no longer exhibit a translucent appearance, but show the mealy properties as completely as if they had been cut from a mealy grain, and they suggest that in a steely corn the whole of the endosperm is under a state of tensile stress which cannot be maintained in the thin sections. If, however, a thin section of a steely barley be cemented to a slide with Canada balsam and then pared away with a razor, steeliness may be preserved even in the thinnest sections. Brown and his co-workers determine the coefficient of mealiness of a barley as follows: Five hundred corns are cut transversely in a corn cutter and the percentage of mealy, half mealy and steely corns is noted. The number 100 is taken to represent complete mealiness, 1 complete steeliness, and 50 the intermediate class. If the percentage of each class be multiplied by its special value, and the sum of the products divided by 100, the result is the coefficient of mealiness. By steeping and drying a very steely Scottish barley the coefficient of mealiness was raised from 29·7 to 87·1, whilst concurrently the specific gravity fell from 1·417 to 1·289.

Barley even of the same kind varies widely in its chemical composition, but on an average the proximate constituents of British malting barleys lie within the following limits:—

	%
Moisture	18 —12
Nitrogenous matters expressed as proteins	8 —15
Fat	2 — 2·5
Starch	42 —50
Sugars	1·5— 2·0
Hemi celluloses, pectins, etc.	8 —10
Fibre, cellulose, etc.	5 — 7
Ash	2 — 2·5

Any sample of barley which contains more than 20% of moisture would be considered damp. The late Prof. Lintner expressed the view several years ago that a good malting barley should not contain more than 10% of protein, but R. Wahl asserts that in America six-rowed barleys containing a far higher percentage of protein have been used successfully, indeed preferably, for malting purposes. A summary of our knowledge of the nitrogenous constituents of barley and malt was published by H. F. E. Hulton in 1922. According to T. B. Osborne barley contains the undermentioned proteins in the following proportions:—

		%
Soluble in water:	Leucosin (albumin), Proteose	0·30
Soluble in salt solution:	Edestin (globulin)	1·95
Soluble in 75% alcohol:	Hordein	4·00
	Insoluble protein	4·50
Total		10·75

Raw barley contains enzymes, thus diastase of translocation, so called by Horace T. Brown and G. H. Morris, and catalase (H. van Laer). Proteolytic enzymes appear only to arise with the beginning of germination; but it has been asserted that raw barley contains proenzymes (zymogens), which can be rendered active by treatment with dilute lactic acid at an appropriate temperature. The action of the diastase of raw barley on starch has been studied by Julian L. Baker. According to Ling and Nanji the diastase of barley converts the α amylose constituent of starch into maltose and the amylo-pectin constituent into $\alpha\beta$ hexa-amylose.

Maturing and Storage.—Barley should not be cut until it is properly ripe, but over-ripeness is much more to be guarded against. Very wet seasons are prejudicial to the ripening of the grain, and when the latter is stacked in too moist a condition it is apt to become what is known as mow burnt. This results in the corns becoming black at the tips; they are then said to be magpied. H. T. Brown and F. Escombe find that maturation is attended by deformation and ultimate disintegration of the cell nuclei. The change which is denoted by the term nuclear senescence is said to begin in the starch-containing cells, near the periphery of the corn, immediately underlying the layer next to the aleurone layer. This deformation is followed by complete disintegration of the nucleus, and at the end of seven or eight days nearly the whole endosperm has been involved. Malting barleys should weigh 52–56 lb. per bushel, the standard weight for malting barleys being 56 lb.

During the storage of barley access of air is necessary, otherwise the grain dies from asphyxiation. Sound barley after being kiln-dried retains its vitality for a number of years; but the statement that the corns found in the Egyptian mummy cases, in which they had remained for several thousands of years, were still capable of germination, is contrary to modern experience. Moisture must also be carefully excluded, as it initiates germination in a few cells only of the endosperm and causes heating. A constant repetition of wetting such as may take place on account of alterations of the atmospheric temperature, which causes moisture to be deposited, in the form of dew, may ultimately destroy the vitality and foster the growth and development of mould fungi which usually grow on broken and damaged corns. In this connection the advantage of screening and sweating of barley before storing it will be apparent.

An immense amount of damage is caused to the grain, during storage, by various insects, one of the most destructive of these being the common weevil (*Calandra granaria*). When fully developed this insect measures $\frac{1}{6}$ to $\frac{1}{8}$ of an inch in length, and is of a bright chestnut colour. The larvae are freshly legless grubs, shorter than the perfect insect, with a series of tubercles along each side of the body; the head is round with strong jaws. The pupa is white, clear and transparent, showing the form of the future weevil. The female bores a hole in the grain with her snout and deposits an egg. The larva when hatched lives on the contents of the grain and undergoes its changes therein. Grain which is only slightly attacked should be kilned at a temperature of 122° F., which destroys the weevil in all stages of development. To detect weevil in a sample of barley, the grain should be spread out on a sheet of white paper in bright sunlight. If weevils are present they soon appear, and betake themselves to a position outside the sunlight, to which they are averse.

Malting.—There are two systems of malting used in England—floor malting and pneumatic or drum malting. These systems will be described separately.

A floor malting consists of a rectangular building of several storeys, having the cisterns at one end and the kilns at the other. The uppermost floor is devoted to barley.

On arrival at the malting the barley has to be put through the following operations seriatim: receiving, hoisting and weighing, rough screening, drying and sweating, storing until required for use, screening, grading and removing broken corns, steeping, couching, flooring, withering, drying and curing, dressing and polishing, storing, weighing, sacking and discharging the finished malt.

In sweating barley the temperature should not be allowed to rise above 120° F.; it is usually conducted at 100° F.; and subsequently the barley should be stored for some weeks before it is steeped.

The capacity of a malting is described by the number of quarters which can be put through it every four days. A fifty quarter malting does not merely mean that the cisterns have a capacity of fifty quarters, but that this quantity of barley goes through the house every four days. The average time the germinating barley is on the floors is 12 days, and, as a rule, kilning occupies four days. If, as sometimes happens, the malt has to be kept on the floors 13, 14, 15 days, or even longer, the malting is not being worked at the capacity under which it is described, and the kilns may remain unused for a day or more. Conversely, when the malt is loaded at less than 12 days, a day or two has to be missed in steeping. In the former case when the kilns are not being used for drying and curing malt, advantage may be taken to utilize them for sweating barley.

Steeping cisterns were formerly rectangular vessels, of slate, brick or cement, from which the barley had to be discharged by shovelling it out. The forms approved most at the present day are conical and constructed of iron; they have arrangements at the apex of the cone, the lower portion, for discharging the grain by gravitation. The steeping period ranges from 48 to 70 hours; it varies according to the kind of barley, and the time of the year. In some of the older maltings there are no arrangements for heating the steep water, and in the winter steeping has occasionally to be performed with water at a temperature near its freezing-point. Steeping should be carried out at a temperature as near as possible to 55° and not higher than 60° F. The usual practice is to fill the cistern up to a certain height with water and throw the barley into it, stirring it until it is about level; the normal corns will then sink directly to the bottom, whilst the light corns and refuse float on the surface and may be skimmed off. During the time the barley remains in the cistern it is usual to change the steep water two or three times, generally at intervals of 12 hours or tides. The advantage of this is not merely to keep the grain fresh and sweet, but to bring it into contact with the air during the time it is taking up water. Aëration of the steep has long been recognized in Germany as promoting germination, and several arrangements are on the market enabling air to be passed through the grain while it is in the cistern. It has been recommended by Graham, Stopes, Moritz and Morris, and experimental evidence as to its beneficial effects has been published by Windisch, Bleisch, Will and Baker and Dick. When the corn is steep ripe it contains some 50% of water. Steeping does not consist, however, merely in the imbibition of a certain amount of water; in order to bring about germination this water must remain within the corn a certain length of time. The following average data are useful to remember in connection with the steeping process:—Amount of water in steep-ripe barley (about) 50%. Matter removed from barley during steeping (about) 1·5%. Increase in volume of barley due to water absorption (about) 18–20%.

There has been much discussion as to the influence of saline matters in water on the steeping process. Professor Lintner stated that common salt in water tended to extract the nitrogenous constituents of the grain, but impeded its germination. Mills and Pettigrew found that waters containing calcium salts extracted a minimum of nitrogenous compounds from the barley; they also came to the conclusion that the esteem in which the Lichfield water is held for steeping purposes is due to the presence of nitrates which, they assert, have a stimulating effect on the subsequent germination of the grain. The writer has added lime-water to the extent of one-third of the total volume of water at the first change, believing it to promote regularity of germination. Bearing in mind, however, the observations of Adrian J. Brown, that the barleycorn is enclosed in a membrane permeable to water but impermeable to most salts, it is difficult to see how the saline constituents of water can have any effect except in removing matter from the external portions of the grain and on those corns which are broken. The apparent beneficial effect of lime-water in the steep is probably entirely due to the removal of matters from the husks or paleae.

Malting floors may be constructed of cement, tiles or slate, the two former being preferable to the latter. Ford, in 1849, recommended 200sq.ft. per quarter of barley steeped as the area of the working floors, and he was quite convinced of the necessity of allowing ample floor room, so that the grain could be worked on the slow, cool system. Subsequently, however, maltsters reduced their floor area, and put the grain rapidly through the malting, thus producing what is termed "forced" malt. At the present time the approved area may be placed at 175–200sq.ft. per quarter of barley steeped. The area is, however, largely ruled by the kind of barley to be malted.

After the barley has been thrown out of the cistern it is made up in a rectangular heap 16–20in. deep, called the "couch"; the object of this is to enable it to gather heat and so start germinating. It usually remains in couch for 12–24 hours, until in fact the interior portion of the heap registers a temperature of about 60° F. During the days of the malt tax the exciseman gauged the quantity of the barley while it was in the couch. After couching the barley is spread thinly and evenly on the floor, forming what is known as the young floor or No. 1 piece. The first visible sign of germination is the sprouting of the rootlet, termed "chitting," and this occurs either while the grain is on the couch or on the young floor. As already mentioned, it may be quickened by aërating the grain in the cistern. From the time the barley is first cast out of the cistern up to the stage of the young floor, or No. 1 piece, it has a pleasant odour resembling apples.

The thickness at which the young floor is spread depends upon the outside temperature and the nature of the barley. If the weather be warm, or if there be a tendency for the barley to heat, the piece must be spread all the thinner. At this stage the grain loses its external wet appearance. When spread too thickly the grain will begin to sweat, and the rootlets will be thrown out suddenly and unevenly. As a rule, under these circumstances, the rootlets will be long and thin, when they are said to be "wild." A piece which has been allowed to get into this condition must at once be spread thinner. If the sweating has not continued long, the harm done may be confined to increased loss by respiration. The young floor is usually turned with a plough twice during 12 hours, and it may be forked between whiles, but no hard and fast rule can be laid down as to when this is necessary; it must be left to the maltster's judgment, as it depends entirely on what is going on within the grain. The object of turning is in the first place to aërate the grain and freshen it, secondly to check excessive rise of temperature, and thirdly to promote evenness of growth. Too frequent turning is not to be advised. After remaining four days on the young floor three or four rootlets should have appeared, and the acrospire should have begun to grow up the back of the corn. The apple-like odour of the piece then gives place to one resembling that of the common rush, and this should continue the whole time that the malt remains on the floor. On the fifth day the piece is next moved to No. 2 position, a stage nearer the kiln. It is here that sprinkling is resorted to when necessary. The amount of the sprinkling and the time it is given cannot be exactly prescribed. The amount may vary from one to five gallons per quarter, and it should only be given when the rootlets, which ought to be short and curly, and five or more in number, show signs of losing their freshness. If an excessive amount of sprinkling be given forced growth ensues. It is preferable not to add the whole of the water at one time, but to divide it over two lots; and immediately after the piece has been sprinkled it should be thoroughly and carefully mixed, otherwise some of the grain will receive an undue proportion of water. When all the sprinkling water has been given to the piece, which as a rule should not be done later than at the sixth or seventh day of flooring, the temperature should be kept down to about 55° F. by turning. Too frequent turning may, however, detach the rootlet, and it may cause the grain to lose its vitality prematurely, so that growth of the acrospire stops.

By about the eighth day of flooring the acrospire should be on an average about three-quarters up the corn. After this the germinating corn is moved forward to No. 3 piece, which is at first spread as thinly on the floors as in the previous pieces. Here it gradually dries and incipient withering of the rootlets sets in. The only treatment which is now given to the grain is to heap it up thicker and thicker by degrees until it is ready for loading on the kiln. This increase in thickness of the piece (now called the old piece) should not be too sudden, especially if the grain be fresh in appearance and contain a large quantity of water. When the piece is thickened up to say 10in. in depth, while it is in a very moist condition, heating and sweating take place, with additional growth of acrospire and rootlet. Under such forcing conditions a large production of sugar and degradation of the proteins will take place. When, however, the moisture has been gradually reduced before thickening up, the rootlet dies off; and although increase of temperature may occur, this is accompanied by little or no further growth of the acrospire, action being confined to the mellowing of the grain by the enzymes. When the malt is ready for loading on the kiln it should be possible to break down the contents of each corn between the thumb and finger. Opinions differ as to what the final temperature on the withering floor should be. If the moisture content of the malt be about 50%, the piece must be kept thin to avoid sweating. But under these conditions mellowing does not occur, hence the necessity of reducing the moisture content gradually after the last sprinkling water has been given. When the process has been conducted properly the temperature of the old piece may be allowed to rise as high as 70° F. during the six hours previous to loading. The moisture content of the green malt when loaded should not be much above 40%.

The endosperm of green malt which is ready for the kiln should be soft and mealy, and should not exude moisture when pressed between the thumb-nails, but should crumble and disintegrate to a chalky mass having little or no adhesiveness.

The foregoing observations are not to be regarded as hard and fast rules, but they are simply intended to give some indication of the malting process when it proceeds on normal lines; it may be that on account of the presence of damaged corns the piece begins to develop mould by about the tenth day, and it then has to be kept thin and sometimes even loaded on kiln prematurely.

The malt made for grain distillers, in which a high diastatic activity is required, is manufactured on quite different lines from those above indicated. It is often sprinkled late, and loaded on kiln often in a sodden condition. In some cases sprinkling on kiln is resorted to, but it is doubtful if this leads to the desired object. Other things being equal, the smaller the corns—*i.e.*, the greater number of embryos in a given weight—the higher the diastatic activity of the malt. In selecting a barley for the production of highly diastatic malt, the diastatic power of the original raw grain is a factor of great importance.

Kilning.—When loaded on kiln, malt intended for brewing ale and stout is, if properly withered, in a moribund condition; nevertheless, during the first stages of the kilning process a certain amount of vital activity is manifested, and the malt undergoes mellowing by the action of enzymes on the contents of the endosperm. If the malt be loaded while the rootlets appear fresh on account of the presence of too much moisture, rapid growth of the acrospire ensues, giving rise to overshot corns, known as "cock spurs." To check this the moisture must be rapidly removed by the passage of large volumes of air through the malt. But under such circumstances mellowing does not occur. The ideal conditions of kilning are when the malt has been properly withered on the floors before loading, and, assuming that drying and curing occupy four days, that 25–30% of the moisture be removed very gradually, this occupying the first three days, at the end of which the malt is said to be hand-dry. The thickness at which the malt is spread on the kiln should not exceed 7–8 in., and until hand-dry (that is to say, reduced to a moisture content of 12–15%) it should not be turned; if moved at all (and that only is necessary when reek occurs), it should only be lightly forked. The rate at which the temperature is raised depends largely on the kind of malt to be made and the construction of the kiln. If high flavour and colour are required, these are produced by keeping the malt for several hours near a temperature of 160° F. while it still contains 12–15% of moisture. If more than this amount of moisture be present when the temperature reaches the limit just mentioned, the conditions known as stewing would obtain, with the result that "forced" malt would be produced. A certain amount of colour is produced at the final temperature to which the malt is raised; but when such means are relied upon for the production of the greater part of the colour, reduction of extract and deficiency of flavour follow, the colour being then almost exclusively the result of caramelization of the carbohydrates.

The so-called curing stage constitutes the last part of the kilning process, and the malt must then be turned frequently to ensure uniformity of action. Mechanical turners are exceedingly useful for this purpose. Curing in a drum, as in the so-called pneumatic malting process, also effects satisfactory curing.

The following table will give an idea of the kilning temperatures usually employed for the three kinds of malt mentioned, but it must be remembered that these temperatures are largely regulated by the construction of the kiln and the amount of draught available. In this connection it may be mentioned that the final curing temperature is not necessarily a criterion of the tint of the malt. A malt may have been finished off at a very high temperature and still be a pale malt, provided the moisture percentage has been sufficiently reduced in the initial stages of kilning.

Day temp.	Pale malt.	Running ale malt.	Amber malt.
1st .	90–100° F.	90–100° F.	90–100° F.
2nd .	100–120	100–120	100–130
3rd .	120–130 (10 hrs.)	120–130 (6 hrs.)	130–150 (6 hrs.)
3rd .	130–180 (8 hrs.)	130–150 (12 hrs.)	150–160 (12 hrs.)
3rd .	180–190 (6 hrs.)	150–180 (6 hrs.)	160–180 (6 hrs.)
4th .	Drop to 170 (12 hrs.)	180–190 (12 hrs.)	180–200 (12 hrs.)
4th .	..	190–200 (6 hrs.)	200–220 (6 hrs.)
4th .	..	Drop to 180 (6 hrs.)	Drop to 190 (6 hrs.)

The average laboratory values obtained from malts of the descriptions after about two months' storage should be as follows:—

	Pale malt.	Running ale malt.	Amber malt.
Extract per standard quarter of 336 lb . . .	95–98 lb.	94–96 lb.	94–96 lb.
Moisture	about 2·0% in each case.		
Diastatic activity (Lintner)	30–35	20–30	8–10
Tint (Lovibond 52 series neutral)	3–5	6–8	20–25

Metabolic Changes.—All through the malting process metabolic changes are proceeding in which both carbohydrates and proteins are concerned. In its resting stage the embryo of a barleycorn is generally free from starch; as soon as germination sets in, however, starch appears in the scutellum, while the amount of sucrose there present increases, these being apparently formed from maltose originating from the action of diastase on the starch of the endosperm. Sucrose also augments in the aleurone layer, but starch is never formed in the aleurone cells. These changes occur when the malt is first loaded on kiln.

Fuel.—The fuel used for drying and curing malt is either anthracite or coke, and the greatest care is necessary in selecting it on account of its liability to contain arsenic, which is to a greater or less extent an invariable constituent of all coal. The fuel used for malting purposes should not contain more arsenic than $\frac{1}{20}$ grain per pound. Gas coke should on no account be used, unless it has been proved to be sufficiently free from arsenic; but the best oven coke frequently contains so little arsenic that it may be employed with perfect safety, especially if it be mixed with a proportion (*e.g.*, 5%) of milk of lime, which retains the arsenic as calcium arsenate. In Germany malt is, as a rule, dried and cured with hot air, whilst in Great Britain the products of combustion are passed through the malt, as it is believed that they exert a beneficial influence on the flavour.

Storing the Malt.—After the malt has passed through the curing stage it is generally heaped up for a few hours. This is believed to increase its flavour. The malt is then stripped from the kiln, and the rootlets, technically known as the coombs, are removed. Formerly this was effected by workmen treading the malt, who wore heavy boots for the purpose. At the present time, however, the rootlets are usually removed by machinery, special forms of which have been devised for this as well as for dressing and polishing the malt. It is the custom of some maltsters to store malt with the rootlets still attached; but this is an objectionable practice, since malt coombs attract moisture, and the presence of more than 3% of moisture in malt produces the condition known as "slackness." When the malt is packed in bins it is often covered with a layer of coombs, which then prevent access of atmospheric moisture. Malt, to preserve its good qualities intact, should be stored in bins made as nearly as possible air-tight, and it should never be placed in bin until it is quite cool. It is probably wrong to store malt in bins adjacent to the kilns, where it is kept at a higher temperature than that of the surrounding atmosphere. During storage of the malt a kind of mellowing occurs, the mechanism of which is not understood. It is, however, known by practical brewers that the best results cannot be obtained when new malt is used.

Compartment Malting.—The tremendous amount of labour involved in the floor malting system has prompted many inventions and developments to mechanize the procedure. The so-called Saladin system is best known of these and permits the germinating piece to be held in large rectangular boxes or bins. The grain is then turned by means of vertical helices which traverse the length of the compartment. This mechanical turning has replaced practically all floor malting today.

Pneumatic Malting.—Several years ago Galland suggested germinating barley in a drum, his idea being to do away with handling of the grain, and also to be independent of changes of atmospheric temperature. The latest development of this system, the so-called Galland-Henning process of pneumatic malting, has been improved by Mr. R. Blair Robertson. The drums are provided with a perforated channel for the passage of air through the malt, which is packed in the annular space between this channel and the outside wall of the drum. Each drum is capable of revolving on its axis, and there are arrangements for passing either moist, saturated or dry air through the malt. The system as now improved is capable of producing some of the best malt, especially if, after germination has been completed in the drums, the green malt is loaded on an ordinary kiln and the initial stages of kilning conducted in the usual way; the curing, however, may be carried out successfully in a special form of drum.

Yield and Weight.—The malting process is attended with a certain amount of loss of dry substance of the barley, as follows:—

In the steep	1·5 to 2·0%
By respiration on floors and on kilns	3·0 to 5·0%
Coombs	3·5 to 5·0%

In addition to this, barley, as already mentioned, contains from 12 to 18% of moisture, whereas finished malt contains 1 to 2%. The total loss in weight which barley undergoes in the malting process may be put down at from 17 to 28%. Since, however, malt is lighter than barley (and the quantity of both was in former years measured exclusively by volume) it frequently happens that a given number of quarters of barley yield a large number of quarters of finished malt. When this happens it is usual to speak of an increase having been obtained. At the present time weight replaces measure for both barley and malt, and although it is usual to speak of the quantity of grain in terms of quarters, what is meant is not the measured quarter, but so many weighed standard quarters. The standard quarter for English malting barley is 448 lb. and for malt 336 lb. From this it will be seen that when a given number of weighed quarters of barley yields the same number of quarters of finished malt, the actual yield is 75%, and there is then said to be neither increase nor decrease. As a rule, in practical working the yield of malt varies from a 4% decrease to a 10% increase, corresponding to an actual yield on the original barley of 72 to 82·5%. J. Baverstock, an old writer, says that finished malt should weigh one-fifth less than the barley from which it is produced. This corresponds to a malting increase of about 7%, which is a high yield. As a rule, foreign barley will give a greater malting increase than English barley, because, on the one hand, the former usually contains less moisture than the latter, and, further, because there is less loss on the floors by respiration and rootlet growth.

The yield of malt from barley may be determined in the laboratory in an extremely simple manner. Since every grain of barley must yield a grain of malt, if we know the respective weights of a definite number of barley and malt grains, provided that this number is large enough to represent the average, then obviously this gives the data requisite for calculating the yield of malt from barley. The number of corns the weight of which is determined for this purpose is usually 1,000, and if the weight of this number be determined on several different 1,000 corns, the average will closely approximate to the truth. Instead of counting the corns by hand, an instrument may be used for this purpose.

If 1,000 corns of a barley were found to weigh 42 grammes, and 1,000 corns of a finished malt from the same barley 32 grammes, then the yield of malt is $\frac{32 \times 100}{42} = 76{\cdot}1$, this corresponding to a 1% increase. Assuming that the moisture content of the barley was 15% and that of the finished malt 2%, 100 grammes of malt will contain 2 grammes of moisture, and 76·1 grammes will contain $\frac{76{\cdot}1 \times 2}{100} = 1{\cdot}5$ grammes moisture; therefore 76·1 grammes of malt contain $76{\cdot}1 - 1{\cdot}5 = 74{\cdot}6$ grammes of dry matter. This was obtained from $100 - 15 = 85$ grammes of barley dry substance. Hence 100 parts of barley dry substance will yield $\frac{74{\cdot}6 \times 100}{85} = 87{\cdot}7$, corresponding with a loss of dry substance equal to 12·5% of the dry substance of the barley, or with a loss of 10·7% on the barley containing 15% of moisture.

The results obtained by this method of laboratory control when it is accurately carried out agree very closely with those deduced from the practical results of weighing the barley, malt and coombs in the malting.

Special Malts.—In addition to the kinds of malt considered in what precedes, there are others mostly used for imparting specific flavours and colour to beers and stout. These are crystal malt, imperial malt, brown or blown malt, and black or roasted malt. Crystal malt is grown for a shortened period on the floors, and then placed in a wire cylinder, which is rotated over a fire so that it is dried at a very high temperature. The weight per quarter is from 250 to 280 lb. Imperial malt is dried off on an ordinary kiln at a final temperature of 240–270° F., but it is not allowed the usual length of time on the withering floor. It is placed on the drying kiln in a layer not exceeding one inch and a half in thickness. A moderate heat from burnt wood is applied until the bulk of the moisture has been driven off, when the temperature is suddenly raised so that the grains swell 25% and the malt takes up a strong empyreumatic flavour from the products of combustion. This malt weighs 270–300 lb. per quarter. Black or roasted malt is prepared by roasting malt in a cylinder. Its weight per quarter varies as much as from 215 to 290 pounds.

MALTA. The Maltese Islands are situated between Europe and Africa, in the central channel which connects the eastern and western basins of the Mediterranean Sea. The group belongs to the British Empire and consists of Malta, 91 sq.mi., Gozo (*q.v.*) 26 sq.mi., Comino, 1 sq.mi., and the uninhabited rocks called Cominotto and Filfia. Malta (lat. of Valletta Observatory 35° 53′ 55″ N., long. 14° 30′ 45″ E.) is about 60 mi. from the nearest point of Sicily, 140 mi. from the mainland of Europe and 180 mi. from Africa; it has a magnificent natural harbour.

Malta is about $17\frac{1}{2}$ mi. long by 9 broad; Gozo is $8\frac{3}{4}$ by $4\frac{1}{2}$ mi. This chain of islands stretches 29 mi. from northwest to southeast. On the southwest the declivities towards the sea are steep, and in places rise abruptly from deep water some 400 feet. The general slope of these ridges is towards the northeast, facing Sicily and snow-capped Etna, the source of cool evening breezes. The Bingemma range, rising 726 ft., is nearly at right angles to the axis of the main island. The geological "Great Fault" stretches from sea to sea at the foot of these hills. There are good anchorages in the channels between Gozo and Comino, and between Comino and Malta. In addition to the harbours of Valletta, there are in Malta, facing northeast, the bays called Mellieha and St. Paul's, the inlets of the Saline, of Madalena, of St. Julian and of St. Thomas; on the southeast there is the large bay of Marsa Scirocco. There are landing places on the southwest at Fomh-il-rih and Miggiarro. Mount Sceberras (on which Valletta is built) is a precipitous promontory about 1 m. long, pointing northeast. It rises out of deep water; well-sheltered creeks indent the opposite shores on both sides. The waters on the southeast of Valletta form the "Grand Harbour," having its entrance between Ricasoli Point and Fort St. Elmo. The series of bays to the northwest, approached between the points of Tigne and St. Elmo, is known as the Marsamuscetto (or Quarantine) Harbour.

Geology and Water Supply.—The Maltese Islands consist largely of Tertiary Limestone, with somewhat variable beds of Crystalline Sandstone, Greensand and Marl or Blue Clay. The series appears to be in line with similar formations at Tripoli in Africa, Cagliari in Sardinia, and to the east of Marseilles. To the southeast of the Great Fault (already mentioned) the beds are more regular, comprising, in descending order, (*a*) Upper Coralline Limestone; (*b*) Yellow, Black or Greensand; (*c*) Marl or Blue Clay; (*d*) White, Grey and Pale Yellow Sandstone; (*e*) Chocolate-coloured nodules with shells, etc.; (*f*) Yellow Sandstone; (*g*) Lower Crystalline Limestone. The Lower Limestone probably belongs to the Tongarian stage of the Oligocene series, and the Upper Coralline Limestone to the Tortonian stage of the Miocene. The beds are not folded. The general dip of the strata is from west-south-west to east-north-east. North of the Great Fault and at Comino the level of the beds is about 400 ft. lower, bringing (*e*), the Marl, in juxtaposition with (*g*), the semi-crystalline Limestone. Mammalian remains found in Pleistocene deposits are of exceptional interest. Among the more remarkable forms are a species of hippopotamus, the elephant (including a pigmy variety), and a gigantic dormouse. In the Coralline Limestone the following fossils have been noted:—*Spondylus, Ostrea, Pecten, Cytherea, Arca, Terebratula, Orthis, Clavagella, Echinus, Cidaris, Nucleolites, Brissus, Spatangus;* in the Marl the *Nautilus zigzag;* in the Yellow, Black and Greensand shells of *Lenticulites complanatus,* teeth and vertebrae of *Squalidae* and *Cetacea;* in the Sandstone, *Vaginula depressa, Crystallaria, Nodosaria, Brissus, Nucleolites, Pecten burdigallensis, Scalaria, Scutella subrotunda, Spatangus, Nautilus, Ostrea navicularis* and *Pecten cristatus.*

The Blue Clay forms, at the higher levels, a stratum impervious to water, and holds up the rainfall, which soaks through the spongy mass of the superimposed coralline formations. Hence arise the springs which run perennially, several of which have been collected into the gravitation water supplies of the Vignacourt and Fawara aqueducts. There is no river or rivulet in the island, however, and the larger part of the water supply is pumped from strata at about sea-level.

Climate and Hygiene.—The climate is, for the greater part of the year, temperate and healthful. During the winter the weather is pleasantly cool and sometimes cold, owing to the strong winds, but there is much bright sunshine, and the air is clear and invigorating. The thermometer records an annual mean of 64.5° F. Between June and September the temperature ranges from 75° to 90°; the mean for December, January and February, the three coldest months, is 56°, the mean maximum being 65.5° and the mean minimum 46.6°. Pleasant northeast winds blow for an average of 150 days a year, cool northerly winds for 31 days, east winds 70 days, west for 34 days. The northwest "Gregale" (Euroclydon of *Acts* xxvii, 14) blows about the equinox, and occasionally, in the winter months, sometimes with almost hurricane force for three days together; it is recorded to have caused the drowning of 600 persons in the harbour in 1555. This wind was a constant menace to shipping at anchor; the breakwater on the Monarch shoal was designed to resist its ravages. The "Sirocco," an enervating southeast wind, blows at intervals during the summer months, causing close, damp and misty weather. The regular tides are hardly perceptible, but, under the influence of barometric pressure and wind, the sea-level occasionally varies as much as 2 ft. Rainfall is irregular; it averages 21 in., varying from 12 to 27 in. in the year. However, rainfall is uncertain, and periods of drought have extended over three years. Snow is seen once or twice in a generation; violent hailstorms occur. Undulant fever was traced by Sir David Bruce to a *micrococcus melitensis.* There is a modern system of drainage.

Flora.—It is hardly possible to differentiate between imported and indigenous plants. Among the marine flora may be mentioned *Porphyra laciniata,* the edible laver; *Codium tomentosum,* a coarse species; *Padina pavonia,* common in shallow water; *Ulva latissima; Haliseris polypodioides; Sargassum bacciferum;* the well-known gulf weed, probably transported from the Atlantic; *Zostera marina,* forming dense beds in muddy bays; the roots are cast up by storms and are valuable as a fertilizer to dress the fields. Among the land plants may be noted the blue anemone; the ranunculus along the road-sides, with a strong perfume of violets; the Malta heath which flowers at all seasons; *Cynomorium coccineum,* the curious "Malta fungus," formerly so valued for medicinal purposes that a guard was set for its preservation under the rule of the Knights; the pheasant's-eye; three species of mallow and geranium; *Oxalis cernua,* a very troublesome imported weed; *Lotus edulis; Scorpiurus subvillosa,* wild and cultivated as forage; two species of the horseshoe-vetch; the opium poppy; the yellow and claret-coloured poppy; wild rose; *Crataegus azarolus,* of which the fruit is delicious preserved; the ice-plant; squirting cucumber; many species of *Umbelliferae; Labiatae,* to which the spicy flavour of the honey (equal to that of Mt. Hymettus) is ascribed; snapdragons; broom-rape; glasswort; *Salsola soda,* which produces when burned a considerable amount of alkali; there are 15 species of orchids; the *gladiolus* and *iris* are also found; *Urginia scilla,* the medicinal squill, abounds with its large bulbous roots near the sea; 17 species of sedges and 77 grasses have been recorded.

Fauna.—There are four species of lizard and three non-venomous snakes; a land tortoise, a turtle and a frog. Of birds very few are indigenous; the jackdaw, blue solitary thrush, spectacled warbler, the robin, kestrel and the herring-gull. Over 200 migratory bird-species have been enumerated. The only wild mammalia in the island are the hedgehogs and two species of weasel.

Malta has several species of zoophytes, sponges, mollusca and crustacea. Insect life is represented by plant-bugs, locusts, crickets, grasshoppers, cockroaches, dragon-flies, butterflies, numerous varieties of moths, bees and mosquitoes.

Among the fish may be mentioned the tunny, dolphin, mackerel, sardine, sea-bream, dentice and pagnell; wrasse, of exquisite rainbow hue and good for food; members of the herring family, sardines, anchovies, flying-fish; sea-pike; a few representatives of the cod family, and some flat fish; soles (very rare); *Cernus* which grows to large size; several species of gray and red mullet; 11 species of *Triglidae,* including the beautiful flying gurnard; and 18 species of mackerel, all migratory.

People.—The upper classes have Norman, Spanish and Italian blood. The knights of St. John, commonly called "of Malta," were drawn from the nobility of Catholic Europe. They took vows of obedience and celibacy. At the time of the British occupation there were about two dozen families bearing titles of nobility granted, or recognized, by the Grand Masters, and descending by primogeniture. No government has ever recognized papal titles in Malta.

In appearance the Maltese are a handsome race, about the middle height, well formed and sturdily set up; they have escaped the negroid contamination by former importations of black troops noticeable in Sicily, and their features are less dark than those of the southern Italians. The women are generally smaller than the men, with black eyes, fine hair and graceful carriage. They are a thrifty and industrious people, prolific and devoted to their offspring, good-humoured, quick-tempered and impressionable. The Maltese are adherents to the Roman Catholic Church.

The phenomenal congestion of population gives interest to records of its growth; in the 10th century there were 16,767 inhabitants in Malta and 4,514 in Gozo. Estimates made at the arrival of the Knights (1530) varied from 15,000 to 25,000, and at the end of their rule (1798) the population was estimated at 100,000. Subsequently the population more than doubled, and in the 20th century there was a net average increase of nearly 3,000 a year. Including Gozo and Comino, the civil population on Dec. 31, 1938, was 268,668, giving a density of 2,277 to the sq.mi., compared with a density of 468 in the United Kingdom. Emigration largely reduced the overcrowding. Besides the considerable Maltese population found in the United States, colonies were built up throughout the Mediterranean (especially Egypt) and in Tunisia. (St.; X.)

Language.—For the most part the people have no racial affinities in Europe and, high and low, all speak among themselves the Phoenician Maltese, a tongue akin to Syriac and Arabic. It is altogether different from the Italian language; the latter is spoken with a limited vocabulary and peculiar intonation by only about one-sixth of the population. However, although Maltese was the medium of daily intercourse and business in the island, it had no official standing until 1933, the two official languages being English and Italian. In 1934 letters patent removed Italian from its position as one of the two official languages and provided that "the English language, as the official language of the British Empire, and the Maltese language, as the language of the people of Malta, shall be the official languages of Malta." The use of Italian was discontinued in the courts and schools (*see* below), and a knowledge of Maltese was required of all candidates for admission to the public service.

Legislation.—Latin was the language of the courts until 1784, and was not completely supplanted by Italian until 1815. Maltese were liable for trial in the courts in Italian, to them a foreign language, until 1933, when trial in their own language was permitted for the first time. In 1934 Maltese succeeded Italian as the official language of the courts, and Italian was removed from the faculty of law in the university. The laws of Justinian remained the basis of the common law, the code of Rohan was not altogether abrogated, and considerable weight was still given to the Roman canon law. Civil law was framed mainly on the Napoleonic code, with substantial alterations to meet the conditions and usages of the population. The commercial maritime laws were taken from the French commercial code and contained provisions from the Merchant Shipping act of the United Kingdom.

Education.—Elementary education is free in government schools, of which, in 1938–39, there were 157 (94 day schools and 63 night schools), with an average attendance of 32,735 pupils. In 1924 it was laid down that a parent, although at liberty to decide whether his children should or should not go to school, had to leave them therein, once admitted, until they reached the age of 14 or, alternately, until they passed the final examination of the highest class in their school. The two departments of elementary and secondary education were merged in 1933, and three years later a preparatory secondary school was opened for children who had not attended the government elementary schools but desired preparation for secondary education. The Montessori method was introduced in Malta in 1936. One central school for boys and three central schools for girls provided special secondary school courses for those planning to become teachers. The government also maintained a lyceum for boys and a secondary school for girls. The university, founded in 1769, had in 1938–39 an average attendance of about 150 students. Low fees were payable at the lyceum and the university.

About the middle of the 19th century a mixed system of both English and Italian, called *pari passu,* was adopted as the basis of Maltese education. This was followed by a new system of education based on the principle of beginning from the bottom, by teaching to read and write in Maltese as the medium for assimilating, at a later stage, either English or Italian, one at a time, and aiming at imparting general knowledge in colloquial English. Parents and guardians were called upon to select whether each child should learn English or Italian next after learning reading, writing and arithmetic in Maltese. However, the teaching of Italian in all grades again became general, and it was not until 1923 that the teaching of that language was abolished in the infant schools and in the first and second years of the elementary schools. In 1933 the teaching of Italian was discontinued in all grades of the elementary schools, both Maltese and English being taught in all government educational institutions, and the department of education produced textbooks of Maltese history, told in the Maltese language. A British institute was founded in Valletta in 1939 to impart a knowledge of British history, language, literature and music, ways of living and thinking.

Towns and Villages.—The capital is named after its founder, the Grand Master de la Valette, but from its foundation it has been called Valletta (*q.v.*); it contained the palace of the Grand Masters, the magnificent *auberges* of the several subdivisions or "Langues" of the order, the unique cathedral of St. John with the tombs of the Knights and magnificent tapestries and marble work; a fine opera house and hospital were conspicuous. During World War II attacks by Italo-German aircraft inflicted damage to these and other historic buildings beyond possibility of restoration. Before Italy surrendered in 1943, about three out of every four houses in Valletta were damaged or demolished. In January of that year the British government made a free gift of £10,000,000 toward the cost of rebuilding in Malta, but much had disappeared that money could never replace. Malta was an important naval and air base. Great naval docks, refitting yards, magazines and stores were built on the southeast side of the Grand Harbour at Valletta.

Between the inner fortifications of Valletta and the outer works, across the neck of the peninsula, is the suburb of Floriana. To the southeast of Valletta, at the other side of the Grand Harbour, are the cities of Senglea, Vittoriosa and Cospicua; this group is often spoken of as "the Three Cities." The old capital, near the centre of the island, is variously called Città Vecchia (*q.v.*), Notabile and (in Maltese) Mdina, with its suburb Rabat; here are the catacombs and the ancient cathedral of Malta. Across the Marsamuscetto harbour of Valletta is a considerable modern town called Sliema. The villages of Malta arc Mellieha, St. Paul's Bay, Musta, Birchircara, Lia, Atterd, Balzan, Naxaro, Gargur, Misida, S. Julian's, S. Giuseppe, Dingli, Zebbug, Siggieui, Curmi, Luca, Tarxein, Zurrico, Crendi, Micabbiba, Circop, Zabbar, Asciak, Zeitun, Gudia and Marsa Scirocco. In Gozo, the chief town is called Victoria (prior to 1897 known as Rabat), and there are several large villages.

Communications.—Numerous regular and occasional calls were made at Malta by both British and foreign shipping lines, despite inadequate port facilities for the loading and discharge of cargo and the lack of deep water at quayside. These deficiencies, and the necessity of allowing precedence to admiralty requirements, resulted, after World War I, in diminution of the coal bunkering trade.

Telegraphic communication was maintained by Cable and Wireless, Ltd., with Europe and the rest of the world, and the government-controlled telephone service in Malta and Gozo. The railway which ran from Valletta to Città Vecchia, and the tramway services which used formerly to operate, were replaced by an extensive motor omnibus service which was efficient and extremely cheap. Between Malta and Gozo was a ferry service on which cars could be transported. First class roads were excellent, being well surfaced and, in most cases, wide. A daily mail service travelled by way of Syracuse, in Sicily.

Money, Weights and Measures.—The legal tender currency was exclusively British. Bank of England notes and British coin were the legal tender, supplemented in 1939 with Malta's own paper notes. The three local banks were the Bank of Malta, the Anglo-Maltese bank and Scicluna's bank (the last a private institution), and there were branches of Barclays bank (Dominion, Colonial and Overseas), the Banco di Roma, the Crédit Foncier d'Algérie et de Tunisie and other foreign banks. Local weights and measures included the cantar, 175 lb.; salm, one imperial quarter; cafiso, $4\frac{1}{2}$ gal.; canna, 6 ft. $10\frac{1}{2}$ in.; the tumolo, 256 sq.ca. Imperial measures were used for most commercial purposes.

Finance and Trade.—The small area of the Maltese group of islands, the limitations of their agriculture and the inevitably restricted nature of their manufacturing activities combined to preclude any very large economic development. The agricultural produce of the islands could support the dense population only for three months in the year; the balance of foodstuffs and necessaries had to be paid for by the purchasing power of the armed forces stationed there, and by work done for the forces in the dockyard and elsewhere and for visitors and tourists. Relatives at home also received large remittances from Maltese abroad; and interest from investments outside the islands, and accumulated capital furnished margins to adjust the adverse balance.

Agriculture.—The main industry of the Maltese islands was agriculture, but its extent and productivity were severely limited. Prior to World War II, land under cultivation was decreasing as the result of encroachments by the building of houses, the widening and opening of roads, and the construction of playgrounds and aerodromes. As a rule the tillers of the soil lived away from their lands, in some neighbouring village. The total cultivable area was only about 43,000 ac., and much of this land was very near the margin, having little depth of soil above the coralline limestone. Little use was made of modern methods or machinery. Two, and often three, crops were raised in the year; on irrigated land (about 4% of the cultivable area) more than twice as many crops were possible. The presence of phosphates accounted for the fertility of the shallow soil. There were about 11,000 farms, so that their average size was less than four acres. For the most part the fields were composed of terraces by which the soil had been walled up along the contours of the hills, with enormous labour, to save it from being washed away. Owing to the operation of the laws of inheritance farms were nearly always divided up into separate strips of land not adjacent to each other.

The grain crops are wheat and barley (frequently sown together), and the principal fodder crops are green barley and a tall clover called "sulla" (*Hedysarum coronarum*), with beautiful purple blossoms. Vegetables of all sorts are easily grown, and a rotation of these is raised on land irrigated from wells and springs. Potatoes and onions are grown for exportation at seasons when they are scarce in northern Europe. Grapes are extensively cultivated (chiefly for wine making but also for table use). Some of the best oranges in the world are grown, and exported; but sufficient care is not taken to keep down insect pests, and to replace old trees. Cumin seed is produced for export, while figs, apricots, nectarines and peaches grow to perfection. Animal industries are also of some importance. Cattle, though few in number, are of fine breed, while goats abound everywhere; cows of a large and very powerful build are used for ploughing. Pig breeding and poultry keeping are carried on successfully.

Industry.—Women and children are engaged in producing Maltese lace. After World War I the demand for export diminished, partly because of deterioration in the quality of much of the lace produced, and partly because of changes in fashion. The weaving of Malta cloth by hand-looms survived as a languishing industry. Good building stone is quarried and cut in Malta and, in addition to being used locally, is exported, principally to Greece. Ornamental carvings made in Maltese stone were exported to a limited extent, and pottery was manufactured on a small scale. Maltese craftsmen turned out boots and shoes of good design and workmanship, and this industry received some measure of tariff protection.

Overseas Trade.—The most important export items were potatoes, the bulk of them generally going to the Netherlands, and that country also took more than half of Malta's shipments of onions. Germany was the largest buyer of cumin seed, and Italy and Greece purchased almost half the hides and skins. Most of the island's tallow and old and scrap metals also went to Italy.

Prior to World War II only about one-third of Malta's imports came from British territories. In 1938, of total imports amounting to £3,869,606, no less than £2,424,883 were of foreign origin. Italy did a larger trade with Malta than any other country. The principal imports were wheat, gasoline, coal, flour and semola, sugar, textiles, metals and manufactures thereof. Imports into the United States from Malta were negligible, but that country sold to the islands in 1938 goods to the value of £138,000, mainly unmanufactured tobacco, motor cars and typewriters.

ARCHAEOLOGY

Although Malta is a fragment of an old land-bridge uniting Italy and Africa, evidence of the former existence of palaeolithic man on the island continues to be in doubt. Human teeth claimed to have Neanderthal characteristics have been found in a cave near Ghar Dalam, but they were unaccompanied by palaeolithic artefacts, and their association with fossil elephant and hippopotamus is not convincingly proved.

The neolithic civilization, however, was both rich and remarkable. A few dolmens and menhirs may perhaps be signs of its simple beginnings, and there are also one or two towers of uncertain date that can be compared with the *nuraghi* of Sardinia; but a more complicated and ambitious megalithic architecture is its most important feature. This is represented by the structures known as sanctuaries, or temples (the theory that they were palaces is untenable); of these some 15 or 16 are known in Malta, and there are also two in Gozo. Among the largest of these buildings are the Mnaidra group and Hagiar Kim on the south coast, Corradino near Valetta, and the adjacent Hal Tarxien, where there are three structures juxtaposed (and to some extent superposed), and Gigantia in Gozo. Of these only Hal Tarxien, explored by Dr. T. Zammit, has been scientifically excavated. The sanctuaries consist of two double apses facing a central passage; but are usually complicated by the presence of additional apses and small side-chambers, or even by the linking up of two or more units. They are built of orthostatic limestone blocks of large size, sometimes with courses of horizontal stones above them; it is probable that the entrances and corridors were roofed by capstones laid flat across them, and there is no doubt that many of the apses and small rooms had corbelled roofs. In the courts were many temple-accessories, such as the so-called "altars" and oracular chambers (cells with porthole apertures), conical pillars that were doubtless idols, small baetylic stones, and figurines of clay and stone; there was also abundant pottery. The spiral occurs as an ornament both in stone-carving and on pottery, but this motif is not found in the earliest building at Hal Tarxien; sculptured bas-reliefs of animals, the puncture-dressing of the columns and altars are other important characteristics of the temple ornament. Of the figures the most notable is the lower portion (the legs and bottom of a flounced skirt) of an image about 7ft. in height, still in situ at Hal Tarxien.

The Hypogeum at Hal Saflieni is clearly of the same period as the Sanctuaries, but it is peculiar in that it is cut in the solid rock. It consists of a maze of small rooms (two are decorated with red lines and spirals on the wall) disposed in two stories; and it is interesting to note that the corbelled roofs of the sanctuaries and other features of the megalithic structures above ground were imitated here. Whatever may have been its original purpose it is certain that it was eventually employed as an ossuary. But little is known of the other graves of the neolithic period; possibly the dolmens are the earliest of these. In addition, however, a series of extended and also crouched burials have been found in a cave at Burmeghez near Mkabba, while at Bukana near Casal Attard is a rock-cut tomb revealing ossuary-practice accompanied by much red ochre. As to dwelling-places, there are occasionally groups of small rooms, perhaps habitations, near the Sanctuaries, as on the Corradino Hill and it seems likely that such structures as Borg-en-Nadur in Malta and Tal-Kaghan in Gozo were fortified settlements. The question of the origin of this neolithic civilization is one of the outstanding problems of Mediterranean archaeology. There are certain architectural resemblances between the megalithic buildings and Hypogeum of Malta and those of the other western Mediterranean islands, particularly as regards the Hypogeum and the rock-cut tombs of Sardinia and Sicily. Some of the pottery, furthermore, has affinities with sherds found in Sardinia, and also in Sicily, where it is noteworthy that spiral carvings on rock are known; Spanish affinities for the Maltese pottery have also been claimed. There is, therefore, hardly room to doubt the general relationship of the neolithic civilization in Malta with the megalithic civilization of the Western Mediterranean; but stock must be taken of possible influences from other directions. The resemblance of some of the Malta pottery to the spiral-meander ware of Italy (Salerno) and central Europe and the Balkans (*e.g.* Butmir) must be noted; nor are the connections with Crete especially as regards the horned spiraliform ornament to be neglected. It now seems probable, however, that north Africa supplied a determining factor in the formation of the Maltese civilization; but, though this view is gaining ground, a fuller knowledge of the Tunisian prehistoric cultures is required before a connection between Africa and the Mediterranean islands can be effectively demonstrated.

The Bronze Age in Malta is signalized by a new pottery, but this has been found in direct stratigraphical relations with neolithic remains at Hal Tarxien where a cemetery of large urns containing cremated bones was found in a part of the second temple that, after it had first fallen into ruins, had been levelled to receive the new graves. These urns were accompanied by daggers and flat axes, mostly of copper, and by peculiar discoid "sitting" figures made of pottery. The Bronze Age ware also occurs in the Hypogeum, and in the Sanctuary of Santa Verna; it has been referred, very doubtfully, to Middle Minoan I, and on this view the beginning of the neolithic must be put back at least as far as 3000 B.C. to allow for the full development of the Sanctuary architecture and for the partial ruin of Hal Tarxien before the deposition of the cemetery. This Bronze Age ware has Italic affinities suggesting a rather later date than M.M.I.

There is seemingly a break between the Bronze Age culture and the coming of the Phoenicians. The first arrival of these folk dates from the beginning of the last millennium B.C., but the period of the foundation of the towns is later, that is to say, about the 7th or 8th century B.C. The island was clearly an important colony, and the Phoenician remains are of considerable interest. Three distinct types of Punic graves are recognised, the earliest having a round cell and round chamber, and the latest variety having both cell and chamber square. These last probably overlap the beginning of the Roman occupation.

Finally the "cart-ruts" (deep parallel grooves worn in the rock and having a span of about 4½ft.) must also be noted among the antiquities of Malta, though their age and significance is still obscure. They are at least older than the late Punic graves, since these in two instances cut across them, and the fact that they run out under the sea at Birzebuggia is another proof of their antiquity.

HISTORY

To the Phoenician period, besides the tombs already mentioned, belong some remains of houses and cisterns, and (probably) a few round towers which are scattered about the island, while the important Roman house at Città Vecchia is the finest monument of this period in the islands.

The Carthaginians came to Malta in the 6th century B.C., not as conquerors, but as friends of a sister Phoenician colony (Freeman, *Hist. Sicily,* i. 255): Carthage in her struggle with Rome was at last driven to levy oppressive tribute, whereupon the Maltese gave up the Punic garrison to Titus Sempronius in circumstances described by Livy (xxi. 51). The Romans did not treat the Maltese as conquered enemies, and at once gave them the privileges of a *municipium;* Cicero (*in Verrem*) refers to the Maltese as "Socii." Nothing was to be gained by displacing the Phoenician inhabitants in a country from which any race less thrifty would find life impossible by agriculture. On the strength of a monument bearing his name, it has been surmised that Hannibal was born in Malta, while his father was governor-general of Sicily; he certainly did not die in Malta. There is evidence from Cicero (*in Verrem*) that a very high stage of manufacturing and commercial prosperity, attained in Carthaginian times, continued in Malta under the Romans. The Phoenician temple of Juno, which stood on the site of Fort St. Angelo, is also mentioned by Valerius Maximus. An inscription records the restoration of the temple of Proserpine by Cheriston, a freedman of Augustus and procurator of Malta. Diodorus Siculus (L. V., c. 4) speaks of the importance and ornamentation of Maltese dwellings, and to this day remains of palaces and dwellings of the Roman period indicate a high degree of civilization and wealth. When forced to select a place of exile, Cicero was at first (*ad Att.* III. 4, X. i. 8, 9) attracted to Malta, over which he had ruled as quaestor 75 B.C. Publius was "chief of the island" when St. Paul was shipwrecked (Acts xxvii. 7); and is said to have become the first Christian bishop of Malta. The site where the cathedral at Città Vecchia stands is reputed to have been the residence of Publius and to have been converted by him into the first Christian place of worship, which was rebuilt in 1090 by Count Roger, the Norman conqueror of Malta. The Maltese catacombs are strikingly similar to those of Rome, and were likewise used as places of burial and of refuge in time of persecution. They contain clear indication of the interment of martyrs. St. Paul's Bay was the site of shipwreck of the apostle in A.D. 58; the "topon diathalasson" referred to in Acts is the strait between Malta and the islet of Selmun. According to tradition and to St. Chrysostom (*Hom.* 54) the stay of the apostle resulted in the conversion of the Maltese to Christianity. The description of the islanders in Acts as "barbaroi" confirms the testimony of Diodorus Siculus that they were Phoenicians, neither hellenized nor romanized. The bishopric of Malta is referred to by Rocco Pirro (*Sicilia sacra*), and by Gregory the Great (*Epist.* 2, 44; 9, 63; 10, 1). It appears that Malta was not materially affected by the Greek schism, and remained subject to Rome.

On the final division of the Roman dominions in A.D. 395 Malta was assigned to the empire of Constantinople. On the third Arab invasion, A.D. 870, the Maltese joined forces against the Byzantine garrison, and 3,000 Greeks were massacred. Unable to garrison the island with a large force, the Arabs cleared a zone between the central stronghold, Medina, and the suburb called Rabat, to restrict the fortified area. Many Arab coins, some Kufic inscriptions and several burial-places were left by the Arabs; but they did not establish their religion or leave a permanent impression on the Phoenician inhabitants, or deprive the Maltese language of the characteristics which differentiate it from Arabic. There is no historical evidence that the domination of the Goths and Vandals in the Mediterranean ever extended to Malta: there are fine Gothic arches in two old palaces at Notabile, but these were built after the Norman conquest of Malta. In 1090 Count Roger the Norman (son of Tancred de Hauteville), then master of Sicily, came to Malta with a small retinue; the Arab garrison was unable to offer effective opposition, and the Maltese were willing and able to welcome the Normans as deliverers and to hold the island after the immediate withdrawal of Count Roger. A bishop of Malta was witness to a document in 1090. The Phoenician population had continued Christian during the mild Arab rule. Under the Normans the power of the Roman Church quickly augmented, tithes were granted and ecclesiastical buildings erected and endowed. The Normans, like the Arabs, were not numerically strong; the rule of both, in Sicily as well as Malta, was based on a recognition of municipal institutions under local officials; the Normans, however, exterminated the Mohammedans. Gradually feudal customs asserted themselves. In 1193 Margarito Brundusio received Malta as a fief with the title of count; he was Grand Admiral of Sicily. Constance, wife of the emperor Henry IV. of Germany became, in 1194, heiress of Sicily and Malta; she was the last of the Norman dynasty. The Grand Admiral of Sicily in 1223 was Henry, count of Malta. He had led 300 Maltese at the capture of two forts in Tripoli by the Genoese.

In 1427 the Turks raided Malta and Gozo, they carried many of the inhabitants into captivity, but gained no foothold. The Maltese joined the Spaniards in a disastrous raid against Gerbi on the African coast in 1432. In 1492 the Aragonese expelled the Jews. Dissatisfaction arose under Aragonese rule from the periodical grants of Malta, as a marquisate or countship, to great officers of state or illegitimate descendants of the sovereign. Exemption was obtained from these incidences of feudalism by large payments to the Crown in return for charters covenanting that Malta should for ever be administered under the royal exchequer without the intervention of intermediary feudal lords. This compact was twice broken, and in 1428 the Maltese paid King Alfonso 30,000 florins for a confirmation of privileges, with a proviso that entitled them to resist by force of arms any intermediate lord that his successors might attempt to impose. Under the Aragonese, Malta, as regards local affairs, was administered by a *Università* or municipal commonwealth with wide and indefinite powers, including the election of its officers, Capitan di Verga, Jurats, etc. The minutes of the "Consiglio Popolare" of this period are preserved, showing it had no legislative power; this was vested in the king, and was exercised despotically in the interests of the Crown. The knights of St. John having been driven from Rhodes by the Turks, obtained the grant of Malta, Gozo and Tripoli in 1530 from the emperor Charles V., subject to a reversion in favour of the emperor's successor in the kingdom of Aragon should the knights leave Malta, and to the annual tribute of a falcon in acknowledgment that Malta was under the suzerainty of Spain. The Maltese, at first, challenged the grant as a breach of the charter of King Alfonso, but eventually welcomed the knights. The Grand Master de l'Isle Adam, on entering the ancient capital of Notabile, swore for himself and his successors to maintain the rights and liberties of the Maltese. The Order of St. John took up its abode on the promontory guarded by the castle of St. Angelo on the southern shore of the Grand Harbour, and, in expectation of attacks from the Turks, commenced to fortify the neighbouring town called the Borgo. The knights lived apart from the Maltese, and derived their principal revenues from estates of the Order in the richest countries of Europe. They accumulated wealth by war, or by privateering against the Turks and their allies. The African Arabs under Selim Pasha in 1551 ravaged Gozo, after an unsuccessful attempt on Malta, repulsed by cavalry under Upton, an English knight. The Order of St. John and the Christian Maltese now realized that an attempt to exterminate them would soon be made by Soliman II., and careful preparations were made to meet the attack.

The great siege of Malta which made the island and its knights famous, and checked the advance of Mohammedan power in southern and western Europe, began in May 1565. The fighting men of the defenders are variously recorded between 6,100 and 9,121; the roll comprises one English knight, Oliver Starkey. The Mohammedan forces were estimated from 29,000 to 38,500. The Sultan placed his troops under the veteran Mustapha, and his galleys under his youthful relative Piali; he hesitated to make either supreme and ordered them to await the arrival of Dragut with his Algerian allies, before deciding on their final plans. Meanwhile, against Mustapha's better judgment, Piali induced the council of war to attack St. Elmo, in order to open the way for his fleet to an anchorage, safe in all weathers, in Marsamuscetto harbour. This strategical blunder was turned to the best advantage by La Valette, who so prolonged the most heroic defence of St. Elmo that the Turks lost 7,000 killed and as many wounded before exterminating the 1,200 defenders, who fell at their post. In the interval Dragut was mortally wounded, the attack on Notabile was neglected, valuable time lost, and the main objective (the Borgo) and St. Angelo left intact. The subsequent siege of St. Angelo, and its supporting fortifications, was marked by the greatest bravery on both sides. The knights and their Maltese troops fought for death or victory, without asking or giving quarter. Finally, Mustapha was driven to his ships on Sept. 8.

The Order thus reached the highest pinnacle of its fame, and new knights flocked to be enrolled therein from the flower of the nobility of Europe; La Valette refused a cardinal's hat, determined not to impair his independence. He made his name immortal by making Valletta a magnificent example of fortification, unrivalled in the world. Throughout the 16th and 18th centuries they harassed Turkish commerce and took part as an allied Christian power in the great victory of Lepanto. With the growth of wealth and security the martial spirit of the Order began to wane, and so also did its friendly relations with the Maltese. The civil government became neglected and disorganized, licentiousness increased and riots began to be threatening. In 1614 the Vignacourt aqueduct was constructed. The Jesuits established a university, but they were expelled and their property confiscated in 1768. British ships of war visited Malta in 1675, and in 1688 a fleet under the duke of Grafton came to Valletta. The fortifications of the "Three Cities" were greatly strengthened under the Grand Master Cotoner.

In 1722 the Turkish prisoners and slaves, then very numerous, formed a conspiracy to rise and seize the island. Premature discovery was followed by prompt suppression. Castle St. Angelo and the fort of St. James were, in 1775, surprised by rebels, clamouring against bad government; this rising is known as the Rebellion of the Priests, from its leader, Mannarino. The last but one of the Grand Masters who reigned in Malta, de Rohan, restored good government, abated abuses and promulgated a code

6. A street in Malta. The woman at the foot of the stairs wears the typical black dress of the islanders

of laws. On the death of Rohan the French knights disagreed as to the selection of his successor, and a minority were able to elect, in 1797, a German of weak character, Ferdinand Hompesch, as the last Grand Master to rule in Malta. Bonaparte had arranged to obtain Malta by treachery, and he took possession without resistance in June 1798; after a stay of six days he proceeded with the bulk of his forces to Egypt, leaving General Vaubois with 6,000 troops to hold Valletta.

Towards the close of the rule of the knights in Malta feudal institutions had been shaken to their foundations, but the transition to republican rule was too sudden and extreme for the people to accept it. Among other laws Bonaparte enacted that French should at once be the official language, that 30 young men should every year be sent to France for their education; that all foreign monks be expelled, that no new priests be ordained before employment could be found for those existing; that ecclesiastical jurisdiction should cease; that neither the bishop nor the priests could charge fees for sacramental ministrations, etc. Stoppage of trade, absence of work (in a population of which more than half had been living on foreign revenues of the knights), and famine, followed the defeat of Bonaparte at the Nile, and the failure of his plans to make Malta a centre of French trade. An attempt to seize church valuables at Notabile was forcibly resisted by the Maltese, and general discontent broke out into open rebellion on the 2nd of September 1798. The French soon discovered to their dismay that, from behind the rubble walls of every field, the agile Maltese were unassailable. The prospect of an English blockade of Malta encouraged the revolt, of which Canon Caruana became the leader. Nelson was appealed to, and with the aid of Portuguese allies he established a blockade and deputed Captain Ball, R.N. (afterwards the first governor) to assume, on the 9th of February 1799, the provisional administration of Malta and to superintend operations on land. Nelson recognized the movement in Malta as a successful revolution against the French, and upheld the contention that the king of Sicily (as successor to Charles V in that part of the former kingdom of Aragon) was the legitimate sovereign of Malta. British troops were landed to assist in the siege; few lives were lost in actual combat, nevertheless famine and sickness killed thousands, and finally forced the French to surrender to the allies.

The treaty of Amiens (1802) provided for the restoration of the island to the Order of St. John; against this the Maltese strongly protested, realizing that it would be followed by the reestablishment of French influence. The English flag was flown side by side with the Neapolitan, and England actually renewed war with France sooner than give up Malta. The treaty of Paris (1814), with the acclamations of the Maltese, confirmed Great Britain in the aggregation of Malta to the empire.

A period elapsed before the government of Malta again became self-supporting, during which over £600,000 was contributed by the British exchequer in aid of revenue, and for the importation of food-stuffs. After the treaty of Paris stability of government developed, and many important reforms were introduced under the strong government of the masterful Sir Thomas Maitland. Trial by jury for criminal cases was established in 1829. A council of government, of which the members were nominated, was constituted by letters patent in 1835, but this measure only increased the agitation for a representative legislature. Freedom of the press and many salutary innovations were brought about on a report of John Austin and G. C. Lewis, royal commissioners, appointed in 1836. The basis of taxation was widened, sinecures abolished, schools opened in the country districts, legal procedure simplified, and Police established on an English footing. Queen Adelaide visited Malta in 1838 and founded the Anglican collegiate church of St. Paul. Sir F. Hankey as chief secretary was for many years the principal official of the civil administration. In 1847 R. Moore O'Ferrall was appointed civil governor. In June 1849 the constitution of the council was altered to comprise ten nominated and eight elected members.

The Crimean War brought great wealth and commercial prosperity to Malta. The nominal rule of military governors was reestablished in 1858, though the civil administration was largely confided to the chief secretary, with real power in the hands of the crown advocate. The civil service gravitated into the hands of a clique. At this period much money was spent on the Marsa extension of the Grand Harbour, while the military defenses were entirely remodelled, and considerable municipal improvements and embellishments were completed.

An executive council was established in 1881, and the franchise was extended in 1883. A policy of *laissez-faire* was changed in 1883 by the appointment of Sir Walter Hely-Hutchinson as chief secretary. A regulation excluding Maltese from the navy (because of their speaking on board a language that their officers did not understand) was protested by Gerald (later Lord) Strickland (Count Della Catena) on the ground that it was an infringement of the islanders' constitutional rights. The subject attracted considerable attention in Great Britain, and as one result, Malta received in 1887 a new (the "Strickland-Mizzi") constitution. This constitution, which ended a period of government by presidential casting votes and official ascendancy, was received by the Maltese with acclamation. Strickland, who had been elected to the legislature while an undergraduate at Cambridge university on the cry of equality of rights for Maltese and English, and Mizzi, the leader of the anti-English agitation, were, as soon as elected, given seats in the executive council to co-operate with the government; but their aims were irreconcilable. Mizzi wanted to ensure the predominance of the Italian language, while Strickland desired to replace bureaucratic government by a more democratic system and to introduce English ideas and precedents. Friction soon arose, and Mizzi resigned his post in the government.

Strickland became chief secretary in 1889, and without delay he carried out reforms that had been retarded for years. The civil service was reorganized so as to reward merit and work by promotion. Tenders were strictly enforced in letting government property and contracts; a largely increased revenue was applied on water supply, drainage and other works. Lepers were segregated by law. During the 1890s there was widespread agitation respecting the laws as to marriage, the Maltese relying on the Roman canon law and the English on the common law of England. The Holy See was consulted on the subject of civil marriage, and an agreement was made with Rome which obviated clerical agitation and obstruction in the council. However, the language question and educational reform, as well as the system of taxation, became matters of violent dispute and were contested in the legislature by the elected members of the Italian party. As a consequence, the Strickland-Mizzi constitution of 1887 was repealed by letters patent in 1903. Bureaucratic government, with an official majority, was again fully re-established for all local affairs, great and small.

During World War I the Maltese provided a garrison for the island, many seamen for men-of-war and minesweepers as well as labour battalions for service at Gallipoli and Salonika. In addition, Maltese did excellent service in various hospitals. As a mark of appreciation for these services a grant of responsible government was established by the constitution of 1921 and further letters patent in 1928. Members of the senate and house of assembly were elected by proportional representation; judges, appointed by the governor in council, could be removed only by a joint address from both houses of the legislature; while debates might be conducted in English, Italian or Maltese, all official entries were to be in English or Italian. English was declared the official language of the administration, and Italian the official language of record in the law courts. After a decade of fairly satisfactory government, friction developed between the Italian Catholic leaders and the British governor when use of the Italian language in the courts and the primary schools was restricted. The constitution was suspended in 1930 but restored in 1932. Following a second suspension of the constitution in 1933, Italian lost its position as an official language and as that of the courts, and by letters patent dated Aug. 12, 1936, the constitution was revoked. Executive power was then vested in the governor, aided by an executive council of ex-officio and nominated members, but by another constitution in 1939 limited representation without responsibility was again granted Malta. A council of government of 30 members was created, 10 being elected, with two nominated and eight officials; the governor had a casting though not an original vote.

After Italy entered World War II in 1940 Malta became subject to ceaseless aerial attacks by both German and Italian bombers from bases in Sicily, within 20 minutes flying time. The island, which was 1,000 mi. from the nearest British position, became of the very first importance as a base of operations. For three years Malta was defended by both the garrison and the people. At the height of the siege it was possible to send supplies of aviation gasoline and munitions to Malta only by submarine, while additional fighter aircraft of the R.A.F. were flown to the island from the decks of distant carriers. Despite the hardships, civilian morale stood high.

In April 1942, George VI awarded the George cross "to the island fortress of Malta to bear witness to a heroism and devotion that will long be famous in history." This was the first time that a medal had been conferred upon any part of the British commonwealth. The siege ended in 1943. By June 30 of that year 1,436 civilians had been killed, 3,415 wounded or injured, and 6,952 buildings destroyed or damaged. The British government made a gift of £10,000,000 for rebuilding, and announced that after the war full responsible government was to be restored to Malta. (*See* World War II.)

MALTA or MEDITERRANEAN FEVER, a disease long prevalent in Malta and formerly at Gibraltar, as well as other Mediterranean centres, characterized by prolonged high temperature, with anaemia, pain and swelling in the joints and neuritis, lasting on an average four months but extending even to two or three years. Its pathology was long obscure, but owing to conclusive research on the part of Col. (afterwards Sir) David Bruce, to which contributions were made by various officers of the R.A.M.C. and others, this problem has now been solved. A specific micro-organism, the *Micrococcus melitensis,* was discovered in 1887, and it was traced to the milk of the Maltese goats. A commission was sent out to Malta in 1904 to investigate the question, and after three years' work its conclusions were embodied in a report by Col. Bruce in 1907. It was shown that the disappearance of the disease from Gibraltar had synchronized with the non-importation of goats from Malta; and preventive measures adopted in Malta in 1906, by banishing goats' milk from the military and naval dietary, put a stop to the occurrence of cases. In the treatment of Malta fever a vaccine has been used with considerable success.

MALTE-BRUN, CONRAD (1775–1826), French geographer, was born on Aug. 12, 1775, at Thisted in Denmark, and died at Paris on Dec. 14, 1826. His original name was Malte Conrad Bruun. In 1800 he was banished from Denmark and he ultimately settled in Paris. He wrote the learned *Précis de la géographie universelle* (6 vols., 1810–29), continued by other hands after his death, and founded the *Annales des voyages* (1808), and was one of the founders of the Geographical Society of Paris.

MALTESE CROSS: *see* Cross and Crucifixion.

MALTESE LANGUAGE. The dominance of Arabic affinities in Maltese is evident, but there are good grounds for suspecting the presence of elements, probably much earlier, of Phoenician derivation. Contact with Crete existed about 2,000 B.C. (Sir Arthur Evans, *Palace of Minos,* vol. ii., 1928), and it is highly probable that the prospectors whose enterprise carried them to Britain and Scandinavia, left their mark on the linguistics of this interesting island. Italian words have been brought into use—supplementing and supplanting earlier forms. As an example of linguistic convergence, which has occasioned hot debate, the word *Missier,* "father," may be cited. It has been traced back and regarded as more primitive than Classical or Saracenic Arabic, though its resemblance to Italian is obvious.

See R. N. Bradley, *Malta and the Mediterranean Race.*

MALTHUS, THOMAS ROBERT (1766–1834), English economist, was born in 1766 at the Rookery near Guildford, Surrey, a small estate owned by his father Daniel Malthus, who was a friend and one of the executors of Rousseau. After being privately educated, Malthus entered Jesus college, Cambridge, where he was a contemporary of S. T. Coleridge. He was ninth wrangler in 1788, and was elected to a fellowship in 1793. He took orders in 1797, and held for a short while the curacy of Albury in Surrey. In 1798 he published the first edition of his great work, *An Essay on the Principle of Population as it affects the Future Improvement of Society, with Remarks on the Speculations of Mr. Godwin, M. Condorcet, and other Writers.* This was followed five years later by the second greatly enlarged and amended edition of his work in 1803; he published several subsequent revised editions, the sixth and last during his lifetime appearing in 1826. In 1805 Malthus married, and soon after was appointed professor of modern history and political economy in the East India Company's college at Haileybury where he died on Dec. 23, 1834.

Malthus's *Essay on Population* grew out of some discussions with his father respecting the perfectibility of society. His father shared the theories on that subject of Condorcet and Godwin, but his son combated them on the ground that the realization of a happy society will always be hindered by the miseries consequent on the tendency of population to increase faster than the means of subsistence. His father was struck by the weight and originality of his views, asked him to put them in writing, and then recommended the publication of the manuscript.

The first edition is in the nature of a long pamphlet. It is brilliantly written, with a marked felicity of phrase and illustration, and it immediately captured the imagination of his readers. It put forward the view that population, when unchecked, increases in a geometrical ratio while subsistence only increases in an arithmetical ratio, and Malthus asserts as a fact that population always increases up to the limits of the means of subsistence. Population is prevented from increasing beyond these limits by the positive checks of war, famine and pestilence, and by the influence of misery and vice. From this theory Malthus drew the important practical conclusion for the England of his day that the existing poor law system, with its indiscriminate doles and bounties upon large families, was utterly to be condemned as tending to aggravate the very evils which it was supposed to remedy. The publication of the *Essay* roused a storm of controversy, and bitter abuse was hurled at Malthus from the most diverse quarters. Undaunted by the attacks to which he was subjected, he set to work to collect material bearing on the rates of increase of population, in all times and countries, and five years later published the second edition of his *Essay* in an entirely different form. In its new guise the Essay is a long, soberly worded and scholarly treatise, full of detailed facts and statistics and abundantly documented. Nor was it the form alone that underwent a change. While maintaining his "principle" of population—the universal tendency of population to outrun the means of subsistence—he allowed the question of the mathematical ratios to fall rather into the background. But, above all, he introduced a most important modification into his original doctrine by recognizing the existence, in addition to the positive checks to the increase of population, of a preventive check which he termed "moral restraint." By this term Malthus understood the postponement of the age of marriage, accompanied by strict sexual continence. It may be noted that the views and methods advocated by those modern upholders of small families, who call themselves Neo-Malthusians, would have received nothing but condemnation from Malthus. The introduction of the notion of moral restraint, coupled with the realization that subsistence did not necessarily mean merely the bare necessaries for existence, give a slightly more hopeful colour to Malthus's views as set out in the later editions of his work. Nevertheless he remained profoundly pessimistic in his general outlook on the possibilities of the future progress of mankind, for he had scant faith in the capacity of the human race to regulate its numbers by the exercise of prudence and restraint. The positive checks had alone operated in the past and they, with all the vice and misery that follow in their train, were likely to continue to do so in the future.

It would be scarcely fair to convict Malthus of error on the ground that he failed to foresee the astonishing development of transport and colonization which took place in the 19th century and has increased so enormously the area from which foodstuffs and raw materials can be drawn during that period. On the other hand, he did undoubtedly underestimate the importance of the reactions of industrial progress upon the output and cost of production of agricultural produce. There is some truth in the contention of those who disagreed with him that, while every addition to the population means another mouth to feed, it also implies another pair of hands. The law of increasing returns has operated very powerfully in industry and the influence of inventions and new methods of cultivation have held in check that recourse to poorer soils which Malthus gleaned must result from any growth of population. Furthermore, progressive standards of living have contributed to raise the marriage age and lower the birth rate in western countries to a far greater extent than Malthus would ever have dared to contemplate. Even so, the decline in the death rate has been so great that the absolute rate of increase of population is still large in most countries, while in the East the Malthusian "principle" still seems to reign supreme.

Malthus's views influenced public opinion in the first half of the 19th century, yet later it had become common to disparage his doctrines as out of date. Since the European War of 1914–18, however, the spectre of over-population has returned and Malthus is coming into his own again.

A chance reading of the *Essay,* in which the phrase "struggle for existence" struck an answering chord, stimulated Charles Darwin to find the key to biological change in the process of natural selection brought about by this struggle for existence.

Malthus was also a writer of considerable importance for the development of economic theory. The close friend and correspondent of Ricardo, he not merely stimulated the latter but himself made independent contributions to the theory of value. He is generally credited with being the first writer to formulate the law of diminishing returns as applied to agriculture, though he did not call it by this name and perhaps himself failed to realize the full significance of this conception. He combated the rigid Ricardian labour cost theory of value and adumbrated a theory which was much closer to that of most modern economists.

Besides his great work, the first edition of which was reprinted by the Royal Economic Society in 1926, Malthus wrote *Observations on the Effect of the Corn Laws: An Inquiry into the Nature and Progress of Rent; Principles of Political Economy;* and *Definitions in Political Economy.* His views on rent were of real importance.

For his life see *Memoir* by his friend Dr. Otter, bishop of Chichester (prefixed to 2nd ed. 1836, of the *Principles of Political Economy*), and *Malthus and his Work,* by J. Bonar (London, 1885); *see* also Soetbeer, *Die Stellung der Sozialisten zur malthusschen Bevolkerungslehre* (Berlin, 1886); G. de Molinari, *Malthus, essai pour le principe de population* (Paris, 1889); Cossa, *Il Principio di popolazione di T. R. Malthus* (Milan, 1895); and Ricardo, *Letters to Malthus,* ed. J. Bonar (1887). (C. W. G.)

MALTHUSIANISM: *see* POPULATION.

MALTON, a town and urban district in the North Riding of Yorkshire, England, 21 mi. N.E. of York by the L.N.E.R. on the river Derwent, and connected with Norton, on the opposite bank, in the East Riding. Pop. (1938) 4,121. Area 6.3 sq.mi. Malton lies in the Malton or Kirkham gap which separates the clay Vale of Pickering from the Vale of York.

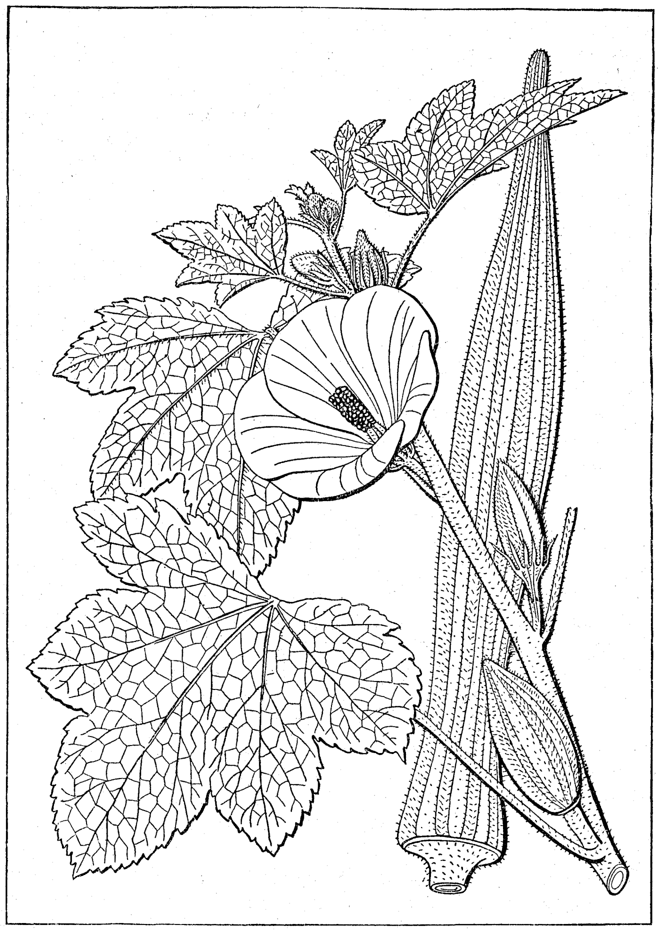
Traces of a Romano-British village exist east of the town. The greater part of the town belonged to the Crown in 1086 and was apparently retained until the reign of Henry I. The church of St. Mary at Old Malton was attached to a Gilbertine priory founded in 1150. The nave, a magnificent remain, is transitional Norman and Early English, with later insertions. Very little remains of the priory, with the exception of the crypt under a modern house. The church of St. Michael is a Late Norman building. The church of St. Leonard, with a square tower and spire, is of mixed architecture but has three Norman arches and a Norman font. Six mi. S.W. of Malton are the small but beautiful remains of Kirkham abbey, an Early English Augustinian foundation of 1131. The grammar school was founded in 1547. Castle Howard, a seat of the earl of Carlisle, lies 5 mi. to the southwest. Agricultural implements are manufactured, and there are corn mills, tanneries and breweries, also lime and whinstone quarries. Markets dating from the 13th century are held on Saturdays and Fridays and still belong to the lord of the manor.

MALTZAN, HEINRICH VON, BARON ZU WARTENBURG UND PENZLIN (1826–1874), German traveller, was born on Sept. 6, 1826 near Dresden. After extensive travels in North Africa and the Levant, he succeeded in 1860 in making the pilgrimage to Mecca, which he afterwards described in *Meine Wallfahrt nach Mecca* (Leipzig, 1865), but had to flee for his life to Jidda without visiting Medina. He died by his own hand at Pisa.

His works include *Drei Jahre im Nordwesten von Afrika* (Leipzig, 1863); *Reise nach Südarabien* (Brunswick, 1873), *Reise in Tunis und Tripolis* (Leipzig, 1870), which contains a collection of Punic inscriptions; and an edition of A. von Wrede's *Reise in Hadramaut* (Brunswick, 1870).

MALUS, ÉTIENNE LOUIS (1775–1812), French physicist, was born at Paris on June 23, 1775. He went to the military engineering school at Mezières and then served in the French army in Germany and Egypt. On his return he held official posts successively at Antwerp, Strasbourg and Paris, and devoted himself to optical research. A paper published in 1809 ("Sur une propriété de la lumière réfléchie par les corps diaphanes") contained the discovery of the polarization of light by reflection, which is specially associated with his name. In 1810 he won a prize from the Institute with his memoir, "Théorie de la double refraction de la lumière dans les substances cristallines."

MALVACEAE, a large and economically important family of flowering plants. It contains 45 genera with about 900 species, and occurs in all world regions except the coldest, the number of species increasing toward the tropics. The most conspicuously useful plant is cotton (*Gossypium*). It is represented in Britain by three genera: *Malva,* mallow; *Althaea,* marsh-mallow; and *Lavatera,* tree-mallow. In the United States there are about 20 genera, the best known ones, after *Gossypium,* being *Althaea* (marsh-mallow and hollyhock), *Malva* (mallow), *Sida Abutilon* (Indian mallow or velvet-leaf), and *Hibiscus* (rose mallow, and also okra or gumbo). The plants are herbs, as in the British mallows, or, in the warmer parts of the earth, shrubs or trees. The leaves are alternate and often palmately lobed or divided; the stipules generally fall early. The leaves and young shoots often bear stellate hairs and the tissues contain mucilage-sacs. The



HIBISCUS (HIBISCUS ESCULENTUS), SHOWING UPPER PART OF FLOWERING PLANT (ANNUAL) AND AN UNRIPE FRUIT

regular, hermaphrodite, often showy flowers are borne in the leaf-axils, solitary or in fasicles, or form more or less complicated cymose arrangements. An epicalyx formed by a whorl of three or more bracteoles is generally present just beneath the calyx; sometimes, as in *Abutilon,* it is absent. The parts of the flowers are typically in fives; the five sepals, which have a valvate aestivation, are succeeded by five often large showy petals which are twisted in the bud; they are free to the base, where they are attached to the staminal tube and fall with it when the flower withers. The very numerous stamens are united into a tube at the base, and bear kidney-shaped one-celled anthers which open by a slit across the top. The large spherical pollen-grains are covered with spines. The carpels are one to numerous; when five in number, as in *Abutilon,* they are opposite the petals, or, as in *Hibiscus,* opposite the sepals. In the British genera and many others they are numerous, forming a whorl around the top of the axis in the centre of the flower, the united styles rising from the centre and bearing a corresponding number of stigmatic branches. In *Malope* the numerous carpels are arranged one above the other in vertical rows. One or more anatropous ovules are attached to the inner angle of each carpel; they are generally ascending but sometimes pendulous or horizontal; the position may vary, as in *Abutilon,* in one and the same carpel.

The flowers are protandrous; when the flower opens the unripe stigmas are hidden in the staminal tube and the anthers occupy the centre of the flower; as the anthers dehisce the filaments bend backwards and finally the ripe stigmas spread in the centre. Pollination is effected by insects which visit the flower for the honey, which is secreted in pits one between the base of each petal and is protected from rain by hairs on the lower margin of the petals. In small pale-flowered forms, like *Malva rotundifolia,* which attract few insects, self-pollination is found, the style-arms twisting later to bring the stigmatic surfaces into contact with the anthers.

Except in *Malvaviscus* which has a berry, the fruits are dry. In *Malva* (*see* MALLOW) and allied genera they form one-seeded schizocarps separating from the persistent central column and from each other. In *Hibiscus* and *Gossypium* (the cotton-plant), the fruit is a capsule splitting loculicidally. Distribution of the seeds is sometimes aided by hooked outgrowths on the wall of the schizocarp, or by a hairy covering on the seed, an extreme case of which is the cotton-plant where the seed is buried in a mass of long tangled hairs—the cotton. The embryo is generally large with much-folded cotyledons and little endosperm.

The largest genus, *Hibiscus,* contains 160 species, which are widely distributed chiefly in the tropics; *H. Rosa sinensis* is a well-known greenhouse plant. *Abutilon* (*q.v.*) contains 120 species, mainly tropical; *Lavatera,* with 20 species, is chiefly Mediterranean; *Althaea* has about 15 species in temperate and warm regions, *A. rosea* being the hollyhock (*q.v.*); *Malva* has about 30 species in the north-temperate zone. Several genera are largely or exclusively American.

MALVASIA (Gr. *Monemvasia,* "city of the single approach"; Ital. *Napoli di Malvasia;* Turk. *Mengeshe* or *Beneshe*) on the east coast of the Morea, Greece, contiguous to the site of the ancient Epidaurus Limera, of which it took the place; one of the principal fortresses and commercial centres of the Levant during the middle ages, still represented by considerable ruins and a town of about 550 inhabitants. So extensive was its trade in wine that the name became familiar throughout Europe as that of a special kind—Ital. *Malvasia;* Span. *Malvagia;* Fr. *Malvoisie;* Eng. *Malvesie* or *Malmsey.* The wine was not of local growth, but came from the Cyclades, and Malavisi province of Crete.

The Byzantine emperors valued Malvasia as a fortress in the Morea, and rewarded its inhabitants for their fidelity by unusual privileges. The emperor Maurice made the city (previously dependent in ecclesiastical matters on Corinth) an archbishop's see, and Alexius Comnenus, and more especially Andronicus II. (Palaeologus) gave the Monembasiotes freedom from all sorts of exactions throughout the empire. It was captured after three years' siege by Guillaume de Villehardouin in 1248, but retained its liberties and privileges, and was restored to the Byzantine emperors in 1262. It placed itself under Venice from 1463 to 1540, when it was ceded to the Turks. In 1689 it was the only town of the Morea which held out against Morosini, and his successor Cornaro only succeeded in reducing it by famine. In 1715 it capitulated to the Turks, and on the failure of the insurrection of 1770 the leading families were scattered abroad. As the first fortress which fell into the hands of the Greeks in 1821, it became in the following year the seat of the first national assembly.

See Curtius, *Peloponnesos,* ii. 293 and 328; Castellan, *Lettres sur la Morée* (1808), for a plan; Valiero, *Hist. della guerra di Candia* (Venice, 1679), for details as to the fortress; W. Miller in *Journal of Hellenic Studies* (1907).

MALVERN, inland watering place, urban district, Bewdley parliamentary division, Worcestershire, England, 128 mi. N.W. of London by the G.W.R., served also by the L.M.S.R. Pop. (1938) 17,320. Area 12 sq.mi. It is situated on the eastern slopes of the Malvern hills, which rise from the valley of the Severn to a height of 1,395 ft. in the Worcestershire Beacon. The district bears the name of Malvern Chase, originally a Crown-land and forest, though it was granted to the earl of Gloucester by Edward I. An ancient trench, now the county boundary, along the summit of the hills determined the ancient boundary. Malvern was in early times an ecclesiastical settlement, but today it depends upon its schools and colleges. Mineral waters are manufactured.

The name Malvern is collectively applied to a line of small towns and villages, extending along the foot of the Malvern hills, 1,200 ac. of which to the south are administered by the National Trust. The principal is Great Malvern, lying beneath the Worcestershire Beacon. Here was the Benedictine priory which arose in 1083 out of a hermitage endowed by Edward the Confessor. The priory church of SS. Mary and Michael is a cruciform Perpendicular building, with an ornate central tower, Norman nave, and much early glass. At Malvern Wells, $2\frac{1}{2}$ mi. S., are the medicinal springs, extensive fishponds and hatcheries. Little Malvern, with remains of a Benedictine priory, lies at the foot of the Herefordshire Beacon, which is crowned by an ancient and well-preserved entrenched camp. Malvern Link, and West and North Malvern, on the hills, are suburbs of Great Malvern. The council owns the concert hall, the theatre and the cinema.

MALVY, LOUIS JEAN (1875–), French Socialist-Radical politician, was born at Figeac on Dec. 1, 1875. In 1906 he entered the chamber as a Socialist-Radical and was an under-secretary in the Monis and Caillaux cabinets (1911), minister of commerce and postal services under Doumergue (Dec. 1913) and minister of the interior in the Viviani ministry (June 1914). He retained this post under Briand and Ribot. On July 22, 1917, Clemenceau charged him with lax administration in dealing with defeatists and agitators, and he resigned on Aug. 31. His resignation brought about the fall of the Ribot cabinet. In October Léon Daudet brought against him a general accusation of treason. A commission, appointed at Malvy's own suggestion, decided on behalf of the chamber that the senate, sitting as a high court, should pronounce judgment on all the stated charges. On Aug. 6, 1918, the high court acquitted Malvy of the charge of treason, but found him guilty of *forfaiture, i.e.,* culpable negligence, in the performance of his duties as minister of the interior from 1914–17, and sentenced him to banishment for five years, which he passed in Spain. In 1924 he was re-elected to the chamber, he represented France at the Morocco negotiations which arranged for joint action against Abdel Krim, and in October of the same year became president of the finance commission of the chamber. Malvy again became minister of the interior in the Briand cabinet of March 1926, but his appointment roused old and bitter controversies and after a stormy sitting in which he was violently attacked he fainted in the chamber. The deputies then voted in support of the government, ashamed of their violence. But Malvy resigned on the ground that his presence in the cabinet deprived it support. In 1928 he was elected chairman of the finance committee of the chamber; again in 1932, serving until 1940.

See Albert, *Le procès Malvy* (1920); and E. Gomez Carillo, *Mystère de la vie et de la mort de Mata Hari* (1925).

MALWA, an historic province of India, which has given its name to one of the political agencies into which Central India is divided. Strictly, the name is confined to the hilly tableland, bounded S. by the Vindhyan range, which drains north into the river Chambal; but it has been extended to include the Nerbudda valley farther south. Its derivation is from the ancient tribe of Malavas who founded the Vikrama Samvat, an era dating from 57 B.C., which is popularly associated with a mythical king Vikramaditya. The position of the Malwa or Moholo mentioned by Hsuan Tsang (7th century) is plausibly assigned to Gujarat. The first records of a local dynasty are those of the Paramaras, a famous Rajput clan, who ruled for about four centuries (800–1200), with their capital at Ujjain and afterwards at Dhar. The Mohammedans invaded Malwa in 1235; and in 1401 Dilawar Khan Ghori founded an independent kingdom, which lasted till 1531. In 1562 Malwa was annexed to the Mogul empire by Akbar.

On the breakup of that empire, Malwa was one of the first provinces to be conquered by the Mahrattas, when it became a cockpit for fighting between the rival Mahratta powers, and the headquarters of the Pindaris or irregular plunderers. The Pindaris were extirpated by the campaign of Lord Hastings in 1817, and the country was reduced to order by Sir John Malcolm. Malwa is traditionally the land of plenty, in which sufferers from famine could take refuge. But in 1899–1900 it was visited by drought, followed by plague. A product used to be opium.

The Malwa agency comprises the states of Dhar, Jaora, Ratlam, Sitamau, Sailana, Jhabua, Barwani and Alirajpur and five petty chiefships. The area is 7,378 sq.mi. and the population in 1941 was 1,037,716 excluding the petty chiefships. The headquarters of the political agent are at Indore.

Malwa is also the name of a large tract in the Punjab, south of the river Sutlej, which is one of the two chief homes of the Sikhs, the other being known as Manjha. It includes the British districts of Ferozpore and Ludhiana, together with the native states of Patiala, Jind, Nabha and Maler Kotla.

MAM. This Indian tribe, speaking a Maya dialect, occupies in part the departments of Huehuetenango, Quezaltenango, Totonicapán and San Marcos in Guatemala, and also some of the adjacent portion of Mexico. Long ago they extended farther south and east into the ancient kingdoms of the Cakchiquel and Quiché (*q.v.*), but they were defeated by the Quiché king, Kicab, in alliance with the Cakchiquel, and forced to withdraw to their present limits. Before the conquest the Mam were regarded by their neighbours of Maya stock as uncouth and provincial. The Cakchiquel "Annals" speak of them as barbarians who did not speak distinctly. Their very name means "the stutterers." From this and other evidence it is thought that they may represent an early wave of Maya migration into Guatemala, forced to retreat to their present mountainous habitat by later comers. In 1525, after a fierce resistance, the Mam were conquered by the Spaniards under Gonzalo de Alvarado. The campaign ended by the siege of the famous fortress of Zacaleu, which the Spaniards finally starved into submission. Traces of its circular walls encompassing a steep hill can be seen today. At present the Mam number somewhat more than 100,000 individuals, of whom less than 10,000 live in Mexico. Like the other Indians of the Guatemalan highlands they follow agriculture, and dress in coloured costumes of local manufacture.

MAMAMU, the Hawaiian, it having no English name, of one of the most highly prized Pacific food fishes, *Monotaxis grandoculis,* belonging to the family Sparidae, or Sea Breams, and notable for its very large eyes. It reaches a length of over two feet, and occurs from the Red sea to the Hawaiian Islands (*see* BREAM).

(J. T. N.)

MAMARONECK (mạ-măr′ō-nĕk), a village of Westchester county, New York, U.S.A., 20 mi. N.E. of New York city, on Long Island sound, the Boston Post road and the New York, New Haven and Hartford railroad. Population in 1940 (federal census) was 13,034. The site of Mamaroneck (an Indian word meaning "where the fresh water falls into the salt") was part of a tract bought from the Indians in 1661 by John Richbell, an Englishman, and settled in 1676 by relatives of his. Heathcote hill, now dotted with residences, was the scene of a skirmish in the Revolution (Oct. 21, 1776). J. Fenimore Cooper lived in Mamaroneck for several years. The village was incorporated in 1895.

MAMELI, GOFFREDO (1827–1849), Italian poet and patriot, born at Genoa of a noble Sardinian family, studied law and philosophy at the University of Genoa. He was wholeheartedly devoted to Mazzini; among other patriotic poems he wrote a hymn to the Bandiera brothers, and in the autumn of 1847 a song called "Fratelli d'Italia," which as Carducci wrote, "resounded through every district and on every battlefield of the peninsula in 1848 and 1849." Mameli served in the national guard at Genoa, and then joined the volunteers in the Lombard campaign of 1848, but after the collapse of the movement in Lombardy he went to Rome, whence he sent the famous despatch to Mazzini: "Roma! Repubblica! Venite!" Although wounded in the engagement of April 30 for the defence of Rome, he at once resumed his place in the ranks, but on June 3 he was again wounded, and died in the Pellegrini hospital on July 6, 1849. Mameli was called "the Tyrtaeus of the Italian revolution."

MAMELUKE, the name given to a series of Egyptian sultans, originating (1250) in the usurpation of supreme power by the bodyguard of Turkish slaves first formed in Egypt under the successors of Saladin. *See* EGYPT: *History.*

MAMERTINI, or "children of Mars," the name taken by a band of Campanian (or Samnite) freebooters who about 289 B.C. seized the Greek colony of Messana at the northeast corner of

Sicily, after having been hired by Agathocles to defend it (Polyb. I. 7. 2). The members of the expedition are said to have been the male children born in a particular spring of which the produce had been vowed to Apollo (*see* SAMNITES), and to have settled first in Sicily near Tauromenium. An inscription survives (R. S. Conway, *Italic Dialects*, 1), which shows that they took with them the Oscan language as it was spoken in Capua or Nola at that date, and the constitution usual in Italic towns of a free community (*touta*) governed by two annual magistrates (*meddices*). On the Roman conquest of Sicily the town secured an independence under treaty (Cicero, *In Verr.* 3. 6. 13). The inhabitants were still called Mamertines in the time of Strabo (vi. 2. 3).

See also Mommsen, *C.I.L.* x.

MĀMERTINUS, CLAUDIUS (4th century A.D.), one of the Latin panegyrists. He was praefect of Italy (365) under Valens and Valentinian, but in 368 was deprived of his office for embezzlement. He was the author of an extant speech of thanks to Julian for raising him to the consulship, delivered on Jan. 1, 362, at Constantinople. Two panegyrical addresses (also extant) to Maximian (emperor A.D. 286–305) are attributed to an older *magister* Mamertinus, but it is probable that the corrupt ms. superscription contains the word *memoriae,* and that they are by an unknown *magister memoriae* (an official who announced imperial rescripts and decisions). The first of these was delivered on the birthday of Rome (April 21, 289), probably at Maximian's palace at Augusta Trevirorum (Trèves), the second in 290 or 291, on the birthday of the emperor. By some they are attributed to Eumenius (*q.v.*) also a *magister memoriae.*

The three speeches will be found in E. Bährens, *Panegyrici latini* (1874); *see* also Teuffel-Schwabe, *Hist. of Roman Literature* (Eng. trans.), § 417, 7.

MAMMALIA, a term invented by Linnaeus (1758) to include that class of animals in which the young are brought forth alive and nourished with milk from the mother's breasts (mammae). Typical examples are the dog, cow, rabbit, monkey, man. Whales are also mammals, although externally fish-like in appearance. Hair (*q.v.*) is a typical mammalian structure. Mammals, like birds, are "warm-blooded" or homoeothermal animals, that is, they differ from "cold-blooded" or poecilothermal forms, such as fishes, amphibians and reptiles, in their superior ability to regulate their own body temperature, so that in spite of wide variations in the temperature of the surrounding medium the body temperature of a typical mammal is maintained in health at a high level and within the relatively narrow limits that are best adapted to the needs of the animal. Some of the most characteristic features of mammals are the expression of the relatively high pace maintained by the vital processes. Here may be mentioned the flexible skin, together with the sweat glands and sebaceous glands, the diaphragm, the complex lungs and heart.

The origin of the mammals lies among the extinct mammal-like reptiles of the Triassic age. The subject may be divided into the following headings, I. Nutrition; II. Locomotion; III. Control Systems; IV. Reproduction; V. Rise of the Mammalian Orders; VI. Continental Dispersal of Orders.

NUTRITION

Jaws and Teeth.—The main divisions of the digestive tract (*see* ALIMENTARY CANAL) are already established in the vertebrates below mammals; indeed the organs and the processes of digestion (*see* NUTRITION AND DIGESTION) in the most primitive mammals have been inherited directly from their premammalian ancestors. In typical mammals the most striking morphological advances beyond the reptilian grade are the jaws and teeth.

Mammals are distinguished from lower vertebrates by the fact that the mandible, consisting on each side of a single element (corresponding with the dentary bone of lower vertebrates), articulates directly with the squamosal without the intervention of the quadrate and articular which form the functional mandibular joint in the lower vertebrates. Early embryos of man, and many other mammals, show the dentary of each side forming on the outer side of the stout cartilaginous lower jaw, which corresponds with the Meckel's cartilage or core of the lower jaw of lower vertebrates. The back of this in the embryo mammal ends in a well-developed joint corresponding to the joint between the quadrate and articular elements of the lower vertebrates. As development proceeds the dentary grows upward and establishes a new joint with the squamosal bone of the skull, while the old reptilian joint dwindles in size, pulls away from the dentary bone, and gives rise to the joint between the malleus and incus of the middle ear, which are thus vestiges of the articular and quadrate of lower vertebrates.

In the higher mammal-like reptiles of the Triassic of Russia and South Africa the adult dentition was already differentiated into four kinds of teeth: incisors, canines, premolars and molars; the premolars and molars were cuspidate and in some genera had acquired accessory basal spurs and additional cusps; moreover, the teeth were set in sockets and in some the cheek teeth show an incipient division of the single roots, while the dentition as a whole was reduced to two sets corresponding to the deciduous and permanent dentitions of mammals.

Specialization of Teeth.—The food of mammals, like that of lower vertebrates, may be either chiefly proteids, or chiefly carbohydrates, or a mixture of the two. The pure proteid eaters are typically fierce rapacious forms, in which the digestive tract, the prehensile and masticatory apparatus and the locomotor machinery are all designed for aggression. On the other hand, the carbohydrate feeders are peaceful herbivorous creatures, who spend most of their time in consuming and storing away great quantities of relatively innutritious food.

The anatomical and physiological differences between these two extreme types, *e.g.*, the cat and the cow, are largely correlated with this fundamental contrast in food habits. The cat as a proteid eater receives its food in a highly concentrated and elaborate form. Consequently its digestive tract is relatively short and simple, the stomach is not subdivided and the gastric juice shows a high percentage of hydrochloric acid.

On the other hand, the cow, representing the extreme carbohydrate-feeding type, normally has in its stomach from 14 to 18% of its own total weight in bulky herbaceous food, which contains a great amount of cellulose. The cow's digestive juices are unable to dissolve this indigestible food, but the cow produces an enormous quantity of saliva, which softens the food. By regurgitating and chewing the cud it mashes up the food in preparation for the fermentation caused by the anaerobic bacteria and infusoria in its stomach. In this way the mass gradually becomes fit for digestion by the long digestive tract.

The differences in diet between the cat and the cow are reflected in the differences in their dental mechanism and associated parts of the skull, as set forth in the following table.

	Cat	*Cow*
Jaws:	Short, powerful, wide, for strong vertical movements	Long, slender, narrow, for oblique side swing
Incisor teeth:	Present in both jaws	Absent in upper jaw, replaced by pad
Lower incisors:	Sharp, for piercing, holding and tearing flesh	Blunt, opposed to pad, for cropping grass
Canines:	Prominent, for killing and dragging the prey	Upper canines absent; lower canines incisor-like, for cropping grass
Crowns of premolars and molars:	Compressed, blade-like, for shearing flesh and cutting bones	Crescentic, long-crowned for chewing the cud
Articular condyle of lower jaw:	Placed far down, on level with teeth; to produce a scissors effect, the back teeth engaging first	Placed far above the level of teeth; to bring all the cheek teeth on one side into play at once
Ascending branch of lower jaw:	Very large, for attachment of powerful temporal muscle	Slender, for small temporal muscle
Body of jaw:	Massive, for attachment of powerful masseter muscle	Slender, for attachment of slender masseter muscle

	Cat	*Cow*
Method of cutting up food:	Into large chunks, with a few powerful bites	Into many very small bits, with many strokes of the jaw

Relatively few mammals attain either of these extreme specializations, the majority subsisting on a more or less mixed diet.

Incisors and Canine Teeth.—The front teeth of mammals are adapted, according to the nature of the food, into insectivorous, carnivorous, gnawing, omnivorous, frugivorous, browsing, grazing, piscivorous and various derived and mixed types.

In the more primitive insectivorous forms the incisors ($\frac{3}{3}$ on each side in primitive placentals and $\frac{5}{4}$ in primitive marsupials) are small nipping teeth, suitable for catching insects, the lower centrals slightly procumbent, the crowns simple with blunt points or slightly sharp edges. In the cat the incisors are fairly primitive in form but are nearly vertical, so giving a more powerful bite.

In rodents the incisors become long-crowned, curved, flattened cylinders with chisel-like edges growing continuously from persistent pulps. In the lower Oligocene forerunners of the Proboscidea (*q.v.*) or elephants (*Moeritherium*), one pair of upper incisors and one pair of lowers are moderately enlarged and adapted for cutting and plucking vegetation from the ground. In *Palaeomastodon* the next higher stage, the upper incisor tusks are much enlarged; through the development of a proboscis, they no longer oppose the lower incisors but function as levers and weapons. In certain later mastodons and elephants the lower incisors are gradually eliminated and the upper incisors attain great size, reaching in the extinct *Elephas ganesa* to 10 ft. 8½ inches.

A reduction or loss of the incisors has frequently occurred in animals with a protrusile tongue, as in the sloths, anteaters, etc.

In the horse family, which are grazers, both the upper and lower incisors have become long-crowned, with cup-like insinkings from the incisal surface of the crown. This arrangement strengthens the tooth for cutting off siliceous grass stems, while the long crown insures a long period of use.

In the cow, representing the browsing and grazing ruminant artiodactyls, the upper incisors and canines have been replaced by a horny pad, the lower incisors and lower canines have spatulate crowns arranged in a semicircle, adapted, with the horny pad above, for plucking herbage.

The canine teeth of carnivores are peculiarly fitted for killing living prey. This type of tooth culminates in the great canines of the extinct sabre-tooth tigers. On the other hand, in herbivorous forms the canine teeth are either reduced or adapted to some other function, as in the lower canines of ruminants above mentioned, or the upper canines or fighting tusks of the boar.

Deciduous or Milk Teeth.—In mammals the true molars, although erupting late, appear to belong to the same series as the deciduous incisors, canines and premolars, but have long lost their permanent successors. Since as soon as the young animal is weaned it usually feeds upon the same food as its parents, it will be obvious that it usually needs a functional set of teeth of the same general kind as those of its parents but smaller. Thus the milk teeth are usually not notably different from the permanent set. The presence of the milk teeth makes it possible for the permanent teeth to grow to any desirable size before eruption, teeth once erupted no longer grow except at the roots. Usually the hindmost milk teeth are more molariform than the permanent teeth that replace them, apparently because the young animal needs such teeth where the bite is the strongest.

Dental Formulae.—With few exceptions the right and left sides of the jaws have the same numbers of incisors, canines, premolars and molars respectively. Consequently the "dental formula" as ordinarily written represents only one side of the whole dentition and the total number of teeth is equal to twice the sum of the numbers in the "formula." The adult dental formula of man, for example:

$\left(I\frac{2}{2}\ C\frac{1}{1}\ P\frac{2}{2}\ M\frac{3}{3}\right)$, is simply an abbreviated form of:

Incisors: upper, 2 / lower, 2 Canines: upper, 1 / lower, 1 Premolars: upper, 2 / lower, 2

Molars: upper, 3 / lower, 3

The following dental formulae illustrate the progressive reduction as we pass from the more primitive forms to the highly specialized dentition of the cat:

Typical pantotherian mammal of Jurassic age	$(I\frac{?4}{4}\ C\frac{1}{1}\ P\frac{4}{4}\ M\frac{7?}{8?}) \times 2 = 66$
Typical polyprotodont marsupial (Opossum)	$(I\frac{5}{4}\ C\frac{1}{1}\ P\frac{3}{3}\ M\frac{4}{4}) \times 2 = 50$
Modern insectivore (Gymnura)	$(I\frac{3}{3}\ C\frac{1}{1}\ P\frac{4}{4}\ M\frac{3}{3}) \times 2 = 44$
Modern dog	$(I\frac{3}{3}\ C\frac{1}{1}\ P\frac{4}{4}\ M\frac{2}{2}) \times 2 = 40$
Modern cat	$(I\frac{3}{3}\ C\frac{1}{1}\ P\frac{3}{3}\ M\frac{1}{1}) \times 2 = 32$

On the other hand, a secondary increase in number of molars occurs in several groups. Thus in anthropoids and man a fourth molar is sometimes developed. The high number of simple teeth in the toothed cetaceans is the result of degenerative specialization.

Molars.—Primitive insectivorous molars are small and bear V-shaped cusps with sharp little blades; in shearing types the molars are reduced in number but are large, with one or two long blades; in omnivorous types either the cusps become rounded, often connected with other cusps by low ridges as in anthropoid apes and man, or they become conic and multiplied in number as in the wart-hog; or the whole crown becomes a swollen mass with low cusps as in the bear; in herbivorous types the molar crowns acquire crests and hillocks, arranged in patterns characteristic of the different species.

In 1883 E. D. Cope observed that the teeth and skeletons of the carnivores and primitive ungulates of the Lower Eocene were far less dissimilar than those of their modern descendants, and especially that, while the patterns of their upper molars were already diversified, there were three main cusps or elevations, two on the outer and one on the inner side of the upper molars, evidently homologous in both carnivores and herbivores. This was the "tritubercular" upper molar type of the Eocene mammals. A fourth main cusp on the hinder inner side of the upper molars could be seen in earlier stages of evolution in the carnivores and in more advanced stages in the primitive herbivorous mammals.

In the lower jaws Cope observed that in both carnivores and herbivores each lower molar tended to conform to a type in which the tooth crown was divided into two moieties arranged in tandem: the first or anterior moiety (the *trigonid*) elevated and supporting a triangle of cusps, of which the chief lay on the outer side of the crown, the other two on the inner; the second or posterior moiety (the *talonid*) depressed below the trigonid, consisting chiefly of a central concavity flanked on the inner and outer sides by single cusps. This central type of lower molar Cope called *tuberculo-sectorial*. Among recent mammals the tuberculo-sectorial pattern may still be seen in the lower molar teeth of civets, opossums, hedgehogs and other flesh-eating and insectivorous mammals.

H. F. Osborn (1888) gave names to the principal cusps of the upper and lower molars, as follows:

Upper Molar		*Lower Molar*	
Trigon		*Trigonid*	
Antero-internal: (pr)	Protocone	Antero-external: (prd)	Protoconid
Antero-external: (pa)	Paracone	Antero-internal: (pad)	Paraconid
Postero-external: (me)	Metacone	Postero-internal: (med)	Metaconid
		Talonid	
Talon		Postero-external: (hyd)	Hypoconid
Postero-internal: (hy)	Hypocone	Postero-internal: (end)	Entoconid

Both Cope and Osborn sought to trace the origin of the tritubercular molars of Eocene mammals back to the "single reptilian cone" of the earliest reptiles. For details of molar evolution *see* H. F. Osborn, *The Origin of the Mammalian Molar Teeth to and from the Tritubercular Type* (1907) and W. K. Gregory, *The Origin and Evolution of the Human Dentition* (1922).

LOCOMOTION

Origin of the Mammalian Locomotor Apparatus.—The locomotor machinery of mammals, like that of other vertebrates, involves four closely interconnected systems: (1) the motor elements proper; (2) the passive or supporting elements; (3) the combustion; (4) the activating, controlling and directive system.

The motor elements include the striped or red muscle cells and the parts built up from them, muscle fibres, muscles and muscle systems (*see* MUSCULAR SYSTEM, ANATOMY OF). The supporting elements include: (*a*) the sheaths and connective tissue surrounding the active elements; (*b*) the tendons that attach the muscles to the bones; (*c*) the ligaments that tie the parts of the skeleton together and (*d*) the articulated bony skeleton, including the backbone, skull, ribs, sternum, pectoral and pelvic girdles and limb bones. The locomotor apparatus of mammals, like that of lower vertebrates, is typically adapted for quadrupedal progression by running on relatively open ground, though many forms have learned to progress in special ways: leaping, climbing, volplaning and even flying, swimming, digging, tunneling. But no matter how elaborate the locomotor mechanism may be, it has all been evolved from the simple crawling mechanism of the earliest amphibians, and this in turn from the undulatory movements of certain air-breathing, lobe-finned fishes of Devonian age.

When the earliest amphibians crawled up out of the water the fore and hind paddles were bent downwards to assist the wriggling movement of the body. At first, the limbs sprawled widely. In such forms the humerus, or first segment of the skeleton of the forelimb, had a very short shaft and widely-expanded ends. There was a sharp bend at the elbow and the radius, or front forearm bone, articulated on the under side of the humerus rather than on its further end. Similarly in the hind-limb, the femur was short and was held widely out from the body.

But in the extinct mammal-like reptiles of the Permian and Triassic of South Africa and Russia the skeleton of the pectoral and pelvic girdles and limbs progressively approaches the mammalian type. Their limbs were adapted for running rather than crawling; the body was lifted well above the ground and the trackway became narrower so that the feet gave a more direct support to the weight. In the later mammal-like reptiles the feet were small and short, and from the reduction in the number of phalanges or toe-joints, to the mammalian number (three in each toe, except the first, which has two) we may infer that the fore-feet were at least partly "digitigrade," *i.e.*, raised off the ground at the wrist. So too the humerus of the cynodonts, or higher mammal-like reptiles, approached the lower mammalian types, and from the form and position of its joint surfaces we may infer that the angle at the elbow was opening out toward the mammalian condition.

The Fore-Limb.—The typical mammalian shoulder-girdle exhibits a distinct advance beyond that of the cynodont reptiles in the following features: (1) complete loss of all parts of the outer shoulder-girdle except the clavicles; (2) the scapula has an anterior shelf or extension supporting the supraspinatus muscle; (3) the dorsal part of the supracoracoid muscle mass has extended upward on to the scapula to give rise to the supraspinatus and the infraspinatus muscles; (4) the coracoid has become greatly reduced and has lost its contact with the sternum; (5) the anterior coracoid plate has disappeared or become vestigial; (6) the interclavicle has disappeared. All these changes have been associated with the raising of the body and the drawing-in of the fore-limbs so that the feet could be planted beneath the body. The egg-laying monotremes now the lowest of existing mammals, are still largely reptilian in the anatomy of the shoulder-girdle.

The remaining elements of the primitive mammalian fore-limb, the humerus, radius and ulna, carpus, metacarpus and digits, were derived with only minor changes from those of the cynodonts.

The Hind Limb.—The primitive mammalian ilium has apparently been derived from that of the cynodonts through the pronounced narrowing of the region above the root of the tail, accompanying the reduction of the tail muscles. The result of this and other changes has been to narrow and lengthen the gluteal area on the back of the ilium and to extend the area on the front inner surface for the origin of the iliacus muscle, so that the primitive mammalian ilium has become a narrow trihedral rod, with well defined iliacus, gluteal and sacral planes.

Meanwhile the femur has undergone corresponding changes in the passage from crawling to running habits. In the primitive crawling types the short stout femur projected widely from the body, its head, or surface for articulation with the pelvis, was a broad oval set directly on top of the shaft; there was a large deep pit for the insertion of the obturator muscles on the under-side of the femur below the head, and a high ridge for the adductor muscles, also on the under-side of the shaft. In primitive mammals, the femur is long, slender, with a cylindrical shaft, the head is globular, set off at a sharp angle and separated from the shaft by a well-defined neck; there is a large flange (greater trochanter) on the outer upper part of the shaft, the proximal pit (or digital fossa) is small, the primary adductor ridge is lost and there is a process, the lesser trochanter, not found in reptiles.

In primitive reptiles the bend between the lower end of the shank and the foot was not sharp; the two main bones of the tarsus, the astragalus and calcaneum, were flat, more or less circular elements located in the same general plane; the calcaneum did not project backward to form a heel-bone. In the running foot of the typical mammal, on the other hand, there is a sharp bend between the shin-bone and the instep, the astragalus and calcaneum are highly differentiated, the former resting upon the latter, the one forming a pulley for the tibia, the other a heel or lever for the powerful muscles of the shank.

Adaptive Radiation of the Limbs.—Among existing mammals the monotremes are adapted for burrowing and swimming but these are the habits of refugees from direct, above-ground competition with higher types. Among marsupials the primitive forms were arboreal, much like the existing opossums, and these gave rise to the numerous ground-living forms adapted for running, leaping and digging. W. D. Matthew has argued that the little-known primitive placental mammals of the early Cretaceous were also arboreal, inasmuch as many of their descendants in the Lower Eocene had five-toed spreading hands and feet, partly divergent thumbs and great toes, and a primitive skeleton not unlike that of an opossum. However, the evidence for arboreal derivation is less decisive than in the marsupials.

Scampering Types.—Small mammals in general have what may be called the scampering habit,—the ability to scurry away quickly in time of danger, without any pronounced specializations of the skeleton for running; and it seems safe to assign this habit to the pre-Eocene insectivorous ancestors of the placentals. From such a scampering type, with small semi-plantigrade hind feet and semi-digitigrade forefeet, adaptive radiation for different habits has brought about profound modifications of all parts of the skeleton.

Cursorial Types.—In quadrupedal running or cursorial forms length and rapidity of stride, combined with strength and endurance, are the great desiderata. The lower segments of the limbs become long, rod-like, angulated compound levers for striking the hard ground and catapulting the body forward; the principal muscles are bunched at the upper parts of the limbs and transmit their pulls through long cord-like tendons that pass over smooth pulley-like surfaces and are inserted into the lower segments of the leg. In extreme forms the foot is longer than the humerus, which gives great speed but requires great muscular strength.

The long narrow feet in running forms have parallel rather than spreading digits; rising on its toes, the animal finally runs on its enlarged hoofs alone. The thumb and great toe are reduced in size and raised off the ground; later they disappear, as do the fifth or outer digits of the fore- and hind-feet. In the perissodactyls or odd-toed ungulates the middle or third digit in both feet becomes predominant, in the horses finally forming the sole functional axis of the foot, the second and fourth digits being reduced to slender splints. In the artiodactyls, on the other hand, after the loss of the first digit the others become paired, the inner and outer digits, II. and V., being smaller, while III. and IV. are larger; in the final stages II. and V. become reduced and almost disappear, while III. and IV. become very long and fuse into the cannon-bone.

As the fore-and-aft movements of the limbs become emphasized, the elbows and knees are turned outward as little as possible; twisting movements diminish. Consequently the shoulder-girdle tends to lose the clavicle and the acromial process of the scapula disappears. In connection with the predominant fore-and-aft movements there are hinge-like joints between the humerus and the forearm, at the wrist and between the metacarpals and the digits.

The scapula is variously shaped: V-shaped in the swift-running artiodactyls, with vertically extended fossa for the infraspinatus muscle; it is usually at least as long as the humerus, which is relatively short with a projecting greater tuberosity for the attachment of the powerful shoulder muscles. The olecranon process of the ulna becomes a broad thickened lever for the insertion of the massive and powerful triceps; the strong tendon of the biceps passes through a broad channel in the humerus.

These and many other detailed adaptations for swift running have been worked out independently in many families and even in different orders of mammals, notably among the numerous plains-living ungulates, as in the horses of the northern world, the extinct pseudo-horses or smaller litopterns of Patagonia, the antelopes and deer. The less advanced stages are seen among the carnivorous hunters such as wolves and certain of the extinct creodonts, as well as in the marsupial wolf (*Thylacinus*) of Australia. Even some of the plains-living rodents, such as the chinchilla, show cursorial adaptations in the limbs. The ilium in cursorial types is a strongly braced T-shaped bone supporting the thick deep gluteal muscles which are inserted nearly at right angle to the long axis of the femur.

Graviportal or Striding Types.—Given an abundant food supply, many lines of evolving animals exploit the opportunity of becoming larger, living longer and leaving a larger progeny. These conditions have tended to transform slender speedy animals into great lumbering brutes. In these heavy-bodied forms the lateral or transverse growth components increase relatively faster than the linear ones; slender bodies and narrow limbs and feet become broad and robust. This is clearly seen in such races as the extinct titanotheres, the rhinoceroses and other lines of ungulates, in which the earlier forms have slender narrow feet, the later ones broad short feet.

In such cases the extent to which the earlier cursorial adaptations are disguised by the overlying graviportal changes depends *inter alia* upon how early the graviportal tendencies gain the ascendancy. When the graviportal tendency supervenes immediately upon the short-footed scampering stage, so that the cursorial stage is passed by, we have the extreme graviportal modifications illustrated in the Eocene Amblypoda and to a less extent in the elephants. The excessively short-toed feet, instead of catapulting the body, roll forward on a great elastic cushion and the straightened legs, with long humeri and femora, swing forward like massive beams. The ilium widens transversely into a huge fan.

Saltatorial or Leaping Types are usually developed from the scampering or cursorial types. In the jerboas and kangaroo rats, which have evolved from scampering rodents, the animals leap on their powerful hind-limbs, holding the body erect and using the fore-limbs chiefly in manipulating the food. The tail is used as a balancing organ in leaping. The kangaroos have doubtless been derived from arboreal phalangers, in which the fourth digit of the hind-foot was already enlarged, the first digit divergent and prehensile, the second and third small and closely appressed or syndactylous. The early hopping stage is illustrated by the tiny musk kangaroo (*Hypsiprymnodon*), in which the great toe is still present though reduced. In later stages the great toe disappears and the fourth digit becomes enormously enlarged, forming the lower joint of a catapult, the power for which is supplied by the massive muscles of the buttocks, thigh and shank. The tail acts as the third leg of a tripod. Bipedal leaping is convenient for hurdling obstacles in sudden alarms, but for heavy animals it is uneconomical for long distances.

Fossorial or Digging Types have been developed usually from scampering short-footed types with short powerful arms. In the mole, an extreme and unique fossorial type, the fore-limbs have been moved forward under the neck to enable the enormous, wide hands to reach in front of the nose. The humeri have acquired a secondary contact with the clavicles, which have become solid blocks that form the pivots of the forearm and rest on a keel-shaped forward extension of the sternum. The scapulae are elongate, to give long shoulder muscles and a long reach of the humeri; the enormous triceps is inserted into a great hooked olecranon process of the ulna, the lower surface of which supports the powerful flexors of the carpus. The hind limb is small and not much modified.

The Cape golden moles (Chrysochloridae) differ widely from the true moles. Their forefeet are very narrow and adapted for digging in hard soil, with one or two sickle-like claws. The armadillos and many rodents dig with their large claws and powerful fore-limbs.

Natatorial or Swimming Types have been developed in many orders, although the extreme form of aquatic adaptation is limited to the Cetacea and Sirenia (*q.v.*). The end-results of prolonged aquatic adaptation naturally depend partly on what type of terrestrial forms the given aquatic types took rise from. Thus among the marsupials the aquatic opossum or yapok is simply an opossum with webbed feet. Among the Mustelidae the ordinary otter, the African *Aonyx* and the sea-otter (*Latax*) represent progressive adaptation to aquatic life, in which the feet become webbed and enlarged. The sea-lions carry this line of adaptation much further, greatly enlarging the hands and feet into flippers, but retaining the power to support the body on all four limbs. Finally, the earless seals (Phocidae) have lost the power of bringing the hind limbs forward under the body and all four feet are specialized paddles. The body, enclosed in a thick layer of fat, has become streamlined and in the cetaceans becomes fish-like. These specializations were already under way in the oldest known whales, the Eocone Archaeoceti. Nevertheless, evidence from comparative anatomy and embryology proves that the Cetacea have been derived from terrestrial, quadrupedal placentals, perhaps allied with the stem of the insectivores and carnivores. The manatees and dugongs (Sirenia) approach the Cetacea in aquatic specialization, but the resemblance is due to convergence as the anatomical differences indicate that the Sirenia have been derived from herbivorous ancestors, possibly related to the ancestral elephants.

Scansorial or Climbing Types.—Many small mammals with well-developed claws and spreading hands and feet supplied with interdigital pads can climb tree-trunks. In the marsupials the opossums afford an example of a primitive stage of arboreal specialization. The phalangers illustrate a more advanced type of highly specialized hind feet; the great toe is strongly divergent and flattened, the second and third toes slender, closely appressed and enclosed in a common skin, the fourth and fifth enlarged and forming the outer fork of a clamp, the great toe forming the inner.

The tree-shrews (Tupaidae), which are probably very primitive Primates, give the initial stages of arboreal adaptation in that order. The pen-tailed tree-shrew (*Ptilocercus*) of Borneo has small spreading hands and feet and a generalized skeleton. The lemurs and their Eocene forerunners Adapidae and Notharctidae, have grasping hind-feet with a wide flat nail on the large great toe; the digits are elongate, slender with small nails, except the second digit, which bears a small claw. Lemurs are essentially arboreal quadrupeds, running along the tops of the branches, and the same is true of the typical monkeys. The New World monkeys, which have a prehensile tail, can also hang and swing from the branches. The monkeys, especially those of the Old World division, sit upright, or partly so, resting on the ischial callosities. The hands are used in manipulating the food.

Brachiating or Acrobatic Forms.—The gibbons do not run on all fours but hold the body erect, raising the long arms above the head. They make long leaps through the air, catching the branches. In their skeleton as well as in their internal anatomy they are closer to man than to the lower primates.

Of the larger anthropoids the orang-utan (*q.v.*) is extremely specialized for arboreal life, using the suspension grasp of the hands and feet. The arms are excessively long, with enfeebled thumbs, the legs very short. Progression on the ground is awkward, the long arms being used as crutches.

The chimpanzee (*q.v.*) is a moderately heavy-bodied brachiating form, less specialized than the orang. In running on the ground a secondarily quadrupedal gait is employed, the weight of the heavy forepart of the body resting on the bent knuckles. Nevertheless tame chimpanzees, when carrying large objects in their arms, walk erect.

Old male gorillas are gigantic, extremely massive animals which run on the ground on all fours upon bent knuckles. Nevertheless the locomotor skeleton as a whole is surprisingly close to that of man, except in certain parts such as the ilium and the great toe, in which the brachiating features are conspicuous.

Biped Type.—This is exemplified by man and the adaptations are treated elsewhere (*see* MAN, EVOLUTION OF).

Volplaning Types.—Certain active climbing types with long limbs, leaping boldly from the trees skim downward easily by holding extended their patagium, a fold of skin stretching from the neck outward and from the arms to the legs and sometimes from the legs to the tail. Such an adaptation has been acquired independently among marsupials in the flying phalangers, among rodents in the flying squirrels and in the anomalures, and also in the colugos ("flying lemurs"), an isolated type remotely related perhaps to the tree-shrews and lemurs. No marked skeletal specializations except the lengthening of the limbs distinguish the volplaning types from their arboreal relatives.

Flying Types.—The Chiroptera (*q.v.*) or bats are the only mammals to achieve true flight. Their wings are enormously elongated hands and arms covered with thin skin. The hind legs are weak and mostly used for suspension. It is supposed that bats have been derived from skimming forms in which the web of skin extended between the long fingers.

The Backbone.—In the line of ascent to the mammals there was a tendency toward simplification of the complex eight-piece vertebrae (*see* AMPHIBIA), with progressive reduction of certain elements, until in the dorsal vertebrae of the mammal-like reptiles four of the original eight pieces were nearly or quite eliminated, and we have left a vertebra composed of two main parts: (*a*) the neurocentrum, an inverted Y-shaped piece, arising from the fusion of the opposite "basidorsals," which cover the spinal nerve cord and afford origin for the spinal muscles; (*b*) the centrum proper, a short cylinder somewhat constricted in the middle, consisting of the opposite pleurocentra, or interdorsals, of earlier vertebrates and serving for the insertion of the ribs and for the support of the body as a whole.

In the oldest Amphibia there was a gradual regional differentiation of the backbone as we pass from the neck to the tail; in the mammal-like reptiles, especially in the cynodonts, regional differentiation is pronounced though not sudden. The ribs of the cervical or neck region are short, but still have shafts, while at least in the higher mammals these shafts are lost. The cynodonts were progressing in the direction of the mammals in the fact that their lumbar ribs were suturally connected with the sides of the vertebrae as in some very young marsupials. In many more advanced mammals the lumbar ribs are completely replaced by transverse processes which grow out from the sides of the vertebrae Similarly in the sacral region the cynodonts and less specialized mammals had free sacral ribs, whereas in more specialized mammals the rib elements of the sacrum are replaced by transverse processes.

In the older mammal-like reptiles the condyle was median and ball-like as in typical reptiles, but in the cynodonts the lateral parts grew outward while the median part retreated so that a double condyle almost of mammalian type was attained.

The mammalian atlas-axis complex is a contrivance of great functional and morphologic intricacy, the purpose of which is to provide a wide range of movement combined with automatic checks, to prevent sudden stresses from dislocating the joint and squeezing the spinal cord. One of the most essential morphological features of the atlas-axis complex of cynodonts and mammals is that the paired occipital protuberances are received into the upper or neural arches of the atlas or first vertebra and that the centrum or body of the atlas becomes a buffer which in the adult is closely united to the centrum of the second vertebra or axis, of which in adults it forms the odontoid process. Meanwhile the neural spine of the second vertebra becomes enlarged vertically to give origin to some of the powerful muscles that raise the head.

In the dorsal vertebrae the stout neural spines act as levers for the powerful spinal muscles in extending the back, while the transverse processes and centra serve as bases for the movable ribs enclosing the heart, lungs and diaphragm.

The contour of the vertebral column in the standing pose in the side view differs widely in accordance with the habits. In scampering types with short legs the column is usually strongly arched in the mid-dorsal region. This culminates in the short-footed carnivorous types such as weasels. In long-limbed running types, especially those with a long neck or a heavy head, the backbone may bear long stout spines on the neck and forepart of the back, to which are attached the heavy ligaments of the neck and the deeper muscles of the occiput.

A profound difference between a typical reptile and a typical mammal is that in the former the great muscles on the lower side of the tail act powerfully in pulling the hind limbs backward in running. In mammals, on the contrary, the tail muscles are greatly diminished and of slight importance in locomotion.

Skull.—The mammalian skull is here treated under the section locomotion because the vertebrate skull in the first place arose as a fulcrum or thrust-block to withstand the forward thrust of the locomotor muscles acting through the vertebral column in the rear and the resistance of the water in front. Hence even in the oldest known chordates, the ostracoderms, the skull consists of two parts: (1) a wedge-like sloping roof and sides, forming a bony *dermocranium* and (2) a cartilaginous or partly ossified inner skull or *endocranium,* comprising (*a*) the capsules surrounding the olfactory, optic and balancing organs and (*b*) the central brain-trough or trabecular region.

Modifications of the jaws and teeth in the mammals, in adaptation to different food habits, have a profound effect upon the form of the skull as a whole, since the jaws usually form the greater part of the bony face, while the jaw muscles cause the upgrowth of ridges on the top and sides of the braincase and condition in many ways the form of the base of the skull.

On the whole the mammalian braincase has advanced beyond that of primitive reptiles in the following features:

(1) The elimination of several dermal bones of the circum-orbital and occipito-temporal series, the tabulars, supratemporals, postorbital, postfrontal, prefrontals;

(2) The widening-out of the brain-trough through the widening of the brain; the change of the reptilian epipterygoid into the mammalian alisphenoid;

(3) The elaboration of the turbinate bones, scroll-like outgrowths from the median cartilaginous septum of the nasal chamber;

(4) The consolidation of the bony elements surrounding the inner ear into a single dense bone, the periotic, and the fusion of this with the squamosal;

(5) The shifting of the inner ear from the side to the base of the skull.

CONTROL SYSTEMS

The mammalian nervous system, which reaches unprecedented complexity in man, can scarcely be understood apart from other regulating devices or control systems, which greatly condition its activities. In all vertebrates the ductless or endocrine glands (*q.v.*) play an important part in the production and maintenance of the specific and individual patterns of growth and behaviour, since they pour into the blood-stream certain hormones which give the chemical impetus to particular changes in the direction of growth. (*See* ENDOCRINOLOGY: *Endocrinology in Animals.*)

On the whole there is a marked contrast, however, between chemically and nervously determined functions. Chemical regulation (as from the ductless glands) tends to be rigid and determinate. Nervous regulation, on the other hand, has tended toward flexibility, modifiability, choice of several courses of action. Mammals, especially man, have achieved extraordinary adaptability to wide ranges of environmental changes largely through the greater flexibility and range of response of their nervous system.

The nervous system of mammals (more fully treated in the article BRAIN), like that of other vertebrates, comprises the following elements: (1) paired organs of smell, sight, balance, hearing; (2) numerous organs of touch and taste and "somesthetic" sense (organs which convey sensations of bodily posture and movement); (3) "motor nerves," which release the activities of glands and muscles; (4) innumerable connecting tracts, relay stations and control systems of amazing intricacy.

In general the mammalian brain differs from that of lower vertebrates in the fact that the upper part and sides of the end-brain have grown outward into sack-like expansions, which form the neopallium or cerebral cortex of mammals. In the lower mammals this new part of the brain is but moderately developed and the localization of functional areas is at best incipient but in the higher mammals, including man, the neopallium becomes enormously complex, dominating the entire organism and tending to differentiate the cortical "centres" described in the article BRAIN. Meanwhile the thalamus and the "brain stem" have likewise become extremely complex, developing a bewildering maze of connections with other parts of the brain. The result of these expansions and complications is that the old primary control systems pass under the dominance of the newer and higher centres. (*See* C. J. Herrick, *Brains of Rats and Men,* and F. Tilney and H. A. Riley, *The Brain from Ape to Man.*)

REPRODUCTION

In a typical placental mammal the minute fertilized egg is developed internally and the embryo is nourished by an outgrowth of its own "allantoic bladder" which becomes appressed to the wall of the maternal uterus, finally uniting with the latter, at least along certain zones. Thus the embryo is enabled to draw nourishing blood directly from the mother (*see* VERTEBRATE EMBRYOLOGY). At birth the placenta is pulled away from the uterine wall but excessive uterine hemorrhage is normally stopped automatically by appropriate chemical substances in the maternal blood.

After birth the development of higher mammals is prolonged over the period corresponding in man to infancy, childhood and adolescence; the delayed maturity affording opportunity for long-continued growth and differentiation of the brain, with a correspondingly extended period of learning.

In wide contrast with this are the conditions found in the lowest existing mammals, the egg-laying mammals of Australia (*see* MONOTREMATA) While these lay eggs, like reptiles, the embryo nevertheless derives some of its nourishment from the uterine wall as well as from the yolk stored in the egg.

In typical placental mammals the right and left uteri are fused in the mid-line, making a single uterus. In the lowest mammals, the monotremes, the right and left uteri are entirely separate as in reptiles. Various intergrading conditions between these extremes occur in the marsupials, edentates and rodents.

The milk-glands of female mammals are highly characteristic of the whole class. They are arranged in pairs on the ventral surface of the body, varying in number from one pair in man and other primates to eleven pairs in the insectivore *Centetes.* They are usually surmounted by nipples, raised folds of skin with a central tunnel for the passage of the milk. In the placental mammals the milk is actively sucked or pumped by the young but in the monotremes the nipples are represented only by depressed glandular areas with raised borders and the milk is said to be licked by the young from the base of the hairs in the mammary field. This condition may well give the clue to the origin of the milking habit, which must have originated after the sebaceous glands of the skin had developed an albuminous secretion, which may have served originally either to attach the eggs to the under-surface of the brooding mother, or to anoint the eggs with a heat-retaining coating. At any rate, the habit of milking in its initial stages seems to require some voluntary action by the young, such as licking.

THE RISE OF THE MAMMALIAN ORDERS

During the Triassic, Jurassic and Cretaceous, the fossil record of the mammals is meagre; later it is relatively abundant; but even then there are blank intervals and imperfectly preserved records. As many existing orders of mammals began to diverge during the Age of Reptiles, when the record is most imperfect, it is difficult to reconstruct the earlier history of the mammalian orders from present data.

Probably by Upper Triassic times some of the smaller mammal-like reptiles, a group already almost mammals, had crossed the line by acquiring a hairy covering and a new contact between the dentary bones of the lower jaw and the squamosal bone of the skull. With the coming of Lower Jurassic times the mammalian stock had split into three distinct groups: (1) the Allotheria or Multituberculata (*q.v.*), rodent-like mammals with gnawing front teeth and many-cusped grinding teeth; (2) the Triconodonta, small carnivorous forms with triconodont molar teeth, each crown consisting typically of three cusps in a fore-and-aft line and (3) the Pantotheria, or Trituberculata, very small insectivorous mammals typically with sharp-cusped lower molars of the most primitive tuberculo-sectorial type. The Allotheria were probably not closely related to any other order of mammals but were a peculiar, now wholly extinct group extending in time from the Upper Triassic to the summit of the basal Eocene. The Triconodonts also appear to be an isolated and extinct group, but certain of the Pantotherians, such as *Amphitherium,* appear sufficiently generalized to be the potential ancestors of all later mammals except the recent monotremes which at present show distant relationships with the marsupials, but are still without known fossil ancestors, the features they share with the Allotheria being offset by many others that indicate wide differences. The marsupials may well be the descendants of some of the Pantotheria but actual connecting links are wanting. The same is true of the Placentals, which are first known in abundance in the basal Eocene of North America. Recently, however, the field parties of the American Museum of Natural History in Mongolia have discovered several incomplete skulls of small mammals which appear to represent some of the Cretaceous forerunners of the centetoid insectivores and perhaps also of the most primitive carnivores or creodonts.

From comparison of the osteology and anatomy of the recent monotremes, marsupials and placentals, however, we may infer with high probability that the ancestral mammal was an egg-laying vertebrate that retained a primitive reptilian type of shoulder-girdle with two complete coracoid plates on either side and with the beginnings of the neopallium in the brain. From such primitive types the marsupials (*see* MARSUPIALIA) evolved by developing, among other characters: (1) a three-way, vaginal passage; (2) the true or allantoic placenta was early replaced by a false or yolk-sack placenta; (3) the corpus callosum or great cross-band between the opposite halves of the neopallium was not developed; (4) all the milk teeth were suppressed except the hindermost premolars and (5) the dental formula of the adult dentition was reduced from a higher number to $I\frac{5}{4}\,C\frac{1}{1}\,P\frac{3}{3}\,M\frac{3}{4}$. On the other hand, the primitive placentals apparently never developed either the three-way vagina, or the yolk-sack placenta, but their true placenta early became highly developed, as did the corpus callosum; the entire set of milk teeth was retained and the dental formula was early reduced to $I\frac{3}{3}\;C\frac{1}{1}\;P\frac{4}{4}\;M\frac{3}{3}$ The marsupial group may have been dominant in the Lower Cretaceous, when fossil records are practically blank. By the Lower Eocene the marsupials were already a defeated group which took to the trees and persisted in North America only in the form of the opossums, among the most primitive of all living animals; in South America, however, they gave rise to several extinct families (Borhyaenidae, Caenolestidae, Didelphidae) and in Australia they became the dominant mammalian forms and gave rise to a great series of families, including the dasyures, bandicoots, phalangers, kangaroos and others.

The placental group is first known from primitive insectivorous representatives from Mongolia, as already noted; apparently it originated somewhere in the north and by basal Eocene times its diversified descendants are found in western North America and western Europe but as yet nowhere else. These were small-brained forms, many belonging to families that became extinct before the close of the Eocene. Here belong most of the archaic carnivores or creodonts, amblypods, tillodonts and others. Besides the "archaic" placental families that became wholly extinct were others apparently related to later groups. Here belong (1) the Plesiadapidae (apparently related to the tree-shrews and thus representing an early phase in evolution of the primates); (2) early forerunners of the tarsioid primates; (3) the insectivore *Palaeoryctes,* representing a primitive phase of the modern centetoid insectivores; (4) the progressive creodont *Didymictis* (in or near to the ancestry of the modern carnivores); (5) the palaeanodonts, including primitive relatives of the armadillo group of edentates. The bats (Chiroptera, *q.v.*), too, appear to be an old group, possibly dating back to the Basal Eocene or even earlier. Conspicuously absent from the Basal Eocene are the modernized or caeneutherian placental orders, including especially the perissodactyls, the artiodactyls, the rodents, the Proboscidea.

The condylarths or primitive ungulates of the Basal and Lower Eocene are not regarded by modern authorities as ancestral either to the perissodactyls or artiodactyls; it is however probable that some of the condylarths gave rise to the peculiar South American orders of litopterns, toxodonts, etc. By the Lower and Middle Eocene we find in Europe and western North America, side by side with the later families of meseutherian placentals, the earliest known representatives of the more progressive modern families: *Eohippus,* representing the horses (Equidae); *Hyrachyus* and other genera, forerunners of the lophiodonts and rhinoceroses; *Trigonolestes,* a primitive representative of the artiodactyls; *Metachiromys,* a specialized armadillo-like edentate; *Viveravus,* close to the ancestors of the later carnivores; *Paramys,* a forerunner of the sciuroid rodents; *Pelycodus* and *Notharctus,* early lemuroids, and the numerous anaptomorphids, relatives of the primate *Tarsius.* Even the Cetacea were represented by the peculiar zeuglodont group. During the Lower Eocene, western Europe and North America had several fossil genera in common (including the earliest stages of the horse family) which may perhaps have spread from central Asia.

In many cases the molar teeth of the Eocene placental mammals, while variously specialized, still retained distinct traces of derivation from an earlier tritubercular type characteristic of the basal Eocene; the hands and feet were either five-toed or bore clear traces of derivation by reduction from the five-toed type; the humerus had an entepicondylar foramen and the femur a third trochanter. So that it seems reasonable to infer that all the varied placental orders of Eocene times were descendants of some group that lived perhaps in the Lower Cretaceous; but as to the more precise interrelationships of the mammalian orders, extended research on the anatomy and osteology of the recent forms and on the osteology and dentition of the fossil forms has so far rather revealed the complexity of the problem than solved it. From present evidence the tree-shrews, lemuroids and primates, with *Galeopithecus* and the bats, appear to form one great superordinal assemblage, probably derived from arboreal Cretaceous insectivores. On the other hand, the old order of ungulates, formerly supposed to be a natural group, seems to consist of a heterogeneous assemblage of orders (condylarths, taligrades, amblypods, perissodactyls, hyracoids, proboscideans, sirenians, artiodactyls, notoungulates, arsinoitheres, etc.), related chiefly by descent from various as yet unknown protoungulates.

The aardvarks, formerly classed with the edentates, may prove to be highly specialized descendants of the condylarths, while the edentates themselves are probably the descendants of the palaeanodonts, which in turn may be remotely related to the insectivore-creodont stock. The earliest known cetaceans, the zeuglodonts, were not directly ancestral to the true cetaceans; nevertheless they tie in that order with the insectivore-creodont division of the placentals. On the other hand, the Sirenia, although resembling the cetaceans in general body-form, are herbivores and their real affinities are with the ungulates.

CONTINENTAL DISPERSAL OF MAMMALIAN ORDERS

From the studies of palaeontologists and mammalogists emerge the following among other general results bearing on geographic dispersal of the mammalian orders:

(1) At various times during the Age of Mammals pathways were opened by which a given group of mammals, acquiring its special characters in regional isolation, could pass from central Asia westward to Europe or eastward to North America, or from either Europe or America to Asia. Among the orders and families of placental mammals that may have originated in the northern realm (including Europe, Asia, North America) may be mentioned the perissodactyls and artiodactyls, the insectivores, the fissipede carnivores, the rodents, the edentates, the lemuroids, catarrhine primates, anthropoids and probably man. The families of rhinoceroses, lophiodonts, titanotheres and camels afford examples of the more or less free intercontinental commerce at certain periods.

(2) South America was early in contact with North America; then the contact was broken and for millions of years the country was left to develop its own fauna of litopterns, toxodonts, ground-sloths and other strange beasts. In late Tertiary times the way was again opened and mastodons, camels, tapirs, deer and other animals streamed in from the north, while South America sent platyrrhine monkeys, ground-sloths and other animals northward.

(3) Africa, especially in the north, was frequently in contact with the northern land mass but in late Eocene and early Oligocene times the Fayum district in Egypt may have been an outlier of some central African region which seems to have produced the Proboscidea, arsinoitheres, hyracoids and sirenians. The most primitive known cetaceans (*Pappocetus, Protocetus, Prozeuglodon*) are also found there. Madagascar, possibly part of a broad archipelago formerly connected with India, was the centre of peculiar families of carnivores (viverrids) lemuroids, insectivores (centetoids). Broadly, Africa's mammalian fauna to-day represents Europe and Asia of Miocene and Pliocene times.

(4) Australia, receiving its original marsupials at some early date, was then cut off from Asia and developed one of the most interesting mammalian faunas of all time, in which the marsupial stock was fashioned into herbivorous, carnivorous and rodent-like mammals, strangely similar in habitus to their analogues of the placental world and yet always preserving their marsupial heritage in brain and reproductive system and in the deeper characters of the skull and skeleton. At times during this long period placental invaders from the north managed to get in; first a peculiar family of rats and much later the dingo or native dog, together with that most devastating of all placentals, man. Australia, on the other hand, succeeded in sending some marsupials into New Guinea and as far northwest as Celebes. Some hold also that from Australia by way of Antarctica came the extinct carnivorous marsupials and caenolestoids of South America. (*See* MARSUPIALIA.)

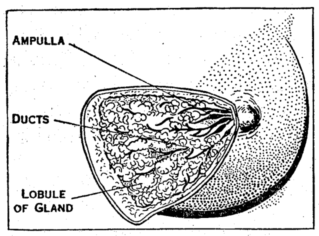
(W. K. G.)

MAMMARY GLAND, the organ by means of which the young are suckled, and the possession of which, in some region of the trunk, entitles the animal bearing it to a place in the order of Mammalia. In the male the organ is present but undeveloped.

Anatomy.—In the human female the gland extends vertically from the second to the sixth rib, and transversely from the edge of the sternum to the mid axillary line; it is embedded in the fat superficial to the pectoralis major muscle, and a process which extends toward the armpit is sometimes called the axillary tail. A little below the centre of the glandular swelling is the *nipple,* surrounding which is a pigmented circular patch called the areola; this is studded with slight nodules, which are the openings of areolar glands secreting an oily fluid to protect the skin during suckling. During the second or third month of pregnancy the areola becomes more or less deeply pigmented, but this to a large extent passes off after lactation ceases. In structure the gland consists of some 15 to 20 lobules, each of which has a *lactiferous duct* opening at the summit of the nipple, and branches in the substance of the gland to form secondary lobules, the walls of which are lined by cubical epithelium in which the milk is secreted. These secondary lobules project into the surrounding fat, so that it is difficult to dissect out the gland cleanly. Before opening at the nipple each lactiferous duct has a fusiform dilatation called the *ampulla.*



FROM A. F. DIXON, IN "CUNNINGHAM'S TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

MAMMARY GLAND, DISSECTED TO SHOW STRUCTURE AND CONVERGENCE OF LACTEAL DUCTS ON NIPPLE

After the child-bearing period of life the breasts atrophy and tend to become pendulous, while in some African races they are pendulous throughout life. Variations in the mammary glands are common; often the left breast is larger than the right, and in those rare cases in which one breast is suppressed it is usually the right, though this does not necessarily include absence of the nipple.

Supernumerary nipples and glands are not uncommon, and are usually situated in the mammary line which extends from the anterior axillary fold to the spine of the pubis; hence, when an extra nipple appears above the normal one, it is external to it, but, when below, it is nearer the middle line. Extra nipples are commoner in males than in females.

Embryology.—The mammary glands are modified and hypertrophied sebaceous glands, and transitional stages are seen in the areolar glands, which sometimes secrete milk. At an early stage of foetal life a raised patch of ectoderm is seen, which later on becomes a saucer-like depression; from the bottom of this 15 or 20 solid processes of cells, each presumably representing a sebaceous gland, grow into the mesoderm which forms the connective-tissue stroma of the mamma. Later on these processes branch. The last stage is that the centre of the *mammary pit* or saucer-like depression once more grows up to form the nipple, and at birth the processes become tubular, thus forming lactiferous ducts. The glands grow little until the age of puberty, but their full development is not reached until the birth of the first child.

Comparative Anatomy.—In the lower Mammals the mammary line, already mentioned, appears in the embryo as a ridge, and in those which have many young at a birth patches of this develop in the thoracic and abdominal regions to form the mammae, while the intervening parts of the ridge disappear. The number of mammae is not constant in animals of the same species. When only a few young are produced at a time the mammae are few, and it seems to depend on the convenience of suckling in which part of the mammary line the glands are developed. In the pouched Mammals (Monotremes and Marsupials) inguinal mammae are found, and so they are in most Ungulates as well as in the Cetacea. In the elephants, Sirenia, Chiroptera and most of the Primates, on the other hand, they are confined to the pectoral region, and this is also the case in some Rodents, *e.g.*, the jumping hare (*Pedetes caffer*). In the monotremes the mammary pit remains throughout life, and the milk is conducted along the hairs to the young, but in other Mammals nipples are formed in one of two ways. One is that already described in Man, which is common to the Marsupials and Primates, while in the other the margin or *vallum* of the mammary pit grows up, and so forms a nipple with a very deep pit, into the bottom of which the lactiferous ducts open. The latter is regarded as the primary arrangement. In the monotremes the mammae are looked upon, not as modified sebaceous glands, as in other Mammals, but as altered sweat glands. In these primitive Mammals the glands are equally developed in both sexes, and it is thought that among the bats the male often assists in suckling the young (*see* G. Dobson, *Brit. Museum Cat. of the Chiroptera,* London, 1878). These facts, together with the occasional occurrence of functional activity of the organ in the human male, make it probable that among ancestral Mammals both sexes helped in the process of lactation.

For further details see *Comparative Anatomy of Vertebrates,* by R. Wiedersheim, adapted by W. N. Parker (1907), and Bronn's *Classen und Ordnungen des Thierreichs.*

MAMMARY GLAND, DISEASES OF. Inflammation of the breast (*mastitis*) is apt to occur in a woman who is suckling, and is due to the presence of septic micro-organisms, which, as a rule, have found their way into the milk-ducts, the lymphatics or the veins, through a crack, or other wound, in a nipple which has been made sore by the infant's vigorous attempts to obtain food. Especially is this septic inflammation apt to occur if the nipple is depressed, or so badly formed that the infant has difficulty in feeding from it. The inflamed breast is enlarged, tender and painful, and the skin over it is hot, and perhaps reddened. The woman feels ill and feverish, and she may shiver or have a definite rigor if the inflammation is passing on to the formation of an abscess. The abscess may be superficial to, or beneath, the breast, but it is usually within the breast itself. The infant should at once be weaned, the milk-tension being relieved by the breast-pump. Fomentations should be applied under waterproof jaconette, and the breast should be evenly supported by a bandage. Belladonna and glycerine should be smeared over the breast, with the view of checking the secretion of milk, as well as of easing pain. On the first indication that pus is collecting, an incision must be made to prevent extension of the disease. As the discharge begins to cease, firm strapping of the breast will prove useful.

Chronic Eczema of the breast may occur, but when present around the nipple of a woman late in life, with perhaps, localized ulceration, it is known as *Paget's Disease* and has a sinister significance, for it indicates that the superficial layers of the true skin are in all probability infiltrated with cancer. Hence, when eczema about the nipple refuses to clear up in a few days under the influence of soothing treatment, it is well to insist on the removal of the entire breast. The nipple is retracted in most of these cases, which, however, are not often met with.

Chronic Mastitis is not very uncommon in women who are past middle age. The part of the breast involved is enlarged, hard, and more or less tender and painful. It is sometimes impossible clinically to distinguish this disease from cancer. True, the tumour is not so definite or so hard as a cancer, nor is it attached to the skin, nor to the muscles of the chest wall, and if there are any glands secondarily enlarged in the arm-pit they are not so hard as they may be in cancer. But all these are questions of degree, and the indications given for a diagnosis of cancer indicate also that the disease is so advanced as to have reduced the chance of successful operation to a minimum. Moreover, it is highly inadvisable to leave it to time to clear up the diagnosis, for a chronic mastitis, innocent at first, may become cancerous, while cancer and chronic mastitis often co-exist in the same breast. Hence the only safe course is removal of the breast, and some authorities recommend that this course should be adopted in every case of chronic mastitis.

Fibro-adenoma.—A simple glandular tumour is apt to be found in the breasts of youngish women, who may possibly give an account of some blow or other injury; there may, however, be no history of injury. The tumour is smooth, rounded or oval, and lies loose in the midst of the breast; as a rule it is not tender.

It is not associated with enlarged glands in the arm-pit. The tumour had best be removed, though innocent, for such growths may become cancerous later.

Cysts of the Breast.—A *galactocele* is a tumour due to the locking up of milk in a greatly dilated duct. Other forms of cystic disease are usually special modifications of chronic mastitis. Such cysts are best treated by free incision, and by passing a gauze dressing into their depths. If the tissue is occupied by many cysts, the whole breast had better be removed.

Cancer is the commonest disease of the breast and occurs chiefly among women between 40 and 60 years of age, but men are not entirely immune and women older or younger than the ages mentioned may suffer. The early symptoms have been given elsewhere (*see* CANCER) and the later symptoms are those of cancer in general, viz., local spread, destruction of normal tissue, ulceration, early extension to the nearest group of lymphatic glands (in this case, axillary) and from these to neighbouring groups of glands (in this case, supraclavicular) and formation of secondary growths in skin, liver, bones, muscle, indeed in any tissue of the body. With the exception of melanotic sarcoma the secondary growths in cancer of the breast are more widely spread than in cancer affecting any other primary site. Probably this is in part due to the fact that the natural duration, *i.e.*, duration apart from all treatment, of breast cancer is relatively long, viz., about three and a quarter years. The pain and distress are usually great, particularly in the later stages when probably ulceration will have occurred and pressure of the cancerous mass in the armpit on the veins and lymphatics may have led to great swelling of the arm. Death may be brought about in various ways, the immediate cause often being some intercurrent disorder which the patient, enfeebled by absorption of toxic material from the ulcerated surface, anaemia and pain, cannot resist; or by extension of the growth to the pleura and lung, with coincident pleurisy and pneumonia.

Cancer of the breast is usually spheroidal cell carcinoma but the columnar cell type also occurs notably in so-called "duct carcinoma" which is a less malignant variety. Sarcoma is also met with. Carcinoma is either hard and fibrolic (scirrhus) or highly cellular (encephaloid) but many intermediate forms occur even in different parts of the same breast. A scirrhous growth is relatively smaller and runs, locally, a less rapid and extensive course than encephaloid, but as regards extension from the primary focus and the occurrence of secondary growths there is little difference between them. Sarcoma of the breast locally forms a large growth and the secondary growths have a somewhat different distribution. Speaking generally, scirrhus is associated with an atrophied and shrivelled breast and retraction of the nipple.

It is often said that cancer runs a more rapid course in the young; statistical evidence does not support this view, though many cases in the very aged progress but slowly. On the other hand during pregnancy a cancer of the breast participates in the rapid growth of the organ. But there is no evidence that suckling conduces to cancer; on the contrary, abeyance of the natural function seems to be related to the occurrence of chronic mastitis and consequently to local cancer after a longer or shorter interval.

The *treatment* of cancer of the breast depends to an overwhelming extent upon the earliness with which the disease comes under full and proper treatment. If cancer of the breast is dealt with by the modern complete operation while the growth has not extended beyond the limits of the organ some 90% of the patients are alive and well ten years later and their expectation of life is not materially different from that of women of the same age who have not suffered from cancer. But if the cancer has extended beyond the limits of the gland, a matter of a few weeks from the time when it first becomes recognizable, the case is very different. For in spite of the same operative treatment 90% of the patients will be dead by the end of ten years. No better evidence could be given for the paramount value of early and adequate operation, but the surgeon is dependent upon the patient and there is evidence that about half the number of patients dying with cancer of the breast do not seek medical treatment at all till the last days of life and of the remainder who seek advice an average period of six months or more has elapsed between their first noticing that something was wrong and consulting a surgeon. There may be many explanations of this delay but the fact remains that with each hour they have been throwing away a good chance of healthy life. In cancer of the breast early and complete operation easily holds the first place for success so far as our present knowledge goes. Radium and *X*-ray treatment, though highly valuable in some other sites, are far inferior to surgery as curative agents in cancer of the breast with the present technique. Possibly it will remain so even with improved technique because of the special peculiarities appertaining to cancer of this organ. Upon this point no confident opinion can be given. When the disease is beyond operative treatment, radiation methods may nevertheless afford relief.

(W. S. L.-B.)

MAMMEE APPLE, MAMEY or ST. DOMINGO APRICOT, the fruit of *Mammea americana,* a large tree of the garcinia family (Guttiferae), with opposite leathery gland-dotted leaves, white, sweet-scented, short-stalked, solitary or clustered axillary flowers and yellow or russet fruit 3 to 6 in. in diameter. The bitter rind encloses a sweet aromatic flesh, which is eaten raw or with sugar, and is also used for preserves. There are one to four large rough seeds, which are bitter and resinous, and used as anthelmintics. An aromatic liqueur distilled from the flowers is known as *eau de Créole* in the West Indies, and the acrid resinous gum is used extensively for destroying the chigoes which attack the naked feet of the Negroes.

MAMMON, an Aramaic word *māmōn* "wealth" (ממון Ecclus. xxxi. 8; Targ. Onq. Ex. xxi. 30) found in Mt. vi. 24; Lk. xvi. 11. It is probably derived from *Ma'amōn,* something entrusted to safe keeping. In any case there was apparently a threefold play on this meaning in Lk. xvi. 11: "If therefore ye have not been *faithful* in the unrighteous *mammon,* who will *commit to your trust* the *true* riches," the words italicised representing forms of the Semitic root *'amen.* There is no evidence that the word was the name of an angel or a god, as in Milton (*Par. Lost* i. 678; *cf.* Spenser *F.Q.* II. vii. 8). (A. L. W.)

MAMMOTH. The name mammoth is supposed to be derived from an old Russian word given by ivory-hunters to an extinct elephant, *Mammuthus primigenius.* The animal is an elephant (*q.v.*) about the same size as the existing Indian form, characterized by possessing a short, high and pointed skull, which supports a pair of tusks unique in their spiral curvature, the roots diverging from one another, the middle part of the tusks turning upwards and outwards, and the tips being directed towards one another. This fully developed tusk only occurs in old individuals, the young tusks being similar to those of an Indian elephant. Mammoth tusks, although they may be extremely long, possibly reaching a maximum length of 10 ft. 6 in. from the socket, are usually rather slender, and must from their shape have been incapable of being used as pickaxes, as are those of an Indian elephant. The tusks of the frozen mammoths of Siberia are so well preserved that they can still be used industrially and the animals were so abundant that fossil ivory has been exported from Siberia to China and to Europe from mediaeval times.

The molar teeth of the mammoth are very variable in character but the number of plates is always large from 14–16 in the second molars and from 18–27 in the third molars. The teeth are very deep and wide so that in the dentition the mammoth reached perhaps the highest point in the evolution of the elephants.

The mammoth is found only in Pleistocene times and is in Europe always associated with a fauna whose character indicates a cold or arctic climate. When, as in England, warm interglacial periods intervened, the mammoth and his associates migrated to the north, following the retreating ice-field, and his place was taken by the straight tusked *Loxodonta antiquus.*

The mammoth was hunted by late Palaeolithic man who has left drawings and statuettes representing the animal in French caves. From these drawings it is apparent that the creature was covered with hair so long that it almost reached the ground, and that the body was produced into a great hump at the back of the neck; the ear was small. The accuracy of these drawings has been confirmed by the evidence afforded by frozen mammoths discovered in the tundra of north-eastern Siberia. These animals owe their preservation to the fact that, owing to their great weight, they became bogged in marshy plains, sinking down into ice cold mud, which subsequently became frozen and has so remained ever since. From these specimens we have learnt that the whole body was covered with an undercoat of yellowish brown woolly hair through which projected long black thicker hairs which formed patches on the cheeks, flanks, abdomen, etc. The tail is short and like that of a modern elephant, provided with a terminal tuft of long, stiff bristles. The small ears were covered with fur.

The food has been found in the stomach and mouth of frozen individuals and in the most recently reported case might have been gathered in north-eastern Siberia to-day. It consisted mainly of grasses and sedges, but also wild thyme, the Alpine poppy and upright crowfoot. Thus the mammoth alone of elephants became adapted to life in cold climates. It is not known when the mammoth became extinct, but it survived in France into Magdalenian times, that is to the extreme end of the glacial period. It may have lived on in Siberia to a much more recent period.

Closely related to the mammoth are several species of elephant found in Europe, India and North America. These animals were apparently inhabitants of warmer countries. They are first known in India in such forms as *Elephas hysudricus,* and wandered from thence not only throughout southern Europe and Asia, but even into America. In America these southern mammoths attained a gigantic size, *Mammuthus imperator* being perhaps the largest of all elephants, attaining a height of some 14 feet. (D. M. S. W.; X.)

MAMMOTH CAVE, a cave in Edmonson county, central Kentucky, U.S.A., 37° 14′ N. lat. and 86° 12′ W. longitude. It is a distinct part of an extensive system of caves in the soluble St. Louis limestone, overlain by the Chester (Mauch Chunk) sandstone both of the Mississippian or Lower Carboniferous series. The area of the cave-bearing formation is over 8,000 sq.m. in southern Indiana, through central Kentucky and into northern Tennessee. The cave is said to have been discovered in 1809, when a hunter named Hutchins is reported as having pursued a bear into its entrance; but it must have been known earlier, for its entrance was designated in the county records of 1797. Readily accessible to the majority of the Eastern States it is visited by many tourists. It is now a national park.

The St. Louis limestone throughout the cave-bearing area is massive and homogeneous, lying almost horizontal and showing few traces of tectonic or structural deformation. Owing to its relative purity and consequent solubility, it has been carved, chiefly since the Miocene period, by underground waters percolating and flowing along its joint and fracture planes, into a great series of caves. Where its cap of Chester sandstone has given way it has been perforated by hundreds of "sink-holes," more or less funnel-shaped depressions distinctive of the landscape of the region, and interrupted by scarp-rimmed valleys with little or no relation to surface erosion. The depth to which the cavern has been cut has been determined by the level of Green river, to which the Mammoth cave system is tributary by subterranean passages opening along its banks. As Green river graved itself deeper into its bed, the dissolving and eroding waters passing through the limestone were enabled to proceed with their carving deeper and deeper. The thickness of the St. Louis limestone approaches and in places exceeds a thickness of 300 ft. The sections of the cave ordinarily traversed have been surveyed by civil engineers and geologists; but owing to insurmountable difficulties, many avenues are still unexplored. The temperature of most of the cavern and its passages is fairly uniform at 54° F. Just within the entrance a noticeable draught sweeps, outward for most of the year when the exterior air is the warmer, inward occasionally in winter when the exterior air is the colder. The upper galleries are dry; the lower damp owing to streams and pools, and the air is pure and wholesome.

The entrance is 118 ft. below the summit of a limestone bluff and 194 ft. above the level of Green river, but a half mile distant. The arch at the entrance has a span of 70 feet. The vestibule within the entrance rapidly contracts 300 ft. within to a passage called the Narrows where a gateway has been built. A short distance beyond the Narrows the passage opens upon the Rotunda, the first notable chamber of the main cave. It was in the Rotunda where during the War of 1812 and at other times nitre was prepared for powder, from the guano, chiefly the excrement of myriad bats. By crude processes calcium nitrate worth $20,000 was obtained in 1914, when the industry reached its peak. The main cave is from 40 to 300 ft. wide and from 35 to 125 ft. high. It extends through the Rotunda, thence by Star Chamber, Chief City and minor chambers connected by long passages or narrow defiles to its rather abrupt termination 4 m. from the entrance. Though the entire cave extends under an area but 10 m. in diameter, the main cave and the accessible tributary passages with their domes and chambers on its five different levels aggregate a length of at least 150 miles. The extent charted includes 225 avenues, 47 domes, 23 pits, eight cataracts, three rivers, two lakes and one sea. Streams and pools contribute to the majesty of the cave. They are navigable from May to October when Green river, with which they are connected, subsides. The Dead sea is a pool walled by cliffs 60 ft. high and in length 100 ft., along which a pathway runs to a stairway leading downward to the River Styx, a body of water 40 ft. long, crossed by a natural bridge. Lake Lethe, in a broad basin with mural cliffs 90 ft. high, becomes shallow and turbid at times. Many blind fish have been taken from it. A narrow path along Lake Lethe leads to a pontoon at the neck of the lake, and beyond it, a beach of fine yellow sand to Echo river, a stream or pool ¾ m. long, 20 to 200 ft. wide and 10 to 40 ft. deep, with a symmetrical arched roof, varying in height from 19 to 35 feet. It is famous for the resonance of the tones given out by its vibrant stone which reverberate for from 10 to 30 sec. along its vaulted gallery. Other streams and pools, some of them even miles in length, occupy some chambers and galleries. They are fed by surface waters, which in the rainy season percolate and cascade into the cave in great volume, and collect in River Hall. For about seven months of the year these streams are unnavigable. When Green river is in freshet the waters in the cave become connected, sometimes rising 60 ft. above low-water mark.

For many years trips through the cave were designated as "The Long Route" and "The Short Route," the latter being the cisfluvial route and requiring about four hours for its passage, and the former, the transfluvial route, occupying from nine to 12 hours. These long-established routes were changed in 1924 to four routes which are summarized best as follows.

Route No. 1.—Echo River; Mammoth Dome with six majestic columns, royally fluted, 80 ft. high and 25 ft. in diameter; Gorin's Dome, 217 ft. high, the walls of which are draped with three immense calcic curtains of exquisite tint and texture; River Hall, by which the gardens of crystal roses are approached; Grand Crossing; and the Natural bridge.

Route No. 2.—Rotunda, with its ruins of the nitre works; Banquet Hall, equipped with tables, seats, lights and table service; Olive's Bower; Gothic Avenue, where the mummies of a race reputed to antedate the Indians were found; the Pillars of Hercules, gigantic columns; the Bridal Altar, a majestic shrine where many weddings have taken place; the Arm-chair; Elbow Crevice; Annetta's Dome; the Giant's Coffin 40 ft. long, 20 ft. wide, and 8 ft. deep, resembling a sarcophagus; Martha Washington's statue, a lighted silhouette in fancied resemblance of the first Lady of the Land; and the resplendent Star Chamber, a colossal hall of sable walls and ceiling thick set with immaculate patens of magnesium sulphate efflorescence gleaming by lantern light.

Route No. 3.—Violet City, the new section discovered and explored in 1908, comprising the resonant Chimes, the glorious Marble Temple, Albert's Stairway, the Grand Portal, Elizabeth's Dome and Valhalla; Proctor's Arcade, a symmetrical chamber, near the Star Chamber and one of the sensations of the cave when lighted by blue flares; Indian Relics; Wright's Rotunda, 400 ft. in its shortest diameter; Chief City, two ac. of troglodytic grandeur where Indian chiefs gathered in council and by blazing flambeaux and faggot fires smoked the calumet and decided for peace or war; cataracts, of impressive beauty; Waldach's Dome; the Epsom Salts deposits, their drifts of snow-white crystals; Haines Dome; the Grand Portal and the Marble Temple.

Route No. 4.—Echo river, its waters reflecting the beauties of every passage through which it flows and its ripples waking the tinkling cymbals of tiny stalactites and reverberant walls to eerie music; the Valley of Flowers; the Snowball Room; Cleveland Avenue, a treasure gallery of alabaster brilliants, the oulopholites of the mineralogist, which are declared to mimic in their fantastic fibrous and pellucid calcite crystals the forms of every flower; Florist's Garden, another fantasy of floral forms in stone; Donna's Garden; Diamond Grotto where Aladdin may have garnered his gems; the Rocky Mountains; Dismal Hollow; the famous Maelstrom, rich in tale and legend; Ganter Avenue; and the Corkscrew, a tortuous exit which reduces the journey from "Great Relief" to the mouth of the cave by nearly a mile.

Evidence of Indian occupancy of Mammoth cave has not been wholly lacking, but it has not yielded any such wealth of archaeologic material as have others in Europe, Asia and even America. Two mummies preserved by the nitrous earth were uncovered in 1813 in Short cave, not far from Mammoth cave. One was of an infant one year old and the other of an adult woman of a race antedating the Indians. See *Proceedings of the Boston Society of Natural History* (1875). In the early years following the discovery of Mammoth cave and while its guano deposits were mined for nitre, many valuable data may have been obliterated.

The biota of the cave is distinctly subterranean in character. The most interesting occupants are the blind, wingless grasshoppers with extended antennae; the blind colourless crayfish and blindfish, the latter (*Amblyopsis spelaeus*) being from 1 to 6 in. long. All the known forms of plant life are either fungi or allied to them, many but microscopic. A bed of mushrooms (*Agaricus sp.*) has been reported. While the true subterranean fauna is chiefly of Pleistocene origin, certain forms may possibly be Tertiary relics or developed from them.

BIBLIOGRAPHY.—*See* complete list of 90 titles referring to Mammoth and other Kentucky caves given on pp. 97–104 of *Mammoth Cave and the Cave Region of Kentucky* by Helen F. Randolph. Other works are: H. Gratz, "Green River or Mammoth Cave" in *Medical Repository* vol. xvii. (1814); A. S. Pachard, "The Mammoth Cave and Its Inhabitants" in *Annual Report* of the Peabody Academy of Science (1871); J. W. Turner, *Wonders of the Great Mammoth Cave of Kentucky* (1912); and N. C. Nelson, "Contributions to the Archaeology of Mammoth Cave and Vicinity, Kentucky" in *Anthropological Papers of the American Museum of Natural History* vol. xxii., pt. 1 (1917). (W. E. E.)

MAMORÉ, a large river of Bolivia which unites with the Beni to form the Madeira, one of the largest tributaries of the Amazon. It rises on the northern slope of the Sierra de Tunari east of the city of Cochabamba. Its larger tributaries are the Chaparé, Securé, Apere and Yacuma from the west, and the Ichila, Guapay or Grande, Ivari and Guaporé from the east. The Mamoré is interrupted by rapids a few miles above its junction with the Beni, but a railway 186 m. long has been built from below the rapids of the Madeira. Between the rapids and Chimoré at the foot of the *Sierra,* the river is navigable, as are most of its tributaries.

MAMUN (*c.* 786–833), originally ABDALLAH, surnamed AL-MA'MŪN ("in whom men trust"), the seventh of the Abbasid caliphs of Baghdad, was the second son of Harun al-Rashīd and successor-designate to his brother Amin. A five years' struggle between the two ended in the death of Amin and the proclamation of Mamun as caliph (Sept. 813). A serious rebellion, due to his countenancing the heretical sect of Ali, soon after threatened his throne. In the period of tranquillity which followed Mamun, who had already founded a college at Khorasan, did much to foster literature and science. The first Arabic translation of Euclid was dedicated to him in 813. He founded observatories at Baghdad and Kassium, determined the inclination of the ecliptic, caused a degree of the meridian to be measured on the plain of Shinar, and constructed wonderfully accurate astronomical tables.

In 827 he was converted to the heterodox faith of the Mo'tazilites. The later years of his reign were distracted by warfare and revolts, and in 833, when marching against the Greeks, he died near Tarsus, leaving his crown to a younger brother, Motasim. His death ended the period of Arabian culture and prosperity. *See* further under CALIPHATE.

MAN, EVOLUTION OF. The late Sir E. B. Tylor, writing on the evolutionary theory of man's origin, made the following statement: "In one form or another such a theory of human descent has, in our time, become part of an accepted framework of zoology, if not as a demonstrable truth, at any rate as a working hypothesis which has no effective rival." When Sir Edward Tylor made this statement in 1910 he was in his 78th year; his memory could carry him back to a time when it was believed that man had come into the world as a special creation some 4,000 years before the birth of Christ and owed no kinship to other living things. He was 27 years of age when Darwin's *Origin of Species* was published in 1859; in 1865, two years after Huxley had issued his renowned treatise on *Man's Place in Nature,* he himself published a work which threw a new light on human history, *Researches into the Early History of Mankind and the Development of Civilization.* When Darwin's *Descent of Man* came out in 1871, Tylor's *Primitive Culture; Researches into the Development of Mythology, Philosophy, Religion, Art and Custom,* kept it company. By the end of the 19th century he had seen chair after chair in the universities of the world filled by men who were convinced that evolution was true; at his death in 1917, at the age of 85, he had seen another generation of enquirers grow up who, after applying Darwin's teaching to all departments of man's world—to his body, mind and culture—remained convinced that, as a working hypothesis, the doctrine of evolution had no rival.

SUMMARY OF THE EVIDENCE

Embryology.—No matter what aspect of man the student of to-day may select for study, the conviction that evolution (*q.v.*) is true is forced on him. If he investigates the development of the child in the womb he comes across a complicated series of appearances which can be explained only if Darwin's teaching is accepted.

Comparative Anatomy.—If he studies the structure of man's body he finds it framed on the mammalian plan, and if he compares it with that of anthropoid apes he finds the points of resemblance to be so numerous and so close that he cannot think that such a degree of resemblance could be a result of mere chance. If he enquires into the periods through which a newly born child passes to reach manhood or womanhood, he finds the animals which are most human in this respect are the great anthropoids—the gorilla, chimpanzee and orang. If he takes into consideration the diseases to which man is liable, he finds that human diseases are more readily communicated to the great anthropoids than to any other living animals. Particularly is he impressed by the fact that the blood of man and of the anthropoid apes, when tested against each other, react almost in the same way. To account for the presence of so many vestigial structures in man's anatomy, he feels impelled to suppose that man has come of an ancestry in which these vestiges were fully grown and useful. A child may be born with its body malformed; it may suffer from hare-lip, cleft-palate or many other kinds of deformity, including the presence of a tail; medical men cannot account for such malformations if they look on man as a special creation; they can give a rational explanation of their occurrence if they accept evolution.

Palaeontology.—In recently formed strata of the earth fossil forms of man are found; those from the older strata are more ape-like than those from the newer. In still older strata are found fossil fragments of great anthropoids; in still more ancient, the remains of small anthropoids; deeper still in the earth's records no trace of anthropoid has yet been discovered. In these older strata occur fossil remains of small monkey-like primates. The geological records, so far as they are yet known, support Darwin's theory of man's origin; they are altogether against the belief that man appeared suddenly—by a special act of creation.

Human Races.—More especially is the student of human races driven to Darwinism for an explanation of his many problems; even if he believed that man had appeared originally by an act of special creation he must formulate a theory of evolution in order to account for the divergent races now living. Although in thought and deed man rises far above any member of the brute creation, yet students of his brain find that it is modelled, part for part, on exactly the same pattern as that of the anthropoid ape. Those who enquire into man's mental qualities, his emotions, his habits, his tendencies and his modes of thought, find many indications that he has ascended from a lower order.

But there are still numbers of unconvinced people who, impressed by the great and real differences which separate the mentality of the lowest grades of mankind from that of the highest grade of ape, cannot believe that man has arisen from a lower form by any natural or evolutionary process. The State of Tennessee has passed a law forbidding, in State-supported schools, "the teaching that man has descended from a lower order of animals." In June 1925 Scopes, a school teacher, was prosecuted under this law, found guilty and fined $100. Since then certain other States have enacted similar laws. Even in England, Darwin's native land, the theory of man's origin from an ape-like animal is far from finding universal acceptance. This was made apparent in 1927 when the writer, being then president of the British Association for the Advancement of Science, made Darwin's theory of man's origin the subject of his address. Although the opinions expressed were those held by the vast majority of anthropologists, they were met with a strenuous opposition on the part of a large section of the public.

MAN'S GENEALOGY

Darwin's Views.—Although there is a complete agreement among professional students that man is a member of that order of mammals to which Linnaeus gave the name "Primates" and that his lineage, when traced backwards, will be found to branch off from the primate tree, there is a sharp difference of opinion as to the exact point in the tree, and the approximate date in geological time, at which the human branch separates from those other main branches which represent the lineage of anthropoid apes and of monkeys. It is clear from statements made in the *Descent of Man,* that Darwin regarded the gorilla and chimpanzee as more nearly akin to man than other living primates and, on the evidence available in 1871, thought it probable that man and the African anthropoids were co-descendants of a common anthropoid which had its habitat in Africa (fig. 1). He regarded the catarhine type of monkey—the type exemplified by the monkeys of the Old World—as representatives of a still older ancestral form. Darwin traced the common anthropoid stock, which gave birth not only to the ancestral lines of man, the gorilla and chimpanzee, but also to those of the orang and gibbon, back to a common catarhine type. This catarhine type, he presumed, was the offspring of a still older common simian or monkey-like type, one which existed in the Eocene period of the earth's history and gave origin not only to the catarhine monkeys of the Old World but also to the platyrhine monkeys of the New World. Thus man's history, as Darwin saw it, did not begin until after the ancestral type of anthropoid had been evolved; the appearance of an anthropoid type from a common catarhine ancestor and this from a common simian stock, represent prehuman stages in the evolution of the higher primates. It is noteworthy that Darwin's mind remained open as to the exact point at which the human stock branched off from the general primate tree (fig. 1a).

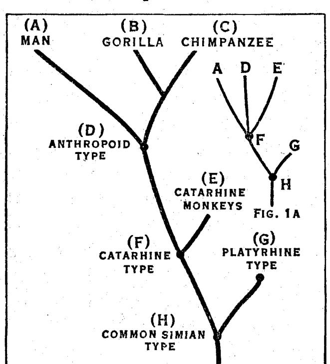

FIG. 1.—A DIAGRAM TO ILLUSTRATE DARWIN'S CONCEPTION OF MAN'S LINEAGE

FIG. 1A.—ANOTHER POSSIBLE RELATIONSHIP, ALSO MENTIONED BY DARWIN

Haeckel's Views.—On no occasion did Darwin throw his conception of man's lineage into a diagrammatic form. The first to construct an evolutionary tree of man's descent was Ernst Haeckel; this appeared in his *Generelle Morphologie* published in 1866, five years before Darwin's *Descent of Man* was issued. This pedigree is still worthy of study (fig. 2). Haeckel perceived that the small form of anthropoid ape, the gibbon, was more primitive and earlier in point of evolution than the three living great anthropoid apes (orang, chimpanzee and gorilla) and supposed that in the evolution of the great anthropoids from the ancestral catarhine type there was interposed a small anthropoid stage to which he gave the name Lipocerca (λιπεῖν, to lack, κέρκος, tail). This small anthropoid stock (Lipocerca) gave origin, he supposed, to gibbons and to the ancestral stock of the great anthropoids—for which Haeckel proposed the name Lipotyla (λιπεῖν, to lack, τύλη, cushion)—anthropoids which, unlike the gibbons, were destitute of ischial callosities or natural cushions on which gibbons and Old World monkeys seat themselves. This cushionless anthropoid stock (Lipotyla) he regarded as ancestral to the various races of mankind. From the Lipotyla, which gave origin to man, there also branched off, at an early stage, the ancestry of the orang and, at a later, the common ancestry of the chimpanzee and gorilla. Thus Haeckel regarded the gorilla and chimpanzee as more nearly related to man than other living anthropoids. It is also remarkable that he placed the extinct Miocene form of anthropoid ape, known as Dryopithecus, on the line which led up to the gorilla and chimpanzee on the one hand and to human races on the other. Thus it will be seen that in Haeckel's opinion man was the descendant of an anthropoid ape.

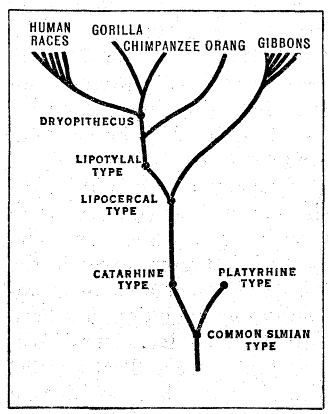

FIG. 2.—HAECKEL'S CONCEPTION OF MAN'S DESCENT AS ILLUSTRATED BY A PHYLOGENETIC TREE, PUBLISHED IN 1866

Later, he introduced considerable modifications into this family tree. In the third edition of his *Evolution of Man* (English translation, 1879) he interpolated into man's ascent from an anthropoid to a human state an intermediate stage represented by *ape-like* men—beings who were manlike in form and in gait but lacked man's power of speech. To such hypothetical beings he gave the name *Pithecanthropi.*

Modern Views.—In 1892 Prof. E. Dubois discovered in the island of Java the fossil remains of a being which answered very well to this hypothetical stage, and named this fossil form of evolving man *Pithecanthropus erectus.* Haeckel presumed that his pithecanthropi had lived in the Pliocene period; Prof. Dubois is of opinion that his transitional form of man lived in Java towards the end of the Pliocene period. Discoveries made by Dr.

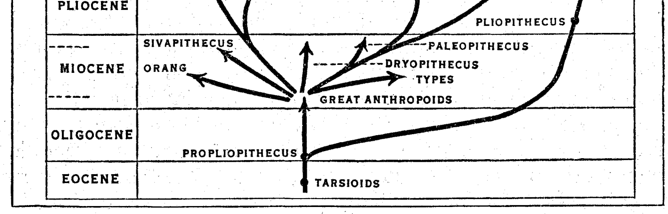

FIG. 3.—A PHYLOGENETIC TREE OF THE HIGHER PRIMATES (AFTER W. K. GREGORY, 1916)

G. E. Pilgrim of the Geological Survey of India and by members of that survey in the latter part of the 19th century have proved that India, during the Miocene period and the earlier part of the Pliocene, was the home of great anthropoids of many and diverse kinds, several of them belonging to the type of Dryopithecus which Haeckel, at an early period, regarded as a possible ancestor to man. Others of these fossil Indian or Siwalik anthropoids show affinities to the orang, to the chimpanzee and to the gorilla, while still another—*Sivapithecus*—is regarded by Dr. Pilgrim as an early representative of the human family. Notwithstanding these revelations from India and taking all their bearings into consideration the majority of modern authorities (Dubois, W. K. Gregory, Elliot Smith, Keith), in constructing diagrams to illustrate the affinities and lines of descent for the higher primates, depict the human stem (fig. 3) as springing from the vicinity of the stem which gave rise to the gorilla and chimpanzee. The conception, first formulated by Haeckel, that a Miocene anthropoid of the type of Dryopithecus (fig. 3) may stand as a common ancestor to man and to the African anthropoids is still regarded as possible.

Doubts Raised by the Occurrence of Parallel Evolution.—There is a line of evidence, accumulating at the present moment, which tends to undermine the confidence of those who have drawn up phylogenetic trees of man's descent. All who have enquired into the evolution of horses and elephants, by the study of fossil forms found in widely separated regions of the world, have become impressed by the fact that horses and elephants in America have passed through evolutionary changes of the same kind and in the same order as have done their representatives in the Old World. This tendency for the descendants of a common ancestry to undergo *parallel* or even *converging* evolution, has been very fully expounded in the published works of Dr. Henry Fairfield Osborn (*Origin and Evolution of Life,* 1918). That parallel evolution has been potent in the order of mammals to which man is assigned there can be no doubt. The monkeys of the New World parted company from those of the Old early in the Eocene period; it is probable that at the time of their separation they had only reached the stage represented by the Tarsioids, a family of monkey-like primates, which has now only one living representative—the Tarsier (*Tarsius spectrum*) of Borneo and other islands of the Malay Archipelago. Although parted thus early, New and Old World monkeys have acquired corresponding structural modifications—modifications of a kind which we cannot suppose to have been present in their common ancestor. The brain of the South American spider monkey (Ateles), that of the Old World monkeys of the semnopithek type, and that of the small anthropoid or gibbon, have many common characters which could not have been present in the brain of their Eocene ancestor.

We may legitimately infer, however, that a bias or tendency to produce similar or almost identical modifications was latent in the common ancestor. If parallel evolution has been at work in one section of the order of primates it may have been at work in another, and we must therefore keep in mind the possibility that man and the gorilla may have acquired their many and striking points of structural similarity independently. Cope (1882) and Hubrecht (1897) supposed that human lineage had parted from that of the anthropoids near the base of the primate phylum; if this were so man would have an independent pedigree of immense length. In more recent times Prof. F. Wood Jones (*The Problem of Man's Ancestry,* 1918) has put forward the theory that man, because of the number of primitive and generalized features of his structure, is to be traced back to an independent origin from a tarsioid ancestor. In 1927 Dr. Henry Fairfield Osborn also championed the early separation of man's ancestry from the primate phylum. Such a view entails the need of supposing that the multitude of structural similarities shared by man and the great anthropoids must have been acquired by each independently.

Klaatsch (*Die Stellung der Menschen im Naturganzen,* 1911) (*Evolution and Progress of Mankind,* 1923) made a larger demand on the powers of evolution to reach the same end by diverse routes. This voluminous author traced the origin of mankind to an anthropoid ancestry, but supposed that the ancient inhabitants of Europe—Neanderthal man, known only from his fossil remains, and the living Negro peoples of Africa had arisen from the same stock as the gorilla and chimpanzee, while Mongolian peoples and men of the modern European type had sprung from the same lineage as the orang. Klaatsch believed in the polygenetic origin of human races.

Man an Aberrant Primate.—In charting the family tree of the Higher Primates modern authorities differ as to the position which should be assigned to man. Prof. Eugène Dubois represents the human stem as the main and direct continuation of the trunk of the primate tree (*Nature,* vol. liii., p. 245, 1896); from this main trunk all the other members of the primate order are made to come off as side branches. Man is given the central position of his order; he forms the apex of the primate tree. Prof. Elliot Smith (*Evolution of Man,* 1925) also gives the human family the central position as a direct continuation of the main primate stem. In reality man is the most aberrant member of his order; in brain and in the modifications of his lower limbs he has departed farther from the ancestral primate state, so far as we know that state by the study of fossil remains, than any member of the order; he has retained less of the structural organization of the original primate than all the others. Apparently in the evolution of the higher primates there has been the same tendency as is to be noted in modern political parties—a tendency for an extreme wing to move ever further from the central group of conservatism. The human family represents the extreme wing in the order of primates; *Tarsius,* greatly modified as it is, retains the essentials of the central or conservative group.

MAN'S ZOOLOGICAL POSITION

Zoologists classify animals into families, sub-families, genera and species, according to their degrees of structural likeness; they presume, although fully aware that parallel evolution can and does take place, that two animals, such as the gorilla and chimpanzee, which are so similar in the structural details of their bodies, owe that similarity to their descent from a common ancestry. Darwin urged rightly that in settling the zoological relationship of one group of animals to another, more weight must be attached to the points wherein they agree than to those in which they differ.

Huxley's Views.—In the masterly analysis of man's structural relationships given by Huxley in *Man's Place in Nature* (1863), more stress was laid on the anatomical differences which separate man from the gorilla than on the points wherein they agree. Huxley held that differences which separated man from the gorilla were like in kind and similar in degree to those which separated the gorilla from any form of catarhine or platyrhine monkey a critic might choose for comparison. He held that if evolution could produce the structural gap which separates a monkey from the gorilla it could also bring about the abyss which divides the gorilla from man. Huxley's conclusions are still valid; indeed, the modern anatomist is convinced that the structural hiatus which lies between a baboon or any other form of monkey and the gorilla is much wider than that which lies between the gorilla or chimpanzee and man. When tested by modern methods, the blood of the chimpanzee shows a much closer affinity in its reactions to that of man than to that of any Old World monkey; the blood of monkeys of the New World, when submitted to the same tests, reveals a still more distant affinity (Prof. G. H. Nuttall, *Blood Immunity and Blood Relationship,* 1904). Huxley included in one family the great anthropoids (gorilla, chimpanzee and orang), the small anthropoids (siamang, gibbon), and the various genera of monkeys of the Old World; if we are to be guided by anatomical considerations we must give to each of these groups the rank of a family. The same rank—that of a primate family—must be given to the section which embraces all the various races and types of mankind, living and extinct. The various genera of New World monkeys make up a fifth family of primates.

The Primate Families.—Thus in that part of the living animal kingdom to which man belongs, there are five families—the human family, that of the great anthropoids, that of the small anthropoids, the family of catarhine or Old World monkeys and the family of platyrhine or New World monkeys. These families are separated by structural gaps of about equal magnitude. From the platyrhine monkeys upwards, these families form an ascending series in the sense that each succeeding family marks a further departure from the ancestral tarsioid type, the point of highest differentiation being reached in the human family.

EVIDENCE OF MAN'S DESCENT

Anatomical.—The members of these five families of primates have a common structural substratum—an inheritance from the ancestral stock from which they have all descended. Each family in the course of evolution has come by anatomical features which are peculiar to itself. A full analysis of the structural details of man's body shows that about 30% of them are peculiar to himself. The corresponding characters of the gorilla number 16%; the gibbon has about the same proportion of features peculiar to its own family (Keith, *Rivista di Antropologia,* vol. xx., p. 1, 1916). As examples of man's peculiar characters we may cite his nude skin, his projecting nose with well marked wings, the size of his brain, the strength of his thigh, the form of his leg, the shape of his foot.

Common Characters.—Further analysis reveals in man's body a series of characters which he shares with only two other living animals—namely, the gorilla and chimpanzee. These amount to nearly 9% of the total points selected for comparison, but if we include in this group features which man shares with the gorilla alone or with the chimpanzee alone, then man has in his body about 26% of characters which he shares with gorilla and chimpanzee or with gorilla alone or chimpanzee alone. Such characters, we presume, are derived from a common ancestor which gave birth to man and to the great anthropoids of Africa. As examples of characters common to the three we may cite the air chambers which branch off from the nasal cavity. These have the same arrangement and are of the same number in man, gorilla and chimpanzee. Another example is to be found in the small bones of the wrist. Of the higher primates, only in these three has the *os centrale* disappeared as a separate unit from the carpus; yet in a foetal stage this bone is present in all three; and as a separate element in adults of all the other higher primates.

Descending still lower in the strata of human anatomy we encounter a group of characters which man shares with the three great anthropoids. We may speak of man and these three as the giant primates, for compared with the earlier types they are giants, or we may apply to this group Haeckel's convenient name —*Lipotyla.* Man shares with the other giant primates 10% of similarities of structural detail; to this we may add 5% which he shares with the orang and with the orang only, characters which the chimpanzee and gorilla have apparently lost or perhaps never possessed. Going still lower in our analysis, we find over 8% of characters which are common to the gibbon as well as to the great anthropoids. With the gibbon, man shares 8% of structural features which are not to be seen in the bodies of the great anthropoids. In this case, again, we have to suppose that man and the gibbon came by those characters long after they separated from a common ancestor, or that the great anthropoids have lost them in the course of evolution while man and the gibbon have retained them.

Lower in the scale of our analysis we come upon features in man's body which he has apparently retained from a catarhine ancestry; at least, to find their counterparts we have to go to the bodies of Old World monkeys. In man's body there are 5% of such catarhine features; in the gorilla's body such features are three times as numerous. It is remarkable that platyrhine characters, features to be seen in the bodies of the New World monkeys, should be as numerous as catarhine in man's body.

There is a small residue of anatomical details in human anatomy attributable to a still more distant past, a heritage from a tarsioid or lemuroid ancestry. From the details revealed by anatomical analysis it is plain that evolution has not proceeded in an orderly or simple manner in shaping the bodies of the higher primates; characters are curiously scattered. Yet to explain the distribution of characters in the various families we must suppose that man's ancestry is linked closely to that of the African anthropoids—the gorilla and chimpanzee. In some instances we obtain help in explaining the distribution of characters by calling in the aid of *collateral* or parallel evolution; in other cases Mendel's discoveries in heredity assist us; further, we see that the body of man and of ape is a great mosaic work of structural elements and that progressive changes may occur in one set of units while retrograde changes affect another set.

Embryological Evidence.—In recent years the formation of the human embryo in the womb, the complicated changes which transform the embryo into a foetus and the elaborate processes which produce the organs of the ripe child from embryonic rudiments, have been studied by an ever-growing army of enquirers and by methods which possess an ever-increasing precision. Embryologists find it necessary to assume that the law of evolution holds for man; unless they make this assumption they can offer no rational explanation of the complex changes which engage their attention. In its broad lines development pursues the same course in the human body as in that of all vertebrate animals. What Francis Balfour in 1885 saw taking place with diagrammatic clearness in the embryo of the dog-fish has given clues to the more complex and obscure processes now known to occur in the embryo of man.

The developing human egg, when it becomes established in the mother's womb, undergoes a series of elaborate and peculiar changes. The investigations carried out by the late Dr. Emil Selenka (*Menschenaffen. Studien über Entwickelung und Schädelbau,* 1898–1906) revealed the fact that only in the wombs of four other living mammals, the gorilla, chimpanzee, orang and gibbon, do the same changes take place. The process by which the placenta is formed, thus establishing a means of supplying the unborn child with nourishment, is exactly the same in man as in anthropoid apes. It is true that in *Tarsius* we see outlined the basal plan of placentation met with in the higher primates, but it is also true that in the placentation of the monkeys of the Old World and also in that of the New World we see a stage which leads on from the lower or tarsioid condition to the higher or anthropoid form. In the embryos of man and of the anthropoids an external jointed tail is produced in the fifth week of development; by the end of the eighth week it has shrivelled and becomes submerged, leaving a dimple at the point of the caudal region where it sinks below the surface. These are a few examples of some of the remarkable similarities which link the embryological history of man with that of the anthropoid apes.

Recapitulation, Interpolation, Adaptation.—When in the later decades of the 19th century anatomists applied themselves to unravelling the development of man's body, they expected it to recapitulate, in full detail, the various stages of his evolution. In this they have been disappointed, because in the growth of the embryo and of the foetus we see three different processes at work. We see recapitulation taking place; we also see new characters being interpolated from the time the embryo makes its first appearance until all the parts of a formed child are laid down; further we see at every stage the body of the embryo and of the foetus being adapted to a life within the womb. When gill-clefts appear in the neck of the human embryo towards the end of the first month of development we see a recapitulatory and very distant phase exemplified. When we look at the developing human foot, with the expectation of finding an anthropoid phase, we search in vain. The great toe is never a free and separate member in the human foot as in the adults of all other primates. There is a stage in the development of the feet of primates when all the digits diverge equally from the tarsal base; man and ape pass through this stage and man clings to it as it were, whereas all the other primates pass on to a final prehensile stage. Yet in the sole of the newly born child we see the same flexion lines as in that of the gorilla; we find the same muscles in the great toe of the human foot as in that of the gorilla; we find the joint at the base of man's great toe, especially in the foetus, moulded in the same form as the gorilla. We cannot explain these appearances unless we believe that the human foot has been evolved from one like that of the gorilla, more especially as the foot of the gorilla shows a curious blend of human and monkey-like features.

The human great toe does not recapitulate ancestral history; developmental changes which mould the great toe into the human pattern set in just when the simian ones are due; the human changes do not succeed but replace those that give the ape its prehensile foot. New changes have been intercalated in the evolutionary sequence. In a multitude of details the human embryo no longer recapitulates the series of changes gone through by its ancestors. It is true of every part of the human body; human characters begin to peer through its higher primate qualities before development is a month old.

Of the changes which affect the developing human body those which represent adaptations to life within the womb are the most important. The child draws its living from its mother's body; it is sheltered and kept warm; it has not to seek its living nor defend itself; such qualities need not be attained until the time of birth; until then nature is free to work out what experiments she will. It is a remarkable fact that many of man's distinguishing features are to be met with during foetal stages in the development of anthropoid apes. A stage which is transient in the foetal ape becomes permanent in man. We may take as an example the comparative hairlessness of man's body. A foetal chimpanzee, in the eighth month of development, resembles a human foetus of the same age; both have hair growing freely on their scalps, but the rest of their bodies, although provided with lanugo, appear to be nude. By birth the chimpanzee's body is covered with hair, but the human child retains the foetal state. Yet all known primates save man have their bodies thickly covered with hair; hairlessness is not an ancestral condition, but one made possible by the retention of the young in the shelter of the womb. The skin provides us with another example of foetal inheritance. In the fair or white stock of mankind the skin has become relatively free from pigment. In their earlier stages of foetal development apes are unpigmented; they darken as the time of birth approaches. White men have come by their colouring through the inheritance of a foetal condition, one which is certainly not ancestral.

Many examples might be cited of man coming by distinctive characters by retaining foetal states, but the following may be taken as representative. In all foetal primates the brain is relatively large and the jaws absolutely small; this is certainly not an ancestral state, for in all the older forms of primate the brain is small and the jaws large. Man is distinguished by the large size of his brain and the relatively small size of his teeth and jaws. How he compares with adults of great anthropoid apes may be seen from the following data. We may take the capacity of the cranial cavity to represent the size of brain and the area of the palate to represent the size of the jaws. In a well-grown adult European male we expect a cranial capacity of 1,500 c.c. and a palatal area of 25 sq. cm., there being 60 c.c. of brain space for every square centimetre of palate. The average male gorilla has a cranial capacity of 470 c.c., a palatal area of 72 sq. cm., that is, 5·8 c.c. of brain space for every square centimetre of palate. The corresponding figures for the average male orang are: 412 c.c., 62 sq. cm., giving a cranio-palatal ratio 6·6:1; in the average male chimpanzee the figures are: 390 c.c., 46 sq. cm., giving a ratio of 8·5:1. There is a wide gap between the European cranio-palatal ratio 60:1 and that of the chimpanzee, 8·5:1. We may fill the gap somewhat by citing a Tasmanian skull with a capacity of 1,350 c.c., a palatal area of 36·7 sq. cm. and a ratio of 36·7:1.

We find a still nearer approach to the anthropoid condition in the fossil skull of Rhodesian man in which the cranial capacity is 1,300 c.c., the palatal area 41 sq. cm., the cranio-palatal ratio 31·7:1. Even this ratio is far above that of the chimpanzee, 8·5:1; but if we take a suckling chimpanzee, in which the cranial capacity is 260 c.c. and the area of palate 13·6 sq. cm., we obtain a ratio 19:1, an approach to the human proportion. If we take a still earlier stage, such as may be observed in a chimpanzee foetus during the eighth month of development, we find a ratio which is human in its magnitude. Man has come by his small palate by retaining a foetal anthropoid condition, and this is true of all the parts of man's skull which are concerned in mastication. This tendency to foetal inheritance is not confined to the human branch of primates; in certain genera of New World monkeys, particularly in Chrysothrix and Cebus, we see in their small jaws and large heads the same law at work.

The belief that many of man's foetal characters do not reflect ancestral stages, but foreshadow the trend of future evolution, was held by several anatomists in Germany towards the end of the 19th century, particularly by Ranke. The law of foetal inheritance, so far as it relates to man, has been greatly extended during recent years in a series of papers by Prof. L. Bolk of Amsterdam (*Proc. of the Roy. Acad. of Sc. of Amsterdam,* 1921–5). Embryological evidence, if it has failed to reveal the pithecoid states through which man has passed in his ascent, does provide conclusive evidence of his simian ancestry. In the development of his brain, for example, we see that the first fissures to appear are those which occur in the brains of the higher monkeys; the next are those which are found in the brains of the great anthropoids, and later still the secondary human sulci are formed; but never at any stage does the human brain correspond to that of monkey or of anthropoid. If embryology has failed to reveal the details of man's history, it has shown that the processes of evolution are at work on the foetal body; if the study of the foetus does not help us to decipher man's past, it does seem to provide a basis on which we may forecast the future of the human body. The brain of the gorilla, in the totality of its characters, is the most like that of man; these two are structural allies, yet evolution has moulded their bodies in opposite directions. During growth the gorilla replaces all its foetal characters by those of brutality and strength; in man the tendency has been to retain the delicate physique of the young and to shed those of a more brutal nature. Why the one fate overtook the gorilla and another fell to man remains an enigma.

BIOLOGICAL EVIDENCE OF MAN'S EVOLUTION

Blood Tests.—Not only are the bodies of man and anthropoid apes fashioned on similar lines, but, as was demonstrated at the beginning of the present century, their living tissues give like reactions. In 1900 Dr. Hans Friedenthal injected a small amount of human blood into the veins of a chimpanzee; its vital qualities were so similar to those of the chimpanzee that no disturbance followed the operation. When an equal amount of the blood of a macaque monkey was injected into the veins of the chimpanzee there was a slight reaction; the corpuscles of the macaque's blood were destroyed and ejected by the kidneys. When the blood of an ox was used a violent reaction was produced, the foreign blood being destroyed and thrown out.

Prof. G. H. F. Nuttall, of Cambridge university, thereafter elaborated a more precise method of estimating blood-affinities, by which very small quantities of blood can be tested against specially prepared antisera. In 1904 appeared his classical work *Blood, Immunity and Blood Relationship,* containing the results of tests carried out on three species of anthropoid apes, 28 species of Old World monkeys, and nine species from the New World. The blood of all these species was tested against a human antiserum. The blood of the anthropoids gave a full reaction—100%; that of the Old World monkeys gave a lesser reaction or precipitation, one equivalent to 92% of the full; that of the New World monkeys 78%. At the time Prof. Nuttall was making these investigations in England, Dr. Uhlenhuth was carrying out independent enquiries in Germany, and reached corresponding conclusions as to degrees of affinity. The tests devised by Nuttall and by Uhlenhuth utilize the fluid or serum of the blood. Recently Drs. Landsteiner and Miller (*Jour. Experim. Med.,* vol. xlii., p. 841, 1925) have utilized the corpuscular elements of the blood and find that they give more delicate reactions than those given by the serum. They devised tests which serve to distinguish the blood of the chimpanzee from that of man, but which fail to discriminate the blood of the white man from that of the negro.

Disease Reactions.—The reactions of living tissue are also tested by disease. Man is peculiarly susceptible to syphilis; the animals most akin to him in this respect are the great anthropoid apes. Monkeys are difficult to inoculate with syphilis, and when they suffer, take the disease in its mildest form. Anthropoid apes are almost as susceptible to typhoid fever as man is. When chimpanzees are kept in confinement they are liable to that modern disease of man—appendicitis. Anthropoids react to stimulants, sedatives and poisons in the same manner as human beings. The brains of the great anthropoid apes are smaller and are less convoluted than is the case in man, yet when the living cortex is stimulated by electrical methods, be it in man or anthropoid ape, the same reactions follow when corresponding convolutions are excited. Surgeons have found that observations made by experimental physiologists on the brains of anthropoid apes afford reliable guidance when they have to operate on the brain of man.

Thus the evidence supplied by vital tests bears out the conclusions forced on anatomists by similarity of structure—namely, that great anthropoid apes, in an evolutionary sense, are near akin to man.

EVIDENCE OF VESTIGIAL STRUCTURES

Nearly all the structures which have become greatly reduced or are mere vestiges in the body of man have undergone a similar fate in the bodies of the anthropoid apes. In them as in man the tail has disappeared, all save its basal part, which has sunk beneath the surface to form the coccyx. It is true that the vermiform appendix of man is smaller than that of any of the anthropoid apes, and that in half of the Europeans who reach the age of 70 its lumen has become closed, yet it is more than doubtful if this structure should be reckoned vestigial in the body of either man or anthropoid. The *palmaris longus,* the *plantaris,* and the *pyramidalis,* muscles which are reduced or fibrous in man, are in the same state in anthropoid apes. Such evidence points to a common origin for anthropoids and man, but it throws no light on man's more immediate relationship to any member of the anthropoid group.

There are two muscular vestiges, however, which point to man's kinship to the African anthropoids. There is a muscle in the neck of monkeys which helps to lift the shoulder; it is called the *levator claviculae.* It has almost disappeared from man's body; it is met with only once in a hundred dissections. This muscle shows definite signs of reduction in the gorilla and chimpanzee, but not in the orang or gibbon. All monkeys have a strong muscle called the *latissimo-condyloideus.* When a monkey is climbing, and has seized a branch with its hand, it uses this muscle to pull the trunk upwards. It is a particularly strong muscle in the gibbon, well developed in the orang, somewhat reduced in the chimpanzee, partly fibrous in the gorilla, wholly fibrous in man, although in 5% of human bodies some muscle fibres may be detected. Lately Dr. A. H. Schultz, of the Carnegie Institution of Washington, has found a remarkable example of the persistence of a vestige in man's body (*Amer. Jour. Physic. Anthrop.,* vol. vii., p. 149, 1924). Lemurs, which branched off from the primate stem at a very distant geological period, have a tuft of touch vibrissae at the wrist. Monkeys were supposed to have lost these vibrissae; Dr. Schultz found them in foetal stages of monkeys both of the Old World and of the New. On examining the wrists of human foetuses in the second month of development he found a raised plaque at the spot where the touch vibrissae are situated in lemurs.

THE EVIDENCE OF FOSSIL REMAINS

Pithecanthropus Erectus.—The discovery which throws most light on the evolutionary progress was made in Java in 1891–92 by Prof. Eugène Dubois (1858–1941), then a surgeon in the colonial military service, and later professor of geology in the University of Amsterdam. In a stratum which contained the fossil bones of many extinct species of animals he obtained five fragments of a strange kind of being, one of which he regarded as a transitional form between man and ape—a real missing link. He named it *Pithecanthropus erectus,* and assigned it to a separate family of primates—one lying on the borderline between anthropoids and man. (*Pithecanthropus erectus, eine menschenaehnliche Uebergangsform aus Java,* 1894.) The five fossil fragments found were: a skull cap which outwardly had the form which might be expected in a giant form of gibbon, a left thigh bone and three teeth. The most distant of the fragments were 20 paces apart. Later he added a sixth fragment—part of a lower jaw found in another part of the island but in a stratum of the same geological age. The skull cap is flat, low and has great eyebrow ridges; its characters are more simian than human, yet when Prof. Dubois succeeded in obtaining a cast from the interior of the skull cap, that cast bore on it the convolutionary pattern of the brain of Pithecanthropus, and that pattern proved to be altogether human. Pithecanthropus, the fossil man of Java, had a brain which was smaller, simpler and infinitely more primitive than that of the lowest living men.

By this discovery Prof. Dubois caught the human brain in the act of evolving. Certain cortical or convolutionary areas in man's brain are known to be concerned with sight, hearing and touch, and the reception of messages from other sense organs; a "motor" area is concerned in the initiation and control of voluntary movements. Between these primary areas of the cortex lie association areas which have to do with the memory and the interpretation of what is seen, heard or felt. The cortex of part of the frontal lobe—the prefrontal cortex—is concerned in the acquisition of skilled movements. These secondary or association areas of cortex, which lie between and separate the primary areas, are the basis of man's educability—his capacity to learn from experience. In the brain of Pithecanthropus the association areas are much less developed than in the brains of the lowest of living human races. Yet all the essentially human parts are represented. It is even possible that the owner of this brain was capable of speech.

A further study of the brain-cast has convinced Prof. Dubois that Pithecanthropus must be placed in the human family (*Proc. Roy. Acad. Sc. Amsterdam,* vol. xxvii., nos. 5, 6, 1924). The brain of this "fossil" man is now estimated to have had a volume of at least 900 c.c.; the largest-brained gorillas rarely rise above 600 c.c.; the lowest-brained of human beings occasionally falls below 1,000 cubic centimetres. Pithecanthropus in size of brain lies on the verge of humanity. His teeth, if large, are essentially human in form of crown and root; the socket for the canine, in the fragment of lower jaw, shows that this tooth was not massive and pointed as in anthropoid apes. The thigh bone is human altogether, and gives proof that Pithecanthropus walked as men do.

Pithecanthropus was assigned by Prof. Dubois, on reliable evidence, to a date late in the Pliocene period; others on weighing the evidence suppose that he lived early in the Pleistocene period. If we accept the duration of the Pleistocene as 250,000 years, and regard Pithecanthropus as representing the evolutionary stage reached by mankind at the beginning of this period, then we have to conclude that man's body had become adapted to its peculiar posture and gait before the end of the Pliocene period, and that the higher development of the brain took place in the ensuing Pleistocene period.

Eoanthropus.—The discovery which ranks next in importance to that of Pithecanthropus was made by Mr. Charles Dawson at Piltdown, Sussex, between the years 1911 and 1915. He found the greater part of the left half of a deeply mineralized human skull, also part of the right half; the right half of the lower jaw, damaged at certain parts but carrying the first and second molar teeth and the socket of the third molar or wisdom tooth. The lower jaw, in the region beneath the chin, had a bar of bone known as the "simian shelf," which until then had been regarded as a mark of the ape. Later a pointed upper canine tooth was added; its characters were simian rather than human. The stratum of gravel proved to have been laid down early in the Pleistocene period, and it is certain that the fossil fragments of this human skull were as old as the date of deposition. From the fossil fragments thus found, Sir Arthur Smith Woodward reconstructed an extinct genus of mankind, *Eoanthropus,* the dawn man (*Quar. Jour. Geol. Soc.,* 1913–15). Subsequently (1915) there was found a remarkable bone implement hewn from the thigh bone of an extinct kind of elephant; its state of mineralization and its colouring show that it had been embedded originally in the deepest stratum and was certainly as old as the human fossil remains; in a neighbouring field two other fragments of a human skull of the same kind came to light, and another molar tooth.

Some experts still doubt whether a lower jaw which resembles that of a chimpanzee in several respects should be assigned to a skull which is purely human in its characters. At first there were differences of opinion as to the size and characters of the brain of Eoanthropus. Amongst British authorities there is now agreement that the skull and jaw are parts of the same individual, and that the brain, as revealed by casts taken from the interior of the skull, is human in its size and in all its characters. If we divide living races into three classes according to the size of brain, the large-brained having a cranial capacity above 1,450 c.c., the small-brained a capacity under 1,350 c.c., then Eoanthropus certainly reached the upper limits of the small-brained class if not actually a member of the medium-brained group. The brain of Eoanthropus has risen many stages above that of Pithecanthropus; the bone implement affords evidence of manual skill and of inventive ability on the part of its owner. The eyebrow ridges of Pithecanthropus are shaped as in the gibbon, chimpanzee and gorilla; in Piltdown man they are fashioned nearer to the form seen in the skull of the orang. Professor Frassetto of Bologna has drawn attention to several points in which the Piltdown mandible resembles that of the Orang (*Man.*, July 1927). The discovery at Piltdown shows that at the beginning of the Pleistocene period a race of mankind had come by a brain that had reached a human estate, and that this race still retained certain definite simian characteristics in its jaws, teeth and face.

Neanderthal Man.—In 1857 while workmen were clearing out the Neanderthal cave near Düsseldorf, Germany, they found the vault of a fossilized skull and limb bones of a man who proved to be, in the light of further discoveries, a representative of an extinct species of man—*Homo neanderthalensis.* A fossil skull which was dug up at Gibraltar in 1848 is of the Neanderthal type. In 1926 Miss Dorothy Garrod, while excavating the floor of a recently discovered cave at Gibraltar, unearthed the greater part of the skull of a Neanderthal child, aged about five years. The stratum in which it was embedded contained flint implements worked in the upper or later Mousterian style. This skull is as capacious as that of a modern child of the same age and as the supraorbital ridges are still undeveloped, the forehead is not so unlike that of modern children. The skull of a Neanderthal child, older than the Gibraltar example, was found at La Quina, France, in 1921 by Dr. Henri Martin. Fossil remains of the same species have been found in Belgium (at Naulette, 1866, and at Spy, 1886), but the caves of France have proved the richest source of Neanderthal remains, particularly those in the valley of the Dordogne.

The evidence found at La Chapelle (1908), at La Ferrassie (1909), at Le Moustier (1908) and at La Quina (1911) made it quite clear that this extinct type of man, marked as he was by many simian traits of body, buried his dead with signs of respect. He worked flint implements with great skill, in the style or culture known as Mousterian. He was a hunter and lived in caves and rock shelters. His molar teeth were often shaped in a peculiar manner; his teeth have been found in cave deposits in Jersey (1911) and in Malta (1917). His remains have been found in Moravia (1906) and at Krapina in Croatia (1899–1906). His culture has been found in Italy and in England, but no trace of his body. Only once have fossil remains of Neanderthal man been found outside the limits of Europe, in a cave situated on the western shores of the Sea of Galilee (1925).

Neanderthal man appears to have been the sole occupant of Europe during the middle of the Pleistocene period—throughout the time in which the Mousterian culture prevailed in that continent. The date of this culture may be put down tentatively as extending from 40000 B.C. to 20000 B.C.; perhaps its duration was much longer. Remains of Neanderthal man rather more primitive in type, and found in strata older than the Mousterian strata of France, have been discovered at Taubach (1895) and at Ehringsdorf (1914), both of these sites being near Weimar, Germany. In 1925 a human skull was discovered in the limestone deposit of Ehringsdorf. This discovery is of especial importance for the geological evidence gives to it a greater antiquity than that of the Neanderthal skulls of France. The fauna embedded in the same stratum as the skull is that of the warm period which preceded the Mousterian glaciation. Yet the new Ehringsdorf skull (Weidenreich, *Verhand. Gesellsch. f. Phys. Anthrop.*, 1927, p. 34) has all the characteristics of the Neanderthal species, but is very capacious, particularly when its feminine features are taken into account. Weidenreich estimates the cranial capacity of this woman to have been 1,450 c.c. Her skull had been fractured by a blow given by a wedge-shaped weapon at, or soon after, death. *The Heidelberg mandible* was found at a depth of 78 ft. in a sandpit at Mauer, ten miles to the east of Heidelberg, in 1907. The stratum in which it was found belongs to the deeper and older Pleistocene series; this fossil jaw thus represents a race which lived long before the men who practised the Mousterian culture. Yet so like is the mandible of Heidelberg man to that of Neanderthal man, in the majority of its characters, that we may safely regard him as an ancestral representative of the Neanderthal species. In Heidelberg man the canine tooth did not project above its neighbours as in Eoanthropus. At the close of 1927 it was announced that many further fragments of Heidelberg man had been discovered at Mauer; his leg bones are even more anthropoid in their characterization than those of Neanderthal man. In a still older stratum of the same formation were found the fossil remains of a species of man—a forerunner of the Neanderthal type—of a large anthropoid ape and of two smaller apes, akin to the gibbon, showing that at the end of the Pliocene period Europe was inhabited by a low species of humanity and by various species of anthropoid apes.

At one time it was believed that Neanderthal man represented an ancestral phase of modern man. Every bone of his body shows distinctive markings, many of these being of a simian nature. His eyebrow ridges were like those of the gorilla and chimpanzee; the roof of his skull was low like theirs, and yet in size of brain he equalled, if he did not surpass, modern Europeans. He had, however, certain specializations of structure which modern or Neanthropic man does not possess. Besides, the archaeological evidence is now complete that he was replaced in Europe by the arrival of men of the modern kind—represented by people of the Cromagnon type. For these reasons Neanderthal man cannot be regarded as an ancestor of modern man. Neanderthal man and men of the modern type, however, have so much in common that they must be looked upon as descendants of a common ancestor.

Rhodesian Man.—The fossil remains of Rhodesian man which were discovered in the Broken Hill mine, Northern Rhodesia, in the summer of 1921, also bear evidence to the truth of man's evolution. His fossil remains lay deep in a filled-up cave; he was probably alive in Africa when men of the Neanderthal type dominated Europe. His limb bones show that he was tall, quite 5 ft. 10 in. in height, and stoutly made, after the manner of modern man. His skull, which is complete save the lower jaw, possesses many primitive traits. His brain space was small (1,300 c. c.); in point of development the brain falls below that of Eoanthropus. The eyebrow ridges are extremely massive, and the face has features which recall those of the gorilla. Yet his teeth, although large, are human in every respect and were ravaged by caries. Rhodesian man might well stand as an ancestral type to modern man.

Cromagnon and Other Races.—The Cromagnon type of man and other forms which appear in Europe after the disappearance of Neanderthal man are fully developed men of the modern type; they differ from us only in robusticity of build and strength of jaw. The fossilized, capacious skull discovered at Boskop, Transvaal, in 1913, represents an extinct form of man of the Bushman type. The Talgai skull, derived from a Pleistocene deposit and described by Dr. S. A. Smith (*Phil. Trans.*, ser. B, vol. ccviii., p. 351, 1918), is of the same form as that of living Australian aborigines, but possesses additional primitive features. In 1926 Dr. W. Colin Mackenzie announced the discovery of a fossil skull showing the same primitive features as the Talgai specimen. It was found in a swamp at Cohuna, in the basin of the Murray river, northern Victoria. Prof. E. Dubois discovered a Pleistocene form of man at Wadjak, Java, one with a very large cranial capacity (*Proc. Roy. Acad. Sc. Amsterdam*, vol. xxiii., pt. 7, 1920). Such discoveries, although they bear out the truth of evolution, do not throw light on man's evolutionary pedigree.

ANTIQUITY OF MAN

Until the year 1860 the majority of scientific men, relying on scriptural authority, believed that man's existence on earth covered a span of less than 6,000 years. Throughout the first six decades of the 19th century certain lines of enquiries kept bringing to their notice facts which could not be reconciled with orthodox beliefs. The first line of enquiry which brought unexpected facts to light was the systematic excavation of ancient graves and burial places. During the third and fourth decades, Danish antiquarians discovered that ancient graves could be arranged in the order of their antiquity; those which contained only weapons or implements of stone were of one period—the oldest; those, in which stone was replaced by bronze were of another and later period, and those in which iron had replaced bronze were of a third and more recent time. By 1860 archaeologists had proved that the sequence of events, first discovered in Denmark, held true for graves in all parts of Europe and that prehistoric time could be divided into three periods or ages—the age of stone, the age of bronze and the age of iron. In this way archaeologists came to realize that authentic human history could be compiled by a careful study of ancient burial places.

A second line of enquiry served to carry human history into a more remote past. This was the excavation of the materials which had accumulated in the floors of caves during prehistoric times. During the opening decades of the 19th century cave exploration was carried out with ardour in many parts of Europe; the fossil bones of many kinds of extinct animals were found, but as these were regarded as the wrack of the creation which preceded man's first appearance, it was deemed useless to search for traces of man's existence in the strata of such caves. In 1825 a Roman Catholic priest, the Rev. J. MacEnery, while excavating Kents Cavern, Torquay, found, deep in the undisturbed floor, a stone weapon in a seam containing fossil bones of extinct animals. He rightly drew the inference that man had been the contemporary of these animals. MacEnery's discovery was rejected by the leading experts of the time. The same fate was meted out to Prof. Schmerling of Liège in 1833 when he announced the discovery of a human skull in the stalagmitic floor of a cave, "surrounded on all sides by the fossilized teeth of rhinoceros, horse, hyena and bear." Then in 1858 came a discovery which arrested the attention of the most sceptical. Dr. Hugh Falconer and William Pengelly, two most reliable investigators, excavated a cave at Brixham, near Torquay, under the aegis of two learned societies—the Royal and Geological Societies of London. Deep in the undisturbed cave earth, mingled with the bones of extinct animals, they found stone implements which must have been fashioned by human hands. Then in 1860 southern France yielded incontrovertible evidence of man's great antiquity; the excavation of a cave near the village of Aurignac, Haute Garonne, by Edouard Lartet proved conclusively that man was the contemporary of extinct mammals, for in the floor of this cave were found the ashes of man's hearths, amidst which were mingled bones of extinct animals. These bones were charred, cut and artificially broken—the debris of long past feasts.

A third line of enquiry carried man's history into a still more remote period—one which in its older parts, preceded the age of caves. Beyond a doubt the man who opened up this new source of human history was Boucher de Perthes, an exciseman, stationed at Abbeville, on the estuary of the Somme. In 1832 he began to collect curiously fashioned stones which were found in gravel pits situated on the sides of the valley. These gravels and sands contained the bones of extinct animals; Boucher de Perthes was convinced that the stones he collected were human weapons and implements and that therefore man had been living in northern France when extinct animals were alive and when gravel deposits were being laid down on the sides of the valley—clear evidence that man's antiquity was infinitely greater than was then thought. Although he began to publish his discoveries in 1847 it was not until 1858 that their authenticity and importance was recognized. In that year Dr. Hugh Falconer visited Abbeville, examined the evidence and was convinced that Boucher de Perthes had opened a new chapter in the prehistory of man. In 1859 Sir John Evans, after visiting the gravel pits of the Somme valley, returned to England and discovered that the gravel pits of the lower valley of the Thames contained the same kind of stone implements as Boucher de Perthes had found in those of the lower valley of the Somme. Thus in 1860 a certain group of geologists was convinced that man's antiquity was so great that a new system of chronology would have to be devised to cover the human period.

A fourth line of enquiry, opened up by Charles Darwin, placed the problem of man's antiquity in a new setting. His *Origin of Species*, which was published at the end of 1859, clearly indicated to his readers of 1860, that man had arisen, as had all forms of life, by a gradual process of evolution from older types and thus prepared their minds for the discovery, in geological strata, of intermediate forms which would link man to a lower and older form of primate.

Evidence of Antiquity Afforded by Ancient Cemeteries.—Since 1860 all four lines of enquiry have been vigorously pursued and each has yielded evidence which compels us to place human beginnings at an ever-receding point of geological time. Excavation of ancient cemeteries and of former sites of human habitation, in Egypt, Mesopotamia and India have demonstrated that parts of these lands were densely populated before the middle of the fourth millennium B.C. and that their peoples inhabited cities, cultivated many kinds of crops, kept domesticated animals, prepared and used copper for many purposes and enjoyed the benefits of organized government. It is clear that to find the rise of man from a state of barbarism we must go far beyond the year 4004 B.C., the date which was assigned by Archbishop Usher to mark man's first appearance on earth.

Evidence of Antiquity Afforded by Caves.—Excavations carried out in the caves of France during the last four decades of the 19th century permitted archaeologists to establish a chronological system for the period which covers man's habitation of caves. The prehistoric periods thus established, with the names given to them and estimates of their duration are dealt with elsewhere. (ARCHAEOLOGY, *q.v.*) The evidence yielded by caves consists of fossil remains of man, fossil remains of animals, weapons and ornaments of stone and bone and ancient graves. In no cave in Europe, with perhaps the exception of Kent's Cavern (*q.v.*) in the south of England, is the human record carried beyond, if even up to, the middle of the Pleistocene (*q.v.*). European caves of Pleistocene date have yielded fossil remains of two species of mankind; in the upper deposits the remains are those of present-day or Neanthropic man; the deeper and older strata contain the skulls and bones of an extinct species, *Homo neanderthalensis* or *primigenius*. In size of brain both Neanthropic and Neanderthal man had reached the higher human scale long before the end of the cave period. The stone implements found in the deepest and oldest strata show that man was already a skilled workman when he took to cave life.

The Evidence of Antiquity Yielded by Valley Deposits.—During the whole of the Pleistocene period, deposits of gravel, sand and loam were being accumulated in the floor and on the sides of the river valleys of Europe. Such deposits or "terraces" thus offer us a means of tracing the changes which have overtaken man and beast during a whole geological epoch—one which witnessed several extreme changes in climate. Man's history in Europe has been traced throughout the Pleistocene period by the discovery of his fossil remains and of his stone weapons. The deeper or older valley deposits have yielded fossil remains of two types of men—the type found at Piltdown in Sussex, and that found at Mauer, near Heidelberg. Each represents a special *genus* of humanity and both differ from the *genus* to which all living races are assigned. Primitive though those early Pleistocene Europeans undoubtedly were we cannot withhold from them the right to be called human. Man was certainly in existence at the beginning of the Pleistocene period. Unfortunately we have no sure means of estimating the duration of this period in terms of years; estimates given by geologists vary from 250,000 years to 1,500,000 years, but the tendency is towards accepting the lower figure.

Shaped stones, showing evidence of human workmanship, have been found in Pleistocene deposits of all dates in France, Belgium and England. In the 100 ft. (30 metre) terrace of the Thames valley Messrs. R. A. Smith and H. Dewey (*Archaeologia*, 1912, vol. lxiv., p. 177) found deposits of three ages. The middle deposit contained implements of the *Chelles* type—pieces which show very skilful workmanship—and certainly do not represent man's earliest attempts at fabricating weapons. In the deeper and older deposit of this terrace, one laid down in early Pleistocene times, they also found implements—but of a much cruder kind, to which the elastic name *pre-Chellean* is given. In the corresponding terrace (30 metre) of the Somme valley M. V. Commont had previously found the same sequence of deposits and a corresponding succession of implements (*Les gisements paléolithiques d'Abbeville,* Lille, 1910). M. Rutot has traced a succession of implements throughout the Pleistocene deposits of Belgium. The most definite evidence of man's great antiquity in Europe comes from East Anglia. Its easternmost part is covered by deposits laid down at all phases of the Pleistocene; these accumulations cover others which were deposited in the latter half of the previous geological period—the Pliocene. The Cromerian formations mark the transition from the earlier to the later of these two periods. Even so long ago as 1863 Sir Charles Lyell expressed the opinion that "signs of man's existence" would be met with in the Cromer forest bed. In 1879 Lewis Abbott discovered flints in this bed showing unmistakable evidence of human workmanship (*Natural Science,* 1897, vol. x., p. 89). In more recent years—from 1909 onwards—J. Reid Moir (1879–1944) carried out a systematic search for traces of man in the deposits of East Anglia. He published accounts of flint implements found under the Cromer forest bed (*The Great Flint Implements of Cromer,* 1923); within the Red-Crag, a deposit of late Pliocene date (Upper Pliocene), and under the Red-Crag he has gathered many examples of early stone industries, thus carrying the evidence of man's existence—at least that of a tool-fabricating animal—far into the Pliocene period. (*Pre-Palaeolithic Man,* 1919; *Early Man in East Anglia,* 1927.) In older Pliocene deposits it becomes increasingly difficult to distinguish between stones shaped by natural forces and those fashioned by man's apprentice hand. Perhaps the earliest traces of man's handiwork are represented by the "eoliths" which Benjamin Harrison first discerned in the plateau gravels of Kent in 1885 and which were accepted by Sir Joseph Prestwich as showing definite signs of human workmanship. Reid Moir regarded the plateau "eoliths" as being at least mid-Pliocene date. Many authorities are inclined to accept shaped stones found in deposits of the geological period which precedes the Pliocene—the Miocene, as evidence of the existence of beings with brains sufficiently advanced to conceive the use of stone tools, and with hands sufficiently skilled to fashion them. By such evidence human antiquity is carried into a past which must be measured by a million, perhaps millions, of years. All the evidence of this kind, which bears on the antiquity of man, has been fully discussed by Prof. W. J. Sollas (*Ancient Hunters,* 3rd ed., 1924; *see* also *Apes and Men,* by Harold Peake and H. J. Fleure, 1927; *A Text-book of European Archaeology,* vol. i., Palaeolithic Period, by R. A. S. Macalister, 1921).

Galley Hill Man and the Antiquity of Man of the Modern Type.—In 1888 there was found in the middle or Chellean deposit of the 100 ft. terrace of the Thames valley a human skeleton amidst circumstances which led highly skilled geologists to infer that it had been naturally entombed when the terrace was being laid down. The site of discovery was near the Schoolhouse of Galley Hill and hence the skeleton became known by that name. If the skeleton was as old as the deposit in which it lay then men of the modern type had a great antiquity, for in no important respect did Galley Hill man differ from modern man. Discoveries of a similar import were made in terrace deposits at Clichy, Paris, in 1868. The evidence which has accumulated since these skeletons were unearthed make it increasingly difficult to accept the geological age attributed to them. The most reliable evidence now at our disposal leads us to believe that Neanthropic or modern man made his first appearance in Europe late in the Pleistocene period. Until we trace him to the part of the earth from whence he came and discover the transitional stages of his evolution in situ, we cannot frame any precise estimate of the antiquity of our own type. Such discoveries of fossil man as have been made lead us to infer that early Pleistocene times, so far as concerns our direct ancestry, was a period of rapid evolutionary change; it was then that our brain underwent its latest unfolding and the grosser marks of the ape were shed from our frames. When we consider the very diverse forms into which Neanthropic man is now divided—Australoid, Negroid, Mongoloid and Caucasoid—it is clear we must postulate a considerable period for the differentiation of a common ancestral stock into modern races—one which must cover the whole of the Pleistocene period at least. The faculty of speech must be of ancient origin—or how otherwise can we explain the extraordinary diversity and number of languages—extinct and living? The conquests which man has won over nature also bespeak a long past for him.

Difficulties Which Surround the Problem of Man's Antiquity.—Are we justified in giving the name of man to the beings which shaped the crude stone tools found in deposits of the Pliocene period? At what evolutionary point are we to say that the Rubicon which separates ape from man has been passed? Until we have fixed such a point we cannot discuss the antiquity of man with any measure of precision. Let us take a concrete instance. Are we to regard Pithecanthropus as man or as ape? The answer is that he was human because of the following reasons. In point of size and conformation, his brain attained almost the lowest limit of modern or Neanthropic man; his posture and mode of progression were human; his hands and arms were freed from locomotion; his teeth fall within range of human variation. Pithecanthropus represents one of the dawn forms of humanity, and with his discovery it became possible to affirm that man's antiquity could be carried back with certainty to the close of the Pliocene period. It is not unlikely that higher forms than Pithecanthropus were evolved before the end of the Pliocene period; the stage reached by Piltdown man early in the Pleistocene period supports such an inference. A consideration of all the evidence leads us to expect that the fossil remains of emerging primitive man have to be sought for in strata of the Pliocene period, and those of emerging Neanthropic man in deposits of the Pleistocene.

Indirect Evidence of Man's Antiquity.—The evidence so far considered has had a direct and positive bearing on man's antiquity; by the discovery of fossil remains and stone implements man has been traced through the Pleistocene into the Pliocene period of the earth's history. We have now to consider a line of evidence which has an indirect but very important bearing on the date of man's origin. Students of modern culture are well aware that a certain stage of knowledge has to be reached before a particular invention becomes possible. The invention of the aeroplane early in the 20th century was conditioned by the evolution of the internal combustion engine in the latter part of the 19th century; that, in turn, only became possible when a host of discoveries had been made during the length of the 19th century. The same line of evidence applies to living types. Man's body and brain became possible only after the order of primates had undergone many and profound evolutionary changes. The full anthropoid stage had to be attained before a human form became possible. We have direct evidence of the existence of great anthropoid apes in Europe and in Asia during the long Pliocene period; in the same continents we have traced them, by their fossil remains, far into the long geological period which preceded the Pliocene—the Miocene. The great anthropoidal type seems to have come into existence first during Miocene times, for we have found no trace of them as yet in the deposits of the still older period—the Oligocene. The meagre fossil remains of primates, so far discovered in strata of the Oligocene period indicate the existence of very generalized, small apes, one of which may well represent the ancestor of the gibbon—the smallest and most monkey-like of living anthropoids. It is useless to go beyond the Oligocene in search of a separate ancestry for mankind; not even the small anthropoid had come into existence in pre-Oligocene times. Thus a survey of our knowledge of the evolution of the higher primates—imperfect as that knowledge still is—leads us to the conclusion that the differentiation of the stem which culminated in modern man, cannot have commenced until the Miocene period was reached.

The oldest trace of a small anthropoid so far discovered comes from strata of the Fayum, Egypt, laid down in the earlier phase of the Oligocene period. The half of a lower jaw with its teeth is all that has been found of this small anthropoid which was described by Von Schlosser in 1911. He named it *Propliopith-*

ecus, and regarded it as an ancestral form of gibbon (W. K. Gregory, *The Evolution of the Human Dentition,* 1922).

Of Miocene and Pliocene great anthropoids at least 11 distinct species, representing several genera, are known by the discovery of fossil remains—all of them, unfortunately, being of a fragmentary nature. The type of anthropoid prevalent in Miocene times is best represented by the genus *Dryopithecus*—anthropoids representing the chimpanzee in point of size and posture and showing in their teeth and jaws characters which indicate that the ancestries of the gorilla, chimpanzee and man may have descended or ascended from a Dryopithecque form. So great and intimate are the resemblances between the teeth of primitive man and those of *Dryopithecus* that Dr. W. K. Gregory is convinced that it was this anthropoidal type which gave evolutionary birth to the human phylum. Great anthropoids of many kinds abounded in the Miocene jungles of northern India as we know from discoveries made by Dr. Guy Pilgrim (*Records of the Geological Survey of India,* 1915, vol. xlv., p. 1; *Memoirs of the Geological Survey of India,* 1927, vol. xiv., p. 1). One of these, *Sivapithecus,* known by fragments of jaws and teeth found in Siwalik deposits, is regarded as a possible ancestor of man by Dr. Pilgrim, but a definite decision cannot be made until more material is available for study.

So far no fossil trace of an anthropoidal type has been discovered in America; man had reached his Neanthropic stage of evolution before he entered the New World. In 1922 a much eroded tooth was found in beds of Pliocene date at Snake Creek quarry, Nebraska, which was attributed to an anthropoid ape—*Hesperopithecus,* was the name proposed for it—but later discoveries have shown that a mistake had been made and that the tooth belonged to a being of another order.

Early in 1925 Prof. Raymond Dart announced the discovery of the fossil skull of a young anthropoid ape, found in a limestone quarry at Taungs, on the eastern border of the Bechuanaland Protectorate and near the Transvaal frontier (*Nature,* 1925, vol. cxv., p. 195). The geological evidence goes to prove that this anthropoid which Prof. Dart named *Australopithecus,* cannot be older than the beginning of the Pleistocene—a date at which primitive types of humanity were already in existence. In size of brain, in shape of head, conformation of jaw and tooth, this very interesting and extinct form of anthropoid shows close relationships to the two surviving African anthropoids—the gorilla and chimpanzee—and, as Prof. Dart has rightly maintained, possessed certain features which may be called human.

Summary.—Thus, taking all lines of evidence into consideration, anatomical, biological, embryological and geological, we are led to the conclusion that man has been evolved from a lower form, and that human races, as we know them to-day, are the products of evolutionary processes. There remain great blanks in the line of evidence which links the origin of modern man to an extinct form of anthropoid ape. Between the highest kind of anthropoid and the lowest type of man, represented at present by Pithecanthropus, there still exists a great gap; the transitional forms which fill this gap still remain to be discovered. Yet the evidence as it stands, imperfect as it is, points to man's departure from an anthropoid status early in the Miocene period, certainly 1,000,000 years ago, perhaps more; that in the Miocene and Pliocene periods his body and limbs became adapted to a plantigrade posture; that his brain underwent expansion in the Pliocene, and particularly in the earlier part of the Pleistocene period, and that as the brain reached a full human status the coarser outward appearances of the ape were shed. Of the vital processes which brought about these changes we are as yet ignorant, but it is manifest that in his evolutionary progress man has tended to acquire and preserve in adult years states which appear at first as transient conditions in foetal or infantile stages. (Prof. L. Bolk, *Proc. Acad. of Science, Amsterdam,* 1927, vol. xxx., No. 2.)

It is becoming clear that the machinery of evolution is that which regulates development and growth, and in these matters knowledge is growing. Experimental embryologists have proved that one group of developing cells can and does regulate the growth and behaviour of a neighbouring group. The theory of hormones has thrown a flood of light on the machinery of evolution (Prof. Chas. R. Stockard, *Publications of Cornell University Medical College,* 1924, vol. 10; Keith, *Supplement to Nature,* Aug. 18, 1923). It has been proved that substances or hormones are carried by the circulation throughout the living body from a series of glands which include those of reproduction, the adrenal, the thyroid, the pituitary and pineal, and that the substances thus liberated in the body do control its vital reactions and its structural form.

MAN, ISLE OF (anc. *Mona*), a possession of the crown of England, in the Irish sea, 33 m. long by 12 broad in the broadest part. The area is 220.7 sq.mi. Oval in general form, its outline is very irregular, being indented with numerous bays and creeks. Its chief physical characteristic is the close juxtaposition of mountain, glen and sea, which has produced a great variety and beauty of scenery. The greater part of its surface is hilly. The hills (culminating point Snaefell 2,034 ft.), have a trend in the direction of the longer axis, but throw out radiating spurs, which frequently reach the coast line. The outline of the hills is smooth and rounded, the rocks, the Manx Slate series, being a group of slates, flags, grits and conglomerates which have suffered much from folding, crushing and overthrusting.

No satisfactory fossils have yet been found in these rocks, but they are regarded provisionally as of Upper Cambrian age. The series is penetrated by masses of granite at Dhoon, Foxdale, etc. Streams have frequently rent steep-walled gulleys in the hill-sides, and the westerly winds have caused them to be treeless, except in some of the lower slopes. Rising almost directly from the sea, they present a much more imposing appearance than many hills of greater altitude. On the south-west, they descend precipitously into the sea, and unite with the cliffs to produce most striking coast scenery. The whole coast from Peel round by the Calf-of-Man, to near Ramsey, is distinguished by rugged grandeur. The Calf-of-Man is a precipitous island reaching an altitude of 360 feet. From Ramsey round by the Point of Ayre to near Peel, extend low sandy cliffs, bordered by flat sandy shores.

The low-lying northern plain extends northward from the road between Ramsey and Ballough and is composed of Carboniferous (limestones, sandstones and conglomerates) and Triassic rocks entirely covered by glacial drift. This plain is relieved only by a low range of hills, the highest attaining an elevation of 270 feet. There is a small tract (8 sq.m.) of Carboniferous rocks in the neighbourhood of Castletown, which are of great economic importance forming the only source of lime and also the best building stone in the island. The drainage of the island radiates from around Snaefell. Narrow, winding glens studded with fir, sycamore, and mountain ash, with patches of gorse, heather and fern, afford a striking contrast to the bare mountain tops. Traces of an older system of drainage are noticeable, especially in the central depression between Douglas and Peel. There are no lakes.

The chief bays are, on the east coast, Ramsey, with an excellent anchorage, Laxey, Douglas, Derbyhaven, Castletown and Port St. Mary; and on the west coast Port Erin and Peel.

Climate.—The island is liable to heavy gales from the south-west but its winters are mild, and, influenced by the less changeable temperature of the sea, its summers cool. The mean annual temperature is 49° F, the temperature of the coldest month (January) being 41·5°, and the warmest (August) 58·5°, Fuchsias, hydrangeas, myrtles and escallonias grow luxuriantly in the open air. There are remarkable divergences in the amounts of rain in the different parts of the island, varying from 61 in. at Snaefell to 25 in. at the Calf-of-Man.

Fauna.—Like Ireland, the Isle of Man is exempt from snakes and toads. Frogs have been introduced and both the sand lizard and the common lizard are found. Badgers, moles, squirrels, and voles are absent and foxes are extinct. The red deer became extinct by the beginning of the 18th century. Hares are less plentiful than formerly and rabbits are not numerous. Snipe are fairly common, and there are a few partridges and grouse. Woodcock, wild geese, wild ducks, plover, widgeon, teal, heron, bittern, kingfisher and the Manx shearwater (*Puffinus puffinus*) visit the island, but do not breed there. The puffin (*Fratercula artica*) is still numerous on the Calf islet in the summer time. The peregrine falcon and the chough have become very scarce. The legal protection of sea birds (local act of 1867) led to an enormous increase in the number of gulls. A domestic cat, the Manx, remarkable for a stunted or absent tail, is peculiar to the island.

Flora.—Like the fauna, the flora is chiefly remarkable for its meagreness. It contains at most 450 species, as compared with 690 in Jersey. Alpine forms are absent. But what it lacks in variety it makes up in beauty and quantity. For the profusion of spring flowers, the Isle of Man is famous.

The People.—The centre of the island retains remnants of an early population, mainly short, dark and long-headed, while the coastal areas are said to show a broad-headed element, tall and well-built with dark features. The majority of the population, however, show marked Nordic characters—tall, fair, with light eyes, undoubtedly due to the large Scandinavian settlements reinforced by later immigrants both Norman and English. The population of the island (est. 1939) was 50,829, but visitors considerably augment this total.

History and Early Settlement.—The earliest evidences of man on the island are probably to be found in the numerous flint chipping floors along the coasts and elsewhere. Such floors are found near Ronaldsway, Ballakaighan, German and Port St. Mary. There are evidences of pile dwellings near the foot of Snaefell and Ballakaighan. The latter site has a dug-out boat. There, also, in 1940–42, a "rath" was excavated and found to represent a single circular house 90 ft. in diameter and covered with a turf roof. It is thought to date from about A.D. 500. Almost all the polished stone axes on the island are of foreign make, a fact that suggests that they were brought as articles of trade and were in use long after the period from which they date typologically. Prehistoric burial sites range from Neolithic to Scandinavian.

The position of the island in the western seas suggests that it was a station of no little importance in megalithic times and there are many old stone monuments still surviving, though many of the sites seem to have been occupied both before and after this time. Mull Hill circle with its cists in the south of the island is well known. Other stone monuments are found on Bradda mountain, Spanish head, the Braid, Marown, the Ballachrink cairn, Maughold and the famous King Orry's grave in Laxey. The latter seems to have maintained a tradition of sanctity down until the dark ages and possibly in the local cults through the middle ages. There are cup and ring markings at Bradan camp, Oatland circle and Grainvick bay. The Bronze Age discoveries are few, but there are traces of the Iron Age.

The history of the Isle of Man during the Celtic period is mainly associated with the spread of Celtic Christianity. During this period the island had a close association with Ireland as the early Christian *Keeills* or oratories show. Man is rich in sculptured crosses, and there is a round tower on Peel islet. If the supposed conquest of the Menavian islands—Man and Anglesey—by Edwin of Northumbria, in 616, did take place, the results were hardly permanent. It is, however, possible that in 684, when Ecfrid laid Ireland waste from Dublin to Drogheda, he temporarily occupied Man.

During the period of Scandinavian domination there are two main epochs—one before the conquest of Man by Godred Crovan in 1079, and the other after it. The earlier epoch is characterized by warfare and unsettled rule, the later is comparatively peaceful. Between about 800 and 815 the Vikings came to Man chiefly for plunder; between about 850 and 990, when they settled in it, the island fell under the rule of the Scandinavian kings of Dublin; and between 990 and 1079, it was subject to the powerful earls of Orkney. The conquerer Godred Crovan was evidently a remarkable man, and it seems probable that he is the person commemorated in Manx legend under the name of King Gorse or Orry. The islands which were under his rule were called the *Suðr-eyjar* (Sudreys or the south isles, in contradistinction to the *norðr-eyjar,* or the north isles, *i.e.*, the Orkneys and Shetlands, and they consisted of the Hebrides, and of all the smaller western islands of Scotland, with Man. At a later date his successors took the title of *Rex Manniae et Insularum.* Olaf (1113–1152), Godred's son, was a powerful monarch. His son, Godred, who for a short period ruled over Dublin also, as a result of a quarrel with Somerled, the ruler of Argyll, in 1156, lost the smaller islands off the coast of Argyll. An independent sovereignty was thus interposed between the two divisions of his kingdom.

Early in the 13th century, when Reginald of Man did homage to King John, we hear for the first time of English intervention in the affairs of Man, but it was into the hands of Scotland that the islands were ultimately to fall. During the whole of the Scandinavian period the isles were nominally under the suzerainty of the kings of Norway. The first to assert this authority was Harold Haarfager about 885, then came Magnus Barfod about 1100, both of whom conquered the isles. From the middle of the 12th century till 1217 the suzerainty had been of a very shadowy character. But after that date it became a reality and Norway consequently came into collision with the growing power of Scotland. Finally, in 1261, Alexander III. of Scotland sent envoys to Norway to negotiate for the cession of the isles, but their efforts led to no result. He therefore initiated hostilities which terminated in the complete defeat of the Norwegian fleet at Largs in 1263. Magnus, king of Man and the Isles, was compelled to surrender all the islands over which he had ruled, except Man, for which he did homage. Two years later Magnus died and in 1266 the king of Norway ceded the islands, including Man, to Scotland. But Scotland's rule over Man was not firmly established till 1275, when the Manx were defeated at Ronaldsway, near Castletown. In 1290 we find Edward I. of England in possession of Man, and till 1346, when the battle of Neville's Cross decided the long struggle between England and Scotland in England's favour, there followed a confused period when Man was sometimes under English and sometimes under Scottish rule.

About 1333 it had been granted by King Edward III. to William de Montacute, 1st earl of Salisbury, as his absolute possession. In 1392 his son sold the island "with the crowne" to Sir William Le Scroope. In 1399 Henry IV. caused Le Scroope to be beheaded. The island then came into the possession of the crown and was granted to Henry de Percy, earl of Northumberland, but, he having been attainted, Henry IV., in 1406, made a grant of it to Sir John Stanley, his heirs and assigns.

With the accession of the Stanleys to the throne there begins a better epoch in Manx history. Though the island's new rulers rarely visited its shores they placed it under responsible governors, who seem to have treated it with justice. Of the thirteen members of the family who ruled in Man, the second Sir John Stanley (1414–1432), James, the 7th earl (1627–1651), and the 10th earl of the same name (1702–1736) had the most important influence on it. The first curbed the power of the spiritual barons, introduced trial by jury and ordered the laws to be written.

The second, known as the Great Stanley, and his wife, Charlotte de la Tremoille, are probably the most striking figures in Manx history. In 1643 Charles I. ordered him to go to Man, where the people threatened to revolt. But his arrival, with English soldiers, soon put a stop to anything of this kind. He conciliated the people by his affability, brought in Englishmen to teach various handicrafts and tried to help the farmers by improving the breed of Manx horses, and, at the same time, he restricted the exactions of the Church. But the Manx people never had less liberty than under his rule. They were heavily taxed; troops were quartered upon them; and they had to accept short leases for holding their land. In 1649 Stanley received a summons from General Ireton to surrender the island, which he haughtily declined. In Aug. 1651 he went to England with 300 Manxmen among his troops, to join King Charles II., and took part in the decisive defeat of the Royalists at Worcester. He was captured, confined in Chester castle, tried by court martial and executed at Wigan.

Soon after his death the Manx Militia, under the command of William Christian, rose against the Countess and captured all the insular forts except Rushen and Peel. They were then joined by a parliamentary force under Colonel Duckenfield, to whom the Countess surrendered. Fairfax had been appointed "Lord of Man and the Isles" in September. The restoration of Stanley government (1660) caused as little friction and alteration as its temporary cessation had. William Christian was tried and executed while of the other persons implicated in the rebellion three only were excepted from the general amnesty, but by Order in Council they were pardoned, and the judges responsible for the sentence on Christian were punished. Stanley disputed the permanency of the tenants' holdings, which they had not at first regarded as being affected by the acceptance of leases. Almost open rebellion and the neglect of agriculture followed. In lieu of it the people turned to the fisheries and to contraband trade.

The agrarian question was not settled till 1704, when James, Charles's brother and successor, largely through the influence of Bishop Wilson, entered into a compact with his tenants, which secured the tenants in the possession of their estates in perpetuity on condition principally of a fixed rent. This act has been called the *Magna Carta* of the Manx people. As time went on, and the value of the estates increased, the rent payable to the lord became so small in proportion as to be almost nominal. James died in 1736 and was succeeded by James Murray, 2nd duke of Atholl. In 1764 he was succeeded by Charlotte, Baroness Strange, and her husband, John Murray, who, in right of his wife, became Lord of Man. About 1720 the contraband trade greatly increased. In 1726 it was, for a time, somewhat checked by parliament, but during the last ten years of the Atholl régime (1756–1765) it assumed such proportions that it became necessary to suppress it. The "Revesting Act," was passed in 1765, under which the sovereign and manorial rights and the customs revenues and certain other perquisites were purchased.

Up to the time of the Revestment the Tynwald court passed laws concerning the government of the island in all respects and had control over its finances, subject to the approval of the lord. After the Revestment, Imperial Parliament legislated with respect to customs, harbours and merchant shipping, and, in measures of a general character, it occasionally inserted clauses by which penalties in contravention of the acts of which they formed part might be enforced in the island. It also assumed the control of the customs duties. Such were the changes which modified the Constitution of the Isle of Man. Its ancient laws and tenures were not interfered with. The hereditary lords were far from being model rulers, but most of them had taken some personal share in its government, and had interested themselves in the well-being of its inhabitants. But now officials who regarded the island as a pestilent nest of smugglers, from which it was their duty to extract as much revenue as possible, were in charge. Between 1793 and 1826, the 4th Duke of Atholl, as governor, improved matters. After his departure the English officials resumed their sway, but were more considerate than before. Since smuggling had by that time almost disappeared, and the Manx revenue was producing a large surplus, the Isle of Man came to be regarded more favourably, and it obtained a less stringent customs tariff and an occasional dole toward erecting its much neglected public works. After 1866, when they obtained at least a nominal "home rule," the Manx people flourished greatly.

The island has complete financial autonomy and until 1918 the only form of taxation was customs and excise, though the inequity of this method of taxation led to the introduction of income tax in that year. However, this tax remained considerably below that of the mainland. After World War I, old age pensions and health insurance were introduced. During World War II the island was used as an alien internment camp.

Arms.—There has been much controversy about the origin of the arms of the island—the "three-legs" found on a beautiful pillar cross near Maughhold churchyard belonging to the latter part of the 14th century. It was probably originally a sun symbol and was brought from Sicily by the Vikings. The motto *quocumque jeceris stabit* is of comparatively recent origin.

Church.—The Christianity of Early Irish associations seems to have suffered beneath the Scandinavian power, though a Christianity with both Irish and Scandinavian affinities reasserts itself in the 11th century. The two most important events in the history of the mediaeval Manx Church were the formation of the diocese of Sodor (*q.v.*) and the foundation of the abbey of Rushen, a branch of the Cistercian abbey of Furness, in 1134. From this time till the Reformation there was an almost continuous struggle between the laity and the spiritual barons and monks, who had obtained great power and much property in the island. In 1458 the diocese was placed under York. The dissolution of the religious houses in Man was brought about by the arbitrary action of Henry VIII, and the Reformation was a very slow process. Successful missions by John Wesley and others resulted in the establishment of Nonconformity. In 1878 a Sodor and Man theological school was established for the training of candidates for holy orders. In 1880 four rural deaneries were established, and commissioners were constituted as trustees of endowments for Church purposes. In 1895 a cathedral chapter, with four canons, was constituted under the name of the "Dean and Chapter of Man," the bishop being the dean of the cathedral church. Several acts give Nonconformists (probably a majority) equal rights with Churchmen. There are a few Roman Catholics and Presbyterians. The Manx Church is a separate national Church governed by its own laws, which, however, must be approved by the insular legislature.

Education.—In 1872, when the insular legislature passed the Public Elementary Education act, the Manx state undertook direct responsibility for education. It became free in 1892, and a higher-grade school was established in Douglas in 1894. The public elementary schools are managed by the Isle of Man Education authority. They are examined by English inspectors and compelled to attain the same standard of efficiency as the English and Welsh schools. In 1907 an act establishing a system of secondary education was passed by the legislature. The Manx language (*see* CELTIC LANGUAGES) still lingers, but there is now no one who does not speak English.

Government.—This is vested in a lieutenant-governor, appointed by the Crown; in a council (the upper House); in the House of Keys (the lower House); and in the Tynwald court. The two Houses sit separately as legislative bodies, but they sit in the Tynwald court as distinct bodies with co-ordinate powers to transact executive business and to sign bills. The Tynwald court controls the revenue, and is subject to the supervision of the Treasury, and it appoints boards to manage the harbour, highways, education, local government, agriculture and lunatic and poor asylums. The Imperial Government, after intimating its intention to Tynwald, fixes the rates of the customs duties, but Tynwald can by resolution "impose, abolish or vary" the customs duties, subject to the approval of parliament. The approval of the sovereign of the United Kingdom and of the lieutenant-governor is essential to every legislative enactment.

Acts of the imperial parliament do not affect the island except it be specially named in them. The lieutenant-governor (the representative of the sovereign) presides in the Council, in the

Tynwald court. He is the supreme executive authority, and he has certain powers of veto. It has been the practice for him to act as chancellor of the exchequer.

The Council consists of the lieutenant-governor, lord-bishop of the diocese, clerk of the rolls, the two deemsters, attorney general, two members appointed by the lieutenant-governor and four members appointed by the House of Keys. The House of Keys (for origin of the name *see* KEY) is one of the most ancient legislative assemblies in the world. It consists of twenty-four members, elected by male and female voters, there being manhood and womanhood suffrage for all above 21 years of age. Each of four sheadings elects three members and the other two sheadings, two members each; the towns of Castletown, Peel and Ramsey one each, and Douglas five. The House sits for five years unless previously dissolved by the lieutenant-governor.

Law.—The High Court of Justice, of which the lieutenant-governor is president, contains three divisions: viz., the Chancery division, the Common Law division, and an Appeal court. The jurisdiction of the Chancery and Common Law division is in the main similar to that of the corresponding divisions in the English courts. Appellate jurisdiction is exercised by the Appeal court consisting of the High Court judge and an appeal judge, the latter being an eminent barrister approved by the crown, and acts only when required. The Common Law courts (southern division) are held at Douglas and Castletown alternately and for the northern division at Ramsey, once in three months. Actions are heard by a deemster and a special or common jury. The Chancery court sits once a fortnight at Douglas. Deemsters' courts for minor cases are held weekly, alternately at Douglas and Castletown and alternately at Ramsey and Peel. Criminal cases are heard by the magistrates or a high-bailiff and are sent on by them for trial by a deemster and a jury of six, which discharge the functions of the Grand Jury in England. The Court of General Gaol Delivery is the supreme criminal court and is presided over by the clerk of the rolls and the deemsters. The High Bailiffs (comparable to a stipendiary magistrate) hold weekly courts in the four towns and magistrates (J.P.s) also hold regular courts. There is a coroner in each of the six sheadings.

The Manx Bar is distinct from that of England. Its members, called "Advocates," combine the functions of barrister and solicitor. The laws relating to real property still retain much of their ancient peculiarity, but other branches of law have been made practically identical with English law. As regards real property the general tenure is a customary freehold devolving from each possesser to his next heir-at-law.

Chief Political Divisions and Towns.—The island is divided into six sheadings (from the Scandinavian "Ship-District") called Glenfaba, Middle, Rushen, Garff, Ayre and Michael, each of which has its officer, the coroner, whose functions are similar to those of a sheriff; and there are seventeen parishes. The chief towns are, Douglas, Ramsey, Peel, Castletown, Onchan, Port Erin, Port St. Mary, Laxey and Braddon.

Communications.—There is communication by steamers during the summer season with Liverpool, Fleetwood, Heysham, Glasgow, Greenock and Blackpool and with Liverpool, Greenock, Dublin and Belfast throughout the year. A daily mail was established in 1879. There is a regular air service to Liverpool. The internal communications are good. The Isle of Man Railway company has lines from Douglas to Castletown, Douglas to St. John's, where the line branches to Peel, Ramsey and Foxdale. In addition, the Manx Electric Railway company has a service from Douglas to Laxey and Ramsey, and from Laxey to the summit of Snaefell, while the Southern Electric railway connects Douglas to Port Soderick. The island is also well served by road motor transport companies.

Agriculture.—The best land is in the north and south. The farms are principally held on lease and small holdings have almost entirely disappeared. In 1940 the area under crops was 78,778 ac., or about 54% of the whole, and 39,751 ac. were rough grazings, the commons and uncultivated mountain lands being used for pasturage. Oats occupied about 91% of the area under corn crops (12,059 ac.). Turnips, an excellent crop, are largely exported; potatoes are grown on the dry sandy soil of the north. The pasturage is good. Some of the low-lying land is much in need of systematic drainage. The livestock now approximates very closely in quality to the stock in the north of England. Dairying is the most profitable department of agricultural industry. Apples, pears and wall fruit do not succeed very well, but the soil is favourable for strawberries, raspberries, gooseberries, currants and vegetables. Both agricultural and market-garden produce are quite insufficient to supply the demand in the summer.

Fishing.—The most numerous fish are herring, cod, mackerel, ling, haddock, plaice, sole, fluke, turbot and brett. The industry is, however, in a decaying condition, especially the herring fishery, which fails periodically. The amount of fish caught, except herring, is not sufficient to supply the demand in the summer. About 250 vessels, aggregating 4,260 tons, with crews numbering 4,250 are employed in this industry. A fish hatchery and marine biology station have been established at Port Erin.

Industries.—In proportion to its area the metalliferous wealth of the Isle of Man has been considerable, but little or no mining is done to-day. Two of its mines, Laxey and Foxdale, have produced lead and zinc for many years. Copper pyrites and haematite iron, and small amounts of the ores of nickel and antimony have been found. The mines are rented from the Crown as lord of the manor. Other economic products are clay, granite, limestone, sandstone, slate and salt. The principal manufactured articles are woollen cloth and blankets, hemp ropes and cotton, and herring nets. A few fishing vessels are built, and brewing is a prosperous industry. The most important occupation of the people is that of the provision for summer visitors, half a million of whom ordinarily come to the island annually. The chief exports are turnips, ropes, cotton nets and salt. The imports consist chiefly of timber and various foodstuffs.

BIBLIOGRAPHY.—For History and Law see *The Manx Society's publications. See* also *Bibliotheca Monensis* (*Manx Society*) with a list of MSS. and books up to 1876, and A. W. Moore's *History of the Isle of Man* has a list of MSS. and books up to 1900. Other more recent books include:—P. M. C. Kermode, *Manx Crosses* (1907); E. A. Jones, *The old Church plate of the Isle of Man* (1907); A. Herbert, *Isle of Man* (1926); J. J. Kneen, *Place names of the Isle of Man* (1927); G. W. Lamplugh, *Geology of the Isle of Man* (Geol. Surv. 1913); A. W. Moore, *Surnames and place names of the Isle of Man* (1906); P. G. Ralfe, *Birds of the Isle of Man* (1905); P. M. C. Kermode & W. A. Herdman, *Manks Antiquities* (1914); Hall Caine's novels have no doubt tended to popularize the island as well as a novel entitled *The Captain of the Parish,* by John Quine.

MANA is a word meaning "occult power" and occurs in many languages of Oceania. It is of uncertain origin, though probably introduced by immigrants from the West. While having also a wider and vaguer application, it stands for the "divine right" of the aristocratic class to wield authority and to enforce religious prohibitions; the sanction behind the *taboo* being the *mana* of the governing class, while conversely that *taboo* serves to keep the tribal *mana* intact, that is, ensures the good luck for all that waits on sound government. As a term of general anthropology *mana* may be treated as the positive, while *taboo* is the negative aspect, of the occult. In other words the occult as such is *taboo,* or "not to be lightly approached," because it is *mana,* or charged with wonder-working power.

Noa Contrasted.—In the Pacific region the word *noa* is used to signify the opposite kind of object or situation which is "common," that is, ordinary. The man who wields *mana* with impunity must abstain from all that is sordid. There are two worlds, a low-level and a high-level condition of spiritual activity, and a man cannot dwell in both at once. Thus by the very virtue of his profession the medicine man or the divine king must hold himself apart from those who by status or by choice are *noa,* laymen. The latter may live in brutish contentment; but to the end they lack enlightenment, participating in the highest mysteries at best from without. Every member of a primitive society is in some degree versed in experience of the occult, though for the most part some better qualified person is present to help him through it.

The Crises of Life.—The initiation of youths, puberty, marriage, a battle, a hunt may all lead to privations whereby one may acquire *mana*, "a strong heart," "uplift." Tradition has devised very efficient means of coping with crises, whether of organic origin or due to circumstance, by laying down a prescribed discipline which as it were enables the sick soul to go into retreat, so as by concentration on its inner resources to obtain an access of strength and comfort. (*See* PASSAGE RITES.)

Mana and Ritual.—Old-world religion is inarticulate, and *mana* stands for the power set in motion by ritual (*q.v.*), almost regardless of the intention behind the ritual; which among savages is always apprehended rather than comprehended. Thus when the ritual is of a public nature and guaranteed by custom and tradition, the *mana* therefrom resulting is felt by all to be a good *mana*. Such and such is known to be the ceremony proper to the occasion, and everyone is sure that the society will be the better for it. If, on the other hand, a private individual in overt and sinister fashion trafficks with the occult everyone is equally sure that a bad *mana* liable to afflict all and sundry will be unloosed. Sometimes, too, it is rather difficult to know which way a professional wonder-worker will use his power; for if he can heal he can also hurt, and it might occur to him to hurt if one did not make it worth his while to play the healer. Or, again, a man in authority will certainly use his *mana* to blast the public enemy, or even to suppress the unruly within his own society, and so far he will be acting legitimately.

Ambivalence.—*Mana*, then, is, as Freud would say, an "ambivalent" notion; it cuts both ways, implying alike divine and diabolic effects as possible manifestations of the awful power lurking in the occult. It is thus equally the root-idea of religion and of black magic, since both equally use rites that, duly performed by the expert, bring *mana* into play; and the procedure will electrify or electrocute according to the will of the operator. In a dim way the primitive mind perceives, if it hardly conceives, that intention or will has to be incorporated in the notion of *mana* before its moral value can be expressed. Thus not only from the Pacific but from many other parts of the world, Australia, for example, and North America, evidence is forthcoming of a tendency to split the notion into two, and distinguish a good and a bad kind of *mana;* as, for instance, *orenda* and *otgon* in the Huron dialect. For the Huron everything had its modicum of *orenda*, the deer, for instance, that might be clever enough to escape the hunter and thus outmatch his luck by greater luck of its own; but in this world of relative powers there were some that transcended man's so completely that in regard to them he must "lay down his *orenda*," which simply meant that he must "pray." Moreover, in such a warfare of competing agencies many might be expected to display *otgon*, the bad kind of *orenda*. If the primitive mind were clearer about the direction in which to turn for help in what is a pandaemonic rather than a pantheistic universe, the moralization of religion would correspondingly be brought about. As it is, the notion of the divine power would seem to be historically prior to that of the divine goodness, whether displayed as justice or as love.

Pervasiveness.—In particular, the very fluidity of *mana* makes it hard for religion to identify it with the good will of a personal god. It is all-pervasive, manifesting itself here, there and everywhere in the most momentary experiences of the occult. Or, even when as in the case of the living medicine-man or king it can be referred to a definite owner, it is apt to discharge itself through anything that has been in contact with him; so that, with so many transmitters in the shape of his bones or other belongings, secondary storage-cells of divine energy are distributed in all directions. *Mana* thus implies a religious experience that is primarily of the perceptual order, a frame of mind in which the sacred is simply "sensed." A conceptual attitude is not likely to come into being until the manifestation is individualized by being invested with a proper name. A god, or even the merest demon who can be propitiated by name, has a chance of acquiring a personality and a moral character.

The "Numinous."—It may be, however, that little more than the binding force of the bare name is involved in the ritual invocation, as when the Roman ejaculated a number of preposterous vocables corresponding to the parts of the door that he wished to construct *rite* "according to form." When *nomina* are thus *numina* and no more, the stage of *mana* has not been left behind; and indeed the word "numinous" has been suggested to cover the sacred in its more impersonal forms. It only remains to add that the *mana-taboo* formula, together with animatism, pre-animism, dynamism, numinism, or any other terms—the now discarded word fetishism is one of them—that have been used by theorists in the same connection, may or may not apply closely to the beliefs and institutions of some particular people, and may or may not be represented by appropriate words in a given language. Their value consists entirely in such help as they may afford in describing generally a phase of the religious life in which the need of coming to terms with the mysteries that beset life at once from within and without is satisfied mainly by ritual action, running ahead of articulate and reasoned doctrine, but none the less powerfully moving.

Fox, *The Threshold of the Pacific* (1924). (R. R. M.)

MANAAR, GULF OF, a portion of the Indian ocean lying between the coast of Madras and Ceylon. Its northern limit is the line of rocks and islands called Adam's Bridge. Its extreme width from Cape Comorin to Point de Galle is about 200 miles.

MANACOR, a town of Spain in the island of Majorca. Pop. (1940) 13,585 (mun., 19,060). Near by are the caves of Drach, with underground lakes, Els Hams and Artá, one of the largest and finest groups of stalactite caverns in western Europe.

MANADO, a residency of the island of Celebes (*q.v.*), Netherlands Indies, comprising the N.E. peninsula and the coast of the Gulf of Tomini; area 34,203 sq.mi.; pop. (1930) 1,138,655.

MANAGEMENT: *see* SCIENTIFIC MANAGEMENT.

MANAGUA, capital of Nicaragua, and of the department of Managua, the largest city in the Central American republic. Population (1940) 83,546. The city lies on the southern shore of Lake Managua (38 mi. long by 10 to 16 wide), the lesser of the two great lakes which are the chief physical characteristics of the country. It is on the Pacific R.R., 87 mi. from the port of Corinto. Its importance dates from 1855, when, as a result of the continuous rivalry between the older cities of León (*q.v.*) and Granada (*q.v.*), Managua was chosen as the capital of the country and the seat of an archbishop who would thus outrank the bishops of León and Granada. Two major catastrophes in Managua (the earthquake and fire of 1931 and the fire of 1936) necessitated the rebuilding of many parts of the city. The main business streets are paved; and many modern homes, business establishments and public buildings were built. A magnificent cathedral near the shores of Lake Managua is under construction (1943), while nearby is the attractive new capitol. On the southern outskirts of the city are the Presidential palace and the ultra-modern U. S. legation. The U. S. marines, who occupied the Campo del Marte barracks in Managua almost continuously since 1912, were withdrawn early in 1933 under one of the last acts of the Hoover administration.

MANAKIN, applied to the small birds which form the family *Pipridae*, a passerine family allied to the *Tyrannidae*. They are peculiar to the neotropical region, living in deep forests, associating in small bands, and keeping continually in motion, but feeding almost wholly on the large soft berries of the different kinds of *Melastoma*.

The manakins are nearly all birds of gay appearance, generally exhibiting rich tints, of blue, crimson, scarlet, orange or yellow, in combination with chestnut, deep black, black and white, or olive green; among their most obvious characteristics are their short bill and feeble feet, with the outer and middle toes united for a good part of their length. *P. leucilla*, one of the best known, has a wide distribution from the Isthmus of Panama to Guiana and the valley of the Amazon; but it is one of the most plainly coloured of the family, being black with a white head. They are often kept in captivity.

MANAOAG, a municipality in the north central part of the province of Pangasinan, Luzon, Philippine Islands, on the Angalacan river, 21 mi. N.E. of Lingayen. Pop. (1939) 29,030; 8 whites. Rice, tobacco, corn, sugar and various fruits and vegetables are cultivated. A statue of the Virgin Mary here is visited annually (in May) by thousands from Pangasinan and adjoining provinces. The Pangasinan and Ilocano languages are both spoken. Of the inhabitants aged 6 to 19 inclusive, 38.3% in 1939 attended school, and of those 10 years old and over 51.9% were literate.

MANASSAS, an incorporated town of Prince William county, Va., about 30 mi. W.S.W. of Washington, D.C. Pop. (1930) 1,215; and 1,302 in 1940 federal census. The town of Manassas, known also as Manassas Junction, is served by the Southern railway and by bus lines. North of the junction is Bull Run, a mountain stream which empties into the Occoquan, an arm of the Potomac. In this neighbourhood two important battles of the American Civil War, the first and second battles of Bull Run (*q.v.*), were fought on July 21, 1861 and on August 29, 1862 respectively; by Southern historians these battles are called the battles of Manassas.

MANASSEH, king of Judah, succeeded his father Hezekiah, and reigned about 692–638 B.C. That he maintained his position so long is a tribute to his statesmanship, and probably his kingdom prospered materially. We hear, however, very little about him, because his recognition of alien cults was a grave offense in the eyes of those who edited the historical writings. He is, indeed, held responsible for the ultimate ruin of the kingdom. He was very much under the influence of Assyria, and documents from his reign unearthed at Gezer disclose the presence of Assyrians in his realm, the use of their language and method of dating. No doubt his introduction of the worship of the host of heaven and other Assyrian cults was dictated by political rather than religious motives. He may well have been involved in the conspiracies of Shamash-shum-ukin, the rebellious brother of Assur-bani-pal. If so, the account of his deportation to Babylon, and subsequent return, 2 Chronicles xxxiii 11–13, may be historical, though the chronicler's religious interpretation of it is a fiction. Manasseh appears in inscriptions of Esarhaddon and Assur-bani-pal as an Assyrian vassal. (W. L. W.)

MANASSEH, a tribe of Israel, was descended, according to the traditions, from Manasseh, the elder of the two sons born to Joseph by his Egyptian wife Asenath, the younger being Ephraim. Numbers xxxii states that half the tribe received an allotment of territory in the conquered land of Gilead, east of Jordan. In Joshua iv 12 we read that this part of Manasseh joined with Reuben and Gad in support of the tribes who were fighting for a foothold on the west of the river. But other traditions tell of a Manasseh tribe settled west of the Jordan. In Joshua xvi–xviii we find Manasseh, regarded as forming with Ephraim a single tribe, settled in the hill country south of the fertile Esdraelon plain, and cut off from it by a strong chain of fortified Canaanite towns. Its western border is the Mediterranean; but the territory occupied by it cannot be defined with precision. Machir, the "son" of Manasseh, seems to represent sometimes that part of Manasseh dwelling in central Palestine, sometimes an element of that part of the tribe dwelling east of the Jordan, and sometimes the whole tribe. Machir appears in the ancient poem Judges v as taking part in the struggle against Sisera, and seems to have Zebulon on the one side, Ephraim and Benjamin on the other, as neighbours. From 1 Chronicles vii 14 it may be deduced that the tribe contained some Aramean elements. The various traditions are so confused that certainty in detail seems unattainable. To Manasseh belonged the deliverers Gideon and Jephthah. (W. L. W.)

MANASSES, CONSTANTINE, Byzantine chronicler, flourished in the 12th century during the reign of Manuel I (Comnenus) (1143–1180). He was the author of a *Chronicle* written in "political" verse, from the creation of the world to the end of the reign of Nicephorus Botaniates (1081), written by direction of Irene, the emperor's sister-in-law. The poetical romance of the *Loves of Aristander and Callithea,* also in "political" verse, is only known from the fragments preserved in the Ῥοδωνία (rose-garden) of Macarius Chrysocephalus (14th century). Manasses also wrote a short biography of Oppian, and some descriptive pieces on artistic and other subjects.

EDITIONS.—*Chronicle* in Bonn, *Corpus scriptorum hist. Byz.,* 1st ed. Bekker (1837) and in J. P. Migne, *Patrologia graeca,* cxxvii.; *Aristander and Callithea* in R. Hercher's *Scriptores erotici graeci,* ii. (1859); "Life of Oppian" in A. Westermann, *Vitarum scriptores graeci minores* (1845). A long didactic poem in "political" verse (edited by E. Miller in *Annuaire de l'assoc. pour l'encouragement des études grecques en France,* ix. 1875) is attributed to Manasses or one of his imitators.

MANASSES, PRAYER OF, an apocryphal book of the Old Testament. It purports to be the prayer of the Judaean king referred to in 2 Chron. xxiii 12, 13, 18, 19. Ewald held that the Greek was an actual translation of the lost Hebrew; but Ball more wisely takes it as a free rendering of a lost Haggadic narrative founded on the older document, from which the chronicler drew his information. This view he supports by showing that there was once a considerable literature in circulation regarding Manasseh's later history. On the other hand most scholars take the Prayer to have been written in Greek, *e.g.,* Fritzsche, Schürer and Ryssel (Kautzsch, *Apok. u. Pseud.* i 165–168).

This fine penitential prayer seems to have been modelled after the penitential psalms. It exhibits considerable unity of thought, and the style is, in the main, dignified and simple.

As regards the date, Fritzsche, Ball and Ryssel agree in assigning this psalm to the Maccabean period. Its eschatology and doctrine of "divine forgiveness" may point to an earlier date; on the other hand, there are some indications of a doctrinal character which point to post-Maccabean times.

The best short account of the book is given by Ball (*Speaker's Apocrypha,* ii 361–371); *see* also Ryle in Charles' *Apocrypha and Pseudepigrapha.* (R. H. CH.; W. O. E. O.)

MANATEE or MANATI, the name of the American representative of a small group of herbivorous aquatic mammals, constituting the order Sirenia (*q.v.*). Manatees are somewhat whale-like in shape, with a similar horizontally expanded tail-fin; but here the resemblance to the Cetacea ceases. The American manatee, *Trichechus manatus,* inhabits the rivers of Florida, Mexico, Central America and the West Indies and measures from 9 to 13 ft. in length. The body is somewhat fishlike, but depressed and ending posteriorly in a broad, shovel-like horizontal tail, with rounded edges. The head is of moderate size, oblong, with a blunt muzzle, and divided from the body by a slight constriction. The fore limbs are flattened oval paddles, placed rather low, with no external signs of division into fingers, save three diminutive flat nails near their extremities. No traces of hind limbs are discernible either externally or internally. The mouth is peculiar, the swollen upper lip being cleft in the middle line into two lobes, each of which is separately movable. The nostrils are two valve-like slits at the tip of the muzzle. The eyes are minute and nearly circular with wrinkled margins; external ears are wanting. The skin is dark grayish and finely wrinkled. There is a scanty covering of delicate hairs, and both lips are supplied with short, stiff bristles.

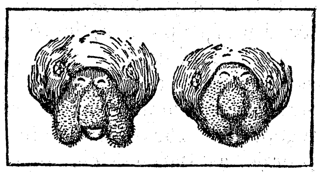
FROM VOGT AND SPECHT, "NATURAL HISTORY OF ANIMALS" (BLACKIE)

THE MANATEE (TRICHECHUS INUNGUIS), OF THE AMAZON

Manatees have a number—as many as 20 pairs in each jaw—of two-ridged teeth, of which, however, comparatively few are in use at once. They lack the large tusks of the male dugong (*q.v.*). In life the palate has a horny plate, with a similar one in the lower jaw.

Manatees inhabit bays, lagoons, estuaries and large rivers but not the open sea. As a rule they prefer shallow water, in which, when not feeding, they lie near the bottom. In deeper water they often float, with the body much arched, the rounded back close to the surface, and the head, limbs and tail hanging downward. They feed below water on aquatic plants. They are slow of movement and perfectly harmless but are persecuted for the sake of their oil, skin and flesh. From the shoulder-joint the flippers can be moved in all directions, and the elbow and wrist permit of free extension and flexion. In feeding, manatees push the food toward their mouths by means of the hands. The lateral pads of the upper lip have the power of transversely approaching toward and receding from one another simultaneously. The animal is thus enabled to introduce food placed before it without the assistance of the lower lip, the action recalling that of the mandibles of caterpillars.

The Amazonian manatee (*T. inunguis*) is smaller, not exceeding 8 ft. in length, with less well-developed lip-pads and without nails to the flippers. It ascends most of the tributaries of the Amazon until stopped by rapids. The West African *T. senegalensis* extends about 10° south and 16° north of the equator and ranges into the continent as far as Lake Tchad. From 8 to 10 ft. appears to be the normal length; the weight of one specimen was 590 lb. The colour is bluish-black, with a tinge of olive-green above and yellow below.



AFTER MURIE, IN THE "TRANSACTIONS OF THE ZOOLOGICAL SOCIETY"

AMERICAN MANATEE OR MANATI
Front view of head showing left, with the lobes of the upper lip divaricated; right, with the lips contracted

The manatee is said to be the origin of many legends of mermaids, while the Amazonian species is the object of superstitious reverence by the Indians.

MANATÍ, an important town of Puerto Rico. It is situated in the northern part of the island, about 3 mi. from the Atlantic ocean and about equidistant east and west; pop. (1940) 6,771, federal census. The pop. of the municipal district in 1940 was 29,366. Manatí is located in a beautiful valley drained by the Manatí river, from which it derives its name. The soil of the surrounding territory is very fertile and sugar-cane is extensively cultivated. Coffee is also raised in the uplands, and pineapples, grapefruit. oranges, bananas and other tropical fruits are also produced. The town is prosperous, has good schools, water-works, electric lights, a municipal market and a hospital, and has a number of small industries. (H. M. T.; X.)

MANAUS or **MANÁOS,** a city and port of Brazil, and capital of the state of Amazonas, on the left bank of the Rio Negro, 12 mi. above its junction with the Solimões, or Amazon, and 908 mi. (according to Wappäus) above the mouth of the latter, in lat. 3° 8′ 4″ S., long. 60° W. Pop. of city (1940) 67,866; *município* 109,302, including a large percentage of Indians, Negroes and mixed-bloods. Manaus stands on a slight eminence overlooking the river, 106 ft. above sea level, traversed by several *igarapés* (canoe paths) or side channels, and beautified by the luxuriant vegetation of the Amazon valley. The average annual temperature between 1911 and 1919 was 80.9°, the number of rainy days 153 and the total rainfall 78.4 in. Up to the beginning of the 20th century the only noteworthy public edifices were the church of N.S. da Conceição, the St. Sebastião asylum and, possibly, a Misericordia hospital; but a government building, a customhouse, a municipal hall, courts of justice, a marketplace and a handsome opera house were subsequently erected, and a modern water-supply system, electric light and electric tramways were provided. The *igarapés* are spanned by a number of bridges. Higher education is offered by a lyceum or high school, besides which there is a noteworthy school (bearing the name of Benjamin Constant) for poor orphan girls. Manaus has a famous botanical garden, a zoölogical garden, an interesting museum, a public library, an agricultural experiment station run by the national government, and a meteorological observatory. The port of Manaus, which is the commercial centre of the whole upper Amazon region, was nothing but a river anchorage before 1902. In that year a foreign corporation began improvements, which included a stone river-wall or quay, storehouses for merchandise and floating wharves or landing stages connected with the quay by floating bridges or roadways. The floating wharves and bridges are made necessary by the rise and fall of the river, the difference between the maximum and minimum levels being about 33 ft. The principal exports are nuts, cacao, rubber, dried fish, hides and piassava fibre. The markets of Manaus receive their supplies of beef from the national stock ranges on the upper Rio Branco, and it is from this region that hides and horns come for export. The port has direct steamship connections with New York and Liverpool by two companies, and Pan-American Airways (Panair do Brasil) maintains a regular service between Belém, Manaus and Pôrto Velho via the Amazon river.

The first European settlement on the site of Manaus was made in 1660, when a small fort was built there by Francisco da Motta Falcão, and was named São José de Rio Negro. The mission and village which followed were called Villa de Barra, or Barra do Rio Negro (the name "Barra" being derived from the "bar" in the current of the river, occasioned by the setback at its encounter with the Amazon). It succeeded Barcellos as the capital of the old *capitania* of Rio Negro in 1809, and became the capital of Amazonas when that province was created in 1850, its name being then changed to Manaus after the principal tribe of Indians living on the Rio Negro at the time of its discovery. In 1892 Manaus became the see of the new bishopric of Amazonas.

MANBHUM, a district of British India, in the Chota Nagpur division of Bihar province. Area, 4,131 sq.mi.; pop. (1941) 2,032,146. Manbhum district forms the first step of a gradual descent from the table-land of Chota Nagpur to the delta of lower Bengal. In the northern and eastern portions the country is open and consists of a series of rolling downs dotted here and there with isolated conical hills. In the western and southern tracts the country is more broken and the scenery much more picturesque. The principal hills are Dalma (3,407 ft.), the crowning peak of a range of the same name; Gangabari or Gajburu (2,220 ft.), the highest peak of the Baghmundi range; and Pachet (1,600 ft.), on which stands the old fort of the rajahs of Pachet. The hills are covered with dense jungle. The chief river is the Kasai, which flows through the district from northwest to southeast into Midnapore. A large proportion of the population is of aboriginal descent, the chief tribes being the Santals, the Bhumij and Bauris; the latter two have adopted Hindu customs and are fast becoming Hindus in religion.

Containing the Jharia coal field and part of the Raniganj coal field, which lies mainly in Bengal, Manbhum is the chief colliery district in Bihar. The growth of the industry is comparatively recent, for the output in 1894 was only 127,000 tons. In that year the railway was opened from Barakar to Dhanbad, and in the 20th century coal mining developed rapidly, especially after the Bengal-Nagpur railway was extended to the Jharia coal field in 1904. In 1938 the mines in this field had an output of 15,000,000 tons—over half the output of India. The Raniganj coal field (excluding the Bengal portion) had more than 100 coal fields and averaged more than 1,000,000 tons. The public health of the coal fields, and indeed of the whole Dhanbad subdivision and of a small area to the south, with a total area of 900 sq.mi. and a population of 500,000, is in charge of the mines board of health, which has done admirable work.

Besides the administrative headquarters, Purulia, pop. (1941) 30,445, which is at the junction of the narrow gauge line to Ranchi, the only town is Dhanbad (1941) 15,945, the headquarters of a subdivision and a railway settlement.

MANCE, SIR HENRY CHRISTOPHER (1840–1926), English scientist, was born in London. In 1863 he went to the East in the service of the Persian Gulf Telegraph department of the Indian government. He became superintendent in 1866 and engineer and electrician to the section in 1879. Mance invented the heliograph, an instrument which reflects the rays of the sun at a mirror on to a distant station; by this means signalling can be carried out. The Indian government would not adopt the heliograph, but it was used successfully by Lord Roberts during the second Afghan War. Mance also devised a method, known by his name, of detecting and localizing faults in cables, and a method of measuring the internal resistance of a battery. He recruited volunteers from the telegraph service and acted for a number of years as a captain in the Sind Volunteers. He was awarded the C.I.E. in 1883 and was knighted when he retired in 1885. After his retirement he maintained his interest in electricity. He was a member of scientific societies and acted on the board of directors of a number of electrical companies. He died at Oxford on April 21, 1926.

MANCHA, LA (Arabic, *Al Mansha,* "the dry land" or "wilderness"), in its widest sense denotes the bare and monotonous elevated plateau of central Spain that stretches between the mountains of Toledo and the western spurs of the hills of Cuenca, being bounded on the south by the Sierra Morena and on the north by the Alcarria region. It thus comprises portions of the modern provinces of Toledo, Albacete and Cuenca, and the greater part of Ciudad Real. Down to the 16th century the eastern portion was known as La Mancha de Montearagon or de Aragon, and the western simply as La Mancha; afterwards the north-eastern and south-western sections respectively were distinguished by the epithets *Alta* and *Baja* (upper and lower). La Mancha remains almost exactly as Cervantes described it. Many villages, such as El Toboso and Argamasilla de Alba, both near Alcázar de San Juan, are connected by tradition with episodes in *Don Quixote*.

MANCHE, a department of north-western France, made up chiefly of the Cotentin and the Avranchin districts of Normandy, and bounded west, north and north-east by the English Channel (Fr. *La Manche*), from which it derives its name, east by the department of Calvados, south-east by Orne, south by Mayenne and Ille-et-Vilaine. Pop. (1936) 438,539. Area, 2,476 sq. miles.

The department south of Coutances and St. Lô is composed of folded Palaeozoic rocks of the Armorican system, with east and west zones of granite, rising in the south-east to 1,200 feet. There are younger and softer deposits on the east. The west coast is an ancient structural line from north to south and is marked by cliffs up to 420 ft. alternating with bays, at the south end the great bay of Mont Saint Michel, with its famed abbey surmounting a rock 400 ft. high. Reefs off the coast make navigation perilous, the chief forming Les Iles Chausey. The north coast also seems to be a structural line and is marked by the great roadstead of Cherbourg. The greater part of the department may be described as a dissected plateau with deeply-cut valleys. The chief streams are the Vire running northwards past St. Lô and the Sienne running north-westward just south of Coutances.

The climate of Manche is mild and humid; myrtles flourish in the open air.

The characteristic industry of the department is horse and cattle rearing, carried on especially in eastern Cotentin; sheep are raised in the west. Wheat, buckwheat, barley and oats are cultivated. Manche is a foremost department for the production of cider-apples and pears; plums and figs are also largely grown. Butter, poultry and eggs are important sources of profit. Flourishing market-gardens are in the west. The department contains valuable granite quarries in the Cherbourg arrondissement and the Chausey islands; building and other stone is quarried.

There are metal industries, and the weaving of osiers is a local feature. Oyster-beds are on the coast (St. Vaast, etc.); and the maritime population, besides fishing in home and distant waters, collects seaweed for manure. Coutances is the seat of a bishopric of the province of Rouen. The north of the department forms part of the region of the III. (Rouen), and the south of the X. (Rennes) army corps and of the circumscriptions of the académie (educational division) and appeal-court of Caen. Cherbourg (*q.v.*), with its important port, arsenal and shipbuilding yards, is the chief centre of population. St. Lô (*q.v.*) is the capital; there are four arrondissements (St. Lô, Avranches, Cherbourg and Coutances), comprising 48 cantons and 647 communes. Valognes, Mortain, Coutances, Granville and Mont Saint-Michel are also important. At Lessay and St. Sauveur-le-Vicomte there are the remains of ancient Benedictine abbeys, and Torigni-sur-Vire and Tourlaville (close to Cherbourg) have interesting châteaux of the 16th century. Valognes, which in the 17th and 18th centuries was a provincial centre of culture, has a church remarkable for its dome, the only one of Gothic architecture in France.

MANCHESTER, EARLS AND DUKES OF. The Manchester title, in the English peerage, belongs to a branch of the family of Montagu (*q.v.*). The first earl was SIR HENRY MONTAGU (*c.* 1563–1642), grandson of Sir Edward Montagu, chief justice of the king's bench 1539–45. He was born at Boughton, Northamptonshire, was educated at Christ's college, Cambridge, and, having been called to the bar, was elected recorder of London in 1603, and in 1616 was made chief justice of the king's bench, in which office he passed sentence on Sir Walter Raleigh in 1618. In 1620 he was appointed lord high treasurer, being raised to the peerage as Baron Montagu of Kimbolton, Huntingdonshire, and Viscount Mandeville. He became president of the council in 1621, and Charles I. created him earl of Manchester[1] in 1626. In 1628 he became lord privy seal, and in 1635 a commissioner of the treasury. He was a judge of the Star Chamber, and one of the most trusted councillors of Charles I. In conjunction with Coventry, the lord keeper, he pronounced in favour of the legality of ship-money in 1634. He died on Nov. 7, 1642.

EDWARD MONTAGU, 2nd earl of Manchester (1602–71), eldest son of the 1st earl by his first wife, was educated at Sidney Sussex college, Cambridge. He was member of parliament for Huntingdonshire 1623–26, and in the latter year was raised to the peerage as Baron Montagu of Kimbolton, but was known generally by his courtesy title of Viscount Mandeville. At the beginning of the Long Parliament he was one of the recognized leaders of the popular party in the upper House, his name being joined with those of the five members of the House of Commons impeached by the king in 1642. At the outbreak of the Civil War, having succeeded his father in the earldom in November 1642, Manchester commanded a regiment in the army of the earl of Essex, and in August 1643 he was appointed major-general of the parliamentary forces in the eastern counties, with Cromwell as his second in command. Having become a member of the "committee of both kingdoms" in 1644, he was in supreme command at Marston Moor (July 1, 1644); but subsequently he disagreed with Cromwell, and in November 1644 he strongly expressed his disapproval of continuing the war (*see* CROMWELL, OLIVER). Cromwell brought the shortcomings of Manchester before parliament in 1644; and early in the following year Manchester resigned his command. He took a leading part in the frequent negotiations for an arrangement with Charles and was custodian with Lenthall of the great seal 1646–48. He opposed the trial of the king, and retired from public life during the Commonwealth; but after the Restoration, which he actively assisted, he was honoured by Charles II. In 1667 he was made a general. He died on May 5, 1671. Manchester was made a K.G. in 1661, and became F.R.S. in 1667.

See Lord Clarendon, *History of the Rebellion and Civil Wars in England* (7 vols., 1839) and *Life of Clarendon* (1827); S. R. Gardiner, *History of the Great Civil War, 1642–1649* (4 vols., 1886–91); *The Quarrel between Manchester and Cromwell,* Camden Soc., N.S. 12 (1875); P. Warwick, *Memoirs of the Reign of Charles I.* (1701).

CHARLES MONTAGU, 1st duke of Manchester (*c.* 1656–1722), son of Robert, 3rd earl of Manchester, was educated at Trinity college, Cambridge, and succeeded to his father's earldom in 1683. He fought under William at the Boyne, became a privy councillor in 1698, and held various important diplomatic posts between that date and 1714, when he received an appointment in the household of George I., by whom in 1719 he was created duke of Manchester. He died on Jan. 20, 1722.

GEORGE MONTAGU, 4th duke of Manchester (1737–88), was the son of Robert, the 3rd duke. He was a supporter of Lord Rockingham, and an active opponent in the House of Lords of Lord North's American policy. In the Rockingham ministry of 1782 Manchester became lord chamberlain. He died in September 1788.

WILLIAM MONTAGU, 5th duke of Manchester (1768–1843), second son of the preceding, was educated at Harrow, and having become a colonel in the army in 1794, was appointed governor of Jamaica in 1808. Here he remained, except for a visit to

[1]The title was derived, not from Manchester in Lancashire, but from Manchester (or Godmanchester) in Huntingdonshire, where the Montagu family estates were.

England (1811–13) till 1827, doing much to prepare the way for emancipation of the slaves. From 1827 to 1830 he was postmaster-general in the cabinet of the duke of Wellington.

MANCHESTER, city, county and parliamentary borough, Lancashire, England, 189 mi. N.W. of London, and 31 mi. E. of Liverpool. Pop. (est. 1938) 732,900. Area, 42.6 sq.mi. It stands for the most part on a level plain, the rising ground being chiefly on the north side. The rivers are the Irwell, the Medlock, the Irk and the Tib, the last being entirely overarched. The Irwell, which separates Manchester from Salford (*q.v.*), is crossed by a series of bridges and discharges itself into the Mersey, which is about 10 mi. distant. Most of the district is covered with superficial drift of sand, gravel and clay, beneath which is red sandstone (Trias) with Permian marls, sandstone and limestone, and carboniferous shales and clays of the contiguous coal fields. The city, as its thousands of brick-built houses show, has been for the most part dug out of its own clay fields.

There are four large railway stations:—Victoria (L.M.S.), Exchange (L.M.S. and G.W.)—these stations are contiguous—London Road (L.M.S. and L.N.E.), Central (L.M.S., L.N.E. and Cheshire lines), and many subsidiary stations for local traffic. Tramways, as well as railways, run from Manchester to all the large neighbouring towns. There is a municipal airport at Barton, 5 mi. west of the city, though that at Ringway, to the south, will be larger. A direct trunk road to Liverpool has been projected. As a matter of fact, the whole of southeast Lancashire and some portions of Cheshire are so linked that they form one great urban area. Manchester is also the centre of a network of canals, chief among them being the Manchester ship canal (*q.v.*). The making of this waterway was an event only less important than the opening of the Manchester and Liverpool railway in 1830. The township of Manchester, which forms the nucleus of the city, is comparatively small, and outlying hamlets having been added, its size has increased without regularity of plan. Manchester, probably more than other cities, has suffered by this method of growth and even to-day, after frequent widening, the streets are far too narrow. The congestion of traffic is very serious at times and an extensive regional planning scheme has been elaborated. There are 777 mi. of highways in the city. The housing problem has been felt in its acutest form in Manchester and has been attacked with great determination. Under the various housing acts after 1919 the corporation had, by 1943, erected 31,100 houses. It was also developing the Wythenshawe estate of 3,862 ac. as a planned town. This area was added to the city in 1931. The centre of the city is occupied by business premises; the factories and workshops are mainly on the outskirts. The opening of the Manchester ship canal caused the establishment of a large engineering and industrial centre around the docks, and another similar centre sprang up on the eastern side of the town upon a small coal field. The most important of the public buildings are in the centre and the south. The latter is also the most favoured residential district, and its extremity is semi-rural in character. Large masses of the population live beyond the city boundary and come to their daily work by train or tram. Manchester attracts citizens from every part of the globe; there are considerable numbers of German, Armenian and Jewish residents. The houses are for the most part brick, the public buildings of stone which is speedily blackened by the smoky atmosphere. Many of the warehouses are of considerable architectural merit, and terra cotta is increasingly used. The air is laden with black dust, and the rivers, in spite of all efforts, are in the central part of the city mere dirty ditches. The city owes its importance to the cotton industry favoured by the damp atmosphere, by soft water from the millstone grit with a heavy runoff and consequent large water power, also to the proximity of coal and to the chemical industries helped by the salt of Cheshire to the south.

Churches.—Manchester is the seat of an Anglican bishopric, and the chief ecclesiastical building is the cathedral, which, however, was built simply as a parish church and, although a fine specimen of the Perpendicular period, is not what might be expected as the cathedral of an important and wealthy diocese. In the course of restoration a piece of Saxon sculpture, the "Angel stone," came to light. The bulk of the building belongs to the latter part of the 15th century. The first warden was John Huntington, rector of Ashton, who built the choir. The building did not stand time or weather well, and by 1845 some portions of it were rapidly decaying. This led to its restoration by James P. Holden. By 1868 the tower was almost completely renovated. Further restorations and additions were carried out by J. S. Crowther, and by Basil Champneys. In the stalls there are some curious *miserere* carvings. There are two organs, one by Father Smith, and a modern one in an oak case designed by Sir G. Scott. The parish church was made collegiate in 1422, and when in 1847 the bishopric of Manchester was created, the warden and fellows became dean and canons and the parish church became the cathedral. The first bishop was James Prince Lee (d. 1869), followed by James Fraser (d. 1885), James Moorhouse (resigned 1903), Edmund Arbuthnott Knox (died 1937), Dr. William Temple (became archbishop of York, 1929), and Dr. F. Guy Warman. The church endowments are considerable and have been the subject of a special act of parliament, known as the Manchester Rectory Division act (1845), which has determined the salary of the dean and the four canons, and has provided funds for the incumbents of new churches. Hulme and Middleton are bishoprics suffragan.

Of the Roman Catholic churches, that of the Holy Name, which belongs to the Jesuits, is remarkable for its costly decoration. The Greek Church and most of the Nonconformist bodies have places of worship. There are Jewish synagogues as well as a meetinghouse of the Society of Friends.

Public Buildings.—The royal infirmary (founded 1752) occupies a new building on the south side of the city near the university. It was opened in 1909 by King Edward VII. The central site in Piccadilly, where the old infirmary stood, thus became available for other purposes, and the corporation in 1925 approved of plans for the erection of a new art gallery on the site. The present art gallery was founded as the royal institution, but in 1882 passed under the control of the city council. The most striking of the public buildings is the town hall, one of the largest municipal buildings in the country, but no longer adequate to the increasing business of the city council. It was completed in 1877 from designs by Alfred Waterhouse, who selected as the style of architecture a form of Gothic. The principal tower is 286 ft. high. The tower contains a peal of bells by Taylor of Loughborough, forming an almost perfect chromatic scale of 21 bells. The great hall is 100 ft. long and 50 ft. wide, and contains a magnificent organ built by Cavaillé-Coll of Paris. The 12 panels of this room are filled with paintings by Ford Madox Brown illustrating the history of the city. An extension to the town hall, designed by Vincent Harris, was opened by King George VI in 1938. It lies between the central library and the old town hall and faces Mount street. The new central library is circular, the exterior being in the Early English Renaissance style.

The royal exchange is a fine specimen of Italian architecture and was erected in 1869 and extended and reconstructed in 1914–21; the great meeting hall is one of the largest rooms in England. The exchange is seen at its best on market days (Tuesday and Friday). The assize courts were built in 1864 from designs by Waterhouse. The style is a mixture of Early English and Decorative, and a large amount of decorative art has been expended on the building. The branch Bank of England is a Doric building designed by C. R. Cockerell. There are separate town halls for the townships of Ardwick, Chorlton, Hulme, and Cheetham. The Free Trade hall, purchased by the corporation in 1921, is a fine structure in the Lombardo-Venetian style and its great hall will accommodate about 5,000 people. It is used for public meetings, concerts, etc., and was built by Edward Walters. The Athenaeum, designed by Barry, was founded by Richard Cobden and others for "the advancement and diffusion of knowledge." The institution has perhaps not followed exactly on the lines contemplated, but it has been very useful, having developed more along the lines of a club. The mechanics' institution developed into the municipal college of technology, which now forms a part of the university. The Portico is a good specimen of the older proprietary libraries and newsrooms. It dates from 1806. The Memorial hall (built 1662) is used for meetings, scientific, educational, musical and religious. The Whitworth Art gallery stands in the centre of a woodland park of about 25 ac., 2 mi. from the city centre to the south. The park was transferred to the corporation in 1904. John Rylands library (1899) is one of the finest specimens of modern Gothic architecture, but its magnificence is dwarfed by its enclosed position. The post office (1887), the police courts (1871) and the numerous fine buildings which house commercial firms should also be named. Many fine structures suffer from being hemmed in by streets which prevent the proportions from being seen to advantage. The town possesses many monuments and memorials, one of the most interesting being a bronze statue by Matthew Noble of Oliver Cromwell on a rough granite pedestal, which stands near the cathedral.

During World War II some fine buildings were damaged in air raids. The cathedral received a direct hit on the Derby chapel which, along with much of the fine 15th-century woodwork, was ruined, and Cross Street chapel, the city's oldest dissenting church, was wrecked. The noble Free Trade hall and the hall of the Royal exchange were completely burned out and Chetham's hospital was damaged by incendiary bombs. Among other buildings, the Victoria hotel and buildings were demolished, creating an island site in the city centre; two theatres and the assize court were considerably damaged and the university was injured.

Education.—There are many educational facilities. The oldest institution is the grammar school, founded in 1519 by Hugh Oldham, bishop of Exeter. The founder, a native of the town, forbade the appointment of any member of the religious orders as headmaster. The school is richly endowed and has 250 free scholars, while other pupils are received on payment of fees. It moved to new buildings at Rusholme in 1931. It accommodates over 1,200 boys. The oldest educational foundation is that of Humphrey Chetham, whose bluecoat school, founded in 1653, is housed in the building formerly occupied by the college of clergy. This also contains the public library founded by Chetham, and is the most interesting relic of antiquity in the city. The boys, who number about 100, dress in a 17th-century style. The educational charity of William Hulme (1631–91) is administered under a scheme drawn up in 1881. Its income is nearly £10,000 a year, and it supports a grammar school. The Nicholls hospital was founded in 1881 for the education of orphan boys. The Manchester Education committee has replaced the school boards for education supervision. The elementary education scheme embraces education in provided and non-provided schools; district central schools; secondary schools; junior technical, commercial, domestic and art schools; part-time day continuation schools, special schools and evening schools. In addition there is a large and well-equipped college of technology, attended by about 7,000 students, a school of art, teachers' day-training college, special schools for feeble-minded children, and a royal college of music. Schools for the deaf and dumb are situated at Old Trafford, in a building contiguous to the blind asylum, to which Thomas Henshaw left a bequest of £20,000. There is also an adult deaf and dumb institution.

The Victoria University of Manchester has developed from the college founded by John Owens, who in 1846 bequeathed nearly £100,000 to trustees for an institution in which should be taught "such branches of learning and science as were then or might be hereafter usually taught in English universities." It was opened in 1851 in a house which had formerly been the residence of Cobden. In 1872 a new college building was erected on the south side of the town from designs by Waterhouse. In 1880 a university charter was granted, excluding the faculties of theology and medicine, and providing for the incorporation of University college, Liverpool, and the College of Science, Leeds. The federal institution thus created lasted until 1903, when separate universities were formed in the different cities. Manchester university consists of one college—Owens college—in its greatly enlarged form. The buildings include the Whitworth hall (the gift of the legatees of Sir Joseph Whitworth), the Manchester museum and the Christie library, which is a building for the university library given by R. C. Christie who also bequeathed his own collection. Dr. Lee, the first bishop of Manchester, left his library to Owens college, and the legatees of Sir Joseph Whitworth bought and presented E. A. Freeman's books. The library has received other important special collections. In 1936–37 the greater portion of the university library was housed in a new building opened in 1937. The university has received many large gifts but is still urgently in need of help for extensions. A new physics block was opened in 1931, while in 1929 the public health laboratory was extended to house the department of pathology. In 1934 a medical students' hostel (Lister house) was opened and a new staff house was completed in 1937. The university students numbered 2,725 in 1937–38. Among chairs recently founded are those of ancient history (1929), geography (1930), physical chemistry (1933), dental surgery (1933), theoretical physics (1937) and experimental neurology (1937). The chair of social economics was restored in 1936. The Manchester museum, with important collections, is housed in an extension of the university buildings provided through a bequest of Jesse Haworth. Lord Morley, the late chancellor (d. 1923) of the university, bequeathed a large part of his library to Ashburne hall of residence for women students.

There are in Manchester a number of denominational colleges, Wesleyan, Unitarian, Baptist, etc., and many of the students preparing for the ministry receive their arts training at the university, the theological degrees of which are open to students irrespective of creed.

Libraries and Societies.—Manchester is well provided with libraries. The Chetham library contains some rare manuscripts. There is a large collection of matter relating to the history and archaeology of Lancashire and Cheshire. The collections of Broadsides formed by J. O. Halliwell Phillips, and the library of John Byrom, should also be named. The Manchester free libraries were founded by Sir John Potter in 1852. The new central library, opened in 1934 by King George V, comprises, in addition to a reference library containing over 300,000 volumes and a commercial library, the Henry Watson music library and the Thomas Greenwood library for librarians, both of which were presented, and the foreign library, which was purchased. The libraries service also provides 28 district libraries and 12 small branch libraries. The municipal libraries contain in the aggregate over 980,000 volumes. There are also libraries in connection with the Athenaeum, the school of technology, the Portico, the Literary and Philosophical society, the blind (in Braille type), the Law Library society and others. The most remarkable of the Manchester libraries is the John Rylands. This includes the famous Althorp collection of Earl Spencer, and many valuable manuscripts. It was built and richly endowed by Mrs. Rylands.

Manchester possesses numerous literary and scientific associations and there are many textile and other trade associations. The Hallé concerts were founded by Sir Charles Hallé in 1857 and the Hallé orchestra still plays weekly. Several daily papers are published, and various weekly and other periodicals. The journalism of Manchester takes high rank, the *Manchester Guardian* being its most important daily paper. The Manchester Academy of Fine Arts holds an annual exhibition in the city art gallery, whose permanent collection is mainly 19th-century English paintings and includes many works of Ford Madox Brown and the pre-Raphaelites. The sculpture includes casts of the Elgin marbles and a statue of Dr. John Dalton by Chantrey. There are six branch galleries. The Whitworth gallery (1888) contains a fine collection of Coptic garments and fabrics, besides water colours and engravings. Manchester is a favourite place for the holding of exhibitions, etc., both of a local and of a national character. It has a transmitting station of the British Broadcasting corporation.

Manufacture and Commerce.—Manchester is the most important centre for the cotton industry in the world (*see* COTTON AND THE COTTON INDUSTRY). Most of the spinning and the weaving mills, the dyeing, bleaching and finishing workshops are situated in the neighbouring towns and villages, and the city itself is principally the business and warehousing centre for the industry. The general decline in the cotton trade after World War I was offset to a certain extent by the growth of the artificial silk industry. Almost as important as the cotton industry is that of engineering, for which Manchester claims to be one of the largest centres in the world. The manufacture of heavy and light machinery, weaving and spinning plant, locomotives, stationary engines, motors and commercial vehicles, aeroplanes, electrical machinery of all kinds, etc., is carried on. Again of paramount importance to Manchester is the chemical and dye industry, so necessary to the textile trade. The manufacture of cotton goods and ready-made clothing, hats and caps, and knitted goods employs an enormous number of people. The rubber industry and the manufacture of paper, paper goods, cardboard boxes, bookbinding, etc., must also be mentioned. Manchester is one of the chief ports for the import of oil, timber, fruit and grain; and the milling industry is extending rapidly. The port of Manchester (of which the largest docks are in Salford) ranks as the sixth in the British Isles from the point of view of ocean trade. The water area of the docks is 120 ac., with $5\frac{5}{8}$ mi. of quayage. Ships drawing 28 ft. of water can reach Manchester, and steamers of 12,500 tons deadweight capacity regularly navigate the canal. The location of Manchester on the south Lancashire coal fields has had a marked influence upon its prosperity; but for this the rapid expansion of its industries would have been impossible. Manchester occupies a leading position in the English banking world, and the District bank, founded 1829, is the oldest joint-stock bank in the country. The business transacted by the Manchester bankers' clearing house exceeds that of any provincial centre. Likewise the city has an important stock exchange and holds a position next to that of London in the insurance world. There are also within the city branch offices of his majesty's stationery office and of the public trustee. Manchester is the headquarters of the Co-operative Wholesale society, and indeed of the co-operative movement generally.

Municipality.—Manchester received a municipal charter in 1838, the title of city in 1853, and became a county borough in 1889. The mayor received the title of lord mayor in 1893. The water supply is controlled by the corporation. In addition to wells sunk into the New Red Sandstone, there are reservoirs at Longendale (completed 1884), and extensive works at Lake Thirlmere at the foot of Helvellyn, 96 mi. from Manchester. From Thirlmere the water is brought in four pipe lines, and Manchester supplies in bulk many local authorities in the district *en route* as well as a large area in north Cheshire. In consequence the supply was found to be inadequate, so in 1919 powers were obtained and work commenced upon a scheme to obtain a further supply from Haweswater, northwest of Shap Fell. The work, which will involve 84 mi. of aqueducts, was still in progress in 1943. The corporation has also established works for the supply of hydraulic and electric power and lighting. The gas lighting of Manchester is also a municipal undertaking. It supplied 53 sq.mi. in 1943.

The city has a stipendary magistrate who, in conjunction with lay magistrates, tries cases of summary jurisdiction in the police courts. There are also quarter sessions presided over by a recorder. Separate sessions are held for the Salford hundred. Certain sittings of the court of chancery and of the divorce court are held in Manchester. In addition to the county court there is an ancient civil court known as the Salford hundred court of record. Assizes have been held since 1866.

With the exception of the parliament of 1654, Manchester had no representation until the Reform Bill of 1832, when it sent two representatives. In 1868 this was increased to three, but each voter had only two votes. In 1885 the city was divided into six divisions and in 1918 into ten divisions, each returning one member.

History.—Very little is known with certainty of the early history of Manchester. (*See* MANCUNIUM.) Almost the only point of certainty in its history before the Conquest is that it suffered greatly from the Danes, and that in 923 Edward sent his Mercian troops to repair and garrison it. In Domesday Book, Manchester, Salford, Rochdale and Radcliffe are the only places named in southeast Lancashire. The church of St. Mary and the church of St. Michael in Manchester are both named in Domesday, and some difficulty has arisen as to their identification. In 1301 Manchester received a charter from its baron, Thomas, Lord Grelle. The Grelles were succeeded by the De la Warrs, the last of whom became rector of the town and made considerable additions to the lands of the church. The manorial rights passed to Sir Reynold West, a descendant of Joan, sister of Lord Grelle, who was summoned to parliament as Baron De la Warr. The West family in 1579 sold the manorial rights to John Lacy, who, in 1596, resold them to Sir Nicholas Mosley, whose descendants enjoyed the emoluments derived from them until 1845, when they were purchased by the municipality of Manchester. The lord of the manor had the right to tax all articles brought for sale into the market, but although thus taxed, the inhabitants had, in the court leet, nearly all the powers now possessed by municipal corporations. This court had control over the watching and warding of the town, the regulation of the water supply, and the cleaning of the streets.

The town appears to have steadily increased in prosperity, and it early became an important seat of the textile manufactures. Fulling mills were at work in the district in the 13th century, and woollen manufactures were carried on in Ancoats at that period. The college of Manchester was dissolved in 1547, but was refounded in Mary's reign. Under her successor the town became the headquarters of the commission for establishing the Reformed religion. In 1641 Manchester people purchased linen yarn from the Irish, weaving it, and returning it for sale in a finished state. They also bought cotton wool from Smyrna to work into fustians and dimities. An act passed in the reign of Edward VI regulates the length of cottons called Manchester, Lancashire and Cheshire cottons. These were probably all woollen textures. It is thought that some of the Flemish weavers introduced into England by Queen Phillippa of Hainault were settled at Manchester. The Flemish weavers were in all probability reinforced by religious refugees from the Low Countries. Cotton, in the modern sense, is first mentioned about 1620.

In the civil wars, the town was besieged by the Royalists, but was successfully defended. The year 1694 witnessed the trial and acquittal of those concerned in the "Lancashire Plot." In the rising of 1715 the clergy ranged themselves to a large extent on the side of the Pretender; and in the rebellion of 1745, when the town was occupied by Prince Charles Edward Stuart, a regiment known afterward as the Manchester regiment was formed and placed under the command of Colonel Francis Townley. In the retreat the Manchester contingent was left to garrison Carlisle, and surrendered to the duke of Cumberland. The officers were taken to London, where they were tried for high treason and beheaded on Kennington common. The variations of political action in Manchester were marked. In the 16th century, although it produced both Roman Catholic and Protestant martyrs, it was in favour of the Reformed faith, and in the succeeding century it became a stronghold of Puritanism. Yet the successors of the Roundheads who defeated the army of Charles I were Jacobite in their sympathies, and by the latter half of the 18th century had become imbued with the aggressive form of patriotic sentiment known as anti-Jacobinism.

A change, however, was imminent. The distress caused by war and taxation led to bitter discontent, while the scandal of the pocket boroughs was very serious for Manchester, which was entirely without representation. The popular discontent was met by a policy of repression, culminating in the affair of Peterloo, which may be regarded as the starting point of the modern reform agitation. This was in 1819, when an immense crowd assembled at St. Peter's fields (now covered by the Free Trade hall and warehouses) to petition parliament for a redress of their grievances. The Riot act was read, but in such a manner as to be quite unheard by the mass of people; and drunken cavalry were then turned loose upon the unresisting mass of spectators. Several people were killed and many more injured, and the incident aroused the deepest indignation throughout the whole country. The Manchester politicians took an important part in the reform agitations; when the Act of 1832 was passed, the town sent as its representatives the Right Hon. C. P. Thomson, vice-president of the Board of Trade, and Mark Phillips. Only two other men had represented the town in parliament before: these were Charles Worsley, the man commanded by Cromwell to "remove that bauble," and R. Radcliffe, both of whom sat in the 1654 parliament. The agitation for the repeal of the corn laws had its headquarters at Manchester, and the success which attended it, not less than the active interest taken by the inhabitants in public questions, has made the city the home of other projects of reform. The Lancashire cotton famine, caused by the Civil War in the United States, produced much distress in the Manchester district, and led to a national movement to help the starving operatives. The more recent annals of Manchester are a record of industrial and commercial developments and of increase in educational opportunities of all kinds.

(W. E. A. A.; J. I. P.; X.)

MANCHESTER, a town of Hartford county, Connecticut, U.S.A., 9 mi. E. of Hartford; served by the New York, New Haven and Hartford railroad. Pop. (1940) 23,799. Manchester covers an area of 27.1 sq.mi. The silk mills established in 1836 by Ralph, Ward, Rush and Frank Cheney are still operated by their descendants. They were the first silk factories in the United States and are the only ones which carry through all the processes of transforming raw silk into finished fabrics. Other factories also produce rayons, velvets, coats, suits, machine tools, papers, soap products and parachutes. The first settlement within the present limits of Manchester was made in 1672, and the land was bought from the Indians in 1676. In 1823 the town was separated from East Hartford and incorporated.

MANCHESTER (popularly Manchester-by-the-Sea), a town of Essex county, Massachusetts, U.S.A., on Massachusetts bay, between Beverly and Gloucester, 25 mi. N.E. of Boston. It is served by the Boston and Maine railroad. The population was 2,472 in 1940, federal census. It is one of the most beautiful resorts on the Atlantic coast, with heavily wooded areas and sandy beaches alternating with rocky headlands, and was for some years a favourite summer residence of many foreign diplomats. Manchester was settled about 1630. It was set off from Salem and incorporated in 1645.

MANCHESTER, the largest city of New Hampshire, U.S.A., and one of the county seats of Hillsboro county; on the Merrimack river at the mouth of the Piscataquog, 55 mi. N.N.W. of Boston. It is on federal highway 3, has a municipal airport of 80 ac. which has been designated as an army air base, and is served by the Boston and Maine railroad and interurban motorbus lines. In 1930 the population was 76,834, and in 1940 by the federal census it was 77,685. The city occupies 33.96 sq.mi., on a plain 90 ft. above the river. Within its limits is Lake Massabesic (2,530 ac.), a beautiful resort and the source of the city's water supply. The public parks, covering 226 ac., provide facilities for both summer and winter sports. Just above the city great ledges across the path of the Merrimack cause a fall of 55 ft., from which power is developed for the large manufacturing plants lining both banks of the river. Important manufactures are shoes (valued at $22,000,000 annually), cigars (especially a widely known "two-for-a-quarter" grade) and brushes. The 144 manufacturing plants in the city make more than 100 different products, and had a total output in 1939 valued at $52,587,341. The public school system provides special opportunities for the industrial workers. Manchester is the seat of a Roman Catholic cathedral, four convents, St. Anselm's college (Roman Catholic; 1893), the state industrial school and several charitable institutions under religious auspices. The assessed valuation in 1940 was $86,445,329. A zoning and planning board was created in 1927.

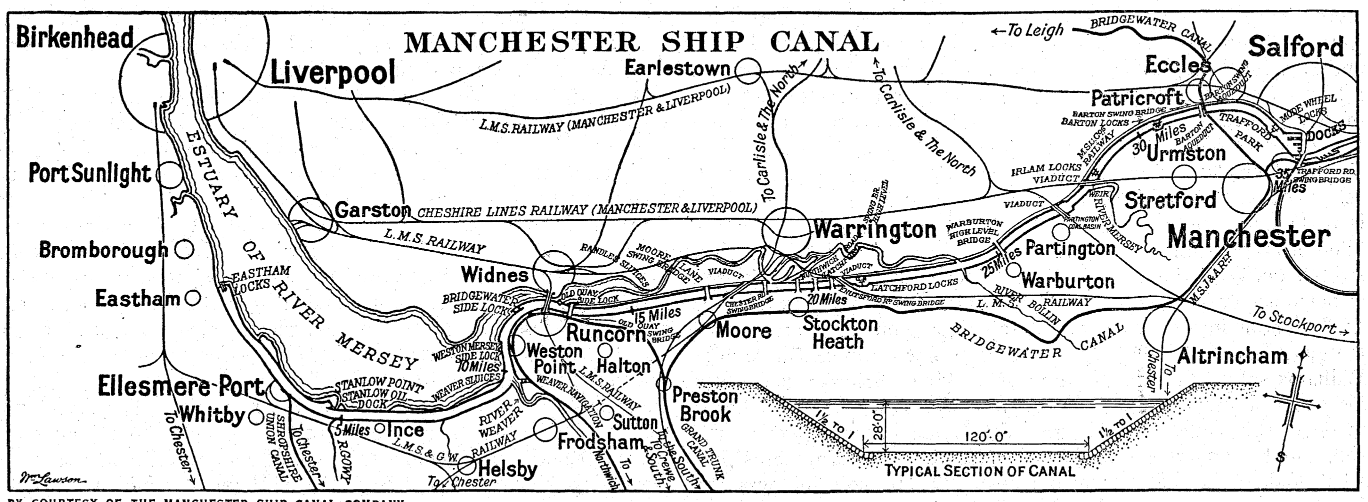
Amoskeag falls (or Namoskeag, "a place of much fish") was a favourite resort of the Penacook Indians, and tradition says that John Eliot preached to them there in the summer of 1851. The first white settlers (Scotch-Irish) came in 1722–23. Through its early years the settlement was known chiefly for its fisheries. Towards the end of the 18th century Judge Samuel Blodget saw the industrial possibilities in the falls and dreamed of duplicating here the great English textile centre. He planned and carried through the construction (1794–1807) of the first canal around the falls, which, together with the Middlesex canal in Massachusetts, gave a navigable waterway all the way to Boston; and he saw the establishment of the first cotton mills in 1805. In 1810 the name of Manchester was adopted to honour his memory, and the first mills bearing the name of Amoskeag were opened. In 1840 the population of the town was 3,235; in 1846 it was incorporated as a city, and by 1860 it had a population of 20,107. Manchester was the home of Gen. John Stark, and the house in which he lived from 1758 to 1765 still stands.

MANCHESTER SHIP CANAL, an important artificial waterway affording passage for ocean-going vessels between the inland city of Manchester, England, and the Mersey estuary opening into the Irish sea. This great undertaking plays so important a part in the commercial life of Lancashire that there is sometimes difficulty in remembering how new it is. Its making began on Nov. 11, 1887, and on May 21, 1894, Queen Victoria attended its formal opening.

Manchester lies on a plain whose many streams provided the power which made possible a prosperous cotton industry. The city became the reservoir into which the product of the hills surrounding the plain naturally flowed, and its task of disseminating that product was easy enough, as it could be carried on by pack horses and mules so long as commerce was content with the leisurely ways that preceded the Industrial Revolution. Even before that great upheaval Manchester was looking towards the sea. Barge traffic had long been in existence on the river Mersey between Liverpool and Warrington; and a body of men called the Mersey and Irwell Navigation Proprietors was empowered by an act of parliament dated 1720 to carry this process further, and to make the Mersey and its tributary the Irwell navigable from Warrington into the heart of Manchester. A second contact with the sea was given to Manchester by the third duke of Bridgewater, who, working with his famous self-taught engineer James Brindley, had made a canal to carry coal from his estate at Worsley into Manchester. Brindley, overcoming difficulties which were new to modern engineering, made the Bridgewater canal from Manchester to Runcorn, at the head of the Mersey estuary.

Thus in the 18th century Manchester had two ways open to the sea: a canal and a navigable river. Barges were used on both, and they could not carry much more than 50 tons at a time. The beginning of the 19th century saw a third way open: the Manchester-Liverpool railway. But none of these things was of much use to Manchester. Richard Arkwright's spinning jenny and Samuel Crompton's spinning mule had revolutionised the manufacture of cotton goods. The leisurely days were gone for ever. Manchester, if she was to survive, must become a port.

The position was grave when the second half of the 19th century had set in. A plague of empty houses came upon Manchester. Everywhere the fatal sign might be seen: another family gone, following the factories to the coast. In 1881 there were 18,632 empty houses in the town. In the Ancoats district alone, ten months before the canal opened, establishments employing 12,650 workers had been closed, and there were whole streets uninhabited. Fifty houses, with a rental of £14,000 per annum, were to let in the centre of the city. Nor could anyone wonder at this state of things. Trade could not prosper with Liverpool as its main outlet, for the railway charges to Liverpool, added to the Liverpool dock dues, were ruinous. A ton of goods could be carried in 1881 from Manchester to Calcutta for 19s 3d, and 12s 6d of this had been charged before the goods left Liverpool. Liverpool dock dues were so heavy that Oldham spinners could buy cotton in Bremen or Havre, pay shipping freights to Hull and railway charges from Hull to Oldham, and still save a farthing a pound on the price they would have paid for the same cotton at Liverpool. On June 27, 1882 a group of men met at dinner in the house of Daniel Adamson at Didsbury, and after dinner they and others talked about how the situation might be met. They fell



BY COURTESY OF THE MANCHESTER SHIP CANAL COMPANY

MAP OF THE MANCHESTER SHIP CANAL, 35½ MILES LONG

back on the proposal of not a barge canal but a ship canal; in a word, the transforming of an inland town into a port. That dinner-party was the turning-point in Manchester's fortunes.

The Parliamentary Fight.—On Aug. 6, 1885 the Manchester Canal bill received the royal assent. The intervening three years had witnessed a stiffer fight, it is commonly admitted, than had ever before been put up for a private bill. It was the fight mainly of the middle classes of the community for something they passionately believed in. Against them was every sort of interest: the Liverpool docks board and corporation and chamber of commerce, many Liverpool trading companies, landowners, railway companies, the ridicule, indifference or hostility of the press of the country with few exceptions. In Manchester itself only one newspaper—the *City News*—spoke up consistently for the ship canal; and while Adamson and his friends were holding meetings of workmen and small tradespeople, the rich men, for the most part, stood aside. £100,000 was asked for, and £62,000 came in sums of less than £10. There were three bills. The one of 1883 was thrown out by the Lords; the one of 1884 by the Commons; the one of 1885 was passed. The sum spent by the promoters and opponents of these three bills was estimated at £350,000. The passing of the bill caused widespread popular rejoicing. Adamson, returning from London, was met by workmen who presented him with an address, took the horses from his carriage, and dragged him home.

Daniel Adamson died in Jan. 1890 while the canal was being made. Though he was wrong in assuming that so large a sum as £8,000,000 could come from the pounds and shillings of Lancashire workers, he was right in his conviction that the feeling behind the scheme, and the hope of the scheme were democratic. The Co-operative Wholesale Society took £20,000 worth of shares, and a list published on Dec. 1, 1887 showed that of the 39,000 shareholders 36,300 were middle-class or working people. But the bulk of the capital came from the other 2,700.

Making the Canal.—On July 4, 1887 the Bridgewater Navigation Company were paid by one cheque £1,710,000 for their property. On Nov. 4 Lord Egerton cut the first sod at Eastham and the work at once began. Like the fight for the parliamentary bill, like the fight for the capital, the making of the canal was attended with every sort of disaster and delay. The engineer was Edward Leader Williams, who was knighted on the completion of the work, and the contractor was T. A. Walker, who had carried through the Severn tunnel contract. Walker died on Nov. 25, 1889, and there followed an unfortunate period of controversy between his executors and the canal directors, complicated by labour troubles and disputes, which cheered the enemies of the canal and made it clear that the work would not be finished within the contracted time. Late in 1890 the directors determined to settle with Walker's executors and to take the completion of the contract into their own hands. No sooner had they done this than floods of exceptional violence fell upon the work. Already in Jan. 1890 the work of months had been destroyed in a single night; and in November of the same year even worse befell. Storms were added to floods; six miles of the excavated bed were in parts 40ft. below water. Steam navvies, locomotives, workmen's tools and plant and material of all sorts were submerged. In places the tops of cranes could be seen a few inches above water. Bridges and temporary erections were overthrown and the slopes of the canal were washed away in long stretches. Towards the end of the month the weather repeated its blow. In Jan. 1891 ice and snow followed the floods. The Bridgewater canal—the only profit-making asset the directors possessed—was frozen and out of action; and it was realised that the work could not proceed unless more capital was raised. Once more the democratic urge behind the movement was apparent. There were ward meetings all over Manchester and district and the cry "Finish the canal" was everywhere. It was finished. The corporation of Manchester, which had already in one year applied the proceeds of a 2d. rate to the parliamentary fight, came in with £5,000,000; and from that moment the success of the canal was in no doubt. That is why the corporation of Manchester is represented on the ship canal directors' board. It has eleven directors, and the shareholders have ten.

The Canal Described.—The canal is $35\frac{1}{2}$ miles long. From Eastham to Runcorn it is near or through the Mersey estuary for $13\frac{3}{4}$m. Thence to Latchford, near Warrington, it is for $8\frac{1}{4}$m. inland. Both these sections have the same water level, which is raised by high tides. At Latchford the tidal action is stopped by locks, and from here to Manchester, $14\frac{1}{2}$m., the canal is fed by the Mersey and Irwell. At Eastham there are three entrance locks which maintain the water level in the canal nearly to mean high-water level (14ft. 2in. above the Liverpool datum). When the tide rises above that height the lock gates are opened and the tide flows up to Latchford, giving on high spring tides about 7ft. more of water. On the ebb this water is returned through sluices. The canal throughout has a minimum depth of 28ft. In 1927 the stretch from Eastham locks as far as the river Gowy was deepened to 30ft., and the approach channel to Eastham was also deepened. The minimum width at bottom is 120ft., so that large vessels may pass each other at any point. At various places under the canal it was necessary to lay cast iron siphon pipes to carry off land drainage which was at a lower level than the canal. The largest of these, 400ft. long and 12ft. in diameter, allow the tidal and fresh water of the Gowy to pass under the canal at Stanlow point, between Eastham and Ellesmere port. The whole length of the canal passes through the new red sandstone formation with overlying beds of gravel, clay, sand and silt, which in many places made it necessary to build retaining walls of stone and brick.

After the almost straight stretch from Runcorn to Latchford, the canal goes through the valleys of the Mersey and Irwell. Both these rivers wind a great deal, and therefore the line of the canal, kept as straight as possible, had to cross and recross the river channels. When these cuttings were finished, the end dams were removed, the Mersey and Irwell flowed into the new channel and became the upper portion of the ship canal. This has proved a blessing to districts which had come to regard periodical floods of great severity as something that could not be cured. There is a rise of 60ft. 6in. from the tidal part of the canal to the Manchester docks level, and the water is carried up about 15ft. at each set of locks: at Latchford, Irlam, Barton and Mode Wheel, which is at the entrance to the docks. The locks are in duplicate, and are filled or emptied in five minutes. For the greater part of the $3\frac{1}{2}$m. stretch between Barton and Mode Wheel the canal is widened at bottom from its normal 120ft. to 170ft. so that wharves may be used without impeding traffic. In solving a problem in an original manner, James Brindley left another problem which Sir Leader Williams solved in a manner no less striking. Brindley had taken his canal across the Irwell in the first navigable aqueduct to be made in this country; and when the Irwell became part of the ship canal Williams had to face the question of taking ships past what looked like an immovable obstacle. His solution was the Barton swing aqueduct—like Brindley's aqueduct, the first thing of its kind in the country. The swing aqueduct moves on a pivot. When it is closed, traffic on the Bridgewater canal goes on as usual; when it is open, pointing up and down the ship canal, vessels may pass on either side of it. The water at these times is retained in the swung portion by iron doors, and similar doors seal the ends of the Bridgewater canal. So that as the Gowy flows under the ship canal, the Bridgewater canal flows over it; and five lines of railway were taken across it, too. The viaducts give a clear headway of 75ft. at ordinary water level. Nine main roads cross the canal on swing bridges, which vary in width from 20 to 36 feet. The total amount of excavation was 54 million cu.yd., nearly one-fourth of this being sandstone rock. About 17,000 men were employed, and the plant used cost nearly £1,000,000.

In the port of Manchester there are eight docks with a water space of 120 acres, and provision has been made for a ninth which will be larger than any of these. The largest in 1928 was 2,700ft. long and 250ft. wide. The Manchester Dry Docks Company had three graving docks, and there were two pontoon dry docks with a lifting capacity of 2,000 tons. Great attention was paid at the beginning, and is still paid, to arranging docks, cranes, railways, transit sheds, grain elevators, warehouses, etc., in such relation to one another that goods can be quickly handled. Ships are unloaded straight into sheds or trains or lorries with one handling, and every quay is directly linked up by rail with the railway systems of Britain. The company's own railways cover 161m. of single track, and another 31m. are leased or worked. There are 60 locomotives and 2,438 railway wagons; and the cranes number 248: 53 hydraulic, 53 steam and 142 electric, with a radius of from 16 to 40ft. They are capable of lifting from one to seven tons up to a height of from 13 to 80ft. above rail level. There are also six electric grab cranes of 5 tons capacity each, a 30 ton steam crane, a pontoon sheers capable of dealing with weights up to 250 tons with a lift of 21ft., a coaling crane which can manipulate 12-ton waggons for cargo or bunkers, and a floating crane that can handle 60 tons. Each of the two grain elevators can store 40,000 tons (1,500,000 bushels). The warehouses, transit sheds and cold storage houses are of varying size, growing with the growth of the port. The two latest and greatest at No. 9 dock are of five floors each, 450ft. long and 110ft. wide. They cost something like £500,000. The Trafford wharf is 2,500ft. long, and near it is the lairage where cattle from Ireland and from across the Atlantic are disembarked. There is accommodation for 1,850 cattle and 1,500 sheep, and when reserve land is used these numbers will be doubled. The chief subsidiary ports along the canal are the Stanlow oil dock, near the entrance on the Mersey, where petroleum spirit and other oils of low flash point are dealt with; Runcorn where there are six docks and a water space of 15 acres; the Partington coaling basin, with 20 acres of quays and $6\frac{1}{2}$acres of water; and Ellesmere Port, which has a grain warehouse of 20,000 tons capacity and a most modern coaling plant. The total area of the dock estate is $406\frac{1}{2}$ acres. The quays are a little more than $5\frac{1}{2}$m. in length, and the quay and storage areas cover $286\frac{1}{2}$ acres. The great industrial area of Trafford Park adjoins the dock estate and is directly linked up with it, forming, as it were, one huge workshop.

The Effect on Manchester.—The effect of the canal on Manchester justified the faith of Adamson and the pioneers. Not only were the empty houses quickly filled but between 1894 and 1911 32,623 new ones were built. In that same period the rateable value of towns within 20m. of Manchester increased from £2,200,000 to £7,100,000. Old industries prospered and new industries came to the port. Their variety is seen in this list of Manchester's principal exports: manufactured cotton and woollen goods, yarns, machinery, locomotives, implements, tools, hardware, earthenware, paper-making materials, chemicals, coal, salt and pitch. Once this new duct was opened, Manchester became in a more real sense than ever before the railhead and clearing house to the enormous industrial population that lies about her. Within a 75m. radius of the city there are 14,106,432 people, compared with 13,131,319 within a similar radius of London. This is the most densely-packed population in the world, and it could not fail to ensure the prosperity of a port lying at its heart. The cotton industry alone, pursued in 32 towns, employing 60,000,000 spindles and 300,000 looms, inevitably enriched, and was in turn enriched by, the enterprising city which had removed a crippling disability. As the hub of so vast an industrial activity, Manchester, after London, is the greatest commercial centre in the British empire.

In its first year of work (1894) the canal earned £97,901 and carried 925,659 tons. With some slight fluctuations, the rise was steady after that, and in the year before the war (1913) it reached 5,780,161 tons and £654,937. After 1921, the lowest point touched since 1901, the rise began again and in 1927 6,359,420 tons were carried and the revenue was £1,576,237. The first dividend to ordinary shareholders was paid for the year 1915. At the end of 1927, the issued capital was £19,488,000, the expenditure on capital account to that date being £16,675,000.

Ship Canal House, the new headquarters of the Ship Canal Company, was opened in 1927. It is the most distinguished of the city's modern buildings, and stands out, like the realisation of Adamson's dream, dominating an inland town which has succeeded in making itself, in the face of great natural difficulties, the fourth port of Great Britain.

Bibliography.—*The History of the Manchester Ship Canal* (Manchester, 2 vols.) was written by Sir Bosdin Leech, who was closely associated with the movement from the beginning. "The Economic Value of the Ship Canal to Manchester and District," a paper read by James S. McConechy to the Manchester Statistical Society on Nov. 13, 1912, was published by John Heywood, in Manchester, and London.

MANCHOUKUO: *see* Manchuria.

MANCHU LANGUAGE. Manchu belongs to the Tungus group of languages. The Tungus people probably inhabited the present Manchuria already in the 3rd century B.C. The real founder of Manchu power was Nurhatsi who proclaimed himself emperor in 1616 and established his capital at Mukden in 1625. Under his reign the Manchus adopted for their own use the Mongolian alphabet which they had copied from the Uigurs. In course of time changes were made in order to adapt this writing to the Manchu language and in its final form it became far more elaborate and serviceable than its Mongolian prototype. Books had been printed in Manchu by 1647. The two emperors K'ang-hsi and Ch'ien-lung did most to establish and stereotype this somewhat artificial language by causing translations to be made of Chinese and Mongolian works and by the publication of numerous polyglot dictionaries. All officials had to pass an examination in Manchu; but in spite of these efforts this language continued to change more and more both in pronunciation and in grammar under the influence of Chinese, and at the death of one of the emperors in 1761 the examinations in Manchu were abolished, although imperial decrees and most official documents continued to be issued in this language in addition to Chinese.

With the abdication of the young Emperor Pu Yi and the proclamation of the Republic in 1912, Manchu may be said to have disappeared from China Proper. It is, however, still spoken in parts of northern Manchuria and elsewhere. Regarded as a dead language, Manchu has received a considerable amount of attention from European scholars because the literal translations made into that language from the Chinese classics have simplified the interpretation of the latter. The vocalic harmony is not so strictly observed in Manchu as in Mongolian and in the case of grammatical suffixes (postpositions) there are no alternative hard or soft forms. The postpositions are as follows: Accusative, *be;* genitive instrumental, *i* or *ni;* dative locative, *de;* ablative, *chi.* The Manchu verb, like the Chinese, does not distinguish either person or number, the tenses are imperfectly expressed and general notions are conveyed by adverbial and participial forms. Manchu has no relative pronoun and expresses a relative preposition by means of participles.

Manchu like the other Tatar languages adds affixes to the verbal theme to form derived verbs expressing some extended meaning; thus the syllable *bu* added to *ara,* "to write" gives *arabu,* "to cause to write," and the syllable *ja* added to *wa,* "to kill" gives *waja,* "to kill oneself," and so forth. A peculiarity of Manchu is the indication of masculine and feminine, or strong and weak, by the change of the vowel *a* into the vowel *e*. Thus *ama* "father," and *eme* "mother." Even foreign words undergo this change, and we find the Turkish *arsalan* "lion" modified into *erselen* "lioness," and the Sanskrit *garudai* "the male phoenix" becomes *gerudei* for the female of that species; *ganggan* "strong" becomes *genggen* "weak," and *wasime* "to descend" becomes *wesime* "to climb."

MANCHURIA (MANCHOUKUO), the name of the territory to the north-east of China Proper which, at the time when European powers were beginning to establish trading relations with China, was the land of the Manchus and the home-country of the Manchu dynasty (1644–1911), then on the imperial throne.

Although long essentially marginal to China Proper and during much of its history in the occupation of hostile peoples, its fortunes came to be definitely linked with China after the Manchu conquest, and as an integral part of the Chinese Republic, it is officially styled by the national government the "Northeastern Provinces" (Fengtien or Shengking, Kirin, and Heilungkiang).

Originally a frontier territory, it has no well defined limits and the international boundary follows in large measure the river courses of the Argun, Amur, Ussuri, Tumen, and Yalu, which offer definite features but do not indicate zones of separation in the geographical sense.

The lines of the Argun, Amur, and Ussuri were adopted as the boundary between the Chinese and Russian empires by a series of treaties, of which the first was signed at Nerchinsk in 1689 after the great eastward expansion of Russia across Siberia.

By the Treaty of Nerchinsk the Russian boundary advanced to the Argun, by the Treaty of Aigun (1858) to the Amur, and by the Treaty of Peking (1860) to the Ussuri. The northern boundary of Manchuria runs therefore along the very axis of the Amur basin, leaving northern Manchuria especially open to Russian penetration.

The Tumen and the Yalu have been recognized as the boundary with Korea from the time of the Ming dynasty (1368–1644) onwards. The internal boundary with Mongolia in the west is more indefinite and has considerably changed in recent times. With the expansion of Chinese agricultural colonization, Manchuria has extended at the expense of pastoral Mongolia. The present boundary is well to the west of the scarped edge of the Great Khingan in the north and follows the crest in the centre but in the south is still to the east of it, leaving the upper basin of the Liao-ho, although draining to Manchuria, within Jehol, the easternmost part of Inner Mongolia.

The Japanese claims to special privileges in South Manchuria always specifically included Eastern Inner Mongolia, by which was meant that part lying east of the Great Khingan.

The Country.—The core of Manchuria so marked out is a vast gently undulating plain lying between the scarped edge of the Great Khingan in the west and a more tangled mountain country in the east which culminates in the Chang-pai shan overlooking the Korean border. The drainage from the highlands converges onto the plain—the Nonni from the Khingan, the Liao from Jehol, and the Sungari from the Chang-pai shan. It has been built up and levelled by their detritus. The plain narrows quickly both to the north and the south. In the north it is separated from the lowlands along the Amur by the Little Khingan which stretches across from the Great Khingan almost to the East Manchurian Highlands, and even in the gap between them the Sungari penetrates through to the Amur only by a series of gorges. In the south the uplands of Jehol also approach close to the Eastern Highlands but there still remains a lowland corridor (drained by the lower Liao-ho) through to the Gulf of Liaotung, an inner arm of the Yellow sea. Only by a narrow lowland strip guarded by Shanhaikwan ("the gateway between the mountains and the sea") does this lowland corridor of South Manchuria communicate with the great plain of North China. But the East Manchurian Highlands thrust far southward in the terminal peninsula of Liaotung which approaches close to that of Shantung in China Proper. Together these two peninsulas lie athwart the seaward approaches not only to the Manchurian plain but also to Peking (Peiping), with one interval, for six centuries prior to the summer of 1928 the capital of China. The Manchurian plain, although thus ringed round by hill-masses, is not isolated by them for they are old denuded uplands of no great complexity and of only moderate relief.

The climate of this basin-land of Manchuria is continental in its temperature regime and monsoonal in the seasonal distribution of its rainfall, thus reflecting its proximity to Central Asia and its position on the northern margins of China. Hot summers succeed intensely cold winters and light southerly breezes the northerly blasts of winter. Midsummer temperatures are uniformly high averaging 70–75° F as compared with 80° F in China Proper and in the depth of winter the variation is only in the degree of cold. The temperature of Dairen at the tip of the Liaotung peninsula falls to 24° F and of Harbin in the central plain to below zero. The rivers are all frozen over, in the north until the end of April and even in the south until the beginning of April. Only the ports, Port Arthur and Dairen, at the tip of the Liaotung peninsula are free from ice all the year round. This enhances immeasurably their strategic significance. Practically the whole of the rather scanty rains fall in the summer months, the time when they are of most agricultural value. The rainfall is heaviest in the East Manchurian Highlands, decreases westwards toward the foot of the Great Khingan, and is least in what is now north-western Fengtien but was long part of Mongolia and is still known as the Eastern Gobi. The average rainfall of the central plain, agriculturally the most valuable part of the country, is between 20 and 25 inches.

The effect of the Manchurian plain, encased by hill-masses, is heightened by its open steppe vegetation in contrast to the forests of the East Manchurian Highlands, of the Amurian lowlands and the Little Khingan, and of the scarp face of the northern Great Khingan. But the woods clothing the Manchurian face of the northern Great Khingan disappear on its Mongolian slope and do not interrupt the continuity of the belt of steppe which stretches across Eurasia to its eastern terminus in the Manchurian plain. The extreme south-west of the central plain—the Eastern Gobi—is in part covered with sand-dunes and between the Liao and Nonni forms a region of inland drainage. The lowland corridor reaching down to the Gulf of Liaotung is richer grassland. The forests of the East Manchurian Highlands and Amuria, like those of the northern Appalachians and the St. Lawrence valley in North America, contain both coniferous and deciduous species. Oak, elm, and poplar clothe the lower slopes and fir, pine, spruce, and larch reach up to the hill-tops. These forest resources have especial value in view of the treeless character of North China and of the shortage of large timber in Japan. In the Amurian lowlands only scattered copses interspersed with meadow remain and the forests of the Eastern Highlands, even those remote from Chinese agricultural colonization, are being cut into for commercial lumber.

The Peopling of Manchuria.—The historic development of Manchuria has been conditioned by its physical character as a steppe backed by immense forests to the north and east, completely open on the west to the vast grasslands of Central Asia but communicating with the agricultural civilization of China to the south by only a narrow lowland strip. It has been held until quite recent times by a non-Chinese people, the Tungus, whose racial affinities are closer with the Mongols than with the Chinese. According to the Russian anthropologist, S. M. Shirokogoroff, the Tungus originally dwelt in north-eastern China and retreated into Manchuria in the second millennium B.C. before the Chinese advancing from the loess-lands of north-western China. The tide of Chinese colonization then swung south into the Yangtze valley and, while the northern branches of the Tungus spread into the northern forest, the southern remained in possession of Manchuria. The Tungus of the forest retained their old hunting nomadic life but those of the central and southern plains in time acquired the arts of cultivation, probably from their Chinese neighbours, and, according to Chinese annals, were already dependent by the first millennium A.D. on the "five kinds of cereal." Although excellent horsemen as befitted dwellers on the steppe, the Tungus of the plain, as evidenced by the Manchus, were ignorant of the art of milking and were essentially not pastoral nomads. True pastoral nomads of Mongol affinities did however occupy the drier western part of the Manchurian steppe adjacent to Mongolia.

Until the final victory of the Manchus in the early 17th century first one group and then another gained the upper hand and for a time dominated Manchuria. Now, Manchuria is the north-eastern antechamber of China and the Power holding it is in a unique position for the invasion of the Celestial Empire. On three occasions has this position been utilized by steppe-land dynasties—by the Khitan Tatars in the 10th, by the Kin Tatars in the 12th, and by the Manchus in the early 17th centuries. The Manchu dynasty when on the imperial throne (1644–1911) continued to regard Manchuria as the recruiting ground for the garrisons with which it held China.

The immigration of Chinese was long forbidden but after 1776 this prohibition was relaxed in the case of Fengtien, the southern province, and in the third quarter of the 19th century the Manchus had to recognize colonization in Kirin. The dense agricultural population of North China was beginning to spill over in considerable numbers into vacant lands whose settlements, always sparse, had been further depleted by recruitment for the Manchu garrisons in China. By the end of the 19th century the population of Manchuria is estimated to have reached 14,-000,000 of which 80% were Chinese. In comparison with what was to follow this movement, however, was no more than an infiltration and consisted mainly of males who intermixed with the Manchus and in time absorbed them. Pure Manchu groups remain only in northern Manchuria, chiefly in the Aigun district, and these are the descendants of soldier-colonists planted by the early Manchu emperors in the Amur valley. The rapid economic development of South Manchuria under Japanese auspices after 1905 and the security which it offered in contrast to the turmoil of China, rent by civil war and ravaged in the north by frequent famines, set in motion a mass migration. Coming mainly from Hopei (Chihli) and Shantung, the most densely peopled provinces of North China, this for years involved 300,000–400,000 annually, but of these half or three-quarters used to return to China after the Manchurian harvest. In the 1920s this seasonal migration of labourers became a permanent migration of families which in 1927 was more than 800,000 and in the summer of 1928, 40,000 a week. These Chinese peasant-farmers penetrated inland along the railways and settled in central and southern Manchuria, along the Chinese Eastern as well as the South Manchurian railway. They constituted quite 90% of the total population which was estimated in Dec. 1937 at 37,000,000, exclusive of 1,000,000 in the Kwantung leased territory. The Japanese in both regions together numbered about 600,000, and there were nearly 1,000,000 Koreans. The net inflow of Chinese in 1938 was 291,000, then the highest figure since 1927, the peak year, when over 1,000,000 entered. Population is densest in the plains of South Manchuria and in the eastern part of the central lowland, traversed by the railway leading toward Harbin. The total population of Manchuria (including Jehol and the leased territory) was 43,233,954 in 1940.

Modern Political Evolution.—This enormous increase in the Chinese population is destined to play a very important part in the political future of Manchuria. But for the last few decades Manchuria has been a frontier territory only partly under the control of the Chinese Government and subject to the penetration of foreign Powers, Russia and Japan. Their interests in Manchuria developed in the closing decades of the 19th century when China, politically weak, seemed on the eve of disruption, and when the Great Powers were carving out "spheres of influence" which often, as in Africa, were but the prelude to the declaration of protectorates and ultimate annexation. Such seemed likely to be the fate of Manchuria, which both on account of its intrinsic resources and as the antechamber of China, threatening the imperial capital, Peking, was coveted. For Tsarist Russia, Manchuria was to be the eastern outpost and the eastern terminus of the Trans-Siberian railway which was to bind that empire together. But Japan with an overflowing population and with only limited resources had a more vital interest than Russia in Manchuria, which, as a relatively undeveloped but potentially productive country, promised not only an exportable surplus both of foodstuffs and industrial raw materials but a field for Japanese colonization. Manchuria has failed to attract the surplus population of Japan, but as this has been in part absorbed by industrial development within the country itself, Japan has a greater interest in Manchuria as a source of supplies and as a market.

The conflict between Russia and Japan for the control of Manchuria first raged over the possession of the Liaotung peninsula, which is not only the southern gateway into Manchuria but commands the seaward approach to Peking. Its possession by a foreign power seemed to China a veritable pistol pointed at her head. The first move was taken by Japan. As the prize of her victory in the Sino-Japanese war of 1894–95, she demanded the cession of the Liaotung peninsula from the mouth of the Yalu to the mouth of the Liao. But Russia, backed by France and Germany, forced her to abandon this claim. Then by means of intrigue and a show of force, Russia (1898) acquired the lease for 25 years of the territory of Kwantung at the very tip of the peninsula, containing the naval station of Port Arthur and what has since become the great commercial entrepôt of Dairen. Japan returned to the attack and by the Treaty of Portsmouth (1905), which registered her victory over Russia in the war of 1904–05, obtained the transfer of the Kwantung lease. Meanwhile Russia had been pushing forward her scheme of railway construction. She had already built the Chinese Eastern railway (C.E.R.) across northern Manchuria to connect with the line to Vladivostok and when the Russo-Japanese War broke out was engaged in the construction of a branch from it through southern Manchuria to Port Arthur. By the Treaty of Portsmouth Japan became heir not only to the lease of Kwantung but also to the rights of railway construction in Fengtien, to be vested in the South Manchuria Railway Company (S.M.R). Russian interests were thus pushed back into northern Manchuria, into the provinces of Kirin and Heilung-kiang traversed by the Chinese Eastern railway. Neither of these companies were nominally Government concerns and the properties of each were held on leases, the S.M.R. on one of 99 years and the C.E.R. on one of 80 years. China had also the option of purchasing the latter after 36 years, an option which was to fall due in 1932. But investment in the S.M.R. was limited to Chinese and Japanese subjects and in the C.E.R. to Chinese and Russian and in effect the paramount interests were the Japanese and the Russian. In fact the officials of the S.M.R. were appointed by the Japanese Government from the share-holders.

In possession of the arterial railway through South Manchuria and of its seaward terminus in the entrepôt of Dairen, Japan held the chief key to the economic penetration of South Manchuria. It became in effect if not in name the Japanese "sphere of influence" in which Japan time and time again claimed a privileged position. The famous Twenty-One Demands presented to China in 1915 affirmed "the predominant position of Japan in South Manchuria and Eastern (Inner) Mongolia," and on the formation of the banking Consortium in 1920, which was an agreement to pool loans to the Chinese Government equally between the four great Powers (Britain, France, the United States, and Japan), Japan secured the exclusion of nearly all South Manchurian railways from its scope.

At the Washington Conference of 1921–22 Japan was a party to the Nine Power Treaty which repudiated the policy of "spheres of influence" and re-affirmed the principle of the Open Door. But on the strong representation of Baron Shidehara the original resolution committing the Powers concerned to submit existing concessions, so far as they were judged inconsistent with these declarations, to a board of reference was dropped altogether, and the revision of the 1915 treaties was not pressed. At the conclusion of the Conference Japan voluntarily made certain concessions with regard to her railway monopoly but in essentials her status in South Manchuria was left unchanged by the Washington agreements. During the Chinese Civil War, which broke out almost immediately afterwards, Japan continued to exercise a controlling influence in South Manchuria and the presence of Japanese troops in the railway zone was the chief factor in the maintenance of peace in that country. Japan repeatedly declared that her only military concern in Manchuria was the preservation of order necessary to safeguard her economic interests and the security of her own shores. What was in effect a *condominium* could not but be unstable and must sooner or later be terminated. With China, Japan, and Russia each having holdings in the region, any adjustment of the claims of the three could not but be an uneasy truce. Partition would scarcely be the solution, for the great plain of Manchuria is too clearly a geographic unit to permit of a natural boundary across it. Sooner or later two of the three contestants would have to withdraw and leave one in control. Nor was it clear that even this would be a permanent settlement of the conflict. The dispossessed would be certain to remember their historic interests and to seek to repossess them. Because of its history and of its geographic location between three strong peoples, the Russians, the Japanese, and the Chinese, Manchuria was certain to remain indefinitely a bone of contention.

For a few years it looked as though the first of the three Powers to be eliminated would be Russia. The Russian Revolution of 1917 was followed by the break-down of orderly Russian administration in the Far East. The situation was complicated by the dispatch of troops to Eastern Siberia by Great Britain, France, Japan, the United States, and China. In numbers of troops Japan outdistanced the others and for a time it appeared that Japan might supplant Russia in that region. That would, of course, have led to Japanese ownership of the former Russian holdings in Northern Manchuria. Partly to prevent this development, the C.E.R. was placed under the control of an inter-allied commission with an American at its head. In 1919, after the Communists had gained control in Russia, they announced their renunciation of all special privileges acquired by the Tsarist Government in China and promised the restoration to China of the C.E.R. and of the mines and forests acquired by the Tsarist regime. When it came to actual negotiations with China, however, by an agreement signed May 31, 1924, Soviet Russia, while surrendering extraterritoriality and the former Russian concessions and agreeing in principle to the eventual repurchase by China of the road, insisted upon retaining a share in the administration of the C.E.R. A somewhat similar agreement regarding the C.E.R. was signed between Russia and Chang Tso-lin, the ruler of Manchuria, Sept. 20, 1924. Friction followed, accentuated by the anti-Communist, anti-Russian reaction in China after 1927. In 1929, under the youthful successor of Chang Tso-lin, Chang Hsüeh-liang, and impelled by the rising tide of nationalism, the Chinese attempted to oust the Russians from their participation in the C.E.R. The Russians struck back, and in a sharp, brief, undeclared war compelled the Chinese to restore the *status quo*.

Creation and History of Manchoukuo.—It was not Russia but China which was the first of the three Powers to be eliminated from Manchuria. The mounting Chinese nationalism clashed with Japanese militarism, the latter made more aggressive in an effort to solve the economic ills of Japan which had been accentuated by the world-wide economic depression which began in 1929.

In various ways the Chinese were attempting to restrict the Japanese. Notable was the progress in constructing a system of railways which would be independent of the islanders and have an outlet to the sea through the port of Hulutao, free from Japanese domination. Friction, too, developed between Koreans and Chinese in Manchuria, the former being Japanese subjects. On the night of Sept. 18–19, 1931, the Japanese military forces struck, giving as the reason what they alleged to be the blowing up by Chinese of a part of the South Manchurian railway just outside of Mukden. In the following few weeks they occupied a number of strategic centres. At the time Chang Hsüeh-liang had most of his forces south of the Great Wall and before the Japanese Army his rule in Manchuria quickly collapsed.

China appealed to the League of Nations. That body appointed a commission, headed by the earl of Lytton, which, after investigation, in the autumn of 1932 reported in the main unfavourably to the Japanese. Geneva proved unable to implement its decision, but its action led to Tokyo's withdrawal from League membership.

In the meantime the Japanese, faced with the necessity of maintaining some kind of order in the provinces where they had destroyed Chang Hsüeh-liang's regime, were stimulating the erection of a new administration. Local and provincial provisional governments were set up, mostly by resident Chinese (and, in some areas, Mongols) with Japanese advisers. Early in 1932 a Manchuria-wide government was organized and on February 18 of that year this declared the independence of the Three Eastern Provinces under the name of Manchoukuo. Pu Yi, who with the title of Hsüan T'ung had been the emperor of the Manchu dynasty when it abdicated its control of China in 1912, and who had since been living in retirement in Peking and Tientsin, became "chief executive." This seemed to connect Manchoukuo ("The State of Manchu"), or Manchoutikuo ("The Empire of Manchu"), with its historic past and to give it an air of legitimacy. A step farther was taken when, on March 1, 1934, Pu Yi formally announced his ascent to the throne under the title of Kang Tê. His residence was established at Changchun, renamed Hsinching, or Hsinking ("The New Capital"), and here extensive building operations produced an impressive physical emblem of the new State. In Jan. 1933, Japanese and Manchoukuoan forces invaded Jehol, the easternmost province of what is often known as Inner Mongolia, and soon added it to Pu Yi's domains. Conjointly with the Japanese, Manchoukuo has undertaken extensive projects for the economic development of its resources. Railways have been built rapidly. Currency and banking have been reorganized. Efforts have been made, sometimes successfully, to repress banditry.

The Japanese have poured capital into Manchoukuo in an attempt to develop the land and to realize economic profit on their huge investment in military expenditure. They have sought to encourage Japanese immigration. They have endeavoured to knit Manchoukuo into an economic bloc with the other parts of their empire. Even so late as 1939, however, their success was in doubt. Some of Manchoukuo's products, including coal, compete with those of Japan. World economic conditions have diminished the demand for one of the former chief exports, products of the soya bean.

Japanese immigration has not taken kindly to farming and has been confined chiefly to soldiers, businessmen, and Government employees. Manchoukuo, on a short view, except for its strategic value, seemed to be an unprofitable investment.

In Manchoukuo the Kwantung army (that section of the Japanese army which serves in the land) is dominant. The other major Japanese unit is the South Manchuria Railway company, but by

1939 it had lost most of its autonomy to the army.

Administratively Manchoukuo was in 1939 organized into 18 divisions (Fengtien, Kirin, Lungkiang, Jehol, Pinkiang, Chinchow, Antung, Chientao, Sankiang, Tunghua, Mutankiang, Heiho, Peian, Tungan, East Hsingan, West Hsingan, South Hsingan, North Hsingan) together with the special municipality of Hsinking, the capital. The former division into the three provinces of Chinese days (Liaoning, Kirin and Heilungkiang) is no longer observed and the Japanese, when creating the province of Hsingan (subsequently subdivided into four areas), where the Mongols were given a special status, incorporated in it the Mongol-inhabited portion of northern Jehol, a province which by the Chinese had been regarded as part of Inner Mongolia and not of Manchuria.

Manchoukuo has had a most anomalous position internationally. It has been recognized by no governments except those of Japan and her axis partners and El Salvador, though some degree of recognition was implicit in the U.S.S.R. nonaggression pact of 1941 with Japan.

Relations with Russia have entailed peculiar difficulties, partly because of the long common frontier, partly because of Russian influence in another neighbour land, Outer Mongolia, but chiefly over the Chinese Eastern railway. After long negotiations, in March 1935, the Russian interest in the line was sold to Manchoukuo. Thus the already tenuous Russian sphere of influence was finally eliminated.

Manchoukuo, although held by Japan to be independent, is closely supervised and controlled by Japanese advisers. Presumably it would fall if not supported by Japanese bayonets. By practically all the rest of the world it is technically regarded as still a part of China. The Chinese are not reconciled to Japanese control, apparently not even in Manchoukuo itself. Continued clashes with the Russians occurred on the borders until the conclusion of the Russo-Japanese nonaggression pact—notably in 1937 over an island in the Amur, in 1938 near the corner where Korea, Manchoukuo and Siberia join, and in 1939 on the ill-defined border between Manchoukuo and Outer Mongolia.

Modern Economic Development.—However baneful and dangerous the political effects of foreign penetration may have been, it has certainly stimulated the economic development of the country. The influx of foreign capital—Japanese investments alone in Manchuria were said to amount to more than 3,500,000,000 yen at the end of 1938—and of a Chinese peasant population have combined to expand the area of the plain under cultivation, to exploit the mineral and forest resources of the hills, and to increase enormously the contribution of Manchuria to foreign trade. The framework on which this economic development has proceeded, and is still proceeding, is the railway system. It offers an avenue of penetration into the interior both for Japanese capital and for Chinese immigration and a way of communication with the coast for the export of surplus production. Moreover, the leases of both the S.M.R. and the C.E.R. (now incorporated in the "Manchoukuo" system, but here for convenience called the North Manchuria railway or N.M.R.) included a wide zone on either side of the railway line, in which the companies could themselves engage in productive enterprises, work collieries and direct agricultural development. The story of the opening up of the Manchuria steppe is not unlike that of the Canadian prairie with which it is physically comparable, for in both the railway has preceded settlement and further railway construction will bring in its train an expansion of the area under cultivation. The economic development of Manchuria can therefore be best understood after an outline of the railway system.

The arterial railway lines are, firstly, the main line of the C.E.R. (N.M.R.) from Manchouli to Suifenho, which when under Russian control formed the chord to the arc of the Trans-Siberian, the latter keeping on the outside of the northern river boundary of Manchuria, and, secondly, at right angles to the above, the main line of the S.M.R. from Dairen to Changchun where it connects with a branch of the N.M.R. from Harbin. Harbin is thus the great railway junction and, as Manchuria is a "new" country, the metropolis of northern Manchuria. The corresponding railway junction and metropolis in South Manchuria is Mukden, where the main line of the S.M.R. is joined from the southeast by its own branch from Antung, which is connected with the Korean railways, and from the southwest by the Peking-Mukden railway, one of the arterial lines of the Chinese railway system. It is therefore by way of Manchuria that China communicates by rail with Europe. This outline system as well as that of North China was completed before the Revolution of 1911. But while in China Proper, distracted by civil war, there was very little construction for nearly 20 years after that date, the "new" and comparatively peaceful country of Manchuria, with its constant stream of immigrants, was the scene of active railway development.

So long as it was under the direction of the Chinese, much of this activity had as its objective the construction of north-south lines parallel to the S.M.R. and leading toward independent junctions on the east-west main line of the C.E.R. (N.M.R.). Japanese capital built an exceedingly important railway leaving the S.M.R. main line at Supingkai, half-way between Mukden and Changchun (Hsinching), and passing by way of Taonanfu to join the main line of the N.M.R. at Angangchi, near Tsitsihar. This line parallels not so much the S.M.R. as the branch of the N.M.R. from Changchun (Hsinching) to Harbin and gives the S.M.R. direct access, without the intermediary of Harbin, to a rapidly developing part of the central plain. Farther south the Chinese themselves were engaged in railway construction on both sides of the S.M.R. main line. On the west a branch led off from the Peking-Mukden line and headed toward the Japanese Supingkai-Taonanfu-Angangchi branch, with the possibility that in the future it might effect a junction with the N.M.R. independently of the Japanese line. On the east the Peking-Mukden railway was extended beyond its Mukden terminus to Hailung, half-way to Kirin, to which it was planned ultimately to continue it. Both of these railways paralleled the S.M.R. main line and both communicated with Hulutao on the Peking-Mukden system, an ice-free port on the Gulf of Liaotung whose harbour works the Chinese engaged in developing. Japan saw in this Chinese railway construction a threat to Dairen and alleged that China had on two occasions, in 1905 and in 1915, promised not to construct any lines parallel to and in competition with the S.M.R. until the expiry of the company's lease. China in reply maintained that the agreements referred only to foreign projects other than Japanese. It was generally admitted, however, that these lines, although numerous, would be no more than sufficient to carry the intense traffic that was likely to develop in the future.

After the creation of Manchoukuo, the Japanese entered upon a period of intense railway building. They purchased from Russia (1935) the latter's interest in the Chinese Eastern railway. To the approximately 4,000 mi. of railway in existence in 1931 they have added about 2,000 mi. They completed some of the lines begun by the Chinese. They pushed the Changchun (Hsinching) line eastward to Seishin and Rashin, on the northern coast of Korea. At Rashin, only a short distance south of the Russian border, they developed a new port, obviously partly with strategic purposes in mind. From Harbin and Tsitsihar they built lines northward toward the Amur, obviously again in part with the purpose in mind that they would prove useful in the war with Russia which the army regarded as inevitable. They completed a new line from Mukden to Peking by way of Jehol. All of these lines also contributed to the economic development of the country.

In parentheses it must be noted that the waterways within Manchuria function only as the adjunct of the railway system. The main objective of the river traffic is Harbin, the point of transhipment from the river to the railway of the trade of the whole Sungari valley.

Many of the steamers plying on the Sungari were until recently the property of the C.E.R. (N.M.R.). The course of the Amur is not the great artery of river traffic that might be expected, for its mouth lies far to the north away from all ocean trade routes, and its middle course from the point of view of through traffic is paralleled by both the Trans-Siberian and the North Manchuria railways.

Apart from the lines penetrating across or skirting the edges of the great timber reserves of the East Manchurian Highlands, this intense railway activity is primarily intended to promote the agricultural development of the plains. The lowland corridor of South Manchuria has hitherto been the main seat of cultivation but it is being rapidly overtaken by the central plain which is not only much greater in area but has also, apart from its southwestern section (eastern Gobi), considerably more fertile soils. Potentially the richest districts of all lie in an arc passing from Changchun (Hsinching) and Kirin through Harbin toward Tsitsihar, and it is this area that in the 1920s was the main scene of Chinese colonization. It lay significantly enough, in the zone of the C.E.R. (N.M.R.) rather than of the S.M.R. and was therefore the objective of the branch railways constructed by Japanese interests, seeking to divert traffic from Vladivostok to Dairen. Although the three provinces of the Chinese regime divided the central plain between them, yet the following figures for Fengtien and for Kirin and Heilungkiang give some indication of the relative agricultural value of south and north respectively. Fengtien had a total area of 57,800,000 ac. of which 19,100,000 were cultivable and 12,700,000 actually cultivated. Kirin and Heilungkiang (*i.e.*, North Manchuria) together had an area of 187,200,000 ac. of which 38,200,000 were cultivable and 18,200,000 cultivated.

Manchuria is climatically similar to North China and has much the same agricultural character. The cold winters limit cultivation to the summer half-year during which only one crop can be grown, apart perhaps from a catch-crop after the main harvest. The staple crops are those adapted to a relatively low rainfall: millet, kaoliang, maize, wheat, barley, and legumes, especially beans. Cereals and beans form the essential elements in the rotation system. These features are characteristic of all Manchuria and indeed of North China, but as between the north and south there is a difference as regards the relative importance of particular crops. In South Manchuria the warm temperate cereals (millet, kaoliang, and maize) predominate, but northwards they gradually give place to wheat, barley, and oats (not grown at all in the south) which are the staple crops of Heilungkiang. Moreover, much of the millet grown in North Manchuria is harvested green, because of the short growing season. Certain subtropical crops, rice, and cotton, characteristic of the Yangtze valley, are cultivated where the conditions are favourable in North China and even as far north as South Manchuria, which has over 1,000,000 ac. under rice and about 400,000 under cotton. Some rice is grown in Kirin, but both crops are absent from Heilungkiang.

Although, on the whole, similar both in the type of its crops and in the antecedents of its population, Manchuria has a far greater surplus production available for export than North China. The one is a new and relatively under-peopled country, the other saturated with population. But as the Chinese peasants, who constitute the bulk of its farming population, are by tradition and practice subsistence farmers, there is little of the purely commercial farming that characterizes the Canadian prairies. The surplus production that enters commerce is mainly of soya beans and wheat, both of which receive some industrial treatment in the region of their production before they are exported out of the country. A small sugar beet industry is developing on exactly the same lines. It is in the industrial treatment of field crops on a large scale that Manchurian agriculture differs from that of North China.

To the Chinese the soya bean is a crop, like bamboo, which can be made to serve innumerable purposes (*see* under CHINA: *Agriculture*) and, as it has a great number of varieties adapted to varying rainfall conditions, its cultivation is widespread and in most districts of Manchuria it constitutes the largest single crop. It is estimated that of a total bean production in Manchuria of 6,000,000 tons about half is available for export, 2,000,000 tons of which originates from the zone of the N.M.R. and over 1,000,000 tons from that of the S.M.R. There was long intense competition between the two railways for the transport of this exportable surplus to the coast, and between Dairen and Vladivostok for its shipment abroad. Of the total exported about half is of raw beans and half in the semi-manufactured form of bean-oil and bean-cake. These are products of the oil mills spread along the railway zone but focused especially in the South Manchurian ports, above all Dairen, and in Harbin, the railway centre of North Manchuria. At present oil mills are much more numerous in South than in North Manchuria but the latter is already the centre of surplus bean production and the number of oil mills is steadily increasing. The bulk of the export of beans and bean-cake goes to Japan for use as food and fertilizer and the bulk of the bean-oil to Europe for industrial consumption. After beans the most important commercial crop in Manchuria is wheat, whose cultivation is centred especially in North Manchuria. Much of this wheat production is handled by flour mills along the railway zone which are most numerous in Harbin and Changchun (Hsinching). Of nearly 200 flour mills in the whole of China in 1928, North Manchuria accounted for 62 (Harbin 30) and South Manchuria for 12. Flour-milling was originally introduced by Russian interests to feed the Russian population in Manchuria and along the Trans-Siberian, but the dominant interest became Chinese and the industry already supplies the greater part of the Manchurian market, once an American preserve. Only during World War I did an export trade in flour of any magnitude develop from the country. The consumption of wheat-flour in China is steadily increasing and it would seem that wheat cultivation in Manchuria is assured of a continually expanding market.

The most important of all the Manchurian forests, the distribution of which has been indicated above, are those of the East Manchurian Highlands whose lumber supplies the needs not only of the Manchurian plain but also of North China and to a less degree of Japan. These are being tapped in three districts—along the Yalu valley which opens out into Korea bay, along the headstreams of the Sungari which focus on Kirin, and along the N.M.R. in its traverse of the Highlands. Logs are rafted down the Yalu and Sungari to Antung and Kirin respectively, whence they are transported by the S.M.R. into the plains of Manchuria or shipped by steamer across to Tientsin and the Shantung ports. The timber resources of the East Manchurian Highlands are therefore being rapidly exploited, but there are few efforts as yet at re-afforestation, apart from those in the S.M.R. zone. On the bare hills of the Liaotung peninsula considerable numbers of oak seedlings have been planted not so much for their lumber as for the needs of the tussah silk industry, dependent on the leaves of the oak tree. (*See* ANTUNG.)

The economic wealth of Manchuria is not confined to agriculture in the plains or to lumbering among the hills, but includes also the mining of coal and iron, for which South Manchuria is one of the chief centres in the Far East. This intensity of production is the result partly of the accessibility of the coal and iron-fields and partly of the interests of Japan. Considering the scale of her industrial development, the coal resources of Japan are of no great magnitude and her iron resources are quite insufficient for her needs. Manchuria has coal reserves about equal to those of Japan (4,000,000,000 tons) and iron reserves that are quite ten times as great. The bulk of both coal and iron lies in South Manchuria, whose attraction to Japan on this account alone requires no further emphasis.

The coalfields of Manchuria fall into two main divisions, those occurring in isolated synclines within the East Manchurian Highlands and those lying in a more or less continuous strip along their western foothills where the Highlands sink down into the plain. The fields within the Highlands yield the better bituminous coals but only those which are accessible from the railways crossing the Highland zone are worked for more than local consumption. These include the Penchihu field along the Mukden-Antung line, the Mulin field along the N.M.R., and the Suchan field (actually outside Manchuria) close to Vladivostok. The belt of coalfields along the western foothills of the Highlands, lying near to the arterial railway from Mukden to Harbin, is more accessible but produces brown coals of much poorer quality, and they are worked only on a small scale. The coalfield of Fushun close to Mukden is of quite a different nature from any of the above. Although Tertiary in age, its seams are of enormous thickness and its coals of good quality. Its intrinsic character combined with its strategic position near to the railway focus of Mukden and the Japanese interest in its development have given it the greatest production (by 1940 over 10,000,000 tons) of all the Manchurian coalfields. It dominates the coal trade of South Manchuria, supplies one-fifth of the coal consumption of North Manchuria and even then has about half of its total production available for export to the ports of North China and Japan. The consumption of coal in North Manchuria is more limited than in the south. It is supplied partly from Fushun, partly from Mulin and Suchan along the eastern N.M.R., and partly from the Chalainor field along the western N.M.R. on the Mongolian slope of the Great Khingan.

The Liaotung peninsula contains the iron-field with the greatest reserve of iron ore workable by modern methods in the whole of China. According to the Chinese Geological survey, its reserve amounts to 740,000,000 tons out of a total of 952,000,000 tons for the whole country. These have not, however, a very high content of iron, and until strategic considerations became paramount the Japanese tended to rely more upon the richer ores of the Yangtze valley than on intensive working of the Liaotung fields. A handicap to the iron and steel industry of Manchuria has been the shortage of suitable coking coal, large quantities of which now have to be brought from the Kailan mines in North China for the blast furnaces at Anshan, near Mukden.

As the economy of Japan progressed from a quasi-wartime economy between 1932 and 1937 to a full wartime economy after the outbreak of war with China, and as state control of industry was intensified in Japan, so the Manchurian authorities, under pressure from the Japanese army, embarked upon a parallel policy which included a five-year industrial plan and a program of state control and state monopolies designed principally to supplement deficiencies in Japan's strategic industrial fabric. The emphasis was laid upon mining and metallurgical industries, but it included also a number of other undertakings designed to increase Japan's war potential and to promote self-supply of a number of important strategic materials and munitions of war within the "inner zone" of the so-called co-prosperity sphere. A revised five-year plan announced in 1938 aimed at the annual production by 1941 of 5,000,000 tons of pig iron, 5,000,000 tons of steel, 12,000,000 tons of iron ore, and 28,000,000 tons of coal, as well as considerable increases in the output of electric power, liquid fuel, chemicals, machinery and other items. It is doubtful whether these ambitious targets could have been approached in favourable peacetime circumstances, and it is certain that after the outbreak of war with China neither capital, materials nor labour were available in sufficient quantities. Figures are not, of course, published to show the actual performance, but it is unlikely that pig iron capacity, to say nothing of production, had by the end of 1941 reached half the projected quantity and something of the kind is no doubt true of other items in the program. There can be no doubt, however, that the Japanese are making strenuous efforts (1944) to increase industrial output in Manchuria, despite the handicaps mentioned above and the additional difficulties created by the war in the Pacific; and it is certain that Manchuria has played a very important part in providing Japan with essential war materials.

MANCHUS. The term Manchu, which is recent in origin, has a dynastic connotation, and refers to those people, linguistically and culturally, connected with the eastern Tungus, who in the 17th century conquered China and placed their chief on the Dragon Throne. Somatologically they appear to belong to two strains; one is closely akin to the northern Chinese, the other to an element extremely common among the Buriats. While the first are only moderately roundheaded, the latter are extremely brachycephalic and probably represent an old mixture of Alpine and Yellow man. While some of the Manchus are hardly to be distinguished from the northern Chinese, others have a distinctly western type of countenance. It has been suggested by Shirokogoroff that originally the distribution of the people culturally akin to the Tungus stretched into the plain of China. If this is the case, the gradual absorption of the Manchus by immigrant Chinese is a continuation of a process which has been going on for a long period.

Since the advent of the Manchu dynasty the Manchus, organized on a military basis as "bannermen," have been widely scattered over China, where as a kind of hereditary militia they were supported as a charge on the imperial treasury. For the most part, however, they have become absorbed physically and culturally among the Chinese, and have acquired Chinese culture in the place of their old fishing and hunting habits.

An interesting problem is raised by the long association of the Manchus and the Chinese, first as enemies but with definite separate organizations, and later as a mixed people with the Manchus in a nominal ascendancy, occupying the Dragon Throne. The Manchus achieved supremacy in north China at a time when Chinese activity was at a low ebb, all the glories of the T'ang and Lung periods had become submerged and scholars felt the oppression of the long Mongol régime still upon them. Moreover, the Chinese were wasted and weakened by the struggle of warfare.

The Manchu dynasty provided just this necessary stimulation. Flushed with victory and with long-desired power over her southern neighbour, Manchuria determined to mark the whole empire with her personality. The arts were encouraged and special schools for research were established. The Manchus were fully alive to the necessity for continuing Chinese customs and a form of government which, by long usage, had become not merely palatable but sacrosanct to the Chinese.

Perhaps the greatest work of the Manchus was the issue of parallel editions of Chinese texts. Many of the Chinese classical books, written in the *Ku Wên,* a very complicated, highly elliptical style, were in later days not understood in parts. Various commentators had attempted expansion of the text in order to bring some meaning out of the passages in question but textual criticism had not yet become a real study.

The Emperor K'ang Hsi, however, gathered together from all parts of the empire the best scholars and grammarians and set them to work on an "Imperial Edition" of the classics. This edition was to appear with the text in parallel columns, Chinese and Manchu, and since an acceptable Manchu translation of a passage not understood was impossible, the best commentators were employed to elucidate the texts before they went to the Board of Translators. From a careful study of the Manchu versions, light was for the first time thrown on many obscure passages in the classical library.

Another activity of the Manchu dynasty, of great importance to the literary student of Further Asia, was the publication, again bilingual, of Manchu works which were now translated into Chinese. This brought a new force into Chinese effort and the literary changes, small though they were, passed into art in its various forms, being especially marked in the pottery of the Ming dynasty. Paintings also suffered a slight change; again the stream of active life was informing the latent powers of the Chinese and another golden age was begun.

The well-known capacity of the Chinese for absorption of an alien people is clearly shown in the case of the Manchu. Originally essentially different from the Celestial, he has, through the centuries been impressed with the Chinese seal until to-day there is no means of distinguishing between the members of the two peoples; they are in effect one and the same. The Manchus began well, full of vigour and animated by a passion for reorganization, they occupied themselves with multifarious activities calculated to bring again the Chinese Empire into its former eminence. But the inevitable result of a too highly concentrated period of achievement was the incidence of a time of indulgence and licence and the Manchus were finally overthrown by their subjects.

MANCINI, PASQUALE STANISLAO (1817–1888), Italian jurist and statesman, was born at Castel Baronia, in the province of Avellino, on March 17, 1817. In 1848 he helped to persuade Ferdinand II. of Naples to participate in the war against Austria. Upon the triumph of the reactionary party he undertook the defence of the Liberal political prisoners. Threatened with imprisonment in his turn, he fled to Piedmont, where he obtained a university professorship and became preceptor of the crown prince Humbert. After the fall of the Bourbons, he went to Naples as administrator of justice, in which capacity he suppressed the religious orders, revoked the Concordat, proclaimed the right of the state to Church property, and unified civil and commercial jurisprudence. In 1862 he became minister of public instruction in the Rattazzi cabinet, and induced the Chamber to abolish capital punishment. For the next 14 years, he devoted himself chiefly to questions of international law and arbitration, but in 1876, upon the advent of the Left to power, became minister of justice in the Depretis cabinet.

Mancini's Liberalism found expression in the extension of press freedom, the repeal of imprisonment for debt and the abolition of ecclesiastical tithes. During the Conclave of 1878 he succeeded, by negotiations with Cardinal Pecci (afterwards Leo XIII.), in inducing the Sacred college to remain in Rome, and, after the election of the new pope, arranged for his temporary absence from the Vatican for the purpose of settling private business. Resigning office in March 1878, he resumed the practice of law, and secured the annulment of Garibaldi's marriage. The fall of Cairoli led to Mancini's appointment (1881) to the ministry of foreign affairs. An indiscreet announcement of the limitations of the Triple Alliance contributed to his fall in June 1885, when he was succeeded by Count di Robilant. He died in Rome on Dec. 26, 1888.

MANCUNIUM, the name often (though probably incorrectly) given as the Romano-British name of Manchester. Here, close to the Medlock, in the district still called Castlefield near Knott Mill, stood in Roman days a fort of 5 acres garrisoned by a cohort of Roman auxiliary soldiers. The site is now obscured by houses, railways and the Rochdale canal, but vestiges of Roman ramparts can still be seen, and other remains were found in 1907 and previous years. Traces of Romano-British inhabitation have been noted elsewhere in Manchester, especially near the cathedral. But there was no town here; we can trace nothing more than a fort guarding the roads running north through Lancashire and east into Yorkshire, and the dwellings of women-folk and traders which would naturally spring up outside such a fort. The ancient name is unknown. Our Roman authorities give both Mancunium and Mamucium, but it is not clear that either form is correct.

See numerous articles by J. J. Phelps, C. Roeder and F. A. Bruton throughout the *Transactions of the Lancashire and Cheshire Antiquarian Society*.

MANDAEANS, also known as Subba (Ṣabians), Naṣoraeans, or St. John's Christians, are an ancient sect akin to the Gnostic Christians of the 2nd and 3rd centuries, which still exists in lower Mesopotamia, in such places as Basra and Kut and Sūḳ-esh-Shuyūkh. They number now not more than about 2,000, and are said to be diminishing. Ṣubba (sing. ṣubbi) is the modern Arabic name, referring to their frequent baptisms (in Mandaean *maṣbuta*); Naṣoraeans, like the Arabic *Naṣāra*, is ultimately connected with Ναζωραῖοι (*comp.* Acts 24, 5 and נוצרי), and is used by Mandaeans in the sense of "true believers"; St. John's Christians is the inappropriate name given to the Mandaeans by Christian missionaries from the 17th century onwards, who mistook their frequent immersions and the reverence paid by them to John the Baptist for signs that they were derived from the Baptist's disciples. This is not so, and their interest in the Baptist is grounded in their hostility to the Church as it was under the Sassanian empire, *i.e.*, the Nestorians. Mandaeans means γνωστικοί (מאנדאייא, from מאנדא, Syriac *mad'ā*): the Gnosis of which they profess themselves adherents is a personification, the aeon and mediator "knowledge of life" (*Manda d'hayye*).

The present condition and practices of the Mandaeans may be gathered from Siouffi's book, published in 1880. A later account, including a detailed description of a Mandaean baptism, is to be found in the *Quest* for Oct. 1924 and Jan. 1925. (See *Bibliography.*) The sacred books of the Mandaeans are: (1) the *Ginza* ("Treasure"), known also as *Sidra rabba* ("the Great Book"); (2) the *John-Book*, a later collection; (3) *Qolasta*, a sort of hymnbook, *cf.* the Syriac *ḳullāsā* ("praise") and some minor works, partly astrological. The editions of the *Ginza* (1925) and the *John-Book* (1905–15), both by Mark Lidzbarski, have now made the chief Mandaean writings generally accessible to scholars.

Mandaean mss. are written in a peculiar Aramaic. As in the Babylonian (cuneiform) documents the characteristic Semitic gutturals have disappeared; on the other hand the vowels are represented, *a* by א, *e* by ע, while י is used both for *i* and *y*, ו for *w* and *u* and *o*. Initial *u* (or *o*) is represented by עו, initial *i* by עי. No ms. older than the 16th century seems to have survived, but the texts show few variations of importance.

The *Ginza* is the oldest document. It begins at both ends, like many ms. note-books. The longer part is called the Right-hand Ginza (GR), the shorter (about a quarter of the whole) is the Left-hand Ginza (GL). It is usually cited by the pages of Peterman's facsimile, given in the margin of Lidzbarski's edition. The last chapter of GR presents a kind of world-history, and as the dominion of the Arabs is placed at only 71 years it is evident that it must have been compiled very shortly before A.D. 700.

GR contains general cosmological, hortatory and doctrinal pieces. GL consists chiefly of hymns and doctrinal pieces about the fate of the soul after death. This part (GL) shows most clearly the essence of the Mandaean religion; this is the σῶμα-σῆμα ("the body, a tomb") philosophy, which Mandaism shares with almost all the religions which flourished in the early days of Christianity, except Judaism and Catholic Christianity itself. For the world in itself, both visible heavens and this earth, together with the bodies of all men, there is no redemption, and the final end of everything on the earth, except for the souls of the righteous, is to be swallowed by Leviathan and so annihilated (GR 393). Our world had been a kind of mistake from the beginning. There was a light-world, and a world of darkness in which the evil woman-demon lived, whom the Mandaeans call *Ruha*. That world seems to consist of the dark (or black) waters and things thereto allied, and in GR v. 134–172 we read the fantastic tale of how Hibil the Bright (Hibil-Ziwa, lit. "Abel-Splendouro": Hibil is the Mandaean form, *Hābēl* the Syriac form of Abel), son not of Adam but of Manda d'Hayye, traversed all these dark lower regions, despoiling the principalities and powers and enchaining them. But somehow—the account itself is not clear (GR 150ff.)—Ruha, as the result of this visit, bore a monstrous son called *Ur* (possibly a corruption of ὕλη), and from Ur and his mother Ruha came broods of Seven and of Twelve, which are the planets and the zodiacal constellations. Meanwhile a lower being of the light-world called *Abathur* had looked below into the dark waters and seen his image, which thereupon took independent shape and was called *Ptahil*. This Ptahil had in him therefore some of the substance or quality of the dark waters: he was told to form a solid world out of the dark waters, but failed to do so till he was helped by Hibil, who put some of his brightness into the mixture. Ruha also took some part, for she saw that this new world was partly formed out of her waters. This is our world, formed out of the dark substance, yet with a little of the light mingled with it.

Hibil set the sons of Ruha as sun and moon and planets in the sky. When man was made these constructed the body of Adam, while Hibil brought out a soul from the treasury of life and put it into Adam's body (GR 172).

No satisfactory derivation for the names Abatur and Ptahil has yet been found. (*See* Pallis: *Mandaean Studies*, pp. 111–114.) Abathur has become the judge and "weigher" of Mandaean souls (*see* esp. *JB* 70–72), but this does not seem to have been his original function.

Manda corresponds exactly to the Syriac *mad'ā*, which Bardaisan used for the Divine element in man (Mitchell ii. 158), distinct from knowledge, and corresponding to something between "reason" and "revelation." The actual phrase *mad'ā d'ḥayyē* occurs in the Syriac Bible in Luke i. 77 (=γνῶσιν σωτηρίας).

The Mandaean hostility to *Eshu mshiha* (Syr. *Ishō' mshīḥā*, Jesus Christ) is hostility to the fully developed post-Nicene Church. In several places "Christ" is actually called "the Byzantine" (Rumaya), and we read that the disciples of this Christ become "Christians," and turn into monks and nuns who have no children and who keep fasts and never wear white clothes like the Mandaeans (GR 55). The Holy Spirit of Catholic theology is identified by the Mandaeans with the evil Ruha. The peculiar Mandaean terminology sometimes makes the ordinary use of familiar terms impossible and other words have to be substituted. Thus *Ruha* to the Mandaeans means exclusively the evil spirit, so that they never use it, as all other Aramaic dialects do, for "wind," but use *ziḳa* (lit. "storm") instead. Similarly *Alaha* means to them "false god," so for "true God" they speak of "the Great *Mana*" or other titles. Now we have seen that "Jesus Christ" was to the Mandaeans only the Pseudo-messiah worshipped by the official Christians: the Mandaean name for the true Jesus was *Anush* (or *Enush*). In GR 29 and 53 we read that Anush-Utra comes into the world in the days of Piliaṭus (or Palṭus, *i.e.*, Pilate) the king of the world; he heals the sick, makes the blind to see, cleanses the lepers, etc. (*cf.* Luke vii. 22). (*Utra* [Syr. uthra, lit. "wealth," "treasure"] is the Mandaean term for a good spirit, so that Anush-Utra might almost be rendered "St. Enosh.") With the power of the high King of Light he raises the dead. Those who believe in him among the Jews he teaches that there is truth and error, life and death, light and darkness and burning fire. At his word 360 (or 365) prophets go out of Jerusalem and preach: then Anush ascends to the Mandaean paradise (Mshune-Kushta, "the abode of Truth") and will not be seen again by mankind till the end comes. *Kushṭa*, lit. "truth," is much used by Mandaeans for "true religion" generally; "to give Kushṭa" means to shake hands (always the *right* hand), a ceremony which takes the place of the laying on of hands in Catholic ritual. (Note that this word is spelt by Mandaeans with *k* not *ḳ*.) Before he ascended, however, he will have unmasked the Deceiver, the Byzantine Christ, who will confess that he is only Hermes-Mercury (*Nbo*), one of the deceiving Seven Planets; he will be seized by the Jews and crucified (GR 58).

What more or less orthodox Christians thought of the Mandaeans we learn from the *Scholion* of Theodore bar Konai (?Kēwāni=Saturninus) who compiled a sort of catalogue of heretics in A.D. 792. He treats them as a comparatively recent sect, founded by one Ado, a beggar (*i.e.*, a wandering fakir) from Adiabene, and says that their doctrine is borrowed from the Marcionites, from the Manichees and from the Kantaeans (or Knathaeans). Of these last, who are only known from Theodore himself, the one significant fact handed down is that they professed to derive their teaching from Abel, as in part the Mandaeans do.

In polemic against Catholic Christianity some Mandaean writers must have studied the Bible. In all cases it is the *Syriac* Bible (the Peshiṭta) of which they show knowledge. Their general grasp of Bible history and geography is extremely slight and they do not clearly distinguish the Jews from the Church Christians. (*See* esp. Pallis: *Mandaean Studies,* p. 141.) The evidence which has from time to time been brought forward to show independent Mandaean knowledge of Jewish traditions or literature breaks down on closer investigation.

Especially is this the case with regard to Mandaean tales about John the Baptist. Mandaeans use for Baptism a different word from that used by Catholic Christians, so that their conception of baptism may be more or less independent of Catholic Christianity, but the fact that they call all running water in which baptism may be performed "Jordan" must ultimately be based on the biblical stories about John.

John plays very little part in the *Ginza.* Manda d'Hayye goes down to the place where he baptizes, but the Jordan draws back before him, and he takes John (*Yuhana*) away to heavenly regions. In the *John-Book,* on the other hand, a long section is devoted to John, in which he is also called *Yahia,* the Arabic form of the name John. The tale, at least in its present form, is therefore later than the Arab conquests. In this, and also in GR 57, we read of John's aged parents, the priest Zacharia and his wife Enishbai (*i.e.,* the Syriac name *Elishba'* corrupted): it is difficult to believe that this is not derived from Luke i. Presently *Eshu meshiha* goes down and asks baptism from John, who is at first unwilling but finally complies on hearing a voice from heaven. It was, of course, a trump card for the Mandaean controversialist to be able to point out that the Jesus of the Catholics had had to be baptized by John, while the Mandaean Anush-Utra had not needed baptism. (Note that in GR v. 189–196 we have what Lidzbarski calls "the baptism of Manda d'Hayye by John." But in this tale Manda d'Hayye is *not* baptized: Manda d'Hayye asks baptism from John, but at His approach Jordan is driven back, and when Manda d'Hayye at length "gives truth"; *i.e.,* holds John by the right hand, John's soul is drawn out of his body and goes to Paradise.) But from the point of view of the modern investigator of Christian origins, the Mandaean accounts of the Baptist are both too fantastic and too near in some details to the Christian tale preserved in Luke to be regarded as in any sense independent tradition.

Baptism is called by Mandaeans *maṣbuta,* the corresponding form of which in Syriac would be *maṣbo'ithā.* The common Syriac term for baptism is *ma'modīthā,* only used by Mandaeans in speaking of Catholic baptism, which they regard with contempt as being administered in "cut off," *i.e.,* not running water. It should be noted that the Christian Palestinian dialect uses the term *maṣbo'ithā.* The Jewish term is *ṭibbūlā.* But the main difference between the Mandaean and the Christian rite is that the Mandaean *maṣbuta* is continually being repeated; it is a purification, not an initiation. Everything defiles, but running water makes all things clean: that is the Mandaean idea.

The Mandaeans have a clergy: the assistant or deacon (*shkanda*), the priest (*tarmida,* lit. "disciple") and the bishop (*ganzibra,* lit. "treasurer"). The priestly garment is called *rasta.* A sort of eucharist is given, consisting of a dough-cake (*pehta,*? Syr. *pitthā* "bit of bread") and a draught of water (*Mambuha,* lit. "fountain"): there is some reason to think that the original rite consisted of the *mambuha* alone. Their temples (*mashkana*) are small, being merely receptacles for objects used in the services, which are conducted in the courtyard outside. The congregations assemble on Sundays.

History.—No Arab accounts of "Ṣabians" or "Mughtasila" are detailed or accurate enough to be useful. Portuguese missionaries came to lower Babylonia as a result of the Portuguese occupation of Basra at the end of the 16th century, and found the Mandaeans there, a flourishing community estimated at over 14,000 souls. They were regarded as Christians of John the Baptist, and as such amenable to the Inquisition. The first account of them in Europe was in a letter from the Jesuit Pietro della Valle, dated June 1622, in which year the Portuguese lost their ascendancy in the Persian gulf. From about 1622–1651 the Jesuits were replaced by Carmelites under Ignatius a Jesu, who published in 1658 at Rome an account of the Mandaeans. A few years later some Mandaean mss. were bought for Robert Huntington, then in Aleppo, who left them to the Bodleian Library at Oxford. In 1854 the German orientalist, H. Petermann, spent three months at Suḳ esh-Shuyūkh and learnt the language from the local priest Yahya; in 1875 the grandson of this Yahya, having become a Christian, expounded the Mandaean religion to N. Siouffi, then French Consul at Baghdad, who published a full account of the modern Mandaeans at Paris in 1880.

Incantation Documents.—Quite distinct from the religious literature of the Mandaeans are two series of magical formulae described respectively by H. Pognon and M. Lidzbarski. (See *Bibliography.*) The former are written on earthenware saucers found at Khouabir, on the Euphrates between Baghdad and Kerbela. They are all formulae designed to protect so-and-so from hostile incantations.

Lidzbarski's documents consist of leaden tablets of similar content: in these the names of deities, etc., are of a more definitely Mandaean caste.

MANDALAY, formerly capital of independent Burma, now headquarters of the Mandalay division and district, as well as the chief town in Upper Burma, stands on the Irrawaddy, in 21° 59′ N. and 96° 8′ E. Built in 1856–57 by King Mindōn, it is now a municipality.

The area inside the old walls of the palace and environs was called Fort Dufferin after the annexation, though no longer used as a fort. In the centre the palace, a group of wooden buildings, many of them highly carved and gilt, resting on a brick platform 900 ft. by 500 ft., and 6 ft. high, stood until its destruction during World War II. Pop. (1941) 163,537. The population is mixed, but Burmese Buddhists number over 77% of the whole. Mandalay is thus far more Burmese than Rangoon and is a great Buddhist religious centre and the abode of very large numbers of monks (*Hpongyis*). Besides Burmese there are Zerbadis (the offspring of a Mohammedan with a Burman wife), Mohammedans, Hindus, Jews, Chinese, Shans and Manipuris (called Kathe). Trains run from Mandalay to Rangoon, to Myit-kyina, and to Lashio, the beginning of the Burma road to Kunming. Steamers also ply in all directions. There are 20 bazaars.

The MANDALAY DISTRICT has an area of 2,115 sq.mi. and a pop. (1941) of 408,926. About 600 sq.mi. along the Irrawaddy are flat land, nearly all cultivated. In the north and east there are 1,500 sq.mi. of hills and table-lands, forming geographically a portion of the Shan table-land. This part of the district is well wooded and watered. The Maymyo subdivision has plateaux of 3,000 to 3,600 feet.

The highest peaks are between 4,000 and 5,000 feet. The Irrawaddy, the Myit-ngè and the Madaya are the chief rivers. The last two come from the Shan States, and are navigable for between 20 and 30 mi.

The Sagyin hills near Madaya are noted for their alabaster. On the plains the climate is dry and healthful, the rainfall averaging about 30 inches. Considerable areas are irrigated. The hilly eastern tracts have a heavier rainfall—about 60 in.—and are forested. The extremes of temperature on the plains are considerable, the thermometer in December going down to 55° and in July up to 110°.

The DIVISION in 1941 included the districts of Mandalay, Kyaukse, Meiktila, Myingyan and Yamethin, with an area of 12,504 sq.mi. and a pop. of 1,907,703.

MANDAMUS, WRIT OF: *see* PRACTICE AND PROCEDURE; WRIT.

MANDAN. This Siouan tribe formed, with the Hidatsa and Arikara (*q.v.*), the so-called village Indians among the bison-hunting nomads of the plains in central United States. Their speech allies them rather with the Winnebago than with the Hidatsa, who in turn are close to the Crow. They lived in dome-shaped, earth-covered lodges clustered in stockaded villages; planted maize, beans, pumpkins and sunflowers; hunted buffalo seasonally; made pottery; had an origin myth of emergence from the lower world by a vine; treasured a sacred palladium in an ark; and performed ceremonies which, while containing Plains elements, were rather distinctive. The culture thus had eastern or south-eastern affiliations; their drift in the historic period was upward along the Missouri river. Numbering 1,250 in 1804, they were reduced to a fraction a few decades later by disease, especially smallpox. The recent population has been variously given, owing to virtual loss of tribal identity among the Hidatsa. Theories deriving them from the mound builders of Ohio are unwarranted, and from the Welsh, fantastic. They were known as "tattooed people" in the sign language.

MANDAN, a city of North Dakota, U.S.A., on the west bank of the Missouri river and the north bank of the Heart, 1,667 ft. above sea level; the county seat of Morton county. It is on federal highway 10 and the main line of the Northern Pacific railway. The population was 5,068 in 1925 (state census) and was 5,037 in 1930 and 6,685 in 1940 by the federal census. It is an important grain and live stock market, and division headquarters for the railroad, which has large repair shops here. There is a large flour-mill, 2 creameries, a turkey-packing plant and other manufacturing industries, and several wholesale houses with a trade territory 400 m. wide. Mandan is the seat of the State training school, a Federal dairy unit, and the U.S. Northern Great Plains Station of the Department of Agriculture, the largest dry-farming experiment station in the country. The region has vast deposits of lignite coal. Several Indian reservations are near the city, and representatives of various tribes (Sioux, Gros Ventres, Arikara and Mandan) frequent the streets. Crying Hill, now crowned by the county court-house, was the site of a village of the Mandan Indians, and was visited by La Vérendrye about 1738. Lewis and Clark spent the winter of 1804–05 a few miles north of the city. From Ft. Abraham Lincoln, 5 m. south, Gen. Custer started on his last campaign in 1876. Mandan was founded in 1872. The railroad was laid through it in 1878–79. Since 1907 it has had a commission form of government.

MANDARIN, the common name for all public officials in China, the Chinese name for whom is *kuan.* The word comes through the Portuguese from Malay *mantri,* a counsellor or minister of state. With the passing of the old order in China the term, as applied to officials, is going out of use.

By the "mandarin language" was originally meant the Chinese spoken in official and legal circles. This was the language of the capital and that of the capital was one form of the vernacular of the northern and central parts of China. Hence Mandarin is the name given to the language of common speech of these regions. It has variations, but as used by the educated it provides a commonly understood speech for more than half the nation. Latterly it is being taught in the schools in the non-Mandarin speaking sections, and so is becoming the national tongue.

Mandarin duck (*anas galericulata*) and Mandarin orange (*citrus nobilis*) possibly derive their names, by analogy, from the sense of superiority implied in the title "mandarin."

MANDASOR or MANDSAUR, a town of Central India, in the state of Gwalior, 31 mi. S. of Neemuch. Population 16,217. It gave its name to the treaty with Holkar, which concluded the Mahratta-Pindari War in 1818. It was a centre of the Malwa opium trade.

Mandasor and its neighbourhood are full of archaeological interest. An inscription discovered near the town indicated the erection of a temple of the sun in 437, and at Sondani are two great monolith pillars recording a victory of Yasodharma, king of Malwa, in 528. The fort dates from the 14th and 15th centuries.

MANDATE, a contract in Roman law constituted by one person (the *mandatarius*) promising to do something gratuitously at the request of another (the *mandator*), who undertakes to indemnify him against loss. (*See* ROMAN LAW.) The essentials and the terminology of the contract are preserved in most modern systems; but in English law mandate, under that name, can hardly be said to exist as a separate form of contract. To some extent the law of *mandatum* corresponds to the law of principal and agent (*q.v.*). "Mandate" is retained to signify the contract more generally known as gratuitous bailment. It is restricted to personal property, and it implies the delivery of something to the bailee, both of which conditions are unknown in the *mandatum* of the civil law (*see* BAILMENT).

The Mandate System.—This is a term applied to the conditions set up by the Treaty of Versailles for the administration of the former overseas possessions of Germany and Turkey. Mandatory Powers are those Powers which were selected by the Supreme Council of the Allies to administer these territories under mandate. The system is a novel experiment in the relations between a sovereign State and a country under its control, involving new departures in international law. It was created by Art. 22 of the Covenant of the League of Nations, which formed part of the Treaty of Versailles, and has thus gained the recognition of all States that are members of the League.

In its origin it was in the nature of a compromise. After the World War the victorious Allies naturally wished to retain the German and Turkish colonies, in the conquest of which they had in most cases made great sacrifices. It was believed that these colonies had been subjected to misrule; pledges had been made to the native inhabitants, some of whom had taken part with the victors in the fighting, that they should not be handed over to the vengeance of their former masters; and finally, a misgiving existed lest, in case of rendition, Germany might use them as recruiting grounds for black armies, and their ports as bases for submarines in a future war. On the other hand the Allies had declared (more particularly in the pre-Armistice statement of Nov. 5, 1918) that annexation of territory was not their aim in the war.

International control of some kind was the only alternative. Joint administration was condemned as impracticable and opposed to the interests of the people. Even as a condominium between two Powers only, it had given rise to friction in Egypt, Samoa and the New Hebrides. The only other course lay in the appointment of an individual Power in whom could be vested responsibility for the administration of each separate territory as an agent, or mandatory, of the League. For this course there were analogies in the delegation of quasi-sovereign powers to British and Dutch chartered companies and in the control of the Ionian Isles on behalf of the Powers by Great Britain in 1859. Individuals also had been appointed as mandatories of the Powers, as when King Leopold undertook control of the "International Free State of the Congo," and when Prince George of Greece was made governor of Crete in 1898.

The main defect of these delegations of sovereignty was that they provided no machinery to ensure the due execution of the trust, and it is the distinctive feature of the mandate system that it attempts to remedy this defect. The League of Nations afforded just such a supervisory authority as was needed, and its supervision is exercised through the medium of a standing committee, known as the "Permanent Mandates Commission." The League had nothing to do with the assignment of the mandates or with their terms, or with the extent and boundaries of the territories. These were determined by the Supreme Council. The United States, not being a member of the League, was no party to this arrangement, and she insisted that as an Associated Power her consent was necessary. The mandates therefore were submitted to her, and approved on condition that "free and equal treatment in law and in fact was secured to the commerce of all nations." Where the mandate did not ensure this she negotiated separate treaties with the mandatory concerned.

Terms of the Mandates.—The mandates were framed to give expression in detail to the principles embodied in Art. 22 of the Covenant (*q.v.*), and since that article prescribes that their character must vary with the varying conditions of each territory, they were divided into three classes to correspond with the three paragraphs of that article.

Class A included the former Turkish vilayets of 'Iraq, Palestine and Syria, whose independence was to be provisionally recognized until they were able to stand alone. The two former were assigned to Great Britain, the latter to France. The mandates for 'Iraq and Syria ended in 1932 and 1936 respectively.

Class B comprises the ex-German central African colonies—Togoland, Cameroons, Tanganyika and Ruanda—in which the mandatory is responsible for the administration and undertakes to promote the moral and material welfare of the people. Tanganyika, and a small part of the Cameroons and Togo fell to Great Britain, the major portions of the two latter being assigned to France, while Belgium became responsible for Ruanda.

Class C territories include those which "can best be administered under the laws of the mandatory as integral portions of its territories, subject to the safeguards in the interests of the indigenous population" which are laid down for Class B. They are south-west Africa, Samoa, New Guinea, the islands north of the equator in the west Pacific and the tiny island of Nauru. For these respectively the Union of South Africa, New Zealand, Australia, Japan and the British empire accepted mandates.

In the case of Nauru, Great Britain, Australia and New Zealand had by agreement in July 1919 (before the issue of the mandate), jointly acquired control of the phosphate deposits, which constitute the sole value of the island, and they jointly undertook the execution of the mandate. Since, however, the British empire has no single code of laws, the administration was assigned by the two others to Australia for five years.

The "safeguards in the interests of the indigenous population" to which reference is made are: (1) freedom of conscience and religion, subject only to the maintenance of public order and morals; (2) prohibition of abuses such as the arms and liquor traffic and the slave-trade; and (3) prevention of fortifications, naval and military bases, and the military training of natives except for police and the defence of the territory.

The mandates after acceptance by each mandatory were submitted to the Council of the League, which was charged with the duty of seeing that their terms were in accord with the Covenant. The A class could not be issued until the Treaty of Lausanne came into force (Aug. 1924). Meanwhile an Arab Government had been set up in 'Iraq, and a treaty had been concluded by Great Britain with it. On Sept. 27, 1925, the council formally accepted the undertaking of the mandatory to see that the terms of this treaty (which embodied the obligations of the Covenant) were adhered to, and this undertaking was substituted for the mandate. Pending the issue of the mandate, the territories were administered in accordance with the terms of the Covenant or under provisional mandates. These terms are explicit. The mandate is a "sacred trust of civilization" to be assumed by nations who (*inter alia*) "by reason of their resources can best undertake this responsibility and are willing to accept it." The altruistic nature of this pledge was confirmed in a reply to a German protest. "The Mandatory Powers," said the Allies, "in so far as they may be appointed trustees by the League of Nations, will derive no benefit from such trusteeship."

A mandated territory differs from a protectorate in that the protecting Power in the latter obtains rights over the population and against other Powers, whereas a mandatory in its capacity as guardian assumes obligations both toward the population and the League.

League Supervision.—The system, it has been said, differs from such partial precedents as have been cited, in that it attempts to set up machinery by which the proper execution of the mandate may be assured. This consists in the unqualified right of supervision vested in the League which imposes upon each mandatory the obligation to submit an annual report on its administration.

These reports are examined by a permanent mandates commission in the presence of an accredited representative of the mandatory concerned. The commission originally consisted of nine members of the following nationalities: Belgian, British, Dutch, French, Italian, Japanese, Portuguese, Spanish and Swedish. To these a Swiss and a German have since been added. The majority are nationals of non-mandatory States. They are selected "for personal merit and competence" as private individuals, and not as representatives of their respective nations. They are nominated by their Governments, but approved and appointed by the Council of the League, and may not hold any office under their Government. A representative of the International Labour office attends the sessions, and takes part in any discussions relative to labour. This international composition negatives any suspicion of bias, and gives to the commission the aspect of an impartial tribunal of practical men, whose object it is to promote co-operation while fearlessly exposing any breach of the Covenant. Its functions are purely advisory to the council.

In addition to the annual review of the reports of the mandatories, the commission receives any petitions and memorials from inhabitants of the territories and others interested, and these, unless trivial or irrelevant, are forwarded to the mandatory concerned for his comments before examination by the commission. The proceedings are conducted in French and English, and are generally held in private to facilitate freedom of discussion. Full minutes are printed, which, together with the memoranda on special subjects and all other pertinent papers, can be obtained from the League publication department, or from its agents in London and other European capitals. A permanent secretariat, under a director, collects and circulates all documents of interest concerning mandates and conducts the routine business. The commission meets at least twice in the year at Geneva, and its procedure is governed by rules approved by the council.

The weak point in the system lies in the impossibility of independent verification of statements contained in the reports—a difficulty inherent in the circumstances. For information not contained in the report, therefore, the commission must rely on those public bodies or individuals who interest themselves in the welfare of native races, and on such memorials and petitions as may be presented to it. In order to obtain more accurate information, the actual administrators now generally appear as the mandatory's representatives. The sole means at the disposal of the League for compelling the proper execution of the mandate is the force of public opinion.

The French mandates in west Africa—unlike the British mandates for portions of the same territories (Cameroons and Togo) —contain a clause to the effect that "troops thus raised" (*i.e.*, for purposes of local defence and police) "may in the event of general war be utilized to repel an attack, or for defence of the territory outside that subject to the mandate." It is difficult to reconcile this clause with the words of the Covenant. At the instance of the Mandates Commission the British Government was willing to go even further than the Covenant prescribes, and to agree to pledge itself not to enlist the natives of a mandated territory, even though they offered themselves for enlistment outside its frontiers—thus limiting its sovereign rights in adjacent territories not under mandate. The French Government has declared its willingness to accept the same restriction.

Liquor Traffic.—The Covenant enjoins the "prohibition of abuses such as the slave-trade, the arms traffic and the liquor traffic." Some have urged that these words mean the enforcement of total prohibition alike for natives and non-natives. The mandates, however, only prescribe a "strict *control* over the sale of spirituous liquors," and the St. Germain Convention (Sept. 1919), concluded soon after the Versailles Treaty by the same signatories, forbids the import of "trade spirits" only. The commission, therefore, asked the council for an authoritative decision as to the precise meaning of the terms used in the mandates and the Covenant, and at its request submitted the following definitions which were referred to the mandatories.

Spirituous Liquors shall be taken to mean (*a*) all distilled beverages, (*b*) all fermented beverages to which distilled products have been added so as to contain over 20 degrees of pure alcohol by weight. *Trade Spirits* shall be taken to mean cheap spirits utilized as articles of trade or barter with the natives. *Intoxicating beverages* means any beverage containing more than three degrees of pure alcohol by weight.

In the matter of equal commercial opportunity for all nations, the Covenant itself failed to fulfil the expectations raised by the pre-Armistice declarations of the Allies. No obligation in this regard is imposed in the C mandates, while in the B class it is restricted to States which are members of the League.

Boundaries.—Another cause of practical difficulty is presented by the fact that in most cases the boundaries of the territories assigned under mandate were not defined, and it was apparently left to the individual mandatories to adjust them without reference to the League.

In the case of 'Iraq this led to an acute dispute with Turkey in regard to the northern boundary. It was eventually settled by a special commission appointed by the League, at the instance of Great Britain. The southern frontiers were the subject of an agreement with the sultan of Nejd, and an Anglo-French agreement determined the frontiers with Syria. The French in northern Syria had similar difficulties with Turkey, to whom they ceded Cilesia. In the Cameroons a joint commission was set up to determine the precise boundaries, while as regards Ruanda, the mandatory (Belgium) complained that the agreed boundary involved the loss to King Musinga of a considerable part of his territory. The British at once agreed that this area should be restored to him, and the consequent changes in the mandates were approved by the council. In south-west Africa a "neutral zone" had long existed between the German and Portuguese colonies, which has now been replaced by a precise demarcation, embodied in a treaty between the Union of South Africa and the Portuguese Government.

Wider issues are raised by such questions as the nature and extent of sovereignty exercised by a mandatory and the international status of the inhabitants of a mandated territory. The former—which has been much debated by American publicists—is rather academic and juridical than of practical interest. It suffices for practical purposes that the mandatory has the absolute right to make and enforce laws, to raise troops, to set up tribunals, to appoint officials and to raise and spend revenues. Sovereignty was not ceded by the Treaty of Versailles to the League, but to the victorious Allies—indeed the highest court in South Africa has recorded the opinion that the territories were not ceded at all, but placed by Germany at the disposal of the Allies, to be administered under mandate—a status new to international law.

The mandatory's powers are exercised "in its capacity as such." It has, for instance, been satisfactorily established by the Mandates Commission that such terms as "Crown (or State) lands" and *domaines d'état*, where they appear in local ordinances, refer only to lands which are the property of the mandatory as such, in other words, to the mandated territory, and that any action on the part of the mandatory which had for its object (or would ultimately involve) annexation—as for instance the acquisition of large monopolistic rights, or of essential public services—would be contrary to the spirit of the Covenant and the mandate.

Status of Natives.—The status of the indigenous inhabitants of a B or C mandate territory has on the other hand been the subject of special definition. Obviously, since the country is not annexed, they do not become the subjects of the mandatory. The formula was therefore adopted by the council that "they should be designated by some form of descriptive title which will identify them as such," viz., as "persons administered or protected under mandate." This confers no juridical status, and no privilege of citizenship, but Art. 327 of the treaty stipulates that they should be entitled to the diplomatic protection of the mandatory when outside the mandated territory, and individuals may if they so desire become naturalized subjects of the mandatory.

The application to mandated territories of special conventions, entered into by a mandatory Power, has also been the subject of investigation and recommendation by the Mandates Commission, in order to ensure that "persons protected under mandate" shall not be in a less favourable position in regard to their persons and property and their economic interests than the inhabitants of a protectorate or colony.

The revocation of a mandate for maladministration, though theoretically possible, is in practice unthinkable. The terms of the Covenant therefore contemplate self-government as the natural fruition of the mandate—in the case of the A class at no distant date. The new State would then take its place as a member of the League.

The mandate system accords, for the first time in history, international sanction to the principle of trusteeship, and of public responsibility to a supervising authority for the obligations laid down in the trust deed in regard to mandated territories. The annual report forms an effective means of inviting a popular verdict on the fulfilment of the trust, and this supervision constitutes a fundamental distinction from annexation, whatever the degree of assimilation to other possessions of the mandatory. The League exercises supervision but not control, for the ultimate authority to which the stewardship of the mandatory is submitted is the public opinion of the civilized world. The standards of the Covenant must obviously in the future be regarded as principles of general application. The mandate system is an international acknowledgment of the responsibility which the advantages of a superior intellectual culture and 20 centuries of Christian ethics no less than the physical superiority conferred by the monopoly of firearms impose upon those Powers which have accepted control of backward races. (*See* LEAGUE OF NATIONS.)

BIBLIOGRAPHY.—The mandates section of the League secretariat has issued a *List of Books and Pamphlets relating to the Mandates System and to Territories under Mandate*. A bibliography has also been prepared by the Royal Colonial Institute. *See* especially Freda White, *Mandates, etc.* (1926); D. P. W. Van Rees, *Les Mandats Internationaux* (1927); L. M. Palacios, *Los Mandatos Internacionales de la Sociedad de Naciones* (1927). (LU.)

MANDAUE, a municipality (with administrative centre and 26 *barrios* or districts) of the province and island of Cebu, Philippine Islands, on the east coast about four miles N.E. of Cebu, the provincial capital. Pop. (1939) 17,431 of whom 8,464 were males and four white. The principal industries are agriculture and the manufacture of salt from sea water. The chief crops are maize (corn) and sugar. The vernacular is Cebuano, a dialect of Bisayan. Of the inhabitants aged 6 to 19 inclusive, 39·2% in 1939 attended school; 47·7% of the population 10 years old and over was literate.

MANDAYA, a tribe of Mindanao island in the Philippines, which lives in tree dwellings, several families in one house; cultivates scanty plots of rice and other crops; practises slavery and ceremonial cannibalism, eating part of the liver of a slain enemy, but not genuine head-hunting (*q.v.*). As offensive weapons, spears, daos, daggers and poisoned arrows are used; as defensive, light wooden shields, cloth protective armour, and bamboo caltrops. The turtle-dove is regarded as sacred and spirits are worshipped by mediums (*ballyan*), generally female, and are associated with wooden figures representing ancestors. Groups are governed by warrior leaders (*bagani*) whose rank is acquired by the killing of many enemies, as insignia for which a red costume is worn. Half a red costume (trousers only) is awarded for exploits not worthy of the whole. They do not tattoo, but file and blacken the teeth. They have been erroneously reported to be white in complexion.

See Cole, *Wild Tribes of Davao District* (1913).

MANDELIC ACID, discovered by F. L. Winckler (1832) in an emulsion of bitter almonds. (*See* GLYCOSIDES, NATURAL.) It is most conveniently obtained in colourless rhombic prisms, melting at 118° C, with sp.gr. 1.364, and soluble in water, alcohol or ether, from commercial benzaldehyde (*q.v.*) by adding concentrated aqueous sodium hydrogen sulphite to a mixture of benzaldehyde and aqueous sodium cyanide; oily mandelonitrile, $C_6H_5.CH(OH).CN$, separates and is hydrolysed to mandelic acid (phenylglycollic acid, phenyl-α-hydroxyacetic acid), $C_6H_5.CH(OH)\cdot CO_2H$, at the ordinary temperature with concentrated hydrochloric acid. The acid may be extracted with benzene or ether (*see* H. Gilman and others, *Organic Syntheses,* vol. VI., 1926). Mandelic acid contains an asymmetric carbon atom and is accordingly resolvable into two optically active isomerides (*see* STEREOCHEMISTRY). This resolution has been accomplished, (1) through the agency of the alkaloid cinchonine, which furnishes a less soluble salt with *dextro*-mandelic acid, and (2) by means of living organisms. The yeast *Saccharomyces ellipsoideus* removes the *d*-modification and leaves the *laevo*-mandelic acid, whereas the mould, *Penicillium Glaucum,* destroys the *l*-form in a solution of ammonium mandelate, leaving the *dextro*-mandelic acid. The two optically active forms, which melt at 132·8° C, are less fusible and more sparingly soluble in water than the inactive or racemoid variety, which has been termed paramandelic acid. A mixture of equal weights of the two active forms produces the inactive acid, which is also obtained on heating either active form at 160° C.

MANDER, CAREL VAN (1548–1606), Dutch painter, poet and biographer, was born of a noble family at Meulebeke. He studied under Lucas de Heere at Ghent, and in 1568–69 under Pieter Vlerick at Courtrai and Tournai. The next five years he devoted to writing religious plays, for which he painted the scenery. Then for three years (1574–1577), he studied in Rome under various masters and drew in the catacombs. On his return journey he passed through Vienna, where, together with the sculptor Hans Mont, he made the triumphal arch for the entry of the emperor Rudolph. After many vicissitudes he settled at Haarlem, where, with Goltzius and Cornelisz, he founded a successful academy of painting. His fame is principally based upon a biographical work on the paintings of various epochs—a book that has become for the northern countries what Vasari's *Lives of the Painters* became for Italy. It was completed in 1603 and published in 1604, in which year Van Mander went to Amsterdam, where he died on Sept. 2, 1606. He translated Virgil's *Bucolics* and *Georgics.*

His *Het Schilderbouck* (Haarlem, 1604) was translated into French by H. Hymans (Paris, 1884), and into German by H. Floerke (Munich, 1906). The poem in 14 chapters dealing with the technique of painting, which forms the introduction, was used as a source of information by Charles Eastlake in *Materials for a History of Oil Painting* (1847, pub. separately with German trs. by R. Haecker, *Das Lehrgedicht des Karel van Mander,* The Hague, 1916).

MANDEVILLE, BERNARD DE (1670–1733), English philosopher and satirist, was born at Dordrecht, where his father practised as a physician. On leaving the Erasmus school at Rotterdam he gave proof of his ability by an *Oratio scholastica de medicina* (1685), and at Leyden university in 1689 he maintained a thesis *De brutorum operationibus,* in which he advocated the Cartesian theory of automatism among animals. In 1691 he took his medical degree, pronouncing an "inaugural disputation," *De chylosi vitiata.* Afterwards he came to England "to learn the language," and succeeded so remarkably that many refused to believe he was a foreigner. He died in January (19th or 21st) 1733–4 at Hackney.

The work by which he is known is the *Fable of the Bees or Private Vices made Public Benefits,* published first in 1705 under the title of *The Grumbling Hive, or Knaves Turn'd Honest* (two hundred doggerel couplets) and often reprinted, with additions. The book was primarily written as a political satire on the state of England in 1705, when the Tories were accusing Marlborough and the ministry of advocating the French War for personal reasons. The edition of 1723 was presented as a nuisance by the Grand Jury of Middlesex, was denounced in the *London Journal* by "Theophilus Philo-Britannus," and attacked by many writers, notably by Archibald Campbell (1691–1756) in his *Aretelogia* (published as his own by Alexander Innes in 1728; afterwards by Campbell, under his own name, in 1733, as *Enquiry into the Original of Moral Virtue*). Berkeley attacked it in the second dialogue of the *Alciphron* (1732) and John Brown criticized him in his *Essay upon Shaftesbury's Characteristics* (1751).

Mandeville's main thesis is that the actions of men cannot be divided into lower and higher. The higher life of man is merely a fiction introduced by philosophers and rulers to simplify government and the relations of society. It is the vices (*i.e.,* the self-regarding actions of men) which alone, by means of inventions and the circulation of capital in connection with luxurious living, stimulate society into action and progress. Mandeville's ironical paradoxes are interesting mainly as a criticism of the "amiable" idealism of Shaftesbury, and in comparison with the serious egoistic systems of Hobbes and Helvetius. He may be said to have cleared the ground for the coming utilitarianism.

WORKS.—*Typhon: a Burlesque Poem* (1704); *Aesop Dress'd, or a Collection of Fables writ in Familiar Verse* (1704); *The Planter's Charity* (1704); *The Virgin Unmasked* (1709, 1724, 1731, 1742), a work in which the coarser side of his nature is prominent; *Treatise of the Hypochondriack and Hysterick Passions* (1711, 1715, 1730) admired by Johnson (Mandeville here protests against merely speculative therapeutics, and advances fanciful theories of his own about animal spirits in connection with "stomachic ferment": he shows a knowledge of Locke's methods, and an admiration for Sydenham); *Free Thoughts on Religion* (1720); *A Conference about Whoring* (1725); *An Enquiry into the Causes of the Frequent Executions at Tyburn* (1725); *The Origin of Honour and the Usefulness of Christianity in War* (1732); *A Letter to Dion occasioned by his book called Alciphron* (1732). Other works attributed, probably wrongly, to him are *A Modest Defence of Public Stews* (1724); *The World Unmasked* (1736) and *Zoologia medicinalis hibernica* (1744).

See Hill's *Boswell,* iii. 291–293; L. Stephen's *English Thought in the Eighteenth Century;* A. Bain's *Moral Science* (593–598); Windelband's *History of Ethics* (Eng. trans. Tufts); J. M. Robertson, *Pioneer Humanists* (1907); P. Sakmann, *Bernard de Mandeville und die Bienenfabel-Controverse* (Freiburg i/Br., 1897), and articles ETHICS; SHAFTESBURY, ANTHONY ASHLEY COOPER; HOBBES, THOMAS.

MANDEVILLE, GEOFFREY DE (d. 1144), earl of Essex, succeeded his father, William, as constable of the Tower of London in or shortly before 1130. Though a great Essex landowner, he played no conspicuous part in history till 1140, when Stephen created him earl of Essex in reward for his services against the empress Matilda. After the defeat and capture of Stephen at Lincoln (1141) the earl deserted to Matilda, but before the end of the year, learning that Stephen's release was imminent, returned to his original allegiance. In 1142 he was again intriguing with the empress; but before he could openly join her cause he was detected and deprived of his castles by the king. In 1143–1144 Geoffrey maintained himself as a rebel and a bandit in the fen-country, using the Isle of Ely and Ramsey Abbey as his headquarters. He was besieged by Stephen in the fens, and met his death in Sept. 1144 in consequence of a wound received in a skirmish. His career is interesting for two reasons. The charters which he extorted from Stephen and Matilda illustrate the peculiar form taken by the ambitions of English feudatories. The most important concessions are grants of offices and jurisdictions which had the effect of making Mandeville a viceroy with full powers in Essex, Middlesex and London, and Hertfordshire. His career as an outlaw exemplifies the worst excesses of the anarchy which prevailed in some parts of England during the civil wars of 1140–47, and it is probable that Mandeville inspired the rhetorical description, in the Peterborough Chronicle of this period, when "men said openly that Christ and his saints were asleep."

See J. H. Round, *Geoffrey de Mandeville, a Study of the Anarchy* (1892). (H. W. C. D.)

MANDEVILLE, JEHAN DE ("Sir John Mandeville"), the name claimed by the compiler of a singular book of travels, written in French, and published between 1357 and 1371. By aid of translations into many other languages it acquired extraordinary popularity, while a few interpolated words in a particular edition of an English version gained for Mandeville in modern times the certainly spurious credit of being "the father of English prose."

In his preface the compiler calls himself a knight, and states that he was born and bred in England, of the town of St. Albans; had crossed the sea on Michaelmas Day 1322; had travelled by way of Turkey (Asia Minor), Armenia the little (Cilicia) and the great, Tartary, Persia, Syria, Arabia, Egypt upper and lower, Libya, great part of Ethiopia, Chaldaea, Amazonia, India the less, the greater and the middle, and many countries about India; had often been to Jerusalem, and had written in Romance as more generally understood than Latin. In the body of the work we hear that he had been at Paris and Constantinople; had served the sultan of Egypt a long time in his wars against the Bedawin, had been vainly offered by him a princely marriage and a great estate on condition of renouncing Christianity, and had left Egypt under sultan Melech Madabron, *i.e.,* Muzaffar or Mudhaffar[1] (who reigned in 1346–1347); had been at Mount Sinai, and had visited the Holy Land with letters under the great seal of the sultan, which gave him extraordinary facilities; had been in Russia, Livonia, Cracow, Lithuania, "en roialme daresten" (? of Daresten or Silistria), and many other parts near Tartary, but not in Tartary itself; had drunk of the well of youth at Polombe (Quilon on the Malabar coast), and still seemed to feel the better; had taken astronomical observations on the way to Lamory (Sumatra), as well as in Brabant, Germany, Bohemia and still farther north; had been at an isle called Pathen in the Indian Ocean; had been at Cansay (Hangchow-fu) in China, and had served the emperor of China fifteen months against the king of Manzi; had been among rocks of adamant in the Indian Ocean; had been through a haunted valley, which he places near "Milstorak" (*i.e.,* Malasgird in Armenia); had been driven home against his will in 1357 by arthritic gout; and had written his book as a consolation for his "wretched rest."

This personal history of Mandeville is mere invention. There is no reasonable doubt that the travels were in large part compiled by a Liége physician, known as Johains à la Barbe or Jehan à la Barbe, otherwise Jehan de Bourgogne, who drew his information not from his own travels, but from the works of Odoric, Carpini, Vincent de Beauvais, and others. Jehan à la Barbe is himself a man of mystery.

A modernized extract quoted by the Liége herald, Louis Abry (1643–1720), at third or fourth hand from the lost fourth book of the *Myreur des Hystors* of Johans des Preis, styled d'Outremeuse, states that "Jean de Bourgogne, dit à la Barbe," revealed himself on his deathbed to d'Outremeuse, whom he made his executor, and described himself in his will as "messire Jean de Mandeville, chevalier, comte de Montfort en Angleterre et seigneur de l'isle de Campdi et du château Pérouse." Having had the misfortune to kill an unnamed count in his own country, he engaged himself to travel through the three parts of the world, arrived at Liége in 1343, was a great naturalist, profound philosopher and astrologer, and had a remarkable knowledge of physic. In the now destroyed church of the Guillelmins was a tombstone of Mandeville, with a Latin inscription stating that he was otherwise named "ad Barbam," was a professor of medicine, and died at Liége on Nov. 17, 1372; this inscription is quoted as far back as 1462.

[1]The *on* in Madabron apparently represents the Arabic form, though, as a matter of fact, its use in such a case is very odd.

Whether after the appearance of the *Travels* either de Bourgogne or "Mangevilayn" visited England is very doubtful. St. Albans Abbey had a sapphire ring, and Canterbury a crystal orb, said to have been given by Mandeville; but these might have been sent from Liége, and it will appear later that the Liége physician possessed and wrote about precious stones. St. Albans also had a legend that a ruined marble tomb of Mandeville (represented cross-legged and in armour, with sword and shield) once stood in the abbey.

It is a little curious that the name preceding Mangevilayn in the list of persons pardoned is "Johan le Barber." But Dr. G. F. Warner has ingeniously suggested that de Bourgogne may be a certain Johan de Bourgogne, who was pardoned on Aug. 20, 1321. Did this suggest to de Bourgogne the *alias* "à le Barbe," or was that only a Liége nickname? Note also that the arms on Mandeville's tomb were borne by the Tyrrells of Hertfordshire (the county in which St. Albans lies); for of course the crescent on the lion's breast is only the "difference" indicating a second son.

The Sources.—Leaving aside the stories which have grown up around the Liége physician, there remains the question whether the book contains any facts and knowledge acquired by actual travels and residence in the East. Possibly it may, but only in a small portion of the section which treats of the Holy Land and the ways of getting thither, of Egypt, and in general of the Levant. Even this section seems to be based on the travels of William of Boldensele (1336). The prologue, indeed, points almost exclusively to the Holy Land as the subject of the work. The mention of more distant regions comes in only towards the end of this prologue, and (in a manner) as an afterthought.

By far the greater part of these more distant travels, extending in fact from Trebizond to Hormuz, India, the Malay Archipelago, and China, and back again to western Asia, has been appropriated from the narrative of Friar Odoric (written in 1330). These passages, as served up by Mandeville, are almost always, indeed, swollen with interpolated particulars, usually of an extravagant kind, whilst in some cases the writer has failed to understand the passages which he adopts from Odoric and professes to give as his own experiences. Thus where Odoric has given a most curious and veracious account of the Chinese custom of employing tame cormorants to catch fish, the cormorants are converted by Mandeville into "little beasts called *loyres* (*layre,* B), which are taught to go into the water" (the word *loyre* being apparently used here for "otter," *lutra,* for which the Provençal is *luria* or *loiria*). Much, again, of Mandeville's matter, particularly in Asiatic geography and history, is taken from the *Historiae Orientis* of Hetoum, an Armenian of princely family, who became a monk of the Praemonstrant order, and in 1307 dictated this work on the East, in the French tongue at Poitiers. A good deal about the manners and customs of the Tatars is demonstrably derived from the famous work of the Franciscan Joannes de Plano Carpini (*q.v.*), but Dr. Warner considers that much was taken at second hand and that Mandeville's immediate source was the *Speculum historiale* of Vincent de Beauvais.

The account of Prester John (*q.v.*) is taken from the famous *Epistle,* which was so widely diffused in the 13th century, and created that renown which made it incumbent on every traveller in Asia to find some new tale to tell of him. Many fabulous stories, again, of monsters, such as Pliny has collected, are introduced here and there, derived no doubt from him, Solinus, the bestiaries, or the *Speculum naturale.* And interspersed, especially in the chapters about the Levant, are the stories and legends that were retailed to every pilgrim, such as the legend of Seth and the grains of paradise from which grew the wood of the cross, that of the shooting of old Cain by Lamech, that of the castle of the sparrow-hawk (which appears in the tale of Melusina), those of the origin of the balsam plants at Maṭarīya, of the dragon of Cos, of the river Sabbation, etc.

While recording Mandeville's borrowings it is only fair to recognize his imaginative powers; a notorious passage, filched, with additions, from Boldensele, seems likely to have inspired the Valley of the Shadow of Death in *Pilgrim's Progress.* Nor does it follow that the whole work is borrowed or fictitious. In such works as those of Jan van Hees and Arnold von Harff we have examples of pilgrims to the Holy Land whose narratives begin apparently in sober truth, and gradually pass into flourishes of fiction and extravagance. So in Mandeville also we find particulars not yet traced to other writers, and which may therefore be provisionally assigned either to the writer's own experience or to knowledge acquired by colloquial intercourse in the East.

BIBLIOGRAPHY.—The oldest known ms. of the original—once Barrois's, afterwards the earl of Ashburnham's, now Nouv. Acq. Franç. 4515 in the Bibliothèque Nationale, Paris—is dated 1371, but is nevertheless very inaccurate in proper names. The first English translation direct from the French was made (at least as early as the beginning of the 15th century) from a ms. of which many pages were lost.

For Mandeville's sources *see* A. Bovenschen, *Die Quellen für die Reisebeschreibung des Johann von Mandeville, Inaugural-Dissertation . . . Leipzig* (Berlin, 1888), revised and enlarged as "Untersuchungen über Johann von Mandeville und die Quellen seiner Reisebeschreibung," in the *Zeitschrift der Gesellschaft für Erdkunde zu Berlin,* Bd. 23, Heft 3 u. 4 (No. 135, 136), and G. F. Warner, in the edition prepared for the Roxburghe Club.

All English printed texts before 1725, and Ashton's 1887 edition, follow these defective copies.

The Egerton text (Brit. Mus. ms. Egerton 1982) edited by Dr. G. F. Warner, has been printed by the Roxburghe Club, while the Cotton text (Brit. Mus. ms. Cotton Titus C xvi.), first printed in 1725 and 1727, is in modern reprints the current English version.

That none of the forms of the English version can be from the same hand which wrote the original is made patent by their glaring errors of translation, but the Cotton text asserts in the preface that it was made by Mandeville himself. Mätzner (*Altenglische Sprachproben,* I., ii., 154–155) seems to have been the first to show that the current English text cannot possibly have been made by Mandeville himself. Other works bearing the name of Mandeville or de Bourgogne are a short French life of St. Alban of *Germany,* the author of which calls himself Johan Mandivill[e], knight, formerly of the town of St. Alban, contained in ms. Add. C. 280 of the Bodleian; a *Lapidaire* printed in L. Pannier, *Les Lapidaires français;* and there are medical and alchemical receipts in the Ashmolean mss. in the Bodleian by John de Villa Magna. Finally, de Bourgogne wrote under his own name a treatise on the plague, *see* David Murray, *The Black Book of Paisley,* etc. (1885), and *John de Burdeus,* etc. (1891) extant in Latin, French and English texts, and in Latin and English abridgments. Herein he describes himself as Johannes de Burgundia, otherwise called *cum Barba,* citizen of Liége and professor of the art of medicine; says that he had practised forty years and had been in Liége in the plague of 1365; and adds that he had previously written a treatise on the cause of the plague, according to the indications of astrology (beginning *Deus deorum*), and another on distinguishing pestilential diseases (beginning *Cum nimium propter instans tempus epidimiale*). "Burgundia" is sometimes corrupted into "Burdegalia," and in English translations of the abridgment almost always appears as "Burdews" (Bordeaux) or the like. Ms. Rawlinson D. 251 (15th century) in the Bodleian also contains a large number of English medical receipts, headed "Practica phisicalia Magistri Johannis de Burgundia."

See further Dr. G. F. Warner's article in the *Dictionary of National Biography* for a comprehensive account, and for bibliographical references; Ulysse Chevalier's *Répertoire des sources historiques du moyen age* for references generally; and the *Zeitschr. f. celt. Philologie* II., i. 126, for an edition and translation, by Dr. Whitley Stokes, of Fingin O'Mahony's Irish version of the *Travels.* (E. W. B. N.; H. Y.)

MANDHATA, a famous place of Hindu pilgrimage in the Nimar district of the Central Provinces of India, partly on the south bank of the River Nerbudda and partly on an island in the river. One of the temples is famous for containing one of the twelve great *Lingas* of Siva. Its annual fair was formerly the scene of the self-immolation of devotees who threw themselves from the high cliffs into the river. The last sacrifice, which was witnessed by a British officer, occurred in 1824.

MANDI, an important Indian hill State, within the Punjab, under British influence since the first Sikh War (1846). The country is intersected by two great parallel ranges, with average height 5,000 to 7,000 ft. above sea-level. The valleys are fertile, and produce all ordinary grains, besides more valuable crops of rice, maize, sugar-cane, and tobacco. Area, 1,139 sq.mi.; pop. (1941), 232,593; estimated revenue, £93,000. An important product of the state is salt, mined in two places.

The town of Mandi is on the Beas, a mountain torrent, crossed by a fine iron bridge, 2,991 ft. above sea-level. Pop. (1941), 9,033. It is a mart for transfrontier trade with Tibet and Yarkand.

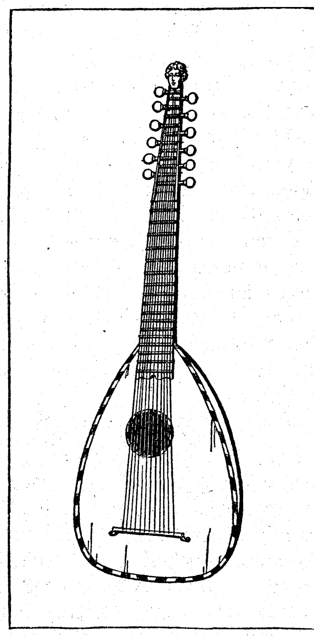
MANDINGA, a vigorous, well-proportioned, longheaded, big-jowled, flat-nosed people with projecting cheekbones and regular features, inhabiting the western Sudan, originally from an area known as Mane, Mande, Mani, Mandi or Manding, in the Upper Niger. The Fulani call them Malinke and the Hausa name for them is Wangara. From 1235 to 1680 they formed an empire but are no longer even a political unity. The following groups are distinguishable: (*a*) the Malinke (upper valleys of the Niger, Bafing and Gambia, and the district on the fringe of the dense forest); (*b*) the Bambara or Banmana (between the Niger and the Bani rivers, the Bamako district, and Sahel); and (*c*) the Jula (colonies east of the Bani). The language of the Mandinga belongs to the Niger-Senegalese family, with dialects Malinke, Bambara and Jula. Marriage by exchange is common, the women having no voice in the matter; both dowry and dower are customary. Descent is matrilineal among the Malinke. The extended family group (*Gwa* or *Gba*), ordinarily comprising four generations, is the social unit, with family property in common but individual ownership of personal possessions. Inheritance passes to the brother of the deceased and then to the eldest son; women never inherit but are themselves part of the heritable property. A number of such family groups form the village (*dugu*); several villages and their townlands constitute the territorial group (*kafo*), and a number of such groups constitute the county (*jamana*) ruled by the *Mansa* or *Massa* with councillors and a chancellor of the exchequer. Clans, whose members have the same name and common taboos, still exist but are unorganized. The village and the territorial group are the units of Mandinga organization; the politico-religious hierarchies depend on the secret societies (*Ntomo, Nama, Komo*), which group the people into age classes. Cultivators and cattle-raisers for the most part, some of the Mandinga (the Jula) are traders. In mediaeval times certain noble families became adherents of Islam but the people in general are still animists and have agrarian festivals and seasonal rites.

See Monteil, *Les Khassonké* (1915), *Les Bambara de Ségou et de Kaarta* (1924); Moussa Travelé, *Proverbes et Contes Bambara accompagnés d'une traduction française et d'un abrégé de droit coutumier* (1923).

MANDLA, a town and district of British India in the Jubbulpore division of the Central Provinces on the river Nerbudda, notable for the manufacture of bell-metal vessels. A large part of the town was submerged by the flood of 1926. Pop. (1941), 12,209.

The district of Mandla (area 5,115 sq.mi.) is in the Satpura hills. It is a wild highland region broken up by the valleys of numerous rivers and streams. The Nerbudda flows through the centre of the district receiving several tributaries which take their rise in the Maikal hills, a range thickly clothed with "sal" forests, and forming part of the great watershed between eastern and western India. Except for one small fertile area producing wheat, it is a district of jungle, rice and millets, with a large aboriginal population. The forest area is very large, including some "sal" forests and some fine grazing areas on the plateau lands. The forests abound with big game and tigers are numerous. A few main roads have opened up the district to some extent and the Bengal-Nagpur railway (Satpura section) touches the district at Mandla town. The great famine caused a large decrease in the population and the influenza of 1918 was severe, but the pop. (1941) has nevertheless expanded to 504,580 (60% aboriginal tribes, principally Gonds). The backwardness of the district has excluded it from political reforms. There is some export of food grains and oil seeds, and a larger export of timber and forest produce. It is a favourite shooting district, but very malarious.

MANDOLINE, the treble member of the lute (*q.v.*) family, and therefore a stringed instrument of great antiquity. There are two varieties and both Italian: (1) the *Neapolitan,* 2 ft. long, the best known, which has for strings four courses of pairs of unisons, tuned like the violin in fifths; (2) the *Milanese,* which is slightly larger and has five or six courses of pairs of unisons. The strings, of wire-spun gut, steel and brass, are twanged by means of a plectrum or pick. The Neapolitan mandoline was scored for by Mozart as an accompaniment to the celebrated serenade in *Don Giovanni.* Beethoven wrote for it a "Sonatina per il mandolino" and an Adagio for mandoline and harpsichord. Grétry and Paisiello also introduced it into their operas as an accompaniment to serenades.



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

THE MANDOLINE, THE DESCENDANT AND ONLY SURVIVOR OF THE LUTE

MANDRAKE (*Mandragora officinarum*), a plant of the potato family, Solanaceae, and a native of the Mediterranean region. It has a short stem bearing a tuft of ovate flowers, with a thick fleshy and often forked root. The flowers are solitary, with a purple bell-shaped corolla; the fruit is a fleshy orange-coloured berry. The mandrake has been long known for its poisonous properties and supposed virtues. It acts as an emetic, purgative and narcotic, and was much esteemed in old times; but, except in Africa and the East, where it is used as a narcotic and antispasmodic, it has fallen into disrepute. In ancient times, according to Isidorus and Serapion, it was used as a narcotic to diminish sensibility under surgical operations. Shakespeare more than once alludes to this plant, as in *Antony and Cleopatra*: "Give me to drink mandragora." The notion that the plant shrieked when touched is alluded to in *Romeo and Juliet*: "And shrieks like mandrakes torn out of the earth, that living mortals, hearing them, run mad." The mandrake, often growing like the lower limbs of a man, was supposed to have other virtues, and was much used for love philtres, while the fruit was supposed, and in the East is still supposed, to facilitate pregnancy. The North American may apple (*q.v.*) is known also as mandrake.

MANDRILL, the most hideous and most brilliantly coloured of the baboons (*Papio*). The mandrill (*P. sphinx*) inhabits West Africa and is characterized by the shortness of its tail, heavy body, prominent brow-ridges, small, deeply-sunk eyes placed close together, and by the vivid colouring of the bare skin on the face and buttocks. In the latter region it is crimson, shading into blue at the sides and varying in intensity according to the condition of the animals. The cheek-prominences are intense blue, while the central line and termination of the nose are scarlet. The fur is light olive above and silvery-gray beneath, with a small pointed yellow beard. The female is much smaller and less brightly coloured. Young males have black faces. Mandrills feed on fruit, roots, reptiles, insects, scorpions, etc., and inhabit rocky country in large troops. The old males are very ferocious, but, when young, the animals can be easily tamed.

MANDU or MANDOGARH, a ruined city in the Dhar state of Central India, the ancient capital of the Mohammedan kingdom of Malwa. The city is situated at an elevation of 2,079 ft. and extends for 8 m. along the crest of the Vindhyan mountains. It reached its greatest splendour in the 15th century under Hoshang Shah (1405–1434). The circuit of the battlemented wall is nearly 23 m., enclosing a large number of palaces, mosques and other buildings. The oldest mosque dates from 1405; the finest is the Jama Masjid or great mosque, a notable example of Pathan architecture, founded by Hoshang Shah. The marble-domed tomb of this ruler is also magnificent.

MANDURIA, city, Apulia, Italy, province of Taranto, 27 m. west by road from the town of Lecce (22 m. east of Taranto), 270 ft. above sea-level, and 8 m. north of the coast. Pop. (1936), 17,475 (town); 19,594 (commune). It is close to the site of the ancient Manduria, the defences of which consisted of a double line of wall built of blocks of stone, with a broad ditch in front. Some tombs with gold ornaments were found in 1886. It was an important stronghold of the Messapii against Tarentum, and Archidamus III., king of Sparta, fell beneath its walls in 338 B.C., while leading the army of the latter (*see* ARCHIDAMUS). It revolted to Hannibal, but was stormed by the Romans in 209 B.C. Pliny mentions a spring here which never changed its level, and may still be seen. The town was destroyed by the Saracens in the 10th century; the inhabitants settled themselves on the site of the present town, at first called Casalnuovo, which resumed the old name in 1789.

MANES, the inhabitants of the underworld, especially the ghosts of the dead. (Lat. "good people," an obvious euphemism.) In pure Roman cult we hear nothing of the worship of individual dead persons, and fear of ghosts does not seem to have been prevalent. But the collectivity of the inhabitants of the underworld was regarded as divine (*di manes*). Properly, the ancestral ghosts of a family are called *di parentes* or *parentum,* the *di manes* being the same as the *di inferi;* but this distinction tends to disappear about the beginning of our era, hence the common formula on tombstones, *dis manibus* followed by a name in the genitive or dative, *i.e.,* "to the glorified spirit of so-and-so" or "to so-and-so, a glorified spirit." The formula is clumsy at best.

Of public cult of the *manes* we hear little. They are mentioned in a few prayers (*see* ANCESTOR-WORSHIP); such things as burial-grounds are sacred to them; certain persons guilty of very serious offences were devoted (*sacri*) to them (*see* CONSECRATION). It was supposed, at least in later times, that they came forth when the *mundus,* or ritual pit dug at the foundation of a city and opened three times a year (Aug. 24, Oct. 5, Nov. 8) was uncovered. Their dwelling-place was the bowels of the earth, to which any deep chasm might lead (*see* Livy, vii., 6, 4).

In private cult, they, or properly the *di parentes,* were propitiated with offerings of food, wine, garlands, etc., left on potsherds in the middle of the road, during the *dies parentales,* Feb. 13–21. On Feb. 22 followed a family reunion, the Caristia. At the Lemuria (May 9, 11, 13) each householder rose in the night, dropped beans from his mouth, saying "with these beans I ransom me and mine," and then bade the *manes paterni, i.e.,* the *di parentum,* be gone (Ovid, *Fasti,* ii., 531, *et seq.;* v. 419 *et seq.*). Hence, perhaps, is derived the name *lemures* for ghosts. The *larvae* were malignant phantoms, supposed to possess and madden people (Plautus, *Capt.,* 598, *Menaech.,* 890); they had no part in cult.

See G. Wissowa, *Religion u. Kultus* (2nd ed.) p. 232, *et seq.,* and in Pauly-Wissowa, *Realencyklopädie, s.v.* Lemuria; W. Warde Fowler, *Roman Essays,* p. 24 *et seq.*

MANET, ÉDOUARD (1832–1883), French painter, regarded as the most important master of Impressionism (*q.v.*), was born in Paris on Jan. 23, 1832. He studied at Collège Rollin, where his passion for drawing led him to neglect all his other lessons. In 1848 he was placed on board the ship *Guadeloupe,* voyaging to Rio de Janeiro. On his return he first studied in Couture's studio (1851), where his independence often infuriated his master. For six years he was an intermittent visitor to the studio, constantly taking leave to travel, and going first to Cassel, Dresden, Vienna and Munich, and afterwards to Florence, Rome and Venice, where he made some stay. Some important drawings date from this period, and one picture, "A Nymph Surprised." Then, after imitating Couture, more or less, in "The Absinthe-drinker" (1866), and Courbet in "The Old Musician," he devoted himself almost exclusively to the study of the Spanish masters in the Louvre. A group was already gathering round him—Whistler, Legros and Fantin-Latour haunted his studio in the Rue Guyot. His "Spaniard playing the Guitar," in the Salon of 1861, excited much criticism. Delacroix alone defended Manet, but, this notwithstanding, his "Fifer of the Guard" and "Breakfast on the Grass" were refused by the jury.

Then the "Exhibition of the Rejected" was opened, and round Manet a group was formed, including Bracquemond, Legros, Jongkind, Whistler, Harpignies and Fantin-Latour, the writers Zola, Duranty and Duret, and Astruc the sculptor. In 1863, when an amateur, M. Martinet, lent an exhibition-room to Manet, the painter exhibited fourteen pictures; and then, in 1864, contributed again to the Salon "The Angels at the Tomb" and "A Bullfight." Of this picture he afterwards kept nothing but the toreador in the foreground, and it is now known as "The Dead Man." In 1865 he sent to the Salon "Christ reviled by the Soldiers" and the famous "Olympia," which was hailed with mockery and laughter. It represents a nude woman reclining on a couch, behind which is seen the head of a negress who carries a bunch of flowers. A black cat at her feet emphasizes the whiteness of the sheet on which the woman lies. This work (now in the Louvre) was presented to the Luxembourg by a subscription started by Claude Monet (1890). It was hung in 1897 among the Caillebotte collection, which included the "Balcony," and a study of a female head called "Angelina." This production, of a highly independent individuality, secured Manet's exclusion from the Salon of 1866, so that he determined to exhibit his pictures in a place apart during the Great Exhibition of 1867. In a large gallery in the Avenue de l'Alma, half of which was occupied by Courbet, he hung no fewer than fifty paintings. Only one important picture was absent, "The Execution of the Emperor Maximilian"; its exhibition was prohibited by the authorities. From that time, in spite of the fierce hostility of some adversaries, Manet's energy and that of his supporters began to gain the day. His "Young Girl" (Salon of 1868) was justly appreciated, as well as the portrait of Lola; but the "Balcony" and the "Breakfast" (1869) were as severely handled as the "Olympia" had been. In 1870 he exhibited "The Music Lesson" and a portrait of Mlle E. Gonzales.

Not long before the Franco-Prussian War, Manet, finding himself in the country with a friend, for the first time discovered the true value of open air to the effects of painting in his picture "The Garden," which gave rise to the "open air" or *plein air* school. After fighting as a gunner, he returned to his family in the Pyrenees, where he painted "The Battle of the *Kearsarge* and the *Alabama*." His "Bon Bock" (1873) created a *furore*. But in 1875, as in 1869, there was a fresh outburst of abuse, this time of the "Railroad," "Polichinelle," and "Argenteuil," and the jury excluded the artist, who for the second time arranged an exhibition in his studio. In 1877 his "Hamlet" was admitted to the Salon, but "Nana" was rejected. The following works were exhibited at the Salon of 1881: "In the Conservatory," "In a Boat," and the portraits of Rochefort and Proust; and the Cross of the Legion of Honour was conferred on the painter on the 31st of December in that year. Manet died in Paris on Apr. 20, 1883. He left, besides his pictures, a number of pastels and engravings. He illustrated *Les Chats* by Champfleury, and Edgar Allan Poe's *The Raven*. (H. Fr.)

MANETHO (Μανέθων in an inscription of Carthage; Μανεθῶς in a papyrus), Egyptian priest and annalist, was a native of Sebennytus in the Delta. The evidence of Plutarch and other indications connect him with the reigns of Ptolemy I. and II. His most important work was an Egyptian history in Greek, for which he translated the native records. It is now only known by some fragments of narrative in Josephus's treatise *Against Apion,* and by tables of dynasties and kings with lengths of reigns, divided into three books, in the works of Christian chronographers. The earliest and best of the latter is Julius Africanus, besides whom Eusebius and some falsifying apologists offer the same materials; the chief text is that preserved in the *Chronographia* of Georgius Syncellus. Notwithstanding all their defects, the fragments of Manetho have been of great service to scholars ever since Champollion's first decipherments.

See C. Müller, *Fragmenta historicorum graecorum,* ii. 511–616; A. Wiedemann, *Aegyptische Geschichte* (Gotha, 1884), pp. 121 *et sqq.;* J. Krall in *Festgaben für Büdinger* (Innsbruck, 1898); Grenfell and Hunt, *El Hibeh Papyri,* i. 223; also the section on chronology in Egypt, and generally books on Egyptian history and chronology.

MANFRED (*c.* 1232–1266), king of Sicily, was a natural son of the emperor Frederick II. by Bianca Lancia, or Lanzia. Frederick appears to have regarded Manfred as legitimate, and by his will named him as prince of Tarentum and representative in Italy of his half-brother, the German king, Conrad IV. Manfred acted loyally and with vigour in the execution of his trust, and when Conrad appeared in southern Italy in 1252 his authority was quickly and generally acknowledged. When Conrad died (1254) Manfred, after refusing to surrender Sicily to Pope Innocent IV., accepted the regency on behalf of the infant Conradin.

On a rumour (1258) that Conradin was dead, Manfred was crowned king of Sicily at Palermo on Aug. 10 in that year. The report was false; but the new king declined to abdicate, and pointed out the necessity for a strong native ruler. The pope declared Manfred's coronation void and pronounced sentence of excommunication. In conjunction with the Ghibellines Manfred's forces defeated the Guelphs at Monte Aperto on Sept. 4, 1260. He was eventually defeated and killed near Benevento, Feb. 26, 1266. Contemporaries praise his noble and magnanimous character. He was renowned for his physical beauty and great intellectual attainments.

Manfred forms the subject of dramas by E. B. S. Raupach, O. Marbach, F. W. Roggee and Byron. Three letters written by Manfred are found in *Bibliotheca historica regni Siciliae.* (Palermo, 1732).

MANFREDONIA, town and archiepiscopal see (with Vieste), Apulia, Italy, province of Foggia, 22½ mi. N.E. of Foggia by rail, on the coast, 13 ft. above sea-level, to the south of Monte Gargano, and giving its name to the gulf to the east of it. Pop. (1936) 18,787 (town), 19,228 (commune). Founded by Manfred (1263); the Turks destroyed it in 1620, but the castle of the Angevins and parts of the walls are preserved. In the church of S. Domenico, the chapel of the Maddalena contains 14th century paintings. Two miles southwest is the cathedral of S. Maria Maggiore di Siponto, built in 1117 in the Romanesque style, with a dome and crypt. This marks the site of the ancient Sipontum, the harbour of Arpi, which became a Roman colony in 194 B.C., and was not deserted in favour of Manfredonia until the 13th century, having become unhealthy owing to the stagnant lagoons.

See A. Beltramelli, *Il Gargano* (Bergamo, Arti Grafiche, 1907); A. Haseloff, *Bauten der Hohenstaufen in Unteritalien,* i. (Leipzig, 1914), 385 *sqq.*

MANGABEY, a name applied to the West African monkeys of the genus *Cercocebus,* characterized by their bare, flesh-coloured upper eye-lids, and the uniformly coloured hairs of the fur. (*See* Primates.)

MANGALDAN, a municipality (with administrative centre and 29 *barrios* or districts) in the north part of the province of Pangasinan, Luzon, Philippine Islands, about 2 mi. from the Gulf of Lingayen, and located on the Manila-Dagupan railway. Pop. (1939) 18,997 (a gain of 2,236 since 1918) of whom 8,877 were males and none was white. The cultivation of palay (rice) is the chief occupation in the surrounding country. Pangasinan is the vernacular, but Ilocano is also spoken. Of the inhabitants aged 6 to 19 inclusive, 41% in 1939 attended school, while 51·9% of the population 10 years old and over was literate.

MANGALIA, a town and watering-place in the department of Constanţa, Rumania, situated on the Black sea, and at the mouth of a small stream, the Mangalia, 18 m. S. of Constanta. Pop. (1931) 2,776. The inhabitants, among whom are many Turks, Tatars and Bulgarians, are mostly fisherfolk. Mangalia is to be identified with the Thracian Kallatis or Acervetis, a colony of Miletus which continued to be a flourishing place to the close of the Roman period.

In the 14th century it had 30,000 inhabitants, and a large trade with Genoa. Mangalia has a small harbour, with a depth alongside of 3 to 12 ft.

MANGALORE, a seaport of British India, administrative headquarters of the South Kanara district of Madras, and terminus of the west coast line of the Madras railway. Pop. (1941), 81,069. The harbour is formed by the backwater of two small rivers, and large vessels lie 3 mi. offshore. The chief exports are coffee, pepper, sandalwood, fish and fish manure, etc. Mangalore trades directly with Ceylon and the Persian gulf, and is a port of call of the British India Company. There is a small shipbuilding industry, and fishing, coffee-curing and manure-making are carried on. The town has a large Roman Catholic population, with a European bishop, several churches and a convent, and is an industrial and educational centre. It is the headquarters of the Basel Lutheran mission, which has successfully introduced the industries of printing, carpentry and the manufacture of tiles. There are two colleges and a training school. Mangalore was gallantly defended by Colonel John Campbell in 1784, with a garrison of 1,850 men, of whom 412 were English, against Tippoo Sultan's whole army.

MANGAN, JAMES CLARENCE (1803–1849), Irish poet, was born in Dublin on May 1, 1803. His baptismal name was James, the "Clarence" being his own addition. His father, a grocer, who boasted of the terror with which he inspired his children, had ruined himself by imprudent speculation and extravagant hospitality. The burden of supporting the family fell on James, who entered a scrivener's office, at the age of fifteen, and drudged as a copying clerk for ten years. He was employed for some time in the library of Trinity college, and in 1833 he found a place in the Irish ordnance survey. He suffered a disappointment in love, and continued ill health drove him to the use of opium. He was habitually the victim of hallucinations which at times threatened his reason. For Charles Maturin, the eccentric author of *Melmoth,* he cherished a deep admiration, the results of which are evident in his prose stories. He belonged to the Comet Club, a group of youthful enthusiasts who carried on war in their paper, the *Comet,* against the levying of tithes on behalf of the Protestant clergy. Contributions to the *Dublin Penny Journal* followed; and to the *Dublin University Magazine* he sent translations from the German poets. The mystical tendency of German poetry had a special appeal for him. He also wrote versions of old Irish poems, though his knowledge of the language, at any rate at the beginning of his career, was but slight. Some of his best-known Irish poems, however, *O'Hussey's Ode to the Maguire,* for instance, follow the originals very closely. Besides these were "translations" from Arabic, Turkish and Persian. How much of these languages he knew is uncertain, but he had read widely in Oriental subjects, and some of the poems are exquisite though the original authors whom he cites are frequently mythical. He took a mischievous pleasure in mystifying his readers, and in practising extraordinary metres. For the *Nation* he wrote from the beginning (1842) of its career, and much of his best work appeared in it. He afterwards contributed to the *United Irishman.* On June 20, 1849 he died at Meath hospital, Dublin, of cholera. It is not true that starvation was the real cause, but there is no doubt that his wretched poverty made him ill able to withstand disease.

Mangan's fame was deferred by the inequality and mass of his work, much of which lay buried in inaccessible newspaper files under his many pseudonyms, "Vacuus," "Terrae Filius," "Clarence," etc. Of his genius, morbid though it sometimes is, as in his tragic autobiographical ballad of *The Nameless One,* there can be no question. He expressed with rare sincerity the tragedy of Irish hopes and aspirations, and he furnished abundant proof of his versatility in his excellent nonsense verses, which are in strange contrast with the general trend of his work.

The Poems of James Clarence Mangan (1903), and the *Prose Writings* (1904), were both edited by D. J. O'Donoghue, who wrote in 1897 a complete account of the *Life and Writings* of the poet.

MANGANESE, a metallic chemical element which is of a slightly brown appearance and has considerable hardness. Its dioxide (pyrolusite) has been known from very early times, and was at first mistaken for a magnetic oxide of iron. In 1740 J. H. Pott showed that pyrolusite did not contain iron and that it yielded a definite series of salts, whilst in 1774 C. Scheele proved that it was the oxide of a distinctive metal. Manganese (symbol Mn; atomic number 25, atomic weight 54·93) is found widely distributed in nature, being generally found to a greater or less extent associated with the carbonates and silicates of iron, calcium, and magnesium and also as the minerals braunite, hausmannite, psilomelane, manganite, manganese spar and hauerite. It has also been recognized in the atmosphere of the sun, in sea water, and in many mineral waters.

The metal was isolated by J. G. Gahn in 1774, and in 1807 J. F. John obtained an impure metal by reducing the carbonate at a high temperature with charcoal mixed with a small quantity of oil. R. Bunsen prepared the metal by electrolysing manganese chloride in a porous cell surrounded by a carbon crucible containing hydrochloric acid. Various reduction methods have been employed for the isolation of the metal. C. Brunner reduced the fluoride by metallic sodium, and E. Glatzel the chloride by magnesium; H. Moissan reduced the oxide with carbon in the electric furnace. Mostly, manganese is now prepared by the reduction of the oxide by aluminium as in H. Goldschmidt's "thermite" process. It is also prepared in large quantities as ferro-manganese by reduction of the mixed ores of iron and manganese in the blast furnace. (*See* IRON AND STEEL.)

Manganese has a specific gravity of 7·42, and the variety obtained by distilling pure manganese amalgam *in vacuo* is pyrophoric, and burns when heated in a current of sulphur dioxide. The pure metal readily evolves hydrogen when acted upon by sulphuric and hydrochloric acids, and is readily attacked by dilute nitric acid. It precipitates many metals from solutions of their salts. It melts at 1230° C.

COMPOUNDS

Oxides.—Manganous oxide, MnO, is obtained by heating a mixture of anhydrous manganese chloride and sodium carbonate with a small quantity of ammonium chloride; or by reducing the higher oxides with hydrogen or carbon monoxide. It is a dark coloured powder of specific gravity 5·09. *Manganous hydroxide,* $Mn(OH)_2$, is obtained as a white precipitate on adding a solution of a caustic alkali to a manganous salt. It rapidly oxidizes on exposure to air and turns brown, going ultimately to the sesquioxide. Trimanganese tetroxide, Mn_3O_4, is produced more or less pure when the other oxides are heated. It may be obtained crystalline by heating manganese sulphate and potassium sulphate to a bright red heat. It is a reddish brown powder, which when heated with hydrochloric acid yields chlorine. *Manganese sesquioxide,* Mn_2O_3, is found native as the mineral braunite. The hydrated form, found native as the mineral manganite, is produced by the spontaneous oxidation of manganous hydroxide. In the hydrated condition it is a dark brown powder which readily loses water at above 100° C; it dissolves in hot nitric acid, giving manganous nitrate and manganese dioxide: $2MnO(OH)+2HNO_3=Mn(NO_3)_2+MnO_2+2H_2O$. *Manganese dioxide,* or pyrolusite (*q.v.*), MnO_2, which is the most important oxide, may be prepared by heating crystallized manganous nitrate until red fumes are given off, decanting the clear liquid, and heating to 150° to 160° C for 40 to 60 hours, or by heating manganese carbonate to 260° C in the presence of air and washing the residue with very dilute cold hydrochloric acid. It is a hard black solid which readily loses oxygen when strongly heated, leaving a residue of Mn_3O_4. When heated with concentrated hydrochloric acid it yields chlorine, and with concentrated sulphuric acid it yields oxygen. It is reduced to the monoxide when heated in a current of hydrogen. It is a strong oxidizing agent. It dissolves in cold concentrated hydrochloric acid, forming a dark brown solution which probably contains manganic chloride, since salts of the type $MnCl_3,2KCl$ may be prepared from it. Salts corresponding to $MnCl_4$, *e.g.,* K_2MnCl_6, have been obtained by boiling potassium permanganate in glacial acetic acid and separating the solution with hydrogen chloride. It is almost impossible to prepare a pure hydrated manganese dioxide owing to the readiness with which it loses oxygen, leaving residues of the type $x MnO,y MnO_2$. Such mixtures are obtained by the action of alkaline hypochlorites on manganous salts, or by suspending manganous carbonate in water and passing chlorine through the mixture. Manganese dioxide combines with other basic oxides to form *manganites,* and on this property is based the Weldon process for the recovery of manganese from the waste liquors of the chlorine stills. (*See* CHLORINE.) The manganites are amorphous brown solids, insoluble in water, and decomposed by hydrochloric acid with the evolution of chlorine. *Manganese trioxide,* MnO_3, is obtained in small quantity as an unstable deliquescent red solid by dropping a solution of potassium permanganate in sulphuric acid on to dry sodium carbonate. Above 50° C it decomposes into the dioxide and oxygen. It dissolves in water, forming manganic acid, H_2MnO_4, and permanganic acid. *Manganese heptoxide,* Mn_2O_7, prepared by adding pure potassium permanganate to well cooled, concentrated sulphuric acid, when the oxide separates as a dark oil, is very unstable, continually giving off oxygen. It decomposes violently on heating, and explodes in contact with hydrogen, sulphur, phosphorus, etc. It dissolves in water to form a deep red solution which contains *permanganic acid,* $HMnO_4$. This acid is also formed by decomposing barium or lead permanganate with dilute sulphuric acid. It is only known in aqueous solution. This solution is of a deep violet red colour, and is somewhat fluorescent; it decomposes on exposure to light, or when heated. It is a monobasic acid, and a very powerful oxidizing agent.

Manganous Salts.—The anhydrous *chloride,* $MnCl_2$, is obtained as a rose red crystalline solid by passing hydrochloric acid gas over manganese carbonate, first in the cold and afterwards at a moderate red heat. The hydrated chloride, $MnCl_2 4H_2O$, is obtained in rose red crystals by dissolving the metal or its carbonate in aqueous hydrochloric acid and concentrating the solution. It may be obtained in at least two different forms, one isomorphous with $NaCl,2H_2O$, by concentrating the solution between 15° C and 20° C; the other, isomorphous with $FeCl_2 \cdot 4H_2O$, by slow evaporation of the mother liquors from the former. It forms double salts with the chlorides of the alkali metals. The *bromide,* $MnBr_2,4H_2O$, *iodide,* MnI_2, and *fluoride,* MnF_2, are known.

Manganous sulphate, $MnSO_4$, is prepared by strongly heating a paste of pyrolusite and concentrated sulphuric acid until acid fumes cease to be evolved. The ferric and aluminium sulphates present are thus converted into insoluble basic salts, and the residue yields manganous sulphate when extracted with water. The salt crystallizes with varying quantities of water, according to the temperature at which crystallization is effected: between −4° C and +6° C with $7H_2O$, between 15° C and 20° C with $5H_2O$, and between 25° C and 31° C with $4H_2O$. It crystallizes in large pink crystals and combines with the sulphates of the alkali metals to form double salts.

Manganous nitrate, $Mn(NO_3)_2,6H_2O$, obtained by dissolving the carbonate in nitric acid and concentrating the solution, crystallizes from nitric acid solutions in long colourless needles, which melt at 25·8° C.

Manganous carbonate, $MnCO_3$, found native as manganese spar, may be prepared as an amorphous powder by heating manganese chloride with sodium carbonate in a sealed tube to 150° C, or in the hydrated form as a white flocculent precipitate by adding sodium carbonate to a manganous salt. In the moist condition it rapidly turns brown on exposure to air.

Manganous sulphide, MnS, found native as manganese glance, may be obtained by heating the monoxide or carbonate in a porcelain tube in a current of carbon disulphide vapour. R. Schneider obtained a crystalline variety by melting sulphur with anhydrous manganous sulphate and dry potassium carbonate, extracting the residue and drying it in a current of hydrogen. Ammonium sulphide alone gives incomplete precipitation of the sulphide. In the presence of ammonium salts the precipitate is dirty white in colour, whilst in the presence of free ammonia it is a buff colour. This form of the sulphide is readily oxidized when exposed in the moist condition, and is easily decomposed by dilute mineral acids.

Manganic Salts.—The sulphate, $Mn_2(SO_4)_3$, is prepared by gradually heating at 138° C a mixture of concentrated sulphuric and manganese dioxide until the whole becomes of a dark green colour. The excess of acid is removed by spreading the mass on a porous plate, the residue stirred for some hours with nitric acid, again spread on a porous plate, and finally dried quickly at about 130° C. It is a dark green deliquescent powder which decomposes on heating or on exposure to moist air. It is readily decomposed by dilute acids. With potassium sulphate in the presence of sulphuric acid it forms $K_2SO_4 \cdot Mn_2(SO_4)_3 \cdot 24H_2O$, potassium manganese alum. *Manganic fluoride,* MnF_3, a solid obtained by the action of fluorine on manganous chloride, is decomposed by heat into manganous fluoride and fluorine. It readily forms double fluorides such as K_2MnF_5. Manganifluorides, K_2MnF_6, are also known.

Manganese carbide, Mn_3C, is prepared by heating manganous oxide with sugar charcoal in an electric furnace, or by fusing manganese chloride and calcium carbide. Water decomposes it, giving methane and hydrogen, $Mn_3C+6H_2O=3Mn(OH)_2+CH_4+H_2$ (H. Moissan).

Manganates.—These salts are derived from manganic acid, H_2MnO_4. Those of the alkali metals are prepared by fusing manganese dioxide with sodium or potassium hydroxide in the presence of air or of some oxidizing agent (nitre, potassium chlorate, etc.), $MnO_2+2KHO+O=K_2MnO_4+H_2O$. In the absence of air the reaction proceeds slightly differently, some manganese sesquioxide being formed, $3MnO_2+2KHO=K_2MnO_4+Mn_2O_3+H_2O$. The fused mass has a dark olive green colour, and dissolves in a small quantity of cold water to a green solution, which is, however, only stable in the presence of an excess of alkali. The green solution is readily converted into a pink one of permanganate by a large dilution with water, or by passing carbon dioxide through it: $3K_2MnO_4+2CO_2=2K_2CO_3+2KMnO_4+MnO_2$.

Permanganates are the salts of permanganic acid, $HMnO_4$. The *potassium salt,* $KMnO_4$, may be prepared by passing chlorine or carbon dioxide through an aqueous solution of potassium manganate, or by the electrolytic oxidation of the manganate at the anode. It crystallizes in dark purple-red prisms, isomorphous with potassium perchlorate. It acts as a powerful oxidizing agent both in acid and alkaline solution; in the first case two molecules yield five atoms of available oxygen and in the second, three atoms:

$$2KMnO_4+3H_2SO_4=K_2SO_4+2MnSO_4+3H_2O+5O;$$
$$2KMnO_4+3H_2O\quad=2MnO_2,H_2O+2KHO+3O.$$

It completely decomposes hydrogen peroxide in sulphuric acid solution—

$$2KMnO_4+5H_2O_2+3H_2SO_4=K_2SO_4+2MnSO_4+8H_2O+5O_2.$$

It decomposes when heated to 200°–240° C:

$$2KMnO_4=K_2MnO_4+MnO_2+O_2;$$

and when warmed with hydrochloric acid it yields chlorine:

$$2KMnO_4+16HCl=2KCl+2MnCl_2+8H_2O+5Cl_2.$$

It is used extensively in analytical work, especially in estimating ferrous salts and oxalic acid or oxalates, and also in organic chemistry for oxidations.

Sodium permanganate, $NaMnO_4,3H_2O$ (?), may be prepared in a similar manner, or by precipitating the silver salt with sodium chloride. It crystallizes with great difficulty. A solution of the crude salt is used as a disinfectant (Condy's Fluid).

Ammonium permanganate, $NH_4 \cdot MnO_4$, explodes violently on rubbing, and its aqueous solution decomposes on boiling: $2NH_4MnO_4=2MnO_2+N_2+4H_2O$.

Barium permanganate, $BaMn_2O_8$, crystallizes in almost black needles, and is formed by passing carbon dioxide through water containing suspended barium manganate.

Detection.—Manganese salts can be detected by the amethyst colour they impart to a borax-bead when heated in the Bunsen flame, and by the green mass formed when they are fused with a mixture of sodium carbonate and potassium nitrate. Manganese may be estimated quantitatively by precipitation as carbonate, this salt being then converted into the oxide, Mn_3O_4, by ignition, or to the sulphate, $MnSO_4$; or by precipitation as hydrated dioxide by means of ammonia and bromine water, followed by ignition to Mn_3O_4. The valuation of pyrolusite is generally carried out by means of a distillation with hydrochloric acid, the liberated chlorine passing through a solution of potassium iodide, and the amount of iodine liberated being ascertained by means of a standard solution of sodium thiosulphate. (X.)

PRODUCTION

The principal use of manganese is in the manufacture of iron and steel, about 95% of the world's production of manganese ores, manganiferous iron-ores, and manganiferous zinc residuum being consumed in metallurgical processes. Its chief chemical uses are as a constituent of oxidizing agents and colouring materials, and as a flux in the smelting of silver and lead ores. Salts of manganese are used as fertilizers and massive rhodonite as an ornamental stone. Manganese is also used for medical purposes. Ores of the metal are widely distributed, but deposits of commercial importance are known only in a few countries. The principal of these are Russia (Caucasus), the ore of which consists mainly of pyrolusite; India, Brazil and West Africa. Minor producers of the metal are Italy, Spain, the United States, Cuba and Japan; while deposits are also known in Germany, Greece, Egypt, Canada, Mexico, Colombia, Chile and Queensland. *See* PHYSICAL RESOURCES: *Manganese.*

Manganese Ore Produced in Principal Countries (in metric tons)

Country	1933	1935	1937

(N. M. P.)

MANGANESE STEEL. In modern steels manganese is used as a strengthener and toughener; carbon-free alloys are remarkably ductile in a wide range; while cast manganese steel containing over 10% of manganese is the toughest material known. Crucible or electric steels can be properly deoxidized without manganese, consequently high carbon steels have a sharply limited quantity. Bessemer or open-hearth steels require at least 0·3% manganese to counteract the effect of oxygen and sulphur; a slight excess also improves the rolling properties. For these reasons the tonnage steels contain from 0·3% to 0·9% manganese. Increasing wheel loads have caused a demand for harder rails to resist the wear. Recent American specifications for 120 to 140-lb. rails call for carbon 0·72 to 0·89, manganese 0·5 to 0·9 and silicon more than 0·15%.

A new high strength boiler plate and structural steel has been produced, misnamed in America "silicon steels." This and the excellent ship-building material (D-Quality Structural Steel) of this general type, used by the British admiralty since the Washington conference, is described in the article on STEELS, ALLOY. Continental engineers favour even higher silicons. The "Freund" or "F" steel produced in Germany contains 0·13 to 0·17 carbon, 0·90 to 1·20 silicon, and 0·7 to 1·0 manganese. Freund steel's ultimate strength is somewhat less than that of D-steel, and the elongation correspondingly higher. Most leaf springs for vehicles are made with a "silico-manganese" steel containing 0·45 to 0·60 carbon, 1·8 to 2·2% silicon and 0·6 to 0·9 manganese. European practice favours the lower chemical ranges. Such steels permit a wider temperature range in forming the hardening than high carbon spring steels. "Non-deforming" steels for gauges, master tools, intricate dies, and broaches contain 0·80 to 0·95 carbon and 1·5 to 1·75 manganese. For any of these steels a heat treatment schedule can be fixed so that the principal dimensions will be the same after hardening, drawing, and polishing off the scale as when the piece left the machine tool. High strength steel castings, made in America since 1909, contain 0·20 to 0·30 carbon and 1·10 to 1·40 manganese. Such castings when properly made approach D-steel and are used for artillery mounts, freight car couplers, and places where the maximum quality is desired.

Manganese acquired a bad reputation as an alloying element, except in large quantities, from Hadfield's early experiments wherein carbon always increased with the manganese. When ferromanganese with low carbon became available, its moderate use had no bad effects—quite the contrary. (Commercial production of electrolytic manganese in 1939 presages an entirely new alloy family of hitherto unattainable properties.) Hence we find wide use for plain carbon steels, strengthened by 1% manganese rather than the ordinary 0·5% for deoxidation; 1½% manganese added to free-cutting steels with high sulphur to improve their toughness; 1¾% manganese added to medium carbon steels (0·30 to 0·50% carbon) for a type of true alloy steel, for such important parts as automobile axles, oil quenched forgings, steam valves, rifle barrels, cylinders for compressed gas; and the same with 0·15% vanadium for forgings too large to be effectively quenched. Manganese, properly proportioned to the carbon, in a well-made steel will increase its hardenability in a very useful way. Mass production also approves of the low cost of this alloying element. Development of special open-hearth furnace techniques, and especially of new deoxidizers and addition agents, produces these medium manganese steels of fine grain, and therefore of unusually good toughness added to inherent strength. For these reasons American use is rapidly growing at the expense of alloy steels containing the more expensive nickel and chromium. (E. E. T.)

MANGANITE, a mineral consisting of hydrated manganese sesquioxide, $Mn_2O_3.H_2O$, crystallizing in the orthorhombic system and isomorphous with diaspore and goethite. Crystals are prismatic and deeply striated parallel to their length; they are often grouped together in bundles. The colour is dark steel-grey to iron-black, and the lustre brilliant and submetallic; the streak is dark reddish-brown. The hardness is 4, and the specific gravity 4·3. There is a perfect cleavage parallel to the brachypinacoid. The mineral contains 89·7% of manganese sesquioxide; it dissolves in hydrochloric acid with evolution of chlorine. The best crystallized specimens are those from Ilfeld in the Harz, where the mineral occurs with calcite and barytes. As an ore of manganese it is much less abundant than pyrolusite or psilomelane. French authors use the name "acerdèse" (Gr. ἀκερδής, unprofitable), because the mineral is of little value for bleaching purposes as compared with pyrolusite.

MANGBETTU (*Monbuttu*), a negroid people of Central Africa living to the south of the Niam-Niam in the Welle district of Belgian Congo. The Mangbettu were some of the most inveterate cannibals in Africa. Physically the Mangbettu differ from their negro neighbours, are not so black and are less negroid, many having quite aquiline noses. The beard, too, is fuller than in most negroes. The men wear bark cloth, the women a simple loin cloth, often not that. Both sexes paint the body in elaborate designs. As potters, sculptors, boatbuilders and masons the Mangbettu have had few rivals in Africa. Their huts, with pointed roofs, were larger, better built, and cleaner than those of their neighbours, and some of their more important buildings were of great size and exhibited some skill in architecture.

See G. A. Schweinfurth, *Heart of Africa* (1874); W. Junker, *Travels in Africa* (1890); G. Casati, *Ten Years in Equatoria* (1891); C. van Overbergh and Ed de Jonghe, *Les Mangbetu* (1909).

MANGEL, mangel-wurzel or mangold is a large type of beet belonging to the species *Beta vulgaris* which also includes vegetable and sugar beets and Swiss chard. These types interbreed freely. The species probably originated from the wild beet *Beta maritima* and had its principal developmental centre in the eastern Mediterranean region. Mangold, the original name, is German and it has been somewhat modified in use. In France mangels are known as disettes. The mangel root is a store of food stuffs in the forms of sugar and other carbohydrates. The sugar percentage is approximately 7-8%, being about half that of sugar beets. The principal use of the crop is to provide a high tonnage of a succulent, nutritious feed for use in livestock, including poultry, feeding. As feed for cattle and sheep, mangel roots are highly regarded and being very palatable they are often utilized as a relish for stimulating milk production. They are also considered valuable in conditioning animals for show purposes. Pound for pound the dry matter of mangels is equivalent in feed value to grain. The crop is usually grown in regions too cool or seasons too short for corn and where other conditions, such as soil fertility, soil type, and moisture supply, are particularly favourable. Corn as compared with mangels will produce nearly double the yields of dry matter in the regions of its adaptation. Mangels are grown chiefly in northern and coastal western Europe and on the Pacific coast of the United States and Canada.

The plant is a biennial. During the first year of growth the stem remains very short and a rosette of large, crisp, prominent-veined leaves arises from it. In the second year the upper portion of the primary root becomes very large during midsummer and autumn, attaining a diameter of from 4–10 in. and a length of from 6–30 in. The shape of the root is a varietal characteristic. If it remains in place and survives the winter, or if it is properly stored, and transplanted the following spring, tall angular, branching stems grow to heights of 3 ft. or more and produce inconspicuous flowers and seeds. The flowers are perfect and arranged in dense, sessile clusters, each subtended by a small bract, along an axis. The seeds are embedded in the flower parts and usually several flowers clustered together give rise to the "seed ball," from which several seedlings may develop. Five groups of varieties are recognized based upon root shape and colour and leaf colour. Shapes recognized are globular, flattened, cylindrical and fusiform while colours may be white, yellow, orange or red. Zonal colouration may also occur within the root.

Culture.—Like other root plants the mangel is a row crop. The seed is drilled about 1½ in. deep in rows 24–36 in. apart at a rate of 10–15 lb. per acre. After emergence of the seedlings cultivation is begun and continued until late summer. When the plants reach the four-leaved stage they are spaced about 10–14 in. apart in the rows by thinning. Hand-hoeing is then begun and the crop is weeded as required. Harvesting is done by mechanically lifting the roots previous to heavy frosts in the fall and removing the tops by cutting. The roots may be stored in large heaps or in covered pits or root cellars. Successful storage is dependent upon careful handling to avoid severe bruising, and also upon good ventilation. The roots may be pulled and fed directly as needed without topping.

Best soils for mangels are those rich, well drained and in good tilth. On more shallow land varieties with shorter roots may be grown. The crop responds markedly to heavy applications of barnyard manure and to potash, phosphate and nitrogen fertilizers. Although mangels are sometimes grown for several years on the same land they more commonly occupy a place in rotation with grain and forage crops. Requiring careful cultivation and weed control, they leave the soil in excellent condition for succeeding crops.

The principal values of the mangel are its productiveness, yields usually being 20–45 tons per acre, and its succulence. Very few crops will produce as much succulent feed per area. Mangels require much hand labour in thinning, cultivating, harvesting and storage. In corn regions cost of producing corn ensilage for succulent feed is much less than with mangels or other root crops. Mangels are more drought and heat-tolerant but more sensitive to frost than turnips or rutabagas, often grown for similar uses. Also, they are less affected by root maggots and aphis than the latter crops. Important objectives sought in better varieties are high yield of sugar and dry matter, freedom from disease and premature seed-stalk formation (bolting) and smooth, well shaped roots of good keeping quality. (D. C. SH.)

MANGIN, CHARLES EMMANUEL (1866–1925), French soldier, was born at Sarrebourg, Moselle, on July 6, 1866, of a military family. Mangin left the École Spéciale Militaire at Saint Cyr in 1888 for Africa, and with the exception of three years spent in Tongking, and 10 months in France, he remained for 26 years in different parts of Africa. In Aug. 1913 he was promoted to the rank of general of brigade. He was a member of Marchand's expedition and was one of the legendary company who were said to have marched "for three days without a halt." It was he who, at the head of 5,000 men routed the bandit El'hiba in the plain of Ben Guerir and so relieved Marrakesh. His book, *La Force Noire* (1910) brought home to Frenchmen the immeasurable resources of their empire.

In 1917 during World War I he was in command of the 5th army, and in the following year the supreme command imposed upon him the hard task of checking the German offensive directed against Compiègne. Eight fresh divisions were entrusted to him, and with these 60,000 men he checked von Hutier's advance at Noyon. Subsequently he was entrusted with the 10th army and was ordered in conjunction with General Degoutte, to break in the German salient south of the Aisne. This he accomplished. For a year he commanded the Army of Occupation on the Rhine. He died on May 12, 1925.

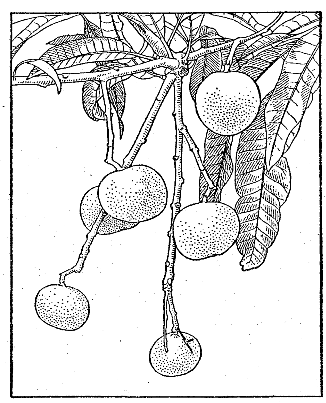
MANGNALL, RICHMAL (1769–1820), born probably at Manchester, on March 7, 1769, became a schoolmistress at Crofton Hall, Yorkshire, which she conducted most successfully until her death. She was the author of *Historical and Miscellaneous Questions for the Use of Young People* (1800), generally known as "Mangnall's Questions," which was prominent in the education of English girls in the first half of the 19th century. She died on May 1, 1820.

MANGO, one of the most important and widely-cultivated fruits of the tropical world. Its origin is lost in antiquity: according to some authorities, horticultural forms are derived from *Mangifera indica* (family Anacardiaceae), considered indigenous to the region of eastern India, Burma and Assam; but other species, such as *M. laurina* may have entered into the composition of some, particularly those of the Malayan region.

Few fruits have the historic background of the mango, and few are so inextricably connected with the folklore and religious ceremonies of India. Buddha himself was presented with a mango grove, that he might find repose in its grateful shade. The economic importance of the mango in ancient times is attested by one of the Sanskrit names, *am*, which has an alternative meaning of provisions or victuals. The Chinese traveler Hwen T'sang, who visited Hindustan between A.D. 632 and 645, was the first person, so far as known, to bring the mango to the attention of the outside world. Friar Jordanus wrote of it in 1328, and John de Marignolli in 1349. Akbar, the Mughal emperor who reigned at Delhi from 1556 to 1605, planted near Darbhanga the Lakh Bagh, an orchard of 100,000 mango trees. Nothing better attests the esteem in which the fruit has long been held than this immense planting, made at a time when large orchards of fruit trees were almost unknown.

The name mango, by which the fruit is known in English- and Spanish-speaking countries, is derived from the Tamil *man-kay* or *man-gay*, which the Portuguese adopted as *manga* when they settled in western India. Probably because of the difficulty in transporting seeds (they retain their viability a short time only), introduction of the tree into the western hemisphere did not take place until about 1700, when it was planted in Brazil; thence it reached the West Indies about 1740. It has taken on the appearance of a wild species in many parts of tropical America, trees springing up everywhere from seeds scattered by the roadside. During the ripening season, mangos are a major foodstuff wherever grown.

The tree is evergreen, often reaching large size (50–60 ft.) and attaining great age. It is one of the favourite shade trees of the tropics. The leaves are lanceolate, up to 12 in. long: the flowers, which are small, pinkish and fragrant, are borne in large terminal panicles. They are polygamous, *i.e.*, some have both stamens and pistil, others stamens only. The fruit varies greatly in size and character, as would be expected of a species (or combination of species) which has been in cultivation for a long time. The smallest mangos are no larger than plums, while others may weigh 4 or even 5 lb. The form is oval, round, heart-shaped, kidney-shaped or long and slender. Some varieties are beautifully coloured with shades of red and yellow, while others are dull green. The single large seed is flattened, the flesh which surrounds it yellow to orange in colour, juicy and of delicious spicy flavour. Fryer, writing of mangos in 1673, said "for Taste, the Nectarine, Peach and Apricot fall short." Hamilton, who wrote in 1727, went even further. "The Goa mango," he declared, "is reckoned the largest and most delicious to the taste of any in the world, and I may add, the wholesomest and best tasted of any Fruit in the World." There are ample grounds for considering the mango—as has been done by many writers—the "king of tropical fruits."



BUREAU OF PLANT INDUSTRY, U.S. DEPARTMENT OF AGRICULTURE

CLUSTER OF FRUIT OF ITOMARACA MANGO TREE (MANGIFERA INDICA), RIO DE JANEIRO, BRAZIL

But the seedlings so abundant throughout the tropics do not represent this fruit at its best. These are characterized by coarse fibres throughout the flesh which makes eating an annoying process; while the fine varieties of India as well as those of the race cultivated in the Philippines, Indo-China, and the Malayan region generally, are devoid of fibre and frequently are of excellent quality.

In 1889 the U.S. department of agriculture introduced into Florida the first of the grafted East Indian varieties, *Mulgoba.* In subsequent years, mainly through the efforts of Reasoner Brothers and of David

Fairchild, more than fifty others were taken to the U.S., whence their cultivation gradually spread to many parts of the American tropics. Some of the best Indian sorts are *Amini, Pairi,* and a seedling of Mulgoba which originated in Florida and is known as *Haden.* The Philippine or Cambodiana race is represented by such varieties as *Saigon* and *Carabao. Julie* is an excellent dwarf variety which first received horticultural attention in the French West Indies.

Mango trees are injured by a few degrees of frost. They are successfully cultivated in southern Florida, where a small commercial industry developed, but they have not been wholly successful in any part of California, though occasional trees have fruited in that state. They are not particular as to soil, but the finer varieties produce fruit abundantly only in regions where there is a well-marked dry season corresponding to the flowering and fruiting period of the tree. This is due in large part to a fungous disease known as anthracnose (*Colletotrichum*) which destroys flowers and young fruits whenever moist atmospheric conditions prevail.

Propagation of the finer sorts is by means of grafting or budding. Inarching is generally practiced in tropical Asia; crown-grafting and shield-budding are more popular in Florida, since they are less laborious and result in better trees. It is to be noted that the Indian varieties do not come true from seed, whereas seedlings of the Philippine race produce fruit closely resembling that of the parent. This is due to the fact that the Indian sorts are usually monoembryonic, while those of the Philippine race are polyembryonic; several young plants, not the result of fertilization of the egg-cell, but arising as vegetative buds in the nucellar tissue, may grow from a single seed.

Except with dwarf varieties such as Julie, commercial plantings are spaced 30x30 or even 35x35 ft. Cultural requirements are difficult to satisfy in most regions, due to the tendency of many fine varieties to fruit sparingly under orchard conditions favourable to many other fruit trees. The mango has a number of enemies, the most serious of which are anthracnose, mentioned above, and fruit flies of several species. Larvae of the latter infest the ripe fruits in many countries.

(W. Po.)

MANGOLD: *see* MANGEL.

MANGOSTEEN (*Garcinia mangostana*), a tree belonging to the family Guttiferae. It is a native of the Malay peninsula, and is extensively cultivated in southern Tenasserim, and in some places in the Madras presidency. Poor results have followed the attempt to introduce it to other countries; and A. de Candolle refers to it as one of the most local among cultivated plants both in its origin, habitation and cultivation. It belongs to a family in which the mean area of the species is very restricted. It is an evergreen about 20 ft. high, and is somewhat fir-like in general form, but the leaves are large, oval, entire, leathery and glistening. Its fruit, the much-valued mangosteen, is about the size and shape of an orange, and is somewhat similarly partitioned, but is of a reddish-brown to chestnut colour. Its thick rind yields a very astringent juice, rich in tannin, and containing a gamboge-like resin. The soft and juicy pulp is snow-white or rose-coloured, and of delicious flavour and perfume. It is wholesome, and may be administered in fever.

MANGROVE. The "mangrove forests" along tidal estuaries, in salt marshes, and on muddy coasts in the tropics of both old and

BY COURTESY OF A. M. HALLIGEY

A LAGOON, SHOWING MANGROVES

new worlds, are composed of trees and shrubs belonging mainly to the genus *Rhizophora* of the family Rhizophoraceae, but including, especially in the eastern mangrove formations of Further India and the Malay archipelago, members of other families, such as Lythraceae (*Sonneratia*), Verbenaceae (*Avicennia*), and the acaulescent Nipa-palm. Their trunks and branches constantly produce adventitious roots, which, descending in arched fashion, strike at some distance from the parent stem, and send up new trunks, the forest thus spreading like a banyan grove. An advantage in dispersal, very characteristic of the order, is afforded by the seeds, which have a striking peculiarity of germination. While the fruit is still attached to the parent branch the long radicle emerges from the seed and grows rapidly downwards. When the seed falls the young root is in the right position to be driven into the mud; the plant being thus rooted the plumule makes its appearance. The young root may grow to such a length that it becomes fixed in the mud before the fruit separates from the parent tree. An interesting feature of the mangrove is the air-roots, erect or kneed branches of the roots, which project above the mud, and are provided with minute openings (lenticels), into which the air diffuses and then passes by means of passages in the soft spongy tissue to the roots which spread beneath the mud. The wood of some species is hard and durable, and the astringent bark is used in tanning, yielding *cutch.* The fruit of the common mangrove, *Rhizophora mangle,* is sweet and wholesome.

MANHATTAN, an island $12\frac{1}{2}$ mi. long and $2\frac{1}{2}$ mi. wide lying between the Hudson and East rivers, is one of the five boroughs comprising New York city, U.S.A. Broadway, the longest street in the world, runs 16 mi. from the southern tip of the island, cutting through financial, civic, needle-trades, amusement, automobile, residential and educational sections, to a semisuburban road at the northern city limits. It is the world's greatest business centre. The population in 1940 was 1,889,924. (*See* NEW YORK CITY.)

MANHATTAN, a city of northeastern Kansas, U.S.A., on the Kansas (Kaw) river near the mouth of the Big Blue; the county seat of Riley county and the seat of the Kansas state college. It is on federal highways 40 and 24 and is served by the Rock Island and the Union Pacific railways. The population was 7,989 in 1920 (92% being native white) and was 11,659 in 1940 by the federal census. The college was opened in 1863 in the building of Bluemont college (chartered 1858) and moved in 1873 to its present location on the western edge of the city. The city was founded in 1854 and incorporated in 1857.

MANICHAEISM, the religion of Mani or Manes, which spread from Babylonia and during the 4th century was widely influential in the Empire.

Life of Mani.—According to the Mohammedan tradition, Mani was born in the year 527 of the astronomers of Babylon (A.D. 215–216). He received a careful education at Ctesiphon from his father Fatak or Patak (Πατέκιος). As the father connected himself at a later period with the confession of the *Moghtasilah,* or "Baptists," in southern Babylonia, the son also was brought up in the religious doctrines and exercises of this sect. These Baptists were apparently connected with the Elkesaites and the Hemerobaptists, and certainly with the Mandaeans. It is probable that this Babylonian sect had absorbed Christian elements. Thus the boy early became acquainted with very different forms of religion.

When Mani had reached the age of twenty-five or thirty years he began to proclaim his new religion. This he did at the court of the Persian king, Shāpūr I, and, according to the story, on the coronation day of that monarch (241–2). He did not remain in Persia, but undertook long journeys for the purpose of spreading his religion, and also sent forth disciples. According to the *Acta Archelai,* his missionary activity extended westwards into the territory of the Christian church; but from oriental sources it is certain that Mani rather went into Transoxiana, western China, and southwards as far as India. His labours there as well as in Persia were not without result. Like Mahomet after him and the founder of the Elkesaites before him, he gave himself out for the last and highest prophet, who was to surpass all previous divine revelation, which only possessed a relative value, and to set up the perfect religion. In the closing years of the reign of Shāpūr I. (*c.* 270) Mani returned to the Persian capital, and gained adherents even at court. But the dominant priestly caste of the Zoroastrian Magians, on whose support the king was dependent, were naturally hostile to him, and after some successes Mani was made a prisoner, and had then to flee. The successor of Shāpūr, Hōrmizd (272–273), appears to have been favourably disposed towards him, but Bahrām I. abandoned him to the fanaticism of the Magians, and caused him to be executed in the capital in the year 276–7. The Persian government made great efforts to exterminate the new religion, but in vain. Mani composed a number of books and epistles in Aramaic and at least one in Persian. These were in great part still known to the Mohammedan historians, but are now mostly lost.

Manichaean System.—The Manichaean system is one of consistent, uncompromising dualism, in the form of a fantastic philosophy of nature. The distinction between the physical and the ethical, the natural and the spiritual, did not exist for Mani. When he co-ordinates good with light, and evil with darkness, this is no mere figure of speech, but light is actually good and darkness evil. From this it follows that religious knowledge involves the knowledge of nature and her elements, and that redemption consists in a process of freeing the element of light from the darkness. Under such circumstances ethics becomes a doctrine of abstinence in regard to all elements originating within the sphere of darkness.

The self-contradictory character of the present world forms the point of departure for Mani's speculations. From the contradictory character of the world he concludes the existence of two beings, originally quite separate from each other—light and darkness. Each is to be thought of according to the analogy of a kingdom. Light presents itself to us as the good primal spirit (God, radiant with the virtues of love, faith, fidelity, high-mindedness, wisdom, meekness, knowledge, understanding, mystery and insight), and then further as the heavens of light and the earth of light, with their guardians the glorious aeons or angels. Darkness is likewise a spiritual kingdom (more correctly, it also is conceived of as a spiritual and feminine personification), but it has no "God" at its head. It embraces an "earth of darkness." As the earth of light has five tokens (the mild zephyr, cooling wind, bright light, quickening fire, and clear water), so has the earth of darkness also five (mist, heat, the sirocco, darkness and vapour). Satan with his demons was born from the kingdom of darkness. These two kingdoms stood opposed to each other from all eternity, touching each other on one side, but remaining unmingled. Then Satan made an incursion into the kingdom of light, into the earth of light. The God of light, with his *syzygy*, "the spirit of his right hand," now begot the primal man, and sent him, equipped with the five pure elements, to fight against Satan. But the latter proved himself the stronger, and the primal man was for a moment vanquished. And although the God of light himself now took to the field, and with the help of new aeons (the spirit of life, etc.) inflicted total defeat upon Satan, and set the primal man free; the latter had already been robbed of part of his light by the darkness, and the five dark elements had already mingled themselves with the generations of light.

Creation of Man.—It is significant of the pessimistic character of the system that, while the formation of the world is considered as a work of the good spirits, the creation of man is referred to the princes of darkness. The first man, Adam, was engendered by Satan in conjunction with "sin," "cupidity," "desire." But the spirit of darkness drove into him all the portions of light he had stolen, in order to be able to dominate them the more securely. Hence Adam is a discordant being, created in the image of Satan, but carrying within him the stronger spark of light. Eve is given him by Satan as his companion. She is seductive sensuousness, though also having in her a small spark of light. But if the first human beings thus stood entirely under the dominion of the devil, the glorious spirits took them under their care from the very outset, sending aeons down to them (including Jesus), who instructed them regarding their nature, and in particular warned Adam against sensuality. But this first man fell under the temptation of sexual desire. Cain and Abel indeed are not sons of Adam, but of Satan and Eve; Seth, however, who is full of light, is the offspring of Adam by Eve. Thus did mankind come into existence, its various members possessing very different shares of light, but the men having uniformly a larger measure of it than the women. In the course of history the demons sought to bind men to themselves by means of sensuality, error and false religions (among which is to be reckoned above all the religion of Moses and the prophets), while the spirits of light carried on their process of distillation with the view of gaining the pure light which exists in the world. But these good spirits can only save men by imparting to them the true *gnosis* concerning nature and her forces, and by calling them away from the service of darkness and sensuality. To this end prophets, preachers of true knowledge, have been sent into the world. Mani, following the example of the gnostic Jewish Christians, appears to have held Adam, Noah, Abraham (perhaps Zoroaster and Buddha) to be such prophets. Probably Jesus was also accounted a prophet who had descended from the world of light—not, however, the historical Jesus, but a contemporaneous phantom Jesus, who neither suffered nor died (*Jesus impatibilis*). According to the teaching of some Manichaeans, it was the primal man who disseminated the true gnosis in the character of Christ.

Mani, the "Ambassador of Light."—But at all events Mani himself, on his own claim, is to be reckoned the last and greatest prophet, who took up the work of Jesus impatibilis, and first brought full knowledge. He is the "leader," the "ambassador of the light," the "Paraclete." It is only through his agency and that of his imitators, "the elect," that the separation of the light from the darkness can be completed. The system contains very fantastic descriptions of the processes by which the portions of light when once set free finally ascend even to the God of light. He who during his lifetime did not become one of the elect, who did not completely redeem himself, has to go through a severe process of purification on the other side of the grave, till he too is gathered to the blessedness of the light. When the imprisoned elements of light have at last been completely, or as far as possible, delivered from the world, the end of all things comes. All glorious spirits assemble, the God of light himself appears, accompanied by the aeons and the perfected just ones. The angels supporting the world withdraw themselves from their burden, and everything falls in ruins. A tremendous conflagration consumes the world; the perfect separation of the two powers takes place once more.

Ethics of the Manichaeans.—On the basis of such a cosmical philosophy, ethics can only have a dualistic ascetic character. Manichaean ethics is not merely negative, however, since it is necessary to cherish, strengthen and purify the elements of light, as well as free oneself from the elements of darkness. The aim is not self-destruction, but self-preservation; and yet the ethics of Manichaeism appears in point of fact as ascetic, to an extent that could only be practised by few; hence the religion must have abandoned all attempts at an extensive propaganda had it not conceded the principle of a twofold morality. A distinction was made in the community between the *electi* (*perfecti*), the perfect Manichaeans, and the *catechumeni* (*auditores*), the secular Manichaeans. Only the former submitted themselves to all the demands made by their religion; for the latter the stringency of the precepts was relaxed. They had to avoid idolatry, sorcery, avarice, falsehood, fornication, etc.; above all, they were not allowed to kill any living being (the ten commandments of Mani). They had also to free themselves as much as possible from the world; but in truth they lived very much as their non-Manichaean fellow-citizens. We have here essentially the same condition of things as in the Catholic Church, where a twofold morality is also in force, that of the religious orders and that of secular Christians—only that the position of the *electi* in Manichaeism was a more distinguished one than that of the monks in Catholicism. For, after all, the Christian monks never quite forgot that salvation is given by God through Christ, whereas the Manichaean *electi* were actually themselves redeemers.

It is evident that the religion of Mani borrowed various elements from older Oriental faiths, especially from Babylonian and Zoroastrian sources. It arose "in a country where several religions were competing with one another, and where, in consequence of this, various hybrid sects had been formed." The relations of Manichaeism to other religions have been investigated in much detail by Kessler and Cumont (*see* references given below); but special mention must be made here of its relation to Christianity.

Manichaeism and Christianity.—It is very difficult to determine what was the extent of Mani's knowledge of Christianity, how much he himself borrowed from it, and through what channels it reached him. It is certain that Manichaeism, in those districts where it was brought much into contact with Christianity, became additionally influenced by the latter at a very early period. The Western Manichaeans of the 4th and 5th centuries are much more like Christians than their Eastern brethren. In this respect Manichaeism experienced the same kind of development as Neo-Platonism. As regards Mani himself, it is safest to assume that he held both Judaism and Catholic Christianity to be false religions.

Finally, the Manichaean doctrines exhibit points of similarity to those of the Christian Elkesaites. The historical relation of Mani to Christianity is then as follows. From Catholicism, of which he very probably had no detailed knowledge, he borrowed nothing. On the other hand, he looked upon what he considered to be Christianity proper—that is, Christianity as it had been developed among the sects of Basilidians, Marcionites, and perhaps Bardesanites, as a comparatively valuable and sound religion. He took from it the moral teaching of the Sermon on the Mount, and a criticism of the Old Testament and of Judaism so far as he required it. Indications of the influence of Marcionitism are found in the high estimation in which Mani held the apostle Paul, and in the fact that he explicitly rejects the Book of Acts.

The Secret of Manichaeism.—How are we to explain the rapid spread of Manichaeism, and the fact that it really became one of the great religions? What gave it strength was that it united an ancient mythology and a thorough-going materialistic dualism with an exceedingly simple spiritual worship and a strict morality. On comparing it with the Semitic religions of nature we perceive that it was free from their sensuous *cultus,* substituting instead a spiritual worship as well as a strict morality. Manichaeism was thus able to satisfy the new wants of an old world. It offered revelation, redemption, moral virtue and immortality, spiritual benefits on the basis of the religion of nature. A further source of strength lay in the simple yet firm social organization which was given by Mani himself to his new institution. The wise man and the ignorant, the enthusiast and the man of the world, could all find acceptance here, and there was laid on no one more than he was able and willing to bear.

Originally furnished from fragments of various religions, Manichaeism could increase or diminish this possession without rupturing its own elastic framework. And, after all, great adaptability is just as necessary for a universal religion as a divine founder in whom the highest revelation of God may be seen and reverenced. Manichaeism indeed, though it applies the title "redeemer" to Mani, has really no knowledge of a redeemer, but only of a physical and gnostic process of redemption; on the other hand, it possesses in Mani the supreme prophet of God. If we consider in conclusion that Manichaeism gave a simple, apparently profound, and yet convenient solution of the problem of good and evil, a problem that had become peculiarly oppressive to the human race in the 2nd and 3rd centuries, we shall have named the main factors which account for the rapid spread of the system.

History of Manichaeism.—Manichaeism first gained a firm footing in the East, *i.e.,* in Persia, Mesopotamia and Transoxiana. The persecutions it had to endure did not hinder its extension. Even after the conquests of Islam the Manichaean Church continued to maintain itself, indeed it seems to have become still more widely diffused by the victorious campaigns of the Mohammedans, and it frequently gained secret adherents among the latter themselves. Its doctrine and discipline underwent little change in the East; in particular, it drew no nearer to the Christian religion. It first penetrated the Greek-Roman Empire about the year 280, in the time of the emperor Probus (*see* the *Chronicon* of Eusebius).

It was only subsequent to about 330 that Manichaeism spread rapidly in the Roman Empire. Its adherents were recruited on the one hand from the old gnostic sects (especially from the Marcionites—Manichaeism exerted besides this a strong influence on the development of the Marcionite churches of the 4th century), on the other hand from the large number of the "cultured," who were striving after a "rational" and yet in some manner Christian religion. Its polemics and its criticism of the Catholic Church now became the strong side of Manichaeism, especially in the West. It admitted the stumbling-blocks which the Old Testament offers to every intelligent reader, and gave itself out as a Christianity without the Old Testament. Instead of the subtle Catholic theories concerning divine predestination and human freedom, and instead of a difficult theodicaea, it offered an exceedingly simple conception of sin and goodness. The doctrine of the incarnation of God, which was especially objectionable to those who were going over to the new universal religion from the old cults, was not proclaimed by Manichaeism.

The farther Manichaeism advanced into the West the more Christian and philosophic did it become. In Syria it maintained itself in comparative purity. In North Africa it found its most numerous adherents, gaining secret support even among the clergy. Augustine was an *auditor* for nine years, while Faustus was at that time the most esteemed Manichaean teacher in the West. Augustine in his later writings against the Manichaeans deals chiefly with the following problems: (1) the relation between knowledge and faith, and between reason and authority; (2) the nature of good and evil, and the origin of the latter; (3) the existence of free will, and its relation to the divine omnipotence; (4) the relation of the evil in the world to the divine government.

Opposition of Roman Emperors.—The Christian Byzantine and Roman emperors, from Valens onwards, enacted strict laws against the Manichaeans. But at first these bore little fruit. The *auditores* were difficult to trace out, and besides they really gave little occasion for persecution. In Rome itself between 370 and 440 Manichaeism gained a large amount of support, especially among the scholars and public teachers. It also made its way into the life of the people by means of a popular literature in which the apostles were made to play a prominent part (*Apocryphal Acts of the Apostles*). In Rome Leo the Great was the first who took energetic measures, along with the state authorities, against the system. Valentinian III. decreed banishment against its adherents, Justinian the punishment of death. In North Africa Manichaeism appears to have been extinguished by the persecution of the Vandals. But it still continued to exist elsewhere, both in the Byzantine Empire and in the West, and in the earlier part of the middle ages it gave an impulse to the formation of new sects, which remained related to it. It is at least undoubted that the Paulicians and Bogomils, as well as the Catharists and the Albigenses, are to be traced back to Manichaeism (and Marcionitism). Thus the system, not indeed of Mani the Persian, but of Manichaeism as modified by Christian influences, accompanied Catholicism until the 13th century.

Sources.—(*a*) Oriental. Among the sources for a history of Manichaeism the most important are the Oriental. Of these the Mohammedan, though of comparatively late date, are distinguished by the excellent manner in which they have been transmitted to us, as well as by their impartiality. They must be named first, because ancient Manichaean writings have been used in their construction. At the head of all stands En-Nedīm, author of the *Fihrist* or "Catalogue" (*c.* 980) containing an account of Manichaeism which has been published separately with translation and notes by G. Flügel, *Mani, seine Lehre u. seine Schriften* (1862).

Of the Christian Orientals those that afford most information are Ephraem Syrus (d. 373), in various writings; the Armenian Esnik (German translation by J. M. Schmid, 1900, *see* also *Zeitsch. f. hist. Theol.,* 1840, ii.; Langlois, *Collection,* ii. 375 *seq.*), who wrote in the 5th century against Marcion and Mani; and the Alexandrian patriarch Eutychius (d. 916), *Annales,* ed. Pococke (1628). There are, besides, scattered pieces of information in Aphraates (4th cent.), Bar-Hebraeus (13th cent.) and others. The newly found Syriac *Book of Scholia* of Theodor bar Khouni (*see* Pognon, *Les Coupes de Kouabir*, Paris, 1898) gives many details about Mani's teaching (also ed. without translation by Dr. M. Lewin, Berlin, 1905).

(*b*) Greek and Latin. The earliest mention of the Manichaeans in the Graeco-Roman Empire is to be found in an edict of Diocletian (*see* Hänel, *Cod. Gregor.*, tit. xv.), which is held by some to be spurious, while others assign it to one or other of the years 287, 290, 296, 308 (so Mason, *The Persec. of Diocl.*, pp. 275 *seq.*). Eusebius gives a short account of the sect (*H. E.*, vii. 31). It was the *Acta Archelai*, however, that became the principal source on the subject of Manichaeism for Greek and Roman writers. In the form in which we now possess them, they are a compilation after the pattern of the *Clementine Homilies*, and have been subjected to manifold redactions, and give an account of Manichaeism which is largely legendary. These *Acta* were used by Cyril of Jerusalem (*Catech.* 6), Epiphanius (*Haer.* 66), and a great number of other writers. Important matter is to be found in the resolutions of the councils from the 4th century onwards (*see* Mansi, *Acta concil.*, and Hefele, *Conciliengeschichte*, vols. i.–iii.), and also in the controversial writings of Titus of Bostra (6th century), Πρὸς Μανιχαίους (ed. Lagarde, 1859), and of Alexander of Lycopolis Λόγος πρὸς τὰς Μανιχαίου δόξας (ed. Combefis; transl. in *Ante-Nic. Lib.*, vol. xiv.). Of the Byzantines, the most worthy of mention are John of Damascus (*De haeres.* and *Dialog.*) and Photius (*cod.* 179 *Biblioth.*).

Bibliography.—The most important works on Manichaeism are Beausobre, *Hist. critique de Manichée et du Manichéisme* (2 vols., 1734 *seq.*; the Christian elements in Manichaeism are here strongly, indeed too strongly, emphasized); Baur, *Das manich. Religionssystem* (1831; in this work Manichaean speculation is exhibited from a speculative standpoint); Flügel, *Mani* (1862; a very careful investigation on the basis of the *Fihrist*); Kessler, *Untersuchung zur Genesis des manich. Religionssystems* (1876); and the article "Mani, Manichäer," by the same writer in Herzog-Hauck's *R.E.*, xii. 193–228; Kessler, *Mani* (2 vols., Berlin, 1889, 1903); *Recherches sur le manichéisme: I. La cosmogonie manichéenne d'après Théodore Bar Khôui*, by Franz Cumont (Brussels, 1908); *II. Fragments syriaques d'ouvrages manichéens*, by Kugener and F. Cumont. *III. Les Formules grecques d'abjuration imposées aux manichéens*, by F. Cumont. *See* also A. A. Bevan, art. "Manichaeism" in Hastings' *Encyclopaedia of Religion and Ethics* (vol. viii. 1915).

MANICURING is the art of treating the nails of the hands to protect and improve their health and to beautify them according to the current standards of fashion. In the days of Salome and Cleopatra, women stained their nails with henna, and this vogue persists among some primitive peoples to-day. Under the social régime of the Chinese Empire, finger nails worn several inches long, and covered with gold cases, were a symbol of the aristocracy who did not have to work with their hands. The present mode is to shape the nails like the finger-ends and pink them to emphasize or suggest their healthy colour.

These rules, almost the same as those for a professional manicure, should be followed in the home manicure:

The nails should be thoroughly cleaned with a nail brush and warm soap suds. They should then be filed and shaped. Extreme points or blunt nails are not natural or in good taste. The tip of the nail should conform to the curved shape of the cuticle at the base of the nail, when this is normal.

When the filing is completed, immerse the fingers in soapy water for about three minutes to soften the cuticle. Then use a cuticle solvent with an orangewood stick (the end of which has been wrapped in a bit of cotton) around the base of the nail, under the edge of the cuticle surrounding the base of the nail, and under the free edge of the nail at the tip of the finger. Gently remove the accumulated loosened cuticle with a blunt pointed cuticle knife, holding the blade of the knife flat against the cuticle at the side of the nail, and wipe off with the end of a small towel.

A little bleach may be applied under the nails to whiten them. Then rub in a little nail cream around the cuticle to nourish the nail and keep the cuticle from becoming dry and cracking or forming hang-nails. Remove any loose bits of cuticle with a nipper or manicure scissors.

If a powder polish is used, first apply a bit of nail burnish cream to the nails and then the powder. Polish each nail with a chamois-covered buffer, using long strokes from left to right until the desired gloss is secured. (D. Co.)

MANIFEST, in commercial law, a document delivered to the officer of customs by the captain of a ship before leaving port, giving a description of the shipped goods of every kind, and setting forth the marks, numbers and descriptions of the packages and the names of the consignors thereof. In England, by the Revenue Act 1884, s. 3, where goods are exported for which no bond is required, a manifest must be delivered to the officer of Customs by the master or owner of the ship within six days after the final clearance, or a declaration in lieu thereof, the penalty in default being a sum not exceeding five pounds.

The U.S. Rev. Stat., § 2807, specifically sets forth the requirements of a manifest. It should list, among other items, the ports of lading and destination, names of consignees, passengers and owners of the vessel.

MANIFOLDS. Two geometrical figures are said to be *homeomorphic* if it is possible to set them into point for point continuous correspondence with one another. To illustrate: a closed curve (of the simple sort which passes through no point more than once) is homeomorphic with the circumference of a circle; the surface of a sphere is homeomorphic with the surface of an ellipsoid or of a cube, but not with a ring shaped surface such as a torus (fig. 1). The *topological* properties of a figure F are those which are shared by all figures homeomorphic with F. For instance, one of the topological properties of a line segment is its separability into two pieces by the removal of just one of its points; a non-topological property of the segment is its length. *Analysis Situs* (*q.v.*), or *Topology*, is the theory of the topological properties of figures. Theorems of analysis situs are very general in character and often synthesize results originally obtained in widely separated fields of mathematics.

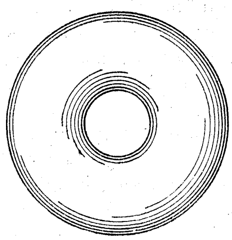


Fig. 1

n-Dimensional Manifolds.—The theory of functions of several variables leads directly to the study of a special class of figures called n-dimensional manifolds. These figures are hard to define with precision in non technical terms. We may say that a *one-dimensional manifold* is a simple, closed curve, a *two-dimensional manifold* a closed surface without singularities and, broadly speaking, an *n-dimensional manifold* the generalization to n dimensions of a closed curve or surface without singularities. One of the important outstanding problems of analysis situs is to classify higher dimensional manifolds into *types* such that two manifolds are of the same type if, and only if, they are homeomorphic. Up to the present, a complete classification has been carried out only for manifolds of dimensions one and two. The case $n=1$ is trivial: all one-dimensional manifolds are of the same type since every simple, closed curve is homeomorphic with the circumference of a circle. We shall outline below the results of the classification for the case $n=2$.

Möbius Strip.—First, it will be necessary to call attention to a rather curiously shaped surface known as a *Möbius* strip. This surface may be obtained by taking a plane rectangular region *ABCD*, where A and C denote diagonally opposite points, and deforming the region in three dimensional space so as to bring the point A into contact with the point C and the edge AB into contact with the edge CD. The resulting strip will be a belt-shaped surface with a twist in it (fig. 2). It obviously differs in type from an ordinary belt-shaped surface without the twist, since its boundary consists of a single curve, whereas the boundary of the untwisted surface consists of a pair of curves.

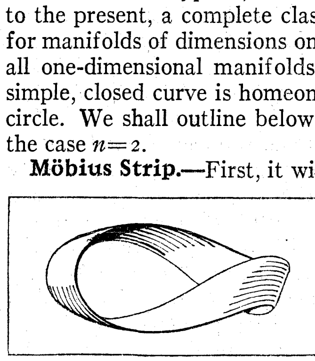

Fig. 2

A two dimensional manifold is said to be *orientable* if no portion of it is homeomorphic with a Möbius strip; otherwise, it is said to be non orientable. The manifold is said to have the *connectivity* k if the maximum number of simple, closed curves that may be traced upon it without separating it into two or more pieces is $k-1$. The type of a two dimensional manifold is completely fixed when we know the connectivity of the manifold and whether or not the manifold is orientable.

A model of the most general orientable, two dimensional manifold M may be obtained by making a target out of a spherical block and shooting a suitable number of bullet holes completely through the block. The surface of the pierced block will then be homeomorphic with the manifold M. The connectivity of the manifold M is $k=2p+1$, where p is the number of bullet holes in the target; consequently, the connectivity of M is always odd in this case. The number p is called the genus of the manifold M. The sphere is of genus zero, the torus of genus one.

Genus of a Manifold.—The notion of the genus of a manifold plays an important rôle in the theory of algebraic equations of the form

$$F(x, y) = 0 \tag{1}$$

The solutions (x,y) of an irreducible algebraic equation (1) may always be represented by the points of an orientable two dimensional manifold of suitable genus p, where p is a function of the expression $F(x,y)$. Many of the properties of equation (1) depend upon the value of the number p. In Riemann's classical theory of the integrals of rational functions,

$$\int \Phi(x, y)dx, \tag{2}$$

where x and y are connected by a relation of the form (1) the genus of the manifold determined by (1) again comes into evidence. When p is zero the integral (2) is elementary, in the sense that it may be expressed in terms of rational functions and logarithms; when p is unity, the evaluation of (2) leads to the theory of elliptic functions, and so on.

A non orientable two dimensional manifold M cannot be immersed in a Euclidean space of less than four dimensions. It may, however, be represented schematically by a plane region R bounded by a suitable finite number q of non intersecting circles, where pairs of opposite points on the various bounding circles are each to be thought of as representing a single point of the manifold. In four dimensional space it would be possible to reconstruct a model of the manifold M by deforming the region R in such a manner as to bring into coincidence opposite points on the bounding circles. The connectivity of the manifold M is $k=q+1$, so that, in this case, k may be any integer greater than unity. The plane of real, projective geometry (with a line of points at infinity) is a non orientable manifold of the simplest type, with k equal to two.

Combinatorial Method.—A very effective way of studying manifolds is the so-called *combinatorial* one. Consider a convex polyhedral surface in ordinary space. Regarded as a set of points, the surface is an ordinary manifold of genus zero of the same type as the sphere. But the surface may also be regarded as a collection of vertices, edges and faces. Let the number of these vertices, edges and faces be α_0, α_1 and α_2 respectively. We then find that a relation of the form

$$\alpha_0-\alpha_1+\alpha_2 = 2 \tag{3}$$

is always satisfied, irrespective of the polyhedron chosen. Now, in reality, relation (3) has an underlying topological significance. Let us use the terms 0-*cell*, 1-*cell* and 2-*cell* to denote figures homeomorphic with the vertices, edges and faces respectively of a convex polyhedron. Then if we take any two dimensional manifold M and subdivide it in a perfectly arbitrary manner into a finite number of cells we always obtain the relation

$$\alpha_0-\alpha_1+\alpha_2 = 3-k \tag{4}$$

where, this time, α_0, α_1 and α_2 denote the number of 0-, 1- and 2-cells of the subdivision respectively. Relation (3) is a special case of relation (4), where we have $k=1$, and where the cells are all straight. The number $\alpha_0-\alpha_1+\alpha_2$ is called the *Euler number* of the manifold M. In view of relation (4), a knowledge of the Euler number of a manifold is equivalent to a knowledge of the connectivity number k.

Manifolds of more than two dimensions were considered by Riemann and Betti, but Poincaré was the real founder of the higher dimensional theory. Poincaré extended to n dimensions the combinatorial method of cellular subdivision described above and discovered a number of new topological invariants. Of these last, the most important ones are his "Betti numbers" $P_1, P_2, \ldots, P_{n-1}$ which are generalizations of the connectivity number k. The Betti numbers satisfy a duality relation

$$P_i = P_{n-i}, \; (i = 1, 2, \ldots, n-1)$$

and a generalized Euler relation

$$\sum_{i=0}^{n}(-1)^i\alpha_i = 1+\sum_{i=1}^{n-1}(-1)^iP_i+(-1)^n$$

which reduces to (4) in the two dimensional case. Alexander has shown that the invariants of Poincaré are insufficient to fix the type of a higher dimensional manifold, and has found further invariants which appear, also, to be insufficient. Heegaard has studied the theory of three dimensional manifolds by a somewhat different method which would, no doubt, bear further exploitation.

An important class of problems has to do with the possible types of continuous transformations of a manifold into itself, and with the existence of points left invariant by these transformations. Brouwer has studied the transformations of a sphere of n dimensions and has shown, in particular, that a one-to-one sense preserving transformation of a two dimensional sphere always leaves at least one point invariant. Lefschetz has obtained a very general theorem about the fixed points of an arbitrary transformation of an arbitrary n-dimensional manifold. Morse, Nielsen and others have made noteworthy contributions to the theory. Numerous applications are to be found for this branch of analysis situs. For example, to take a very simple case, the so-called fundamental theorem of algebra to the effect that every algebraic equation

$$F(x) = 0$$

has a root obviously reduces to the theorem that the transformation

$$y = x+F(x)$$

has a fixed point. Birkhoff and Kellogg have proved that extremely general systems of differential and integral equations admit solutions by studying the transformations of a sphere of infinitely many dimensions. (*See* also KNOTS; ANALYSIS SITUS.)

(J. W. A.)

MANIHIKI (MANAHIKI), a scattered archipelago in the central Pacific Ocean, between 4° and 11° S., and 150° and 162° W., seldom visited, and producing only a little copra and guano. Manihiki may be taken to include Caroline Island, Vostok and Flint to the east; Suvorov, Manihiki or Humphrey, and Tongareva or Penrhyn to the west, and Starbuck and Malden to the north, the whole thus roughly forming the three corners of a triangle. There are pearl and pearl-shell fisheries at Tongareva and Suvorov. The natives are Polynesians. The islands were mostly discovered early in the 19th century, and were annexed by Britain mainly in 1888–89. Pop. (1936) 1,244 (25 non-native).

MANILA (Spanish pronunciation mah-nee-lah; probably from Tagalog *manilad,* place of nilads—*Ixora Manila,* a white blossoming shrub which grew there in profusion); the capital and largest of the twelve chartered municipalities of the Philippines, chief port and centre of political and intellectual activity in the islands. It has a polyglot population: brown race (Tagalogs predominating) 556,141; yellow race (Chinese 46,233; Japanese 4,730) 51,088; white race (U.S. 3,191; Spaniards 2,124; British 481) 8,372; blacks 86; mixed 7,517; others 2,345. These were the figures of the 1939 census, which also gave a total of 623,492, of which 326,287 were males. Compared with the 1918 census of 285,306, these figures disclosed a remarkable growth, mainly among the oriental elements.

Geography and Topography.—Situated at latitude 14° 35′ 31″ N. and longitude 120° 58′ 8″ E., Manila is about 5,450 mi. from Honolulu, 1,550 mi. from Singapore and 1,400 mi. from Nagasaki, the nearest port in Japan proper. Hongkong, the nearest Chinese port, is about 600 mi. to the northwest. The city lies on the eastern shore of Manila bay, one of the world's largest landlocked harbours, with a circumference of about 120 mi., on the west coast of Luzon island and on the plain stretching from Lingayen gulf to the bay. Sunsets on the latter, viewed from the city, are among the most gorgeous to be seen anywhere. To the north Mt. Arayat, a sacred mountain of the early Malays, is plainly visible from the bay; to the west are the Mariveles mountains, and to the east the terrain rises to Laguna de Bay, a large lake from which the Pasig river issues and flows through the city, bisecting it, into the bay. Various *esteros* (tidewater creeks) find their way through the city, connecting with the river or directly with the bay.

The city is divided into 14 districts of unequal size, half of them on each side of the Pasig. As there are three Romes—classical, Christian-mediaeval and modern—so there are three Manilas—not indeed, distinct, like watertight compartments, but rather as layers and threads running through the city.

(1) *The primitive Malay,* typical of which is Tondo, the most populous district. It lies north of the Pasig, bordering the bay, and is almost entirely inhabited by native labourers and fisherfolk, living, as did their ancestors for unnumbered generations, in houses of nipa and bamboo, built along narrow streets and *esteros.* The district of Santa Cruz lies east of Tondo and has a narrow frontage on the Pasig, which is crossed there by the Santa Cruz bridge. Besides a large native population it contains the *Cementerio del Norte* and the racing park and grandstand. Still farther east is Sampaloc, largest in area of all the districts and mainly native, but containing the modern suburb of Santa Mesa, inhabited largely by whites. South of Tondo, and fronting the Pasig, are the two small districts of San Nicolas, with shipping establishments, and Binondo, which contains the city's most famous business thoroughfare—the Escolta—and Calle Rosario, with its "Chino" stores and embroidery shops. The approach from the south is by the Jones bridge. South of Sampaloc, and east of Santa Cruz, are the districts of Quiapo, a former Jesuit mission station, and San Miguel, in which is located, at the river's brink, the stately Malacañan palace, formerly the residence of Spanish and U.S. governors general, then occupied by the commonwealth president. Leaving the north side of the Pasig we cross either the Jones or Santa Cruz bridge to (2) *Spanish mediaeval Manila,* represented by Intramuros (the walled city). This was founded and fortified by the early Spanish *conquistadores.* Its thick stone walls, some two-thirds of which were intact in 1941, are about $2\frac{1}{2}$ mi. in circumference and rise to a height of about 25 ft. Ft. Santiago, the oldest portion of the wall, was long used as the headquarters of the United States army in the Philippines. Formerly the wall abutted on the bay at the west; but the creation of the Port Area from land reclaimed from the bay left the wall inland while the ancient moat which once flanked it on the land side was drained and filled about 1905 and converted into sunken gardens and a municipal golf course. Along the western side of the wall and between it and the Port Area is the Bonifacio drive, extending from the Anda monument on the south bank of the Pasig to the Luneta. Until late Dec. 1941, when the Japanese aerial depredations began, Intramuros was a museum of Spanish architecture; but on Dec. 27 of that year it became "a roaring mass of flames" and a cable four days later announced the destruction of Santo Domingo church and convent and the colleges of Santa Rosa, Santa Catalina and San Juan de Letran. Apparently the Roman Catholic cathedral, located on Plaza McKinley, the Dominican University of Santo Tomás and the Jesuit Ateneo were still intact. Reminiscent of Spanish art are the statue of Magellan, the pioneer world navigator; of his lieutenant El Cano (in the Ayuntamiento), who guided the expedition back to Spain; of Legazpi and Urdaneta, who founded the first successful Spanish colony in the Philippines (1565, also the year of St. Augustine's founding); of Benavides (near the Dominican convent), first Roman Catholic archbishop of the Philippines; of Simon de Anda y Salazar, who resisted the British occupation (1762–64); of Carlos IV in Plaza McKinley; and of Isabela II in Malate. Native art is represented by Juan Luna's famous painting (in Malacañan palace), *El Pacto de Sangre* ("The Blood Compact"), and by the Rizal monument on the Luneta; while American art is most apparent in the architecture of new structures, especially at Quezon City. For (3) *modern Americanized Manila* finds a striking representative in the Port Area (El Puerto), created entirely under U.S. auspices with soil reclaimed from the bay, into which were extended the substantial government piers. The area is protected from the sometimes heavy surf of the bay by an extensive breakwater, constructed also under U.S. direction, enclosing a basin regularly dredged to a depth of about 30 ft., through which most of the country's foreign shipping enters the city, thus largely superseding the channel connecting the bay with the sluggish Pasig, which, however, is dredged to a depth of about 18 ft. so that lighter craft may enter the river for a considerable distance. The government customhouse faces the bay in the Port Area.

South of Intramuros lies the Luneta, Manila's "common," where an official band plays in the evening and vast gatherings of the populace are held. It was extended, like the Port Area, by reclaiming land from the bay, and it is in the centre of this park that the Rizal monument rises. West of the old Luneta lies Burnham green, named from its designer, and to the east is Wallace field, also a place of assembly, and the site of the annual Philippine carnival. Some noted boulevards, reminiscent of U.S. rule, touch this area. Taft avenue, a broad thoroughfare, stretches from the eastern wall of Intramuros to the Luneta. Traversing it, one passes notable buildings like the General hospital, the new Scottish Rite temple and the Jai-alai building, "the city's best designed edifice." The Dewey boulevard extends from the Luneta and Burnham green southward to the Pasig, and fronting it is the spacious, combined residence and office building of the United States high commissioner. Southeast of Intramuros and the Port Area is Ermita and still farther south, Malate. Both are leading white residential districts with broad streets and attractive homes. East of Ermita lies Paco, containing a large cemetery, and beyond it Pandakan and Santa Ana. The latter extends over the San Juan river, where San Juan Heights, another white residential suburb, is located.

Quezon City.—Northeast of Sampaloc, but outside the limits of Manila, a new city was rising in 1941, administratively independent of the old, but apparently destined to have an important influence on its future. Quezon City (the name may have been suggested by Ciudad Trujillo in Santo Domingo) is located on elevated land northeast of Manila and is two and a half times its area (30 sq.mi.). A chartered municipality with villages aggregating 40,000 in population in 1941, this project was intended as the future Philippine capital.

Corregidor.—At the entrance to the bay, 28 mi. from Manila, is Corregidor island, a natural fortress of volcanic rock, approximately 3 mi. wide and 5 mi. long. First fortified by the Spanish, it was greatly strengthened by the Americans, who built Ft. Mills, installed coastal defense guns and carved a maze of underground tunnels and galleries in the rock. The island was the anchor of the U.S.-Filipino army's epic defense of Bataan against the Japanese, Jan.–April 1942.

Climate.—Manila has a Type I climate (*see* PHILIPPINE ISLANDS), the three warmer months coming from April to June, the four colder ones from November to February and the other five of intermediate temperature. In 1939 the mean air temperature was 80·2° F., less than one-half of a degree above normal for the period 1885 to 1939. The highest mean monthly reading was 83·5° F. in April, and the lowest was 75·6° F. in December—a range of 7·9° F. The absolute maximum for the year was 98·1° F. on April 17 and the absolute minimum was 64·4° F. on March 3 and December 14 and 26, giving an absolute range of 33·7° F. The city had a total rainfall of 86·3 in. in 1939, 44·3 in. above normal for the period 1865–1939. It had 158 rainy days, 12 more than normal, the heaviest fall in a single day being 7 in. on July 14.

Cultural, Religious and Eleemosynary Institutions.—The early schools and churches in the islands were founded mostly by the religious orders and in Manila. The Dominican order, which specializes in higher education, founded the University of Santo Tomás in 1619 and, as a feeder thereto, the Collegio de San Juan de Letran in 1640. Both were limited to male students and the university confers degrees upon Catholics only. It and the Dominican church and convent were all located in the walled city. The main university buildings, built later, are in Sampaloc. Public schools in 1941 numbered 87—42 primary, 38 intermediate and 7 secondary, with a total enrolment of 110,702 or 56.4% of the school population (1939 census)—a decline of nearly 14% since 1926. Under the insular bureau of education the city superintendent is in charge of these schools. At the apex of the public educational system is the University of the Philippines, opened in 1908, and with an enrolment in 1940 of 8,109. In 1938 President Quezon vetoed a bill, supported by the Roman Catholic clergy, requiring religious instruction in the public schools.

The Jesuit order, as early as 1601, founded the Collegio de San José. In 1859, after the Jesuit order returned to the islands, it established the Escuela Municipal which later became the Ateneo de Manila. The policy, from early in the 20th century, was to replace Spanish with U.S. Jesuits. At the close of the academic year 1939–40 there were in the islands 79 Jesuits, of whom 23 were Filipinos, reported as engaged in educational work. The Ateneo offers instruction in the grades, high school and college, premedical, prelaw, law, commerce and industrial technology. It reported, in the year last mentioned, a student body of 2,094 and a faculty of 43 Jesuits and 92 lay professors and instructors. The order also undertook an interesting experiment, long antedated in the public school system, of extension, in establishing a trade school with classes for labourers at night, in the old convento of Sampaloc. Instruction is given in "English, Tagalog, arithmetic, automechanics, mechanical drawing, good citizenship and religion." No prior educational tests were imposed in 1941, and tuition was limited to one peso per month for those able to pay. The Jesuit church of San Ignacio (Intramuros) is noted for its artistic carvings. The order has also a church in Ermita and conducts the government observatory and weather bureau. The Augustinians (original and Recollectos) also have churches and convents in the walled city, and those of the first named—the oldest parts of which antedate 1600—are ascribed to a nephew of Herrera, builder of the Escorial.

The Protestant churches have generally supported the public schools; but there is a union theological school—Ellinwood seminary—for the training of Protestant ministers, and a school for Moros in Jolo was established under Episcopalian auspices. The imposing Episcopal Cathedral of St. Mary and St. John is located in Ermita, as is the Union (formerly Presbyterian) church.

Libraries.—Though there had been attempts to found a Philippine library as early as 1887, the real foundation dates from the arrival in the islands of Dr. James A. Robertson, who had been selected for the task because of his work in compiling the monumental enterprise of 55 volumes on *The Philippine Islands*. In an all too brief service of about six years, he established the library on a modern basis with an especially good start in Filipiniana, including the purchase of the valuable collection of the Compañia General de Tabacos. In 1941 the library's division on that subject was the most extensive anywhere save possibly that in the royal archives at Seville, Spain. The library also contains large collections of other orientalia and of works on history and economics; but thousands of volumes on special subjects are housed in buildings attached to other departments. There is a modern publishing house, the Ramon Roces Publications, Inc. Besides the Philippine General hospital on Taft avenue there is a U.S. Army hospital, St. Paul's, the Hospicio de San Juan de Dios, the San Lazaro (the three latter being Roman Catholic), St. Luke's (Episcopal), Mary J. Johnson Memorial (Methodist), the Mary Chiles Christian and a Chinese hospital.

Administration.—Under the Spaniards the city formed part of a province of the same name. This was abolished by the U.S. government after about three years of military rule, and on July 31, 1901, by an act of the Philippine commission, Manila became the first of the Philippine chartered cities; other municipalities of the old province had become part of the new province of Rizal. The so-called "administrative code" of 1917, amended in 1921, provided for a mayor appointed by the governor general (later by the commonwealth president) and confirmed by the senate, and a municipal board of 10 members elected at large and serving for three years. Administrative departments were: engineering and public works, police, law, fire, finance, assessment, health and welfare, the latter serving under the general supervision of the Philippine public health department. In 1941 there was a court of first instance for the city, a municipal court, with four judges, and a fiscal (city attorney), with 22 assistants.

With the Japanese invasion came a return to military rule, but of a very different character from that enjoyed by the city from 1898 to 1901. As in Shanghai, where the Japanese had been in control since 1937, their soldiers appeared to delight in subjecting the civilian, especially the white, population to indignities and oppressions. Martial law was declared and an attempt was made soon after entry to establish a puppet government, as in Manchuria and Nanking, by the appointment as "mayor" of a Filipino, who had remained in the city after the U.S. high commissioner and the commonwealth government had moved therefrom, and who is said to have "issued a statement promising to do everything in his power to create a greater East Asia" and to have agreed to the "inclusion of Japanese controllers and advisers in the city administration."

Trade and Industry.—By the census of 1939 there were 313,748 persons over ten years of age (about 50% of the total population) engaged in gainful occupations. Of these, 142,882 were in domestic and personal service; 60,127 in manufacturing and mechanical industries; 34,572 in trade, of whom 521 were wholesale dealers; 18,669 in professional service; 6,960 in the public service; 1,688 in fishing; 1,411 in agriculture; and 421 in mining and quarrying. By the same census there were 3,183 corporations in the city; the assessed valuation of all buildings and structures declared for taxation was 219,695,790 pesos; those of private ownership were assessed at 168,462,480 pesos. Figures for exports and imports, mainly through the port of Manila, later than 1939, obtained through the U.S. trade commissioner in Manila, showed: imports: 1st half, 1940, 143,387,398 pesos; 1st half, 1941, 135,901,992 pesos; exports: 1st half, 1940, 157,601,529 pesos; 1st half, 1941, 177,754,390 pesos. Most of the 1941 increase of 12,717,455 pesos was due to the output of minerals. For the Philippines, once almost exclusively an agricultural country, had rapidly become a mining country as well. Exports of manganese, for example, reached 43,515 tons (valued at $627,243) in 1940, as compared with 6,966 tons (valued at $89,784) in 1939 and 4,002 (valued at $44,075) in 1938. Exports of chromite, most of which went to the U.S., were as in the accompanying table.

Year	Metric Tons	Valuation, pesos
1935	1,292.0	27,558
1936	11,890.6	307,518
1937	69,855.6	1,542,100
1938	66,910.8	1,576,845
1939	126,748.6	2,153,640

These figures may serve to illustrate the vast extent of the

Philippines' mineral wealth, barely touched in 1941.

History.—When Miguel López de Legazpi, who in 1565 had established a Spanish colony in Cebu, came to found another on the banks of the Pasig in 1571, a Mohammedan rajah (Lakandola) reigned in Tondo. We read soon after of "a lucrative trade with the Chinese"; that thrifty race had probably been in touch with the locality for a considerable period. The so-called "piratical" expedition of Li Ma Hong in 1574 may have been the last of many. Legazpi, who was the first Spanish governor, died Aug. 20, 1572, and Guido de Lavezares, treasurer of the expedition, acted instead until the second governor's arrival in 1575. As the Philippines were placed under the viceroy of new Spain in Mexico City, official communication between the two widely separated areas was maintained by a galleon, which plied annually between Acapulco and Manila, and trade of considerable proportions was developed. Chinese junks crossed the China sea about the time of each galleon's arrival in order to exchange cargoes. As the galleon was the sole medium of communication with the western world, Spanish culture filtered in from Mexico, which accounts for the variety of Spanish in the islands being Mexican rather than Castilian.

Accompanying Legazpi to the islands was an Augustinian friar, Urdaneta, with others of that order, some of whom went on to Manila. In 1577 came Franciscans, who were followed by Dominicans, Jesuits and Augustinian Recollectos. These orders founded convents, churches and schools and became very powerful in the government. In 1580 the first, and only, Roman Catholic bishop of Manila arrived in the person of Domingo de Salazar, a Dominican; but in 1595 the diocese was raised to a metropolitan see, and Ignacio Santibañez became the first of a long line of Spanish archbishops which ended with Nozaleda about 1900. In 1583 an *audiencia* (supreme court) was established. Abolished later, it was re-established in 1598 and continued as a Spanish institution for three centuries. The Spanish law was applied in those portions of the archipelago actually ruled by Spain; but the Spanish civil code came into force there only in 1889.

In the 17th century Spain warred with the Dutch and Moros, and Manila was menaced repeatedly. During the "World War" of the 18th century, in 1762, the city was captured by British forces under General Draper and Admiral Cornish, who held it until 1764, the treaty of Paris (1763) having restored it to Spain. The 19th century was marked by some signs of progress. In 1825 Russell and Sturgis of Boston opened a branch of their Canton mercantile house—the first U.S. enterprise in the Philippines—and in 1837 the city was opened generally to foreign trade. On the completion, a generation later, of the Suez canal, direct means of communication with Europe were provided and commerce accordingly was stimulated. The first Masonic lodge was founded at Cavite, near Manila, in 1856 and the Katipunan, a revolutionary society, borrowing some of its features from Masonry, but never sanctioned by Rizal, acquired a large following. The execution of Rizal on Dec. 30, 1896, was the signal for the outbreak of revolution, and the Spanish-American War brought Admiral Dewey and his fleet, which destroyed the Spanish fleet at Cavite on May 1, 1898. The city of Manila surrendered to the United States forces on Aug. 13 and for nearly 44 years the Stars and Stripes floated continuously thereover. Then came the Japanese invasion on Dec. 8, 1941 (Philippine time), and their occupation of the city on Jan. 2, 1942—its fourth capture by a foreign power. (C. S. L.)

MANILA HEMP: *see* ABACÁ FIBRE.

MANILIUS, a Roman poet, author of a poem in five books called *Astronomica.* The work is never quoted in antiquity, and even his name is uncertain. It was probably Marcus Manilius. The poem seems to have been written in the time of Augustus or Tiberius, the latest event mentioned being the defeat of Varus in A.D. 9.

The work, which is incomplete and was probably never published, is of great learning and represents the most advanced views on the subject. He frequently imitates Lucretius, whom he resembles in his power of giving life to his subject.

See editions by J. Scaliger (1579); R. Bentley (1739); F. Jacob (1846); A. G. Pingré (1786); T. Breiter (Leipzig, 1907; and commentary 1909); H. W. Garrod (with trans., 1911); with introd. by A. E. Housman (1903). On the subject generally *see* M. Bechert, *De emendandi Manilii Ratione* (1878) and *De M. M. Astronomicorum Poeta* (1891); B. Freier, *De M. Astronom. Aetate* (1880); A. Cramer, *De Manilii Elocutione* (very full; 1882); G. Lanson, *De Manilio Poeta* (1887, bibl.); P. Monceaux, *Les Africains* (a study of the Latin literature of Africa; 1894); R. Ellis, *Noctes Manilianae* (1891); J. P. Postgate, *Silva Maniliana* (1897), chiefly on textual questions; P. Thomas, *Lucubrationes Manilianae* (1888), a collation of the Gemblacensis (Gembloux) ms.

MANILIUS, GAIUS, Roman tribune of the people in 66 B.C. At the beginning of his year of office (Dec. 67) he promoted a law (*de libertinorum suffragiis*) which gave freedmen the privilege of voting in the same tribe as their patroni (*see* PATRON AND CLIENT); this law was almost immediately declared void by the senate. Manilius then endeavoured to secure the support of Pompey by proposing to confer upon him the command of the war against Mithridates with unlimited power (*see* POMPEY). The proposal was supported by Cicero in his speech, *Pro lege Manilia,* and carried almost unanimously. Manilius was later accused by the aristocratical party on some unknown charge and defended by Cicero. He was probably convicted, but nothing further is heard of him.

See Cicero's speech; Dio Cassius xxxvi 25–27; Plutarch, *Pompey,* 30; Vell. Pat. ii 33; art. ROME: *Ancient History.*

MANIN, DANIELE (1804–57), Venetian patriot and statesman, was born in Venice, on May 13, 1804. He was the son of a converted Jew, who took the name of Manin because that patrician family stood sponsors to him, as the custom then was. He studied law at Padua, and then practised at the bar of his native city. A man of great learning and a profound jurist, he was inspired from an early age with a deep hatred for Austria. The heroic but foolhardy attempt of the brothers Bandiera, Venetians who had served in the Austrian navy against the Neapolitan Bourbons in 1844, was the first event to cause an awakening of Venetian patriotism, and in 1847 Manin presented a petition to the Venetian congregation, a shadowy consultative assembly tolerated by Austria but without any power, informing the emperor of the wants of the nation. He was arrested on a charge of high treason (Jan. 18, 1848), but this only served to increase the agitation of the Venetians, who were beginning to know and love Manin. Two months later, when all Italy and half the rest of Europe were in the throes of revolution, the people forced Count Palffy, the Austrian governor, to release him (March 17). The Austrians soon lost all control of the city, and under the direction of Manin a civic guard and a provisional government were instituted.

The Austrians evacuated Venice on March 26, and Manin became president of the Venetian republic. He was already in favour of Italian unity, and though not anxious for annexation to Piedmont (he would have preferred to invoke French aid) he gave way to the majority, and resigned his powers to the Piedmontese commissioners on Aug. 7. But after the Piedmontese defeats in Lombardy, and the armistice by which King Charles Albert abandoned Lombardy and Venetia to Austria, the Venetians attempted to lynch the royal commissioners, whose lives Manin saved with difficulty; an assembly was summoned, and a triumvirate formed with Manin at its head. Toward the end of 1848 the Austrians, having been heavily reinforced, reoccupied all the Venetian mainland. Early in 1849 Manin was again chosen president of the republic and conducted the defense of the city.

After the defeat of Charles Albert's forlorn hope at Novara in March the Venetian assembly voted "Resistance at all costs!" and granted Manin unlimited powers. Meanwhile the Austrian forces closed round the city; but Manin, assisted by G. Pepe, showed an astonishing power of organization. On May 26, however, the Venetians were forced to abandon Ft. Malghera, halfway between the city and the mainland; food was becoming scarce, on June 19 the powder magazine blew up and in July cholera broke out. Then the Austrian batteries began to bombard Venice itself, and when the Sardinian fleet withdrew from the Adriatic the city was also attacked by sea, while certain demagogues caused internal trouble. At last, on Aug. 24, 1849, Manin, who had courted death in vain, negotiated an honourable capitulation, on terms of amnesty to all save Manin himself, Pepe and some others, who were to go into exile.

On the 27th Manin left Venice forever on board a French ship. His wife died at Marseilles, and he himself reached Paris broken in health and almost destitute, having spent all his fortune for Venice. In Paris he became a leader among the Italian exiles. There he became a convert to monarchism, being convinced that only under the auspices of King Victor Emmanuel could Italy be freed, and together with Giorgio Pallavicini and Giuseppe La Farina he founded the *Società Nazionale Italiana* with the object of propagating the idea of unity under the Piedmontese monarchy.

His last years were embittered by the terrible sufferings of his daughter, who died in 1854; and he himself died on Sept. 22, 1857, and was buried in Ary Scheffer's family tomb. In 1868, two years after the Austrians finally departed from Venice, his remains were brought to his native city and honoured with a public funeral.

Manin was a man of the greatest honesty and possessed genuinely statesmanlike qualities. He believed in Italian unity when most men, even Cavour, regarded it as a vain thing, and his work of propaganda by means of the National society greatly contributed to the success of the cause.

See A. Errera, *Daniele Manin e Venezia (1804–1853)* (Florence, 1875); A. Errera and C. Finzi, *La vita e i tempi di D. Manin (1804–1858)* (Venice, 1873); Ferrari-Bravo and Maloni, *Daniele Manin e i suoi tempi* (1904); and G. M. Trevelyan, *Manin and the Venetian Revolution* (1923).

MANIN, LODOVICO or **LUDOVICO** (1726–1802?), last doge of Venice, was born June 23, 1726. He held a number of state positions before 1789, when, on the death of Paolo Renier, he was elected doge. He was far from eager to accept the office and protested strenuously that he was not qualified, but to no avail. He took office on March 9, 1789, less than two months before the opening of the French Revolution, the results of which were ultimately to cause the downfall of the Venetian republic.

Venetian policy in the subsequent years was one of unarmed neutrality. The nobles of the Great Council, mistakenly thinking that these tactics would preclude attack and that no harm could come to the oldest government in Europe, would not agree to join Austria in that country's anti-Napoleonic war. Napoleon encouraged the Venetians in this view by continually professing his friendship, but he had determined to take Venice and on April 18, 1797, nearly a month before he actually captured it, promised the republic to Austria. He then seized on a minor excuse to declare war on Venice, and Manin and the nobles were too frightened to resist. On May 12 the Great Council, in its final session, voted itself out of existence, substituting a representative government. Manin resigned his office and spent the rest of his life in retirement.

It is probable that the Venetian republic, as it existed in the late 18th century, was doomed in any case, and Manin was certainly not wholly responsible for the conditions which led to its final downfall. He was in large part only a victim of the circumstances in which he happened to be placed, but he has been widely censured for his refusal to face the fact that the French were a definite menace until too late, and for his weak behaviour immediately preceding Venice's fall, when he was too frightened to allow the citizens to attempt to defend the city of Venice, although they were eager to do so.

MANING, FREDERICK EDWARD (1812–1883), New Zealand judge and author, son of Frederick Maning, of Johnville, county Dublin, was born July 5, 1812. His father emigrated to Tasmania in the ship "Ardent" in 1824 and took up a grant of land there. Young Maning served in the fatuous expedition which attempted to drive in the Tasmanian blacks by sweeping with an unbroken line of armed men across the island. Soon afterward he decided to try the life of a trader among the wild tribes of New Zealand and, landing in the inlet of Hokianga in 1833, took up his abode among the Ngapuhi. With them the tall Irish lad—he stood 6 ft. 3 in.—full of daring and good humour and as fond of fun as of fighting, quickly became a prime favourite, was adopted into the tribe, married a chief's daughter and became a "Pakeha-Maori" (foreigner turned Maori). With the profits of his trading he bought a farm of 200 ac. on the Hokianga, for which, unlike most white adventurers of the time, he paid full value. When New Zealand was peacefully annexed in 1840, Maning's advice to the Maori was against the arrangement, but from the moment of annexation he became a loyal friend to the government, and in the wars of 1845–46 his influence was exerted with effect in the settlers' favour. Again, in 1860, he persuaded the Ngapuhi to volunteer to put down the insurrection in Taranaki. From 1865 to 1881 he was a judge of the native lands court, where his unequalled knowledge of the Maori language, customs, traditions and prejudices was of solid value. He died in London on July 25, 1883. At his wish, his body was taken back to New Zealand and buried there. Maning wrote *Old New Zealand* and *History of the War in the North of New Zealand against the Chief Heké,* reprinted in London in 1876 and 1884.

MANIPLE, a liturgical vestment of the Catholic Church, proper to all orders from the subdeacon upward. It is a narrow strip of material, silk or half-silk, about a yard long, worn on the left fore-arm in such a way that the ends hang down to an equal length on either side. In order to secure it, it is sometimes tied on with strings attached underneath, sometimes provided with a hole in the lining through which the arm is passed. It is ornamented with three crosses, one in the centre and one at each end, that in the centre being obligatory, and is often elaborately embroidered. It is the special ensign of the office of subdeacon and at the ordination is placed on the arm of the new subdeacon by the bishop with the words: "Take the maniple, the symbol of the fruit of good works." It is strictly a "mass vestment," being worn, with certain exceptions (*e.g.,* by a deacon singing the Gospel at the service of blessing the palms), only at mass, by the celebrant and the ministers assisting.

The earliest extant specimen of the band-like maniple is that found in the grave of St. Cuthbert (early 10th century); by the 11th century (except in the case of subdeacons, whose maniples would seem to have continued for a while to be cloths in practical use) the maniple had universally assumed its present general form and purely ceremonial character.

The maniple was originally carried in the left hand. In pictures of the 9th, 10th and 11th centuries it is represented either as so carried or as hung over the left fore-arm. By the 12th century the rule according to which it is worn over the left arm had been universally accepted. According to present usage the maniple is put on by priests after the alb and girdle; by deacons and subdeacons after the dalmatic or tunicle; by bishops at the altar after the *Confiteor,* except at masses for the dead, when it is assumed before the stole.

In the east the maniple in its western form is known only to the Armenians, where it is peculiar to subdeacons. This vestment is not derived from the Roman rite but is properly a stole, which the subdeacons used to carry in the left hand. It is now laid over the subdeacon's left arm at ordination. The true equivalent of the maniple (in the Greek and Armenian rites only) is not, as has been assumed, the *epimanikion,* a sort of loose, embroidered cuff (*see* VESTMENTS), but the *epigonation.*

See J. Braun, S. J., *Die liturgische Gewandung* (Freiburg im Breisgau, 1907), pp. 515–561, and the bibliography to VESTMENTS.

MANIPULATIVE SURGERY. The earliest practitioners of "bone-setting"—the old name for what is now described as manipulative surgery—date back into very remote times, and Hippocrates was the author of a treatise on dislocations. The history of the Roman Republic tells of successful practitioners of this ancient craft.

During the years when surgery was gradually being regularized and its seats of learning were being established, "bone setters" were the only orthopaedic surgeons of those days, and the doctors apparently countenanced them as legitimate exponents of that section of therapeutics. The famous surgeon William Cheselden, in the middle of the 18th century, used to send cases to the bone-setters for treatment, and frankly admitted that he did so because he was not competent to treat them himself.

The renowned surgeon, John Hunter, was amongst the first of eminent surgeons to realize the value of early movements in cases of sprains and joint injuries. He wrote: "Nothing can promote contraction of a joint as much as motion before the disease is removed, but when all inflammation is gone off . . . a little motion and frequently repeated is necessary to prevent healing taking place with the parts fixed in one position."

The world of conservative surgery owes an unpayable debt of gratitude to Sir James Paget who, in his desire for the public weal and the true interests of science, wrote to *The British Medical Journal* in Jan. 1867, urging his professional brethren to "learn what was good in the methods of the bone-setter, and eschew what was harmful." Paget stood on firm ground when he declared that "too long rest is by far the most frequent cause of delayed recovery after the injuries of joints, and not only to injured joints but to those that are kept at rest because parts near them have been injured."

Later, Dr. Wharton Hood, who had conceived the greatest admiration and respect for Robert Hutton, the bone-setter, and who recognized the false teaching of his profession in regard to many forms of joint injuries and derangements, made a thorough investigation of Hutton's methods, and after the bone-setter's death published a description of them in *The Lancet*.

Types of Cases.—Flat-foot, with its distressing deformity and painful crippling of the patient, occupies a front place amongst those cases which yield most satisfactorily to skilled manipulative treatment. To commence to correct this abnormality in its early stages is important, though cases might be instanced of patients even up to 60 years of age making perfect recoveries. The time of puberty is the period at which the irregularity usually makes its appearance, and the progress of the trouble is usually rapid and the deformation very marked.

It is difficult to assign with certainty the predisposing factor in such cases, though heredity probably plays some part in its origin. As many as four members of one family have been known to suffer from the complaint. The hands of the operator—if sufficiently powerful—constitute a much more effective instrument for forcing the foot and ankle into their normal positions than the Thomas wrench which is largely used even now. Several corrections should be made at short intervals, followed immediately by certain exercises in place of the one or two adjustments which used to be considered sufficient. The encasement of the joint in plaster of paris is secure immobilization and rest in bed must on no account be recommended. The anatomical contour of the foot is palpably bettered even after the first manipulation, and each operation brings the patient nearer full recovery. Almost all cases of adhesive and acquired flat-foot should recover. Congenital cases are much less satisfactory, though even in these improvement can generally be looked for. The technique is difficult and should be taught by cinematographic pictures so slowly reproduced that students can follow each manipulation carefully.

The Shoulder Joint.—The habitual derangement of the shoulder joint—sometimes on the slightest provocation, such as sneezing, stretching or ordinary reaching—is a most troublesome affection and is usually attributed to a rent or tear in the capsule, brought about in the first instance by a severe wrench, although cases could be recorded where no history of accident can be remembered. The disability is probably more often caused by adhesive contracture of a section of the capsule with an accompanying exaggerated relaxation of the remaining portion which allows the dislocation to take place. Although surgeons frequently advise a surgical operation, certain manipulations bring about a condition of the capsule which will enable it to exercise normal control of the head of the bone followed by exercises designed to re-establish the surrounding weakened tissues. Out of a number of cases only two or three can be remembered as not having yielded satisfactorily to treatment. The procedure, under an anaesthetic, is quite devoid of danger, and the after-effects are of brief duration and only slightly painful.

Subluxations and Dislocations.—The actual reductions of gross dislocations do not enter to any great extent into the purlieu of the manipulative surgeon. There is, however, a large number of conditions due to minor displacements which constitute an important branch of his work. Principal among these must be placed displacements and fracture-displacements of the semilunar cartilages of the knee-joint. This field is an enormous and most important one, for the number of persons of both sexes who sustain such injuries is legion. In original unreduced displacements, reduction must be carried out by appropriate manipulation at the earliest possible moment. In chronic or recurrent cases, manipulation is also very frequently effective in bringing about a cure of a very troublesome and disabling condition.

The brilliant results obtained in this type of case have been known for many years, but the underlying pathology has been a profound puzzle until it was recently shown:

(a) that by far the commonest type of injury of the internal semi-lunar cartilage is the complete longitudinal tear;

(b) that in this type of case, the outer portion of cartilage is nearly always found in the interior of the joint;

(c) that by appropriate manipulative technique this displaced fragment may be made to retrace its steps and come into apposition with the inner fragment;

(d) that when this has been effected, there is a good chance of repair occurring between the two fragments.

Cases with Adhesions.—These constitute another important class. It is essential first of all to make quite clear what we mean by the term "adhesion." It is probably known to most that an inflammatory process is usually accompanied by the exudation of lymph from the blood-vessels of the part. This lymph tends after a short while to become organized, *i.e.,* changed into connective tissue, or, as it is usually called, "fibrous tissue." Let us imagine, for example, that owing to a severe sprain of the knee the lining membrane of the joint has become inflamed. As a result there is an outpouring of this lymph by the blood-vessels of the membrane, and various folds and layers of this self-same membrane tend to become adherent by this inflammatory exudate. When this has become converted into fibrous tissue, adhesions are actually present which may give rise to marked disability. It is characteristic of adhesions, that, when pulled upon or stretched, severe pain usually results. Further adhesions give rise to a variable amount of limitation of some particular movement or movements of the joint, which is apt to be overlooked unless a most careful examination be made.

Swelling of the joint after exercise, muscular wasting and a sensation of weakness and often an actual giving-way of the joint, are not infrequent characteristics of adhesions.

Danger of Rest for Joint Cases.—As previously stressed, the doctrine "rest inflamed structures" has been responsible for the formation of countless thousands of joints disabled by adhesions. However true the doctrine may be in certain other organs and structures of the body, and even this is debatable, in the case of a joint it is dangerous, for the function of a joint is movement and movement must always be instituted at the earliest possible moment in almost any inflammatory condition, except in those ultra-acute conditions where movement is impossible and in some cases of tubercular disease and of myositis ossificans. When a joint has become crippled owing to the presence of adhesions, how is the joint to be restored to its pristine health and vigour? The answer is manipulation.

It is obviously impossible, in a short article of this nature, to detail the various technical methods of manipulation that apply to the different joints. Anaesthesia, although not absolutely essential, is a valuable aid in many cases, owing to the complete muscular relaxation thereby attained. The cases that are attended with the greatest success are those in which the adhesions are slight and in which the subsequent reaction is negligible. In more marked cases much benefit often follows from a series of manipulations separated by short intervals.

Although particular emphasis has been laid on adhesion in connection with joints, it is most important to remember that this may occur in many other important situations, particularly in the vicinity of muscles, or in their sheaths, or between different groups of muscles. This may also occur in connection with tendons and their sheaths, and in fascial or connective-tissue structures.

Functional or Hysterical Cases.—These constitute an interesting and important group in which good results by manipulation are sometimes attained. It must be remembered that a functional case is primarily mental and this condition is particularly apt to occur after injury in a person of nervous temperament. Although there is no actual organic disease of the joint—at any rate in the early stages—yet it is extraordinary how a functional condition of a joint may simulate some organic disability of the same joint. Great experience and clinical acumen are often required to form a correct diagnosis of such types.

The great value of manipulation in these cases is that a vicious circle is thereby broken, and, although an anaesthetic is not absolutely essential, yet, if some such anaesthetic as gas or gas and oxygen be given, it has a powerful suggestive effect upon the patient. It is usually found that, as soon as the patient is under the influence of the anaesthetic, the joint, which previously was held awkwardly and stiffly, becomes relaxed. The manipulator places the joint in the position which was erstwhile impossible and retains it thus until the patient is fully conscious. The patient is then shown the increased mobility and encouraged immediately to move the joint through this increased range. Much subsequently depends upon the patient being surrounded by an atmosphere of cheerfulness and encouragement, and everyone with whom the patient comes in contact must endeavour to play his or her part in the cure and to assure the patient of its completeness and finality.

In cases of long standing, actual organic changes may occur in an hysterical contracture, and the contracture, which was previously due to muscular sprain, becomes fixed by scar tissue. It is therefore important that manipulation should not be delayed too long, especially as the mental state becomes more fixed and more difficult to treat with the passage of years.

Cases Partially Relieved by Manipulation.—This large group includes a great many conditions due to disease rather than injury, the principal probably being the group of infections and intoxications usually known by the name "rheumatic," especially in its more chronic forms. Here again it is obvious that those cases in which only a slight degree of stiffness of a joint is present are much more satisfactory from the point of view of treatment than cases of marked stiffness or cases in which well marked destruction of the joint surfaces has occurred. It is important also to wait until all signs of activity have subsided and furthermore to eradicate the cause wherever possible before having recourse to manipulative measures. In nearly all cases of strains and sprains gentle manipulation at the earliest moment is recommended because the reparative processes of nature act most effectually when, as far as possible, no interference whatever with their functions is resorted to.

(H. BAR.)

MANIPUR, a state on the northeast frontier of India. Area, 8,620 square miles. Pop. (1941) 512,069. It is bounded on the north by the Naga country and the hills overlooking the Assam valley, on the west by Cachar district, on the east by Upper Burma, and on the south by the Lushai hills. The State consists of a wide valley, with an area of about 650 sq.m., and a large surrounding tract of mountainous country. The hill ranges generally run north and south, with occasional connecting spurs and ridges of lower elevation between. Their greatest altitude is in the north, where they reach to upwards of 8,000 ft. above sea-level. The principal geographical feature in the valley is the Loktak lake, over 25 sq.m. in area, but said to be gradually growing smaller. The valley is watered by numerous rivers, the Barak being the most important. The hills are densely clothed with tree jungle and large forest timber. Rice and forest produce are the principal exports. The road from Manipur to the Assam-Bengal railway at Dimapur is the principal trade route.

Although their general facial characteristics are Mongolian, there is a great diversity of feature among the Manipuris, some of them showing a regularity approaching the Aryan type. In the valley the people are chiefly Hindus, that religion being of recent introduction. Their own name for themselves is Meithei, and their language is a branch of the Kuki-Chin family. One of their peculiarities is the high position enjoyed by women, who conduct most of the trade of the valley. The aboriginal hillmen belong to one of the two great divisions of Nagas and Kukis, and are subdivided into innumerable clans and sections. The State is noted for the excellence of its breed of ponies. The English game of polo was introduced from Manipur, where it forms a great national pastime.

The first relations of the British with Manipur date from 1762, when the rajah solicited British aid to repel a Burmese invasion and a treaty was entered into. Little further communication took place until 1824, on the outbreak of the first Burmese War. British assistance was again invoked by the rajah, and the Burmese were finally expelled from both the Assam and the Manipur valleys. Disputed successions have always been a cause of trouble and in 1891 of a tragedy. In 1890 a brother of the rajah, the *senapati,* or commander-in-chief, dethroned the rajah, and installed the *jubraj* or heir-apparent as rajah. In 1891 the chief commissioner of Assam (Quinton) marched to Manipur with 400 Gurkhas, in order to recognize the new ruler, and remove the *senapati.* An attempt was made to arrest the *senapati,* but after some sharp fighting he escaped. The Manipuris then attacked the British residency with an overwhelming force. An armistice having been declared, Quinton with the Political Resident (Grimwood) and three other officers went to the fort, under promise of safe conduct, to negotiate. They were all treacherously murdered. The attack on the Residency was resumed and the defenders, thinking it untenable, retreated to Cachar, taking Mrs. Grimwood and the wounded with them. A month later a military expedition occupied Manipur. The *senapati* was captured, tried and hanged and the new rajah transported for life. It was decided to preserve the existence of the State, and a child of the ruling family, named Chura Chand, of the age of five, was nominated rajah.

During his minority the administration was conducted under British supervision. The opportunity was seized to abolish slavery and unpaid forced labour, to open up the State by roads and to introduce other reforms. In 1907 the government of the State was handed over to the rajah and Darbar, or council, with a member of the Indian civil service as vice-president. Subsequently the administration of the State was transferred to the rajah from the Darbar, of which the vice-president became president. During World War I a corps of 2,000 labourers was raised in Manipur and sent to France. When an attempt was made to raise a second corps in 1917, the Kukis broke out in rebellion, which was not suppressed until the cold weather of 1918–19 by a large force of Assam Rifles and Burma military police. A new system of administration was adopted after this, three subdivisions being established, each under an officer lent by the Assam government. Revenue is estimated at Rs. 9,62,000. The capital is Imphal, which is a collection of villages. Pop. (1941) 99,716. The ruler, a maharaja, has a salute of 11 guns.

See Mrs. Ethel St. Clair Grimwood, *My Three Years in Manipur* (1891); *Manipur State Gazetteer* (Calcutta, 1905); T. C. Hodson, *The Meitheis* (1908).

MANIS: *see* PANGOLIN; EDENTATA.

MANISA (anc. *Magnesia ad Sipylum*), the chief town of the Manisa vilayet in Turkey, situated in the valley of the Gediz Chai (Hermus), at the foot of Mt. Sipylus, and connected by railway with Smyrna and Afium Kara-Hissar. Population (1940) 37,623. Manisa is an important commercial centre, and contains interesting buildings dating from the times of the Seljuk and early Osmanli sultans, including mosques built by Murad II. and III. and a Mevlevi *Tekke* second only to that at Konia. In 1204 Manisa was occupied by John Ducas, who when he became emperor made it the Byzantine seat of government. In 1305, Roger de Flor besieged it unsuccessfully. In 1313 the town was taken by Saru Khan and became the capital of the Turcoman emirate of that name. In 1398 it submitted to the Osmanli sultan Bayezid

I, and in 1402 was made a treasure city by Timur. In 1419 it was the scene of the insurrection of Bedr ed-Din, which was crushed by Prince Murad, residing in the town as Murad II. In the 17th century Manisa became the residence of the greatest of the Dere Bey families, Kara Osman Oglu, Turcoman in origin, and possibly connected with the former emirs of Sarukhan.

MANISTEE, a city of western Michigan, U.S.A., on Lake Michigan and Lake Manistee, which is formed by the Big Manistee and Little Manistee rivers. A port of entry and the county seat of Manistee county. It is on federal highway 31 and is served by the Manistee and Northeastern and Pere Marquette railways, lake steamers, bus and truck service. The population was 8,078 in 1930 and 8,694 in 1940. The commerce of the harbour amounted to 1,340,650 tons in 1940. The city has two large salt plants, a paper mill, drop forge, ironworks, three chemical plants and other industries. Orchard Beach state park is two miles north. Manistee was settled in 1841 and chartered as a city in 1869. Since 1914 it has had a city-manager form of government.

MANISTIQUE, a city of the Upper Peninsula of Michigan, U.S.A., on the N. shore of Lake Michigan, at the mouth of the Manistique river; a port of entry and the county seat of Schoolcraft county.

It is on federal highway 2, and is served by the Ann Arbor (by car ferry to Frankfort), the Manistique and Lake Superior and the Soo Line railways and lake steamers.

The population was 5,198 in 1930, and it was 5,399 in 1940. The city has a considerable fishing industry, lime quarries, pulp and paper mills and various other lumber manufactures. It is the centre of a summer resort and fishing region, with many hotels, cottages, camps and private homes roundabout.

In the woods adjoining Indian lake (5 mi. W.) is an enormous spring, Kitch-iti-kippi, "the big spring," worshipped by the ancient Chippewas, a bowl 400 ft. across and 100 ft. deep. Manistique has a city-manager form of government.

MANITOBA, a province of the Dominion of Canada situated almost in the centre of the continent about midway between the Atlantic and Pacific oceans and also about midway between the Gulf of Mexico and the Arctic ocean (area 246,512 sq.mi.). The original boundaries of the province were settled by the Manitoba Act of 1870 (see *History*) as being the parallels of north latitude 49° and 50° 30′ and the meridians of west longitude 96° to 99°, an area of about 14,340 sq.mi. The boundaries were extended later (1881), and finally by a statute of 1912 were settled as the parallels of lat. 49° and 60° N., the meridian 102° W. and, on the east side, the meridian 95° W. from the 49th to the 60th parallel north latitude and thence northeast to a point on Hudson bay midway between the Nelson and Severn rivers. Manitoba thus has a sea coast on the Hudson bay.

Geology, Geography and Climate.—Geologically the province falls into three areas, the Laurentian shield area on the Hudson bay side, developed on Pre-Cambrian rocks; the Red river lowlands (occupied by lakes Winnipeg, Winnipegosis, Lake Manitoba and the Red river itself), where the Pre-Cambrian rocks dip beneath the palaeozoic limestone floor of the region and, on the prairie side, the western plateaus presenting an almost continuous cretaceous scarp overlooking the palaeozoic lowland.

A full account of the geology of the province in its continental relation is found in the general article on CANADA.

Geographically the province may be said to be based on the three large lakes named above, Winnipeg area 9,459 sq.mi., (*cf.* Ontario 7,540), Winnipegosis 2,080 and Manitoba 1,817, into which flow the English and Red rivers from the south and the Saskatchewan from the northwest, the whole system draining by the Nelson river to Hudson bay. The northern part of the province is similarly drained by the Churchill.

The lake area is about 1,000 ft. above the sea, the ground westward rising to about 1,600 ft.

Climate.—Manitoba represents the continental type of climate, as opposed to the littoral, with great extremes of heat and cold. Thus the mean range of the year at Winnipeg is one of 70°, at Victoria, B.C. only 21°. A change of 40° in 24 hours often happens during the Manitoba winter. Winter may be said to last five months, November to March, the ground usually covered with snow from December to March, with an annual fall in the province of from 40 in. to 55 in. Southern Manitoba has a January mean temperature of −5°, northern Manitoba −15°; for July respectively, 65° and 60°. Spring comes rapidly; the mean Manitoba temperature in May is as high as in England. In July and August temperatures of over 100° are on record. The rainfall is usually ample, with annual precipitation recorded from 14 in. to 29 in., but in summer, rain and hail often fall in violent storms, with occasionally dry summers as in 1886 with only 4.23 in. of rain May to August.

Area and Population.—The area of Manitoba is 246,512 sq.mi., including 26,789 of fresh water. The population (1941) was 729,744 (males 378,079); compare population 1871, 25,228; 1881, 60,260; 1901, 255,211; 1921, 610,118; the slackening rate of increase being due to the decline of immigration. In point of racial origin the people of the province are 52% British, nearly 7% French, 5½% Polish, 5% German with a scattering of other races that makes the European portion (other than French) about 38% of the total.

The Indians of the province number over 15,000, their numbers not declining; they are under the care and education of the dominion government, occupying 529,000 acres of reserved land.

Government and Public Finance.—The government of Manitoba rests upon the Imperial British North America act of 1867 and of that of 1871, validating all clauses of the Manitoba act (passed by the Canadian parliament in 1870) on all pre-existing laws and institutions of the Northwest Territory not abolished or altered by these statutes, including the British Common Law and with this, the conventions of the British constitutional system.

Manitoba became part of the dominion July 15, 1870 by virtue of an Imperial Order in Council June 23, 1870 declaring the Manitoba act in force. The statutes quoted provide for provincial representation in the parliament at Ottawa (in 1940, senate 6, house of commons 17). The provincial government at Winnipeg, the capital, consists of a lieutenant-governor, appointed and paid by the dominion government, a prime minister and ministry on British cabinet tenure, and a legislative assembly of 55 members elected for 5 years unless sooner dissolved.

The public revenue of Manitoba in its earlier years was based, like that of all provinces, on dominion subsidies. But within the 20th century the growth of provincial expenditure has gone vastly beyond its original limits (Manitoba, 1881, $226,000; in 1940, $20,000,000). These new expenditures were met from new sources which far exceeded the subsidies—corporation taxes, succession duties, taxes arising from gasoline and licences, and the net revenue from liquor control. The gross public debt of Manitoba in 1940 was $90,000,000.

Municipal government, as throughout Canada, is the creation of the province (B.N.A. Act 1867) and is organized in Manitoba on an elective basis in 4 cities, 37 towns (to include the "Flin Flon municipal district" and 5 suburban municipalities) together with 22 incorporated villages and 111 rural municipalities.

Agriculture and the Forest.—Of the whole land area (219,723 sq.mi.) of the province 50,590 sq.mi. are classed as agricultural, most of which is the treeless alluvial land of the prairies in the southern part of the province; 19,150 sq.mi. are classed as forest land fit for agriculture if cleared, and beyond this is the forest land chiefly in the north; much of it (62,500 sq.mi.) being of scrub and poor growth officially classed as unproductive forest land. This with other waste land of rock and muskeg gives a total of 95,343 sq.mi. in Manitoba (43% of the land) classed as unproductive. The land and natural resources of Manitoba remained at its inception (1870) in the hands of the dominion government but were transferred to provincial control in 1929. Of the forested area, good and bad, 8,500 sq.mi. are privately owned and 84,440 still crown land. Manitoba is predominantly an agricultural country, the net value of agriculture being estimated at 42% of provincial production (*cf.* agriculture in Canada 25%, Saskatchewan 71%, B.C. 13%). Statistics show the acreage under field crops (five years average) as 7,342,100. The main crop is spring wheat 41,130,000 bu. on 2,880,000 ac.; oats 33,-935,000 bu. on 1,427,000 ac., barley 27,178,000 bu. on 1,327,000 ac., hay and clover 445,000 ac., potatoes only 33,000 ac., all these on 5 year average and sugar beets, newly introduced, 18,000 ac. in 1940. In livestock Manitoba raised about 9% of the cows and cattle of Canada, 8% of the swine and 10% of the poultry.

There is practically no commercial fruit growing and no production of tobacco or maple sugar. The Manitoba department of agriculture carries on experimental work, and extension instruction work with assistance to boys' and girls' clubs and agricultural and similar societies (*see* also under CANADA: *Products and Industry,* for detailed statistics and the aid given by the dominion government through mortgage loans, etc.).

Minerals and Mining.—Manitoba has only recently taken its place, even now subordinate, in the production of minerals and metals. Statistics of 1940 show 136 mines and plants in the province as compared with 13,665 in all Canada, 6,406 in Ontario. The discovery of gold and copper in northern Manitoba (Flin Flon, etc.) has brought the production of gold from about $4,000 in 1926 to a value of $5,795,135 reported in 1941, the production of silver from 18 fine oz. in 1926 to $1,033,512, and of copper from a production that was *nil* as late as 1930, to over 70,000,-000 lb. in 1939. Manitoba was not in 1943 a serious producer of iron, nickel or lead but after its beginning in 1930 the production of coal amounted yearly to from 1,000,000 to 4,000,000 short tons. Indications showed that the northern and north-eastern portions of the province long regarded as worthless wilderness are the seat of great mineral deposits of high value.

Manufactures.—Manitoba has practically no manufactures except those which arise in a secondary way in an agricultural and wooded country. Lumber, shingle and other sawmill products represent about 60 to 77 M. ft.b.m. each year, a value in 1940 of $1,736,000. This is less than 3% of the output of British Columbia. The total manufactures of the province employed, in 1940, 26,679 people in 1,171 plants, a scale about one-twelfth that of Ontario. Of 18,765 employed in leading industries before the war in 1939, over 4,000 were in railway shops, 1,700 in meat packing and the rest distributed in dairy and cheese factories, flour mills, clothing factories, etc. But in point of potential power for manufacture Manitoba is well situated, having an available horsepower (24 hr., at ordinary six months flow) of 5,344,500 (*cf.* the other prairie provinces about 1,000,000 each, all Canada 33,000,000). This power was by 1943 only developed (420,000 h.p.) in central electric stations and not applied to pulp and paper or any other industry.

Communications.—Geographically the southern area of Manitoba enjoys a peculiarly advantageous position in east-and-west traffic, since the water and wilderness to the north and the frontier to the south make the Winnipeg area the funnel through which traffic from the east passes to expand all over the west. This is seen in the radiating lines of the two great railroads, the Canadian National railways and the Canadian Pacific. The earliest access was by Hudson bay (see *History* below), now of little importance. But the later opening up of the province was by the Red river from the south (steamboat and stage coach and rail in 1878) and hence traffic lines also have been developed to reach Manitoba via Chicago and St. Paul. Until recently through communication with Manitoba was only by rail but the development of air traffic now makes Winnipeg the central point for the National Trans-Canada system and a general point of aerial departure for the north. Motor highways only reached the province via the United States until the completion of the Trans-Canada highway in 1942 made all-Canada motor traffic possible, even while war conditions still kept it from actuality.

History.—In 1670 the Hudson's Bay company received a charter for territorial rights over the entire watershed of Hudson bay, including what is now Manitoba. Apart from the trading posts of this company and of its rival, the North West Fur company, there was no attempt at settlement till Lord Selkirk in 1811 planted a little colony on land acquired from the company at the junction of the Red and Assiniboine rivers. Opposition from the fur traders culminated in the affray of Seven Oaks, when Governor Semple and his followers were killed by the Métis incited by the North West company in 1816. The settlement was re-established at the close of the year.

Assiniboia, as Lord Selkirk's district was called in the records of the Hudson's Bay company, was re-conveyed to the company in 1835 who then controlled its council until 1870. During the regime of the company, development was slow. There was no output for farm produce, and a large proportion of the small population was French and Métis. In 1869 the imperial government bought and transferred to Canada the territorial rights of the company. The French and Métis of Assiniboia, fearing for their land titles and for their religion, and led by the half-breed Louis J. Riel, rebelled against the impending assumption of government by Canada. In 1870 General Wolseley's expedition was sent to ensure order and the province of Manitoba was created (Manitoba Act of Dom. of Canada, 1870) with a population of some 12,000 people (1,565 white, 558 Indian, 9,840 Métis).

The opening of the era of machine grain-farming (in Minnesota, and in the Dakotas) drew population to the northwest and with the completion of railway connection to Manitoba (1878) led to a rush of settlers, and the expansion of the Winnipeg boom (1881–82). The collapse of the boom was followed in provincial history by the building of the C.P.R. across the prairies, by the Northwest Rebellion of 1885 (occasioned by the settlement-survey of the Saskatchewan valley), transcontinental through traffic (1886), and the struggle in Manitoba against the north-and-south monopoly clause of the C.P.R. The middle years of the '90s witnessed the long-drawn conflict over the provincial abolition of separate (Roman Catholic) schools which occasioned the defeat of the Conservative party in 1896. The advent of the Liberals to power under Sir Wilfrid Laurier was followed by a new and more rapid development of the west which lasted till World War I and witnessed an increase of population in Manitoba from 255,211 in 1901 to 461,304 in 1911. Provincial history in Manitoba in the period between the wars turned on the agrarian question of the conflict between western agricultural and eastern capital and manufacturing interests. It was marked by the rise of the United Farmers, formation of the wheat pools and in Manitoba by the elevation to power (1922) of a Progressive government under John Bracken, later (1942) leader of the Progressive Conservative party of Canada.

BIBLIOGRAPHY.—*Canadian Census; Canada Year Book;* D. Mackay, *Canada and Its Provinces* (23 vol. 1912); George F. G. Stanley, *The Birth of Western Canada* (1936). (S. LEA.)

MANITOBA, a lake of Manitoba province, Canada, situated between 50° 11′ and 51° 48′ N. and 97° 56′ and 99° 35′ W., at an altitude of 810 ft. above the sea. It has an average depth of 12 ft.

Its shores are low, and for the most part swampy. It is drained by the Little Saskatchewan river into Lake Winnipeg. It was discovered by De la Verendrye in 1739.

MANITOU, among certain American Indian tribes, a spirit or genius of good or evil; Algonkin, "mystery," "supernatural." It has been regarded as monotheistic in tendency.

Ideas of guardianship, of ethical direction, of cosmic authority are blended in it.

MANITOU SPRINGS, a health resort in Colorado, U.S.A., the starting point of the Pikes Peak cog railway, and with radioactive mineral springs. Resident population (1940) 1,462.

MANITOWOC, a city of eastern Wisconsin, U.S.A., on Lake Michigan, at the mouth of the Manitowoc river, 80 mi. N. of Milwaukee; a port of entry and the county seat of Manitowoc county. It is on federal highways 10, 141 and 151; has a municipal airport; and is served by the Chicago and North Western and the Soo Line railways, and also by ferries of the Ann Arbor and the Pere Marquette railways to Frankfort and Ludington, Mich., and by bus and truck lines. Pop., federal census (1930), 22,963; (1940) 24,404 (92% native white). There is a good harbour, open throughout the year. General vessel traffic amounted in 1939 to 477,581 tons (largely receipts of coal and limestone) and car-ferry traffic to 1,444,493 tons. Shipbuilding, the city's pioneer industry, employs 1,800 men, and plants manufacturing aluminium ware employ about 2,000 men and women. These industries, and the various other manufacturing establishments, have an aggregate annual output valued at $35,000,000. In 1795 Jacques Vieau established a fur-trading post there for the Northwest company. Permanent settlement began about 1836. In 1853 Manitowoc became the county seat, and in 1870 it was chartered as a city. The name is an Indian word meaning "spirit-land."

MANIU, JULIUS (1873–), Rumanian politician, was born at Şimleul-Silvaniei (Transylvania). He studied at the universities of Cluj, Vienna and Budapest, and was for many years professor of law at the theological academy in Blaj. At the age of 26 he joined the National Rumanian party of Transylvania. In spite of the bitter opposition of Count Stephen Tisza, Maniu was elected deputy and sat in the parliament at Budapest from 1906 till 1910. When the World War broke out Maniu was sent to the front and in 1918 was fighting against Italy. When he realized that the collapse of the Central Empire was in sight, he went to Budapest, where a National Rumanian Council was formed, Maniu taking charge of military and foreign affairs. He then went to Vienna and organized the revolt of Hungarian regiments, composed of Rumanians of Transylvania, stationed in Vienna and Prague. On Dec. 1, 1918 the Rumanian National Assembly at Alba-Julia proclaimed the union of Transylvania and the Banat with Rumania and elected Maniu president of the *Consiliul Dirigent* (local government) which took over administrative control throughout Transylvania. In 1919 Maniu was elected president of the National Rumanian party of Transylvania, which in 1925 coalesced with the Nationalist-Democratic party. Maniu became the chief of this new formation, which took the name of the National Rumanian party, and shortly afterwards coalesced with the Peasant or Tsaranist party. From 1928 to 1930 he was premier. (*See* RUMANIA.)

MANIZALES, a city of Colombia and capital of the department of Caldas, 75 m. S. of Medellín, on the old trade route across the Cordillera between Honda, on the Magdalena, and the Cauca Valley. Pop. (1938) 51,025 The city is situated on a plateau of the western slope of the Cordillera, 6,988 ft. above the sea. It is surrounded by rich mineral and agricultural districts. The town suffered heavily from fire in 1925.

MANKATO, a city of southern Minnesota, U.S.A., at the confluence of the Minnesota and the Blue Earth rivers, 84 m. S.W. of St. Paul; the county seat of Blue Earth county. It is on Federal highway 14, and is served by the Chicago Great Western, the Chicago, Milwaukee, St. Paul and Pacific, the Chicago and North Western, the Chicago, St. Paul, Minneapolis and Omaha, and the Minneapolis, Northfield and Southern railways, and by many motor bus lines. Pop. (1920) was 12,469 (86% native white); 1940 federal census 15,654.

The region is a rich farming and dairying country, dotted with many lakes. Mankato is a manufacturing city. It is the seat of a State Teachers college (established 1868); and it has an extensive trade in agricultural and manufactured products and in lime, cement and stone from its fine quarries. The city was founded about 1853 and chartered in 1868. On or near its site had stood a village of the Mankato ("blue earth") band of the Sioux, and in this region occurred the Sioux uprising of 1862. Operations against the Indians were carried on from Mankato, and after their subjugation 38 leaders of the revolt were hanged here in Dec. 1862.

MAN LANGUAGES. The term "Măn" (in Chinese, Southern Barbarian) is applied to languages spoken by hill tribes in Indo-China of whom the Miao and Yao are found in upper Burma. These languages are imperfectly known and must provisionally be regarded as an independent group, with some relationship to Karan.

See *Linguistic Survey of India,* vol. i. (1927) p. 39. *Census of Burma* (1921); *Gazetteer of Upper Burma,* vol. i. part 1.

MANLEY, MARY DE LA RIVIÈRE (*c.* 1663–1724), English writer, daughter of Sir Roger Manley, governor of the Channel Islands, was born on April 7, 1663 in Jersey. She wrote her own biography under the title of *The Adventures of Rivella, or the History of the Author of the Atalantis* by "Sir Charles Lovemore" (1714). In 1709 she achieved her principal triumph as a writer by her *Secret Memoirs . . . of Several Persons of Quality,* a scandalous chronicle "from the New Atalantis, an island in the Mediterranean." She was arrested in the autumn of 1709 as the author of a libellous publication, but was discharged by the court of queen's bench on Feb. 13, 1710. Mrs. Manley sought in this scandalous narrative to expose the private vices of the ministers whom Swift, Bolingbroke and Harley combined to drive from office. Later were published her tragedy *Lucius* (1717); *The Power of Love, in Seven Novels* (1720) and *A Stage Coach Journey to Exeter* (1725).

MANLIUS, the name of a Roman gens, chiefly patrician, but containing plebeian families also.

1. MARCUS MANLIUS CAPITOLINUS, a patrician, consul (392 B.C.). According to tradition, when in 390 B.C. the besieging Gauls were attempting to scale the Capitol, he was roused by the cackling of the sacred geese, rushed to the spot and threw down the foremost assailants (Livy. v. 47; Plutarch, *Camillus,* 27). Several years after, seeing a centurion led to prison for debt, he freed him with his own money, and sold his estate to relieve other debtors. He was charged with aspiring to kingly power, and condemned by the comitia when the assembly had adjourned to a place whence they could no longer see the Capitol which he had saved. His house on the Capitol (the origin of his surname) was razed, and the Manlii resolved that henceforth no patrician Manlius should bear the name of Marcus.

See Livy vi. 14–20, Plutarch, *Camillus,* 36; and Cicero, *De domo,* 38.

2. TITUS MANLIUS IMPERIOSUS TORQUATUS, twice dictator (353, 349 B.C.) and three times consul (347, 344, 340). When his father was brought to trial by the tribune M. Pomponius for abusing his office of dictator, he forced Pomponius to drop the accusation by threatening his life (Livy vii. 3–5). In 360, during a war with the Gauls, he slew one of the enemy, a man of gigantic stature, in single combat, and took from him a *torques* (neck-ornament), whence his surname. When the Latins demanded an equal share in the government of the confederacy, Manlius vowed to kill with his own hand the first Latin he saw in the senate-house. The Latins and Campanians revolted, and Manlius, consul for the third time, gained two great victories in Campania. In this campaign Manlius executed his own son, who had killed an enemy in single combat, and thus disobeyed the express command of the consuls.

See Livy vii. 4, 10, 27, viii. 3; Cicero, *De off.* iii. 31.

MANN, HEINRICH (1871–), German novelist, elder brother of Thomas Mann (*q.v.*), was born at Lübeck on March 27, 1871. Educated in Lübeck and Berlin, he travelled in Italy and Germany and produced a series of novels which, if less remarkable than his brother's, displayed a deep feeling for beauty and much satiric power. *Im Schlaraffenland* (1900) was a mordant account of high finance in Berlin. *Die Göttinnen* (3 vols., 1903) was a romantic and often very beautiful, but fantastic, account of a Dalmatian duchess with political, artistic and erotic aspirations. Later works described and satirized German society. They include *Die Jagd nach der Liebe, Professor Unrat* (1905), *Die kleine Stadt* and *Der Untertan* (1914), which contained a portrait, by reflection, of the emperor William II. so unflattering as to make its publication impossible until following the German revolution. Heinrich Mann left Germany in 1933.

MANN, HORACE (1796–1859), educator and statesman, was born in Franklin, Mass., May 4, 1796. His parents' poverty subjected him to privations, and until he was 15, he never attended school more than eight or ten weeks in a year. He received effective instruction, however, from the able pastor of the village church. In his 20th year he fell in with a good college preparatory teacher. In six months he fitted himself for admission to the sophomore class of Brown university, which he entered in Sept., 1816. He graduated with highest honours in 1819. He then entered a lawyer's office at Wrentham, but was soon called back to the university, where he served for two years as tutor in the Latin and Greek languages and as librarian. On leaving Providence the second time, in 1821, he entered the celebrated law school conducted by Judge Gould, at Litchfield, Conn., where he had a fine record. In 1823 he was admitted to the bar. He continued very successfully in the practice of law for 14 years, until he entered upon an educational career in 1837. At first he made his residence at Dedham, but in 1833 removed to Boston.

About the time that he established himself at Dedham, he began to take an active interest in public affairs. He was elected to the Massachusetts house of representatives in 1827, and was re-elected each year until transferred to the State senate in 1833. Here he served four years, the last two as president of the senate, where he was directly responsible for the enactment of four important measures: (1) a law against the use of alcoholic beverages: (2) against the traffic in lottery tickets; (3) the establishment of State hospitals for the insane; (4) an act creating the State board of education.

For a long period prior to the establishment of a State board of education, there had been in Massachusetts an apparent retrogression of education, due to the increase of local self-government and the decrease of central authority. It was evident that public schools diminished in efficiency. A twofold opposition began some years before 1828, which took, on the one hand, the form of an attempt to remedy the deficiency of public schools by the establishment of academies, and on the other hand, that of a vigorous attack by educational reformers, such as Horace Mann, who sought to replace the district system by a township unit. The establishment of a State board of education and the appointment of Mann as its secretary, therefore, mark an era of return from the extreme of decentralization to the proper union of local and central authority.

Horace Mann was chosen secretary of the new State board of education because an educational statesman was needed rather than a mere schoolman. At a considerable financial sacrifice, Mann accepted the small salary attached to the position. It was a board of limited powers, and its success depended upon the personality of its secretary. It could neither found nor administer schools. Its function was to collect and diffuse information; it could pursuade but could not command. As secretary, Mann's plan of campaign included four leading features: (1) The holding of public meetings and the agency of public addresses; (2) Better training of teachers by a system of county institutes, conducted by the leading educators of Massachusetts and other States, and the founding of normal schools; (3) Ample provision for the collection of statistics; (4) Establishment of a periodical, *The Common School Journal,* to influence the educational public in Massachusetts.

The 12 annual reports prepared by Mann, as secretary, on the condition of education in Massachusetts and elsewhere, including his discussions of the aims, purposes and means of education, occupy a commanding position in American educational history. In May, 1843, Mann went to Europe, where he spent five months in the study of educational conditions. His 7th report embodied the result of this tour abroad, and drew an attack upon him from a group of schoolmasters of Boston. His praise of European schools, and particularly his commendation of oral instruction, the word method in teaching reading, and the abolition of corporal punishment in Germany, wounded the sensibilities of the Boston schoolmasters, and a bitter controversy ensued. He was also assailed by religious sectarians, on the ground that he was secularizing the public schools. His skilful administration as secretary gave him a central position in the history of American educational development. It proved a stimulus to educational progress in Massachusetts and made the Massachusetts system the prototype of other State systems.

In 1848, Mann resigned the secretaryship of the Massachusetts board of education in order to accept a seat in Congress, to which he was elected to fill the place made vacant by the death of John Quincy Adams. In politics Mann was a Whig of moderate anti-slavery views. In the controversy regarding the Compromise of 1850, he became an open critic of Webster's views regarding slavery as stated in his famous speech of March 7. The opposition of the Webster faction caused Mann to lose a renomination to Congress in the Whig convention of 1850. However, he ran as an independent candidate, and was triumphantly re-elected. In 1852, he was the Free-soil candidate for governor of Massachusetts, but was defeated. While in Congress Mann was unable to accomplish anything for education.

In 1853 Mann assumed the presidency of Antioch college, a new institution established at Yellow Springs, O., which was to be non-sectarian and open on equal terms to both sexes. The determining reason which led him westward was the prospect that this new position offered for supplementing his achievement in reorganizing the public schools, by the establishment of his ideals of co-education and non-sectarianism in higher education. While in this position he was harassed by the financial difficulties of the college, and by the opposition of various professors and supporters of the institution who distrusted his religious views. However, staunch friends from time to time supplied him with funds to carry on the college, and he won the loyalty of his students. Worn out by his arduous labours in the administration of the college, Horace Mann died at Yellow Springs on Aug. 2, 1859. His parting words to his students had been delivered in his baccalaureate address in 1859 a few weeks previously: "Be ashamed to die until you have won some victory for humanity."

MANN, THOMAS (1875–), German writer, was born at Lübeck on June 6, 1875, his father being a senator of an old patrician merchant family. At the age of 19 he moved with his family to Munich, worked in an insurance office (meanwhile devoting himself to literature), then studied the humanities, visited Italy, and worked for a time on the staff of *Simplicissimus.* In 1903 he published *Buddenbrooks: Verfall einer Familie* (English trans. 1924), a very remarkable character and period novel, the scene of which is mostly laid in Lübeck. A series of short stories, *Tristan,* appeared in the same year; a full-length but much slighter novel, *Königliche Hoheit,* in 1915 (English trans. 1925), short stories *Der Tod in Venedig* (1912), *Tonio Kröger* (1914); a political declaration of conservatism, *Betrachtungen einer Unpolitischen* (1918), and a second long novel, *Der Zauberberg* (1925), English trans. *The Magic Mountain* (1926). His characterization and sense of environment are remarkable, his technique unsurpassed. His method is leisurely, fond of lingering among sometimes trivial details with a certain irony; but these are selected with unerring skill, and the sense of tragedy has remarkable force. He was awarded in 1929 the Nobel prize for literature. In 1934 he began his great Joseph series: *Joseph and His Brothers* (1934); *The Young Joseph* (1935); *Joseph in Egypt* (1938). Exiled from Germany, he was appointed lecturer at Princeton university in 1938.

MANNA, a saccharine exudation obtained by making incisions on the trunk of the flowering or manna ash tree, *Fraxinus Ornus.* The manna ash is a small tree found in Italy, and extending to Switzerland, South Tirol, Hungary, Greece, Turkey and Asia Minor. It also grows in the islands of Sicily, Corsica and Sardinia. It blossoms early in summer, producing numerous clusters of whitish flowers. At the present day the manna of commerce is collected exclusively in Sicily from cultivated trees. In the *frassinetti* or plantations the trees are placed about 7 ft. apart, and after they are eight years old, and the trunk at least 3 in. in diameter, the collection of manna is begun. This operation is performed in July or August during the dry weather, by making transverse incisions $1\frac{1}{2}$ to 2 in. long, and about 1 in. apart, through the bark, one cut being made each day, the first at the bottom of the tree, another directly above the first, and so on. In succeeding years the process is repeated on the untouched sides of the trunk, until the tree has been cut all round and exhausted. It is then cut down, and a young plant arising from the same root takes its place. The finest or flaky manna appears to have been allowed to harden on the stem. A very superior kind, obtained by allowing the juice to encrust pieces of wood or straws inserted in the cuts, is called *manna a cannolo.*

Manna of good quality dissolves at ordinary temperatures in about 6 parts of water, forming a clear liquid. Its chief constituent is mannitol or manna sugar, a hexatomic alcohol, $C_6H_8(OH)_6$, which likewise occurs, in much smaller quantity, in certain species of the brown seaweed *Fucus,* and in plants of several widely separated families. The best manna contains 70 to 80%. It crystallizes in shining rhombic prisms from its aqueous solution and as delicate needles from alcohol. Manna possesses mildly laxative properties, and on account of its sweet taste is employed as a mild aperient for children. It is less used in England now than formerly, but is still largely consumed in South America.

The manna of the present day appears to have been unknown before the 15th century, although a mountain in Sicily with the Arabic name Gibelman, *i.e.,* "manna mountain," appears to point to its collection there during the period that the island was held by the Saracens, 827–1070.

Various other kinds of manna are known, but none of these has been found to contain mannitol. Alhagi manna is the produce of *Alhagi maurorum,* a small, spiny, leguminous plant, growing in south-western Asia. This manna occurs in the form of small, roundish, hard, dry tears, varying from the size of a mustard seed to that of a coriander, of a light-brown colour, sweet taste and senna-like odour. Tamarisk manna exudes in June and July from the slender branches of *Tamarix gallica,* var. *mannifera,* in the form of honey-like drops, which, in the cold temperature of the early morning, are found in the solid state. This secretion is caused by the puncture of an insect, *Coccus manniparus.* This kind of manna seems to be alluded to by Herodotus (vii. 31). Under the same name of *gaz-angubīn* there are sold commonly in the Persian bazaars round cakes, of which a chief ingredient is a manna obtained to the south-west of Ispahan, in August, by shaking the branches or scraping the stems of *Astragalus florulentus* and *A. adscendens.*

Oak manna or *Gueze-elefi,* according to Haussknecht, is collected from the twigs of *Quercus Vallonia* and *Q. persica,* on which it is produced by the puncture of an insect during August. A substance collected by the inhabitants of Laristan from *Pyrus glabra* strongly resembles oak manna in appearance. Australian or Eucalyptus manna is found on the leaves of *Eucalyptus viminalis, E. Gunnii,* var. *rubida, E. pulverulenta,* etc. The Lerp manna of Australia is of animal origin. Briançon manna is met with on the leaves of the common larch (*q.v.*), and *bide-khecht* on those of the willow, *Salix fragilis;* and a kind of manna was at one time obtained from the cedar. The manna of the Biblical narrative answers in its description very closely to the tamarisk manna.

See Bentley and Trimen, *Medicinal Plants* (1880); Watt, *Dictionary of Economic Products of India,* under "Manna" (1891); H. W. Youngken, *Text-Book of Pharmacognosy* (1943).

MANNERS, CHARLES (1857–1935), English musician, whose real name was Southcote Mansergh, was born in London, son of Colonel Mansergh, an Irishman. He had a fine bass voice, and studied at the Royal Academy of Music in London. He began singing in opera in 1881, and in 1882 had great success as the sentry in *Iolanthe* at the Savoy, following this with numerous engagements in opera both in England and America. He married the singer Fanny Moody, already a leading soprano on the operatic stage, in 1890; and in 1897 they formed the Moody-Manners opera company, which had a great success in the provinces and undertook seasons in London in 1902, 1903 and 1904.

MANNERS-SUTTON, CHARLES (1755–1828), archbishop of Canterbury, was educated at Charterhouse and Cambridge, where he graduated in 1777. He became dean of Peterborough (1791), bishop of Norwich (1792), dean of Windsor (1794), and archbishop of Canterbury (1805). During his primacy the old archiepiscopal palace at Croydon was sold, and the country palace of Addington bought with the proceeds. For his son Charles *see* CANTERBURY, CHARLES MANNERS-SUTTON.

MANNHEIM, a town of Germany, in the *Land* of Baden, on the Rhine, at its confluence with the Neckar, 39 m. by rail N. of Karlsruhe, 10 m. W. of Heidelberg and 55 m. S. of Frankfort-on-Main. Pop. (1939) 283,801. The name of Mannheim was connected with its present site in the 8th century, when a village of the abbey of Lorsch lay between the Neckar and the Rhine. The history of modern Mannheim begins with the opening of the 17th century, when the elector palatine Frederick IV. founded a town here, peopled chiefly with Protestant refugees from Holland, and built a castle which led to its being much attacked in the Thirty Years' War. In 1688 Mannheim was captured by the French, and in 1689 it was burned down. Ten years later it was rebuilt and fortified. For its subsequent importance it was indebted to the elector Charles Philip, who transferred his residence from Heidelberg to Mannheim in 1720, and it remained the capital of the palatinate for nearly 60 years. In 1795 Mannheim was taken by the Austrians, and in 1803 the town was assigned to the grand duke of Baden, who razed the fortifications. Schiller's plays were performed for the first time at Mannheim towards the end of the 18th century.

Nearly the whole of the south-west side of the town is occupied by the palace (1720–59), formerly the residence of the elector palatine of the Rhine. The left wing was totally destroyed by bombardment in 1795, but was later restored. During World War II, Mannheim's factories, railway yards and docks were targets for frequent and severe British bombing attacks.

Mannheim is the chief commercial town on the upper Rhine, and yields in importance to Cologne alone among the lower Rhenish towns. Barges of 2,000 tons go up the Rhine to Mannheim, but only those not exceeding 1,000 tons go up beyond it to Kehl. Mannheim is thus the chief port of the upper navigation of the Rhine, with about 30 m. of quays. It is the principal emporium for south Germany for cereals, coal, petroleum, timber, sugar and tobacco, with a large trade in hops, wine and other south German produce.

MANNING, HENRY EDWARD (1808–1892), English Roman Catholic cardinal, was born at Totteridge, Hertfordshire, on July 15, 1808[1], being the third and youngest son of William Manning, a West India merchant, who was a director of the Bank of England and governor, 1812–1813, and who sat in Parliament for some thirty years. Manning's boyhood was mainly spent at Coombe Bank, Sundridge, Kent, where he had for companions Charles and Christopher Wordsworth, afterwards bishops of St. Andrews and of Lincoln. He was educated at Harrow, and at Balliol college, Oxford. He made his mark in the Union, where Gladstone succeeded him as president in 1830. He graduated with first-class honours in 1830, and obtained, in 1831, through Viscount Goderich, a post as supernumerary clerk in the colonial office. But he returned to Oxford in 1832, was elected a fellow of Merton College, and was ordained; and in 1833 he was presented to the rectory of Lavington-with-Graffham in Sussex by Mrs. Sargent, whose granddaughter Caroline he married on Nov. 7, 1833. Manning's married life was of brief duration. His young and beautiful wife was of a consumptive family, and died childless (July 24, 1837). This bereavement tended to facilitate his acceptance of the austere teaching of the Oxford Tracts; and though he was never an acknowledged disciple of Newman, it was due to the latter's influence that from this date his theology assumed an increasingly High Church character, and his printed sermon on the "Rule of Faith" was taken as a public profession of his alliance with the Tractarians.

In 1838 Manning took a leading part in the Church education movement, by which diocesan boards were established throughout the country; and he wrote an open letter to his bishop in criticism of the recent appointment of the ecclesiastical commission. In December of that year he paid his first visit to Rome, and called on Dr. Wiseman in company with W. E. Gladstone. In Jan. 1841 Shuttleworth, bishop of Chichester, appointed him archdeacon. In 1842 he published a treatise on *The Unity of the Church,* and in that year he was appointed select

[1]Purcell's assertion that the year of his birth was 1807 rests on no trustworthy evidence.

preacher by his university. Four volumes of his sermons appeared between the years 1842 and 1850, and these had reached the 7th, 4th, 3rd and 2nd editions respectively in 1850, but were not afterwards reprinted.

Newman's secession from the Church of England in 1845 placed Manning in a position of greater responsibility, as one of the High Church leaders, along with Pusey and Keble and Marriott; but it was with Gladstone and James Hope (afterwards Hope-Scott) that he was at this time most closely associated. In the spring of 1847 he was seriously ill, and that autumn and the following winter he spent abroad, chiefly in Rome, where he saw Newman "wearing the Oratorian habit and dead to the world." He had public and private audiences with the pope on April 9 and May 11, 1848, but recorded next to nothing in his diary concerning them, though numerous other entries show an eager interest in everything connected with the Roman Catholic Church, and private papers also indicate that he recognized at this time grave defects in the Church of England and an attraction in Roman Catholicism. Returning to England, he protested, but with moderation, against the appointment of Hampden as bishop of Hereford, and continued to take an active part in the religious education controversy. Through the influence of Samuel Wilberforce he was offered the post of sub-almoner to Queen Victoria, always recognized as a stepping-stone to the episcopal bench, and his refusal of it was honourably consonant with all else in his career as an Anglican dignitary, in which he united pastoral diligence with an asceticism that was then quite exceptional.

In 1850 the decision of the privy council, that the bishop of Exeter was bound to institute the Rev. G. C. Gorham to the benefice of Brampford Speke in spite of the latter's acknowledged disbelief in the doctrine of baptismal regeneration, brought to a crisis the position within the Church of England of those who believed in that Church as a legitimate part of the infallible *Ecclesia docens*. Manning made it clear that he regarded the matter as vital, though he did not act on this conviction until no hope remained of the decision being set aside or practically annulled by joint action of the bishops. In July he addressed to his bishop an open letter on "The Appellate Jurisdiction of the Crown in Matters Spiritual," and he also took part in a meeting in London which protested against the decision. In the autumn of this year (1850) was the great popular outcry against the "Papal aggression" (*see* WISEMAN, NICHOLAS PATRICK STEPHEN), and Manning, feeling himself unable to take part in this protest, resigned, early in December his benefice and his archdeaconry; and writing to Hope-Scott, who a little later became a Roman Catholic with him, stated his conviction that the alternative was "either Rome or licence of thought and will."

He was received into the Roman Catholic Church by Father Brownbill, S.J., at the church in Farm Street, on Passion Sunday, April 6, 1851. On the following Sunday he was confirmed and received to communion by Cardinal Wiseman, who also, within ten weeks of his reception, ordained him priest. Manning thereupon proceeded to Rome to pursue his theological studies, residing at the college known as the "Academy for Noble Ecclesiastics," and attending lectures by Perrone and Passaglia among others. The pope frequently received him in private audience, and in 1854 conferred on him the degree of D.D. In 1857 the pope, *proprio motu,* appointed him provost (or head of the chapter) of Westminster, and the same year he took up his residence in Bayswater as superior of a community known as the "Oblates of St. Charles," an association of secular priests on the same lines as the institute of the Oratory, but with this difference, that they are by their constitution at the beck and call of the bishop in whose diocese they live.

The community was thus of the greatest service to Cardinal Wiseman, whose right-hand man Manning thenceforward became. During the eight years of his life at Bayswater he was most active in all the duties of the priesthood, preaching, hearing confessions, and receiving converts; and he was notably zealous to promote in England all that was specially Roman and papal, thus giving offence to old-fashioned Catholics, both clerical and lay, many of whom were largely influenced by Gallican ideas, and had with difficulty accepted the restoration of the hierarchy in 1850. In 1860 he delivered a course of lectures on the pope's temporal power, at that date seriously threatened, and shortly afterwards he was appointed a papal domestic prelate.

He was now generally recognized as the able and effective leader of the Ultramontane party among English Roman Catholics, acting always, however, in subordination to Cardinal Wiseman; and on the latter's death (Feb. 15, 1865) it was felt that, if Manning should succeed to the vacant archbishopric, the triumph of Ultramontanism would be secured. Such a consummation not being desired by the Westminster chapter, they submitted to the pope three names, and Manning's was not one of them. Pius IX. ignored the nominations, and appointed Manning to the archi-episcopal see. Consecrated at the pro-cathedral at Moorfields (since destroyed) by Dr. Ullathorne, bishop of Birmingham (June 8, 1865), and enthroned there (Nov. 6), after receiving the *pallium* in Rome, Manning began his work as archbishop by devoting himself especially to the religious education of the poor and to the establishment of Catholic industrial and reformatory schools. He steadily opposed whatever might encourage the admission of Catholics to the national universities, and so put his foot down on Newman's project to open a branch house of the Oratory at Oxford with himself as superior. He made an unsuccessful and costly effort to establish a Catholic university at Kensington, and he also made provision for a diocesan seminary of strictly ecclesiastical type. He procured a further condemnation at Rome of the "Association for the Promotion of the Unity of Christendom," which advocated prayers for the accomplishment of a kind of federal union between the Roman, Greek and Anglican Churches, and in a pastoral letter he insisted on the heretical assumption implied in such an undertaking. He also worked for the due recognition of the dignity of the secular or pastoral clergy, whose position seemed to be threatened by the growing ascendancy of the regulars, and especially of the Jesuits, whom, as a practically distinct organization within the Church, he steadily opposed.

In addition to his diocesan synods, he presided in 1873 over the fourth provincial synod of Westminster, which legislated on "acatholic" universities, church music, mixed marriages, and the order of a priest's household, having previously taken part, as theologian, in the provincial synods of 1853 and 1859, with a hand in the preparation of their decrees. But it was chiefly through his strenuous advocacy of the policy of defining papal infallibility at the Vatican council (1869–1870) that Manning's name obtained world-wide renown. In this he was instant in season and out of season. He brought to Rome a petition in its favour from his chapter at Westminster, and during the progress of the council he laboured incessantly to overcome the opposition of the "inopportunists." And he never ceased to regard it as one of the chief privileges of his life that he had been able to take an active part in securing the definition, and in having heard with his own ears that doctrine proclaimed as a part of divine revelation. In 1875 he published a reply to Gladstone's attack on the Vatican decrees; and on March 15 in that year he was created cardinal, with the title of SS. Andrew and Gregory on the Coelian. He was present at the death of Pius IX. (Feb. 7, 1878); and in the subsequent conclave, while some Italian cardinals were prepared to vote for his election to fill the vacant chair, he himself supported Cardinal Pecci, afterwards known as Leo XIII.

With Leo XIII. Manning found less sympathy than with his predecessor, though Manning's advocacy of the claims of labour attracted Leo's attention, and influenced the encyclical which he issued on the subject. After the Vatican council, and more especially after the death of Pius IX., Manning devoted his attention mainly to social questions, and with these his name was popularly associated during the last fifteen years of his life. From 1872 onwards he was a strict teetotaller, not touching alcohol even as a medicine. His example and his zeal profoundly influenced for good the Irish poor forming the majority of his flock; and the "League of the Cross" which he founded, and which held annual demonstrations at the Crystal Palace, numbered nearly

30,000 members in London alone in 1874. He sat on two royal commissions, the one on the housing of the working classes (1884), and the other on primary education (1886); and in each case the report showed evident marks of his influence, which his fellow-commissioners recognized as that of a wise and competent social reformer. In the cause of labour he was active for many years, and in 1872 he set an example to the clergy of all the churches by taking a prominent part in a meeting held in Exeter Hall on behalf of the newly established Agricultural Labourers' Union, Joseph Arch and Charles Bradlaugh being among those who sat with him on the platform.

In later years Manning's strenuous advocacy of the claims of the working classes, and his declaration that "every man has a right to work or to bread" led to his being denounced as a Socialist. That he was such he denied more than once (Lemire, *Le Cardinal Manning et son action sociale,* Paris, 1893, p. 210), nor was he ever a Socialist in principle; but he favoured some of the methods of Socialism, because they alone seemed to him practically to meet the case of that pressing poverty which appealed to his heart. He took a leading part in the settlement of the dockers' strike in the autumn of 1889, and his patient and effectual action on this and on similar occasions secured for him the esteem and affection of great numbers of working men, so that his death on Jan. 14, 1892, and his funeral a week later, were the occasion for a remarkable demonstration. The Cathedral at Westminster is his joint memorial with his predecessor, Cardinal Wiseman.

Preeminently Manning was a devout ecclesiastic, a "great priest"; and his sermons, both Anglican and Catholic, are marked by fervour and dignity, by a conviction of his own authoritative mission as preacher, and by an eloquent insistence on considerations such as warm the heart and bend the will rather than on such as force the intellect to assent. But many of his instincts were those of a statesman, a diplomatist, a man of the world, even of a business man; and herein lay, at least in part, the secret of his influence and success. In the later years of his life especially he showed that he loved righteousness and hated iniquity, and that he realized as clearly as any one that the service of God was incomplete without the service of man.

The publication in 1896 of Manning's *Life,* by Edward Purcell, with its very frank revelation of character was the occasion for some controversy on the ethics of biography. Edward Purcell was a Roman Catholic journalist, to whom Manning, late in life, had entrusted, rather by way of charitable bequest, his private diaries and other confidential papers. It thus came to pass that in Purcell's voluminous biography much that was obviously never intended for the public eye was, perhaps inadvertently, printed, together with a good deal of ungenerous comment. The facts disclosed which mainly attracted attention were: (1) that Manning, while yet formally an Anglican, and while publicly and privately dissuading others from joining the Roman Catholic Church, was yet within a little convinced that it was his own duty and destiny to take that step himself; (2) that he was continually intriguing at the back-stairs of the Vatican for the furtherance of his own views as to what was desirable in matters ecclesiastical; (3) that his relations with Newman were very unfriendly; and (4) that, while for the most part he exhibited towards his own clergy a frigid and masterful demeanour, he held privately very cordial relations with men of diverse religions or of no theological beliefs at all. And certainly Manning does betray in these autobiographical fragments an unheroic sensitiveness to the verdict of posterity on his career. But independent critics (among whom may specially be named François de Pressensé) held that Manning came well through the ordeal, and that Purcell's *Life* had great value as an unintentionally frank revelation of character. *See* also sketches by J. E. C. Bodley, *Cardinal Manning* (and other essays) (1912); Lytton Strachey's *Eminent Victorians* (1918); Shane Leslie's *Henry Edward Manning, His Life and Labours* (1921), in which Purcell is supplemented by correspondence not before used, and the Cardinal's letters are sympathetically interpreted.

(A. W. Hu.; X.)

MANNING, WILLIAM THOMAS (1866–), American Protestant Episcopal divine, was born in Northampton, England on May 12, 1866. He entered the ministry from the diocese of California, being ordained deacon 1889 and priest 1891. He became rector of Trinity church, Redlands (Calif.), 1892, and in 1893 was appointed professor of theology in the University of the South, where in the same year he received the degree of bachelor of divinity. He became successively rector of St. John's, Lansdowne (Pa.), 1896; rector of Christ church, Nashville (Tenn.) 1898; Vicar of St. Agnes's chapel, Trinity parish, New York city, 1903. In 1904 he was appointed assistant rector of Trinity church, New York city, becoming rector in 1908. He was consecrated bishop of New York, May 11, 1921. In 1925 he inaugurated the public movement for the completion of the cathedral of St. John the Divine, New York city.

MANNY, SIR WALTER DE MANNY, Baron de (d. 1372), soldier of fortune and founder of the Charterhouse (*q.v.*), was a native of Hainaut, from whose counts he claimed descent. He was a patron and friend of Froissart, in whose chronicles his exploits have a conspicuous and probably an exaggerated place. He appears to have come to England as an esquire of Queen Philippa in 1327, and he took a distinguished part in the Scottish wars of Edward III. In 1337 he was placed in command of an English fleet, and in the following years proved himself an able military commander. He was summoned to parliament as a baron by writ from Nov. 1347 to Jan. 1371. In 1359 he was made a knight of the Garter, and at various times received extensive lands both in England and in France. He was frequently employed by King Edward in the conduct of diplomatic negotiations as well as in military commands. He was one of those charged with the safe custody of the French king John when a prisoner at Calais in 1360; in 1369 he was second in command under John of Gaunt.

Manny is remembered for his share in the foundation of the Charterhouse in London. In 1349 he bought some land near Smithfield and built a chapel, afterwards sold to the bishop of London, Michael de Northburgh, who died in 1361 and bequeathed a large sum of money to found there a Carthusian convent. It is not clear whether this direction was carried out; for in 1371 Manny obtained letters patent from Edward III. permitting him to found, apparently on the same site, a Carthusian monastery called "La Salutation Mère Dieu," where the monks were to pray for the soul of Northburgh as well as for the soul of Manny himself. The bishop's bequest may have contributed to the building and endowment of the house; or possibly, as seems to be implied by a bull granted by Urban VI., in 1378, there were originally two kindred establishments owing their foundation to Northburgh and Manny respectively. At all events, Manny who died early in 1372 left instructions that he was to be buried in the church of the Carthusian monastery founded by himself. About 1335 he married Margaret, daughter and heiress of Thomas Plantagenet, earl of Norfolk, son of King Edward I.

See *Oeuvres de Froissart, I. Chroniques,* ed. by Baron Kervyn de Lettenhove (Brussels, 1867–77), and the Globe edition of *Froissart's Chronicles* (Eng. trans., 1895); G. F. Beltz, *Memorials of the Most Noble Order of the Garter* (1841); *Chronicon Angliae 1323–1388,* ed. by E. Maunde Thompson (Rolls series 64, 1874); P. Bearcroft, *An Historical Account of Thomas Sutton and of his Foundation in Charterhouse* (1737).

MANNYNG, ROBERT (Robert of Brunne) (*c.* 1264–1340?), English poet, was a native of Brunne, now Bourne, in Lincolnshire. About 6 m. from Bourne was the Gilbertine monastery of Sempringham, founded by Sir Gilbert de Sempringham in 1139. The foundation provided for seven to 13 canons, with a number of lay brothers and a community of nuns. No books were allowed to the lay brothers and nothing could be written in the monastery without the prior's consent. Mannyng entered this house in 1288, when, according to the rules, he must have been at least 24 years of age, if, as is supposed, he was a lay brother. He says he was at Cambridge with Robert de Bruce and his two brothers, Thomas and Alexander, but this does not necessarily imply that he was a fellow-student. There was a Gilbertine monastery at Cambridge, and Mannyng may have been there on business connected with his order. When he wrote *Handlyng Synne* he had been (ll. 63–76) 15 years in the priory, beginning to write in "englysch rime in 1303." Thirty-five years later he began his *Story of Inglande,* and had removed (ll. 139, etc.) to the monastery of Sixille (now Sixhills), near Market Rasen.

Handlyng Synne, a poem of nearly 13,000 lines, is a free translation, with many additions and amplifications, from William of Waddington's *Manuel des Pechiez.* It is a series of metrical homilies on the Ten Commandments, the Seven Deadly Sins and the Seven Sacraments, illustrated by a number of amusing stories from various sources. The *Cursor Mundi* had turned religious history into something not very different from a romance of chivalry, and in the stories of *Handlyng Synne* the influence of the *fabliaux* is not far to seek. Mannyng wrote in the English tongue not for learned but for "lewd" men, "that talys and ryme wyl blethly here," to occupy the leisure hours during which they might otherwise fall into "vylanye, dedly synne or other folye."

Each of his 24 topics has its complement of stories. He tells of the English observance of Saturday afternoon as holy to the Virgin, and has much to say of popular amusements, which become sins when they keep people away from church. Tournaments in particular are fertile occasions of all the deadly sins; and mystery plays, except those of the birth and resurrection of Christ performed in the churches, also lead men into transgression. He inveighs against the oppression of the poor by the rich, reproves those who, weary of matins or mass, spend their time in church "jangling," telling tales, and wondering where they will get the best ale, and revives the legend of the dancers at the church door during mass who were cursed by the priest and went on dancing for a twelvemonth without cessation. He loved music himself, and justified this profane pleasure by the example of Bishop Grosseteste, who lodged his harper in the chamber next his own; but he holds up as a warning to gleemen the fate of the minstrel who sang loud while the bishop said grace, and was miserably killed by a falling stone in consequence. The old monk's keen observation makes the book a far more valuable contribution to history than his professed chronicle. It is a storehouse of quaint stories and out-of-the-way information on manners and customs.

His chronicle, *The Story of Inglande,* was also written for the solace and amusement of the unlearned when they sit together in fellowship (11. 6–10). The earlier half is written in octosyllabic verse, and begins with the story of the Deluge. The genealogy of Locrine, king of Britain, is traced back to Noah, through Aeneas, and the chronicler relates the incidents of the Trojan war as told by Dares the Phrygian. From this point he follows closely the *Brut* of Wace. He loved stories for their own sake, and found fault with Wace for questioning the miraculous elements in the legend of Arthur. In the second half of his chronicle, which is less simple in style, he translates from the French of Pierre de Langtoft. He writes in rhyming alexandrines, and in the latter part of the work uses middle rhymes. Mannyng's *Chronicle* marks a change in national sentiment. Though he regards the Norman domination as a "bondage," he is loud in his praises of Edward I., "Edward of Inglond."

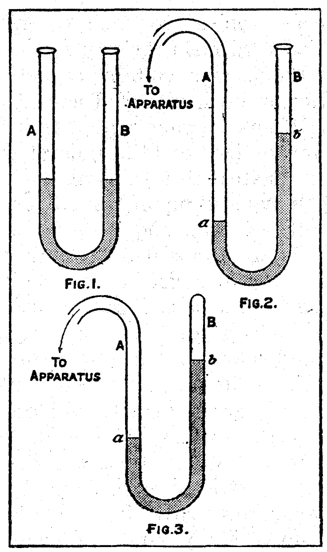
The linguistic importance of Mannyng's work is very great. He used very few of those Teutonic words which, though still in use, were eventually to drop out of the language, and he introduced a great number of French words destined to be permanently adopted in English. Moreover, he employed comparatively few obsolete inflexions, and his work no doubt furthered the adoption of the Midland dialect as the acknowledged literary instrument. T. L. Kington-Oliphant (*Old and Middle English,* 1878) regards his work as the definite starting point of the New English which with slight changes was to form the language of the Book of Common Prayer.

A third work, usually ascribed to Mannyng, chiefly on the ground of its existing side by side with the *Handlyng Synne* in the Harleian and Bodleian mss., is the *Medytacyuns of the Soper of oure lorde Jhesu, And also of hys passyun And eke of the peynes of his swete modyr, Mayden marye,* a free translation of St. Bonaventura's *De coena et passione Domini. . . .*

Robert of Brunne's *Chronicle* exists in two mss.: Petyt ms. 511, written in the Northern dialect, in the Inner Temple library; and Lambeth ms. 131 in a Midland dialect. The first part was edited *The Story of England . . .* (1887) for the Rolls Series, with an introductory essay by F. J. Furnivall; the second part was published by Thomas Hearne as *Peter Langtoft's Chronicle . . .* (1725). Peter Langtoft's French version was edited by Thomas Wright for the "Rolls Series" in 1866. Of *Handlyng Synne* there are complete mss. in the Bodleian library (ms. 415) and in the British Museum (Harleian ms. 1701), and a fragment in the library of Dulwich college (ms. 24). It was edited, with Waddington's text in parallel columns, by F. J. Furnivall for the Roxburghe club (1862), and for the Early English Text Society (1901–03). The *Meditacyun* was edited from the Bodleian and Harleian mss. by J. Meadow Cooper for the same society (1875). *See* also Gerhard Hellmers, *Ueber die Sprache Robert Mannyngs of Brunne und über die Autorschaft der ihm zugeschriebenen Meditations . . .* (Göttingen, 1885), which contains an analysis of the dialectic peculiarities of Mannyng's work; O. Boerner, "Die Sprache Robert Mannyngs" . . . in *Studien zur engl. Philologie* (vol. xii., Halle, 1904) and Oskar Preussner, *Robert Mannyng of Brunne's Übersetzung von Pierre de Langtofts Chronicle* (Breslau, 1891). All accounts of his life are based on his own work.

MANOEL II., ex-king of Portugal (1889–1932), was born at Lisbon on Nov. 15, 1889, the younger son of Carlos I. by his wife Marie Amélie of Orleans. On the assassination of King Carlos and of the crown prince Luis, duke of Braganza, on Feb. 1, 1908, Dom Manoel succeeded to the throne of Portugal, but he only retained it for a short time, as the revolution of Oct. 3, 1910 forced him to flee the country (*see* PORTUGAL). He took refuge with his mother in England, and finally settled at Fulwell Park, Twickenham. He became a familiar and popular figure in English society. On Sept. 4, 1913 he married, at Sigmaringen, Princess Augusta Victoria of Hohenzollern, daughter of Prince Wilhelm of Hohenzollern. Dom Manoel died July 2, 1932.

MANOMETER, an instrument for measuring the pressures exerted by gases or vapours (Gr. μανός, thin or loose; μέτρον, a measure). A form of pressure gauge (*q.v.*). The manometer is simply a **U** tube (fig. 1), containing a liquid: if the pressures on the surfaces of the liquid be equal, then the surfaces will be at the same height. If, on the other hand, the pressure in one limb be greater than the pressure in the other, the surfaces will be at different heights, the difference being directly proportional to the difference of pressures and inversely as the specific gravity of the liquid used. One limb of such a tube (limb A) is connected to the apparatus containing the gas or vapour whose pressure it is desired to determine. The other limb (limb B) may be either open to the air (fig. 2), or closed. In the open-tube type the pressure in one limb is equal to the atmospheric pressure, and in the closed-tube type the experimental pressure is balanced against the liquid column and the pressure of the air compressed into the upper part of a closed limb of the tube (fig. 3). In the "open tube" form (fig. 2) the pressure on the surface a is equal to the pressure on the surface at b (one atmosphere) *plus* the hydrostatic pressure exerted by the liquid column of height ab. The liquid commonly used is mercury. If a scale be placed behind the limbs of the tube, so that the difference ab can be directly determined, then the pressure in a is at once expressible as $P+ab$ in millimetres or inches of mercury, where P is the atmospheric pressure, known from an ordinary barometric observation.



MANOMETERS OF THE OPEN AND CLOSED TUBE TYPE

In the "closed tube" form (fig. 3) the calculation is not so simple, since pressure on the mercury surface in the closed limb will vary with the position of that surface. Suppose the length of the air column in the closed limb be h and its pressure p when the mercury is at the same height in both tubes. Applying pressure at a the mercury column will rise and the air column diminish in the closed limb. Let the length of the air column be h', then its pressure is ph/h'. The difference in height of the mercury columns in the two limbs is $2(h-h')$, hence the pressure in the open limb is equal to that of a column of mercury of length $2(h-h')\ pl+s\frac{ph}{h'}$, and if p is known the pressure applied at a can be determined. A particular case occurs when p is zero—the pressure at a is then equal to the difference in height of the mercury columns. Such instruments are serviceable for measuring pressures less than one atmosphere and are used in the laboratory to measure roughly the degree of vacuum obtained (*see* VACUUM).

MANOR. Any definition of a manor, in land tenure, must take note of two elements—economic and political. The manor has an estate for its basis, although it need not coincide with an estate, but may be wider. It is also a political unit, a district formed for purposes of government, although the political functions made over to it may greatly vary. As a lordship based on land tenure, the manor necessarily comprises a ruler and a population dependent on him, and the characteristic trait of such dependence consists in various forms and degrees of subjection, chiefly regulated by custom. In the sense mentioned the manor is by no means a peculiarly English institution; it occurs in every country where feudalism got a hold. Under other names we find it not only in France, Germany, Italy, Spain, but also, to a certain extent, in the Byzantine empire, Russia, Japan, etc. It is especially representative of an aristocratic stage in the development of European nations. When tribal notions and arrangements ceased to be sufficient for upholding their commonwealths, when social and political life had to be built up on the basis of land-tenure, the type of manorial organization came forward in natural course.

Origin and Development.—One problem common to the entire European world has to be considered from the very beginning. Does the manor date from the Roman empire, or not? Can its chief features be traced in Roman institutions? There can be no doubt that at the end of the Roman period certain traits are noticeable which might, under favourable conditions, develop into a manorial combination. Great estates with political functions, populations subjected to the political lordship of landowners, appear in the closing centuries of the empire, and have to be reckoned with as precursors of mediaeval manorial life. During the last centuries of its existence the Western empire became more and more a conglomerate of barbaric and half-civilized populations. The central power, after claiming an absolute sway over its subjects, is obliged more and more to lean on private forces in order to maintain itself. One of its favourite resources in the 4th and 5th centuries consists in making great landowners responsible for the good behaviour of their tenants and even of their less important neighbours. The *saltus,* the great domain, is occasionally recognized as a separate district exempt from the ordinary administration of the city, subordinated to its owner in respect of taxes and police. Even in ordinary estates (*fundi*) there is a tendency to make the landowner responsible for military conscription, for the presentation of criminals to justice. On the other hand the incumbents of ecclesiastical offices are nominated in accordance with the wishes of patrons among the landowners; in the administration of justice the influence of this same class makes itself felt more and more. Nor are signs of a convergent evolution wanting on the economic side. Slaves are used more and more as small householders provided with rural tenements and burdened with rents and services. Free peasant farmers holding by free agreement get more and more reduced to a status of half-free settlers occupying their tenancies on the strength of custom and traditional ascription to the glebe. Eventually this status is recognized as a distinct class by imperial legislation. Yet there could be no talk of a manorial system as long as the empire and the commercial intercourse protected by it continued to exist.

The fall of the empire hastened the course of evolution. It brought into prominence barbaric tribes who were unable to uphold either the political power or the economic system of the Romans. The Germans had from of old certain manorial features in the constitution of their government and husbandry. The owner of a house had always been possessed of a certain political power within its precincts, as well as within the fenced area surrounding it: the peace of the dwelling and the peace of the hedged-in yard were recognized by the legal customs of all the German tribes. The aristocratic superiority of warriors over all classes engaged in base peaceful work was also deeply engraved in the minds of the fighting and conquering tribes. On the other hand the downfall of complicated forms of civilization and civil intercourse rendered necessary a kind of subjection in which tributary labourers were left to a certain extent to manage their own affairs. The Germanic conqueror was unable to move slaves about like draughts: he had no scope for a complicated administration of capital and work. The natural outcome was to have recourse to serfdom with its convenient system of tribute and services.

But, as in the case of the Roman empire, the formation of regular manors was held back for a time in the early Germanic monarchies by the lingering influence of tribal organization. In the second period of mediaeval development in continental Europe, in the Carolingian epoch, the features of the estate as a political unit are more sharply marked. Notwithstanding the immense efforts of Charles Martel, Pippin and Charlemagne to strengthen the tottering edifice of the Frankish empire, public authority had to compromise with aristocratic forces in order to ensure regular government. As regards military organization this is expressed in the recognition of the power of *seniores,* called upon to lead their vassals in the host; as regards jurisdiction, in the increase of the numbers of commended freemen who seek to interpose the powerful patronage of lay and secular magnates between themselves and the Crown. Great estates arose not only on the lands belonging to the king, but on that of churches and of lay potentates, and the constitution of these estates reminds us forcibly of that of later feudal estates.

The struggle against Northmen, Magyars and Slavs gave a crowning touch to the process of localization of political life and of the aristocratic constitution of society.

France.—In order to describe the full-grown continental manor of the 11th century it is better to take French examples than German, Italian or Spanish. Feudalism in France attained the greatest extension and utmost regularity, while in other European countries it was hampered and intermixed with other institutional features. The expression best corresponding to the English "manor," in the sense of an organized district, was *seigneurie.* *Manoir* is in use but meant strictly "mansion" or chief homestead in France.

The *seigneurie* may be considered from three points of view—as a unit of administration, as an economic unit, and as a union of social classes.

(*a*) In principle the disruption of political life brought about by feudalism ought to have resulted in the complete administrative independence of the manor. *Chaque baron est souverain dans sa baronie* is a proverb meant to express this radical view of manorial separatism. As a matter of fact this separatism was never completely realized, and even at the time of the greatest prevalence of feudalism the little sovereigns of France were combined into a loose federation of independent fiefs. The institutional expression of this aspect of feudalism in the life of the *seigneurie* was the jurisdiction combined with the latter. The principal origin of this jurisdiction was the dismemberment of royal justice, the acquisition by certain landowners of the right of holding royal pleas. The assumption of authority over public tribunals of any kind was naturally considered as equivalent to such a transmission of royal right. But other sources may be noticed also. It was assumed by French feudal law that in all cases when land was granted by a *seigneur* in subinfeudation the recipients would be bound to appear as members of a court of tenants for the settlement of conflicts in regard to land. A third source may be traced in the extension of the patrimonial justice of a person over his serfs and personal dependents to the classes of free and half-free population connected with the *seigneurie* in one way or another. There arose in consequence of these assumptions of jurisdiction a most bewildering confusion of tribunals and judicial rights. A certain order was brought into this feudal chaos by the classification of judiciary functions according to the four categories of high, middle, low and tenurial justice. The scope of the first three subdivisions is sufficiently explained by their names; the fourth concerned cases arising from subinfeudation. As a rule the baron or *seigneur* sat in justice with a court of assessors or peers, but the constitution of such courts varied a great deal.

(*b*) The economic fabric of the French *seigneurie* varied greatly, according to localities. In the north of France it was not unlike that of the English manor. The capital messuage, or castle, and the home-farm of the lord, were surrounded by dependent holdings, *censives,* paying rent, and villein tenements burdened with services. Between these tenancies there were various ties of neighbourhood and economic solidarity recalling the open-field cultivation in England and Germany. When the harvest was removed from the open strips they returned to a state of undivided pasture in which the householders of the village exercised rights of common with their cattle. Wild pasture and woods were used more or less in the same fashion as in England (*droit de pacage de vaine pâture*). The inhabitants often formed courts and held meetings in order to settle the by-laws, and to adjudicate as to trespasses and encroachments (*courts colongères*).

(*c*) The social relations between the manorial lord and his subjects are marked by various forms of the exploitation of the latter by the former. Apart from jurisdictional profits, rents and agricultural services, dues of all kinds are exacted from the rural population. Some of these dues have to be traced to servile origins, although they were evidently gradually extended to groups of people who were not descended from downright serfs but had lapsed into a state of considerable subjection. The *main morte* of rustic tenants meant that they had no goods of their own, but held movable property on sufferance without the right of passing it on to their successors, although after payment of a heavy fine, succession might be permitted. The *formariage* corresponded to the English *merchetum,* and was exacted from rustics on the marriage of their daughters; this payment was considered a badge of serfdom. *Chevage* (*capitagium*) might be exacted as a poll-tax from all the unfree inhabitants of a *seigneurie,* or, more especially, from those who left it to look for sustenance abroad. The power of the lord as a landowner was more particularly expressed in his right of pre-emption (*retrait seigneurial*), and in taxes on alienation (*lods et ventes*). As a person wielding political authority, a kind of sovereignty, the lord enjoyed divers rights which are commonly attributed to the State—the right of coining money, of levying direct taxes and toll (*tallagium, tolneta*) and of instituting monopolies, such as the use of the lord's mill (*moulin banal*), or of his oven (*four banal*) or of his bull (*taureau banal*).

(P. Vi.)

THE MANOR IN ENGLAND

The typical English Manor, if there be a recognized or definite type, is known to us through the records of the 13th century. There is much valuable material in the somewhat cryptic descriptions in the Domesday survey; there are admirable pictures of the custom and working of a manor in the 12th century extents, surveys, custumals and cartularies, but in the 13th century we find in addition to these, systematic information as to the economic progress of the manor, in the Ministers' accounts, and as to the judicial proceedings of the manorial courts, in the court rolls. By the 14th century we are confronted with a picture of change and decay, emancipation and development.

Topography.—Topographically, a manor is a complex estate, consisting of (*a*) the lord's demesne, scattered in strips in the open fields, or in consolidated blocks of fields; (*b*) the land of the free tenants, who owe the lord small rents in money or in kind, and certain fixed labour-services; (*c*) the land of the villeins, lying for the most part in the open fields, and owing more onerous and uncertain services, as well as rents in money and in kind. The land of the manor is partly arable, partly meadow (very highly valued), partly rough pasture, waste or wood. In central and southern England the arable land was divided into three great fields, arranged for a three year rotation of crops and fallow; the fields were divided into acre or $\frac{1}{2}$-acre strips, grouped in "shots" or furlongs. The lord, the free tenants and the villeins all held more or less defined rights to a share in the meadow and the waste. Much of the communal administrative action of the manorial courts is connected with these rights. In the north and west, and again in Kent and East Anglia the three-field division is hardly to be found, and the whole agrarian system varies sharply from the "normal"; this fact is important in local investigations.

Inhabitants of the Manor.—The inhabitants of the manor have all their separate rights, asserted and defended by the manorial court. The lord at the head of the society, in his hall or manor-house, enjoys his own demesne, holds a certain "superiority" over the lands of the villeins (which, the later lawyers describe as ownership of the freehold of all villein or copyhold land) and possesses rights over the waste paramount to those enjoyed by the other inhabitants. These rights were to some extent limited by the Statute of Merton (1236) and the second Statute of Westminster (1285). The lord's rights of jurisdiction will be better treated in connection with the courts. The free tenant is not yet a modern free-holder; economically he is often hardly distinguishable from a villein, but his status is clearly marked by his power to appeal to the royal courts of justice, even against his lord. Below the free-tenants came the villeins (*nativi, rustici,* bondmen, virgaters, customers, etc.)—customary tenants holding a house, a virgate or half-virgate in acre strips, and a share in the meadows and waste. A virgate was normally about 30 acres—the fourth part of a hide; but it might vary from 10–15 acres up to 60 or 80, while the acre itself varies in different districts. The villein was in certain respects unfree; in the eye of the law he had no rights against his lord, who "was protected from all suits by the *exceptio villenagii";* he might not leave the manor without permission, and he could be reclaimed if he did, by the writ *"de nativo habendo";* he could not, in theory, own any property, and he was subject to certain "base" incidents, such as the payment of *merchet,* and the need to ask permission to put his son to school or to allow him to seek ordination. But in practice the villein bought and sold like other men, after payment of a small fee; he leased, exchanged or sold his land, through the very efficient machinery of the manorial court; he made wills, and at times appears even to have disposed of his villein lands by will—proved in the lord's court. He could, no doubt, be ejected by the lord, but such ejection was very rare, and seemed to require a complete cessation of services, by physical or mental incapacity, before it could be accomplished "according to the custom of the manor." The villein was never exposed to the arbitrary will of the lord, but was always protected by the court, which interpreted the "custom" by the spoken witness of the *villata* (or the *curia,* the *homagium,* the *jurati*) or the written testimony of court roll or custumal. The inevitable confusion which arose between unfree status, and unfree tenure usually reacted to the advantage of the villein by blood, but on some estates (notably monastic lands) there was a determined attempt to impose the whole burden of unfree status upon free men holding villein tenements. Individual villeins, with their *sequela,* or villein brood, were sometimes bought and sold, but they could not be separated from their tenements, and all that is implied by sale is transfer from one lord to another as regards services and jurisdiction. The hardship or prosperity of a villein's lot depended mainly upon his economic position, which would seem to have steadily improved in the 14th century. His rents in money, in kind, and in services were for the most part fixed. The rents of assize (probably a commutation of earlier rents in kind rather than of services) varied considerably on different manors, but as they remained fixed for centuries, the advantage of any fall in the value of money remained with the villein. The dues in kind were gradually almost all commuted, or dropped.

Labour Services.—Although it happened that the villein paid small rents in moneys and in kind, labour dues were the most serious part of a villein's obligations. Two or three days week-work throughout the year might be combined with two or three extra days per week in harvest to make an apparently insupportable burden. It should be noted, however, that a day's work sometimes means, by definition, half a day's work, or a fixed measure of reaping or mowing. Moreover, the labour was due from the virgate, and not from each man; hence a father might send his son to fulfill his obligation. Generally the harvest works (boon-days) survived longest as they were available for emergencies.

One of the most important problems in connection with the manor is the local distribution of labour services, and the varying reasons for their commutation. The history of the manor in the 14th century is the story of the change from typical mediaeval methods to an elementary form of the modern farm worked by hired labour. By the end of the 14th century the class of villeins included men of varied economic status; cottiers or bordars holding a plot of 4 or 5 acres and a cottage at one end of the scale were legally in the same position as men who had laid field to field, virgates and enclosures, until they might hold 100 to 200 acres of land, and require the services of wage-paid men, even while they themselves owed "base" services.

Administration of the Manor.—A very important factor in the development of the manor was the administrative system, the history of which has as yet been imperfectly explored. This aspect of manorial history is, however, useful in correcting over-sweeping generalizations. The lord of a manor might be the king, the duke of Lancaster, a wealthy bishop or monastic house, or, on the other hand the humblest of knights or freemen. Upon his status and the number of his manors depended the character of the administration. The minimum staff would be the lord's bailiff, working with the provost or reeve, who was usually elected by the "homage," and who had under him certain regular servants of the manor—a hay-ward, a reap-reeve, a shepherd, swineherd, bee-keeper, etc. Whenever it happened that the lord held a number of manors, he required a seneschal, or steward, whose office is variously described as agricultural supervision, or as judicial and legal (*cf.* Walter of Henley, etc.). The seneschal was usually assisted by a group of clerks and auditors, and other officials, who were responsible for the final presentation of the manorial accounts. The seneschal and his subordinates were admitted to office by an oath, closely parallel to that of a royal councillor; the whole group of officials tended to develop into a private council, which often contained professional lawyers, described as *utrius jurisperiti.* Rudimentary forms of these private councils may be found in the 12th century, and they were evidently well established by the end of the 13th century (*e.g.,* for the abbey of St. Albans, or the bishoprics of Durham, Worcester and Ely, and the archbishopric of Canterbury).

Manor Court.—The manor court is a complicated structure, though the division court leet, court baron and court customary does not belong to its early history. It originally exercised its criminal, civil, or manorial jurisdiction as one court; its names may differ, the parties before it may be free or unfree, but the court is the same. Its president was the lord's steward; the bailiff was the lord's representative and the public prosecutor; and the tenants of the manor, both free and unfree, attended at the court and gave judgment in the cases brought before it. To modern ears the constitution sounds unfamiliar. The president of the court settled the procedure of the court, carried it out, and gave the final sentence, but over the law of the court he had no power. All that is comprised in the word "judgment" was settled by the body of tenants present at the court. The business of the court may be divided into criminal, manorial and civil. The powers under the first head depended on the franchises enjoyed by the lord in the particular manor; for the most part only petty offences were triable, such as small thefts, breaches of the assize of bread and ale, assaults, and the like; except under special conditions, the justice of great offenses remaining in the king. But offences against the custom of the manor, such as bad ploughing, improper taking of wood from the lord's woods, and the like, were of course the staple business of the court. Under the head of manorial business the court dealt with the choice of manorial officers, and had some power of making regulations for the management of the manor; but its chief function was the recording of the surrenders and admittances of the villein tenants.

It is in this function that we find the origin of copyhold tenure. The manorial court acted as a registry of an active land market, and, provided the fees on transfer were paid, lords evidently made no effort to maintain static conditions. On some estates we find an almost complete replica of the system of royal writs for possessory and even proprietary actions. Litigation became so common that the written record takes the place of the testimony of the old men or of the court. Court rolls were constantly produced in court, as evidence, and from the first half of the 14th century, we find tenants in possession of a copy of court roll. By 1400 the possession of a copy is often enforced, and the existence of the copyholder is thus acknowledged. Besides land questions, the manorial court dealt with any other civil suits that might arise, such as questions of debt, detinue, damages, or contract. In semi-urban manorial courts, which might have to deal with fairs or with industry, these civil cases became of considerable importance. Occasionally, the manor court would appear to encroach upon the province of the courts christian—*e.g.,* in dealing with wills of villeins and copyholders, and in proceedings against usurers.

During the 15th century, the villein slowly developed into a copyholder, and the importance of the manorial court was correspondingly diminished. After ten well-known decisions of Danby, C.J., and Bryan, C.J., in 7 Ed. IV. and 21 Ed. IV., it was established that the courts of law could entertain an action of trespass brought against his lord by a customary tenant. From this time onward, the courts, both of law and of equity, began to intervene, and the records of the courts of Chancery, Star Chamber, and Requests show that in the Tudor period equitable suits brought by tenants against their lords were not infrequent. The few remaining "bondsmen" of the 16th century were constrained to pay heavily for their manumission. Gradually the manor ceased to have any social or economic importance, and its few remaining privileges and peculiarities of tenure were swept away by the Law of Property Acts 1922.

It is clear that the manor court as here described consisted of conflicting elements of very different origin and history. Founded partly on express grants of franchises, partly on the inherent right of a feudal lord to hold a court for his free tenants, partly on the obscure community traceable among the unfree inhabitants of the manor, it is incapable of strict legal definition. All these elements, moreover, contain in themselves reasons for the decay which gradually came over the system. In some cases of urban development, the manorial court was strengthened. But for the most part only a shadow of its former powers survived to control the few remaining copyholders, until the passing of the Law of Property Acts 1922.

Later Legal Theory.—A few words must be given to the legal theories of the 15th century on the manor court. It would seem to have become the law that to the existence of the manor two courts were necessary—a court customary for customary tenants, and a court baron for free tenants. If the freeholders in the manor diminish to less than two, the court baron cannot be held, and the manor perishes. This distinction seems to be without historical justification, as the court of the 13th century was not differentiated in this way; the terms were also very loosely applied, and it is not unusual in the 16th century to find a so-called court baron exercising all the functions of a customary court.

Apart from the change in the court of the manor, the most important thread in its later history is the process, mentioned above, which converted the villein into the copyholder. Although it seems hardly accurate to describe the villein of the 13th century as holding at the will of the lord, yet he could claim no protection from the king's courts. If, however, the villein were a tenant on the king's Ancient Demesne, his condition was distinctly more secure. He was protected by the writs of *monstraverunt* and the little writ of right close from the improper exactions of services and from ejection by the lord. But in ordinary manors there was no such immunity. That ejection was legally possible has already been shown, and it was not until the well-known decision of

Danby, C. J. and Bryan, C. J. in 7 Edw. IV., and 21 Edw. IV., that the courts of law would entertain an action of trespass brought against his lord by a customary tenant. There was nothing, however, to prevent a customary tenant from proceeding by way of petition to the king, and there are cases of such petitions as early as the end of the 14th century.

Moreover, in 1381 royal justice had come to the aid of the lords against their villeins, and it was not unknown that a lord should call in the private aid of a distinguished justice or counsel. In time the process is reversed, and the royal courts begin to help the villein or copyholder against his lord. From the decision of Bryan and Danby onwards, the courts, both of law and of equity, begin to intervene and the records of the courts of Chancery, Star Chamber, and Requests show that in the Tudor period equitable suits brought by tenants against their lords are not infrequent. The 16th century also saw the manumission of the few remaining "bondsmen," who were constrained to pay heavily for their personal freedom. From that period onwards the manor ceased to have any social importance, and survived merely as the nucleus of a peculiar form of land tenure.

MANOR HOUSE, the house of the lord of the manor, or holder of one of the smaller feudal fiefs, distinguished from a castle by the fact that it did not possess developed towers or a keep, and was not designed to withstand an extended siege. Feudal regulations in regard to which fiefs could possess castles were strict and complex. Early manors were, nevertheless, fortified, and, during the 13th and 14th centuries, the manor house took the form of a rectangular, masonry walled building, frequently with battlements (*q.v.*) and often surrounded by a moat. This central building was itself surrounded by barns, stables and other farm buildings, and the whole group enclosed by a wall. Ruined examples of this type have been studied carefully in France, as the *castera* of S. Médard en Jalle, near Bordeaux (first half 13th century); Camarsac on the banks of the Gironde (early 14th century). Near Southampton, England, the walls of a manor house built by Richard Coeur de Lion in the 12th century still stand and the castle of Stokesay in Shropshire is an example of the English 13th century manor house. All these are noteworthy in that they show a definite attempt to produce, however crudely, carefully thought out living quarters in which the idea of comfort plays an important part. One or more great halls (*see* Hall) was a necessary feature, and in English houses furnished the controlling element in the planning of all manor houses from the 14th century on. As life became more settled and the need of defence less, the single rectangular block became inadequate and various schemes round a court were adopted. In France, the manor house of Xaintrailles near Nérac is a good example of the early 15th century. Ightham Mote, built largely in the reign of Henry VII., is the best preserved English example of the 15th century.

From 1500 on, the need of defence began to disappear and the manor house became a large country house, following in every country the architectural ideals of its period, style and location. Thus, in France, the Renaissance tendency towards classic composition led to the gradual substitution of a rectangular block form for earlier, more informal types. Such a château (*q.v.*) as Azay-le-Rideau (early 16th century) is characteristic of the transition. In Normandy, however, the earlier type continued in use and many Norman farms, to this day, in their enclosing walls, their great courts surrounded by farm buildings, and their rectangular blocks of living quarters, preserve the arrangements of a typical 15th century manor house. The most famous Norman example is the great *manoir d'Ango* at Varengeville near Dieppe, with remarkable, rich, patterned brick work and interesting Francis I. detail.

In England the more informal ideals of the Elizabethan and Jacobean periods controlled 16th and 17th century manor house detail. The most usual plan has a hall in the centre with living quarters at one end and service rooms at the other. Later, as the desire for formality increased and the need for the hall diminished, more symmetrical block treatments became common. The most interesting examples of the earlier type are Great Chalfield manor, South Wraxwell manor (both in Wiltshire) and Ockwell manor in Berkshire, all of the 15th century, and Layer Marney Hall, Essex, and Sutton Place, Surrey, of the 16th century. (*See* also House.)

MANRESA, a town of Spain, in the province of Barcelona, on the river Cardoner and the Barcelona–Lérida railway. Pop. (1940), 34,075 (mun., 36,381). It is probably the *Munorisa* of the Romans, the capital of the Jacetani or Jaccetani. A large part of the town was burned by the French in 1811. Manresa is the chief town of the highlands watered by the Cardoner and upper Llobregat, which meet below the town, and are also connected by a canal 18 mi. long. Two bridges, one dating from the Roman period, the other constructed in 1804, unite the older part of Manresa with the modern suburbs. The principal buildings are the collegiate church of Santa Maria de la Seo, the Dominican monastery, and the church of San Ignacio, built over the cavern where Ignatius de Loyola spent most of the year 1522 in penitentiary exercises and the composition of his *Exercitia spiritualia.* Manresa has iron-foundries and manufactures of woollen, cotton and linen goods, ribbons, hats, paper, soap, chemicals, spirits and flour. Building stone is quarried nearby. Manresa was captured by insurgents near the close of the civil war of 1936–39.

MANRIQUE, GÓMEZ (1415?–1490?), Spanish poet, soldier, politician and dramatist, took a prominent part in the rebellions of the nobles during the reigns of John II. and Henry IV. His place in the history of Spanish literature is secure as the earliest Spanish dramatist whose name has reached posterity. His *Representación del Nacimiento de Nuestro Señor* and [*Lamentaciones*] *fechas para Semana Santa* and his two *momos,* or interludes, played at court, contain the elements of the religious and secular drama of the future.

MANRIQUE, JORGE (1440?–1479), Spanish poet and soldier, nephew of Gómez Manrique. His love-songs, satires, and acrostic verses are merely ingenious compositions in the taste of his age; he owes his imperishable renown to a single poem, the *Coplas por la muerte de su padre,* an elegy of 40 stanzas on the death of his father. The great sonorous commonplaces on death are vitalized by the intensely personal grief of the poet, who lent a new solemnity and significance to thoughts which had been for centuries the common property of mankind. It was given to Jorge Manrique to have one single moment of sublime expression, and this isolated achievement has won him a fame undimmed by any change of taste during four centuries.

MANSARD, JULES HARDOUIN (1646?–1708), French architect, was born at Paris, probably on April 16, 1646, although this date is contested. He was the son of Raphael (?) Hardouin, painter to the king, and distantly related to François Mansart. For some time he worked under the instruction of Liberal Bruant, with whom he collaborated in the Hôtel de Vendôme; then, having attracted the king's notice, he was commissioned in 1672 to design a château for Madame de Montespan, which was executed later. He was by this time launched upon a brilliant career, under the consistent patronage of Louis XIV. Among his earlier additions to St. Germain were a number of fine private houses, including the Hôtel de Lorges (later Hôtel de Conti), his own residence. After receiving various honours from the king, he was commanded to design and erect the Palace of Versailles. He was working on the great façade, too well known and too noble for description, about 1685, the stables and the Grand Commun being already completed, and Nôtre Dame de Versailles nearly so. At this period of his life he was working, and causing others to work, with almost incredible celerity. In 1685 the foundations of the Pont-Royal were laid, and that year and the following were also occupied with the Institut de St. Cyr. In 1688 he began to work upon the Trianon.

There seemed to be no conception, however magnificent or delightful, of which Mansard was not capable, no branch of construction with which he was not conversant. After making additions to the Palais Royal, and building part of Orleans cathedral, he completed the dome of the Invalides in 1693, and, already ennobled, was further distinguished by the king. Still working with astonishing fertility, he built many country houses in the following years, among which may be mentioned the Château de Lunéville and the Château de Sagonne (his own residence, where he was visited by the king), while still engaged in laying out the gardens of Versailles. He was working on the chapel there when he died in 1708.

MANSARD ROOF, a hipped roof, sloping up on all four sides of a building from a horizontal cornice, in two slopes, of which the lower is more nearly vertical than the other; also a somewhat similar roof in which the upper, more nearly horizontal slope is replaced by a flat roof. *See* MANSART, FRANÇOIS.

MANSART, FRANÇOIS (1598–1666), French architect, was born in Paris on Jan. 23, 1598, and is said to be the descendant of a long line of architects, at one time resident in Italy. He was the son of a carpenter to the king, and for some time studied under Germain Gaulthier, the king's architect. On taking up independent work, of which he was very prolific, he designed and carried out many churches, in whole or in part, and numerous large private houses, while many buildings of uncertain origin have been ascribed to him. Much of his work has since been destroyed. Mansart appears to have interested himself in problems of construction, and is generally considered to be the originator of the so-called "mansard" or curb roof, a modification of contemporary practice which became popular by affording an increased area of floor-space on the top storey of houses. "Mansarde," in modern French a garret or attic chamber, is derived from his name. Among his works may be mentioned the church of the Visitation des Filles de Sainte-Marie, an early work; the Hôtel Carnavalet; Hôtel de la Vrillière (where the bank of France now is), which he did not finish; Château de Maisons at St. Germain-en-Laye; Hôtel Mazarin, part of which has since been used for a time by the Bibliothèque Nationale; several church portals and altars; and many provincial castles, of which La Ferté-Reuilly is a good example. He was commissioned by Colbert to make a design for the Louvres; his plan was approved subject to his undertaking not to alter the design during the construction of the building. This he refused to do, and the Italian, Bertini, was sent for in his stead.

MANSEL, HENRY LONGUEVILLE (1820–1871), English philosopher, was born at Cosgrove, Northamptonshire on Oct. 6, 1820. He was educated at Merchant Taylors' school and St. John's college, Oxford. He took a double first in 1843, and became tutor of his college. He was appointed reader in moral and metaphysical philosophy at Magdalen college in 1855, and Waynflete professor in 1859. He was a great opponent of university reform and of the Hegelianism which was then beginning to take root in Oxford. In 1867 he succeeded A. P. Stanley as professor of ecclesiastical history, and in 1868 he was appointed dean of St. Paul's. He died on July 31, 1871.

Mansel maintained the purely formal character of logic, the duality of consciousness as testifying to both self and the external world, and the limitation of knowledge to the finite and "conditioned." His doctrines were developed in his edition of Aldrich's *Artis logicae rudimenta* (1849)—his chief contribution to the reviving study of Aristotle—and in his *Prolegomena logica: an Inquiry into the Psychological Character of Logical Processes* (1851, 2nd ed. enlarged 1862), in which the limits of logic as the "science of formal thinking" are rigorously determined. In his Bampton lectures on *The Limits of Religious Thought* (1858, 5th ed. 1867; Danish trans. 1888) he applied to Christian theology the metaphysical agnosticism which seemed to result from Kant's criticism, and which had been developed in Hamilton's *Philosophy of the Unconditioned.*

Mansel wrote also *The Philosophy of the Conditioned* (1866) in reply to Mill's criticism of Hamilton; *Letters, Lectures, and Reviews* (ed. Chandler, 1873), and *The Gnostic Heresies* (ed. J. B. Lightfoot, 1875, with a biographical sketch by Lord Carnarvon).

MANSFELD, a German family which took its name from Mansfeld in Saxony, where it was seated from the 11th to the 18th century. One of its earliest members was Hoyer von Mansfeld (d. 1115), a partisan of the emperor Henry V. during his struggles with the Saxons; he fought for Henry at Warnstädt and was killed in his service at Welfesholz. Albert, count of Mansfeld (1480–1560), was an intimate friend of Luther and one of the earliest and staunchest supporters of the Reformation.

With Albert was associated his brother Gebhard, and another member of the family was Johann Gebhard, elector of Cologne from 1558 to 1562. A scion of another branch of the Mansfelds was Peter Ernst, Fürst von Mansfeld (1517–1604), governor of Luxemburg, who, unlike his kinsmen, was loyal to Charles V. He went with the emperor to Tunis and fought for him in France. He served Philip II. at St. Quentin and in the Netherlands, and led a body of troops to aid the king of France against the Huguenots. In this capacity he was present in 1569 at the battle of Moncontour, where another member of his family, Count Wolrad of Mansfeld (d. 1578) was among the Huguenot leaders.

See L. F. Niemann, *Geschichte der Grafen von Mansfeld* (Aschersleben, 1834).

MANSFELD, ERNST, GRAF VON (*c.* 1580–1626), German soldier, was an illegitimate son of Peter Ernst, Fürst von Mansfeld, and passed his early years in his father's palace at Luxemburg. He gained his earliest military experiences in Hungary, where his half-brother Charles (1543–1595) held a high command in the imperial army. He allied himself with the Protestant princes, and was despatched by Charles Emmanuel, duke of Savoy, at the head of about 2,000 men to aid the revolting Bohemians at the outbreak of the Thirty Years' War in 1618. He took Pilsen, but in the summer of 1619 he was defeated at Zablat; after this he offered his services to the emperor Ferdinand II. and remained inactive while the titular king of Bohemia, Frederick V., elector palatine of the Rhine, was driven in headlong rout from Prague. Mansfeld was appointed by Frederick to command his army in Bohemia, and in 1621 he established himself in the Upper Palatinate, successfully resisting the efforts made by Tilly to dislodge him. From the Upper he passed into the Rhenish Palatinate. Here he relieved Frankenthal and took Hagenau; then, joined by his master, the elector Frederick, he defeated Tilly at Wiesloch in April 1622 and plundered Alsace and Hesse. Mansfeld's ravages were ruinous to the districts he was commissioned to defend, and at length Frederick was obliged to dismiss Mansfeld's troops from his service. Joining Christian of Brunswick the count then led his army through Lorraine, devastating the country, and in August 1622 defeating the Spaniards at Fleurus. He next entered the service of the United Provinces. A mercenary and a leader of mercenaries, Mansfeld sold his services to the highest bidder. About 1624 he paid three visits to London, where he was hailed as a hero. James I. was anxious to furnish him with men and money for the recovery of the Palatinate, and in January 1625 Mansfeld and his army of "raw and poor rascals" sailed from Dover to the Netherlands. On the renewal of operations in Germany in the autumn Mansfeld was again engaged. Defeated by Wallenstein at Dessau (1626), he raised another army, and pursued by Wallenstein he pressed forward towards Hungary, where he hoped for aid from Bethlen Gabor, prince of Transylvania. But Gabor made peace with the emperor, and Mansfeld was compelled to disband his troops. He died at Rakowitza Nov. 20, 1626.

See F. Stieve, *Ernst von Mansfeld* (Munich, 1890).

MANSFIELD, KATHERINE (1890–1923), British writer, was born at Wellington, New Zealand, the daughter of Sir H. Beauchamp, and spent most of her girlhood in New Zealand. She published *In a German Pension* (1911), and in 1913 married John Middleton Murry, the critic, with whom she had been associated in the publication of a literary review, *Rhythm*. Her brilliant talent for the short story form was displayed in a collection issued as *Bliss* (1920), and her acute critical powers in frequent contributions to *The Athenaeum,* then edited by her husband. This was followed by *The Garden Party* (1922), but a career of great promise, and small but perfect achievement, was cut short by death, after a long illness, at Fontainebleau, on Jan. 9, 1923. Further stories, *The Doves' Nest,* appeared later in that year, also a volume of *Poems;* in 1924 was published *Something Childish,* tales and fragments of minor interest, and in 1927 the *Journal of Katherine Mansfield* (1914–22). Her *Letters* were published in 1928 (2 vols.).

MANSFIELD, RICHARD (1857–1907), American actor, was born on May 24, 1857, in Berlin, his mother being Madame Rudersdorff (1822–82), the singer, and his father, Maurice Mansfield (d. 1861), a London wine merchant. He first appeared on the stage at St. George's Hall, London, and then drifted into light opera, playing the major-general in *The Pirates of Penzance,* and the lord high executioner in *The Mikado,* both in the English provinces and in America.

In 1883 he joined A. M. Palmer's Union Square theatre company in New York, and made a great hit as Baron Chevrial in *A Parisian Romance*. His rendering (1887) of the doubled title-parts in R. L. Stevenson's *Strange Case of Dr. Jekyll and Mr. Hyde* created a profound impression. By invitation of Sir Henry Irving, he played at the Lyceum theatre in London in 1888. He produced *Richard III.* the next year at the Globe theatre, New York. Among his other chief successes were *Prince Karl, Cyrano de Bergerac* and *Monsieur Beaucaire.*

He was one of the earliest to produce G. Bernard Shaw's plays in America, appearing in 1894 as Bluntschli in *Arms and the Man,* and as Dick Dudgeon in *The Devil's Disciple* in 1897. He died in New London (Conn.), Aug. 30, 1907.

See the lives by Paul Wilstach (1908) and William Winter (1910).

MANSFIELD, WILLIAM MURRAY, 1st Earl of (1705–1793), English judge, was born at Scone in Perthshire, on March 2, 1705, the son of the 5th Viscount Stormont. He was educated at Perth grammar school, Westminster School and Christ Church, Oxford. He was called to the bar at Lincoln's Inn in 1730. He was a good scholar and mixed with the best literary society, being an intimate friend of Alexander Pope. His appearance in some important Scottish appeal cases brought him into notice, and in Scotland at least he acquired an immense reputation by his appearance for the city of Edinburgh when it was threatened with disfranchisement for the affair of the Porteous mob. His English practice had as yet been scanty, but in 1737 a single speech in a jury trial of note placed him at the head of the bar, and from this time he had all he could attend to. In 1738 he married Lady Elizabeth Finch, daughter of the earl of Winchelsea. In 1742 he was appointed solicitor-general.

During the next 14 years Mansfield was one of the most conspicuous figures in the parliamentary history of the time. By birth a Jacobite, by association a Tory, he was nevertheless a Moderate. In the year 1754 he became attorney-general, and for the next two years acted as leader of the House of Commons under the administration of the duke of Newcastle. But in 1756, a vacancy occurred in the chief justiceship of the king's bench, and he claimed the office, being at the same time raised to the peerage as Baron Mansfield.

From this time the chief interest of his career lies in his judicial work, but he did not wholly dissever himself from politics. He became by a singular arrangement, only repeated in the case of Lord Ellenborough, a member of the cabinet, and remained in that position through various changes of administration for nearly fifteen years, and, although he persistently refused the chancellorship, he acted as Speaker of the House of Lords while the Great Seal was in commission. During the time of Pitt's ascendancy he took but little part in politics, but while Lord Bute was in power his influence was very considerable, and seems mostly to have been exerted in favour of a more moderate line of policy. He was a supporter of the prerogative. In 1776 he was created earl of Mansfield. In 1783, although he declined to re-enter the cabinet, he acted as Speaker of the House of Lords during the coalition ministry, and with this his political career may be said to have closed. He continued to act as chief justice until his resignation in June 1788, and died on March 20, 1793.

It is as a judge, however, that Mansfield is chiefly remembered. In the sphere of commercial law he stands alone as having reduced it almost to an exact science, where before it was a chaos of unselected decisions. And the same may be said of the doctrine of quasi-contract, where he found the law again in a chaotic state just fitted for his systematising genius, and left it a coherent body of rules founded on the principle of unjust enrichment. (See *Moses* v. *Macfarland, 2 Burr.* 1005.) But when he had to deal with a body of law already elaborately worked out with settled principles, he went wrong. Thus his attempts to "rationalise by a side wind" our law of seisin (*Taylor and Atkyns* v. *Horde,* 1 *Burr.* 113), and to anticipate the Judicative Act by allowing a plaintiff to set up an equitable title, was bound to fail, as was his more ambitious and very nearly successful attempt to revolutionise the doctrine of consideration by basing contract on moral obligation and reducing consideration to credentiary value only (*Pillans* v. *Van Mierop,* 3 *Burr.* 1663). But while his wide acquaintance with continental jurisprudence sometimes led him astray in matters dependent exclusively on English Common Law the trend of legislation in the 19th century has often followed the lines he tried to lay down.

See Holliday's *Life* (1797); Campbell's *Chief Justices;* Foss's *Judges;* Greville's *Memoirs, passim;* Horace Walpole's *Letters;* and other memoirs and works on the period. And *see* Holdsworth, *History of English Law,* esp. vols. 6, 7 and 8.

MANSFIELD, a market town and municipal borough in the Mansfield parliamentary division of Nottinghamshire, England, on the small river Mann or Maun; the junction of several branches of the Midland railway, by which it is 142 mi. N.N.W. from London. Pop. (1938 est.) 47,420. Area, 11 sq.mi. During the heptarchy Mansfield was occasionally the residence of the Mercian kings, and it was afterwards a resort of Norman sovereigns, since it lay on the western outskirts of Sherwood forest. By Henry VIII the manor was granted to the earl of Surrey. Afterwards it went by exchange to the duke of Newcastle, and thence to the Portland family. The town obtained a fair from Richard II in 1377. It became a municipal borough in 1891. The church of St. Peter is partly Early Norman, and partly Perpendicular. There is a grammar school founded by Queen Elizabeth in 1561, occupying modern buildings. A technical college was opened in 1928. Twelve almshouses were founded by Elizabeth Heath in 1693. Mansfield is in a coal mining area, and its industries are the manufacture of lace, thread, boots and machinery, iron-founding and brewing. In the neighbourhood, there are quarries of limestone, sandstone and freestone.

MANSFIELD, a town of Bristol county, Massachusetts, U.S.A., 24 mi. S. by W. of Boston, on the New York, New Haven and Hartford railroad. The population was 6,530 in 1940 (federal census). It has a large number of greenhouses and a great variety of manufacturing industries. The town was incorporated in 1775.

MANSFIELD, a city of northern Ohio, U.S.A., 75 m. S.W. of Cleveland, on Federal highways 30 and 42; the county seat of Richland county. It has a municipal airport, and is served by the Baltimore and Ohio, the Erie, and the Pennsylvania railways. Pop. was 27,824 in 1920 (88% native white); in 1940, 37,154 by the federal census, with an additional 5,000 in suburbs immediately adjacent. The city occupies 6·4 sq.mi. of rolling ground. It is the highest city in the state with an altitude of

1,154 feet. It is in a rich agricultural region. It is the seat of the State reformatory. There are producing oil wells within 30 mi., and large deposits of sand and blue shale just outside the city. Mansfield has a large wholesale and retail trade, and is an important manufacturing centre. Among its diversity of products are sheet steel, brass goods, stoves, rubber and electrical goods, pumps, motors and generators, bed springs, mattresses and transportation seating.

Bank clearings in 1926 aggregated $108,577,509. From 1920 to 1925 a "child health demonstration" was carried on here under the auspices of the Commonwealth fund, and after the close of the demonstration the special activities for the health of the children of the city and the county were continued by the local health authorities and private organizations.

Mansfield was laid out in 1808 and was named after Lieut.-Col. Jared Mansfield, then U.S. surveyor for Ohio and the North-west Territory. It was incorporated as a village in 1828 and as a city in 1857.

MANSHIP, PAUL (1885–), American sculptor, was born in St. Paul, Minn., on Dec. 25, 1885. He studied at the St. Paul Institute of Art, the Pennsylvania Academy of Fine Arts at Philadelphia, and in New York city. In 1909 he went to Rome, having been awarded a scholarship at the American Academy there, and remained abroad three years. On his return to the United States his works quickly attracted attention by their individuality, and his figures, exhibiting archaic traits skilfully coupled with intensely modern feeling, placed him in the front rank of American sculptors. In 1914 he was awarded the G. F. Widener Memorial Gold Medal at the Pennsylvania Academy of Fine Arts, obtaining also a gold medal at the San Francisco Exposition, 1915. In 1924 he won the medal of the American Numismatic Society, and in 1925 the gold medal of the Philadelphia Art Week. He devoted himself chiefly to classical subjects, but executed two very striking portraits, "John D. Rockefeller" and "Miss Manship," the latter being a study of his daughter, aged three days, which is in the Metropolitan Museum of Art, New York city. Among his other chief works are the J. P. Morgan memorial in the Metropolitan Museum of Art; the "Infant Hercules" fountain in the courtyard of the American Academy at Rome; "Dancing Girl and Fauns" and "Indian and Pronghorn Antelope" in the Art Institute, Chicago; "Yawning" in the St. Paul Institute; "Centaurs" and "Little Brother" (statuette) in the Detroit Museum of Art; "Playfulness" in the Minneapolis Institute of Art; and "Dancer and Gazelles" in the Cleveland museum, also statues in the Luxembourg, Paris, and the Corcoran Gallery of Art, Washington, D.C. In 1920 he made a portrait bust of John Barrymore.

MANSLAUGHTER, a term in English law signifying "unlawful homicide without malice aforethought" (Stephen, *Digest of the Criminal Law*). The distinction between manslaughter and murder and other forms of homicide is treated under HOMICIDE.

MANSON, GEORGE (1850–1876), Scottish water-colour painter, was born in Edinburgh on Dec. 3, 1850. He was apprenticed as wood-engraver with W. and R. Chambers, with whom he remained for over five years, employing his spare hours in the study of water-colour. In 1871 he began to devote himself exclusively to painting. His subjects were derived from humble Scottish life—especially child-life, varied occasionally by portraiture, landscape and views of picturesque architecture. In 1873 he visited Normandy, Belgium and Holland; and in 1875 resided at St. Lô, and in Paris, where he mastered the processes of etching and greatly enlarged the scope of his water-colour work. He died at Lympstone in Devonshire on Feb. 27, 1876.

A volume of photographs from his water-colours and sketches, with a memoir by J. M. Gray, was published in 1880. For an account of Manson's technical method as a wood-engraver *see* P. G. Hamerton's *Graphic Arts*, p. 311.

MANSUR: *see* AL-MANṢŪR.

MANSURA, the capital of the province of Dakahlia, Lower Egypt, near the west side of Lake Menzala, and on the Cairo-Damietta railway. Area, 3 sq.mi. Pop. (1937) 69,036. It dates from 1221, and is famous as the scene of the battle of Mansura, fought on the 8th of February 1250, between the crusaders commanded by the king of France, St. Louis, and the Egyptians. The old fortress of St. Louis is still to be seen. Mansura has several cotton-ginning, cotton, linen and sail-cloth factories.

The Battle of Mansura, Feb. 8, 1250.—This was the disastrous battle in which the Crusade of St. Louis lost its best hope of success. It is of particular historical interest as an illustration of the cumulative military faults which marked the Crusading campaigns in general, with the rare exception of that under Richard Coeur-de-Lion (*see* RICHARD I. and ARSUF). The Crusade of 1249 was aimed at the Islamic power in Egypt, and the landing took place at a favourable moment, for the Sultan was dying and the country consequently in disorder. But King Louis first forfeited the chance for a rapid march on Cairo and then took the worst possible route—from Damietta through the maze of canals and watercourses of the Nile Delta. The French army took four weeks to cover 50m. of such ground and then, on Dec. 19, 1249, reaching the west bank of the Ashmoum canal opposite Mansura, it found the enemy encamped on the far bank. Nearly two months were wasted before the French at last succeeded in crossing. The battle was waged with reckless daring, and, though in a sense a victory, left the French with a gravely depleted army in face of an almost intact adversary, and the knowledge caused a depression which portended the eventual failure of the expedition.

MANTEGNA, ANDREA (1431–1506), Italian painter of the Paduan school, the chief representative of the Early Renaissance in north Italy, was born at Isola di Carturo, near Vicenza, and at an early age went to Padua, where he entered the studio of Francesco Squarcione.

Mantegna was Squarcione's most brilliant pupil and was adopted as his son. At the age of ten he was entered in the guild of painters; at 17 he completed an altar-piece for the church of S. Lucia which established his fame. Reared among fragments of ancient art, in a town overshadowed by a famous university, where the study of the ancient world had become a cult, Mantegna grew up a devotee of antiquity. He had, moreover, the stimulus of seeing the work of Donatello and of Paolo Uccello in Padua, of Andrea Carstagno in Venice, and he learned the lessons which these great representatives of the Florentine school of form could teach. He mastered the newly discovered rules of perspective and he delighted in rendering foreshortened views of the human figure.

In 1454 Mantegna married Nicolasia, the daughter of Jacopo Bellini, the sister of Gentile and Giovanni. His connection with these great initiators of the pictorial tradition of Venice may have contributed to his estrangement from Squarcione. For Mantegna no longer cared to act as an executant of his master's commissions; and he fought and won his case before the tribunals of Padua. Between 1453 and 1459 he completed the cycle of paintings in the Ovetari chapel of S. Agostino degli Eremitani on which Niccolo Pizzolo of Padua, Bono of Ferrara, and Ansuino of Forli had been employed. The frescoes on the left wall representing the "Life of St. James" were executed by Mantegna; "The Martyrdom of St. Christopher," on the opposite wall, is also by him, but is sadly injured. This is his most important early work extant; and by comparing the upper frescoes which were painted first with the later frescoes below we can trace the master's progress to maturity. Other works of this early period are the polyptych representing "St. Luke and other Saints," in the Brera at Milan, and "St. Euphemia," now in the museum at Naples, both dated 1454, and the frescoes of two saints over the entrance porch of the church of S. Antonio, in Padua, dated 1452.

Mantegna's fame spread rapidly beyond Padua and he received various commissions from Verona. He was asked to paint an altar-piece for the church of S. Zeno in that city. This work occupied him from 1457 to 1459 and is one of his masterpieces. It is a triptych representing the "Madonna Enthroned" flanked by saints, with a tripartite predella underneath. The picture was carried off to France in 1797 with many other valuable works, and when restored to Verona in 1814 was found to have been deprived of the predella. Its central portion, representing "the Crucifixion," is in the Louvre; the two side portions, representing "the Agony in the Garden" and "the Resurrection," are in the museum at

Tours. In 1460 Mantegna took service with the Gonzagas, whose court at Mantua was one of the most cultured in Italy. He was at first employed in their castle at Goito on work now destroyed. After a short stay in Florence in May 1466, he settled at Mantua, where he built himself a house. Unfortunately many of his works are no longer extant. A notable exception are the frescoes completed in 1474 in the State room called "Camera degli Sposi." On the walls are the lifelike portraits of the Gonzaga family, perhaps the earliest portrait group of the Italian Renaissance, a powerful work with strongly defined personalities.

He rapidly rose in favour and esteem. In a letter dated July 1487 Cardinal Francesco Gonzaga expressed the wish to have Mantegna with him during his stay in a resort near Bologna that they might enjoy and study a collection of antique bronzes and gems. Lorenzo il Magnifico visited him in his studio and admired his paintings and his antiques. In 1488 he was knighted and repaired to Rome with a recommendation to Pope Innocent VIII., who asked him to decorate a chapel in the Vatican; but although the work was much admired the chapel was destroyed by Pius VI. in order to make room for the enlargement of the Vatican gallery. On his return to Mantua in 1490 Mantegna completed a series of nine tempera paintings which he had begun before his departure for the palace of San Sebastiano. The subject, "the Triumph of Caesar," afforded a welcome opportunity for displaying his admiration of the antique world. The triumphal car is preceded by a rhythmic procession of soldiers, prisoners, elephants, etc., carrying an infinite variety of trophies, including statuary, vases and arms of all kinds. It was considered by Vasari to be Mantegna's best work; it was acquired by Charles I. and is now at Hampton Court greatly damaged by repaintings.

Meanwhile Isabella d'Este had become duchess at Mantua by her marriage with Gian Francesco Gonzaga. She enlisted Mantegna's help for the decoration of her study, a small apartment, in the arrangement of which she took a keen interest prescribing the mythological and allegorical subjects of the five panels which adorned the walls. Two of these, "the Parnassus" and the "Allegory of Virtue and Vice," were painted by Mantegna; the remaining three were done by Pietro Perugino and Lorenzo Costa. The whole set are now in the Louvre. Among Mantegna's last works was the picture which he painted in 1495 for Santa Maria della Vittoria, a church built after his design to commemorate the battle of Fornovo, which Gian Francesco Gonzaga, commander of the Italian forces, found it convenient to celebrate as his victory, though in fact it seems to have been a French victory. This picture is now in the Louvre. Mantegna passed the latter part of his life in poverty; he was in debt and not able to continue in the house he had built, and had to sell his beloved antique bust of Faustina. He died on Sept. 13, 1506, at Mantua, and was buried in a chapel which he had built for himself in S. Andrea, at Mantua. Over his tomb a fine bronze head by an unknown contemporary sculptor presents his strong and austere features. At the time of his death his art seemed surpassed by the rising glory of Titian, of Michelangelo and Raphael.

Besides the paintings described above the following may be mentioned: "The Agony in the Garden," in the National Gallery, London; the portrait of the Cardinal Scarampo, in the Berlin museum; the "Death of the Virgin," in the Prado at Madrid; the "Adoration of the Magi," in the Johnson collection, Philadelphia; the triptych in the Uffizi, Florence, representing "the Adoration of the Magi," "the Circumcision," and "the Ascension," with its delicate and precise finish and its rich decorative effects, is a fine example of the master's power of concentration in works on a small scale. To the same class belong "the Madonna seated in front of a Grotto," in the Uffizi; the "St. George," in the academy at Venice; and the "St. Sebastian," at Vienna. All these are early works. Of a later period are "The Virgin in glory with four Saints" (1497), painted for S. Maria in Organo, at Verona, and now in the collection of Prince Trivulzio at Milan; "the Madonna with John the Baptist and the Magdalen," in the National Gallery, London; "the Triumph of Scipio" (1506) and "Samson and Delilah," in the same gallery, both executed in monochrome; the "Virgin and Child," in the Carrara collection at Bergamo, "the Virgin and Child surrounded by Cherubim," in the Brera at Milan; "Christ upheld by Angels," in the museum at Copenhagen; "The Dead Christ" (1506), at the Brera gallery, Milan, a study of a foreshortened human figure which may be regarded as his last picture.

Mantegna contributed towards the development of the art of engraving; his plates are among the first productions in that medium. By means of delicate shading lines he obtained a chiaroscuro of rich quality. The outline is clear and gemlike; the figures, rhythmically arranged, stand out within their small compass with monumental grandeur. Engraving is here no longer a convenient process for reproducing designs, but a fine art. According to Vasari, Mantegna was prompted to take up engraving during his stay in Rome, but there were artists practising engraving at Mantua as far back as 1475 and the question of the period covered by Mantegna's engravings is not yet solved. Bartsch assigned to Mantegna no fewer than 27 engravings, but present-day criticism acknowledges only seven as original. The earliest is "the Virgin and Child"; then follow "Bacchanalia with Silenus"; "Bacchanalia with a Wine Press"; "The Battle of Sea Gods," in two parts; "The Entombment"; and "the Risen Christ between St. Andrew and Longinus."

Mantegna* (1910), vol. xvi. of the series *Klassiker der Kunst;* G. Fiocco, *Andrea Mantegna* (Bologna, 1927). V. Lassarini and A. Moschetti, *Documenti relativi-alla pittura padovana del Secolo XV.* (Venice, 1908) is important for documents on Mantegna's early life. *See* also T. Borenius, *Four early Italian Engravers* (1923). (I. A. R.)

MANTELL, GIDEON ALGERNON (1790–1852), English geologist and palaeontologist, born at Lewes, Sussex. Educated for the medical profession, he practised at Lewes, Brighton and Clapham. He studied the palaeontology of the Secondary rocks, particularly in Sussex—a region which he made classical in the history of discovery. His most remarkable discoveries were made in the Wealden formations. He demonstrated the freshwater origin of the strata, and from them he brought to light and described the remarkable Dinosaurian reptiles known as *Iguanodon, Hylaeosaurus, Pelorosaurus* and *Regnosaurus.* He was elected F.R.S. in 1825. He also described the Triassic reptile *Telerpeton elginense.* Towards the end of his life Dr. Mantell retired to London, where he died on Nov. 10, 1852.

His son Walter Mantell (1820–1895) settled in New Zealand, where he discovered remains of *Notornis.*

MANTES-GASSICOURT, a town of northern France in the department of Seine-et-Oise on the Seine, 34 mi. W.N.W. of Paris by rail. Pop. (1936) 13,978. The chief building of the town is the 12th century church of Notre-Dame. The plan, which bears a marked resemblance to that of Notre-Dame at Paris, includes a nave, aisles and choir, but no transepts. Three portals open into the church on the west; the two northernmost date from the 12th century; that to the south is of the 14th century. In the interior are chapels dating from the 13th and 14th centuries. A previous edifice was burned by William the Conqueror together with the rest of the town, at the capture of which he lost his life in 1087. The tower of St. Maclou (14th century), relic of an old church, built from tolls levied on boats, and destroyed during the Revolution, and the hôtel de ville (15th to 17th centuries) are among the older buildings. Modern bridges and a mediaeval bridge unite the town with the town of Limay. Its trade is in cereals and agricultural products. Its industries include the manufacture of musical instruments, baskets, brushes, tiles and hosiery; tanning is also carried on. Mantes was occupied by the English from 1346 to 1364, and from 1416 to 1440. Until 1930 it was called Mantes-sur-Seine.

MANTEUFFEL, EDWIN, Freiherr von (1809–1885), Prussian general field marshal, son of the president of the superior court of Magdeburg, was born at Dresden on Feb. 24, 1809. He was brought up with his cousin, Otto von Manteuffel (1805–1882), the Prussian statesman, and entered the guard cavalry at Berlin in 1827. In 1848 he became aide-de-camp to Frederick William IV., whose confidence he had gained during the revolutionary movement in Berlin. Promoted lieutenant-colonel in 1852, and colonel to command the 5th Uhlans in 1853, he was sent on important diplomatic missions to Vienna and St. Petersburg. In 1857 he became major-general and chief of the military cabinet. He supported the prince regent's plans for the reorganization of the army. He served in the Danish war of 1864, and at its conclusion was appointed civil and military governor of Schleswig. In the Austrian War of 1866 he occupied Holstein and afterwards commanded a division under Vogel von Falkenstein in the Hanoverian campaign, and succeeded him, in July, in command of the Army of the Main (*see* SEVEN WEEKS' WAR). His successful operations ended with the occupation of Würzburg, and he received the order *pour le mérite*. He then went on a diplomatic mission to St. Petersburg, where he was *persona grata,* and succeeded in gaining Russia's assent to the new position in north Germany. In the war of 1870–71 he led the I. corps under Steinmetz, distinguishing himself in the battle of Colombey-Neuilly, and in the repulse of Bazaine at Noisseville (*see* FRANCO-GERMAN WAR; and METZ). He succeeded Steinmetz in October in the command of the I. army, won the battle of Amiens against General Farre, and occupied Rouen, but was less fortunate against Faidherbe at Pont Noyelles and Bapaume. In January 1871 he commanded the newly formed Army of the South, which he led, in spite of hard frost, through the Côte d'Or and over the plateau of Langres, cut off Bourbaki's army of the east (80,000 men), and, after the action of Pontarlier, compelled it to cross the Swiss frontier, where it was disarmed. When the Southern Army was disbanded Manteuffel commanded first the II. army, and, from June 1871 until 1873, the army of occupation left in France, showing great tact in a difficult position. He was rewarded by promotion to the rank of general field marshal and a large grant in money. He was employed on several diplomatic missions, was for a time governor of Berlin, and in 1879 was appointed governor-general of Alsace-Lorraine; and this office he filled until his death at Carlsbad, Bohemia, on June 17, 1885.

See lives by v. Collas (Berlin, 1874), and K. H. Keck (Bielefeld and Leipzig, 1890).

MANTINEIA (MANTINEA), an ancient city of Arcadia, in a long narrow marshy plain (now called after the chief town Tripolitsa) bounded on the W. by Mt. Maenalus, on the E. by Mt. Artemision, and without opening to the coast, the water percolating through underground passages (*katavothra*) to the sea. Tegea (*q.v.*), about 10 m. S. of Mantineia, continually disputed the supremacy of the district.

Mantineia is mentioned in the Homeric catalogue of ships, but in early Greek times was only a cluster of villages, insignificant compared with Tegea, and submissive to Sparta. But soon after the Persian wars, its five constituent villages, at the suggestion of Argos, were merged into one city, whose policy was henceforth guided by three main considerations: its democratic constitution of small freeholders; its ambition to control the Alpheus watershed and Arcadian roads to the Isthmus, and its chronic disputes with Tegea. About 469 B.C. Mantineia alone of Arcadian townships refused to join the league of Tegea and Argos against Sparta. Though formally on the same side in the Peloponnesian War it employed the truce of 423 in fierce but indecisive war with Tegea. Mantineia regained its autonomous position in the Achaean League in 192, and its original name in A.D. 133. Under the later Roman Empire the city dwindled into a mere village (which since the 6th century bore the Slavonic name Goritza) and as a result of malaria and Turkish rule has disappeared.

The site was excavated by the French school at Athens, in 1888. The agora and adjacent buildings, and the walls about $2\frac{1}{2}$ m. in circumference have been investigated. When the city was rebuilt in 370 B.C., the river Ophis, which formerly ran through the town, was divided so as to encircle the walls.

The battles of 362 and 207 are discussed at length by J. Kromayer, *Antike Schlachtfelder in Griechenland* (Berlin, 1903), 27–123, 281–314; *Wiener Studien* (1905), pp. 1–16.

Battles of Mantineia were fought in the years 418 B.C., 362 B.C. and 207 B.C.

(1). The first battle, in the Peloponnesian War (*q.v.*), is of no strategic importance but of some interest in the evolution of tactics. On the one side were the Spartans and their allies under the Spartan king Agis, while the other was mainly composed of Argives and Mantineans. As the Spartan line advanced, a drift to the right occurred—a common occurrence in ancient battles, due to the natural instinct of each man to hug closely to his neighbour's shield as a protection to his own unguarded, *i.e.,* non-shield bearing, side. Agis, seeing that this drift would cause his left flank to be overlapped by the enemy, sought to prolong his left. This stretching caused a gap in the centre, and the enemy, pouring into the gap, broke up the Spartan left wing. This disaster, however, was offset by the success of the Spartan right. (See *Thucydides* v. 71.)

(2). The second, and more justly famous battle, took place in 362 B.C., and is memorable not only for Epameinondas's further development of the epoch-making tactics which he had introduced at Leuctra (*q.v.*), but also for his death in the moment of victory. He is immortalized by two battles. A year after Leuctra, Epameinondas had led the forces of the newly formed Arcadian League in a march on virgin Sparta itself. The march had been admirably carried out in three converging columns over mountain routes in mid-winter and with deep strategical insight Epameinondas had made an indirect approach to his goal, slipping past Sparta and then moving up from its rear. Strong reinforcements came to Sparta from her allies in the Peloponnesian League, and his own design was thwarted by the dwindling away of his own allies, whose troops preferred easy plunder to the chance of decisive victory. He was thus compelled to retire rather than pay exorbitantly for military success, but only after establishing the new Messenian state as a check on, and counterpoise to, Sparta in southern Greece. And with his subsequent foundation of Megalopolis as a further check his grand strategy had attained the greater political object of definitely overthrowing Sparta's long supremacy in the Peloponnese. But with his subsequent if temporary supersession, Theban democracy forfeited its advantages by short-sighted policy and blundering diplomacy, and enabled its Arcadian allies, repudiating gratitude in growing conceit and ambition, to dispute Theban leadership.

Thus in 362 Thebes was driven to choose between reasserting her authority and sacrificing her prestige. Her move against Arcadia caused Greece to divide afresh into two hostile coalitions. Once more Epameinondas made a surprise spring at Sparta, but he was deprived of the fruits of his night march through a deserter warning the Spartan main army in time for it to hurry back and safeguard the capital. Epameinondas then stood on guard at Tegea while the enemy forces concentrated at Mantineia. The valley in which these places lay is shaped like an hour-glass by the surrounding mountain ranges, and at the mile-wide waist the Spartans and their allies took up a strong position. He determined to seek a decision by battle, but as in his strategy so in his grand tactics showed his art by an indirect approach.

At first Epameinondas marched direct towards the Spartan camp, causing the enemy to form up in battle order facing his line of approach. But when still several miles distant, he suddenly changed direction to the left, turning in beneath a projecting spur. This surprise manoeuvre threatened to take in enfilade the Spartan right, and to dislocate still further the Spartans' battle dispositions he halted his troops and made them ground arms as if to encamp. The deception succeeded; the enemy were induced to relax their battle order, allowing men to fall out and the horses to be unbridled. Meanwhile Epameinondas was actually completing his battle dispositions behind a screen of light troops.

Then, on a signal, the Theban army took up its arms and swept forward. Caught by surprise the enemy made haste to reform, but their cavalry were driven back by the Theban cavalry covering the left flank of the massed column, and this striking the Spartan line "like the prow of a galley" pierced it in two. But in the moment of decision Epameinondas himself was mortally wounded, and with his fall the advance came to a stop and failed to complete the victory already won. (*See* Xenophon, *Hellenica,* vii. 5; *Cambridge Ancient History,* vi. 89-102.)

(3). The third battle for which Mantineia is notable was that of 207 B.C., in which Philopoemen, the commander of the forces of the Achaean League, routed Machanidas, tyrant of Sparta. As Cicero acclaims Epameinondas as "the first man of Greece" —and might justly have acclaimed him, in a time sense, as the first great captain of history—so Plutarch refers to Philopoemen as "the last of the Greeks." As a military artist he was worthy to take a place in the illustrious company of Epameinondas and Xenophon, with Alexander and Pyrrhus. Mantineia was his first battle in chief command, and before beginning operations he had devoted eight months to the preparation and training of his forces. On the approach of Machinadas from Tegea he moved out from Mantineia to accept battle and drew up in order behind a shallow ravine. The interesting feature of his formation was that his phalanx of heavy foot was broken up into small companies with intervals between, and formed in two lines, the rear companies apparently covering the intervals in the front line. This is clearly a modification inspired by Roman practice.

Machinadas advanced in three columns directed on the Achaean right, but on nearing his enemy deployed into line to the right. He then arrayed his catapults for an artillery "preparation," intended to demoralize and disorganize the Achaean ranks, but this move was interrupted by Philopoemen, who launched his light horse. This led to a general engagement of the light troops on both sides in which Machanidas's mercenaries gradually gained the upper hand. The Achaeans on the left wing broke, and Machanidas rashly threw himself into the pursuit, which swept like a tide past the firm rock formed by the Achaean phalanx. Philopoemen thereupon wheeled the forward companies of the phalanx to the left and moved them swiftly to occupy the abandoned flank position, thus cutting off the pursuers and at the same time preventing his flank being turned by the Spartan phalanx, which now advanced. But at the moment when crossing the ravine, and their ranks inevitably becoming disordered, Philopoemen launched his own more flexible phalanx in a decisive riposte. Having dispersed the Spartan phalanx, Philopoemen, while part of his army followed them up, turned with the rest to bar Machanidas's expected return. Thus when the Spartan light troops came in sight of the strongly held ravine they lost heart and melted away, leaving Machanidas himself to fall, according to the reliable Polybius, in personal combat with Philopoemen.

As Rome, on intervening in Greece, recognized the independence of the Achaean League, her generals never had to meet this one accomplished Greek leader. (*See* Polybius, xi. 8–18; Plutarch, *Philopoemen.*) (B. H. L. H.)

MANTIS, an insect belonging to the family *Manteidae* of the order Orthoptera (*q.v.*). Probably no other insect has been the subject of so many and widespread legends and superstitions as the common praying mantis, *Mantis religiosa,* L. of Southern Europe. The ancient Greeks endowed it with supernatural powers (*μάντις,* a diviner); the Turks and Arabs hold that it prays constantly with its face turned towards Mecca, and the Provençals call it *Prega-Diou* (*Prie-Dieu*). Notwithstanding these attributes, mantids are creatures of voracious habits. The front pair of limbs are very peculiarly modified—the coxae being greatly elongated, while the strong third joint or femur bears on its curved underside a channel armed on each edge by strong movable spines. Into this groove the stout tibia is capable of closing like the blade of a penknife, its sharp, serrated edge being adapted to cut and hold. Thus armed, with head raised upon the much-elongated and semi-erect prothorax, and with the half-opened fore-limbs held outwards in the characteristic devotional attitude, it rests motionless upon the four posterior limbs waiting for prey, or occasionally stalks it with slow and silent movements, finally seizing it with its knife-blades and devouring it. These insects destroy great numbers of flies, grasshoppers and caterpillars, and the larger South-American species even attack small frogs, lizards and birds. They are very pugnacious, fencing with their sword-like limbs, the larger frequently devouring the smaller, and the females the males.

Mantis religiosa fixes its somewhat nut-like egg capsules on the stems of plants in September. The young are hatched in early summer, and resemble the adults, but are without wings. The green coloration and shape of the typical mantis are procryptic, serving to conceal the insect alike from its enemies and prey. The passage from leaf to flower simulation has been perfected in certain tropical species of *Manteidae* by the development on the prothorax and raptorial limbs of laminate expansions so coloured on the under side as to resemble papillionaceous or other blossoms, to which the likeness is enhanced by a gentle swaying kept up by the insect in imitation of the effect of a lightly blowing breeze. As instances of this may be cited *Idolum diabolicum,* an African insect, and *Gongylus gongyloides,* which comes from India. Examples of another species (*Empusa egena*) when standing upon the ground deceptively imitate in shape and hue a greenish white anemone tinted at the edges with rose; and Bates records what appears to be a true case of aggressive mimicry practised by a Brazilian species which exactly resembles the white ants it preys upon. More than 800 species of mantids are known and about 20 of these occur in Europe, and a similar number in the United States, but none are found in the British Isles.

PRAYING MANTIS

MANTIS-FLY, the name given to neuropterous insects of the family *Mantispidae,* related to the ant-lions, lace-wing flies, etc., and named from their superficial resemblance to a *Mantis* owing to the length of the prothorax and the shape and prehensorial nature of the anterior legs. The larva, at first campodeiform, makes its way into the egg-case of a spider or the nest of a wasp to feed on the eggs or young. Subsequently it changes into a fat grub with short legs. When full grown it spins a silken cocoon in which the transformation into the pupa is effected. Mantis-flies are widely distributed in both the old and new worlds, but occur chiefly in warm countries.

MAN-TRAPS, mechanical devices for catching poachers and trespassers. They have taken many forms, the most usual being like a large rat-trap, the steel springs being armed with teeth which meet in the victim's leg. Since 1827 they have been illegal in England, except in houses between sunset and sunrise as a defence against burglars.

MANTUA, fortified city, Lombardy (Ital. *Mantova*), Italy, capital of the province of Mantua, see of a bishop and centre of a military district, 25 mi. south-southwest of Verona and 100 mi. east-southeast of Milan by rail. Pop. (1936) 36,489 (town), 40,-467 (commune). It is 88 ft. above the level of the Adriatic on an almost insular site among swampy lagoons of the Mincio. On the west lies Lago Superiore, on the east Lago Inferiore—the boundary between the two being marked by the *Argine del Mulino,* a long mole stretching northward from the northwest angle of the city to the citadel, along which run the road and the railway.

On the highest ground in the city rises the cathedral, the interior of which was built after his death according to the plans of Giulio Romano. The church of St. Andrea after plans by Leon Battista Alberti, has a single, barrel-vaulted nave 338 ft. long by 62 ft. wide (1472–1494 and later); the dome was added in 1732–82. It has a noble façade with a deeply recessed portico, and a brick campanile of 1414. Mantegna is buried here. The immense ducal palace was begun in 1302 for Guido Bonaccolsi, but many of the fine apartments are of much later date, and the internal decorations are largely by Giulio Romano and his pupils. In one of the rooms is a set of tapestries after Raphael's cartoons now at South Kensington Museum. Castello di Corte, the castle of the Gonzagas (1395–1406), erected by Bartolino da Novara, the architect of the castle of Ferrara, now contains the archives, and has some fine frescoes by Mantegna with scenes from the life of Ludovico Gonzaga. Close by are the Piazza dell' Erbe and the Piazza Sordello, with Gothic palaces. Outside the city stands the Palazzo del Te, Giulio's architectural masterpiece, erected for

Frederick Gonzaga in 1523–1535, with numerous fresco-covered rooms. At the villa of Marmiruolo are other works by him. The architecture of Giulio's own house in the town is also good.

Mantua has an academy of arts and sciences (*Accademia Vergiliana*), occupying a fine building erected by Piermarini, containing a theatre designed by Antonio Bibiena (1769), and a museum of antiquities.

Mantua had still a strong Etruscan element in its population during the Roman period. Its main interest is as the birthplace of Virgil (*q.v.*). In 568 the Lombards took Mantua with difficulty; recovered in 590 by the exarch of Ravenna, it was recaptured by Agilulf in 601. The 9th century was the period of episcopal supremacy, and in the 11th the city belonged to Bonifacio, marquis of Canossa. It passed to Geoffrey, duke of Lorraine, and afterwards to the countess Matilda, but was taken by the emperor Henry IV. in 1090. Reduced to obedience by Matilda in 1113, the city on her death instituted a communal government of its own. It afterwards joined the Lombard League. But after internal discords Ludovico Gonzaga attained to power (1328), and was recognized as imperial vicar (1329); and until 1708 the Gonzagas were masters of Mantua (*see* GONZAGA). Under Gian Francesco II., the first marquis, Ludovico III., Gian Francesco III. (whose wife was Isabella d'Este), and Federico II., the first duke of Mantua, the city rose rapidly into importance. It was stormed and sacked by the Austrians in 1630. It was claimed in 1708 as a fief of the empire by Joseph I. Besieged by Napoleon in June 1796, it held out till February 1797. In 1799 it fell to the Austrians; restored to the French by the peace of Lunéville (1801), it became Austrian again (1814–66).

MANU, the Hindu Noah. In post-Vedic myth he is warned by a huge fish to build an ark, and after the deluge his sacrifices bear him a daughter, by whom he becomes the ancestor of mankind. More historically he is the author of the Code of Manu, a compilation of laws reflecting Hindu thought in the Buddhist period, but only preserved in a metrical recension made probably about A.D. 100.

MANUCODE, the name given to the birds of paradise (*q.v.*) comprising the genus *Manucodia* and found in northern Queensland and New Guinea. Four or five species are recognized.

MANUEL I. COMNENUS (*c.* 1120–1180), Byzantine emperor (1143–1180), the fourth son of John II, was born about 1120. Having distinguished himself as a soldier, he was nominated emperor in preference to his elder surviving brother. He endeavoured to restore by force of arms the predominance of the Byzantine empire in the Mediterranean countries. In 1144 he brought back Raymund of Antioch to his allegiance, and in the following year drove the Turks out of Isauria. In 1147 he granted a passage through his dominions to two armies of crusaders under Conrad III. of Germany and Louis VII. of France; but the numerous outbreaks of hostility between the Franks and the Greeks on their line of march, nearly precipitated a conflict between Manuel and his guests. In the same year the emperor made war upon Roger of Sicily, whose fleet captured Corfu and plundered the Greek towns, but in 1148 was defeated with the help of the Venetians. In 1149 Manuel recovered Corfu and prepared to take the offensive against the Normans. With an army mainly composed of mercenary Italians he invaded Sicily and Apulia, and although defeated both on land and sea, Manuel maintained a foothold in southern Italy, which was secured to him by a peace in 1155.

Manuel made treaties with Pisa and Genoa, and supported the free Italian cities with his gold and negotiated with pope Alexander III. In spite of his friendliness towards the Roman church Manuel was refused the title of "Augustus" and he nowhere succeeded in attaching the Italians permanently to his interests. None the less in a war with the Venetians (1172–74), he actually drove his enemies out of the Aegean Sea. On his northern frontier Manuel defeated the rebellious Serbs (1150–52) and made repeated attacks upon the Hungarians. In the wars of 1151–53 and 1163–68 he led his troops into Hungary but failed to maintain himself there; in 1168, however, a decisive victory near Semlin enabled him to conclude a peace by which Dalmatia and other frontier strips were ceded to him. In 1169 he sent a joint expedition with King Amalric of Jerusalem to Egypt, which retired after an ineffectual attempt to capture Damietta. In 1158–59 he fought with success against Raymund of Antioch and the Turks of Iconium. In 1176 he was decisively beaten by them in the pass of Myriocephalum. This disaster, though partly retrieved in the campaign of the following year, had a serious effect upon his vitality; henceforth he declined in health and in 1180 succumbed to a slow fever.

In spite of his military prowess Manuel achieved but in a slight degree his object of restoring the East Roman empire. His victories were counterbalanced by numerous defeats, and his lack of statesmanlike talent prevented his securing the loyalty of his subjects. The expense of keeping up his mercenary establishment put a severe strain upon the financial resources of the state. The subsequent rapid collapse of the Byzantine empire was largely due to his brilliant but unproductive reign. Manuel married, firstly, a sister-in-law of Conrad III of Germany; and secondly, a daughter of Raymund of Antioch. His successor, Alexis II, was a son of the latter.

See John Cinnamus, *History of John and Manuel* (ed. 1836, Bonn); E. Gibbon, *The Decline and Fall of the Roman Empire* (ed. Bury, London, 1896), v. 229 *sqq.*, vi. 214 *sqq.*; G. Finlay, *History of Greece* (ed. 1877, Oxford), iii. 143–197; H. v. Kap-Herr, *Die abendländische Politik Kaiser Manuels* (Strassburg, 1881). (M. C.)

MANUEL II. PALAEOLOGUS (1350–1425), Byzantine emperor from 1391 to 1425, was born in 1350. At the time of his father's death he was a hostage at the court of Bayezid at Brusa, but succeeded in making his escape; he was forthwith besieged in Constantinople, but with some loss, beat off the attack. Manuel subsequently set out in person to seek help from the West, and for this purpose visited Italy, France, Germany and England, but without material success; the defeat of Bayazet at the hands of Timur (1402) gave him a genuine respite from the Ottomans. He stood on friendly terms with Mahommed I., but was again besieged in his capital by Murad II. in 1422. Shortly before his death he was forced to pay tribute to the sultan.

Manuel was the author of numerous works of varied character—theological, rhetorical, poetical and letters. Most of these are printed in Migne, *Patrologia graeca*, clvi.; the letters have been edited by E. Legrand (1893). *See* also C. Krumbacher, *Geschichte der byzantinischen Litteratur* (1897).

MANUEL I. (d. 1263), emperor of Trebizond, was the second son of Alexius I., first emperor of Trebizond, and ruled from 1228 to 1263. He was unable to deliver his empire from vassalage, first to the Seljuks and afterwards to the Mongols. He vainly negotiated for a dynastic alliance with the Franks, by which he hoped to secure the help of Crusaders.

MANUEL II., the descendant of Manuel I., reigned only a few months in 1332–1333. Manuel III. reigned from 1390 to 1417, but the only interest attaching to his name arises from his connection with Timur, whose vassal he became without resistance.

See G. Finlay, *History of Greece* (ed. 1877, Oxford), iv. 338–340, 340–341, 386; Ph. Fallmerayer, *Geschichte des Kaisertums Trapezunt* (Munich, 1827), i. chs. 8, 14, ii. chs. 4, 5; T. E. Evangelides, Ἱστορια τῆς Τραπεζοῦντος (Odessa, 1898), 71–73, 87–88, 126–132.

MANUEL, LOUIS PIERRE (1751–1793), French writer and revolutionary was born at Montargis (Loiret), and became a tutor in Paris. In 1783 he was imprisoned for three months in the Bastille for publishing his *Essais historiques, critiques, littéraires, et philosophiques*. He was one of the leaders of the *émeutes* of June 20 and Aug. 10, 1792, and was made *procureur* of the commune. On Sept. 7, 1792 he was elected one of the deputies from Paris to the Convention and on Nov. 5 made an eloquent speech at the Jacobins club in defence of Robespierre. His missions to the king, however, reconciled him to Louis, and he had to resign from the Convention. He retired to Montargis, where he was arrested, and was guillotined in Paris on Nov. 17, 1793.

His works include *Coup d'oeil philosophique sur le règne de St. Louis* (1786); *L'Année francaise* (1788); *La Bastille dévoilée* (1789); *La Police de Paris dévoilée* (1791); and *Lettres sur la Révolution* (1792).

MANUEL DE MELLO, DOM FRANCISCO (1608–1666), Portuguese writer, a connection on his father's side of the royal house of Braganza, was a native of Lisbon. He studied the Humanities at the Jesuit College of S. Antão, where he showed a precocious talent. The death of his father, Dom Luiz de Mello, drove him early to soldiering, and having joined a contingent for the Flanders war he suffered shipwreck in the Bay of Biscay. At Madrid, he contracted a friendship with Quevedo and earned the favour of the powerful minister Olivares. In 1639 he was appointed colonel of one of the regiments raised for service in Flanders, and in June that year he took a leading part in defending Corunna against a French fleet commanded by the archbishop of Bordeaux. He came safely through the naval defeat in the Channel suffered by the Spaniards at the hands of Van Tromp, and on the outbreak of the Catalan rebellion acted as chief of the staff to the commander-in-chief of the royal forces; his *Historia de la guerra de Cataluña* became a Spanish classic. On the proclamation of Portuguese independence in 1640 he was imprisoned by order of Olivares, and when released hastened to offer his sword to John IV. He travelled to England, where he spent some time at the court of Charles I. and thence passing over to Holland assisted the Portuguese ambassador to equip a fleet in aid of Portugal, and himself brought it safely to Lisbon in Oct. 1641. For the next three years he was employed in various important military commissions. An intrigue with the beautiful countess of Villa Nova, and her husband's jealousy, led to his arrest on Nov. 19, 1644, on a false charge of assassination, and he lay in prison about nine years. Owing perhaps to the intercession of the queen regent of France and other powerful friends, his sentence was finally commuted into one of exile to Brazil. During his long imprisonment he finished and printed his history of the Catalan war, and also wrote other volumes including the *Carta de Guia de Casados* and a *Memorial* in his own defence to the king, which Herculano considered "perhaps the most eloquent piece of reasoning in the language." During his exile in Brazil, whither he sailed on April 17, 1655, he lived at Bahia, where he wrote one of his *Epanaphoras de varia historia* and two parts of his masterpiece, the *Apologos dialogaes*. He returned home in 1659, and in 1663 Alphonso VI. charged him to negotiate with the Curia about the provision of bishops for Portuguese sees. During his stay in Rome he published his *Obras moraes,* dedicated to Queen Catherine, wife of Charles II. of England, and his *Cartas familiares.* On his way back to Portugal he printed his *Obras metricas* at Lyons in May 1665. He died in August of the following year.

Manuel de Mello's early Spanish verses are tainted with Gongorism, but his Portuguese sonnets and *cartas* on moral subjects are notable for their power, sincerity and perfection of form. His *Letters* are written in a conversational style illumined by flashes of wit. His commerce with the best authors appears in the *Hospital das lettras,* a brilliant chapter of criticism forming part of the *Apologos dialogaes.* His comedy in *redondilhas,* the *Auto do Fidalgo Aprendiz,* may be considered an anticipation of Molière's *Le Bourgeois gentilhomme.*

BIBLIOGRAPHY.—There is no uniform edition of Manuel de Mello's works, but a list of them will be found in his *Obras moraes. See* E. Prestage, *Dom Francisco Manuel de Mello, his Life and Writings* (Manchester, 1905); "D. Francisco Manuel de Mello, documentos biographicos" and "D. Francisco Manuel de Mello, obras autographas e ineditas" in *Archivo historico portuguez* for 1909; and *D. Francisco Manuel de Mello, Esboço biografico* (Coimbra, 1914).

MANUFACTURING PRODUCTION: *see* PRODUCTION, CENSUS OF.

MANUL (*Felis manul*), a small desert wild cat, ranging from Tibet to Siberia. The coat is long and soft, of pale silvery grey or light buff, marked with black on the chest and upper parts of the limbs, with transverse stripes on the loins and rings on the tail of the same hue. It preys upon small mammals and birds.

MANURE DISTRIBUTION: *see* TILLAGE MACHINERY.

MANURES AND MANURING: *see* FERTILIZERS.

MANUTIUS, the Latin name of an Italian family (Mannucci, Manuzio), famous in the history of printing as organizers of the Aldine press.

1. ALDUS MANUTIUS (1450–1515). Teobaldo Mannucci, better known as Aldo Manuzio, the founder of the Aldine press, was born at Sermoneta in the Papal States. After studying at Rome and at Ferrara, in 1482 he went to reside at Mirandola with his old friend, the illustrious Giovanni Pico, whose nephew Alberto Pio, prince of Carpi, supplied him with funds for starting his printing press, and gave him lands at Carpi. Settling in Venice in 1490, he gathered Greek scholars and compositors around him, and Greek was the language of his household. He soon published undated editions of the *Hero and Leander* of Musaeus, the *Galeomyomachia,* and the Greek Psalter. During 1495–98 he issued five volumes of Aristotle; in 1498 nine comedies of Aristophanes; Thucydides, Sophocles and Herodotus followed in 1502; Xenophon's *Hellenics* and Euripides in 1503; Demosthenes in 1504; an edition of the minor Greek orators in 1508; and in 1509 the lesser works of Plutarch. During the struggle of Venice with the allied powers of Europe, Aldo's labours were suspended until 1513 when he published his Plato. Pindar, Hesychius, and Athenaeus followed in 1514. Besides these Greek texts, Aldo published the *Asolani* of Bembo, the collected writings of Poliziano, the *Hypnerotomachia Poliphili,* Dante's *Divine Comedy,* Petrarch's poems, a collection of early Latin poets of the Christian era, the letters of the younger Pliny, the poems of Pontanus, Sannazzaro's *Arcadia,* Quintilian, Valerius Maximus, the *Adagia* of Erasmus and many reprints. To promote Greek studies, Aldo founded an academy of Hellenists in 1500 under the title of the New Academy. Its rules were written in Greek; its members were obliged to speak Greek, and their names were Hellenized. The biographies of those enrolled in this academy, including Erasmus and Linacre, are given in Didot's *Alde Manuce.*

2. PAULUS MANUTIUS (1512–1574). After the death of Aldo, his brothers-in-law, the Asolani, carried on the Aldine press, until his youngest son, Paolo, took it over in 1533. The Asolani attempted the duties of editing, and to reserve the honours for themselves, dispensed with the service of competent collaborators. The result was that some of their editions, especially their Aeschylus of 1518, are singularly bad. Paolo determined to restore the glories of the house, and in 1540 separated from his uncles. The field of Greek literature having been well-nigh exhausted, he devoted himself principally to the Latin classics. He was a passionate Ciceronian, and perhaps his chief contributions to scholarship are the corrected editions of Cicero's letters and orations, his own epistles in a Ciceronian style, his Latin version of Demosthenes, and his four treatises on Roman antiquities. Owing to Paolo's financial difficulties, Pius IV. in 1561 invited him to Rome, offering him a yearly stipend of 500 ducats, and undertaking to maintain his press there. The profits on publications were to be divided between Paolo and the Apostolic camera. Paolo accepted the invitation, and spent the larger portion of his life in Rome under three papacies.

3. ALDUS MANUTIUS, JUNIOR (1547–1597), eldest son of Paolo, produced at the age of fourteen a work upon Latin spelling, called *Orthographiae ratio.* Remaining in Venice to superintend the Aldine press after his father's removal to Rome, he published in 1575 his *Epitome orthographiae.* In the same year, in concert with his father-in-law, Giunta, he edited an extensive collection of Italian letters, and in 1576 he published his commentary upon the *Ars poetica* of Horace. About the same time, he was appointed professor of literature to the Cancelleria at Venice. In 1585 Aldo moved to Bologna, but after two years went to Pisa where he made the curious mistake of printing Alberti's comedy *Philodoxius* as a work of the classic Lepidus. Sixtus V. called him in 1588 to Rome. In 1597 he died, leaving children, but none who carried on the Aldine press. Aldo himself, though a precocious student, a scholar of no mean ability, and a publisher of some distinction, was the least remarkable of the three publishers.

See A. Renouard, *Annales de l'imprimerie des Aldes* (3rd ed. Paris, 1834); Didot, *Alde Manuce* (Paris, 1873); Omont's *Catalogue* of Aldine publications (Paris, 1892).

MANWARING, ROBERT (*fl.* 1760), English 18th-century furniture designer and cabinet-maker. The dates of his birth and death are unknown. He was a contemporary, imitator and rival of Chippendale. His work shows the same surprising variations of quality characteristic of that of nearly all the English cabinet-makers of the second half of the 18th century. His best had an undeniable elegance, his worst was squat and ill-proportioned. He introduced the small bracket between the front rail of the seat and the top of the chair leg, or at all events made such constant use of it that it has come to be regarded as characteristic of his work.

Among Manwaring's writings were *The Cabinet and Chair Makers' Real Friend and Companion, or the Whole System of Chairmaking Made Plain and Easy* (1765); *The Carpenters' Compleat Guide to Gothic Railing* (1765); and *The Chair-makers' Guide* (1766).

MANX LANGUAGE AND LITERATURE. Manx is the Celtic speech of the Isle of Man (*q.v.*). The earliest vernacular material is contained in the version of the Book of Common Prayer made in 1610 by Bishop Phillips. The mode of spelling used was not that used in Ireland, but was as phonetic as a language system based on Anglo-Scottish orthography could be. It is therefore very difficult to discover the real sound values attached to the various symbols. Manx is more closely related to Scottish Gaelic than the Irish. A dialectical difference between North and South shows it has not the treatment of short accented vowels before *ll*, *nn*, and *m* and vocalic *s* or *sh* tends to become voiced to *d*. (*See* J. Rhys, *The Outlines of the Phonology of Manx Gaelic* [1895]; H. Jenner, *Transactions* of the London Philological Society [1875].)

Literature.—The literary remains written in the Manx language are considerably slighter than those of any other Celtic dialect. With one small exception nothing pertaining to the saga literature of Ireland has been preserved. The little we possess falls under two heads—original compositions and translations. With regard to the first we must give the place of honour to an Ossianic poem contained in a ms. in the British Museum (written in 1789), which relates how Orree, Finn's enemy, was tormented by the women of Finn's household when the latter was away hunting, how he in revenge set fire to the house, and how Finn had him torn in pieces by wild horses. Most of the literature of native origin consists of ballads and carols, locally called carvels. These used to be sung on Christmas eve in the churches, the members of the congregation each bringing a candle. Any one who pleased could get up and sing one. These carvels deal largely with the end of the world, the judgment-day and the horrors of hell. About 80 of them were published under the title of *Carvalyn Gailckagh* (Douglas, 1891). An attempt has been made in the present century by *Yn Cheshaght Gailckagh* to revive the *Oiel Voirrey* (=Irish *Oidhche Fhéile Mhuire*), "the feast of Mary," as the festival used to be called, and gatherings in the old style have been held in Peel. Apart from the carvels there are other ballads in existence. The earliest is an 18th-century song of Manannan Mac y Lheir, traditionally supposed to have been written in the 16th century, which tells of the conversion of the island by St. Patrick. Then comes *Baase Illiam Dhône* (The Death of Brown William), dealing with the death of William Christian, who was shot as a traitor in 1662. The best-known Manx song is *Mylecharaine* (=Irish *Maolchiarán*). It is directed against a man of this name who was the first to give a dowry to his daughter, the custom having previously been for the bridegroom to pay money to the father of the bride. Others are *Ny Kirree fo Sniaghtey* (The Sheep under the Snow), a song about the loss of the Douglas herring fleet in 1787 (reprinted at Douglas, 1872), and *O Vannin Veg Veen* (Dear little Mona). In 1760 Joseph Bridson wrote a "Short Account of the Isle of Man" in Manx (*Coontey Ghiare jeh Ellan Vannin ayns Gailck*). The translated literature is almost entirely of a religious character. Jenner prints a list of 23 volumes in his article referred to below. The first is the translation of the English Prayer-Book by Bishop Phillips, 1610 (published by A. W. Moore, Oxford, 1895). The *Sermons* of Bishop Wilson (1783). intended to be in 3 vols., of which only one was ever printed, is a very rare work, highly important for our knowledge of Manx prose. A later translation of the Church of England Prayer-Book was printed in 1765, but by far the most important of all is the translation of the Bible. The energetic Bishop Wilson managed to get parts of the Scriptures translated and the Gospel of St. Matthew was printed in 1748. Wilson's successor, Bishop Hildesley, completed the work, and in 1775 the whole Bible appeared. As a curiosity it may be mentioned that *Aesop's Fables* have been translated into the vernacular (Douglas, 1901).

See H. Jenner, "The Manx Language: its Grammar, Literature and Present State," *Transactions of the London Philological Society* (1875), pp. 172 ff.; *Publications of the Manx Society*, vols. xvi., xx., xxi.; L. C. Stern, *Die Kultur d. Gegenwart*, i. xi. 1, pp. 110–11.

MANYCH, a river and depression in S. Russia, stretching between the lower river Don and the Caspian sea, through the North Caucasian area and the autonomous Kalmuck area. During the greater part of the year it is either dry or occupied in part by a string of saline lakes (*limans* or *ilmens*); but in spring when the streams swell which empty into it, the water flows in two opposite directions from the highest point (near Shara-Khulusun). One stream flows westwards with an inclination northwards, until it reaches the Don, though when the latter river is running high, its water penetrates some 60 miles up the Manych. The eastern stream dies away in the sandy steppe about 25 miles from the Caspian, though it is said sometimes to reach the Kuma through the Huiduk, a tributary of the Kuma. Total length of the depression, 330 m. For its significance as a former (geologic) connection between the Sea of Azov and the Caspian sea, *see* CASPIAN SEA.

MANZANARES, a town of Spain, in the province of Ciudad Real, on the River Azuer, a sub-tributary of the Záncara, and on the railways from Madrid to Ciudad Real and Linares. Pop. (1940) 18,182 (mun., 18,451). Manzanares is one of the chief towns of La Mancha, and thus in the centre of the district described by Cervantes in *Don Quixote*. Its citadel was founded as a Christian fortress after the defeat of the Moors at Las Navas de Tolosa (1212). Manzanares manufactures soap and pottery, and has an active trade in wheat, wine and spirits.

MANZANILLO, one of the important ports and trade centres of south-eastern Cuba, located in the Province of Oriente, and a shipping point for sugar, hides, tobacco and hardwood timbers. Pop. (1943) 36,295. Manzanillo lies west and slightly north of Santiago (112 mi.), on the so-called west coast of Cuba, facing Manzanillo bay, although it is south-east of Havana (487 mi.). East and south of the city rises the Sierra Maestra, through which the rivers Cauto (17 mi. N. of Manzanillo) and the Yara and the Buey flow to the sea. The town was founded in 1784, although, like many ports of Cuba, it had long before that time been well known to pirates and buccaneers, who came there to build or repair ships with the fine native woods. The settlement was sacked by the French in 1792, and was fortified the following year. It was opened to foreign ships in 1827, and in 1833 was given its local government. In 1837 it was officially invested with the title Manzanillo el Fiel, or faithful, for its support of the Spanish Constitution.

MANZANILLO, a town and port on the Pacific coast of Mexico, in the State of Colima, 52 mi. by rail W.S.W. of the city of that name. Pop. in 1940 was 6,831. It is situated on a large harbour partly formed and sheltered by a long island extending southwards parallel with the coast. Southward also, and in the vicinity of the town, is the large, stagnant, shallow lagoon of Cuyutlán which renders the town unhealthful. Manzanillo is a commercial town of comparatively recent creation. Manzanillo is connected by the Mexican National railway with Guadalajara and central Mexico. Construction of the harbour works was begun in 1899. These works include a breakwater 1,300 ft. long, with a depth of 12 to 70 ft. and a maximum breadth of 320 ft. at the base and 25 ft. on top, and all the necessary berthing and mechanical facilities for the handling of cargoes. The exports include hides and skins, palm-leaf hats, Indian corn, coffee, palm oil, fruit, lumber and minerals.

MANZANITA, the name given to numerous shrubs of the botanical genus *Arctostaphylos* belonging to the heath family (Ericaceae), comprising about 40 species, confined chiefly to western North America, 25 species being found in California.

They are evergreen shrubs, mostly from 3 to 12 ft. high, with dark red or chocolate-coloured, smooth and polished bark; very crooked, usually stiff branches; small, mostly toothless, often vertical leaves, and handsome white or pink flowers borne in terminal, usually nodding, globose clusters. The fruit, which becomes brownish and berry-like at maturity, is somewhat suggestive when young of a tiny apple, from whence comes the Spanish name *manzanita,* "little apple."

MANZIKERT, BATTLE OF (1071). In the spring of 1071 Romanus Diogenes, the Byzantine emperor, having collected together an army of some 60,000 men marched into Armenia to recover the fortresses of Akhlat and Manzikert which had been captured by Alp Arslan and his Seljūk Turks. His forces were composite, consisting of Byzantine cavalry and infantry, German mercenaries and Franks. At Akhlat he divided his army leaving there a division to besiege the fortress, and with the main body marched on to Manzikert and reduced that place. Hardly had he done so when he fell in with Alp Arslan's advanced guard. The Sultan's army was 100,000 strong, and mainly consisted of horse archers. The tactics which the emperor should have employed were those laid down by Leo the Wise, namely, to maintain an unbroken front, to beware of surprise and never to fight with uncovered flanks or rear.

Romanus was a brave soldier but impetuous. In the advanced guard encounter one of his generals, Basilakes, fell into an ambush losing all his men. The emperor then drew up his army in front of his camp. The right wing was composed of Asiatic cavalry, the left of European and the centre of Byzantine horse. In rear he drew up a strong second line of Germans and Normans under Andronicus Ducas. As he advanced on his enemy, the Turks refused to close, hovering round the two lines and plying them with arrows. In the evening a halt was called, and the emperor fearing that his camp was in danger ordered a retirement. This order was misinterpreted, and confusion resulted, whereupon the Turks closing in compelled the emperor to face about. Andronicus refused to halt and retired to the camp. The loss of the rear line left the rear of the front line open to attack. Eventually this line was overwhelmed and Romanus was decisively defeated and made a prisoner. The result of this defeat was disastrous, Asia Minor was overrun, and by 1080 the old Byzantine army had all but ceased to exist.

MANZOLLI, PIER ANGELO, Italian author, was born about the end of the fifteenth century at La Stellata, near Ferrara. His didactic poem, *Zodiacus vitae* (Basel 1543), dedicated to Hercules II. of Ferrara, combines metaphysical speculation with satirical attacks on ecclesiastical hypocrisy, and especially on the Pope and on Luther. It was banned by the Inquisition for its rationalizing tendencies.

MANZONI, ALESSANDRO FRANCESCO TOMMASO ANTONIO (1785–1873), Italian poet and novelist, was born at Milan on March 7, 1785. He was descended on his father's side from the feudal lords of Barzio, in the Valsassina; his mother was the daughter of Cesare Beccaria (*q.v.*). Manzoni was educated at various schools, the last being the Barnabiti School in Milan. In 1805, he accompanied his mother to Paris, where he mixed in the literary set of the so-called "ideologues," and imbibed the negative creed of Voltairianism. The fervent Catholicism which coloured his later life only developed after his marriage. In 1806–07, he published two pieces, one entitled *Urania,* in the classical style, the other an elegy in blank verse, on the death of Count Carlo Imbonati, his mother's lover, who left him considerable property, including the villa of Brusuglio.

He married in 1808 Henriette Blondel, daughter of a Genevese banker, and led for many years a retired life, divided between literature and his farm in Lombardy. To this period belong his *Inni sacri,* a series of sacred lyrics, and a treatise on Catholic morality. In 1818 he had to sell his paternal inheritance, as his affairs had gone to ruin in the hands of a dishonest agent. He cancelled on the spot the record of all sums owing to him by the peasants, and gave them the whole of the coming maize harvest.

In 1819 Manzoni published his first tragedy, *Il Conte di Carmagnola,* which boldly violated all classical conventions, and was severely criticized in the *Quarterly Review,* in an article to which Goethe replied in its defence, "one genius," as Count de Gubernatis remarks, "having divined the other." The Piedmontese revolution of 1821 inspired Manzoni's *Marzo, 1821,* but under Austrian rule the publication of the poem was impossible. It only appeared in 1848. On the death of Napoleon he wrote the famous ode *Il cinque Maggio* (circulated at first in ms. and printed in 1822) which Goethe declared to be the greatest of the many which celebrated that event. Manzoni also wrote at this time the tragedies *Il conte del Carmagnola* (1820) and *Adelchi* (1822), in which he broke loose from the classical convention.

He then turned to the form which gave his genius full scope. Round the episode of the *Innominato,* historically identified with Bernardino Visconti, the romantic novel *I Promessi sposi* began to grow into shape; it was completed in Sept. 1822, published in 1825–27, and at once raised its author to the first rank of literary fame. It was translated into many languages, but it was his last considerable work. Manzoni laboriously revised *I Promessi sposi* in the Tuscan idiom, and in 1840 republished it in that form, with *La Storia della Colonna infame.*

Manzoni's sons took part in the Five Days revolt in Milan in '48. The Austrians did not molest him, but he declined all honours until after the Liberation when he became a senator.

The end of his life was saddened by domestic sorrows. The loss of his wife in 1833 was followed by that of several of his children, and of his mother. In 1837 he married his second wife, Teresa Borri, widow of Count Stampa, whom he also survived, while of nine children born in his two marriages all but two predeceased him. The death of his eldest son, Pier Luigi, on April 28, 1873, was the final blow; he fell ill immediately, and died of cerebral meningitis, on May 22. His remains, after lying in state for some days, were followed to the cemetery of Milan by a vast cortège, including the royal princes and all the great officers of state. But his noblest monument was Verdi's *Requiem,* specially written to honour his memory.

See his *Opere Complete* (7 vols., 1905 *seq.*); his correspondence (ed. G. Sforza 2 vols. 1882–83); further correspondence, *Lettere inedite* (ed. E. Grecchi 2nd ed. 1900); A. Galletti, *A. Gentile, *Dante e Manzoni* (Florence 1923); F. de Sanctis, *Manzoni* (Bari 1922); A. Stoppani, *I primi e gli ultimi anni di A. Manzoni* (Milan 1923).

MAORI. The Maori come of sea-faring stock. A section of the great Polynesian race which inhabits the far-scattered island groups of the Eastern Pacific, they are the result of an inter-mixture of several distinct waves of canoe-voyagers. The last of these is now established as having come from Tahiti, with Rarotonga as the port of call, about the middle of the fourteenth century. Evidence of this is provided by comparison of the traditions and genealogies most scrupulously preserved by the learned men in each tribe. Prior to this time the country was inhabited by the *tangata whenua,* "the people of the land," some of whom were descended from Toi-kai-rakau, a Polynesian immigrant of about 1150, and others probably from drift-voyagers. With these folk the later arrivals inter-married and fought, ultimately gaining the ascendancy. The visit of Toi was in the nature of a search party for his lost grandson; the later migration, however, was a premeditated colonization, hence the *kumara* (sweet potato), *taro,* yam and other cultivated plants were introduced, as also the native dog.

For general culture the most important element in the Maori population is provided by the fleet of 1350, and on this the present social organization largely depends.

Social Grouping.—The Maori people are divided into a score or more tribes, *iwi,* each with its own well defined lands, and tracing kinship to a common ancestor. Thus all members of Ngati Maru, a tribe around Hauraki, claim descent from Marutuahu, the famous 14th century chief whose name they bear. The principal canoes associated with the fleet are Tainui, Arawa, Matatua, Takitimu, Tokomaru and Aotea, and, generally speaking, the particular group of tribes descended from the captain and crew of each vessel occupy contiguous territory and form a separate unit of a loose political nature, known as a *waka* (canoe). Thus Ngati Maru, together with Waikato and the tribes of the King Country make up the Tainui *waka,* a human "canoe" which extends from Hauraki to Mokau. The tribe is made up of several principal *hapu* or clans, each of which might in olden days number about a thousand fighting men. The *hapu* was not a unilateral group, *i.e.,* a person could belong to it through either his father or his mother, nor was it exogamous, marriage within the group being favoured provided that the parties were not first cousins. Within these major social units were lesser *hapu,* tracing descent to more immediate ancestors, and these in turn were composed of *whanau,* family groups of near relatives who together often occupied a dwelling hut. The individual family of parents and children existed, but, not forming a separate household, did not play a large part in public life. Through all Maori social structure ran this principle of kinship tie by common descent, a bond which linked men together and welded *whanau* to form *hapu,* and *hapu* to form tribe. One *hapu* might fight another but on the approach of a tribal enemy their quarrel was laid aside and their arms were turned against the common foe.

The system of primogeniture played a great part in the social organization. The highest chief of all was the *ariki,* eldest son in a line of first-born men of rank. His *mana* (power) was very great; his word was law. The people of his tribe were his relatives, their rank being broadly represented by the closeness of their kinship to him. Next to him came the chiefs of his own family, then the *rangatira,* "gentlemen," and finally the commonalty (*ware*). But every ordinary man, however undistinguished, could claim some sort of distant connection with his chief and with a noble family. Slaves (*taurekareka*) were mainly prisoners of war, and performed much of the menial labour.

Mode of Life.—The Maori lived in villages (*kainga*), usually with a fort or defended position (*pa*) close at hand. The economic life of the different tribes varied according to the resources at their command. In the north, fertile soil and a warm climate allowed of the cultivation of the *kumara* (sweet potato), but in less favoured districts forest products and the edible rhizome of the bracken (*aruhe, Pteris esculenta*) formed the staple food supply. Birds and the frugivorous native rat were snared and preserved by inland tribes, eels were taken by weirs on the Whanganui river, while around Rotorua and the adjacent lakes crayfish and the fresh water mussel were obtained, while fish was the main food of the dwellers on the sea coast. In these economic pursuits the Maori was very industrious. Advantage was taken of the communal mode of life to secure co-operation in the various tasks, and such labour was lightened by work-songs. Division of labour was practised, though in somewhat rudimentary form. The men did the harder, more exacting work, requiring more initiative and skill, as tree climbing, carving, fishing and fowling and breaking up of ground for crops. The women weeded the soil, collected shellfish, plaited mats and wove garments from the useful *harakeke* (*Phormium tenax,* N. Z. flax) and attended to the cooking of the two daily meals. In each industry there were specialists (*tohunga*) who had received a definite course of training, including knowledge of the magic of the craft.

Warfare was frequent in olden days and each man was trained in the use of weapons. Hand-to-hand fighting was preferred, and ambuscade and stratagem were frequent. In later warfare against Europeans the Maori showed himself extraordinarily proficient in the military art. In time of peace the social side of life was developed, visits were made, and neighbouring tribes were invited to feasts at which dart-throwing, wrestling, top-spinning and posture dancing held the interest of the people. Such receptions were held on the *marae,* the meeting place in the centre of the village. Feasts also took place at *tangi,* the ceremonial wailing for the dead, at which many relatives assembled from long distances.

Religion.—The religion of the Maori was closely bound up with his social and economic life. The ordinary people recognized a number of departmental gods, as Tane-mahuta, guardian deity of the forest, trees and birds, or Tangaroa, the Polynesian Neptune, lord of the sea and fish. The higher priests and chiefs also held belief in Io, a supreme god of rather negative attributes, to whom appeals were made in birth, baptism and marriage ceremonies for people of rank. This knowledge was jealously conserved, being kept from the common people, as also from European ethnographers until recent years. All Maori believed in a host of minor *atua,* rather malignant beings who provided omens, gave force to black magic, and punished breaches of *tapu.* The *tapu* (Polynesian=*taboo*) was one of the strongest forces of law in the Maori community. With the significance of sacred or unclean according to circumstances it conveyed in essential the idea of a prohibition. For instance, the person of a chief, his goods, his place by the fire and the remnants of his meal; all things connected with the gods; a corpse and the surroundings of death were all *tapu,* as were also a cultivated field, or a new house or canoe. Thus things of social importance to the native were protected from improper interference.

According to Maori belief, man was endowed with several spiritual *potentiae,* the *wairua,* the spirit which wanders abroad in dreams, the *mauri* and the *hau,* allied metaphysical concepts representing the vitality of a person, his essential life principle. At death the latter are dissolved, but the *wairua,* the soul, wends its way to Te Reinga, or Te Po, the underworld beneath the sea, a peaceful abode where men pursue their ordinary avocations as in life.

The Modern Maori.—A high degree of intelligence is shown by the Maori, who, on the impact of white civilization, adopted its material symbols eagerly at first, but reacted vigorously when they began to realize its full implications, especially as threatening their tribal land, their greatest treasure.

The majority are farmers. Such men as the late Sir James Carroll, Sir Maui Pomare, Sir Apirana Ngata and Dr. P. H. Buck, have rendered excellent service to the community as doctors, lawyers and Cabinet Ministers. At present the native people number about 54,000, but the percentage of white blood is rapidly increasing, so that ultimately miscegenation may be expected to absorb the Maori into our New Zealand population.

MAP (or MAPES), **WALTER** (d. *c.* 1208/9), mediaeval ecclesiastic, author and wit, to whose authority the main body of prose Arthurian literature has, at one time or another, been assigned, flourished in the latter part of the 12th and early years of the 13th centuries. He studied at Paris under Girard la Pucelle, who began to teach in or about 1160, but as he states in his book *De nugis curialium* that he was at the court of Henry II. before 1162, his residence at Paris must have been practically comprised in the decade 1150–1160.

Map was clerk of the royal household and justice itinerant; in 1179 he was present at the Lateran council at Rome, on his way thither being entertained by the count of Champagne; at this time he apparently held a plurality of ecclesiastical benefices, being a prebend of St. Paul's, canon and precentor of Lincoln and parson of Westbury, Gloucestershire. There seems to be no record of his ordination, but as he was a candidate for the see of Hereford in 1199 it is most probable that he was in priest's orders. The last reference to him, as living, is in 1208, when an order for payment to him is on record, but Giraldus Cambrensis, in the second edition of his *Hibernica,* redacted in 1210, utters a prayer for his soul, "cujus animae propitietur Deus," a proof that he was no longer alive.

The special interest of Map lies in the perplexing question of his relation to the Arthurian legend and literature. (*See* ARTHURIAN LEGEND.) To him have been attributed the *Lancelot* proper, the *Mort Artus* and the *Queste*. He is constantly referred to as an authority. It seems unlikely that a busy court official could have written the long prose romances attributed to him. But he seems to have been the man who linked up the Arthur legend proper to the cycle of the Holy Grail. His undoubted work is the *De nugis curialium*, and he is reputed to be the author of various witty goliardic verses. Taking all the evidence into consideration it seems more probable that Map had, at a comparatively early date, before he became so important an official, composed a poem on the subject of Lancelot, which was the direct source of the German version, and which Chrétien also knew and followed.

The form in which certain of the references to him are couched favours the above view; the compiler of *Guiron le Cortois* says in his prologue that *"maistre Gautier Map qui fu clers au roi Henry—devisa cil l'estoire de monseigneur Lancelot du Lac, que d'autre chose ne parla il mie gramment en son livre"*; and in another place he refers to Map, *"qui fit lou propre livre de monsoingnour Lancelot dou Lac."* Now only during the early part of his career could Map fairly be referred to as simple *"clers au roi Henry,"* and both extracts emphasize the fact that his work dealt, almost exclusively, with Lancelot. Neither of these passages would fit the prose romance, as we know it, but both might well suit the lost French source of the *Lanzelet;* where we are in a position to compare the German versions of French romances with their originals we find, as a rule, that the translators have followed their source faithfully.

See art. "Map" in *Dict. Nat. Biog. De nugis curialium* and the *Latin Poems attributed to Map* have been edited for the Camden Society by T. Wright (1841). For discussion of his authorship of the *Lancelot* cf. *The Three Days' Tournament*, Grimm Library XV. *See* also under LANCELOT. The passages relating to Map cited above have been frequently quoted by scholars, *e.g.*, Hucher, *Le Grand Saint Graal;* Paulin Paris, *Romans de la Table Ronde;* Alfred Nutt, *Studies in the Legend of the Holy Grail.* (J. L. W.)

MAP, a representation, on a plane and a reduced scale, of part or the whole of the earth's surface. If specially designed to meet the requirements of seamen it is called a chart, if on an exceptionally large scale a plan. A collection of maps is called an atlas, after the figure of Atlas, the Titan, supporting the heavens.

Classification of Maps.—Maps differ greatly, not only as to the scale on which they are drawn, but also with respect to the fullness or the character of the information which they convey. Broadly speaking, they may be divided into two classes, of which the first includes topographical and general maps, the second the great variety designed for special purposes.

Topographical maps and plans are drawn on a scale sufficiently large to show most objects on a scale true to nature.

General maps are either reduced from topographical maps or compiled from such miscellaneous sources as are available. In the former case the cartographer is merely called upon to reduce and generalize the information given by his originals. In the latter case no surveys are available, and the map has to be compiled from a variety of sources. These materials generally include reconnaissance survey of small districts, route surveys and astronomical observations supplied by travellers, and information from native sources. The compiler, in combining these materials, is called upon to examine the various sources of information, and to form an estimate of their value, which he can only do if he have himself some knowledge of surveying and of the methods of determining positions by astronomical observation. A knowledge of the languages of the written accounts and even of native languages, is almost indispensable. Frequently the explorer himself, or the draughtsman employed by him fails to introduce into his map the whole of the information available. Latitudes from the observations of old-time travellers may generally be trusted, but their longitudes should be accepted with caution.

Scale of Maps.—Formerly map-makers contented themselves with placing upon their maps a linear scale of miles. They now usually add the proportion which the units have to nature.

The linear scale of maps can obviously be used only in the case of maps covering a small area, for in the case of maps of greater extension measurements would be vitiated owing to the distortion or exaggeration inherent in all projections.

Map Projections are dealt with separately below. It will suffice therefore to point out that the ordinary needs of the cartographer can be met by conical projections. The indiscriminate use of Mercator's projection, for maps of the world, is to be deprecated owing to the exaggeration of areas in high latitudes.

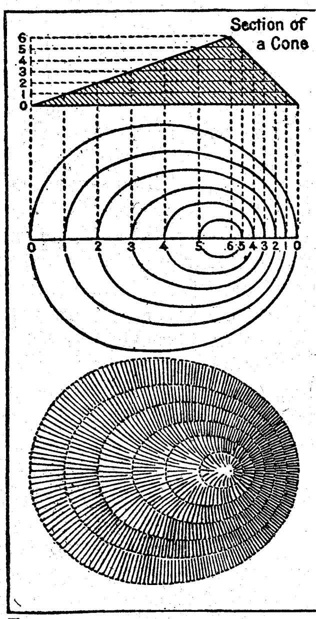

FIG. 1.—DELINEATION OF GROUND SHOWING HORIZONTAL CONTOURS AND HACHURES REGULATED ACCORDING TO INCLINATION OF SLOPE

Delineation of the Ground.—The mole-hills and serrated ridges of mediaeval maps were still in almost general use at the close of the 18th century, and are occasionally met with at the present day, being cheaply produced, readily understood by the unlearned, and in reality preferable to the uncouth and misleading hatchings still to be seen on many maps. Far superior are those scenographic representations which enable a person consulting the map to identify prominent landmarks.

Delineations such as these do not, however, satisfy scientific requirements. This was recognized by J. Picard and other members of the Academy of Science whom Colbert, in 1668, directed to prepare a new map of France, for on David Vivier's map of the environs of Paris (1674, scale 1:86,400) very crude hachures bounding the rivers have been substituted for the scenographic hills of older maps. Towards the close of the 18th century horizontal contours and hachures regulated according to the angle of inclination of all slopes were adopted. These *contours* are the intersections of the surface and horizontal planes (*see* fig. 1). Contours of this kind were first utilized by M. S. Cruquius in his chart of the Merwede (1728); Philip Buache (1737) introduced such contours or isobaths (Gr. ἴσος, equal; βαθύς, deep) upon his chart of the Channel, and intended to introduce smaller contours or isohypses (ὕψος, height) for a representation of the land.

LAYER MAPS

Carl Ritter, in 1806, employed graduated tints, decreasing in depth, from the lowlands to the highlands; while Gen. F. von Hauslab, director of the Austrian Surveys, in 1842, advised that the darkest tints should be allotted to the highlands, so as not to obscure details in the densely peopled plains. C. von Sonklar, in his map of the Hohe Tauern coloured plains and valleys green; mountain slopes in five shades of brown; glaciers blue or white. E. G. Ravenstein's map of Ben Nevis (1887) first employed the spectrum colours, viz., green to brown, in ascending order for the land: blue, indigo and violet for the sea. On the international map of the world, on a scale of 1:1,000,000, which has been undertaken by the leading governments of the world, the ground is shown by contours at intervals of 100m., the strata are in graded tints, viz., blue for the sea, green for lowlands up to 300m., yellow between 300 and 500m., brown up to 2,000m., and reddish tints beyond that height.

Until the 20th century the declivities of the ground were indicated in most topographical maps by a system of strokes or hachures, first devised by L. Chr. Müller (*Plan und Kartenzeichnen,* 1788) and J. G. Lehmann, who directed a survey of Saxony, 1780–1806, and published his *Theorie der Bergzeichnung* in 1799. By this method the slopes are indicated by strokes or hachures crossing the contour lines at right angles, in the direction of flowing water, and varying in thickness according to the degree of declivity they represent. Typical modern topographical maps, on scales from 1:25,000 to 1:250,000, have, generally, contours closely spaced, printed in colours. Hachures may occasionally be found combined with contours, as in the maps of Italy on the 1:100,000 scale.

As to the interval at which the contours should be spaced, a good rule in normal, not mountainous, country is to space them at 50ft. for a scale of 1in. to the mile, and for other scales in proportion. Thus, on a ½in. map the contours would be at 100ft. intervals and so on.

Selection of Names and Orthography.—The nomenclature or "lettering" of maps is a subject deserving special attention. Not only should the names be carefully selected with special reference to the objects which the map is intended to serve, and to prevent overcrowding, but they should also be arranged in such a manner as to be read easily by a person consulting the map. It is an accepted rule now that the spelling of names in countries using the Roman alphabet should be retained, with such exceptions as have been familiarized by long usage. In such cases, however, the correct native form should be added within brackets, as Florence (Firenze), Leghorn (Livorno), Prague (Praha) and so on. At the same time these corrupted forms should be eliminated as far as possible. Names in languages not using the Roman alphabet, or having no written alphabet, should be spelt phonetically, as pronounced on the spot. An elaborate universal alphabet, abounding in diacritical marks, has been devised for the purpose by Prof. Lepsius, and various other systems have been adopted for oriental languages, and by certain missionary societies, adapted to the languages in which they teach. The simple rules laid down by the Royal Geographical Society, will be found sufficient.

The United States Geographic Board acts upon rules practically identical with those indicated, and compiles official lists of place-names, the use of which is binding upon Government departments.

MEASUREMENT ON MAPS

Measurement of Distance.—The shortest distance between two places on the surface of a globe is represented by the arc of a great circle. If the two places are upon the same meridian or upon the equator the exact distance separating them is to be found by reference to a table giving the lengths of arcs of a meridian and of the equator. In all other cases recourse must be had to a map, a globe or mathematical formula. Measurements made on a topographical map yield the most satisfactory results. Even a general map may be trusted, as long as we keep within ten degrees of its centre. In the case of more considerable distances, however, a globe of suitable size should be consulted, or—and this seems preferable—they should be calculated by the rules of spherical trigonometry for the solution of a spherical triangle.

Orthodromic, *i.e.*, great-circle, distances are of course shorter than those measured along a loxodromic line, which intersects all parallels at the same angle. Thus the distance between New York and Oporto, following the former (great-circle sailing), amounts to 3,000m., while following the rhumb, as in Mercator sailing, it would amount to 3,120 miles.

Direct distances may of course differ widely from the distance which it is necessary to travel between two places along a road, down a winding river or a sinuous coast-line. Thus, the direct distance, as the crow flies, between Brig and the hospice of the Simplon amounts to 4·42 geogr. m. (slope nearly 9°), while the distance by road measures 13·85 geogr. m. (slope nearly 3°). Distances such as these can be measured only on a topographical map of a fairly large scale, for on general maps many of the details needed for that purpose can no longer be represented. Space runners for facilitating these measurements have been devised in great variety.

MEASUREMENT OF AREAS

This is easy if the map at our disposal is drawn on an equal area projection. In that case we need simply cover the map with a network of squares—the area of each of which has been determined with reference to the scale of the map—count the squares, and estimate the contents of those only partially enclosed within the boundary, and the result will give the area desired. A planimeter is still quicker.

When dealing with maps not drawn on an equal area projection we substitute quadrilaterals bounded by meridians and parallels, the areas for which are given in the "Smithsonian Geographical Tables" (1894), or similar works.

Models or Relief Maps.—These are intended to present a representation of the ground which shall be absolutely true to nature. The object, however, can be fully attained only if the scale of the map is sufficiently large, if the horizontal and vertical scales are identical, so that there shall be no exaggeration of the heights, and if regard is had, eventually, to the curvature of the earth's surface. Relief maps on a small scale necessitate a generalization of the features of the ground, as in the case of ordinary maps, as likewise an exaggeration of the heights. Thus on a relief on a scale of 1:1,000,000 a mountain like Ben Nevis would only rise to a height of 1·3 millimetres.

The methods of producing reliefs vary according to the scale and the materials available. A simple plan is as follows: draw an outline of the country of which a map is to be produced upon a board; mark all points the altitude of which is known or can be estimated by pins or wires clipped off so as to denote the heights; mark river-courses and suitable profiles by strips of vellum and finally finish your model with the aid of a good map, in clay or wax. A pantograph armed with cutting-files which carve the relief out of plaster of Paris may be used.

Globes.—It is impossible to represent on a plane the whole of the earth's surface, or even a large extent of it, without a considerable amount of distortion. On the other hand a map drawn on the surface of a sphere representing a terrestrial globe will prove true to nature, for it possesses, in combination, the qualities which the ingenuity of no mathematician has hitherto succeeded in imparting to a projection intended for a map of some extent, namely, equivalence of areas, of distances and angles.

It should be observed here that our globes take no account of the oblateness of our sphere; but as the difference in length between the two axes of the earth only amounts to about $\frac{1}{300}$ it could be shown only on a globe of unusual size.

Map Printing.—Maps were first printed in the second half of the 15th century. Those in the *Rudimentum novitiarum* published at Lübeck in 1475 are from woodcuts, while the maps in the first two editions of Ptolemy published in Italy in 1472 are from copper plates. Wood engraving kept its ground for a considerable period, especially in Germany, but copper in the end supplanted it. The art of lithography has greatly affected the production of maps. Owing to the great weight of stones, their cost and their liability of being fractured in the press, zinc plates or aluminium plates, have largely taken the place of stone. The processes of zincography are essentially the same as lithography. Photographic processes are utilized not only in reducing maps to a smaller scale, but also for producing stones and plates from which they may be printed. The manuscript maps intended to be produced by photographic processes upon stone, zinc or aluminium, are drawn on a scale somewhat larger than the scale on which they are to be printed, thus eliminating all those imperfections which are inherent in a pen-drawing. The saving in time and cost by adopting this process is considerable.

For details of the various methods of reproduction *see* LITHOGRAPHY: *Lithography As An Art: The Process.*

HISTORY OF CARTOGRAPHY

A capacity to understand the nature of maps is possessed even by peoples whom we are in the habit of describing as "savages." Wandering tribes naturally enjoy a great advantage in this respect over sedentary ones. Many arctic voyagers have profited from rough maps drawn for them by Eskimos. Specimens of such maps are given in C. F. Hall's *Life with the Esquimaux* (London, 1864). Henry Youle Hind, in his work on the Labrador Peninsula (London, 1863) praises the map which the Montagnais and Nasquapee Indians drew upon bark.

Tupaya, a Tahitian, when on board the "Endeavour," gave an account of his navigations, and having a very complete knowledge of the islands, and having soon mastered the meaning and use of charts, was able to give directions for the construction of a chart showing the islands. Raraka drew a map in chalk of the Paumotu archipelago on the deck of Capt. Wilkes's vessel; Marshall islanders possessed curious cane charts. Far superior were maps found among the semi-civilized Mexicans when the Spaniards invaded their country: cadastral plans of villages and maps of the provinces of the empire of the Aztecs, of towns and the coast. Montezuma presented Cortes with a map, painted on Nequen cloth, of the Gulf coast. Peru, the empire of the Incas, had not only ordinary maps, but also maps in relief, for Pedro Sarmiento da Gamboa (*History of the Incas,* translated by A. R. Markham, 1907) tells us that the 9th Inca (died 1191) ordered such reliefs of certain localities in a district which he had recently conquered and intended to colonize. These were the first relief maps.

The ancient Egyptians were famed as "geometers," and as early as the days of Rameses II. (Sesostris of the Greek, 1333–1300 B.C.) there had been made a cadastral survey of the country showing the rows of pillars which separated the nomes as well as the boundaries of landed estates. It was upon a map based upon such a source that Eratosthenes (276–196 B.C.) measured the distance between Syene and Alexandria which he required for his determination of the length of a degree. Ptolemy, who had access to the famous library of Alexandria was able, no doubt, to use these cadastral plans when compiling his *geography.* Few specimens of ancient Egyptian cartography have survived. In the Turin museum are preserved two papyri with rough drawings of gold mines established by Sesostris in the Nubian desert. These drawings have been commented upon by S. Birch, F. Chabas, R. J. Lauth and other Egyptologists, and have been referred to as the two most ancient maps in existence. They can, however, hardly be described as maps, while in age they are surpassed by several cartographical clay tablets discovered in Babylonia. On another papyrus in the same museum is depicted the victorious return of Seti I. (1366–1333) from Syria, showing the road from Pelusium to Heroopolis, the canal from the Nile with crocodiles, and a lake (mod. Lake Timsah) with fish in it. Apollonius of Rhodes, who succeeded Eratosthenes as chief librarian at Alexandria (196 B.C.), reports in his *Argonautica* (iv. 279) that the inhabitants of Colchis whom, like Herodotus (ii. 104) he looks upon as the descendants of Egyptian colonists, preserved, as heirlooms, certain graven tablets (κύρβεις) on which land and sea, roads and towns were accurately indicated. Eustathius (since 1160 archbishop of Thessalonica), in his commentary on Dionysius Periegetes, mentions route-maps which Sesostris caused to be prepared, while Strabo dwells at length upon the wealth of geographical documents to be found in the library of Alexandria.

A cadastral survey for purposes of taxation was already at work in Babylonia during the age of Sargon of Akkad. In the British Museum may be seen a series of clay tablets, circular in shape and dating back to 2300 or 2100 B.C., which contain surveys of lands. One of these depicts in a rough way lower Babylonia encircled by a "salt water river," Oceanus.

Development of Map-making among the Greeks.—Ionian mercenaries and traders arrived in Egypt, on the invitation of Psammetichus I., about the middle of the 7th century B.C. One of the most distinguished was Thales of Miletus (640–543 B.C.), the founder of the Ionian school of philosophy, whose pupil, Anaximander (611–547 B.C.) is credited by Eratosthenes with having designed the first map of the world. Anaximander looked upon the earth as a section of a cylinder, of considerable thickness, suspended in the centre of the circular vault of the heavens, an idea perhaps from the Babylonians (*see* Job xxvi. 7). Like Homer he looked upon the habitable world (οἰκουμένη) as being circular in outline and bounded by a circumfluent river. The geographical knowledge of Anaximander extended from the Cassiterides or Tin islands in the west to the Caspian in the east, which he conceived to open out into Oceanus. The Aegean sea occupied the centre of the map, while the line where ocean and firmament seemed to meet represented an enlarged horizon.

Anaximenes, a pupil of Anaximander, was the first to reject the view that the earth was a circular plane, but held it to be an oblong rectangle, buoyed up in the midst of the heavens by the compressed air upon which it rested.

The map of the world brought upon the stage in Aristophanes' *The Clouds* (423 B.C.), whereon a disciple of the Sophists points out Athens and other places known to the audience, was probably of the popular circular type, which Herodotus (iv. 36) not many years before had derided and which was discarded by Greek cartographers ever after. Thus Democritus of Abdera (b. *c.* 450, d. after 360), the great philosopher and founder, with Leucippus, of the atomic theory, was also the author of a map of the inhabited world which he supposed to be half as long again from west to east, as it was broad.

Dicaearchus of Messana in Sicily, a pupil of Aristotle (326–296 B.C.), is the author of a topographical account of Hellas, with maps, of which only fragments are preserved; he is credited with having estimated the size of the earth, and, as far as known he was the first to draw a parallel across a map. The map of Dicaearchus resembled that of Democritus.

Scientific geography profited largely from the labours of Eratosthenes of Cyrene, whom Ptolemy Euergetes appointed keeper of the famous library of Alexandria in 247 B.C., and died in that city in 195 B.C. He won fame as having been the first to determine the size of the earth by a scientific method. Having determined the difference of latitude between Alexandria and Syene which he erroneously believed to lie on the same meridian, and obtained the distance of those places from each other from the surveys made by Egyptian geometers, he concluded that a degree of the meridian measured 700 stadia.

Eratosthenes is the author of a treatise which deals systematically with the geographical knowledge of his time, but of which only fragments have been preserved by Strabo and others. This treatise was intended to illustrate and explain his map of the world. In this task he was much helped by the materials collected in his library. His map formed a parallelogram measuring 75,800 stadia from Usisama (Ushant island) or Sacrum Promontorium in the west to the mouth of the Ganges and the land of the Coniaci (Comorin) in the east, and 46,000 stadia from Thule in the north to the supposed southern limit of Libya. Across it were drawn seven parallels, running through Meroe, Syene, Alexandria, Rhodes, Lysimachia on the Hellespont, the mouth of the Borysthenes and Thule, and these were crossed at right angles by seven meridians, drawn at irregular intervals. In his text Eratosthenes ignored the popular division of the world into Europe, Asia and Libya, and substituted for it a northern and southern division, divided by the parallel of Rhodes, each of which he subdivided into *sphragides* or *plinthia*—seals or plinths. The principles on which these divisions were made remain an enigma to the present day. This map of Eratosthenes, notwithstanding its many errors, such as the assumed connection of the Caspian with a northern ocean and the supposition that Carthage, Sicily and Rome lay on the same meridian, enjoyed a high reputation in his day. Even Strabo (*c.* 30 B.C.) adopted its main features.

Hipparchus, the famous astronomer, on the other hand (*c.* 150 B.C.) proved a somewhat captious critic. He justly objected to the arbitrary network of the map of Eratosthenes. The parallels or *climata* drawn through places, of which the longest day is of equal length and the decimation (distance) from the equator is the same, he maintained, ought to have been inserted at equal intervals, say of half an hour, and the meridians inserted on a like principle. In fact, he demanded that maps should be based upon a regular projection, several descriptions of which he had adopted for his star maps. He moreover accuses Eratosthenes (whose determination of a degree he accepts without hesitation) with trusting too much to hypothesis in compiling his map instead of having recourse to latitudes and longitudes deduced by astronomical observations. Such observations, however, were but rarely available at the time. Hipparchus is not known to have compiled a map himself.

About the same time Crates of Mallus (d. 145 B.C.) embodied the views of the Stoic school of philosophy in a globe which has

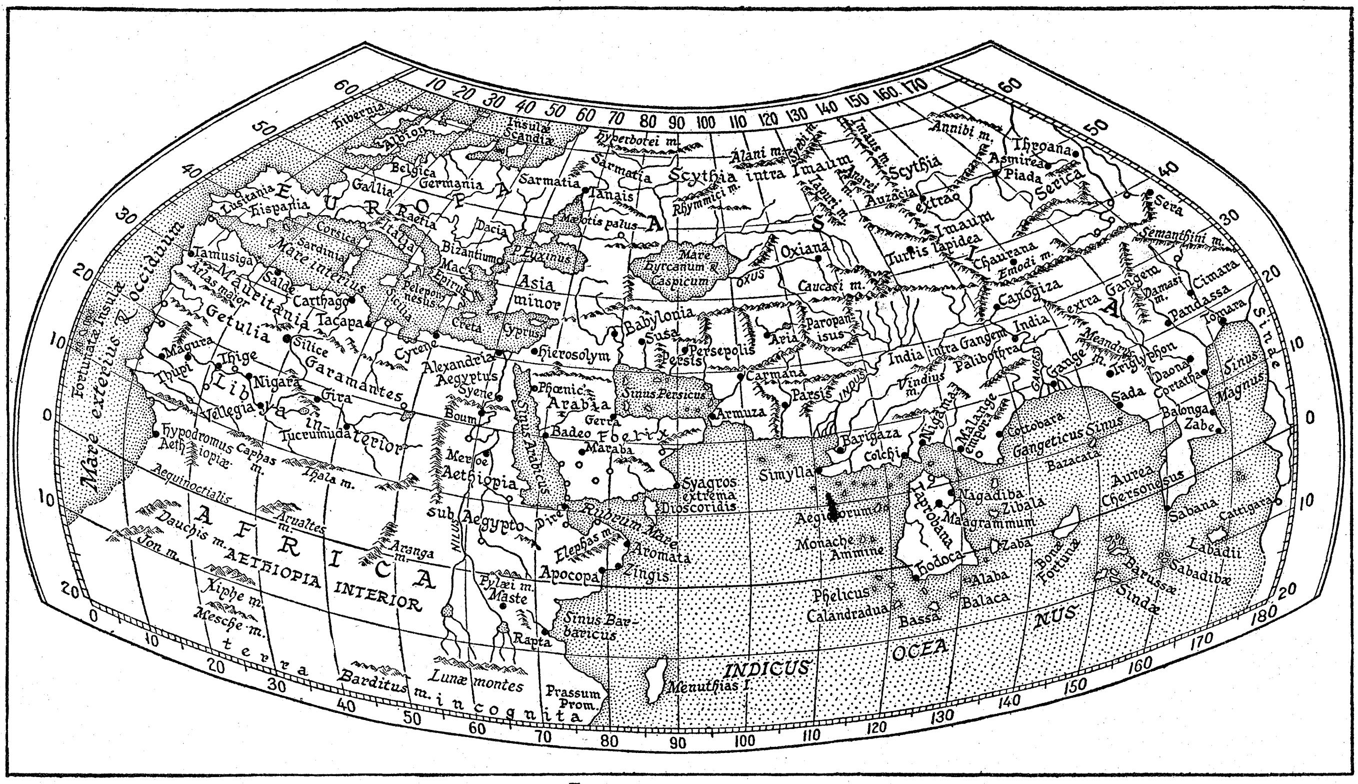

FIG. 2.—PTOLEMY'S MAP

become typical as one of the insignia of royalty. On this globe an equatorial and a meridional ocean divide our earth into four quarters, each inhabited, thus anticipating the discovery of North and South America and Australia.

The period between Eratosthenes and Marinus of Tyre was one of great political importance. Military operations added to our knowledge of the world but scientific cartography was utterly neglected.

Among Greek works written during this period there are several which either give us an idea of the maps available at that time, or furnish information of direct service to the compiler of a map. Among the latter a Periplus or coastal guide of the Erythrean sea, which clearly reveals the peninsular shape of India (A.D. 90) and Arrian's *Periplus Ponti Euxeni* (A.D. 131) which Festus Avienus translated into Latin. Among geographers should be mentioned Posidonius (130–50 B.C.), the head of the Stoic school of Rhodes, who is stated to be responsible for having reduced the length of a degree to 500 stadia; Artemidorus of Ephesus, whose "Geographumena" (*c.* 100 B.C.) are based upon his own travels and a study of itineraries, and above all, Strabo, who adhered to the scientific theories of Eratosthenes.

The credit of having returned to the scientific principles introduced by Eratosthenes and Hipparchus is due to Marinus of Tyre (*c.* A.D. 120). His map and the descriptive accounts which accompanied it have perished, but we learn sufficient concerning them from Ptolemy to be able to appreciate their merits and demerits. Marinus was the first who laid down the position of places on a projection according to their latitude and longitude, but the projection used by him was of the rudest. Parallels and meridians were represented by straight lines intersecting each other at right angles, the relative proportions between degrees of longitude and latitude being retained only along the parallel of Rhodes. The distortion of the countries represented would thus increase with the distance, north and south, from this central parallel. The number of places whose position had been determined by astronomical observation was as yet very small, and the map had thus to be compiled mainly from itineraries furnished by travellers or the dead reckoning of seamen. The errors of distance were still further increased by his assuming a degree to be equal to 500 stadia. There was a list of places arranged according to latitude and longitude. It must have been much in demand, for three editions of it were prepared. Masudi (10th century) saw a copy of it and declared it to be superior to Ptolemy's map.

Ptolemy (*q.v.*) was the author of a *Geography* (*c.* A.D. 150) in eight books. "Geography," in the sense in which he uses the term, signifies the delineation of the known world, in the shape of a map, while chorography carries out the same object in fuller detail, with regard to a particular country. In Book I. he deals with the principles of mathematical geography, map projections and sources of information. Books II. to VII. index the longitudes, and thus it is possible to reconstruct the maps.

Ptolemy's great merit consists in having accepted the views of Hipparchus with respect to a projection suited for a map of the world. Of the two projections proposed by him one is a modified conical projection with curved parallels and straight meridians; in the second projection (*see* fig. 2) both parallels and meridians are curved. The correct relations in the length of degrees of latitude and longitude are maintained in the first case along the latitude of Thule and the equator, in the second along the parallel of Agisymba, the equator and the parallels of Meroe, Syene and Thule. Following Hipparchus he divided the equator into 360° drawing his prime meridian through the Fortunate islands.

As a map compiler Ptolemy does not take a high rank. In the main he copied Marinus whose work he revised and supplemented in some points, but he failed to realize the peninsular shape of India, erroneously exaggerated the size of Taprobane (Ceylon), and suggested that the Indian ocean had no connection with the western ocean, but formed Mare Clausum. Ptolemy knew but of a few latitudes which had been determined by actual observation, while of three longitudes resulting from simultaneous observation of eclipses he unfortunately accepted the least satisfactory, namely, that which placed Arbela 45° to the east of Carthage, while the actual meridian distance only amounts to 34°. An even graver source of error was Ptolemy's acceptance of a degree of 500 stadia (fig. 2). But in spite of his errors the scientific method pursued by Ptolemy was correct, and though he was neglected by the Romans and during the middle ages, once he had become known, in the 15th century, he became the teacher of the modern world.

Map-making Among the Romans.—We learn from Cicero,

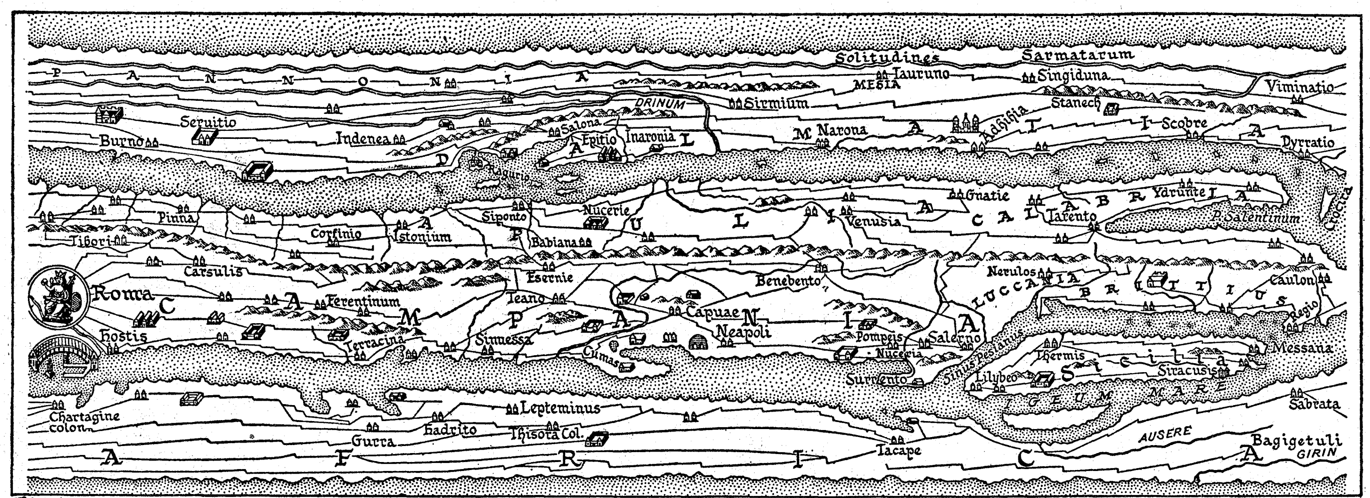

FIG. 3.—A SECTION OF PEUTINGER'S TABULA

Vitruvius, Seneca, Suetonius, Pliny and others, that the Romans had both general and topographical maps. Thus, Varro (*De rustici*) mentions a map of Italy engraved on marble, in the temple of Tellus, Pliny, a map of the seat of war in Armenia, of the time of the emperor Nero, and the more famous map of the Roman empire which was ordered to be prepared for Julius Caesar (44 B.C.), but only completed in the reign of Augustus, who placed a copy of it, engraved in marble, in the Porticus of his sister Octavia (7 B.C.). M. Vipsanius Agrippa, the son-in-law of Augustus (d. 12 B.C.), who superintended the completion of this famous map, also wrote a commentary illustrating it. It must have been a work of superior excellence. A copy of it may possibly have been utilized by Marinus and Ptolemy in their compilations. The Romans have been reproached for having neglected the scientific methods of map-making advocated by Hipparchus. Their maps seem to have met the practical requirements of political administration and of military undertakings.

Only two specimens of Roman cartography have come down to us, viz., parts of a plan of Rome, of the time of the emperor Septimius Severus (A.D. 193–211), now in the Museo Capitolino, and an *itinerarium scriptum,* or road map of the world, compressed within a strip 745mm. in length and 34mm. broad. Of its character the reduced copy of one of its 12 sections (fig. 3) conveys an idea. The map, apparently of the 3rd century, was copied by a monk at Colmar, in 1265, who fortunately contented himself with adding a few scriptural names, and having been acquired by the learned Konrad Peutinger of Augsburg it became known as *Tabula peutingeriana.* The original is now in the State library of Vienna.

Map-making in the Middle Ages.—In scientific matters the early middle ages were marked by stagnation and retrogression. The fathers of the Church did not encourage scientific pursuits. The doctrine of the sphericity of the earth was held by the more learned, but the heads of the Church held it to be unscriptural. Even after Gerbert of Aurillac, who is better known as Pope Sylvester II. (999–1063), Adam of Bremen (1075), Albertus Magnus (d. 1286), Roger Bacon (d. 1294), and indeed all men of leading had accepted as a fact and not a mere hypothesis the geocentric system of the universe and sphericity of the globe, the authors of maps of the world, nearly all of whom were monks, still looked in the main to the Holy Scriptures for guidance in outlining the inhabited world. We have to deal thus with three types of these early maps, viz., an oblong rectangular, a circular and an oval type, the latter being either a compromise between the two former, or an artistic development of the circular type. In every instance the inhabited world is surrounded by the ocean. The authors of rectangular maps look upon the Tabernacle as an image of the world at large. On the other hand there was the expression "circuit of the earth" (Isa. xl. 22), and the statement (Ezek. v. 5) that "God had set Jerusalem in the midst of the nations and countries." In nearly every case the East occupies the top of the map. Neither parallels nor meridians are indicated, nor is there a scale. Paradise is placed in the Far East.

The oldest rectangular map of the world is contained in a most valuable work written by Cosmas, an Alexandrian monk, surnamed Indicopleustes, after returning from a voyage to India (A.D. 535), and entitled *Christian Topography.* According to Cosmas the inhabited earth has the shape of an oblong rectangle surrounded by an ocean in four great gulfs. A small map of the world of the 8th century is found in a codex in the library of Albi, an archiepiscopal seat in the department of Tarn. Its scanty nomenclature is almost wholly derived from the "Historiae adversum paganos" of Paulus Orosius (418). Far greater interest attaches to the so-called Anglo-Saxon map of the world in the British museum (Cotton mss.), where it is bound up in a codex which also contains a copy of the *Periegesis* of Priscianus. Map and Periegesis are copies by the same hand, but no other connection exists between them. More than half the nomenclature of the map is derived from Orosius, an annotated Anglo-Saxon version of which had been produced by King Alfred (848–901). The Anglo-Saxons of the time were of course well acquainted

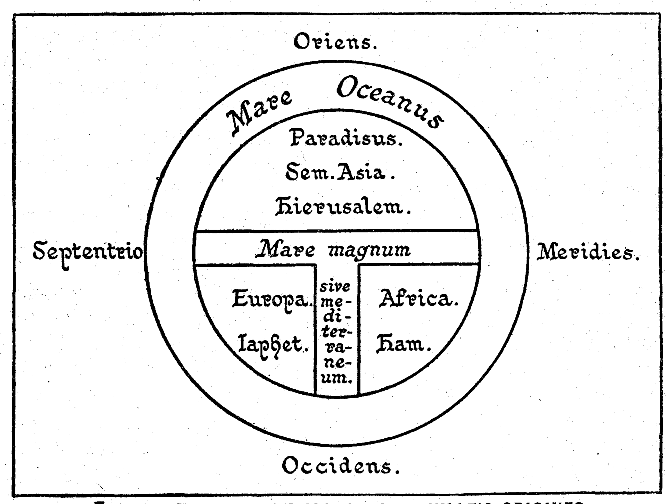

FIG. 4.—T. MAP FROM ISODOR OF SEVILLE'S ORIGINES

with Island (first thus named in 870), Slesvic and Norweci (Norway), and there is no need to have recourse to Adam of Bremen (1076) to account for their presence upon this map. The broad features of the map were derived no doubt from an older document which may likewise have served as the basis for the map of the world engraved on silver for Charlemagne, and which was also consulted by the compilers of the Hereford and Ebstorf maps.

The map or diagram of which Leonardo Dati in his poem on the Sphere (Della Spera) wrote in 1422 "un T dentre a uno O mostra il disegno" (a T within an O shows the design) is one of the most persistent types among the circular or wheel maps of the world. It perpetuates the tripartite division of the world by the ancient Greeks and survives in the Royal Orb. (*See* figs. 9 and 10.)

The map in Hereford cathedral (fig. 5) is the work of Richard of Haldingham, and has a diameter of 134cm. (53 inches). The "survey" ordered by Julius Caesar is referred to in the legend,

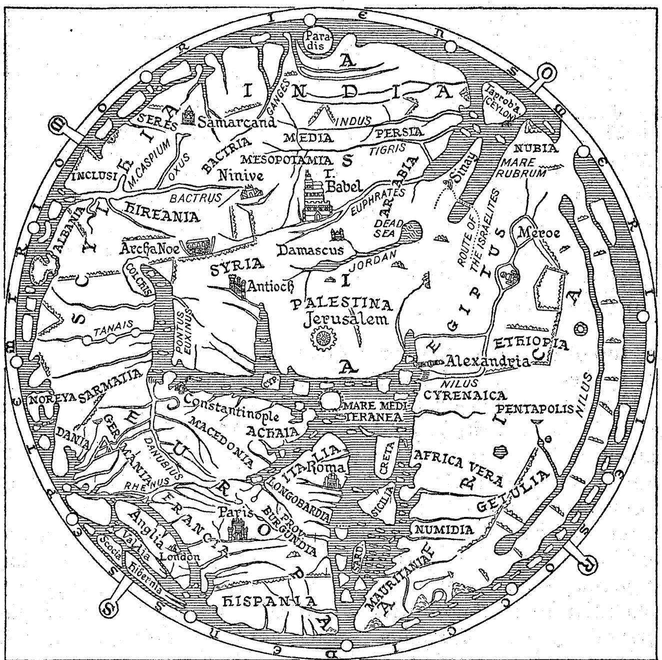

FIG. 5.—THE HEREFORD MAP. (ABOUT 1280)

evidently derived from the Cosmography of Aethicus a work widely read at the time, but this does not prove that the author was able to avail himself of a map based upon that survey. A map essentially identical with that of Hereford, but larger—its diameter is 156cm. (60in.), and consequently fuller of information—was discovered in 1830 in the old monastery of Ebstorf in Hanover. Its date is 1484.

Pomponius Mela tells us that beyond the Ethiopian ocean which sweeps round Africa in the south and the uninhabitable torrid zone, there lies an *alter orbis,* or fourth part of the world inhabited by *Antichthones.* On a diagram illustrating the *Origines* of Isidore of Seville (d. 636) this country is shown, but is described as a *terra inhabitabilis.* It is shown likewise upon a number of maps which illustrate the *Commentaries on the Apocalypse,* by Beatus, a Benedictine monk of the abbey of Valcavado at the foot of the hills of Liebana in Austria (776). There are similar maps illustrating the *Commentaries* existing at St. Sever (1050), Paris (1203) and Tunis; others are rectangular, the oldest being in Lord Ashburnham's library (970). Beatus, too, describes the southern land as *inhabitabilis.* The habitable world is divided among the twelve apostles, whose portraits are given. On the maps illustrating the encyclopaedic *Liber floridus* by Lambert, a canon of St. Omer (1120), this south land "unknown to the sons of Adam," is stated to be inhabited "according to the philosophers" by Antipodes. Lambert, indeed, seems to have believed in the sphericity of the earth. Diagrams illustrating the division of the world into climata are to be found in the *opus majus* of Roger Bacon (d. 1294) and in Cardinal Pierre d'Ailly's *De imagine Mundi* (1410).

Among countries represented on a larger scale on maps, Palestine not unnaturally occupies a prominent place in this age of pilgrimages and crusades (1095–1291). Maps of Palestine accompany St. Jerome's translation of the *Onomasticon* of St. Eusebius (388). The same subject is illustrated by a picture-map in mosaic, portions of which were discovered in 1884 on the floor of the church of Medeba to the east of the Jordan. This is the oldest original of a map in existence, for it dates back to the 6th century and shows the country before the Mohammedan conquest.

There also exist a few special maps of European countries. Of Great Britain we may mention the one of the 12th century, another by Matthew of Paris, the famous historiographer of the monastery of St. Albans (fig. 6) (1236–1259); and the map at the Bodleian Library at Oxford, dated about A.D. 1300. This is a genuine piece of map-making and may perhaps have been used by officials of the king's court.

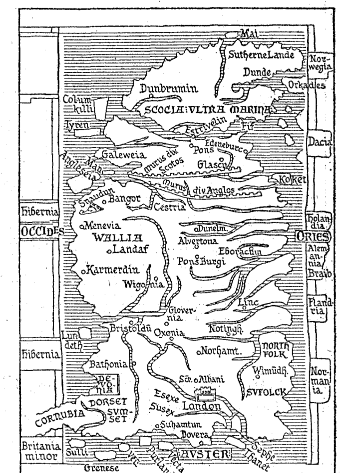

FIG. 6.—MATTHEW OF PARIS (1236–1259)

Celestial globes were known in the time of Bede; they formed part of the educational apparatus of the monastic schools. Gerbert of Aurillac is known to have made such globes (929). Their manufacture is described by Alphonso the Wise (1252), as also in *De sphaera solida* of G. Campanus of Novara (1303). Terrestrial globes, however, are not referred to.

Map-making Among the Arabians and Other Nations of the East.—Baghdad early became a famous seat of learning. Indian astronomers found apt pupils there among the Arabs; the works of Ptolemy were translated into Arabic, and in 827, in the reign of the caliph Abdullah al Mamun, an arc of the meridian was measured in the plain of Mesopotamia. Most famous among these Arabian astronomers were Al Batani (d. 998), Ibn Yunis of Cairo (d. 1008), Zarkala (Azarchel), who determined the meridian distance between his observatory in Toledo and Baghdad to amount to 51° 30′, an error of 3° only, as compared with Ptolemy's error of 18°, and Abul Hassan (1230) who reduced the great axis of the Mediterranean to 44°.

Further materials serviceable to the compilers of maps were supplied by numerous Arabian travellers and geographers, among

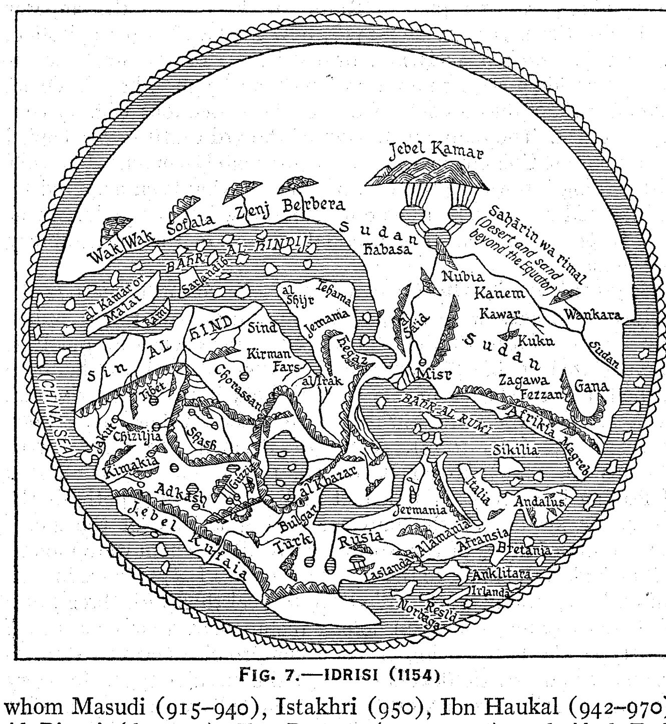

FIG. 7.—IDRISI (1154)

whom Masudi (915–940), Istakhri (950), Ibn Haukal (942–970), Al Biruni (d. 1038), Ibn Batuta (1325–1356) and Abul Feda (1331–1370), occupy a foremost place, yet the few maps which have reached us are crude in the extreme. Neither Idrisi's map of the world (fig. 7), engraved for King Roger of Sicily upon a silver plate, nor the rectangular map in 70 sheets which accompanies his geography (Nushat-ul Mushtat) take rank with Ptolemy's work.

The Arabians are not known to have produced a terrestrial globe, but several of their celestial globes are to be found in our collections. The oldest of these globes was made at Valentia, and is now in the museum of Florence. Another globe (of 1225) is at Velletri; a third by Ibn Hula of Mosul (1275) is the property of the Royal Asiatic Society of London; a fourth (1289) from the observatory of Maragha, in the Dresden museum; two globes of uncertain age at Paris, and another in London. All these globes are of metal (bronze).

The charts in use by the mediaeval navigators of the Indian Ocean—Arabs, Persians or Dravidas—were equal in value if not superior to the charts of the Mediterranean. Marco Polo mentions such charts; Vasco da Gama (1498) found them in the hands of his Indian pilot, and their nature is fully explained in the *Mohit* or encyclopaedia of the sea compiled from ancient sources by the Turkish admiral Sidi Ali Ben Hosein in 1554. These charts are covered with a close network of lines intersecting each other at right angles. The horizontal lines are parallels, depending upon the altitude of the pole star, the Calves of the Little Bear and the Barrow of the Great Bear above the horizon. This altitude was expressed in *isbas* or inches each equivalent to 1° 42′ 50″. Each *isba* was divided into *zams* or eighths. The interval between two parallels thus only amounted to 12′ 51″. These intervals were mistaken by the Portuguese occasionally for degrees, which account for Malacca, which is in lat. 2′ 13″ N., being placed on Cantino's chart (1502) in lat. 14′ S. It may have been a map of this kind which accounts for Ptolemy's moderate exaggerations of the size of Taprobana (Ceylon). A first meridian, separating a leeward from a windward region, passed through Ras Kumhari (Comorin) and was thus nearly identical with the first meridian of the Indian astronomer which passed through the sacred city of Ujjain (Ozere of Ptolemy) or the meridian of Azin of the Arabs. Additional meridians were drawn at intervals of *zams,* supposed to be equal to three hours' sail.

In China, maps in the olden time were engraved on bronze or stone, but after the 10th century they were printed from wood-blocks. Among the more important productions of more recent times may be mentioned a map of the empire, said to be based upon actual surveys by Yhang (721), who also manufactured a celestial globe (an older globe by Ho-shing-tien, 4m. in circumference was produced in 450), and an atlas of the empire on a large scale by Thu-sie-pun (1311–1312) of which new enlarged editions with many maps were published in the 16th century and in 1799. None of these maps was graduated, which is all the more surprising as the Chinese astronomers are credited with having made use of the gnomon as early as 1000 B.C. for determining latitudes.

In the case of Japan, the earliest reference to a map is of 646, in which year the emperor ordered surveys of certain provinces to be made.

Portolano Maps.—During the long period of stagnation in cartography, which we have already dealt with, there survived among the seamen of the Mediterranean charts of remarkable accuracy, illustrating the *Portolani* or sailing directories in use among them. They antedate 1270, and in the eastern part of the Mediterranean embody materials available even in the days before Ptolemy, while the correct delineation of the west seems to be of a later date, and many have been due to Catalan seamen. These charts are based upon estimated bearings and distances between the principal ports or capes, the intervening coast-line being filled in from more detailed surveys. The bearings were dependent upon the seaman's observation of the heavens, for these charts were in use long before the compass had been introduced on board ship (as early as 1205, according to Guiot de Provins). It is therefore misleading to describe them as *Compass or Loxodromic* charts, and they are now known as *Portolano* charts.

None of these charts is graduated, and the horizontal and vertical lines which cross many of them represent neither parallels nor meridians. Their most characteristic feature, and one by which they can most readily be recognized, is presented by groups or systems of rhumb-lines, each group of these lines radiating from a common centre, the central group being generally encircled by eight or 16 satellite groups. Each chart was furnished with a scale of Portolano miles whose length was only 1,233 metres.

On these old charts the Mediterranean is delineated with surprising fidelity. The meridian distance between the Straits of Gibraltar and Beirut in Syria amounts upon them to about 3,000 Portolano miles, equal in lat. 36° N. to 40·9°, as compared with an

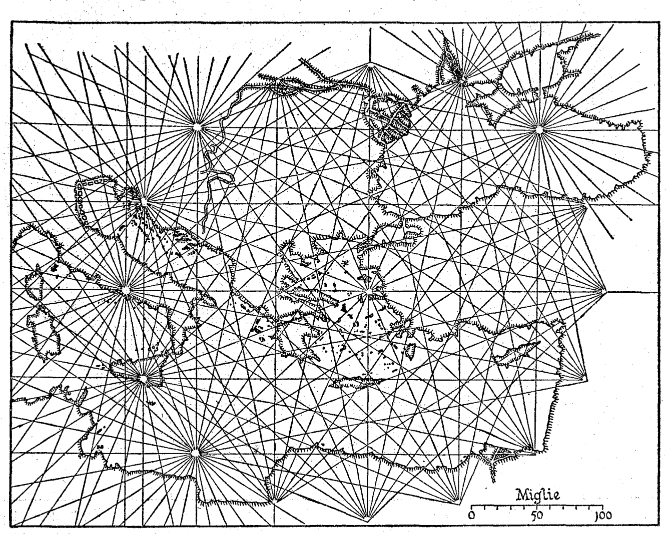

FIG. 8.—THE EASTERN MEDITERRANEAN, BY PETRUS VESCONTE (1311)

actual difference of 41·2°, and a difference of 61° assumed by Ptolemy. There exists, however, a serious error of orientation, due, according to Prof. H. Wagner, to the inexperience of the cartographers who first combined the charts of the separate basins of the Mediterranean so as to produce a chart of the whole. This accounts for Gibraltar and Alexandria being shown as lying due east and west of each other, although there is a difference of 5° of latitude between them, a fact known long before Ptolemy. The oldest of these maps which have been preserved, the so-called "Pisan chart," which belongs probably to the middle of the 13th century, and a set of eight charts, known by the name of its former owner, the Cavaliere Tamar Luxoro, of somewhat later date, are both the work of Genoese artists. Petrus Vesconte, who worked in 1311 and 1327, is the draughtsman of the maps illustrating Marino Sanuto's *Liber secretorum fidelium crucis,* which was to have roused Christendom to engage in another crusade (fig. 8).

The expansions of Portolano maps into maps of the world resemble the wheel maps of an earlier period. This is the character of the map of Petrus Vesconte of 1320, of that of Giovanni Leardo (1448) and of a Catalan map of 1450.

Very different in character is the Catalan map of 1375, for its author, discarding Ptolemy, shows India as a peninsula. On the other hand, an anonymous Genoese would-be reformer of maps (1457), still adheres to the erroneous Ptolemaic delineation of southern Asia, and the very same error is perpetuated by Henricus Marvellus Germanus on a rough map showing the Portuguese discoveries up to 1489. None of these maps is graduated, but if we give the Mediterranean a length of 3,000 Portolano miles, equivalent in 36° N. to 41°, then the longitudinal extent of the old world as measured on the Genoese map of 1457 would be 136° instead of 177° or more as given by Ptolemy.

The Revival of Ptolemy.—Ptolemy's great work became known in western Europe after Jacobus Angelus de Scarparia had translated it into Latin in 1410. This version was first printed in 1475 at Vicenza, but its contents had become known through ms. copies before this, and their study influenced the construction of maps in two respects. They led firstly to the addition of degree lines to maps, and secondly to the compilation of new maps of those countries which had been inadequately represented by Ptolemy. Thus Claudius Clavus Swartha (Niger), who was at Rome in 1424, compiled a map of the world, extending westward as far as Greenland. The learned Cardinal Nicolaus Krebs, of Cusa (Cues) on the Moselle, who died 1464, drew a map of Ger-

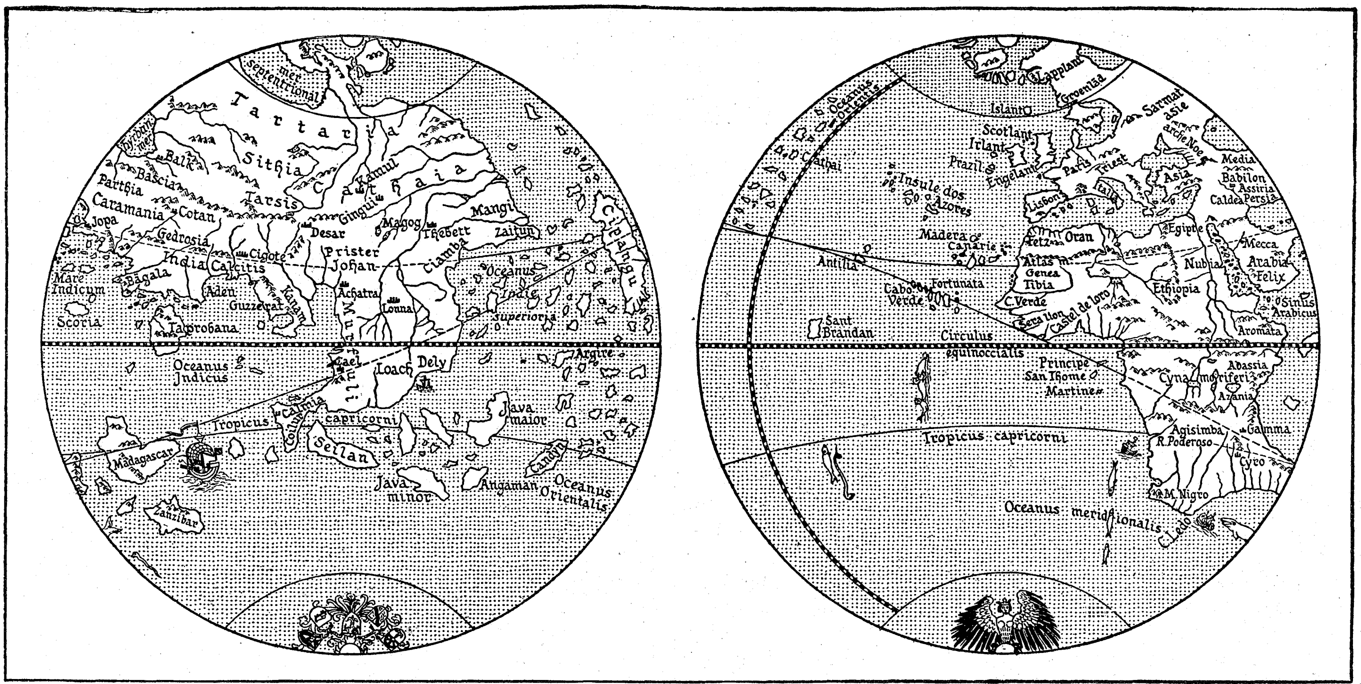

FIG. 9.—BEHAIM'S GLOBE

many which was first published in 1491; D. Nicolaus Germanus, a monk of Reichenbach, in 1466 prepared a set of Ptolemy's maps on a new projection with converging meridians; and Paolo del Pozzo Toscanelli in 1474 compiled a new chart on a rectangular projection, which was to guide the explorer across the western ocean to Cathay and India.

The geographical ideas which prevailed at the time Columbus started in search of Cathay may be most readily gathered from two contemporary globes, the one known as the Laon globe because it was picked up in 1860 at a curiosity shop in that town, the other produced at Nuremberg in 1492 by Martin Behaim. The information which it furnishes, in spite of a legend intended to lead us to believe that it presents us with the results of Portuguese explorations up to the year 1493, is of more ancient date. The Nuremberg globe (fig. 9), a work of a more ambitious order, was undertaken at the suggestion of George Holzschuher, a travelled member of the town council. The work was entrusted to Martin Behaim, who had resided for six years in Portugal and the Azores, and was believed to be a thoroughly qualified cosmographer. The globe is of pasteboard covered with whiting and parchment, and has a diameter of 507mm. (20 inches). The author followed Ptolemy not only in Asia, but also in the Mediterranean. He did not avail himself of the materials available in his day. Not even the coasts of western Africa are laid down correctly, although the author claimed to have taken part in one of the Portuguese expeditions. The ocean separating Europe from Asia is assumed as being only 126° wide, in accordance with Toscanelli's ideas of 1474. Very inadequate use has been made of the travels of Marco Polo, Nicolo de' Conti, and of others in the east.

The maritime discoveries and surveys of that age of great discoveries were laid down upon so-called "plane-charts," that is, charts having merely equidistant parallels indicated upon them, together with the equator, the tropics and polar circles, or, in a more advanced stage, meridians. For his longitude the mariner was dependent upon dead reckoning. Errors of 30° in longitude were by no means rare. It was only after the publication of Kepler's *Rudolphine Table* (1626) that more exact results could be obtained. A further difficulty arose in connection with the variation of the compass, which induced Pedro Reinel to introduce two scales of latitude on his map of the northern Atlantic (1504).

The chart of the world by Juan de la Cosa, the companion of Columbus, is the earliest extant which depicts the discoveries in the New World (1500), and there is the map which Alberto Cantino caused to be drawn at Lisbon for Hercules d'Este of Ferrara (1502), illustrating in addition the recent discoveries of the Portuguese in the East. Other cosmographers of distinction were Pedro Reinel (1504–42), Nuno Garcia de Toreno (1520), to whom we are indebted for 21 charts, illustrating Magellan's voyage, Diogo Ribero (maps of the world 1527, 1529), Alonzo de Santa Cruz, of Seville, whose *Isolario general* includes charts of all parts of the world (1541), John Rotz or Rut (1542), Sebastian Cabot (1544), as also Nicolas Desliens, Pierre Desceliers, G. Breton and V. Vallard, all of Arques, near Dieppe, whose charts were compiled between 1541 and 1554.

The Strasbourg Ptolemy of 1513 has a supplement of as many as 20 modern maps by Martin Waldseemüller or Ilacomilus, several among which are copied from Portuguese originals. Waldseemüller was one of the most distinguished cartographers of his day. He published in 1507 a map of the world, in 12 sheets, together with a small globe of a diameter of 110mm., the segments for which were printed from wood-blocks. On these documents the new world is called America, after Amerigo Vespucci.

Equally interesting with these Ptolemaic supplements are collections like that of Anton Lafreri, which contains reprints of 142 maps of all parts of the world originally published between 1556 and 1572 (*Geografica tavole moderne,* Rome, n.d.), or that of J. F. Camocio, published at Venice in 1576, which contains 88 reprints. The number of cartographers throughout Europe was considerable. Germany is represented by G. Glockendon, the author of an interesting road-map of central Europe (1501), Sebastian Münster (1489–1552), Elias Camerarius, whose map of the mark of Brandenburg won the praise of Mercator; Wolfgang Latz von Lazius, to whom we are indebted for maps of Austria and Hungary (1561), and Philip Apianus, who made a survey of Bavaria (1553–63), which was published 1568 on the reduced scale of 1:144,000, and is fairly described as the topographical masterpiece of the 16th century. For maps of Switzerland we are indebted to Konrad Türst (1495–97), Johann Stumpf (1548) and Aegidius Tschudi (1538). A map of the Netherlands from actual survey was produced by Jacob of Deventer (1536–39). Leonardo da Vinci, the famous artist, while in the service of Cesare Borgia as military engineer, made surveys of several districts in central Italy. New maps of Spain and Portugal appeared in 1560, the former being due to Pedro de Medina, the latter to Fernando Alvarez Secco and Hernando Alvaro. Among the French map-makers of this period may be mentioned Oronce Finé (Finaeus), who in 1525 published a map of France, and Jean Jolivet (*c.* 1560). Gregorio Lilly (1546) and Humphrey

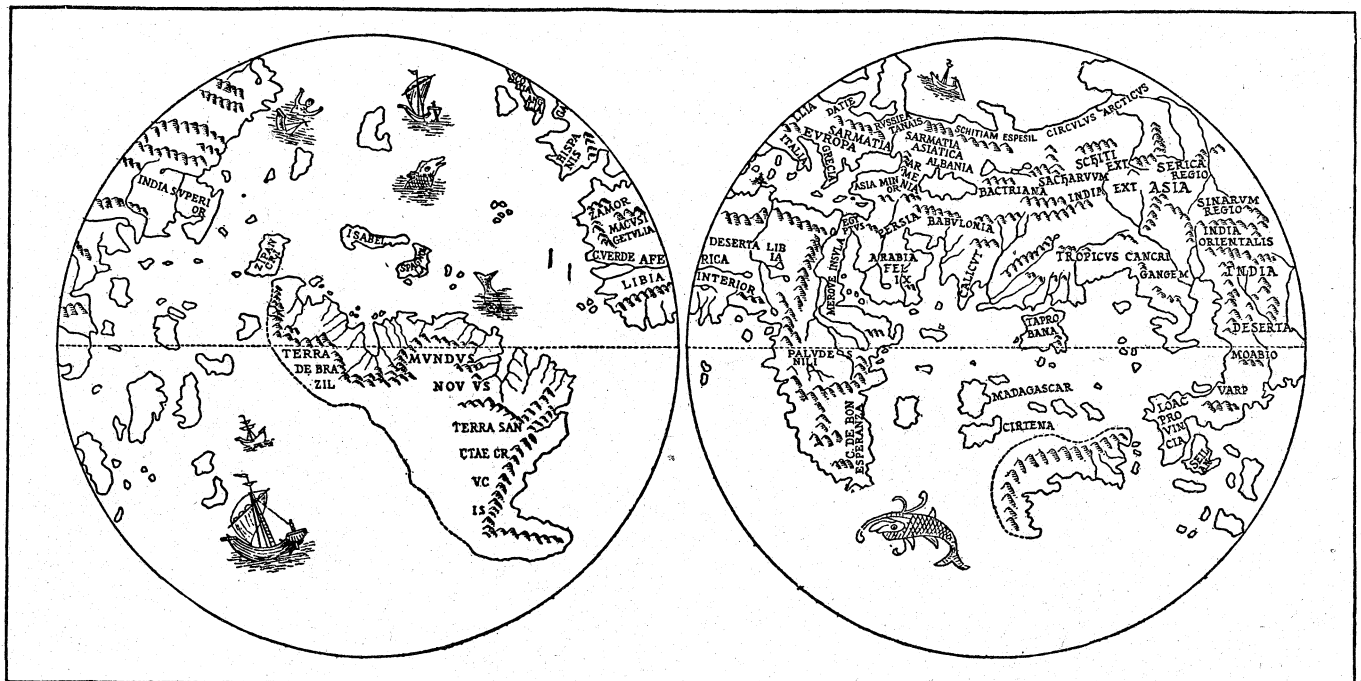

FIG. 10.—LENOX GLOBES (1510)

Lhuyd of Denbigh (d. 1510) furnished maps of the British Isles, Olaus Magnus (1539) of Scandinavia, Anton Wied (1542), Sigismund von Herberstein (1549) and Jenkinson (1562) of Muscovy.

The cylindrical and modified conical projections of Marinus and Ptolemy were still widely used, the stereographical projection of Hipparchus was for the first time employed for terrestrial maps in the 16th century, but new projections were introduced in addition to these. A trapeziform projection with equidistant parallels, by D. Nicolaus Germanus (1466), led to Flamsteed's projection. Joh. Stabius (1502) and his pupil J. Werner (1514) devised three heart-shaped projections, one of which was equal-area. Petrus Apianus (1524) gave his map an elliptical shape. H. Glareanus (1510) first employed an equidistant zenithal polar projection.

No reasonable fault can be found with the marine surveyors of this period, but the scientific cartographers allowed themselves too frequently to be influenced by Ptolemaic traditions. Any cartographer of the period in regions the successful delineation of which depended upon an intelligent interpretation of itineraries, and of information collected by recent travellers, is generally found to fail utterly.

Columbus, trusting to Toscanelli's misleading chart, looked upon the countries discovered by him as belonging to eastern Asia, a view still shared about 1507 by his brother Bartolomeo. Waldseemüller (1507) was the first to separate America and Asia by an ocean of considerable width, but J. Ruysch (1508) returns to the old idea, and even joins Greenland (Gruenlant) to eastern Asia.

Globes, both celestial and terrestrial, were popular after the discovery of America. They were included among the scientific apparatus of ships and of educational establishments. Columbus and Magellan had such globes, those of the latter produced by P. Reinel (1519), and Conrad Celtes tells us that he illustrated his lectures at the University of Vienna with the help of globes (1501). Since 1507, in which year Waldseemüller published a small globe of a diameter of 110mm., covered with printed segments or gores, this cheap and expeditious method has come into general use. Waldseemüller constructed his gores graphically. A. Dürer (1525) and Hen. Loriti Glareanus (1527) were the first who dealt scientifically with the principles of their construction.

Among engraved globes, one of the most interesting is that which was discovered by R. M. Hunt in Paris, and is now in the Lenox Library, New York (fig. 10). Its diameter is only 4½in. (127mm.).

Mercator and His Successors.—Of Gerhard Kremer (1512–94) the earliest works are a map of Palestine (1537), a map of the world on a double heart-shaped projection (1525), and a topographical map of Flanders based upon his own surveys (1540), a pair of globes (1541, diam. 120mm.), and a large map of Europe which has been praised deservedly for its accuracy (1554). He is best known by his marine chart (1569) (fig. 11) and his atlas. The projection of the former may have been suggested by W. Pirkheimer's note in his edition of Ptolemy (1525). Mercator constructed it graphically, the mathematical principles underlying it being first explained by E. Wright (1594). The "Atlas" was only published after Mercator's death, in 1595. It only contained nine maps, but after the plates had been sold to Jodocus (Jesse) Hondius the number of maps was rapidly increased, although Mercator's name was retained. Mercator's maps are carefully engraved on copper. Latin letters are used throughout; the miniatures of older maps are superseded by symbols, and in the better-known countries the maps are fairly correct, but they fail lamentably in regions of imperfect information.

Even before Mercator's death, Antwerp and Amsterdam had become great centres of cartographic activity, and they maintained their pre-eminence until the beginning of the 18th century. Lucas Janszon Waghenaer (Aurigarius) of Enkhuizen published the first edition of his *Spiegel der Zeevaart* (Mariners' Mirror) at Leiden in 1585. It was the first collection of marine maps, lived through many editions, was issued in several languages and became known as *Charettier* and *Waggoner*. Jodocus Hondius was mentioned as purchaser of Mercator's plates. In 1608 Hondius published a map of the world in 12 sheets, on Mercator's projection. Only one copy is known and this is in the possession of the Royal Geographical Society. E. Heawood has written a memoir on this map (1927). The business founded by him about 1602 was continued by his sons, his son-in-law, Jan Janszon (Jansonius) and others. Another map firm was established at Amsterdam in 1612 by Willem Janszon Blaeu (1571–1638), a friend of Tycho Brahe, from 1633 "mapmaker" of the States-General, and a man of scientific culture. He was succeeded by his son Jan (d. 1673) and grandson Cornelius, and before the end of the century turned out a *Zee-Spiegel* of 108 charts (1623).

In France, in the meantime, an arc of the meridian had been measured (1669–70) by Jean Picard, numerous longitudes had been observed between 1672 and 1680 by the same, and by Phil. de Lahire (d. 1719), and these were utilized in a *Carte de France* "as corrected from the observations of the members of the Academy of Sciences" (1666–1699), in a map of the world (1694)

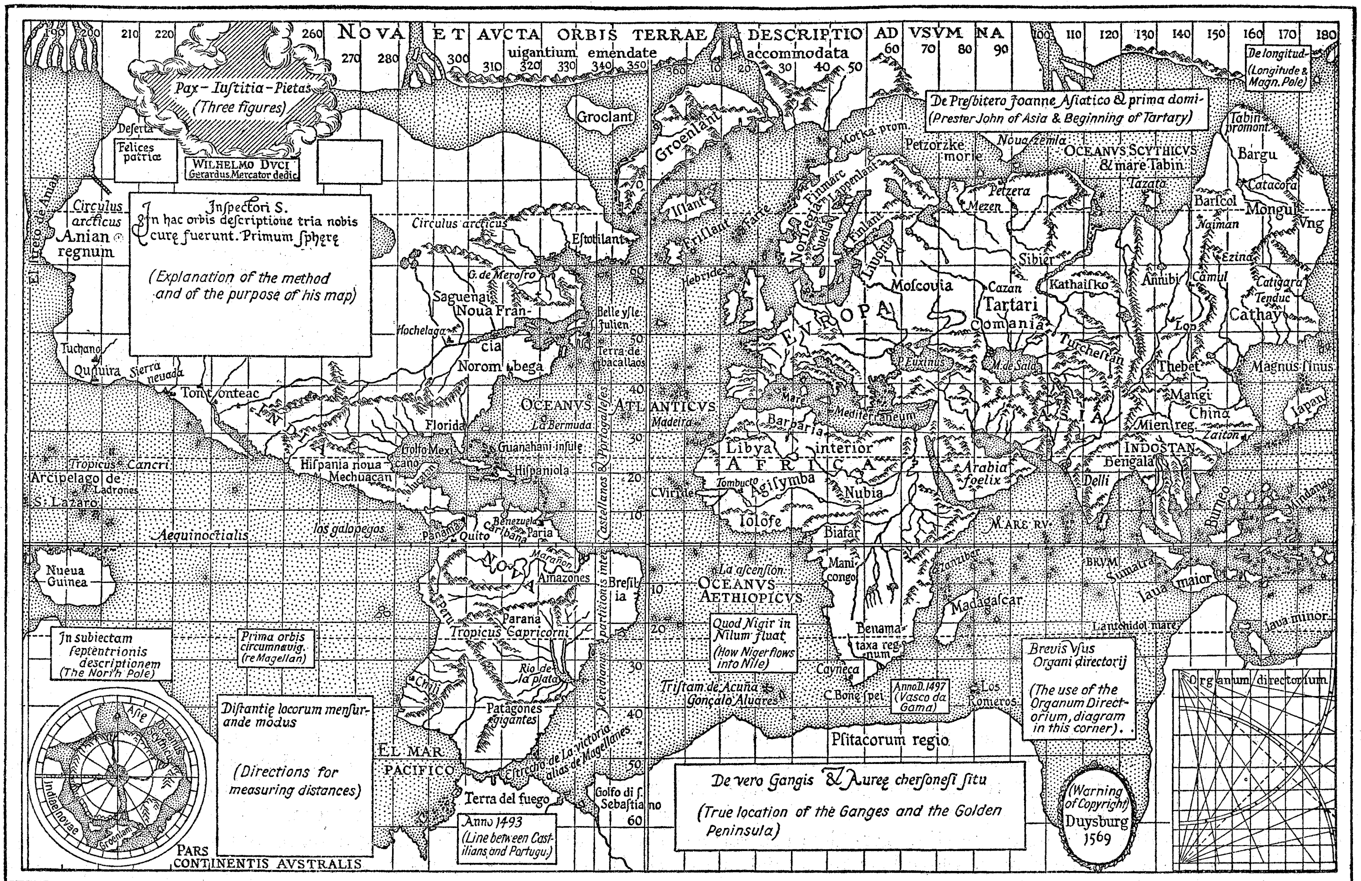

FIG. 11.—MERCATOR'S CHART OF THE WORLD (1569)

by D. Cassini, as also in *Le Neptune François* (1693) with contributions by Pene, D. Cassini and others. These corrected longitudes were not yet available for the maps produced by Nicolas Sanson of Abbeville, since 1627. The cartographical establishment founded by him in that year was carried on after his death in 1667 by his sons, his son-in-law, P. Duval (d. 1683) and his grandson Robert du Vaugondy (d. 1766).

In no other country of Europe was there at the close of the 16th century a geographical establishment capable of competing with the Dutch towns or with Sanson, but the number of those who produced maps, in many instances based upon original surveys, was large.

The first maps illustrating the variation of the compass were published by Chris. Burrus (d. 1632) and Athanasius Kircher (*Magnes,* Rome, 1643), and maps of the ocean and tidal currents by the latter in his *Mundus subterraneus* (1665). Edmund Halley, the astronomer, compiled the first variation chart of scientific value (1683), as also a chart of the winds (1686).

The Eighteenth Century.—It was no mere accident which enabled France to enjoy a pre-eminence in cartographic work during the greater part of the 18th century. Not only had French men of science and scientific travellers done excellent work as explorers in different parts of the world, but France could also boast of two men, Guillaume Delisle and J. B. Bourguignon d'Anville, able to utilize in the compilation of their maps the information they acquired.

Delisle (1675–1726) published 98 maps, and although as works of art they were inferior to the maps of certain contemporaries, they were far superior to them in scientific value. On one of his earliest maps compiled under advice of his father Claude (1700), he gave the Mediterranean its true longitudinal extension of 41°. It was Delisle who assumed the meridian of Ferro, which had been imposed upon French navigators by royal order (1634), to lie exactly 20° to the west of Paris. The work of reform was carried further by B. D'Anville (1697–1782). Altogether he published 211 maps, of which 66 are included in his *Atlas Général* (1737–80); he swept away the fanciful lakes from off the face of Africa, thus forcibly bringing home to us the poverty of our knowledge, delineated the Chinese empire in accordance with the map based on the surveys conducted during the reign of the emperor Kanghi, with the aid of Jesuit missionaries, and published in 1718; boldly refused to believe in the existence of an Antarctic continent covering half the southern hemisphere, and always brought a sound judgment to bear upon the materials which the ever-increasing number of travellers placed at his disposal. Among other French works of importance deserving notice are *Le Neptune oriental* of Mannevillette (1745) and more especially the *Carte géometrique de la France,* which is based upon surveys carried on (1744–83) by César François Cassini de Thury and his son Dominique de Cassini. It is on a transversal cylindrical (rectangular) projection devised by Jacques Cassini (d. 1746). The hills are shown in rough hachures.

England, which had entered upon a career of naval conquest and scientific exploration, had reason to be proud of J. F. W. Desbarres, *Atlantic Neptune* (1774), a North American pilot (1779), who first made known the naval surveys of Capt. Cook and of others; and Tho. Jefferys's *West Indian* and *American Atlases* (1775, 1778). James Rennell (1742–1830), who was surveyor-general of Bengal, published the *Bengal Atlas* (1781). Aaron Arrowsmith, who came to London in 1778, and his successors constitute the glory of the older school of cartographers. His nephew John died in 1873.

In Germany J. B. Homann (d. 1724) founded a geographical establishment in 1702, which depended at first upon copies of British and French maps, but in course of time published also original maps such as J. M. Hase's *Africa* (1727) and Tobias Meyer's *Mappa critica* of Germany (1780), J. T. Güssfeld's map of Brandenburg (1773), John Majer's Württemburg (1710) and J. C. Müller's Bavaria, both based on trigonometrical surveys. Col. Schmettau's excellent survey of the country to the west of the Weser (1767–87) was never published. Switzerland and other European states were worthily represented. Charts illustrating the variation of the compass and of magnetic "dip" were published by E. Dunn (1776) and J. C. Wiffe (1768). Map projections were dealt with by two eminent mathematicians, J. H. Lambert (1772) and Leonh. Euler (1777).

On the maps of Delisle and d'Anville the ground is still represented by "molehills." Hachures of a rude nature first made their appearance on David Vivier's map of the environs of Paris (1674), and on Cassini's *Carte de la France*. Contour lines (isobaths) were introduced for the first time on a chart of the Merwede by M. S. Cruquius (1728), and on a chart of the English Channel by Phil. Buache (1737). J. G. Lehmann (1783) based his hill-shading or hachuring upon these horizontal contours.

Modern Cartography.—The compiler of maps of the present day enjoys many advantages not enjoyed by men similarly occupied a hundred years ago. Topographical surveys are gradually extending, explorers are better trained for their work, and mere outline maps, such as formerly satisfied the public, suffice no longer.

As to atlases, from the middle to the end of the 19th century Germany might be considered as the headquarters of scientific cartography. This was due as much to the inspiriting teachings of Ritter and Humboldt as to the culture and scientific training combined with technical skill commanded by men who devote themselves to this branch of geography. H. Berghaus (1797–1884), H. Kiepert (1818–99) and A. Petermann (1822–78) must occupy a foremost place in the history of cartography. Among the geographical establishments of Germany, that founded by Justus Perthes (1785), at Gotha, occupies the highest rank. To it we are indebted for Petermann's *Mitteilungen*, started in 1855 by A. Petermann. Among other geographical institutes in Germany which deserve mention are the Weimar Institut, founded in 1791; Paul Fleming at Glogau, A. Ravenstein at Frankfort, D. Reimer at Berlin (H. Kiepert, *Handatlas*, 1860); R. Andree (*Hand-Atlas*, 1880) and E. Debes (*Hand-Atlas*, 1894) in Leipzig, and E. Hölzer in Vienna (Vincenz von Haardt's maps).

France is represented by the publishing firms of Ch. Delagrave (Levaseur's maps), Hachette (F. Schrader's *Atlas de géographie moderne*, 1880), and Armand Colin (Vidal de la Blache's *Atlas général*, 1894).

In Great Britain, A. Arrowsmith established himself in London in 1770 (*General Atlas*, 1817), but the cartographical business ceased on the death of John Arrowsmith in 1873. John Cary (1754–1835) produced a very large number of plans, road maps, maps and itineraries. His work is important in the history of British cartography. (*John Cary*, Cambridge University Press, 1925). To John Walker the charts published by the Admiralty were indebted for the perspicuous, firm and yet artistic execution which facilitated their use by the mariner. Among later firms are W. and A. K. Johnston (founded 1825; *Royal Atlas*, 1855); J. Bartholomew, whose publications have had a great effect in popularizing *hypsometrically* coloured maps; Philip and Sons; and E. Stanford.

Amongst recent Continental publications the magnificent *Atlante Internazionale del Touring Club Italiano*, Milan, 1927, deserves mention.

Bibliography.—The history of maps is dealt with ably in Vivien de Saint Martin's *Histoire de la géographie* (Paris, 1875), and in Peschel's *Geschichte der Erdkunde* (2nd ed., Sophus Ruge, Berlin, 1877), as also by W. Wollkenhauer (*Leitfaden zur Geschichte der Kartographie*, Breslau, 1895), and H. Zondervan (*Allgemeine Kartenkunde*, Leipzig, 1901). There are a number of works, beautifully illustrated, which deal fully with particular periods of the subject. Among these may be mentioned Konrad Miller's *Die ältesten Weltkarten* (Stuttgart, 1895–97). The contents of the following collections are more varied in their nature, viz., E. F. Jomard's *Monuments de la géographie* (Paris, 1862), Santarem's *Atlas composé de mappemondes et de portulans*, etc. (Paris, 1842–53, 78 plates), A. E. Nordenskiöld's *Facsimile Atlas* (Stockholm, 1889), Gabriel Marcell, *Choix de cartes et de mappemondes XIV^{e} et XV^{e} siècles* (Paris, 1896), C. H. Coote's *Remarkable Maps of the XVth, XVIth and XVIIth Centuries reproduced in their Original Size* (Amsterdam, 1894–97), and *Bibliotheca lindesiana* (London, 1898) with facsimiles of the Harleian and other Dieppese maps of the 16th century. Nautical charts are dealt with in A. E. Nordenskiöld's *Periplus* (Stockholm, 1869), and Th. Fischer's *Sammlung mittelälterlicher Welt- und Seekarten* (Vienna, 1886). The discovery and mapping of America are illustrated by F. Kunstmann's *Entdeckung Amerikas* (Munich, 1859), K. Kretschmer's *Atlas zur Entdeckung Amerikas* (Berlin, 1892), G. Marcel's *Reproductions de cartes et de globes relatives à la découverte de l'Amerique du XVI^{e} au XVIII^{e} siècle* (Paris, 1893) and E. L. Stevenson's *Maps Illustrating the early Discovery and Exploration of America, 1502–1530* (New Brunswick, N.J., 1906). An important guide to the subject of British cartography is Sir G. Fordham's *Hand-List of Catalogues and Works of Reference relating to Carto-bibliography for Great Britain and Ireland*, Camb. Univ. Press (1928). (E. G. R.; C. F. A. C.)

MODERN MAPS

From the middle of the 18th century to the early part of the 19th was a period which witnessed the beginning of regular topographical surveys in many countries. Thus, in France, Cassini de Thury commenced the first regular topographical map in 1744. The scale of this map was 1:86,400. In 1817 the *Carte de France de l'état major,* on the scale of 1:80,000, was begun, but this was not finished until 1880. These were both engraved on copper.

In Great Britain the Ordnance Survey was founded in 1791; its original purpose was the construction of a map on the scale of 1in. to 1m., or 1:63,360. The survey of Ireland on the scale of 6in. to 1m. was commenced in 1825. Great Britain and Ireland have been mapped on the scale of 1:2,500, or about 25in. to 1m., excepting only waste and mountainous areas. Both the large-scale maps and the small-scale maps of Great Britain (1in., $\frac{1}{2}$in. and $\frac{1}{4}$in. to the mile), are revised periodically.

By the middle of the 19th century topographical maps of the various German States were complete. The Austrian 1:75,000 series was completed in 1889. The famous map of Switzerland, with which is associated the name of Gen. Dufour, was finished in 1865; it is on the scale of 1:100,000. Generally speaking, we may say that during the 19th century all European States except Russia had completed their small-scale mapping, and the sheets were, as a rule, printed from engraved copper plates. In India, Maj. James Rennell commenced the first reliable surveys of Bengal in 1764, and the Survey of India has, since that date, continued to map the Indian empire.

The scales adopted by the United States Geological Survey, which carries out the topographical mapping, are 1:62,500, 1:125,000 and 1:250,000. The continent of Africa is slowly being surveyed on topographical scales, the early topographical surveys being mainly those along the international boundaries, needed for the partition of Africa, which began in 1884.

International Map of the World.—The official title of this international undertaking is *Carte du Monde au Millionième,* and references to it will generally be found under this title. It owes its origin to the initiative of Prof. A. Penck, who put forward the project of a map of the world on a uniform scale at the Geographical Congress held at Berne in 1891. The scale proposed was one-millionth of nature, equivalent to 1km. to 1 millimetre. The scheme and the scale were accepted by the congress, and an international, but unofficial, committee was appointed for the purpose of prosecuting the idea. This committee reported to successive Geographical Congresses held in London in 1895, in Berlin in 1899 and in Washington in 1904, but slight progress was made.

An important step was, however, taken at the Geographical Congress held at Geneva in 1908. At this congress the delegates of the United States made a proposal for the definite standardization of the map and for the drawing-up of fixed rules to govern its production. The geographical section of the British general staff took up the subject and an official conference was effected.

In Nov. 1909 the official conference assembled at the Foreign Office in London. The conference came to unanimous conclusions, and an account of it was published in a report issued by the British Government.

At the Geographical Congress at Rome in 1913 the scheme as formulated in London was accepted generally, but there was a feeling that a more comprehensive official conference was needed in order to put the matter before those countries not hitherto represented officially. An official conference was accordingly held in Paris in Dec. 1913. Thirty-four States sent representatives, and a very thorough examination was made of the London resolutions. In the main they were accepted, and the modifications made were of detail only. The *Carte du Monde au Millionième* is now a world undertaking on lines accepted by practically all civilized countries.

The Paris Conference approved the establishment of a *"bureau permanent,"* comprising a central office at the headquarters of the Ordnance Survey at Southampton, with a branch office at the Royal Geographical Society.

A third Conference was held in London in July, 1928, to decide some points of detail which had arisen since 1913. These were settled unanimously.

MAPS FOR WAR PURPOSES

The Paris Conference concluded on Dec. 18, 1913, but the report was not published when war broke out early in Aug. 1914. The effect of the war on the scheme was twofold. First, it resulted in the immediate cessation of all work on the map so far as the belligerent countries were concerned; but in the second place it led to a demand for maps on, or about, the one-to-a-million scale. In England and France much official cartography was carried out on the million scale. A large series of maps, the initiative of the general staff, were compiled by the Royal Geographical Society.

This important series comprises 90 maps extending from the Persian gulf to the Arctic ocean, and from the western shores of Ireland to beyond the Caspian sea.

The trench warfare of 1914–18 in France and Belgium created a demand for maps on a larger scale than had hitherto been in general use by great armies, and large-scale maps became indispensable for the operations of trench warfare, particularly in connection with the use of artillery. Eventually all the maps of the western front were redrawn from special surveys, the chief scale being 1:20,000.

MAP PROJECTIONS

In the construction of maps, one finds the sphere cannot be opened out into a plane like the cone or cylinder; consequently in a plane representation of configurations on a sphere it is impossible to retain throughout the proportions of lines or areas or equality of angles, though we may have in the representation similarity to all very small portions of the original, but at the expense of the areas, which will be quite misrepresented; or we may retain equality of areas if we give up the idea of similarity. A globe of ordinary dimensions serves scarcely any other purpose than to convey a clear conception of the earth's surface as a whole. For this purpose it is absolutely essential. The construction of a map resolves itself into the drawing of two sets of lines, one set to represent meridians, the other to represent parallels.

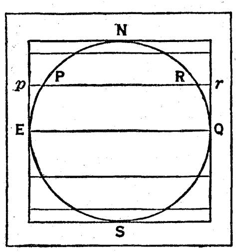

FIG. 12

Cylindrical Equal Area Projection.—Let us suppose a model of the earth to be enveloped by a cylinder in such a way that the cylinder touches the equator, and let the plane of each parallel such as PR be prolonged to intersect the cylinder in the circle *pr* (fig. 12). Now unroll the cylinder and the projection will appear as in fig. 13. The whole world is now represented as a rectangle, each parallel is a straight line, and its total length is the same as that of the equator, the distance of each parallel from the equator is sin l (where l is the latitude and the radius of the model earth is taken as unity). The meridians are parallel straight lines spaced at equal distances.

This projection possesses an important property: each strip of the projection is *equal in area* to the zone on the model which it represents, and that each portion of a strip is equal in area to the corresponding portion of a zone. Any figure, of any shape on the model, is correctly represented as regards area by its corresponding figure on the projection. This is "the cylindrical equal-area projection." It is clear that in this case all meridian lengths are too small and all lengths along the parallels, except the equator, are too large; thus although the areas are preserved the shapes are, especially away from the equator, much distorted. The property of preserving areas is, however, a valuable one when the purpose of the map is to exhibit areas. Mercator's projection commonly used in atlases, preserves local shape at the expense of area.

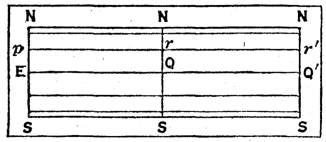

FIG. 13

PERSPECTIVE PROJECTIONS

In perspective drawings of the sphere, the plane on which the representation is actually made may generally be any plane perpendicular to the line joining the centre of the sphere and the point of vision. If V be the point of vision, P any point on the spherical surface, then *p,* the point in which the straight line VP intersects the plane of the representation, is the projection of P.

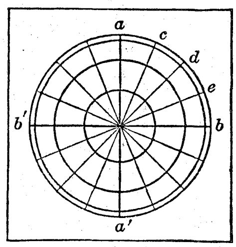

FIG. 14

Orthographic Projection.—In this projection the point of vision is at an infinite distance and the rays consequently parallel; in this case the plane of the drawing may be supposed to pass through the centre of the sphere. Let the circle (fig. 14) represent the plane of the equator on which we propose to make an orthographic representation of meridians and parallels. The centre of this circle is clearly the projection of the pole, and the parallels are projected into circles having the pole for a common centre. The diameters *aa′*, *bb′* being at right angles, let the semicircle *bab′*, be divided into the required number of equal parts; the diameters drawn through these points are the projections of meridians. It is clear that, when the points of division are very close, the parallels will be very much crowded towards the outside of the map; so much so, that this projection is not much used.

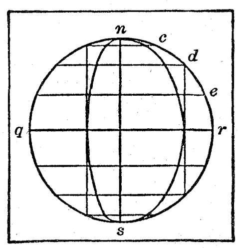

FIG. 15

For an orthographic projection of the globe on a meridian plane let *qnrs* (fig. 15) be the meridian, *ns* the axis of rotation, then *qr* is the projection of the equator. The parallels will be represented by straight lines passing through the points of equal division; these lines are, like the equator, perpendicular to *ns*. The meridians will in this case be ellipses described on *ns* as a common major axis, the distances of *c*, of *d* and of *e* from *ns* being the minor semiaxes.

Fig. 16 shows an orthographic projection of the sphere on the horizon of any place.

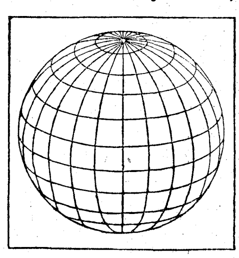

FIG. 16

Stereographic Projection.—In this case the point of vision is on the surface, and the projection is made on the plane of the great circle whose pole is V. Let *kpl*V (fig. 17) be a great circle through the point of vision, and *ors* the trace of the plane of projection. Let *c* be the centre of a small circle whose radius is $cp = cl$.

Since the representation of every infinitely small circle on the surface is itself a circle, it follows that in this projection the representation of small parts is strictly similar. Another inference is that the angle in which two lines on the sphere intersect is represented by the same angle in the projection. In this projection the angles are correctly represented and every small triangle is represented by a similar triangle. Projections having this property are called *orthomorphic* or *conformable.*

External Perspective Projection.—We now come to the general case in which the point of vision has any position outside the sphere. Let *abcd* (fig. 19) be the great circle section of the sphere by a plane passing through *c*, the central point of the portion of surface to be represented, and *V* the point of vision. Let *pj* perpendicular to *Vc* be the plane of representation, join *mV* cutting *pj* in *f*, then *f* is the projection of any point *m* in the circle *abc*, and *ef* is the representation of *cm* (see *Phil. Mag.* 1862).

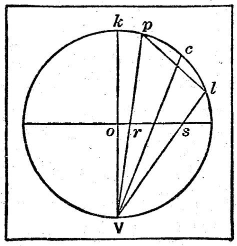

FIG. 17

Clarke's Projection.—The constants *h* and *k* can be determined, so that the total misrepresentation, viz.:

$$M=\int_0^\beta \{(\sigma-1)^2+(\sigma'-1)^2\}\sin u\,du,$$

shall be a minimum, β being the greatest value of *u*, or the spherical radius of the map. Fig. 20 is a map of Asia having the meridians and parallels laid down on this system.

Central or Gnomonic (Perspective) Projection.—In this projection the eye is imagined to be at the centre of the sphere. It is evident that, since the planes of all great circles of the sphere

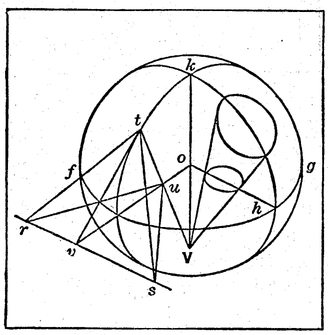

FIG. 18

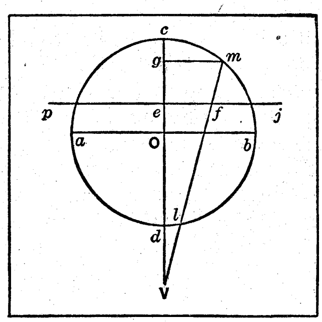

FIG. 19

pass through the centre, the representations of all great circles on this projection will be straight lines, and this is the special property of the *central projection*, that any great circle (*i.e.*, short-

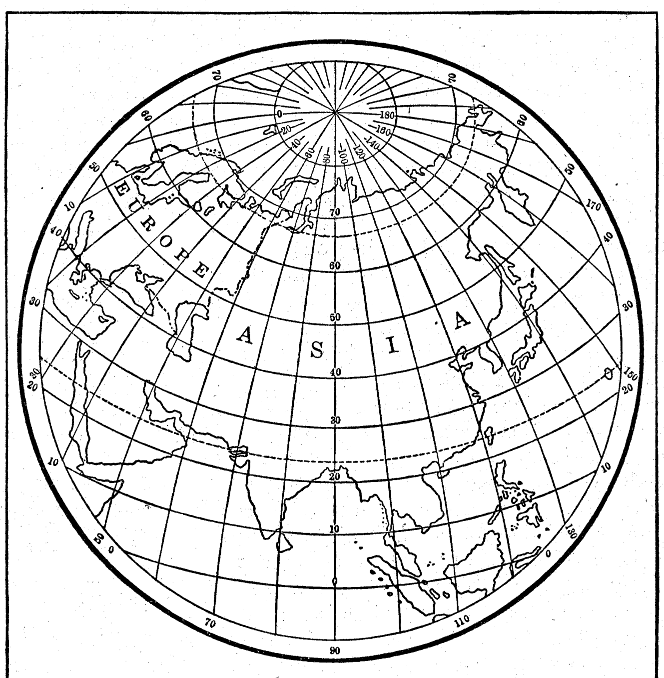

FIG. 20

est line on the spherical surface) is represented by a straight line. The plane of projection may be either parallel to the plane of the equator, in which case the parallels are represented by concentric circles and the meridians by straight lines radiating from the common centre; it may be parallel to the plane of some meridian, the meridians being parallel straight lines and the parallels hyperbolas; or it may be inclined to the axis of the sphere at any angle λ, in which case the central meridian is a straight line at right angles to the equator, which is also a straight line (fig. 10). These three varieties of the central projection are known as polar, meridian or horizontal.

Fig. 22 is an example of a *meridian central projection* of part of the Atlantic ocean. The term *gnomonic* was applied to this projection because the projection of the meridians is a similar problem to that of the graduation of a sun-dial. The gnomonic projection is useful for the study of direct routes by sea and land. The United States hydrographic department has published some charts on this projection. False notions of the direction of shortest lines, which are engendered by a study of maps on Mercator's projection, may be corrected by an inspection of maps drawn on the central projection.

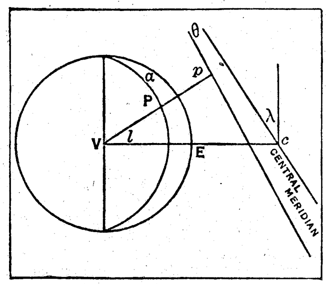

FIG. 21

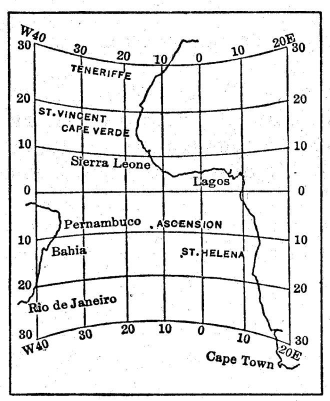

TEXTBOOK OF TOPOGRAPHICAL SURVEYING BY PERMISSION OF THE CONTROLLER OF H. M. STATIONERY OFFICE
FIG. 22

Until 1922 it was thought that the gnomonic was the only projection which showed the great circles as straight lines, but H. Maurer has shown that, if the projection be compressed uniformly in any direction, the great circles will still be represented as straight lines. He calls this new projection *orthodromic.*

Moreover, there are two points in this projection which have the property that azimuths from them to any other points are correct. This gives a means for plotting ships' positions from bearings sent by wireless from two points (*see Zeitschrift für Vermessungswesen,* 1922.

CONICAL PROJECTIONS

Conical projections are those in which the parallels are represented by concentric circles and the meridians by equally spaced radii. There is no necessary connection between a conical projection and any touching or secant cone. Projections which are derived by geometrical construction from secant cones exhibit large errors, and will not be discussed.

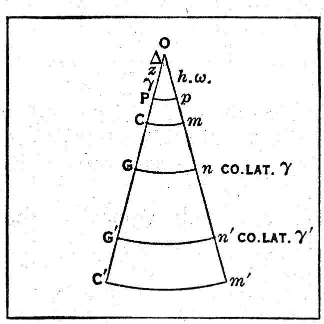

FIG. 23

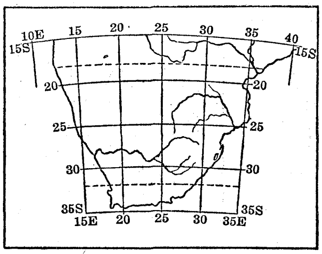
Conical Projection with Rectified Meridians and Two Standard Parallels.—In some books this has been termed the "secant conical," the use of which term has caused much confusion. Two selected parallels are represented by concentric circular arcs of their true lengths; the meridians are their radii. The degrees along the meridians are represented by their true lengths; and the other parallels are circular arcs through points so determined and are concentric with the chosen parallels.

Thus in fig. 23 two parallels *Gn* and *G'n'* are represented by their true lengths on the sphere; all the distances along the meridians *PGG'*, *pnn'* are the true spherical lengths rectified. Let γ be the co-latitude of *Gn*; γ' that of *Gn'*; ω be the true difference of longitude of *PGG'* and *pnn'*; $h\omega$ be the angle at *O*; and $OP=z$, where *Pp* is the representation of the pole. Then the true length of parallel *Gn* on the sphere is $\omega \sin \gamma$, and this is equal to the length on the projection. The radius of the sphere is assumed to be unity, and z and γ are expressed in circular measure, hence h and z are easily found. It has been assumed that the two errorless parallels have been *selected*, but it is usually desirable to impose some condition which itself will fix the errorless parallels. In fig. 23 let Cm and $C'm'$ represent the extreme parallels of the map, and let the co-latitudes of these parallels be c and c', then any one of the following conditions may be fulfilled:



TEXTBOOK OF TOPOGRAPHICAL SURVEYING BY PERMISSION OF THE CONTROLLER OF H. M. STATIONERY OFFICE

FIG. 24

(a) The errors of scale of the extreme parallels may be made equal and may be equated to the error of scale of the parallel of maximum error (which is near the mean parallel). This class of projection is accurate, simple and useful.

(b) Or the errors of scale of the extreme parallels may be equated to that of the mean parallel.

(c) Or the absolute errors of the extreme and mean parallels may be equated.

(d) Or in the last the parallel of maximum error may be considered instead of the mean parallel.

(e) Or the mean length of all the parallels may be made correct. This is equivalent to making the total area between the extreme parallels correct, and must be combined with another condition, for example, that the errors of scale on the extreme parallels shall be equal.

Simple Conical Projection.—If in the last group of projections the two selected parallels which are to be errorless approach each other, we get a projection in which all the meridians are of the true rectified lengths and in which one parallel is errorless, the curvature of that parallel being clearly that which would result from the unrolling of a cone touching the sphere along the parallel represented.

Imagine a cone to touch the sphere along any selected parallel, the radius of this parallel on paper (Pp, fig. 25) will be $r \cot \phi$, where r is the radius of the sphere and ϕ is the latitude; or if the spheroidal shape is taken into account, the radius of the parallel on paper will be $\nu \cot \phi$ where ν is the normal terminated by the minor axis (the value ν can be found from ordinary geodetic tables). The meridians are generators of the cone and every parallel such as HH' is a circle, concentric with the selected parallel Pp and distant from it the true rectified length of the meridian arc between them.

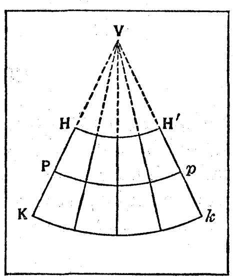


FIG. 25

The errors of scale along the parallels increase rapidly as the selected parallel is departed from, the parallels on paper being always too large. The projection has no merits as compared with the group just described.

Bonne's Projection is derived from the simple conical in the following way: a central meridian is chosen and drawn as a straight line; degrees of latitude spaced at the true rectified distances are marked along this line; the parallels are concentric circular arcs drawn through the proper points on the central meridian, the centre of the arcs being fixed by describing one chosen parallel with a radius of $\nu \cot \phi$; the meridians on each side of the central meridian are drawn through distances at the true lengths along the parallels on sphere or spheroid (fig. 26).

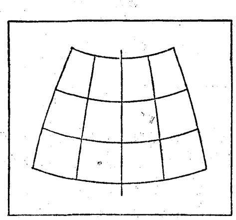

FIG. 26

This system is ill-adapted for countries having great extent in longitude. Where an equal-area projection is required for a country such as France, Scotland or Madagascar, this projection is a good one.

Sinusoidal Equal-area Projection, sometimes known as Sanson's and sometimes incorrectly called Flamsteed's, is a particular case of Bonne's in which the selected parallel is the equator. It is a very suitable projection for an equal-area map of Africa (fig. 27).

POLYCONIC PROJECTIONS

These pseudo-conical projections are valuable not so much for their intrinsic merits as for the fact that they lend themselves to tabulation. There are two forms, the *simple* or *equidistant polyconic*, and the *rectangular polyconic*.

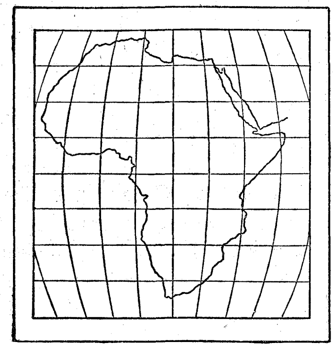

FIG. 27

The Simple Polyconic.—If a cone touches the sphere or spheroid along a parallel of latitude ϕ and is then unrolled, the parallel will on paper have a radius of $\nu \cot \phi$, where ν is the normal terminated by the minor axis. If we imagine a series of cones, each of which touches one of a selected series of parallels, the apex of each cone will lie on the prolonged axis of the spheroid; the generators of each cone lie in meridian planes, and if each cone is unrolled and the generators in any one plane are superposed to form a straight central meridian, we obtain a projection in which the central meridian is a straight line and the parallels are circular arcs each of which has a different centre which lies on the prolongation of the central meridian, the radius of any parallel being $\nu \cot \phi$.

So far the construction is the same for both forms of polyconic. In the *simple polyconic* the meridians are obtained by measuring outwards from the central meridian along each parallel the true lengths of the degrees of longitude. Through corresponding points so found the meridian curves are drawn. The resulting projection is accurate near the central meridian, but, as this is departed from, the parallels increasingly separate from each other, and the parallels and meridians (except along the equator) intersect at angles which increasingly differ from a right angle. The real merit of the projection is that each particular parallel has for every map the same absolute radius, and it is thus easy to construct tables which shall be of universal use. The simple polyconic when used for single sheets and large scales is a sufficiently close approximation to the better forms of conical projection.

Rectangular Polyconic.—In this the central meridian and the parallels are drawn as in the simple polyconic, but the meridians are curves which cut the parallels at right angles.

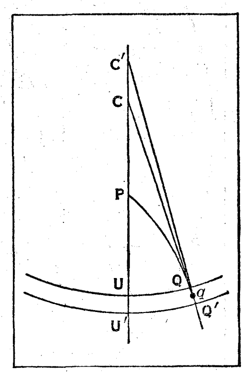

FIG. 28

Let P (fig. 28) be the north pole, CPU the central meridian, U, U' points in that meridian whose co-latitudes are z and $z+dz$. Make $PU=z$, $UC=\tan z$, $U'C'=\tan (z+dz)$; and with CC' as centres describe the arcs UQ, $U'Q'$, which represent the parallels of co-latitude z and $z+dz$. Let PQQ' be part of a meridian curve cutting the parallels at right angles. Join CQ, $C'Q'$; these will be tangents to the curve. Let $UCQ=2\alpha$, $UC'Q'=2(\alpha+d\alpha)$, then the angle between the tangents at QQ', will $=2d\alpha$. Now

$$CC'=\tan (z+dz)-\tan z-dz=\tan^2 z dz.$$

The tangents CQ, CQ' will intersect at q, and in the triangle $CC'q$ the perpendicular from C on $C'q$ is (omitting small quantities of the second order) equal to either side of the equation

$$\tan^2 z dz \sin 2\alpha = -2 \tan z d\alpha.$$
$$-\tan z dz = 2d\alpha / \sin 2\alpha,$$

which is the differential equation of the meridian: the integral is $\tan\alpha = \omega\cos z$, where ω, a constant, determines a particular meridian curve. The distance of Q from the central meridian, $\tan z \sin 2\alpha$, is equal to

$$\frac{2\tan z \tan\alpha}{1+\tan^2\alpha} = \frac{2\omega\sin z}{1+\omega^2\cos^2 z}$$

At the equator this becomes simply 2ω. Let any equatorial point whose actual longitude is 2ω be represented by a point on the developed equator at the distance 2ω from the central meridian, then we have the very simple construction (due to O'Farrell of the Ordnance Survey) (fig. 29).

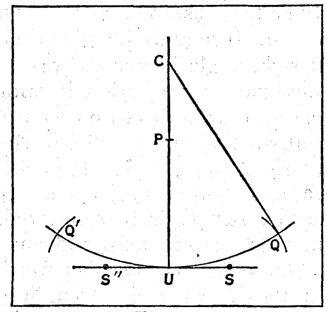

FIG. 29

ZENITHAL PROJECTIONS

Some point on the earth is selected as the central point of the map; great circles radiating from this point are represented by straight lines which are inclined at their true angles at the point of intersection. Distances along the radiating lines vary according to any law outwards from the centre. It follows (on the spherical assumption), that circles of which the selected point is the centre are also circles on the projection. It is obvious that all perspective projections are zenithal.

Equidistant Zenithal Projection.—In this projection, which is commonly called the "equidistant projection," any point on the sphere being taken as the centre of the map, great circles through this point are represented by straight lines of the true rectified lengths, and intersect each other at the true angles.

If z_1 is the co-latitude of the centre of the map, z the co-latitude of any other point, α the difference of longitude of the two points, A the azimuth of the line joining them, and c the spherical length of the line joining them, then the position of the intersection of any meridian with any parallel is given (on the spherical assumption) by the solution of a simple spherical triangle. Thus, let $\tan\theta = \tan z \cos\alpha$, then $\cos c = \cos z \sec\theta \cos(z-\theta)$, and $\sin A = \sin z \sin\alpha \operatorname{cosec} c$.

The most useful case is that in which the central point is the pole; the meridians are straight lines inclined to each other at the true angular differences of longitude, and the parallels are equidistant circles with the pole as centre. This is the best projection to use for maps exhibiting the progress of polar discovery, and is called the *polar equidistant projection*. The errors are smaller than might be supposed. There are no scale errors along the meridians, and along the parallels the scale error is $(z/\sin z) - 1$.

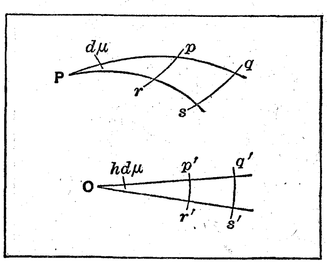

FIG. 30

General Theory of Zenithal Projections.—For the sake of simplicity it will be at first assumed that the pole is the centre of the map, and that the earth is a sphere. The meridians are now straight lines diverging from the pole, and the parallels are represented by circles having the pole as centre, the radius of the parallel whose co-latitude is z being ρ, a function of z determining the nature of the projection.

Let Ppq, Prs (fig. 30) be two contiguous meridians crossed by parallels rp, sq, and $Op'q'$, $Or's'$ the straight lines representing these meridians. If the angle at P is $d\mu$, this also is the value of the angle at O. Let

$$Pp = z,\ Pq = z+dz;\ Op' = \rho,\ Oq' = \rho+d\rho,$$

the circular arcs $p'r'$, $q's'$ representing the parallels pr, qs. If the radius of the sphere be unity,

$$p'q' = d\rho;\quad p'r' = \rho\,d\mu,$$
$$pq = dz;\quad pr = \sin z\,d\mu.$$

Put $\sigma = d\rho/dz$; $\sigma' = \rho/\sin z$,

then $p'q' = \sigma pq$ and $p'r' = \sigma' pr$. That is to say, σ, σ' may be regarded as the relative scales, at co-latitude z, of the representation, σ applying to meridional measurements, σ' to measurements perpendicular to the meridian. A small square situated in co-latitude z, having one side in the direction of the meridian—the length of its side being i—is represented by a rectangle whose sides are $i\sigma$ and $i\sigma'$; its area consequently is $i^2\sigma\sigma'$. If it were possible to make a perfect representation, then we should have $\sigma = 1$, $\sigma' = 1$ throughout. This, however, is impossible.

We may make $\sigma = 1$ throughout by taking $\rho = z$. This is the *Equidistant Projection*, a very simple and effective method of representation.

If we make $\sigma' = 1$ throughout this gives $\rho = \sin z$, a perspective projection, namely, the *Orthographic*.

We may require that areas be strictly represented in the development. This will be effected by making $\sigma\sigma' = 1$, or $\rho\,d\rho = \sin z\,dz$, the integral of which is $\rho = 2\sin\frac{1}{2}z$, which is the *Zenithal Equal-area Projection* of Lambert, sometimes wrongly referred to as *Lorgna's Projection* after Antonio Lorgna (b. 1736). In this system there is misrepresentation of form, but no misrepresentation of areas.

We may require a projection in which all small parts are to be represented in their true forms, *i.e.*, an orthomorphic projection. This condition will be attained by making $\sigma = \sigma'$, or $d\rho/\rho = dz/\sin z$, the integral of which is, c being an arbitrary constant, $\rho = c\tan\frac{1}{2}z$. This, again, is a perspective projection, namely, the *Stereographic*. In this the *whole* is not a similar representation of the original. The scale, $\sigma = \frac{1}{2}c\sec^2\frac{1}{2}z$, at any point, applies to all directions round that point.

These two last projections are, as it were, at the extremes of the scale. We may avoid both extremes by the following considerations. Although we cannot make $\sigma = 1$ and $\sigma' = 1$, so as to have a perfect picture of the spherical surface, yet considering $\sigma - 1$ and $\sigma' - 1$ as the local errors of the representation, we may make $(\sigma-1)^2 + (\sigma'-1)^2$ a minimum over the whole surface to be represented. This projection, known as the *Projection by Balance of Errors*, is due to Sir George Airy (*q.v.*). Airy's investigation was corrected by Clarke (*Phil. Mag.* 1862), and A. E. Young has extended the principle to the conical class generally (see *Some Investigations in the Theory of Map Projections*, 1920).

GENERAL THEORY OF CONICAL PROJECTIONS

Meridians are represented by straight lines drawn through a point, and a difference of longitude ω is represented by an angle $h\omega$. The parallels of latitude are circular arcs, all having as centre the point of divergence of the meridian lines.

Let z be the co-latitude of a parallel, and ρ, a function of z, the radius of the circle representing this parallel. Consider the infinitely small space on the sphere contained by two consecutive meridians, the difference of whose longitude is $d\mu$, and two consecutive parallels whose co-latitudes are z and $z+dz$ (fig. 31). The sides of this rectangle are $pq = dz$, $pr = \sin z\,d\mu$; in the projection $p'q'r's'$ these become $p'q' = d\rho$, and $p'r' = \rho h\,d\mu$.

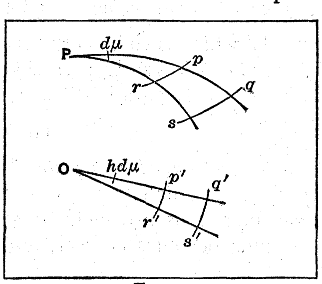

FIG. 31

The scales of the projection as compared with the sphere are $p'q'/pq = d\rho/dz =$ the scale of meridian measurements $= \sigma$, say, and $p'r'/pr = \rho h\,d\mu/\sin z\,d\mu = \rho h/\sin z =$ scale of measurements perpendicular to the meridian $= \sigma'$, say.

Now we may make $\sigma = 1$ throughout, then $\rho = z + \text{const}$. This gives either the group of *conical projections with rectified meridians*, or as a particular case the *equidistant zenithal*.

We may make $\sigma = \sigma'$ throughout, which is the same as requiring that at any point the scale shall be the same in all directions. This gives a group of *orthomorphic projections*.

In this case $d\rho/dz=\rho h/\sin z$, or $d\rho/\rho=hdz/\sin z$.

Integrating, $$\rho=k(\tan\tfrac{1}{2}z)^h, \qquad \text{(i.)}$$

where k is a constant.

Now h is at our disposal and we may give it such a value that two selected parallels are of the correct lengths. Let z_1, z_2 be the co-latitudes of these parallels, then it can be shown that

$$h=\frac{\log\sin z_1-\log\sin z_2}{\log\tan\frac{1}{2}z_1-\log\tan\frac{1}{2}z_2} \qquad \text{(ii.)}$$

This projection, given by equations (i.) and (ii.), is Lambert's orthomorphic projection—commonly called Gauss's projection; its descriptive name is the *orthomorphic conical projection with two standard parallels.*

Mercator's Projection.—This projection retains the characteristic property of orthomorphic projections, viz., similarity of representation of small parts of the surface. The equator is represented by a straight line, which is crossed at right angles at equidistant points by a system of lines representing the meridians. The parallels are straight lines parallel to the equator, and the distance of the parallel of latitude ϕ from the equator is, as we have seen above, $r=a\log_e\tan(45°+\frac{1}{2}\phi)$. In the vicinity of the equator, or indeed within 30° of latitude of the equator, the representation is good, but as we proceed northwards or southwards the exaggeration of area becomes larger, and eventually excessive—the poles being at infinity. This distance of the parallels may be expressed in the form $r=a\,(\sin\phi+\frac{1}{3}\sin{}^3\phi+\frac{1}{5}\sin{}^5\phi+\ldots)$, showing that near the equator r is nearly proportional to the latitude. As a consequence of the similar representation of small parts, a curve drawn on the sphere cutting all meridians at the same angle—the loxodromic curve—is projected into a straight line, and it is this property which renders Mercator's chart so valuable to seamen. The projection of a great circle (being neither a meridian nor the equator) is a curve which cannot be represented by a simple algebraic equation. Mercator's projection although indispensable at sea, is of little value for land maps. The misconceptions arising from this exaggeration of scale may, however, be corrected by the juxtaposition of a map of the world on an equal-area projection.

It is now necessary to revert to the general consideration of conical projections. It has been shown that the scales of the projection (fig. 20) as compared with the sphere are $p'q'/pq=dp/dz=\sigma$ along a meridian, and $p'r'/=ph/\sin z=\sigma'$ at right angles to a meridian. Now if $\sigma\sigma'=1$ the areas are correctly represented, then

$$hpdp=\sin z dz,\ \text{and integrating}\ \tfrac{1}{2}hp^2=C-\cos z; \qquad \text{(i.)}$$

this gives the whole group of *equal-area conical projections.* As a special case let the pole be the centre of the projected parallel, then when

$$z=0,\ p=0,\ \text{and const}=1,\ \text{we have}\ p=2\sin\tfrac{1}{2}z/\delta h \qquad \text{(ii.)}$$

Let z_1 be the co-latitude of some parallel which is to be correctly represented, then $2h\sin\frac{1}{2}z_1/\delta h=\sin z_1$, and $h=\cos^2\frac{1}{2}z_1$; putting this value of h in equation (ii.) the radius of any parallel

$$=p=2\sin\tfrac{1}{2}z\sec\tfrac{1}{2}z_1 \qquad \text{(iii.)}$$

This is Lambert's *conical equal-area projection with one standard parallel,* the pole being the centre of the parallels.

If we put $z_1=\theta$ then $h=1$, and the meridians are inclined at their true angles, also the scale at the pole becomes correct, and equation (iii.) becomes

$$p=2\sin\tfrac{1}{2}z; \qquad \text{(iv.)}$$

this is the *zenithal equal-area projection.*

Reverting to the general expression for *equal-area conical projections,*

$$p=\sqrt{\{2(C-\cos z)/h\}} \qquad \text{(i.)}$$

we can dispose of C and h so that any two selected parallels shall be their true lengths; let their co-latitudes be z_1 and z_2, then

$$2h(C-\cos z_1)=\sin^2 z_1 \qquad \text{(v.)}$$
$$2h(C-\cos z_2)=\sin^2 z_2 \qquad \text{(vi.)}$$

from which C and h are easily found, and the radii are obtained from (i.). This is H. C. Albers' *conical equal-area projection with two standard parallels.* The pole is not the centre of the parallels.

PROJECTION BY RECTANGULAR SPHEROIDAL CO-ORDINATES

If in the simple conical projection the selected parallel is the equator, this and the other parallels become parallel straight lines and the meridians are straight lines spaced at equatorial distances, cutting the parallels at right angles; the parallels are their true distances apart. This projection is the *simple cylindrical.* If now we imagine the touching cylinder turned through a right-angle in such a way as to touch the sphere along any meridian, a projection is obtained exactly similar to the last, except that in this case we represent, not parallels and meridians, but small circles parallel to the given meridian and great circles at right angles to it. It is clear that the projection is a special case of conical projection. The position of any point on the earth's surface is thus referred, on this projection, to a selected meridian as one axis, and any great circle at right angles to it as the other. Or, in other words, any point is fixed by the length of the perpendicular from it on to the fixed meridian and the distance of the foot of the perpendicular from some fixed point on the meridian, these spherical or spheroidal co-ordinates being plotted as plane rectangular co-ordinates.

The perpendicular is really a plane section of the surface through the given point at right angles to the chosen meridian, and may be briefly called a great circle. Such a great circle clearly diverges from the parallel; the difference in latitude and longitude between the point and the foot of the perpendicular can be at once obtained by ordinary geodetic formulae, putting the azimuth $=90°$. Approximately the difference of latitude in seconds is $x^2\tan\phi\operatorname{cosec}1''/2p\nu$ where x is the length of the perpendicular, p that of the radius of curvature to the meridian, ν that of the normal terminated by the minor axis, ϕ the latitude of the foot of the perpendicular. The difference of longitude in seconds is approximately $x\sec p\operatorname{cosec}1''/\nu$. The resulting error consists principally of an exaggeration of scale north and south and is approximately equal to $\sec x$ (expressing x in arc); it is practically independent of the extent in latitude.

It is on this projection that the 1:2,500 ordnance maps and the 6in. ordnance maps of the United Kingdom are plotted, a meridian being chosen for a group of counties. This projection is only suitable for cadastral plans. As regards errors, a range of 100 miles each side of the central meridian will give a maximum error in scale in a north and south direction of about 1/3000.

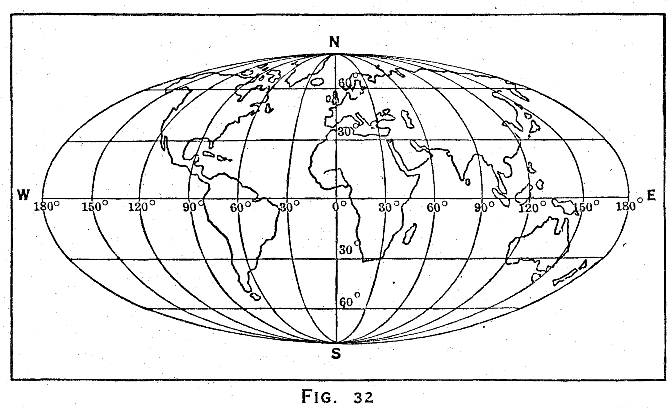

FIG. 32

ELLIPTICAL EQUAL-AREA PROJECTION

In this projection (fig. 32), also called Mollweide's projection, the parallels are parallel straight lines and the meridians are ellipses, the central meridian being a straight line at right angles to the equator, which is equally divided.

If we imagine the poles moved so that the major axis of the ellipse now represents a meridian, we obtain the *Transverse Elliptical Equal-area Projection* as shown in fig. 33 (see *Ordnance Survey Professional Paper,* 1927).

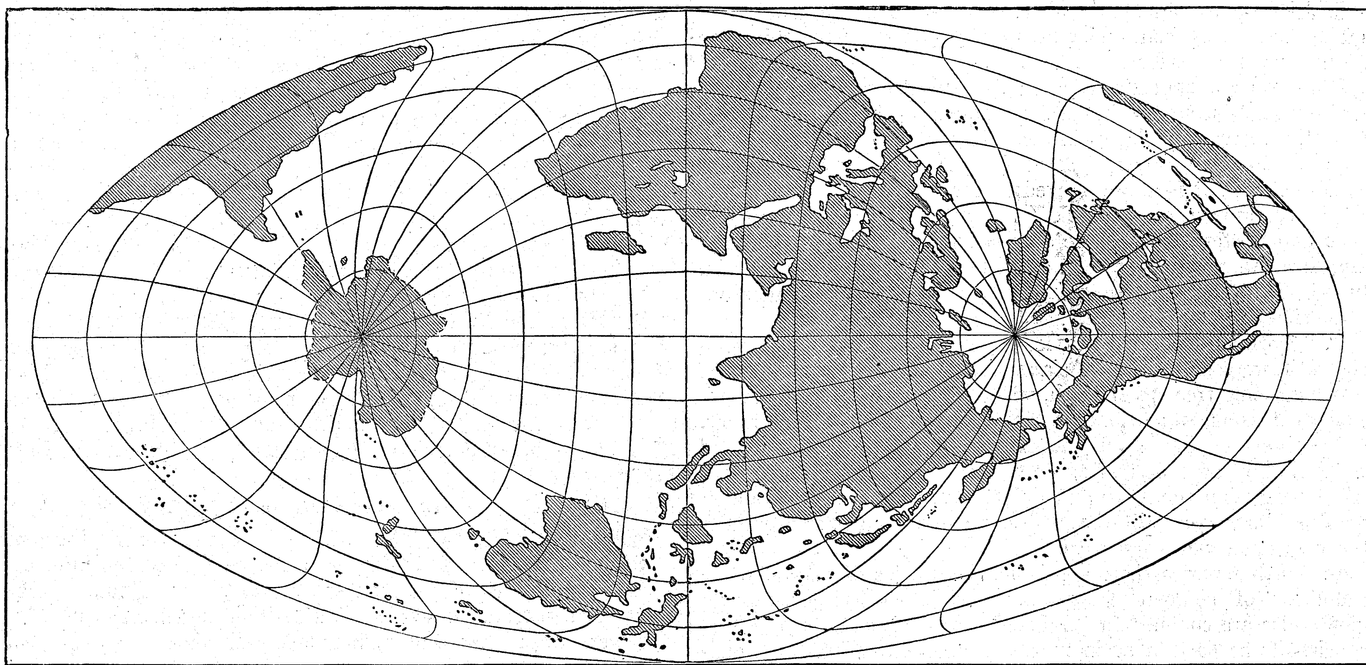

FIG. 33

SPECIAL PURPOSE PROJECTIONS

These projections are devised for simplicity of drawing and not for any special properties. The most useful projection of this class is the *globular projection.* This is a conventional representation of a hemisphere in which the equator and central meridian are two equal straight lines at right angles, their intersection being the centre of the circular boundary. The meridians divide the equator into equal parts and are arcs of circles passing through points so determined and the poles. The parallels are arcs of circles which divide the central and extreme meridians into equal parts. This is a simple and effective projection, well suited for conveying ideas of the general shape and position of the chief land masses.

Field sheets for topographical surveys should be on conical projections with rectified meridians; these projections for small areas and ordinary topographical scales—not less than 1:500,000—are sensibly errorless. But to save labour it is customary to employ for this purpose either form of polyconic projection, in which the errors for such scales are also negligible. In some surveys, to avoid the difficulty of plotting the flat arcs required for the parallels, the arcs are replaced by polygons, each side being the length of the portion of the arc it replaces. This method is especially suitable for scales of 1:125,000 and larger, but it is also sometimes used for smaller scales.

Among projections which have not been described may be mentioned the circular orthomorphic (Lagrange's) and the rectilinear equal-area (Collignon's) and a considerable number of conventional projections, which latter are for the most part of little value.

The choice of a projection depends on the function which the map is intended to fulfil. If the map is intended for statistical purposes to show areas, density of population, incidence of rainfall, of disease, distribution of wealth, etc., an *equal-area* projection should be chosen. In such a case an area scale should be given. At sea, *Mercator's* is practically the only projection used except when it is desired to determine graphically great circle courses in great oceans, when the *central* projection must be employed. For conveying general ideas of the shape and distribution of the surface features of continents or of a hemisphere *Clarke's perspective* projection is a good one. For exhibiting the progress of polar exploration the *polar equidistant* projection should be selected. For special maps for general use on scales of 1:1,000,000 and smaller, and for a series of which the sheets are to fit together, the *conical, with rectified meridians and two standard parallels,* is a good projection. For topographical maps, in which each sheet is plotted independently and the scale is not smaller than 1:500,000, either form of *polyconic* is very convenient.

Projections may be devised to fulfil a special purpose. Thus, Mr. J. T. Craig invented a projection the special property of which is that, from every point on the map, the true bearing of Mecca can be accurately measured. He called this the Mecca *Azimuthal Projection* (*see* J. T. Craig, *Map Projections,* Survey of Egypt publication, Cairo, 1909). Another example of a projection which was devised to be used for a special purpose is the *Two Point Equidistant Projection.* In this projection, having chosen two points on the sphere (or spheroid), the distances on the map from these two points, to all other points, are true to scale. So that, if the chosen points are the beginning and ending points of a journey, such a projection will enable the traveller to ascertain accurately, by direct measurement the distances that he is from his starting point or his goal (*Ordnance Survey Professional Paper* no. 5).

The Projection of the International Map of the World on the 1:1,000,000 scale is a slightly modified form of simple polyconic. Each sheet is 4° in latitude by 6° in longitude, and each sheet is plotted independently. The upper and lower parallels have the radius ν cot lat., where ν in each case is the normal terminated by the minor axis. Instead of the central meridian (which is a straight line) being exactly to scale, the meridians 2° to the east and west of it are true to scale; the object of this device is to reduce the maximum error. Along the limiting parallels the degrees of longitude are marked off in their true lengths to scale, and the meridians are straight lines joining the appropriate points on the limiting parallels. The meridians themselves are divided equally, and the inner parallels join the appropriate points on the meridians. The largest scale error is about 1/1270 (*La Carte du Monde au Millionième,* Association Française pour l'Avancement des Sciences, 1911).

(C. F. CL.; A. R. C.)

MAPLE, the name given to trees of the botanical genus *Acer* (fam. Aceraceae), comprising about 115 species native chiefly to north temperate regions.

Maples have opposite, long-stalked, mostly palmately lobed leaves. The flowers are in fascicles appearing before the leaves, as in the Norway maple; or in corymbs with the leaves, as in the sugar maple; or in racemes after the leaves, as in the sycamore maple. The fruit is a two-winged samara.

The common or small maple (*A. campestre*), of northern Europe and western Asia, is the only species native to Great Britain. It grows usually less than 20 ft. high, with leaves about 2 in. broad. The compact, fine-grained wood has been used since ancient times for making tables.

The sycamore or great maple (*A. pseudoplatanus*), native to central Europe and western Asia and naturalized in Great Britain, is a handsome tree, 70 ft. high, with leaves 4 in. to 8 in. broad. The hard wood, which takes a high polish, is valued in turnery.

The Norway maple (*A. platanoides*), native to Europe and western Asia and introduced into Great Britain in 1683, is a lofty tree, sometimes 100 ft. high, resembling the sycamore maple. Many ornamental varieties are in cultivation, especially the handsome var. *schwedleri*.

In North America there are 13 native species of maple; 9 are found east of the great plains, 2 occur in the Rocky mountain region and 2 are confined to the Pacific coast. The eastern maples consist of the hard or sugar maples, the soft maples, the mountain maples and the boxelder.

The sugar, hard or rock maple (*A. saccharum*), highly valued as a timber and shade tree and the chief source of maple sugar (*q.v.*), grows from Newfoundland to South Dakota and southward to South Carolina and Texas, sometimes attaining a height of 120 ft. and a trunk diameter of 4 ft. The heavy, hard, very strong wood is extensively utilized, the varieties known as *bird's-eye*, *curly* and *wavy* maple being highly prized for cabinet work and finishings.

The very similar black maple (*A. nigrum*), of more restricted range, is likewise very valuable. The southern sugar maple (*A. floridanum*) and the whitebark maple (*A. leucoderme*) are small trees of the southern states.

The soft maples include the white or silver maple (*A. saccharinum*), with the leaves white below, and the red or swamp maple (*A. rubrum*), with dull red flowers in spring and flame-red foliage in autumn. Both are common trees, similar in size to the sugar maple and of nearly the same geographical range. They furnish a softer lumber than the sugar and black maples and are widely planted for ornament.

The mountain maple (*A. spicatum*) and the striped maple or moosewood (*A. pennsylvanicum*) are small late-flowering trees of northern range but extending southerly in the mountains. The boxelder or ash-leaved maple (*A. negundo*), a small tree with leaves of three to five leaflets, grows along streams from Vermont to Alberta and south to Florida and Arizona. The California boxelder (var. *californicum*), with leaves of three leaflets, occurs in the Sacramento valley and southward.

The bigtooth maple (*A. grandidentatum*) and the dwarf maple (*A. glabrum*) are small trees of the Rocky mountain region, the latter extending to northern California and Oregon and its variety (var. *douglasii*) to Alaska. The bigleaf maple (*A. macrophyllum*), a valuable timber tree, sometimes 100 ft. high, with leaves 4 in. to 10 in. broad, occurs near the coast from southern California to Alaska.

The highly ornamental vine maple (*A. circinatum*), usually a small tree, but sometimes vine-like or prostrate, is found from northern California to British Columbia.

In 1940 the total cut of maple lumber was 462,947,000 bd.ft., valued at approximately $15,000,000.

Bailey, *Standard Cyclopedia of Horticulture* (1914–27) and *Manual of Cultivated Plants* (1924). (E. S. Hr.)

MAPLE SUGAR, a sugar of characteristic flavour obtained by evaporating the sap of various species of maple, but principally the sugar maple (*see* Maple), found chiefly in the north-eastern United States and in Canada. The States of Vermont, New York, and Ohio and the Province of Quebec contribute over three-fourths of the total production. From 1926 to 1935 the average annual production of sugar and syrup, calculated as sugar, was over 24,000,000lb. in the United States and over 25,000,000lb. in Canada. (*See* Sugar.) (H. G. K.)

MAPLEWOOD, a residential suburb of Saint Louis, Missouri, U.S.A., in St. Louis county, on federal highway 50 and the Missouri Pacific railroad, 7 mi. from the Union station. Pop. 7,431 in 1920 (90% native white); in 1930, 12,657; in 1940, 12,875, by federal census.

MAPU, ABRAHAM (1808–1867), Hebrew novelist. His most famous books were the *Love of Zion* and the *Transgression of Samaria*. Besides their intrinsic merits, these novels stand high among the works which produced the romantic movement in modern Hebrew literature. An English translation of the *Love of Zion* bears the title *Amnon, Prince and Peasant*, by F. Jaffe (1887).

See N. Slouschz, *The Renascence of Hebrew Literature* (1909), ch. v.

MAR, EARLDOM OF. Mar, one of the ancient divisions of Scotland, comprised the larger portion of Aberdeenshire, extending from north of the Don southward to the Mounth. Like other such districts, it was in Celtic times under the rule of a *mormaer*. In the 12th century his place was taken by an earl, but no definite succession of earls appears till the 13th century. Earl Gratney (*fl. c.* 1300) married a sister of (King) Robert Bruce, who brought him the lordship of Garioch and castle of Kildrummy, which she held against the earl of Athole, an ally of the English (1335). Their son Donald was made regent in July 1332, but was defeated and slain at Dupplin next month. His daughter and eventual heir, Margaret, brought the earldom to her husband, William, earl of Douglas, and on the accession of her daughter Isabel a troublous time followed. While she was living as a widow at her castle of Kildrummy, it was stormed by Alexander Stewart, a bastard, who forced her to execute a charter (Aug. 1404) settling the reversion to the earldom on himself and his heirs. This act she revoked by a charter of September 1404, but on marrying him in December, she granted him the earldom for life, the king confirming this in June 1405. After her death in 1408 the earl commanded the royal forces at the battle of Harlaw, when the Lord of the Isles was defeated in 1411, and afterwards acted as warden of the Marches.

In 1426 he resigned the earldom to the Crown, the king granting it by a fresh creation to him and certain heirs, with reversion to the Crown. In the following centuries the earldom had a complicated and chequered history, the title eventually remaining in the Erskine family. As a result of the attainder of the 11th earl, John (1675–1732), a prominent Jacobite (*see* below), the earldom remained under forfeiture for 108 years.

Alloa and other Erskine estates of the attainted earl were repurchased for the family, and descended to John Francis Erskine (1741–1825), his heir-male, who was also his heir of line through his daughter. To him, in his 83rd year, as grandson and lineal representative of the attainted earl, the earldom was restored by act of parliament. His grandson, who succeeded him in 1828, inherited the earldom of Kellie (1619) and other Erskine dignities by decision of 1835. At his death in 1866, his earldom of Mar was the subject of rival claims, and the right to the succession was not determined till 1875. For the prolonged proceedings for the settlement of this case, in which the decision of the House of Lords (Feb. 25, 1875), in favour of the late earl's cousin and heir-male, was reversed by a special act, the Earldom of Mar Restitution act in 1885, in favour of the son of the late earl's cousin, J. F. E. Goodeve (Erskine), *see* the authorities quoted below.

MAR, JOHN ERSKINE, 1st or 6th Earl of (d. 1572), regent of Scotland, was a son of John, 5th Lord Erskine (d. 1552), who was guardian of King James V., and afterwards of Mary Queen of Scots. The custody of Edinburgh castle was in his hands, and during the struggle between the regent, Mary of Lorraine, and the lords of the Congregation he appears to have acted consistently in the interests of peace. When Mary Stuart returned to Scotland in 1561 Lord Erskine was a member of her council, and favoured her marriage with Lord Darnley. In 1565 Erskine was granted the earldom of Mar (*see* p. 852). As guardian of James, afterwards King James VI., he prevented the young prince from falling into the hands of Bothwell, and when the Scottish nobles rose against Mary and Bothwell, Mar was one of their leaders. He took part in the government of Scotland during Mary's imprisonment at Lochleven, and also after her subsequent abdication. In 1571 he was chosen regent of Scotland, but he was overshadowed by the earl of Morton. He died at Stirling on Oct. 29, 1572.

MAR, JOHN ERSKINE, 2nd or 7th Earl of (*c.* 1558–1634), Scottish politician, was the only son of the preceding. He was nominally the guardian of the young king James VI., who lived with him at Stirling; but he was in reality a puppet in the hands of the regent, the earl of Morton; and he lost power when Morton was imprisoned. He was concerned in the seizure of James VI. in 1582; but when James escaped the earl fled into the west of Scotland. Leaving his hiding-place Mar seized Stirling castle, whereupon James marched against him, and he took refuge in England. Queen Elizabeth interceded for him in vain, and Mar and his friends gathered an army, entered the presence of the king at Stirling, and were soon in authority (1585). Mar was restored to his lands and titles. He became governor of Edinburgh castle and tutor to James's son, Prince Henry, and for his second wife he married Mary, daughter of Esmé Stewart, duke of Lennox. In 1601 the earl was sent as envoy to London; here Elizabeth assured him that James should be her successor, and his mission was conducted with tact and prudence. Mar was created Lord Cardross in 1610; he was a member of the Court of High Commission and was lord high treasurer of Scotland from 1615 to 1630. He died at Stirling on Dec. 14, 1634.

MAR, JOHN ERSKINE, 6th or 11th Earl of (1675–1732), Scottish Jacobite, was the eldest son of Charles, the 5th earl (1650–89). He was associated with the party favourable to the English Government; he was one of the commissioners for the Union, and was made a Scottish secretary of State, becoming after the Union of 1707 a representative peer for Scotland, keeper of the signet and a privy councillor. In 1713 Mar was made an English secretary of State by the Tories, but under George I. he was deprived of his office, and in 1715 he went in disguise to Scotland and placed himself at the head of the adherents of James Edward, the Old Pretender. Meeting many Highland chieftains at Aboyne he avowed a desire for the independence of Scotland, and at Braemar in Sept. 1715 he proclaimed James VIII. king of Scotland, England, France and Ireland. At Sheriffmuir, in Nov. 1715, Mar's forces were defeated by those of his opponent, Archibald Campbell, afterwards 3rd duke of Argyll. Mar then met James Edward at Fetteresso; he fled with him to France. In the course of time he became thoroughly distrusted by the Jacobites. In 1721 he accepted a pension of £3,500 a year from George I., and in 1724 he left the Pretender's service. His later years were spent in Paris and at Aix-la-Chapelle, where he died in May, 1732. He had been attainted in 1716, and his only son, Thomas, Lord Erskine, died childless in March 1766.

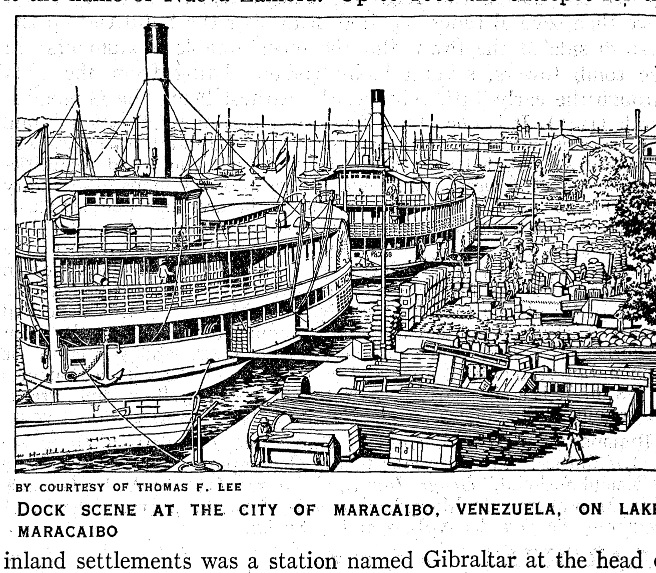
See the *Journal of the Earl of Mar* (1716); R. Patten, *History of the late Rebellion* (1717); and A. Lang, *History of Scotland,* vol. iv. (1907).

MARABOUT, in Islam a hermit or devotee (Fr. from Arab *murābit,* "one who pickets his horse on a hostile frontier"). The word is derived from *ribāt,* a fortified frontier station, which, later, came to mean a religious house or hospice (*zāwiya*). In North Africa the marabouts enjoy extraordinary influence, being esteemed as living saints and mediators. They are liberally supported by alms, direct all popular assemblies, and have a decisive voice in intertribal quarrels and all matters of consequence. On their death their sanctity is transferred to their tombs (also called marabouts), where chapels are erected at, and gifts and prayers offered to, their tombs.

See Dervish.

MARACAIBO, a city and seaport of Venezuela and capital of the State of Zulia, is situated on the west shore of the broad channel which connects Lake Maracaibo with the Gulf of Venezuela, or Maracaibo, about 25m. from the mouth of the channel opening into the latter. Pop. (1905), 49,817; (1941), 112,519; there is a considerable foreign element in the vicinity, largely engaged in petroleum operations. The best residential suburb, Haticos, extends along the lake shore toward the south. The city is provided with tramways, telephone service and electric lighting, but the water supply and drainage are inferior. The most important buildings are the executive's residence, the legislative chambers, the municipal hall, the prison, the market, a hospital and six churches. The city also has a school of arts, a public library and public gardens. Within the past few years the development of petroleum around the shore of Maracaibo lake has greatly promoted business activity in the city. In colonial times Maracaibo had a famous Jesuits' college (now gone) and was one of the educational centres of Spanish America; the city now has a national college and a nautical school. The industries include shipbuilding, and the manufacture of saddlery and other leather products, bricks and tile, rum, beer, chocolate and coconut oil. Maracaibo has become one of the most important petroleum export centres in Latin America. Some oil is also refined here. The bar at the entrance to Maracaibo channel does not admit vessels drawing more than 12ft., but there is a depth of 30ft. inside and near the city. Steam communication is maintained on the Catatumbo and Zulia rivers to Villamizar, and on the Escalante to Santa Cruz. The principal exports from Maracaibo are petroleum, coffee, hides and skins, cabinet and dyewoods, cocoa and mangrove bark, to which may be added dividivi, sugar, copaiba, gamela and hemp straw for paper-making, and fruits.

Maracaibo was founded in 1571 by Alonso Pacheco, who gave it the name of Nueva Zamora. Up to 1668 the entrepôt for the



BY COURTESY OF THOMAS F. LEE

Dock scene at the city of Maracaibo, Venezuela, on Lake Maracaibo

inland settlements was a station named Gibraltar at the head of the lake, but the destruction of that station by pirates in that year transferred this valuable trade to Maracaibo. The city did not figure actively in the War of Independence until 1821 (Jan. 28), when the province declared its independence and sought an alliance with Colombia. This brought to an end the armistice between Bolívar and Morillo, and thenceforward the city experienced all the changing fortunes of war until its final capture by the revolutionists in 1823.

MARACAIBO, a large lake of western Venezuela, extending southward from the Gulf of Venezuela, into which it opens through a long neck, or strait, obstructed at its mouth by islands and bars. The lake is roughly quadrangular in shape, and extends from the 9th to the 11th parallel of S. lat. and from the 71st to the 72nd meridian. It opens into the Gulf through 13 channels, the depth on the bar in the main channel ranging from 7ft. at low water to 12ft. at high water. Inside the bar the depth is about 30ft., and the lake is navigable for vessels of large size. It receives the waters of many rivers, principally on its west and south sides, the largest of which are the Catatumbo and Zulia, Escalante, Chanudo, Ceniza, Santa Ana, Negro, Apan and Palmar. The first three have navigable channels for river steamers. There are a number of small lakes near Lake Maracaibo's southern and western margins, the largest of which is the Laguna de Zulia. The heavy rainfall on the eastern slopes of the Eastern Cordillera, which is said to exceed 86in. per annum, is responsible for the great volume of water discharged into the lake. The average annual precipitation over the whole basin is said to be 70 inches. In the upper half of the lake the water is sweet, but below that, where the tidal influence is stronger, it becomes brackish. The most important port on the lake is Maracaibo, but there are ports of lesser trade at its upper end which are in direct communication with the inland cities of Trujillo, Mérida and San Cristóbal. The Catatumbo river, which enters from the west near the north end of the lake, and its principal tributary, the Zulia, are navigable as far as Villamizar, in Colombia, and afford an excellent transportation route for the coffee and other products of Santander. During the last few years petroleum exploitation around the shore of Lake Maracaibo has been active under the direction of various European, United States and native companies. Population of Maracaibo city in 1936 census was 110,010; all lines of business have expanded. There are several refineries, some within the gulf area and others on Curaçao and nearby islands of the Caribbean.

MARAGHA, a town of Iran in the province of Azerbaijan, on the Safi river, in 37° 23′ N., 46° 16′ E., 80 mi. from Tabriz. Pop. about 35,000. It is pleasantly situated in a narrow valley running nearly north and south at the eastern extremity of a well-cultivated plain opening toward Lake Urmia, which lies 18 mi. to the west. Two stone bridges in good condition, said to have been constructed during the reign of Hulagu Khan (1256–65), and since then several times repaired, lead over the Safid rud on the western side of the town. But the most notable monuments are five tomb towers, several badly ruined, dating from the 12th through the early 14th century, the earliest being the Gunbad-i-Surkh (1147). It is one of the finest examples of brickwork in Iran. The place is surrounded by extensive vineyards and orchards, well watered by canals led from the river, and producing great quantities of fruit. On a hill west of the town are traces of a famous observatory (*rasad*) constructed under the direction of the great astronomer Nasr-ud-Din of Tus. The building, which no doubt served as a citadel as well, enclosed a space of 380 yd. by 150, and the foundations of the walls were 4½ to 5 ft. in thickness. The marble, which is known throughout Iran as Maragha marble, is a travertine obtained at the village of Dashkesen (about 30 mi. N.W. of Maragha). It is deposited from water, which bubbles up from a number of springs, in the form of horizontal layers, which at first are thin crusts and can easily be broken, but gradually solidify and harden into blocks with a thickness of 7–8 in. It is a singularly beautiful substance, of yellow, pink, greenish or milk-white colour, streaked with reddish, copper-coloured veins.

Journ.*, xiv, p. 517 (1899); Andre Godard, "Les Monuments de Maragha," *Athar-é-Iran,* 1, p. 130 (1936); *A Survey of Persian Art*, vols. 2 and 3 *passim*.

MARANHÃO, a northern State of Brazil, bounded N. by the Atlantic, E. and S.E. by Piauí, S.W. and W. by Goiaz and Pará. Having an area of 133,674 sq.mi., its pop. in 1940 was 1,242,-721. The coastal zone and the northwest corner of the state belong to the Amazon valley region, being a heavily forested plain traversed by numerous rivers. The eastern and southern parts, however, belong to the lower terraces of the great Brazilian plateau, broken by eroded river-courses between which are high open plains. There are no true mountain ranges in Maranhão, those indicated on the maps being only plateau escarpments marking either its northern margin or the outlines of river valleys. The climate is hot, and the year is divided into a wet and dry season, extreme humidity being characteristic of the former but no part of the year is rainless. The heat, however, is greatly modified on the coast by the south-east trade winds, and the climate is generally considered healthful, though beri-beri and eruptive diseases are common in some places.

The coast itself is broken and dangerous, there being many small indentations, which are usually masked by islands or shoals. The largest of these are the Bay of Turiassú, facing which is the island of Tocansa, and several others of small size and the contiguous bays of São Marcos and São José, between which is the large island of São Luiz. The rivers of the state all flow northward to the Atlantic, and a majority of them have navigable channels. The Parnaíba forms the eastern boundary while the Tocantins and the Gurupí bound the state on the west. The principal rivers are the Maracassumé and Turiassú, the Mearim and its larger tributaries (the Pindaré, Grajaú, Flores and Corda) which discharge into the Bay of São Marcos, and the Itapecurú and Monim which discharge into the Bay of São José.

The principal industries of Maranhão are agricultural, the river valleys and coastal zone being highly fertile and being devoted to the cultivation of sugar-cane, cotton, rice, coffee, tobacco, mandioca and a great variety of fruits. The southern highlands, however, are devoted to stockraising, which was once an important industry. Troublesome insects, vampire bats and the failure to introduce new blood into the degenerated herds are responsible for its decline. A railway, 250 mi. long, crosses the eastern part of the state connecting São Luiz on the coast with Teresina, the capital of Piauí. São Luiz, capital (pop. of the *município* 86,546 in 1940); other principal towns, with the population of their municipal districts in 1940, are: Caxias 78,327; Pedreiras 43,437; Barra do Corda 35,818 and Viana 29,287.

The coast of Maranhão was first discovered by Pinzón in 1500, but it was included in the Portuguese grant of captaincies in 1534. The first European settlement was made by a French trading expedition under Jacques Riffault, of Dieppe, in 1594, who left a part of his men when he returned home. Subsequently Daniel de la Rivardière, commissioned by the French crown, founded a colony on the island in 1612. The French were expelled by the Portuguese in 1615 and the Dutch held the island from 1641 to 1644. In 1621 Ceará, Maranhão and Pará were united and called the "Estado do Maranhão," which was made independent of the southern captaincies. Ceará was later detached, but the "State" of Maranhão remained independent until 1774, when it became subject to the colonial administration of Brazil. Maranhão did not join in the declaration of independence of 1822, but in 1823 the Portuguese were driven out by Admiral Lord Cochrane, and the province became a part of the empire of Brazil.

MARANTACEAE, the arrowroot family, monocotyledonous perennials, comprising 26 genera and 300 species, all tropical and mainly American. The West Indian *Maranta arundinacea* is the source of arrowroot (*q.v.*). Various species of *Calathea* are cultivated for their ornamental foliage. For a monographic treatment *see* K. Schumann, "Marantaceae," *Pflanzenreich* 11 (iv 48); 1–184, fig. 1–23 (1902).

MARASH or Maraş, a city in Turkey, east of the Jihan river at the foot of Mt. Taurus; pop. (1940) 27,744, and capital of the vilayet of the same name. The American mission has a college here and the Americans and Jesuits, churches and schools. The climate for the greater part of the year is good. A railway connects Marash with the Istanbul-Baghdad line.

History.—Marash was anciently a Hittite town and several Hittite monuments have been discovered including an inscribed lion and several stelae. As Marasi it appears in Assyrian records, but little or nothing is known of the town at that period. It reappears in history in the 2nd century A.D. with the name Germanicia. The identification of Germanicia with Marash has been questioned without any real justification. Nor is the attempt by Honigmann to distinguish two Germanicias in fairly close proximity likely to meet with favour. The Armenians have called Marash Kermanig since the 12th century at least. Heraclius visited the town in A.D. 640. Before 700 it had passed into Muslim hands. The Khalif Muʿāwiya rebuilt it and it figured in the struggles with the Byzantines; after 770, however, it remained definitely in Muslim hands. Hārūn al-Rashēd (786–809) strengthened its fortifications. The crusaders captured the town (1097), as did the Seljuks half a century later. It became part of the Turkish empire in the 16th century. In 1832 the Egyptian army in its march towards Constantinople stayed its advance there at the bidding of the Powers. Marash was brought within the sphere of military operations consequent on the Franco-Turkish dispute of 1920–21.

MARAT, JEAN PAUL (1743–1793), French revolutionary leader, son of Jean Paul Marat, a designer of Cagliari in Sardinia, and Louise Cabrol of Geneva, was born at Boudry, Neuchâtel, on May 24, 1743. On his mother's death in 1759 Marat set out on his travels, and studied medicine for two years at Bordeaux, whence he moved to Paris, where he made use of his knowledge of optics and electricity to subdue an obstinate disease of the eyes. After some years in Paris he went to Holland, and then to London, where he practised medicine. In 1773 he published a *Philosophical Essay on Man.* The book directly attacks Helvétius, who had in his *De l'esprit* declared a knowledge of science unnecessary for a philosopher. Marat declares that physiology alone can solve the problems of the connection between soul and body, and proposes the existence of a nervous fluid as the true solution. In 1774 he published *The Chains of Slavery,* which was intended to influence constituencies to return popular members, and reject the king's friends. In 1775 he published in London his *Essay on Gleets,* and in Amsterdam a French translation of the first two volumes of his *Essay on Man.* In this year he visited Edinburgh, and was made an M.D. of St. Andrews. On his return to London he published an *Enquiry into the Nature, Cause, and Cure of a Singular Disease of the Eyes,* with a dedication to the Royal Society. In the same year there appeared the third volume of the French edition of the *Philosophical Essay on Man,* which exasperated Voltaire, whose attack made the young author more conspicuous. His fame as a doctor was now great, and on June 24, 1777, the comte d'Artois, afterwards Charles X. of France, made him physician to his guards with 2,000 livres a year and allowances.

Marat soon had an aristocratic practice. He presented memoirs on heat, light and electricity to the Académie des Sciences, but the academicians were horrified at his temerity in differing from Newton and would not receive him. In 1780 he had published at Neuchâtel a *Plan de législation criminelle,* founded on the principles of Beccaria. In April 1786 he resigned his court appointment. The results of his leisure were in 1787 a new translation of Newton's *Optics,* and in 1788 his *Mémoires académiques, ou nouvelles découvertes sur la lumière.*

In the notoriety of the political life which was now to begin, his scientific and philosophical knowledge was to be forgotten, the high position he had given up denied, and he himself scoffed at as an ignorant charlatan, who had sold quack medicines about the streets of Paris, and been glad to earn a few sous in the stables of the comte d'Artois. In 1788 the elections for the States-general were the cause of a flood of pamphlets, of which Marat's *Offrande à la patrie* dwelt on much the same points as the famous brochure of the Abbé Siéyès: *Qu'est-ce que le tiers état?* In June 1789 he published a supplement to his *Offrande,* followed in July by *La constitution,* in which he embodies his idea of a constitution for France, and in September by his *Tableau des vices de la constitution d'Angleterre,* which he presented to the Assembly. The latter alone deserves remark. The Assembly was at this time full of anglomaniacs, who desired to establish in France a constitution similar to that of England. Marat had seen that England was at this time being ruled by an oligarchy using the forms of liberty, which, while pretending to represent the country, was really being gradually mastered by the royal power. His heart was now all in politics; and he decided to start a paper. At first appeared a single number of the *Moniteur patriote,* followed on Sept. 12 by the first number of the *Publiciste parisien,* which on Sept. 16 took the title of *L'Ami du peuple* and which he edited, with some interruptions, until Sept. 21, 1792.

The life of Marat now becomes part of the history of the French Revolution. From the beginning to the end he stood alone. He was never attached to any party; the tone of his mind was to suspect whoever was in power. About his paper, the incarnation of himself, the first thing to be said is that the man always meant what he said; no poverty, no misery or persecution, could keep him quiet; he was perpetually crying, "Nous sommes trahis." Whoever suspected any one had only to denounce him to the *Ami du peuple,* and the denounced was never let alone till he was proved innocent or guilty. Marat began by attacking the most powerful bodies in Paris—the Constituent Assembly, the ministers, the corps municipal, and the court of the Châtelet. Denounced and arrested, he was imprisoned from Oct. 8 to Nov. 5, 1789. A second time, owing to his violent campaign against Lafayette, he narrowly escaped arrest and had to flee to London (Jan. 1790). There he wrote his *Dénonciation contre Necker,* and in May dared to return to Paris and continue the *Ami du peuple.* He was embittered by persecution, and continued his vehement attacks against all in power, and at last, after the day of the Champs du Mars (July 17, 1790), against the king himself. All this time he was in hiding in cellars and sewers, where he was attacked by a horrible skin disease, tended only by the woman Simonne Evrard, who remained true to him. The end of the Constituent Assembly he heard of with joy and with bright hopes for the future, soon dashed by the behaviour of the Legislative Assembly. When almost despairing, in December 1791, he fled once more to London, where he wrote his *Ecole du citoyen.* In April 1792, summoned again by the Cordeliers' Club, he returned to Paris, and published No. 627 of the *Ami.*

The war was now the question, and Marat saw clearly that it was to serve the purposes of the Royalists and the Girondins, who thought of themselves alone. Again denounced, Marat had to remain in hiding until Aug. 10. The proclamation of the duke of Brunswick excited all hearts; who could go to save France on the frontiers and leave Paris in the hands of his enemies? Marat, like Danton, foresaw the massacres of September. After the events of Aug. 10 he took his seat at the commune, and demanded a tribunal to try the Royalists in prison. No tribunal was formed, and the massacres in the prisons were the inevitable result. In the elections to the Convention, Marat was elected seventh out of the twenty-four deputies for Paris, and for the first time took his seat in an assembly of the nation. At the declaration of the republic, he closed his *Ami du peuple,* and commenced, on the 25th, a new paper, the *Journal de la république française,* which was to contain his sentiments as its predecessor had done, and to be always on the watch. In the Assembly Marat had no party; he would always suspect and oppose the powerful, refuse power for himself. After the battle of Valmy, Dumouriez was the greatest man in France; he could almost have restored the monarchy; yet Marat did not fear to denounce him in placards as a traitor.

His unpopularity in the Assembly was extreme, yet he insisted on speaking on the question of the king's trial, declared it unfair to accuse Louis for anything anterior to his acceptance of the constitution, and though implacable towards the king, as *the* one man who must die for the people's good, he would not allow Malesherbes, the king's counsel, to be attacked in his paper, and speaks of him as a "sage et respectable vieillard." The king dead, the months from January to May 1793 were spent in an unrelenting struggle between Marat and the Girondins. Marat despised the ruling party because they had suffered nothing for the republic, because they talked too much of their feelings and their antique virtue, because they had for their own virtues plunged the country into war; while the Girondins hated Marat as representative of that rough red republicanism which would not yield itself to a Roman republic, with themselves for tribunes, orators and generals.

The Girondins conquered at first in the Convention, and ordered that Marat should be tried before the Revolutionary Tribunal. But their victory ruined them, for on April 24 Marat was acquitted, and returned to the Convention with the people at his back. The fall of the Girondins on May 31 was a triumph for Marat. But it was his last. The skin disease he had contracted in the subterranean haunts was rapidly closing his life; he could only ease his pain by sitting in a warm bath, where he wrote his journal, and accused the Girondins, who were trying to raise France against Paris. Sitting thus on July 13, he heard in the evening a young woman begging to be admitted to see him, saying that she brought news from Caen, where the escaped Girondins were trying to rouse Normandy. He ordered her to be admitted, asked her the names of the deputies then at Caen, and, after writing their names, said, "They shall soon be guillotined," when the young girl, whose name was Charlotte Corday (*q.v.*), stabbed him to the heart.

The Convention attended his funeral, and placed his bust in the hall where it held its sessions. Louis David painted "Marat Assassinated," and a veritable cult was rendered to the Friend of the People, whose ashes were transferred to the Panthéon with great pomp on Sept. 21, 1794—to be cast out again in virtue of the decree of Feb. 8, 1795. (R. An.)

Besides the works mentioned above, Marat wrote: *Recherches physiques sur l'électricité*, etc. (1782); *Recherches sur l'électricité médicale* (1783); *Notions élémentaires d'optique* (1764); *Lettres de l'observateur Bon Sens à M. de M. . . . sur la fatale catastrophe des infortunés Pilatre de Rozier et Romain, les aéronautes et l'aérostation* (1785); *Observations de M. l'amateur Avec à M. l'abbé Sans . . .* etc. (1785); *Éloge de Montesquieu* (1785), published 1883 by M. de Bresetz; *Les Charlatans modernes, ou lettres sur le charlatanisme académique* (1791); *Les Aventures du comte Potowski* (published in 1847 by Paul Lacroix, the "bibliophile Jacob"); *Lettres polonaises* (unpublished). Marat's works were published by A. Vermorel, *Oeuvres de J. P. Marat, l'ami du peuple, recueillies et annotées* (1869). Two of his tracts, (1) *On Gleets,* (2) *A Disease of the Eyes,* were reprinted, ed. J. B. Bailey, in 1891.

Marat* (1900). The *Correspondance de Marat* has been edited with notes by C. Villay (1908); L. R. Gottschalk, *Jean Paul Marat* (1927).

MARATHI (properly *Marāthī*), the name of an important Indo-Aryan language spoken in western and central India. The name is sometimes spelt *Mahrāthī,* with an *h* before the *r,* but, according to a phonetic law of the Aryan languages of western India, this is incorrect. The original *h* in "Māhārāṣṭrī," from which the word is derived, is elided between two vowels.

Marathi occupies an irregular triangular area of approximately 100,000 sq.m., having its apex about the district of Balaghat in the Central Provinces, and for its base the western coast of the peninsula from Daman on the Gulf of Cambay in the north to Karwar on the open Arabian Sea in the south. It covers parts of two provinces of British India—Bombay and the Central Provinces (including Berar)—with numerous settlers in Central India and Madras, and is also the principal language of Portuguese India and of the north-western portion of His Highness the Nizam's dominions. The standard form of speech is that of Poona in Bombay, and in its various dialects it covers the larger part of that province.

Dialects.—Besides the standard form of speech, there is only one real dialect of Marathi, viz., Konkani (Kōnkaṇī), spoken in the country near Goa. There are also several local varieties, and we may conveniently distinguish between the Marathi of the Deccan, that of the Central Provinces (including Berar), and that of the northern and central Konkan. In the southern part of the district of Ratnagiri this latter Konkani variety of Marathi gradually merges into the true Konkani dialect through a number of intermediate forms of speech. There are also several broken jargons, based upon Marathi, employed by aboriginal tribes surviving in the hill country.

Relations with other Indo-Aryan Languages.—Marathi has to its north, in order from west to east, Gujarati, Rajasthani, Western Hindi and Eastern Hindi. To its east and south it has the Dravidian languages, Gondi, Telugu and Kanarese. Marathi does not merge into any of the cognate neighbouring forms of speech, but possesses a distinct linguistic frontier. This isolated character of Marathi is partly due to the barrier of the Vindhya range which lies to its north, and partly to the fact that none of the northern languages belongs now to the Outer Band, but they are in more or less close relationship to the language of the Midland. Eastern Hindi is more closely related to Marathi than the others, and in its case, in its bordering dialects, we do find a few traces of the influence of Marathi.

Written character.—Marathi books are generally printed in the Nagari character (*see* Sanskrit Language and Literature), and this is also used in private transactions and correspondence. In the Maratha country it is known as the *Bālbōdh* ("teachable to children," *i.e.,* "easy") character. A cursive form of Nagari called *Mōḍī,* or "twisted," is also employed as a handwriting. It is said to have been invented in the 17th century by Balaji Avaji, the secretary of the celebrated Sivaji. Each word can be written as a whole without lifting the pen from the paper.

Origin of the Language.—The word "Marāthī" signifies the language of the Maratha country. It is the modern form of the Sanskrit *Māhārāṣṭrī,* just as "Marāthā" represents the old *Māhārāṣṭra,* or Great Kingdom. *Māhārāṣṭrī* was the name given by Sanskrit writers to the Prakrit spoken in Mahārāṣṭra, the great Aryan kingdom extending southwards from the Vindhya range to the Kistna, broadly corresponding to the southern part of the Bombay Presidency and to the state of Hyderabad. This Māhārāṣṭrī became the form of Prakrit employed as the language of lyric poetry and of the formal epic (*kāvya*). Dramatic works were composed in it, and it was the vehicle of the non-canonical scriptures of the Jaina religion. The oldest work in the language is the *Sattasaī,* or Seven Centuries of verses, compiled at Pratiṣṭhāna, on the Gōdāvarī, the capital of King Hāla, at some time between the 3rd and 7th centuries A.D.

General Character of the Language.—The Prakrits fall into two well-defined groups, an Inner, Śaurasēnī, and its connected dialects on the one hand, and an Outer, Māhārāṣṭrī, Ardhamāgadhī, and Māgadhī with their connected dialects on the other. These two groups differed in their phonetic laws, in their systems of declension and conjugation, in vocabulary, and in general character. Meaningless suffixes such as *-alla, -illa, -ulla,* etc. can be added, almost *ad libitum* to any noun, adjective or particle in Māhārāṣṭrī and Ardhamāgadhī, but are hardly ever met in Śaurasēnī. These give rise to numerous secondary forms of words, which give a distinct flavour to the whole language.

Vocabulary.—Māhārāṣṭrī Prakrit, the most independent of the Outer languages, was distinguished by the large proportion of *dēśyas* (*see* Indo-Aryan Languages) found in its vocabulary, and the same is consequently the case in Marathi, although the proportion of *tatsamas* to *tadbhavas* in the language is fairly high. The proportion of Persian and, through Persian, of Arabic words in the Marathi vocabulary is comparatively low.

Phonetics.—In the standard dialect the vowels are the same as in Sanskrit, but *ṛ* and *l* only appear in words borrowed directly from that language (*tatsamas*). Final short vowels (*a, i* and *u*) have all disappeared in prose pronunciation, except in a few local dialects, and final *i* and *u* are not even written. After an accented syllable a medial *a* is pronounced very lightly, even when the accent is not the main accent of the word. Almost the only compound consonants which survived in the Prakrit stage were double letters, and in M. these are usually simplified, the preceding vowel being lengthened in compensation. It is not usual to lengthen the vowel in compensation in Konkani, which appears to contain many relics of the old Prakrit (Saurāṣṭrī) spoken in the Gujarat country before the invasion from the Midland.

On the whole, the consonantal system is much the same as in other Indian languages. Nasalization of long vowels is very common, especially in Konkani. The palatals are pronounced as in Skr. in words borrowed from that language or from Hindustani, and also in Marathi *tadbhavas* before *i, ī, ē* or *y.* In other cases they are pronounced *ts, tsh, dz, dzh* respectively. There are two *s*-sounds in the standard dialect which are very similarly distinguished, *ś*, pronounced like an English *sh*, is used before *i, ī, ē* or *y;* and *s*, as in English "sin," elsewhere. In the dialects *s* is practically the only sibilant used, and that is changed by the vulgar speakers of Konkani to *h* (again as in north-western India). Aspirated letters show a tendency to lose their aspiration, especially in Konkani. Generally speaking Marathi closely follows Māhārāṣṭrī when that differs from the Prakrits of other parts of India. There is similarly both in Marathi and Māhārāṣṭrī a laxness in distinguishing between cerebral and dental letters.

Declension.—Marathi retains the three genders, masculine, feminine and neuter. In Marathi the neuter denotes both inanimate things and animate beings when both sexes are included, or when the sex is left undecided. In the Konkani the neuter gender is further employed to denote females below the age of puberty. Numerous masculine and feminine words, however, denote inanimate objects. The rules for distinguishing the gender of such nouns must be learned from the grammars. For the most part, but not always, words follow the genders of the Skt. originals. Strong bases in *ā*—and these do not include *tatsamas*—are masculine, and the corresponding feminine and neuter words end in *ī* and *ẽ* respectively. Sex is usually distinguished by the use of the masculine and feminine genders, and large and powerful inanimate objects are generally masculine, while small, delicate things are generally feminine. In the case of some animals sex is distinguished by the use of different words.

A pleonastic suffix of -(*a*)*ka*-(masc. and neut.), could in Sanskrit be added to any noun, whatever the termination of the base might be. Modern forms made with this pleonastic suffix, and ending in *ā, ī* or *ẽ* are called "strong forms," while all those made without it are called "weak forms." As a rule the fact that a noun is in a weak or strong form does not affect its meaning, but sometimes the use of a masculine strong form indicates clumsiness or hugeness. Other pleonastic suffixes are employed in Marathi, usually with specific senses. Thus the suffix-*illa*-generally forms adjectives, while -*ḍa-ka* implies contempt.

The synthetic declension of Sanskrit and Prakrit has been preserved in Marathi more completely than in any other Indo-Aryan language. In the formation of the plural the Prakrit declensions are very closely followed by Marathi.

The usual post-positions are:—

Instrumental: *nẽ*, plural *nĩ*, by. Dative: *lā*, plural also *nā*, to or for. Ablative: *hūn, ūn*, from. Genitive: *tsā*, of. Locative: *āt*, in.

The accusative is usually the same as the nominative, but when definiteness is required the dative is employed instead. The termination *nẽ*, with its plural *nĩ*, is really the oblique form, by origin a locative, of the *nā* or *nō*. The suffix *nā* of the dative plural is derived from the same word. The post-position *lā* is probably a corruption of the Sanskrit *lābhē*, for the benefit (of). The locative termination *ā̃t* is a contraction of the Pr. *antō*, Skt. *antar*, within. The genitive *gharātsā* is really an adjective meaning "belonging to the house," and agrees in gender, number and case with the noun which is possessed. The suffix *tsā, cī, cẽ*, is derived from the Sanskrit suffix *tyakas*, Pr. *caō*, which is used in much the same sense.

Strong adjectives, including genitives, can be declined like substantives, and agree with the qualified noun in gender, number and case. When the substantive is in an oblique case, the adjective is put into the general oblique form without any defining post-position, which is added to the substantive alone. Weak adjectives are not inflected in modern prose, but are inflected in poetry. Comparison is effected by putting the noun with which comparison is made in the ablative case.

The pronouns closely follow the Prakrit originals. There is no pronoun of the third person, its place being supplied by the demonstratives. In all the plural is employed honorifically instead of the singular.

Conjugation.—Marathi has two conjugations. The first as a rule consists of intransitive verbs, and the second, corresponding to the *e*-or causal-class, of transitive verbs, but there are numerous exceptions.

In Marathi the present has lost its original meaning and is now a habitual past. It is also the base of the Marathi future, which is formed by adding *l*, or in the first person singular *n*, to the old present. In the second person singular the *l* has been added to a form derived from the Pr. *uṭ ṭhasi*, which is also the origin of the old present *uṭhēs*. The remaining tenses are modern forms derived from the participles. The conjunctive participle is derived from the Apabhramśa form *uṭṭhiu*, to which the dative suffix *n*. (old Marathi *ni, niyā*) has been added.

Various tenses are formed by adding personal suffixes to the present, past or future passive participle. When the subject of the verb is in the nominative the tense so formed agrees with it in gender, number and person. In the present, the terminations are relics of the verb substantive, and in the other tenses of the personal pronouns.

The present tense is formed by compounding the present participle with the verb substantive. Further tenses are similarly made by suffixing, without compounding, various tenses of the verb substantive to the various participles.

Literature.—The modern vernacular literature of the Maratha country arose under the influence of the religious reformation inaugurated by Rāmānuja early in the 12th century. The earliest writer is Nāmdēv (13th century), whose hymns in honour of Vithoba, a personal form of Vishnu, are found in the Sikh *Ādi Granth*. Dnyānōbā, a younger contemporary, wrote a paraphrase of the Sanskrit *Bhagavad Gītā*, which is still much admired. Sivaji was a disciple of Rāmdās, (1608–1681), who exercised great influence over him, and whose *Dāsbōdh*, a work on religious duty, is a classic. Contemporary with Rāmdās and Sivaji was Tukārām (1608–1649), a Śudra by caste, the greatest writer in the language. Being unsuccessful both in his business and in his family relations, he abandoned the world and became a wandering ascetic. His *Abhangs* or "unbroken" hymns are famous in the country of his birth, but do not rise to any great height as poetry. Other Marathi poets are Srīdhar (1678–1728), who translated the *Bhāgavata Purāṇa*, and the learned Mayūra or Mōrōpant (1729–94). Mahīpati (1715–90) was an imitator of Tukārām, who collected the popular traditions about national saints. *Lāvaṇīs*, or erotic lyrics, by various writers, are popular, but are often more passionate than decent. The *Pawaḍas* or war-ballads, mostly by nameless poets, are sung everywhere throughout the country. There is a small prose literature consisting of narratives of historical events (the so-called *Bakhars*), moral maxims and popular tales.

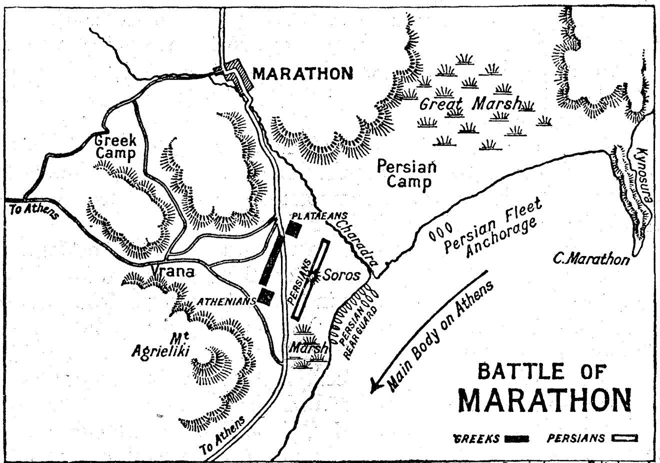
Konkani once had a literature of its own, which is said to have been destroyed by the Inquisition at Goa. Temples and manuscripts were burnt wholesale. Under Roman Catholic auspices a new literature arose, the earliest writer being an Englishman, Thomas Stephens (Thomaz Esteyão), who came to Goa in 1579, wrote the first Konkani grammar, and died there in 1619. Amongst other works, he was the author of a Konkani paraphrase of the New Testament in metrical form.

BIBLIOGRAPHY.—Marathi is fortunate in possessing the best dictionary of any modern Indian language, J. T. Molesworth's (1857). For learners Navalkar's (1894) and R. B. Joshi's (Poona, 1900) are the best grammars, while in J. Bloch's *La Formation de la Langue Marathe* (1914) we have an admirable history of the language, and of its present conditions, written by a trained philologist. *See* also *Grammatica da lingua Concani no dialecto do norte* by J. F. da Cunha Rivara (1858). For Konkani proper *see* A. F. X. Maffei's *Grammar* (Mangalore, 1882) and *Dictionaries* (*ibid.*, 1883) (in English). Monsenhor S. R. Dalgado is the author of a *Konkan-Portuguese Dictionary* (1893). A full account of Marathi, given in great detail, will be found in vol. vii. of the *Linguistic Survey of India* (1905).

MARATHON, a plain about 5m. long by 2m. wide on the east coast of Attica 24m. N.E. of Athens. There is a large marsh at the northern end from which extremity the Kynosura promontory a mile long ending in Cape Marathon forms an anchorage sheltered from the north and east. From the village of Marathon the Charadra brook bisects the plain and a small marsh lies at the southern end. Here (490 B.C.) 9,000 Athenian and 1,000 Plataean heavy infantry defeated part of a Persian army under Datis and Artaphernes. During the Ionian revolt the Athenians and Eretrians had aided the rebels in the attack on Sardis. The Persian king, Darius, ordered his generals to "enslave Athens and Eretria and bring the slaves into his presence." (Herodotus vi. 94.)

Eretria, after a siege, was surrendered by treachery. The city was destroyed and the inhabitants enslaved. The Persian host, guided by Hippias, the former tyrant of Athens, landed at Marathon "thinking to do the same to the Athenians." (Herodotus vi. 102.)

When news of the fall of Eretria reached Athens a courier, Pheidippides, was sent to Sparta for aid. Miltiades, with knowledge



Bartholomew, Edinburgh

of war and of the Persians, was selected as one of the Athenian generals under the Polemarch, Callimachus, and seems to have dominated the war council and dictated the plan of campaign. The Athenians marched on Marathon to delay the Persian advance in the passes leading to Athens and to enable the Plataeans and Spartans to join. On the march the Plataeans came up. The passes were found unoccupied and the Greeks took up a position in the Avlona valley covering the direct roads to Athens and flanking the southern road. The result was to pin down the Persians. Against the Greek position in a narrow valley with both flanks secured by hills they could not use their cavalry. To advance by the southern road would commit their column to a defile between the mountains and the sea and enable the Greeks to fall upon their rear while the main body would be unable to come up. To re-embark would expose part of their army to almost certain disaster. In spite of the Spartan delay on account of a religious festival, time fought for the Athenians.

While the Spartans were on the Isthmus of Corinth the Persians embarked their cavalry and part of their infantry to make a dash on Athens by sea. A rear guard, probably about 20,000 strong, was drawn up on the southern part of the plain parallel with the beach. Callimachus, probably on the advice of Miltiades, decided to attack—the date was probably Sept. 21. A mile from the Persian line the Greeks were marshalled, the centre thinned so as to extend the line to equal that of the Persians and to strengthen the Athenian right under Callimachus and the Plataeans on the left. Down the sloping plain moved the bronze-clad Greeks. When the ranks came within range of the Persian missiles they broke into a charge. The weak Athenian centre recoiled; but the shock of the heavy Greek wings crushed in and rolled up the Persian flanks. The victorious Persian centre was then dealt with. The hostile rear guard was destroyed losing 6,400 killed. The Greeks lost 192. The Athenians then marched back to Athens and arrived in time to forestall a landing by the Persian main body.

The failure of the Persians was due to neglect of security measures and lack of aggressive action which resulted in failure to make use of superior numbers, and finally to a division of forces. The Greeks were prompt in action and sought to unite their strength for the decisive battle, and bring it to bear against a part of the Persian army. Tactically, the successful double envelopment of the hostile flanks foreshadowed the design of Cannae. If at Marathon the situation is unlikely to have been created intentionally, the opportunity at least was ably exploited. (*See* GRAECO-PERSIAN WARS.)

MARATHON RACE, a race run over a distance of 26m. 385yds., which still commemorates the epic feat of Pheidippides in 490 B.C. News had reached the Athenians that Darius the Mede was crossing the Aegean sea to conquer the Greek States. Pheidippides, an Olympic champion runner, was despatched to enlist the aid of the Spartans. For two days and two nights he travelled, swimming the rivers and climbing the mountains in his path. Then he returned with the news that the Spartan army would start at the full moon. Meanwhile the Persians had landed and the Athenians, accompanied by Pheidippides, bearing his long spear and heavy shield, set out to meet the invaders in battle at Marathon. That encounter resulted in a victory for the Greeks and, forthwith, Pheidippides set out to bear the news to the capital. Unencumbered by his weapons he ran the 22 miles from Marathon to Athens, only to fall dead on the outskirts of the city as he gasped (in Greek), "Rejoice, we conquer!"

When the Olympic games were reinstated at Athens in 1896 a marathon race was included in the programme and, most appropriately, won by Loues, a Greek peasant, who covered the course in 2 hours 55mins. 20secs. The scenes which signallized the success of Loues were remarkable. When he entered the stadium at the end of the race, the Greek spectators rose as one man to celebrate their countryman's victory, women tore off their jewellery to fling it at his feet, a hotel proprietor gave him an order for 365 free meals, and even a street urchin pressed forward with the promise to black his boots for nothing for the rest of his life. Another memorable marathon race was that of 1908, run from Windsor Castle to the Olympic stadium at Shepherd's Bush, London. In that year the 2,000-year-old tragedy of Pheidippides was very nearly repeated. Dorando Pietri, 23 years of age and a restaurant waiter by calling, was entered as the chief representative of Italy. The race was run in exceptionally hot weather and the British representatives set up a pace at the start which was largely responsible for the terrible condition of the leading runners at the finish. Many of the 75 competitors who had started from Windsor collapsed by the way. Dorando, who ran pluckily throughout, was forced to abate his pace to a crawl when approaching the Stadium and collapsed, for the first time, at the entrance to the track; first aid was rendered and he rose to totter on around the arena. Fifty yards further and he went down again, and was again helped up. He fell for the third time and was afterwards almost carried past the winning post. Not unnaturally, protests were lodged by J. J. Hayes, U.S.A., and C. Hefferon, South Africa, who had finished second and third respectively, and Dorando Pietri, who could never have reached the tape without assistance, was disqualified. Her Majesty, the late Queen Alexandra, however, presented the plucky little Italian with a gold cup.

The event is now regarded as the blue-ribbon of the Olympic games and is honoured as a championship in all countries. Of the Olympic victors the United States, Finland, and France have each produced two, the other victors coming singly from Greece, South Africa, Argentina, and Japan.

It is impossible to assess truly either the world's or Olympic records on account of the varying conditions in different countries.

The fastest time recorded is that of K. Son, Japan, who won the Olympic Marathon Race, 1936, in 2 hrs. 29 mins. 19.2 secs., beating E. Harper, Great Britain, by 2 mins. 4 secs. In 1932 S. Ferris, Great Britain, was second to J. Zabala, Argentina.

Great Britain has been unfortunate in this event. In 1932 J. Zabala was forced to make a new Olympic record of 2 hrs. 31 mins. 36 secs. to beat S. Ferris; and although Harper beat this in 1936 by 12.8 secs., a badly blistered foot prevented him from keeping on terms with K. Son of Japan.

Marathon racing is far more strenuous than any form of track or cross-country running, since it is all road-work. The runner who aspires to marathon fame must go through a period of at least three months' rigorous training to make himself sound in wind and limb, so that he may gradually, and by constant practice, bring his muscles and sinews to the highest pitch of endurance. In this form of racing it is the pace and not the distance that kills. Style counts for little over this trying course. Tall, heavy runners are not well suited to the event. Small, light men, with powerful legs and plenty of lung and heart room, are the most likely to develop into long-distance champions, and to this class belong Dorando Pietri, J. J. Hayes and the Finnish Olympic champions, Hannes Kolehmainen and A. O. Stenross. It is unwise for young and immature athletes to attempt the marathon distance; it has, indeed, been proved that men of over 30 years are generally best fitted for this endurance race—witness the repeated success of Paavo Nurmi, Finland, in the Boston marathon.

MARATTA (Maratti), **CARLO** (1625–1713), Italian painter of the Roman school. He was born at Camerano between Loreto and Ancona on May 13, 1625, and went early to Rome where he worked under Andrea Sacchi. He formed his style by studying the paintings of the Caracci and of Raphael. After the deaths of his master and of Pietro da Cortona he was for nearly half a century the most eminent painter in Rome. Six successive popes honoured him with their patronage. Innocent II. made him curator of the apartments in the Vatican and in the years 1702–03 he restored by order of Clement XI. the frescoes of Raphael in the Vatican and the Farnesina. For this service he was given the knighthood of the order of Christ. Louis XIV. nominated him a court painter. He died in Rome on Dec. 15, 1713. Maratta was an ardent admirer of Raphael, whose style, modified by the eclectic influence of the Caracci, he followed in opposition to the then prevailing Baroque style of Pietro da Cortona. His chief works, which are very numerous, are easel pictures in oil. His conceptions are graceful and lacking in vigour. There are several etchings by this painter. His life has been described by his intimate friend G. P. Bellori in *La Vita di Carlo Maratta* (1731).

MARAZION, a small seaport of Cornwall, England, on the shore of Mount's bay, 2 m. E. of Penzance. Pop. (1931) 1,126. A causeway of boulders and pebbles, thrown up by the sea and passable at low tide, unites Marazion with the insular St. Michael's Mount (*q.v.*). The charter attributed to Robert, count of Mortain, granting lands and liberties to St. Michael's Mount, opposite Marazion, included a market on Thursdays. This appears to have been held from the first on the mainland. From it is probably derived the Marghasbigan (*Parvum Forum*) of the earlier and the Marghasyewe or Marketjew (*Forum Tovis*) of the later charters. Richard, king of the Romans, provided that the three fairs, on the two feasts of St. Michael and at Mid-Lent, and the three markets which had hitherto been held by the priors of St. Michael's Mount on land not their own at Marghasbigan, should in future be held on their own land at Marchadyou. To remedy the loss incurred by this measure Ralph Bloyou in 1331 procured for himself and his heirs a market on Mondays and a fair on the vigil, feast and morrow of St. Andrew at Marghasyon. In 1595 Queen Elizabeth granted to Marazion a charter of incorporation. This ratified the grant of St. Andrew's fair, provided for another on the Feast of St. Barnabas and established a market on Saturdays. In 1883 the old corporation ceased to function, and its property was vested in the charity commissioners. Of the fairs only the Michaelmas fair has survived and all the markets have gone. Remains of an ancient bronze furnace, discovered near the town, tend to prove that tin-smelting was practised here at an early period. Marazion was once a flourishing town, and owed its prosperity to the throng of pilgrims who came to visit St. Michael's Mount. During the first half of the 16th century it was twice plundered; first by the French, and later by the Cornish rebels. The rise and progress of the neighbouring borough of Penzance in the 17th century seriously affected Marazion.

The church of St. Hilary, destroyed by fire in 1853, had a very fine spire, which has been reproduced in the restored building. The inscribed stones in the churchyard date from the 4th century, one being in honour of Constantine the Great. Another has Cornish lettering, which can no longer be deciphered; and there are British and Roman crosses. Market gardening is extensively carried on, and there is a fishing industry.

MARBLE, a term applied to any limestone or dolomite which is sufficiently close in texture to admit of being polished (from Lat. *marmor*, Gr. *μάρμαρος* shining stone). Many other ornamental stones—such as serpentine, alabaster and even granite—are sometimes loosely designated marble, but by accurate writers the term is invariably restricted to those crystalline and compact varieties of carbonate of lime (occasionally with carbonate of magnesia) which, when polished, are decorative. The crystalline structure is typically shown in statuary marble. A fractured surface of this stone displays a multitude of sparkling facets, which are the rhombohedral cleavage-planes of the component grains. The beautiful lustre of polished statuary marble is due to the light penetrating for a short distance into the rock and then suffering reflection at the surfaces of the deeper-lying crystals. The durability of marble in a dry atmosphere or when protected from rain renders it a valuable building stone; on the other hand, when exposed to the weather or the acid atmosphere of large cities, its surface readily crumbles.

Statuary and Economic Marbles.—Among statuary marbles the first place may be assigned to the famous Pentelic marble, the material in which Pheidias, Praxiteles and other Greek sculptors executed their principal works; it came from the quarries of Mount Pentelicus in Attica, and its characteristics are well seen in the Elgin marbles from the Parthenon at Athens now at the British Museum. Parian marble, another stone much used by Greek sculptors and architects, was quarried in the isle of Paros, chiefly at Mount Marpessa. It is called by ancient writers *lychnites* (Gr. *λύχνος*, a lamp) in allusion to the fact that the quarries were worked by the light of lamps. The Venus de' Medici is a notable example of work in this material. Carrara marble is better known than any of the Greek marbles, inasmuch as it constitutes the stone invariably employed by the best sculptors of the present day; it occurs abundantly in the Apuan Alps, an offshoot of the Apennines, and is largely worked in the neighbourhood of Carrara, Massa and Serravezza. Stone from this district was employed in Rome for architectural purposes in the time of Augustus, but the finer varieties, adapted to the needs of the sculptor, were not discovered until some time later. It is in Carrara marble that the finest works of Michelangelo and of Canova are executed; the purest varieties are snow-white and are of fine saccharoidal texture. Silica is disseminated through some of the marble, becoming a source of annoyance to the workman; while occasionally it separates as beautifully pellucid crystals of quartz known as "Carrara diamonds."

Other Varieties of Marble.—Certain calcareous metamorphic rocks frequently form stones which are sufficiently beautiful to be used for ornamental purposes, and are generally classed as marbles. Such serpentinous limestones are included by petrologists under the term *ophicalcite*. The famous *verde antico* is a rock of this character.

Many marbles which are prized for the variegated patterns they display owe these patterns to their formation in concentric zones—such marbles being in fact stalagmitic deposits of carbonate of lime, sometimes consisting of aragonite. One of the most beautiful stalagmitic rocks is the so-called onyx marble of Algeria. This was largely used in the buildings of Carthage and Rome, but the quarries which yielded it were rediscovered near Oued-Abdallah only in 1849. The stone is a beautifully translucent material, delicately clouded with yellow and brown, and is greatly prized by French workmen. Large deposits of a very fine onyx-like marble, similar to the Algerian stone, have been worked at Técali, about 35 m. from the city of Mexico. Among other stalagmitic marbles, mention may be made of the well-known Gibraltar stone, which is often worked into models of cannon and other ornamental objects. This stalagmite is much deeper in colour and less translucent than the onyx marbles of Algeria and Mexico. A richly tinted stalagmitic stone worked in California is known as Californian marble. It is worth noting that the "alabaster" of the ancients was stalagmitic carbonate of lime, and that this stone is therefore called by mineralogists "Oriental alabaster" in order to distinguish it from our modern "alabaster," which is a sulphate, and not a carbonate, of lime. Gypsum capable of taking a polish is found at Fauld in Staffordshire and in Italy and Spain.

The brown and yellow colours which stalagmitic marbles usually present are due to the presence of oxide of iron. This colouring matter gives special characters to certain stones, such as the *giallo antico,* or antique yellow marble of the Italian antiquaries. Siena marble is a reddish mottled stone obtained from the neighbourhood of Siena in Tuscany; and a somewhat similar stone is found in King's county, Ireland. True red marble is by no means common, but it does occur, of bright and uniform colour, though in very small quantity, in the Carboniferous limestone of Derbyshire and north-east Staffordshire. The red marble called *rosso antico* is often confounded with the *porfido rosso antico,* which is really a mica-hornblende-porphyrite owing its red colour to the mineral withamite.

Fire marble is a brown shelly limestone containing ammonites and other fossil shells, which present a brilliant display of iridescent colours, like those of precious opal. It occurs in rocks of Liassic age at the lead-mines of Bleiberg in Carinthia, and is worked into small ornamental objects.

Occurrence in Great Britain.—Although crystalline marbles fit for statuary work are not found to any extent in Great Britain, the limestones of the Palaeozoic formations yield a great variety of marbles well suited for architectural purposes. The Devonian rocks of south Devon are rich in handsome marbles, presenting great diversity of tint and pattern. Plymouth, Torquay, Ipplepen, Babbacombe and Chudleigh may be named as the principal localities. Many of these limestones owe their beauty to the fossil corals which they contain, and are hence known as "madrepore marbles." Of far greater importance, however, are the marbles from the Carboniferous or Mountain Limestone, whence British marbles are mainly derived. Marbles of this age are worked in Derbyshire and Yorkshire, in the neighbourhood of Bristol, in North Wales, in the Isle of Man, and in various parts of Ireland; one of the most beautiful is the "encrinital marble," a material which owes its peculiarities to the presence of numerous encrinites, or stone-lilies, fossils which, when cut in various directions, give a characteristic pattern to the stone. The joints of the stems and arms are known from their shape as "wheel-stones," and the rock itself has been called "entrochal marble." The most beautiful varieties are those in which the calcareous fossils appear as white markings on a ground of grey limestone. In Belgium a black marble with small sections of crinoid stems is known as *petit granit,* while in Derbyshire a similar rock, crowded with fragments of minute encrinites, is termed "bird's-eye marble."

Perhaps the most generally useful marbles yielded by the Carboniferous system are the black varieties, which are largely employed for chimney-pieces, vases, etc. The colour of most black limestone is due to the presence of bituminous matter. Such limestone commonly emits a fetid odour when struck; and the colour, being of organic origin, is discharged on calcination.

British limestones of Mesozoic and Tertiary age are not generally compact enough to be used as marbles, but some of the shelly beds are employed to a limited extent for decorative purposes. The most important Mesozoic marbles are the shelly limestones of the Purbeck formation, which were a favourite material with mediaeval architects for slender clustered columns and sepulchral monuments. It consists of a mass of the shells of a freshwater snail, *Paludina carinifera,* embedded in a blue, grey or greenish limestone, and is found in the Upper Purbeck beds of Swanage. Excellent examples of its use may be seen in Westminster Abbey and in the Temple Church, as well as in the cathedrals of Salisbury, Winchester, Worcester and Lincoln. Sussex marble is very similar, occurring in thin beds in the Weald clay and consisting largely of the shells of *Paludina,* principally *P. sussexiensis* and *P. fluviorum.* The altar stones and the episcopal chair in the cathedral at Canterbury are made of this material.

Marble in the United States.—America possesses some valuable deposits which, in the eastern States, have been extensively worked. The crystalline limestones of western New England furnish an abundance of white and grey marble, while a beautiful material fit for statuary has been quarried near Rutland, Vt. A grey bird's-eye marble is obtained from central New York, and the greyish clouded limestones of Thomaston, Me., have been extensively quarried. Of the variegated and coloured marbles, perhaps the most beautiful are those from the northern part of Vermont, in the neighbourhood of lake Champlain. A fine brecciated marble is found on the Maryland side of the Potomac, below Point of Rocks. Among the principal localities for black marble may be mentioned Shoreham, Vt., and Glens Falls, N.Y. In 1937 the production of dimension marble in the United States was valued at $5,134,721, of which $3,336,545 was building marble and $1,798,176 monumental marble. Production by leading States in 1937 was Vermont, $1,539,571; Tennessee, $1,384,961; Georgia, $1,030,407; Missouri, $445,114; Alabama, $313,663; Arkansas, $22,902; all other States, $398,103.

In Canada the crystalline limestones of the pre-Cambrian series yield beautiful marbles.

Marble in Other Countries.—The quarries of France, Belgium, Italy and Spain, not to mention less important localities, yield a great diversity of marbles, and almost every stone bears a distinctive name, often of trivial meaning; but in this article it is impossible to enumerate the local names used by marble-workers in different countries. In India we find important quarries at Makrana in Rajputana—a locality which is said to have yielded the marble for the famous Taj Mahal at Agra. In the valley of the Nerbudda, near Jabalpur, there is a large development of marble. The white marble which is used for the delicately pierced screens called *jalee* work is obtained from near Raialo, in Ulwar. (F. W. R.; X.)

Petrography.—Marbles are uniformly crystalline, and hence have no bedding or schistosity which would tend to make them fissile, but are entirely massive and free from grain. The microstructure of pure marble is comparatively simple. Thin sections are seen to be built up of somewhat rounded grains of calcite, fitting closely together in a mosaic; very rarely do any grains show traces of crystalline form. They are colourless and transparent, and are usually traversed by a lattice-work of sharply defined cleavage cracks, which correspond to the rhombohedral faces. In polarized light the colours are pinkish or greenish white, or in very thin sections iridescent because the mineral has a very strong double refraction. They may also be crossed by bars or stripes, each of which indicates a twin plate, for the crystals are usually polysynthetic. This twinning may be produced by pressure acting either during the crystallization of the rock or at a later period.

The purest marbles generally contain some accessory minerals, and in many they form a considerable proportion of the mass. The commonest are quartz in small rounded grains, scales of colourless or pale yellow mica (muscovite and phlogopite), dark shining flakes of graphite and small crystals of pyrites or iron oxides. Even fine Carrara marble leaves a residue of this sort when dissolved in acid. Many marbles contain other minerals which are usually silicates of lime or magnesia. The list of these accessories is a very large one. Diopside is very frequent and may be white or pale green; hornblende occurs as white bladed tremolite or pale green actinolite; feldspars may be present also, such as orthoclase, or more frequently some plagioclase such as albite, labradorite and anorthite, scapolite (or wernerite); various kinds of garnet; vesuvianite, spinel, forsterite, periclase, brucite, talc, zoisite and epidote, chondrodite, biotite, datolite, sphene and apatite may be mentioned as typical accessory minerals. The presence of metalliferous minerals such as galena,

grey or red silver ores, zinc blende, antimonite, chalcopyrite, molybdenite, cassiterite, usually indicates impregnation by ore-bearing solutions, especially if these substances occur in workable quantities. The rubies of Burma are found in crystalline limestones and are constantly accompanied by precious spinel (or balasruby).

These minerals represent impurities in the original limestone which crystallized at the time that the marble became crystalline. The silicates derive their silica mainly from sand or infiltrated siliceous deposits; the alumina represents an admixture of clay; the iron came from limonite or hematite in the original state of the rock. Where the silicates bulk largely because the original limestone was highly impure, all the carbonic acid may be driven out and replaced by silica during the process of recrystallization. The rock is then a calc-silicate rock, hard, tough, flinty and no longer readily soluble in acids. They are sometimes fine-grained hornstones (known as calc-silicate hornfelses). Where white minerals predominate (wollastonite, tremolite, feldspar) these rocks may have a close resemblance to marbles, but often they are green from the abundance of green pyroxenes and amphiboles, or brown (when garnet and vesuvianite are present in quantity) or yellow (with epidote, chondrodite or sphene). Decomposition induces further changes in colour owing to the formation of green or yellow serpentine, pale green talc, red hematite, and brown limonite. Most of the coloured or variegated crystalline marbles have originated in this manner. Often bands of calc-silicate rock alternate with bands of marble, and they may be folded or bent; in other cases, nodules and patches of silicates occur in a matrix of pure marble. Earth movements may shatter the rocks, producing fissures afterwards filled with veins of calcite; in this way the beautiful brecciated or veined marbles are produced. Sometimes the broken fragments are rolled and rounded by the flow of the marble under pressure and pseudo-conglomerates or "crush conglomerates" result. In other cases the banding of the marble indicates the original bedding of the calcareous sediments. Crystalline limestones which contain much mica may be called cipollins; in them quartz, garnet and hornblende often also occur. The *ophicalcites* are marbles containing much serpentine, which has been formed by the decomposition of forsterite or diopside. The much-discussed *Eozoon,* at one time supposed to be the earliest known fossil and found in Archaean limestones in Canada, is now known to be inorganic and to belong to the ophicalcites.

Many marbles, probably all, are metamorphosed limestones. The passage of limestones rich in fossils into true marbles as they approach great crystalline intrusions of granite is a phenomenon seen in many parts of the world; occasionally the recrystallization of the rock has not completely obliterated the organic structures (*e.g.,* at Carrara and at Bergen in Norway). The agencies which have induced the metamorphism are heat and pressure, the heat arising from the granite and the pressure from overlying masses of rock, for these changes took place before the granite cooled and while it was still deeply buried beneath the surface. As rocks which have undergone changes of this kind are commonest in the oldest and deepest layers of the earth's crust, most marbles are Palaeozoic or pre-Cambrian. They occur very often with mica schists, phyllites, etc., which were beds of clay alternating with the original limestone. In regions where the sedimentary rocks have been converted into schists, gneisses and granulites, the limestones are represented by calc schists, cipollins and marbles. Often no granite or other intrusive rock is present which may be regarded as the cause of the metamorphism. The marbles are often banded or schistose, and under the microscope show crushing and deformation of the component crystals, such as would have been produced by the earth pressures which accompany rock-folding. These crush structures have been obtained experimentally in marbles subjected to great pressures in steel cylinders. In the recrystallization of these limestones the direct heating action of igneous intrusions may have played no part, but the rise of temperature and increase of pressure due to the folding of great rock masses have probably been the operating causes.

(J. S. F.)

MARBLEHEAD, a town of Essex county, Massachusetts, U.S.A., on Massachusetts bay, 16 m. N.E. of Boston. It is served by the Boston and Maine railroad. The population was 10,856 in 1940 federal census. It is a quaint old town, occupying a rocky promontory about 4 sq.m. in area. Among the older buildings are the Lee Mansion (1768), which houses the Marblehead Historical Society, St. Michael's Church (Protestant Episcopal; 1714), the old Town Hall (1727), the Old Brig, and the Gerry house, where Elbridge Gerry was born. The harbour, formed by a rocky peninsula known as Marblehead Neck, is now a yachting centre. Along the picturesque rocky coast are the modern hotels, cottages and club-houses of the summer colony. The principal industries of the town are the manufacture of children's shoes, yacht and launch building and fishing. Marblehead was settled about 1629, and was set off from Salem and incorporated in 1649. In the early 17th century it received many colonists from the Channel islands. In the colonial period it was an important commercial, fishing and shipbuilding port, and at one period was one of the largest communities in Massachusetts. After the passage of the Boston Port Bill (1774) it was made the port of entry in place of Boston, but its merchants patriotically put their wharves and warehouses at the disposition of the Boston merchants and refused to profit by the opportunity. During the Revolution many vessels set out from this port, including the "Lee," which in Nov., 1775 captured the "Nancy," with military stores valued at £20,541. The sea fight between the "Chesapeake" and the "Shannon" (June 1, 1813) took place off the adjacent coast. Marblehead claims to be the birthplace of the American Navy, as the schooner "Hannah," manned and fitted here, was the first American warship regularly commissioned (Sept. 2, 1775, by General Washington) by authority derived from the United Colonies.

MARBOT, JEAN BAPTISTE ANTOINE MARCELIN, Baron de (1782–1854), French soldier, son of General Jean Antoine de Marbot (1754–1800), who died in the defence of Genoa under Masséna, was born at La Rivière (Corrèze) on Aug. 18, 1782. He joined the republican army as a volunteer in 1799. He was aide-de-camp to Marshal Augereau, commanding the VII. corps, in the war against Prussia and Russia in 1806–7. After this he served in the Peninsular War under Lannes and Masséna, in the Russian War of 1812 and the German campaign of the following year. After a slow recovery from the wounds he had received at Leipzig and Hanau, he was promoted general of brigade by Napoleon during the Hundred Days, and took part in, and was wounded at, the battle of Waterloo. He was exiled at the second restoration and only returned to France in 1819. His intimacy with the duke of Orleans secured him important military positions. Under the July monarchy he was present at the siege of Antwerp in 1832. He was promoted lieutenant-general in 1836. From 1835 to 1840 he served in various Algerian expeditions, and in 1845 he was made a member of the Chamber of Peers. Three years later, at the fall of Louis Philippe, he retired into private life. He died at Paris on Nov. 16, 1854. Marbot's fame rests on the fascinating *Memoirs of his Life and Campaigns* (1891; Eng. trans., 1902).

His elder brother, Antoine Adolphe Marcelin de Marbot (1781–1844), served in Napoleon's campaigns of 1808 to 1812, and again in the Hundred Days. He returned to the army after 1830.

MARBURG, a university town in the Prussian province of Hesse-Nassau, Germany, on the right bank of the Lahn, 60 mi. by rail N. of Frankfort-on-Main, on the main line to Cassel. Pop. (1939) 29,010. Marburg is first historically mentioned in a document of the beginning of the 13th century, and received its municipal charter from the landgrave Louis of Thuringia in 1227. By 1247 Marburg had already become the second town of Hesse, and in the 15th and 16th centuries it alternated with Cassel as the seat of the landgraves. In 1529 the famous conference between Luther and Zwingli on the subject of Transubstantiation took place there in the Rittersaal of the Schloss. The hill on which the town lies is crowned by the Schloss, a Gothic building, the most noteworthy parts of which are the Rittersaal, dating from 1277–1312, and the little chapel. This Schloss is now the repository of the archives of Hesse. The Elizabethenkirche, in the purest Early Gothic style, was erected by the grand master of the Teutonic Order in 1235–83, to contain the tomb of St. Elizabeth of Hungary, who was the wife of the landgrave Louis. She built a hospital here, and died in 1231, worn out with works of charity. In 1235 she was canonized at the instance of the Teutonic Knights who were zealous in promoting her cult. Her rich silver-gilt sarcophagus may still be seen, but the Protestant zeal of Landgrave Philip the Generous caused him to remove the body to some unknown spot in the church. The Lutheran church is another Gothic edifice, mainly 15th century. The town hall, built in 1512, and several houses in the Renaissance style, also deserve mention. The university of Marburg, founded in 1527, was the first university established without papal privileges, and acquired a great reputation throughout Protestant Europe. Marburg is the seat of a district court. Marburg pottery is renowned; and soap, iron wares and surgical instruments are also manufactured there.

MARBURG, COLLOQUY OF, the name given to a conference of divines held in 1529 in the interests of the unity of Protestant Germany. The circumstances in which it was held, the influence of the men who conducted its deliberations, and the result of its proceedings, combine to render it of no small importance for the history of the Reformation in Germany.

The measures taken by the Catholic party to resist the progress of the Reformation, especially by resolutions at Speyer (1526 and 1529), would be met only by the united force of all the princes and states subscribing to the Evangelical teaching; and this unity was wanting. The feud which raged round the doctrine of the Lord's Supper had already broken out before the first diet of Spires, and had aroused great and immediate excitement. At a very early period, however, efforts were made to allay the dissension. Strassburg pronounced for conciliation: but the most powerful and zealous champion of peace was to be found in the landgrave Philip of Hesse, who recognized the absolute necessity—from a political standpoint—of the union of all German Protestants. It was obvious that a permanent coalition could not be expected unless some definite understanding on the debated point could be attained; and the landgrave succeeded in bringing about a conference or "colloquy" at Marburg, in October 1529.

The proceedings opened on the 1st of October with conferences between Luther and Oecolampadius, and Melanchthon and Zwingli: then on the two following days the discussion proper—confined almost entirely to Luther and Zwingli—was held before the landgrave and his guest Duke Ulrich of Württemberg, in the presence of more than fifty persons. As regards the main point of contention, *i.e.,* the doctrine of the Lord's Supper, no agreement was found practicable; and the private conversations on the 4th of October, which formed the sequel of the debate, carried matters no farther. Since the landgrave, however, was reluctant to see the colloquy brought to an absolutely fruitless close, he requested Luther to draw up a list of the most important points of doctrine on which it might yet be possible to arrive at some degree of unanimity. This was done on the 4th of October; and a few alterations were introduced to meet the wishes of the Swiss deputies. The *Articles of Marburg,* which thus came into being, contain the doctrine of the Trinity, of the personality of Christ, of faith and justification, of the Scriptures, of baptism, of good works, of confession, of government, of tradition and of infant baptism. The fifteenth article, treating of the Lord's Supper, defines the ground common to both parties even in this debatable region, recognizing the necessity of participation in both kinds, and rejecting the sacrifice of the Mass. It then proceeds to fix the point of difference in the fact that no agreement had been reached on the question "whether the true body and blood of Christ are corporeally present in the bread and wine."

MARC, FRANZ (1880–1916), German painter, was born at Munich on July 4, 1880, the son of the painter, Wilhelm Marc. He studied at Munich under Hackl and W. von Dietz. The decisive impulse came only when he got into touch with the group of painters including Kandinsky, Jawlenski and Macke who founded the "Blue Knight" (*Blauer Reiter*) in 1911. One of his most famous pictures entitled "Tierschicksale" (Destinies of Beasts) is characteristic of his whole work, which is singularly compact, not merely in choice of motive, but also in pictorial composition. A leaning towards metaphysics, towards abstraction from the world of reality, gives many of his pictures a problematic character. Marc was killed near Verdun on March 4, 1916.

MARCA, PIERRE DE (1594–1662), French prelate and historian, born at Gan, near Pau, on Jan. 24, 1594, attracted the notice of Richelieu by his support of the Catholic cause in the south during the wars of religion. Richelieu brought him to Paris as counsellor of State in 1640. He defended the "Gallican liberties" in the famous treatise, *De concordia sacerdotii et imperii, seu de libertatibus ecclesiae gallicanae* (1641). He was governor of Catalonia during the French occupation and, after holding various ecclesiastical preferments, was nominated archbishop of Paris in succession to De Retz in February 1662. He died on June 29 of the same year.

Marca made a minute study of the archives of Béarn and of the history of Catalonia. His *Histoire de Béarn* (1640) is valuable for the number of charters and other documents which it contains. *Marca hispanica* (1688), left unfinished at his death, was completed by his friend Baluze.

See the article "Marca" in Bayle's *Dictionnaire historique et critique.*

MARCANTONIO [MARCANTONIO RAIMONDI] (*c.* 1480–*c.* 1530), the chief Italian master of the art of engraving of the Renaissance, and the first who practised it in order to reproduce, not designs of his own invention, as earlier craftsmen had commonly done, but those of other artists almost exclusively. He was born probably about 1480 at Bologna. As early as 1504 he is mentioned as an artist of repute in G. P. Achillini's *Viridario.* His earliest dated plate, illustrating the story of Pyramus and Thisbe, is ascribed to the year 1505. Marcantonio received his training in the workshop of the famous goldsmith and painter, Francesco Raibolini, called Francia. "Having more aptitude in design," says Vasari, "than his master, and managing the graver with facility and grace, he made waist-buckles and many other things in niello, such being then greatly in fashion, and made them most beautifully, as being in truth most excellent in that craft."

The real fame, however, of Marcantonio was destined to be founded on his attainments in that particular development of the goldsmith's art which consists of engraving designs on metal plates for reproduction by the printing press. About eighty engravings can be referred to the first five or six years of his career (1505–1511). Their subjects are very various, including many of pagan mythology, and some of obscure allegory, along with those of Christian devotion. The types of figures and drapery, and the general character of the compositions, bespeak for the most part the inspiration, and sometimes the direct authorship, of Francia. But the influence of German example is very perceptible also, particularly in the landscape backgrounds, and in the endeavour to express form by means of light and shadow with greater freedom than had been hitherto the practice of the Italian schools.

It may have been for the sake of commercial profit or for the sake of improving his style that he by-and-by produced a series of direct counterfeits on copper from Albrecht Dürer's woodcuts. These facsimiles are sixty-nine in number, including seventeen of Dürer's "Life of the Virgin," thirty-seven of his "Little Passion," on wood, and a number of single pieces. The "Life of the Virgin" was copied in 1506 and signed with Dürer's signature. Dürer who visited Italy in that year complained to the Venetian Senate of this action of Marcantonio, who then added his own signature to the copies which he subsequently made and completed in 1510 of Dürer's "Little Passion." The Bolognese engraver profited greatly by the study of the energetic line work and the method of modelling by cross-hatching of the Nuremberg master. He was soon to come under a totally different influence, and to turn the experience he had gained to account in interpreting the work of a master of a quite other stamp. Up till the year 1510 Marcantonio had lived entirely at Bologna, with the exception, it would appear, of a visit or visits to Venice. A few of his early engravings are from drawings of the school of Giorgione.

Very soon afterwards he was attracted, for good and all, into the circle which surrounded Raphael at Rome. Where or when he had first made Raphael's acquaintance is uncertain. His passage to Rome by way of Florence has been supposed to be marked by an engraving, dated 1510, and known as "The Climbers," *Les Grimpeurs* (Bartsch, 487), in which he has reproduced a portion of the design of Michelangelo's cartoon of the soldiers surprised bathing, and has added behind the figures a landscape imitated from the then young Dutch engraver Lucas of Leiden. Contemporary or somewhat earlier than this is a large engraving done by him from a design by Baldassare Peruzzi, a Sienese artist drawn about the same time into the Raphael circle. The piece in which he is recorded to have first tried his hand after Raphael himself is the Lucretia (Bartsch, 192). From that time until he disappears in the catastrophe of 1527, Marcantonio was almost exclusively engaged in reproducing by means of engraving the designs of Raphael or of his immediate pupils. Raphael, the story goes, was so delighted with the print of the Lucretia that he personally trained and helped Marcantonio afterwards.

A printing establishment was set up under the charge of Raphael's colour-grinder, Il Baviera, and the profits, in the early stage of the business, were shared between the engraver and the printer. The sale soon became very great; pupils gathered round about Marcantonio, of whom the two most distinguished were Marco Dente, known as Marco da Ravenna, and Agostino de' Musi, known as Agostino Veneziano; and he and they, during the last ten years of Raphael's life, and for several years following his death, gave forth a great profusion of engravings after the master's work—not copying, in most instances, his finished paintings, but working up, with the addition of simple backgrounds and accessories, his first sketches and trials, which often give the composition in a different form from the finished work, and are all the more interesting on that account.

Marcantonio's best engravings were done during the first few years after he had attached himself to Raphael. In them he enters into the genius of his master, and loses little of the chastened science and rhythmical purity of Raphael's contours, or of the inspired and winning sentiment of his faces; while in the parts where he is left to himself—the rounding and shading, the background and landscape—he manages his burin with all the skill and freedom which he had gained by the imitation of northern models, but puts away the northern emphasis and redundance of detail. His work, however, does not long remain at the height marked by pieces like the Lucretia, the Dido, the Judgment of Paris, the Poetry, the Philosophy, or the first Massacre of the Innocents. Marcantonio's engravings after the works of Raphael's later years are cold, ostentatious, and soulless by comparison. Still more so, as is natural, were those which he and his pupils produced after the designs of the followers of Raphael and Michelangelo, of a Giulio Romano, a Polidoro, or a Bandinelli.

Marcantonio's association with Giulio Romano was the cause of his first great disaster in life. He engraved a series of obscene designs by that painter in illustration of the *Sonnetti lussuriosi* of Pietro Aretino, which caused his temporary banishment from Rome. Marcantonio's ruin was completed by the calamities attendant on the sack of Rome in 1527. He had to pay a heavy ransom in order to escape from the hands of the Spaniards, and fled from Rome, in the words of Vasari, "all but a beggar." It is said that he took refuge in his native city, Bologna; but he never again emerges from obscurity, and all we know with certainty is that in 1534 he was dead.

See H. Delaborde, *Marcantonio Raimondi* (1887); H. Hirth, *Marcanton und sein Styl* (Munich, 1898); Wickhoff, *Jahrbuch* (Vienna, xx. 181, 1899); P. Kristeller, *Kupferstich u. Holzschnitt* (1905); A. M. Hind, *Great Engravers* (1912); and *History of Engraving and Etching* (1923).

MARCASITE, a mineral with the same chemical composition as pyrite, being iron disulphide FeS_2, but crystallizing in the orthorhombic instead of in the cubic system. The name is of Arabic origin and was long applied to crystallized pyrites in general. It was known to G. Agricola in 1546 as *Wasserkies* or *Weisserkies* and *Leberkies*, and it has been variously known as white pyrites, hepatic pyrites, lamellar pyrites, radiated pyrites (German *Strahlkies*) and prismatic pyrites.

The crystals are isomorphous with mispickel (*q.v.*), but only rarely are they distinctly developed and simple. Often they are twinned on a prism plane producing pentagonal stellate groups of five crystals. This frequent twinning gives rise to characteristic forms, with many re-entrant angles, to which the names "spear pyrites" and "cockscomb pyrites" are applied. The commonest state of aggregation is that of radially arranged fibres, the external surface of the mass being globular, nodular or stalactitic in form.

Apart from crystalline form, the external characters of marcasite are very similar to those of pyrite, and when distinct crystals are not available the two species cannot always be easily distinguished. The colour is usually pale bronze-yellow, often rather lighter than that of pyrite; on freshly fractured surfaces of pure marcasite the colour is tin-white, but this rapidly tarnishes on exposure to air. The lustre is metallic and brilliant, the streak greyish or brownish-black. The hardness (6–6½) is the same as that of pyrite, and the specific gravity (4·8–4·9) as a rule rather less. It readily oxidizes on exposure to moist air, with the production of sulphuric acid and a white fibrous efflorescence of ferrous sulphate, and in course of time specimens in collections often become completely disintegrated. In nature it is frequently altered to limonite. Marcasite is thus the less stable of the two modifications of iron disulphide. Many experiments have been made with a view to determining the difference in chemical constitution of marcasite and pyrite, but with no very definite results. Marcasite has been prepared artificially from acid solutions, whilst pyrite is formed only from slightly acid or neutral solutions.

Marcasite occurs under the same conditions as pyrite, but is much less common. While pyrite is found abundantly in the older crystalline rocks and slates, marcasite is more abundant in clays, and has often been formed as a concretion around organic remains. It is abundant, for example, in the plastic clay of the brown coal formation at Littmitz, near Carlsbad, where it has been extensively mined for the manufacture of sulphur and ferrous sulphate. In the chalk of the south-east of England nodules of marcasite with a fibrous radiated structure are abundant (these bodies being often mistaken for "thunderbolts" or meteorites), and in the chalk marl between Dover and Folkestone fine twinned groups of "spear pyrites" are common. The mineral is also met with in metalliferous veins; for example the "cockscomb pyrites" of the lead mines of Derbyshire and Cumberland.

MARCEAU, FRANÇOIS SEVERIN DESGRAVIERS (1769–1796), French general, was born at Chartres on March 1, 1769. He studied law, but joined the army in 1785. He joined in the attack on the Bastille (July 14, 1789), and then took his discharge from the regular army. Later he joined the National Guard, and in March 1792 became lieutenant-colonel of a battalion of the Eure-et-Loire, taking part in the defence of Verdun in 1792. He was re-employed as captain in the regular service, but in 1793 was imprisoned for some time with other officers as a "suspect." On his release he fought at Saumur against the Vendéen royalists, and rescued Bourbotte (June 10, 1793) from the insurgents. Marceau became general of division (Nov. 10), and with Kléber, who became his personal friend, won important victories near Le Mans (Dec. 12–13) and Savenay (Dec. 21), but after their retirement from the war they were only saved from arrest and execution by the intervention of Bourbotte. After spending the winter of 1793–94 in Paris, Marceau took command in the army under Jourdan in which Kléber also served, and distinguished himself in the campaigns of 1794 and 1795. In the campaign of 1796 Marceau's men covered Jourdan's retreat over the Rhine. He fought the desperate actions on the Lahn (Sept. 16 and 18), and at Altenkirchen on Sept. 19 received a mortal wound, of which he died on the 21st. His body was burned, and his ashes, which at the time were placed under a pyramid designed by Kléber, were transferred in 1889 to the Pantheon at Paris.

See Maze, *Le Général Marceau* (1888); Parfait, *Le Général Marceau* (1892); and T. C. Johnson, *Marceau* (London, 1896).

MARCEL, ÉTIENNE (d. 1358), provost of the merchants of Paris under King John II., is mentioned as provost of the Grande-Confrérie of Notre Dame in 1350, and in 1354 he succeeded Jean de Pacy as provost of the Parisian merchants. His political career began in 1356, when John was made prisoner after the battle of Poitiers. In conjunction with Robert le Coq, bishop of Laon, he played a leading part in the states-general called together by the dauphin Charles on Oct. 17. A committee of eighty members, constituted on their initiative, pressed their demands with such insistence that the dauphin prorogued the states-general; but financial straits obliged him to summon them once more on Feb. 3, 1357, and the promulgation of an edict of reform was the consequence. John the Good forbade its being put into effect, whereupon a conflict began between Marcel and the dauphin, Marcel endeavouring to set up Charles the Bad, king of Navarre, in opposition to him. The states-general assembled again on Jan. 13, 1358, and on Feb. 22, the populace of Paris, led by Marcel, invaded the palace and murdered the marshals of Champagne and Normandy before the prince's eyes. Thenceforward Marcel was in open hostility to the throne. After vainly hoping that the insurrection of the Jacquerie might turn to his advantage, he next supported the king of Navarre, whose armed bands infested the neighbourhood of Paris. On the night of July 31 Marcel was about to open the gates of the capital to them, but Jean Maillart prevented the execution of this design, and killed him before the Porte Saint-Antoine.

See F. T. Perrens, *Étienne Marcel et le gouvernement de la bourgeoisie au xiv*e *siècle* (1860); P. Frémaux, *La Famille d'Étienne Marcel*, in the *Mémoires* of the *Société de l'histoire de Paris et de l'Île de France* (1903), vol. xxx.; and Hon. R. D. Denman, *Étienne Marcel* (1898).

MARCELLINUS, ST., according to the Liberian catalogue, became bishop of Rome on June 30, 296; his predecessor was Caius or Gaius. He is not mentioned in the *Martyrologium hieronymianum*, or in the *Depositio episcoporum*, or in the *Depositio martyrum*. The *Liber pontificalis*, basing itself on the Acts of St. Marcellinus, the text of which is lost, relates that during Diocletian's persecution Marcellinus was called upon to sacrifice, and offered incense to idols, but that, repenting shortly afterwards, he confessed the faith of Christ and suffered martyrdom with several companions. According to the *Liber pontificalis*, Marcellinus was buried, on April 26, 304, in the cemetery of Priscilla, on the Via Salaria, 25 days after his martyrdom; the Liberian catalogue gives as the date Oct. 25. After a considerable interregnum he was succeeded by Marcellus, with whom he has sometimes been confounded.

See L. Duchesne, *Liber pontificalis*, I. lxxiii.–lxxiv. 162–163, and II. 563.

MARCELLO, BENEDETTO (1686–1739), Italian musical composer, was a pupil of Lotti and Gasparini, but was intended by his father for the law. In 1711 he was a member of the Council of Forty, and in 1730 went to Pola as Provveditore. He retired after eight years to Brescia in the capacity of *camerlengo*, and died there on July 24, 1739.

Marcello is best remembered by his *Estro poetico-armonico* (Venice, 1724–1727), a musical setting for voices and strings of the first fifty Psalms, as paraphrased in Italian by G. Giustiniani. Charles Avison and John Garth brought out an edition with English words (London, 1757). His other works are chiefly cantatas.

A catalogue of his works is given in *Monatshefte für Musikgeschichte*, vol. xxiii. (1891).

MARCELLUS, the name of two popes.

MARCELLUS I. succeeded Marcellinus, after a considerable interval, most probably in May 308, under Maxentius. He was banished from Rome in 309 on account of the tumult caused by the severity of the penances he had imposed on Christians who had lapsed under the recent persecution. He died the same year, being succeeded by Eusebius. He is commemorated on Jan. 16.

MARCELLUS II. (Marcello Cervini), the successor of Julius III., was born on May 6, 1501, and was elected pope on April 9, 1555. As president of the Council of Trent he had incurred the anger of the emperor by his jealous defence of papal prerogative. He died on April 30, 1555. He was followed by Paul IV.

Contemporary lives are to be found in Panvinio, continuator of Platina, *De vitis pontiff. rom.*; and Ciaconius, *Vitae et res gestae summorum pontiff. rom.* (Rome, 1601–02). P. Polidoro, *De gestis, vita et moribus Marcelli II.* (Rome, 1744), makes use of an unpublished biography of the pope by his brother, Alessandro Cervini. *See* also Brilli, *Intorno alla vita e alle azioni di Marcello II.* (Montepulciano, 1846); Ranke, *Popes* (Eng. trans., Austin), i. 284 *seq.*; A. von Reumont, *Gesch. der Stadt Rom*), iii. 2, 512, *seq.*

MARCELLUS, a Roman plebeian family belonging to the Claudian gens. Its most distinguished members were the following:—

1. MARCUS CLAUDIUS MARCELLUS (*c.* 268–208 B.C.), one of the Roman generals during the Second Punic War and conqueror of Syracuse. He first served against Hamilcar in Sicily. In his first consulship (222) he was engaged, with Cn. Cornelius Scipio as colleague, in war against the Insubrian Gauls, and won the *spolia opima* for the third and last time in Roman history by slaying their chief Viridomarus or Virdumarus (Polybius ii. 34; Propertius v. 10, 39). In 216, after Cannae, he took command of the remnant of the army at Canusium, and although he was unable to prevent Capua going over to Hannibal, he saved Nola and southern Campania. In 214 he was in Sicily as consul at the time of the revolt of Syracuse; he stormed Leontini and besieged Syracuse, but the skill of Archimedes repelled his attacks. He took it after a two years' siege, and set the example of carrying away the art treasures of a captured city. Consul again in 210, he took Salapia in Apulia, which had revolted to Hannibal, and put to death the Numidian garrison. Proconsul in 209, he attacked Hannibal near Venusia, into which he retired after a desperate battle. In his last consulship (208), he and his colleague, while reconnoitring near Venusia, were unexpectedly attacked, and Marcellus was killed. His successes have been exaggerated by Livy, but the name often given to him, the "sword of Rome," was well deserved.

Livy xxiii. 14–17, 41–46; xxiv. 27–32, 35–39; xxv. 5–7, 23–31; xxvi. 26, 29–32; xxvii. 1–5, 21–28; Polybius viii. 5–9, x. 32; Appian, *Hannib.* 50; Florus ii. 6.

2. M. CLAUDIUS MARCELLUS, an inveterate opponent of Julius Caesar. During his consulship (51 B.C.) he proposed to remove Caesar from his army in March 49, but was outmanoeuvred by Curio. In January 49 he tried to put off declaring war against Caesar till an army could be got ready, but his advice was not taken. He followed Pompey when he left for Italy, and after Pharsalus retired to Mytilene, where he practised rhetoric and studied philosophy. In 46 the senate successfully appealed to Caesar to pardon him, this being the occasion of the speech *Pro Marcello* attributed to Cicero. Marcellus left for Italy, but was murdered in May by one of his own attendants, P. Magius Chilo, in the Peiraeus. Marcellus was a thorough aristocrat. He was an eloquent speaker (Cicero, *Brutus*, 71), and a man of firm character, although not free from avarice.

See Cicero, *Ad fam.* iv. 4, 7, 10, and *Ad Att.* v. 11 (ed. Tyrrell and Purser); Caesar, *B. C.* i. 2; Suetonius, *Caesar*, 29; G. Boissier, *Cicero and his Friends* (Eng. trans., 1897).

3. M. CLAUDIUS MARCELLUS (*c.* 43–23 B.C.), son of C. Marcellus and Octavia, sister of Augustus. In 25 he was adopted by the emperor and married to his daughter Julia. This seemed to mark him out as the heir to the throne. In 23 Marcellus, then curule aedile, died at Baiae. Great hopes had been built on the youth, and he was celebrated by many writers, especially by Virgil in a famous passage (*Aeneid*, vi. 860). He was buried in the Campus Martius, and Augustus himself pronounced the funeral oration. The Theatrum Marcelli (remains of which can still be seen) was afterwards dedicated in his honour.

See Horace, *Odes*, i. 12; Propertius iii. 18; Dio Cassius liii. 28, 30; Tacitus, *Annals*, ii. 41; Suetonius, *Augustus*, 63; Vell. Pat. ii. 93.

MARCH, AUZIAS (1379–1459), Catalan poet, was born at Valencia. An undisguised follower of Petrarch, he carries the imitation to such a point that he addresses his *Cants d'amor* to a lady whom he professes to have seen first in church on Good Friday; so far as the difference of language allows, he reproduces the rhythmical cadences of his model, and in the *Cants de mort* touches a note of brooding sentiment peculiar to himself. The success of his metrical innovation no doubt encouraged Boscán (*q.v.*) to introduce the Italian metres into Castilian.

MARCH, EARLS OF, title derived from the "marches" or boundaries (1) between England and Wales, and (2) England and Scotland, and held severally by great feudal families possessed of lands in those border districts. The earls of March on the Welsh borders were descended from Roger de Mortemer (so called from his castle of Mortemer in Normandy), who was connected by marriage with the dukes of Normandy. His son Ralph (d. *c.* 1104) figures in Domesday as the holder of vast estates in Shropshire, Herefordshire and other parts of England, especially in the west; and his grandson Hugh de Mortimer, founder of the priory of Wigmore, Herefordshire, was one of the most powerful of the barons reduced to submission by Henry II. The Mortimers, however, continued to exercise almost undisputed sway, as lords of Wigmore, over the western counties and the Welsh marches.

I. **Welsh Marches.**—Roger de Mortimer (*c.* 1286–1330), 8th baron of Wigmore and 1st earl of March, being an infant at the death of his father, Edmund, was placed by Edward I. under the guardianship of Piers Gaveston, and was knighted by Edward in 1306. Through his marriage with Joan de Joinville, or Genevill, Roger acquired increased possessions on the Welsh marches, including the important castle of Ludlow, and extensive estates in Ireland, whither he went in 1308 to enforce his authority. This brought him into conflict with the De Lacys, who turned for support to Edward Bruce, brother of Robert Bruce, king of Scotland. Mortimer was appointed lord-lieutenant of Ireland by Edward II. in 1316, and at the head of a large army drove Bruce to Carrickfergus, and the De Lacys into Connaught. About 1318 he began to interest himself in the growing opposition to Edward II. and his favourites, the Despensers; and he supported Humphrey de Bohun, earl of Hereford, in refusing to obey the king's summons to appear before him in 1321. Forced to surrender to the king at Shrewsbury in 1322, Mortimer was consigned to the Tower of London, whence he escaped to France in Aug. 1324. At the French court Queen Isabella found Roger Mortimer; she became his mistress and refused to return to England so long as the Despensers retained power as the king's favourites. Isabella's relations with Mortimer compelled them to withdraw to Flanders, where they obtained assistance for an invasion of England. Landing in England in 1326, they were joined by Henry, earl of Lancaster; London rose in support of the queen; and Edward took flight to the west, where he was captured in November, and compelled to abdicate in favour of his son. The country was now ruled by Mortimer and Isabella, who procured the murder of Edward II. in the following September. In 1328 Mortimer was created earl of March. The jealousy of Lancaster having been excited by March's arrogance, Lancaster prevailed upon the young Edward III., to throw off the yoke of his mother's paramour. March was arrested and conveyed to the Tower. Accused of assuming royal power and of various other high misdemeanours, he was condemned without trial and hanged on Nov. 29, 1330, his vast estates being forfeited to the Crown. His eldest son, Edmund, was father of Roger Mortimer (*c.* 1328–60), who was knighted by Edward III. in 1346, and restored to his grandfather's title as 2nd earl of March.

Edmund de Mortimer (1351–1381), 3rd earl of March, was son of Roger, 2nd earl of March, by his wife Philippa, daughter of William Montacute, 1st earl of Salisbury. Being an infant at the death of his father, Edmund, as a ward of the Crown, was placed by Edward III. under the care of William of Wykeham and Richard Fitzalan, earl of Arundel. The young earl married in 1368 Philippa, only daughter of Lionel, duke of Clarence, and of Elizabeth, daughter and heiress of William de Burgh, 6th lord of Connaught and 3rd earl of Ulster. The earl of March, therefore, not only became the representative of one of the chief Anglo-Norman lordships in Ireland in right of his wife Philippa, but the latter, on the death of her father shortly after her marriage, stood next in succession to the crown after the Black Prince and his sickly son, afterwards King Richard II. This marriage had, therefore, far-reaching consequences in the history of England, giving rise to the claim of the house of York to the crown of England, contested in the Wars of the Roses. He died at Cork in 1381. The earl had two sons and two daughters, the elder of whom, Elizabeth, married Henry Percy (Hotspur), son of the earl of Northumberland. His eldest son Roger succeeded him as 4th earl of March and Ulster.

Roger de Mortimer, 4th earl of March and Ulster (1374–98), succeeded to the titles and estates of his family when a child of seven, and a month afterwards he was appointed lord-lieutenant of Ireland. March's daughter Anne married Richard earl of Cambridge, son of Edmund duke of York, fifth son of Edward III.; their son Richard, duke of York, was father of King Edward IV., who thus derived his title to the crown and acquired the estates of the house of Mortimer.

Edmund de Mortimer (1391–1425), 5th earl of March and Ulster, son of the 4th earl, succeeded to his father's claim to the crown as well as to his title and estates. When Richard II. was deposed and the crown seized by Henry of Lancaster in 1399, the young earl of March and his brother Roger were kept in custody by Henry IV., who, however, treated them honourably, until March 1405, when they were carried off by the opponents of the Lancastrian dynasty, of whom their uncle Sir Edmund Mortimer and his brother-in-law Henry Percy (Hotspur) were leaders in league with Owen Glendower. The boys were recaptured, and in 1409 were committed to the care of the prince of Wales. On the accession of the latter as Henry V., in 1413, the earl of March was restored to his estates, his brother Roger having died some years previously; and he continued to enjoy the favour of the king in spite of a conspiracy in 1415 to place him on the throne. March accompanied Henry V. throughout his wars in France, and on the king's death in 1422 became a member of the council of regency. He died in Ireland in 1425, and as he left no issue the earldom of March in the house of Mortimer became extinct, the estates passing to the last earl's nephew Richard, who in 1435 was officially styled duke of York, earl of March and Ulster, and baron of Wigmore. Richard's son Edward having ascended the throne in 1461 as Edward IV., the earldom of March became merged in the crown.

See T. Rymer, *Foedera,* etc. (1704–32); T. F. Tout, *The Political History of England,* vol. iii., ed. by W. Hunt and R. L. Poole (1905); W. Dugdale, *Monasticon anglicanum* (3 vols., 1655–73); W. Stubbs, *Constitutional History of England* (1874–78), vol. ii.

II. **Scottish Marches.**—The Scottish earls of March were descended from Crinan, whose son Maldred married Algitha, daughter of Ughtred, earl of Northumberland, by Elgiva, daughter of the Saxon king Aethelred. Maldred's son Cospatric, or Gospatric, was made earl of Northumberland by William the Conqueror; but being soon afterwards deprived of this position he fled to Scotland, where Malcolm Canmore, king of Scotland, granted him Dunbar and adjoining lands. Two generations of Cospatrics followed in lineal succession, bearing the title of earl, but without territorial designation. Cospatric II witnessed the charter of Alexander I founding the abbey of Scone in 1115. The 3rd earl, also named Cospatric, a liberal benefactor of Melrose abbey, died in 1166, leaving two sons, the younger of whom was the ancestor of the earls of Home. The elder son, Waltheof, was the first of the family to be styled "comes de Dunbar," about 1174. He was one of the hostages for the performance of the Treaty of Falaise for the liberation of William the Lion in 1175. Waltheof's son Patrick Dunbar (the name Dunbar, derived from the family estates, now becoming an hereditary surname), styled 5th earl of Dunbar, although his father had been the first to adopt the territorial designation, was keeper of Berwick castle, and married Ada, natural daughter of William the Lion. His grandson Patrick, 7th earl, headed the party that liberated King Alexander III. in 1255 from the Comyns, and in the same year was nominated guardian of the king and queen by the Treaty of Roxburgh. He signed the Treaty of Perth (July 6, 1266) by which Magnus VI. of Norway ceded the Isle of Man and the Hebrides to Scotland. His wife was Christian, daughter of Robert Bruce.

Patrick Dunbar, 8th earl of Dunbar and 1st earl of March, claimed the crown of Scotland in 1291 as descendant of Ada, daughter of William the Lion. He was one of the "seven earls of Scotland," a distinct body separate from the other estates of the realm, who claimed the right to elect a king in cases of disputed succession. He was the first of the earls of Dunbar to appear in the records as "comes de Marchia," or earl of March. He was favourable to the English interest in Scottish affairs, and he did homage to Edward I. In 1298 he was appointed the English king's lieutenant in Scotland.

Patrick Dunbar (1285–1369), 9th earl of Dunbar and 2nd earl of March, son of the preceding, gave refuge to Edward II. after Bannockburn, and contrived his escape by sea to England. Later, he made peace with Robert Bruce, and by him was appointed governor of Berwick castle, which he held against Edward III. until the defeat of the Scots at Halidon Hill (July 19, 1333). His countess, known in Scottish history and romance as "Black Agnes," daughter of Thomas Randolph, earl of Moray (Murray), and grandniece of Robert Bruce, is famous for her defence of Dunbar castle against the English under the earl of Salisbury in 1338. This lady succeeded to the estates and titles of her brother, John Randolph, 3rd earl of Moray. The earldom of Moray passed after her death to her second son, John Dunbar, who married Marjory, daughter of King Robert II.

George Dunbar (d. 1420), 10th earl of Dunbar and 3rd earl of March, great-nephew of the 8th earl and warden of the marches, accompanied Douglas in his foray into England in 1388, and commanded the Scots after Otterburn. He afterwards quarrelled with the Douglases, and when his lands were seized, fled to England, where he was welcomed by Henry IV. He fought on the English side at Homildon Hill; and, having revealed to Henry the defection of the Percies, who were in league with Douglas and Owen Glendower, he fought against those allies at Shrewsbury (July 23, 1403). Becoming reconciled with Douglas, he returned to Scotland in 1409, and was restored to his earldom by the regent Albany.

George Dunbar, 11th earl of Dunbar and 4th earl of March, was one of the negotiators for the release of James I. of Scotland in 1423 from his captivity in England, and was knighted at that king's coronation. In 1434, however, on the ground that the regent had had no power to reverse his father's forfeiture for treason, March was imprisoned and his castle of Dunbar seized by the king; and the parliament at Perth declared his lands and titles forfeited to the Crown.

The earldom of March in the house of Dunbar having thus been forfeited to the Crown, James II. in 1455 conferred the title, together with that of warden of the marches, on his second son Alexander, duke of Albany; but this prince entered into treasonable correspondence with Edward IV. of England, and in 1487 the earldom of March and the barony and castle of Dunbar were again annexed to the crown of Scotland.

The title of earl of March was next held by the house of Lennox. (*See* Richmond, Earls and Dukes of; and Lennox.)

The title of earl of March in the peerage of Scotland, by another creation, was conferred in 1697 on William Douglas, second son of William, 1st duke of Queensberry. (*See* Queensberry, Earls, Marquises and Dukes of.)

See Andrew Lang, *History of Scotland* (4 vols., 1900–07); Sir Bernard Burke, *A Genealogical History of Dormant and Extinct Peerages* (1866); Sir Robert Douglas, *The Peerage of Scotland* (2 vols., 1813); Lady Elizabeth Cust, *Some Account of the Stuarts of Aubigny in France* (1891).

MARCH, FRANCIS ANDREW (1825–1911), American philologist and educationist, was born on Oct. 25, 1825, in Millbury, Mass. He graduated in 1845 at Amherst, where his attention was turned to the study of Anglo-Saxon by Noah Webster. After teaching in secondary schools and at Amherst, he went in 1855 as a tutor to Lafayette college, where he became in 1857 professor of English language and comparative philology—the first chair of the kind established. In 1907 he became professor emeritus, and he died in Easton, Pa., on Sept. 9, 1911. In 1865 he published *Method of Philological Study of the English Language,* and in 1870 *A Comparative Grammar of the Anglo-Saxon Language,* a monumental work, and *An Anglo-Saxon Reader,* both marking a new era in the study of English in America. To the "Douglass Series of Christian Greek and Latin Classics," which he edited, he contributed *Latin Hymns* (1874). He was consulting editor of the *Standard Dictionary* (1890–95) and in 1879–82 was director of the American readers for the Philological Society's *New English Dictionary.* Among American linguistic scholars March ranks with Whitney, Child and Gildersleeve. His article "On Recent Discussions of Grimm's Law" in the *Transactions and Proceedings* of the American Philological Association for 1873 in large part anticipated Verner's law. With his son, Francis Andrew March, jr., also a professor at Lafayette, he edited *A Thesaurus Dictionary of the English Language* (1903).

See *Addresses in Honor of Professor Francis A. March, LL.D., L.H.D.* (1895), and J. W. Bright's tribute in Modern Language Association, *Publications* (vol. xxix., 1914).

MARCH, PEYTON CONWAY (1864–), American soldier, was born at Easton, Pa., on Dec. 27, 1864. He graduated from Lafayette college in 1884 and four years later from the U.S. Military academy. He graduated from the artillery school in 1898, and on the outbreak of the Spanish-American War went to the Philippines, remaining there three years and rising to the grade of lieutenant-colonel of volunteers. After honourable discharge from the volunteers in 1901 he was appointed captain of artillery in the regular army. From 1903–07 he was a member of the general staff and in 1904, during the Russo-Japanese War, was with the Japanese army in Manchuria as observer. He was promoted major in 1907, lieutenant-colonel in 1912 and colonel in 1916. Soon after America's entrance into the World War in 1917 he was made a brigadier-general, U.S.A., and later major-general of the national army and in Sept. 1917, major-general of the regular army. In 1917 he was with the A.E.F. in France in charge of the American artillery forces. In March 1918 he was appointed acting chief of staff, and the following May chief of staff with the rank of general. On June 30, 1920, his rank reverted to that of major-general, and at his own request he was retired from active service Nov. 1, 1921. As chief of staff of the army, he reorganized the war department, consolidated the regular army, National Guard and national army divisions into a single army—the U.S. army—and initiated and carried into execution a programme which landed in France, by the time of the Armistice, 2,000,000 men.

MARCH, a town in Isle of Ely, England, 30 mi. N.W. of Cambridge. Pop. of urban district (1938) 12,290. Area, 30.9 sq.mi. It lies in the flat fen country, on the old course of the river Nene. It is an important junction on the L.N.E.R. and the starting-point of a line to Lincoln and Doncaster. The church of St. Wendreda (Early English and later) has a Perpendicular timber roof. Agriculture is the chief industry.

MARCH, the third month of the modern calendar, containing 31 days. It was the Romans' first month until the adoption of the Julian calendar, 46 B.C., and it continued to be the beginning of the legal year in England until the 18th century. In France it was reckoned the first month of the year until 1564, when, by an edict of Charles IX., January was decreed to be thenceforth the first month. Scotland followed the example of France in 1599; but in England the change did not take place before 1752. The Romans called the month *Martius,* from Mars, the god of war. The Anglo-Saxons called March *Hlyd-monath,* "loud or stormy month," or *Lencten-monath,* "lengthening month," in allusion to the fact that the days then rapidly become longer. There is an old saying, common to both England and Scotland, representing March as borrowing three days from April; the last three days of March being called the "borrowing" or the "borrowed days."

In music, the march is the familiar type of composition used to accompany and stimulate the marching of soldiers. For this purpose it is naturally strongly rhythmic in character, being generally written in common time, with the principal accents vigorously marked by the drum. The pace may be either brisk, as in a quick march, or slow, as in a funeral march. In the matter of structure, a trio, or alternative section in a more melodious vein, is generally provided by way of contrast to the main tune. Apart from actual military marches, the form has had attraction in all times for eminent composers, who have left many memorable examples. Such are the Dead March in *Saul* (Handel), Beethoven's funeral marches (pianoforte sonata in A flat and Eroicasymphony), many by Schubert, Mendelssohn's Wedding March (*Midsummer Night's Dream* music), Chopin's Marche Funèbre (B flat minor sonata), several by Wagner (*Tannhäuser, Lohengrin, Huldigungsmarsch* and *Kaisermarsch*), Elgar's *Pomp and Circumstance* series, many by the "March King" among bandmasters, John P. Sousa, *e.g.*, Stars and Stripes Forever, etc.

MARCHAND, JEAN (1883–1941), French painter, was born in Paris on Nov. 22, 1883. He studied with Bonnat and Merson (1902–6), but deserted conventional teaching, and exhibited at the Salon des Indépendants in 1908. He visited Russia and England on several occasions. Though Marchand came under the influence of cubism between 1910 and 1912, his work was not greatly affected by it. His human forms are treated with power and discretion, while his landscapes and still life are tinged with an intense melancholy. His death in Paris was reported Oct. 10, 1941.

MARCHAND, JEAN BAPTISTE (1863–1934), French general and African explorer, was born at Thoissey (Ain) on Nov. 22, 1863. After four years' service in the ranks, he was, in 1887, appointed a sub-lieutenant. In 1889 he was on active service in Senegal, was twice wounded, and made a chevalier of the Legion of Honour. In 1898 he carried out his historic occupation of Fashoda and for this he was promoted to commander in the Legion of Honour. In 1902 he was made colonel and shortly after the outbreak of war in 1914 he was appointed to command the Colonial Brigade of the XIV Corps, and in 1915 was promoted a temporary-general of brigade. A few months later he assumed command of the 10th (Colonial) Division and was wounded in Sept. 1915. On April 4, 1917 he was promoted general of division. He retired in 1919, and received the grand cross of the Legion of Honour in 1920. Gen. Marchand died Jan. 14, 1934.

MARCHE or **LA MARCHE,** one of the former provinces of France. It owes its name to its position, it having been in the 10th century a march or border district between the duchy of Aquitaine and the domains of the Frankish kings in central France. Sometimes it was called the *Marche Limousine,* and originally it was a small district cut partly from Limousin and partly from Poitou. Its area was increased during the 13th century, after which, however, it remained unaltered until the time of the Revolution. It was bounded on the north by Berry; on the east by Bourbonnais and Auvergne; on the south by Limousin; and on the west by Poitou. It embraced the greater part of the modern department of Creuse, a considerable part of Haute Vienne, and a fragment of Indre. Its area was about 1,900 sq. mi.; its capital was Charroux and later Guéret, and among its other principal towns were Dorat, Bellac and Confolens.

Marche first appears as a separate fief about the middle of the 10th century when William III., duke of Aquitaine, gave it to one of his vassals named Boso, who took the title of count. In the 12th century it passed to the counts of Limousin, and this house retained it until the death of the childless Count Hugh in 1303, when it was seized by the French king, Philip IV. In 1316 it was made a duchy for Prince Charles, afterwards King Charles IV., and a few years later (1327) it passed into the hands of the family of Bourbon. The family of Armagnac held it from 1435 to 1477, when it reverted to the Bourbons, and in 1527 it was seized by Francis I. and became part of the domains of the French crown. It was divided into Haute Marche and Basse Marche, the estates of the former being in existence until the 17th century. From 1470 until the Revolution the province was under the jurisdiction of the parlement of Paris.

See A. Thomas, *Les États provinciaux de la France centrale* (1879).

MARCHES, THE (It. *Le Marche*), a territorial division (region) of Italy, embracing from north to south the provinces of Pesaro and Urbino, Ancona, Macerata, and Ascoli Piceno, with a population of 1,278,071 in 1936, a rise of 189,358 since 1901. It is bounded by Emilia on the north, the Adriatic on the east, the Abruzzi on the south, and Umbria and Tuscany on the west. The chief rivers, all of which run into the Adriatic eastwards and northeastwards, are the Metauro (anc. *Metaurus, q.v.*) and the Tronto (anc. *Truentus*), the latter forming the southern boundary of the Marches for some distance. Except for the river valleys and the coast strip (often very narrow), the general level is more than 500 ft. above the sea. The lower hills are very largely composed of loose, clayey, unstable earth, while the Appenines are of limestone. The province of Pesaro and Urbino falls within the boundaries of the ancient Umbria (*q.v.*), while the territory of the other three belonged to Picenum (*q.v.*). The railway from Bologna to Brindisi runs along the coast-line of the entire territory.

At Fano there is a branch to Fermignano, on the line from Fabriano to Urbino; at Falconara, near Ancona it is joined by the main line from Foligno and Rome; at Porto Civitanova is a branch to Macerata, San Severino and Fabriano (a station on the line from Ancona to Rome and the junction for Urbino); at Porto S. Giorgio is a branch to Fermo and Amandola, and, at Porto d'Ascoli, a branch to Ascoli Piceno.

Agriculture and Industry.—Owing largely to the *mezzadria* or *metayer* system the soil is fairly highly cultivated.

The silk industries, making of strawplait and straw hats, rearing of silk-worms and cocoons, with sugar-refining, tobacco, terra-cotta manufacture, brickworks and ironworks, furnish the chief occupations of the people of the Marches next after agriculture and pastoral pursuits.

The chief agricultural products in 1938 were:

	Acres under cultivation	Production in tons
Wheat	652,591	497,900
Maize	159,874	82,600
Barley	19,027	10,100
Oats	6,324	4,200
Garden produce	. .	86,500
Sugar beet	. .	14,200
Flax	8,401	1,800
Tobacco	. .	900
Potatoes	32,617	89,500
Beans	94,145	13,700
Vines	924,895	60,660,300 gal. (wine)
Olives	402,032	369,900 gal. (olive oil)
Forage	1,269,847	1,797,100
Fruits	. .	25,200

Another important branch of activity is the paper industry, especially at Fabriano. Limestone quarries and sulphur mines supply building stone and sulphur to the regions of central Italy; chalk and petroleum are also found. Ancona is the only really good harbour.

Fishing is carried on along the entire coast.

History.—For the early history of the territory of the Marches, *see* PICENUM. From the Carolingian period onwards the name Marca begins to appear—first the Marca Fermana for the mountainous part of Picenum, the Marca Camerinese for the district farther north, including a part of Umbria, and the Marca Anconitana for the former Pentapolis. In 1080 the Marca Anconitana was given in investiture to Robert Guiscard by Gregory VII., to whom the countess Matilda ceded the Marches of Camerino and of Fermo. In 1105 we find the emperor Henry IV. investing Werner with the whole territory of the three marches under the name of March of Ancona. It was afterwards once more recovered by the Church and governed by papal legates. It became part of the kingdom of Italy in 1860. The pictorial art of the Marches from the 13th century onwards has become the object of considerable interest.

See L. Serra, *Le Gallerie Comunali delle Marche* (1926); *L'Arte nelle Marche* (Pesaro, 1927).

MARCHESI, MATHILDE (née Mathilde Graumann) (1826–1913), German singer and teacher, was born at Frankfort-on-Main on March 26, 1826. She made her début as a singer in 1844, but in 1849 began her teaching career, speedily earning a wide reputation at the conservatories of Vienna and Cologne, as well as in London and Paris. In 1852 she married Salvatore Marchesi, Cavaliere de Castrone (d. 1908), a well-known singer and teacher. Among Madame Marchesi's pupils were Emma Calvé, Emma Eames, Melba, Emma Nevada, Gabrielle Kraus and Etelka Gerster. She published various works on the technique of singing, and in 1897 a volume of reminiscences, *Marchesi and Music*. She died in London on Nov. 17, 1913.

Her daughter, Blanche Marchesi (1863–1940), was also a famous singer and teacher.

MARCHMONT, EARLS OF. The 1st earl of Marchmont was Sir Patrick Hume or Home (1641–1724), son of Sir Patrick Hume, bart. (d. 1648), of Polwarth, Berwickshire. He became a member of the Scottish parliament in 1665, and opposed the harsh policy of the earl of Lauderdale towards the Covenanters, and for his contumacy he was imprisoned. After his release he went to London, where he associated himself with the duke of Monmouth. Suspected of complicity in the Rye House plot, he crossed to the Netherlands, where he took part in the deliberations of Monmouth, the earl of Argyll and other exiles about the projected invasion of Great Britain. Polwarth sailed to Scotland with Argyll in 1685, and after the failure of the rising escaped to Utrecht. He accompanied William of Orange to England, and in 1689 he was again a member of the Scottish parliament. In 1690 he was made a peer as Lord Polwarth; in 1696 he became lord high chancellor of Scotland, and in 1697 was created earl of Marchmont. When Anne became queen in 1702 he was deprived of the chancellorship. He died on Aug. 2, 1724.

His son Alexander, the 2nd earl (1676–1740), took the name of Campbell instead of Hume after his marriage in 1697 with Margaret, daughter and heiress of Sir George Campbell of Cessnock, Ayrshire. The earldom became dormant on the death of the 3rd earl in 1794.

See *The Marchmont Papers,* ed. Sir G. H. Rose (1831).

MARCIAN (*c.* 390–457), emperor of the East (450–457), was born of humble parentage in Thrace, and entered the army at an early age. Eventually through the influence of Aspar and Ardaburius he became a captain of the guards, and later tribune and senator. On the death of Theodosius II. he was chosen as consort by the latter's sister and successor, Pulcheria. Marcian repudiated the payment of tribute to Attila; and reformed the finances. He repelled attacks upon Syria and Egypt (452), and quelled disturbances on the Armenian frontier (456). The other notable event of his reign is the Council of Chalcedon (451).

See Gibbon, *The Decline and Fall of the Roman Empire* (ed. Bury, London, 1896), iii. 384, iv. 444–445; J. Bury, *The Later Roman Empire* (London, 1889), i. 135–136.

MARCIANUS (*c.* A.D. 400), Greek geographer, was born at Heraclea in Pontus. Two of his works have been preserved in a more or less mutilated condition. In the first, the *Periplus of the Outer Sea,* in two books, in which he proposed to give a complete description of the coasts of the eastern and western oceans, his chief authority is Ptolemy; the distances from one point to another are given in stades, with the object of rendering the work easier for the ordinary student. The second, the *Periplus of the Inner Sea* (the Mediterranean), is a meagre epitome of a similar work by Menippus of Pergamum, who lived during the times of Augustus and Tiberius. It contains a description of the southern coast of the Euxine from the Thracian Bosporus to the river Iris in Pontus. A few fragments remain of an epitome by Marcianus of the 11 books of the *Geographumena* of Artemidorus of Ephesus.

See J. Hudson, *Geographia veteris scriptores graeci minores,* vol. i. (1698), with Dodwell's dissertation; C. W. Müller, *Geographici graeci minores,* vol. i., pp. cxxix., 515–573; E. Miller, *Périple de Marcien d'Héraclée* (1839); S. F. G. Hoffmann, *Marciani Periplus* (1841); E. H. Bunbury, *Hist. of Ancient Geography* (1879), ii. 660; A. Forbiger, *Handbuch der alten Geographie,* vol. i. (1842).

MARCION and **THE MARCIONITE CHURCHES.** Among the Christian organisations of the middle period of the second century the most important, next to Catholicism, was the Marcionite community. It admitted all believers without distinction of age, sex, rank or culture. It was no mere school for the learned, disclosed no mysteries for the privileged, but sought to lay the foundation of the Christian community on the pure and authentic gospel of Christ. The pure gospel, however, Marcion found to be everywhere more or less corrupted and mutilated in the Christian circles of his time. His undertaking thus resolved itself into a reformation of Christendom. This reformation was to deliver Christendom from false Jewish doctrines by restoring the Pauline conception of the gospel—Paul being, according to Marcion, the only apostle who had rightly understood the new message of salvation as delivered by Christ. In Marcion's own view, therefore, the founding of his church—to which he was first driven by opposition—amounts to a reformation of Christendom through a return to the gospel of Christ and to Paul; nothing was to be accepted beyond that. This of itself shows that it is a mistake to reckon Marcion among the Gnostics. For he ascribed salvation, not to "knowledge" but to "faith"; he appealed openly to the whole Christian world; and he nowhere consciously added foreign elements to the revelation given through Christ. It is true that in many features his Christian system resembles the so-called Gnostic systems; but the first duty of the historian is to point out what Marcion plainly aimed at; only in the second place have we to inquire how far the result corresponded with those purposes.

Marcion was a wealthy shipowner, belonging to Sinope in Pontus. He appears to have been a convert from Paganism to Christianity. About A.D. 140 he arrived in Rome as a Christian, and made himself known to the local church. Even then, however, the leading features of his peculiar system must have been already thought out. At Rome he tried to gain acceptance for them in the college of presbyters and in the church; but he now encountered such determined opposition from the majority of the congregation that he found it necessary to withdraw from the great church and establish in Rome a community of his own. This was about the year 144. The new society increased in the two following decades; and very soon numerous sister-churches were flourishing in the east and west of the empire. Marcion took up his residence permanently in Rome, but still undertook journeys for the propagation of his opinions; and he seems never to have abandoned his design of gaining over the whole Church to his gospel.

The distinctive teaching of Marcion originated in a comparison of the Old Testament with the gospel of Christ and the theology of the apostle Paul. Its motive was not metaphysical, but religious and historical. In the gospel he found a God revealed who is goodness and love, and who desires faith and love from men. This God he could not discover in the Old Testament; on the contrary, he saw there the revelation of a just, stern, jealous, wrathful and variable God, who requires from his servants blind obedience, fear and outward righteousness. Overpowered by the majesty and novelty of the Christian message of salvation, too conscientious to rest satisfied with the ordinary attempts at the solution of difficulties, while prevented by the limitations of his time from reaching an historical insight into the relation of Christianity to the Old Testament and to Judaism, he believed that he expressed Paul's view by the hypothesis of two Gods: the just God of the law (the God of the Jews, who is also the Creator of the world), and the good God, the Father of Jesus Christ. Paradoxes in the history of religion and revelation which Paul draws out, and which Marcion's contemporaries passed by as utterly incomprehensible, are here made the foundation of a dualistic conception of history and of religion. It may be said that in the 2nd century only one Christian—Marcion—took the trouble to understand Paul; but it must be added that he misunderstood him. The profound reflections of the apostle on the radical antithesis of law and gospel, works and faith, were not appreciated in the 2nd century. Marcion alone perceived their decisive religious importance, and with them confronted the legalizing, and in this sense judaizing, tendencies of his Christian contemporaries. But the Pauline ideas lost their truth under his treatment; for, when it is denied that the God of redemption is at the same time the almighty Lord of heaven and earth, the gospel is turned upside down.

DUALISTIC THEORY

The general outlines of his teaching are as follows. Man is, in spirit, soul and body, a creature of the just and wrathful god. This god created man from ὕλη (matter), and imposed on him a strict law. Since no one could keep this law, the whole human race fell under the curse, temporal and eternal, of the Demiurge. Then a higher God, hitherto unknown, and concealed even from the Demiurge, took pity on the wretched, condemned race of men.

He sent his Son (whom Marcion probably regarded as a manifestation of the supreme God Himself) down to this earth in order to redeem men. Clothed in a visionary body, in the likeness of a man of thirty years old, the Son made his appearance in the fifteenth year of Tiberius, and preached in the synagogue at Capernaum. But none of the Jewish people understood him. Even the disciples whom he chose did not recognize his true nature, but mistook him for the Messiah promised by the Demiurge through the prophets, who as warrior and king was to come and set up the Jewish empire. The Demiurge himself did not suspect who the stranger was; nevertheless he became angry with him, and, although Jesus had punctually fulfilled his law, caused him to be nailed to the cross. By that act, however, he pronounced his own doom. For the risen Christ appeared before him in his glory, and charged him with having acted contrary to his own law. To make amends for this crime, the Demiurge had now to deliver up to the good God the souls of those who were to be redeemed; they are, as it were, purchased from him by the death of Christ. Christ then proceeded to the underworld to deliver the spirits of the departed. Then, to gain the living, Christ raised up Paul as his apostle. He alone understood the gospel, and recognized the difference between the just God and the good. Accordingly, he opposed the original apostles with their Judaistic doctrines, and founded small congregations of true Christians. But the preaching of the false Jewish Christians gained the upper hand; nay, they even falsified the evangelical oracles and the letters of Paul. Marcion himself was the next raised up by the good God, to proclaim once more the true gospel. This he did by setting aside the spurious gospels, purging the real gospel (the Gospel of Luke) from supposed judaizing interpolations, and restoring the true text of the Pauline epistles. Marcion was the earliest critical student of the New Testament canon and text. It is noteworthy that he refused to admit the genuineness of the Pastoral Epistles and said that the letter to the Ephesians was really addressed to the Laodiceans.

On the basis of these writings Marcion proclaimed the true Christianity, and founded churches. He taught that all who put their trust in the good God, and his crucified Son, renounce their allegiance to the Demiurge, and approve themselves by good works of love, shall be saved. But he taught further—and here we trace the influence of the current gnosticism on Marcion—that only the spirit of man is saved by the good God; the body, because material, perishes. Accordingly his ethics also were thoroughly dualistic. By the "works of the Demiurge," which the Christian is to flee, he meant the whole "service of the perishable." The Christian must shun everything sensual, and especially marriage, and free himself from the body by strict asceticism. The golden age of the Marcionite churches falls between the years 150 and 250. During that time they were really dangerous to the great Church; for in fact they maintained certain genuine Christian ideas, which the Catholic Church had forgotten. The earliest inscription (A.D. 318) on a Christian place of worship is Marcionite, and was found on a stone which had stood over the doorway of a house in a Syrian village. From the beginning of the 4th century they began to die out in the West, or rather they fell a prey to Manichaeism. In the East also many Marcionites went over to the Manichaeans; but there they survived much longer. They can be traced down to the 7th century, and then they seem to vanish. But it was unquestionably from Marcionite impulses that the new sects of the Paulicians and Bogomils arose; and in so far as the western Cathari, and the antinomian and anticlerical sects of the 13th century are connected with these, they also may be included in the history of Marcionitism.

Krüger, *Early Christian Literature,* and art. in Herzog-Hauck's *Realencyklopädie für prot. Theol. und Kirche,* xii.; F. J. Foakes Jackson's *Christian Difficulties of the Second and Twentieth Centuries,* is a study of Marcion and his relation to modern thought.

MARCOMANNI, the name of a Suevic tribe "men of the mark, or border." They were often in conflict with the Roman empire, and gave their name to the Marcomannic war, a struggle waged by the emperor Marcus Aurelius against them. The Marcomanni disappeared from history during the 4th century, being probably merged in the Baiouarii, the later Bavarians.

See Suebi; and E. Devrient, "Hermunduren und Markomannen" in *Neues Jahrb. f. das klassische Altertum* (1901), 51.

MARCONI, MARCHESE GUGLIELMO (1874–1937), Italian inventor who put wireless telegraphy on a commercial basis, was born at Bologna on April 25, 1874, the younger son of an Italian father and an Irish mother. He was educated privately at Bologna, Florence and Leghorn. As a boy he took a keen interest in physical and electrical science. In 1895 the idea became firmly rooted in his mind that a system of telegraphy through space could be provided by means of electromagnetic waves, the existence of which had been foreseen mathematically by Clerk Maxwell in 1864 and later investigated experimentally by Heinrich Hertz, Oliver Lodge, Righi and others. Interesting scientific experiments had been carried out in London and elsewhere with these electric waves, but Marconi was the first to devise the practical means by which they could be made to provide a new and revolutionary method of telegraphic communication. In the early summer of 1895, Marconi conducted a number of experiments at his father's country house at Pontecchio, near Bologna. These experiments, made with crude and inefficient apparatus, soon began to give results which appeared to Marconi to be remarkable, communication being established in that year over distances in excess of a mile. He was created a Marchese in 1929.

In 1896 Marconi came to England, and on June 2 of that year took out the first patent ever granted for wireless telegraphy based on the use of electric waves. He continued his experiments in London, and in the same year demonstrated his invention before officials of the Post Office and other representatives of British and Foreign Government departments. These demonstrations were first carried out on the roof of the General Post Office, St. Martin's-le-Grand, London. Later experiments for the Post Office were carried out on Salisbury plain and across the Bristol channel from Penarth to Brean down, near Weston-super-Mare, ranges first of two, then of four, and afterwards of nine miles were obtained. In June 1897, at the invitation of the Italian Government, Marconi went to Spezia, where a land station was erected and communication with Italian warships was established up to a distance of 12 miles. He was then invited to demonstrate his apparatus in Rome, where successful tests were carried out in the presence of the late King Humbert and Queen Margherita. Other tests also took place at the Italian Chamber of Deputies.

The time was now almost ripe for wireless telegraphy to be applied to commercial and utilitarian purposes, and in July 1897 a company was formed in London to acquire the Marconi patents in all countries except Italy. This company was called the Wireless Telegraph and Signal Company, Limited, which in 1900 changed its name to that of Marconi's Wireless Telegraph Company, Limited (*q.v.*). For some time the company's efforts were confined to furthering Marconi's pioneer work. A number of interesting tests and demonstrations were undertaken round the coasts of the British Isles and abroad. Permanent stations were erected at Alum bay in the Isle of Wight and at Bournemouth, this station being subsequently removed to Poole.

In 1898 wireless telegraphy was first employed as a means of communication between lightships and the shore by installations on the East Goodwin lightship and the South Foreland lighthouse, separated by a distance of about 12 miles. The utility of wireless in saving life at sea was demonstrated for the first time when, on March 3, 1899, that lightship was run down by a steamer. The accident was at once reported by wireless to the South Foreland, enabling life-boats to be promptly sent to the assistance of the light vessel. In March 1898 Marconi established communication across the English Channel between England and France. During this year wireless was also first utilised in the naval manoeuvres for communication between warships over distances of 74 miles. The first military application of wireless took place during the South African War.

In Oct. 1900 the erection of a long distance wireless telegraph station in Cornwall was commenced by Marconi and preliminary tests were carried out up to a distance of about 200 miles. On

Dec. 12, 1901, Marconi, on his first attempt, succeeded in transmitting and receiving signals across the Atlantic Ocean from Poldhu in Cornwall to St. John's, Newfoundland.

In 1902 Marconi, during a voyage on the American liner S.S. "Philadelphia," received messages up to a distance of 700 miles by day and 2,000 miles by night, thus first discovering the now well-known fact that wireless signals can usually be received over much greater distances at night than during the hours of daylight.

In 1902 he patented a magnetic detector, and in 1905 he took out his patents for the horizontal directional aerial. In 1910 Marconi, assisted by Mr. H. J. Round, received signals and messages at Buenos Aires from Clifden (Ireland) over a distance of about 6,000 miles. In 1912 he introduced "the timed spark system" for generating continuous waves. This system was employed for several years at many important long distance stations and by its means Marconi sent the first messages ever transmitted by wireless from England to Australia on Sept. 22, 1918.

In 1916, during the World War, experiments were commenced by Marconi in Italy with very short waves, with the object of devising a directive, or beam system, of wireless telegraphy for war purposes. Later, in England, with the assistance of Mr. G. S. Franklin, important results were obtained by the use of 15-metre waves between London and Birmingham. Short waves have proved themselves capable, even when used with a minimum of power, of carrying out communications by night as well as by day over any distance, even to the antipodes. They are much more amenable to control than long waves. (*See* WIRELESS TELEGRAPHY.)

During the World War Marconi served in both the Italian army and navy. He also visited America as a member of the Italian war mission to the United States Government. In 1919 the King of Italy appointed him plenipotentiary delegate to the Peace Conference in Paris, and in that capacity he attended the meetings of that conference and signed on behalf of Italy the peace treaties with Austria and Bulgaria. He also attended in the same capacity the meetings of the commission on mandates held in Paris and in London. Marconi was awarded the Nobel Prize for physics in 1909, the Albert Medal of the Royal Society of Arts, and, in the United States, the Franklin and the John Fritz Medals. In the same year he was nominated by the King of Italy to be a member of the Italian Senate. He died on July 20, 1937 at Rome.

MARCONI'S WIRELESS TELEGRAPH CO., LTD. In 1896 Guglielmo Marconi, then a young and unknown Italian inventor, came to England and took out the first patent for wireless telegraphy by means of Hertzian waves. On July 20, 1897, the Wireless Telegraph and Signal Co., Ltd., was formed to acquire Marconi's patents and develop them commercially. In 1900 the name of the company was changed to Marconi's Wireless Telegraph Co., Ltd., under which name it has remained registered. In 1899 Marconi succeeded in establishing communication between England and France. This was followed by the transmission of signals across the Atlantic, an achievement which laid the foundations of world-wide wireless communication. These successes led to a considerable extension of the commercial activities of the Marconi company. The Marconi International Marine Communication company was formed in 1900 to develop marine wireless, and, as time went on, wireless companies were formed by the Marconi company in the British Dominions and in other countries throughout the world.

The invention of the thermionic valve has revolutionized the design of wireless apparatus. The Marconi company rapidly evolved new apparatus using thermionic valves, various types of which now cover the requirements of many fields of communication. This development opened the way for the practical transmission of music and speech, and between Feb. 23 and March 6, 1920, the first broadcasting of musical items in England took place from the Marconi company's works at Chelmsford. Regular broadcasting of music and speech was instituted from Marconi stations at Writtle, Chelmsford, in 1921, and Marconi house, London, in 1922 before the establishment of the British Broadcasting company, now the British Broadcasting Corporation (B.B.C.), which began its activities in 1922.

One of the latest developments in wireless telegraphy is the short-wave *beam system* which has revolutionized long distance wireless communication. During 1926 and 1927 beam stations for communicating between Great Britain and Canada, Australia, South Africa and India, U.S.A. and South America were built. Beam stations have also been built in other countries, and this system is fast replacing the long-wave high-power system for long distance communication. The beam system has made it possible to transmit wireless telephone messages over great distances at much lower cost. (L. C. M.)

MARCOS DE NIZA (*c.* 1495–1558), a Franciscan friar born in Nice about 1495. He went to America in 1531, and after serving in Peru, Guatemala and Mexico, was chosen to explore the country north of Sonora. Preceded by Estevanico, the negro companion of Cabeza de Vaca and the "Black Mexican" of Zuñi traditions, Fray Marcos left Culiacan in March 1539, and penetrated to Zuñi or the "Seven Cities of Cibola," which he described as equal in size to the city of Mexico. He embodied much mere hearsay in his report, the *Descubrimiento de las siete ciudades,* which led F. V. de Coronado to make his expedition next year to Zuñi, of which Fray Marcos was the guide; and the realities proved a great disappointment. Fray Marcos was made Provincial of his order for Mexico before the second trip to Zuñi, and returned in 1541 to the capital, where he died on March 25, 1558.

The *Descubrimiento* is one of the world's famous narratives of travel. It may be found in J. F. Pacheco's *Documentos* (vol. iii.) and Hakluyt's *Voyages* (vol. iii.); also in G. Ramusio, *Navigazione* (vol. iii.) and H. Ternaux-Compans, *Voyages* (vol. iii.). *See* A. F. A. Bandelier, *The Gilded Man (El Dorado)* (1893); H. H. Bancroft, *Arizona and New Mexico* (San Francisco, 1888), and, for critical opinions, G. P. Winship, "The Coronado Expedition," in *U.S. Bureau of Ethnology, Fourteenth Annual Report* (for 1892–93, 1896).

MARCUS AURELIUS ANTONINUS (121–180), Roman emperor and Stoic philosopher, was born in Rome A.D. 121, the date of his birth being variously stated as April 6, 21 and 26. His original name was Marcus Annius Verus. His father Annius Verus (prefect of the city and thrice consul), who came of Spanish stock, had received patrician rank from Vespasian. Marcus was three months old when his father died, and was thereupon adopted by his grandfather. Hadrian adopted, as his successor, Titus Antoninus Pius (uncle of Marcus), on condition that he in turn adopt both Marcus (then 17) and Lucius Ceionius Commodus, the son of Aelius Caesar, who had originally been intended by Hadrian as his successor, but had died before him. Marcus had been, at the age of 15, betrothed to Fabia, the sister of Commodus; the engagement was broken off by Antoninus Pius, and he was betrothed to Faustina, the daughter of the latter. In 139 the title of Caesar was conferred upon him and he dropped the name of Verus. The full name he then bore was Marcus Aelius Aurelius Antoninus, Aelius coming from Hadrian's family, and Aurelius being the original name of Antoninus Pius. In 140 he was made consul. He was educated, not at school, but by tutors, Herodes Atticus and M. Cornelius Fronto (*q.v.*) in the usual curriculum of rhetoric and poetry; but Stoicism attracted him from the first, and at 25 he definitely abandoned Fronto, whose training was wholly literary, to learn philosophy under Rusticus the Stoic, and law under L. Volusius Moecianus. A Stoic he remained in practice, but retained the humanity of his disposition.

Emperor.—Antoninus Pius died in 161, having recommended as his successor Aurelius, then 40 years of age, without mentioning Commodus, his other adopted son, commonly called Lucius Verus. It is believed that the senate urged Aurelius to take the sole administration. But he admitted Verus as his partner, giving him the tribunician and proconsular powers, and the titles Caesar and Augustus. In the first year of his reign Faustina gave birth to twins, one of whom became the emperor Commodus.

Aurelius' reign was largely occupied in defending the empire against attacks from all sides. First of all the Parthians under Vologeses III. broke into Syria. Verus went out in nominal command of the war against them, which was really conducted by Avidius Cassius. The war was concluded in 165, but the returning army brought a pestilence with them that spread over the whole empire. Aurelius accompanied Verus in wars in Pannonia and Noricum in 167–8, and peace was made with the Marcomanni in 168. Early in 169 Verus died, leaving Aurelius sole emperor. In the autumn of 169 war again broke out on the Rhine-Danube frontier, and Marcus Aurelius lived almost entirely at Carnuntum for three years. The Marcomanni were eventually driven out of Pannonia and almost annihilated, and in 174 Aurelius won over the Quadi the celebrated victory of the "thundering legion," commemorated on the column of Antonina.

Germany.—Aurelius next marched to Germany. There news reached him that Avidius Cassius, the commander of the Roman troops in Asia, had revolted and proclaimed himself emperor (175). But after three months Cassius was assassinated, and his head was brought to Aurelius, who with characteristic magnanimity, persuaded the senate to pardon all the family of Cassius.

During his journey of pacification, Faustina, who had borne him 11 children, died. Aurelius trusted her while she lived, and mourned her loss.

After the death of Faustina and the pacification of Syria, Aurelius proceeded, on his return to Italy, through Athens, and was initiated in the Eleusinian mysteries. He gave large sums of money for the endowment of chairs in philosophy and rhetoric, with a view to making the schools the resort of students from all parts of the empire. Along with his son Commodus he entered Rome in 176, and obtained a triumph for victories in Germany. In 177 occurred that persecution of Christians, the share of Aurelius in which has been the subject of so much controversy. Meanwhile the German War continued, and the two Quintilii, who had been left in command, begged Aurelius once more to take the field.

Death.—In this campaign Aurelius, after a series of successes, was attacked, according to some authorities, by an infectious disease, of which he died after a week's illness, either in his camp at Sirmium (Mitrovitz), on the Save, in Lower Pannonia, or at Vindobona (Vienna), on March 17, 180, in the fifty-ninth year of his age. Other accounts are: (1) that he was poisoned in the interests of Commodus (Dio. Cass. lxxi. 33, 4), (2) that he died of a chronic stomachic disease; the latter is perhaps the most likely. His ashes (according to some authorities, his body) were taken to Rome. By common consent he was deified and all those who could afford the cost obtained his statue or bust; for a long time his statues held a place among the penates of the Romans. Commodus, who was with his father when he died, erected to his memory the Antonine column (now in the Piazza Colonna at Rome), round the shaft of which are sculptures in relief commemorating the miracle of the thundering legion and the various victories of Aurelius over the Quadi and the Marcomanni. A bronze equestrian statue was set up in the Forum, now on the Capitol.

Aurelius was consistently hostile to Christianity, and persecution, unknown or forbidden under earlier reigns, was systematically pursued under his directions. His attitude was logical enough. The State religion was to him an essential part of the imperial system, and the Christians, particularly in their opposition to emperor-worship, were a danger to the established order.

In his work on the internal administration Marcus Aurelius was equally untiring. His reign is especially notable for legal reforms, and an attempt to arrest the fall in the legitimate birth-rate. His provincial administration was not made easier by the drain on the Treasury caused by the defence of the empire. Against his will he had to increase taxation, and he risked alienating his soldiers by refusing an increase of pay. Last of a line of emperors who all seemed to come little short of the Stoic ideal of the philosopher king, Marcus Aurelius was the best of them all.

Philosophy.—The book which contains the philosophy of Aurelius is known by the title of his *Reflections,* or *Meditations,* although that is not the name which he gave to it himself (Τὰ εἰς ἑαυτόν). Of the genuineness of the work no doubts are now entertained. It is believed that he wrote also an autobiography, which has perished. The *Meditations* were written, it is evident, as occasion offered—in the midst of public business, and on the eve of battles on which the fate of the empire depended—hence their fragmentary appearance, but hence also much of their practical value and even of their charm.

Throughout his life he was a practising, but he was not strictly an orthodox, Stoic. In his hands Stoicism is a practical rule of life, not a philosophy of quietism. In the *Meditations* are no speculations on the absolute nature of the deity, and no clear expressions of opinion as to a future state. He is, above all things, a practical moralist. The goal in life to be aimed at, according to him, is not happiness, but tranquillity, or equanimity. This condition of mind can be obtained only by "living conformably to nature," that is to say, one's whole nature, and as a means to that man must cultivate the four chief virtues, each of which has its distinct sphere—wisdom, or the knowledge of good and evil; justice, or the giving to every man his due; fortitude, or the enduring of labour and pain; and temperance, or moderation in all things. It is no "fugitive and cloistered virtue" that Aurelius seeks to encourage; on the contrary, man must lead the "life of the social animal." While he held that the prime principle in man is the social, "the next in order is not to yield to the persuasions of the body, when they are not conformable to the rational principle which must govern." This divinity "within a man," this "legislating faculty," which, looked at from one point of view, is conscience, and from another is reason, must be implicitly obeyed. He who thus obeys it will attain tranquillity of mind.

What gives the sentences of Marcus Aurelius their enduring value and fascination, and renders them superior to the utterances of Epictetus and Seneca, is that they are the gospel of his life. His precepts are simply the records of his practice. To the saintliness of the cloister he added the wisdom of the man of the world; he was constant in misfortune, not elated by prosperity, never "carrying things to the sweating-point," but preserving, in a time of universal corruption, unreality and self-indulgence, a nature sweet, pure, self-denying, unaffected.

Bibliography.—P. B. Watson's *M. Aurelius Antoninus* (1884) contains a general account—life, character, philosophy, relations with Christianity—as well as a bibliography; see also art. in Pauly-Wissowa, *Realencyclopädie, s.v.* "Annius" (No. 94), col. 2279, and H. D. Sedgwick, *Marcus Aurelius* (New Haven, 1921). For special points see: (1) *Historical:* Authorities under Rome: *Ancient History;* S. Dill, *Roman Society from Nero to M. Aurelius* (1904); M. Rostovtzev, *Social and Economic History of the Roman Empire* (1926). (2) *Relations to Christianity:* Sir W. M. Ramsay, *The Church in the Roman Empire* (1898); W. Möller, *History of the Christian Church, A.D. 1–600* (Eng. trans., A. Rutherford, 1892); W. E. Addis, *Christianity and the Roman Empire* (1893); E. G. Hardy, *Christianity and the Roman Government* (1894), pp. 145 *sqq.,* and Leonard Alston, *Stoic and Christian of the 2nd century* (1906); J. Dartigue-Peyrou, *Marc-Aurèle dans ses rapports avec le christianisme* (1897). (3) *Philosophical:* Besides article Stoics, E. Renan, *Marc. Dickson, London, 1886); for the Aurelius column, E. Petersen, A. von Domaszewski, and G. Calderini, *Die Marcussäule* (Munich, 1896), with historical introduction by Th. Mommsen. (5) The *Meditations* were published by Xylander in 1558; the best critical edition is that of J. Stich in the Teubner series (Leipzig, 1882; 2nd ed., 1903). Translations exist in almost every language; that of George Long (1862, re-edited 1900) has been superseded by those of G. H. Rendall (1898, with valuable introduction) and J. Jackson (1906, with introduction by Charles Bigg). (6) For the correspondence of Aurelius and Fronto, *see* Robinson Ellis, *Correspondence of Fronto and M. Aurelius* and *Class Rev.* vol. 34 p. 14 (1904).

MARCUS HOOK, a borough of Delaware county, Pennsylvania, U.S.A., on the Delaware river and the Pennsylvania railroad, 19 mi. S.W. of Philadelphia. Pop. in 1930, 4,867; in 1940, 4,123, federal census. It has a considerable shipping trade, oil refineries and factories making synthetic fibres, chemicals, barrels and congoleum. Settlement dates from 1640. The streets were laid out by William Penn, who granted a charter to the borough in 1701.

MARCY, WILLIAM LEARNED (1786–1857), American statesman, was born in Southbridge, Mass., on Dec. 12, 1786. He graduated at Brown university in 1808, studied law, was admitted to the bar in Troy, N.Y., and began practice there in 1810. During the War of 1812 he served as a captain of volunteers, and Oct.

22, 1812 took part in the storming of the British post at St. Regis, Canada. In 1816 he became recorder of Troy, but he was removed from office in 1818 by his political opponents. As editor of the Troy *Budget* he was a vigorous supporter of Martin Van Buren, and when Van Buren's followers acquired control of the legislature in 1821 Marcy was made adjutant-general of the New York militia. From 1823 to 1829 Marcy was comptroller of the State, an office then especially important on account of the large expenditures for internal improvements, and during this period he became the leading member of the famous "Albany regency" (*q.v.*), a group of able Democratic politicians who exerted a powerful influence throughout the State by their control of the party patronage and machinery. He was one of the associate justices of the New York supreme court from 1829 to 1831, presiding over the trial of the alleged murderers of William Morgan and in other important cases; and was a member of the United States Senate from Dec. 1831 to July 1832, when he resigned to become governor of New York. In a speech in the Senate defending Van Buren against an attack by Henry Clay, Marcy made the unfortunate remark that "to the victors belong the spoils of the enemy," and thereby became widely known as a champion of the proscription of political opponents. He served as governor of New York for six years (1833–38 inclusive). As governor he secured the enactment, in 1838, of a general banking law, which abolished the monopoly features incident to the old banking system. In 1844–45 he was recognized as one of the leaders of the "Hunkers," or regular Democrats in New York, and an active opponent of the "Barnburners." He was secretary of war under President Polk from 1845 to 1849, and as such discharged with ability the especially onerous duties incident to the conduct of the Mexican War.

From 1853 to 1857 he served the term as secretary of State in the cabinet of President Pierce. Few cabinet officers in time of peace have had more engrossing duties. His circular in 1853 to American diplomatic agents abroad, recommending that, whenever practicable, they should "appear in the simple dress of an American citizen," created much discussion in Europe; in 1867 his recommendation was enacted into a law of Congress.

In 1853 Marcy secured the negotiation of the Gadsden Treaty (*see* GADSDEN, JAMES), by which the boundary dispute between Mexico and the United States was adjusted and a large area was added to the Federal domain. The expedition of William Walker (*q.v.*) to Nicaragua in 1855 further complicated the Central American situation. The diplomatic relations of the United States and Spain growing out of the noted "Black Warrior Case" furnished, perhaps, the most perplexing of Marcy's problems, and it was largely due to his influence that war was averted. However, he was not averse to increasing his popularity and his chances for the presidency by obtaining Cuba in an honourable manner, and it was at his suggestion that James Buchanan, J. Y. Mason and Pierre Soulé, the ministers respectively to Great Britain, France and Spain, met at Ostend and Aix-la-Chapelle in Oct. 1854 to discuss the Cuban question. But the remarkable "Ostend Manifesto" (*q.v.*), the outcome of their conference, was quite unexpected, and Marcy promptly disavowed the document. In domestic affairs Marcy was a shrewd, but honest partisan; in diplomacy he exhibited the qualities of a broadminded, patriotic statesman, endowed, however, with vigour, rather than brilliancy, of intellect. He died at Ballston Spa, N.Y., on July 4, 1857.

For his early career, consult J. S. Jenkins, *Lives of the Governors of New York* (Auburn, N.Y., 1851); and for his work as secretary of State, *see* James Ford Rhodes, *History of the United States* (vols. i. and ii., 1892), and an article by Sidney Webster, "Mr. Marcy, the Cuban Question, and the Ostend Manifesto" (in vol. viii. of the *Political Science Quarterly*, 1893); J. B. Moore, "A Great Secretary of State," *Pol. Sci. Quart.* (vol. xxx., P. 377–396, Lancaster, Pa., 1915); "Diary and Memoranda of William L. Marcy, 1849–51," *American Hist. Rev.* (vol. xxiv., P. 444–462, 641–653, Lancaster, Pa., 1919); De Alva S. Alexander, *A Political History of the State of New York* (1906–1923).

MARDI GRAS: *see* SHROVE TUESDAY.

MARDIN, a town in a vilayet of the same name in Kurdistan, Turkey, and *c.* 30 m. north-west of Nisibin, on the line of the Baghdad railway. The town is of some importance on the caravan route between the east and west. From Mardin one road leads west to Urfah and so to Aleppo or Aintab. A second runs north-west to Diarbekr. South-east runs the road to the Tigris and so to Mosul and Baghdad. The town is the centre of a rich agricultural district, the principal products being wheat, barley and sesame. A certain amount of wool is produced and there is a small cotton and woollen weaving industry. The population is very mixed and is 23,270 for the city and 252,505 for the vilayet. It includes Arabs, Armenians, Jacobites, Kurds and a medley of Asiatics.

MARDONIUS (*fl.* 479 B.C.), Persian general, was the son of Gobryas, one of the conspirators against Smerdis the Magian. He married Artazostra, daughter of Darius Hystaspis, and in 492 was sent to succeed Artaphernes in the settlement of Ionia with a special commission to attack Athens and Eretria. Contrary to the usual Persian policy, he restored democracies in Ionia, and then crossed the Hellespont and invaded Thrace and Macedonia. His fleet was wrecked off Athos with enormous loss, and Mardonius abandoned further progress and came back to Aria; he was superseded in 490. On the accession of Xerxes Mardonius was one of the chief instigators in the invasion of Greece. After Salamis he persuaded Xerxes to return, and himself stayed behind with a large army. He was defeated by Pausanius and killed at Plataea in September 479.

See Herodotus: Books vi.–ix.; *Diod.* xi., i. 28–31.

MARDUK, a late name for the god of the city of Babylon, who appears regularly in the classical Sumerian liturgies under the titles *Asar-lu-dug* and *Enbilulu*. The original title is *Asaru,* which occurs in the old pantheon at Fara, *c.* 3200 B.C., and so far as known, long before the city of Babylon was founded. *Asaru, Asar-ri,* is a title of this, originally inferior, deity of the cult of Enki at Eridu, as son of the water god, a deity of lustration. His connection with Babylon, which is first mentioned as a small city by Sargon in the 28th century B.C., may be original and very old. The title *Marduk* lays special emphasis upon his solar aspect. It is certain that all the older titles of this god, Asaru, Asar-alim, Asar-alim-nun-na, Asarludug, describe him as an inferior deity of the water cult of Eridu, and how he came to be transferred to Babylon is at present inexplicable. *Alim* means the mythical fish ram, symbol of his father, the water god of Eridu, and *Asaru* was the god of lustration at Habur in Eridu. Asarludug means "Asaru who restores man to happiness," and describes his original activity as agent of Enki in all magical rituals of the water cult against demons. Marduk is pre-eminently the god of the magicians in Babylonian and Assyrian religion, and this was his sole sphere in the original Sumerian pantheon.

With the rapid rise of Babylon under the 11 kings of the 1st dynasty (2169–1870), the priests of the local cult looked for some means of increasing the respect due to the god of the great capital and a theological reason for it. Inasmuch as the Sumerian pantheon had been universally accepted by the Accadians, and had now a firm hold upon the religious beliefs of the Semites in Assyria, Cappadocia and the Amoritic western country, it was impossible to make *Asaru* one of the three heads of the trinity; these were securely held by Anu, Enlil and Enki. But the old war and sun god Ninurta, Zamama, son of Enlil, was largely drawn upon to make Asaru also a sun god, and more especially the god of the spring sun. This addition to his original character as a god of lustration and magic was brought about by rewriting the Sumerian legend of Creation in which Ninurta championed the gods against the dragon of Chaos, the storm demon Zû, and then created the world. The new Semitic version in six books attributed this victory of the gods to Marduk. The name itself was introduced at this time, *amar-udu, amar-utu,* and means "young bull, the sun," becoming, after the regular rule of Sumerian loan-words, *Marutukku, Marudukku, Má-rû-tu-*[*uk-ku*], *Maruduk, Marduku, Marduk*. (*See* S. Langdon, *Oxford Editions of Cuneiform Texts*, vol. vi. 99, 113, and *Cuneiform Texts* . . in the British Museum, vol. xxv. 34, ii. 17.) The Hebrew transcription is Merodak, and the Greek, *Maradouchos, Mardakos, Mardokos, Maradach.*

In the Semitic version of the Epic, Marduk's birth and education are described. The old theological view, that he was the son of Enki or Ea of Eridu, is preserved, except in the Assyrian editions, where he is displaced by Ashur, son of Lahmu. The legend of how he was unanimously raised to the rank of a great god (in the convocation of the gods), because of his magical power to cause objects to vanish and reappear, and for his promise to go forth to battle with Tiamat, Kingu and the dragons of darkness, is one of the principal episodes of the epic. After Tiamat was slain and the dragons bound, Marduk created heaven and earth, the constellations and planets, and fixed their movements. Finally, he ordered man to be created on the advice of his father, Ea. Kingu was then slain and from his blood "mankind" was created. This was the Eridu legend of the creation of man, but in the rival Nippurian school his creation is said to have been by the mother goddess, Aruru, from clay. Undoubtedly the Hebrew legend of the creation of Adam from clay combines the legend of Marduk and Aruru.

Upon the epic of Creation and the myth of the conquest of light over darkness is based the Babylonian new year festival, described in the article BABYLONIAN AND ASSYRIAN RELIGION. For the later identification of Marduk with Tammuz and the Resurrection of Bêl, *see* TAMMUZ. So completely did Marduk finally dominate the religion of Babylonia that he is chiefly known to Greek and Roman writers as "lord," Bêlos, *see* BÊL. A text proves that in the late period theological speculation went so far as to assimilate all the important deities to Marduk, but this advance toward real monotheism was obviously confined to priests at Babylon. (*See* Jensen, *Keilinschriftliche Bibliothek,* vi. pt. 2, p. 118.) Unlike other great and older deities, Marduk had no temples and shrines outside his own city. The Sumerian cities of the south never admitted his new rôle in the pantheon, but only his original names and character as an inferior water deity of Eridu. At Babylon his temple, Esagila, and his stage tower, Etemenanki, were the largest of the kind in Babylonia and Assyria. To Esagila, at least in the late period, all the statues of the great gods of Babylonia were brought in ships and wagons to assemble in the hall of convocation (Dukug) and fix the fates of men for the coming year at the Nisan festival.

Marduk's principal rôle in astronomy was as the planet Jupiter; as such he was known as Shulpaé, a title of a deity which originally had no connection with Asaru or Marduk. The title belongs originally to Enlil, the ancient *Bêl* of Nippur, and is found in the oldest inscriptions. The planet must have been known as *mul Shulpaé,* and identified with Enlil before the 22nd century, otherwise the name would not have been chosen for Marduk when the theologians assigned to him the largest of the planets.

MARE, the female of any animal of the family *Equidae,* particularly of the horse. It is also used of the camel. To find a "mare's nest" is an old saying for a purely imaginary discovery. In "night-mare," an oppressive or terrifying dream, the termination is a word for a goblin, supposed to cause these dreams: *cf.* ELF.

MARE CLAUSUM and **MARE LIBERUM** (Lat. for "closed sea" and "free sea") in international law, terms associated with the historic controversy which arose out of demands on the part of different States to assert exclusive dominion over areas of the open or high sea. Thus Spain and Portugal laid claim to exclusive dominion over whole oceans, Great Britain to the narrow seas, and so on. These claims gave rise to vigorous opposition by other powers and led to the publication of Grotius's work *Mare liberum* (1608). In *Mare clausum,* written in 1617–18 and published in 1635, Selden asserted "that the sea by the law of nature or nations is not common to all men but capable of private dominion or property as well as the land."

A formula was found by Bynkershoek in his *De dominio maris* (1702) for the restriction of dominion over the sea to the actual distance to which cannon range, *i.e.,* three marine miles, could protect it (*see* WATERS, TERRITORIAL).

See Grotius, *The Freedom of the Seas* (tr. by R. van D. Magoffin, 1916); Sir J. Boroughs, *The Sovereignty of the British Seas* (ed. Wade, 1920).

MAREE, LOCH, a fresh-water lake in the county of Ross and Cromarty, Scotland. Its name commemorates St. Maelrubha, who, in 671 founded a monastery at Applecross and a chapel (now in ruins) on Isle Maree. The lake is $13\frac{1}{2}$ m. long from Kinlochewe at the head of the dam erected in the 16th century (or earlier) by the iron-smelters of the Ceardach Ruardh, or Red Smiddy, on the river Ewe by which it drains to the sea. Its greatest breadth is just over 2 m. at Slattadale, and the greatest depth 367 ft. There are over 30 islands, covering an area of nearly 1 sq.m. and lying mostly north and east of Slattadale. The largest is Eilean Subhainn, or St. Swithin's Isle, which contains two small lakes. For two-thirds of its length the loch is flanked by mountains. On the north-east the principal heights are Ben Slioch (3,217 ft.), Ben Lair and Ben Airidh-a-Char, and, on the south-west, the peaks of Ben Eay, four of which exceed 3,000 ft. Sea trout and salmon are taken in the loch.

MARÉES, HANS VON (1837–1887), German painter, was born at Elberfeld on Dec. 24, 1837. In 1853 he went to Berlin, where he studied for two years under Steffeck. For the next eight years he worked chiefly in Munich, coming under the influence of the historical school, and in 1864 he went to Rome. He also travelled in Spain and France and spent some time in Berlin. In 1873 he received his most important commission, the painting of frescoes in the library of the Zoological museum at Naples. Although ambitious, Marées lacked self-confidence, and in the latter part of his life ceased to exhibit his work. He died in Rome on June 5, 1887, a disappointed and practically unknown man. When his works were collected at the Munich exhibition in 1891, their real value became apparent.

See Meier-Gräfe, *Hans von Marées* (vol. iii., 1909); Conrad Fiedler, *H. v. Marées,* 2 vols., one of illustrations (Munich, 1889); Hans von Marées, *Briefe* (Munich, 1920); Meier-Gräfe, *Der Zeichner Hans von Marées* (Munich, 1925).

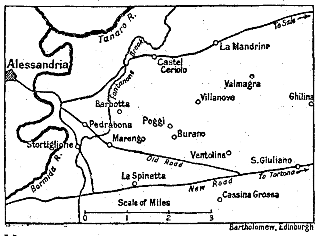
MAREMMA, a marshy region of Tuscany, Italy, from the mouth of the Cecina to Orbetello, 15 to 20 m. broad. In Etruscan and Roman times the Maremma was a populous and fertile coast plain, with considerable towns situated on the hills—Populonia, Rusdellae, Cosa, etc.—and was drained by subterranean canals, which were brought to light when excavations were in progress for the building of railways. The decline of agriculture at the end of the Republic led to a conversion of the land to pasture, and the fall of the Empire resulted in neglect of watercourses. Leopold II. of Tuscany (1822–1844) made the first successful efforts to counteract malaria by drainage, filling up of swamps, and establishment of new farms, and since his time continuous efforts have been made with considerable success.

See C. Nicolosi, *Il Litorale Maremmano; La Montagna Maremmana* (Bergamo, Arti Grafiche, 1911), well illustrated.

MARENGO, a village of north Italy, on the road between Alessandria and Tortona, and $4\frac{3}{4}$m. E.S.E. of the gates of the former. It is situated on the Fontanone brook, a small affluent of the Tanaro which marks the western edge of the plain of Marengo, the scene of the great victory won by Napoleon Bonaparte over the Austrians under Baron Melas (1729–1806) on June 14, 1800. The antecedents of the battle are described under FRENCH REVOLUTIONARY WARS.

The French army, uncertain of its opponent's position, had advanced westward from the Scrivia towards Alessandria on the 12th, and its outposts had reached the Bormida on the evening of the 13th. But contact with the main Austrian army was not obtained, and on the assumption that it was moving towards either Valenza or Genoa Bonaparte weakened his army by considerable detachments sent out right and left to find the enemy and to delay his progress. Unknown, however, to Bonaparte Melas's army was still at Alessandria, and on the morning of June 14 it filed out of the fortress and began its advance into the great plain of Marengo, one of the few favourable cavalry battle-grounds in north Italy.

Gen. Victor had not carried out Bonaparte's evening order to destroy the bridges over the Bormida, and the dispersion of the French army allowed only a fragmentary, though most energetic, resistance to be offered to the Austrian onset. The latter, considerably delayed at first by the crossing of the river Bormida, broke up into two columns,[1] advanced, the right by the main road on Marengo, the left on Castel Ceriolo. The former, personally commanded by Melas, was 20,000 strong, and Gen. Victor, its immediate opponent, about 10,000, or including some 5,000 of Lannes' corps who fought on his right, about 15,000 strong; the Austrians were, moreover, greatly superior in guns (in all 192 to 14) and cavalry. The French disputed every yard of ground, holding their first line until they had by fire and counter-attack forced practically the whole of the Austrian right to deploy, and two hours passed before the Austrians managed to reach the Fontanone brook. But Victor's troops, being disorganized and short of ammunition, had then to retire more rapidly across the plain. The retreat was orderly, according to Victor's report, and made in échelon from the centre, and it is certain that at any rate the regiments held together, for the 6,000 Austrian sabres found no opportunity to charge home. Many guns and wagons were, however, abandoned.



MAP OF MARENGO, THE SCENE OF NAPOLEON'S VICTORY OVER THE AUSTRIANS, JUNE 14, 1800

On the French right, opposed to the column of Lieut.-Field-Marshal Ott, was Lannes, with some 4,000 men (excluding Watrin's division which was with Victor) against 7,500. He too was after a time forced to retire, with heavy losses. Thus, about 11 A.M., Bonaparte, who was at some distance from the field, became convinced that he had to deal with Melas's army. At once he sent out his staff officers to bring back his detachments, and pushed forward his only reserve, Monnier's division, to support Lannes and Victor. But before this help arrived Lannes had been driven out of Castel Ceriolo, and Victor and Watrin forced back almost to San Giuliano. A little after 2 P.M. Monnier's division (3,500) came into action, and its impetuous advance drove the Austrians out of Castel Ceriolo. But after an hour it was forced back in its turn, and by 3 P.M., therefore, the 20,000 French troops, disordered and exhausted, and in one line without reserves,[2] held a ragged line of battle to the right and left of San Giuliano. The best that could be expected was a prolongation of the struggle till nightfall and a fairly orderly retreat. Melas, slightly wounded and believing that the battle was won, returned to Alessandria, leaving a younger man, his chief of staff Zach, to organize the pursuit.

Then followed one of the most dramatic events in military history. Of the two detachments sent away by Napoleon in search of the enemy, one only received its orders of recall. This was Boudet's division of Desaix's corps, away to the south at Rivalta and at noon heading for Pozzolo-Formigaro on the Alessandria-Genoa road. At 1 P.M. a brief message, "Revenez, au nom de Dieu!" altered the direction of the column, and between 4 and 5, after a forced march, the division, headed by Desaix, came on to the battle-field. It was deployed as a unit and moved forward at the word of command along the main road Alessandria-Tortona, the sight of their closed line giving fresh courage to the men of Lannes and Victor. Then, while on the other side Zach was arraying a deep column of troops to pursue along the main road, Napoleon and Desaix, themselves under fire, hastily framed a plan of attack. All arms were combined. First, Marmont with eight of Boudet's guns and ten others (the rest had been abandoned in the retirement) came into action on the right of the road, replying to the fire of the Austrian guns and checking their advanced infantry; close in rear of the artillery was Desaix's infantry with the remnants of Lannes' and Victor's troops rallying on its right and left; on Lannes' right, still facing Ott's column, was Monnier, supported by the Consular Guard of horse and foot; lastly 400 sabres of Kellermann's cavalry brigade, which had already been engaged several times and had lost heavily, formed up on the right of Desaix. About 5 P.M. Desaix advanced against the head of the Austrian main column formed by Zach. He himself fell in the attack, but the onset of his intact troops drove back the leading Austrians upon their supports, and at the critical moment when the attack of Boudet's single weak division had almost spent its force, Kellermann with his 400 sabres sallied out of the French line. Marmont had brought up two guns to assist the infantry, and as he fired his last round of case-shot the cavalry raced past him to the front, wheeled inwards against the flank of the great column, and rode through and through it. Zach was taken prisoner with more than 2,000 men, and Kellermann, rallying some of his troopers, flung himself upon the astonished Austrian cavalry and with the assistance of the Consular Guard cavalry defeated it. The "will to conquer" spread along the whole French line, while the surprise of the Austrians suddenly and strangely became mere panic. Lannes, Victor and Monnier advanced afresh, pushing the Austrians back on Marengo. A few Austrian battalions made a gallant stand at that place, while Melas himself, as night came on, rallied the fugitives beyond. Next day the completely exhausted, but victorious, French army extorted from the dazed Austrians a convention by which all Italy up to the Mincio was evacuated by them. The respective losses were: French about 4,000, Austrians 9,500.

See the French official *Campagne de l'armée de réserve,* vol. ii., by C. de Cugnac.

[1]A third column was sent out to the extreme right (3,000 under O'Reilly). This destroyed a small French detachment on the extreme left, but took little or no part in the main battle.

[2]The Austrians, too, fighting in "linear" formation had few reserves. About one-third only of the imperial forces in Italy was actually engaged in the battle.

MARENZIO, LUCA (before 1560–1599), Italian composer, was born probably at Coccaglia in the Bergamask before 1560. According to some accounts he was descended from a noble family of Bergamo. He was a pupil of Giovanni Contini, organist of Brescia, and began to publish books of madrigals at an early age. In 1581 he was in Venice and from 1582 to 1585 in Rome, where he was at one period chapel-master to the Cardinal d'Este. For two years he held a handsome appointment at the court of Poland, but 1595 found him back in Rome with an appointment at the Papal chapel. In Rome he became a warm friend of Cardinal Aldobrandino, the pope's nephew. He died in Rome on Aug. 22, 1599. Marenzio's most important compositions consist of the 16 books of madrigals, 5 books of vilanelles and airs, 2 books of motets and 1 mass. (The complete list is in Eitner's *Quellen-lexikon.*) The 5-part and 6-part madrigals in two books are in the British Museum. The *Musica transalpina* (1588) contains some of his works, and several motets are included in Proske's *Musica divina* (1853).

See also "Marenzio" in Grove *Dictionary of Music and Musicians.*

MAREOTIS, the most westerly of the lakes in the Delta of Egypt (Arab. *Mariut*). On the narrow strip of land separating the lake from the Mediterranean the city of Alexandria is built. (*See* EGYPT and ALEXANDRIA.) In classical times its shores were a region of great fertility, and in the middle ages the lake was practically dry. During the siege of Alexandria in 1801 the British cut the ridge of dunes at Aboukir and flooded the area with sea water. Now, by means of pumps, the water-level of the lake is kept about 8 ft. below sea-level, and cultivation has been largeiy restored.

MARE'S-TAIL, the popular name for an aquatic herb known botanically as *Hippuris vulgaris* (water-milfoil family Hippuridaceae). Mare's-tail grows on margins of lakes, ponds and similar localities, and has a submerged stout creeping rootstock from which spring many-jointed cylindrical stems bearing numerous narrow leaves close-set in whorls. The minute greenish flowers are borne in the leaf-axils. Like many freshwater plants it has a wide distribution, occurring in arctic and temperate regions in the northern hemisphere. It reappears in Antarctic South America.

MARET, HUGUES-BERNARD, Duc de Bassano (1763–1839), French statesman and publicist, was born at Dijon. After receiving a sound education, he entered the legal profession and became advocate at the King's Council at Paris. The interest aroused by the debates of the first National Assembly suggested to him the idea of publishing them, conjointly with Méjean, in the *Bulletin de l'Assemblée.* The publicist Charles Joseph Panckoucke (1736–1798), owner of the *Mercure de France* and publisher of the famous *Encyclopédie* (1781), persuaded him to merge this in a larger paper, the *Moniteur universel,* which gained a wide repute for correctness and impartiality. He was a member of the moderate club, the Feuillants; but after the overthrow of the monarchy on Aug. 10, 1792 he accepted an office in the ministry of foreign affairs, where he sometimes exercised a steadying influence. On the withdrawal of the British legation from Paris Maret went on a mission to London, where he had a favourable interview with Pitt on Dec. 2, 1792. All hope of an accommodation was, however, in vain. After the execution of Louis XVI. (Jan. 21, 1793), the chief French diplomatic agent, Chauvelin, was ordered to leave England, while the French Convention declared war (Feb. 1, 1793). These events precluded the possibility of success attending a second mission of Maret to London in January. He was sent to Naples as ambassador of the French Republic; but he was captured by the Austrians, and was only released in 1795 when the duchess of Angoulême was set free. Maret took part in the negotiations with Great Britain at Lille during the summer of 1797, until the *coup d'état* of Fructidor frustrated any peace. On the return of Bonaparte from Egypt in 1799 Maret joined the general's party which came to power with the *coup d'état* of Brumaire (Nov. 9–10, 1799).

Maret now became one of the First Consul's secretaries and shortly afterwards secretary of state. The *Moniteur,* which became the official journal of the state in 1800, was placed under his control. In 1804 he became minister; in 1807 he was named count, and in 1809 he received the title of duc de Bassano. His personal devotion to the emperor was of that absolute unwavering kind which Napoleon highly valued. Maret accompanied Napoleon through most of his campaigns, including that of 1809; and in the spring of 1811 he replaced Champagny, duc de Cadore, as minister of Foreign Affairs. In this capacity he concluded the treaties between France and Austria and France and Prussia, which preceded the French invasion of Russia in 1812. He was with Napoleon through the greater part of that campaign; and after its disastrous conclusion helped to prepare the new forces with which Napoleon waged the equally disastrous campaign of 1813. But in November 1813 Napoleon replaced him by Caulaincourt, duc de Vicence.

Maret, however, as private secretary of the emperor, remained with his master through the campaign of 1814, as also during that of 1815. After the second restoration of the Bourbons he was exiled, and retired to Grätz where he occupied himself with literary work. In 1820 he was allowed to return to France, and after the Revolution of 1830, Louis Philippe, king of the French, made him a peer of France; he also held two high offices for a few days. He died at Paris in 1839. He shares with Daru the honour of being the hardest worker and most devoted supported in Napoleon's service; but it has generally been considered that he carried devotion to the length of servility, and thus often compromised the real interests of France. This view has been contested by Baron Ernouf in his work *Maret, duc de Bassano,* which is the best biography.

For Maret's mission to England in 1792 and his work at Lille in 1797, *see* Augustus W. Miles, *Letters on the French Revolution.*

MARGARET, a female proper name, which became very popular in all Christian countries as that of Saint Margaret (*q.v.*). (Fr. *Marguerite,* It. *Margherita,* Ger. *Margareta,* fr. Lat., *margarita,* Gr. *μαργαρίτης,* a pearl.)

MARGARET, ST. (Sancta Margarita), virgin and martyr, is celebrated by the Church of Rome on July 20. According to the legend, she was a native of Antioch, daughter of a pagan priest named Aedesius. She was scorned by her father for her Christian faith, and lived in the country with a foster mother keeping sheep. Olybrius, the "praeses orientis," offered her marriage as the price of her renunciation of Christianity. Her refusal led to her being cruelly tortured, and after various miraculous incidents, she was put to death. Among the Greeks she is known as Marina, and her festival is on the 17th of July. She has been identified with St. Pelagia (*q.v.*)—Marina being the Latin equivalent of Pelagia—who, according to a legend, was also called Margarito. The cult of St. Margaret was very widespread in England, where more than 250 churches are dedicated to her.

See *Acta sanctorum,* July, v. 24–45; *Bibliotheca hagiographica, Latina* (Brussels, 1899), n. 5303–13; Frances Arnold-Forster, *Studies in Church Dedications* (London, 1899), i. 131–133 and iii. 19.

MARGARET, ST. (*c.* 1045–1093), queen of Malcolm III. Canmore king of Scotland, was the daughter of the English prince Edward, son of Edmund Ironside, and sister of Edgar Aetheling. In 1067 the widow and children of Edward fled from Northumberland and sought the protection of the Scottish king. The marriage of Malcolm and Margaret was followed by several invasions of Northumberland by the Scottish king, probably in support of the claims of his brother-in-law Edgar. A considerable portion of the old Northumbrian kingdom had been reduced by the Scottish kings in the previous century, but up to this time the English population had little influence upon the ruling element of the kingdom. Malcolm's marriage undoubtedly improved the condition of the English, and under Margaret's sons, Edgar, Alexander I. and David I., the Scottish court practically became Anglicized. Margaret died on Nov. 17, 1093, four days after her husband and her eldest son Edward, who were slain in an invasion of Northumberland. She rebuilt the monastery of Iona, and was canonized in 1251 on account of her benefactions to the Church.

MARGARET (1353–1412), queen of Denmark, Norway and Sweden, the daughter of Valdemar IV. of Denmark, was born in 1353 and married ten years later to King Haakon VI. of Norway. Her first act, after her father's death (1375), was to procure the election of her infant son Olaf as king of Denmark. Olaf died in 1387, having in 1380 also succeeded his father; and in the following year Margaret, who had ruled both kingdoms in his name, was chosen regent of Norway and Denmark. She now turned to Sweden, where the nobles were in arms against their unpopular king, Albert of Mecklenburg.

At a conference held at Dalaborg castle, in March 1388, the Swedes were compelled to accept all Margaret's conditions, elected her "Sovereign Lady and Ruler," and engaged to accept from her any king she chose to appoint. On Feb. 24, 1389, Albert, who had returned from Mecklenburg with an army of mercenaries, was routed and taken prisoner at Aasle near Falköping, and Margaret was now the omnipotent mistress of three kingdoms. Stockholm, then almost entirely a German city, still held out; fear of Margaret induced both the Mecklenburg princes and the Wendish towns to hasten to its assistance; and the Baltic and the North Sea speedily swarmed with the privateers of the *Viktualien brödre* or *Vitalianer,* so called because their professed object was to revictual Stockholm. Finally the Hansa intervened, and by the compact of Lindholm (1395) Albert was released by Margaret on promising to pay 60,000 marks within three years, the Hansa in the meantime to hold Stockholm in pawn. Albert failing to pay his ransom within the stipulated time, the Hansa surrendered Stockholm to Margaret in September 1398, in exchange for very considerable commercial privileges.

It had been understood that Margaret should, at the first convenient opportunity, provide the three kingdoms with a king who was to be her nearest kinsman, and in 1389 she proclaimed her infant cousin, Eric of Pomerania, king of Norway. In 1396 homage was rendered to him in Denmark and Sweden likewise, Margaret reserving to herself the office of regent during his minority. To weld the united kingdoms still more closely together, Margaret summoned a congress of the three councils of state to Kalmar in June 1397; and on Trinity Sunday, June 17, Eric was crowned king of Denmark, Norway and Sweden. The proposed act of union divided the three *Rigsraads,* but the actual deed embodying the terms of the union never got beyond the stage of an unratified draft. Margaret revolted at the clauses which insisted that each country should retain its own laws and customs, and be administered by its own dignitaries, as tending to prevent amalgamation, but she avoided every appearance of an open rupture.

A few years after the union of Kalmar, Eric, now in his eighteenth year, was declared of age and homage was rendered to him in all his three kingdoms, but during her lifetime Margaret was the real ruler of Scandinavia. So long as the union was insecure, Margaret had tolerated the presence near the throne of "good men" from all three realms (the *Rigsraad,* or council of state, as these councillors now began to be called); but their influence was always insignificant. In every direction the royal authority remained supreme. The offices of high constable and earl marshal were left vacant; the *Danehoffer* or national assemblies fell into desuetude, and the great queen, an ideal despot, ruled through her court officials acting as superior clerks. Margaret also recovered for the Crown all the landed property which had been alienated during the troublous days of Valdemar IV. This so-called "reduktion," or land-recovery, was carried out with the utmost rigour, and hundreds of estates fell to the Crown. Margaret also reformed the Danish currency. In foreign politics she maintained a strict system of neutrality. On the other hand she spared no pains to recover lost Danish territory. Gotland she purchased from its actual possessors, Albert of Mecklenburg and the Livonian Order, and the greater part of Schleswig was regained in the same way. Margaret died suddenly on board her ship in Flensborg harbour on Oct. 28, 1412.

See *Danmarks riges historie, den senere Middelalder,* pp. 358–412 (Copenhagen, 1897–1905); Erslev, *Danmarks historie under dronning Margrethe* (Copenhagen, 1882–1901); Hill, *Margaret of Denmark* (London, 1898). (R. N. B.)

MARGARET (1489–1541), queen of Scotland, eldest daughter of Henry VII., king of England, by his wife Elizabeth, daughter of Edward IV., was born at Westminster on Nov. 29, 1489. She married James IV. of Scotland on Aug. 8, 1503, but the scanty dowry given by her avaricious father embittered the relations between the two kingdoms, which the marriage, although accompanied by a treaty of perpetual peace, did nothing to heal. The whole of Margaret's life after her marriage was an unending series of intrigues, first with one political faction then with another; her conduct being mainly influenced by considerations affecting her pocket.

Margaret was crowned at Edinburgh in March 1504. Between 1507 and 1510 two sons and a daughter were born, all of whom died in infancy; in 1512 she gave birth to a son who succeeded his father as James V.; in 1514 she bore a posthumous son, Alexander, created duke of Ross, who died in the following year. A dispute with her brother Henry VIII. over a legacy was a contributory cause of the war which ended at Flodden, where James IV. was killed in Sept. 1513, having by his will appointed Margaret sole guardian of her infant son, now James V. Scotland was divided mainly into two parties, one in favour of alliance with England, and the other with France. The leader of the latter was John Stewart, duke of Albany, next heir to the crown of Scotland after Margaret's sons; Margaret herself for the most part inclined to the English faction; and when Albany returned to Scotland from France on the invitation of the Scottish parliament in the spring of 1514, the conflict grew almost to civil war. Her marriage to Archibald Douglas, earl of Angus, on Aug. 6, 1514 alienated many of the nobility, especially the earls of Arran and Home, and made her entirely dependent on the house of Douglas. It also furnished the council with a pretext for removing her from the regency and guardianship of the king in favour of Albany in July 1515. She fled to England in September, where a month later she bore to Angus a daughter, Margaret, who afterwards became countess of Lennox, mother of Lord Darnley and grandmother of James I. of England.

In 1516 Margaret went to her brother's court in London, while Angus, much to his wife's displeasure, returned to Scotland, where he made peace with Albany and was restored to his estates. The rivalry between the French and English factions in Scotland was complicated by private feuds of the Hamiltons and Douglases, the respective heads of which houses, Arran and Angus, were contending for the supreme power in the absence of Albany in France, where at the instance of Henry VIII. he was detained by Francis I. Margaret, quarrelling with her husband over money matters, sided at first with Arran and began to agitate for a divorce from Angus. In this she was probably aided by Albany, who found an unexpected ally in the queen-mother, Margaret being temporarily alienated from the English party by her brother Henry's opposition to her divorce. When Albany returned to Scotland in 1521 his association with Margaret gave rise to the accusation that it was with the intention of marrying her that he favoured her divorce from Angus. As Albany was strongly supported by the Scottish parliament, Angus found it necessary to withdraw to France till 1524. During these years there was constant warfare between the English and the Scots on the border, but in May 1524 Albany was obliged to retire to France. Henry VIII. continually aimed at securing the person of his nephew, the king of Scots, but he was proclaimed a reigning sovereign in July 1524. The queen-mother married Henry Stewart, second son of Lord Avondale, immediately after her divorce from Angus in 1527. Margaret and her new husband, who was created Lord Methven, now became for a time the ruling influence in the counsels of James V. But when her desire to arrange a meeting between James and Henry VIII. in 1534 was frustrated by the clergy and the council, Margaret in her disappointment revealed certain secrets to Henry which led to her being accused by her son of betraying him for money and of acting as an English spy. She died at Methven Castle on Oct. 18, 1541.

Bain (2 vols., Edinburgh, 1890); John Leslie, *History of Scotland,* ed. by T. Thompson (4 vols., Edinburgh, 1830); Sir H. Ellis, *Original Letters Illustrative of English History* (1825–46).

MARGARET (1283–1290), titular queen of Scotland, and generally known as the "maid of Norway," was the daughter of Eric II., king of Norway, and Margaret, daughter of Alexander III., king of Scotland. Her mother died soon after Margaret's birth, and in 1284 the estates of Scotland decided that if Alexander died childless the crown should pass to his granddaughter. In March 1286 Alexander was killed and Margaret became queen. The English king Edward I. was watching affairs in Scotland, and in 1289 a marriage was arranged between the infant queen and Edward's son, afterwards Edward II. Margaret sailed from Norway and reached the Orkneys, where she died in Sept. 1290. Some mystery surrounded her death, and about 1300 a woman from Leipzig declared she was Queen Margaret. The impostor, if she were such, was burned as a witch at Bergen.

See A. Lang, *History of Scotland,* vol. i. (Edinburgh, 1904); A. O. Anderson, *Early Sources of Scottish History,* A.D. *500–1286,* vol. 2 (1922).

MARGARET MAULTASCH (1318–1369), countess of Tirol, nicknamed Maultasch (pocket-mouth) on account of the shape of her mouth, was the daughter and heiress of Henry, duke of Carinthia and count of Tirol. When Henry died in 1335 Carinthia passed to Albert II., duke of Austria; but Tirol was inherited by Margaret and her young husband, John Henry, son of John, king of Bohemia, whom she had married in 1330. This union was not a happy one, and the Tirolese disliked the government of Charles, afterwards the emperor Charles IV., who ruled the county for his brother. Margaret combined with the Estates and expelled her husband, being supported by the Emperor Louis IV., who, declaring her marriage null and void, married her in 1342 to his own son Louis, margrave of Brandenburg, whom Margaret then pronounced Count of Tirol. The local nobles were, however, soon discontented with their new rulers. Supported by the Pope, who placed the Emperor and his son under the ban, they attacked Margaret, who defended herself bravely until her husband put down the rebellion. Louis died in 1361 and Margaret's only son, Meinhard, in 1363. On Sept. 29, 1363, Margaret handed over Tirol to Rudolph IV., duke of Austria, and retired to Vienna, where she died on Oct. 3, 1369. She lived long in the memory of the people of Carinthia, who regarded her as an amazon, and called her the *Wicked Gretl*.

See A. Huber, *Geschichte der Vereinigung Tirols mit Oesterreich* (Innsbruck, 1864). Her story is the subject of Lion Feuchtwanger's novel *The Ugly Duchess*.

MARGARET OF ANJOU (1430–1482), queen of England, daughter of René of Anjou, titular king of Naples and Jerusalem, was born on March 23, 1430. She married Henry VI. king of England on April 23, 1445. Her marriage had been negotiated by William de la Pole, duke of Suffolk, and when she came to England, Suffolk and his wife were her only friends. Naturally she fell under his influence, and supported his policy. This, added to her French origin and sympathies, made her unpopular. Her active share in politics began after Suffolk's fall in 1450. She not only supported Edmund Beaufort, duke of Somerset, in his opposition to Richard of York, but concerned herself also in the details of government, seeking pecuniary benefits for herself and her friends. As a childless queen her influence was limited; and when her only son, Edward, was born on Oct. 13, 1453, her husband, was stricken with insanity. From this time she was the ardent champion of her husband's and son's rights; to her energy the cause of Lancaster owed its endurance, but her implacable spirit contributed to its failure.

When York's protectorate was ended by Henry's recovery in January 1455, Margaret, not content with the restoration of Somerset and her other friends to liberty and office, pushed her politics to extremes. The result was the defeat of the Lancastrians at St. Albans, and for a year Margaret had to acquiesce in York's power. Ultimately, in October 1456 at Coventry, she procured some change in the government. Though formally reconciled to York in March 1458, she continued to intrigue with her partisans in England, and even with friends in France. After the Yorkist failure at Ludlow in 1459, Margaret embittered the struggle by a wholesale proscription of her opponents in the parliament at Coventry. She was not present with her husband at Northampton on July 10, 1460. She made her way to Scotland, and from Mary of Gelderland, the queen regent, purchased the promise of help at the price of surrendering Berwick. Margaret was still in Scotland at the date of Wakefield, so was not, as alleged by hostile writers, responsible for the barbarous treatment of York's body. But she was with the northern army which defeated Warwick at St. Albans on Feb. 17, 1461; for the executions which followed she must bear the blame. After Towton Margaret with her husband and son once more took refuge in Scotland.

A year later she went to France, and with help from her father and Louis XI. equipped an expedition which landed in Northumberland in October, and achieved some slight success; but on the way to seek further help from Scotland the fleet was overwhelmed in a storm. In the spring she was again trying to raid Northumberland. In August 1463 she crossed to Sluys in Flanders. She was almost destitute, but was courteously treated by Charles the Bold, then count of Charolais, and joined her father in France. Margaret never lost her hopes of her son's restoration. But when at last the quarrel between Warwick and Edward IV. brought her the opportunity, it was with difficulty that she could consent to be reconciled to so bitter an enemy. After Warwick's success and Henry's restoration Margaret still remained in France. On the day of Warwick's defeat at Barnet (April 14) Margaret and Edward landed at Weymouth. Three weeks later the Lancastrians were defeated at Tewkesbury, and Edward was killed. Margaret was captured a few days after, and brought to London where for five years she remained a prisoner. Finally Louis XI. ransomed her under the Treaty of Pecquigny, and she returned to France in January 1476. Margaret lived for six years in Bar and Anjou, in poverty and dependent for a pension on Louis, who made her surrender in return her claims to her father's inheritance. She died on April 25, 1482 and was buried at Angers cathedral.

BIBLIOGRAPHY.—For contemporary English authorities *see* under HENRY VI. French authorities and especially the *Chroniques* of George de Chastellain, and the *Mémoires* of Philippes de Comines contain much that is of value. The *Letters of Margaret of Anjou* (Camden Soc., 1863) have small historical importance. There have been numerous biographies, the chief is Mrs. Hookham's *Life of Margaret of Anjou* (1872).

MARGARET OF AUSTRIA (1522–1586), duchess of Parma and regent of the Netherlands from 1559 to 1567, was a natural daughter of Charles V. Her mother, Margaret van Ghent, was a Fleming. She was brought up by her aunts Margaret of Austria and Maria of Hungary, who were successively regents of the Netherlands from 1507 to 1530 and from 1530 to 1555. In 1533 she was married to Alexander de' Medici, duke of Florence, who was assassinated in 1537, after which she became the wife of Ottavio Farnese, duke of Parma, in 1542. The union proved an unhappy one. Like her aunts, who had trained her, she was a woman of masculine abilities, and Philip II., when he left the Netherlands in 1559 for Spain, acted wisely in appointing her regent. In ordinary times she would probably have proved as successful a ruler as her two predecessors in that post, but her task was very different from theirs. She had to face the rising storm of discontent against the Inquisition and Spanish despotism, and Philip left her but nominal authority. He was determined to pursue his own arbitrary course, and the issue was the revolt of the Netherlands. In 1567 Margaret resigned her post into the hands of the duke of Alva and retired to Italy. She died at Ortona in 1586.

Rachfahl, *Margaretha von Parma, Statthalterin der Niederlande, 1559–1567* (Munich, 1895); also bibliography in *Cambridge Modern History*, iii. 795–809 (1904).

MARGARET OF AUSTRIA (1480–1530), duchess of Savoy and regent of the Netherlands from 1507 to 1530, daughter of the archduke Maximilian of Austria, afterwards the emperor Maximilian I., was born at Brussels on Jan. 10, 1480. In April 1497 she was married at Burgos to the Infant John, heir to the throne of Castile and Aragon. She was left a widow, however, a few months later. In 1501 Margaret became the wife of Philibert II., duke of Savoy, who only survived until 1504. The sudden death of her brother the archduke, Philip the Handsome (Sept. 25, 1506), opened out to her a new career. In 1507 she was appointed by her father regent of the Netherlands and guardian of her nephew Charles, afterwards the emperor Charles V. Charles came of age in 1515, but he entrusted Margaret with the regency, and she held the post until her death in 1530. She was a wise and prudent ruler, of masculine temper and intrepidity, and very capable in affairs.

Tremayne, *The First Governors of the Netherlands: Margaret of Austria* (1908).

MARGARINE, legally designated oleomargarine in the United States of America, is essentially a mixture of edible fat, water, salt, and minor quantities of solids and flavours derived from ripened skim milk or whole milk. Margarine resembles butter in form, taste, fat content, and utility. Additional ingredients sometimes incorporated are yellow colouring, preservatives, emulsifying agents, and vitamins.

Invention of margarine was the culmination of experiments conducted by the French chemist, Hippolyte Mège-Mouriez prior to 1870. His objective was to make butterfat from beef suet by a process simulating the natural formation of milk fat. Mège-Mouriez observed that cows on restricted rations lost weight but continued to produce milk containing fat. Fat of milk according to his erroneous conception was derived from body fat, which was absorbed, deprived of its stearin, and transformed into butterfat by the action of pepsin in the mammary glands. Guided by this faulty hypothesis Mège-Mouriez designed a successful process for making margarine by (1) crushing fresh beef suet and washing it with water; (2) warming and digesting the washed suet with artificial gastric juice; (3) separating the softer fats from the harder stearin by filtration; (4) digesting and emulsifying the soft fats with water, milk, sodium bicarbonate, mammary tissue, and yellow colouring; (5) solidifying, washing, and salting the resulting emulsion of fat and water. To the finished product he gave the name margarine, which he claimed to be "a fatty body identical in composition with butter." The basis of this claim was the assumption that the fat of butter-like consistency obtained by digesting and filtering partially melted beef fats was an artificial butterfat composed of olein and margarin. He called this product oleomargarine. The term margarine applied by Mège-Mouriez to his finished product was derived from the Greek word, *margarites,* meaning pearl. A fatty substance previously prepared and named margarin by Chevreul because of its pearly lustre, was later shown to be a eutectic mixture of the two common fats stearin and palmitin. The terms oleomargarine and margarine, though misnomers in the chemical sense, were widely adopted and assigned definite meanings through legal definitions of the products to which they are applied.

The first published description of the Mège-Mouriez process was an English patent issued to the inventor in 1869. The following year Mège-Mouriez was awarded the prize offered by Napoleon III for a successful process for preparing commercially a fat as appetizing, nutritious, and stable as butter. This recognition of Mège-Mouriez's achievements was followed by the establishment and rapid growth of the margarine industry in Europe and America. In 1873 the Paris Council of Hygiene approved the sale of margarine but prohibited the use of the term butter in connection with products of this type. A similar policy has been invoked in other countries to prevent representation of margarine as butter.

Progress in the technology of margarine manufacture began with early abandonment of digestion reactions with gastric and mammary tissue extracts. Contrary to the inventor's theory, these digestion procedures did not change beef fat to butterfat or contribute favourable flavours to the final product. Utilization of fats other than oleo oil from beef fat began with additions of neutral lard and then butter. American margarines containing substantial proportions of neutral lard and butter were for a time called "butterine" and during the 1880's were favoured for their superior texture and flavour. However, the general trend throughout the history of the industry has been the replacement of animal fats by vegetable oils. This shift in raw materials, which greatly increased the available quantity and variety of suitable fats, resulted from advances in the technology of refining, deodorizing, and hardening of vegetable oils by hydrogenation. Improvements in the flavour of margarines made from purified bland oils and fats have been brought about through adaptations of the technology of butter making. Sour milk was found to impart more flavour to the fats than sweet milk. Subsequently the margarine industry adopted the butter makers' technique for securing desirable flavours by inoculating pasteurized milk with selected cultures of lactic acid organisms and controlling the degree of ripening. A later development was the substitution of pasteurized cultured skim milk for whole milk. Incorporation of emulsifying agents began about 1885 in Germany with addition of egg yolk to margarine. Other emulsifying agents that have been more widely used include lecithins and other derivatives of glycerol and fatty acids. Advantages sought by the addition of emulsifiers are improvements in texture, appearance, plasticity, and foaming and browning instead of spattering when the margarine is used for frying. The most recent innovation, other than mechanical improvements in manufacture, has been the addition of substantial quantities of vitamins A and D.

The margarine industry originated in France when there was urgent need to supplement deficient supplies of butter and other fatty foods. Manufacture of margarine spread rapidly to other countries where similar needs existed and also proved to be a profitable enterprise in countries producing butter and other edible fats on an export basis. Both manufacture and sale of margarine have generally encountered opposition owing to the fact that a product resembling butter in appearance, flavour, and nutritive value could be made from a wide variety of animal and vegetable fats available at prices far below the cost of production of butterfat. Moreover, similarity between butter and margarine everywhere created regulatory problems in preventing adulteration of butter with margarine, or fraudulent representation of margarine as butter. In most countries legislative action has been promoted to regulate, restrict, or prohibit manufacture and sale of margarine.

The nutritive qualities of margarine have long been debated, particularly with respect to consequences of its use in place of butter. Margarine contains 80 to 85% fat, the proportion being generally the same as prescribed by law for butter. Edible fats and oils, whether from animal or vegetable sources, are mixtures of glycerides of fatty acids, and are equivalent in caloric value. Fats used in margarine differ among themselves and differ from butterfat in the proportion of constituent fatty acids and in vitamin content. In human nutrition no significant differences in dietary value have been demonstrated among the varied mixtures of glycerides (fats) found in margarine or butter. With respect to vitamin content, much emphasis has been placed on the fact that fats used in margarine are generally deficient in vitamins A and D. This deficiency may be compensated by the addition of vitamins, a practice required in some countries and in others prompted by competition.

MARGARITA, an island in the Caribbean sea belonging to Venezuela, about 12m. north of the peninsula of Araya, and constituting—with Tortuga, Cubagua and Coche—a political division called the Eastern Federal district now known as the state of Nueva Esparta (from 1904 to 1909). The island is about 40m. long from east to west, has an area of 400sq.m., and consists of two mountainous extremities, nearly separated by the Laguna Grande on the south, but connected by a low, narrow isthmus. The highest elevation on the island is the peak of Macanao, 4,484ft., in the western part, the highest point in the eastern part being the peak of Copei, 4,170 feet. The higher valleys of the interior are highly fertile and are well adapted to grazing and stock-raising. The principal industries are fishing and the making of salt. The pearl fisheries, which were so productive in the 16th and 17th centuries, have been continued ever since with more or less success. The Venezuelan pearls are not considered to be as good as the oriental pearls. A domestic industry of the women is that of making coarse straw hats, which are sold on the mainland. The islands have abundant marine life and the fishing is a constant source of livelihood for the people. The products of Margarita, however, are insufficient to support its population, and large numbers periodically emigrate to the mainland. The population was estimated in 1904 at 40,000, composed in great part of half-caste Guayqueri Indians. The population in 1941 was 69,195. The capital is La Asunción (pop. in 1941, 4,061), on the east side of the island and its principal port is Pompatar on the south coast. The two small ports of Puebla de la Mar (Porlamar) and Puebla del Norte are merely open roadsteads. The silicate deposits on the Island of Margarita cover 1,700ac. of property totalling 7,400ac. in extent. The magnesia occurs in massive veins. The Margarita deposit lies in a soft decomposed serpentine formation, where it can be easily handled by steam shovels or other mechanical excavating equipment. The deposit on Margarita island has always been characterized as the highest grade of magnesia yet discovered.

The island of Margarita was discovered by Columbus in 1498, and was bestowed in 1524 upon Marceto Villalobos by Charles V. In 1561 the freebooter Lope de Aguirre ravaged the island, and in 1662 the town of Pompatar was destroyed by the Dutch. For a long time Margarita was attached to Cumana, but in the 18th century it was made administratively independent. Its traders rendered invaluable assistance to the revolutionists in the War of Independence, and the Spanish general, Morillo, was driven from its shores in 1817; in recognition of this it was made a separate State and with the surrounding smaller islands was renamed Nueva Esparta (New Sparta). The first Spanish settlement in South America was Nueva Cadiz, founded in 1515 on the barren island of Cubagua; but the place was abandoned when pearl-fishing and slave-trading ceased to be profitable. The settlement was totally destroyed by earthquake and tidal wave in 1543.

MARGATE, a municipal borough and seaside resort in the Isle of Thanet parliamentary division of Kent, England, 74 mi. S.E. of London by rail. Pop. (1938) 39,470. Area, 10.9 sq.mi. Margate, on the north coast of Thanet, was an ancient and senior non-corporate member of Dover. In 1347 it contributed 15 ships of small tonnage at the time of the siege of Calais. A pier existed before 1500, but by the reign of Henry VIII it was in a decayed condition. The amount of corn shipped was small, the *droits* being insufficient to keep the pier in repair. Under Elizabeth Margate was still an obscure fishing village employing about 20 small vessels ("hoys") in the coasting and river trades, on which in 1791 it chiefly subsisted. In 1777 the pier was rebuilt and about this time Margate first began to be known as a bathing-place. In 1835 it was still a liberty of Dover and no right of citizenship could be acquired. In 1857 it was incorporated.

In 1935 the borough was extended to include the neighbouring resorts of Westgate-on-Sea and Birchington. It is practically contiguous with Broadstairs on the southeast, and during the season is served by pleasure steamers from London. The municipality owns over 8 mi. of sea-front, with promenades along almost the whole distance. Many works to improve the three resorts were undertaken, and Northdown park ($38\frac{1}{2}$ ac.) was purchased as a public park. Margate suffered considerably, however, from air raids in World War II, 8,000 houses having been damaged in 1940–41. A pier constructed in 1815 is now chiefly used by fishermen and colliers. The church of St. John the Baptist, founded in 1050, contains some portions of Norman architecture, the remainder being Decorated and Perpendicular. The manor house of Daundelyon, or Dent de Lion, with its early 15th century gateway remains between Margate and Westgate. During the widening of the Minster road in 1922 an Anglo-Saxon cemetery was discovered.

MARGGRAF, ANDREAS SIGISMUND (1709–1782), German chemist, was born at Berlin on March 3, 1709. He studied chemistry at Berlin and Strasbourg, medicine at Halle, and mineralogy and metallurgy at Freiberg, and returned to his native city in 1735 as assistant to his father, who was chief apothecary at the court. In 1738 he was elected to the Berlin Academy of Sciences, which in 1754 put him in charge of its chemical laboratory and in 1760 appointed him director of its physics class. He died in Berlin on Aug. 7, 1782. His name is especially associated with the discovery of sugar in beetroot in 1747. Marggraf introduced the microscope as an aid to chemical enquiry, and used this instrument to detect the presence of minute sugar crystals. In another research dealing with the nature of alum he showed that one of the constituents of that substance, alumina, is contained in common clay, and that it is quite distinct from lime. He explained and simplified the process of obtaining phosphorus from urine, and made some observations on phosphoric acid; but though he noted the increase in weight that attends the oxidation of phosphorus he remained an adherent of the phlogistic doctrine. For his time he was a skilful chemical analyst.

His papers were presented to the Berlin Academy, and with the exception of a few of the latest were collected in two volumes of *Chymische Schriften* in 1761–67.

MARGHELAN: *see* FERGHANA.

MARGHILOMAN, ALEXANDRE (1854–1925), Rumanian statesman, was born at Buzeu on July 4, 1854. He studied law and political science in Paris. In 1884 he was elected a deputy as a member of the Conservative party, of which he became leader in 1914. Marghiloman was convinced that economic reasons demanded close relations between Rumania and Germany and Austria-Hungary. At the beginning of the World War, he advocated Rumania's neutrality and when in 1916 Bratianu offered him a portfolio in his cabinet, Marghiloman refused on the ground that he could not assume the responsibility of an insufficient military preparation. He remained in Bucharest under the German occupation, where he organized the relief work for the population, but rejected the proposals of the German commander to form in Bucharest a Government for the purpose of concluding a separate peace. In March, 1918, Marghiloman went to Jassy at the request of the king and formed a Government which eventually signed the separate peace with the Central Powers. This treaty, however, was never ratified. When the war ended Marghiloman, whose party had lost all influence in Rumania owing to its Germanophile record, ceased to play any part in Rumanian politics and after his death in Buzeu on May 10, 1925, the Conservative party ceased to exist, its members joining General Averescu's (People's) party.

MARGIN, the amount by which the value of collateral given as security for a loan exceeds the amount of the loan itself. In making collateral loans, banks demand such an excess in order to safeguard themselves in case of shrinkage in the value of the collateral. The margin usually required is about 40%, and when, through decrease in the value of collateral, it falls appreciably below this percentage, the borrower may be required to deposit additional collateral. In the security market *margin* signifies the amount of cash which a person places with his broker when he wishes to buy or sell stock or bonds "on margin." In buying on margin the purchaser supplies only a certain percentage, or margin, of the amount of money required, and the remainder of the funds for the deal are advanced by the broker, either from his own capital or by borrowing.

The minimum margin which a customer must deposit with his broker depends on regulations of the Federal Reserve Board under a law passed by Congress in 1934.

If the market price declines after the purchase, the customer may be called upon for additional margin in order to comply with the margin requirements of his broker. Likewise if a customer sells *short* and the price of the security advances he may be called upon for additional margin. In either case if the additional margin is not supplied and the customer's equity decreases to the point where the broker is in danger of sustaining a loss, the broker may close out the account by the sale or purchase of the security as the case may be. (J. H. B.; X.)

MARGOLIOUTH, DAVID SAMUEL (1858–1940), British Arabic scholar, was born in London on Oct. 17, 1858, the son of a missionary. Educated at Winchester and New College, Oxford, he devoted himself to Arabic studies, in which he obtained a European reputation. In 1889 he became Laudian professor of Arabic at Oxford. He was a member of the council of the Royal Asiatic Society from 1905 onwards, its director in 1927, was awarded its triennial gold medal in 1928, and was its president 1934–37. He held many other honours. His work was done mainly in two branches, the study of the Arabic commentaries on Aristotle and the history of Mohammedanism. With H. F. Amedroz he wrote a standard work on the *Eclipse of the Abbasid Caliphate* (7 vols., 1922).

MARGRAVE (Ger. *Markgraf*), a German title meaning "count of the March." The margraves had their origin in the counts established by Charlemagne and his successors to guard the frontier districts of the empire, and for centuries the title was always associated with this function. In the 12th century the margraves of Brandenburg and Austria (the north and east marks) asserted their position as tenants-in-chief of the empire; with the break-up of the great duchies the others did the same; and the margraves henceforward took rank with the great German princes. The title of margrave very early lost its original significance, and was borne by princes whose territories were in no sense frontier districts; *e.g.*, by Hermann, a son of Hermann, margrave of Verona, who assumed in 1112 the title of margrave of Baden.

MARGUERITE, the popular name for the plant known botanically as *Chrysanthemum frutescens* (family Compositae), a shrubby perennial with smooth leaves cut pinnately into narrow segments and flower-heads two or three inches across produced singly in summer and autumn on slender erect stalks. The white ray-florets surround a yellow disk. It is a native of the Canary isles, and a favourite for decoration and for greenhouse cultivation, window-boxes and open ground in the summer. The yellow marguerite (*étoile d'or*) has somewhat larger pale yellow flowers and glaucous leaves. The plant is propagated from cuttings taken in autumn from old plants and placed in sandy loamy soil in cold frames. By pruning the shoots in autumn the plants may be grown into very large specimens in the course of a few seasons.

The African subshrub, *Felicia amelloides* (family Compositae) known in cultivation as blue daisy, is also called blue marguerite.

MARGUERITE D'ANGOULÊME (1492–1549), queen of Navarre, was the daughter of Charles d'Orléans, count d'Angoulême and was born in Angoulême on April 11, 1492. She was two years older than her brother Francis I. She was betrothed early to Charles, duke d'Alençon, and married him in 1509. She was not very fortunate in this first marriage, but her brother's accession to the throne made her, next to their mother, Louise of Savoy, the most powerful woman of the kingdom. She became a widow in 1525, and married in 1527 Henri d'Albret, titular king of Navarre. Navarre was not reconquered for the couple as Francis had promised, but ample apanages were assigned to Marguerite, and at Nérac and Pau miniature courts were kept up, which yielded to none in Europe in the intellectual brilliancy of their frequenters. Marguerite was at once one of the chief patronesses of letters that France possessed, and the chief refuge and defender of advocates of the Reformed doctrines. Round her gathered C. Marot, Bonaventure Des Périers, N. Denisot, J. Peletier, V. Brodeau, Boaistuau, Le Maçon and many other men of letters, while she protected Rabelais, E. Dolet and others. For a time her influence with her brother prevailed, but latterly political rather than religious considerations led him to wage a fierce persecution against both Protestants and freethinkers, a persecution which drove Des Périers to suicide and brought Dolet to the stake. Marguerite's own inclinations seem to have been rather towards a mystical pietism than towards dogmatic Protestant sentiments. Marguerite died in Odot-en-Bigorre on Sept. 21, 1549. By her first husband she had no children, by her second a son who died in infancy, and a daughter, Jeanne d'Albret, who became the mother of Henry IV. She does not, from the portraits which exist, appear to have been regularly beautiful, but as to her sweetness of disposition and strength of mind there is universal consent.

Her literary work consists of the *Heptaméron,* of poems entitled *Les Marguerites de la marguerite des princesses,* and of *Letters.* The *Heptaméron,* constructed, as its name indicates, on the lines of the *Decameron* of Boccaccio, consists of 72 short stories told to each other by a company of ladies and gentlemen who are stopped in the journey homewards from Cauterets by the swelling of a river. It was not printed till 1558, ten years after the author's death, and then under the title of *Les Amants fortunés.* Internal evidence is strongly in favour of its having been a joint work, in which more than one of the men of letters who composed Marguerite's household took part. It is a delightful book, and strongly characteristic of the French Renaissance. The *Letters* are interesting and good. The *Marguerites* consist of a very miscellaneous collection of poems, mysteries, farces, devotional poems of considerable length, spiritual and miscellaneous songs, etc. The *Dernières poésies,* not printed till 1896 (by M. A. Lefranc), are interesting and characteristic, consisting of verse-epistles, *comédies* (pieces in dramatic form on the death of Francis I., etc.), *Les Prisons,* a long allegorical poem of amorous-religious-historical tenor; some miscellaneous verse chiefly in dizains, and a later and remarkable piece, *Le Navire,* expressing her despair at her brother's death.

Bibliography.—Of the other works, never yet completely edited, the best editions are, for the *Heptaméron,* Leroux de Lincy (1855); for the *Lettres,* F. Genin (1841); and for the *Marguerites,* F. Frank (1873). English translation of the *Heptaméron;* A. Machen (1887), with introduction by A. M. F. Robinson (Mme. Darmesteter), and an anonymous translation (1894) with introduction by G. Saintsbury. The religious poem, *Le Miroir de L'Âme Pécheresse,* was translated by Queen Elizabeth. *See* also V. Durand, *Marguerite de Valois et la Cour de François Ier* (1848); F. Lotheissen, *Königin Margarethe von Navarra* (1885); H. de la Ferrière, *Marguerite d'Angoulême* (1891); Edith Sichel, *Women and Men of the French Renaissance* (1901); P. Courtault, *Marguerite de Navarre* (1904); A. Lefranc, *Grands écrivains de la renaissance* (1914).

MARGUERITE DE VALOIS, (1523–1574), duchess of Savoy, daughter of Francis I., was born on June 5, 1523, in St. Germain-en-Laye, and married Emmanuel Philibert, duke of Savoy, in 1559. She was a good scholar, and at the court of her brother, Henry II, encouraged the early efforts of the Pléiade. (*See* Ronsard, Pierre de.) At the Savoy court at Turin she continued her patronage of literature.

MARGUERITE (MARGOT) DE VALOIS (1553–1615), queen of Navarre, was born on May 14, 1553, daughter of Henry II. by Catherine de' Medici. Famous for her beauty, her learning, and the looseness of her conduct, she was married, after a liaison with the duke of Guise, to Henry of Navarre, afterwards Henry IV., on the eve of St. Bartholomew's day. There were no children of the marriage. Marguerite was established in the castle of Usson in Auvergne, and after the accession of Henry the marriage was dissolved by the pope. But Henry and Marguerite still continued friends; she still bore the title of queen; she visited Marie de' Medici on equal terms; and the king frequently consulted her on important affairs, though his somewhat parsimonious spirit was grieved by her extravagance. Marguerite died in Paris on March 27, 1615. She left letters and memoirs the latter of which are admirably written, and rank among the best of the 16th century. She was the idol of Brantôme, and is the "Reine Margot" of anecdotic history and romance.

Bibliography.—The *Mémoires, Poésies et Lettres* were edited by F. Guessard (1842), L. Lalanne (1858), C. Caboche (1860). The chief of many lampoons against her was the famous *Divorce satirique,* variously attributed to Agrippa d'Aubigné, Palma Cayet and others. *See* L. de Saint Poncy, *Histoire dé Marguerite de Valois* (1887); C. Merki, *La Reine Margot et la fin des Valois* (1905); A. Savine, *La Vraie Reine Margot* (1908); H. N. Williams, *Queen Margot* (1907, 2nd ed. 1911); J. H. Mariéjol, *La Vie de M. de Valois* (1928).

MARGUERITTE, PAUL (1860–1918) **AND VICTOR** (1866–1942), French novelists, both born in Algeria, were the sons of General Jean Auguste Margueritte (1823–70). Paul Margueritte, born Feb. 1, 1860, who has given a picture of his home in Algiers in *Le Jardin du passé* (1895), was sent to the military school of La Flèche for the sons of officers, and became in 1880 clerk to the minister of public instruction. His earlier novels include: *Amants* (1890), *La Force des choses* (1891), *Sur le retour* (1892), *La Tourmente* (1893), *Ma grande* (1892), *Âme d'enfant* (1894) and *L'Eau qui dort* (1896). From the time of his collaboration with his younger brother Victor Paul Margueritte's work gained in colour and force.

Among the books written in common by the brothers, the most famous is the series known under the collective title, *Une Époque,* dealing with the events of 1870–71, and including the novels *Le Désastre* (1898), *Les Tronçons du glaive* (1900), *Les Braves gens* (1901), *La Commune* (1904). They also collaborated in an *Histoire de la guerre de 1870–1871* (1903). These books were founded on documentary and verbal information, amassed with great care and arranged with admirable art; the authors were, in this case, historians rather than novelists. *La Commune* is a bold indictment of the methods adopted by the victorious party. The novelists also attacked the laws governing marriage and divorce and the abuses entailed by the dowry demanded from the bride, in pamphlets and in the novels, *Femmes nouvelles* (1899), *Les Deux vies* (1902), and *Le Prisme* (1905). One of the best is the child story *Poum* (1898). Their literary partnership was dissolved in 1907. Paul Margueritte was one of the original members of the Académie de Goncourt. He died on Dec. 30, 1918.

After World War I Victor Margueritte wrote other novels, the most famous of which is *La Garçonne* (1922), and entered political controversy with two books on the question of responsibility for the war; *Les Coupables* and *Appel Aux Consciences,* both written in 1925. He died March 23, 1942.

MARHEINEKE, PHILIP KONRAD (1780–1846), German Protestant divine, was born at Hildesheim, Hanover, on May 1, 1780. He studied at Göttingen, and lectured at Erlangen and Heidelberg. In 1811 he became professor ordinarius at Berlin, where from 1820 he was also preacher at Trinity Church and worked with Schleiermacher. When he died, on May 31, 1846, he was a member of the supreme consistorial council. At first influenced by Schelling, Marheineke found a new master in Hegel, and came to be regarded as the leader of the Hegelian Right. He sought to explain all the orthodox doctrines of the

Church in an orthodox way in terms of Hegel's philosophy. Marheineke's developed views on dogmatics are given in the third edition (1847) of his *Die Grundlehren der christlichen Dogmatik als Wissenschaft*. When he published the first edition (1819) he was still under the influence of Schelling; the second edition (1827) marked his change of view. His works on symbolics show profound scholarship, keen critical insight, and rare impartiality. The *Christliche Symbolik* (1810–14) has been pronounced his masterpiece.

See A. Weber, *Le Système dogmatique de Marheineke* (1857).

MARI, a Baluch tribe on the Dera Ghazi Khan border of Baluchistan. Land is periodically divided, by lots, according to males—occasionally by families. What has been called hypergamous endogamy prevails among the chiefly families. Artificial defloration seems to be practised on women just before marriage. Female infanticide, attributable to the strict endogamy of females in chiefly families, is no longer practised.

See Census of India, 1911, 1921 and 1931.

MARIANA, JUAN DE (1536–1624), Spanish historian and Jesuit, was born at Talavera. In 1561 he went to teach theology in Rome, reckoning among his pupils Robert Bellarmine, afterwards cardinal; then passed into Sicily, and in 1569 was sent to Paris, where his expositions of the writings of Thomas Aquinas attracted large audiences. He returned to Spain in 1574.

Mariana's great work, *Historiae de rebus Hispaniae,* first appeared in 25 books at Toledo in 1592; ten books were subsequently added (1605), bringing the work down to the accession of Charles V. in 1519, and in a still later abstract of events the author completed it to the accession of Philip IV. in 1621. It was so well received that Mariana was induced to translate it into Spanish 1601–23. Though in many parts uncritical, the work is justly esteemed for its research, accuracy, sagacity and style. Of his other writings the most interesting is the treatise *De rege et regis institutione* (1599). In its sixth chapter the question whether it is lawful to overthrow a tyrant is freely discussed and answered in the affirmative, a circumstance which brought much odium upon the Jesuits, especially after the assassination of Henry IV. of France, in 1610.

See L. von Ranke, *Zur Kritik neuerer Geschichtsschreiber* (Leipzig, 1874); and Cirot, *Études sur les historiographes espagnols; Mariana, historien* (Bordeaux, 1905).

MARIANAO, a suburb of Havana, Cuba, 6 m. from the capital, and about 1,500 ft. above the sea. It, therefore, possesses a pleasant climate which has brought a population (1943) of 120,163 people. On the coast below is Marianao beach, a popular watering-place.

MARIANAS, MARIANNES or **LADRONES ISLANDS:** *see* PACIFIC ISLANDS.

MARIANAS or **MARANHAS,** a tribe of South American Indians on the river Jutahy, north-western Brazil. They wear small pieces of wood in their ears and lips, but are not tattooed. Marianas were found on the upper reaches of the Putumayo across to the Yapurá.

MARIANNA, city of E. Arkansas, U.S.A., on L'Anguille river and Missouri Pacific railway; county seat of Lee Co. Pop. (1940) 4,449. It is the home of the Cotton Branch experiment station, College of Agriculture of University of Arkansas; and a shipping point for agricultural products and livestock.

MARIANUS SCOTUS (1028–1082 or 1083), chronicler (who must be distinguished from his namesake Marianus Scotus [d. 1088], abbot of St. Peter's, Regensburg), was an Irishman by birth, and called Moelbrigte, or servant of Bridget. He was educated by a certain Tigernach, and having become a monk he crossed over to the continent of Europe in 1056, and his subsequent life was passed in the abbeys of St. Martin at Cologne and of Fulda, and at Mainz. He died Dec. 22, 1082 or 1083.

Marianus wrote a *Chronicon,* which purports to be a universal history from the creation of the world to 1082. The *Chronicon* was very popular during the middle ages, and in England was extensively used by Florence of Worcester and other writers. It was first printed at Basle in 1559, and has been edited with an introduction by G. Waitz for the *Monumenta Germaniae historica. Scriptores* (Bd. v.).

MARIA STELLA, the self-styled legitimate daughter of Philip, duke of Orleans. According to her, Louis Philippe was not the son of Philip duke of Orleans, but a supposititious child, his father being one Lorenzo Chiappini, constable at the village of Modigliana in Tuscany. The story is that the duke and duchess of Orleans, travelling under the incognito of Comte and Comtesse de Joinville, were at this village in April 1773, when the duchess gave birth to a daughter; and that the duke, desiring a son in order to prevent the rich Penthièvre inheritance from reverting to his wife's relations in the event of her death, bribed the Chiappinis to substitute their newly-born male child for his own.

Maria Stella, the supposed daughter of Chiappini, went on the stage at Florence and married, at thirteen, the first Lord Newborough, after whose death she married the Russian Count Ungern-Sternberg. In 1830 she published *Maria Stella ou un échange d'une demoiselle du plus haut rang contre un garçon de plus vile condition* (reprinted 1839 and 1849). This coincided with the advent of Louis Philippe to the throne, and her claim became a weapon for those who wished to throw discredit and ridicule on the "bourgeois monarch." She died in poverty in Paris on Dec. 23, 1843.

See R. P. Gallwey, *Mystery of Maria Stella, Lady Newborough* (1907); M. Vitrac, *Philippe-Égalité et M. Chiappini* (1907), which is based on unpublished material in the *Archives nationales,* and destroys Maria Stella's case.

MARIA THERESA (1717–1780), archduchess of Austria, queen of Hungary and Bohemia, and wife of the Holy Roman emperor Francis I., was born at Vienna on May 13, 1717, eldest daughter of the Emperor Charles VI. (*q.v.*) and Elizabeth of Brunswick-Wolfenbüttel. On Feb. 12, 1736 she married her cousin Francis of Lorraine (*q.v.*), then grand duke of Tuscany, and afterwards emperor. Five sons and eleven daughters were born of this marriage. From the date of her father's death on Oct. 20, 1740, till her own death in 1780, Maria Theresa was one of the central figures in the wars and politics of Europe. But unlike some sovereigns, whose reigns have been agitated, but whose personal character has left little trace, Maria Theresa had a strong and in the main a noble individuality. There was no affectation in her assumption of a becoming bearing or in her picturesque words. The common story, that she appeared before the Hungarian magnates in the diet at Pressburg in 1741 with her infant son, afterwards Joseph II., in her arms, and so worked on their feelings that they shouted *Moriamur pro rege nostro Maria Theresia,* is only mythically true. But during the delicate negotiations to secure the support of the Hungarian nobles she undoubtedly did appeal to them with passionate eloquence, and with a pardonable sense of the advantage she obtained from her youth, her beauty and her sex. Maria Theresa was especially preoccupied with her position as heiress of the rights of the house of Austria. Therefore, when her inheritance was assailed by Frederick of Prussia, she fought for it with the utmost determination, and for years cherished the hope of recovering the lost province of Silesia. Her practical sense showed her the necessity of submitting to spoliation when she was overpowered. She accepted the peace of Berlin in 1742 in order to have a free hand against her Bavarian enemy, the emperor Charles VII. (*q.v.*). When Frederick renewed the war she accepted the struggle cheerfully, because she hoped to recover her own. Down to the peace of Aix-la-Chapelle in 1748 she went on fighting for Silesia or its equivalent. In the years following the peace she applied herself to finding allies in France and Russia who would help her to recover Silesia. Here, as later in the case of Poland, she subordinated her feelings to her duty to the state. Though she denied that she had ever written directly to Madame de Pompadour, it is certain that she allowed her ministers to make use of the favourite's influence over the French king. When fate decided against her in the Seven Years' War she bowed to the inevitable, and was thenceforward a resolute advocate of peace.

In internal government she worked to promote the prosperity of her people, and to give more unity to an administration made up by the juxtaposition of many states and races with different characters and constitutions. Her instincts, like those of her enemy Frederick and her son Joseph II., were emphatically absolutist. She suspended the meetings of the estates in most parts of her dominions. She was able to do so because the mass of her subjects found her hand much lighter than that of the privileged classes who composed these bodies. Education, trade, religious toleration, the emancipation of the agricultural population from feudal burdens—all had her approval up to a certain point. She would favour them, but on the distinct condition that nothing was to be done to weaken the bonds of authority. She took part in the suppression of the Jesuits, and she resisted the pope in the interest of the state. Her methods were those of her cautious younger son, Leopold II., and not of her eldest son and immediate successor, Joseph II. She did not give her consent even to the suppression of torture in legal procedure without hesitation, lest the authority of the law should be weakened. Her caution had its reward, for whatever she did was permanently gained, whereas her successor in his boundless zeal for reform brought his empire to the verge of a general rebellion.

In her private life Maria Theresa was equally the servant of the state and the sovereign of all about her. She was an affectionate wife to her husband Francis I.; but she was always the queen of Hungary and Bohemia and archduchess of Austria, like her ancestress, Isabella the Catholic, who never forgot, nor allowed her husband to forget, that she was "proprietary queen" of Castile and Leon. She married her daughters in the interest of Austria, and taught them *not* to forget their people and their father's house. In the case of Marie Antoinette (*q.v.*), who married the dauphin, afterwards Louis XVI., she gave an extraordinary proof of her readiness to subordinate everything to the reason of state. She instructed her daughter to show a proper respect to her husband's grandfather, Louis XV., by behaving with politeness to his mistresses, in order that the alliance between the two courts might run no risk. The signing of the peace of Teschen, which averted a great war with Prussia, on May 13, 1779, was the last great act of her reign, and so Maria Theresa judged it to be in a letter to Prince Kaunitz; she said that she had now finished her life's journey and could sing a *Te Deum,* for she had secured the repose of her people at whatever cost to herself. The rest, she said, would not last long. Her fatal illness developed in the autumn of the following year, and she died on Nov. 28, 1780. When she lay painfully on her deathbed her son Joseph said to her, "You are not at ease," and her last words were the answer, "I am sufficiently at my ease to die."

See A. von Arneth, *Geschichte Maria Theresas* (Vienna, 1863–79) and J. F. Bright, *Maria Theresa* (1897); M. Gael, *Maria Theresa* (1900); also AUSTRIA-HUNGARY.

MARIAZELL, a town in Styria, Austria, situated in the valley of the Salza, near Lake Erlauf and surrounded by peaks of the north Styrian Alps, grows in importance as a summer resort and as a centre for winter sports. It possesses a 12th century miracle-working image of the Virgin enshrined in a special chapel of the 14th century church, which is visited by over 150,000 pilgrims each year. Population 1,900; annexed to Germany in 1938.

See O. Eigner, *Geschichte des aufgehobenen Benedictinerstiftes Mariazell* (Vienna, 1900).

MARIBOR, a town of Slovenia, Yugoslavia, the German *Marburg*. Pop. (1931) 33,331, mainly Slovenes. It is a popular summer resort and tourist centre, picturesquely situated on the Drave, here spanned by a magnificent iron bridge. There was a settlement at Maribor in Roman times, but the present town arose in the 10th century; in the 12th and 13th centuries the town ruled a vast district. The principal buildings are the Cathedral, dating from the 12th century, but with many later additions, among them a 17th century tower 136 ft. high; and the 15th century castle, famous for its sculptures. Maribor, served both by rail and first class roads, and in the midst of a fertile fruit and wine-growing district, has a large trade in wine and grain, and especially in timber from the surrounding forests. Its industrial products are leather, boots and shoes, iron and tinware, liqueurs and sparkling wine, oil refining and milling and it has a weekly market for pork, poultry and eggs. Near by is the village of Mariast, the church of which is a popular place of pilgrimage. Maribor became part of Yugoslavia in 1918, but was occupied by Hungary in 1941, after Yugoslavia's dismemberment. Its population was ruthlessly Germanized.

MARICOPA, a Yuman tribe living near the Pima on Gila river, Arizona; originally no doubt driven out from the lower Colorado by intertribal warfare, like the Halchidhoma and Kohuana whom they absorbed in the 19th century. The date of the Maricopa removal is not known.

MARIE, queen of Rumania (1875–1938), was born at Eastwell Park, Kent, on Oct. 29, 1875, the eldest daughter of Alfred, duke of Edinburgh, second son of Queen Victoria. On Jan. 10, 1893 she married Prince Ferdinand, afterwards king of Rumania. From this marriage six children were born: Prince Charles, who married Princess Helen of Greece, Princess Elizabeth, married to the ex-king George of Greece, Princess Marie, later queen of Yugoslavia, the princes Nicolas and Mircea (d. 1916) and Princess Ileana. The queen was a Protestant, but the children, in accordance with the Rumanian constitution, were brought up in the Orthodox faith. Queen Marie took a great interest in the development of her adopted country. Red Cross and charity organizations were formed at her initiative, and during World War I she saw active service as a Red Cross nurse. She devoted much of her time to writing, and her published works include *The Lily of Life* (1913), *My Country* (1916), and *Ilderim* (1925). With King Ferdinand, Marie was crowned at Alba Julia on Oct. 15, 1922. She visited America in 1926. The following year King Ferdinand died, and she retired from active politics. Queen Marie died at the royal summer residence in Sinaia, July 18, 1938, and was buried at Kurtea de Argesch.

MARIE AMÉLIE THERESE (1782–1866), queen of Louis Philippe, king of the French, was the daughter of Ferdinand IV., king of Naples, and the archduchess Maria Carolina. She was born at Caserta, on April 26, 1782, and received a pious education. Her girlhood was spent in exile. She married Louis Philippe in November 1809. Returning to France in 1814, the duke and duchess of Orleans had barely established themselves in the Palais Royal in Paris when the Hundred Days drove them into exile. Marie Amélie took refuge with her four children in England, where she spent two years at Orleans House, Twickenham. Again in France in 1817, her life at Neuilly until 1828 was the happiest period of her existence. Her attention was absorbed by the care and education of her numerous family, even after the revolution of 1830 had made her queen of the French, a position accepted with forebodings of disaster justified by her early experience of revolutions. During her second exile, from 1848 to her death on March 24, 1866, she lived at Claremont.

See A. L. Baron Imbert de St. Amand, *La Jeunesse de Marie Amélie* (1891), *Marie Amélie au Palais Royal* (1892), *Marie Amélie et la cour de Palerme* (1891), *Marie Amélie et la cour des Tuileries* (1892), *Marie Amélie et l'apogée de règne de Louis Philippe* (1893), *Marie Amélie et la société française en 1847* (1894), and *Marie Amélie et la duchesse d'Orleans* (1893).

MARIE ANTOINETTE (1755–1793), queen of France, ninth child of Maria Theresa and the emperor Francis I., was born at Vienna, on Nov. 2, 1755. She was brought up under an austere régime and educated with a view to the French marriage arranged by Maria Theresa, the abbé Vermond being appointed as her tutor in 1769. Her marriage with the dauphin, which took place at Versailles on May 16, 1770, was intended to crown the policy of Choiseul and confirm the alliance between Austria and France. This fact, combined with her youth and the extreme corruption of the French court, made her position very difficult. Madame du Barry, whose influence over Louis XV. was supreme, formed the centre of a powerful anti-Choiseul cabal, which succeeded in less than a year after the dauphin's marriage in bringing about the fall of Choiseul and seriously threatening the Austrian alliance. Thus the young princess was surrounded by enemies both at court and in the dauphin's household, and came to rely almost entirely upon the Austrian ambassador, the comte de Mercy-Argenteau, whom Maria Theresa had instructed to act as her mentor, at the same time arranging that she herself should be kept informed of all that concerned her daughter, so that she might at once advise her and safeguard the alliance. Hence arose the secret correspondence of Mercy-Argenteau, an invaluable record of all the details of Marie Antoinette's life from her marriage in 1770 till the death of Maria Theresa in 1780.

Marie Antoinette soon won the affection and confidence of the dauphin and endeared herself to the king, but her position was precarious, and both Mercy and Maria Theresa had continually to urge her to conquer her violent dislike for Madame du Barry.

The accession of the young king and queen on the death of Louis XV (May 10, 1774), was hailed with great popular enthusiasm. But her first steps brought Marie Antoinette into open hostility with the anti-Austrian party. She was urgent in obtaining the dismissal of d'Aiguillon, and did all in her power to secure the recall of Choiseul, though without success. Her impatience of the cumbrous court etiquette shocked many people, and her taste for pleasure led her to seek the society of the comte d'Artois and his young and dissolute circle. But the greatest weakness in her position lay in her unsatisfactory relations with her husband. The king, though affectionate, was cold and apathetic, and it was not until seven years after her marriage that there was any possibility of her bearing him an heir.

The end of the period of mourning for the late king was the signal for a succession of gaieties, during which the queen displayed a passion for amusement and excitement which led to unfortunate results. Being childless, and with a husband whom she could not respect, her longing for affection led her to form various intimate friendships, above all with the princesse de Lamballe and the comtesse Jules de Polignac, who soon obtained such an empire over her affections that no favour was too great for them to ask, and often to obtain. In frequenting the salons of her friends the queen not only came in contact with a number of the younger and more dissipated courtiers, but also fell under the influence of various ambitious intriguers whose interested manoeuvres she was induced to further by her affection for her favourites. Thus she was often led to interfere for frivolous reasons in public affairs, sometimes with serious results, as in the case of the trial of the comte de Guines (1776), when her interference led to the fall of Turgot. At the same time her extravagance in dress, jewellery and amusements (including the gardens and theatricals at Trianon which was opened in May 1780 and of the cost of which exaggerated reports were spread), and her presence at horse races and masked balls in Paris without the king gave rise to scandal. At this critical period her brother, the emperor Joseph II, decided to visit France. As the result of his visit he left with the queen a memorandum in which he pointed out to her in plain terms the dangers of her conduct. For a time the emperor's remonstrances had some effect, and after the birth of her daughter, Marie Thérèse Charlotte (afterwards duchesse d'Angoulême), in Dec. 1778, the queen lived a quieter life. The death of Maria Theresa (Nov. 29, 1780) deprived her of a wise friend, and by removing all restraint on the rashness of Joseph II was bound to increase the dislike of the Austrian alliance and cause embarrassment to Marie Antoinette. Her position was much strengthened by the birth (Oct. 22, 1781) of a dauphin, Louis Joseph Xavier François; and on the death of Maurepas, which left the king without a chief minister, she might have exerted great influence in public affairs. But personal motives alone would lead her to interfere in public affairs, especially when it was a question of obtaining places or favours for her favourites and their friends. The influence of the Polignacs was now at its height, and they obtained large sums of money, a dukedom, and many nominations to places. But, in response to Mercy's and Joseph II's urgent representations, Marie Antoinette exerted herself on behalf of Austria in the affairs of the opening of the Scheldt (1783–1784) and the exchange of Bavaria (1785), in which, though she failed to provoke active interference on the part of France, she succeeded in obtaining the payment of considerable indemnities to Austria.

Two more children were born to her: Louis Charles, duke of Normandy, afterward dauphin, on March 27, 1785, and Sophie Hélène Beatrix (d. June 19, 1787), on July 9, 1786. In 1785–1786 the affair of the Diamond Necklace (*q.v.*) revealed the depth of the hatred which her own follies and the calumnies of her enemies had aroused against her. The public held her responsible for the bankrupt state of the country which was the immediate cause of the revolution.

The year 1789 was one of disaster for Marie Antoinette; on March 10 her brother Joseph II died and on June 4 her eldest son. The same year saw the assembling of the states-general, the taking of the Bastille, and the events leading to the terrible days of Oct. 5 and 6 at Versailles and the removal of the royal family to Paris. Then began the negotiations with Mirabeau, whose high estimate of the queen is well-known. But the queen was violently prejudiced against him and he never gained her full confidence. She was naturally incapable of seeing the full import of the revolution. She dreaded the thought of civil war; and even when she had realized the necessity for decisive action the king's apathy and indecision made it impossible for her to persuade him to carry into effect Mirabeau's plan of leaving Paris and appealing to the provinces. Her difficulties were increased by the departure of Mercy for The Hague in Sept. 1790, for Montmorin, who now took his place in the negotiations with Mirabeau, had not her confidence to the same extent. Feeling herself helpless and almost isolated in Paris, she now relied chiefly on her friends outside France—Mercy, Count Axel Fersen and the baron de Breteuil; and it was by their help and that of Bouillé that after the death of Mirabeau, on April 8, 1791, the plan was arranged of escaping to Montmédy, which ended in the flight to Varennes (June 21, 1791).

After the return from Varennes the royal family were closely guarded, but they still found channels of communication with the outside world. The king being sunk in apathy, the task of negotiation devolved upon the queen; but in her inexperience of affairs and the uncertainty of information from abroad, it was hard for her to follow any clear policy. Her courageous bearing during the return from Varennes had greatly impressed Barnave, and he now approached her on behalf of the constitutional party. For about a year she continued to negotiate with them, forwarding to Mercy and the emperor Leopold II letters and memoranda dictated by them, while at the same time secretly warning them not to accept these letters as her own opinions, but to realize that she was dependent on the Constitutionals. She agreed with their plan of an armed congress, and Fersen left Brussels on a mission to the emperor to try to gain his support and checkmate the *émigrés,* whose rashness threatened the queen's plans.

As for the constitution (Sept. 1791), "tissue of absurdities" though the queen thought it, she considered that in the circumstances the king was bound to accept it in order to inspire confidence. Mercy was also in correspondence with the Constitutionals, and in letter after letter to him and the emperor, the queen, strongly supported by Fersen, insisted that the congress should meet as soon as possible, her appeals increasing in urgency as she saw that Barnave's party would soon be powerless against the extremists. But the congress was continually postponed. On March 7, 1792, Leopold II died and was succeeded by the young Francis II. Marie Antoinette's actions were now directed entirely by Fersen, for she suspected Mercy and the emperor of sacrificing her to the interests of Austria. The declaration of war which the king was forced to make (April 20) threw her definitely into opposition to the revolution and she betrayed to Mercy and Fersen the plans of the French generals. She was now certain that the life of the king was threatened, and the events of June 20 added to her terrors. She considered their only hope to lie in the armed intervention of the powers, and endorsed the suggestion of a threatening manifesto which should hold the national assembly and Paris responsible for the safety of the king and royal family. Immediately after Brunswick's manifesto followed the storming of the Tuileries and the removal of the royal family to the temple (Aug. 10). During all these events and the captivity in the temple Marie Antoinette showed an unvarying courage and dignity, in spite of her failing health and the illness of her son. After the execution of the king (Jan. 21, 1793) several unsuccessful attempts were made to rescue her and her children, and negotiations for her release or exchange were even opened with Danton; but as the allied armies approached, her trial and condemnation became a certainty. She had already been separated from her son, the sight of whose ill-treatment added to her sufferings;

she was now parted from her daughter and Madame Elizabeth, and removed on Aug. 1, 1793 to the Conciergerie, where she was under the closest guard and subjected to the most offensive espionage.

On Oct. 14 began her trial. Her noble attitude, even in the face of the atrocious accusations of Fouquier-Tinville, commanded the admiration even of her enemies, and her answers during her long examination were clear and skilful. The following were the questions finally put to the jury:—

(1) Is it established that manoeuvres and communications have existed with foreign powers and other external enemies of the republic, the said manoeuvres, etc., tending to furnish them with assistance in money, give them an entry into French territory, and facilitate the progress of their armies?

(2) Is Marie Antoinette of Austria, the widow Capet, convicted of having co-operated in these manoeuvres and maintained these communications?

(3) Is it established that a plot and conspiracy has existed tending to kindle civil war within the republic, by arming the citizens against one another?

(4) Is Marie Antoinette, the widow Capet, convicted of having participated in this plot and conspiracy?

The jury decided unanimously in the affirmative, and on Oct. 16, 1793 Marie Antoinette was led to the guillotine, leaving behind her a touching letter to Madame Elizabeth, known as her "Testament."

As to the justice of these charges, we have seen how the queen was actually guilty of betraying her country, though it was only natural for her to identify the cause of the monarchy with that of France. To civil war she was consistently opposed, and never ceased to dissociate herself from the plans of the *émigrés*, but here again her very position made her an enemy of the republic. All her actions had as their aim—firstly, the safeguarding of the monarchy and later, when she saw this to be impossible, that of securing the safety of her husband and her son.

BIBLIOGRAPHY.—M. Tourneux, *Marie Antoinette devant l'histoire. Essai bibliographique* (2nd ed., Paris, 1901); id. *Bibliogr. de la ville de Paris . . .* (vol. iv, 1906), nos. 20980–21338; also *Bibliogr. de femmes célèbres* (Turin and Paris, 1892, etc.). The most important material for her life is to be found in her letters and in the correspondence of Mercy-Argenteau, but a large number of forgeries have found their way into certain of the collections, such as those of Count Paul Vogt d'Hunolstein and F. Feuillet de Conches, while most of the works on Marie Antoinette published before the appearance of Arneth's publications (1865, etc.) are based partly on these forgeries. For a detailed examination of the question of the authenticity of the letters *see* the introduction to *Lettres de Marie Antoinette. Recueil des lettres authentiques de la reine, publié pour la société d'histoire contemporaine, par M. de la Rocheterie et le marquis de Beaucourt* (2 vols., Paris, 1895–1896). Of the highest importance are the letters from the archives of Vienna published by Alfred von Arneth and others: A. von Arneth, *Maria Theresia und Marie Antoinette, ihr Briefwechsel 1770–1780* (Paris and Vienna, 1865); *Marie Antoinette, Joseph II und Leopold II ihr Briefwechsel* (Leipzig, Paris and Vienna, 1866); id. and A. Geffroy, *Correspondance secrète entre Marie-Thérèse et le comte de Mercy-Argenteau* (3 vols., Paris, 1874–75); id. and J. Flammermont, *Correspondance secrète du comte de Mercy-Argenteau avec Joseph II et le prince de Kaunitz* (2 vols., Paris, 1889–1891); for further letters *see* Comte de Reiset, *Lettres de la reine Marie Antoinette à la landgrave Louise de Hesse-Darmstadt* (1865); id. *Lettres inédites de Marie Antoinette et de Marie-Clotilde, reine de Sardaigne* (1877). *See* also *Correspondance entre le comte de Mirabeau et le comte de la Marck, 1789–1791, recueillie . . . par F. de Bacourl* (3 vols., Paris, 1857), and R. M. de Klinckowström, *Le Comte de Fersen et la cour de France* (2 vols., Paris, 1877–1878). The chief memoirs are: Mme. Campan, *Mémoires sur la vie privée de Marie Antoinette* (5th ed., 2 vols., Paris, 1823, Eng. trans., 1824), the inaccuracy of which is demonstrated by J. Flammermont in *Études critiques sur les sources de l'histoire du xviii^e^ siècle: Les Mémoires de Mme. Campan*, in the *Bulletin de la Faculté des lettres de Poitiers* (4th year, 1886, pp. 56, 109); J. Weber, *Mémoires concernant Marie Antoinette* (3 vols., London, 1804–1809); Eng. trans., 3 vols., London, 1805–1806); *Mémoires de M. le baron de Besenval* (3 vols., Paris, 1805); *Mémoires de M. le duc de Lauzun* (2nd ed., 2 vols., Paris, 1822); E. Bavoux, *Méms. secrets de J. M. Augeard, secrétaire des commandements de la reine M. Antoinette* (Paris, 1866); Mme. Vigée-Le-Brun, *Mes souvenirs* (2 vols., Paris, 1867); *Mémoires de Mme. la duchesse de Tourzel*, ed. by the duc de Cars (2 vols., Paris, 1883); *Mémoires de la baronne d'Oberkirch* (2 vols., Paris, 1853). M. Tourneux (*op. cit.*) discusses the authenticity of many of the memoirs.

GENERAL WORKS:—A. Sorel, *L'Europe et la Rév. fr.* vol. ii (1885–1904), contains a good estimate of Marie Antoinette. *See* also P. de Nolhac, *Marie Antoinette* (Paris, 1936); which gives good descriptions of Versailles, Trianon, etc.; M. de la Rocheterie, *Histoire de Marie Antoinette* (2 vols., Paris, 1890); G. Desjardins, *Le Petit-Trianon* (Versailles, 1885). For her trial and death, *see* E. Campardon, *Marie Antoinette à la Conciergerie* (1863). *See* also A. Vuaflart and H. Bourin, *Les Portraits de Marie Antoinette* (1909); A. Cabanès, *La Princesse de Lamballe intime* (1922); P. M. de Ségur, *Marie Antoinette* (1921; Eng. trans., 1927); John G. Palache, *Marie Antoinette* (1929); Emile Baumann, *Marie Antoinette et Axel Fersen* (Paris, 1931); Katharine Anthony, *Marie Antoinette* (1933); Marjorie Coryn, *Marie Antoinette and Axel de Fersen* (London, 1938); J. MARIE DE FRANCE (*fl. c.* 1175–1190), French poet and fabulist. In spite of her own statement in the epilogue to her fables: "Marie ai num, si suis de France," generally interpreted to mean that Marie was a native of the Île de France, she seems to have been of Norman origin, and certainly spent most of her life in England. Her language, however, shows little trace of Anglo-Norman provincialism. Like Wace, she used a literary dialect which probably differed very widely from common Norman speech. The manuscripts in which Marie's poems are preserved date from the late 13th or even from the 14th century, but the language fixes the date of the poems in the second half of the 12th century.

The *lais* are dedicated to an unknown king, who is identified as Henry II. of England; and the fables, her *Ysopet*, were written according to the *Epilogus* for a Count William, generally recognized to be William Longsword, earl of Salisbury. Marie lived and wrote at the court of Henry II., which was very literary and purely French. Queen Eleanor was a Provençal, and belonged to a family in which the patronage of poetry was a tradition. There is no evidence to show whether Marie was of noble origin or simply pursued the profession of a *trouvère* for her living.

The origin of the *lais* has been the subject of much discussion. Marie herself says that she had heard them sung by Breton minstrels. Gaston Paris (*Romania*, vol. xv.) maintained that Marie had heard the stories from English minstrels, who had assimilated the Celtic legends. In any case the Breton lays offer abundant evidence of borrowing from Scandinavian and oriental sources.

The *lais* which may be definitely attributed to Marie are *Guigemar, Equitan, Le Frêne, Le Bisclavret* (the werewolf), *Les Deux amants, Laustic, Chaitivel, Lanval, Le Chèvrefeuille, Milon, Yonec* and *Eliduc*. The other similar lays are anonymous except the *Lai d'Ignaure* by Renant and the *Lai du cor* of Robert Biket, two authors otherwise unknown. They vary in length from some 12,000 lines to about 100.

Marie's *Ysopet* is a collection of fables translated from an English original which she erroneously attributed to Alfred the Great, who had, she said, translated it from the Latin. Another poem attributed to her is *L'Espurgatoire Seint Patriz*, a translation from the *Tractatus de purgatorio S. Patricii* (*c.* 1185) of Henri de Salterey, which brings her activity down almost to the close of the century.

See *Die Fabeln der Marie de France* (1898), ed. by Karl Warnke with the help of materials left by Eduard Mall; and *Die Lais der Marie de France* (2nd ed., 1900), ed. by Karl Warnke, with comparative notes by Reinhold Köhler; the two works being vols. vi. and iii. of the *Bibliotheca Normannica* of Hermann Suchier; also J. Bédier in *Revue des deux mondes* (Oct. 1891); Alice Kemp-Welch in *Nineteenth Century* (Dec. 1907); and Winkler, "Marie de France" in *Sitzengber. d. Wiener Akad*, vol. 183, 1918. For an analysis of the *Lais* see *Revue de philologie française*, viii. 161 *seq.*; Karl Warnke, *Die Quellen der Esope der Marie de France* (1900). The *Lais* were first published in 1819 by B. de Roquefort. *L'Espurgatoire Seint Patriz* was edited by T. A. Jenkins (Philadelphia, 1894). Some of the *Lays* were paraphrased by Arthur O'Shaughnessy in his *Lays of France* (1872).

MARIE DE' MEDICI (1573–1642), queen consort and queen regent of France, daughter of Francis de' Medici, grand duke of Tuscany, and Joanna, an Austrian archduchess, was born in Florence on April 26, 1573. She married Henry IV. of France in October 1600. Her eldest son, the future Louis XIII., was born at Fontainebleau in September of the next year; the other children who survived were Gaston duke of Orleans; Elizabeth queen of Spain; Christine duchess of Savoy; and Henrietta Maria queen of England. During her husband's lifetime Marie de' Medici showed little sign of political taste or ability; but after his murder in 1610 when she became regent, she devoted herself to affairs with unfailing regularity and developed an inherited passion for power. She gave her confidence chiefly to Concini, afterwards maréchal d'Ancre, the husband of Leonora Galigaï, a friend of her childhood. Under the regent's lax and capricious rule the princes of the blood and the great nobles of the kingdom revolted; and the queen, too weak to assert her authority, consented at Sainte Menehould (May 15, 1614) to buy off the discontented princes. In 1616 Richelieu entered her councils. Louis XIII., who was now 16 years old, threw off the tutelage of his mother and Concini. By his orders Concini was murdered, Leonora Galigaï was tried for sorcery and beheaded, Richelieu was banished to his bishopric, and the queen was exiled to Blois.

After two years of virtual imprisonment she escaped in 1619 and became the centre of a new revolt. Louis XIII. easily dispersed the rebels, but through the mediation of Richelieu was reconciled with his mother, who was allowed to hold a small court at Angers, and resumed her place in the royal council in 1621. For a single day, the *journée des dupes,* Nov. 12, 1630, she seemed to have succeeded against the minister; but the triumph of Richelieu was followed by her exile to Compiègne, whence she escaped in 1631 to Brussels. From that time till her death at Cologne on July 3, 1642 she intrigued in vain against the cardinal.

See A. P. Lord, *The Regency of Marie de Médicis* (1904); L. Batiffol, *La Vie intime d'une reine de France au XVII^e siècle: Marie de Médicis* (1931; Eng. trans., 1908).

MARIE FEODOROVNA (MARIE SOPHIA FREDERIKA DAGMAR) (1847–1928), empress of Russia, second daughter and fourth child of King Christian IX. of Denmark, was born Nov. 26, 1847. Originally betrothed to Nicholas, eldest son of Alexander II., tsar of Russia, on his death she married, on Nov. 9, 1866, the Grand Duke Alexander Alexandrovitch, his younger brother, heir-apparent to the Russian throne, and was known thenceforward as Marie Feodorovna. The grand duke succeeded to the Russian throne as Alexander III., in 1881, on the assassination of his father by revolutionaries. The empress's home life was a happy one, and she took no part in politics. Her husband was for many years in danger of his life and every precaution was taken for his safety. There was on his accession a tendency to reaction, and on the advice of Pobiedonoszeff, Alexander III. refused to accept the Constitution prepared by his father. As his accession to the throne had never been expected, he had been trained as a soldier, and had little political knowledge or ability. The empress interested herself particularly in philanthropy and education, and as head of the "department of the institution of the empress Marie" greatly extended the work of the institution, establishing new schools, hospitals and relief centres of various kinds. She endeared herself to the people of Russia by her personal interest as well as by her wide philanthropic activities. She was trained as a nurse during the Russo-Turkish war, and greatly developed the Russian Red Cross organization, of which she was the head. From the death of Alexander III., in 1894, she lived in retirement in the Anitchkov palace in St. Petersburg (Leningrad), visiting Denmark and England where she was staying on the outbreak of the World War. She returned to Russia, in spite of an attempt in Berlin to send her back to England, and worked actively for the Russian Red Cross. Her attempts to warn her son, Nicholas II., against the influence of Rasputin were unsuccessful. Three months after Rasputin's murder the revolution broke out and the emperor abdicated. The empress Marie, who was at Kiev, met him for the last time at Mohilev. She was permitted, with other members of the royal family, to live in the Crimea, under close guard. When the Crimea came under German occupation she was given the opportunity of returning to Denmark through Germany, but refused, and only left for England after the armistice in April 1919. During her later years she lived at Hvidöre, in Denmark; she died at Copenhagen on Oct. 13, 1928.

The empress had five children, Nicholas, who became emperor as Nicholas II.; George, who died at the age of 23; Xenia, who married the Grand Duke Alexander Mikhailovitch; Michael, who was tsarevich from 1881 until the birth of a direct heir to the throne in 1904; and Olga, whose marriage with Prince Peter Oldenburgsky was dissolved during the war.

MARIE GALANTE, an island in the French West Indies. Pop. (1921) 22,608. It lies in 15° 55′ N. and 61° 17′ W., 16 m. S.E. of Guadeloupe, of which it is a dependency. It is nearly circular in shape and 58 sq.mi. in area. A rocky limestone plateau 675 ft. high occupies the centre of the island, and from it the land descends in a series of well-wooded terraces to the sea. The shores are rocky, there are no harbours, and the roadstead off Grand Bourg is difficult of access, owing to the surrounding reefs. The climate is healthy and the soil rich; sugar, coffee and cotton being the chief products. The largest town is Grand Bourg (pop. 7,000) on the south-west coast. The island was discovered by Columbus in 1493, and received its name from the vessel on which he was sailing. The French who settled here in 1648 suffered numerous attacks both from the Dutch and the British, but since 1766, except for a short period of British rule in the early part of the 19th century, they have held undisturbed possession.

MARIE LESZCZYNSKA (1703–1768), queen consort of France, was born at Breslau on June 23, 1703, being the daughter of Stanislas Leszczynski (who in 1704 became king of Poland) and of Catherine Opalinska. During a temporary flight from Warsaw the child was lost, and eventually discovered in a stable; on another occasion she was for safety's sake hidden in an oven. In his exile Stanislas found his chief consolation in superintending the education of his daughter. Her marriage with Louis XV. took place at Fontainebleau on Sept. 5, 1725. Marie's one attempt to interfere in politics, an effort to prevent the disgrace of the duke of Bourbon, was the beginning of her husband's alienation from her; and after the birth of her seventh child, Louise, Marie was practically deserted by Louis, who openly avowed a series of liaisons. She died at Versailles on June 24, 1768.

See H. Gauthier Villars, *Le Mariage de Louis XV. d'après des documents nouveaux* (1900); P. de Nolhac, *La Reine Marie Leczinska* (1900) and *Louis XV. et Marie Leczynska* (1900); P. Boyé, *Lettres du roi Stanislas à Marie Leszczynska* 1754–66 (Paris and Nancy, 1901); and C. Stryienski's book on Marie Joséphs de Saxe (*La Mère des trois derniers Bourbons,* 1902).

MARIE LOUISE (1791–1847), second wife of Napoleon I., was the daughter of Francis I., emperor of Austria, and of the princess Theresa of Naples, and was born on Dec. 12, 1791. It is probable, though not quite certain, that the first suggestions of a marriage between Napoleon and Marie Louise emanated secretly from the Austrian chancellor, Metternich. The prince de Ligne claimed to have been instrumental in arranging it. In any case the proposal was well received at Paris both by Napoleon and by his ministers; and the difficulties respecting the divorce of Josephine, were surmounted. The marriage took place by proxy in the church of St. Augustine, Vienna, on March 11, 1810. The new empress was escorted into France by Queen Caroline Murat, for whom she soon conceived a feeling of distrust. The civil and religious contracts took place at Paris early in April, and during the honeymoon, spent at the palace of Compiègne, the emperor showed the greatest regard for his wife. "He is so evidently in love with her," wrote Metternich, "that he cannot conceal his feelings, and all his customary ways of life are subordinate to her wishes." His joy was complete when on March 20, 1811, she bore him a son who was destined to bear the empty titles of "king of Rome" and "Napoleon II." Before the campaign of 1812 she accompanied the emperor to Dresden; but after that scene of splendour misfortunes crowded upon Napoleon. In January 1814 he appointed her to act as regent of France (with Joseph Bonaparte as lieutenant-general) during his absence in the field.

At the time of Napoleon's first abdication (April 11, 1814), she succeeded in spite of the efforts of Joseph and Jerome Bonaparte in reaching her father, the emperor Francis, while Napoleon was on his way to Elba. She, along with her son, was escorted into Austria by Count von Neipperg, and refused to comply with the entreaties of Napoleon to proceed to Elba; and her alienation from him was completed when he ventured to threaten her with a forcible abduction. During the Hundred Days she remained in Austria, and manifested no desire for the success of Napoleon in France. At the Congress of Vienna the Powers awarded to her and her son the duchies of Parma, Piacenzá and Guastalla, in conformity with the terms of the treaty of Fontainebleau (March, 1814); in spite of the determined opposition of Louis XVIII. she gained this right for herself owing largely to the support of the emperor Alexander, but she failed to make good the claims of her son to the inheritance. (*See* REICHSTADT, NAPOLEON FRANCIS JOSEPH CHARLES.) She proceeded alone to Parma, and had to acquiesce in the title "duke of Reichstadt" accorded to her son.

Long before the news of Napoleon's death reached her she was living in intimate relations with Neipperg at Parma, and bore a son to him not long after that event. Napoleon on the other hand spoke of her in his will with marked tenderness, and both excused and forgave her infidelity. Neipperg became her morganatic husband; and they had other children. In 1832 she visited the duke of Reichstadt at Vienna when he was dying. Her rule in Parma, conjointly with Neipperg, was characterized by a clemency and moderation which were lacking in the other Italian states in that time of reaction. She preserved some of the Napoleonic laws and institutions; in 1817 she established the equality of women in heritage, and ordered the compilation of a civil code which was promulgated in January 1820. On the death of Neipperg in 1829 his place was taken by Baron Werklein, whose influence was hostile to popular liberty. In 1831 Marie Louise had to take refuge with the Austrian garrison at Piacenza; on the restoration of her rule by the Austrians its character deteriorated, Parma becoming an outwork of the Austrian empire. She died at Vienna on Dec. 18, 1847.

Wertheimer, *Die Heirath der Erzherzogin Marie Louise mit Napoléon I.* (Vienna, 1882); and *The Duke of Reichstadt* (Eng. ed., 1905). *See* also the *Memoirs* of Bausset, Mme. Durand Méneval and Metternich; and Max Billard, *The Marriage Ventures of Marie Louise,* English version by Evelyn, duchess of Wellington (1910); D. Masson, *L'impératrice Marie Louise* (1902); Cuthell, *An Imperial Victim* (1912); Gachot, *Marie Louise intime* (1912); C. de Clary-et-Aldringen, *Souvenirs* (1914).

MARIENBAD (Czech *Marianské Lázně*), a watering-place in northwest Bohemia on the southeastern outskirts of the Císařský Les at an altitude of 2,093 ft., enclosed on all sides except the south by gently sloping hills clad with pine forests intersected by lovely walks. Pop. (1930) 7,177. Although its mineral springs have been known for centuries and are mentioned in a document dated 1341 as belonging to the abbey of Tepl, they attracted few people until Josef Nehr, the doctor of the abbey, demonstrated their curative properties during the period 1779–1820, and the town did not receive a charter until 1868.

After this date it grew in popularity and became one of the most frequented spas in Europe. The waters are cold and varied in composition, some, like those of Carlsbad, being alkaline-saline but of greater strength, others being rich in iron, and are used in the treatment of liver troubles, gout, diabetes and obesity. Most are used for bottling and drinking but the cure also involves a carefully regulated diet; the water is also bottled and exported in large quantities. In addition to the springs there are peat baths very rich in iron. The town is small and well-built, most of its hospitals, bathing establishments and other public buildings being quite modern.

In the vicinity lie many places of interest, *e.g.,* the rock of Podhorn (2,776 ft.), about 3 mi. E., with extensive views of the Böhmer Wald and Erz Gebirge, and, about 7 mi. E., the old abbey of Tepl, founded in 1193, though the present building dates from the 17th–18th centuries and has a fine library and collection of rare manuscripts; and, to the northeast, the small spa of Königswart. In 1938 Marienbad, as part of the Sudetenland, came under German rule.

MARIENBURG (Polish, *Malborg*), a town in the Prussian province of East Prussia, Germany, 30 mi. by rail to Danzig, on the right bank of the Nogat, a channel of the Vistula, here spanned by bridges. Pop. (1939) 27,013. The castle of the Teutonic order here was originally founded in 1274 as the seat of a simple commandery against the pagan Prussians, but in 1309 the headquarters of the grand master were transferred hither from Venice, and the "Marienburger Schloss" soon became one of the largest and most strongly fortified buildings in Germany. In the middle of the 15th century, the castle passed into the hands of the Poles, by whom it was allowed to fall into neglect and decay. It came into the possession of Prussia in 1772, and was carefully restored at the beginning of the 19th century. It consists of three parts, the Alt- or Hochschloss, the Mittelschloss, and the Vorburg, and is built of brick, in a style of architecture peculiar to the Baltic provinces. Marienburg manufactures agricultural machinery, sugar, and has saw mills. It carries on a considerable trade in grain, wood, flax and is the seat of important cattle and horse markets. In the old market-place, many of the houses of which are built with arcades, stands a Gothic town-hall dating from the end of the 14th century.

MARIENWERDER, a town in the Prussian province of East Prussia, Germany, 3 mi. E. of the Vistula, 23 mi. S. of Marienburg. Pop. (1939) 19,945. The town was founded in the year 1233 by the Teutonic order. It has a cathedral of the 14th century, a triple Gothic edifice, restored in 1874. In the cathedral were buried two grand masters of the Teutonic order. Under Article 96 of the Treaty of Versailles a plebiscite was held to decide whether the territory should belong to Poland or to East Prussia, which resulted in favour of the latter. The industries include saw mills, sugar-refineries, breweries and printing-works.

MARIE THÉRÈSE OF AUSTRIA (1638–1683), queen consort of France, was born on Sept. 10, 1638, at the Escorial, the daughter of Philip IV of Spain and Elizabeth of France. The treaty of the Pyrenees in 1659 stipulated for her marriage with Louis XIV, Marie renouncing any claim to the Spanish succession. Marie Thérèse was married in June 1660, when Philip IV with his whole court accompanied the bride to the Isle of Pheasants in the Bidassoa, where she was met by Louis. She died on July 30, 1683, at Versailles, not without suspicion of foul play on the part of her doctors. Of her six children only one survived her, the dauphin Louis, who died in 1711.

See the funeral oration of Bossuet (Paris, 1684), E. Ducéré, *Le Mariage de Louis XIV. d'après les contemporains et des documents inédits* (Bayonne, 1905); Dr. Cabanès, *Les Morts mystérieuses de l'histoire* (1923); M. Duclos, *Madame de La Vallière et Marie Thérèse d'Austriche* (1904), and the literature dealing with her rivals Louise de la Vallière, Madame de Montespan and Madame de Maintenon.

MARIETTA, a city of Georgia, U.S.A., 20 mi. N.W. of Atlanta, on federal highway 41, at an altitude of 1,118 ft.; the county seat of Cobb county. It is served by the Louisville and Nashville and the Nashville, Chattanooga and St. Louis railways. The population was 7,638 in 1930; 8,667 in 1940. It is both a winter and a summer resort, and has a variety of manufacturing industries. The city was founded *c.* 1840 and chartered 1852.

At Marietta there is a national cemetery, in which more than 10,000 Federal soldiers are buried. The Kennesaw mountain (1,809 ft.), about 2½ mi. west of the city, was the scene of a stubborn action of the Civil War, in which the Federals lost 2,500 men. After the Confederate retreat from Dalton in May 1864, Gen. W. T. Sherman, the Federal commander, made Marietta his next intermediate point in his Atlanta campaign, and the Confederate commander, Gen. J. E. Johnston, established a line of defense west of the town. After several preliminary engagements Sherman, on June 27, made an unsuccessful attempt to drive the Confederates from their defenses at Kennesaw mountain—the only instance in his campaign of a frontal attack on a strongly entrenched position. He then resorted to a flanking movement which forced the Confederate general to retire (July 2) toward Atlanta.

MARIETTA, a city of southeastern Ohio, U.S.A., the county seat of Washington county; on the Ohio river at the mouth of the Muskingum. It is on federal highways 21 and 50, and is served by the Baltimore and Ohio and the Pennsylvania railways. Pop. 15,140 in 1920 (95% native white); and 14,543 in 1940 by federal census. The city's streets are lined with magnificent old shade trees, including the largest elm on record in the United

States. It is surrounded by a hilly country of much natural beauty, devoted largely to market gardens and apple orchards; is the centre of one of the oldest gas and oil fields in the country, still producing about 1,000,000 bbl. annually; and has substantial and diversified manufacturing industries, with an output in 1940 valued at $10,500,000. The assessed valuation of property for 1940 was $16,295,300. The city operates under the mayor-and-council form of government, and has in addition a "service director" with the functions of a city manager. It is the seat of Marietta college (chartered 1835, continuing an academy founded in 1797) which has a valuable historical museum and rare collections of Americana, including the original records of the Ohio Company, the Rodney M. Stimson collection (relating chiefly to the history of the Ohio and the Mississippi valleys), and the Charles Goddard Slack collection of historical documents and prints. In the centre of Mound cemetery (where many of the pioneers are buried) is one of the most perfect specimens of the mound-builders' work, and there are other prehistoric earthworks in and near the city, including a double embankment leading down to the Muskingum river. Marietta is the oldest settlement in Ohio. It was founded on April 7, 1788 (near Ft. Harmer, built in 1785) by a company of revolutionary officers from New England under the leadership of Gen. Rufus Putnam. The name was chosen to honour Marie Antoinette. Here the North-west territory was formally organized, Marietta was made the capital, and on July 15 Arthur St. Clair took his oath of office as the first governor. The blockhouse ("Campus Martius") in which Gen. Putnam lived at first, his later home, and the original land office of the Ohio Company, still stand, and are carefully preserved as historic monuments. Black Hole cave, in the outskirts of the city, was an important "station" on the Underground railway.

MARIETTE, AUGUSTE FERDINAND FRANÇOIS (1821–1881), French Egyptologist, was born on Feb. 11, 1821 at Boulogne, where his father was town clerk. Entrusted with a government mission for the purpose of seeking and purchasing Coptic, Syriac, Arabic and Ethiopic mss. for the national collection, he started for Egypt in 1850; and soon after his arrival he discovered the ruins of the Serapeum and the subterranean catacombs of the Apis bulls. His original mission being abandoned, funds were now advanced for the prosecution of his researches, and he remained in Egypt for four years, excavating, discovering and despatching archaeological treasures to the Louvre, of which he was on his return appointed an assistant conservator. In 1858 he accepted the position of conservator of Egyptian monuments to the ex-khedive, Ismail Pasha, and removed with his family to Cairo. The museum at Bula was founded immediately. The pyramid-fields of Memphis and Sakkara, and the necropolis of Meydum, and those of Abydos and Thebes were examined; the great temples of Dendera and Edfu were disinterred; important excavations were carried out at Karnak, Medinet-Habu and Deir el-Bahri; Tanis (the Zoan of the Bible) was partially explored in the Delta; and even Gebel Barkal in the Sudan. The Sphinx was bared to the rock-level, and the famous granite and alabaster monument miscalled the "Temple of the Sphinx" was discovered. Mariette was raised successively to the rank of bey and pasha. He died at Cairo on Jan. 19, 1881.

His chief published works are: *Le Sérapéum de Memphis* (1857 and following years); *Dendérah,* five folios and one 4to (1873–75); *Abydos,* two folios and one 4to (1870–80); *Karnak,* folio and 4to (1875); *Deir el-Bahari,* folio and 4to (1877); *Listes géographiques des pylônes de Karnak,* folio (1875); *Catalogue du Musée de Boulaq* (six editions, 1864–76); *Aperçu de l'histoire d'Égypte* (four editions, 1864–74, etc.); *Les Mastabas de l'ancien empire* (edited by Maspero) (1883). *See* "Notice biographique," by Maspero in *Auguste Mariette. Oeuvres diverses* (tome 1, Paris, 1904), and art. EGYPT: *Exploration and Research.*

MARIGNANO, BATTLE OF, fought on Sept. 13 and 14, 1515, between the French army under Francis I. and the Swiss. The scene of the battle—which was also that of a hard fought engagement in 1859 (*see* ITALIAN WARS)—was the northern outskirts of the village of Melegnano, on the river Lambro, 10m. S.E. of Milan. The circumstances out of which the battle of Marignano arose, almost inconceivable to the modern mind, were not abnormal in the conditions of Italian warfare and politics then prevailing. The young king of France had gathered an army about Lyons, wherewith to overrun the Milanese; his allies were the republics of Venice and Genoa. The duke of Milan, Maximilian Sforza, had secured the support of the emperor, the king of Spain, and the pope, and also that of the Swiss cantons, which then supplied the best mercenary soldiers in Europe. (*See* SWISS WARS.) The practicable passes of the Alps and the Apennines were held by Swiss and papal troops. Francis, however, boldly crossed the Col de l'Argentière (Aug. 1515) by paths that no army had hitherto used, and Marshal de La Palisse surprised and captured a papal corps at Villafranca near Pinerolo, whereupon the whole of the enemy's troops fell back on Milan. The king then marching by Vercelli, Novara and Pavia, joined hands with Alviano, the Venetian commander, and secured a foothold in the Milanese. But in order to avoid the necessity of besieging Milan itself, he offered the Swiss a large sum to retire into their own country. They were about to accept his offer, not having received their subsidies from the pope and the king of Spain, when a fresh corps of mercenaries descended into Italy, desirous both of gaining booty and of showing their prowess against their new rivals the French and Lower Rhine "lansquenets" (landsknechts) and against the French gendarmerie, whom (alluding to the "Battle of the Spurs" at Guinegatte in 1513) they called "hares in armour." The French took position at Melegnano to face the Swiss, the Venetians at Lodi to hold in check the Spanish army at Piacenza. Alviano, who was visiting the king when the Swiss appeared before Melegnano, hurried off to bring thither his own army. Meantime the French and the Swiss engaged in an exceedingly fierce struggle.

The king's army was grouped in front of the village, facing in the direction of Milan, with a small stream separating it from the oncoming Swiss. On either side of the Milan road was a large body of landsknechts, a third being in reserve. The French and Gascon infantry (largely armed with arquebuses) was on the extreme right, the various bodies of gendarmerie in the centre. In front of all was the French artillery. The battle opened in the afternoon of Sept. 13. As the Swiss advanced in three huge columns, the French guns fired into them with terrible effect, but the assailants reached the intersected ground bordering the stream, and thus protected from the rush of the French gendarmerie, they debouched on the other side, and fell upon the landsknechts. The crowd of combatants, the gathering darkness, and the dust, prevented any general direction being given to the battle by the leaders of either side. Francis himself at the head of 200 gendarmes charged and drove back two large bodies of Swiss which were pressing the landsknechts hard. The battle went on by moonlight till close on midnight, when the Swiss retired a short distance. Both sides spent the rest of the night on the battlefield, reorganizing their broken corps. Francis and his gendarmes were the outpost line of the French army, and remained all night mounted, lance in hand and helmet on head. Next morning at sunrise, the battle was renewed. The Swiss now left their centre inactive opposite the king and with two strong corps attempted to work round his flanks. That on the left made for the French baggage, but found it strongly guarded by landsknechts, who drove them back. The nearest French gendarmerie joined in the pursuit, but a detachment from the Swiss centre fell upon these and destroyed them. This detachment in turn followed up its advantage until as Francis himself expressed it, "the whole camp turned out" to aid the landsknechts and "hunted out" the Swiss. Meantime the Swiss left attack had closed with the French infantry bands and the "aventuriers" (afterwards the famous corps of Picardie and Piedmont), who were commanded on this day by the famous engineer Pedro Navarro. It was in the main a struggle of arquebus against pike, but it was not the arquebus alone, or even principally, that gave the victory to the French. When the Swiss ranks had been disordered, the short pike and the sword came into play, and aided by the constable de Bourbon with a handful of the gendarmerie, the French right more than held its own until Alviano with the cavalry from Lodi rode on to the field and completed the rout of the Swiss. In the centre meanwhile the two infantries stood fast for eight hours, separated by the brook, while the artillery on both sides fired into it at short range. But the landsknechts, animated by the king, endured it as well as the Swiss; and at the last, Francis leading a final advance of his exhausted troops, the Swiss gave way and fled. Only 3,000 Swiss escaped out of some 25,000 who fought. On the French side probably 8,000 were killed or died of wounds. The battle lasted 28 hours. Its tactical lesson was the efficacy of combining two arms against one. The French gendarmerie, burning to avenge the insult of "hares in armour," made more than thirty charges by squadrons, and they were admirably supported by their light artillery which played havoc with the Swiss pikemen whom the mounted charges had brought to a halt. Marignano was thus a landmark in the power of the new arm, and at the same time the last and greatest triumph of the armoured lancer; and as a fitting close to the battle the young king was knighted by Bayard on the field. But, above all, in signalizing the military decline of the Swiss it afforded yet more proof in history of the truth that good soldiership is not enough, without generalship, and that conservatism towards military progress will undermine the firmest foundations of military power.

MARIGNOLLI, GIOVANNI DE', a notable traveller to the Far East in the 14th century, born probably before 1290, and sprung from a noble family in Florence. In 1338 there arrived at Avignon, where Benedict XII. held his court, an embassy from the great khan of Cathay (the Mongol-Chinese emperor), bearing letters to the pontiff from the khan himself, and from certain Christian nobles of the Alan race in his service, who asked for a priest. The pope replied to the letters, and appointed four ecclesiastics as his legates to the khan's court. The name of John of Florence, *i.e.,* Marignolli, appears third on the letters of commission. A large party was associated with the four chief envoys; when in Peking the embassy still numbered thirty-two, out of an original fifty.

The mission left Avignon in December 1338; picked up the Tatar envoys at Naples; and travelled via Constantinople and the Black Sea to the court of Mohammed Uzbeg, khan of the Golden Horde, at Sarai on the Volga. The khan entertained them hospitably during the winter of 1339–1340 and then sent them across the steppes to Armalec, Almalig or Almaligh (Kulja), the northern seat of the house of Chaghatai, in what is now the province of Ili. "There," says Marignolli, "we built a church, bought a piece of ground . . . sung masses, and baptized several persons, notwithstanding that only the year before the bishop and six other minor friars had there undergone glorious martyrdom for Christ's salvation." Quitting Almaligh in 1341, they seem to have reached Peking (by way of Kamul or Hami) in May or June 1342. They were well received by the reigning khan, the last of the Mongol dynasty in China. An entry in the Chinese annals fixes the year of Marignolli's presentation by its mention of the arrival of the great horses from the kingdom of Fulang (*Farang* or Europe), one of which was 11 ft. 6 in. in length and 6 ft. 8 in. high, and black all over.

Marignolli stayed at Peking or Cambalec three or four years, after which he travelled through eastern China to Zayton or Amoy Harbour, quitting China apparently in December 1347, and reaching Columbum (Kaulam or Quilon in Malabar) in Easter week of 1348. He returned home by way of a circuitous route, reaching Avignon in 1353, where he delivered a letter from the great khan to Pope Innocent VI. In the following year the emperor Charles IV., on a visit to Italy, made Marignolli one of his chaplains. Soon after, the pope made him bishop of Bisignano; but he appears to have accompanied the emperor to Prague in 1354–1355; in 1356 he is found acting as envoy to the pope from Florence; and in 1357 he is at Bologna. The date of his death is unknown.

Nobody seems to have noticed the fragmentary notes left by Marignolli of his journeys interpolated in his *Annals of Bohemia,* compiled by order of the emperor, till 1768, when the chronicle was published in vol. ii. of the *Monumenta hist. Bohemiae nusquam antehac edita* by Father Gelasius Dobner.

MARIGNY, ENGUERRAND DE (1260–1315), French statesman, was born at Lyons-la-Forêt in Normandy. After the death of Pierre Flotte and Hugues de Bonville at the battle of Mons-en-Pevèle in 1304, he became Philip IV.'s grand chamberlain and chief minister. In 1306 he was sent to preside over the exchequer of Normandy. He received numerous gifts of land and money from Philip as well as a pension from Edward II. of England. He was an able instrument of Philip's policy, and shared the popular odium which Philip incurred by debasing the coinage. He obtained rich appointments for many of his relatives, and secured increased revenue for the king. His peace with the Flemings in 1314 disappointed the princes of the blood. He was accused of receiving bribes, and Charles of Valois denounced him to the king himself; but Philip stood by him. After the death of Philip IV. on Nov. 29, 1314 the feudal party, whose power the king had tried to limit, turned on his ministers and chiefly on his chamberlain. Enguerrand was arrested, and twenty-eight articles of accusation including charges of receiving bribes were brought against him. He was refused a hearing; but his accounts were correct, and Louis was inclined to spare him anything more than banishment to the island of Cyprus. Charles of Valois then brought forward a charge of sorcery. Enguerrand was condemned at once and hanged on the public gallows at Montfaucon, protesting that in all his acts he had only been carrying out Philip's commands (April 30, 1315).

See contemporary chroniclers in vols. xx. to xxiii. of D. Bouquet, *Historiens de la France;* P. Clément, *Trois drames historiques* (1857); Ch. Dufayard, *La Réaction féodale sous les fils de Philippe le Bel,* in the *Revue historique* (1894, liv. 241–272) and lv. 241–290.

MARIGNY, JEAN DE (d. 1350), French bishop, was a younger brother of the preceding. In 1313 he was made bishop of Beauvais; he completed the choir of Beauvais Cathedral, the enormous windows of which were filled with the richest glass. But the work was interrupted by the Hundred Years' War. Jean de Marigny was one of the king's lieutenants in southern France in 1341 against the English invasion. In 1346 he held Beauvais against the English, who had overrun the country up to the walls of the city. Created archbishop of Rouen in 1347, he enjoyed his new honours only three years; he died on Dec. 26, 1350.

MARIGOLD. This name has been given to several plants, of which the following are the best known: *Calendula officinalis,* the pot-marigold; *Tagetes erecta,* the African marigold, long thought to be native there, but actually Mexican; *T. patula,* the French marigold; and *Chrysanthemum segetum,* the corn marigold. All these belong to the family Compositae; but *Caltha palustris,* the marsh-marigold (*q.v.*), belongs to the Ranunculaceae. *See* also ICE-PLANT.

The first-mentioned is a familiar garden plant with large orange-coloured blossoms, and is probably not known in a wild state. There are now many fine garden varieties of it. The florets are unisexual, the ray florets being female, the disk florets male. This and the double variety have been in cultivation for at least three hundred years, as well as a proliferous form, the "fruitful marigolde" of Gerard (*Herball,* p. 602), in which small flower heads proceed from beneath the circumference of the flower. The figure of "the greatest double marigold," *C. multiflora maxima,* given by Gerard (*loc. cit.,* p. 600) is larger than most specimens now seen, being 3 in. in diameter. He remarks of "the marigolde" that it is called *Calendula* "as it is to be seene to flower in the calends of almost euerie moneth."

Tagetes patula, and *T. erecta,* the French and African marigolds, are natives of Mexico, and are equally familiar garden plants, having been long in cultivation. Gerard figures five varieties of *Flos africanus,* of the single and double kind (*loc.*

cit., p. 609). Besides the above species the following have been introduced later: *T. lucida* and *T. tenuifolia*, both from Mexico.

The Eurasian *Chrysanthemum segetum*, the corn marigold, is frequent in cornfields in most parts of England. When dried it has been employed as hay. It was also used in Germany for dyeing yellow.

MARII, autonomous republic in the Russian S.F.S.R., created Dec. 5, 1936, with Ioshkar-Ola (Joshkarol) (formerly Krasnokokshaisk and Tsarevokokshisk), as its main town. Area 8,996 sq.mi. Pop. (1939) 579,466, urban 75,873, rural 503,593. It is surrounded by the Tatar A.S.S.R., the Chuvash A.S.S.R., and the provinces of Gorky and Kirov, and lies between 55° 50′ N. and 57° 20′ N. and 45° 39′ and 50° 18′ E. The surface consists of a plain sloping south to the Volga river, with higher ground in the east forming the watershed between the tributaries of the Volga and the Vyatka. The chief rivers are the Volga, which flows through part of the southwest, and after passing through the north of the Chuvash A.S.S.R., forms the southeastern boundary of the Marii region, the Great and Little Kokshag and the Vetluga, tributaries of the Volga. The area lies in the taiga forest zone and 64% of it is covered with coniferous forest, pine and fir predominating. Timber and wooden wares made by the peasants provide the largest source of income, the nearness of the Volga being a great asset for export. A railway was constructed in 1923 from Kazan to Ioshkar-Ola, the administrative centre, a small town of 9,400 inhabitants (1934). Kozmodemiansk, on the Volga, has 9,100 (1934) inhabitants and is a great timber centre with an annual timber fair. Apart from these two, there are no other town centres. The soils are not very favourable for agriculture, consisting mainly of sands, clays and forest earths. The climate is severe and continental, ranging between 7° F. and 68° F. and the rainfall averages 17.3 in., falling mostly in summer. In some years the spring rains fail, as in 1921, and the crops are ruined. In other years, however, in spite of poor methods and implements, sufficient rye and oats are grown in the north to allow of export. Potato and flax cultivation is increasing and there are a few indications that the traditional three-field system is being replaced by more intensive methods. Horses, cows, sheep and pigs are reared, but there is little dairying. The continuation of the railway northwards was expected to encourage dairying.

The Marii area was not a war zone in World War I, but it suffered terribly from the 1921 famine and from a disastrous forest fire, and conditions are by no means stable yet. Chalk is worked in the north and there are extensive peat beds which will prove a valuable asset when better transport is provided. There are small glass and flour-milling enterprises, and besides making wooden goods, the peasants make leather, felt, rope, string, pottery and other articles needed for daily use. There is a factory for the production of resin and turpentine. Plans for the improvement of conditions are hampered by the illiteracy of the people, the literacy rate being only 26.2%. Better provision for the present generation is made here than in some other areas, but a large proportion of children is receiving no education and medical help is altogether inadequate; trachoma, itch and other infectious diseases are widespread.

The population consisted in 1934 of Marii 51.4%, Russians 43.6%, with some Tatars and Chuvashes. The Marii were called by the Russians Cheremis. They speak a Finnish dialect akin to Mordvinian and Permian, but are much more dolichocephalic and it has been suggested that they are connected with the neolithic dolichocephalic population of the shores of Lake Ladoga. They inhabited a region farther to the west than their present habitat up to the 11th century, but moved eastward into the marsh and forest region when Slav colonization began, and were settled in their present home in the 14th century. Moscow annexed the region in the 16th century but the Marii remained separate from the Russian colonists and have retained their language and customs. (*See* also FINNO-UGRIAN.)

MARIINSK (1) a town in the Siberian area of the Russian S.F.S.R. in 56° 16′ N., 87° 50′ E., on the Kiya river, which is navigable for rafts only, and on the Trans-Siberian railway. Pop. (1926) 11,419. It has grown since 1856 as an entrepôt for the gold mines situated in the Mariinsk *taiga*, 45 m. from the railway and 65 m. from the town itself. Aluminium is found with the gold.

(2) A village of Asiatic Russia in 51° 53′ N., 140° 10′ E., occupied by the Russians in 1852, and situated on the right bank of the Amur river. It is the centre for the 27 fishing stations extending for 263 m. along the lower Amur river.

(3) A canal in the Leningrad area of the Russian S.F.S.R. linking the Kovzha river with the Vytegra river. It was built in 1808, and forms part of the Mariinsk series of waterways which connect the Volga river with the Ladoga-Neva system.

MARIMBA, a musical instrument which consists of a series of sticks of wood, cut and shaped so that each stick when struck produces a musical tone of definite pitch. As used in modern orchestras, it is placed on a wooden base, is played by striking with sticks, and has usually a range of five octaves. A liquid tone is secured by the use of metal tubes as resonators, or even by gourds. The marimba is of ancient origin, known in South Africa and Central America. It is most commonly used in popular, especially Spanish-American, dance music, but has occasionally been used by classical composers.

MARIN, LOUIS (1871–), French politician, entered the chamber of deputies in 1905, and worked on the financial commission. He was minister of pensions in the Poincaré cabinet from July 1926 until 1928, minister of health in 1934, and was a member of the Flandin and Laval cabinets, 1935 and 1936.

MARINE BIOLOGY is concerned with all kinds of living things that exist in the sea, or that are by nature dependent upon the sea at its surface or at its coastal boundaries. It deals not only with the kinds of marine organisms but also with their life histories and interrelationships. It endeavors to learn and explain the ways in which the various physical and chemical factors (temperature, light, pressure, currents, salinity, plant nutrients, etc.) of the environment operate, together with the organic factors enabling the organisms to survive and to populate every niche of the ocean from the Arctic to the Antarctic and from the surface to abyssal depths. Insofar as investigations have been made, no part of this great environment is without some type of animal life.

Kinds of Organisms Found in the Sea.—The plant life of the sea consists only of the Thallophyta (the most primitive group of plants) and a few angiosperms or flowering plants. No mosses or ferns occur in the sea. The larger of the marine plants are the green, brown and red algae and the eelgrasses. The algae are anchored to the substratum, mainly in depths less than 50 m., by means of "holdfasts." There are no true roots or vascular systems, hence the plants absorb their food from the water bathing their general surfaces. Typically they reproduce by means of microscopic spores which develop into inconspicuous male or female plants called the gametophyte generation. This generation in turn gives rise to the spore-forming sporophyte generation. The eelgrasses have an underground stem and true roots, which obtain nourishment from the mud and sand in which they grow. They are found in depths ranging up to 15 m. The submerged flowers are pollinated by floating pollen, after which true seeds are formed.

The attached plants form an important source of food for animals in the shallow water. However, the chief producers of primary food in the sea as a whole are the microscopic planktonic diatoms and holophytic dinoflagellates. These tiny plants are exceedingly numerous. Under favourable conditions they reproduce at a prodigious rate by means of simple cell division; and, being independent of the bottom, they are capable of growing anywhere in the sea where light and nutrient supply are favourable. More will be said about their importance later.

Bacteria are abundant and widely distributed in the sea. They are significant mainly in the decay of organic material. There are also marine moulds, but they are of little importance in the economy of the sea.

The animal kingdom has its greatest development in the sea. All of the major divisions (phyla) are to be found there and some (Ctenophora, Echinodermata, Phoronidea, Brachiopoda, Chaetognatha) are strictly confined to this habitat. About 44%

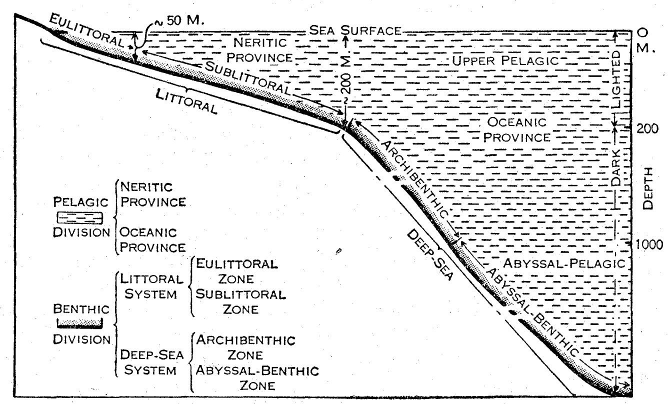
of the recognized classes, the second highest division, are exclusively marine while only about 6% are exclusively nonmarine. The Amphibia are the only type of vertebrates not represented in the sea. The fishes are primarily marine. The reptiles are represented by true snakes and turtles. Many birds are marine in their dependence upon the sea for food. Some, for example the albatrosses, spend much of their life far from land, which they frequent only for nesting. The principal marine mammals are the whales, porpoises, sea cows, seals, sea lions and sea otters.

Of the invertebrates, the crustaceans, molluscs and worms are remarkably diverse and abundant. In the sea, the Crustacea occupy a position comparable numerically to that held by the insects on land. Strangely enough, the insects are almost completely absent from the sea. Only one is known to live its whole life there. A few others skip on the surface or live in the debris on the foreshore.

The life histories of marine animals are extremely diverse. However, it can be stated that most of the invertebrates undergo some type of indirect development in which there is a free-swimming stage (*see* Invertebrate Embryology). Usually the eggs of these animals are spawned free in the water where they are fertilized. Commonly they possess only a small amount of yolk to feed the developing organisms. Correlated with this, they develop first into self-sustaining larvae totally unlike the parents. These larvae drift about in the water for a period of several days or even weeks. Finally, a complete metamorphosis takes place in which the structure and habits of the parent animals are assumed. Animals with this type of life history produce an exceedingly large number of eggs. This serves to compensate for the heavy losses attending a free larval existence. Alternation of generations is another striking feature of many marine animals, especially of the coelenterates. For example, the common jellyfish (hydromedusa) represents the solitary sexual generation, which alternates with the colonial asexual generation. The latter is a sessile hydroid that superficially resembles a tiny plant. Direct development (in which the organism assumes the adult form by gradual growth) is characteristic of the fishes, cephalopods and certain Crustacea.

The Categories of Life in the Sea.—It is possible to classify the marine organisms into three large groups, *i.e.,* the benthos, nekton and plankton, on the basis of their general habitat and locomotory effectiveness. The benthic animals and plants are those that live upon the sea floor either attached, burrowing or creeping. It includes such animals as barnacles, snails, crabs, worms, etc. All of the larger algae and some diatoms, etc., are benthic. In the nekton are placed all of the animals such as fishes, whales, seals, squids, etc., that are capable of swimming effectively against water currents and in making migratory journeys. In the plankton (*q.v.*) are grouped all of the animals and plants, usually microscopic in size, that float in the water with little or no effective swimming and therefore drift about with the water currents. The plankton is divided into (1) phytoplankton, which includes the diatoms, holophytic dinoflagellates and a few other types, and (2) zooplankton, which includes representatives, either adults or young, of nearly all animal groups from the protozoans to the fishes. The floating eggs and larvae of the benthos and nekton are known as the temporary or meroplankton in contrast to the permanent or holoplankton which comprises the organisms that are planktonic during their entire lives.

Zones of Life in the Sea.—As an aid to study of marine biology the environment is commonly classified into a number of divisions and zones based mainly upon a combination of physical and biological criteria (*see* fig.). The two main divisions are the benthic and the pelagic. The former comprises all of the bottom and the latter all of the water overlying the bottom. They are sharply defined, and typically the subdivisions of each are also clearly recognizable, but there is often a good deal of overlapping at the borders (*see* Distribution of Animals). The upper part of the benthic division is known as the littoral system. It is subdivided into an upper or *eulittoral zone,* extending from shore to a depth of about 50 m., and a *sublittoral zone,* from 50 m. to a depth of about 200 m. (considered the edge of the continental shelf). The deep-sea benthic system consists of an archibenthic zone, from 200 m. to about 1,000 m., and an abyssal-benthic zone, from there downward to the greatest depths. Within the littoral zone there is an "intertidal zone" comprising that part of the foreshore that is alternately covered and exposed by the tides. This zone may be broad or narrow, depending upon geographical and topographical position. In the intertidal zone the attached



FROM SVERDRUP, JOHNSON AND FLEMING, "THE OCEANS" (PRENTICE-HALL, INC.)

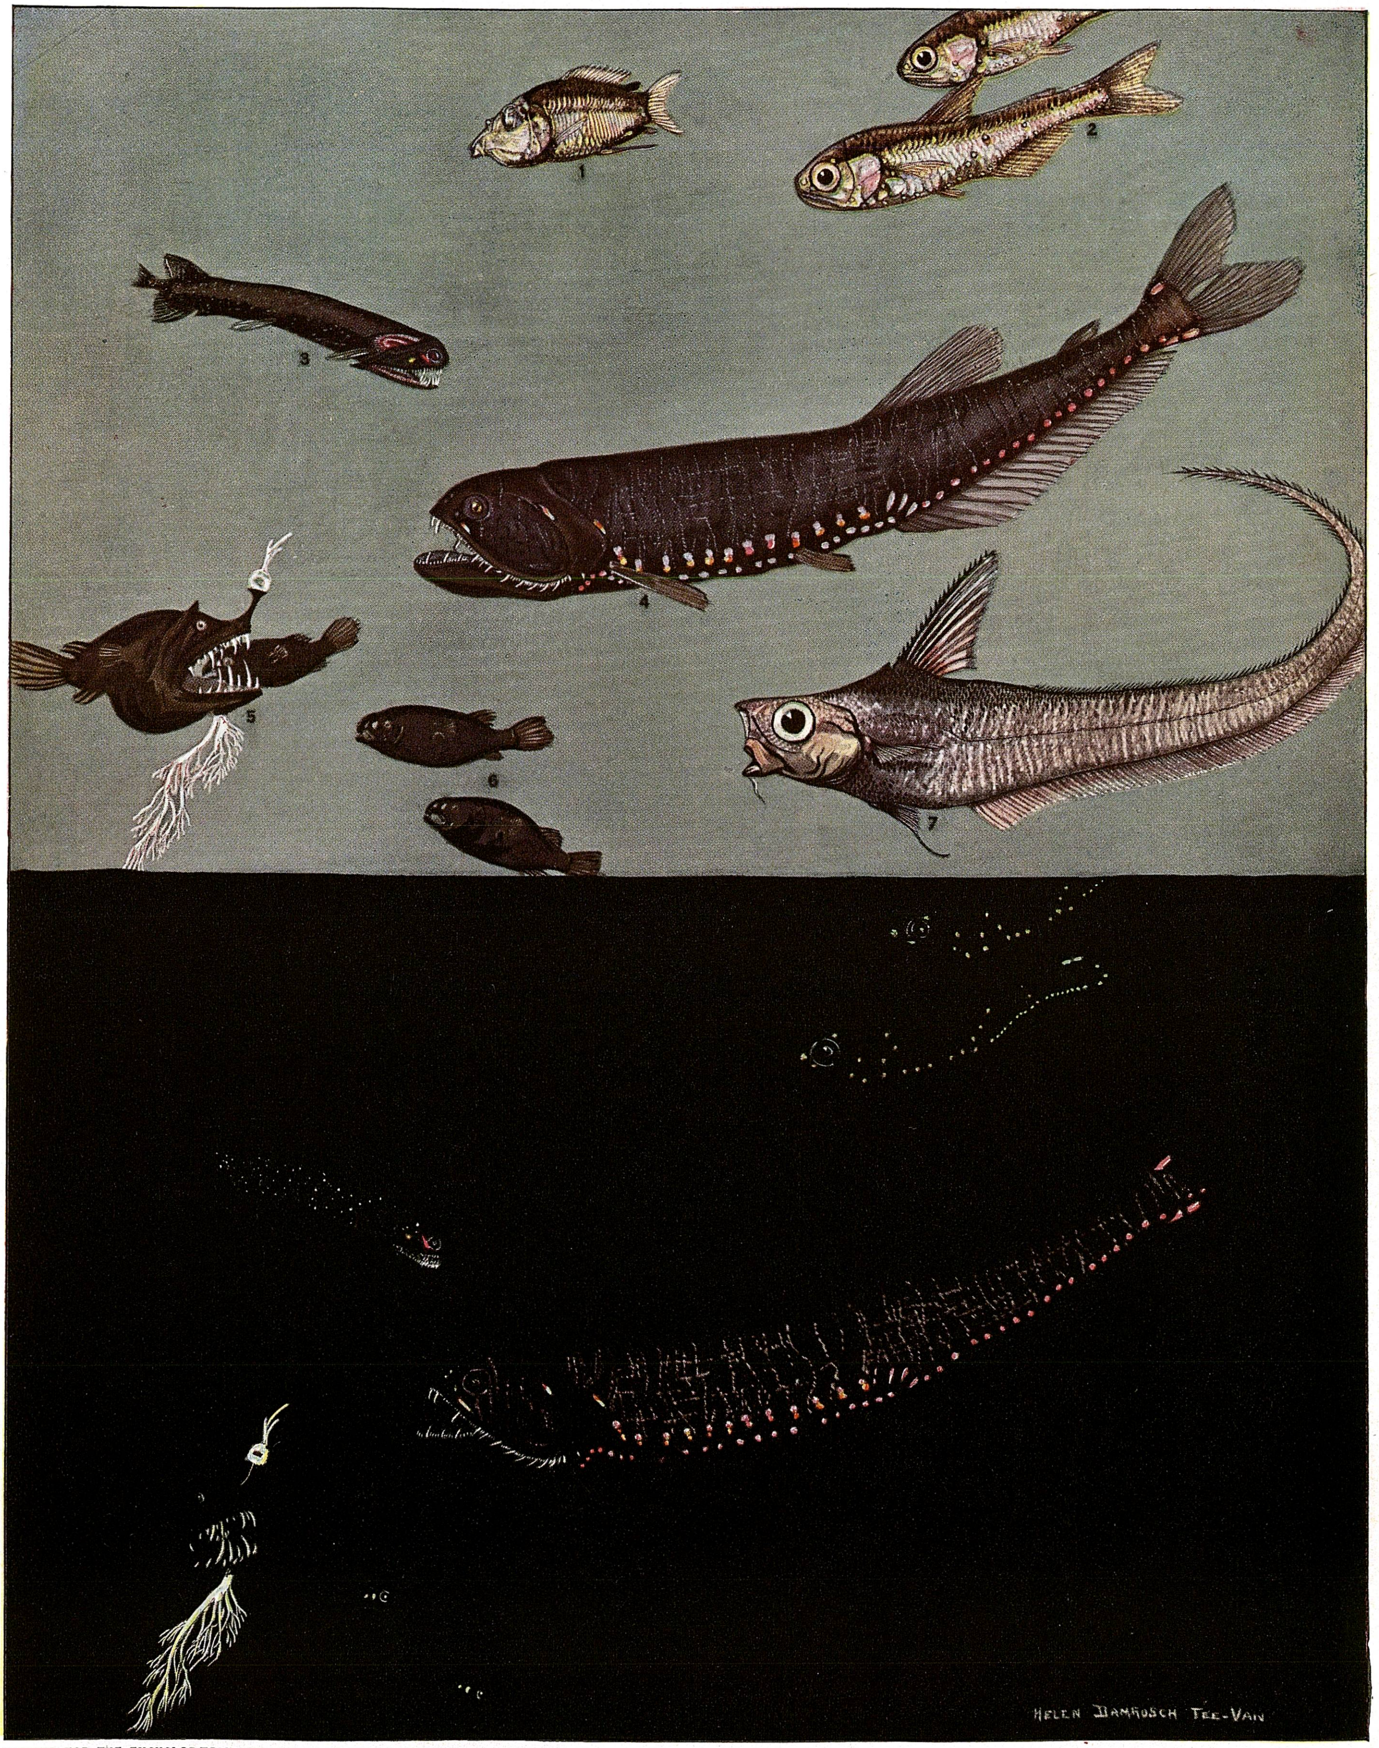
THE MAIN DIVISIONS OF THE MARINE ENVIRONMENT

plants are usually low growing and flexible to withstand the wash of waves. The kinds of animals occurring in this area depend mainly upon the type of bottom, whether rocky or sandy, etc., and upon the degree of exposure to action of the sea. The abundance of life developed in any given section of the zone is determined largely by the degree to which the bottom material can be shifted about by the waves or by other factors such as dilution by rain or runoff, exposure to heat or freezing, or abrasion by ice. During periods of low tide, many animals, such as clams and worms living in mud or sand, find protection from desiccation or heat in their moist burrows. In general, the intertidal animals of rocky exposed coasts are relatively hardy. Often they are provided with heavy streamlined shells and suckerlike structures to hold the close-fitting shell firmly against the rock. Thus they gain protection from impact of waves, and are enabled to retain some water during low-tide periods. Many molluscs, tube worms, and barnacles are firmly and permanently cemented to the rock. The shore crabs and other crustaceans are conveniently flattened to enable concealment in narrow crevices and under rocks. Weak, fragile forms such as the erect lacy bryozoans, sea fans, sea pens, spider crabs, etc., are rare in this zone since they require either the constant mechanical support of water or are unable to tolerate violent water movements. Competition for living space is a serious factor to many littoral animals. It is often critical to the survival of post-larval stages seeking space for attachment.

In the deeper part of the littoral zone the attached plants are more abundant and characteristically larger than in the intertidal area. In the kelp beds of the Pacific the long-stalked *Nereocystis* and *Macrocystis* may grow to a length of more than 100 ft., though most algae are much shorter than this. It is in the subdued light of this zone that we find the beautiful red algae, some of which are used in the manufacture of agar (*q.v.*).

In the sublittoral zone some solar light is available but it is much reduced, hence few plants of importance are found there. Coralline algae grow in the shallower portion where the bottom is rocky or covered with coral or shells. Benthic animals may be abundant in this zone, for much food is washed out in the form of detritus from the upper littoral zone and the production of planktonic plants in the overlying water is favoured by the physical and chemical conditions. (*See* Ocean and Oceanography.)

In the deep-sea benthic system (which includes more than 90% of the bottom of all oceans combined) solar light is still detectable in the shallower (archibenthic) zone while in the abyssal zone perpetual darkness prevails except for the faint and weird light produced by some of the animals living there. The waters are uniformly cold, being but a little above the freezing point for



PAINTED FOR THE ENCYCLOPÆDIA BRITANNICA BY HELEN DAMROSCH TEE-VAN

SOME TYPES OF DEEP SEA FISH

These fishes live in the depths of the sea, half a mile or more beneath the surface, where daylight never penetrates. The water is extremely cold, even at the equator having a temperature near the freezing point. Many have phosphorescent organs that serve to attract prey as well as to shed a faint light around them. In the upper half of the picture the fish are shown in detail and, below, are represented as they would appear in their natural habitat in the ocean depths. 1. *Opisthoproctus grimaldii.* 2. *Myctophum punctatum.* 3. *Malacosteus niger.* 4. *Gonostoma polyphos.* 5. *Linophryne arborifer.* 6. *Rhynchoceratias rostratus.* 7. *Macrourus violaceus*

vast areas of the ocean floor. No primary food is produced within these zones. It must be precipitated from the lighted waters above or be carried in with water currents from the littoral zones. The scarcity of primary food results in a scarcity of animals in the abyssal depths. In general, chemical conditions are not favourable for production of planktonic plants in the lighted waters of the oceanic province which lies above the deep-sea zones. Much of the plant material that is produced is eaten or disintegrated in the course of sinking to the great depths where the abyssal animals live. The deep-sea animals, in general, are modified representatives of familiar shallower-water types. As in the littoral fauna, many species are similar to or related to ancient fossil types, indicating that they too have existed for a very long time.

The Pelagic Division is the home of the plankton and nekton. It comprises all of the water overlying the floor of the sea. The coastal waters to depths of about 200 m. are the Neritic Province and the waters with greater depths are the Oceanic Province. Though no sharp line can be drawn between these two, yet each has its characteristic planktonic plants and animals. For example, the temporary plankton, *i.e.,* the eggs and young of bottom animals and the jellyfish with sessile stages, is a conspicuous part of the neritic plankton. Neritic diatoms frequently form resting spores that sink to the bottom when temperature or other living conditions become unfavourable. In the oceanic province there is greater stability of living conditions, and the formation of spores of the neritic type is not the rule. Resting spores that sink to the bottom in great depths could have no value unless they be returned to the lighted surface, and this is unlikely. The surface oceanic animals are often blue in colour. Many are hyaline. In the deep waters of the oceanic province where solar light is much reduced or absent the colours are mostly red, brown, violet-black or black. Light-producing organs are notably conspicuous, especially among the fishes living at about 300–500 m. These organs may be arranged in specific patterns, and the colour of the light produced may also be specific. This is perhaps an aid to the animals in recognizing their kind, for eyes are functional in these depths and are often unusually large or protruding, the better to intercept the faint rays of light. Below mid-depths blind fishes and squids are found, and the light-producing organs are reduced or absent. But the bottom-feeding fishes of great depths possess eyes, made useful presumably because of the luminescence of benthic animals.

FUNDAMENTAL ECOLOGICAL FACTORS IN THE SEA
I. PHYSICO-CHEMICAL

The biologically important physico-chemical factors are usually interactive and affect the organisms in various and complicated ways. It is useful, however, to discuss a few of these factors and their general applications under separate headings.

The Sea-Water Medium.—Sea water is chemically a most suitable biological medium, for it contains in solution all of the elements necessary to the structure and maintenance of organisms. The ratios of the major salts entering into the salinity of sea water are similar to those of body fluids, and the total concentration of the salts is also similar to that found in the bodies of most marine organisms, particularly in the invertebrates. Thus, there is maintained a favourable osmotic relationship between the external environment and the internal body medium. This isotonic relationship lessens the labour required by excretory organs in maintaining the proper concentration of fluids within the body and precludes the need of impervious membranes. This is in contrast with the hypertonic condition of fresh-water forms where the body fluids are more concentrated than the water and therefore tend to become diluted through osmosis.

Sea water is normally alkaline and tends to remain so because of its buffer capacity, which resists any change in pH (hydrogen ion concentration). This is a boon to the many calcium-precipitating forms.

The density of the water offers the mechanical support necessary to unarmoured or flaccid forms such as jellyfishes and sea anemones, and provides the buoyancy required by all pelagic forms.

Hydrostatic pressure increases about one atmosphere for each ten metres of depth. This restricts the vertical range of many animals that are intolerant to pressure change, but it does not act to eliminate life from the abyssal depths, where the pressure is upward of 1,000 atmospheres, *i.e.,* about 15,000 lb. per sq.in. The pressure can be tolerated because it is equal inside and outside the body tissues, and water is but little compressed. Some eurybathic (tolerating a wide range of depths) pelagic forms migrate through depths corresponding to a pressure variation of 40 or more atmospheres.

Temperature.—Compared with aerial temperatures the marine environment has only a narrow range of about $-2°$ to $30°$ C. Rarely is the seasonal range over $26°$ C, and in the deep sea there is no season with respect to this factor. Along the coast in boreal waters of Europe the difference between summer and winter temperatures is about $10°$ to $15°$ C. Though this is a relatively small range, it is sufficient to permit favourable spawning seasons for a mixed fauna of arctic-boreal (spawning from January to April between $-1°$ and $11°$ C), boreal (spawning from March to July between $4°$ and $6°$ C), and Mediterranean-boreal (spawning from May to October between $7°$ and $22°$ C) forms.

An outstanding example of temperature control of biological activity is that associated with calcium precipitation. The fact that calcium is more readily precipitated in warm than in cold water is believed responsible for the preponderance of heavy-shelled animals in the tropical waters as compared to the cold waters of higher latitudes. A temperature of about $20°$ C or more is required for a vigorous growth of the reef-producing corals. They are therefore confined to shallow water of low latitudes, especially to the western portion of tropical seas where upwelling of deep cold water is not so conspicuous a feature as it is along the west coasts of Africa and the American continents. The skeletal structures of deep-sea animals are only weakly developed, owing apparently to the difficulty of calcium precipitation in low temperature combined with great hydrostatic pressure. For instance, the sea urchins of the deep sea are leathery, and the many calcareous sponges occurring in shallow water are entirely replaced by siliceous species below a depth of 300 m.

The number of species of animals occurring in tropical seas is far greater than that of the colder seas, but the density of the population is usually less. This probably results from acceleration of biological processes in general by the higher temperatures.

The animals of cold waters frequently grow to a larger size than the same or related species living in warm water. In the case of planktonic forms it is thought that the greater viscosity of cold water is partly responsible, since it enables larger forms to survive with less expenditure of energy in keeping afloat. A lowering of temperature from $25°$ C to $0°$ C doubles the viscosity and this is very important to floating forms with a density near that of water. In the cold-water forms there is also a longer growing period before sexual maturity is reached, and this may contribute to the larger size and greater age attained.

A study of the temperature and salinity tolerance of organisms is important, not only to an understanding of present-day fauna, but it provides a key to the interpretation of ecological conditions in the ancient seas that have left their histories written in the fossil remains of their inhabitants.

Oxygen.—In the sea the maximum oxygen content is only about 9 ml./litre compared with 200 ml./l. for air. In the "oxygen minimum layer" of mid-depths of the great oceans and at or near the bottom in many bays or basins, there may be little or no free oxygen. Hence many animals have a precarious existence with respect to this factor. In experimental tests *Calanus finmarchicus,* a cosmopolitan planktonic copepod, succumbed when the oxygen content was lowered to between 1 and 2 ml./l. at temperatures of $5°$ to $15°$ C. In nature there appears to be, however, a somewhat greater degree of tolerance to low concentrations, for *Calanus* has been taken from $7°$ C water with an oxygen content of less than 1 ml./l. Sluggish benthic animals sometimes occur on mud bottoms with extremely little oxygen. But only anaerobic bacteria can survive when there is a complete absence of oxygen with its accompanying increase of hydrogen sulphide. There are many such stagnant environments. Classical examples of these are the deep waters of the Black sea and certain deep Norwegian fjords that have at the mouth a shallow sill that prevents free circulation of bottom water with the outside. The water strata overlying these toxic basins may teem with plant and animal life. Occasionally owing to storms, dense water may be forced in over the sill, and creeping along the bottom it displaces the toxic water upward with catastrophic results for the animal life. For the ocean in general, however, there is ample oxygen for animal respiration even in abyssal depths, as discussed below. Respiration in sea water is believed to be facilitated by the presence of carbonates that make the elimination of carbon dioxide easier than in fresh water.

Light.—This factor has its greatest significance as a source of energy for photosynthesis by plants, but it is also closely associated with the behaviour and structure of the animals, as a few selected examples will reveal. It is believed to be the stimulus controlling the diurnal migrations of countless numbers of pelagic animals, especially of the plankton that live at depths of about 50 to 300 m. where the light is much diminished and diffused. The copepods and chaetognaths are the animals that have received most study with respect to this behaviour. During the daylight hours they seek depths well below the surface, but as sunset approaches they slowly swim toward the surface, having their maximum distribution there usually between sunset and midnight.

The reduction of solar light in depths of 300 to 1,000 m., and its total absence in the abyssal depths, has left an unmistakable stamp on the animal life. The uniform colours, light-producing organs, and modifications of the eyes characteristic of these animals have already been mentioned. Various types of tentacular organs, some with luminescent lures, are also characteristic. In some of the fishes the males are dwarfed and parasitic externally upon the females. One or more may occur permanently attached and with the circulatory system united with that of the female. This habit is presumably an adaptation to prevent separation and loss of the sexes from each other in a sparse population.

Plant Nutrients.—In addition to the "conservative" salts that make up the salinity so important to the osmotic balance of the organisms, there are a number of "nutrient" salts, mainly nitrates, phosphates, iron and other trace elements. Unlike the salinity, the concentration of nutrient salts fluctuates widely because of irregular utilization by the phytoplankton. The degree of change in concentration therefore becomes an index of biological activity (photosynthesis) in the lighted water layers.

Upon death of the plants, or of the animals that have been nourished directly or indirectly by the plants, the nutrients are again in time returned to mineralized state. This occurs mostly by bacterial action in the deeper water where the dead organisms have accumulated. There is considerable lag, however, between utilization and regeneration of the nutrients and their return to the lighted waters. This results in seasons of high plant production alternating more or less regularly with others of low production. The function of marine bacteria in this cycle is concerned with transformations of the complex protein molecules of dead organisms and wastes to the simpler mineralized state. This is accomplished by a series of steps. In the nitrogen cycle, for example, the NH_2 group is split off from the amino acids by various bacteria, and the process is carried forward by nitrifying bacteria through oxidation of ammonia to nitrites and nitrates ($NH_3 \rightarrow NO_2 \rightarrow NO_3$). The plants may utilize the ammonia and nitrites but the nitrates appear to be their chief source of nitrogen. Its regeneration is somewhat retarded in nature. It should be mentioned here that bacteria transform not only the particulate organic matter but also the dissolved organic matter. Thus, they reclaim vast quantities of nutrient material not directly utilizable by plants or by animals.

Water Circulation.—To plants water circulation is a vital factor because only through ascending water currents, or through the slow process of diffusion, can the plant nutrients be transported from the deep water to the surface layers where they periodically become depleted owing to organic production. In shallow water the circulation is sufficiently deep to tap the nutrient supply accumulated there. Therefore, coastal areas are rich in marine life. In contrast, the waters of the open sea are commonly relatively barren because of depletion of nutrients at the surface and the absence of effective water circulation to bring about renewal from subsurface layers. There are notable exceptions; for example, along the Pacific equatorial current, where special hydrographic conditions draw subsurface waters to the surface.

To animals the water circulation has many ecological relationships, directly or indirectly. Through this agency the waters are aerated and the wastes of metabolism dispersed. As a result of the great current systems and mixing processes described under OCEAN AND OCEANOGRAPHY, even the waters of abyssal depths have sufficient dissolved oxygen to support some animal life. The distribution of temperature is so closely associated with water currents that the endemic distribution of stenothermic (thermically sensitive) animals coincides with the main current systems which are directly responsible for the dispersal of the pelagic organisms and also of the bottom organisms through their floating larvae. It is the conveyance of particulate food (plankton and organic detritus) by water currents that makes possible the many sessile animals such as barnacles, hydroids, bryozoa, oysters, etc., so characteristic of the sea.

II. ORGANIC

In the foregoing, some of the relations of the external physical and chemical factors to the lives of marine plants and animals have been considered. We have now to consider some of the interrelations of the organisms themselves. These are mainly nutritional, and, to gain an understanding of the fundamental aspects of these relationships, we must look first to the microorganisms making up the phytoplankton and the zooplankton, and the way in which these are utilized.

Pelagic Organisms.—It has been pointed out that sea water is a dilute nutrient medium suitable for plants, but only about 2% (*i.e.,* the upper littoral zone) of the sea bottom has sufficient light for attached plants to flourish, and much of this is unsuitable because of unfavourable bottom for attachment. In order to utilize the vast resources of plant nutrients from the surface to depths of about 50 m. over the entire sea, diatoms, dinoflagellates and a few other microscopic plants have become adapted to a passive floating existence. The principal feature adapting these plants to a floating life is their small size. The rate of sinking of an organism heavier than water is governed by the ratio of surface to volume. The simplest way to increase this ratio is by reduction of absolute size. The development of spines and the formation of chains of cells are additional adaptations of these plants. Attesting to the success of these means of populating the vast surface areas of the oceans is the fact that no other type of plants has come into being that can so completely meet the requirements of the pelagic habitat. An apparent exception is the sargassum weed, which is present in large quantities in the Sargasso Sea. This, however, is a littoral algal plant drifted to sea where it is able to grow vegetatively and to accumulate under special conditions.

In order to utilize the abundant supply of dispersed and microscopic plants mentioned above, special types of plant eaters are required. This demand has led to a planktonic population of very small herbivorous "filter-feeders." Chief among these are the small (0.05 to 8 mm.) but exceedingly numerous Copepoda (*q.v.*). These animals are provided with a screening device formed by bristles of the mouth appendages (first and second maxillae). There are of course many other small grazers including the euphausiids, some protozoans, the larval stages of many benthic invertebrates and some fishes.

These tiny herbivores accomplish two important ends in the economy of the sea; namely, (1) utilization of the microscopic primary food, and (2) conversion into animal substance sufficiently large to be caught by the larger but less numerous carnivorous filter feeders or plankton feeders of the sea. Among these are the plankton-feeding fishes such as the herring, sardine, anchovy, menhaden, mackerel, etc. These fishes screen the copepods and other small plankton food from the water with the aid

SURFACE LIFE OF THE OCEAN

1. Caribbean flying fish *(Halocypselus evolans)* pursued by (2) an oceanic bonito (*Gymnosarda pelamis*). 3. Portuguese man-of-war (*Physalia arethusa*) whose long tentacles are fatal to all invaders except (7) the diminutive Portuguese man-of-war fish (*Nomeus gronovii*), which spends its life undisturbed among the streamer-like arms. 4. *Velella cyanea*. 5. Sargasso weed and small fish that inhabit it: (8) mouse fish (*Pterophryne histrio*), (9) naked mollusc (*Scyllaea pelagica*), (10) swimming crab (*Portunus sayi*). 6. *Nectalia loligo*. 11. *Beroe ovata*. 12. Venus' girdle (*Cestus veneris*). 13. *Dactylometra quinquecirrha*. 14. Common jellyfish (*Aurelia flavidula*). 15. *Pyrosoma atlanticum*

of the "gill rakers" through which the water must pass in its course through the mouth and out over the gills. It is significant that fishes of this type constitute the bulk of the fish population of the sea.

Other notable plankton feeders are the whalebone whales (*see* CETACEA). These giants—among which is the largest of all animals, the blue whale—gather large quantities of plankton by means of the frayed ends of the whalebone plates suspended in the mouth. The copepods, euphausiids, pteropods, etc., are screened from the water as the animals swim with open mouth. Herring are also caught in this manner. It is well known among whalers that these animals make long migrations, seeking out feeding grounds such as the Antarctic, where there is a notable production of phytoplankton and zooplankton. The basking shark, the largest of all fishes, also feeds upon the zooplankton.

The plankton-feeding fishes also feed more or less upon each other and are in turn the prey of other larger predaceous fishes; for example, the tunas, dolphins, salmon, etc., that are not provided with efficient means for filtering the water.

Noteworthy among the predaceous pelagic animals are the toothed whales. The sperm whale dives to great depths in search of the giant squid upon which it feeds. The killer whales are known as wolves of the sea because of their voracity and habit of hunting in packs. They feed not only upon fish, seals and birds, but attack also other larger whales.

Benthic Organisms.—The significance of microscopic particulate food in suspension is also evident in a study of the structure and feeding habits of the bottom-dwelling animals. Many of these animals, such as the barnacles, clams, mussels, sponges, tube worms, hydroids, etc., feed upon plankton or floating detritus as it sinks or is swept within reach by water currents. These animals are often called suspension feeders. Many kinds of screening and concentrating devices are used for this purpose. Usually they consist of bristles, gratings, ciliated tentacles or grooves, or even mucous sheets or films that are eaten after becoming filled with microscopic food. Water is pumped through these structures, or the food-gathering bristles are swept rhythmically through the water. Among the detritus feeders there are also many that, like the sea cucumbers and certain worms, ingest mud and bottom ooze for the digestible material it usually contains. Much of this material is dead plankton precipitated from above. Finally, there are a great number of rapacious benthic animals like crabs, lobsters, bottom-living fishes, cephalopods, sea stars and worms that are relatively active and that feed upon the scavengers and plankton feeders and upon each other.

Many benthic animals are found habitually associated together in more or less distinct communities of greater or lesser extent. The principal components of these associations have similar requirements or tolerances with respect to substratum salinity, exposure, etc. They may, in turn, condition the environment so that yet other forms with similar salinity tolerances become associated with them because of the food they supply or the shelter they offer. As an example we may consider an intertidal association in which mussels and barnacles, both requiring hard surfaces for attachment, cover the rocks and thus provide special shelter and concealment for many small crabs, worms, isopods, etc., while the whole assemblage supplies food for the more highly active and predaceous forms such as fishes, large crabs and sea stars. Thus, through selective survival of pelagic larvae, or through trial and error in seeking out suitable conditions, there are built up markedly different associations on rock, mud and other habitats. Associations of benthic animals (and also the pelagic forms on a larger scale) are striking phenomena of the sea. Frequently the attached plants furnish a great deal of primary food for the coastal communities, but most of this food is used, as explained above, only after it has become detritus. The growing plants are of great ecological significance, however, as animal sanctuaries. They provide protection against predators, afford surfaces for attachment, lessen the shock of waves, and in the intertidal zone they shield against heat and desiccation. Usually the primary food and also the plankton and detrital food of the non-predaceous members of an association are brought into the area through the agency of water currents or precipitated from the water above. Where environmental conditions are rigorous with respect to physical and chemical factors, many potential members are eliminated but those suitable to survive may become very abundant, owing to absence of serious competition for space and food. Among individuals within the community there are always other more restricted and intimate relationships such as commensalism, symbiosis and parasitism.

MARINE BIOLOGICAL METHODS

The preliminary procedure in investigating the organisms in any area of the sea is descriptive and consists of identifying, describing and cataloguing the many species of animals and plants that occur within the area. This is a very large task, especially in hitherto unstudied areas. It requires the labour of several investigators, each of whom is a specialist in one or more of the biological groups involved. The reports and monographs published by these specialists give formal diagnosis of each species and record its distribution. These reports are tools in the hands of subsequent investigators dealing with analytical studies such as the ecology of the individual species or groups of species. (*See* ECOLOGY, ANIMAL.)

The methods of collecting and of analyzing and studying the material after it has been collected depend upon the objectives of the investigations, whether taxonomy, embryology, ecology, etc. These objectives also determine the number and kinds of physical or chemical observations that are made in the field in conjunction with the collecting. The equipment and procedures available for the study of the inorganic factors of the environment have been vastly improved since the famous "Challenger" Expedition of 1873–1876, which has been the model for subsequent work. Accurate reversing thermometers now enable determination of temperatures at any desired depth and the bathythermograph provides a continuous temperature record downward from the surface. Light intensity can now be accurately measured with photoelectric apparatus lowered into the sea. Chemical procedures assure proper evaluation of oxygen, salinity and the major plant nutrient salts. Coring devices are available for use in collecting undisturbed bottom sediments for study of microorganisms in the muds. Sonic depth finders provide numerous or continuous soundings. These are important devices, some of which have grown out of the needs of marine biologists for accurate and quickly obtained data to use in ecological interpretations. Others are borrowed directly from other branches of marine sciences—physics, chemistry and geology—and applied to biological research.

In ecological work the numbers of individuals of any species occurring in a unit space in a given area are determined and correlations made with the external environment. The numerical and nutritional relationships to other animals and plants in the community are also determined in order to ascertain the relative importance and interdependence of the various members. For embryological studies of the animals, living specimens are brought to the laboratory where the processes of fertilization, cleavage and larval development are observed under the microscope. Similarly, the algal spores shed from living plants are cultured under experimental conditions to learn their life histories. The planktonic diatoms are likewise grown to ascertain their nutritional requirements and rate of photosynthesis under various conditions of light. Numerous other studies; for example, the osmotic balance, oxygen consumption, reaction to light, etc., require living material for experimental procedures under controlled conditions. But the common objective of experimental and field observations is to understand the organisms in nature and under natural conditions. For these reasons marine biological laboratories are established at seasides where live material is available and natural conditions observable (*see* below).

Benthic collecting in the intertidal zone requires but simple equipment for digging out the burrowing forms or prying loose those that are attached to rocks or piles. When statistical studies are involved, the area covered and its relative position with respect to mean low tide is carefully recorded, for nowhere else in nature are specific organisms confined to such a narrow vertical range as are some of the species living within the intertidal zone.

In deep water a dredge operated from a power or sail boat is used. Where the bottom is smooth, various types of trawls are commonly used instead of the dredge. For quantitative surveys in shallow water, some type of "grab"—such as the Petersen grab—that scoops up the material from a known area of bottom (*e.g.*, $\frac{1}{4}$ sq.m.) is employed.

In collecting the microscopic plants that make up the phytoplankton, fine silk nets are used for qualitative work; but, for quantitative studies, "water bottles" (cylindrical metal containers of a litre or more capacity) that can be closed at any desired depth are used to obtain a definite volume of water together with its passive organisms.

In the analysis of phytoplankton collections, an aliquot sample of the water collected by means of the water bottle is centrifuged to concentrate the diatoms and dinoflagellates in the sample. The organisms thrown down in this manner are then counted on a ruled slide or in a counting chamber under the microscope. From these counts calculations are made giving the number of plants per litre of water. Sometimes the whole sample is filtered through a fine net and examined, and computations made as above.

Chemical methods are also used for determining the amount of phytoplankton. With this method extractions with acetone are made of the yellow-green pigments in the chlorophyll. The pigment obtained in this manner in a known volume of acetone is determined colorimetrically with an arbitrary standard of 25 mg. of potassium chromate and 430 mg. of nickel sulfate dissolved in one litre of water. The results are reported as "pigment units" which amount to 3.3×10^{-3} mg. of organic carbon. The ratios, by weight, of the major constituents of plankton are carbon, 41; nitrogen, 7.2; phosphorus, 1.

The zooplankton is more sparse and irregular in its distribution than is the phytoplankton, hence larger nets of coarser bolting cloth are used, or other filtering devices—such as the Hardy Plankton Recorder or the Clarke-Bumpus Plankton Sampler—that likewise strain a relatively large quantity of water are employed.

The volume of the material collected with the nets is determined by allowing it to settle in graduated cylinders or by draining off the fluid. The organisms of interest are counted and the stages of development noted. If the volume of water filtered in collecting the sample can be determined, the number of organisms or the volume in cubic centimetres is given for one cubic metre of water or for one square metre of ocean surface.

The methods for collecting nektonic animals for study of marine biology are essentially those of commercial fisheries; various trawls, nets, setlines, traps, etc., being the standard equipment. Much of the biological material studied or the statistics accumulated are obtained directly from the commercial catches of fish or whales. This is particularly true where the biological research is conducted by some government agency for the conservation of marine fisheries resources. Statistics are kept relative to the size of catch, size of fish or whales, area fished, gear and effort involved. In the study of migration of certain fishes like the salmon or the halibut, living specimens are tagged from commercial catches, liberated and later recovered largely from similar catches. Our information on the biology of whales has resulted largely from co-operation between scientists and whalers. (*See* ZOOLOGICAL COLLECTING: *Marine Collecting,* for other details.)

MARINE BIOLOGICAL STATIONS

Marine biological stations are laboratories (usually operated by universities or government agencies) where the various types of research and studies related to marine life can be most efficiently carried on. For this reason they are established at seasides where living plants and animals can be readily collected for laboratory study or observed under natural environmental conditions. They are usually situated well away from harbours that are likely to be contaminated with sewage or oil. Aquaria with circulating sea water are maintained for the purpose of display or study of live material. Vessels equipped for dredging or trawling are often owned or chartered by the laboratories, and row boats are available for work along shore. Some laboratories are also equipped with diving gear for observations in shallow water. Many of the biological stations are officially open only during the summer months, when they are attended by investigators and students from universities or other schools. Some of the stations now maintain resident staffs engaged mainly in research.

The most famous marine biological station is at Naples. It was founded in 1872 by Dr. Anton Dohrn. Another well-known Mediterranean station was founded by Prince Albert I at Monaco. The largest U.S. station is at Woods Hole, Mass., where there are also an oceanographic institute and a fisheries laboratory, combining to make this a famous centre for marine biological studies. Other important U.S. stations are at Mt. Desert Island, Maine; Cold Spring Harbor, Long Island, N.Y.; Solomons Island, Md.; and on the Pacific coast at La Jolla, Calif.; Pacific Grove, Calif.; and Friday Harbor and Seattle, Wash. The Fisheries Research Board of Canada operates stations at Nanaimo, B.C., and at St. Andrews, N.B. Prior to World War II there was one German station, a large excellently equipped laboratory at Helgoland. The Scandinavian countries operate several good stations along their coasts. The principal British station is that founded by the Marine Biological Association of the United Kingdom and is situated at Citadel Hill, Plymouth. Other English and Scottish biological and fishery stations are at Cullercoats in Northumberland; Port Erin in the Isle of Man; Millport and Aberdeen in Scotland and at Lowestoft. There are 15 or more French stations, the better known being at Roscoff and Arago de Banyuls. Russia has about 11 stations most of which are for fisheries research. In the Orient Japan has maintained about 14 stations, and before 1936 China maintained four stations. There are fewer tropical and semitropical stations. Among the better known of these is the Bermuda station.

Throughout the world in 1937 there were about 105 marine biological stations and 25 purely fisheries research stations. About one-half of the former included fisheries investigations and biological instruction as part of their activities, otherwise the work was mainly general biological research. A growing need for a wider scope in marine research has led to establishment of oceanographic laboratories where biological work is carried on as actively as before but with greater facilities to study all phases of the environment as a whole, particularly at sea. *See* T. W. Vaughan (1937) for detailed accounts of the various institutions.

W. J.)

MARINE ENGINEERING. There are three distinct types of marine engines, and these may be grouped as follows: (1) steam engines with coal or oil-fired boilers; (2) internal combustion engines, such as the diesel or semi-diesel engines; and (3) the above two types with electrical transmission of power between the prime mover and the propeller shaft; viz., engines with turbo-electric or diesel-electric drives. Of course, group (1) includes reciprocating steam engines, turbines (geared or otherwise) or combined turbine and reciprocating engines. These types are described on subsequent pages.

Reciprocating Marine Steam Engines.—All marine reciprocating engines now installed are stage-expansion engines, that is, steam expands in stages from the highest pressure cylinder, through the intermediate stages, and finally exhausts into the condenser, where it is condensed and returned to the boiler in the form of feed water.

Stage-expansion engines may be grouped as follows. Compound:—In this type there are two cylinders, the high-pressure and the low-pressure. Steam actuates the piston in the high-pressure cylinder, and from there it passes into the low-pressure cylinder, completes its work in this cylinder, and finally exhausts to the condenser. *Triple expansion.*—In this engine, as its name implies, steam exerts its power in three stages before exhausting to

the condenser. *Quadruple expansion.*—In this type the steam is used four times before exhausting into the condenser, the usual design being to fit two intermediate cylinders.

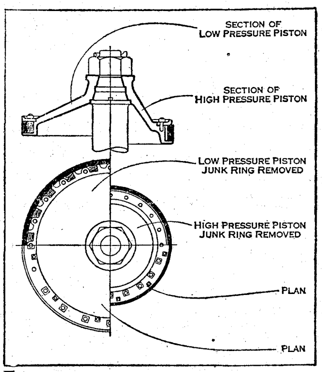

FIG. 1.—HIGH-PRESSURE AND LOW-PRESSURE PISTONS

General Construction.—The engine cylinders are supported by columns, which also act as a guide for the crossheads. This crosshead forms a hinged joint between the piston rod and the connecting rod, which is provided with turned pins on either side, connected to the forked end of the connecting rod, and provided with suitable bearings. The connecting rod is in turn connected to the crank with suitable bearings. The eccentrics governing the valve motion are keyed on to the shaft, the eccentric straps usually being made of a brass composition, lined with white metal. Link motion affords a means of quick reversal, and also allows an earlier or a later cut-off of the steam by regulating the valve admitting the steam to the cylinders. The link operates in conjunction with two eccentrics, and is actuated by means of a small steam reversing engine, or by a hand wheel connected with a reversing shaft. The reversing mechanism is placed along the front of the engine. Fig. 1 shows details of the high-pressure and low-pressure pistons of a high-powered marine reciprocating steam engine.

The advent of the marine steam turbine, the Lentz Double Compound, and the marine internal-combustion engines, and the electric transmission of power for propelling machinery certainly has led many shipbuilders to install one or the other of these

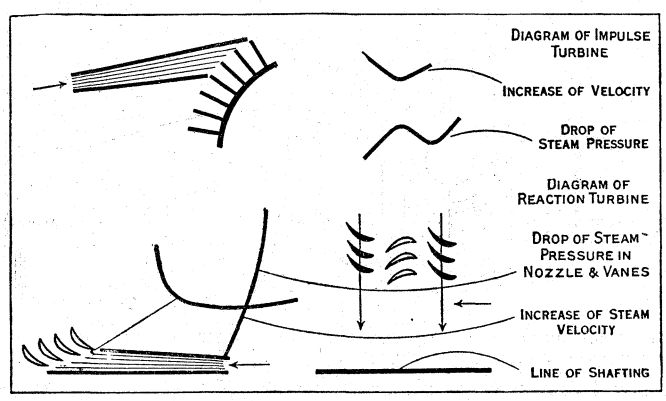

FIG. 2.—DIAGRAM SHOWING ACTION OF STEAM IN IMPULSE AND REACTION TURBINES

types, but it is interesting to note that in some recent large liners the carefully balanced triple-expansion engine has been installed. Experiments are being carried out to utilize steam at a much higher pressure than formerly, and excellent results are expected.

Combined Reciprocating Engines and Steam Turbines.—This method ensures that the whole of the expansive energy of the steam is utilized to its fullest extent. An excellent example of this arrangement is the White Star "Olympic." The arrangement has proved an economical one, and is as follows: each wing propeller shaft is driven by a reciprocating engine, the low pressure cylinder of which exhausts into a Parsons low-pressure turbine driving the central shaft.

MARINE STEAM TURBINES

The advantages of the marine steam turbine which have led to its more general adoption during the past few years are as follows: (*a*) There are fewer working parts, as no slide valves, pistons or connecting rods are required. This means also that fewer spare parts have to be carried; (*b*) the steam is supplied direct from the boilers with no intervening loss, such as occurs through glands, etc., when a reciprocating steam engine is the prime mover; (*c*) there is considerably less danger of breakdown, a big asset in the case of warships and passenger steamers; (*d*) engines are placed well down in vessel, an all-important point in warships; (*e*) there is less expenditure of lubricating oil; (*f*) there is no cylinder lubrication, thus clean feed water is returned to the boilers; (*g*) there is absence of vibration, a big factor in warships and passenger steamers; (*h*) smaller attendance is required than in the case of reciprocating steam engines; (*i*) there is superior governing (balance), good parallel running and even-turning moment; (*j*) priming (the passage of water mixed with the steam from the boilers), which would fracture the cylinder covers of a steam reciprocating engine, has no material effect on a marine steam turbine; (*k*) overloading (forcing the turbines) can be indulged in within reasonable limits; (*l*) it is more economical than the reciprocating marine steam engine except at the lowest speeds.

The large-sized turbines are more economical in steam per horse-power developed than the best triple or quadruple expansion engine, as the turbine is able to take full advantage of the whole of the expansive energy of the steam. Two well-known types of marine turbines in general use are the combined impulse and reaction turbine and the impulse turbine. There are naturally many modifications of these types.

Combined Impulse and Reaction Turbines.—This arrangement consists of the usual reaction turbine with a single impulse stage, in the nozzles of which there is a considerable pressure and consequently loss of heat, giving a large proportion of effective work in this stage. The effect of this is the shortening of the turbine with economy, and permitting for moderate powers of the complete expansion of the steam on a single shaft. There is a saving in weight and space, the machinery arrangement is simplified, and the propulsive efficiency is improved with slower propeller speed. The nozzles are grouped in a box on the forward side of the cylinder, the impulse rotor blading is fitted on a rim, and for astern working, astern nozzles are fitted. This arrangement is particularly suitable for light warships. The action of the impulse turbine and the reaction turbine is shown diagrammatically (fig. 2).

Geared Turbines.—Fig. 3 shows the general arrangement. These turbines are rapidly gaining favour for marine propulsive purposes. The chief trouble with the marine turbine arose with the propeller. It is necessary that a turbine for maximum efficiency should run at a high rate of revolution, while for propeller efficiency, much lower rates of revolution are necessary. The solution for this was by the introduction of some form of gearing between the turbine and the propeller. Experiments have been made with several forms of reduction gearing, such as

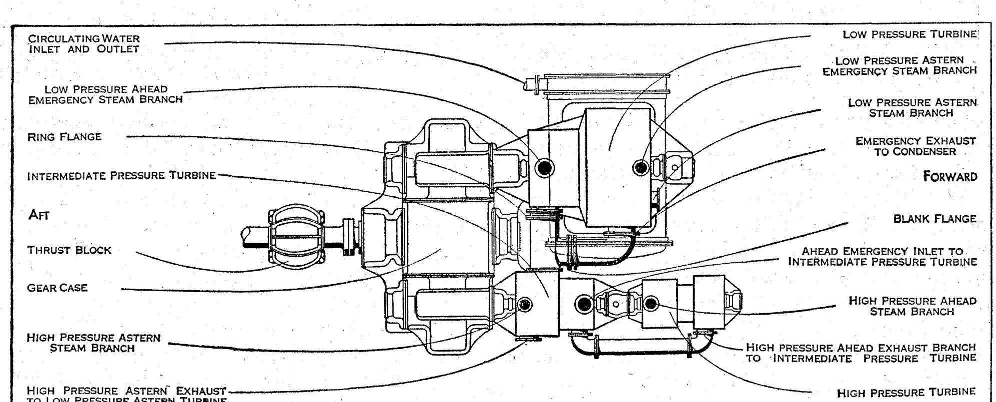

FIG. 3.—GENERAL ARRANGEMENT OF MARINE GEARED TURBINES

the electrical, hydraulic and mechanical. Mechanical gearing appears to show advantages over the other forms, an efficiency of over 98% being obtained in the case of the single reduction and over 97% with the double reduction. There is practically no limit to the ratio of such reduction. A complete unit of geared turbines is to be found in certain twin screw torpedo-boat destroyers. Double-reduction gearing finds favour for the following reasons: (*a*) the type permits larger ratio between revolutions of turbines and propellers without excessive size of gear wheels; higher revolution of turbine permits, for the same power, smaller turbines, and increase in the number of turbines for the same power further reduces the size of each unit; (*b*) high revolutions or greater blade speed are possible, resulting in the nearest approach to the point where the blade speed in relation to the steam speed gives maximum economy; (*c*) a small turbine permits of a pivot-thrust block being used, as the dummy can be omitted, and all unbalanced load taken by the block; (*d*) small turbines have small rotors and can thus be made of a much more robust construction; (*e*) variations in temperature for any single turbine are kept moderate, and these turbines are therefore suitable for use with superheated steam; (*f*) the parts being smaller, the turbines can more easily be overhauled, repaired or renewed. Plate II. (fig. 5) shows an example of double-reduction gearing.

The Turbo-electric Drive.—The first application of electricity for the transmission of power between the prime mover and the propeller shafts in ships was first adopted in America in the year 1908. This proved most successful, and many of the world's warships are now so equipped. The electrical equipment is an alternating current generator suitable for direct coupling to a high-speed turbine, a motor of suitable speed for direct coupling to the propeller shaft, a direct current exciter or an auxiliary generator, from which direct current can be obtained, and suitable control gear. The whole can be regarded as a reduction gear, the ratio of reduction being proportional to the number of poles on the generator and motor. The main driving power is transmitted magnetically across large air gaps giving an elastic medium for absorbing shocks, and thus making it a simple and reliable form of speed reduction. The electric drive lends itself particularly to any speed reduction between the turbine and the propeller. The general advantages are perfect balance with no sliding surfaces and no reciprocating parts, thus making this method free from vibration and smooth in operation; the electric drive is noiseless, an important factor in passenger ships; there is perfect control in heavy seas without danger of the propellers racing; the rapid manoeuvring of the machinery is a very big asset in warships; and the upkeep costs are less than with any other form of marine propelling machinery.

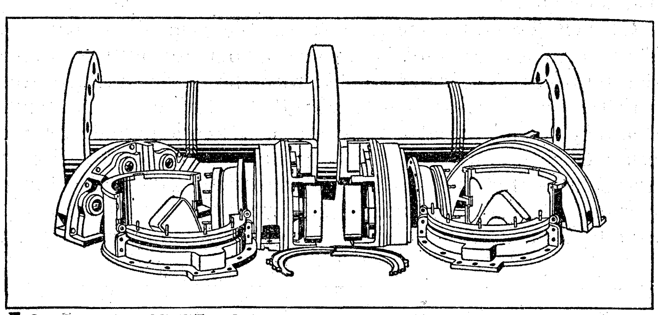

FIG. 4.—COMPONENT PARTS OF MICHELL THRUST BLOCK, SHOWING THE SINGLE COLLAR ON THE SHAFT

The Michell Thrust Block.—With all marine installation of gearing a Michell thrust block is essential to the satisfactory working of the gears. The whole of the gearing is an independent unit as far as attachment to the turbine is concerned, being driven from the turbine by a flexible coupling. It is necessary, therefore, to hold the gearing in a position from which it will not vary more than a predetermined amount. There being no collars for this purpose on the gear shaft, and as a slight lateral movement is necessary when the thrust collar moves over from driving ahead to astern, the whole of the gearing is located from the thrust block. The Michell block possesses marked advantages over the older form of multiblock. The device (fig. 4) consists of one collar on the shaft, the thrust being taken by a series of pads capable of a slight rocking movement. These pads maintain a continuous flow of oil between the metal surfaces, which are thus kept apart by as many oil wedges as there are pads to produce them.

MARINE INTERNAL COMBUSTION ENGINES

One of the principal reasons which has led to the adoption of the internal-combustion engine for marine propulsion is the thermal efficiency of this prime mover. The thermal efficiency of a diesel engine is 40% to 45%, according to size; whereas that of a reciprocating steam engine with coal-fired boilers is 20% to 25%. As regards running, the fuel bill is about half that for an oil-fired boiler ship fitted with geared turbines; there is a very great saving of space occupied by the machinery, and a reduction in personnel. Against these advantages we have the greater initial cost, complication of parts, a greater number of spare parts have to be carried, and it is probable that the repair and upkeep bill will exceed that for steam units. For a given power the diesel compares unfavourably as regards weight with the steam turbine and oil-fired boiler combination, and the head-room is greatly limited (this, especially from a naval point of view, is a marked disadvantage); but the possibilities of this prime mover are endless. The diesel has been and is being installed in large liners, and doubtless when a speed of, say, 25 knots can be reached, combined with a simple and reliable design of engine, this type of engine will be installed in the mammoth Atlantic record-breakers. The present types of marine internal-combustion engines work either on the two-stroke or on the four-stroke principle; but many competent authorities affirm that the marine oil engine of the future will be a double-acting two-stroke with port-scavenging, this design giving an engine of low initial cost and simple construction. The solid (or mechanical) injection of

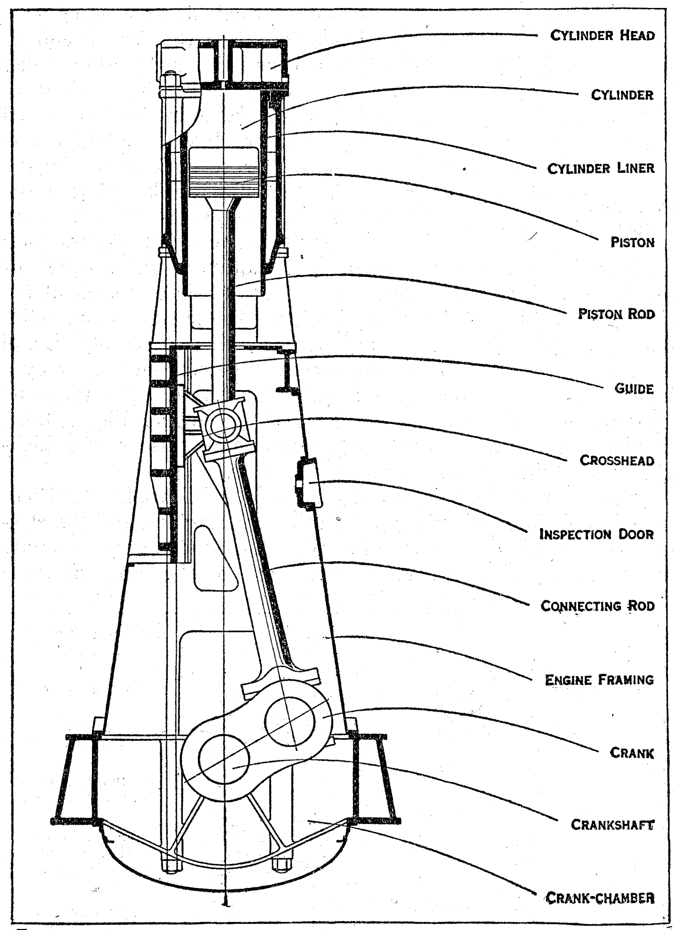

FIG. 5.—BURMEISTER AND WAIN MARINE DIESEL ENGINE, SHOWING SECTION THROUGH ONE CYLINDER

the fuel is likely to be adopted generally in preference to the air injection system, owing to the reduction in first cost that is obtained by its use.

Operation of the Four-stroke Marine Diesel Engine.—The working principle of this engine is as follows: during the first downward stroke the piston draws air in through the suction valve; during the return stroke the suction valve and all other communications with the atmosphere are closed and the air in the cylinder is compressed. Towards the end of the stroke, the fuel pump injects into the cylinder the necessary quantity of oil for the combustion stroke, so that when the piston arrives at dead centre the fuel burns rapidly, raising the pressure and temperature in the cylinder. During the next downward stroke of the piston the burnt gas is expanded, doing work; during the fourth stroke, the piston sweeps out the burnt gasses into the atmosphere through the open exhaust-valve, completing the four cycles. Fig. 5 shows a section through one cylinder of a four-stroke marine engine by Burmeister and Wain. For single-screw ships, long-stroke engines running at low revolutions are employed in order to obtain a good propeller efficiency. For twin-screw ships, short-stroke engines are used, as higher speeds are permissible without reducing the propeller efficiency.

The Two-stroke Marine Diesel Engine.—A good example of this marine internal-combustion engine is the Sulzer two-stroke,

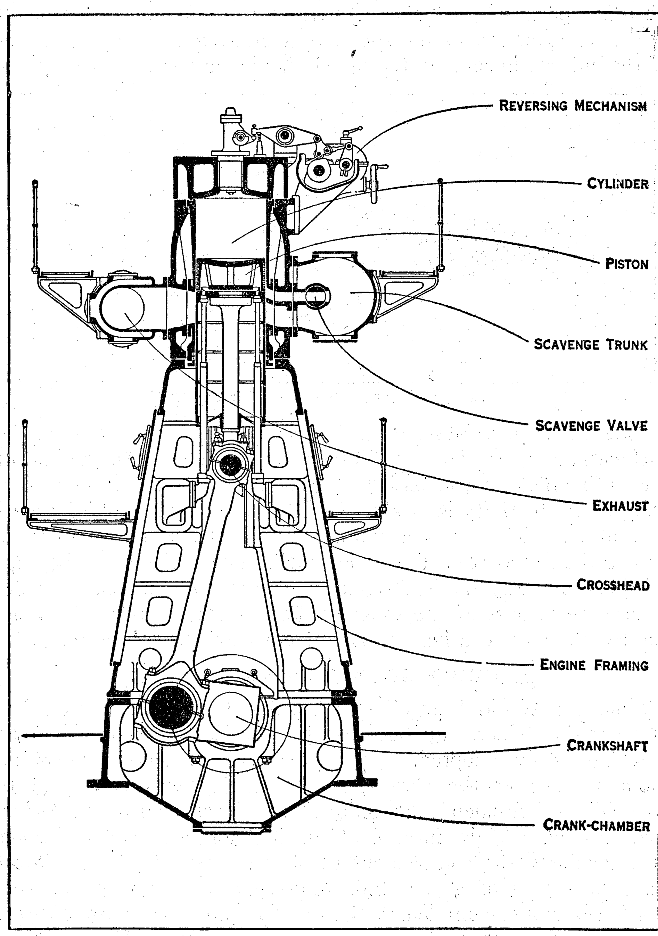

FIG. 6.—SECTION THROUGH SULZER TWO-CYCLE MARINE ENGINE

a section through this engine being shown (fig. 6). The distinctive feature of this design is the method of scavenging and recharging the cylinder; *i.e.*, removing the burnt products of the firing stroke and replacing these with a charge of fresh air. This is accomplished as follows: The scavenge air supplied by a pump is led to the scavenge trunk, which communicates with the cylinder through two ports at the bottom of the liner, the upper port being controlled by a valve. When the piston is at the top of its stroke, and combustion takes place in the usual manner, both ports are closed by the piston skirt. The piston then moves down and first uncovers the upper scavenging port, but the valve being closed no action occurs until the piston moves farther down and uncovers the exhaust ports situated opposite the scavenge ports. Exhaust commences immediately and relieves the pressure in the cylinder, so that when the lower range of scavenging ports is uncovered the air enters the cylinder and commences to sweep out the remainder of the exhaust products. The scavenging valve opens before the completion of the down stroke, so that the scavenging takes place through both upper and lower ports, and continues through the upper port until after the piston on its upward stroke has covered the exhaust port. This arrangement ensures a most effective means of clearing out the exhaust products, and also provides for an excess quantity of air by enabling the compression stroke to commence slightly above atmospheric pressure. In other words, supercharging is possible. In marine engines of over 1,000 h.p. electrically driven scavenging pumps are provided.

The Diesel-electric Drive.—The application of this drive has been made to smaller ships. The employment of electric transmission allows comparatively small diesel engines, each coupled to a generator, to be used, the power being transmitted to motors on the propeller shafts. The arrangement and speed of the engines are independent of the propeller shaft, and the engines are short and not of excessive height. As there is no mechanical connection between the engines and the propeller shaft, the subdivision of the ship with watertight bulkheads, to comply with the regulations, is simplified. In vessels fitted with this type of machinery it will be possible to use the same prime mover for both propelling and auxiliary purposes.

MARINE STEAM GENERATORS

Water-tank Boilers.—In this type of marine steam generator the *fire passes through the tubes* and the water circulates outside the tubes. The principal boiler of the mercantile marine, and, till late years, of the various navies of the world, is the cylindrical Scotch marine boiler (fig. 7), the various parts being clearly indicated. The experience gained after many years with this boiler proved it to be undoubtedly a good, safe and easily understood generator, and also comparatively easy to clean. These boilers are made single-ended and double-ended, and are cylindrical in shape with flat ends. The illustration shows a single-ended type. The furnaces or flues are corrugated in order to allow for expansion and compression. One to four furnaces are fitted, either terminating in a common combustion chamber, or, a better plan, being fitted with an independent combustion chamber to each furnace. In the boiler shown the furnaces are fitted each with separate combustion chambers, and are stayed as shown. The tubes are of commercial size, being obtainable in practically every port in the world, and are fitted with cap ferrules at the combustion chamber end to prevent burning away of the tube ends. The boiler is, however, excessively heavy, unequal strains are set up (unless a feed water circulator is used), and the space per horse-power is much greater than with the water-tube types. Another point against this boiler is the length of time taken to raise steam, ten to 14 hours usually being allowed. Against these disadvantages we have the greater quantity of water carried, with consequent ease of keeping steam and water levels, and the same skill is not required in firing up, cleaning fires, etc., as is necessary with the water-tube types. The boiler is fairly economical as compared with the water-tube types. Of course, in the case of explosion, much greater damage would be done owing to the greater steam and water space.

Water-tube Boilers.—As its name implies, in this type of generator the *water passes through the tubes,* and the heat from the furnaces outside the tubes. It is only within the last few years that the water-tube boiler has been seriously considered as a rival to the cylinder water-tank generator. For naval purposes, of course, there is no question as to which type is suitable; and for both naval and mercantile marine purposes the two outstanding features of the water-tube boiler are common. Briefly, these two points are as follows: (*a*) the water-tube boiler is very much lighter; (*b*) the boiler requires much smaller space for the same horse-power, or gives much greater horse-power for the same space. Both these fac-

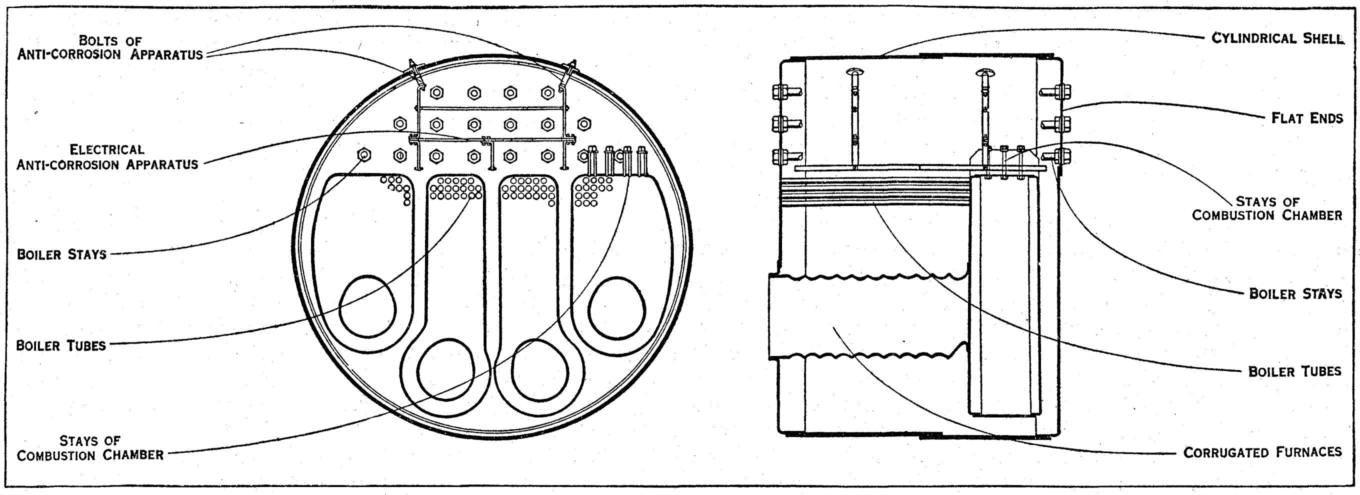

FIG. 7.—SINGLE-ENDED CYLINDRICAL SCOTCH MARINE BOILER

tors are of paramount importance in the merchant service. By the reduction of boiler weight and space the cargo-carrying capacity, or passenger accommodation, is greatly increased, with consequent greater earning power for the vessel.

It must be borne in mind that much higher pressures can be carried, which is essential for warships, mail steamers, and cross-Channel packets, especially when turbine-engined; and this pressure can be carried with perfect safety. Forcing, that is, using a higher pressure than that for which the boiler was designed, can be carried out, and steam can be raised very quickly without undue strain on the working parts.

One of the best known marine water-tube boilers is the *Yarrow* (fig. 8). The construction is simple and thus the process of cleaning, an all-important matter with water-tube boilers, is an easy matter. The Yarrow boiler consists of a large water drum and two lower water drums, connected by a series of inclined generating tubes (fig. 8). The boiler feed water is pumped into the steam drum, descends through the tubes most remote from the fire and rises through the tubes nearest the fire, where it is converted into steam. After leaving the steam drum the steam enters a super-

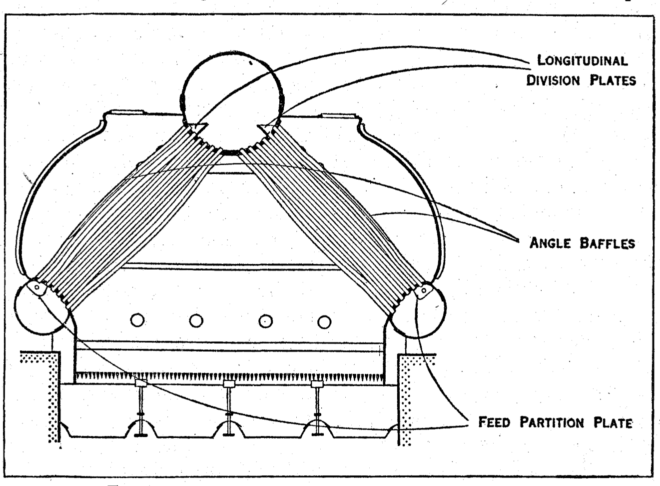

FIG. 8.—YARROW MARINE WATER-TUBE BOILER

heater, where it is superheated, and thence through the steam valve to the engine.

General.—The modern trend is towards much higher boiler pressures, higher temperatures, and the more efficient burning of the fuel and generation of steam in the boilers. There is no reason why pressures of 700 lb. or 800 lb., should not be carried, as the trials of the high-pressure turbine steamer "King George V." were most successful, and showed a marked improvement in the consumption of fuel, in this case coal, compared with such a vessel using steam at the normal working pressure. Superheating the steam, air preheating, increase in boiler feed water temperature and analysis of the funnel gases are all receiving due attention, as are also the best means to adopt to ensure protection and cleanliness of the boiler surfaces against corrosion.

Prevention of Boiler Corrosion.—Zinc slabs or bars are fitted to the interior of marine boilers so as to be electro-negative to all other parts of the boiler to attract the galvanic attention of acids. The zinc slabs are suspended in the steam and water spaces of the boilers; in some water-tube boilers zinc angle bars are used.

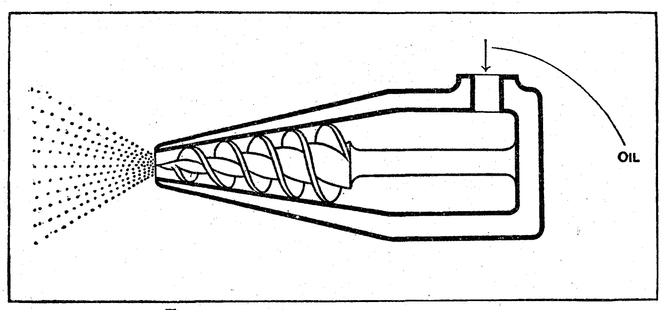

FIG. 9.—SIMPLE OIL FUEL SPRAYER

It is essential that slabs are fitted so as to protect the whole of the surfaces, and worn slabs should be renewed. The latest method of preventing boiler corrosion is the *electrolytic.* By this system electrolytic conductivity is produced in the water by supplying a current of electricity from a source outside the boiler to metallic anodes, insulated from the boiler shell. The current can be supplied continuously and its strength controlled; *i.e.,* increased or decreased regardless of the wear or deterioration produced on the anodes, thereby ensuring permanent efficiency of protection.

OIL BURNING IN MARINE BOILERS

Since the World War oil fuel burning for marine boilers has made rapid strides, and but for the question of cost would be more generally adopted. As an example of saving in boiler room staff, after the Cunarder "Aquitania" was converted to burn oil, her firemen were reduced to 42, as against 320 when coal-burning. Again in a coal-burning torpedo-boat destroyer of 10,000i.h.p. the complement of stokers was 30. In the latest class destroyers of 28,000s.h.p. and 1,400 tons, burning oil fuel alone, the stoker complement is 12. *The advantages of oil fuel are as follows:* (*a*) superior evaporative power per weight of fuel carried, giving increased radius of action—1 lb. of oil with a heat value of 19,000 B.T.U. will evaporate 15 lb. of water up to and at 212°F., and 1 lb. of coal with a heat value of 14,500 B.T.U. will evaporate 10 lb. of water up to and at 212°F.; (*b*) ease of shipping into bunkers and putting into fires—only hoses and attachments are required; (*c*) less stokehold staff and bunker space required; (*d*) absence of coal dust and ashes—a big asset; (*e*) no necessity to open furnace doors with consequent loss; (*f*) proper regulation of combustion, and capability of forcing the boiler; that is, obtaining more than the designed output.

Disadvantages of Liquid Fuel.—(*a*) Uncertainty of obtaining supplies; (*b*) complication of piping and machinery; (*c*) possible leakage and danger from fire; (*d*) special appliances required for burning; (*e*) liquid and solid impurities found in the oil; (*f*) widespread contamination of water-ways.

Method of Burning.—Before entering the boiler furnace the oil has to be atomized, that is, split up into a fine spray, and for this purpose three methods are adopted; *i.e.*, atomizing by means

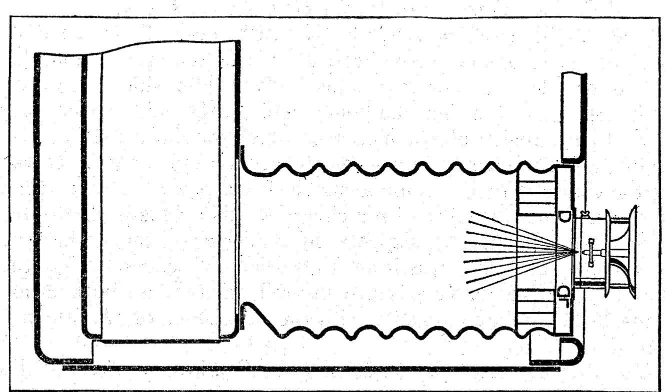

FIG. 10.—MARINE BOILER FURNACE, SHOWING OIL SPRAYER IN POSITION

of steam, compressed air, and pressure. Owing to freedom from breakdown and reliability the last method is generally adopted in naval and marine practice. Many different forms of burners or sprayers are adopted. Fig. 9 shows a simple sprayer, in which the oil is forced round a series of helical threads upon the surface of a cone. By this means a whirling motion is imparted to the oil, the narrowed passage at the exit producing an increase in velocity. These factors greatly assist the spraying. The sprayers are fitted to distribution boxes on the furnace front. Fig. 10 shows a patent form of sprayer fitted to the furnace front of a cylindrical marine boiler. The pressure system of oil burning is very simple and is as follows: oil is drawn from the ship's tanks and strained; this removes all solid impurities which would choke the sprayers. The oil is delivered from the oil pumps under pressure, an air vessel in the pipe-line assisting in maintaining a steady supply. The oil next passes to filters called cold filters and from there to heaters. This heating process may form particles of carbon in the oil, which particles are removed by passing it through filters fitted on the delivery side of the heater. From these filters, called hot filters, the oil passes under pressure to the distribution boxes on the boiler front, and from these through the sprayers, where it is atomized, to the furnace. For warships and fast passenger steamships oil is the ideal boiler fuel, but it is not considered that oil will become general in the mercantile marine owing to the question of cost. Many ships are now fitted to burn oil alone, coal alone or coal and oil combined.

Marine Auxiliaries. The great increase in the number of auxiliary engines now fitted in naval and mercantile vessels calls for as much attention as do the main propelling engines. As regards design, the majority of marine auxiliaries follow accepted practice, but the following units call for special consideration.

Marine Condensers.—The modern method is to ensure high vacuum combined with reliability and that the weight of the apparatus be as low as possible consistent with the work the condenser is called upon to perform. Separate air pumps are installed, one pumping out the feed water, and the other maintaining a high vacuum by pumping air from a cooler part of the condenser. Tube failure, through corrosion, is a frequent source of trouble, and the many experiments carried out with tube metal mixtures have not eliminated this.

Electrolytic Protection, similar to that used to prevent boiler corrosion, has been adopted with good results. Metallic packing for the tubes, in place of the ordinary tape packing, has been tried with excellent results.

In connection with marine condensers a system has been devised known as the *closed feed system.* By this method the condensate is removed from the condenser and discharged to the boiler without exposure to the atmosphere, thus preventing air mixing with the water and causing boiler corrosion. Another method coming into favour is the removal of the air in the feed water by mechanical de-aeration, and this method seems to possess advantages over the removal of the air by chemical means.

MARINE INSURANCE. Marine insurance is the insurance of interests—property and earnings—that may be imperilled in a maritime adventure. These two groups of interest include such as (1) ship and goods, (2) freight and passage money. Marine insurance is also a protection against certain liabilities such as shipowner's liability for collision damages, and carriers' responsibility for goods, and against losses occasioned by sacrifices for the general safety of an adventure. (*See* AVERAGE.) It is transacted in all nations having trade which necessitates transport, even those which have no sea ports, and is the safeguard of the shipowner, merchant, banker, mortgagee, and of any who risk their property, money, or credit in commercial or financial enterprise and of those who have occasion to send valuable objects from one place to another. Primarily marine insurance is concerned with sea transport, but it is adapted to the insurance of transport of any kind, and frequently policies concerning goods for overseas transport include a certain amount of risk on shore. *See* also LLOYDS.

Practice.—In practice marine insurance is a complicated business transacted for the most part through the medium of brokers who, by their expert knowledge, can select the best market in which to place their clients' risks, and obtain the terms most suitable for the adventure to be insured. So far as the hulls of ships are concerned, sailing vessels are generally insured for each voyage, while steamers are insured for periods of time, generally twelve months. The risks against which the hulls of ships are insured by the full (with average) policy, are the perils of the seas, and similar perils covered by the traditional marine policy in common use, including sacrifices made in "General Average" (*see* AVERAGE). It is also customary to add, by the use of clauses, insurance against liability for damage done by collision and certain other liabilities and perils. It is also customary in Great Britain to exclude war risks from the marine policy, these being insured separately, or covered on a mutual basis by associations formed for that purpose amongst shipowners. During World War I the amount to be covered on both ships and cargo against war risks was so great that the British Government instituted a war risk bureau which functioned simultaneously with the open market, and this system of a national war risk insurance office was also adopted by other countries, including some of those which remained neutral. So far as marine perils are concerned, the hulls of ships are also insured under policies which do not include the risk of particular average, and also under policies which cover total loss, general average (other than damage to ships), salvage charges and collision liabilities, these being known as "free of damage absolutely" insurances. Another form of insurance is the "free of particular average" policy which does not pay particular average unless the vessel has been stranded, sunk, on fire, or in collision. "Particular average" is partial loss caused by a peril insured against, and which is not general average. In connection with hull insurances, shipowners also insure their freight, their insurance premiums, and an indefinite interest known as "disbursements," the amount of which represents the financial loss over and above the actual value of the vessel which a shipowner incurs when his vessel is totally lost.

Goods and merchandise, valuables, securities and other concrete transportable interests are insured under the traditional marine form of policy, risks being added by means of clauses, of which the principal are the "with average" and "free of particular average" clauses of the Institute of London Underwriters. The "with average" clauses cover practically every fortuitous accident which may occur during transit, while the "free of particular average" clauses cover total loss, general average and certain other liabilities, but do not cover particular average unless the vessel has been stranded, sunk, on fire or in collision. These clauses also extend the risk of sea transit to cover the goods from the time they leave the warehouse at the port of shipment, until delivery at the consignee's or other warehouse at the destination named in the policy, or until the expiry of fifteen days from midnight of the day on which the discharge of goods from the overseas vessel is completed, whichever may first occur. Extension of the risk to 30 days from the completion of discharge is made when the destination to which the goods are insured is without the limits of the port of discharge.

Legislation.—In Great Britain, marine insurance was the subject of sporadic legislation up to the end of the 19th century. In the reign of Elizabeth an Act was passed (*43 Eliz. c. 12*) setting up a Court of Policies of Insurance to arbitrate in cases of dispute. The Act of 1720 incorporating the Royal Exchange Assurance and London Assurance, has already been mentioned. In 1745 an Act (*19 Geo. 2. c. 37*) prohibited the issue of wagering policies, and also policies of re-insurance, and although this Act was not finally repealed until the passing of the Act of 1906, its provisions with regard to re-insurance became obsolete. From the passing of this Act, until the Act of 1906 there appears to have been no legislation of importance dealing with marine insurance, other than certain finance acts dealing with policy duties, but during that period case law, mainly owing to the efforts of Lord Mansfield, had created precedents on practically every point likely to be raised on marine policy, and the Act of 1906 (*6 Edw. 7 c. 41*) was largely a codification of this case law, although certain provisions with regard to the prohibition of gambling policies were embodied in it. These provisions were amplified by the Marine Insurance (Gambling Policies) Act of 1909.

The Act of 1906, while codifying the existing law, did not, however, do away with litigation over points not previously decided. It is by no means as comprehensive as some of the continental codes, and while its provisions have proved singularly free from ambiguity since they have seldom been the subject of litigation, there still arise questions outside its scope which have to be decided in courts of law. It is, nevertheless, to the Marine Insurance Act of 1906 that reference may best be made on points arising out of marine insurance questions, especially where matters of principle and not of detail are concerned.

The Policy.—Reference has already been made to the marine policy, which, in Great Britain, is invariably based upon the traditional form which has been evolved from the early policies mentioned in the historical review. The Marine Insurance Act gives a form of policy which may be used, but which is not compulsory. This form is based on the traditional policy, and is, in fact, almost identical with the form adopted by Lloyd's underwriters in 1779 (*see* LLOYD'S). The custom is, however, to supplement the policy by a clause excluding war risks, while since 1919, as a result of the case of *British and Foreign Marine Insurance Co.* v. *Sanday* (*Times L.R. 266 and 374*) it has become customary to add the *frustration clause* which prevents underwriters from being held liable for loss due to loss of market caused by the frustration of a voyage owing to arrests, restraints or detainments of kings, princes or peoples.

This policy, archaic in form, and described by Justice Buller as an "absurd and incoherent document," has been so explored in the course of time, by means of legal action, that there remains very little, if any doubt as to the legal interpretation of any of its clauses.

It has already been shown, however, that the policy, by itself, is rarely used, and in modern practice the contract of marine insurance is usually expressed in a policy based upon the traditional form, but supplemented or modified by clauses in which the real terms of the contract are to be sought, rather than in the policy itself.

All policies of marine insurance must be stamped in accordance with the Stamp Act 1891 (*54 and 55 Vict. c. 39*) if they are to have validity in Great Britain.

The scale of stamp duties payable on policies of marine insurance is that of the Finance Act, the current scale in 1928 being that of the Act of 1920 (*10 and 11 Geo. 5 c. 18 s. 41*).

The provisions of the Act, together with those of the schedule, prevent any insurance being effected for more than twelve months, but to meet the cases of vessels insured for time which are at sea or in distress at the time the policy expires, the Act of 1901 provides that a policy of sea insurance may contain a continuation clause, and shall not be invalid on the ground only that by reason of the clause it may become available for a period of more than twelve months. A policy with a clause of this nature is chargeable with a stamp duty of sixpence in addition to that otherwise chargeable, and the "Institute time clauses" under which the majority of British vessels are insured, contain a continuation clause which is in conformity with the provisions of the Finance Act of 1901.

The Revenue Act 1903 (*3 Edw. 7 c. 16*) allows marine policies on building risks to run for periods longer than twelve months, and to be stamped as voyage policies.

The Contract.—From the Marine Insurance Act it is learnt that a contract of marine insurance is one whereby the insurer undertakes to indemnify the assured in a manner and to the extent thereby agreed, against marine losses. It may, by express terms, or by usage of trade, be extended so as to protect the assured against losses on inland waters or on any land risk which may be incidental to any sea voyage. It is to be noted, however, that subsequent litigation, *Muller* v. *l'Union Maritime* (*Ll.L. Rep. KB.17. 90.CA.18. 339. HL. 20.90*) throws doubt on whether the contract is identical, with regard to the risk on land, to that with regard to the risk on sea.

The Act defines "maritime perils" as "perils consequent on or incidental to, the navigation of the sea, that is to say, perils of the seas, fire, war perils, pirates, rovers, thieves, captures, seizures, restraints and detainments of princes and peoples, jettison, barratry and any other perils either of the like kind or which may be designated by the policy." Before the Act was passed, case law had decided that "all other perils" meant only perils *ejusdem generis* with those of the sea, but even now it cannot be said that the end of dispute as to what is, or what is not covered by the policy has been reached, although precedents exist on all the main points. In practice, however, the marine cargo policy is frequently extended by clauses (the express terms of the Act) to cover perils not strictly those of the seas, such as, for instance, theft, the risk of "thieves" in the policy meaning "robbery with violence, or breaking in." Insurances on the hulls of vessels are also extended by clauses, the principal addenda being the indemnification of the assured against liability for collision done to any other ship or vessel; loss or damage due to accident in loading or discharging, or through the negligence of the master, mariners, engineers or pilots, and loss or damage due to the bursting of boilers, or through latent defects in the machinery or hull.

These clauses are, so far as Great Britain is concerned, mostly those issued by the "Institute of London Underwriters," a body composed of representatives of the marine insurance companies.

Insurable Interest.—The Act, after stating that every contract of marine insurance by way of gaming or wagering, is void, proceeds to define what an insurable interest is. A person has an insurable interest when he stands in any legal or equitable relation to the adventure, or to any insurable property at risk therein in consequence of which he may benefit by the safety or due arrival of the insurable property, or may be prejudiced by its loss, or by damage thereto, or by the detention thereof, or may incur liability in respect thereof. He must, however, be interested in the subject matter insured at the time of loss, though he need not be when the insurance is effected. An example of the application of this is when goods are sold in transit, and the insurance is transferred to the purchaser. An assured cannot, however, acquire interest subsequent to a loss by any act or election after he is aware of the loss.

Insurable Value.—Subject to the express provisions or valuation of the policy, the insurable value of ship, freight goods, and other subject matter is laid down by the Act. Broadly speaking, this is the value of the interest at the inception of the risk plus incidental charges, including insurance. It is now the almost invariable practice to insert the value in the policy, in which case that value becomes the basis of all claims and adjustments.

Disclosure and Representation.—The Marine Insurance Act states that "a contract of marine insurance is a contract based upon the utmost good faith, and, if the utmost good faith be not observed by either party, the contract may be avoided by the other party." This is the basis of the whole of the business of marine insurance, which, in Great Britain, is largely transacted by means of verbal representations by the assured or his broker to the underwriter, and this being so, the importance of the observance of the principle of good faith is apparent. According to the Act, the assured must disclose to the insurer, before the contract is concluded, every material circumstance which is known to the assured, who is deemed to know every circumstance which, in the ordinary course of business, ought to be known by him. Failure to make such disclosure voids the contract. The Act also states that every circumstance which would influence the judgment of a prudent insurer in fixing the premium, or determining whether he will take the risk, is material, but no circumstance need be disclosed which is known or presumed to be known to the insurer. Every material representation made by the assured or his agent to the insurer during the negotiations for the contract, and before the contract is concluded, must be true, or the insurer may void the contract. Representations as to matters of expectation or belief must be made in good faith, but representations may be corrected or withdrawn before the contract is concluded. The contract of marine insurance is deemed to be concluded when the proposal of the assured is accepted by the insurer, whether the policy be then issued or not: and for the purpose of showing when the proposal was accepted, reference may be made to the slip, or covering note, or other customary memorandum of the contract, although it be unstamped. To appreciate the meaning of this provision it is necessary to explain that in Great Britain marine insurance is generally transacted by making a brief memorandum of the essential details of a risk on a slip, upon which the insurer writes the amount he will accept on that risk, appending his initials. The contract thus expressed cannot be legally enforced, but when a stamped policy is prepared embodying its terms, the slip may be produced as evidence of the intentions of the parties to the contract. A covering note is a memorandum issued by the insurer, or by a broker, to the assured, stating that the risk is covered, the terms on which the insurance has been effected, and the premium to be paid.

Measure of Indemnity.—According to the Act, the sum which the assured can recover in respect of a loss is, in the case of an unvalued policy, the full extent of the insurable value, or in the case of a valued policy, the full extent of the value fixed by the policy; this, however, is subject to any express provisions of the policy. In the event of total loss the measure of indemnity is the sum fixed by the policy, in the case of a valued policy, or in an unvalued policy, the insurable value of the subject matter insured. In the case of partial loss of a ship, the measure of indemnity is the reasonable cost of repairs, less the customary deductions, but not exceeding the sum insured in respect of any one casualty. The customary deductions are for depreciation, *i.e.,* since new material is substituted for old when repairs are effected, but in the case of steamships it is generally expressly agreed that no deductions shall be made. In the case of freight, the measure of indemnity is such proportion of the sum fixed by the policy, in the case of a valued policy, or the insurable value in the case of an unvalued policy, as the proportion of the freight lost by the assured bears to the whole freight at the risk of the assured under the policy.

In the case of partial loss of goods, the measure of indemnity, in the case of a valued policy, is such proportion of the sum fixed by the policy as the insurable value of the part lost bears to the insurable value of the whole, ascertained as in the case of an unvalued policy. In the case of an unvalued policy, the measure of indemnity for partial loss is ascertained as in the case of total loss, *i.e.,* the insurable value of the subject matter insured. In the case of goods arriving damaged by a peril insured against, the measure of indemnity is such proportion of the sum fixed by the policy in the case of a valued policy, or of the insurable value in the case of an unvalued policy, as the difference between the gross sound and damaged values at the place of arrival, bears to the gross sound value. In the case of general average and salvage charges, the measure of indemnity (subject to the provisions of the policy) is the full amount of the contribution, if the subject matter liable for contribution is insured for its full contributory value, but if it is not so insured, or if only part be insured, the indemnity payable by the insurer must be reduced in proportion to the under-insurance, and where there has been a particular average loss which constitutes a deduction from the contributory value and for which the insurer is liable, the amount must be deducted from the insured value in order to ascertain what the insurer is liable to contribute. Where the assured has effected an insurance in express terms against any liability to a third party the measure of indemnity, subject to any express provision in the policy, is the amount paid or payable by him to such third party in respect of such liability. An instance of this is insurance against collision liability, where it is customary for the insurer to cover only three-fourths of the risk, leaving one-fourth to be borne by the assured. The practice has arisen, however, of covering the assured's one-fourth mutually in associations of shipowners formed for that purpose.

In cases not specifically provided for in the Act, the principle enunciated in the provisions of the Act is to be applied.

Warranties.—In marine insurance a "warranty" is some particular thing that the assured undertakes shall, or shall not be done—an undertaking that some condition shall be fulfilled; or the affirmation or negation of the existence of a particular state of fact. Warranties must be complied with exactly, whether they be material to the risk or not; or the insurer is discharged from liability as from the date of the breach of warranty.

Examples of warranties are where the assured warrants that a vessel is in good safety on a certain date; where he warrants that a vessel shall not proceed on certain voyages; or where he warrants that he is uninsured for a specified proportion of the amount at risk.

These are "express warranties," and must be included in, or written upon, the policy, or must be contained in some document incorporated by reference into the policy.

There are also "implied warranties" as, for instance, that the vessel shall be seaworthy at the commencement of the voyage, but there is no implied warranty of seaworthiness in a policy for a period of time; nor, in the case of goods, that the goods are seaworthy. Breach of warranty is excused, under the Marine Insurance Act, when, by change of circumstance, the warranty ceases to be applicable to the circumstances of the contract, or where compliance with the warranty is rendered unlawful by any subsequent law. A breach of warranty may be waived by the insurer; and in practice it is customary, in the case of some warranties, to make provision in the policy to the effect that in the event of breach, the risk is "held covered" either at a specific premium, or at a premium "to be arranged." According to the Act, when an additional premium is to be arranged in a given event, but no arrangement is made, then a reasonable additional premium is payable.

Where a warranty is broken, the assured cannot avail himself of the defence that the breach has been remedied, and the warranty complied with, before loss.

Double Insurance.—Where two or more policies are effected by or on behalf of the assured on the same adventure and interest, or any part thereof, and the sums insured exceed the indemnity allowed by the Marine Insurance Act, the assured is said to be over-insured by double insurance. In such circumstances he may according to the Act, claim payment from the insurers in such order as he may think fit, unless the policy otherwise provides, but he is not entitled to receive any sum in excess of the indemnity allowed by the Act. Where, however, the policy is a valued policy, the assured must give credit as against the valuation for any sum received by him under any other policy without regard to the actual value of the subject matter insured. Where the policy is unvalued, he must give credit, as against the full insurable value, for any sum received by him under any other policy, and where the assured receives a sum in excess of the indemnity allowed by the Act, he is deemed to hold such sum in trust for the insurers, according to their right of contribution amongst themselves.

The insurers, on their part, are bound, by the Act, to contribute rateably to the loss in proportion to the amount for which they are liable under their contracts, and if any insurer pays more than his proportion of a loss, he is entitled to maintain an action for contribution against the other insurers. Where the assured has over-insured under an unvalued policy, a proportionate part of the premium is returnable, but if the policies have been effected at different times, and the earlier policy has, at any time, borne the entire risk, or if a claim has been paid on the policy in respect of the full sum insured, no premium is returnable in respect of that policy; nor is any premium returnable when a double insurance is effected knowingly by the assured.

Subrogation.—Where there is a loss either partial or total, the insurer becomes entitled to the advantage of every right of the assured in respect of the subject matter of the loss. A good example of this is where there has been a total wreck, and the underwriter has paid a total loss, since he then becomes entitled to the proceeds of the sale of the wreck. On broad lines, the assured must account to the insurer for any diminution of the loss. A very general application of this right of subrogation is where the insurer pays a loss and then proceeds against a third party to recover; for his own benefit, but in the name of the assured; in respect of a liability that third party may have incurred.

Re-Insurance.—Re-insurance is the indemnification of one insurer by another in respect of liabilities that the former has incurred in the course of business, and the Marine Insurance Act of 1906 gives the re-insured an insurable interest in his risks, but stipulates that unless the policy provides, the original assured has no right or interest in respect of such re-insurance. Re-insurance may be either facultative, which is the re-insurance of specified individual risks, or by treaty. A treaty of re-insurance is an agreement by one insurer to accept a stated proportion of the whole, or any specified part of, the business accepted by another, it being customary to place limits as to the maximum amount that may be given off under the treaty. In connection with these treaties an anomalous situation has arisen concerning their validity under British law, for while they are undoubtedly contracts of marine insurance, the fact that they cover no specified amount makes it impossible to pay duty on them in accordance with the provisions of the Stamp Act so that it would seem that they are unenforceable in law. The leading legal decision on this point is that of the House of Lords *In re National Benefit Assurance Co., Ltd.* (31 *Ll. L. Rep.* 321). In practice, however, legal difficulties are not likely often to arise, since most treaties provide that stamped policies shall be issued in respect of the risks accepted under the contract, and in the event of dispute arising, legal action can be taken on these policies.

Institutions.—In marine insurance, the institutions which exist for the purpose of furthering and protecting the interests of underwriters play a very prominent part. In Great Britain the oldest of these institutions is the Liverpool Underwriters Association, founded in 1802, but the leading body is the Institute of London Underwriters, founded in 1884, and composed of the majority of the companies transacting marine business in London, including the London branches of companies in Liverpool and other provincial cities. This body formulates and issues the clauses to which reference has already been made, and a special feature of its work in this connection is the drafting of special sets of clauses for the insurance of trades. These clauses are drafted after consultation with the Trade Associations interested in the commodities to be insured, and are therefore acceptable to both parties to the contract of insurance. Examples of these clauses are the "London Jute Associations Clauses" and the "London Corn Trade Associations Clauses." The institute has established various sub-committees, of which the most important is the "Technical and Clauses Committee," the title of which explains its functions, and which keeps in close touch with various trade associations with a view to maintaining clauses in accordance with the requirements of the trades those associations represent. An important committee which sits under the auspices of the institute, is the "Joint Hull Committee," on which Lloyd's Underwriters and the Liverpool market are represented, and which deals with such matters as the framing of agreements with regard to hull rates and values, the drafting of "warranties," governing voyages and seasons, and similar matters.

Lloyd's Underwriters Association is another important market institution, to which practically all the active underwriting members of Lloyd's belong, and which works in close collaboration with the Institute of London Underwriters on matters of principle, and sometimes on matters of practice. Lloyd's Brokers Association is a body representative of the brokerage side of the business at Lloyd's while the Corporation of Insurance Brokers represents brokers in all parts of Great Britain. The Chartered Insurance Institute, largely educational in function, holds examinations in marine insurance, and there are local institutes in connection with the Chartered Institute.

Market Institutions in Other Countries.—Elsewhere there are, in most markets, local or national institutions concerned with the regulation and government of business, such as the Central Underwriters Association of Norway, the Association for the Improvement of Marine Insurance in Holland, the "Verband" or Union of Underwriters in Germany, and the "Union des Syndicats" in Paris. These are similar, in many respects to the Institute of London Underwriters, and are in constant communication with that body and each other. There is also the "International Marine Insurance Union" with headquarters in Berlin, in which the majority of national markets are represented by the leading companies. This institution holds an annual conference at which matters of common interest are discussed, and has been the means of promoting a number of international agreements, the principal of which is the "dangerous drugs" agreement, by which underwriters are pledged to incorporate in all policies on drugs a clause making it imperative that all claims shall be accompanied by a certificate from the government of the country of origin authorizing the shipment in respect of which the claim is made. This agreement made in the first place at the instance of the British Foreign Office, has proved effective in checking the trade in opium, cocaine, and other drugs scheduled in the International Opium Convention.

UNITED STATES

Marine insurance business in America as in Great Britain, is transacted for the most part through the medium of brokers. Sailing vessels are generally insured for each voyage, and steamers are insured for periods of time, generally 12 months. The risks against which the hulls of ships are insured are about the same in the United States as in Great Britain. Goods and merchandise are insured against various risks and on various terms and conditions dependent on the nature of goods, voyage, trade customs, etc.

The various States all have their insurance laws for the licensing and regulation of the companies and the activities of agents and brokers, and all the States also have a so-called insurance department as a branch of the State Administration. Until recently, there has been no uniformity in the laws of the various States dealing with marine insurance. There has been some effort to bring about uniformity and the District of Columbia, New York, Pennsylvania and New Jersey passed laws bringing about uniformity as to regulation and taxation. There is no Federal act similar to the Marine Insurance Act of 1906 which codified the laws of England, and most of the States have no such code.

The law and practice governing the contract, and regarding insurable interest, insurable value, disclosure and representation, measure of indemnity, warranties, double insurance and reinsurance are substantially the same as in Great Britain. There are some variations and amongst them is the rule of law as to what constitutes a constructive total loss and the extent of the insurers' liability in the case of general average and salvage charges where the contributory value of the interest is in excess of the insured value. As regards an implied warranty of seaworthiness in a policy for a period of time the law of the United States is not as broad and as favourable to the assured as the English act. In the United States many, if not most, double insurance policies provide how losses and premiums shall be dealt with in such cases. The most common clause provides that resort shall first be had to the policy of earlier date for collection of a loss or a claim, and that only the excess of the whole loss or claim over the amount recoverable under the policy of earlier date shall be recovered under the policy of later date, and that the premium attaching to the excess of the amount insured over the insurable interest in the policy of later date shall be refunded.

Regarding subrogation, in the United States, on payment of a loss the insurers acquire the rights of the owners in respect of and to the extent of the amount paid.

The American Institute of Marine Underwriters suggests policy forms and acts on behalf of underwriters in matters affecting the general welfare of the business but does not deal with rates. Practically all the American and various foreign companies admitted to do business in the United States are members of this organization. The United States Salvage Association participated in by most American companies supplies services for the survey and inspection of hulls. The American Marine Insurance Syndicate composed of most American and a large percentage of the foreign admitted companies, issues joint policies on the hull, disbursements, and earnings of steamers. It has become the chief market for the insurance of these risks on American steamers.

The Board of Underwriters of New York, formed in 1820, is composed of the principal American and foreign admitted companies. Its principal functions are the reporting of casualties, handling of losses, surveying of cargo, handling of proceeds, stowage of cargo, inspection of the loading and discharging of vessels, arbitrations, salvage awards, examination of adjustments, reports on maritime inventions and the appointment of commissioners of pilots. (W. N. D.)

See S. B. Ackerman, *Insurance* (1939).

MARINES may be defined as sea-soldiers, that is, soldiers trained for fighting at sea as well as on land. They have been employed from the earliest times. The Greeks and Romans used soldiers specially armed and trained for service in their fleets, called Epibatai and Classiarii respectively. In mediaeval times soldiers were embarked in the ships of war, and in the Tudor navy each ship had its complement of soldiers as well as sailors.

Great Britain.—The marine was not included in the complements of ships until the Admiralty obtained an order in Council, dated Oct. 26, 1664, instituting the "Duke of York and Albany's Regiment of Foot," a regiment of 1,200 "Land souldgers prepared for sea service." It was principally recruited in the City of London, probably from the trained bands, and hence the privilege shared by the marines of marching through the City with colours flying, drums beating and bayonets fixed. This regiment, after service in the Dutch war, was disbanded in 1689. Two other regiments were raised in 1690 and disbanded in 1699.

In June 1702, six marine regiments were raised and six line regiments were detailed for sea service; these regiments captured Gibraltar in 1704, and held it during the subsequent siege from Oct. 1704 to April 1705, for which service the corps still bears the name *Gibraltar* on its appointments. Most of these regiments were transferred to the army in 1713. In 1739 marines were again required in the fleet, and ten regiments in all were formed; also three regiments in New York by the provincial authorities for service at Carthagena; all were disbanded at the peace in 1749.

On April 5, 1755, the Admiralty established the corps on its present basis; organization in regiments having proved unsatisfactory, 60 companies were raised and divided into three divisional headquarters, one each at Chatham, Portsmouth and Plymouth, from which officers and men were, and still are, drafted as required for service afloat or elsewhere. These headquarters are their homes to which they remain attached throughout their service, active or reserve. The Royal Marines are a trained body of soldiers maintained by the Admiralty for service at sea or with the fleet; their charges are borne on the naval estimates. Parliament in the Army Annual Act gives the authority for a force of marines, the numbers being fixed by Order in Council; when ashore, since 1879, they have been subject for discipline to the Army Act; prior to this they had their own Annual Mutiny Act and Articles of War. When afloat they are subject to the disciplinary provisions of the Naval Discipline Act, but in both cases their conditions of service, enlistment and discharge are still governed by the unrepealed portions of their own Acts 11 and 12 Vict. c 63.

The marines were an infantry corps until 1804 when, owing to difficulties with the Royal Artillery manning the bomb vessels, Lord Nelson suggested that the marines should perform the duty; accordingly a company of artillery was formed at each headquarters from picked officers and men, who were then trained and paid as artillery. In 1919 the pay of both branches was assimilated to that of the Royal navy. In 1805 a 4th Division with another artillery company was formed at Woolwich. Before the institution of the naval gunnery school, known as H.M.S. "Excellent," the artillery companies were the only body of seamen or marines who were systematically trained in gunnery. In 1832, however, the artillery companies were ordered to be disbanded, but two were retained. In 1855 the infantry branch became a corps of light infantry and adopted the badge of the Bugle, the R.M.A. Companies wearing the Grenade. In 1862 the artillery companies, which had increased to 17, under a colonel, quartered in Ft. Cumberland but attached to the Portsmouth Division (then stationed at Gosport), were formed into a separate corps as the Royal Marine Artillery, and the officers, who had hitherto been interchangeable, were placed on a separate list. In 1867 the barracks at Eastney were built for them. In 1869 the Woolwich division was abolished, and a depot was established at Deal to train all recruits. In 1904 the naval Band Service was transferred to the Royal Marines, and bandsmen for the navy are now recruited as marines and trained at the R.N. School of Music at Eastney.

In the World War of 1914–18 the corps was largely expanded, and though many auxiliary units had to be raised, the organization worked efficiently and met all demands as they arose. Besides the artillery and infantry units afloat and ashore, the corps provided 2,000 men to man the guns of the defensively armed merchantmen and raised the following units for Admiralty work:—submarine miners, labour corps for discharge of the supply ships in France, engineers and the auxiliary units for the R.N. Division. The R.M. units on shore included the howitzer and anti-aircraft brigades, and the siege guns R.M.A. on the Western Front; the R.M.L.I. brigades in Antwerp, Gallipoli and France; heavy batteries in East Africa; the landing force (4th Bn) at Zeebrugge; garrisons of coast defences and naval bases; and numerous ship landing parties. At the armistice the strengths, including reserves, were:—R.M.A. 9,412, R.M.L.I. 30,140, R.M. Band 1,633. The numbers were gradually reduced until, in 1923, the strength was only 9,000, consequent on which, coupled with the Treasury demands for economy, one division was ordered to be reduced, with the result that the R.M.A. & R.M.L.I. were once more amalgamated into one corps with the title of the Royal Marines; the distinctive badges of the grenade and bugle being replaced by the older badge of the Lion and Crown. Enlistment into the corps is for 12 years with the colours with permission to re-engage for another nine years to earn a pension. There are also two classes of reserve, (i) men who have completed 12 years with the colours, (ii) pensioners.

Training.—The Royal Marine is now a fully trained infantry soldier; he is likewise a naval gunner, similar to the Bluejacket. Selected men qualify as naval gunlayers and gunnery instructors, land artillery specialists, machine gunners, signallers, etc. Recruits are trained in infantry drill and musketry at Deal and are then transferred to one of the headquarters to complete their training; headquarters also carry out the training of all the specialists. Officers are entered by direct competition; they are trained with the corps and at the various naval schools of instruction; they also attend the army instructional schools and pass the army examinations for promotion.

Badges.—The badge of the corps is the "Globe" (granted by King George IV in 1827 in place of inscribing the battle honours—which were too numerous—on the colours) surrounded by the laurel wreath (awarded for services at Belleisle, 1761) with the name *Gibraltar* and the motto *Per Mare Per Terram.* The original badge of the "Foul Anchor" is also worn with the Royal Crest of the Lion and Crown. The corps was granted the title of "Royal" in 1802 for services in the French wars.

United States Marine Corps.—Founded in 1775, and observing its official birthday on Nov. 10, the Marine Corps, instead of following the model of the British marines, was developed to provide the navy with a trained land-fighting force, capable of combat missions ashore that frequently are vital to the execution of sea power. As an offensive weapon, the Marine Corps was used successfully in every war beginning with the Revolution, when it consisted of two battalions, and reached a high state of perfection in World War II as a large army with its own artillery, tanks and air force. Marines have other functions, the duties in which the service was conceived originally by the British. They man the secondary batteries aboard battleships, aircraft carriers, heavy cruisers, and some light cruisers; they protect American bases outside the continental United States, and American embassies throughout the world; they guard naval property within the country, and they have been called upon for police duty in peacetime. From its inception the Marine Corps operated as an entity with its own commanding officer and a complete administrative organization. Originally it was headed by a major; in 1944, by a lieutenant general—the difference in rank affording some idea of the growth of the corps. It is under the direction of the secretary of the navy, and its duty under the nation's naval policy is to support the fleet or any part of it in the accomplishment of its mission.

Amphibious operations were the forte of the Marine Corps beginning as early as 1776, when marines spear-headed the seizure of New Providence, in the Bahamas, by Commodore Hopkins's Continental fleet. From then on its history was studded with exploits which provided a heritage of valour in which the corps take inordinate pride. The Marine Corps hymn, with its famous opening lines, "From the halls of Montezuma to the shores of Tripoli," epitomizes the far-flung services the marines have given the United States. Loyalty to tradition and pride of accomplishment are inculcated into the men of the corps until they are rounded into perhaps the deadliest fighting men in the world. Their motto is *Semper Fidelis.* Their emblem, worn as an insignia and emblazoned on their standards, is the western hemisphere superimposed upon a foul anchor and surmounted by an eagle with wings spread.

The corps expanded and contracted as national or international conditions warranted. After the Revolution it was disbanded for 15 years, but after 1798 it had a continuous existence, although in peaceful periods it had been skeletonized. Beginning with the Spanish American War it had almost a continuous growth. In 1898 it numbered 75 officers and 2,000 enlisted men. In 1917 it had 511 officers and 13,124 men. During the nation's participation in World War I the corps grew steadily, and a total of 31,824 marines was sent to France as part of the American Expeditionary Force. Two regiments, comprising the 4th Brigade of marines, formed a part of the 2nd Division, and served with conspicuous gallantry and success in Belleau Wood and the Argonne. In the period following World War I, the corps again contracted, but not to a serious degree, for it had many peacetime pursuits in the ensuing quarter century. When the United States began to re-arm seriously in 1940, the corps totalled about 30,000 officers and men.

When Japan launched her attack on Pearl Harbor, Dec. 7, 1941, marines were trapped on a number of island outposts, in the Philippines and in China. The heroic marine defenders of Wake Island wrote another page in the corps' tradition. Immediately after the declaration of war against Japan and the axis powers, expansion of the corps began. When the offensive phase of the Pacific warfare began in earnest in Aug. 1942, marines launched the attack which took Guadalcanal and Tulagi, in the Solomons. During 1942 and 1943 four full divisions of marines, the First to Fourth inclusive, were identified as in action from the Solomons, on the south, to the Marshalls, on the north. In 1944, the Marine Corps totalled 403,000 officers and men. (W. B. Ck.)

MARINETTE, a city in northeastern Wisconsin, U.S.A., on the Green Bay waters of Lake Michigan, a port of entry, and the county seat of Marinette county. It is on the "Gulf to Lakes route," federal highway 41, and is served by the Chicago and North Western and the Chicago, Milwaukee, St. Paul and Pacific railways and by the Ann Arbor Railway car ferry across Lake Michigan. The 1940 census recorded the population at 14,183. Marinette with its sister city, Menominee, Mich., handled huge quantities of white pine during the 1890s and early 1900s. The Menominee river, interstate boundary between Wisconsin and Michigan, once famous for huge logging drives, is known for its abundance of silver smelt. An annual carnival celebrates the smelt season. Since the decline of lumbering industries in this section, diversified industry has been developed, and Marinette has become a trading centre for some 80,000 people. Marinette was settled by the French about 1830 and was named for Queen Marinette of the Menominee Indians, a white woman who became a noted fur-trader and was regarded by the Indians as a superior being. The city was incorporated in 1887.

MARINETTI, FILIPPO TOMMASO (1876–1944), Italian writer, born at Alexandria on Dec. 22, 1876, studied in Paris, graduating at the Sorbonne; in 1899 he also graduated in law at the University of Genoa. He was the founder of the futurist movement, publishing the original futurist manifesto in the Paris *Figaro* on Feb. 20, 1909. For a time he edited the international review *Poesia,* but his most characteristic work was *Mafarka le futuriste,* published in French in 1910. He also wrote for the stage *Le roi Bombance* (1905), a satirical tragedy, and other plays, and published a volume on the futurist theatre, *Teatro sintetico futuristo* (1916). In 1914 he wrote an extraordinary volume entitled *Zang-tumb-tumb* on the Balkan war, and particularly on the siege of Adrianople. On the outbreak of World War I he advocated Italian intervention in his *Guerra sola igiene del mondo* (1915). *Otto anime in una bomba* (1919) deals with war experiences, while in *Futurismo e fascismo* (1924) he expresses his support of the fascist movement. He was admitted to the Italian Academy in 1929, and was a member of the National Council of Corporations. Marinetti died Dec. 2, 1944.

MARINI or **MARINO, GIOVANNI BATTISTA** (1569–1625), Italian poet, born at Naples Oct. 18, 1569. After a riotous youth, during which he became known for his *Canzone de' baci,* he secured the powerful patronage of Cardinal Aldobrandini, whom he accompanied from Rome to Ravenna and Turin. An edition of his poems, *La Lira,* was published at Venice in 1602–14. His ungoverned pen and disordered life compelled him to leave Turin and take refuge from 1615 to 1622 in Paris, where he was favourably recognized by Marie de' Medici. There his long poem *Adone* was published in 1623. *Adone* contains over 40,000 lines; the story of Venus and Adonis is overlaid with all kinds of digressions, mythological, descriptive, etc. Its smooth and polished verse and its fanciful style found many imitators. He died at Naples on March 25, 1625. The licence, extravagances and conceits of Marini, the chief of the school of "Seicentisti" (*see* ITALIAN LITERATURE), marked the close of a great era, and the beginning of a period of decadence. "Marinism" was in Italy what "Gongorism" was in Spain. It was part of a general movement in favour of an artificial and ornamented style which was evident throughout western Europe.

Marini also wrote a religious epic, *La strage degli innocenti* (1633) and other works, of which a selection was edited by Zirardini (1862). A new edition of his letters, *Epistolario,* appeared in 1924. *See* A. Gustarelli, *La vita et l'opera di G. Marino* (Leghorn, 1918).

MARINKOVIĆ, DR. VOIESLAV (1876–1935), Yugoslav statesman, was born in Belgrade on May 1, 1876. He was educated in Belgrade and Paris, and in 1901 entered the ministry of finance in Belgrade. In 1906 he entered the Skupština; in 1913 represented Serbia on the Finance conference in Paris charged with liquidating the financial side of the Balkan Wars; in 1916 he was Serb Delegate to the Inter-Allied conference in Paris. He was a Progressive member of the coalition cabinet 1914–7, when he resigned office, and took part in drafting the Corfu Declaration. In Nov. 1918 he rejoined the cabinet. In 1919, with Davidović (*q.v.*) and others, he formed the Democratic Union (afterwards Party). From Dec. 1921–June 1922 he was minister of the interior, and carried through the reorganization of the Electoral Law. In the Davidović Cabinet (1925) he became minister of foreign affairs, and resumed that office after Dr. Ninčić had resigned in Dec. 1926. In his policy Marinković leant definitely more towards France than his predecessor. From April to July 1932 he was prime minister and foreign minister.

MARINO, town, Italy, province of Rome, 15 mi. southeast of Rome by rail, and also accessible by electric tramway. Pop (1936) 8,062 (town); 13,248 (commune). It is on a spur of the Alban Hills, 1,165 ft. above sea level, and occupies the site of the ancient Castrimoenium, a *municipium* of no great importance, though the surrounding district, which now produces much wine, is full of remains of ancient villas. In the early 13th century it belonged to the Frangipani, but passed to the Orsini in 1266. In 1379 a battle took place here between the partisans of Urban VI. and those of the anti-pope Clement VII. of Geneva (the Orsini having taken the side of the latter), who were, however, defeated; and in 1399 Marino was apparently under the Papacy. In 1419 it passed to the Colonna family, to whom it still belongs.

See T. Ashby, in *Papers of the British School at Rome,* vols. iv., v.; F. Tomassetti, *Campagna Romana* iv. (1926) 173 *seq.*

MARINUS, the name of two popes. MARINUS I., sometimes called Martin II., pope from 882 to 884, was the son of a Tuscan priest, and entered the church at an early age, becoming a deacon about 862. Three successive popes sent him as legate to Constantinople, and he also negotiated on behalf of pope John VIII. with the emperor Charles the Fat. About the end of December 882 he succeeded John VIII. as pope. Having secured his position, Marinus restored Formosus, cardinal-bishop of Porto, and anathematized Photius. This pope was on friendly terms with the English king, Alfred the Great. He died in May 884, and was succeeded by Adrian III.

MARINUS II., sometimes called Martin III., pope from 942 to 946, was merely the puppet of Alberic (d. 954), prince and senator of the Romans. He died in May 946, and was succeeded by Agapetus II.

MARINUS, neo-Platonist philosopher, was born in Palestine and was early converted to the old Greek religion. He succeeded to the headship of the neo-Platonic school at Athens on the death of Proclus. But he was compelled to seek refuge at Epidaurus from persecution by the Christians. His chief work was a biography of Proclus, first published with the works of Marcus Antoninus in 1559; separately by Fabricius at Hamburg in 1700, and re-edited in 1814 by Boissonade with emendations and notes.

MARINUS OF TYRE, geographer and mathematician, the founder of mathematical geography, flourished in the 2nd century A.D. He lived before Ptolemy, who acknowledges his great obligations to him. His chief merits were that he assigned to each place its proper latitude and longitude, and introduced improvements in the construction of his maps.

See E. H. Berger, *Geschichte der wissenschaftlichen Erdkunde der Griechen* (1903).

MARIO, GIUSEPPE, COUNT OF CANDIA (1810–1883), Italian singer, the most famous tenor of the 19th century, son of General di Candia, was born at Cagliari in 1810. While serving as an officer in the Sardinian army he was imprisoned at Cagliari for some trifling offence. On his release he fled to Paris. There his success as an amateur vocalist produced an offer of an engagement at the Opera. He studied singing for two years under M. Ponchard and Signor Bordogni, and made his début in 1838 in Meyerbeer's *Robert le Diable.* In 1839 he joined the company of the Théâtre Italien, which then included Malibran, Sontag, Persiani and Grisi, Rubini, Tamburini and Lablache. In a short time he won a European reputation in Italian opera. Mario had a handsome face and a graceful figure, and his voice, though less powerful than that of Rubini or that of Tamberlik, had a softness and richness which have never been equalled. He was an ideal stage lover, and he retained the grace and charm of youth long after his voice had begun to show signs of decay. He created very few new parts, that of Ernesto in *Don Pasquale* (1843) being perhaps the only one deserving of mention. Among his best parts were Otello in Rossini's opera of that name, Gennaro in *Lucrezia Borgia,* Almaviva in *Il Barbiere di Siviglia,* Fernando in *La Favorita,* and Manrico in *Il Trovatore.* In 1856 he married Giulia Grisi, the famous soprano, by whom he had five daughters. Mario bade farewell to the stage in 1871. He died at Rome in reduced circumstances on Dec. 11, 1883.

MARION, FRANCIS (1732–1795), American soldier, was born in 1732, at Winyah, near Georgetown, S.C., of Huguenot ancestry. In 1761 he served in a campaign against the Cherokees. In 1775 he was a member of the South Carolina Provincial Congress. Commissioned a captain, he took an active part in the defence of Ft. Moultrie in Charleston harbour (1776), and in the unsuccessful siege of Savannah (1779). In 1780 the British captured Charleston and overran the State. Made a brigadier-general by Governor Rutledge, Marion showed his genius in organizing a band of guerrilla volunteers; he gained recruits and trained them to be fearless riders and good marksmen, and "Marion's Brigade" became known far and wide for its successful exploits against the British. His sudden attacks often resulted in the capture of superior numbers and intimidated the Tories. Col. Tarleton was sent to capture him, but soon despaired of finding "the old swamp fox," who eluded him by following swamp paths. His men united with Gen. Greene's forces for important engagements at Georgetown, Ft. Watson, Ft. Motte and Eutaw Springs. For a skilful rescue of Col. Harden's men, hemmed in by a superior British force which he defeated at Parker's Ferry, he received the thanks of Congress. In 1782, his brigade deteriorated during his absence; and there was a conspiracy to hand him over to the British. From 1782 to 1790, Marion served in the State senate where he opposed harsh treatment of the Tories. He was made commander of Ft. Johnson with a salary of £500 per annum, in recognition of his services. He died on his estate in Berkeley county on Feb. 27, 1795. As a soldier he was quick, resourceful and calm, a great partisan leader.

MARION, a city of southern Illinois, U.S.A., 100 mi. S.E. of Saint Louis; the county seat of Williamson county. It is served by the Chicago and Eastern Illinois, the Illinois Central and the Missouri Pacific railways. Pop. (1920) 9,582 (93% native white); and 9,251 in 1940 by the federal census. It is the commercial centre of a rich agricultural and coal-mining region, and has various manufacturing industries. The city was founded about 1842 and incorporated in 1896.

MARION, a city of Indiana, U.S.A., 60 mi. N.E. of Indianapolis, on the Mississinewa river; the county seat of Grant county. It is served by the Big Four, the Chesapeake and Ohio, the Nickel Plate, the Pennsylvania and electric railways, and by motorbus and truck lines. The population was 23,747 in 1920; 26,767 in 1940. It is the trade centre for a fertile farming region, and has important manufactures (including glass, radios, electric stoves and lanterns, wire and cables, shoes, food and dairy products, malleable iron, paper and flour) with an estimated output in 1940 valued at $32,616,438. Marion college (established 1889) is an institution of the Wesleyan Methodist church. At Upland (12 mi S.E.) is Taylor university (1846). Marion is the seat of a United States Veterans bureau hospital (accommodating 1,750 psychiatric cases). The city was chartered in 1889 and is named after Gen. Francis Marion. It was a "station" on the underground railroad (the name given to the secret chain of passages by which slaves were passed along into Canada or other free territory).

MARION, a city of Ohio, U.S.A., 44 mi. N. by W. of Columbus; the county seat of Marion county. It is on federal highways 23 and 30, and is served by the New York Central, the Erie, the Chesapeake and Ohio and Pennsylvania railways. Population in 1940 was 30,817. It is the trade centre of a rich farming district. There are many limestone quarries in the county. The principal products manufactured include power shovels, dredges, road rollers, tractors, castings, refrigerator units, soybean products, flour and conveying equipment. Large railroad shops and yards are located there. Marion was the home of former President Warren Gamaliel Harding from 1884 until his death in 1923. It was the scene of his "front-porch campaign" in 1920, and there he is buried. The city was laid out in 1821 and chartered in 1890.

MARIONETTES and **PUPPETS,** jointed figures which, by various devices, are made to move in mimicry of persons or animals—usually for dramatic performances. The closely related shadows are flat cutout figures which are exhibited in silhouette against a lighted screen.

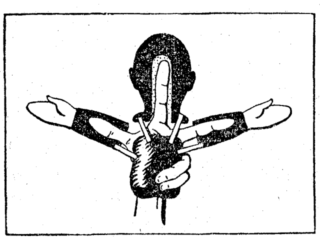

FIG. 1

FIG. 2

The following are commonly accepted methods of producing simple types of hand puppets, rod puppets, string puppets (marionettes), and shadow figures.

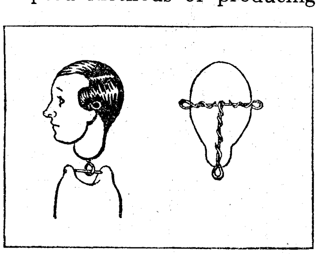

FIG. 3

Hand Puppets can be of wood, plaster, plastic wood, papier-mâché or stuffed cloth. Head and neck are in one piece with a hole running up the neck for the first finger of the operator (fig. 1). The arms consist of cylindrical cuffs (cardboard strengthened with cloth) which are glued or tacked to wooden hands. The operator's second finger and thumb fit, each, into a cuff. A small stuffed bag is suspended by tapes from a ledge at the base of the neck. Grasping this bag in the palm with the two last fingers gives a firmer control. The cuffs also are attached to the bag with tapes. This framework of the hand puppet is then concealed—the head by a mask and wig (unless the face and hair are already carved and painted on), the rest by clothing firmly attached to the ledge at the base of the neck (fig. 2). If desired, legs and feet can be attached.

To operate, put the doll on the hand like a glove, always keeping the forearm upright so that the puppet will stand straight. Arm and head movements are made with the fingers. The stage has no floor; a curtain or a three-sided screen with an opening for the proscenium arch is required. The little roll or draw curtain is suspended from a frame-work or from wooden strips across the top of the screen. Painted or dyed scenery behind the dolls is similarly suspended. Puppets must be held high so that the operator's head is invisible. A ledge along the base of the proscenium arch offers a place on which to rest "properties." The stage lighting (floods or strips) should shine upon the puppets' faces, as well as upon the scenery. Humorous, lively plays are best for this grotesque, intimate type of puppet-show.

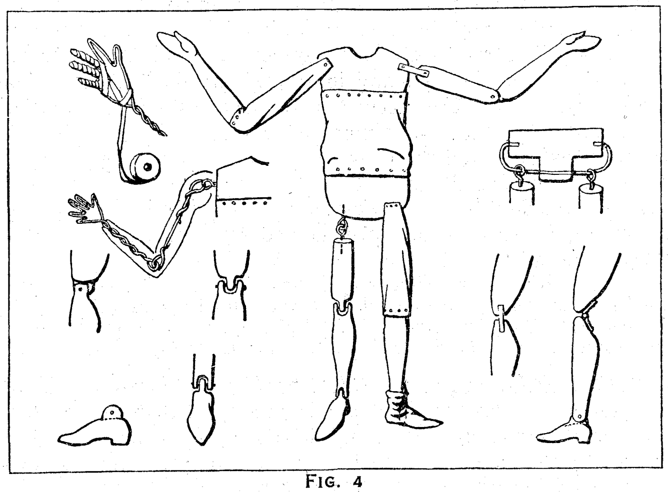

FIG. 4

String Puppets (Marionettes) are made of the same materials as hand puppets. If the head is of plaster or stuffed cloth put a wire from ear to ear with a loop at either end, and another wire, twisted on to this, running down through the neck with a loop at the end (fig. 3). If the head is of wood, screw eyes at sides and at bottom of neck are used. The torso can be one piece; but separate shoulders (fig. 4), and hip pieces of wood with a centre section of loosely stuffed cloth give flexibility to the body. Limbs can be wood, loosely jointed, or a wire skeleton padded, or firmly stuffed cloth. The joints must be flexible: brass hinges, double screw eyes, leather or cloth straps or carved wooden joints. Hands can be of wood, plaster or of wire wound about with narrow tape. If the doll is of stuffed cloth the feet, lower arms and hips should be weighted with lead (fig. 5). Faces and hands should be painted, like theatrical "make-up," to carry at a distance—with either oil or water paints. When dressing the doll freedom must be allowed for movement of neck, elbow, shoulder, etc.

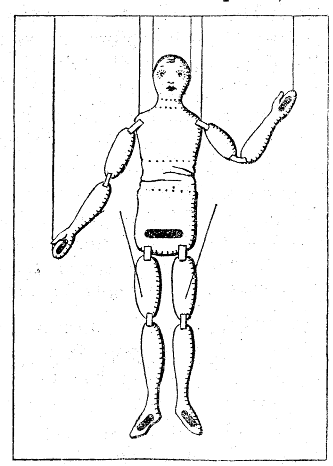

FIG. 5

The marionette is suspended by strings from a controller held in the hand of an operator above. This controller (fig. 6) can be a flat strip of wood about 10 in. long with a shorter cross-bar. A leather strip tacked to the cross-bar slips over the back of the operator's hand. The head strings are tied (from the loops at ears) to ends of cross-bar and hold the weight of the doll. The hand strings are attached to the front end of the controller. The back string from the back waist-line of doll, is attached to the rear

MODERN MARIONETTES

1. Dryad and two fauns in puppet pantomime of a woodland scene, by William Simmonds, London
2. Spejbl and Hurvinek, marionette characters created by Josef Skupa, Pilsen
3. Witch and Dido, marionette characters from Purcell's "Dido and Aeneas," by Harro Siegel, Berlin
4. "Death and the Maiden," by Richard Teschner, Vienna
5. Don Quixote, marionette from the Luxembourg Puppet theatre, directed by Robert Desarthis, Paris
6. Accordionist, a hand puppet from the troupe of Max Jacob, Hohnstein
7. Ice skater, a marionette of Rufus Rose, American
8. Farmer's Boy, by Waldo Lanchester, Malvern
9. Alchemist and Chinese Medicine Man, giant 12-ft. marionettes created by Remo Bufano at New York World's Fair, 1939
10. Tatterman Marionettes "She Stoops to Conquer"
11. One of Tony Sarg's marionettes

end of controller. A separate bar is generally used for the foot controller, and a hole in the centre of this bar allows it to be hung up, when not in use, upon a peg at front of main controller. The strings are attached at the knee, not foot, of the doll. Shoulder strings or extra strings for special gestures can always be added.

Practice is required for operating string puppets smoothly. To turn or bend the head, tip the controller sidewise (or pull on the shoulder strings). To seat or bow the doll, tip the controller forward or pull on the back string. To walk puppet take the foot control in free hand and tilt it from side to side, moving the figure on with main controller at desired speed.

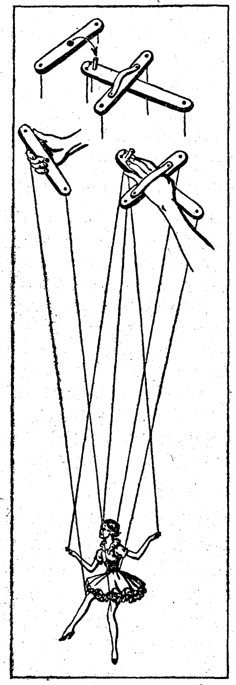

FIG. 6

A marionette stage is a miniature replica of any stage except that the wings are left open to allow passage of dolls, strings and controllers. Operators stand on a platform directly behind and higher than the puppet stage. A strong rail, waist high, in front of this "bridge" supports the weight of the operators, leaning against it. A rail at the back of the bridge is used to hang dolls upon. The bridge and the wings and the space below the puppet stage are concealed from the audience, usually by draperies. Behind these a framework forms the proscenium arch and supports the little curtain, also the front lights of the stage. Lighting and scenery must be planned not to catch the marionette's strings.

Rod Puppets are worked from below by rods (fig. 7). The head (of material similar to other puppets') can be made with a hole bored up the neck. A thin dowel fastened in this hole extends down below the feet and serves to hold and walk the puppet. The body usually consists of wooden shoulder and hip pieces attached horizontally at proper points to the upright dowel. Wire, or cloth stiffly stuffed with cotton, can be made to give a shape to the torso. Arms and legs are constructed as are the limbs for string puppets but the legs are generally allowed to hang without control. The arms are moved from below by thin rods of wood or wire attached to the palms. To articulate the neck of a rod puppet a more complicated construction is required. The head must be hollow and pivoted over the neck which is modelled (hollow) in one piece with the shoulders. A slender hollow metal tube is used instead of the upright dowel to allow strings attached at very precise points inside the head to drop down below the feet. By pulling these strings the operator can nod the figure's head. A convenient method of standing the puppet when not being held is to have two round disks about an inch apart fastened to the dowel just below the feet. Wooden strips must be built in just below the stage floor level at required places. These strips have slots cut into them at intervals into which the rod can be firmly set. Otherwise the stage, lighting, decor, etc., for rod puppets are similar to those for hand puppets. Rod puppets move slowly and gesture gracefully, hence are well suited for religious plays or dramas of fantasy.

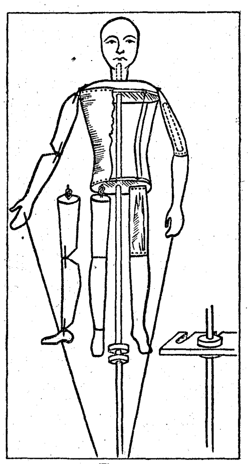

FIG. 7

Shadow Plays.—Somewhat like rod puppets, shadow plays are usually worked from below, at an opening in a screen or curtain; but this opening is covered with white cloth, drawn tight. The figures are cut in silhouette out of cardboard or tin and attached to slender staves by which they are held and moved, directly behind or in front of the cloth (fig. 8). Movable arms or jaws can be cut out separately, joined with brass clips and moved from below by wires or threads concealed behind the figure. Faces must be in profile. A light from behind throws the shadows plainly into view. Some suggestion of scenery can be painted upon the cloth or hung close against it. (*See* DOLLS; PANTOMIME; MASKS; THEATRE.)

MARIOTTE, EDMÉ (*c.* 1620–1684), French physicist, spent most of his life at Dijon, where he was prior of St. Martin-sous-Beaune. He was one of the first members of the Academy of Sciences founded at Paris in 1666. He died at Paris on May 12, 1684. The first volume of the *Histoire et mémoires de l'Académie* (1733) contains many original papers by him upon a great variety of physical subjects, such as the motion of fluids, the nature of colour, the notes of the trumpet, the barometer, the fall of bodies, the recoil of guns, the freezing of water, etc.

His *Essais de physique,* four in number, of which the first three were published at Paris between 1676 and 1679, are his most important works, and form, together with a *Traité de la percussion des corps,* the first volume of the *Oeuvres de Mariotte* (2 vols., Leyden, 1717). The second of these essays (*De la nature de l'air*) contains a statement of Boyle's Law, which Mariotte discovered independently; in France it is called Mariotte's Law.

MARIPOSA LILY (*Calochortus*), the name given to a genus of beautiful plants of the lily family (Liliaceae), comprising about 40 species native to western North America, some 25 of which are found in California. They are tulip-like perennials, with simple or somewhat branched stems, ½ft. to 4ft. tall, rising from coated corms and bearing a few narrow leaves and showy white, yellow, lilac or bluish flowers, often spotted or marked in the centre. The three large broad petals, 1 to 2in. long, usually bear a conspicuous basal gland. Several species are in cultivation. (*See* SEGO LILY.)

MARIPOSAN or YOKUTS, a linguistic stock of North American Indians, including some 40 small tribes. Its former territory was in southern California, around Tulare lake. The Mariposans were fishers and hunters. Their villages were a single row of wedge-shaped huts, with an awning of brush along the front.

MARIS, JACOB (1837–1899), Dutch painter, the eldest of three brothers, all of whom became artists, was born at The Hague on Aug. 25, 1837. He first studied at the Antwerp academy, and subsequently in Hébert's studio in Paris from 1865 till 1871. He worked mainly in Holland. Though he painted, especially in early life, domestic scenes and interiors, it is as a landscape painter that Maris will be famous. He was the painter of bridges and windmills, of old quays, massive towers and level banks; even more was he the painter of water, and misty skies, and chasing clouds. In all his works, whether in water or oil colour, and in his etchings, the subject is always subordinate to the effect. Maris has shown all that is gravest or brightest in the landscape of Holland, all that is heaviest or clearest in its atmosphere—for instance, in the "Grey Tower, Old Amsterdam," in the "Landscape near Dordrecht," in the "Sea-weed Carts, Scheveningen," in "A Village Scene," and in the numerous other pictures which have been exhibited in the Royal Academy, London, in Edinburgh (1885), Paris, Brussels and Holland, and in various private collections. Jacob Maris died at Karlsbad on Aug. 7, 1899.

MATTHEW MARIS (1839–1917), younger brother of Jacob, was born at The Hague on Aug. 17, 1839. He was given an allowance by the Queen of Holland and for some time lived and worked with his brother Jacob, on whom his more spiritual and mystical nature had a refining influence. There is a touch of mediaevalism in many of his figures. "Souvenir of Amsterdam," "Bride of the Church," "The Four Mills," and "Girl Feeding Chickens" are among his most successful works. In 1885 he went to London to design windows. He died there Aug. 17, 1917.

WILLIAM (WILLEM) MARIS (1844–1910), youngest of the brothers, was born at The Hague, Feb. 18, 1844. He developed under the influence of Jacob and Matthew and lived for the greater part of his life in London. His paintings of cattle grazing, the most famous of which is "Cows beside a Ditch" (Ryks Museum, Amsterdam), are modern in treatment and have great charm of colour and feeling. He died in London in 1910.

MARITIME PROVINCE, a former province of Russia, in East Siberia; *see* FAR EASTERN AREA.

MARITIME TERRITORY, a term used in international law to denote coastal waters which are not Territorial Waters although in immediate contact with the sea. Thus any strait through which the right of passage of foreign vessels can be forbidden (as the Solent or the Inland sea of Japan), or bays so landlocked that they cannot be held to form part of any ocean-highway, are maritime territory.

MARIUPOL, a seaport of the Ukrainian S.S.R., at the mouth of the Kalmius, in 47° 6′ N., 37° 35′ E. Pop. (1939) 222,427. The harbour is situated four miles southwest of the town and has a depth of about 24 ft. Pilotage is necessary up the 5-mi. long channel from the harbour to the roadstead. Grain is loaded partly by hand and partly by elevators and iron partly by hand and partly by winches. The town has smelting, graphite and ultramarine works and manufactures knitted goods. Its exports are mainly grains, iron, coal and oilcake, and its imports merchandise for local use. The town is linked by rail with the north, but not directly with Taganrog. A coasting route goes to Berdiansk. The place is said to have been inhabited in remote times under the name of Adamakha; the present town was built only in 1779, by Greek emigrants from the Crimea, and there is a fishing industry.

MARIUS, GAIUS (155–86 B.C.), Roman general, of plebeian descent, the son of a small farmer of Cereatae (mod. *Casamare,* "home of Marius") near Arpinum. He served first in Spain under Scipio Africanus, and rose from the ranks to be an officer. In 119 as tribune he proposed a law intended to limit the influence of the nobles at elections. This brought him into conflict with the aristocratic party, who prevented him from obtaining the aedileship. When about forty years of age he married a lady of patrician rank, Julia, the aunt of Julius Caesar. Praetor in 115, he subdued Further Spain. In the war with Jugurtha (109–106) he came to the front as lieutenant of the consul Quintus Caecilius Metellus Numidicus. He came home in 108 to stand for the consulship, was elected, and proceeded to upset all precedent by over-ruling the Senate on the question of his command, and getting the war with Jugurtha assigned to him by the Assembly. He then raised a large army by another unconstitutional departure, enrolling the classes without property (*capiti censi*), probably the most momentous step he ever took. He superseded his old commander Metellus, and took with him as quaestor L. Sulla, who commanded the cavalry. Between them they brought the war to a triumphant issue, and Marius passed two years in his province of Numidia, which he thoroughly subdued and annexed. The surrender of the person of Jugurtha to Sulla gave rise to the view that he, not Marius, had really ended the war, and so laid the foundation of the subsequent enmity between the two leaders.

Marius was next appointed to the command against the Cimbri and Teutones, who had destroyed two Roman armies near the lake of Geneva. Marius, out of unpromising materials and a demoralized soldiery, organized a well-disciplined army, with which he inflicted on the invaders two decisive defeats, the first in 102 at Aquae Sextiae (Aix), 18 m. north of Marseilles, and the second in the following year near Vercellae (*Vercelli*), about midway between Turin and Milan. In 101 Marius was elected consul a fifth time (previously in 107, 104, 103, 102), hailed as the "saviour of his country," and honoured with a triumph.

The glorious part of his career was now over. A very able soldier, as a politician he on the whole failed, though he retained the confidence of the popular party almost to the last. But he unfortunately associated himself with the demagogues Saturninus (*q.v.*) and Glaucia, in order to secure the consulship for the sixth time (100). Later their excesses forced him to turn against them, and this cost him his popularity. So he left Rome for Asia, where he endeavoured to provoke Mithridates to hostilities. On his return he served as legate in the Social War (90), and defeated the Marsi on two occasions. In 88 war broke out with Mithridates, and Sulla was appointed by the senate to the chief command. While Sulla was at Nola with the army, the tribune Sulpicius Rufus started a programme of revolutionary legislation which included the transfer of the command to Marius. Sulla marched on Rome, crushed the revolution, and outlawed Marius, who fled with a price on his head. After a picturesque series of incidents which included a frustrated attempt to land at Carthage, he settled for the time in Cercina. No sooner had Sulla left for the East, than Cinna's revolution started. Marius joined Cinna, forced his way into Rome and entered on a reign of terror in which senators and nobles were slaughtered wholesale. He had himself elected consul for the seventh time, in fulfilment of a prophecy given to him in early manhood. Less than three weeks afterwards he died of fever, on Jan. 13, 86.

He carried out to their logical conclusion the processes begun by Rufus, and under the new organization the soldier was a man who had no trade but war. He did not himself use the army as a political weapon, but under the new order the great general was bound to become the ruler of the State.

For Marius the original sources are numerous passages in Cicero's works, Sallust's *Jugurtha,* the epitomes of the lost books of Livy, Plutarch's *Lives* of Sulla and Marius, Velleius Paterculus, Florus and Appian's *Bellum civile. See* F. D. Gerlach, *Marius und Sulla* (Basel, 1856); I. Gilles, *Campagne de Marius dans la Gaule* (1870); W. Votsch, *Marius als Reformator des römischen Heerwesens* (with notes and references to ancient authorities) 1886; A. H. J. Greenidge, *History of Rome,* vol. i. (1904); also ROME: *Ancient History: The Republic.*

MARIVAUX, PIERRE CARLET DE CHAMBLAIN DE (1688–1763), French novelist and dramatist, was born at Paris on Feb. 4, 1688. His father became director of the mint at Riom in Auvergne, and Pierre was brought up there and at Limoges. Marivaux began his literary career by writing plays, admirable and graceful comedies, of which the most famous are *Le jeu de l'amour et de l'hasard* (1730), *Les Fausses Confidences* (1736), *Le Legs* (1736) and *L'Epreuve* (1740). If they lacked something in depth and characterization, they were full of witty dialogue, much of it about trifles, but exquisite in its way. This dialogue gave a new word to the French language, *marivaudage;* the style perfectly reflects the gallantry and the *sensibilité* which is the subject matter. Simultaneously Marivaux conducted two or three short-lived periodicals, in the *Spectator* style: *Le Spectateur français* (1722–23), *L'indigent Philosophe* (1727), and *Le Cabinet du philosophe* (1732).

In 1731 Marivaux published the first two parts of his best and greatest work, *Marianne,* a novel of a new and remarkable kind. The eleven parts appeared in batches at intervals during a period of exactly the same number of years, and, after all, it was left unfinished. In 1735, another novel, *Le Paysan parvenu,* was begun, but this also was left unfinished. *Marianne* is an extremely important step in the legitimate development of the French novel—legitimate, that is, in opposition to the brilliant but episodic productions of Le Sage. Its connection, and that of *Le Paysan parvenu,* with the work not only of Richardson but of Fielding is also an interesting though a difficult subject. The subject matter of Marivaux's peculiar style has been generally, and with tolerable exactness, described as the metaphysics of love-making. His characters, in a happy phrase of Crébillon's, not only tell each other and the reader everything they have thought, but everything that they would like to persuade themselves that they have thought. He was elected a member of the Academy in 1742. He survived for more than 20 years, contributing occasionally to the *Mercure* and writing plays. He died on Feb. 12, 1763, aged 75 years.

Marivaux was, though a great cultivator of *sensibilité,* on the whole decent and moral in his writings, and was unsparing in his criticism of the rising *Philosophes.* This last circumstance, and perhaps jealousy as well, made him a dangerous enemy in Voltaire. He had good friends, not merely in the rich, generous and amiable Helvétius, but in Mme. de Tencin, in Fontenelle, and even in Mme. de Pompadour, who gave him, it is said, a considerable pension, of the source of which he was ignorant.

The best and most complete edition of Marivaux is that of 1781 in 12 vols. reprinted with additions 1825–30. The plays had been published during the author's lifetime in 1740 and 1748. There are modern editions by Paul de Saint Heylli Victor (1863), by G. d'Heylli (1876) and by E. Fournier (1878), while issues of selections and separate plays and novels are numerous. Of works concerning him J. Fleury's *Marivaux et le Marivaudage* (Paris, 1881), G. Larroumet's *Marivaux, sa vie et ses oeuvres* (1882; new ed., 1894), the standard work on the subject, and G. Deschamps's *Marivaux* (1897), in the *Grands écrivains français,* are the most important.

MARJORAM, aromatic herbs or undershrubs, belonging to the genera *Origanum* and *Majorana* (family Labiatae). Wild marjoram (*O. vulgare*), a perennial native to Europe and Asia, is common in dry copses and on hedgebanks in England and is naturalized in the eastern United States. It has many stout stems 1 to 3 ft. high, bearing short-stalked somewhat ovate leaves and clusters of purple flowers. Sweet marjoram, *M. hortensis,* and pot marjoram, *M. Onites,* are cultivated for the use of their aromatic leaves, either green or dry, for culinary purposes; the tops are cut as the plants begin to flower and are dried slowly in the shade. (*See* FLAVOURINGS.)

MARK, ST., author of the second Gospel. In Acts (xii. 12) we read of "John, whose surname was Mark," and gather that Peter was a familiar visitor at the house of his mother Mary—a centre of Christian life in Jerusalem. That he was, as his Roman surname suggests, a Hellenist, follows from the fact that he was cousin (Col. iv. 10) of Barnabas, who belonged to Cyprus. When Barnabas and Paul returned from their relief visit to Judaea (*c.* A.D. 46), Mark accompanied them (xii. 25). Practical capacity seems to have been his distinctive excellence (*cf.* 2 Tim. iv. 11); and when, not long after, they started on a joint mission beyond Syria, Mark went as their assistant (xiii. 5). After leaving Cyprus and on arrival at Perga in Pamphylia (*see* PAUL), he withdrew, probably on some matter of principle, and returned to Jerusalem (xiii. 13). When, then, Paul proposed, after the Jerusalem council of Acts xv., to revisit with Barnabas the scenes of their joint labours, he demurred to taking Mark with them again, feeling that he could not be relied on should fresh openings demand a new policy. But Barnabas stood by his younger kinsman, and "took Mark and sailed away to Cyprus" (xv. 38 *seq.*).

When Mark reappears it is in Paul's company at Rome, as a fellow-worker joining in salutations to Christians at Colossae (Col. iv. 10; Philem. 24). This, along with its context, points to a reconciliation during Paul's last sojourn in Jerusalem or Caesarea. Not long after Col. iv. 10 Mark seems to have been sent by Paul to some place in the province of Asia, lying on the route between Ephesus and Rome. For in 2 Tim. iv. 11 Paul bids Timothy, "Pick up Mark and bring him with thee, for he is useful to me for ministering."

Once more Mark's name occurs in the New Testament; this time with another leader, Peter, the friend of his earliest Christian years in Jerusalem, to whom he attached himself after the deaths of Barnabas and Paul. Peter's words, "Mark, my son," show how close was the spiritual tie between the older and the younger man (1 Pet. v. 13); and as he is writing from Rome ("Babylon," since Paul's death and the policy it implied), this forms a link with the early tradition which speaks of Mark as writing his Gospel under the influence of Peter's preaching (in Rome). Such is the gist of the tradition preserved from "the elders of former days" by Clement of Alexandria (in Eus. ii. 15, vi. 14), a tradition probably based on Papias's record (Eus. iii. 39) of the explanation given by "the Elder" (John) as to the contrast in form between Mark's memoirs of Peter's discourses and some other Gospel (*see* MARK, GOSPEL OF), but further defining the place where these memoirs were written as Rome. He had acted to some degree as Peter's interpreter or dragoman (ἑρμηνεύς), owing to the apostle's imperfect mastery of Greek; and the fact that he assisted alike Barnabas, Paul and Peter, helps to show the essential harmony of their message.

The identification of the author of the second Gospel with Mark enables us to fill in our picture a little further. Thus Mark was perhaps himself the youth (νεανίσκος) to whom his Gospel refers as present at Jesus's arrest (xiv. 51 *seq.; cf.* his detailed knowledge as to the place of the last supper, 13 *seq.*). It was probably as writer and not in his own person, that he became known as "he of the stunted extremities" (κολοβοδάκτυλος, "curt-fingered"), a title first found in Hippolytus (*Haer.* vii. 30), in a context which makes such metaphorical reference to his gospel pretty evident. It was too as evangelist that he became a subject of later interest, and of speculative legends due to this; *e.g.,* as one of the Seventy (first found in Adamantius, in the 4th century), the founder of the Alexandrine Church (a tradition in Eusebius, ii. 16) and its first bishop (id. ii. 24), and even author of the local type of liturgy (*cf.* the *Acts of Mark,* ch. vii., not earlier than the end of the 4th century).

As to his last days and death nothing is really known. It is just possible that Alexandria was his final sphere of work, as the earliest tradition on the point implies (the Latin *Prologue,* and Eusebius as above, probably after Julius Africanus in the early 3rd century). That he died and was buried there is first stated by Jerome (*De vir. ill.* 8), to which his *Acts* adds the glory of martyrdom (*cf.* Ps.-Hippolytus, *De LXX Apostolis*).

LITERATURE.—H. B. Swete, *The Gospel acc. to St. Mark* (1898), Introduction, § I., where the authorities are fully cited; also the art. in Hastings's *Dict. of the Bible.* The Patristic and other legends are discussed at length by R. A. Lipsius, *Die apokr. Apostelgesch. u.s.w.* (1884), ii. 2, and T. Schermann, *Propheten- und Apostellegenden* (1907), 285 *seq.;* M.-J. Lagrange, *Evangile selon S. Marc,* 4th ed. (Paris, 1929), pp. xvi–xxxii. (J. V. B.)

MARK, a word of which the principal meanings are in their probable order of development—boundary, an object set up to indicate a boundary or position; hence a sign or token, impression or trace. *See* MARK SYSTEM.

Mark, in the monetary sense, was until recently the name of a German silver coin, and as such is probably a distinct word and not of Teutonic origin; it is found in all Teutonic and Romanic languages, Latinized as *marca* or *marcus.* The mark was originally a measure of weight (varying during the middle ages, but *c.* 8 oz.) for gold and silver only and was common throughout western Europe (*see* Du Cange, *Gloss. med. et infim. Lat. s.v. Marca* for a full list). In England the "mark" was money of account only, and apparently came into use in the 10th century through the Danes. It was first taken as equal to 100d., but after the Norman Conquest was equal to 160d., (20d. to the oz.) = two-thirds of the pound sterling, or 13s.4d., and therefore in Scotland 13½d. English; the mark (merk) Scots was a silver coin of this value, issued first in 1570 and afterwards in 1663. (*See* MONEY, MEDIAEVAL.)

The pre-war German *mark* was adopted in 1873, and first issued in 1875, as the standard of value and the money of account. It was of the value of 6·146 grains of gold, 900 fine, and was equal to English standard gold of the value of 11·747d. (in New York 23·821 cents). After the collapse of the mark (*see* GERMANY; CURRENCY; REICHSBANK) the mark was replaced in 1923 by the *rentenmark,* issued by the newly founded Rentenbank, and in 1924 by the *reichsmark,* issued by the Reichsbank, both of the same nominal value as the mark; the *reichsmark* is a nickel coin; the *rentenmark* is paper only, 5 being the lowest denomination.

MARK, GOSPEL OF, the earliest in date, though the second in canonical order, of the Four Gospels. For the evidence that Mk. was used as a source by the compilers of Mt. and Lk., and that it is therefore older than they, *see* the article GOSPEL. It was clearly of high authority in the period just after it was written. There are reasons for thinking that it was known not only to Mt. and Lk. but to Jn., and it was certainly used by the author of the apocryphal *Gospel of Peter.* It is perhaps quoted or echoed by the Roman writer Hermas about A.D. 140; it was used by Tatian (who had been in Rome, and who about A.D. 170 made a Harmony of the Gospels in Syriac); and it was ranked as one of the Four Gospels by Irenaeus (about A.D. 180). Irenaeus, like Tatian, had been in Rome, and the evidence of early quotations may be thus said to be in favour of Rome as a place of origin for Mk. It must certainly have been backed by some powerful Church in order to secure a place in the Canon, since, despite its vogue in the first century, it fell at a later date into relative disrepute. It is seldom quoted in antiquity—the longer and fuller Gospels of Mt. and Lk. were preferred to it. The earliest known commentary on Mk. dates from the fifth century. There are mss. of the Gospels in which it stands not second, but last, of the four.

Early Traditions Regarding the Gospel.—The earliest tradition with regard to the writing of the Gospel is contained in a fragment of Papias (quoted by Eusebius, *H.E.,* III. xxxix. 15), which may be translated as follows:

"This also the presbyter used to say: Mark indeed, who became the interpreter of Peter, wrote accurately, as far as he remembered them, the things said or done by the Lord, but not, however, in order. For he had neither heard the Lord nor been his personal follower, but at a later stage, as I said, he had followed Peter, who used to adapt the teachings to the needs [of the moment], but not as though he were drawing up a connected account of the oracles of the Lord: so that Mark committed no error in writing certain matters just as he remembered them. For he had one object only in view, viz.:—to leave out nothing of the things which he had heard, and to include no false statement among them."

It is not clear how much of this statement goes back to the unnamed "presbyter," how much represents Papias' own amplification of what the "presbyter" had said. Papias himself appears to have been Bishop of Hierapolis in Phrygia about A.D. 140, and a great champion of oral tradition. It is clear that criticisms had been made on Mk.'s Gospel on the ground of its defective "order"; and it is probable that the Gospel which is being tacitly preferred to it is that of Mt., in which it was thought that the materials were arranged in a more orderly way, and which, moreover, was (wrongly) supposed to be actual work of the Apostle St. Matthew. The fragment in any case embodies the perfectly sound critical judgment that no particular importance is to be attached to the "order" of Mk., who has produced a work which is essentially a "miscellany," a narrative built up out of anecdotes which were originally disconnected, and which had been used "in accordance with the needs of the moment" for the purpose of preaching.

The statement that "Mark became the interpreter of Peter" is less valuable. It is not likely that the unnamed "presbyter" would have possessed precise information upon this point, any more than that the Apostle Peter would have required, in the strict sense, an "interpreter." (Galilee was very largely a bilingual country, and it is probable that the original disciples of Jesus would have been able to speak a little colloquial Greek.) If the Gospel reached Asia Minor from Rome, this fact would suffice by itself to explain the tradition—it would be taken for granted that the authority of Peter, who (with S. Paul) had been a Roman Apostle, was behind it. The Gospel, no doubt, does contain, *inter alia,* authentic "Petrine" traditions, but it is a mistake to regard it as being *exclusively* "Petrine"; and it is of interest to observe that the earliest tradition stresses the fact that the author of the Gospel had not been himself an eye-witness. The claim which is made (and it is probably a just one) is that he represents the traditions of eye-witnesses at second-hand.

Irenaeus, in the account which he gives of the Gospel (Iren. *Adv. Haeres,* III. i. 2; *cf.* III. x. 6), echoes Papias' words, and is clearly dependent on Papias: but he adds one new fact (the knowledge of which he may have owed to his residence at Rome), viz.:—that the Gospel was written *after the deaths of the Apostles Peter and Paul.* The information is, no doubt, to be trusted.

Later traditions are perhaps hardly worth quoting. There are allusions to Mk. in the Muratorian Fragment (end of the second century) and in Hippolytus (who described Mark as "docked" or "curt-fingered"). Clement of Alexandria (conflicting with Irenaeus) suggests that the Gospel was written while S. Peter was still alive, and S. Chrysostom inferred wrongly from some words of Eusebius, who represents Mark as "proclaiming in Egypt the Gospel that he had written" (Euseb., *H.E.,* II. xvi. 1), that the Gospel was written, not at Rome, but in Egypt.

Place of Origin, Authorship, Date.—In the light of the evidence given above, it may be assumed that Rome—not Antioch or Jerusalem—was the place of origin of the Gospel.

The tradition that Mark was the author may be also accepted. A tradition sufficiently in touch with facts to claim for the oldest of our Gospels (itself an anonymous work) the authorship not of an Apostle, but of a personage of the second rank—a companion of the Apostles, but a man not otherwise particularly prominent—is in all probability correct. On the Evangelist *see* the article MARK, ST.

The date of writing is no doubt correctly indicated by Irenaeus —Mark wrote "after the deaths" of Peter and Paul; and the tradition is probably to be trusted which connects their martyrdoms with the persecution of Roman Christians by Nero in A.D. 64–65 (Tacitus, *Annals,* XV. 44). The Gospel is addressed to a Martyr Church (*see* below). It was perhaps written about A.D. 65–67. B. W. Bacon, on the ground mainly of an argument based on a minute study of what he believes to be the historical perspective implied in chapter xiii. of the Gospel, would fix the date ten years later. On the other hand, a comparison of Mk. xiii. 14 with Lk. xxi. 20 may be held to suggest that Mk. (unlike Lk.) was writing *before* A.D. 70—the year in which Jerusalem fell.

Literary Characteristics.—The Gospel is written in rough, colloquial, sometimes ungrammatical Greek, highly Semitic in colouring—the kind of Greek which might be the work of a bilingual teacher whose native speech was Semitic, and who lacked literary culture. There are Aramaic idioms (parataxis, asyndeton); there is a characteristic Semitic monotony of style: there are actual Aramaic phrases and words, with accompanying Greek renderings (Mk. v. 41, vii. 11, 34, xiv. 36, xv. 22, 34). There are vulgarisms (ii., 4, 9, 11—*krabbaton,* "pallet-bed"; iii. 10, v. 29, 34—*mastix,* "scourge," in the sense of "disease"; xv. 43—*euschemon,* "of good social position," here probably in the sense of "rich"), and Latinisms both of vocabulary (v. 9, 15—*legio;* vi. 27—*speculator;* vi. 37, xii. 15, xiv. 5—*denarius;* xii. 14—*census;* xii. 42—*quadrans;* xv. 15—*flagellare;* xv. 16—*praetorium;* xv. 39, 44, 45—*centurio*), and perhaps also of style (ii. 23, xiv. 65, xv. 1, 15). The theory of actual translation from an Aramaic original, advocated by some scholars, is improbable. The phenomena are best explained by the assumption that the author—a Jew writing at Rome for a Greek-speaking Church—was an imperfect Greek scholar, who habitually *thought* in Aramaic, and who wrote such rough, colloquial Greek as he was able to achieve.

Criticism.—On the "Synoptic Problem" *see* the article GOSPEL. That Mk. was known in substance to Mt. and Lk. is quite certain. The question has been raised whether they knew Mk. in its canonical form, or a supposed earlier edition ("Proto-Mark," *Urmarcus*). Neither Mt. nor Lk. contains anything to correspond with Mk. iv. 26–29, Mk. viii. 22–26, or Mk. xiv. 51, 52, and there are a few other "common omissions" of less importance; Lk., moreover, omits bodily the whole of Mk. vi. 45–viii. 27. The theory of an *Urmarcus* is nevertheless to be rejected. The sections omitted by Lk. are Marcan in style, and plausible reasons can be assigned for their omission; and the fact that the conclusion of the Gospel is missing (*see* below), and that a comparison of Mk. xvi. 7 *sqq.* with Lk. xxiv. 6 *sqq.* suggests that it was already missing in the copy of Mk. used by Lk., seems decisive—a later editor who was prepared to add considerable sections in the middle of the book would surely have supplemented also the conclusion. Apart from a few possible interpolations and glosses (i. 2; ii. 19b; ii. 26—the words *when Abiathar was high priest;* viii. 35—the words *and the gospel's;* ix. 41—the words *because ye are Christ's*, and perhaps vii. 3–4—the note on Jewish ceremonial ablutions) it may be presumed that we possess the Gospel (unfinished) in the form given to it by its author.

That the Gospel, as it stands, *is* unfinished seems certain. The authentic text breaks off at Mk. xvi. 8. The verses which follow (Mk. xvi. 9–20) are missing from certain of the mss. of Mk., and are clearly a summary compiled later, and based on the writings of Lk. An alternative and shorter conclusion, contained in some mss. either alone or in combination with Mk. xvi. 9–20, serves as additional evidence that the true conclusion was missing. It would clearly have contained an account of the appearance of the risen Christ to St. Peter (Mk. xvi. 7; *cf.* 1. Cor. xv. 5, Lk. xxiv. 34). The conclusion may have been accidentally lost, but it is more probable that it was never written—the Evangelist broke off, and was prevented from completing his task.

With regard to the question of the possible *sources* of Mk., various conflicting views have been held. The theory of B. Weiss, who believed in a fundamental "Apostolic Source" or "Original Gospel," supposed to underlie both Mk. and the Synoptic tradition in general, is now generally abandoned. The more fashionable theory that the sources of Mk. are to be reduced exclusively to the oral teaching of Peter is probably in process of abandonment. J. Weiss, who maintained that Mk.'s

Gospel was "not a source, but a confluence of sources," attempted to distinguish (1) Petrine traditions, (2) stories of conflicts and discussions between our Lord and His adversaries, (3) isolated *logia* or sayings, with or without an historical framework, and (4) further popular traditions, of which the origin cannot be precisely determined. All these elements are no doubt actually represented in the Gospel; the delimitation and reconstitution of the supposed written or oral sources is a different matter. Attempts at hypothetical "source-criticism" in a case of this kind are rarely profitable, and neither the theory of E. Wendling (who believed in an original *Urmarcus,* the work of an "historian," revised and redacted successively by two subsequent writers, respectively designated by Wendling as "poet" and "theologian"), nor the more recent hypothesis of E. Meyer (a "disciples" source side by side with a source which speaks rather of "the Twelve"), is of any great value. Of greater importance is the question of Mark's possible relation to the Synoptic source known as "Q" (*see* the article GOSPEL). "Q," in some form, is probably earlier than Mk.; and it has been thought that Mk. (which in the main is a narrative Gospel) may have presupposed "Q," and been written to supplement it. There are points at which it has been thought that Mk. actually depended on "Q" —*e.g.,* the Beelzebub controversy (Mk. iii. 22–30), the catena of sayings in Mk. iv. 21–25, the discourse on the sending out of the Twelve (Mk. vi. 7–11), the sayings on discipleship in Mk. ix. 35–37, 41–50, and the brief anti-Pharisaic discourse in Mk. xii. 38–40. A comparison with the parallels in Mt. and Lk. suggests that in all these cases the sayings in question were represented in "Q," and as a rule in a much fuller form. In these cases—and perhaps also in the exceedingly brief and allusive accounts in Mk. of the Baptist's preaching, and of the Temptation of Jesus—it appears in fact not improbable that Mk. presupposed fuller knowledge on the part of his readers, or in other words that behind Mk. (not as a source which he incorporates, but as an already known document, with the contents of which he occasionally makes contact) the "Q" tradition is implied as being *in some form* familiar to the Christians of Rome.

It has been argued, lastly, that St. Mark's Gospel is "Pauline." It is certainly Gentile-Christian, and in its attitude to the Law anti-Jewish (*cf.* esp. Mk. vii. 1–23): but in Galatians St. Paul claims St. Peter's concurrence with his policy as regards "the gospel of the uncircumcision" (Gal. ii. 6 *sqq.*). There is little in Mk. that is *distinctively* Pauline—even the argument about the rejection and "hardening" of Israel (*cf.* Mk. iii. 5, iv. 11–12, vii. 6 *sqq.*), which exhibits affinities with the argument of Romans ix.–xi., may be set down to the account of the general missionary apologetic of the Church. St. Paul would have endorsed St. Mark's Gospel; but so, probably, would St. Peter—the Roman Church in the next generation looked back to the two "good Apostles" as having harmoniously taught and worked side by side (Clem. Rom. *ad Corinth.* v. 3).

Arrangement and Message.—The Gospel falls into three divisions, of which the first (Mk. i. 1–viii. 26) is in the main a collection of stories illustrative of Jesus' activity in Galilee. The starting-point is the preaching and Baptism of John, by whom Jesus Himself is baptised—the ideal type of Christian Baptism with water and with the Spirit: and a Voice hails Him as Son of God. He proclaims the Good News of God's Coming Kingdom, calls four men to follow Him, and in their company heals the sick, casts out demons, and performs mighty works. A collection of "conflict stories" which follows (Mk. ii. 1–iii. 6) serves from one point of view to render intelligible His subsequent Crucifixion, from another point of view to set forth the authority of the Son of Man to forgive sins (Mk. ii. 5–12) and to justify the independence of Christians in respect of the Jewish Sabbath (ii. 23–iii. 6) and of fasting (ii. 18–22). The "mystery of the Kingdom of God" is set forth in parables (iv. 1–34); and Jesus is manifested in mighty works as the Stiller of the Storm (iv. 35–41), Conqueror of Demons (v. 1–20), and Deliverer from Sickness (v. 25–34) and Death (v. 21–24, 35–43). The twice-told story of the Feeding of the Multitudes (vi. 31–44, viii. 1–9) is perhaps meant to suggest Jesus the Giver of the Bread of Life both to Jews and to Gentiles. In the stories of the Deaf-mute (vii. 31–37) and the Blind Man of Bethsaida (viii. 22–26) the Messiah opens blind eyes, and has unstopped the ears of the deaf (*cf.* Is. xxxv. 5).

The second, or central, division of the Gospel extends from Mk. viii. 27 to Mk. x. 45, and is concerned with the theme of the coming Passion. The confession of Peter at Caesarea Philippi is not specially welcomed in Mk. (contrast Mt. xvi. 13–19), and the disciples are enjoined to say nothing about it (Mk. viii. 30): the doctrine of the Passion, on the other hand, is proclaimed openly (Mk. viii. 32). It is by the road of suffering and death that the Son of Man must pass to His coming glory—the glory which the episode of the Transfiguration (a symbolic vision in which the representatives of Law and of Prophecy, seen for a moment in conversation with the Messiah, disappear to leave Jesus alone) heralds by way of anticipation (Mk. ix. 2 *sqq.*). The predictions of the Passion, thrice repeated (Mk. viii. 31, ix. 30–32, x. 32–34), sound like strokes of a bell—the Lord initiates His disciples beforehand into the mystery of His sufferings and death. At the same time there is set forth also the doctrine of discipleship as a *via crucis* for those who would follow. The true greatness consists in humility (Mk. ix. 33–37), it is needful to become as a little child (Mk. x. 13–16), the call is for utter self-sacrifice (x. 17–22)—wealth and worldly possessions are a hindrance (x. 23–31). The Son of Man came to give Himself a ransom (x. 45), it is a question of taking up the Cross after Jesus (viii. 34), of being prepared to drink of His Cup and to be baptised with His Baptism of blood (x. 38). The Gospel here becomes "virtually an impressive sermon addressed to the reader"—a sermon valid for all time, but peculiarly apt for the martyr-Church of first-century Rome.

The third division of the Gospel (x. 46–xvi. 8) is concerned with the actual story of the Passion at Jerusalem. The Messiah enters the Holy City in a guise meant to recall the prophecy of Zech. ix. 9 *sqq.,* and in the capacity of Zion's King (Mk. xi. 1–11). The Temple is cleansed (xi. 15–19), there are conflicts with chief priests and elders and scribes, Pharisees and Herodians and Sadducees (xi. 27–xii. 27). A brief christological section (xii. 35–37) suggests that the Messiah is a Greater than David, and that "Son of David" is an inadequate title. An apocalyptic discourse (Mk. 13) gives expression to the conviction that the grievous calamities and troubles which were to befall both the Church and the world (and which in part had already befallen the former) had been foreseen by the Lord—it is believed by many scholars that a brief Jewish-Christian apocalypse descriptive of the *dénouement* of world-history in three stages, viz.:—(1) Signs of the End (xiii. 7–8), (2) Manifestation of Antichrist, Great Tribulation, Flight of Believers (xiii. 14–20) and (3) Dissolution of the existing World-order, Coming of the Son of Man, Gathering of the Elect (xiii. 24–27), has been here incorporated along with authentic sayings of Jesus.

The remainder of the Gospel (Mk. xiv. 1–xvi. 8) comprises the story of the plot against Jesus' life, the Last Supper and Institution of the Eucharist, the disloyalty of Peter, the Agony and Arrest in the Garden, the examination before the Sanhedrin, the trial before Pilate, the Lord's Sufferings, Crucifixion and Death. The Burial of Jesus is seen by the women (Mk. xv. 40 *sqq.*) and the authentic text of the Gospel breaks off with the account of the Empty Tomb and the message of the Angel (xvi. 1–8).

Theology of the Gospel.—Mark is a frank super-naturalist —there is no non-supernatural Christianity in the New Testament—and his supernaturalism is of a naïve, popular kind. He believes both in demons and in miracles, and his Jesus is predominantly a Wonder-worker. For him Jesus is the Son of God (in the sense of a divine, supernatural Being), to whom witness is borne at His Baptism and Transfiguration by supernatural Voices from heaven, who is recognized by the demons (who are supposed to possess supernatural knowledge) as their destined destroyer and foe, and who is manifested in works of supernatural power. St. Mark's Jesus is clothed with authority from heaven (i. 27), knows the secrets of men's hearts (ii. 8, iii. 4, 5), is ranked higher than the angels (xiii. 32), and as the "Son of Man" is the Judge who shall come "with the clouds" (xiii. 26–27, xiv. 62), who already upon earth has the authority to forgive sins (ii. 10), and who is Lord of the Sabbath (ii. 28). At the same time He is genuinely man. He can be tired (iv. 36), angry (iii. 5) and grieved (iii. 5); He can sigh (vii. 34, viii. 12) and be moved with indignation (x. 14); He can be "greatly amazed" and "sore troubled" (xiv. 33); He dislikes being called "good" (x. 18), and is not omniscient (xiii. 32). He is addressed by His disciples as "Teacher" or "Rabbi" (iv. 38, ix. 38, x. 35, xiii. 1; ix. 5, xi. 21, xiv. 45). He is the Servant of God, who gives His life as "a ransom for many" (x. 45). If the doctrine of the Incarnation is implicit rather than explicit in this Gospel, its fundamental message is the setting forth of two themes: (1) the conviction of primitive Christianity as to the supernatural *power* of the Lord Jesus, and (2) the great doctrine and fact of the Cross.

MARKET. The word "market" or some similar one derived from the Latin *mercatus* appears in most European languages, and always refers to the place or method of contact between buyer and seller. The contact may be relatively simple, direct and personal, as in a market place, meat market, or farmer's roadside market. It may be a highly organized institution such as those for securities, cotton, or grain; or it may be almost an abstraction, such as the "labour market."

Historically the word usually meant a place at which a number of buyers and of sellers met at fairly frequent recurrent fixed times to do business, under certain rules and regulations, in one or at most a few kinds of goods. Meetings at such long intervals as three, six, or twelve months were called fairs; while business conducted by peddlers or in private retail stores or warehouses or by personal orders was not regarded as taking place in the market proper.

In ages when the volume of trade was small and transportation difficult it was good for sellers to know that if they took their wares to a certain spot on an appointed day they would find buyers gathered there. This knowledge centralized supply and demand, saved time and stimulated production for sale. Produce which became available only at certain seasons—wool, grain, cotton, furs, young livestock, etc.—could be disposed of at the end of the productive period in an annual fair. Commodities which were being produced the year round—butter, cheese, eggs, fish, handicraft wares, cloth, etc.—would need to be sold weekly at a market. Further, while a producer of seasonal commodities would not mind a long trip to a remote fair once a year, the seller of goods which were produced continuously needed some nearby market since he could not afford to spend more than one day a week taking his goods to market, selling them, buying what he required, and then returning home.

While fairs were, therefore, located relatively wide apart, markets had to be thickly sprinkled over settled areas. If, however, they became too numerous, the supply of goods or of buyers in each might be inadequate or uncertain, and the owner of the market would suffer a severe decline in the income he received from tolls, stall dues and other charges. During the rapid expansion of the western European economy in the 13th century the supply of markets seems to have outrun the demand to such an extent that strong efforts were made to prevent new ones from being set up wherever they might injure existing ones. Lawyers urged that markets should be at least two leagues (six miles) apart. This figure was probably quite reasonable and acceptable; it was near to the seven-mile radius which even in the early 19th century protected the markets in London from excessive competition; and it emphasized the essentially local character of the business transacted in the market.

Some markets remained general in character, and were chiefly devoted to the exchange of farm produce for urban manufactures. John Ramsay M'Culloch, in his *Dictionary of Commerce and Commercial Navigation* (1835 edition), defined a market as "a public place in a city or town where provisions are sold." Producer and consumer met there face to face. But if an area specialized in some staple product, middlemen would flock there to obtain their supplies for a wider national or foreign market. One classic illustration of this condition was the cloth markets of Yorkshire and other textile areas. To them small producers residing over a radius of not more than five or six miles brought their weekly output of one or two pieces of cloth, and sold it to merchants, commission agents or factors. Held at first in a main street or market place for a fixed period of time on the regular market day, they were eventually transferred indoors when large "cloth halls" were built, often sponsored and financed by the merchants who bought the fabrics. Larger producers did not rely on such local outlets, but sent their wares in bulk to the central market at Blackwell hall in London.

Similar developments took place in many continental markets. In Bruges, Belgium, the large open market place had by 1240 become flanked on one side by a *halle* in which cloth was sold on three days each week. By 1300 a second hall (the *Waterhalle*) was built astride a small river so that goods could easily be unloaded, and was open every day. A third hall, the *Cruudhalle* (Spice Hall) appeared, to serve as market centre for Spanish wool, drugs, spices and other goods from the Mediterranean.

Legally a market was the property and source of income of the person on whose land it was held or to whom it had been granted. In feudal society subordinate lay or religious landowners sought from their superiors the right to hold a fair or market; and in modern states the same rule may prevail that the right has to be obtained from the state. The charter which granted the mediaeval franchise gave the owner power to collect tolls on goods sold—or even on all goods displayed, and fees for the use of stalls; it protected his clients from competition by restricting sales in stores on market day; occasionally it conferred the right to operate a mint. In return it explicitly or by implication imposed the obligation to see that the king's peace or the peace of God prevailed, and to preserve law and order in the market's operations. This involved the provision of a market court to deal promptly with disputes concerning sales, disorder, or violations of the regulations touching weights and measures, price, quality, forestalling, etc. A clerk of the market had to be provided to approve all weights and measures, and a steward to preside over the court.

Some markets passed eventually into the hands of the towns in which they were located; but private or corporate persons continued to seek permission to establish markets well into modern times, as for example the grant of Covent Garden market to the Duke of Bedford in 1670.

With the rise of large towns, factory production, and intensified commercial activity in the 19th century the need for public markets increased in some respects and declined in others. Where production of manufactured articles passed into the hands of fewer larger units, private buying and production to fill orders caused the cloth halls and similar markets to shrink in importance and finally disappear. At the same time the maintenance of direct contact between large bodies of urban consumers and the rural food producers became well-nigh impossible because of the vast number of the former, the need for obtaining supplies from a wider national or international area, and the call for large storage facilities.

The development of large-scale rapid transportation, bulk handling, refrigeration and local or terminal produce warehouses bridged the physical gap so far as the commodities were concerned; but the commercial transactions involved the expansion of the class of intermediaries, whether purchasers or commission agents, wholesalers or retailers. In addition they led to an increase in the importance of private sales, wholesale markets, or auction sales, in which the consuming public played little or no part as buyer, but relied for its supplies on the storekeeper who bought his goods in the wholesale market, often at an hour when most of his customers were fast asleep.

The history of most expanding European cities reveals the efforts made by civic or private enterprise to expand the accommodation for both wholesale and retail purchases. For instance, Leeds, a Yorkshire cloth centre, more than trebled its population between 1801 and 1851. In 1801 it had a weekly market for grain, cattle and hogs, and a twice-weekly one for cloth and provisions. By 1851 it had added a fortnightly fair for cattle and sheep, and eight periodical leather fairs each year; it had removed the markets for provisions and livestock from the narrow main street, created a large open "free market" area for use by farmers, and set up a meat market with an underground slaughterhouse. Meanwhile groups of investors had erected buildings for a bazaar, a meat and fish market, a central provision market, a corn exchange, leather fairs and a stock exchange.

On the continent private and municipal markets were expanded as populations became more dense. The municipal *Halles Centrales* in Paris eventually covered ten acres in the middle of the city, and the customers were retailers and consumers alike. Yet they could not handle all the needs of the metropolis, and other markets, therefore, had to be created or expanded.

In North America the European type of market developed naturally, rather than as the result of charter grants, to meet similar requirements, and in its most simple form can still be seen in operation in the market squares or halls of some of the older United States and Canadian towns. The expectation of getting fresher or cheaper produce from a farmer still takes customers there in spite of the lavish array of retail stores. Of larger markets to supply retailers as well as consumers, the Fulton fish market in New York city or the Faneuil Hall market in Boston are examples. Rapid urbanization and the rising cost of living after 1900 stimulated interest in efficient and economical marketing and led to considerable activity in providing city markets. Private enterprise, especially by the railroads, began to establish terminal markets at which country produce is unloaded and displayed for sale. But in most of the public markets the customer is rarely the consumer. The spread of suburban stores, the extension of chain stores, the congestion of traffic around public markets, and possibly the American consumer's lack of interest in the possibility of saving a few cents by taking a trip to the big market, have all made that institution, even in its most streamlined form, a minor part in the system of distribution. ECONOMIC THEORY

In economic theory the term "market" means the general conditions under which buying and selling are conducted.

In the theory of the market several types are distinguished. At one end of the scale is the perfectly competitive market, at the other end is perfect monopoly, and there are many intermediate forms. It may be said that perfect competition and perfect monopoly are limiting cases rarely to be found in practice, and that most actual markets fall into the intermediate forms known as "imperfect competition." A perfectly competitive market is characterized by the following conditions: (1) the number of buyers and sellers in effective contact must be large enough so that the action of any one of them has no appreciable effect on the price. That is to say, the operations of each individual buyer or seller are so small a proportion of the total, that each can buy or sell as much as he wishes at the prevailing price. (2) The commodity involved must be homogeneous in the sense that each buyer does not care from whom he buys, and each seller does not care to whom he sells, as long as the standard commodity is involved in the transaction. In a perfectly competitive market any price differences between different parts of the market will be equal to the costs of transport of the commodity from one part to the other. This conformity of prices is effected through the operation known as arbitrage, *i.e.,* by operators buying in the "cheap" place (which will raise the price there) and selling in the "dear" place (which will lower the price there). The equilibrium price in a competitive market is that which "clears the market," *i.e.,* the price at which the quantity of the commodity offered for sale is equal to the quantity which people are willing to buy. If the price is above this level, more will be offered for sale than buyers can be found to accept, and the fear of being left without a buyer will induce sellers to lower their prices. If the price is below that level, less will be offered for sale than people are willing to buy, and buyers will raise their prices for fear of not finding a seller.

The closest approach to the perfectly competitive market is to be found in the organized commodity and security exchanges, such as the grain and cotton markets, the metals markets and the stock markets. Such markets tend to arise wherever men deal in exchangeables that are homogeneous and simple enough to be bought and sold by description. Such markets are characterized by great flexibility of prices, and also by short-run speculative price movements which may be due to the temporary emotional states of the marketers rather than to any basic underlying factor. The organized markets in different centres are closely connected by telegraphic communication and by specialized "arbitrageurs" who operate in many centres, so that in peacetime there is a world market for many of the standard raw material commodities and for many securities.

When the commodity is not homogeneous enough to be graded and sold by description, a common form of market is the auction. Wool, livestock, eggs, meat and vegetables are frequently sold in this manner. When the commodities sold by auction are fairly homogeneous, the results of this form of market will not be very different from those of perfect competition. The price will lie somewhere between the highest price which the most eager buyer is willing to pay and the highest price which the second most eager buyer will pay.

At the other extreme to perfect competition stands monopoly. A monopolist may be defined as a seller whose product is different from that of any other seller. A seller is in a situation of perfect monopoly if, in addition, the demand for his product does not depend upon the price or sales policy of any other individual seller or small group of sellers. Whereas the seller in a perfectly competitive market can sell as much as he wishes at the prevailing price, a monopolist must either lower his price or increase his selling cost in order to expand sales. The relationship between price, selling costs, and sales is sometimes known as the "market" of an individual seller. In perfect competition the seller has a "perfect market," and there are no selling costs, for if the seller can sell as much as he wants at the prevailing price, obviously there is no need for him to advertize. The existence of a sales problem is a sign of monopoly.

Probably most firms operate under some form of "imperfect competition" exhibiting both monopolistic and competitive elements. Three main types may be distinguished. Monopolistic competition is a situation where there is a large cluster of sellers (firms) selling similar but not identical products, and where firms are free to enter the cluster or to withdraw from it. The fact that the products are not identical (*i.e.,* there is "differentiation of the product") means that each firm is to some extent in a position of monopoly in that it has an imperfect market; it can have a price and sales policy, for if it lowers its price it will attract only a finite amount of business from its competitors, and if it raises its price it will not lose all its business to its competitors, the products of different firms not being perfect substitutes. On the other hand the ability of new firms to enter the cluster makes it impossible in the long run for the firms in it to make abnormal (monopoly) profits, for if the firms in the cluster are making abnormally high profits, other firms will be attracted into it, and the competition of the products of the new firms will lower the demand for the product of each of the other firms, and so will lower profits. This process will go on until profits are normal—*i.e.,* are at a level at which on balance no firms are attracted or repelled. It can be shown that the end result of monopolistic competition is that firms operate at a level of output which is below the optimum efficiency.

Virtually the whole retailing industry, and the great part of the manufacture of consumers goods, are carried on under monopolistic competition. Thus if a single retail store raises its prices without neighbouring stores raising their prices, it will not lose all its business, since it has a certain clientele that will stay by it for reasons of convenience or of personal preference even if its prices are relatively higher. Similarly the manufacturer of a single breakfast food could raise his price without losing all his sales to other breakfast foods, since the different breakfast foods are not perfect substitutes. Nevertheless, these elements of monopoly probably do not enable retailers, or most manufacturers, as a group to enjoy abnormal profits, because if profits are high new firms will be attracted to that locality or to the production of a similar commodity. It is probable also that most retailers, and many manufacturers, could produce more efficiently if their sales were higher; they are prevented from expanding sales, however, by the limited (*i.e.,* monopolistic) nature of their market.

Another form of imperfect competition is called oligopoly, this being a situation where there are few sellers. If the product of each seller is perfectly substitutable for that of any other the situation is known as perfect oligopoly. In such a case any price change by one firm will be immediately followed by a similar price change by the other firms. It can be shown that this condition is likely to result in price leadership by one firm. This is a common phenomenon in industries producing fairly standardized products—*e.g.,* steel, cement, sugar. If there are few sellers in a cluster producing products which are highly but not perfectly substitutable, a situation known as imperfect oligopoly may develop. In this condition a cut in price by one firm will not be imitated immediately by others. Hence price-cutting, or "cut-throat competition" may arise, and a highly unstable situation ensue. There is, therefore, a strong tendency for firms in oligopoly to come to some agreement on division of markets or on price policy: the "basing point system" found in the steel and cement industries is a case in point, also the market-sharing arrangements of cartels. The possible varieties of oligopoly are many, as many different plausible assumptions about the behaviour of firms under these circumstances may be made.

The market forms which have been described above also apply to buying markets: thus we may have monopsony (a single buyer), oligopsony (few buyers), in various forms, and so on. Various forms of selling markets may be combined with various forms of buying markets in almost infinite variety. A very important market situation is bilateral monopoly, in which a single buyer faces a single seller. All cases of collective bargaining, *e.g.,* between labour unions and employers associations, or between milk producers and milk distributors, fall into this category. The price (or wage) then depends, within certain limits, on the relative bargaining power of the two parties. The "strike" (a temporary failure to effect a bargain) is a characteristic feature of bilateral monopoly. It should be noted that the above classifications are rough divisions only, and that in practice one market form shades imperceptibly into another.

(K. E. B.)

MARKET BOSWORTH, a township of Leicestershire, England, 105 mi. N.N.W. from London by rail and near the Ashby-de-la-Zouch canal. Pop. (1931) 864. The church of St. Peter is Perpendicular. At the grammar school, founded in 1528, Dr. Samuel Johnson was a master about 1732, but found the work unbearable. The trade of Market Bosworth is principally agricultural, but there are brickworks. Two miles south is the scene of the battle of Bosworth (1485), where Richard III fell before Henry earl of Richmond, who thereupon assumed the crown as Henry VII. Pop. of rural district (est. 1938) 24,220.

MARKET DRAYTON, a market town and urban district, Shropshire, England, situated on a high bank overlooking the upper waters of the Tern near the N.E. border of the county. Pop. (est. 1938) 4,896. Area 2.2 sq.mi. It is in the parish of Drayton in Hales. The market for cattle and cheese, granted by Henry III, is well-known, and there are breweries and manufactures of agricultural implements. On Blore Heath, 3 mi. east in Staffordshire, Audley Cross marks a great battle in the Wars of the Roses (1459), in which the Yorkists were successful.

MARKET GARDENING: *see* HORTICULTURE.

MARKET HARBOROUGH, a manufacturing market town in Leicestershire, England; on the river Welland and the Grand Union canal. Pop. of urban district (est. 1938) 9,417. Area, 7.5 sq.mi. It is 82 mi. N.N.W. from London by the L.M.S. railway. The church of St. Dionysius (*c.* 1250) with a tower and spire, is mainly Decorated and Perpendicular. The grammar school, founded in 1614, occupies modern buildings, but the original half-timbered building, raised upon pillars of wood, remains. Industries include rubber and textiles, boots, shoes and corsets. The general market, held for 700 years in the streets, was housed in a new building in 1938. This is an important fox-hunting centre.

MARKET INDEX, a business indicator revealing the activity of one or more industries, or of the actual or potential capacity of a given district to absorb an article or service offered for sale. The "business barometers" which indicate financial, industrial, and commercial conditions may constitute market indexes revealing business activity, but provide no basis for estimating the sale of a particular item. The market index is more than a financial statement for the people of a district. It is rather a system of indicators which reveal the relative conditions of trading areas from which may be computed sales possibilities. The factors necessary for an effective market index are of three classes: (a) Those which indicate the pulse or the tempo of business—its relative activity—such as the barometers; (b) Those which show the ability to buy; the wealth available for buying; (c) Those which reveal the disposition to buy; (d) In addition to these, other influences such as climate, racial characteristics, and habits of living need to be considered.

(a) Business is regarded as "good" or "bad" as it is above or below the average for the past five or ten years. The sale of electric current, car loadings, transactions on the stock market, bank clearings, department store sales, unfilled orders for steel, and the sale of machine tools are the more important factors used in determining the activity of business. The food industry varies little whether other industries are active or slack. Style goods, building materials, home furnishings, clothing, and luxuries are among the goods which move rapidly in good times and slowly when business is poor. Other businesses like those of the cobbler, the hat cleaner, and second-hand stores thrive on "hard times." Increased unemployment, falling wages, and slackening retail sales presage increased business for them. For most manufacturers, however, good business conditions mean more sales, more labour, more raw materials, and often increased operating capital.

(b) The ability to buy means wealth, especially wealth that produces income. It is reflected in such things as the per caput of life and fire insurance in effect; income tax returns; automobile registrations; homes owned; and savings deposits.

(c) Willingness to buy is not always found where wealth is greatest. Of course there must be resources with which to buy as well as a disposition to spend. This is reflected in retail sales, the number of dentists per thousand population, the number of new automobiles sold, and other purchases such as mechanical refrigerators, telephone rentals, attendance at places of amusement, and magazine and newspaper circulation.

(d) No item has been found which year after year sells in direct proportion to the population. Salt might seem to be such an article, but as it is used extensively in packing houses and to feed livestock, per capita sales are much larger in some districts than in others. So a market index for salt would require a factor to represent the number of cattle, sheep, and horses in the district. Tea is consumed in larger quantities by descendants of Northern European stock than by native Americans or those of the Latin countries, so a racial factor must be represented in a market index for tea.

Other things being equal the sale of straw hats would be in proportion to the number of days in the year of "summer heat." But other things are seldom equal. Hence the index becomes complex. The Negroes wear few straw hats, so they should be eliminated from the number of possible customers. The well-to-do buy straw hats more liberally than the poor. So a factor showing the ability to buy should be included. This might be the per capita sales of haberdashery stores. Men of the same town will buy more straw hats when business is good than when it is poor. So a factor indicating the activity of business is indicated. Comparing the possible sales of two districts would then depend upon the sizes of the two populations, excluding Negroes; the number of days of summer heat in each district; the sales of haberdashery stores; and the comparative state of business in the two territories. This index, when properly computed, enables a sales manager to fix sales quotas for the different trading areas, to apportion advertising expenditures in proportion to sales potentials, and to forecast sales more accurately than by reference to past performance.

In the United States it was anticipated that when retail sales became known that fact of itself would provide an unfailing index, sufficiently accurate for practical purposes. But such exceptions as the sales of food stores illustrate the inadequacy of this as a one item index. In urban districts, green vegetables, eggs, and butter and milk are among the items bought, while in rural districts these items are largely provided by the home. So in computing an index for the sale of a package cheese, food store sales would indicate too much for cities and not enough for towns and villages. Most other items have similar exceptions, so the careful marketing man compiles an index, and verifies estimates by all available data. (H. E. A.)

MARKETING. Marketing is essentially the distribution of goods from the producer to the consumer. The central fact is the sale, but to secure sales the goods must be assembled from the places where they were produced, graded when qualities differ, sorted when there are different varieties, stored, moved to market and in many cases thence to the place of consumption. All of these processes constitute a part of the marketing operation.

I. IN THE UNITED STATES

Methods of Marketing.—The simplest form of marketing and the most primitive is the sale by the producer directly to the consumer. In the aggregate, sales made in this way even at present run into immense volume, although but a small part of the total of business. Modern business, the development of large cities and an increasing division of labour in industry, all tend to reduce this form of marketing. There is still a considerable amount of marketing of produce, particularly fruits and vegetables, direct from farmers to consumers, by parcel post and by direct sale. Again, certain specialties, complicated machines and machines requiring much attention and service after the first sale, usually are sold direct by manufacturers to consumers through the medium of specialty salesmen. The salesman is the representative of the producer in the marketing transaction. Again, if a retailing house does so large a business that it can advantageously engage in manufacturing some of the lines of goods it sells, it may combine production with distribution.

MANUFACTURERS' AND PRODUCERS' METHODS

The Wholesaling System.—Most products of common use, such as foods, clothing, footwear, house furnishings, lumber, fuel and so on, are marketed through middlemen. The manufacturer of men's clothing or of shoes usually sells his product to retailers scattered over the country, who in turn sell to consumers. Manufactured food products, dry goods, drugs, hardware and house furnishings are generally sold first to wholesalers, who in turn sell to retailers. Farmers' produce, fruits, vegetables, butter and eggs, are commonly marketed through local buyers, then to wholesalers or wholesale distributors, to jobbers, then to retailers and lastly to consumers.

The Auction System.—In the case of highly perishable goods, such as fruits, where no time may be lost in effecting sales in order that they may reach the consumer before spoiling, the auction system is used. Wholesale buyers and salesmen come together at a designated place at a set time and clear their transactions. The auction is used also for known standards or qualities, which are bought and sold in wholesale quantities at certain dates each year, as carpets, rugs, wool, furs and fruits, and in marketing second-hand goods, works of art, antiques and even real estate.

The Commission Merchant and Broker.—Variation in marketing occurs through variation in ownership of the goods to be marketed. To illustrate: producers or local buyers usually sell outright to wholesalers all goods marketed through the wholesaler-retailer channel of distribution; but in highly perishable goods, such as fruits, dressed poultry, live poultry, etc., and also in cases where the value of the goods runs very high in proportion to the value of the service rendered by the wholesale middleman—as, for example, finished textiles, real estate, commercial paper and stocks and bonds—the wholesaler (or dealer who takes his place) frequently, if not usually, merely sells or buys as the agent of the owner and secures a commission or brokerage instead of a profit for his services. This arrangement in the case of perishable goods relieves the wholesale dealer of the risk from loss, and, in the case of costly goods, of the burden of financing the goods. Such wholesalers are known variously as commission dealers and brokers.

Market Speculation.—While goods are being gathered together in wholesale quantities and made ready for distribution to the retail trade other factors in marketing frequently enter in, factors of a speculative nature. Standardized goods that are not readily perishable, such as grain, cotton, wool, silk, provisions, coffee, sugar and so on, are likely to be bought purely for speculative purposes. Thus a lot of grain or cotton may be bought and sold several times before being moved to consumption. It is but another step for these speculators to make their ventures in hope of gain on what they think future prices will be. Hence "selling futures" is a common occurrence on the great exchanges that deal in the commodities named. Dealing in futures is an essential function of marketing, but it needs careful regulation to prevent unfair practices.

Conditions That Govern Methods.—If producers are many and small, and are located far apart, it is almost certain that their products will have to be assembled by a local buyer of some kind; whereas if the producers are able to turn out large quantities they may be able to deal with wholesalers directly. If consumers use small quantities or small lots of any product at one time it is almost certain that they must purchase from retailers. But a large consumer would be able to buy more advantageously direct from the producer.

Time is a very important element in the marketing of perishable goods. There must be no delay, and little time can be given to the sale of any particular unit. An illustration of a perishable article is the daily paper, the weekly or monthly magazine. Timeliness is the essence of their value. This makes necessary a highly specialized marketing organization to carry papers or magazines over the country and, in the case of magazines, to place them on sale everywhere at the same time. Such specialized handling calls for expense not incurred in goods not perishable.

A low-priced article with a small margin of gross profit to the seller cannot be sold in the same way as an article that offers a wide margin. Where the margin above costs of production is not sufficient to permit the article to be sold direct or to be advertised and sold by itself by the mail-order method, it must take its way to the consumer through the channels of trade followed by thousands of other similar articles.

Competition.—The competition in the sales field of any article may readily determine the channel of distribution that is taken. Certain manufacturers of soaps, perfumes and toilet goods have found it so difficult to place their products advantageously in drug-stores and similar retail outlets because of the number of competing lines that they have found it advisable to sell, especially in country districts or small towns, direct to consumers by means of agents and canvassers working on a commission basis. A motor-car tire maker found it so difficult to break into the market through automobile dealers and garages that he sold his product to a mail-order house. A new product must as a rule be sold through specialized marketing systems which may be abandoned after the public has begun to know and to demand the article.

WHOLESALING

Wholesaling in the United States is in a state of unrest and change. Much of the criticism that has been made against middlemen during the past 25 years as causes of the high costs of living has been specifically levelled at wholesalers. More and more manufacturers on the one hand and more and more retail institutions on the other have adopted direct means of selling or buying their goods with the result that jobbing lines have been greatly limited. National advertising has apparently helped the movement of manufacturers selling direct to retailers. The great increase in interest of the masses of the people in fashion and fashion goods that developed during the World War and at its close has made it necessary for retailers to work more closely with manufacturers on these classes of goods. Practically all lines of wholesaling have declined to some extent, some very greatly. As a result, many old, well-known wholesale houses have gone out of business, others have formed mergers and still others have changed the character of their business. Some wholesalers have through adoption and promotion of their own private brands of goods virtually become manufacturers. Still others have secured their retail outlets for themselves by becoming chain-store organizations.

RETAILING

Types of Retailing.—Goods reach consumers by retail in the following ways: by canvassing, that is, by sale from house to house; from samples; by peddling, that is, by sale from stock carried by wagon or truck or even from a pack carried on the

back of the salesman; by sales made through circular or catalogue by mail; by retail stores owned by independent merchants, chain-store operators, department stores, company or commissary stores and consumers' co-operatives. During the early 1930s there was a rapid extension of house to house selling on such lines as groceries, meats, fruits, vegetables, dry goods, apparel, hosiery, home furnishings, soaps, spices, and patent medicines. In many cases specially constructed trucks or vans were used, veritable stores or shops on wheels. House to house selling by the canvassing method grew enormously during the years from 1921 to 1925 in the United States. There were similar periods of high activity in canvassing following 1893 and 1907, suggesting that this method of selling seems to thrive best in a time immediately following a business depression. The mail-order method of selling to consumers suffered severe declines following the business depression of 1920 and 1921, but has since regained its former position in the system of retail distribution. However, this method of retail selling has apparently reached its maturity in relation to other types of retailing. The leading mail-order concerns are now rapidly expanding into chain-store organizations. Department stores are, in general, showing slight gains in the communities in which they are situated. Individual department stores, here and there, however, continue to show remarkable growth. Chains have enjoyed the most rapid development since 1920, but in recent years even they show indications of having reached their maturity of relative growth. The single, independently owned stores, while hardest hit by competition of the newer types of retailing, are now apparently holding their own. There are now more of such retail stores than ever before. Table I gives the statistics of retailing for the U.S.A. as shown by the censuses of 1929, 1933, and 1935.

Concentrated Buying.—A part of the competitive battle for trade among the various types of institutions consists in the utilization of large buying power. Large chain-store systems, mail-order houses, and large department stores frequently purchase their goods direct from producers and secure the prices usually given wholesale purchasers. But concerns that buy direct from producers, and thereby eliminate the wholesalers, as a rule incur most of the usual expenses of wholesaling, such as interest on the investment in the larger stock of goods, storage risks, buying expense in dealing with numerous producers instead of a few wholesalers, extra record-keeping and, with chain-stores, reshipments to their various stores throughout the country. Since 1920 there has been a rapid development in group, co-operative, and central buying by independent retailers of all kinds. Such organizations are variously known as retailers' co-operatives, retailer owned wholesalers, and voluntary chains.

Comparative Costs of Marketing. — Much interest has centred on the possibility of determining relative economic efficiencies of the various types of marketing institutions by comparison of their respective costs of doing business. Table II shows average costs of operation, not only for wholesale but also for retail institutions.

Comparing the various methods of retailing, as exemplified in the ordinary independent stores, the department stores and the mail-order house, from such facts as are available, it does not seem possible to assert positively that any one method presents decided general economic advantages over the rest. Each presents certain advantages. Where there are differences in service these differences seem to be fully compensated in expense—that is, the public pays for what it gets and in proportion to what it gets.

Costs of selling through mail-order houses are not officially known. They are supposed to range from 18 to 30% of sales. But the knowledge of a general figure of this kind for a large mail-order house with many departments would be of little value for purposes of comparison with other kinds of businesses. Costs of selling in mail-order houses vary from department to department just as in department stores. All things considered, the general costs of running a large mail-order house are probably somewhat lower than those for a large department store handling similar classes of goods. The lower costs of selling, so far as consumers are concerned, are offset in part at least by the costs of transportation and other expenses incidental to ordering by mail.

The figures presented in Table II clearly show a wide range in costs from line to line, but they do not point conclusively to any important differences in costs of operation from one type of distribution to another. Differences in services rendered, not shown at all in the table, account for differences in costs. There are also wide differences in costs from concern to concern due to differences in management efficiency.

*Compiled and adapted from reports of the Harvard bureau of business research, Northwestern university bureau of business research, several national trades associations and personal studies.

POSSIBLE ECONOMIES IN DISTRIBUTION

Avoidable Waste.—The following statements outline briefly a few of the details of distribution which it seems certain must receive attention in order to secure more economical distribution. No doubt many more could be added. Poor roads greatly increase the costs of bringing the farmers' crops and produce to market, costs that must be added to the price that consumers eventually pay. Inadequate truck and railway transportation is another element that makes a considerable addition to the costs.

Handling.—Delay in transportation as a factor of expense in distribution has not been given the attention that it deserves. Poor location of terminals makes a great deal of expensive cartage necessary. Congestion of traffic in city thoroughfares is a growing cause of increased costs in distributing goods. Inadequate, inefficient, poorly located storage facilities cause huge losses. Inadequate, unauthoritative and inaccurate collection and dissemination of market information such as is needed by producers, distributors and consumers is responsible for great waste. Through lack of such information business in many lines now passes constantly from glut to famine and back again. Poor packing of merchandise, inefficient loading, rough handling and uneconomical methods of handling are causes of waste and therefore of higher costs of distribution.

Salesmanship.—To refer more specifically to the activities of marketing through wholesalers and retailers, there is a startling loss of the wholesale salesman's time in finding customers, in making appointments, in fruitless interviews. The time of both salesmen and buyers is lost. Probably less than a sixth of a salesman's time, averaging salesmen of all classes, is actually employed in selling or even in displaying and describing merchandise. Anything that can be done to improve this condition would increase efficiency and decrease costs.

Advertising.—Advertising is or should be an invaluable aid to marketing. In the list of expenses of distribution it occupies a prominent place. There is certainly room for improvement in its administration. Much study has been given in some organizations to such problems as the proper selection of mediums and the right use of the space taken. No doubt much greater progress can and will be made in the future in these directions, but the greatest loss in advertising seems to be in the lack of faith of the public in the advertising. If people gave more credence to advertising, much less of it would be needed to secure the same result. The remedy, of course, lies in the direction of raising the standards and shutting out the dishonest advertiser. (*See* ADVERTISING.)

Duplication.—Duplication in delivery organizations by retail stores is a source of economic waste. There are many who think that there are too many retail stores. Would goods be sold for less if there were fewer? Probably not, because a large part of the competitive losses now occurring are borne by the dealers themselves in unpaid services. It may be argued that if their number were reduced the rentals for the locations that would be eliminated could be saved. This cannot be definitely checked by such experience as has been recorded in any public way. Concentration of retailing seems invariably to result in increasing rents. In fact, rents tend to increase faster than sales, so that the fewer the stores the higher the share of the landlord. More study is needed to determine the exact effects of restriction of the number of stores on costs of distribution. Further there is the fact that the store plant is unused for a large part of the time. Store hours are by custom and legislation steadily growing shorter. This means that the capital invested in stock and plant has fewer hours in which to produce.

Dishonesty.—Finally, there is undoubtedly an enormous loss due to unfairness and dishonesty, a loss that is now carried in large part if not wholly as an expense of distribution, being added to the price paid by the consumer. Failure to return containers lent by distributors seems a small item, but in such a business as milk distribution in large cities the loss to milk distributors due to non-return of empty bottles is enormous. Uncollectable debts and the cost of collecting delayed payments are important items in the expenses of distribution. Disregard of contracts in such matters as refusal of goods after placing orders, failure to deliver goods after orders are placed, abuse of the privilege to return goods, claims for adjustment and many other similar items make up large losses. Unfair competition, efforts made not to increase legitimate business but to impede or even to destroy competitors, commercial bribery, "graft" and the exercise of monopoly, all burden distribution expense far too much. A source of considerable loss is theft by employees, burglars and shoplifters. Some retail establishments count upon a fixed percentage on their sales representing losses due to this cause, a percentage that is added to the gross expenses which form part of the selling prices.

Many of the losses of the distributive business, including theft, breakage, fire and so on, are covered by insurance, the cost of which is carried as an expense against the distributing process. Anything that can be done to reduce these losses will by that much reduce expenses of distribution and prices of goods.

EDUCATION IN MARKETING

The leaks and wastes enumerated above are certainly responsible for at least a quarter of the present costs of marketing. They may be responsible for a third or even more. Here, then, is a great field for reducing costs by improving present methods. The first general step towards such improvement is education. Before 1860 the apprenticeship system was general in England and to some extent in America, in retail, wholesale, and importing houses. The apprenticeship system gradually broke down about the middle of the 19th century, and for years no systematic training was provided for young people other than the haphazard effect of their experience. The first training of modern salesmen in America seems to have been by the subscription book houses that flourished during the '70s and '80s. Their canvassers or book agents were thoroughly drilled or schooled in the art of selling or in securing orders.

During the '90s sales managers in specialty manufacturing concerns, notably the National Cash Register Company, of Dayton, O., began training their men in special schools held at the factory.

Training salespeople for retail stores seems to have begun in the '90s in such subjects as arithmetic, spelling and writing and, in 1905, in sales methods, under the auspices of the Women's Educational and Industrial Union in Boston. Educational service to salespeople and other workers is now commonly found in the better classes of both wholesale and retail stores. A beginning has been made also in education in distribution and marketing in colleges and public schools. Several colleges offer courses in marketing, selling, sales management and advertising. Many high schools give similar but more elementary courses. Trade associations have a marked educational bent in practically all lines pertaining to marketing. Through the trade associations better accounting, better advertising and better personnel work have been the objects of systematic educational programmes.

Training Through the Public Schools.—In 1936 a beginning was made by the nation as a whole in the encouragement of vocational training for retailing and the other distributive trades by the passage of the George-Deen Act of Congress appropriating a modest sum of money for distribution to the various States on the condition that they likewise appropriate similar sums to be used for instruction in these trades. Actual distributions of money were not begun until the latter part of 1937. The States have been prompt in their utilization of these funds and progress is being made in the inauguration of real training for marketing.

II. IN GREAT BRITAIN

The work and methods of the large wholesale markets in London and Liverpool for wheat, raw cotton, wool and tea have now for long been familiar to students of marketing in Great Britain and Ireland. The lack of organization, however, and the inefficiency characteristic of the distributive process throughout the greater part of the United Kingdom have hitherto placed serious obstacles in the way of those who seek to investigate price margins and the profits of middlemen and retailers. Some of these barriers were temporarily removed during the World War. The increase in size of the business unit and a growing willingness on the part of these larger firms to furnish information when requested are gradually removing others. Economy imposed by rising costs and increasing competition from abroad will soon remove the remainder.

In the home trade, regarded from the producers' point of view, there can be distinguished at least five important marketing channels depending mainly, but not entirely, on the nature of the product handled. The simplest is that often adopted by the farmer, the market-gardener and fisherman. Here, arrangements are made with middlemen dealers for outright purchase of the crop or catch. What then happens is the concern of consumers alone. The other four methods apply primarily, but not exclusively, to manufactured goods. Of these the oldest, and still that most frequently employed, is distribution through wholesale merchants who sell to retailers who in turn sell to the consumers. In this case the producer employs no travellers and sets up no selling organization on his own account. If, however, he desires to sell a branded article (which is not infrequent in modern English industry) he may still use the same agents, but he has to advertise and himself employ travellers to canvass the retailer. Selling direct to consumer in retail shops set up and owned by the manufacturer constitutes the third plan. This is of growing importance in the drug and the boot and shoe trade. Again, the plan of canvassing consumers directly through the medium of specially trained salesmen has proved useful, but it appears to be more successful in America than in Great Britain. It is especially applicable to soap, books, corsets and household articles appealing to working class women. The remaining method, postal selling or mail order, is encouraged by the c.o.d. system for parcels worked through the post office. Potential customers are canvassed by letter, catalogue or press advertisement. This plan, however, in England is of more importance to the retailer than to the manufacturer. Generally, a combination of two or more of the five is employed in any comprehensive scheme of distribution.

In the older market organization many manufactured products often passed through four channels from producer to consumer: commission house, factor, wholesaler, retailer; but modern business conditions tend to lessen the number of middlemen and to transfer some of their functions to other agencies such as banks and transport undertakings. Yet, 90% of all groceries, 70% of hardware and dry goods and a smaller per cent of drugs, are sold through the manufacturer-wholesaler-retailer channel.

The wholesaler's services to the manufacturer embrace the provision of warehousing facilities in addition to supplying a complete selling organization, extending credit to retailers and often financing them. He also buys ahead and, therefore, takes risks as to price fluctuations and change of style. Further functions are the packing of goods and the conduct of their transport.

As long as independent manufacturers only are served the system works smoothly; but often wholesalers themselves brand goods and compete with the manufacturers whose goods they distribute. Sometimes they actually own and operate factories themselves. In the case of certain dry goods and silk articles wholesalers' brands are of long standing and cause no restlessness among manufacturers; but in groceries they are new and are the cause of much friction. Other types of middlemen include the sales agent, the factor and the broker; but it is no longer possible to define the precise scope of each of these classes.

The wholesaler works on fairly narrow margins of gross profit. In the drug trade he generally obtains 10% on proprietary articles and 12½% on sundries. In groceries the margin is 5%; but certain food-stuffs in which competition is especially keen leave him as little as 2½. In hardware and dry goods the figure normally exceeds 12½ and reaches 15 on proprietary goods in this group. The smaller the margin the greater is the tendency to instability; but on the other hand the greater also the probable turnover.

The retail shop method of selling is by far the most important in Great Britain. In its modern form it dates from the 1870's when rapidly changing price levels forced the older retailers out of their easygoing ways. The increasing variety of goods produced in consequence of improved manufacturing methods, the decay of industries conducted in the home, the increased urbanization of the population, all demanded from the shop owner a growing efficiency if he was to survive. Further, the rise of the department store constituted a new development which became inevitable when the size of stocks forced the retailer to classify his goods. From classification into sections it was but a step to make each department independent and self-supporting, and thus turn a general store into a group of specialized shops under one roof. Independent of this movement, but simultaneous with it, was the rise of the multiple shop firm. Then, later, came mail order and postal selling, and the concomitant advertising which greatly extended the scope of retail trade.

To-day the general shop is largely confined to villages. In the towns department stores and specialized shops are the rule. Of the two latter it would seem that the specialized shop has secured the greater economies in operation. That this is true of the multiple shop firms dealing each in a single class of commodities is not open to doubt; for figures confidential to the trade which have been worked out and analysed indicate in their favour a margin of 2 to 3% in the cost of conducting business. It is reckoned that this cost for a London department store should be about 10% below the figure for New York and for the provinces about 2% less than for London. This gives 16% for London and 14% for the rest of the country.

Perishable Foodstuffs.—The producers of perishable foodstuffs ordinarily sell their product outright to middlemen who seek to take advantage of the special circumstances which necessarily attend trade in these commodities. Apart, however, from the greater difficulties that growers of such produce must always encounter, the conservatism of all who handle these articles creates and maintains others for the existence of which no adequate justification can be found. It is true that old vested interests, such as market rights on the part of individuals or their assignees and surviving manorial privileges, offer many obstacles to improvement; but scarcely less important hindrances are the reluctance of the smaller British producers to form societies for co-operation in sale of produce and the inability of many existing markets, especially in the larger towns, to cope with a growing volume of business.

Fruit and Vegetable Markets.—In certain centres where local production is insufficient or erratic and foreign imports are needed to ensure supplies or where transport facilities and geographical situation are exceptionally favourable the markets for fruit and vegetables possess more than merely local importance. Many of these are well organized and are sensitive to price movements in other markets. Since, however, they draw a large proportion of their supplies direct from the producer, and these supplies are liable to fluctuation, they require an additional and a more reliable source from which to supplement the local output and from which special lines and imported supplies may be obtained to balance demand.

This source they find in the central markets at important ports, and especially in the Covent Garden market in London, which has become a national distributing centre for fruit and vegetables. Privately owned by the Covent Garden Estates Company, Ltd., this market handles not only produce raised within carting distance of London, which is required for London consumption, but also main crop produce in general demand, part of which is regularly reconsigned to other distributing centres, and certain produce in limited demand or supply, such as glass-house produce which commands a high price and most of which is reconsigned to other markets. Much of this reconsignment business is economically indefensible; but it cannot be replaced entirely by direct consignment to provincial markets until the latter become more developed and price movements in them much less liable to be influenced by small alterations in supply and demand.

Meat and Fish Markets.—Wholesale meat markets are generally owned and managed by local authorities, and exist only in those centres of population (not more than 20 in number) where the magnitude of possible trade justifies their establishment and where retailers are assured of adequate supply with wide range of quality and prices. In smaller towns the place of the municipally owned market is taken by wholesale butchers who purchase live stock, slaughter it and sell the meat to retail dealers; and in the city of Sheffield, where no meat market proper exists, the wholesalers sell at the slaughter-houses which they rent from the local authority. By far the largest and most important of wholesale meat markets proper is the London central market at Smithfield which in a single year handles between 400,000 and 500,000 tons, including 40% of the total imports of meat into the whole country. Unlike Covent Garden, it undertakes practically no reconsignment of produce to other wholesale markets; but its prices for both home and imported meat (although not officially issued under the imprimatur of the City of London Corporation, which is its owner and manager) are largely used as a basis for wholesale dealings in other parts of Great Britain.

In the foreign meat trade a network of depôts has been established by certain large distributing firms in all the principal cities and towns in the country. To them supplies of chilled or frozen meat are despatched from the ports of entry. They, therefore, serve as small markets from which retailers can secure supplies.

Fish is handled at Hull, Grimsby, Fleetwood, Aberdeen and other ports, usually by Dutch auction, and is distributed by the wholesale purchasers to their stalls and to representatives in certain provincial fish markets (Birmingham, Glasgow, Liverpool, Manchester and others) and also to the very important Billingsgate market in London.

Cereals.—Wheat is usually sold by sample in the local corn-market nearest the producer's home. Certain of these small markets, however, attract a considerable quantity of grain from areas outside their immediate neighbourhood, and some of the largest dominate large tracts of country, frequently serving as depôts for the receipt of both home-produced and imported wheat and for its export to other consuming centres. The purchasers at these local markets include millers among their number; but sale outright to merchants and sale by merchants or agents on commission are not uncommon, the latter being, perhaps, the usual plan in Scotland. Producers' co-operative societies may also be employed, which may sell direct to millers, or to merchants whom the larger milling-firms find it more convenient to employ in their purchasing of home-grown wheat in bulk.

Barley when sold for malting and distilling is usually sold in the larger market-towns by merchants acting on a commission basis on behalf of the farmer. Oats are largely consumed on the farms of the growers, but direct sale by the producer to oatmeal millers is common. Merchants, however, frequently buy outright for sale to large consumers such as collieries and railways.

After wheat is milled it is usually sold direct to bakers, confectioners or other users, generally through travellers employed by the milling companies. Occasionally factors or wholesale dealers intervene, who purchase from millers for resale on their own account to small bakers in the more sparsely populated districts. Distribution by this method is uncommon, however, in the case of home-milled flour; although imported flour is nearly always handled by wholesale dealers of this kind.

At the next stage, that of baking, a few firms in several of the more important centres of population confine themselves to a purely wholesale trade. A fair number attempt to combine partial retail distribution with wholesale manufacture and usually possess retail shops where the bread is sold over the counter direct to the consumer or from which door-to-door delivery by van may be undertaken. The majority of baking firms, however, confine themselves strictly to retail trade.

Poultry and Eggs.—Owing to the fact that British producers of poultry and eggs have no export trade to foreign markets, there is no obligation on them to conform to standardized methods in the disposal of their products. There is consequently great variety in the marketing of these commodities and the plan adopted by an individual producer depends partly on the scale upon which he is operating and partly on his situation relative to his market or his customers. Sale may take place (*a*) by private treaty in the producing area; (*b*) by auction in the producing area; (*c*) directly to distant distributors; (*d*) through commission salesmen in distant wholesale markets; (*e*) through co-operative societies. To the first of these classes may be assigned sales at local weekly markets of eggs and dressed poultry to local customers, sales by parcel post or rail direct to the consumer, sales from door to door often in conjunction with milk and vegetables, sales to local distributors in the nearest market town and sales at the farm. This latter plan is common throughout England and Wales, intermediaries known as higglers (also as cadgers and hagglers) going round in districts where the farms are scattered and distant from the larger consuming centres. The higgler calls at the farm with a vehicle once or twice a week, buys all the eggs and poultry available and pays cash without much regard to classification or to quality. He then resells privately or in open market to wholesale and retail distributors; but he may occasionally send consignments to wholesale markets for sale on commission. The system of selling by local auction has been greatly extended in recent years.

Costs of Distribution.—The costs of distribution vary considerably with the nature of the commodity handled, the method adopted and the degree of efficiency in the market organization available to the producer. In the case of cereals the fees paid by the farmers in the local corn-exchange are very small. Sixpence per day, one guinea per year, one penny on each occasion the market is entered, threepence per person entrance fee for sale by sample, are a few examples taken at random of the rentals and fees in actual operation at the present time. Cartage to the market or railway station is also the farmers' expense. This is reckoned at 1s. to 2s. 6d. per quarter of grain up to a distance of eight to ten miles. Merchants selling wheat on commission for growers are paid 9d. to 1s. per quarter or 2d. or 3d. per hundredweight. These figures are slightly higher in the cases of barley and oats. A rent ranging from two guineas to over eight guineas per annum is charged to merchants who operate in the local exchanges and who require stands, desks or space on the market floor. For fruit and vegetables the costs incurred in the complete marketing process are proportionally greater than for cereals. Considerable expense arises in the preparation of produce for the market. Cartage to railway station is estimated in Lincolnshire on the average to amount to 3s. to 4s. per ton. Railway charges are, on the whole, reasonable. In the distributive market itself porterage charges and market tolls are an additional burden and then there are the payments to the commission salesman for his services.

It is calculated that wholesalers make a net profit of about 2% on sales to retailers, and that the latter obtain a net profit of over 6% on the cost of the goods or a little under 4% on turnover.

Meat Costs.—In the meat trade the following estimates taken from the Linlithgow report exhibit well the costs incurred and prices paid and received in the passage of beef from the English farmer to consumers in larger industrial centres.

	£	s.	d.
Farmer receives for one animal from dealer at local market	31	0	0
Farmer's expenses (tolls, etc.)		9	3
Farmer's net receipts	30	10	9
Dealer receives from wholesale butcher	32	10	0
Dealer's expenses (rail, tolls, feeding, etc.)		18	6
Dealer's net profit		11	6
Wholesale butcher receives from retailer	30	3	9
Wholesale butcher receives for hide and offals	3	10	6
Gross receipts of wholesale butcher	33	14	3
Expenses of wholesale butcher (slaughtering)		13	2
Wholesale butcher's gross profit		11	1
Retailer's receipts from consumers	36	9	10
Retailer's payment to wholesale butcher	30	3	9
Retailer's gross profit	6	6	1

The weight of meat sold in this instance was 690 pounds. The net price paid by consumer being £36 9s. 10d. and the receipt from offals being £3 10s. 6d. the difference between the net price received by the farmer and the total made by meat and offals is, therefore, the difference between £40 0s. 4d. and £30 10s. 9d., *i.e.,* £9 9s. 7d. The corresponding differences for Wiltshire bacon and for pork were £3 14s. 7d. and £1 16s. 6d. for weights of 140 and 148 lb. respectively.

The same committee also collected figures showing the receipts from the sale of a forequarter of frozen beef weighing 187 lb. and costing £2 14s. 6½d. or 3½d. per pound. In this case £5 6s. 1½d. was realized, giving a gross profit of 48·6%. When it is remembered that the expenses of the retailer in the case of frozen meat are substantially less than in the case of home-killed meat, owing to the absence of slaughtering and dressing costs, the very remunerative character of trade in foreign meat is readily perceived. Again, competition appears to be less active in the retail meat trade generally than it was before 1914, and this notwithstanding an increase in the number of establishments since that date. It would seem to be the case that butchers, having been encouraged to purchase collectively during the war period, still combine to keep down prices both of stock and meat; and further that retailers to a considerable extent agree on the prices consumers are required to pay and on the whole refrain from underselling one another in open competition.

Poultry, Egg and Milk Costs.—In the selling of poultry and eggs at the local market, apart from the cost of conveying the produce to the place of sale, the vendor usually has to pay market tolls and, in the case of sales by auction, the auctioneer's fee. The average tolls charged (by the local authorities who usually own the markets) are ½d. to 2d. for poultry and from ¼d. per score to 6d. per hundred for eggs. Auction charges generally range from 5 to 7½% of the price realized and, consequently, are higher than those for selling live stock. This, no doubt, is because of the smaller value of the individual lots put up for sale. The higgler's profit in the districts where he flourishes is from 1d. to 2d. per doz. on eggs. This is not excessive; but his service, nevertheless, is not economical.

The dealer's business is more speculative, owing to the rapid fluctuations in prices from day to day and from market to market. His average profit of from 2d. to 4d. per doz. on eggs is, therefore, reasonable, especially as he provides boxes and pays transport charges. Commission salesmen's charge is 5% of the selling price, and wholesale dealers purchasing on their own account aim at a gross profit on eggs of about 2d. per doz. and from 2d. to 3d. per lb. on dead poultry. Probably it is in the retail section that profit margins in this trade are greatest and most open to question, 14% on eggs and 20 to 30% on poultry being the averages for the whole country. Producers complain that the difference between the prices they receive for poultry and those paid by the public has increased disproportionately in recent years.

Milk producers, acting through the National Farmers' Union, succeed in getting 1s. per gal. in summer and 1s.4½d. in winter when consumers pay 2s. and 2s.4d. respectively.

Co-operative Marketing.—The organization of producers on a co-operative basis for the disposal of their produce and for carrying out the processes involved in marketing is not a new development in Great Britain; but the progress made is insignificant compared with what has taken place elsewhere. Figures in the returns furnished to the chief registrar of friendly societies for the year ending March 31, 1925, referring to societies operating only in England and Wales, establish the fact that roughly about 3½% of the total value of agricultural produce marketed in England and Wales was handled by co-operative marketing societies or co-operative societies with marketing branches. The following table which is taken from No. 1, of the economic series published in 1925 by the Ministry of Agriculture and Fisheries (Great Britain), shows the number and turnover of agricultural marketing societies and certain other societies handling agricultural produce as part of their general trading during the period 1923–24. The table excludes turnovers in grain, hay, potatoes, etc., of general trading societies.

Commodity Handled.	Number of Societies.	Turnover.†
		£
Dairy produce	63	1,447,627
Eggs and poultry	43	349,262
Fruit and vegetables	18	301,932
Livestock*	9	375,128
Auction marts (live stock)	18	1,081,953
Slaughterhouses	11	415,270
Bacon factories	6	694,826**
Wool	13	200,000††
Total	181	4,865,998

*This entry covers societies selling live stock on behalf of members otherwise than through an auction mart owned or rented by the society.

†Turnover in respect of produce handled, and not necessarily total turnover of society.

**1924 figures.

††Estimated value.

These 181 societies are widely distributed without any union or centralizing agency which might secure joint action or otherwise look after common interests. Attempts have been made from time to time, but unsuccessfully, to federate them or to institute an advisory body to assist them to sell advantageously.

The present trend is in the direction of the several groups of societies forming their own trading federations on a commodity basis and thus falling into line with the general course of development towards larger scale marketing and trade. The growth under Government encouragement of export associations in the dominions for the marketing of agricultural produce in England and the formation of great co-operative pools by farmers in both the United States and Canada are adding seriously to the difficulties of the smaller home societies. Thus, the union of the latter is hastened under the stimulus of competition from imported produce; and trading federations of groups of such societies are rapidly growing in importance.

MARKET-PLACE, the mediaeval descendant of the Greek agora and the Roman forum (*qq.v.*); an open space, generally approximately rectangular. It was usually placed near the centre of the town, as in the market cross of Chester, at the intersection of the two main streets. The town hall (*see* GOVERNMENTAL ARCHITECTURE) was frequently built on the market-place, and occasionally its ground floor was open and served as additional market space.

A *market cross* was a monument topped by a cross, situated in the market-place; or the market-place itself, so-called from the monument.

MARKETS, PRIMITIVE: *see* TRADE, PRIMITIVE.

MARKHAM, SIR CLEMENTS ROBERT (1830–1916), C.B. (1871), K.C.B. (1896), English geographer and historical writer, son of the Rev. David F. Markham, canon of Windsor, was born on July 20, 1830 at Stillingfleet, near York, and went to Westminster school. He entered the navy in 1844 and passed for a lieutenant in 1851. In 1850–51 he served on the Franklin search expedition in the Arctic regions, under Captain Austin. He retired from the navy in 1852, and then travelled in Peru and the forests of the eastern Andes. In 1853 Markham entered the Civil service, and in 1854 was appointed on the board of control of the East India Company. He visited South America again in 1860, in order to arrange for the introduction of the cinchona plant into India, a service of the highest value. In 1865 he visited Ceylon and India, to report upon the Tinnevelly pearl-fishery and the cinchona plantations. From 1867–77 the geographical section of the India office was under his charge. On the Abyssinian expedition of 1867–68 he served as geographer, and was present at the storming of Magdala. He was elected F.R.S. in 1873. In 1875 he accompanied the Arctic expedition under Sir George Nares as far as Greenland. In later years Sir Clements Markham travelled extensively in western Asia and the United States. He was secretary to the Hakluyt Society from 1858–87, and its president from 1889–1909. From 1863–88 he acted as secretary to the Royal Geographical Society, and was elected president in 1893, retaining office for the unprecedented period of 12 years. He was president of the International Geographical Congress which met in London in 1895. It was almost entirely due to his exertions that funds were obtained for the National Antarctic Expedition under Captain Robert Scott, which left England in the summer of 1901. After his retirement from the India Office, he continued to devote himself to geographical research and travelled widely. He died in London on Jan. 30, 1916.

Sir Clements Markham conducted the *Geographical Magazine* from 1872–78, when it became merged in the *Proceedings of the Royal Geographical Society.* Among his many publications may be mentioned: *Peru* (1880); *The War between Chili and Peru* (1879–81; 3rd ed., 1883); *Life of John Davis the Navigator* (1889); a *Life of Richard III.* (1906); also lives of *Admiral Fairfax, Admiral John Markham, Columbus* and *Major Rennel;* a *History of Peru;* editions with introduction of 20 works for the Hakluyt Society, of which 14 were also translations; about 70 papers in the Royal Geographical Society's *Journal. The Lands of Silence,* an important history of Arctic and Antarctic exploration, was completed posthumously by Dr. H. H. Guillemard and published in 1921.

See Sir A. H. Markham, *The Life of Sir Clements Markham* (1917); Sir J. Scott Keltie, Memoir in *The Geographical Journal* vol. xlvii. (1916).

MARKHAM, EDWIN (1852–1940), an American poet, was born at Oregon City, State of Oregon, on April 23, 1852, but grew to manhood on a lonely but beautiful valley ranch in central California. He attended the State normal school at San José, and later graduated from Christian college at Santa Rosa, after which he became a high school principal and superintendent at various places and finally headmaster at the Tompkins Observation school, Oakland, connected with the University of California. This he gave up in 1899, after his poetry had won favour, and devoted himself to writing and lecturing. He gained national fame in 1899 with the newspaper publication of "The Man with the Hoe," his most widely known poem. It so well expressed the economic and social mood of the time that it was reprinted in nearly every newspaper of the country and was the subject of wide editorial comment. His first book of verse *The Man with the Hoe and Other Poems* (1899) was followed in 1901 by *Lincoln and Other Poems,* the dignified title piece of which found almost as much favour as "The Man with the Hoe." His third and fourth books of verse, *Shoes of Happiness* (1915) and *Gates of Paradise* (1920) show, perhaps, a higher general quality than the first two, though they lack single poems with such wide appeal. In 1937 he published *The Star of Araby.*

MARKHAM, GERVASE (or JERVIS) (1568?–1637), English poet and writer, third son of Sir Robert Markham of Cotham, Nottinghamshire, was born probably in 1568. He was a soldier of fortune in the Low Countries, and later was a captain under the earl of Essex's command in Ireland. He was acquainted with Latin and several modern languages, and had an exhaustive practical acquaintance with the arts of forestry and agriculture. He was a noted horse-breeder, and is said to have imported the first Arab. Very little is known of the events of his life. The story of the murderous quarrel between Gervase Markham and Sir John Holles related in the *Biographia Britannica* (*s.v.* Holles) has been generally connected with him, but in the *Dictionary of National Biography,* Sir Clements R. Markham, a descendant from the same family, refers it to a contemporary of the same name. Gervase Markham was buried at St. Giles's, Cripplegate, London, on Feb. 3, 1637.

Markham's writings include: *The most Honorable Tragedy of Sir Richard Grinvile* (1595), reprinted (1871) by Professor E. Arber; *The Poem of Poems, or Syon's Muse* (1595), dedicated to Elizabeth, daughter of Sir Philip Sidney; *Devoreux, Vertues Teares* (1597); *The Teares of the Beloved* (1600) and *Marie Magdalene's Teares* (1601) long and rather commonplace poems on the Passion and Resurrection of Christ, both reprinted by Dr. A. B. Grosart in the *Miscellanies of the Fuller Worthies Library* (1871); *Herod and Antipater, a Tragedy* (1622) was written with William Sampson, and with Henry Machin he wrote a comedy called *The Dumbe Knight* (1608). *A Discourse of Horsemanshippe* (1593) was followed by other popular treatises on horsemanship and farriery. *Honour in his Perfection* (1624) is in praise of the earls of Oxford, Southampton and Essex, and the *Souldier's Accidence* (1625) turns his military experiences to account. He edited Juliana Berners's *Boke of Saint Albans* under the title of *The Gentleman's Academie* (1595), and produced numerous books on husbandry, many of which are catalogued in Lowndes's *Bibliographer's Manual* (Bohn's ed., 1857–64).

MARKHAM, MRS., the pseudonym of ELIZABETH PENROSE (1780–1837), English writer, daughter of Edmund Cartwright the inventor of the power-loom. She was born at Goadby Marwood, Leicestershire, on Aug. 3, 1780. In 1804 she married the Rev. John Penrose, a voluminous theological writer. Mrs. Penrose took the *nom de plume* of "Mrs. Markham" from a village in Nottinghamshire. Her best known book was *A History of England from the First Invasion by the Romans to the End of the Reign of George III.* (1823), which went through numerous editions. In 1828 she published a *History of France.* The distinctive characteristic of "Mrs. Markham's" histories was the elimination of all the "horrors" of history, and of the complications of modern party politics, as being unsuitable for the youthful mind. "Mrs. Markham" died at Lincoln on Jan. 24, 1837.

See Samuel Smiles, *A Publisher and his Friends* (2 vols., 1891); G. C. Boase and W. P. Courtney, *Bibliotheca Cornubiensis* (3 vols., 1874–82).

MARKHOR (CAPRA FALCONERI)

MARKHOR ["snake-eater"], a large Himalayan wild goat (*Capra falconeri*), characterized by its spirally twisted horns and long shaggy winter coat. From the Pir-Panjal range of Kashmir, the region of the markhor extends westwards into Baltistan, Astor, Hunza, Afghanistan and the trans-Indus ranges of the Punjab. The twist of the horns varies locally.

MARKIRCH: *see* STE-MARIE-AUX-MINES.

MARKO KRALYEVIĆ, Serbian hero, was a son of the Serbian king or prince, Vukašin (d. 1371). Chagrined at not himself becoming king after his father's death, he headed a revolt against the new ruler. Later he took service with the sultan, and was killed in battle about 1394. Stories of strength and wonder have gathered round his name. He is supposed to have lived for 300 years, to have ridden a horse 150 years old, and to have used his enormous physical strength against oppressors, especially against the Turks. He is a great figure in Serbian poetry, and his deeds are also told in the epic poems of the Rumanians and the Bulgarians. One tradition relates how he retired from the world owing to the advent of firearms, which, he held, made strength and valour of no account in battle.

The Serbian poems about him were published in 1878; a German translation by Gröber (*Marko, der Königssohn*) appeared at Vienna in 1883.

MARK SYSTEM. At the middle of the 19th century, the opinion prevailed widely among scholars that throughout the Germanic world society tended to be organized in communities whose members claimed kinship with each other, cultivated their lands in common, and administered justice in their own assemblies. It was held that these communities were known as "Marks," from the march, or boundary, which separated each from its neighbours, and that traces of their existence still survive in the numerous place-names containing the element *-ing,* which are found in all regions of Germanic settlement. Later research proved that early Germanic society was far more complicated than the framers of this theory had realized, and demonstrated a strong element of individualism in primitive Germanic law. On the philological side it has been shown that the element *-ing* bore a far wider sense than that of kindred alone, that, for example, the original *Readingas* of Reading are as likely to have been the free and unfree dependents of *Read* as his actual or reputed kinsmen. The Mark theory, in fact, was much too simple an explanation of the complex phenomena of primitive society, but it still deserves respect as one of the great constructive generalizations which have determined the direction of research into the problems of social history. (F. M. S.)

MARL, a calcareous clay, or mixture of calcium carbonate and argillaceous matter. The term (from O.Fr. *marle,* late Lat. *margila,* dim. of *marga: cf.* Du. and Ger. *Mergel*), is applied to a great variety of rocks and soils with a considerable range of composition. Marls pass, on the one hand, into clays by diminution in the amount of lime, and on the other, into argillaceous limestones; in popular usage, however, many substances are called marls which would be better termed sandy clays. The practice, formerly more extensively in vogue, of top-dressing land with marls to increase fertility, and the use of many different kinds of earth and clay for that purpose, has led to a general misapplication of the term.

Typical marls are soft, earthy and of a white, grey or brownish colour. The lime of some is present in the form of shells, whole or broken (as in the Coralline Crag of East Anglia, the Oligocene marls of the Isle of Wight, etc.); in others it is a fine impalpable powder mixed with the clay. Sand is usually not abundant, but is rarely absent. A large variety of accessory minerals may be proved by microscopic examination to exist in marls. In the Keuper Marls (Trias) of England, small perfect dolomite crystals have been found. Individual crystals or large masses of concretionary gypsum, celestine and strontianite are found in such deposits and are valuable economically. While marls are frequently shallow-water marine deposits, many well-known examples are of fresh-water origin. Such are the Purbeck and Oligocene marls of the south of England. (P. G. H. B.)

MARLBOROUGH, EARLS AND DUKES OF. The earldom of Marlborough was held by the family of Ley from 1626 to 1679. JAMES LEY, the 1st earl (*c.* 1550–1629), was lord chief justice of the King's Bench in Ireland and then in England; he was an English member of parliament and was lord high treasurer from 1624 to 1628. In 1624 he was created Baron Ley and in 1626 earl of Marlborough.

In 1689 John Churchill was created earl and in 1702 duke of Marlborough (*see* below). After the death of his only son Charles in 1703 an act of parliament was passed in 1706 settling the duke's titles upon his daughters and their issue; from them the present family is descended.

The 7th duke of Marlborough, JOHN WINSTON SPENCER-CHURCHILL (1822–83), a prominent Conservative, was lord-lieutenant of Ireland 1876–1880, and when marquess of Blandford (the courtesy title borne by the duke's eldest son in his father's lifetime) was responsible for the act of 1856 called the "Blandford Act," enabling populous parishes to be divided for purposes of Church work.

MARLBOROUGH, JOHN CHURCHILL, 1ST DUKE OF (1650–1722), English soldier, was born in the small manor house of Ash, in Musbury, Devonshire, the son of Winston Churchill of Glanville Wotton, Dorset. He went to St. Paul's school from 1663 to 1665. When fifteen he became page of honour to the duke of York, and about the same time his sister Arabella became maid of honour to the duchess, two events which contributed greatly to the advancement of the Churchills. In 1667 he received through the influence of his master a commission in the Guards, and left England for service at Tangier but returned home in 1670. For a short interval Churchill remained in attendance at the court, and it was during this period that his natural carefulness was shown by his investing in an annuity a present of £5,000 given him by the duchess of Cleveland.

In 1672, when England sent 6,000 troops to aid Louis XIV. in his attempt to subdue the Dutch, Churchill was made a captain in the company of which the duke of York was colonel, and soon attracted the attention of Turenne, especially at the siege of Nimeguen. When Maestricht was besieged in June 1673 he saved the life of the duke of Monmouth, and received the thanks of Louis XIV. In 1678 he married Sarah Jennings (b. June 5, 1660), the favourite attendant on the Princess Anne, younger daughter of the duke of York.

On the accession of James II. the Churchills received a great increase in fortune. Colonel Churchill had been created a Scotch peer as Lord Churchill of Eyemouth in Dec. 1682; and for his services on a special mission from the new monarch to Louis XIV. he was made in May 1685 Baron Churchill of Sandridge in Hertfordshire. When the duke of Monmouth attempted his ill-fated enterprise in the western counties, the second position in command of the king's army was bestowed on Lord Churchill, and in July 1685 he was raised to the rank of major-general. Through his energy at the battle of Sedgemoor (July 6) the king's side was victorious. After the death of Monmouth he withdrew as far as possible from the administration of public business. Whilst on his embassy to the French court he had declared that if the king of England should change the religion of the state he should leave his service, and it was not long before the design of James became apparent. Churchill was one of the first to send overtures of obedience to the prince of Orange, to whom he had gone on a commission in 1678. Although he continued in a high position under James and drew the emoluments of his places, he promised William of Orange to use every exertion to bring over the troops to his side. James had been warned against him, but the warnings were in vain, and on the landing of the Dutch prince at Brixham Churchill was promoted to be lieutenant-general (Nov. 7, 1688) and was sent against him with 5,000 men. When the royal army had advanced to the downs of Wiltshire and a battle seemed imminent, James was dismayed to find that at night his general had gone to the opposite camp.

Churchill was sworn as a privy councillor in Feb. 1688–89 and in April became earl of Marlborough. William felt, however, that he could not place implicit reliance in his friend's integrity; and, with a sense of the manner in which Marlborough's talents might be employed without detriment to the stability of his throne, he sent him in June 1689 with the army into the Netherlands, and in the autumn of 1690 into Ireland, where owing to his generalship Cork and Kinsale fell into his hands after short sieges. For some time there was no open avowal of any distrust in Marlborough's loyalty, but in May 1692 he was thrown into the Tower on an accusation of treason. Though the evidence against him was slight, and he was released, there is no doubt that Marlborough was in close relations with the exiled king at St. Germain, and that he even went so far as to disclose, in May 1694, to his late master the intention of the English to attack Brest. During the Fenwick plot of 1696 he was charged again with treason, but William ignored the accusation.

During the last years of William's reign Marlborough once more was placed in positions of responsibility. Higher honours came on the accession of Anne in March 1702. He was appointed a Knight of the Garter, captain-general of the English troops both at home and abroad, and master-general of the ordnance. A week or two after the death of William it was agreed by England, Holland and Austria that war should be declared against France on the same day, and on May 4, 1702 the War of the Spanish Succession was declared by the three countries. Marlborough was made commander-in-chief of the united armies of England and Holland, but throughout the war his plans were impeded by the jealousy of the commanders who were nominally his inferiors, and by the opposite aims of the allied countries. He himself wished to penetrate into the French lines; the anxiety of the Dutch was for the maintenance of their frontier and for an augmentation of their territory; the desire of the Austrian emperor was to secure that his son the Archduke Charles should rule Spain. In the first year of the campaign it was shown that the armies of the French were not invincible. Several fortresses which Louis XIV. had seized upon surrendered to the allies; Kaiserswerth on the Rhine surrendered in June; Venlo on the Meuse in Sept., and Liége on Oct. 29. For these brilliant exploits Marlborough was raised (Dec. 14, 1702) to be duke of Marlborough, and received £5,000 per annum for the queen's life. His only surviving son, the marquess of Blandford, was seized whilst at King's College, Cambridge, with smallpox, and died on Feb. 20, 1703.

The result of the campaign of 1703 inspired the French king with fresh hopes. The plans of Marlborough were frustrated by his Dutch colleagues. When he wished to invade the French territory they urged him to besiege Bonn, and he was compelled to give way. It surrendered in May, whereupon he returned to his original plan of attacking Antwerp; but because of the incapacity of the Dutch leaders, the French surprised the Dutch division in June and inflicted on it a loss of many thousands of men. Marlborough was forced to abandon his enterprise, and all the compensation which he received was the capture of the insignificant forts of Huy and Limburg. After a year of comparative failure for the allies, Louis XIV. entered upon an offensive movement against Austria; and Marlborough, smarting under the misadventures of 1703, was eager to meet him. The French were sent to join the forces of the elector of Bavaria and to march by the Danube to seize Vienna. Marlborough divined their intention, and while making a feint of marching into Alsace led his troops into Bavaria. The two armies met near the village of Blenheim on the left bank of the Danube. The early part of the fight was in favour of the French. Three times were the troops led by Prince Eugène, which were attacking the Bavarians, the enemy's left wing, driven back in confusion; Marlborough's cavalry failed on their first attack in breaking the line of the enemy's centre. But in the end the victory of the allies was conclusive. Nearly 30,000 of the French and Bavarians were killed and wounded, and 11,000 of the French who had been driven down to the Danube were forced to surrender. Bavaria fell to the allies. Poets and prose writers were employed to do Marlborough honour, and the lines of Addison comparing the English commander to the angel who passed over "pale Britannia" in the storm of 1703 have been famous for over two centuries. The manor of Woodstock, which was transferred by act of parliament from the crown to the duke, was a reward more after his own heart. A palace was built in the park at the royal expense, and £240,000 of public money was spent on the buildings. Marlborough was also created a prince of the empire and the principality of Mindelheim was formed in his honour.

During the following year Marlborough was hampered by tedious formalities at The Hague and by jealousies at the German courts. The armies of the French were again brought up to their full standard, but the generals of Louis were instructed to entrench themselves behind earthworks and to act on the defensive. On a July night these lines were broken through near Tirlemont, and the French were forced to shelter in Louvain. Marlborough in vain urged an attack, and when 1705 had passed away the forces of the French king had suffered no diminution. This tempted Villeroi in the next spring into meeting the allies in an open fight. But through the superior tactics of Marlborough the battle of Ramillies (May 23, 1706) ended in the total rout of the French, and caused the transference of nearly the whole of Brabant and Flanders to the allies. Five days afterwards the victor entered Brussels in state, and the inhabitants acknowledged the rule of the archduke. Antwerp, Ostend, Menin and Dendermonde soon surrendered. Again a year of triumph was succeeded by a period of depression. During 1707 fortune inclined to the other side, with the result that in July 1708 Ghent and Bruges returned to the allegiance of the French, and Marlborough, fearing that their example might be followed by other cities, advanced towards Oudenarde. The battle, which raged on the high ground above Oudenarde, ended in the defeat of the French (July 11, 1708).

Marlborough then wished to advance on Paris, but he was overruled. The allied army invested the town of Lille, and after nearly four months, and a loss to the combatants of 30,000 men, the citadel surrendered in December. By the end of the year Brabant was again subject to the allies. The French king sued for peace, and Torcy his minister endeavoured by promises of large sums to obtain the support of Marlborough to his proposals. These attempts were vain, and when the winter passed a French army of 110,000, under the command of Villars, took the field. In Sept. 1709 Tournay capitulated, and the two leaders, Marlborough and Eugène, led their forces to Mons. For the last time during the protracted war the two armies met in fair fight at Malplaquet, on the south of Mons (Sept. 11, 1709). The fight was long and doubtful, and although the French ultimately retreated, it was in good order, and their losses were less than those of their opponents. The campaign lasted for a year or two after this indecisive contest, but it was not signalized by any such "glorious victory" as Blenheim. The French concentrated on the construction of fresh lines of defence, and the war dragged on until the Peace of Utrecht in June 1712.

These victories had not prevented the position of Marlborough from being undermined by party intrigues at home. In the early part of Anne's reign his political friends were among the Tories, and the ministry under Sidney Godolphin was chiefly composed of members of that party. After a year or two, however, the more ardent Tories withdrew, and two younger adherents of the same cause, Harley and St. John, were introduced in May 1704 into the ministry. The duchess, partly through the influence of her son-in-law, the earl of Sunderland, who came into office against the queen's wish in Dec. 1706, and partly through the opposition of the Tories to the French war, had gone over to the Whig cause, and she pressed her views on the sovereign with more vehemence than discretion. The love of the two friends changed into hate, and no opportunity for humiliating the family of Marlborough was allowed to pass. Sunderland and Godolphin were the first to fall (July–Aug. 1710); a few months later the duchess was dismissed from her offices; and the fall of Marlborough himself came on the last day of 1711. He went to the Continent in Nov. 1712 and remained abroad until the death of Anne (Aug. 1, 1714).

Then he once more returned to England and resumed his old military posts, but he took little part in public affairs. He died on June 16, 1722, at Cranbourn Lodge, near Windsor. His remains were deposited in Westminster Abbey, in the vault at the east end of King Henry VII.'s chapel, but they now rest in a mausoleum in the chapel at Blenheim. His widow, to whom must be assigned a considerable share both in his rise and in his fall, survived till Oct. 18, 1744. To Pitt she left £10,000 and to Chesterfield twice that sum and a reversionary interest in her landed property at Wimbledon.

The rapid rise of Marlborough to the highest position in the State was due to his singular tact and his diplomatic skill in the management of men. Through his consideration for the welfare of his soldiers he held together for years an army drawn from every nation in Christendom. Alike in planning and in executing, he took infinite pains in all points of detail. Nothing escaped his observation, and in the hottest moment of the fight the coolness of his intellect was conspicuous. His enemies affected to attribute his uniform success to fortune, and they magnified his love of money by drawing up balance sheets which included every penny which he had received, but omitted the pounds which he had spent in the cause he had at heart. All that can be alleged in excuse of his attempts to serve two masters, the king whom he had deserted and the king who had received him into favour, is that not one of his associates was without sin in this respect.

Bibliography.—Marlborough's *Letters and Despatches* were edited by Sir George Murray (5 vols., 1845). See *Lives* by W. Coxe (3 vols. 1818–19) and by G. J. Wolseley (1894); G. Saintsbury, *Marlborough* (1885); S. J. Reid, *John and Sarah, Duke and Duchess of Marlborough* (1914); E. Thomas, *The Life of the Duke of Marlborough*, (1915); F. Taylor, *The Wars of Marlborough, 1702–09* (2 vols. 1921); C. T. Atkinson, *Marlborough and the Rise of the British Army* (1921); H. G. Edwards, *A Short Life of Marlborough* (1926); D. B. Chidsey, *Marlborough* (1929). *See* also the article by Sir Leslie Stephen in the *Dict. Nat. Biog.* which gives a full bibliography of the older works.

MARLBOROUGH, a market town and municipal borough in the Eastern parliamentary division of Wiltshire, England, 75¾ mi. W. of London by rail. Pop. (1938) 4,678. Area, 2.3 sq.mi. It is near Savernake forest, and in the valley of the river Kennet.

The antiquity of Marlborough is shown by the Castle mound, an earthwork, which local legend makes the grave of Merlin; and the name of Marlborough has been regarded as a corrupt form of Merlin's berg or rock. Near the site of the modern Marlborough (Merleberge, Marleberge) was originally a Roman *castrum* called Cunetio, and later there was a Norman fortress in which William I. established a mint. In Domesday it was royal demesne. The castle, built under Henry I., by Roger, bishop of Salisbury, was held for Matilda against Stephen, and became a favourite residence of Henry II., Savernake being a royal deer-park. In 1267 Henry III. held his last parliament here, at which the Statute of Marlborough was passed. Marlborough was captured by the royal forces in 1642, and partly burnt. The town was constituted a suffragan see by Henry II. Sacheverell, the politician and divine, was born here in 1674, and educated at the grammar school. In 1653 the town was nearly destroyed by fire, and it again suffered in 1679 and 1690; after which an act was passed forbidding the use of thatch. Marlborough, from its position on the Great Bath road, was a famous coaching centre.

The first charter was granted by John in 1204, and conferred a gild merchant, together with freedom from all pleas except pleas of the Crown and from all secular exactions by sea and land. Later charters were obtained from Henry IV. in 1407 and from Elizabeth in 1576. The former granted some additional exemptions whilst the latter incorporated the town under the title of mayor and burgesses of Marlborough. Marlborough returned two members to parliament until 1867 when the number was reduced to one, and in 1885 the representation was merged in that of the county.

There is one broad street in which most of the houses are Jacobean, those on the north side having projecting upper stories. St. Peter's church, a Perpendicular building, is said to have been the scene of the ordination of Cardinal Wolsey in 1498. The church of Preshute, largely rebuilt, but preserving its Norman pillars, has a curious piscina, and a large black basalt font dating from 1100–50. There is a 16th century grammar school. Marlborough college was opened in 1843, originally for the sons of clergymen. The town's trade is mainly agricultural.

MARLBOROUGH, a city of Middlesex county, Massachusetts, U.S.A., 28 mi. W. of Boston, on federal highway 20, and served by the Boston and Maine and the New York, New Haven and Hartford railways. Pop. (1940) 15,154, federal census. The city occupies 21 sq.mi. in a fertile, hilly region, and has several lakes, including beautiful Williams pond, within its borders. Its manufactures (especially boots, shoes, small metal goods, paper boxes) had a total output in 1940 valued at $15,000,000. The town of Marlborough was incorporated in 1660. It was destroyed by the Indians in March 1676, during King Philip's War, and was abandoned for a year. In 1890 it was incorporated as a city.

MARLIN, a city of Texas, U.S.A., 100 m. S. of Dallas, near the Brazos river; the county seat of Falls county and an important health resort. It is served by the Missouri Pacific and the Southern Pacific railways. Pop. (1930) 5,338 (34% Negroes); 6,542 by the federal census in 1940. It has sanatoria, clinics and hotels developed to utilize the waters (147° F) of its mineral wells, which send out 380,000 gal. a day. The city was founded in 1848 and named after a pioneer settler. It has made steady growth, due to the fertility of the black waxy prairie and river bottomlands surrounding it. In 1890 the city engaged an artesian-well driller to provide a well of soft water. At a depth of 3,350 ft. he struck a flowing well of hot mineral water. The first bath-house was built in 1895, and after that the development of facilities for treatment proceeded rapidly.

MARLOW, a town and urban district in Buckinghamshire, England, on the Thames, 31½ mi. W. of London by G.W.R. Pop. (1938) 5,364. Area 2.5 sq.mi. Great Marlow appears as a manor in Domesday Book, but its "borough and liberties" are not mentioned before 1261. It was then held by the earls of Gloucester, and its importance was probably due to the bridge across the Thames, first built, according to tradition, by the Templars at Bisham. In 1342 the mayor and burgesses presented to a chantry and continued to be patrons till 1394. A market was held by the Despensers who had succeeded the De Clares as lords of the manor in the 14th century. In the 16th century the market was given up, but was revived and held in the 18th century, only to disappear again before 1862. In 1792 there were two fairs, one of which, for horses and cattle, is still held on Oct 29. Lace and satin-stitch work used to be made to a considerable extent. A weir and lock, near the modern church of All Saints, separate two reaches of the river, and the town is a boating and fishing resort. The village of Little Marlow, with foundations of a Benedictine nunnery of the time of Henry III, lies near the river 2 miles below. The town is mainly modern, but a few old houses remain, such as the grammar school, founded as a bluecoat school in 1624, adjoining which is a house occupied by the poet Shelley in 1817. Brewing is the chief industry.

MARLOWE, CHRISTOPHER (1564–1593), English dramatist, the father of English tragedy, and instaurator of dramatic blank verse, the eldest son of a shoemaker, was born in Canterbury on Feb. 6, 1564. He was christened at St. George's Church, Canterbury, on Feb. 26, 1563/4, some two months before Shakespeare's baptism at Stratford-on-Avon. His father, John Marlowe, is said to have been the grandson of John Morley or Marlowe, a substantial tanner of Canterbury. The father, who survived by a dozen years or so his illustrious son, married on May 22, 1561 Catherine, daughter of Christopher Arthur, at one time rector of St. Peter's, Canterbury, who had been ejected by Queen Mary as a married minister. The dramatist had as fellow pupils at the King's School, Canterbury, Richard Boyle, afterwards earl of Cork, and Will Lyly, the brother of the dramatist. He matriculated at Benet (Corpus Christi) College, on March 17, 1571, taking his B.A. degree in 1584, and that of M.A. three or four years later.

Francis Kett, the mystic, burnt in 1589 for heresy, was a fellow and tutor of his college, and may have had some share in developing Marlowe's opinions in religious matters. Marlowe's classical acquirements were of a kind which was then extremely common, being based for the most part upon a minute acquaintance with Roman mythology, as revealed in Ovid's *Metamorphoses.* His spirited translation of Ovid's *Amores* (printed 1596), was at any rate commenced at Cambridge. His translation of "The First Book of Lucan," printed posthumously in 1600, belongs to the last years of his short life. The famous lyric, "Come live with me and be my love" was first printed in its entirety in *England's Helicon* (1600). *Hero and Leander,* based on Musacus, also belongs to the last years. Before 1587 he seems to have quitted Cambridge for London; of his life there, apart from his four great theatrical successes and his connection as a dramatist with the Lord Admiral's and Strange's companies, we know hardly anything; but he evidently knew Thomas Kyd, who shared his unorthodox opinions. Nash criticized his verse, Greene affected to shudder at his atheism; Gabriel Harvey maligned his memory.

On the other hand, Marlowe was intimate with the Walsinghams of Scadbury, Chiselhurst, kinsmen of Sir Francis Walsingham: he was also the personal friend of Sir Walter Raleigh, and perhaps of the poetical earl of Oxford, with both of whom, and with Walter Warner and Robert Hughes the mathematicians, Thomas Harriott the astronomer, and Matthew Royden, the dramatist is said to have met in free converse. He seems at least to have been associated with what was denounced as Sir Walter Raleigh's school of atheism, and to have dallied with opinions which were then regarded as putting a man outside the pale of civilized humanity. In October 1588 Marlowe gave bail for his appearance for an unspecified offence. Serious charges were brought in 1593. As the result of some depositions made by Thomas Kyd under the influence of torture, the Privy Council were upon the eve of investigating some charges against Marlowe when his career was abruptly terminated. Thanks to the researches of Dr. Hotson, it is now established definitely on the evidence of documents in the Public Record Office, that Marlowe was killed by a companion of his, one Ingram Frizer, at an inn at Deptford on May 30th, 1593. Frizer and Marlowe, together with two friends named Robert Poley and Nicholas Skeres, had repaired to the inn to dine and sup. A quarrel arose about paying the bill; Marlowe in a sudden fit of temper attacked Frizer from behind. Frizer in the ensuing struggle stabbed Marlowe, who died instantly. Frizer was subsequently pardoned, as having killed Marlowe in self-defence. A full account of the documentary evidence which supports these facts is given in Dr. Hotson's book, *The Death of Christopher Marlowe* (1925). Dr. Hotson points out that it is important to note that Ingram Frizer was, in the relevant documents, described as "gentleman" and did not forfeit the good graces of his employers, the Walsinghams, who were friends of the man whom he slew.

Thus the various stories of Marlowe's death, as retailed by Thomas Beard (*The Theatre of God's Judgments*) in 1597, Francis Meres in his *Palladis Tamia* (1598), Anthony à Wood in his *Athenae Oxonienses* (1691) and repeated by later writers, may be dismissed as mere legend.

Marlowe was buried on June 1, 1593, at Deptford.

Marlowe's career as a dramatist lies between the years 1587 and 1593, and his four great plays are *Tamburlaine the Great,* an heroic epic in dramatic form divided into two parts of five acts each (*c.* 1587, printed in 1590); *Dr. Faustus* (1588, entered at Stationers' Hall 1601); *The Famous Tragedy of the Rich Jew of Malta* (dating perhaps from 1589, acted in 1592, printed in 1633); and *Edward the Second* (printed 1594). The very first words of *Tamburlaine* sound the trumpet note of attack in the older order of things dramatic:—

> From jigging veins of riming mother wits
> And such conceits as clownage keeps in pay
> We'll lead you to the stately tent of war,
> Where you shall hear the Scythian Tamburlaine
> Threatening the world with high astounding terms
> And scourging kingdoms with his conquering sword.

It leapt with a bound to a place beside Kyd's *Spanish Tragedy,* and few plays have been more imitated by rivals (Greene's *Alphonsus of Aragon,* Peele's *Battle of Alcazar, Selimus, Scanderbeg*) or more keenly satirized by the jealousy and prejudice of out-distanced competitors. Other plays in which Marlowe is said to have had a share are *The Massacre at Paris* (1593), printed in his name; *Dido, Queen of Carthage* (1593), with Nashe; *Lust's Dominion* (*c.* 1600), the original draft of which may have been by Marlowe; and the lost play, *The Maiden's Holiday,* in the list of plays burnt by Warburton's cook. Some critics have traced his hand in other plays, among these being the Shakespearian *Titus Andronicus, Henry VI.,* and *Richard III.* The following notes on the plays and on the poems are taken from the article written by Swinburne for the 9th ed. of the *Encyclopædia Britannica.* (T. S.; X.)

Estimate on the Plays.—With many and heavy faults, there is something of genuine greatness in *Tamburlaine the Great;* and for two grave reasons it must always be remembered with distinction and mentioned with honour. It is the first poem ever written in English blank verse, as distinguished from mere rhymeless decasyllabics; and it contains one of the noblest passages, perhaps indeed the noblest, in the literature of the world, ever written by one of the greatest masters of poetry in loving praise of the glorious delights and sublime submission to the everlasting limits of his art.

The just and generous judgment passed by Goethe on the *Faustus* of his English predecessor in tragic treatment of the same subject is somewhat more than sufficient to counterbalance the slighting or the sneering references to that magnificent poem which might have been expected from the ignorance of Byron or the incompetence of Hallam. What most impressed the author of *Faust* in the work of Marlowe was a quality the want of which in the author of *Manfred* is proof enough to consign his best work to the second or third class at most. "How greatly it is all planned!" the first requisite of all great work, and one of which the highest genius possible to a greatly gifted barbarian could by no possibility understand the nature or conceive the existence.

Tamburlaine is monotonous in the general roll and flow of its stately and sonorous verse through a noisy wilderness of perpetual bluster and slaughter; but the unity of tone and purpose in *Doctor Faustus* is not unrelieved by change of manner and variety of incident. In the vision of Helen, for example, the intense perception of loveliness gives actual sublimity to the sweetness and radiance of mere beauty in the passionate and spontaneous selection of words the most choice and perfect; and in like manner the sublimity of simplicity in Marlowe's conception and expression of the agonies endured by Faustus under the immediate imminence of his doom gives the highest note of beauty, the quality of absolute fitness and propriety, to the sheer straightforwardness of speech in which his agonizing horror finds vent.

It is now a commonplace of criticism to observe and regret the decline of power and interest after the opening acts of *The Jew of Malta.* This decline is undeniable, though even the latter part of the play (the text of which is very corrupt) is not wanting in rough energy; but the first two acts would be sufficient foundation for the durable fame of a dramatic poet. In the blank verse of Milton alone—who perhaps was hardly less indebted than Shakespeare was before him to Marlowe as the first English master of word-music in its grander forms—has the glory or the melody of passages in the opening soliloquy of Barabbas been possibly surpassed.

In *Edward the Second* the interest rises and the execution improves as visibly and as greatly with the course of the advancing story as they decline in *The Jew of Malta.* The scene of the king's deposition at Kenilworth is almost as much finer in tragic effect and poetic quality as it is shorter and less elaborate than the corresponding scene in Shakespeare's *King Richard II.*

Of *The Massacre at Paris* (acted in 1593, printed 1600?) it is impossible to judge fairly from the garbled fragment of its genuine text which is all that has come down to us. To Mr. Collier, among numberless other obligations, we owe the discovery of a noble passage excised in the piratical edition which gives us the only version extant of this unlucky play.

In the tragedy of *Dido, Queen of Carthage* (completed by Thomas Nashe, produced and printed 1594), a servile fidelity to the text of Virgil's narrative has naturally resulted in the failure which might have been expected from an attempt at once to transcribe what is essentially inimitable and to reproduce it under the hopelessly alien conditions of dramatic adaptation.

The Poems—One of the most faultless lyrics and one of the loveliest fragments in the whole range of description and fanciful poetry would have secured a place for Marlowe among the memorable men of his epoch, even if his plays had perished with himself. His *Passionate Shepherd* remains ever since unrivalled in its way—a way of pure fancy and radiant melody without break or lapse. The untitled fragment, on the other hand, has been very closely rivalled, perhaps very happily imitated, but only by the greatest lyric poet of England—by Shelley alone. Marlowe's poem of *Hero and Leander* (entered at Stationers'

Hall in September 1593; completed and brought out by George Chapman, who divided Marlowe's work into two sestiads and added four of his own, 1598), closing with the sunrise which closes the night of the lovers' union, stands alone in its age, and far ahead of the work of any possible competitor between the death of Spenser and the dawn of Milton.

The place and the value of Christopher Marlowe as a leader among English poets it would be almost impossible for historical criticism to over-estimate. To none of them all, perhaps, have so many of the greatest among them been so deeply and so directly indebted. Nor was ever any great writer's influence upon his fellows more utterly and unmixedly an influence for good. He first, and he alone, guided Shakespeare into the right way of work; his music, in which there is no echo of any man's before him, found its own echo in the more prolonged but hardly more exalted harmony of Milton's. He is the greatest discoverer, the most daring and inspired pioneer, in all our poetic literature. Before him there was neither genuine blank verse nor a genuine tragedy in our language. After his arrival the way was prepared, the paths were made straight, for Shakespeare. (A. C. S.)

Marlowe's fame, so finely appreciated by Shakespeare and Drayton, was obscured from the fall of the theatres until the generation of Lamb and Hazlitt. Collected editions are by A. Dyce (1858, 1865, 1876); A. H. Bullen (3 vols., 1884–85); "Best Plays" in the Mermaid series by Havelock Ellis with an Introduction by J. A. Symonds (1887–89). The best modern text is that edited by C. F. Tucker Brooke (Oxf. Univ. Press, 1910). *See* J. G. Lewis, *Marlowe, Outlines of his Life and Works* (1891); J. H. Ingram, *Christopher Marlowe and his Associates* (1904); H. Jung, *Das Verhältnis Marlowes zu Shakespeare* (1904). For further information the reader should consult the histories of the stage by Collier, Ward, Fleay, Schelling and E. K. Chambers, and the studies of Shakespeare's predecessors by Symonds, Mezières, Boas, Manley, Churton Collins, Feuillerat and J. M. Robertson. *See* also Verity's *Essay on Marlowe's Influence* (1886); *Mod. Lang. Rev.* iv. 167 (M. at Cambridge); Swinburne, *Study of Shakespeare* (1880); C. F. T. Brooke, *The Marlowe Canon* (Baltimore 1922), and *Marlowe's Versification and Style* (1922); E. Seaton, *Marlowe's Map* (1924); and the separate editions of *Dr. Faustus, Edward II.*, etc. The main sources of Marlowe were as follows: for *Tamburlaine,* Pedro Mexia's *Life of Timur* in his *Silva* (Madrid, 1543), Anglicized by Fortescue in his *Foreste* (1571) and Petrus Perondinus, *Vita Magni Tamerlanis* (1551); for *Faustus:* a contemporary English version of the Faust-buch or *Historia von D. Johann Fausten* (Frankfort, 1587), and for *Edward II.,* the *Chronicles* of Fabyan (1516), Holinshed (1577) and Stow (1580).

MARLOWE, JULIA [Sarah Frances Frost] (1866–), American actress, was born near Keswick, England, on Aug. 17, 1866, and arrived with her family in America in 1875. Her first formal appearance on the stage was in New York in 1887, although she had before that travelled with a juvenile opera company in *H.M.S. Pinafore,* and afterwards was given such parts as Maria in *Twelfth Night* in Miss Josephine Riley's travelling company. Her first great success was as Parthenia in *Ingomar,* and her subsequent presentations of Rosalind, Viola and Julia in *The Hunchback* confirmed her position as a "star." In 1894 she married Robert Taber, an actor, with whom she played until their divorce in 1900. Subsequently, she had great success as Barbara Frietchie in Clyde Fitch's play of that name, and other dramas. For many years, beginning in 1904, she acted with E. H. Sothern —to whom she was married, Aug. 17, 1911—in a notable series of Shakespeare plays, as well as in modern drama.

MARLY-LE-ROI, a village of northern France in the department of Seine-et-Oise, 5 mi. N. by W. of Versailles by road. Pop. (1936) 2,018.

Marly-le-Roi owes its celebrity to the Château built towards the end of the 17th century by Louis XIV, and now destroyed. The remains now consist of a large basin, the park and a small forest. Near Marly-le-Roi is the hamlet of Marly-la-Machine, where, in 1684, an immense hydraulic engine, driven by the current of the river, was erected; it raised the water to a high tower, where the aqueduct of Marly began (700 yds. in length, 75 in height, with 36 arches) carrying the waters of the Seine to Versailles.

MARMALADE, a preserve originally made of quinces, but now commonly of Seville or other tart oranges, or of other citrus fruit. The term is sometimes (improperly) used for jams. A standard recipe for marmalade is: Two lemons, 12 Seville oranges, slice thin, remove pips, cover and steep for three days in cold water, allowing three pints water to each lb. of fruit. Then boil in a preserving pan till tender, let cool and add 1 lb. of sugar for each lb. of fruit. Boil, skimming well and cook until the mixture stiffens quickly when dropped on a cold plate.

MARMANDE, a town of south-western France, capital of an arrondissement in the department of Lot-et-Garonne, 35 mi. N.W. of Agen, on the Southern railway from Bordeaux to Cette. Pop. (1936) 8,223. Marmande was a *bastide* founded about 1195 and its position on the Garonne made it an important place of toll. It soon passed into the hands of the counts of Toulouse, and was three times besieged and taken during the Albigensian crusade, its capture by Amaury de Montfort in 1219 being followed by a massacre of the inhabitants. It was united to the French crown under Louis IX. A short occupation by the English in 1447, an unsuccessful siege by Henry IV. in 1577 and its resistance of a month to a division of Wellington's army in 1814, are the chief events in its subsequent history. Marmande is situated on the Garonne at its confluence with the Trec. The Garonne is here crossed by a suspension bridge. Public institutions include the sub-prefecture, and tribunals of first instance and commerce. Apart from the administrative offices, the only building of importance is the church of Notre-Dame, which dates from the 13th, 14th and 15th centuries. Among the industries are iron-founding, steam sawing, manufacture of woollens and brandy-distilling.

MARMONT, AUGUSTE FREDERIC LOUIS VIESSE DE, DUKE OF RAGUSA (1774–1852), marshal of France, was born at Châtillon-sur-Seine on July 20, 1774, the son of an ex-officer in the army. He studied mathematics at Dijon with a view to entering the artillery, and there met Bonaparte, with whom he later served in Toulon. Marmont became Bonaparte's aide-de-camp, remained with him during his disgrace, and accompanied him to Italy and Egypt, being promoted to general of brigade. He returned to Europe in 1799, organized the artillery for the expedition to Italy, and was made general of division for his services at Marengo. In 1801 he became inspector-general of artillery, and in 1804 grand officer of the Legion of Honour, but was not made marshal. In 1805 he fought at Ulm, and then became for five years governor of Dalmatia, where his beneficent régime was long remembered. In 1808 he became duke of Ragusa, and in 1809 Napoleon summoned him to take part in the closing operations of the Austrian War, and made him governor-general of the Illyrian provinces of the empire. In July 1810 Marmont succeeded Masséna in command in the north of Spain, and was wounded at Salamanca. He was hardly cured when, in April 1813 Napoleon gave him the command of a corps with which he served throughout the defensive campaign of 1814, until the last battle before Paris, from which he drew back his forces to the commanding position of Essonne, where he had 20,000 men. Marmont then took upon himself a political role which has been stigmatized as treasonable, concluding a secret convention with the enemy. This act was never forgiven by Marmont's countrymen, and although made a peer of France and a major-general of the royal guard at the Restoration, he was never trusted. In July 1830 he was ordered to put down any opposition to the ordinances, and although opposed to the court policy he only gave up the attempt to suppress the revolution when it became clear that his troops were outmatched. The duc d'Angoulême ordered him under arrest, fearing further treachery, but Marmont went into exile with the king, forfeiting his marshalate. He finally settled in Vienna, and became tutor to the duke of Reichstädt. He died at Venice on March 22, 1852. Marmont's *Memoires* are of great value for the military history of his time.

His works include *Voyage en Hongrie, etc.* (4 vols. 1837); *Voyage en Sicile* (1838); *Esprit des institutions militaires* (1845); *Mémoires* (8 volumes, 1856).

MARMONTEL, JEAN FRANÇOIS (1723–1799), French writer, was born at Bort (in Cantal), on July 11, 1723. After studying with the Jesuits at Mauriac, he taught in their colleges at Clermont and Toulouse; and in 1745, acting on the advice of Voltaire, he set out for Paris to try for literary honours. From 1748 to 1753 he wrote a succession of tragedies which, though only moderately successful on the stage, secured the admission of the author to literary and fashionable circles. He wrote a series of articles for the *Encyclopédie;* also the libretti of several comic operas, among others *Sylvain* (1770) and *Zémire et Azore* (1771). In the Gluck-Piccini controversy he was an eager partisan of Piccini with whom he collaborated in *Didon* (1783) and *Pénélope* (1785). In 1758, through Madame de Pompadour, he obtained a place as a civil servant, and the management of the official journal *Le Mercure,* in which he had already begun the famous series of *Contes moraux.* The merit of these tales lies partly in the delicate finish of the style, but mainly in the graphic and charming pictures of French society under Louis XV. The author was elected to the French Academy in 1763. In 1767 he published a romance, *Bélisaire,* which incurred the censure of the Sorbonne and the archbishop of Paris for a chapter on religious toleration. Marmontel retorted in *Les Incas* (1778) by tracing the cruelties in Spanish America to the fanaticism of the invaders.

He was appointed historiographer of France (1771), secretary to the Academy (1783), and professor of history in the Lycée (1786). Marmontel retired in 1792 to Evreux, and soon after to a cottage at Abloville in the department of Eure. To that retreat we owe his *Mémoires d'un père* (4 vols., 1804, new ed. by M. Tourneux, 3 vols., 1891), giving a picturesque review of his whole life, a literary history of two important reigns, a great gallery of portraits extending from the venerable Massillon, whom more than half a century previously he had seen at Clermont, to Mirabeau. He died on Dec. 31, 1799 at Abloville.

The *Contes Moraux* were early translated into English, and many editions of them exist. A summary of the best of them is given by G. G. Saintsbury in *Hist. of the French Novel,* vol. i. (1917).

See also C. A. Sainte-Beuve, *Causeries du lundi,* iv.; S. Lenel, *Un Homme de lettres au XVIII. siècle, Marmontel* (1902).

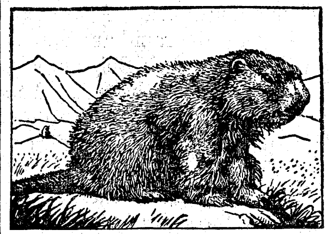
MARMORA (anc. *Proconnesus*), an island in the sea of the same name. (*See* below.) Originally settled by Greeks from Miletus in the 8th century B.C., Proconnesus was annexed by its powerful neighbour Cyzicus in 362. The island has at all times been noted for its quarries of white marble which supplied the material for many of the buildings of Constantinople.

See C. Texier, *Asie mineure* (1839–49); M. I. Gedeon, *Προκόννησος* (Constantinople, 1895); an exhaustive monograph by F. W. Hasluck in *Journ. Hell. Stud.,* xxix. (1909).

MARMORA, SEA OF, the small inland sea which (in part) separates the Turkish dominions in Europe from those in Asia, and is connected through the Bosporus with the Black Sea (*q.v.*) and through the Dardanelles with the Aegean. It is 170 m. long (E. to W.) and nearly 50 m. in extreme width, and has an area of 4,500 sq.m. Its greatest depth is about 700 fathoms, the deepest parts (over 500 fathoms) occurring in three depressions in the northern portion—one close under the European shore to the south of Rodosto, another near the centre of the sea, and a third at the mouth of the Gulf of Ismid. There are several considerable islands, of which the largest, Marmora, lies in the west, off the peninsula of Kapu Dagh, along with Afsia, Aloni and smaller islands. In the east, off the Asiatic shore between the Bosporus and the Gulf of Ismid, are the Princes' Islands. The Sea of Marmora is the ancient *Propontis,* Turk. *Marmara Denizi.*

MARMOSET, the name of any of the small tropical American monkeys classed in the family Callithricidae. Marmosets are not larger than squirrels and present great variation in colour; all have long tails, and many have the ears tufted. They differ from the other American monkeys in having one pair less of molar teeth in each jaw. The common marmoset, or ouistiti, is *Callithrix jacchus. See* PRIMATES.

MARMOT, a large, thickly built, burrowing Alpine rodent allied to the squirrels, and typifying the genus *Marmota,* of which there are numerous species ranging from the Alps through Asia north of the Himalaya, and in North America. All these may be included under the name marmot. In addition to their stout build and thickly haired tails, marmots are characterized by the absence of cheek-pouches. Europe possesses two species, the Alpine or true marmot (*M. marmota*), and the more eastern bobac (*M. bobac*); and there are numerous kinds in Central Asia, one of which, the red marmot (*M. caudata*), is a larger animal, with a longer tail. Marmots inhabit open country, either among mountains, or in the plains; and associate in large colonies, forming burrows, each tenanted by a single family. During the daytime the hillock at the entrance to the burrow is frequently occupied by one or more members of the family. In the winter when the ground is deep in snow, marmots retire to the depths of their burrows, and the winter sleep is probably unbroken. From two to four is the usual number of young in a litter. There are three species in North America, the most widespread of these known as woodchucks (*q.v.*); two other species occur in the western mountains. The red-bellied marmot (*M. flaviventris* ranges from New Mexico and southern California to British Columbia, while the hoary marmot or whistler (*M. caligata*) is found from Alaska to the high mountains of Idaho. (*See* RODENTIA.)



THE ALPINE MARMOT, A RODENT RELATED TO THE GROUND SQUIRRELS

MARNE, a department of north-eastern France, made up from Champagne-Pouilleuse, Rémois, Haute-Champagne, Perthois, Tardenois, Bocage and Brie-Pouilleuse, districts formerly belonging to Champagne, and bounded west by Seine-et-Marne and Aisne, north by Aisne and Ardennes, east by Meuse, and south by Haute-Marne and Aube. Pop. (1936) 410,238. Area 3,168 sq. miles.

The western half of the department is hilly (920 ft. near Reims) with Tertiary rocks of the Paris basin deeply cut by Marne, Vesle and Suippe. From beneath the eastward-facing scarp edge of these rocks the chalk emerges to floor the eastern half of the department (Champagne Pouilleuse), the surface of which rises eastward up the dip slope of the rock to the forested scarp (860 ft.) of the Lower Chalk, again facing east. From beneath this, in turn, emerge the impervious Lower Cretaceous rocks of La Champagne humide, drained by the upper Aisne, which runs northward, parallel to the scarp.

Marne has the temperate climate of the Seine region; the annual mean temperature is 50°, the rainfall about 24 in. Oats, wheat, rye and barley, lucerne, sainfoin and clover, and potatoes, mangold-wurzels and sugar-beet are the principal agricultural crops, and choice vegetables are grown. The raising of mixed merino sheep and of other stock and bees is profitable. The vineyards on the hill slopes of Reims, Épernay and Châlons produce the best Champagne. Pine woods are largely planted in Champagne-Pouilleuse. The department produces peat, fire-clay, millstones and chalk.

Reims has an old-established woollen industry. The manufacture of wine-cases and other goods for the wine trade is carried on. There are also small metalworks. Besides these there are glassworks, whiting and oil works. The chief imports are wool and coal; exports are wine, grain, live-stock, stone, whiting, pit-props and woollen stuffs. Communication is afforded chiefly by the river Marne and by the Eastern railway. There are four arrondissements—namely those of Châlons (the capital), Épernay, Reims, and Vitry-le-François—with 33 cantons and 662 communes. The department belongs partly to the archbishopric of Reims and partly to the see of Châlons. Châlons is the headquarters of the VI. army corps (Metz). Its educational centre and court of appeal are at Paris. The principal towns are Châlons-sur-Marne, Reims, Épernay and Vitry-le-François, Ay and Sézanne.

MARNE, a river of northern France, 328 m. long, rising on the Plateau of Langres, 3 m. S. of Langres, flowing in a wide valley across the Jurassic and Cretaceous rocks of the Paris basin and uniting with the Seine at Charenton, an eastern suburb of Paris. Leaving Langres on the left the river flows northward, passing Chaumont, as far as St. Dizier, where it turns west, receives the Blaise (left), passes Vitry-le-François where it receives the Saulx (right), Châlons and Epernay, where it enters picturesque and undulating country of Tertiary rocks. It passes Chateau-Thierry and Meaux and is joined by the Petit-Morin (left), Ourcq (right) and Grand-Morin (left). It is canalized from Paris to Dizy beyond which it is accompanied by a lateral canal which connects with the Saône. It is also connected by canal with the Rhine and the Aisne.

MARNE, THE FIRST BATTLE OF THE (Sept. 6–9, 1914), the first great turning point in the World War. A strategically decisive victory for the Allies, it brought the rapid and apparently resistless advance of the German hosts through Belgium and France to a halt and forced them to retire northwards. The French reckon in the battle only the Armies west of Verdun, thus excluding Dubail's and de Castelnau's Armies[1] in Alsace-Lorraine; the Germans include the whole front from Belfort round to Paris, and, as they attacked on this with all their seven Armies and the fighting east of Verdun formed an important part of their plan, their definition is followed here.

After the "Battles of the Frontier" in the later part of August and the retreat of the French and British forces, Gen. Joffre attempted to lengthen his line to the westward and prevent envelopment of the Allied left flank by collecting near Amiens on the left of the British Expeditionary Force a new army, under Gen. Maunoury, formed of divisions drawn from other parts of the line. Before this Army could be completely organized, its leading divisions came into contact with the enemy and became involved in the general retirement.

At this period the B.E.F., under Field-Marshal Sir John French, consisted of:—

I. Corps (Lieut.-Gen. Sir D. Haig)
 1st Division (Maj.-Gen. S. H. Lomax),
 2nd Division (Maj.-Gen. C. C. Monro).
II. Corps (General Sir H. L. Smith-Dorrien),
 3rd Division (Maj.-Gen. H. I. W. Hamilton),
 5th Division (Maj.-Gen. Sir C. Fergusson).
III. Corps (Maj.-Gen. W. P. Pulteney),
 4th Division (Maj.-Gen. T. D'O. Snow), with 19th Infantry Brigade attached.

The Cavalry Division (Maj.-Gen. E. H. H. Allenby), of 4 cavalry brigades, and the 5th Cavalry Brigade.

The Royal Flying Corps (Brig.-Gen. Sir D. Henderson) of 5 squadrons.

Lines of Communication troops.

The German Movements and Orders Before the Battle.—As the German pursuit proceeded, Gen. von Kluck, commanding the German I. Army on the extreme west of the line, which had fought at Mons and Le Cateau and occupied Amiens, came to the conclusion that the B.E.F. and Maunoury's troops were routed and practically dispersed, and that Gen. Lanrezac's Army on the right of the British was in consequence the left of the French line. The action of Lanrezac in attacking at the battle of Guise (Aug. 29–31), without assistance on his left, confirmed him in these views. In conjunction, therefore, with Gen. von Bülow (II. Army), instead of continuing the advance in order to cross the Seine below Paris, as ordered, Kluck on Aug. 31 wheeled south-eastwards past the northern front of the French capital, with the object of striking the supposed French flank. After some of his advanced troops and his cavalry corps had been roughly handled by the British on Sept. 1, he turned south, but subsequently resumed his south-eastward course. The German Supreme Command at first accepted Kluck's views, but on Sept. 4 Gen. von Moltke, the Chief of the General Staff and virtual Commander-in-Chief, became alarmed. Information reached him that the French were passing divisions from east to west, and that there were considerable assemblies of troops near Paris. On the evening of the 4th he despatched to the seven German Armies, warning messages, which he consolidated into a formal operation order on the 5th. This order brought to an end the great wheel that was to sweep the French into Switzerland, and substituted for it a plan by which the Paris forces were to be held off by the I. and II. Armies, whilst the other five armies attacked and enveloped what remained of the French forces. The supreme command operation order, the only one issued in regard to the battle, is of such importance that the greater part of it is quoted:—

"The enemy is bringing up new formations and concentrating superior forces in the neighbourhood of Paris to protect the capital and threaten the right flank of the German Armies.

"The I. and II. Armies must therefore remain (*sic*) facing the east front of Paris. Their task is to act against any operations of the enemy from the neighbourhood of Paris and to give each other mutual support to this end.

"The IV. and V. Armies are still operating against superior forces. They must maintain constant pressure to force them south-eastwards . . . Whether by co-operating with the VI. and VII. Armies they will then succeed in forcing any considerable part of the enemy's forces towards Swiss territory cannot yet be foreseen.

"The VI. and VII. Armies will continue to hold the enemy in position in their front, but will take the offensive as soon as possible against the line of the Moselle between Toul and Epinal, securing their flanks against these fortresses.

"The III. Army . . . will be employed as the situation demands either . . . to support the I. and II. Armies or to cooperate . . . in the fighting of our Armies on the left wing."

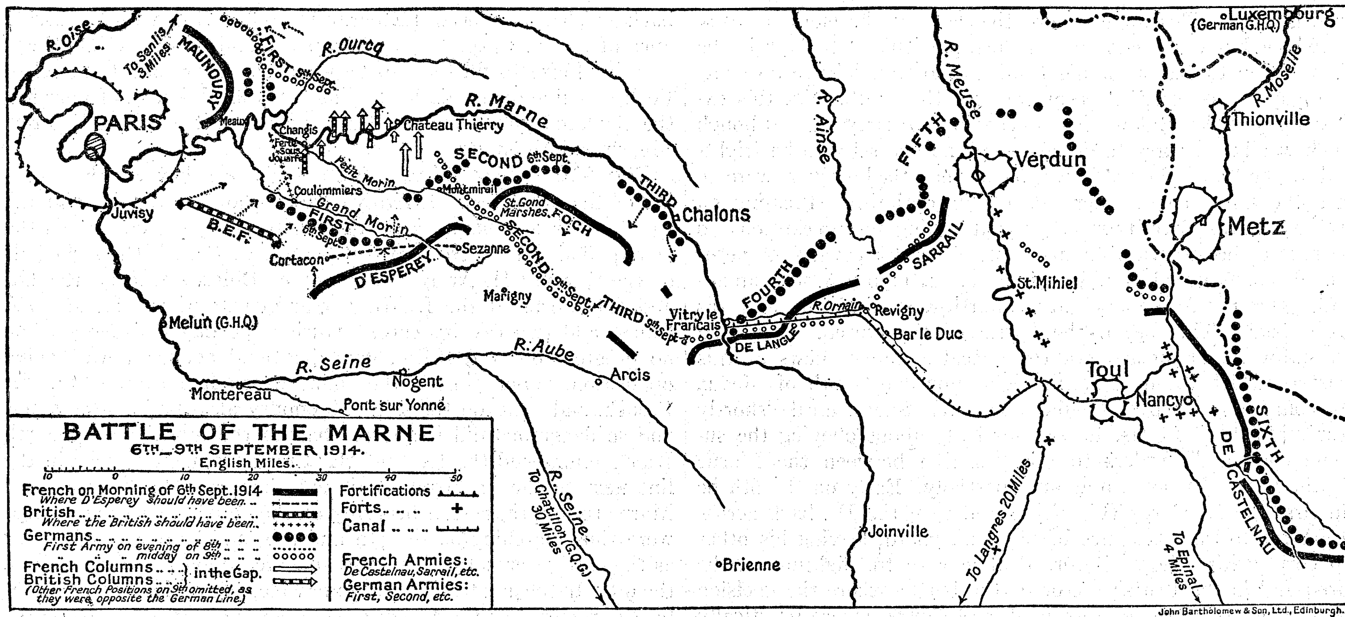
Regardless of the fact that the I. Army was beyond the Marne going south, it was ordered *to remain*, facing west, between the Oise and the Marne, and the II. Army, not yet across the Marne, was ordered to remain between that river and the Seine. The II. Army took immediate steps to obey this order; Bülow ordering his right corps as pivot to halt and the remainder to wheel forward so as to change front from south to west. The first stage of the wheel, to be carried out on the 6th, was to be to the line Montmirail–Marigny, a position not quite reached by the II. Army when the battle came to an end on the 9th. The I. Army continued its advance on Sept. 5 towards the Seine, Kluck reporting that he considered it best to settle with the French armies in the field first and then invest Paris. He, however, began preparatory steps for facing west, and when, in the afternoon, the representative of the supreme command, Lieut.-Col. Hentsch arrived, he approved of the preparations, but added that "the movement to face west might be made at leisure; no special haste was necessary." Thus on the afternoon of September 5 four corps of the I. Army were across the Grand Morin, with two cavalry corps ahead of them; but there was only a weak flank guard, the IV. Reserve Corps (3 infantry brigades) and the remains of the 4th Cavalry Division (smashed up by the British on Sept. 1) in échelon behind its right flank. The II. Army was a day's march behind the I., still facing south; the other German Armies were acting in conformity with their orders.

The French and British Movements and Orders.—The change of direction, to the south-east, of the German I. Army had been observed and reported by British aviators on the morning of Sept. 3, and they added at 5 P.M. that it was crossing the Marne. At 7 P.M. Maunoury reported that there were no German troops west of a line Paris–Senlis; at 8:45 P.M. the British found that there was only one German corps (IV. Reserve) left in the Ourcq valley. All this information was fully confirmed on the 4th. Gen. Joffre, however, did not at once change his plans. Three days previously on Sept. 1, by instruction No. 4, sent out by officers in motor cars at 2 P.M., he had provisionally fixed as the limit of the retirement the moment when his armies were situated as follows:—

"Sarrail's army north of Bar de Duc;
De Langle's army, behind the Ornain east of Vitry;
Foch's army behind the Aube, south of Arcis;
Lanrezac's army, behind the Seine, south of Nogent."

On the 2nd, at 11:40 P.M., he had by a note changed this limit and put the general line on which his forces as a whole should establish themselves considerably farther back on the right. It was defined by Joinville, Brienne, Arcis, Nogent and Pont sur Yonne.

[1]For the sake of clearness, the French Armies are called by the names of their commanders; the Germans by their numbers.



The British were to be behind the Seine, close to Paris, from Melun to Juvisy, their left in touch with Maunoury's Army, now part of the garrison of the entrenched camp of Paris. The Military Governor of Paris, Gen. Galliéni, who had been warned on Sept. 3 (apparently about 8 A.M.) that his troops in the eventual offensive would be required to act in the direction of Meaux, seems to have been the first to realize that there was no time to lose in taking advantage of the tremendous opportunity that the Germans were offering by their flank march past Paris. At 9 A.M. on the 4th he proposed to Gen. Joffre by telephone to use his forces at once to attack from north of Paris eastwards against the German flank. The French commander-in-chief replied at noon by telegraph approving of the idea, but preferring that the attack should be made south not north of the Marne, which meant postponement and loss of time. Joffre then set about ensuring the co-operation of the B.E.F., and about 4 P.M. received through the mission at Sir John French's headquarters at Melun, to which Galliéni had paid a visit, a definite assurance of the fullest support. Meantime he had been in communication with d'Esperey—now in command, vice Lanrezac of the V. Army—as to the condition of his troops and when they could attack. Between 5 P.M. and 8 P.M. two telegraph messages arrived from d'Esperey—the exact hour cannot be fixed, the times of receipt are not marked, but they are between letters received at 5 P.M. and 8 P.M. In these he stated that he could not attack before the 6th, and that Gen. H. Wilson, the sub-chief of the general staff of the British army, who was with him, agreed that the B.E.F. could be on the line Coulommiers–Changis on that date. Gen. Joffre had meantime fixed on the 7th. In the evening, however, Galliéni on return from British G.H.Q. again telephoned personally to him informing him of the measures taken for the eastward march of the Army of Paris and urging him that there was not a moment to be lost, with the result that Joffre definitely informed Galliéni that the general attack would take place on the 6th, and that he might attack north of the Marne as he wished, and gave him a summary of his orders, in which the destination of the B.E.F. as mentioned above was specified. Orders were then prepared, and telegraphed in cypher timed 11:15 P.M. on Sept. 4, to Maunoury and d'Esperey, 11:50 P.M. to Foch and Galliéni, and 12:10 A.M. on the 5th to British headquarters. Duplicates were sent by motor car

General Joffre's orders directed the forces on the left of his line to take up positions during Sept 5 ready to attack on the front and flank of the German I. and II. Armies on the morning of the 6th. Maunoury was to be north-east of Meaux, ready to cross the river Ourcq eastwards in the direction of Château Thierry; the B.E.F. to advance to the line Coulommiers–Changis, ready to move north-eastwards; d'Esperey to fall back to the line Sezanne-Courtacon, and then attack northwards; Foch was to cover the right of d'Esperey by holding the exits of the Marais de St. Gond.

In order to profit by the coolness of the night the troops of Foch, d'Esperey and Sir J. French had marched off before the orders arrived. Galliéni received his copy at 2:35 A.M., but, knowing Joffre's intentions after his telephone conversation, which closed before 10 P.M., had already passed the information on to Maunoury. Foch, whose headquarters were nearest to the Grand Quartier-Général, then at Chatillon, received his at 1:30 A.M. and between 5 and 6 A.M. he was able to stop the retirement of his corps. D'Esperey was not so fortunate; what time he received the telegram is not recorded, but his orders founded on it are timed 6 A.M. His corps, having moved off at midnight to continue their retirement, he could not do more than modify the halting places of some of them; his centre and left passed the line defined by Joffre, and the right detained by rear-guard fighting with the enemy did not reach it. The B.E.F. was in worse case. The orders carried by motor reached G.H.Q. before the telegram, at 3 A.M., and the corps had already started southwards, one of them five hours earlier. Thus the British made a march farther to the south than Joffre counted on, and had two marches to the front to reach the place assigned, instead of one. It was in all probability a fortunate circumstance that the B.E.F. was not in a position to obey and try to reach the line Coulommiers–Changis on the 5th. For if it had done so its five divisions and one cavalry division cut off from all help would have come isolated into collision with the greater part of eight divisions of the German I. Army and four cavalry divisions. Early on Sept. 5, Joffre issued orders to his centre: to de Langle to stay his retreat and attack northwards; to Sarrail to attack westwards against the German flank presented to the troops near Verdun.

Sept. 5: The First Contact.—The Germans, the exponents of envelopment, by thrusting forward between Verdun and Paris, had placed themselves in a position exposed to envelopment on both flanks. They had completely misunderstood the situation, over-estimated their initial successes and under-estimated the fighting powers of the Allies. Gen. von Kuhl, Kluck's chief of the staff, has written:—

"Neither the supreme command nor I. Army headquarters had the remotest idea of an immediately imminent offensive of the whole French Army. The continuation of the French retreat was accepted as settled. There was only a question of our flank being threatened from Paris. . . . The great offensive on the whole front of the forces came as a complete surprise. No sign, no prisoner's statement, no newspaper tattle had given warning of it."

But this was not the end of their mistakes. By Moltke's orders of the evening of Sept. 4, the I. and II. Armies were to face towards Paris. This might guard the flank of the German army as a whole, but would expose their own particular left flank in the new position to the oncoming French, and would leave an enormous gap in the original front towards the south. Yet this extraordinary order Bülow was proceeding to carry out, although Kluck was in no hurry to do so, seeing no necessity to be frightened at the "Paris bogey." Events of the 5th, however, were to scare the latter commander out of his optimism. Pressing on south-eastwards with four corps and taking no precautions to investigate the situation on his flank either by cavalry or aeroplane, his flank guard came in contact about 1:30 P.M. with an advanced guard of Maunoury's army, north-west of Meaux, and was forced back. This began the battle of the Ourcq. Owing to bad staffwork, or an attempt to conceal a defeat, news of this disaster—which meant that his right, now 6m. south of Meaux was completely uncovered—did not reach Kluck until "shortly after midnight." At last he set hurriedly about obeying the supreme command's orders to take position between the Marne and the Oise. But even now only partially. Early on the 6th he sent first the II. Corps (his right) and then the IV. back across the Marne to the assistance of his flank guard, leaving his other two corps with Bülow. Before dealing with the fighting on the Ourcq and in the British sector of the battle, where the decision fell, the events on the eastern flank and centre, where practically deadlock set in, will be summarized.

The Battle on the Eastern Flank and in the Centre.—The German VII. and VI. Armies, under Crown Prince Rupprecht, were "to attack against the Moselle between Toul and Epinal." That is, they were required to force the fortress line of the French eastern frontier. Yet it was to avoid the uncertainties and difficulties of this very task that the German Government had taken the momentous decision to allow their Armies to enter Luxembourg and violate Belgian neutrality. Until Moltke had "watered down" the plan of his predecessor, Field-Marshal Graf Schlieffen, it had been intended to enter Netherlands territory also. The enterprise proved beyond the powers of the Germans. Met by the stout defence of Dubail's and de Castelnau's armies, Rupprecht's armies were unable to make any progress and lost heavily, so that on Sept. 8 he stopped the offensive in order to spare the troops, and was ordered "to prepare to occupy a rear defensive position at once."

The German V. and IV. Armies did no better. Pushing on past the west side of Verdun, the V. (crown prince of Prussia) had to face eastwards towards the fortress. It prevented Sarrail from making any attempt to roll up the German line, but suffered most severely from French artillery fire and for three days was pinned to the ground. A diversion by small forces east of Verdun had no effect. At 2 P.M. on the 9th the Crown Prince, in desperation, ordered a night attack in the hope of capturing the French guns that were killing his men. This operation, owing to short notice, was a complete fiasco, the Germans firing on each other.

The German IV. Army, assisted by half of the III. Army, encountered de Langle, who stood on the defensive and then counter-attacked. After severe fighting on his flanks (actions of Revigny and Vitry), the Germans failed to make ground. By the morning of the 9th, the Germans were reduced by the French artillery fire to seeking what shelter they could in trenches and dead ground. Thus on the eastern half of the battlefield, where the Germans were the attackers, they had the worse of the fighting and there was no decision.

The II. Army (Bülow) and the other half of the German III. Army co-operating with it were at the opening of the battle facing nearly south, half-way between the Seine and Marne. Opposite them were Foch's army and the right of d'Esperey's. The former general—owing to his having received Joffre's orders of Sept. 4 in time to act on them—was actually in contact with the enemy. Severe fighting at once ensued near the Marais de St. Gond. But it was not Bülow's object to break through. He was merely pivoting on his centre so as to change from facing south to facing west towards Paris, between the Seine and the Marne, endeavouring to reach the line Montmirail-Marigny. Thus heavy pressure was brought on Foch, and he was forced back and had to call on d'Esperey for help. But, with the assistance of the X. Corps lent by d'Esperey and of the XVII. Corps sent by Joffre to fill the gap between his army and de Langle's, Foch was able to remain in the line and fulfil his task of guarding the flank of Joffre's main attack of the left wing—d'Esperey, French and Maunoury.

The Allied Left Wing.—It has been seen how on the morning of the 6th Kluck (I. Army) had withdrawn the II. and IV. Corps to succour his flank guard threatened by Maunoury on the Ourcq. This left in front of d'Esperey and French the right half of the German II. Army (the pivot of Bülow's wheel), the IX. and III. Corps of the I. Army, rear guards of the II. and IV. Corps, and two cavalry corps. During the day d'Esperey made no progress but the B.E.F. gained ground against a weakening opposition, about 5m. on the right, which had to wait for the French, and 12m. on the left. Maunoury also made an advance, and so dangerous did it appear that on the morning of the 7th Kluck summoned the IX. and III. Corps from their place in the line next to the II. Army, and sent them also back across the Marne to join the rest of his army on the Ourcq. These two corps were thus marching on the 7th and 8th, and were wasted so far as the battle went; for they only appeared opposite Maunoury on the 9th. In the great gap, some 30m. wide, left in the German front by the removal of the I. Army were now only two cavalry corps (which contained five *Jäger* battalions and extra machine-gun companies) and some infantry detachments, and no one was appointed to take command of them as a whole.

The way through the German front appeared almost open: the Germans themselves had created a gap in their front such as, in the succeeding years of trench warfare, each side strove in vain to batter through its opponent's line. Unfortunately Gen. Joffre's plan, like the famous Plan XVII. with which the campaign had been opened, took no account of ground. In Aug. 1914 the French were committed to an offensive into the defiles of the Vosges and the forests of the Ardennes, where they were ambushed by the enemy. Now the advance of d'Esperey and the B.E.F. was confronted by a series of transverse rivers, the Grand Morin, the Petit Morin and the Marne, all passable only at the bridges, some of which had been destroyed by the French in the retreat. Nevertheless, in very hot, dry and dusty weather, the Allies forced the passage of the Grand Morin on the 7th and of the Petit Morin on the 8th. The German resistance in the gap was practically broken, and there was every chance of cutting off Kluck and falling on his rear, although he hastily despatched first a composite brigade and then the 5th Division to stop the British. On the evening of the 8th Sir John French's five divisions were close up to the Marne. D'Esperey, having farther to go, was not within reach of the river; but his right had driven back the right of the German II. Army and widened the gap. Maunoury's army (of seven divisions, only two of which were active troops, the rest being reserve), had ceased to make any progress against the six divisions of the German I. Army, to reinforce which four more were now on the way.

Sept. 9th: The Passage of the Marne.—Early on Sept. 9 the British cavalry, driving off the Germans, seized two bridges over the Marne below Château Thierry; the 6th Infantry Brigade secured another, and by 7:30 A.M. the I. Corps (Haig), the right of the B.E.F. was beginning to cross the river. In the centre, the II. Corps (Smith-Dorrien) found two bridges intact and undefended, and by 9 A.M. the vanguards of both its divisions were across. Reports were now received from the Flying Corps that there were large masses of Germans north of Château Thierry (actually the German 5th Cavalry Division and infantry attached to it), and the I. Corps, as there were no French troops across the river on its right, halted and began to entrench to secure itself against a counter-stroke. As the French historian, Gen. Palat, has written, "our Allies were very notably ahead of Conneau's Cavalry Corps, which itself was bound to outpace the V. Army (d'Esperey)." The head of the 5th Division, the left of the II. Corps, met with considerable resistance after crossing from a German composite brigade, and the 3rd Division, learning this and finding the I. Corps on its right at a standstill, also halted.

On the left, the 4th Division (Snow) had started at 4:45 A.M. with the intention of crossing at La Ferté sous Jouarre. It found both bridges over the Marne, there nearly a hundred yards wide and very deep, broken (they had been blown up by the French in the retreat); the enemy were holding the farther bank at all likely points of passage. About 1 P.M., two battalions, followed later by a third, managed to cross by a weir a mile above La Ferté, and another battalion crossed at a railway viaduct 3m. above. But by this time, 2:30 P.M., the Germans had abandoned the defence of the passages, and were making off. Conneau's cavalry on the British right did not begin crossing the Marne at Azy just below Château Thierry until 1 P.M. (Palat), and did not get up level with the British I. Corps until the latter had halted for the night. Meanwhile, farther east, Foch was again heavily attacked, particularly on his right, but d'Esperey was making good progress, driving back Bülow's right, so that he was able to lend Foch a division. The latter therefore withdrew Grossetti's division from his left in order to restore the combat on his right by counter-attack.

On the British left, Maunoury's left was being forced back on the exterior defences of Paris, for he had against him the additional weight of the greater part of Kluck's III. and IX. Corps, which had now reached the battlefield, and also the fourth brigade of the IV. Reserve Corps which had appeared from Antwerp on his outer flank. But the farther the German I. Army advanced from the Ourcq the more it suffered from the fire of the heavy guns of the Paris defences, which had been brought into the field, and had already taken heavy toll of it in the previous three days' fighting. Where, therefore, the enemy seemed to be advancing—opposite Foch's right and against Maunoury—further progress was unlikely and a decision impossible. Kuhl goes even farther, and says:—

"Even a victory over Maunoury could not prevent us [I. Army] from having our left flank enveloped by superior force, and from being driven away from the main army. The I. Army stood isolated."

At this crisis, at 1 P.M., the Germans began their retirement from the battlefield.

The German Retirement.—What happened on the German side was the subject of a special enquiry in 1917, after Hindenburg had become chief of the general staff; numberless books have been written in Germany on the battle, and a strenuous endeavour has been made to show that the German retreat was unnecessary. One school would attribute it to a misunderstanding—the I. Army (Kluck) and the II. Army (Bülow) retiring because each thought the other was doing so. The German official history and an official monograph entitled *Das Marnedrama* issued by the *Reichsarchiv* take the view that the retreat was ordered by Lieut.-Col. Hentsch as the representative of the Supreme Command with full powers for the purpose. The monograph sums up the matter in the words:—

"Thanks to the initiative of the German Army and corps commanders, thanks to the ability of the regimental leaders right down to platoon and section leaders, thanks to the valour of the troops, the battle ended with the victory of the German arms at the decisive point. . . . Then the forces on the Western Front were called back from the victory they had won by the word of the representative of the supreme command."

This view does not, however, seem to be borne out by admitted facts. Gen. von Bülow (subsequently promoted to Field-Marshal) definitely claimed to have ordered a retirement of his army, and thereby to have saved the situation. The committee of enquiry found that Bülow came to this decision "independently." At 9 A.M. on the 9th he received definite air reports that six columns (five British and one French cavalry) were approaching the Marne, and, no news of any success of the I. Army reaching him, by 11 A.M. he had issued orders for the retreat to begin at 1 P.M. and so informed the I. Army; the movements took place accordingly, and the III. Army conformed to them.

What happened at I. Army (Kluck) headquarters is not quite so clear. There are two distinct versions, those of Lieut.-Col. Hentsch, the emissary of the supreme command, and Gen. von Kuhl, Kluck's chief of the staff. Hentsch had been despatched by Gen. von Moltke at midday on the 8th to visit the V., IV., III., II. and I. Armies in succession, a round trip of 400m. According to the court of enquiry, the proceedings of which Ludendorff promulgated to the general staff, Hentsch was given full powers to co-ordinate a retreat, "should rearward movements have been initiated"—and he was despatched by Moltke in full expectation that such movements had been begun. Hentsch found none had taken place in the V., IV. and III. Armies, and then spent the night of the 8th–9th at II. Army headquarters, where he observed a spirit of depression and pessimism. He left early on the morning of the 9th, before definite orders for the retreat had been given, but apparently convinced that they would soon be given. Owing to blocks and panic on the road, it was past midday when he arrived at I. Army headquarters, taking seven hours to go 60m.; he did not see Gen. von Kluck, dealing only with Kuhl. Hentsch states that he found orders for retirement had already been issued. Kuhl denies this, but admits that such orders had gone out by telephone owing to the overzeal of a subordinate officer, since dead, who had misunderstood him. What, according to Kuhl, had been ordered at 11:30 A.M., and was in course of execution in view of the British advance, was a wheel backwards of the left only of the I. Army. Thus Kuhl's contention is that Hentsch, in view of the situation of the II. Army, ordered the I. to retreat and quoted his full powers given for the purpose of co-ordinating a retirement. Hentsch's statement is to the effect that the retirement had been decided on, and that he merely gave Kuhl the direction in which the I. Army was to retire, north-eastwards, so as to join up with the II. Army. The court of enquiry accepted Kuhl's view, adding, however, that Hentsch was justified "as the case provided for in his instructions, the initiation of rearward movements, had arisen." A curious feature of the events at German I. Army headquarters is that Kuhl, by his own account, accepted Hentsch's verbal instructions without requiring that so important a decision should be in writing, and without taking him to see Kluck, the army commander. In one of the books that he has written on the battle he has admitted that:—

"The break-through of the British and the French V. Army which was threatening brought about the decision in the battle of the Marne."

At 2 P.M. the retirement of the I. Army in the general direction of Soissons was begun. Its preliminary movements having brought it from facing west to facing south-west, and all the roads having been cleared by sending back the transport and trains, it was a comparatively easy matter. But, owing to the direction of the British advance, the I. Army could not incline inwards towards the II. Army and retreated due north, still leaving a gap in the German line. The German withdrawal, covered by rear guards, was not immediately obvious. It was not until 3 P.M. that the British I. Corps resumed its advance, and then owing to its fatigue only a short one was made to a line 5m. from the Marne. The left (5th) division of the II. Corps remained in contact with the enemy until dusk. It was not until 9 P.M. that the 4th Division on the extreme left was able to begin a bridge over the Marne at La Ferté, ten of its 16 battalions (including the 19th Brigade) being then still south of the river. Conneau's Cavalry Corps had crossed the Marne at Château Thierry, and now came up alongside the I. Corps but none of d'Esperey's infantry had reached the Marne. In Foch's Army Grossetti's division brought from the left to counter-attack arrived too late to follow the enemy except with a few shells. It was not until 5 P.M. that Maunoury, after a hard day's fighting in which he had been reinforced by every man that Galliéni could send from the Paris garrison, was able to report that the Germans were in retreat, covered by their artillery.

The evening reports from the air confirmed that everywhere along the battle line retrograde movements of the enemy were taking place; but, his main bodies having got a good start during the day, and his rear guards being able to slip off in the darkness, there was no pursuit until next day, and then Joffre's instructions to Maunoury were to gain ground to the left and endeavour to envelop the enemy's right; the order to head the columns off by flanking them from the west was not issued until the 13th. The

German I. and II. Armies were thus able to pursue their way practically undisturbed back to the Aisne, there to make another stand. The gap between them was then filled by fresh troops released by the capitulation of Maubeuge. At 5 P.M. on the 10th orders were sent by the supreme command to the IV. Army to retire, and at noon on the 11th to the V. Army. The VI. and VII. Armies had ceased their attacks on the 9th and retired to a selected line.

The Victory.—At 8:15 P.M. on the 9th Sir John French's orders changed the word "advance" of the previous days to "pursuit"; Gen. d'Esperey, in an order issued from the historic field of Montmirail on the same evening, accurately summarized the battle:—

"Held on his flanks, his centre broken, the enemy is now retreating towards the east and north by forced marches."

The Germans had entered Belgium and France with 78 divisions, excluding cavalry divisions. Of these they only managed to bring 44 divisions on to the great front between Verdun and Paris, 22 divisions being engaged on the Alsace-Lorraine front, four sent back to East Prussia and eight (XV., III. Reserve, IX. Reserve Corps) kept from the battle at the investments of Antwerp, Maubeuge, etc. The French, with 23 divisions in Alsace-Lorraine against 22 German, had 51 divisions and five British divisions on the Verdun-Paris front. Thus there were 56 Allied divisions against 44 German. The French Reserve divisions were not up to the standard of the German Reserve formations, but all the Allied divisions in falling back had received reinforcement, whilst the Germans hampered by the destruction of the railways and handicapped by the very rapidity of their advance, had not been able to get up drafts to fill the gaps in their ranks, so that as regards actual combatants, numbers were still more in favour of the Allies. Neither the French nor the Germans have yet published their losses, but the Allies captured 38,000 prisoners and 160 guns besides other trophies including colours.

The moral effect of the victory both on the Allies and on the Germans was immense, for the legend of German invincibility was broken. That the material and tactical results were not more important is due partly to the immense fatigue of the Allies after the earlier battles, the long retreat of 13 days and a four-day battle in summer heat. But it would seem to be partly due to the direction of the main Allied attack having been frontal and across the courses of several rivers. Greater success would no doubt have been achieved had Maunoury's flank attack, between the rivers, been made stronger. Possibly his army would have done better even if it had been no stronger but composed of better troops; for it consisted of only two active divisions (7th and 14th), badly mauled in the frontier fighting, an Algerian division and four Reserve divisions shaken by fighting near Amiens. Had some of the 14 British Territorial Force Divisions and 14 mounted brigades with the 6th Division, still in England, been landed at the Channel coast ports to fall on the German communications and rear, a decisive tactical result might have been obtained and the war finished. In any case, with such addition to their forces, the Allies would have been better placed to have obtained a decision in the "Race to the Sea," in which actually they were always "an army corps too few and 24 hours too late."

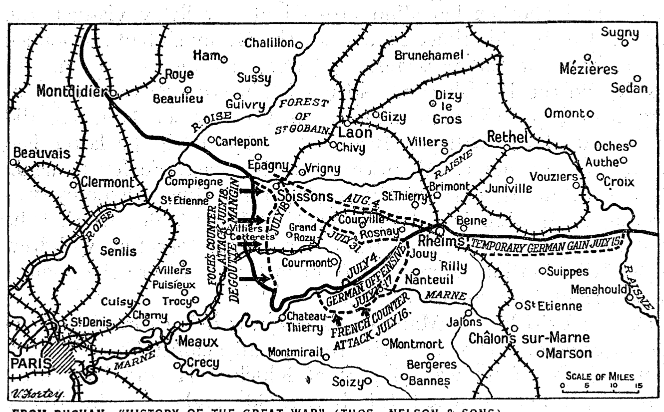
MARNE, SECOND BATTLE OF THE. This marked the turning of the tide in the final year of World War I (*q.v.*). On July 15, 1918, the Rheims district was the scene of the last German offensive on the Western Front, and three days later, when this was stemmed, the ebb began under pressure of the great Allied counterstroke. It was thus composed of two acts, which require separate analysis.

I. THE GERMAN OFFENSIVE IN CHAMPAGNE

This opened on July 15, 1918, and the German plan was to attack on either side of Rheims, the principal effort being made by the German I. and III. Armies towards Châlons, while the VII. Army sought to cross the Marne near Dormans and to converge with the main advance in the region of Épernay. But although this day marked the last German bid for victory, the actual attack was by no means the Germans' supreme effort, nor had it the decisive aims popularly ascribed to it at the time. For Ludendorff still adhered to his guiding idea that the British, severely shaken in the great battles of March and April, should be the



FROM BUCHAN, "HISTORY OF THE GREAT WAR" (THOS. NELSON & SONS)

PLAN OF SECOND BATTLE OF THE MARNE, WHICH DEVELOPED BETWEEN JULY 15 AND AUGUST 4, 1918

target for his decisive blow and that their front in Flanders should be the stage on which he would produce his final drama of victory.

The attack on May 27 (*see* CHEMIN-DES-DAMES, BATTLE OF THE, 1918) across the Aisne had been conceived merely as a diversion to draw the Allied reserves away from Flanders. So also with the June 9 attack, less bountiful in its fruits, that had been launched near Compiègne to break down the buttress of Allied territory that lay between the huge salients created by the German attacks of March and May. When, instead, this German attack was broken off by Ludendorff, with little gained but his own reserves still further drained, he considered "the enemy in Flanders still so strong that the German army could not attack" there yet. So he planned a further diversion—to be made by forty-seven divisions attacking on either side of Rheims.

But the sands of time were slipping out for the Germans, and American reinforcements, like the sands of the shore in potential number, were slipping in to become a cement for the Allied line of battle. Appreciating this, Ludendorff intended his Flanders attack, once more towards the nodal point of Hazebrouck, to follow on the 20th, only five days after the Rheims diversion. On July 16 actually, as soon as the Rheims attack was under way, artillery and aircraft were sent off by train to the Flanders front, and Ludendorff himself moved to Tournai to supervise the preparations.

But preparation was never to be completed by execution. For the Rheims diversion had not even the opening success of its predecessors, and on July 18 the Allied counterstroke so jeopardized the Germans' situation that Ludendorff felt compelled to postpone, if not yet to abandon, the fulfilment of his dream. One reason of the failure of the July 15 attack was that east of Rheims it was met by an "elastic defence" in face of which the German onslaught lost its momentum before it reached the real position of the French resistance. Much misplaced praise has been lavished on this "Gouraud manoeuvre." For this ascription of its origin is yet another of the many war legends. The manoeuvre was actually due to Pétain, that cool, unemotional military economist who, called to be commander-in-chief after the Nivelle fiasco of 1917, had systematically worked to rebuild the French army and to restore the stability of its man-power and *moral,* previously undermined by the extravagant offensives of 1914–1917. One illuminating illustration of the damage done is that cases of desertion alone had risen from 509 in 1914 to 21,174 in 1917.

Not content merely to reorganise, Pétain had set himself to insure against a recurrence of the trouble by tactics that should be an economy both of force and of the nervous force of the combatant. To this end, one method was an elastic defence in depth, to allow the initial shock and impetus of the enemy's attack to be absorbed by a thinly held forward position, and then to await him on a strong position in rear, when the enemy's troops would be beyond the range of the bulk of their supporting artillery. This method Pétain had sought to apply against the attack of June 9, but, although it was partially successful, its full effect was lost through the reluctance of the local commanders, still clinging to their old offensive dogmas, to reconcile themselves to a voluntary yielding up of a few square miles of worthless ground. And before July 15, when the coming German attack was definitely expected, a week's argument was required before Pétain could persuade the lion-hearted Gouraud, in command of the French IV. Army east of Rheims, to adopt this elastic manoeuvre. It was finally decided to leave nothing along the line of outposts (constituted by the Monts de Champagne) but "islands" of resistance, which would be required to sacrifice themselves for the purpose of dissipating the enemy attack and keeping it under the well-controlled fire of the main position established in the rear.

But even when we have ascribed it to the right source, the accumulation of historical error is not fully corrected. For the method was not the revolutionary innovation that it has been termed. The Germans, in fact, had used it on Sept. 25, 1915—nearly three years before—to discomfit the great French autumn offensive in Champagne. And the underlying idea can be traced back another 2,000 years—to Cannae, where Hannibal applied it against the Romans in a distinctly more subtle and decisive way. But it sufficed, even in the mild way of 1918, to thwart the German attack east of Rheims, where its effect was immeasurably strengthened by the German failure to achieve such a surprise as had marked their earlier offensives of 1918. Even the exact hour was discovered by an evening raid on July 14 which brought in 27 prisoners who, on being questioned, revealed the fact that the German attack was to be launched next morning, the artillery preparation being timed for 12.10 A.M. Before it began, the French counter-preparation and counter-battery fire opened on the whole of the enemy front. Between 4.15 and 5.30 A.M., the already shaken German infantry advanced to the attack on a 50 mile front, from Château-Thierry to Massiges (leaving out the Rheims Salient). To the east of Rheims the enemy infantry was broken up by French artillery fire and decimated by the machine-guns distributed along the outpost line before even reaching the main line of resistance, which, in spite of repeated assaults, they failed to break at a single point. To the west of Rheims the situation was less favourable for the French.

German Success at Dormans.—But the dramatic nature of this repulse east of Rheims has obscured the fact that it was not the whole battle. West of Rheims the front had only been stabilised for a month since the last German thrust, and the newly improvised position was a handicap to the execution of the elastic method by commanders who were slow to grasp it. In front of the French V. Army (Berthelot) the Germans made some progress between the Marne and the Ardre in the direction of Épernay, and the French centre (V. French Corps and II. Italian) was thrown back on the second position along the line Pourcy-Belval-Reuil-sur-Marne. Lastly, the right of the VI. Army (Degoutte) was not able to stop the attackers from crossing the Marne on either side of Dormans, between Jaulgonne and Verneuil. The VII. German Army thus established a bridgehead south of the river, in front of the V. Army's left and the VI. Army's right; it also regained touch with the I. German Army on the slopes of the Montagne de Reims. Thus here the German attack had deepened the corner of the great bulge made in May, and not only pushed across the Marne but behind Rheims, so that it threatened to cut under this pivot of the Allied resistance. If the threat had an important influence on the French plan for the counter-stroke, its physical progress was stopped on July 16. The German attack had degenerated into local actions, disconnected and therefore useless. By vigorous counter-attacks the French had even recaptured some of the lost ground, while their artillery and aircraft, by bombarding the Marne crossings, made it increasingly difficult for the Germans to obtain supplies. The only progress in the attack—to the south-west of Rheims between the Vesle and the Marne, on July 16—remained fruitless, for it had cost the enemy too dear for him to repeat such sacrifices. Next day a queer hush of expectation spread over the whole battlefield. The stage was set for the great "revanche."

II. THE COUNTER-OFFENSIVE

The Allied counter-offensive under Pétain's direction comprises two phases: (1) the first extends from July 18–28, and includes the victorious battles of Fayolle's main group of armies in the Soissonnais and on the Ourcq, and the closing stage of the defensive battle of Champagne and Rheims during the same period, in which the centre group under Maistre re-established its front and passed to the attack. This first phase, again, comprised three successive manoeuvres: the breaking of the enemy positions by the Reserve group of armies on July 18 and 19; the re-occupation of Château-Thierry and the south bank of the Marne by the centre group of armies, in combination with the right of the Reserve group, on July 20 and 21; and the co-ordination of the advance of the two groups of armies on both banks of the Ourcq in the general direction of Arcy-Sainte-Restitue and Fère-en-Tardenois on July 23 and 24. (2) The second phase, sometimes called the battle of Tardenois, July 29 to Aug. 4, which included the recapture of Soissons and the push towards the Vesle.

French Preparations.—Acting upon Pétain's instructions, Fayolle, commanding the Reserve group of armies, had prepared a counter-offensive against the west flank of the great German salient which protruded between Soissons and Rheims towards the Marne. These preparations were continued with the utmost secrecy while the centre group of armies (Maistre) were checking the last enemy offensive (July 15 and 16) and (from the 17th) arranging a riposte. This was entrusted to two armies, the V. and the IX.—which adjoined the right of the Reserve group of armies. The V. Army (Berthelot), which had been so heavily attacked at Rheims, had eight divisions in first line (including the Italian 3rd Div.), and one infantry and two cavalry divisions in second line. The British 51st and 62nd Divisions were on the move to reinforce it. The IX. Army (de Mitry) had five divisions, including the American 3rd Division in first line, one division in second line, and two reserve divisions, including the American 28th Division.

The Reserve group was to operate with the X. and VI. Armies. The X. Army, under Gen. Mangin, who was responsible for the principal attack, had 10 divisions in front line, including the American 1st and 2nd Divisions, placed on the flanks of the Moroccan Division in the centre of the army, and six divisions in second line, making a total of 16 infantry divisions—besides three cavalry divisions. In the rear of the army the British 15th and 34th Divisions were in reserve. In addition, the army was given a large number of tanks and strong artillery reinforcements. The task which Mangin set before his troops was "to break through the enemy front between the Aisne and the Ourcq and push straight on in the direction of Fère-en-Tardenois in *liaison* with the offensive of the VI. Army." On his right the VI. Army, commanded by Degoutte, whose own right was engaged in the defensive battle, had only seven divisions in front line—among them the American 4th and 26th Divisions (American I. Corps)—and one division in second line. Degoutte was to attack with his own resources only, reinforced, however, by tanks and by British bombing aircraft.

The attack had been prepared with infinite precautions for maintaining secrecy. The reinforcing divisions were only brought up to the front during the last two days, their movement being carried out by night, between July 14 and 16, the mounted elements marching and the unmounted carried by motor transport. A violent storm which burst during the night of the 17th–18th intensified the darkness and made movements in the woods difficult; but it was favourable to surprise and by 4 A.M. the attacking divisions of the X. and VI. Armies were in position and ready to move without any sign of uneasiness having been shown by the enemy. At 4.35, without a single preliminary round, the whole of the artillery opened fire from the Aisne to the Marne, and 16 front line divisions moved forward with the tanks, while all the air squadrons went up. In the X. Army the infantry and tanks advanced without an artillery preparation behind a rolling barrage, turning the enemy's strong defensive positions and quickly gaining a footing on the plateau north-east of the forest of Villers-Cotterets. In the VI. Army, on the contrary, the attacking divisions continued their artillery preparation against the enemy's defensive position for $1\frac{1}{2}$ hours, and only attacked at 6:15 A.M.

The Attack.—The surprise was complete, and along the whole front the enemy lost practically all his advanced units and batteries. His resistance was only effective in two localities—one on the front of the XI. Army Corps, which had no tanks, the other on that of the II. Corps, which came under oblique fire from the heights of Chouy. Mangin received information of the first results achieved towards 8 o'clock, and exploited them without delay by the judicious use of his reserves. Robillot's Cavalry Corps, however, had experienced extreme difficulty in debouching from the forest of Villers-Cotterets, as it was encumbered with troops and baggage, and could as yet operate only with dismounted squadrons. On the first day the enemy lost 12,000 prisoners and 250 guns. The battle raged throughout the night and the next day. The two French armies made substantial progress, even in the difficult region of Louatre-Chouy-Neuilly-Saint-Front, where the XI. and II. Corps combined their attacks to subdue the enemy resistance. The bombing aircraft attacked the Marne crossings and the enemy concentrations at Oulchy-le-Château and Fère-en-Tardenois.

Meanwhile the centre group was preparing to clear the south bank of the Marne. But its units were exhausted by resisting the German attacks of July 15–18, and to reinvigorate them the British XXII. Corps (51st and 62nd Divs.) was brought in to relieve the Italian Corps. Pétain took care to insist that it was not a question of a simple relief. "It will be carried out on the move—that is to say, it will take the form of a surprise attack, carried out with the co-operation of the French units on either side." Nevertheless it was not until the 20th that the Centre group was able to push forward. On that day its IX. Army reached the south bank of the Marne, evacuated by the enemy during the night, while in the V. Army the British XXII. Corps was heavily engaged in the Courton wood.

The fighting continued to be severe throughout July 21 and 22. On the two extreme wings the Germans offered a stubborn resistance to the attacks of the X. and V. Armies which pressed on their flanks. It was clear that they were seeking to gain time to evacuate the material and troops that had been pushed into the Marne "sack." On July 21 the French 30th Division reoccupied Château-Thierry, and the American 3rd Division crossed the Marne to the east of the town, and entered the Barbillon wood. In the VI. Army the American I. Corps and the French VII. and II. Corps advanced on the plateau of Etrepilly and Latilly, and on the 22nd, at noon, the VI. Army re-established its communications by way of Château-Thierry. On the same evening fractions of the V. and IX. Armies gained a footing north of the Marne.

The interest of the battle came to be focussed on the heights dominating the Ourcq valley from the north—Orme du Grand Rozoy and Butte Chalmont. Once these heights were captured the Germans could not hope to hold on to the line of the Ourcq. A pause occurred for the relief of tired divisions and the redistribution of the forces. The IX. Army was withdrawn from the front, and the convergence of the advance had so shortened the front that the IX. Army was withdrawn, and even the VI. Army, now reinforced by the fresh American 42nd division, closed up.

Advance Checked at Fère-en-Tardenois.—Some progress was made on July 27 and 28: the VI. Army reached the Ourcq and gained a foothold in Fère-en-Tardenois; the V. Army reoccupied its positions on July 15. But from the 28th at noon, the VI. and V. Armies met with a stubborn resistance that was solidly established from Fère-en-Tardenois to Ville-en-Tardenois. The II. Corps was unable to debouch from Fère. The American I. Corps, which had advanced as far as Sergy, was violently counter-attacked there by a Guards Division. The village was taken and retaken four times and finally held by the American 42nd Division, though only at the cost of heavy losses.

In the centre, therefore, the situation remained practically unchanged on July 29 and 30. Only the right of the X. Army made definite progress. On the 28th the XI. Corps took Butte Chalmont, and on the 20th the XXX. and XI. Corps with the British 34th Division occupied Grand Rozoy; but the divisions in line had reached the limit of their powers after several days of incessant fighting.

The Germans had solidly maintained their flanks as a safeguard to cover their line of retreat towards the Vesle. All that could be done was to hasten their retreat by convergent action against the plateaux of the Tardenois. The French counter-offensive had at least cleared the Marne valley and the Paris-Avricourt railway line. The second phase was now to begin, and the French armies, on July 29, received fresh instructions from Pétain. The VI. Army, reinforced by the III. Corps and charged with the main effort was to "push vigorously, and without stopping, in the general direction of Fismes and Bazoches with its whole front, its left to establish itself in the region of Saponay so as to facilitate the debouching of the right wing of the X. Army towards Cramaille." The X. Army was, by successive actions starting from its right (the south), to press in the general direction of Braine. The V. Army was to support the right wing of the VI. Army.

Reliefs were carried out within the armies. The VI. Army put considerable American forces into line: the 42nd and 32nd in the first line, the 4th and 28th in second line, while the 26th and 3rd were being reconstituted in the Marne valley. On the 31st the American 28th, 32nd and 4th Divisions entered Cierges and the Meunière wood. In this way the enemy's attention was drawn to the centre on the evening of the 31st, while the next morning (Aug. 1), at 4:45, the right of the X. Army attacked in its turn and, after severe fighting, occupied the whole crest that extends from L'Orme du Grand Rozoy to Saponay inclusive. On the same day the VI. Army, though it succeeded in capturing the Meunière wood, failed before Saponay on account of the extreme fatigue of its attacking divisions.

German Retirement to the Vesle.—But at dawn on Aug. 2 the three French armies found themselves facing void. The enemy had fallen back on the Vesle, where he intended to establish himself firmly. On the 3rd, the left of the X. Army, which had reoccupied Soissons unopposed the previous evening, reached the Aisne. Its right, together with the VI. and V. Armies, arrived in the immediate vicinity of the Vesle. Contact was reestablished everywhere. All along the front the German artillery and machine-guns were active. On Aug. 4 and 5 the Allied troops aligned themselves along the banks of the Vesle, the American 32nd Division entered Fismes and the advanced guards succeeded in crossing the river at some points. But the enemy counterattacked vigorously, and in view of this well-organized resistance and of the impending Allied operations elsewhere (*see* AMIENS, BATTLE OF, 1918, and WORLD WAR I), Foch decided to suspend the offensive.

III. A STRATEGICAL RETROSPECT

The clue to the course of this battle might aptly be put in terms of the old conundrum—"When is a counter-stroke not a counter-stroke?" Foch's faith in the offensive as a sovereign remedy for all troubles had not been shaken by his hard experience in 1915 and 1916. When the crisis of March 1918 called him to the supreme command of the Allied armies (*see* WORLD WAR I), he had scarcely set about his unenviable task of restoring the bent and battered front before he was contemplating an offensive. Even before the new collapse of the Aisne front on May 27 he had issued a "directive" to Haig and Pétain, commanders of the British and French field armies respectively, for attacks to free the lateral railways.

If this project showed his practical belief in this theory of freedom of action, it is also evidence that he had no idea of luring the Germans into vast salients which he could cut off in flank—as was the conception subsequently extolled by popular propagandists. Similarly, the truth of the great counter-stroke of July

18 is that it was not conceived, by Foch at least, as a counter-stroke. But the refrain *"attaquez"* was chanted so continually that sooner or later it was bound to coincide with a "psychological moment"—as on July 18.

In the meantime Ludendorff's keenness in pursuing a similar policy and the wariness of Pétain and Haig helped to prevent the Allied forces becoming seriously involved in a premature offensive before the balance of numbers changed. It was Pétain who had conceived the plan of the defensive-offensive battle as it was actually waged—first a parry to the enemy's thrust and then a riposte when he was off his balance. On June 4 he had asked Foch to assemble two groups of reserves at Beauvais and Épernay respectively with a view to a counter-stroke against the flank of any fresh German advance. The first group, under Mangin, had been used to break the German attack of June 9, and was then switched a little further east to a position on the west flank of the German salient between Soissons and Rheims which bulged towards the Marne.

Foch, however, planned to use it for the strictly offensive purpose of a push against the rail centre of Soissons. While this was being prepared, the intelligence service made it clear that the Germans were about to launch a fresh attack near Rheims. Foch thereupon determined to anticipate it, not retort to it, by launching his offensive on July 12. Pétain, however, had the contrary idea of first stopping and then smiting the enemy when the latter had entangled himself. And, perchance curiously, the French troops were not ready on July 12, so that the battle was fought rather according to Pétain's than to Foch's conception. But not altogether. For Pétain's plan had comprised three phases—first, to hold up the German attack; second, to launch counter-strokes against the flanks of the fresh pockets it was likely to make on either side of Rheims; third, and only third, when the German reserves had been fully drawn towards those pockets, to unleash Mangin's army in a big counter-offensive eastward along the baseline of the main bulge—the enemy's rear—and so close the neck of the vast sack in which the German forces south of the Aisne would be enclosed.

Events and Foch combined to modify this conception. When the Germans on July 15 and 16 pressed across the Marne west of Rheims, to avert the danger Pétain was driven to use most of the reserves he had intended for the second phase of the counter-stroke. And to replace them he decided to draw from Mangin's army, and postpone the latter's counter-offensive—already ordered by Foch for July 18.

When Foch—full of eagerness and with his spirit still more fortified, if that was possible, by Haig's promise to send British reserves—heard of Pétain's action he promptly countermanded it. Hence on July 18 Mangin and the French left wing launched their counter-offensive while the defensive battle was still in progress in the centre and on the right wing. This meant that the second phase of Pétain's plan had to be dropped out, and instead of the right wing attracting the Germans' reserves in order to enable the left wing to fall on their naked back, the left wing's offensive eased the pressure on the right wing.

To compensate as far as possible the initial passivity of the right wing the British reserves (51st and 62nd Divisions), which were sent thither, were used to relieve the defending troops "on the move," passing direct to an attack. In the centre American reserves were similarly used, and thus a general pressure began along the whole face of the great salient. But this convergent pressure did not begin until July 20, and by that time the opening surprise—due to the sudden release of a mass of tanks without any preparatory bombardment—of the left wing's attack was over and its impetus slackening. Thus the Germans, fighting hard for breathing space, gained the time they required to draw the bulk of their forces out of the sack, even though they left 30,000 prisoners and much material behind. And once they were safely back on a straight and much shortened line along the Vesle, Ludendorff felt able, on Aug. 2, to order preparations for fresh attacks in Flanders and east of Montdidier.

Six days later his offensive dreams were finally dissipated—but it is historically important to realise that it was not the second Battle of the Marne—"Foch's great counter-stroke"—which dissipated them. This July 18 counter-stroke, conceived as such by Pétain and amended by Foch, was by no means decisive in its result. It may be that Foch's impetuosity robbed him of such results; that Pétain's oft-derided "caution" would have reaped a larger harvest.

Nevertheless, if the battle had no clearly decisive material or even moral effect on the Germans, this first taste of victory after such deep and bitter draughts of defeat was an incalculable moral stimulant to the Allies, and perchance its depressing effect on the German morale was more insidiously damaging than was at first visible. So that Foch, who was ever concerned only with moral factors, which cannot be mathematically calculated, may well have been content. He had gained the initiative, and he kept it—that was enough; results mattered little. For his strategy was simple, not the complex masterpiece of art which legend has ascribed to him. It was best expressed in his own vivid illustration: "War is like this. Here is an inclined plane. An attack is like this ball rolling down it. It goes on gaining momentum and getting faster and faster on condition that you do not stop it. If you check it artificially you lose your momentum and have to begin all over again." (B. H. L. H.)

MAROCAIN. A ribbed or corded variety of dress fabric of comparatively light texture, constituting one of several varieties of the crepe or crimped type, of which crepe georgette, crepe-de-Chine and crepe voile are the more typical examples. Although fabrics of this class are usually woven on the principle of the simple plain weave and other elementary structures, the peculiar crepe effect which is the distinctive characteristic feature of these fabrics is not due to the weave, but results partly from the abnormal amount of twist in the warp, weft, or both series of threads, and partly from the employment of yarn spun with the twist in reverse directions. Hence, some threads are spun "twist-way," and others "weft-way," corresponding (in the worsted industry) to "crossband" (left twist) and "openband" (right twist), respectively. The threads of reverse twist are usually disposed in the fabric with a "two-and-two" thread disposition, *i.e.*, two threads spun "twist-way," and two threads spun "weft-way," in succession, uniformly. Also, the relative counts of warp and weft, as well as the relative number of warp-ends and picks per inch in the fabric, are factors which have a marked influence in the development of a more or less pronounced crepe or crimped effect.

This crepe or crimped effect, which characterizes fabrics of this class, results from the natural tendency of the highly-twisted threads of "reverse" twist to untwist in reverse directions, and thereby assume a wavy appearance resulting from their slight distortion from a perfectly straight line. Also, the ribbed or corded effect results from the disparity which exists in respect both of the relative counts and amount of twist in the warp and weft yarn, as well as in the relative number of warp and weft threads per inch, in the fabric.

Marocain fabrics are usually produced from a combination of two different classes of textile material consisting either of a silk or artificial silk warp, and worsted weft; whilst an inferior imitation marocain fabric is produced from all-cotton yarn both for warp and weft. They are also made in a variety of textures from various counts of yarn and with different proportions of warp-ends and picks per inch, according to quality.

A typical example of marocain fabric is woven either with a warp of silk, or else artificial silk, and highly twisted worsted weft of fine counts, with 170 warp threads of 150 denier silk, and 70 picks of 60's worsted weft, per inch, which produces a fabric having a distinctly fine-ribbed effect, with the ribs extending transversely across the width of the fabric, *i.e.*, in the direction of the hard-twisted and coarser picks of worsted weft.

An imitation marocain fabric of very light and open texture is woven from a cotton warp and artificial silk weft, with 56 warp threads of 2/80's highly-twisted cotton yarn (disposed in the fabric with a two-and-two end arrangement of "twist-way" and "weft-way" yarn, uniformly), and 80 picks of 120 to 150 denier artificial silk weft, per inch. Hence, the fine ribs extend lengthwise of the fabric, *i.e.*, in the direction of the warp threads.

(H. N.)

MAROCHETTI, CARLO, Baron (1805–1867), Italian sculptor, was born at Turin. His first systematic instruction was given him by Bosio and Gros in Paris, but between 1822 and 1830 he studied chiefly in Rome. From 1832 to 1848 he lived in France. His "Fallen Angel" was exhibited in 1831. In 1848 Marochetti removed to London, where he executed statues of Queen Victoria, Lord Clyde (the obelisk in Waterloo Place) and Richard Coeur-de-Lion (Westminster). His style was vigorous and effective, but rather popular than artistic. He died in London in 1867.

MARONITES, a Christian people of the Ottoman Empire in communion with the Papal Church, but forming a distinct denomination. The original seat and present home of the nucleus of the Maronites is Mt. Lebanon. It seems most probable that the Lebanon offered refuge to Antiochene Monothelites flying from the ban of the Constantinopolitan Council of A.D. 680; that these converted part of the old mountain folk, who already held some kind of Incarnationist creed; and that their first patriarch and his successors, for about 500 years at any rate, were Monothelite, and perhaps also Monophysite. Nevertheless the question of union with Rome became a practical one in the 12th century; but the local particularism of the Lebanon was averse to union, which was not effected until the 18th century. Clement XII. sent to Syria Assemanus, a Maronite educated at the Roman college of Gregory XIII.; and at last, at a council held at the monastery of Lowaizi on the 30th of September 1736, the Maronite Church accepted from Rome a constitution which is still in force, and agreed to abandon some of its more incongruous usages such as mixed convents of monks and nuns. It retained, however, its Syriac liturgy and a non-celibate priesthood. The former still persists unchanged, while the Bible is read and exhortations are given in Arabic; and priests may still be ordained after marriage. But marriage is not permitted subsequent to ordination, nor does it any longer usually precede it. The tendency to a celibate clergy increases, together with other romanizing usages, promoted by the papal legate in Beirut, the Catholic missioners, and the higher native clergy who are usually educated in Rome or at St. Sulpice. The legate exercises growing influence on patriarchal and other elections, and on Church government and discipline. The patriarch receives confirmation from Rome, and the political representation of the Maronites at Constantinople is in the hands of the vicar apostolic. Rome has incorporated most of the Maronite saints in her calendar, while refusing (despite their apologists) to canonize either of the reputed eponymous founders of Maronism.

The Maronites are most numerous and unmixed in the north of Lebanon. Formerly they were wholly organized on a clan system under feudal chiefs, of whom those of the house of Khazin were the most powerful; and these fought among themselves rather than with the Druses or other denominations down to the 18th century, when some Arabs began to stir up strife between Maronites and Druses (*see* Druses). The Maronite population has greatly increased at the expense of the Druses, and is now obliged to emigrate in considerable numbers. Increase of wealth and the influence of returned emigrants tend to soften Maronite character, and the last remnants of the barbarous state of the community—even the obstinate blood-feud—are disappearing.

See F. J. Bliss in *Pal. Expl. Fund Quarterly Statement* (1892); and authorities for Druses and Lebanon.

MAROONS. A *nègre marron* is defined by Littré as a fugitive slave who betakes himself to the woods; a similar definition of *cimarron* (apparently from *cima,* a mountain top) is given in the *Dictionary* of the Spanish Academy. The old English form of the word is *symaron* (*see* Hawkins's *Voyage,* § 68). The term "Maroons" was applied almost as a proper name to the descendants of those negroes in Jamaica who at the first English occupation in the 17th century fled to the mountains.

MAROT, CLÉMENT (1496–1544), French poet, was born at Cahors, the capital of the province of Quercy, some time during the winter of the year 1496–1497. His father, Jean Marot (*c.* 1463–1523), whose name appears as des Mares, Marais or Marets, was a Norman, a poet of considerable merit, and held the post of *escripvain* (apparently uniting the duties of poet laureate and historiographer) to Anne of Brittany. Clément appears to have been educated at the university of Paris, and to have then begun the study of law. Jean Marot took great pains to instruct his son in the fashionable forms of verse-making, after the complicated rules of the *rhétoriqueurs.* Clément himself practised with diligence this poetry (which he was to do more than any other man to overthrow), and he has left panegyrics of its coryphaeus Guillaume Crétin, the supposed original of the Raminagrobis of Rabelais, while he translated Virgil's first eclogue in 1512. He became page to Nicolas de Neuville, seigneur de Villeroy, and this opened to him the way to court life.

As early as 1514, before the accession of Francis I., Clément presented to him his *Judgment of Minos,* and shortly afterwards he was either styled or styled himself *facteur* (poet) *de la reine* to Queen Claude. In 1519 he was attached to the suite of Marguerite d'Angoulême, the king's sister, the great patron of letters. He was also a great favourite of Francis himself, attended the Field of the Cloth of Gold in 1520, and celebrated it in verse.

In 1524, Marot accompanied Francis on his disastrous Italian campaign. He was wounded and taken at Pavia, but soon released, and he was back again at Paris by the beginning of 1525. His luck had, however, turned. Marguerite for intellectual reasons, and her brother for political, had hitherto favoured the double movement of *Aufklärung,* partly humanist, partly Reforming, which distinguished the beginning of the century. Formidable opposition to both forms of innovation, however, was now manifested, and Marot, who was at no time particularly prudent, was arrested on a charge of heresy and lodged in the Châtelet, February 1526. A friendly prelate, acting for Marguerite, extricated him before Easter. His imprisonment is described in a vigorous poem entitled *Enfer.* His father died about this time, and Marot appears to have succeeded to his place of valet de chambre to the king. He was certainly a member of the royal household in 1528 with a stipend of 250 livres, besides which he had inherited property in Quercy. In 1530, probably, he married. Next year he was again in trouble, not it is said for heresy, but for attempting to rescue a prisoner, and was again delivered; this time the king and queen of Navarre seem to have bailed him themselves.

In 1532 he published (it had perhaps appeared three years earlier), under the title of *Adolescence Clémentine,* the first printed collection of his works. Of the many editions of this work Dolet's edition of 1538 is believed to be the most authoritative. Unfortunately, Marot was implicated in 1535 in the affair of "The Placards,"[1] and this time he was advised or thought it best to fly. He passed through Béarn, and then made his way to Renée, duchess of Ferrara. At her court he wrote his celebrated *Blasons* (a descriptive poem, improved upon mediaeval models), which set all the verse-writers of France imitating them. But the duchess Renée was not able to persuade her husband, Ercole d'Este, to share her sympathy with the Reformers, and Marot had to quit the city. He then went to Venice, but before very long the pope Paul III. remonstrated with Francis I. on the severity with which the Protestants were treated, and they were allowed to return to Paris on condition of recanting their errors. Marot returned with the rest, and abjured his heresy at Lyons. In 1539 Francis gave him a house and grounds in the suburbs.

It was at this time that his famous translations of the psalms appeared. The powerful influence which the book exercised on contemporaries is not denied by anyone. The psalms were sung in court and city, and they materially advanced the cause of the Reformation in France. Indeed, the vernacular prose translations of the Scriptures were in that country of little merit or power, and the form of poetry was still preferred to prose. At the same time Marot engaged in a literary quarrel with a bad poet named Sagon, who represented the reactionary Sorbonne. Half the verse-writers of France ranged themselves among the Marotiques or the Sagontiques. The victory, as far as wit was concerned, naturally rested with Marot, but probably a certain amount of odium was created against him, which may have had

[1] These "placards" were the work of the extreme Protestants. Pasted up in the principal streets of Paris on the night of Oct. 17, 1534, they vilified the Mass and its celebrants, and thus led to a renewal of the religious persecution.

something to do with his subsequent misfortunes.

The publication of the psalms gave the Sorbonne a handle, and the book was condemned by that body. In 1543 it was evident that he could not rely on the protection of Francis. Marot accordingly fled to Geneva; but he had, like most of his friends, been at least as much of a freethinker as of a Protestant, and the austere city of Calvin was no place for him. He had again to fly, and made his way into Piedmont, and he died at Turin in the autumn of 1544.

In character Marot seems to have been a typical Frenchman of the old stamp, cheerful, good-humoured and amiable enough, but probably not very much disposed to elaborately moral life and conversation or to serious reflection. With other poets like Mellin de Saint Gelais and Bordeau, with prose writers like Rabelais and Bonaventure Desperiers, he was always on excellent terms.

His importance in the history of French literature is very great, and was long rather under than over-valued. Coming immediately before a great literary reform—that of the Pléiade—Marot was both eclipsed and decried by the partakers in that reform. In the reaction against the Pléiade he recovered honour; but its restoration to virtual favour, a perfectly just restoration, again unjustly depressed him. Marot was a reformer, and a reformer on perfectly independent lines, and he carried his own reform as far as it would go. His early work was couched in the *rhétoriqueur* style, the distinguishing characteristics of which are elaborate metre and rhyme, allegoric matter and pedantic language. In his second stage he entirely emancipated himself from this, and became one of the easiest, least affected and most vernacular poets of France. In these points indeed he has, with the exception of La Fontaine, no rival, and the lighter verse-writers ever since have taken one or the other or both as model. In his third period he lost a little of this flowing grace and ease, but acquired something in stateliness, while he lost nothing in wit.

The most important early editions of Marot's *Oeuvres* are those published at Lyons in 1538 and 1544. In the second of these the arrangement of his poems which has been accepted in later issues was first adopted. In 1596 an enlarged edition was edited by François Mizière. Among modern editions are those of P. Jannet (1868–72; new ed., 1873–76); and of G. Guiffrey, only vols. ii. and iii. (1875–81) of which were issued. For information about Marot himself *see* the section concerning him in G. Saintsbury's *The Early Renaissance* (1901); A. Tilley, *Literature of the French Renaissance*, vol. i., ch. iv. (1904); P. Villey, *Recherches sur la Chronologie des oeuvres de Marot* (1921); P. A. Becker, *Clément Marot, Sein Leben und Seine Dichtung* (1926).

MAROT, DANIEL (1661–?), French architect, furniture designer and engraver, and the pupil of Jean le Pautre, was the son of Jean Marot (1620–1679), who was also an architect and engraver. He was born in Paris in 1661. He was a Huguenot, and was compelled by the Revocation of the Edict of Nantes in 1685 to settle in Holland. His earlier work is of the second period of Louis XIV., but eventually it became tinged with Dutch influence, and in the end the English style called "Queen Anne" owed much to his manner. In Holland he was taken into the service of the Stadtholder, who, when he became William III. of England, appointed him one of his architects and master of the works. He designed the great hall of audience for the States-General at The Hague and also decorated many Dutch country-houses. In England he concentrated upon the adornment of Hampton Court Palace. Among his plans for gardens is one inscribed: "Parterre d'Amton-court inventé par D. Marot." Much of the furniture—especially the mirrors, guéridons and beds—at Hampton Court bears unmistakable traces of his authorship. Splendour and elaboration are the outstanding characteristics of Marot's style, and he appears to have been responsible for some of the curious silver furniture which was introduced into England from France in the latter part of the 17th century. At Windsor Castle there is a silver table, attributed to him, which is an exceedingly fine example of its type. During his life in France Marot made many designs for André Charles Boulle (*q.v.*), more especially for long case and bracket clocks which were intended to be mounted in chased and gilded bronze. Marot designed practically every detail in the internal ornamentation of the house—carved chimney-pieces, ceilings, panels for walls, girandoles and wall brackets, and was also a prolific designer of gold and silver plate. Marot was still living in 1718, and the date of his death is unknown.

Much of our knowledge of his work is obtained from the volume of his designs published at Amsterdam in 1712: *Oeuvres du Sieur D. Marot, architecte de Guillaume III. Roi de la Grande Bretagne*, and to *Receuil des planches des sieurs Marot, père et fils*. In addition to decorative work these books contain prints of scenes in Dutch history, and engravings of the statues and vases, produced by Marot, at the Palace of Loo. *See* also *Das Ornamentwerk des Daniel Marot* with preface by P. Jenssen (1892).

MARPRELATE CONTROVERSY, a war of pamphlets waged in 1588 and 1589 between a puritan writer who employed the pseudonym "Martin Marprelate" and defenders of the Established Church. Martin's tracts are characterized by violent and personal invective against the Anglican dignitaries, and by a plain and homely style combined with pungent wit. The special point of his attack was the Episcopacy. The pamphlets were printed at a secret press established by John Penry, a Welsh puritan. After three tracts had been issued, it appeared to some of the ecclesiastical authorities that the only way to silence Martin was to have him attacked in his own railing style, and accordingly certain writers of ready wit, among them John Lyly, Thomas Nashe and Robert Greene, were secretly commissioned to answer the pamphlets. Among the productions of this group were *Pappe with an Hatchet* (1589), probably by Lyly, and *An Almond for a Parrat* (1590), which, with certain tracts under the pseudonym of Pasquil, has been attributed to Nashe (*q.v.*). Meanwhile, in July 1589, Penry's press, now at Wolston, near Coventry, produced two tracts purporting to be by "sons" of Martin, but probably by Martin himself, namely, *Theses Martinianae* by Martin Junior, and *The Just Censure of Martin Junior* by Martin Senior. Shortly after this the press was seized; Penry, however, was not found, and in September issued from Wolston or Haseley *The Protestation of Martin Marprelate,* the last work of the series, though several of the anti-Martinist pamphlets appeared later. Penry then fled to Scotland, but was later apprehended in London, charged with inciting rebellion, and hanged (May 1593).

Bibliography.—*See,* for list and full titles of the tracts, related documents and discussion of the authorship, E. Arber's *Introductory Sketch to the Martin Marprelate Controversy* (1880), which, however, gives no connected account of the matter. *See* also articles on John Penry and Job Throckmorton in *Dict. of Nat. Biography*. The more important tracts have been reprinted by Petheram in his series of *Puritan Discipline Tracts* (1842–60), in Arber's *English Scholar's Library* (1879–80), in R. W. Bond's edition of Lyly and in the editions of Nashe.

MARQUAND, HENRY GURDON (1819–1902), American philanthropist and collector, was born in New York city April 11, 1819. He was the first honorary member of the American Institute of Architects, and president (1889–1902) of the Metropolitan Museum of Art, to which he made valuable presents and loans from his collection of paintings. He died in New York city February 26, 1902.

MARQUARDT, JOACHIM (1812–1882), German historian and writer on Roman antiquities, was born at Danzig on April 19, 1812. He studied at Berlin and Leipzig and became in 1859 head of the gymnasium in Gotha, where he died on Nov. 30, 1882. He continued W. A. Becker's *Handbuch der römischen Alterthümer* which took 20 years to complete. Marquardt then embarked on a revised edition of the whole with Theodore Mommsen and other scholars. He himself contributed vols. iv.–vi. (*Römische Staatsverwaltung,* 1873–78; 2nd ed., 1881–85), and vol. vii. (*Das Privatleben der Römer,* 1879–82; 2nd ed., by A. Mau, 1886).

MARQUESAS or **MENDAÑA ISLANDS** (Fr. *Les Marquises*), an archipelago of the Pacific ocean lying between 7° 50′ and 10° 35′ S. and 138° 50′ and 140° 50′ W., and belonging to France. It extends over 250 mi. from southeast to northwest, and has a total area of 480 sq.mi. The southern or Mendaña group consists of the islands Fatuhiva or Magdalena, Motane or San Pedro, Tahuata or Santa Christina and Hivaoa or Dominica. With these is often included the rocky islet of Fatuhuku or Hood, lying in mid-channel to the north of Hivaoa. The northwestern or Washington group is formed of seven islands, the four largest being Huapu or Adams, Huahuna or Washington, Nukuhiva (70 mi. in circumference) and Eiao. Along the centre of each island is a ridge of mountains, attaining an altitude of 4,042 ft. in Huapu, whence rugged spurs forming deep valleys stretch towards the sea. The volcanic origin of the whole archipelago is proved by the principal rocks being of basalt, trachyte and lava. Vegetation is luxuriant in the valleys, which are well watered with streams and terminate seaward in small "bays." The flora includes about four hundred known species, many of them identical with those belonging to the Society Islands. The vegetable products comprise bananas, bread-fruit, yams, plantains, wild cotton, bamboos, sugar-cane, coco-nut and dwarf palms, and several kinds of timber trees. The land fauna however is poor; there are few mammals with the exception of dogs, rats and pigs; and amphibia and insects are also generally scarce. Of twenty species of birds more than half belong to the sea, where animal life is as abundant as about other subtropical Polynesian groups. The climate is hot and damp. During the greater part of the year moderate easterly winds prevail, and on the larger islands there are often both land and sea breezes. The rainy season accompanied by variable winds sets in at the end of November, and lasts for about six months. During this period the thermometer varies from 84° to 91° F.; in the dry season its average range is from 77° to 86°.

The Marquesas Islands were discovered in 1595 by Alvaro Mendaña, who, however, only knew of the southeastern group, to which he gave the name by which they are generally known (although they also bear his own), in honour of Don Garcia Hurtado de Mendoza, marquis of Cañete, viceroy of Peru, and patron of the voyage. Captain Cook pursuing the same track rediscovered this group, with the addition of Fatuhuku, in 1774. The northwestern islands were first sighted by the American Captain Ingraham in 1791, and given the name of Washington by him; the French Captain Marchand followed in the same year, and Lieut. Hergest in 1792. The Russian explorer, Adam Ivan Krusenstern, made an extensive investigation of the archipelago in 1804. In 1813 the American Commodore David Porter failed to establish a colony here; and in May 1842, after French Roman Catholic missionaries had prepared the way, Rear-admiral Dupetit-Thouars took formal possession of the archipelago for France. A complete settlement was not effected without bloodshed and about 1860–70 the colony was practically abandoned. At the time of the French annexation (1842) the population was 20,000 and this had fallen (1941 census) to 2,699. The archipelago, which has some small trade in copra, cotton and cotton seeds, is administered by a French resident. The natives, a pure Polynesian race, are usually described as physically the finest of all South Sea islanders, and therefore pre-eminent among many finely built races.

MARQUESS or **MARQUIS,** a title and rank of nobility. In the British peerage it is the second in order and therefore next to duke. In this sense the word was a reintroduction from abroad; but lords of the Welsh and Scottish "marches" are occasionally termed *marchiones* from an early date. The first marquess in England was Robert de Vere, the 9th earl of Oxford, who was created marquess of Dublin by Richard II, on Dec. 1, 1385, and assigned precedence between dukes and earls. On Oct. 13, following, the patent of this marquessate was recalled, Robert de Vere then having been raised to a dukedom. John de Beaufort, earl of Somerset, the second legitimatized son of John of Gaunt, was raised to the second marquessate as marquess of Dorset on Sept. 29, 1397, but degraded again to earl in 1399. The commons petitioned for the restoration of his marquessate in 1402, but he himself objected because "le noun de Marquys feust estraunge noun en cest Roialme." From that period this title appears to have been dormant till the reign of Henry VI, when it was revived (1442), and thenceforward it maintained its place in the British peerage. Anne Boleyn was created marchioness of Pembroke in 1532. A marquess is "most honourable," and is styled "my lord marquess." His wife, who is also "most honourable," is a marchioness, and is styled "my lady marchioness." The coronet is a circlet of gold on which rest four leaves and as many large pearls, all of them of equal height and connected. The cap and lining, if worn, are the same as in the other coronets (*see* CROWN and CORONET). The mantle of parliament is scarlet, and has three and a half doublings of ermine.

In France, so early as the 9th century, counts who held several counties and had succeeded in making themselves quasi-independent began to describe themselves as *marchiones,* this use of the word being due to the fact that originally none but the margraves, or counts of the marches, had been allowed to hold more than one county. The *marchio* or marquess thus came to be no more than a count of exceptional power and dignity, the original significance of the title being lost. In course of time the title was recognized as ranking between those of duke and count; but with the decay of feudalism it lost much of its dignity, and by the 17th century the savour of pretentiousness attached to it had made it a favourite subject of satire for Molière and other dramatists of the classical comedy. Abolished at the Revolution, the title of marquess was not restored by Napoleon, but it was again revived by Louis XVIII, who created many of Napoleon's counts marquesses. This again tended to cheapen the title, a process hastened under the republic by its frequent assumption on very slender grounds in the absence of any authority to prevent its abuse. In Italy too the title of *marchese,* once borne only by the powerful margraves of Verona, has shared the fate of most other titles of nobility in becoming common and of no great social significance. (*See* also MARGRAVE.) (J. H. R.)

MARQUETRY (Fr. *marqueterie,* from *marqueter,* to inlay, literally to mark, *marquer*), an inlay of ornamental woods, ivory, bone, brass and other metals, tortoise-shell, mother-of-pearl, etc., in which shaped pieces of different materials or tints are combined to form a design. It is a later development of the ornamental inlays of wood known by the name of Intarsia, and though in the main the latter was a true inlay of one or more colours upon a darker or lighter ground, while marquetry is composed of pieces of quite thin wood or other material of equal thickness laid down upon a matrix with glue, there are examples of Intarsia in which this mode of manufacture was evidently followed. In order to gain greater relief the wood was shaded or tinted. A combination of tortoise-shell and metal, the one forming the ground and the other the pattern upon it, which may be classed as marquetry also appears in the 17th century. The subjects of the *intarsiatori* are generally arabesques or panels with elaborate perspectives, either of buildings or cupboards with different articles upon the shelves seen through half-open doors. The later *marqueteurs* used a freer form of design for the most part, and scrolls and bunches of flowers appear in profusion, while if architectural forms occur they are generally in the shape of ruins amid landscape. The greater portion of the examples in England are importations, either from Holland (in which country very fine work was produced during the latter half of the 16th and 17th centuries) or from France. The reputation of the Dutch *marqueteurs* was so great that Colbert engaged two, named Pierre Gole and Vordt, for the Gobelins at the beginning of the 17th century. Jean Macé of Blois, the first Frenchman known to have practised the art, who was at work in Paris from 1644 (when he was lodged in the Louvre), or earlier, till 1672, as a sculptor and painter, learned it in the Netherlands. His title was "menuisier et faiseur de cabinets et tableaux en marqueterie de bois"; but as early as 1576 a certain Hans Kraus had been called "marqueteur du roi." Jean Macé's daughter married Pierre Boulle, and the greatest of the family, André Charles Boulle (*q.v.*), succeeded to his lodging in the Louvre on his death in 1672. The members of this family are perhaps the best known of the French *marqueteurs.* Their greatest triumphs were gained in the marquetry of metal and tortoise-shell combined with beautiful ormolu mountings. The names of Roentgen, under whom the later German marquetry perhaps reached its highest point, Riesener and Oeben, testify to their nationality. A good deal of marquetry was executed in England in the later Stuart period, mainly upon long-case clocks, cabinets and chests of drawers, and it is often of real excellence. Marquetry in a shallower form was also extensively used in the latter part of the 18th century. The most beautiful examples of the art in Italy are mainly panels of choir stalls or sacristy cupboards, though marriage coffers were also often sumptuously decorated in this manner. With the increase in luxury and display in the 17th and 18th centuries in France and Germany cabinets and escritoires became objects upon which extraordinary talent and expenditure were lavished. In south Germany musical instruments, weapons and bride chests were often lavishly decorated with marquetry. In modern practice as many as four or even six thicknesses are put together and so cut. When all the parts have been cut and fitted together face downwards, paper is glued over them to keep them in place and the ground and the veneer are carefully levelled and toothed so as to obtain a freshly worked surface. The ground is then well wetted with glue at a high temperature and the surfaces squeezed tightly together between frames called "cauls" till the glue is hard. There are several modes of ensuring the accurate fitting of the various parts, which is a matter of the first importance if the artistic effect is to be secured. (*See* INLAYING.)

MARQUETTE, JACQUES (1637–1675), French Jesuit missionary and explorer, re-discoverer (with Louis Joliet) of the Mississippi, was born at Laon, went to Canada in 1666, and was sent in 1668 to the upper lakes of the St. Lawrence. In 1673 he was chosen with Joliet for the exploration of the Mississippi, of which the French had begun to gain knowledge from Indians of the central prairies. The route taken lay up the northwest side of Lake Michigan, up Green bay and Fox river, across Lake Winnebago, over the portage to the Wisconsin river, and down the latter into the Mississippi, which was descended to within 700 mi. of the sea, at the confluence of the Arkansas river. Entering the Mississippi on May 17, Joliet and his companion turned back on July 17 and returned to Green bay and Michigan (by way of the Illinois river) at the end of Sept. 1673. On the journey Marquette fell ill of dysentery; and a fresh excursion which he undertook to plant a mission among the Indians of the Illinois river in the winter of 1674–75 proved fatal. He died on his way home to St. Ignace on the banks of a small stream (the lesser and older Marquette river) which enters the east side of Lake Michigan in Marquette bay (May 18, 1675). His name is now borne by a larger watercourse which flows some distance from the scene of his death.

See Marquette's *Journal,* first published in Melchissédech Thévenot's *Recueil de Voyages* (1681), and fully given in Martin's *Relations inédites*, and in Shea's *Discovery and Exploration of the Mississippi Valley* (1852); *cf.* also Pierre Margry's *Découvertes . . . des Français dans l'ouest et dans le sud de l'Amérique septentrionale (1614–1754), Mémoires et documents originaux* (1875), containing Joliet's *Détails* and *Relations;* Francis Parkman, *La Salle and the Discovery of the Great West* (1869); Agnes Repplier, *Père Marquette, Priest, Pioneer and Adventurer* (1929).

MARQUETTE, a city of the Upper Peninsula of Michigan, U.S.A., on the south shore of Lake Superior; a port of entry and the county seat of Marquette county. It is on Federal highway 41, and is served by the Duluth, South Shore and Atlantic and the Lake Superior and Ishpeming railways, and lake steamers. The population was 12,718 in 1920 (24% foreign-born white) and was 15,928 in 1940 by the federal census. Marquette has a beautiful location on a bluff 100 ft. above the lake, in a picturesque summer-resort region. It is the seat of the Northern State Teachers college (established 1899) and the Upper Peninsula State prison and house of correction (1885), and a diocesan centre of the Roman Catholic and the Protestant Episcopal churches. A state park lies just west of the city; there is a state fish hatchery 3 mi. E., and at Ruse, 20 mi. E., a United States forest experiment station.

Presque Isle, within the city, is a great natural park, nearly surrounded by the lake, with herds of deer on its heavily wooded hills.

Marquette is an important manufacturing, mining, ore-shipping and wholesale distributing centre. Its factories are chiefly woodworking and chemical plants. Both the railroads have their general offices and shops here.

Marquette was settled about 1845, incorporated as a village in 1859, and chartered as a city in 1871. For the first few years it was called Worcester.

MARQUIS, DONALD ROBERT PERRY (1878–1937), American poet and playwright, born on July 29, 1878, at Walnut, Illinois, U.S.A. He was educated at Knox college, Galesburg, Ill. Later he worked as a reporter on several newspapers and assisted Joel Chandler Harris in editing the *Uncle Remus* magazine. From 1912 to 1922 he conducted a column, "The Sun Dial," in the *New York Sun,* where his wit and wisdom attracted attention. Among his published collections of humorous poetry, satirical prose and plays the best known are *Danny's Own Story* (1912), *Dreams and Dust* (1915), *Hermione* (1916), *Prefaces* (1919), *The Old Soak,* a play (1921), *Sonnets to a Red Haired Lady* (1922), *The Dark Hours,* a play (1924), *Out of the Sea,* a play (1927).

MARR, CARL (1858–1936), U.S. painter, was born at Milwaukee, Wis., on Feb. 14, 1858. He was a pupil of Henry Vianden in Milwaukee, of Schauss in Weimar, of Gussow in Berlin, and of Otto Seitz, Gabriel and Max Lindenschmitt in Munich. His first work, "Ahasuerus, the Wandering Jew," received a medal in Munich. One of his pictures, "Germany in 1806," received a gold medal in Munich and is in the Eichendorfschule of Königsberg. A large canvas, "The Flagellants," in the Milwaukee Auditorium building, received a gold medal at the Munich exposition in 1889. Another canvas, "Children's Party," in the Phoebe Hearst collection at the University of California, Berkeley, was exhibited in Munich. Marr became a professor in the Munich academy in 1893, and in 1895 a member of the Berlin academy of arts.

MARRADI, GIOVANNI (1852–1922), Italian poet, was born at Leghorn, and educated at Leghorn and Florence. His principal volumes of verse are *Canzoni moderne* (1879), *Fantasie marine* (1881), *Ricordi lirici* (1884), *Poesie* (1887), *Nuovi canti* (1891), *Ballate moderne* (1895) and a *Rapsodia Garibaldina* (3 parts, 1894, 1902 and 1903), *Canzoni e fantasie* (1917). He was much influenced by Carducci, and became well known not only as a critic but also as a charming descriptive poet.

See G. Mazzoni, *L'Ottocento,* 2nd ed., Milan, 1934.

MARRAKESH (erroneously MOROCCO or MAROCCO CITY), southern capital and largest town of Morocco. It lies in a spacious plain—Blad el Hamra, "The Red"—about 15 mi. from the northern underfalls of the Atlas, and 96 mi. E.S.E. of Safi, at a height of 1,500 ft. Ranking during the early centuries of its existence as one of the greatest cities of Islam, Marrakesh has long been in a state of grievous decay, but it is rendered attractive by the exceptional beauty of its situation, the luxuriant groves and gardens by which it is encompassed and interspersed, and the magnificent outlook which it enjoys toward the mountains. Open spaces of great extent are numerous within the walls. *Tabiya* or rammed concrete of red earth and stone is the almost universal building material, and the houses are consequently seldom more than two stories in height. The great square, Djemaâ-el-Fna, situated in the middle of Marrakesh, is crowded daily; the very extensive *suks* are situated on the edges of the square. The palace of the sultan covers an extensive area, and beyond it lie the imperial parks of Agudal, 2 mi. long and about 5,000 feet wide, planted with fruit trees of all sorts; the palm grove which surrounds Marrakesh stretches as far as the Tensift; it covers 32,000 acres and contains 90,000 palm trees.

The ramparts of Marrakesh are pierced by monumental gateways; the most beautiful is the Kasba gate, Bab-Aguenaou. The chief religious buildings are the mosque of Koutoubiya, or Mosque of the Scribes (12th century), with its monumental tower 221 ft. high, the most beautiful monument of Marrakesh; the mosque of Kasba or Djama-Moulay-Yazid, near to which are the tombs of the Sa'adi sharifs, fine monuments in which are buried the sovereigns of the last-but-one Moroccan dynasty (16th–17th centuries); Djama-el-Mouasine; Djama-Bab-Doukkala, the sanctuary of Sidi-ben Slimane-el-Djazouli, that of Sidi-bel-Abbés, patron of Marrakesh; the *medersa* Ben-Youssef (16th century). There are three beautiful monumental fountains, those of El-Mouasine, of Sidi-el-Hassan or Ali and of Sekkaia Echrob ou-Chouf. The palace of Bahia, built from 1894 to 1900, serves as a residency.

A European town was built $1\frac{1}{2}$ mi. from the original one, at the foot of the hill of Gueliz (1,728 ft.), which is crowned by a military camp. Founded in 1913, it is traversed by wide avenues bordered with trees. The pop. (1944) of Marrakesh was 184,400 of which 181,800 were Moslems and 2,600 Europeans. The natives are a mixture of the descendants of Andalusian Moors of original Rehemna of the neighbouring plains, of Chleuh mountaineers and of Sahara Draoua. Marrakesh is the chief town of the region of Marrakesh, the residence of a khalif of the sultan and the centre of action of the grand Kaïd Glaoui. It is connected by good roads with Mazagan, Mogador, Safi Taroudant, Warzazat and Casablanca; a broad-gauge railway (56.7 inches), finished in 1928, joins Marrakesh to Casablanca (158 miles).

Marrakesh, designated Morocco by the old European authors, was founded in 1062 by Youssef-ben-Tachfin, founder of the dynasty of the Almoravides. It was from Marrakesh that Abd-el-Moumen, the first sovereign of the dynasty of the Almohades, set out to conquer all northern Africa, and it was that town that he made the capital of his empire (1147). From 1184 to 1198, the sultan Yakout-el-Mansour built there the mosque and the tower of Koutoubiya, at the same time that he caused to be built the Giralda at Seville and the mosque of the tower of Hassan at Rabat, the most famous monuments of the Almohade period and the best built of the Maghreb. The Merinide sultans preferred Fez to Marrakesh, but the Saadi sharifs again made it the chief Moroccan capital. The Alaouite sharifs of the reigning dynasty, from time to time, stay there for more or less prolonged periods. After a violent combat at Sidi-bou-Othman, where he put to flight the bands of the insurgent El-Hiba, Col. Mangin entered Marrakesh with the French troops on Sept. 7, 1912.

An important airport was constructed there in 1940 which was subsequently greatly enlarged by the U. S. army after the North Africa landings in Nov. 1942.

See A. Chevrillon, *Marrakesh dans les palmes* (Paris, 1919); Z. and I. Tharaud, *Marrakesh ou les seigneurs de l'Atlas* (Paris, 1919).

MARRAM-GRASS (*Ammophila arundinacea*), an important sand-binding grass, called also beach-grass, and sea marram, native to sandy sea coasts of Europe and North America from North Carolina northward and to the shores of the Great Lakes. It is an erect somewhat coarse perennial, with hard, tough, scaly, creeping rootstocks; long, involute leaf-blades; and a pale, dense, spikelike flowering panicle. Marram is employed in Europe to hold in place the barrier dunes along coasts, as in Holland; also with like success on Cape Cod, Mass., and at San Francisco, Calif.

MARRIAGE. Human beings, like all higher animals, multiply by the union of the two sexes. But neither conjugation, nor even the production of offspring, is as a rule sufficient for the maintenance of the species. The further advanced the animal in the order of evolution, the longer the immaturity and the helplessness of the young and the greater the need for prolonged parental care and training. It is thus the combination of mating with parenthood which constitutes marriage in higher animals, including man. Even in its biological aspect, "marriage is rooted in the family rather than the family in marriage" (Westermarck).

1. **The Biological Foundations of Human Mating.**—In human societies, however, there are added to the sexual and parental sides of marriage other elements: marriage is given the hall-mark of social approval; it becomes a legal contract; it defines the relations between husband and wife and between parents and children, as well as the status of the latter; it imposes duties of economic co-operation; it has to be concluded in a public and solemn manner, receiving, as a sacrament, the blessings of religion and, as a rite, the good auspices of magic.

Human marriage also appears in a variety of forms: monogamy, polygyny and polyandry; matriarchal and patriarchal unions; households with patrilocal and matrilocal residence. Other forms, such as "group-marriage," "promiscuity," "anomalous" or "gerontocratic" marriages have been assumed by some writers as an inference from certain symptoms and survivals. At present these forms are not to be found, while their hypothetical existence in prehistoric times is doubtful; and it is important above all in such speculations never to confuse theory with fact.

Marriage again is in no human culture a matter of an entirely free choice. People related by descent or members of certain classes are often debarred from marrying each other, or else they are expected to marry. The rules of incest, of exogamy, of hypergamy and of preferential mating form the sociological conditions of marriage. To these are added in certain societies such preparatory arrangements and conditions as initiation, special training for marriage, moral and economic tests, which have to be satisfied before marriage can be entered upon. The aspects, the forms and the conditions of marriage have to be discussed in turn, though it is not possible to draw a sharp line of division between these subjects.

2. **Love and Marriage.**—Love and marriage are closely associated in day-dreams and in fiction, in folk-lore and poetry, in the manners, morals and institutions of every human community—but marriage is more than the happy ending of a successful courtship. Marriage as an ideal is the end of a romance; it is also the beginning of a sterner task, and this truth finds an emphatic expression in the laws and regulations of marriage throughout humanity.

Love leads to sexual intimacy and this again to the procreation of children. Marriage on the whole is rather a contract for the production and maintenance of children than an authorization of sexual intercourse. The main reason why marriage has not been regarded as establishing an exclusive sexual relationship lies in the fact that in many human societies sexual relations have been allowed under certain conditions before marriage, while marriage did not necessarily exclude the continuance of similar relations.

Marriage, however, remains the most important form of lawful intercourse, and it dominates and determines all extra-connubial liberties. In their relation to marriage the forms of licence can be classified into prenuptial liberty, relaxations of the marriage bond, ceremonial acts of sex, prostitution and concubinage.

3. **Prenuptial Intercourse.**—In the majority of savage tribes unmarried boys and girls are free to mate in temporary unions, subject to the barriers of incest and exogamy and of such social regulations as prevail in their community. But there are other tribes where chastity of the unmarried is regarded as a virtue, especially in girls, and any lapse from it severely censured or even punished. Many of the lowest savages, such as the Veddas, Fuegians, Kubu of Sumatra, Senoi and other Malayan negritos, do not tolerate sexual intercourse before marriage. Among the Bushmen and the Andamanese instances of prenuptial unchastity do occur, but they are not condoned, still less provided for by custom and moral approval. The Australians, however, allow prenuptial freedom, except perhaps a few of the South-eastern tribes.

On a higher level we find considerable variety in this respect. All over the world, in Oceania, in Asia, in Africa and in both Americas, examples could be quoted of peoples who demand continence more or less stringently, and of their neighbours who allow full freedom. In a few cases only can we find the demand of chastity expressed in very definite usages, which physically prevent incontinence, such as infibulation, practiced among the N.E. African, Hamitic and Semitic peoples and reported also from Siam, Burma and Java. The testing of the bride by a publicly exhibited token of defloration, which forms part of certain marriage ceremonies and which expresses the value of virginity, is carried out more or less thoroughly and naturally lends itself to deception and circumvention. It is found sporadically throughout the world, in the noble families of Oceania (Tonga, Samoa, Fiji), in Asia (Yakuts, Koryaks, Chuwash, Brahui of Baluchistan, Southern Celebes), in America (Chichimec of Mexico), in Africa (Mandingo, Kulngo, Ruanda, Yoruba, Swahili, Morocco, Algeria and Egypt) and likewise among many Semitic and Hamitic peoples. In other parts of the world we are merely informed that chastity is praised and prenuptial intercourse censured (Bantu, Kavirondo, Wa Giyama, Galla, Karanga, Bechuana of Africa; Dobu, Solomon Islanders, of Melanesia; Omaha, Mandan, Néz-Pércé, Apache, Takelma of N. America; Canelas and Kanaya of S. America, Bódo and Dhimál of Indo-China, Hill Dyaks of Borneo).

Freedom to mate at will may be fully allowed and even enjoined and provided for by such institutions as the mixed houses for bachelors and girls (Trobriand Islanders. Nandi, Masai, Bontoc

Igorot). In some communities prenuptial intercourse is not meant to lead to marriage, and there are even cases (as among the Masai, Bhuiya and Kumbi of India, Guaycuru and Guana of Brazil), where two prenuptial lovers are not supposed to marry. Elsewhere prenuptial mating is a method of courtship by trial and error, and it leads gradually into stable unions, and is finally transformed into marriage. Thus among the Trobriand Islanders "sexual freedom" is considerable. It begins very early, children already taking a great deal of interest in certain pursuits and amusements which come as near sexuality as their unripe age allows. This is by no means regarded as improper or immoral, is known and tolerated by the elders and abetted by games and customary arrangements. Later on, after boys and girls have reached sexual maturity, their freedom remains the same, with the result that there is a great deal of indiscriminate mating. In fact, at this age both sexes show a great deal of experimental interest, a tendency to vary and to try, and here again a number of arrangements and customs play into the hands of these juvenile lovers. As time goes on, however, and the boys and girls grow older, their intrigues naturally and without any outer pressure, extend in length and depth, the ties between lovers become stronger and more permanent. One decided preference as a rule develops and stands out against the lesser love affairs. It is important to note that such preferences are clearly based on genuine attachment resulting from real affinity of character. The protracted intrigue becomes a matter of public notice as well as a test of mutual compatibility, the girl's family signify their consent and marriage is finally concluded between the two lovers. (Malinowski). Similar forms of prenuptial selection are found in other tribes (Igorot of Luzon, Akamba of E. Africa, Munshi of N. Nigeria).

In no instance, however, is prenuptial liberty regarded by the natives as a negation or substitute for marriage. In fact it always is in such communities in the nature of a preliminary or preparation to marriage; it allows the young people to sow their wild oats, it eliminates the cruder forms of sex impulse from matrimonial selection and it often leads youths and girls to exercise a mature choice based on attraction of personality rather than on sexual appeal.

4. **The Principle of Legitimacy.**—Perhaps the most important fact in the consideration of prenuptial unchastity is the rule that freedom of sexual intercourse does not generally extend to freedom of procreation. One of the symptoms of this is that in all communities where chastity is demanded and enforced, the lapse from it entails more censure on girls than on boys, while prenuptial pregnancy is penalised much more severely than mere wantonness. But even where prenuptial unchastity becomes an institution not merely condoned but enjoined by tribal law, pregnancy is often regarded as a disgrace.

Among the aristocratic fraternities of Polynesia, the *areoi* of Tahiti and the *ulitao* of the Marquesas, licence between the men and the women was universal, but children of such unions were killed, unless adopted by a married couple. Among the Melanesian communities of New Guinea and the adjacent archipelago which allow of full sex liberty before marriage the occurrence of pregnancy under such circumstances is a grave disgrace to the mother and entails disabilities on the child. The Masai punish a girl for prenuptial pregnancy, although with them the free unions of unmarried boys and girls are an institution. A similar combination of prenuptial full licence with severe punishment of illegitimate childbirth is recorded from several African tribes (Wapore, Bakoki, Banyankole, Basoga, Akikuyu, Nandi, Beni Amer), from America (Indians of Brit. Guiana, Guaycuru and Guana of Brazil, Creeks and Cherokees), from Asia (Lisu of Burma, Nias Islanders of Malay Archipelago), from Melanesia (Mekeo and N. Solomon Islanders) and from Siberia (Aleut). In all such cases pregnancy is no doubt prevented by contraceptive practices, which however have been reported from very few savage tribes by trustworthy informants; or by abortion, which is far more frequent; or expiated by a punishment of the mother, and sometimes also of the father.

The main sociological principle embodied in these rules and arrangements is that children should not be produced outside a socially approved contract of marriage. In several tribes, the remedy for the disgrace of a prenuptial child consists therefore in an obligation of the presumptive father to marry the girl (S.E. Bantu, Madi, Bavuma, Kagoro of Africa; Tepehuane and Hupa of America; Kacharis, Rabhas, Hajongs and Billavas of India and Assam; Kayans and Punans of Borneo). In some cases again a child of a free union is desired and expected to come, indeed it is a condition to marriage, which is concluded upon its arrival (Sea Dyak, Hill Dyak, Iruleas, Moi, Bontoc Igorot of Asia; natives of Bismarck Archipelago; Lengua, Guarayos and Pueblo Indians of America; Wolofs and Bambata of Africa). Such cases, although they are in a way the opposite of those in which a prenuptial child is a disgrace, involve the same principle: the provision of a father for the child, that is the elimination of illegitimate offspring. As a matter of fact, in all instances where a prenuptial pregnancy is welcomed, the reason for it is that children are regarded in that community as an advantage. The father consequently need not be forced to marry the mother, he does so of his own accord because fruitful marriage is desirable. Thus in all human societies a father is regarded as indispensable for each child, *i.e.*, a husband for each mother. An illegitimate child—a child born out of wedlock—is an anomaly, whether it be an outcast or an unclaimed asset. A group consisting of a woman and her children is a legally incomplete unit. Marriage thus appears to be an indispensable element in the institution of the family. (*See* Malinowski, *Sex and Repression*, pp. 212–217.)

5. **Relaxations of the Marriage Bond.**—Among tribes where chastity is demanded from unmarried girls and youths, marital fidelity is also usually enjoined. As a rule adultery is regarded as a grave offence and more severely penalised than prenuptial incontinence, though exceptions to this rule do exist. In many communities where freedom is granted before marriage, once the matrimonial knot is tied both partners or the wife at least are bound to remain faithful, under more or less serious penalties (Trobrianders, Mailu, Nukuhiva, Maori of Oceania; Land and Sea Dayaks, Kukis, Hajongs, Saorias, Ceramese of Indonesia; Botocudos and Guarayos of S. America: Illinois, Comanche, Iroquois, Pawnee, Californian Indians of N. America; Timne, Ashanti, Konde, Zulu, Kafirs and Thonga of Africa). The penalty inflicted upon an adulterous wife is invariably much graver than upon an unfaithful husband, and considerable differences obtain according to the circumstances of the offence, the status of the third party, the husband's anger and his attachment to his wife.

There are, however, a number of communities in which the marriage bond is broken as regards the exclusiveness of sex with the consent of both partners and with the sanction of tribal law, custom and morality. In some societies the only occasion on which the wife is allowed connection with other men, nay, has to submit to their embraces, is at the very beginning of marriage. This custom has apparently been known in mediaeval Europe under the name of "ius primae noctis." It certainly exists in many savage cultures (Brazilian Indians, Arawaks, Caribs, Nicaraguans, Tarahumare of S. and C. America; Ballante, Bagele, Berbers of Africa; Bánaro and S. Massim of Melanesia; Aranda, Dieri and other Australian tribes). Such customs are to be regarded not so much as the abrogation of matrimonial exclusiveness, but rather as expressing the superstitious awe with which sexual intercourse, and above all defloration, is regarded by primitive peoples (Crawley, Westermarck). As such they should be considered side by side with the numerous instances in which girls are artificially deprived of their virginity, without the intercourse of any man; with prenuptial defloration by strangers; with temporary prostitution of a religious character, and with sexual intercourse as a puberty rite.

A greater encroachment upon sexual exclusiveness in marriage is found in the custom of wife-lending as a form of hospitality. This is very widely distributed over the world (*see* the comprehensive references in Westermarck, *History of Human Marriage*, vol. 1, pp. 225–226). It must be realised that this practice is not an infringement of the husband's rights, but rather his assertion of authority in disposing of his wife's person. Very often indeed a man will offer his sister, daughter, slave or servant instead, a fact which indicates that this custom is not so much the right of another man to infringe upon the matrimonial bond as the right of the head of the household to dispose of its female inmates.

Very often sexual hospitality is exercised in anticipation of future reciprocal benefits, and must be considered side by side with the custom of wife-exchange (Gilyak, Tungus, Aleuts of N. E. Asia; Bangala, Herero, Banyoro, Akamba, Wayao of Africa; various Himalayan and Indian tribes; S. Massim of Melanesia; Marquesas, Hawaii, Maori of Polynesia; and various Australian tribes). At times there is an exchange of wives at feasts, when general orgiastic license prevails (Araucanos, Bororo, Keres of S. America; Arapahos, Gros Ventres and Lower Mississippi tribes of N. America; Dayaks and Jakun of Indonesia; Bhuiyas, Hos, Kotas of India; Ashanti, Ekoi and various Bantu tribes of Africa; Kiwai Papuans). On such festive and extraordinary occasions not only are the sexual restrictions removed, and the sexual appetite stimulated, but the ordinary discipline is relaxed, the normal occupations abandoned and social barriers over-ridden, while at the same time people indulge in gluttony, in desire for amusement and social intercourse. Sexual license, as well as the other relaxations, liberties and ebullitions at such feasts fulfils the important function of providing a safety-vent which relieves the normal repressions, furnishes people with a different set of experiences, and thus again tends to safeguard ordinary institutions.

These cases where wives are exchanged for sexual intercourse only must be distinguished from the less frequent instances of prolonged exchange, with common habitation, more or less legalised. Among the Eskimo of Repulse Bay, "If a man who is going on a journey has a wife encumbered with a child that would make travelling unpleasant, he exchanges wives with some friend who remains in camp and has no such inconvenience. Sometimes a man will want a younger wife to travel with, and in that case effects an exchange, and sometimes such exchanges are made for no special reason, and among friends it is a usual thing to exchange wives for a week or two about every two months" (Gilder, *Schwatka's Search,* p. 251). Analogous forms of prolonged exchange are found among certain tribes of S. India, while among the Siberian Chukchi a man will often enter on a bond of brotherhood with those of his relatives who dwell in other villages, and when he visits such a village his relative will give him access to his wife, presently returning the visit in order to make the obligation mutual; sometimes cousins will exchange wives for a prolonged period.

Again, among the Dieri, Arabana and cognate tribes of C. Australia, a married woman may be placed in the so-called *pirrauru* relationship to a man other than her husband. Such a man may, with the husband's permission, have access to her on rare occasions. Or if the husband be absent and give his consent the woman may join her paramour for some time at his camp, but this is apparently rare. In order to lend his wife in this way a man must wait until she is allotted by the tribal elders as the *pirrauru* to another man. Then he may consent to waive his marital rights for a short time, though we are expressly told he is under no constraint to do so. Circumstances, jealousy, even the disinclination of the woman are obstacles all of which must make the carrying-out of *pirrauru* rights extremely rare. This custom has been adduced as a present-day occurrence of group marriage, but this is obviously incorrect. It is always a temporary and partial surrender of marital rights consisting of a long and permanent connubium with occasional rare episodes of extra-marital liaison.

It is important to remember that we have come to regard marriage as defined primarily by parenthood. Now social parenthood in native ideas, behaviour, custom and law is not affected by these various forms of relaxation just described. The children are reckoned as belonging to the legal husband, and in this as in many other ways—economic, legal and religious—these temporary relaxations do not seriously disturb the marriage relationship. It must be realised with regard to fatherhood that even where the main principles of physiological procreation are known, savages do not attribute an undue importance to actual physiological paternity (*see* KINSHIP). It is almost always the husband of the woman who is considered the legal father of her children, whether he be their physiological father or not..

6. **Concubinage.**—This can be defined as a legalised form of cohabitation, which differs from marriage in that it implies a considerably lower status of the female partner and her offspring, than that enjoyed by the legal wife. It is a terminological confusion to speak of concubinage, when there is temporary access to a woman, or exclusively sexual rights in her. On primitive levels of culture real concubinage does not exist. Some similarity to it can be found in the institution of subsidiary wives. In certain polygynous communities there is one principal wife and the subsidiary ones have a much lower status, as is the case among the Guarani, Central Eskimo, Araucanians, Apache, Chippewa (America); Chukchi, Koryak, Yakut (N.E. Asia); Marquesas Islanders, Tongans, Tahitians, Maori, Marshall Islanders (Polynesia); Awemba, Wafipa, S.E. Bantu, Herero, Nandi, Yoruba, Ewhe (Africa); Ossetes, Kadaras, Khambis (India); Battas, Bagobo, Kulaman (Indonesia).

It is not correct to regard the institutions of temporary and limited partnership described above, such as the *pirrauru* of C. Australia or the protracted exchange of partners among the Eskimo, as concubinage.

7. **Prostitution.**—The institution of commercial eroticism or prostitution has a very limited range among primitive peoples. It has been reported from Melanesia (Santa Cruz, Rossel Island), Polynesia (Line Islands, Caroline Islands, Easter Island, Hawaii), Greenland, N. America (Omaha), S. America (Karaya, Uitoto, Boro), W. Africa, E. Africa (Banyoro). In its relation to marriage it begins to play a very important part only in higher cultures (*see* PROSTITUTION). On the one hand it provides an easy satisfaction for the sexual appetite to unmarried men or those who for some reason cannot cohabit with their wives. It thus constitutes an institution complementary to marriage. On the other hand, in certain communities, of which Ancient Greece is a notable example, *i.e.,* "hetairism," prostitution in a higher and more refined form, allowed some women to devote themselves to cultural pursuits and to associate with men more freely than was possible to those legally married.

On the whole it is rather a subsidiary institution than either a relaxation or a form of sexual preparation. Unlike the other forms of sexual licence, prostitution is neither directly correlated with marriage nor does it affect its integrity so seriously as do the forms of matrimonial relaxation which involve both husband and wife.

8. **The Economics of the Household and Family.**—We are thus led at all stages of our argument to the conclusion that the institution of marriage is primarily determined by the needs of the offspring, by the dependence of the children upon their parents. More specially, the mother since she is handicapped at pregnancy and for some time after birth, needs the assistance of a male partner. The rôle of male associate and helpmate is almost universally played by the husband exclusively, though in some extremely matrilineal societies the wife's brother shares with the husband in some of the responsibilities and burdens of the household. The economic as well as the biological norm of a family is thus mother, child and husband—or exceptionally both the husband and the wife's brother.

In the vast majority of human societies the individual family, based on monogamous marriage and consisting of mother, father and children, forms a self-contained group, not necessarily however cut off from society. Within the household there is a typical scheme of division in functions, again almost universal. By virtue of natural endowment the wife has not only to give birth to and nourish the children, but she is also destined to give them most of the early tender cares: to keep them warm and clean, to lull them to sleep and soothe their infantile troubles. Even in this the husband often helps to a considerable degree, prompted by natural inclination as well as by custom. This latter often imposes upon him duties and ritual manifestations such as taboos during the pregnancy of his wife and at childbirth, and performances at the time of confinement, of which the couvade (*q.v.*) is the most striking example. All such obligations emphasize the father's responsibility and his devotion to the child. Later on in the education of offspring both parents have to take part, performing their respective duties, which vary with the society and with the sex of the children.

Apart from the special task of producing and rearing the children, the wife normally looks after the preparation of the food, she almost invariably provides the fuel and the water, is the actual attendant at the hearth or fireplace, manufactures, tends and owns the cooking-vessels, and she is also the main carrier of burdens. In the very simplest cultures the woman also erects the hut or shelter and looks after camp arrangements (Australians, Bushmen, Andaman Islanders). The husband is the protector and defender of the family, and he also performs all the work which requires greater strength, courage and decision, such as hunting game, fishing, heavy building of houses and craft, and clearing the timber.

The division of labour between husband and wife outside the household follows the line of men's and women's occupations which differ with the community, but on the whole make fighting, hunting, sailing, metal work purely male occupations; collecting, agriculture, pottery, weaving predominantly female; while fishing, cattle-tending, making of clothing and utensils are done by one sex or the other according to culture.

The division of labour outside the household does not mean merely that husband and wife collect food and manufacture goods for their family each in a different manner. It means also as a rule that each has to collaborate with other members of the community of the same sex in some wider collective enterprise, from which the family benefits only partially and indirectly. In spite of repeated theoretical assertions as to the existence of the "closed household economy" or even of individual search for food among primitive peoples, we find in every community, however simple, a wider economic collaboration embracing all members and welding the various families into larger co-operative units (*cf.* B. Malinowski, "Primitive Economics of the Trobriand Islanders," *Econ. Journal,* 1921; "Labour and Primitive Economics," *Nature,* December, 1925).

The fuller our knowledge of relevant facts, the better we see on the one hand the dependence of the family upon the rest of the community, and on the other hand the duty of each individual to contribute not only to his own household but to those of others as well. Thus in Australia a great part of a man's yield in hunting has to be divided according to fixed rules among his relatives, own and classificatory. Throughout Oceania a network of obligations unites the members of the community and overrules the economic autonomy of the household. In the Trobriand Islands a man has to offer about half of his garden produce to his sister and another part to various relatives, only the remainder being kept for his own household, which in turn is supported substantially by the wife's brother and other relatives. Economic obligations of such a nature cutting across the closed unity of the household could be quoted from every single tribe of which we have adequate information.

The most important examples however come from the communities organised on extreme mother-right, where husband and wife are in most matters members of different households, and their mutual economic contributions show the character of gifts rather than of mutual maintenance.

9. **The Split Household Under Matrilocal Mother-right.**—Most of what has been said so far refers to the marriage based on a united household and associated as a rule both under father-right and mother-right with *patrilocal* residence. This means that the bride moves to the husband's community, when she either joins his family house or camp, or else inhabits a house built for the new couple and owned in the husband's name. Patrilocal marriages are by far the most prevalent all over the world.

Matrilocal marriage consists in the husband's joining the wife's community, taking up residence in her parents' house and often having to do some services for them. Matrilocal residence may be permanent; or it may be temporary, the husband having to remain for a year or two with his parents-in-law, and having also possibly to work for them. (Eskimo, Kwakiutl, Guaycuru, Fuegians of America; Bushmen, Hottentots, Bapedi, Bakumbi, Nuer of Africa; negrites of Philippines; Ainu of Japan.) (*See* also Westermarck, *History of Human Marriage,* vol. ii., 360–364; Briffault, *The Mothers,* vol. i. pp. 268–302.)

In a few cases which might be regarded as the extreme development of mother-right combined with matrilocal conditions, the wife remains at her mother's residence and the husband does not even take up a permanent abode there, but simply joins her as a frequent and regular but still temporary visitor (Menangkabau Malays of Sumatra, Pueblo and Seri Indians of N. America, Nairs of Malabar). Such extreme cases of mother-right are an exception. They are the product of special conditions found as a rule at a high level of culture and should never be taken as the prototype of "primitive marriage" (as has been done by Bachofen, Hartland and Briffault).

The most important fact about such extreme matriarchal conditions is that even there the principle of social legitimacy holds good; that though the father is domestically and economically almost superfluous, he is legally indispensable and the main bond of union between such matrilineal and matrilocal consorts is parenthood. We see also that the economic side can have a symbolic, ritual significance—the gift-exchange functions as token of affection—it marks thus a sociological interdependence, while it has hardly any utilitarian importance.

10. **Marriage as an Economic Contract.**—This last point, together with the foregoing analysis of the household and family economics, allows us to frame the conclusion that while marriage embraces a certain amount of economic co-operation as well as of sexual connubium, it is not primarily an economic partnership any more than a merely sexual appropriation. It is as necessary to guard against the exclusively economic definition of marriage as against the over-emphasis of sex. This materialistic view of marriage, to be found already in older writers such as Lippert, E. Grosse, Dargun, appears again in some recent important works. Criticising the exaggeration of sex, Briffault says about marriage: "The institution, its origin and development, have been almost exclusively viewed and discussed by social historians in terms of the operation of the sexual instincts and of the sentiments connected with those instincts, such as the exercise of personal choice, the effects of jealousy, the manifestations of romantic love. The origin, like the biological foundation, of *individual marriage being essentially economic,* those psychological factors are the products of the association rather than the causes or conditions which have given rise to it." And again: "Individual marriage has its *foundation* in *economic* relations. In the vast majority of uncultured societies marriage is regarded almost *exclusively* in the light of *economic* considerations, and throughout by far the greater part of the history of the institution the various changes which it has undergone have been *conditioned by economic causes.*" (*The Mothers,* vol. ii., p. 1; the italics are those of the present writer.)

This is a distortion of a legitimate view. Marriage is not entered upon for economic considerations, exclusively or even mainly; nor is the primary bond between the two parties established by the mutual economic benefits derived from each other. This is best shown by the importance of matrimonial bonds even where there is neither community of goods nor co-operation nor even full domesticity. Economics are, like sex, a means to an end, which is the rearing, education and dual parental influence over the offspring. Economic co-operation is one of the obligations of marriage and like sexual cohabitation, mutual assistance in legal and moral matters it is prescribed to the married by law and enjoined by religion in most cultures. But it certainly is not either the principal end or the unique cause of marriage.

11. **"Marriage by Purchase."**—As erroneous as the over-emphasis on economics and its hypostasis as the *vera causa* and essence of marriage is also the tearing out of some one economic trait and giving it a special name and thus an artificial entity. This has been done notably with regard to the initial gifts at marriage, especially when given by the husband. More or less considerable gifts from the husband to his wife's family at marriage occur very widely (*see* the comprehensive list of references in Westermarck, *History of Human Marriage,* vol. II., chap. xxiii.).

The term "marriage by purchase" applied to such gifts usually serves to isolate them from their legal and economic context, to introduce the concept of a commercial transaction, which is nowhere to be found in primitive culture as a part of marriage, and to serve as one more starting point for fallacious speculations about the origin of marriage.

The presents given at marriage should always be considered as a link—sometimes very important, sometimes insignificant—in the series of services and gifts which invariably run throughout marriage. The exchange of obligations embraces not only the husband and the wife, but also the children, who under mother-right are counted as one with the mother while under father-right they take over the father's obligations. The family and clan of the wife, and more rarely of the husband, also become part of the scheme of reciprocities. The presents offered at marriage by the husband are often made up of contributions given him towards this end by his relatives and clansmen (Banaka, Bapuka, Thonga, Zulu, Xosa, Bechwana, Madi of Africa; Toradjas, Bogos of Indonesia; Buin, Mekeo, Roro, Trobrianders of Melanesia), and are not all retained by the girl's parents but shared among her relatives and even clansmen (Achomawi, Delaware, Osage, Araucanians of America; S.E. Bantu, Swahili, Pokomo, Turkana, Bavili, Ewhe, Baganda, Masai, Lotuko of Africa; Ossetes, Samoyeds, Aleut, Yakut, Yukaghir of Siberia; Koita, Mekeo, S. Massim, Buin of Melanesia). The giving of presents is thus a transaction binding two groups rather than two individuals, a fact which is reflected in such institutions as the inheritance of wives, sororate, levirate, etc. A correct understanding of the initial marriage gift can be obtained only against the background of the wider economic mutuality of husband and wife, parents and children, maternal and paternal families and clans.

Another type of marriage gift is the *lobola* found among the patrilineal and patrilocal communities of the S.E. Bantu, who live by combined agriculture and cattle-raising. The wife and children are here regarded as a definite economic and sociological asset. The wife is the main agricultural and domestic worker, while the children are valuable because the boys continue the line and the girls bring in wealth at marriage. Marriage is concluded by the payment of cattle, the amount varying greatly according to tribe, rank and other considerations from a couple of head to a few score. These cattle are known as *lobola,* or "bride-price," as is the current but incorrect anthropological expression. The *lobola* in fact is not the motive for the transaction, nor is there any bidding on any market, nor can the cattle be disposed of at will by the receiver, *i.e.,* the girl's father. Some of them have to be distributed by him according to fixed tribal custom among particular relatives of the girl; the rest he has to use for the provision of a wife for his son, *i.e.,* the girl's brother, or else, if he has no male heir, he contracts another wife for himself, in order to obtain the desired male descendants. In case of divorce the marriage gift has to be returned as the identical cattle given and not merely in an equivalent form. The *lobola* is thus rather a symbolic equivalent representing the wife's economic efficiency, and it has to be treated as a deposit to be spent on another marriage.

In Melanesia the husband's initial gift at marriage is a ritual act, and is always reciprocated by the wife's family. This is the case also among certain American tribes (Tshimshian, Coast Salish, Bellacoola, Delaware, Ojibway, Navaho, Miwok); in Siberia (Mordwin, Ainu, Buryat, Samoyed, Koryak), and in Polynesia (Samoa). This return gift may take the form of a dowry given to the bride by her father or parents or other relatives but also directly or indirectly benefiting her husband (Greenlanders, Brazilian aborigines, Yahgans of America; Ibo, Ovambo, S.E. Bantu, Banyoro, Masai of Africa; Buryat, Yukaghir, Samoyed of Siberia; Toda of India; Banks Islanders, Buin, Maori of Oceania). In some communities the balance of gifts is so much in favour of the husband that instead of wife purchase we could speak of buying a husband for the girl (N. Massim; coast tribes of Br. Columbia; Tehuelches of Patagonia; Yakut). Both concepts, however, that of "wife purchase" and "husband purchase" are obviously inadmissible.

12. **Property and Inheritance Within Marriage.**—As a rule, whatever the manner of economic inauguration of marriage, and whatever the mutual services exchanged between the partners, the latter have not only their own sphere of activity but their own possessions. The wife usually claims the title and right of disposing of her articles of apparel, of the domestic utensils and often of the special implements and fruits of her pursuit. The importance of woman's work in agriculture, her social influence due to this and her specific claims to the agricultural produce —not the ownership of the land, which is generally vested in man—have given rise to the economic theory of mother-right (*see* below, 13 and 14).

Very often the possessions of the husband and wife are inherited by their respective kindred, and not by the surviving partner. The inheritance of the wife by the husband's brother (the custom of levirate *q.v.*), which is known from the Old Testament, but has a fairly wide range of distribution (*see* the extensive lists given by Westermarck, *loc. cit.* vol. iii., pp. 208–210; Briffault, *The Mothers,* vol. i., pp. 767–772) is not to be regarded as an economic transaction. Like the inheritance of a widow under mother-right and like the custom of killing the widows and the *suttee* of India, it is the expression of the matrimonial bonds outlasting death, and defining the widow's behaviour afterwards (*see* below, 20).

13. **Marriage as a Legal Contract.**—Marriage is never a mere cohabitation, and in no society are two people of different sex allowed to share life in common and produce children without having the approval of the community. This is obtained by going through the legal and ritual formalities which constitute the act of marriage, by accepting in this the obligations which are entailed in marriage and the privileges which it gives, and by having later on to submit to the consequences of the union as regards children.

The legal side of marriage is therefore not made up of special activities, such as constitute its sexual, economic, domestic or parental aspect. It is rather that special side in each of these aspects, which makes them defined by tradition, formally entered upon, and made binding by special sanctions.

First of all, the whole system of obligations and rights which constitute marriage is in each society laid down by tradition. The way in which people have to cohabit and work together is stipulated by tribal law: whether the man joins his wife or vice versa; whether and how they live together, completely or partially; whether the sexual appropriation is complete, making adultery in either partner an offence, or whether, subject to certain restrictions, there may be waiving of the sexual rights; whether there is economic co-operation and what are its limits. The details and the typical rules and variations of all this have already been discussed, as well as, incidentally, the ways in which the rules are enforced. But it must be added that in no other subject of anthropology is our knowledge so limited as in the dynamic problems of why rules are kept, how they are enforced, and how they are evaded or partially broken. (*Cf.* B. Malinowski, *Crime and Custom in Savage Society,* 1926.)

Only on one or two points are we habitually informed by ethnographic observers, as to what penalties attach to a breach of law and custom and what premiums are set on their careful and generous observance. Thus, we are often informed how adultery is dealt with, though we usually get exaggerated accounts of the severity of the law on this point. Again, to anticipate, incest and exogamy are usually surrounded with definite sanctions, some social and some supernatural. The manners and morals of daily contact within the household are usually laid down and enforced by that complicated and imponderable set of forces which governs all human behaviour in its everyday aspects and makes people distinguish between "good" and "bad form" in every human society. The validity of the economic duties of husband and wife are as a rule based on the fact that the services of the one are conditional on the services of the other, and that a very lazy or unscrupulous partner would eventually be divorced by the other.

14. **Divorce.**—This brings us to the subject of the dissolution of marriage. Marriage is as a rule concluded for life—at times

beyond death, as mentioned above. It is questionable whether the short period "marriages" reported from isolated districts (Eskimo of Ungava district, some tribes of the Indian Archipelago, Arabia, Persia, Tibet) deserve the name of marriage, *i.e.,* whether they should not be put into a different sociological category; but our accounts of them are too slight to allow of deciding this question. In some tribes we are told that marriage is indissoluble (Veddas, Andamanese, certain tribes of the Indian Archipelago and Malay Peninsula). The general rule, however, is that divorce (*q.v.*), is possible, but not easy, and entails damages and disabilities to both partners. Even where divorce is said to be easy for husband and for wife, we find on further enquiry that a considerable price has to be paid for the "liberty to divorce," that it is easy only to exceptionally powerful or successful men and women, and that it involves in most cases loss of prestige and a moral stigma. Often also divorce is easy only before children have been born, and it becomes difficult and undesirable after their arrival. In fact the main ground for divorce, besides adultery, economic insufficiency or bad temper, is sterility in the wife or impotence in the husband. This emphasises the aspect of marriage as an institution for the preservation of children.

The threat of divorce and of the disabilities which it entails is one of the main forces which keep husband and wife to their prescribed conduct. At times the husband is kept in check by the payment he gave at marriage and which he can reclaim only when the union is dissolved through no fault of his. At times the considerable economic value of the wife is the motive of his good and dutiful conduct.

15. **The Status of Husband and Wife.**—The duties of the wife towards the husband are apparently in some communities enforced to a considerable extent by his personal strength and brutality, and by the authority given him by custom. In others, however, husband and wife have an almost equal status. Here again, unfortunately, we find too often in ethnographical accounts generalities and stock phrases such as that "the wife is regarded as the personal property of the husband," as "his slave or chattel," or else again we read that "the status of the wife is high." The only correct definition of status can be given by a full enumeration of all mutual duties, of the limits to personal liberty established by marriage, and of the safeguards against the husband's brutality or remissness, or, on the other hand, against the wife's shrewishness and lack of sense of duty. It is often held that mother-right and the economic importance of woman's work, especially in agricultural communities, go with a high social status of the wife, while in collecting, nomadic and pastoral tribes her status is on the whole lower (E. Grosse, in *Die Formen der Familie und die Formen der Wirtschaft;* Schmidt and Koppers, in *Völker und Kulturen*).

Marriage not only defines the relations of the consorts to each other, but also their status in society. In most tribes, marriage and the establishment of an independent household are a condition for the attainment of the legal status of full tribesman in the male and of the rank and title of matron in the woman. Under the system of age grades (*q.v.*) the passage through certain initiation rites is a condition of marriage and this is as a rule concluded soon after it is permitted (*cf.* Webster, *Primitive Secret Societies;* Schurtz, *Altersklassen und Männerbünde*). In all tribes, however, all normal and healthy tribesmen and women are married, and even widows and widowers remarry if they are not too old, under the penalty of losing some of their influence. The attainment of a full tribal status is always a powerful motive for marriage.

16. **The Laws of Legitimate Descent.**—Marriage affects not only the status of the consorts and their relations, but imposes also a series of duties on the parents with regard to children, and defines the status of children by reference to the parents.

As we know already in virtue of the universal principle of legitimacy, the full tribal or civil status of a child is obtained only through a legal marriage of the parents. Legitimacy is at times sanctioned by penalties which devolve on the parents, at times by the disabilities under which illegitimate children suffer, at times again by inducements for the adoption of children or for their legitimisation by the presumptive father or some other man.

In connection with this latter point it is necessary to realise that the children have invariably to return in later life some of the benefits received earlier. The aged parents are always dependent on their children, usually on the married boys. Girls at marriage often bring in some sort of emolument to their parents and then continue to help them and look after them. The duties of legal solidarity also devolve on the children, uniting them to father or mother according to whether we deal with a matrilineal or a patrilineal society.

One of the most important legal implications of marriage is that it defines the relation of the children to certain wider groups, the local community, the clan, the exogamous division and the tribe. The children as a rule follow one of the parents, though more complex systems are also in existence, and the unilateral principle of descent is never absolute. This however belongs to the subject of Kinship (*q.v.; cf.* also MATRIARCHY).

17. **Modes of Concluding Marriage.**—In studying the legal aspect of marriage, it is extremely important to realise that the matrimonial contract never derives its binding force from one single act or from one sanction. The mistake has often been made in discussing the "origin of marriage," of attributing to this or that mode of concluding it a special genetic importance or legal value. Marriage has in turn been derived from mere subjugation by brutal force (the old patriarchal theory); from appropriation by capture in foreign tribes (McLennan's hypothesis); from feminine revolt against hetairism (Bachofen); from economic appropriation or purchase (the materialist interpretation of early marriages); from pithecanthropic patriarchy (Atkinson, Freud); and from *matria potestas* (Briffault). All these views overstate the importance of one aspect of marriage or even of one element in the modes of its conclusion; some even invent an imaginary state or condition.

In reality marriage is the most important legal contract in every human society, the one which refers to the continuity of the race; it implies a most delicate and difficult adjustment of a passionate and emotional relationship with domestic and economic co-operation; it involves the cohabitation of male and female, perennially attracted and yet in many ways for ever incompatible; it focuses in a difficult personal relationship of two people the interest of wider groups: of their progeny, of their parents, of their kindred, and in fact of the whole community.

The validity of the marriage bond derives its sanctions from all these sources. This expresses one of the most important truths concerning marriage. The complexity of motives for which it is entered, the utility of the partners to each other, their common interest in the children's welfare, last, not least, the interest which the kindred and the community have in the proper upbringing of the offspring—these are the real foundations of marriage and the source of its legally binding character.

All this finds an expression in the modes of contracting marriage. These always contain the element of public approval; the collaboration of the families and the kindred of each partner; some material pledges and securities; some ritual and religious sanctions; last, not least, the consent of the parties concerned.

In the old manuals and statements concerning marriage an important place is usually taken by the classical list of the various "modes of concluding" it: marriage by capture, by purchase and by service, by infant betrothal, elopement, exchange, mutual consent, and so on (*cf.* even such an excellent and recent account as the article on "Marriage," by Rivers, in Hastings' *Enc. of Religion and Ethics*).

This classification is unsatisfactory. It exaggerates as a rule one aspect out of all proportion, and attributes to this one aspect an overwhelming influence upon the whole institution which it never possesses. "Marriage by purchase" we have already dismissed as a crude misnomer, while "service" is but a detail in the economics of certain marriages. "Marriage by capture," which has played such a prominent part in speculation and controversy from McLennan onward, never could have been a real institution: though a man may occasionally wed a woman captured by force in a war, such an occurrence is always an exception; it never was a rule, still less a "stage in human evolution." Tribal endogamy (*see* below, 22) is the universal rule of mankind. Ceremonial fights and ritual capture occur at wedding ceremonies over a wide area (*see* Westermarck, *History of Human Marriage,* ii., 254–277; Crawley, ii., 76–100; Briffault, ii., 230–250). They are capable of interpretation in terms of actual psychology and of existing social conditions (Westermarck, Crawley, Briffault, Havelock Ellis). To regard them as survivals of "marriage by capture" is erroneous, and on this point there is now an almost universal agreement. Capture and violence, as well as purchase from other tribes, or on the slave-market, lead to concubinage, and at times supply prostitutes, but only very rarely legal wives.

Like the contract itself, so also the modes of concluding it contain a great variety of binding and of determining factors. But a real and relevant distinction can still be made between those marriages which are contracted primarily by rules of tradition; those which are arranged for by the families or the kindred of the consorts; and those which arise from free and spontaneous choice of the mates. In no type of marriage is any of these three elements —tradition, arrangement by families or their consent, and free choice—completely absent. But one or other may be conspicuously predominant.

The most usual type of traditionally prescribed union is cross-cousin marriage (*see* Cousin Marriage), with a wide distribution, practised very extensively all over Oceania, Australia and S. India, and sporadically in Africa, N. America and Asia. The marriage of parallel cousins is less frequent, and found notably among Semitic peoples (*cf.* Frazer, *Folk-Lore in the Old Testament,* vol. ii., pp. 145 *sqq.;* B. Z. Seligman, "Studies in Semitic Kinship," *Bull. School Oriental Studies,* 1923–24). Even less common are marriages prescribed between other classes of relatives, *e.g.,* between a man and his brother's daughter (N. Australia, some parts of Melanesia), or his sister's daughter (S. India), or his father's sister (certain parts of Melanesia, Dene of N. America). Another type of prescribed marriage is by inheritance, of which the levirate and sororate (*q.v.*) are the most notable.

Besides such traditionally defined unions, there are also marriages recognised as convenient and desirable by the respective families and arranged for by them. Infant betrothal (prevalent in Australia and Melanesia), where a definite claim is established; or infant marriage (reported especially from India), where the bond is effectively concluded, are two of the most usual forms of these. The main motive for infant unions is the determination of the families to secure a convenient union. In Australia, where an infant is often allotted to a mature male, the power of old men and their keenness to secure young wives, are at the root of this institution. Whether similar conditions existed, or even still survive in Africa, is an interesting problem (*see* B. Z. Seligman, "Marital Gerontocracy in Africa," *Journal of the Royal Anthropological Institute,* 1924).

In many communities, including some advanced nations of Europe, marriage is mainly determined by social or financial considerations, and in this the parents of bride and bridegroom have as much to say as the two people directly concerned. In some primitive tribes two brothers exchange sisters (Australia), or a man's matrilineal uncle or patrilineal aunt has some say (Melanesia). Where the initial payments are very heavy and where they are used to secure a wife for the bride's brother, marriage is usually also a matter for an arrangement rather than free choice.

With all this free choice still remains the most important element. Very often an infant betrothal or some other form of arranged union is broken by one of the people directly affected, and marriage by elopement, with the subsequent consent of family and kindred, overrules all other considerations. Invariably in all communities the majority of unions come from the initiative of the partners. Marriage by free personal choice is the normal marriage, and the choice is mainly determined by personal attraction, which does not mean merely a sexual or erotic attraction. In general the physical appeal combines with compatibility of character, and such social considerations as suitability of rank and of occupation and of economic benefits, also influence the choice. Here again the nature of marriage entails a complexity of motives, and its stability has always to be secured by a suitable compromise between conflicting interests.

18. **The Religious and Ceremonial Side of Marriage.**—The sanctity of the marriage bond is not found merely in the Christian religion, nor is it a prerogative of the higher cultures. The supernatural sanction, derived from a solemn, publicly celebrated, spiritually as well as ethically hallowed ceremony, adds to the binding forces of mere law. Marriage is valid as a legal contract in so far as its breach is visited by worldly retributions and its generous fulfilment carries worldly benefits. As a sacrament, marriage in primitive and civilised societies alike, is protected by spiritual powers, rewarding those who observe matrimonial duties meticulously and piously, and punishing those who neglect them.

The religious aspect of marriage is therefore closely akin to the legal, in that it adds to the validity and sanctity of other functions, rather than establishes new ones. It finds expression in the acts of establishment and those of dissolution: religious rites are to be found at betrothal and wedding, while divorce is often religiously defined and qualified, and at death the breach of the bond finds its spiritual expression in the duties, observances and ceremonies incumbent on the surviving partner. Besides these ceremonial manifestations in which the bonds of marriage are religiously tied or dissolved, religious ethics establish those rules of matrimonial conduct which are sanctioned supernaturally or felt binding through their appeal to moral sense rather than to self-interest.

19. **Ceremonies of Betrothal and Wedding.**—Betrothal can be defined as an act preliminary to marriage, establishing mutually presumptive claims. The period between betrothal and marriage varies, and where it is short, it is often difficult or even impossible to decide whether we deal with an act of betrothal or an inaugural wedding rite. It is also unprofitable to draw a very sharp line of distinction between infant betrothal and infant marriage. Where betrothal imposes real obligations and a valid tie, the rites then observed usually fulfil in their religious bearing the same function as those of marriage, and consist of the same or similar actions, both as regards ritual technique and symbolic meaning. It will be best therefore to discuss the binding rites of marriage and betrothal together.

These rites and ceremonies cover a very wide range, from the simplest act, such as a meal openly taken in common, to complex and elaborate tribal festivities, extended over a considerable period of time. But in every human society marriage is concluded by a ritual enactment. It might be disputed whether such rites in their simplest form present a genuine religious character; but most sociologists would agree that they always possess some religious elements in that they are solemn and public; in their more developed form and in higher cultures they become definitely religious. It will be best in discussing the nature of wedding rites not to draw too pedantic a distinction between their legal and religious aspects, since the two often merge or shade into each other imperceptibly.

"The most general social object" of a wedding rite is "to give publicity to the union" (Westermarck). By this the legal as well as the religious sanction of the union is established. The contract is made binding in that all the members of the community bear witness to it; it is hallowed in that the two mates solemnly and openly declare before man, God or other spiritual powers that they belong to each other.

20. **The Symbolism of Marriage Ritual.**—A marriage rite is as a rule also a ritual act with a symbolic significance, and as such it is often conceived to possess a magical efficacy, it contains a moral precept or expresses a legal principle.

A. Biological Symbolism.—Thus the fundamental purpose of marriage, the continuity of the race, is indicated in wedding ceremonies by ritual, intended to make the union fruitful, to obviate the dangers associated with sexual intercourse, especially with defloration, and to facilitate the various stages of the process of generation from the first act to delivery. Among the fertility rites a prominent place is taken by the use of fruit or grain or other cereals, which are sprinkled over the newly-wedded couple or on or round the nuptial bed, or handed to them or brought into contact with them in some other way. Rites, such as the accompaniment of the bride by a little child, the use of various symbols of generation, and the direct offering of prayers and sacrifices, are all intended to make the union fruitful. The breaking of some object at the wedding serves to avert the dangers of defloration and to facilitate the consummation of the union. The undoing of knots and laces, found in many wedding rites, makes for easy delivery at childbirth. In all these acts we see the ritual expression of the biological nature of marriage.

B. Marriage as a Crisis.—As an official and public recognition of a biological fact, as the most important contract ever entered by two individuals, and as the act which creates a new social entity, the family, marriage is a crisis. Now a crisis in human life is always surrounded by powerful emotions: forebodings and hopes, fears and joyful anticipations. Innumerable wedding rites are in existence which are obviously intended to remove the dangers associated with the crisis of marriage.

Dangers apprehended in subjective forebodings are usually conceived in the form of evil agencies: demons or ghosts or malevolent spirits, forces of black magic, mysterious concatenations of ill-luck. These have to be kept at bay or counteracted, and we find innumerable rites intended to avert ill fortune and bring happiness and good chance to the new household. Among these are the avoidance of certain days and places as unlucky, or on the other hand the selection of certain days as being of good omen; the shutting out of evil influences from the place where the wedding is being celebrated; the making of noises, the firing or brandishing of some weapon; the bathing or washing of bride and bridegroom or sprinkling them with water; the lighting of fires and waving of torches; the circumambulation of the bridegroom's tent or of the church; the beating of the bridegroom's tent, and the observance by the bride and bridegroom of various kinds of abstinences with regard to action and eating. Other forms in which bad luck can be side-tracked are: the disguising of the real actors, who may dress in the clothes of the opposite sex, cover themselves, or paint their faces.; the substitution for them of effigies; marriage by proxy; and the contracting of mock marriages with trees or animals or inanimate objects. Finally an important antidote against all supernatural dangers is the state of spiritual invulnerability which is achieved by moral purity and the observance of those mixed ethical and ritual rules which in primitive culture often surround important acts of human life. The most important tabu of this kind, in connection with marriage is obviously the tabu of sex-continence. The principle that the bride and the bridegroom have to abstain from intercourse for some time after the wedding, is known all over the world from primitive savagery to the most refined ethics of the Christian church, from Australia to the New World (*cf.* Westermarck, II., 547–564), while on the wedding night there are occasionally other minor abstinences.

It is characteristic that while the bride and the bridegroom are often considered in a state dangerous not only to themselves but also to others, they are at the same time a source of blessing and of beneficent influences. Thus certain rites are supposed to influence favourably the welfare of other persons even independently of their relations to the principals; joining in at a wedding is sometimes believed to produce benefit; a wedding is looked upon as a potential cause of other weddings; while good luck is often expected from contact with the bride or bridegroom or something worn by them.

C. Marriage as a Sociological Change.—Marriage is a crisis not merely in the spiritual sense. It is also an actual sociological transition from one state to another, both partners forsaking their old families to form a new one. The rupture with the parental family, clan, local community or tribe is expressed in a number of interesting wedding rites. Sham fighting between the bridegroom or his party and the bride's family, or some other kind of resistance made by the latter; the barring of the wedding procession; weeping and other ritual expressions of grief and unwillingness on the part of the bride and her relatives; and the mimic enactment of capture or abduction of the bride—these are mostly the dramatic expression of the fact that the bride has to be torn from her old home, that this is a violent and critical act, a final one.

D. Marriage as a New Bond.—But the most important type of wedding rite is that which lays down that marriage is a sacramental bond. Here again the symbolism is wide and varied, from the most direct expression of union by the joining of hands or of fingers, the tying of garments, the exchange of rings and chains, to complicated dramatic enactments of the separation and union. An important symbolism of the new ties to be established consists in the performance of some act which in future will constitute one of the normal duties or privileges of married life. Such acts in a way define the nature and exclusiveness of marriage by anticipation in ritual performances. Among them, naturally the most important are the ceremonial performance of the sexual act and the ceremonial participation in a common meal. In certain ceremonies the symbolism lays down the relative domains of marital influence. Thus in some cases the assertion of the husband's power is prominent: he is presented with a whip, or he boxes the bride's ears, or mimically beats her, and so on. In others again the wife may attempt by similar acts to mark her independence and her power over her husband. The economic aspect of marriage is often also expressed in some magical act, intended to ensure prosperity to the future household, *e.g.*, by the smearing of butter and honey by the bride over the pole of the tent to ensure abundance of staple food. Again, the division of economic functions is expressed in other rites, as where the wife tends the fire, prepares and cooks food for her husband, etc.

E. The General Function of Wedding Symbolism.—These examples cover the most important though by no means all the ideas expressed in wedding rites. It is easy to see that the symbolism is extremely rich and varied, and that it embraces almost all the aspects of marriage. There are rites which bear directly upon sex and upon gestation; there are rites with a clear domestic and those with an economic significance; there are rites referring to emotional attitudes at marriage and to moral ideas as to its ends. In technique they are all legal, magical or religious. In short, the ceremonial of marriage covers and expresses all the relevant sides of the institution of marriage, and as such it has been a most fruitful and revelatory subject of anthropological study. It also has been the main source of errors and pitfalls.

In order to avoid them it is important to realise that all ritual symbolism is necessarily vague. Speaking of the marriage ceremonies, Professor Westermarck rightly lays down that "Anthropologists are often apt to look for too much reasoning at the bottom of primitive customs. Many of them are based on vague feelings rather than on definite ideas" (*History of Human Marriage,* II., 563). The ritual symbolism at marriage also expresses as a rule mixed and compound meanings in most of the acts. Thus the spilling of corn over the couple may mean fecundity, prosperity, good husbandry as well as union, and probably it vaguely expresses all these elements. Sham fights and captures, tree marriages or marriages by proxy have obviously a plurality of meanings.

Nor is the function of symbolism exhausted by its direct and literal meaning. A ritual act, fixed by tradition, defining the relevant manner of concluding a contract, impresses by pomp and circumstance its social importance and its binding force in the moral sense. The ethical rules and tabus which usually go hand in hand with ritual add to this spiritualising function of wedding ceremonies. The public and official nature of the marriage act, often marked by the presence of an officiating priest, ruler or magician; heralded by banns and public announcements; sealed by witnesses and documents; enhanced by the sacredness of place and of time constitutes the widest and most general function of the rite, and that is to make marriage public, binding, sacred and morally impressive.

21. **The Dissolution of Marriage in Ritual.**—The binding forces of the marriage contract, and its ritual and moral character, are expressed as clearly at the dissolution by divorce or death as at its inception. Unfortunately our information is so defective on this point that a brief survey only can be given.

Divorce in higher cultures is a religious matter, to be carried out under the supervision of the church, and with the observance of certain formalities which express and safeguard the sanctity of the sacrament. From lower cultures we find only a few examples of divorce rites, where such symbolic acts as the breaking of a rod, the tearing of a leaf, or the casting away of some object are publicly performed (Kacharis, Hajongs, Khasis of N.W. India; Bagobo of Mindanao; Tumbuka of C. Africa; certain Canadian Indians; Maori of New Zealand).

Far more material is at our disposal referring to the persistence of the matrimonial bonds at death. They are never dissolved automatically by the decease of either partner, and their tenacity is greater for the widow than for the widower. But in either case the death of one consort imposes a number of ritual and moral observances on the other, the fulfilment of which is an essential part of the marriage contract.

The widow, or widower, usually plays the most prominent part among all mourners. Thus among certain peoples the widow has to perform various duties, extending over a more or less considerable period, at the grave of her husband. She has to sleep beside or over it; to supply it with provisions; to keep a fire burning there perpetually (Takulli, Kutchin, Mosquito, Pima Indians of America; Minas, Nsakara, Baganda of Africa; Pentecost Islanders and certain Papuans of Oceania; Kukis of India). Even more telling are the long series of tabus and duties to be observed by the widow before she is allowed to remarry: she must remain chaste, refrain from bathing or renewing her garments, avoid certain foods, etc. (Omaha, Stlathlumh, Creek, Chickasaw, Algonkin, Iroquois, Dakota, Eskimo of N. America; Angoni, Bakoba, Baya, Bawele, Baganda, Akamba, Herero, BaThonga, Zulu of Africa; Amoor tribes and Kukis of India; Bontoc Igorot of the Philippines; Maori of New Zealand; Ainu, Yakuts, Kamchadal of N.E. Asia).

Similar regulations prevent the widower from entering into a new alliance immediately after he has been set free by his wife's death. Thus among many peoples (Greenlanders, Eskimo, Aleut; Dakota, Omaha, Shawnee of N. America; Herero, Bushmen, BaThonga, Zulu of Africa; certain Papuan tribes; the Bontoc Igorots and the Ainu) the surviving husband has to live single for a time during which he is subjected to various restrictions and observances, such as refraining from sexual intercourse.

The most definite affirmation of the persistence of marital bonds is found among those people who completely forbid remarriage to widows (Tikopians, Rotumans, Marquesans, Line Islanders in Polynesia; Chinese; Ainu of Japan; Formosans; Brahmans of India) or to widowers (Ainu, Formosans, Biduanda Kallang of Malay Peninsula).

Even this is overshadowed by the institution of *suttee,* the sentence of death passed by religious tradition over the widow at her husband's death so that her spirit might follow his into the next world. This institution is found not only in India, from where we have borrowed its name, but also among the Comanche, Cree and certain Californian tribes of N. America; in Dahomey and among the BaFiote of Africa; in the New Hebrides, Fiji, Solomon Islands, Pentecost Island and New Zealand of Oceania.

22. **The Social Conditions of Marriage. Endogamy.**—With this we have finished the analysis of the various aspects of marriage, biological, domestic, economic, legal and religious. It will be necessary still briefly to consider marriage in relation to other modes of grouping, and to discuss certain barriers to and qualifications for matrimony, connected with membership in wider groups.

Marriage is never free in the sense that any man would be at liberty to marry any woman. Natural and physical impediments obviously do not come here under consideration, since we are only concerned with social rules. Thus it is clear that in order to marry, two people must come into contact with each other, and under primitive conditions this is possible only when they belong to the same tribe, or to tribes who meet in peaceful commerce or in warfare. Tribal or natural endogamy (*q.v.*), is thus the first condition of marriage, but it is of secondary interest to the sociologist, and must be distinguished from strict endogamy.

Endogamy proper is the rule which allows marriage only between members of a section of a tribe and forbids unions between members of two sections. Strict endogamy is rare. It occurs mainly in India where members of the same caste only are allowed to marry (*see Caste and Endogamy*). In other parts of India we find a system called *hypergamy* (*q.v.*) in which a man is allowed to marry a woman of a lower section in his caste. He may also marry a woman of the same section if other conditions allow this. But a woman may not marry a man of a lower section on penalty of loss of status of her whole family. In some communities there is competition to secure husbands of high sections.

In primitive communities endogamy is not very widespread. It occurs in tribes where there is a degraded class of artisans or else stratification by rank (Polynesia; Korea, Japan; Trobriand Islands of Melanesia; Algonkin, Salish of N. America; Masai, Banyankole, Karanga and other tribes of E. and S. Africa). In such cases we often find endogamy in what might be called an approximate form. Indeed such approximate endogamy, as a tendency to marry within the profession, class or rank, is, as an unwritten law, well-nigh universal in primitive and civilized communities.

Another type of endogamy which is widespread is that associated with religion. In few religions is marriage outside the group of the faithful permitted. Islam, Judaism, Christianity and Hinduism are cases in point. Primitive religion as a rule need not be intolerant as regards mixed marriages, because there the tribal barriers and lack of communication act with sufficient stringency.

23. **The Prohibition of Incest.**—The most widely spread and most rigidly enforced qualification to marriage is the set of rules which prohibit unions between the members of the same family. These are known as the rules of incest (*q.v.*), and play a great part in the constitution of the family (*q.v.*) and in the regulation of primitive kinship (*q.v.*). Incest has become also of great importance in modern psychology through the speculations of Freud and the psychoanalytic school (*see* PSYCHOANALYSIS: FREUDIAN SCHOOL).

Although incestuous unions between near relatives are universally abhorred and prohibited, the rules differ greatly from one society to another as regards the prohibited degrees as well as the stringency and character of the sanctions. Marriages between mother and son and between father and daughter are universally prohibited by law, custom and moral sentiment. Statements can be quoted, it is true, of tribes among whom more or less irregular unions between parents and children do occur. Thus marriages between mother and son have been reported from the Caribs, Eskimo, Pioje, Tinne of America; Minahassa of Celebes and Kalang of Java; New Caledonians; and the Banjoro of Africa. Again unions between father and daughter are said to occur among the Minahassa of Celebes, Karens of Burma, and in the Solomon, Marshall and Pelew Islands of Oceania. Even better attested are the marriages between brother and sister (Marshall Islands and Hawaii; ancient Irish, Egyptian and Inca royal families).

When we go beyond the family group, the prohibitions of marriage between uncles and nieces, aunts and nephews, first and second cousins, and so on, vary greatly. In some communities certain of these unions are explicitly encouraged and regarded as desirable; in others forbidden. About preferential marriages between relatives we have already spoken (*see* above, 17). Extensive prohibitions of marriage between distant kindred exist, besides the Western Christian civilizations also among a number of other tribes and cultures (Salish, Eskimo, Pipites of Salvador, Aztecs, Araucanians, Abipones, Ona, Yahgan of America; Koryak, Yukaghir, Kalmuck of N.E. Asia; Torres Straits Islanders, Mekeo, Polynesians of Oceania; S.E. Bantu of Africa).

24. **Exogamy.**—This is the system under which far larger groups of people are regarded as related to each other and their members forbidden to intermarry. It is found mainly in association with the classificatory nomenclature of kinship terms and the clan organisation (*cf.* also EXOGAMY, KINSHIP, RELATIONSHIP TERMS). Whether exogamy is genetically connected with incest, *i.e.,* whether it is an extension of the tabu on intercourse and marriage within the family, or an independent institution, is a

debated question (*see* Westermarck, *H.H.M.*, II., pp. 192–218; Frazer, *Totemism and Exogamy*, vol. IV., *passim;* Malinowski, *Sex and Repression in Savage Society*, part IV.).

Exogamy embraces the widest number of people, where it is based on the dual organisation and debars from intercourse or marriage one half of the tribesmen and tribeswomen (*cf.* DUAL ORGANIZATION). Normally exogamy is an attribute of clan, *i.e.*, of the group of people who trace their descent to a common ancestor, have in most cases the same totem, and fulfill a number of functions together (*see* CLAN, TOTEMISM, KINSHIP). The clans are sometimes a subdivision of the tribe, based numerically on the dual principle, as where we have two, four or eight clans. At times there is an odd and more or less considerable number of clans, and exogamy is enforced only within each of these divisions. The prohibitions as a rule apply unilaterally (Iroquois, Huron, Lenape, Mohegan, Miami, Shawnee, Creek, Sauk, Fox, Kickapoo, Blackfoot, Dakota, Seminole of N. America; Arawak and Goajiro of S. America; Tungus, Yakut, Samoyed, Ostyak, Tartars of N.E. Asia; various aboriginal peoples of India; Torres Straits Islanders, Papuans, Melanesians, Polynesians and Micronesians of Oceania; Hottentot, S.E. Bantu, Anyanja, Wayao, Awemba, Makololo, Akonde, Masai, Akamba, Baganda and other E. African tribes; Ashanti and other W. African tribes). Only in a few cases has exogamy to be observed with regard to the clans of both parents (Omaha, Osage of N. America; certain Naga tribes of Assam; S. Massim of Melanesia; Herero, Lango of Africa).

A specially complex set of conditions prevails in the tribes of C. Australia, where there is a twofold division into (a) totemic clans, which are not strictly exogamous; and (b) matrimonial classes, which strictly correspond to kinship divisions, and which are not only exogamous, but regulate marriage to the extent that a member of one of them has to marry into one and one only of the remaining three or seven classes, as the case may be (*see* AUSTRALIA: *Ethnology*).

25. **The Forms of Marriage.**—From the foregoing description it will be clear that there is a considerable range within which the constitution of marriage can vary. For as we have seen there can be many different arrangements in the domestic, legal, economic and ceremonial sides of marriage, and each of their manifold combinations constitutes a distinct form of marriage.

The term "form of marriage" has been as a rule applied to what might be called the *numeric variation* in marriage, *i.e.*, the variation according to the number of consorts united to each other; and the main "forms of marriage" usually listed are monogamy, polygyny, polyandry and group-marriage. To deal with this classification adequately it is necessary to distinguish hypothetical assumptions from actually existing social arrangements. From this point of view we can at once eliminate "group-marriage," since our previous analysis (*see* above, 5) has shown that the *pirrauru* relationship of Australia and similar institutions among the Eskimo and in Siberia can not in their parental, economic, legal or religious functions be regarded as a form of marriage.

26. **Polyandry.**—This is the name given to a union in which several men are legally bound in marriage to one woman. Polyandry is the rarest of the numeric varieties of marriage, and unfortunately the one on which, in spite of its great theoretical importance, we possess but very meagre and inadequate information. Polyandry is not found among any of the more primitive peoples, and its distribution is almost completely confined to the highlands of S. India and C. Asia, with isolated exceptions, such as one African tribe (Bahima) and some Eskimo, among whom it occurs, but infrequently.

In Tibet and the adjacent countries there exists polyandry of the fraternal type, *i.e.*, several brothers share the wife in common. All the husbands live together with their common wife as members of the same household, and cohabit successively with her. Children born of these marriages are sometimes regarded as the legal descendants of the eldest brother-husband only; in other cases it appears that when a child is born it is attributed to him by whom the mother asserts that she has conceived it.

Among the Nayars of S.W. India there is a so-called form of polyandry which has played an important though rather deceptive part in the theories of marriage. A girl goes through a form of marriage with a man, but then really consorts with a number of men who need not be related to one another. She lives apart from her partners, who cohabit with her successively by agreement among themselves. Owing to the matrilineal institutions of this people, the children of such marriages inherit from their mother's brother, but the social importance of fatherhood is seen in the fact that the woman, when pregnant, always nominates one or other of the men as the father of the child, and he is obliged to provide for it and to educate it.

Another account is that by Dr. Rivers, of the Toda polyandry, which can be taken as the representative of the simpler type of this institution in S. India. Among the Toda, several men, usually two or three brothers, share the wife, but it is the rule that they cohabit with her in succession. Again, the children are not owned in common by the husbands, but each child is allotted individually to one, not with reference to any presumption of physical paternity, but in virtue of a ritual act performed by the man over the child, an act which establishes social paternity and confers legitimate descent on the child (*see* above, 4).

Polyandry is thus a compound marriage, in which cohabitation is usually successive, and not joint, while children and property are not shared by the husbands.

27. **Polygyny.**—This is a form of marriage in which several wives are united to one man, each having the status of legal consort, while her offspring are regarded as the legal descendants of the husband. As an institution polygyny (*q.v.*) exists in all parts of the world. There are very few primitive tribes about whom we are informed that a man is not allowed, if he can, to enter into more than one union. Many peoples have been said to be monogamous, but it is difficult to infer from the data at our disposal whether monogamy is the prevalent practice, the moral ideal, or an institution safeguarded by sanctions. It must be remembered at once that polygyny is never practised throughout the community: there cannot exist a community in which every man would have several wives, since this would entail an enormous surplus of females over males (*cf.* however the important contribution to this subject by G. Pitt-Rivers, *The Clash of Cultures and the Contact of Races*, 1927). The second important point with regard to polygyny, which is seldom brought out clearly, is that in reality it is not so much a form of marriage fundamentally distinct from monogamy as rather a multiple monogamy. It is always in fact the repetition of a marriage contract, entered individually with each wife, establishing an individual relationship between the man and each of his consorts. As a rule each relationship is little affected legally or economically by the others.

Where each wife has her separate household and the husband visits them in turn, polygynous marriage resembles very closely a temporarily interrupted monogamy. In such cases there is a series of individual marriages in which domestic arrangements, economics, parenthood as well as legal and religious elements do not as a rule seriously encroach on each other. The polygyny with separate households is more universally prevalent. Among the great majority of the Bantu and Hamitic peoples of Africa, where the number of wives, especially in the case of chiefs, is often considerable, each wife commonly occupies a separate hut with her children, and manages an independent household with well-defined legal and economic rights. Where, on the other hand, as among many N. American tribes, two or more wives share the same household, polygyny affects the institution of matrimonial life much more deeply.

In most cases the motive for polygyny is economic and political. Thus in the Trobriand Islands (Melanesia) the chief's income is due to his wives' annual endowment. In many African communities the chief derives his wealth from the plurality of his wives, who by means of the produce of their agricultural labour enable him to exercise the lavish hospitality upon which so much of his power rests. A multitude of wives, however, may increase not only a man's wealth but also his social importance, reputation and authority, apart from the influence of the number of his children. Hence we find in many Bantu communities of Africa that the desire to have many wives is one of the leading motives in the life of every man; while the fact that in many Melanesian and Polynesian communities polygyny is a prerogative of the chief testifies to the social prestige attaching to it.

28. **Monogamy.**—Monogamy is not only the most important form of marriage, not only that which predominates in most communities, and which occurs, statistically speaking, in an overwhelming majority of instances, but it is also the pattern and prototype of marriage.

Both polyandry and polygyny are compound marriages, consisting of several unions combined into a larger system, but each of them constituted upon the pattern of a monogamous marriage. As a rule polygamous cohabitation is a successive monogamy and not joint domesticity; children and property are divided, and in every other respect the contracts are entered individually between two partners at a time.

Monogamy as the unique and exclusive form of marriage, in the sense that bigamy is regarded as a grave criminal offence and a sin as well as a sacrilege, is very rare indeed. Such an exclusive ideal and such a rigid legal view of marriage is perhaps not to be found outside the modern, relatively recent development of Western Culture. It is not implied in Christian doctrine even. Apart from such isolated phenomena as the recent Church of Latter Day Saints (Mormons) and the heretical sect of Anabaptists (16th century), polygyny was legally practised and accepted by the Church in the middle ages, and it occurs sporadically as a legal institution accepted by Church and State as recently as the middle of the 17th century (Westermarck, *H.H.M.*, III., 50–51).

Monogamy as pattern and prototype of human marriage, on the other hand, is universal. The whole institution, in its sexual, parental, economic, legal and religious aspects, is founded on the fact that the real function of marriage—sexual union, production and care of children, and the co-operation which it implies—requires essentially two people, and two people only, and that in the overwhelming majority of cases two people only are united in order to fulfil these facts.

Conjugation necessarily takes place only between two organisms; children are produced by two parents only, and always socially regarded as the offspring of one couple; the economics of the household are never conducted group-wise; the legal contract is never entered upon jointly; the religious sanction is given only to the union of two. A form of marriage based on communism in sex, joint parenthood, domesticity, group-contract and a promiscuous sacrament has never been described. Monogamy is, has been and will remain the only true type of marriage. To place polygyny and polyandry as "forms of marriage" co-ordinate with monogamy is erroneous. To speak about "group-marriage" as another variety shows a complete lack of understanding as to the nature of marriage.

29. **Theories of Marriage.**—The last conclusions reveal once more the important truth of scientific method that a full knowledge of facts cuts the ground from under most hypothetical speculations. The theories of human marriage have mainly been concerned with its "origins" and "history," and attempts were made at ranging the various "forms of marriage" into an evolutionary series. Once we come to recognise that marriage is fundamentally one, and that its varieties correspond not to stages of evolution, but are determined by the type of community, its economic and political organisation, and the character of its material culture, the problem becomes one of observation and sociological analysis, and ceases to move on the slippery plane of hypothesis.

The view that marriage originated in "promiscuity," "hetairism" or "matrimonial communism," and that monogamy is a product of gradual development through a multitude of stages, has been advanced by Bachofen, Morgan and McLennan; has found wholehearted or partial support by a number of eminent writers (Lord Avebury, Fison, Howitt, Tylor, Spencer and Gillen, Post, Kohler, Kovalevsky, Lippert, Schurtz, Frazer and others); and has been criticised and combated by Darwin, Westermarck, Lang, Grosse and Crawley.

The writings of Morgan's school suffer from an over-emphasis of the sexual aspect, often coupled with prudish reticences; from a misinterpretation of linguistic evidence (*see* KINSHIP); from a neglect of the parental and economic aspect of marriage. They are full of fantastic and meaningless concepts such as "promiscuity," "group-marriage," "primitive communism," which as a rule are not even laid down with sufficient concrete details to give hold to our imagination and remain mere words on paper. The German writers of this school, who have contributed a voluminous output, especially in the *Zeitschrift für vergleichende Rechtswissenschaft,* have certainly not neglected the legal side of marriage, but in applying to primitive societies the dry legal formalism of modern jurisprudence, and in ruthlessly forcing all facts into the cut and dried scheme of "marriage stages," they have contributed but little which will have lasting value.

The recent advocates of Morgan's and Bachofen's view, notably Sumner, Rivers, Keller, Briffault, have given a much better and more concrete outline of the hypothetical early stages of marriage. But even this last stand of the "group-marriage" theory is based on an inadequate analysis of the institution and an unwarranted assumption of early sexual and economic communism as well as of group-motherhood

Modern theories of marriage follow closely the lead of Darwin on the biological side, of Westermarck in his sociological analysis, and of Crawley in some of his psychological suggestions. Such writers as Lowie, Kroeber and Howard in America; Thurnwald, W. Schmidt and Koppers in Germany; A. R. Brown, Malinowski, and Pitt-Rivers in Great Britain, both in their theories and in their field work show a far greater interest in the sociological analysis of marriage, in its relation to the family, in the correlation of its aspects, in the sociological working of sexual customs, whether these be tabus, relaxations or excesses, in their reference to marriage.

Some new light on marriage has been thrown by those psychoanalysts, notably J. C. Flügel, who are prepared to give serious consideration to facts in their bearing upon the Freudian doctrine (*cf.* Malinowski, *Sex and Repression in Savage Society*). Finally important contributions to the theory of marriage have been made by those students who approach the problem in its practical applications: the eugenists (see *Eugenics Review*): students of population (*see* Raymond Pearl's *Journal of Human Biology*); and scientific aspects of social hygiene (*American J. of Social Hygiene*).

Marriage like most problems of anthropology is ceasing to be a subject of speculation and becoming one of empirical research.

MARRIAGE, LAW OF. Marriage may be defined either (*a*) as the act, ceremony, or process by which the legal relationship of husband and wife is constituted; or (*b*) as a physical, legal, and moral union between man and woman in complete community of life for the establishment of a family. It is possible to discriminate between three stages, taking marriage in the latter sense as an institution—the animal or physical stage, the proprietary or legal stage, and the personal or moral stage. In the first or physical stage the relation of the sexes was unregulated, and in many cases of brief duration. In the second or legal stage greater permanence was secured in marriage by assigning the husband a property right in his wife or wives. In the last stage the proprietary relation falls more and more into the background, and the relation of husband and wife approximates that of two individuals entirely equal before the law. Although in the history of marriage these three stages have been roughly successive, the order of their entering the conscious experience of the individual is usually the reverse of their order in the development of the race; and in the solemnization of a marriage based upon affection and choice the growth of the relation begins with the moral, advances to the legal, and culminates in the physical union, each one of these deriving its meaning and its worth from the preceding. In most legal systems marriage, in the sense of a ceremony, takes the form of a contract—the mutual assent of the parties being the prominent and indispensable feature. While the consent of parties is universally deemed one of the conditions of a legal marriage, all the incidents of the relationship constituted by the act are absolutely fixed by law. The jurist has to deal with marriage in so far as it creates the legal status of husband and wife. It should be added that, while marriage is generally spoken of by lawyers as a contract, its complete isolation from all other contracts is invariably recognized. Its peculiar position may be seen at once by comparing it with other contracts giving rise to continuous relationships with more or less indefinite obligations, like those of landlord and tenant, master and servant, etc. In these the parties may in general make their rights and duties what they please, the law only intervening when they are silent. In marriage every resulting right and duty is fixed by the law.

Inferior Forms of Union.—Besides true marriage, inferior forms of union have from time to time been recognized, and may be briefly noticed here. These have all but disappeared from modern society, depending as they do on matrimonial restrictions now obsolete.

The institution of slavery is a fruitful source of this kind of debased matrimony. In Roman law no slave could contract marriage whether with another slave or a free person. The union of male and female slaves (*contubernium*) was recognized for various purposes; a free woman entering into a union with a slave incurred under the S.C. Claudianum the forfeiture of her own liberty; but the bond-woman might be the concubine of a freeman. In the United States, where slavery was said to be regulated by the principle of the civil law, the marriage of slaves was so far recognized that on emancipation complete matrimony took effect and the children became legitimate without any new ceremony.

In Roman law no legal marriage could be contracted unless there was *connubium* between the parties. Originally there was no connubium between plebs and patricians, and in later times between the Latini and Peregrini, unless it had been expressly conferred. The Lex Julia et Papia Poppaea introduced restrictions depending on the condition of the parties which later legislation extended and perpetuated. Senators under that law were forbidden to marry freedwomen or women of inferior rank, and the husband of a freedwoman becoming a senator was set free from his marriage. In the canon law new restrictions were developed. The order of the clergy were forbidden to marry. And disparity of faith was recognized by the early church as a bar to matrimony, *e.g.*, between Christians and pagans and between orthodox and heretics. (See *Dictionary of Christian Antiquities,* art. "Marriage".)

Concubinage, which such restrictions tended to develop, is noticed under a separate heading. In the left-handed or "morganatic" marriages of the German royal families we have the nearest approach ever made by concubinage to true marriage, the children being legitimate, but neither they nor the wife acquiring any right to the rank or fortune of the husband. The marriage of persons of different religions frequently requires the intervention of the law as to the faith of the children, more particularly in Europe as between Roman Catholics and Protestants. English law gives the father, except under special circumstances, the right to dictate the faith of his children. (*See* Infant.) The practice on this point varies in Europe—the question being ignored in French law, Germany following in some parts the same rule as England, in others giving effect to ante-nuptial stipulations. In Ireland mixed marriages (*i.e.,* between Roman Catholic and Protestant) were by 19 Geo. II. c. 13 null and void if celebrated by a Roman Catholic priest. This act was repealed by 33 & 34 Vict. c. 110, which permits mixed marriages to be validly celebrated by an Episcopalian or Roman Catholic clergyman, subject to conditions set forth in s. 38.

Roman Law.—The three primitive modes of marriage were *confarreatio, coemptio in manum,* and *usus,* all of which had the effect of placing the woman in the "power" (*manus*) of her husband, and on the same footing as the children. The first was a religious ceremony before ten witnesses, in which an ox was sacrificed and a wheaten cake broken and divided between the spouses by the priest. *Coemptio* was a conveyance of the woman by *mancipatio,* and might be described as a fictitious sale *per aes et libram. Usus* was the acquisition of the wife by prescription, through her cohabiting with the husband for one year, without having been absent from his house three continuous nights. But a true marriage might be concluded without adopting any of these modes, which all fell into desuetude and with them the subjection of the wife to the *manus.* Marriage without *manus* was contracted by consent, without writing or formality of any kind. The restrictions as to age, relationship by consanguinity and affinity, previous marriage, etc., were in the main those which have continued to prevail in modern Europe with one important exception. The consent of the *paterfamilias* to the marriage of the children under his power was essential.

Canon Law.—The canon law of marriage is based partly on the Roman law, the validity of which the Church from the first recognized, partly on the Jewish law as modified by the new principles introduced by Christ and his apostles, developed by the fathers of the Church and mediaeval schoolmen, and regulated and defined by popes and councils. The most important of these principles was that of the indissolubility of marriage, proclaimed by Christ without qualification according to Mark x. 11, 12, and with the qualifying clause "saving for the cause of fornication" according to Matt. v. 32. This lofty view of marriage, according to which man and wife are made "one flesh" by the act of God ("What therefore God hath joined together, let no man put asunder," Mark x. 9) was, however, modified by the idea of the consummating act of marriage as in itself something unholy, a result of the Fall. Christ himself, indeed, did not teach this. It is to St. Paul that the idea of marriage as a sacrament is to be traced, in the mystic comparison of the relations of husband and wife to those of Christ and his Church. (Eph. v. 23–32.) Marriage, from being no more than a terminable civil contract, became a thing holy, a mystic union of souls and bodies never to be divided; valid, indeed, but not spiritually complete, without the public blessing of the Church (Tertullian, *Ad uxorem,* lib. ii. cap. 9); and from Augustine's time onward it was reckoned as a sacrament. But at the same time there was a tendency to restrict its rights and its range. So far as marriage was a physical union, this had for its object solely the perpetuation of the race and the avoidance of fornication; the most that was conceded was that the intention of having offspring not only made the conjugal act blameless, but even gave to the desire that inspired it an element of good. (Augustine, *de nupt. et conc.* 3.) But the ideal married life was that attributed to Mary and Joseph. Thus Augustine cited this as an example that a true marriage may exist where there is a mutual vow of chastity (*op. cit.* 12), and held that the sooner this relation was established the better. (*De bono conjug.* 22.) Marriage being then an inferior state, to be discouraged rather than the reverse, the tendency was rapidly to narrow the field within which it might be contracted. Remarriage (bigamy) was only allowed after many struggles, and then only to the laity; St. Paul had laid down that a "bishop" must be "the husband of one wife," and to this day the priests of the Orthodox Eastern Church may not remarry. Clerical celibacy, at first a counsel of perfection, was soon to become the rule of the Church, though it was long before it was universally enforced in the West; in the East it still applies only to monks, nuns and bishops. (*See* Celibacy.) The marriage of the laity was hampered by the creation of a number of impediments. The few and definite prohibitions of the Roman and of the Jewish law (Lev. xviii. 6–18; xx.) in the matter of marriage between kindred, were indefinitely extended; until in 506 the Council of Agde laid it down that any consanguinity or affinity whatever constituted an impediment. Moreover, man and wife being "one flesh," the Church exaggerated relationship by affinity into equal importance with that of consanguinity as an impediment to matrimony; and, finally, to all this added the impediments created by "spiritual affinity," *i.e.,* the relations established between baptizer and baptized, confirmer and confirmed, and between godparents, their godchildren, and their godchildren's relatives.

All this resulted in hopeless confusion and uncertainty, and it was early found necessary to modify it. Thus Pope Gregory I. limited the impediment to the 7th degree of relationship inclusive (civil computation) which was afterwards made the law of the empire by Charlemagne. Later still Innocent III., by a decree (4th Lateran Council), permitted marriages between a husband and the relations of his wife, and vice versa, beyond the 4th degree inclusive. (Canonical computation.) This remains the canonical rule of the Roman Catholic Church. Impediments due to spiritual affinity were limited by the Council of Trent to the relation of the baptizer and baptized; the baptizer and the parents of the baptized; the baptizer and the godfather and godmother; the godparents and the baptized and its parents: *i.e.,* a godfather may not marry the mother of the child he has held at the font, nor the godmother the father of such child.

In the fully developed canon law impediments to marriage are of two kinds, public and private; near relationship, for instance, is a public impediment, impotence and force are private impediments. Impediments are further divided into separating or merely suspensive; to the first class belongs, *e.g.,* a previous marriage not dissolved by death, which involves the nullification of the marriage even where through ignorance the crime of bigamy is not involved; to the second belongs the case of one or both of the contracting parties being under the age of puberty. Impediments, moreover, are absolute or relative; near relationship, for instance, is an absolute impediment, difference of religion between the parties a relative impediment. In addition to consanguinity and affinity, impuberty and existing marriage, the canon law lays down as public and absolute impediments to marriage the taking of holy orders and the vows of chastity made on entering any of the religious orders approved by the Holy See. In these impediments the canon law further distinguishes between those which are based on the law of nature (*jus naturae*) and those which are based on the law of the Church (*jus ecclesiae*). From impediments based on the law of nature, or of God, there is no power even in the pope to dispense; *e.g.,* marriage of father and daughter, brother and sister, or remarriage of husband or wife during the lifetime of the wife or husband of another marriage, which is held to be a violation of the very nature of marriage as an indissoluble union. From impediments arising out of the law of the Church dispensations are granted, more or less readily, either by the pope or by the bishop of the diocese in virtue of powers delegated by the pope. (*See* DISPENSATION.) Thus dispensations may be granted for marriage between persons related by consanguinity in any beyond the 2nd degree and not in the direct line of ascent or descent; *e.g.,* between uncle and niece (confined by the Council of Trent to the case of royal marriages for reasons of State) and between cousins-german, or in the case of marriage with a heretic. In this latter case a dispensation is now (*i.e.,* since the papal decrees *ne temere* of Aug. 2, 1907, which came into force at Easter 1908) only granted on condition that the parties are married by a Catholic bishop, or a priest accredited by him, that no religious ceremony shall take place except in a Catholic church, and that all the children shall be brought up in the Roman Catholic faith.

In the absence of any impediment a marriage is according to the canon law completed between baptized persons by the facts of consent and consummation; the principle is still maintained that the parties to the marriage, not the priest, are the "ministers of the sacrament." From the first, however, the Church, while recognizing the validity of private contracts, enjoined the addition of a public religious ceremony. (1 Tim. iv. 5.) Tertullian (*de pudicitia,* cap. iv.) says that clandestine marriages, not professed in the Church, were reckoned among Christians as all but fornication, and he speaks of the custom of seeking permission to marry from the bishop, priests and deacons. (*De monogamia,* cap. xi.) This latter precaution became increasingly necessary as impediments were multiplied, and Charlemagne, in a capitulary of 802, forbade the celebration of a marriage until "the bishops, priests and elders of the people" had made diligent inquiry into the question of the consanguinity of the parties. This was the origin of the publication of banns which, long customary in France, was made obligatory on the whole Church by Pope Innocent III. In the Eastern Church the primitive practice survives in the ceremonial blessing by the priest of the betrothal, as distinguished from the marriage ceremony. The ecclesiastical recognition of clandestine marriages, however, survived until the crying evil was remedied by a decree of the Council of Trent (Sess. xiv. *de matrim.*), which laid it down that for a valid marriage it was at least necessary that consent should be declared before a priest and in the presence of three witnesses.

Divorce, *i.e.,* the annulment of marriage for any cause but an impediment which makes the marriage *ipso facto* void, is unknown to the Roman Catholic Church. Separation *a vinculo matrimonii* is only possible under the canon law by a judicial decree of nullity (*annullatio matrimonii*), which implies, not the severing of the ties of a real marriage, but the solemn declaration that such marriage has never existed. There may, however, be a "separation from bed and board" (*a thoro et mensa*), even perpetual, which does not however give either party the right to remarry during the lifetime of the other. But, marriage not being regarded as a sacrament until consummated, it may be dissolved, if non-consummation be proved, by one or both parties taking the religious vows, or by papal dispensation. The Church claims exclusive control over marriage, and the Council of Trent anathematized the opinion held by Luther and other reformers, that it was properly a subject for the civil courts (*si quis dixerit causas matrimoniales non spectare ad judices ecclesiasticos anathema sit,* Sess. xxiv. cap. 2). This attitude became of extreme political importance when even in Catholic countries the codes established civil marriage as the only legally binding form.

England.—Marriage may be the subject of an ordinary contract on which an action may be brought by either party. It is not necessary that the promise should be in writing, or that any particular time should be named. Contracts in restraint of marriage, *i.e.,* whose object is to prevent a person from marrying anybody whatever, are void, as are also contracts undertaking for reward to procure a marriage between two persons. These latter are termed marriage brocage contracts.

Any man and woman are capable of marrying, subject to certain disabilities, some of which are said to be canonical as having been formerly under the cognisance of the ecclesiastical courts, others civil. The effect of a canonical disability as such was to make the marriage not void but voidable. The marriage must be set aside by regular process, and sentence pronounced during the lifetime of the parties. Impotence at the time of the marriage is a canonical disability. So was relationship within the prohibited degrees, which has been made an absolute avoidance of marriage by the Marriage Act 1835. Civil disabilities are (1) the fact that either party is already married and has a spouse still living (a decree *nisi* does not enable the parties to marry until it is made absolute); (2) the fact that either person is a party of unsound mind; (3) want of full age which, after remaining for centuries as in the Roman Law, viz., males 14, females 12, was, by the Age of Marriage Act, 1929, fixed at 16 for both sexes; (4) relationship within the prohibited degrees.

The statute which lawyers regard as establishing the rule on this last point is the 32 Hen. VIII. c. 38 (repealed in part by 2 & 3 Edw. VI. c. 23, in whole by 1 & 2 P. and M. c. 8, but revived by 1 Eliz. c. 1, and so left as under the act of Edward), which enacts that "no prohibition, God's law except, shall trouble or impeach any marriage without the Levitical degrees." The forbidden marriages, as more particularly specified in previous statutes, are those between persons in the ascending and descending line *in infinitum,* and those between collaterals to the third degree inclusive, according to the computation of the civil law. The prohibitions extend not only to *consanguinei* (related by blood) but to *affines* (related by marriage), now altered so far as a deceased wife's sister is concerned. (*See* p. 947.) The act of

1835 enacted that "all marriages which shall hereafter be celebrated between persons within the prohibited degrees of consanguinity or affinity shall be absolutely null and void to all intents and purposes whatsoever." They had previously been only voidable. The act at the same time legalized marriages within the prohibited degrees of affinity (but not consanguinity) actually celebrated before Aug. 31, 1835.

For many years an active and ceaseless agitation was carried on on behalf of the legalization in England of marriage with a deceased wife's sister. In all the self-governing colonies, with the exception of Newfoundland, the restriction had ceased to exist. The first act legalizing marriage with a deceased wife's sister was adopted by South Australia. The royal assent, however, was not given till the parliament of that state had five times passed the bill. In quick succession similar statutes followed in Victoria, Tasmania, New South Wales, Queensland, New Zealand, West Australia, Barbados, Canada, Mauritius, Natal and Cape Colony. As regards the Channel Islands, marriages of the kind in question were made legal in 1899, and in 1907 in the Isle of Man. In England, the bill to render marriage with a deceased wife's sister valid was first adopted by the House of Commons in 1850, and only became law by the Deceased Wife's Sister Marriage Act 1907. The act contains a proviso justifying clergymen in refusing to solemnize marriages with a deceased wife's sister, and it preserves the peculiar status of the wife's sister under the Matrimonial Causes Act 1857, under which adultery with her by the husband is incestuous adultery.

The celebration of marriages is now regulated wholly by statutory legislation. A complete list of the acts regulating the solemnization of marriage or confirming marriages, which through some defect might be void, will be found in Phillimore's *Ecclesiastical Law,* 2nd ed. (1895). The most important acts in force are the Marriage Acts 1823, 1836, 1886 and 1898. The first of these regulates marriages within the Church of England, but was intended to be of universal application, Jews and Quakers only being excepted by sec. 31. It requires either the previous publication of banns, or a licence from the proper ecclesiastical authority. As to banns, the rule of the rubric, so far as not altered by the statute, is required to be observed. They must be published on three successive Sundays at morning service after the second lesson, in the church of the parish in which the parties dwell; the bishop may, however, authorize the publication of banns in a public chapel. Seven days' notice must be given to the clergyman of the names of the parties, their place of abode, and the time during which they have lived there. If either party is under age, the dissent of the parents or guardians expressed at the time of publication of banns renders such publication null and void. Licence in lieu of banns may only be granted by the archbishop, bishop or other authority, for the solemnization of a marriage within the church of the parish in which one of the parties shall have resided for 15 days before. Before a licence can be granted an oath must be taken as to the fact of residence and that the necessary consent has been obtained in the case of persons under age. The father, or lawful guardian, is the proper person to consent to the marriage of a minor, and the place of any such person incapacitated mentally is taken by the lord chancellor. The absence of such consent does not, however, avoid a marriage once solemnized. But if persons wilfully intermarry (unless by special licence) in a place not being a church or public chapel, or without due publication of banns or proper licence, or before a person not in holy orders, the marriage is null and void to all purposes. Marriage must be celebrated within three months after banns or licence, and between the hours of eight in the morning and six in the afternoon.

For the relief of the great body of Dissenters the act of 1836 was passed. It permits marriage to be solemnized in two additional ways—viz., (1) by certificate of the superintendent registrar of a district without licence, and (2) by such certificate with licence. In the first case, notice must be given to the registrar of the district or districts within which the parties have resided for seven days previous, which notice is inscribed in a marriage-notice book, open to public inspection at all reasonable times, and thereafter suspended for 21 days in some conspicuous place in the registrar's office. Any person whose consent is necessary to an ecclesiastical licence may forbid the issue of a certificate, but in default of such prohibition the certificate will issue at the end of the 21 days. The marriage may then take place on any day within three months of the entry of notice, and in one of the following ways: (1) in a certified place of religious worship, registered for the solemnization of marriage; in that case a registrar of the district with two witnesses must be present, and the ceremony must include a mutual declaration of assent by the parties and a disavowal of any impediment; (2) at the superintendent registrar's office, with the same declaration, but with no religious service; (3) in a church according to the usual form, the consent of the minister thereof having been previously obtained; (4) according to the usages of Jews and Quakers. The place of marriage in all cases must have been specified in the notice and certificate.

In the second case, when it is desired to proceed by licence, notice must be given to the registrar of the district in which one of the persons resides, together with a declaration that he or she has resided for 15 days therein, that there is no impediment, and that the necessary consents if any have been obtained. The notice is not exhibited in the registrar's office, and the certificate may be obtained at the expiration of one whole day after entry, together with the licence. No registrar's licence can be granted for a marriage in church or according to the forms of the Church of England—the ecclesiastical authorities retaining their jurisdiction in that respect. It is also provided that in the case of persons wilfully intermarrying in a place other than that mentioned in the notice and certificate, or without notice or certificate, etc., the marriage shall be null and void. The various rules as to consent of parents, etc., to the marriages of minors are regulations of procedure only. The absence of the necessary consent is not a disability invalidating a marriage actually solemnized.

The Act 26 Geo. II. c. 33, commonly known as Lord Hardwicke's Act, which forbids the solemnization of marriage without banns or licence, also enacts that "in no case whatsoever shall any suit or proceeding be had in any ecclesiastical court in order to compel a celebration *in facie ecclesiae,* by reason of any contract of matrimony whatsoever whether *per verba de presenti* or *per verba de futuro.*" Blackstone observes that previous to this act "any contract made *per verba de presenti,* or in words of the present tense, and in case of cohabitation *per verba de futuro* also, was deemed valid marriage to many purposes; and the parties might be compelled in the spiritual courts to celebrate it *in facie ecclesiae.*"

Royal marriages in England have been subject to special laws. The Royal Marriage Act of 1772 (12 Geo. III. c. 11), passed in consequence of the marriages of the dukes of Cumberland and Gloucester, enacted that "no descendant of his late majesty George II. (other than the issue of princesses married or who may marry into foreign families) shall be capable of contracting matrimony without the previous consent of his majesty, his heirs and successors, signified under the Great Seal. But in case any descendant of George II., being above 25 years old, shall persist to contract a marriage disapproved of by his majesty, such descendant, after giving 12 months' notice to the privy council, may contract such marriage, and the same may be duly solemnized without the consent of his majesty, etc., and shall be good except both Houses of Parliament shall declare their disapprobation thereto."

In 1886 an act was passed in the British parliament to remove doubts which had been entertained as to the validity of certain marriages solemnized in England when one of the parties was resident in Scotland. The Summary Jurisdiction (Married Women) Act of 1895 enabled a wife whose husband is convicted of an assault on her, or who has been deserted by him, or been obliged owing to his cruelty to live apart from him, to apply to the justices, who are empowered by the act to make an order for separation and for payment by the husband to his wife of such weekly sum, not exceeding two pounds, as they may consider reasonable. The Marriage Act 1898 authorized the celebration of marriages in places of worship duly registered for the solemnization of marriages under the Marriage Act of 1836 without the presence of the registrar, on condition of their being solemnized in the presence of a person duly authorized by the governing body of the place of worship in question. It also made further provision for the due recording of all marriages in the general registers. The Marriages Validity Act of 1899 removed doubts as to the validity of marriages in England on Irish banns and in Ireland on English banns. Lastly, the Marriage with Foreigners Act 1906 enabled a British subject desirous of marrying a foreigner in a foreign country to comply with the foreign law by obtaining from a registrar a certificate that no legal impediment to the marriage has been shown. Similar certificates, by arrangement between His Majesty and foreign countries, are issued in the case of a foreigner desirous of marrying a British subject in Great Britain.

The Foreign Marriage Act 1892 has consolidated the English law relating to marriages celebrated abroad, and brings it into harmony with the current tendencies of marriage law reform generally. Under it a marriage between British subjects abroad is as valid as a marriage duly solemnized in England (as heretofore), if celebrated in accordance with the local law or in the presence of diplomatic or consular agents who are appointed to act as "marriage officers." The old fiction of assimilation of a British embassy to British soil can no longer be relied upon to uphold a marriage at a British embassy solemnized by an ordained clergyman. An order in Council of Oct. 28, 1892, moreover, provides that in the case of any marriage under the act, if it appears to the marriage officer that the woman about to be married is a British subject, and that the man is an alien, he must be satisfied that the marriage will be recognized by the law of the foreign country to which the alien belongs.

A marriage may be solemnized on board one of His Majesty's ships at a foreign station, provided a warrant of a secretary of State has authorized the commanding officer to be a marriage officer. At sea, marriages on British public or private ships seem still valid at common law, if performed by an episcopally ordained minister. The Merchant Shipping Act 1894 (s. 240) provides that the master of a ship for which an official log is required shall enter in it every marriage taking place on board, with the names and ages of the parties.

Again, under the Foreign Marriage Act all marriages solemnized within the British lines by a chaplain or officer or other person officiating under the orders of the commanding officer of a British army serving abroad, are as valid in law as if they had been solemnized in Great Britain subject to due observance of all forms required by law. The Naval Marriages Act 1908 authorizes, for the purpose of marriages in Great Britain, the publication of banns and the issue of certificates on board His Majesty's ships in certain cases, or when one of the parties to a marriage intended to be solemnized in Great Britain is an officer, seaman or marine, borne on the books of one of His Majesty's ships at sea.

The principle of the English law of marriage, that a marriage contracted abroad is valid if it has been solemnized according to the *lex loci,* may be now taken to apply just as much to a marriage in a heathen as in a Christian country. Whether the marriage has or has not been celebrated according to Christian laws has no bearing upon the question, providing it is a monogamous marriage —a marriage which prevents the man who enters into it from marrying any other woman while his wife continues alive.

Scotland.—The chief point of distinction, as compared with English law, is the recognition of irregular marriages. (1) "A public or regular marriage," says Fraser, "is one celebrated, after due proclamation of banns, by a minister of religion; and it may be celebrated either in a church or in a private house, and on any day of the week at any hour of the day." The ministers of the National Church at first alone could perform the ceremony; but the privilege was extended to Episcopalians by 10 Anne c. 7 (1711), and to other ministers by 4 and 5 Will. IV. c. 28 (1834). (2) A marriage may also "be constituted by declarations made by the man and the woman that they *presently* do take each other for husband and wife." These declarations "may be emitted on any day at any time and without the presence of witnesses," and either by writing or orally or by signs, and in any form which is clearly expressive of intention. Such a marriage is as effectual to all intents and purposes as a public marriage. The children of it would be legitimate; and the parties to it would have all the rights in the property of each other, given by the law of Scotland to husband and wife. (3) A promise followed by *copula* does not constitute marriage, unless followed either by solemnization *in facie ecclesiae* or declarator. Lord Moncreiff's opinion in the case of *Brown* v. *Burns* is admitted to be good law, viz. that declarator is essential to the constitution of a marriage of this kind, so that, if no such declarator be brought in the lifetime of both parties, the marriage can never be established afterwards. The *copula* is presumed to have reference to the promise, but evidence may be adduced to show that such was not the case.

By the Marriage (Scotland) Act 1856 it is enacted that no *irregular* marriage shall be valid in Scotland, unless one of the parties has lived in Scotland for the 21 days next preceding the marriage, or has his or her usual residence there at the time. "Habit and repute" has sometimes been spoken of as constituting marriage in the law of Scotland, but it is more correctly described as evidence from which marriage may be inferred. The repute must be the general, constant, and unvarying belief of friends and neighbours, not merely the controverted opinion of a section of them. The cohabitation must be in Scotland, but in one case proof of cohabitation in another country was allowed, as tending to throw light on the nature of the cohabitation in Scotland. The consent of parents is not necessary to the validity of the marriage, even of minors, but marriage under the age of puberty with or without such consent is void.

United States.—The absence of ecclesiastical courts has suggested difficulties as to the extent to which the law of England on this subject continued to prevail after the revolution. Bishop holds it to be the universal fact running through all the cases that everywhere in the country the English decisions on marriage and divorce are referred to with the same apparent deference which is shown on other subjects to the decisions of the English common law and equity tribunals. The same author observes that "all our marriage and divorce laws, and of course all our statutes on the subject, in so far as they pertain to localities embraced within the limits of particular States, are State laws and State statutes, the national power with us not having legislative or judicial cognizance of the matter within those localities." Some of the States have extended the ages below which marriage cannot take place. The common law of the States is assumed to be that "a contract *per verba de presenti,* or *per verba de futuro cum copula,* constitutes a complete marriage." Conditions, however, may be imposed by the various State legislatures, and as to these the rule has established itself in American jurisprudence that "a marriage good at common law is good notwithstanding the existence of any statute on the subject, unless the statute contains express words of nullity." Thus in Pennsylvania, where a statute provided that all marriages "should be solemnized before 12 witnesses," marriages not so celebrated were nevertheless held to be good. In New Hampshire justices and ministers of the gospel are authorized to solemnize marriage, and all other persons are forbidden to do so under penalties; yet a marriage by consent, as at common law, without justice or minister, has been held valid. On the other hand, under a very similar statute in Massachusetts, it was held that "parties could not solemnize their own marriage," and that a marriage by mutual agreement, not in accordance with the statute, was void. Bishop regards this as an isolated exception to the general course of the decisions. So when State legislation requires any particular form to be used the want thereof only invalidates the act if the statute expressly so enacts. Many of the State codes inflict penalties on ministers or justices for celebrating the marriage of minors without the consent of the parents or guardians. The original law as to prohibited degrees has been considerably modified in the States. The prohibition of marriage with a deceased wife's sister has been abolished in the United States. But New Hampshire, Ohio, Indiana, Kansas, Arkansas, Nevada, Washington, the Dakotas and Montana have for long forbidden marriages between first cousins by blood, and Louisiana, Oregon, Pennsylvania, Michigan, Nebraska, Utah and Wisconsin have since adopted the same principle. Virginia prohibits the marriage of a woman with the husband of her brother's or sister's daughter.

Attention is also being paid to the question of marriage from a physical point of view. New Jersey prohibits the marriage of any person who has been confined in any public asylum as an epileptic, insane or feeble-minded patient, without a medical certificate from two physicians of complete recovery, and that there is no probability of the transmission of such defects. This prohibits the granting of a marriage licence where either party is an habitual drunkard, epileptic, imbecile or insane, or where the applicant at the time of making application is under the influence of any intoxicant or narcotic drug. In Michigan, Minnesota, Kansas, New Hampshire and Oregon, marriage is prohibited to epileptics, etc., except when the woman is over 45. In Michigan, also, marriage is forbidden to anyone who has suffered from a venereal disease and has not been cured. The equality of property rights between husband and wife is fully established in America. Indeed, in many States the movement has gone so far as to give the wife in matters of property and in reference to divorce greater privileges than the husband. Thus a husband is often liable for a wife's debts where a wife would not be, *mutatis mutandis,* for a husband's; and a wife may usually obtain a decree of divorce for any ground on which one may be awarded to the husband, and, in addition, for neglect to provide sustenance or support. Emphasis on the personal or moral relation of the parties in marriage tends to throw into the background the legal aspects and requirements; and it tends also to minimize, so far as the State is concerned, the religious and sacramental aspect of marriage. Marriage tends to become a relation established by parties between themselves, and one in which the consent of the parties becomes the only constitutive element. In the theory of American law no ceremony is essential to create the marriage relation. But this position has never been endorsed by any considerable proportion of the community, and in fact probably $\frac{9}{10}$ and perhaps $\frac{99}{100}$ of the marriages in the United States are contracted through some ceremony.

Other Countries.—In France, articles 144–226 of the Code Napoléon, as amended by an act of 1907, prescribe the qualifications and conditions of marriage. The man must be 18 and the woman 15 years of age. A son and daughter under 21 cannot marry without consent of the father and mother, or of the father only if they disagree, or of the survivor if one be dead. If both are dead grandfather and grandmother take their place. Between the ages of 21 and 30 the parties must still obtain the consent of their parents, but if this be refused it can be regulated by means of a "respectful and formal act" before a notary. If the consent is not given within 30 days the marriage may take place without it. If neither parents nor grandparents be alive, parties under 21 require the consent of the family council. These rules apply to natural children when affiliated; those not affiliated require the consent of a specially appointed guardian. Marriage is prohibited between all ascendants and descendants in the direct line, and between persons related by marriage in the same line, between brother and sister, between uncle and niece, and brother-in-law and sister-in-law. Before the solemnization of marriage banns are required to be published for a period of ten days, which must include two Sundays, containing the names, occupations, and domiciles of the parties and their parents. There must be an interval of three days before the marriage can take place, and if a year is allowed to elapse fresh banns must be put up. On the day appointed by the parties, and in the parish to which one of them belongs, the marriage is celebrated by the civil officer or registrar reading over to them the various necessary documents, with the chapter of the code relating to husband and wife, receiving from each a declaration that they take each other for husband and wife, and drawing up the act of marriage. All this has to be done in the presence of four witnesses. Marriages contracted abroad between French subjects or between French subjects and foreigners are valid in France if celebrated according to the forms of the foreign law, provided the French conditions as to consent of parents have been observed. (*See* also Marriage with Foreigners Act, *supra.*)

The code of 1900 lays down rules applicable to the celebration of all marriages in Germany. Civil marriage alone is recognized by the code. It is effected by the declaration of the parties before a registrar in the presence of each other of their intention to be married. Two witnesses of full age must be present. The registrar asks each of the parties whether he or she will marry the other, and on their answer in the affirmative declares them duly married and enters the marriage in the register. The marriage must be preceded by a public notice. Marriages are void between descendants and ascendants; relatives by marriage in the ascending or descending line; brother and sister of the whole or half blood.

In the great majority of the other European countries civil marriage is obligatory. In Roman Catholic countries the parties usually supplement the obligatory civil marriage by a religious ceremony, more especially since the papal decree *Ne temere* of Aug. 2, 1907 (which came into force at Easter 1908), which requires marriages between Roman Catholics, or between Roman Catholics and those not professing that faith, to be celebrated before a bishop or priest duly authorized for the celebration thereof.

MARRIAGE-RATE. In its most usual form, the marriage-rate is expressed as the number of marriages occurring in a community during a calendar year per thousand of total population living in the community in that year. For example, it is estimated that there were 1,426,000 marriages in the United States during 1937. Since the total population for that year was 129,-257,000, the number of marriages per thousand of population was 11·0. This rate would be doubled if the number of persons marrying, instead of the number of marriages, were related to the total population. By expressing annual marriages of communities in terms of a common unit, namely per thousand of population, it is possible to make comparisons between communities of different size, or in the same community over different periods of years. However, the marriage-rate computed in this way is not entirely satisfactory as a measure for comparison. Thus two communities may differ in their marriage-rates simply because one of them happens to have a larger proportion of its total population within the marriageable ages than the other. Even if two communities had the same proportion of their total populations at the marriageable ages, the marriage-rates computed in the manner indicated above might differ markedly if one of them should have a greater proportion of single, widowed, or divorced marriageable persons than the other. Furthermore, the marriage-rates are influenced by the ratio of the number of marriageable men to the number of marriageable women in the community. Obviously, if a community had very few marriageable men, the marriage-rate would be very low. For these reasons, marriage-rates have, on occasion, been computed on bases other than total population, such as total population at ages 15 and over, single population at ages 15 and over, and total females comprised within the ages from 15 to 45 years. Unfortunately, these more refined bases are not in common use and it therefore becomes necessary to make some mental allowance for the foregoing factors in comparing marriage-rates based upon total population.

International Comparisons.—The marriage-rate for the United States is high as compared to that for most other countries of the world for which records are available. None of the European countries had marriage-rates as high as that of the United States, where the rate was 10·7 per 1,000 in 1935–37. The closest approaches were made by Denmark, Germany and Rumania, all with rates over 9 per 1,000 during 1936–38. The next three European countries in order of approach were Austria, England and Wales, and Sweden, with marriage-rates per 1,000 of 8·8, 8·7, and 8·7 respectively.

Of the European countries listed in Table I, Eire had the lowest marriage-rate of all, namely 5·0 per 1,000 during 1936–38. The marriage-rate for Eire was exceeded, in order, by those of Greece, Portugal, Spain, France and Northern Ireland, all of which had rates below 7 per 1,000. The marriage-rate in the United States was barely surpassed by that for white persons in the Union of South Africa, where the rate was 10·8 per 1,000 in the period 1935–36, but it was substantially under that for Egypt, with a rate of 13·5 per 1,000 during 1935–37.

Trend.—The marriage-rates for the United States, England and Wales, and the countries of continental Europe do not show the marked trends toward lower levels exhibited in their birth-rates and death-rates. In fact, the marriage-rate is a relatively stable figure, and notable variations from the usual marriage-rates for each country appear only during great wars or in periods of economic depression.

The United States, in the years since 1901, has had a comparatively stable marriage-rate with figures usually not varying far from 10 per 1,000. (See Table II). The level of the marriage-rates in England and Wales during the period from 1851 to the outbreak of war in 1914 was not appreciably below that for the years since 1921, when they fluctuated around 8 per 1,000. In France there appears to be a downward tendency in the marriage-rate. Whereas the rate in that country was at an average not far under 8 per 1,000 from 1851 to the outbreak of the 1914 war—during which it fell sharply—the resurgence in the rate during the post-war years up to 1930 thereafter gave way to a period of decline which reached a low point of 6·5 per 1,000 in 1938.

The marriage-rate in Germany in the post-war years since 1919 lies, on the whole, at a higher level than it did during the pre-war period from 1851 to 1913. With the advent of the National Socialist regime in 1933, the downward movement in the marriage-rate in Germany of the late '20s was halted and a higher level was then established by active measures to stimulate marriage. In Sweden, marriage-rates have been moving consistently upward in the post-war years since 1921 to a level appreciably higher than during the pre-war years. On the other hand, the marriage-rate in Italy appears to be easing downward since 1921. However, its level in the years 1936–38 was not far different from that during the period 1871 to 1913.

Factors Influencing the Marriage-Rate.—1. *War.*—The outbreak of war in 1914 initiated precipitous declines in the marriage-rates for France and Germany. In France, the rate fell from a pre-war average of 7·7 per 1,000 in 1911–13 to a low point of 2·3 in 1915. The experience of Germany was not quite as bad; from a level of 7·8 per 1,000 in 1911–13, the rate fell to 4·1 in 1915 and 1916. The entrance of Italy into the war in 1915 was signalized by a fall in the marriage-rate to 5·1 per 1,000 for that year from a rate of 7·0 for the previous year. The low point in Italy's marriage-rate during the war, 2·7 per 1,000, was reached in 1917. The situation in England and Wales and in the United States was not as severe as in the other countries. The marriage-rate in England and Wales actually rose from a pre-war level of about 8 per 1,000, extending as far back as 1881, to a high point of 9·7 in 1915, before it fell to its low of 6·9 in 1917. In the United States during the war period, the marriage-rate was at its minimum in 1918. In the immediate years following the close of hostilities in 1918, the marriage-rates rose sharply in the warring countries to peaks in 1920, a situation arising from an accumulation of several years of postponed marriages.

TABLE I.—*Average Annual Marriages per 1,000 Total Population in Certain Countries for the Period 1936 to 1938*

Country	Marriages per 1,000 1936 to 1938	Country	Marriages per 1,000 1936 to 1938

2. *Business.*—A study of American marriage-rates for a group of industrial States (Connecticut, Massachusetts, Michigan and Rhode Island, and the city of New York), in relation to an index of business failures, for the period from 1868 to 1935, established a remarkably close correspondence between the two series. The years of economic depression—1878, 1884, 1893, 1896, 1907–08, 1921–22, and 1932—were also years of low marriage-rates. The phenomenon noted for this group of States has also been observed in other countries.

3. *Social Factors.*—Several European countries have introduced measures to stimulate the marriage-rate in an effort to stem the rapid decline in birth-rates which they have been experiencing. These measures are usually in the form of marriage loans, extra taxes on bachelors, and preferential employment to married men. A factor of some importance in influencing the marriage-rate in the United States is the high divorce rate. Remarriages following divorce bolster the marriage-rate, but do not increase the proportion of married persons in the population.

In practically all countries there is a marked seasonal incidence in the marriage-rate. In the United States and Canada, June is the predominant month. The fall seems to be preferred by agricultural countries. Greek Orthodox countries prefer February, before Lent, while Roman Catholic countries have high marriage-rates in April, after Lent. The influencing factors in the seasonal distribution of marriages seem to be climate, religious customs, and occupation.

Marriage-Rate and Birth-Rate.—An examination of data for New York State from 1919 to 1937 showed that, in any three-year period, an increase in the marriage-rate from the first year to the second was followed, in turn, by an increase in the birth-rate of first children from the second year to the third year. Similarly, a decrease in the marriage-rate was followed by a corresponding decrease in the birth-rate of first children. This correspondence is not usually found when birth-rates in which all children are included are compared with marriage-rates. (A. J. Lo.)

MARRUCINI, an ancient tribe which occupied a small strip of territory round about Teate (mod. Chieti), on the east coast of Italy. It is first mentioned in history as a member of a confederacy with which the Romans came into conflict in the second Samnite War, 325 B.C., and it entered the Roman Alliance as a separate unit at the end of that war (*see* PAELIGNI). The language of the Marrucini is known from an inscription called the "Bronze of Rapino," which belongs to about the middle of the 3rd century B.C. It is written in Latin alphabet, but in a dialect which belongs to the North Oscan group (*see* PAELIGNI). The name of the city or tribe which it gives us is *touta marouca,* and it mentions also a citadel with the epithet *tarincris.* Several of its linguistic features, both in vocabulary and in syntax, are of considerable interest. The earliest Latin inscriptions are of Ciceronian date.

The form of the name shows the suffix -NO- superimposed upon the suffix -CO-, a change which probably indicates some conquest of an earlier tribe by the invading Safini (or Sabini, *q.v.*).

For further details as to Marrucini inscriptions and place-names *see* R. S. Conway, *The Italic Dialects,* p. 253 *et seq.*

MARRYAT, FREDERICK (1792–1848), English sailor and novelist, born at Westminster on July 10, 1792, was the grandson of Thomas Marryat (physician, author of *The Philosophy of Masons,* and writer of verse), and son of Joseph Marryat, agent for the island of Grenada, who wrote pamphlets in defence of the Slave Trade. Young Marryat ran away to sea more than once; at 14 he entered the navy. He served with great distinction in many parts of the world until his retirement in 1830.

Marryat brought ripe experience and unimpaired vivacity to his work when he began to write novels. *Frank Mildmay, or the Naval Officer,* was published in 1829, and *The King's Own* followed in 1830. The freshness of the new field which was opened up to the imagination—so full of vivid lights and shadows, light-hearted fun, grinding hardship, stirring adventure, heroic action, warm friendships, bitter hatreds—was in exhilarating contrast to the world of the historical romancer and the fashionable novelist. Moreover Marryat had an admirable gift of lucid, direct narrative, and an unfailing fund of incident, and of humour, sometimes bordering on farce. Of all his portraits of adventurous sailors, "Gentleman Chucks" in *Peter Simple* and "Equality Jack" in *Mr. Midshipman Easy* are the most famous, but he created many other types which take rank among the characteristic figures in English fiction. He went on, through a quick succession of tales, *Newton Forster* (1832), *Peter Simple* (1834), *Jacob Faithful* (1834), *The Pacha of Many Tales* (1835), *Japhet in Search of a Father* (1836), *Mr. Midshipman Easy* (1836), *The Pirate and the Three Cutters* (1836), till he reached his high-water mark of constructive skill in *Snarley-yow, or the Dog Fiend* (1837). The best of his books after this date are those written expressly for boys, the especial favourites being *Masterman Ready* (1841); *Percival Keene* (1842); *Monsieur Violet* (1842); *The Settlers in Canada* (1844), and *The Children of the New Forest* (1847). Among his other works are *The Phantom Ship* (1839); *A Diary in America* (1839); *Olla Podrida* (1840), a collection of various papers; *Poor Jack* (1840); *Joseph Rushbrook* (1841); *Privateer's Man* (1844); *The Mission, or Scenes in Africa* (1845); *The Little Savage* (1848–49), published posthumously; and *Valerie,* not completed (1849). His novels form an important link between Smollett and Fielding and Charles Dickens.

Captain Marryat had retired from the naval service in 1830, becoming equerry to the duke of Sussex. He edited the *Metropolitan Magazine* from 1832 to 1835, and some of his best stories appeared in that paper. He spent a great part of his time in Brussels. He visited Canada during Papineau's revolt and the United States in 1837, and gave a disparaging account of American institutions in a *Diary* published on his return to England. In 1843 he settled at Langham Manor, Norfolk. He indulged in costly experiments in farming, so that in spite of the large income earned by his books he was not a rich man. He died at Langham on Aug. 9, 1848, his death being hastened by news of the loss of his son by shipwreck.

His daughter, Florence Marryat, herself a novelist, published his *Life and Letters* in 1872. *See* also David Hannay, *Life of Marryat* (1889).

MARS, MLLE. [ANNE FRANÇOISE HYPPOLYTE BOUTET] (1779–1847), French actress, was born in Paris on Feb. 9, 1779, the natural daughter of the actor-author named Monvel (*q.v.*), and Mlle. Mars Salvetat. In 1799, after the rehabilitation of the Comédie Française, she and her sister (Mars *aînée*) joined that company in which she remained for 33 years. She was incomparable in *ingénue* parts, and equally charming as the coquette; she was for many years the darling of Parisian audiences and a favourite with Napoleon I. She retired in 1841; she was then inspectress of dramatic studies at the Conservatoire. She died in Paris on March 20, 1847.

See R. de Beauvoir, *Mémoires de Mlle. Mars,* 2 vols. (1849), and *Confidences de Mlle. Mars,* 3 vols. (1855).

MARS (MAVORS, MARMAR, MARSPITER or MASPITER), after Jupiter the most important deity of the Roman state, and never so much affected by foreign influences as to lose his essentially Roman and Italian character. Traces of his worship are found in all parts of central and southern Italy, and in several communities, as we learn from Ovid (*Fasti,* 3. 93 *seq.*), he gave his name to a month, as at Rome to the first month of the old Roman year. We know little of the character of his cult except at Rome, and even at Rome it has been variously interpreted. In historical times his chief function at Rome was to protect the state in war; it is as a god of war that he is known to all readers of Roman literature,[1] and Wissowa holds this to have been his original and only function.

Until the time of Augustus Mars had but two temples at Rome. One of these was originally only an altar; it was in the Campus Martius, the exercising ground of the army. The other was outside the Porta Capena: here each year the Equites met in order to start in procession through the city (*Dion. Hal.* 6. 13). Each of these sites was outside the *pomerium,* and this has been explained to mean that the war-god "must be kept at a distance" (Carter, *Religion of Numa,* p. 19). But in the heart of the city there was a *sacrarium* of Mars in the *regia,* originally the king's house, in which the sacred spears of Mars were kept, or rather, Mars in spear form (*Mars Hasta*); for on the outbreak of war the consul had to shake these spears, saying as he did it, *Mars vigila* ("Mars, wake up!"). If the spears moved of themselves, the omen was bad and called for expiation. The *ancilia,* or sacred shields, also formed part of this symbolic armoury of the Roman state: they were carried in procession by the Salii (*q.v.*), or dancing warrior-priests of Mars on several occasions during the month of March up to the 23rd (*tubilustrium*), when the military trumpets (*tubae*) were lustrated; and again in October to the 19th (*armilustrium*), when both the *ancilia* and the arms of the exercitus were purified and put away for the winter. During the four months of the Italian winter the worship of Mars seems at a standstill; his activity is all in the warm season, *i.e.,* in the season of warfare. It is only at the end of February that we find indications of the coming Mars-cult; Quirinalia, Feb. 17 (Quirinus closely resembled Mars); first Equirria, Feb. 27. This, like the second Equirria (Mar. 14) was no doubt a rite intended to benefit the war-horses accompanied with sacrifice to Mars, preparatory to the opening of the season of arms.

There is thus abundant evidence that Mars was always a deity especially connected with warfare; and it is hardly necessary to add proof of a less convincing kind, *e.g.,* that Nerio, his feminine cult-partner, seems to be etymologically "the strong one," or that he is in legend the father of Romulus, the warlike king and founder of the Roman army. In founding his famous temple of Mars Ultor (the avenger of Caesar) in the Forum Augusti, Augustus gave a new turn to this worship, and for a time it seems to have been a rival of that of the Capitoline Jupiter (*see* Carter, *Religion of Numa,* p. 174 *seq.*), and by about A.D. 250 Mars became the most prominent of the *di militares* worshipped by the Roman Legions.

There are, however, certain features in the Mars cult which

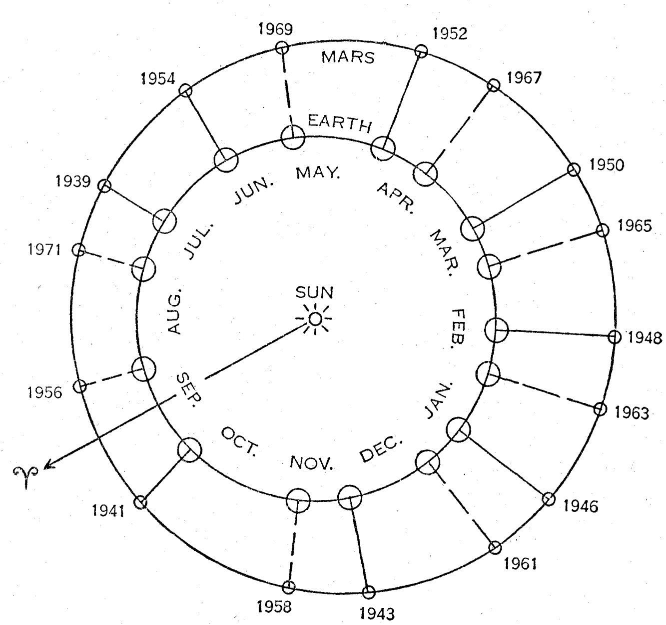
[1]Mars-*bellum* by metonymy; but this could be explained as a Hellenism.

make it probable that this god was in early times, at least, also associated with agriculture; and this is in harmony with the facts: (1) that the season of arms is also the season of the growth, ripening and harvesting of the crops; (2) that the early Roman community was an agricultural as well as a military one, as is indicated in its religious calendar (Fowler, *Roman Festivals,* p. 334). Thus Mars was invoked in the ancient hymn of the Arval Brothers, whose religious duties had as their object to keep off enemies of all kinds from crops and herds (Henzen, *Acta Fratr. Arv.* p. 26), and his association here with the Lares (*q.v.*) proves that he is not regarded as a war-god who could avert the raid of an enemy. Still more striking is the invocation of Mars (with the cult-title Silvanus) in the yearly lustration of his land by the Roman farmer (Cato, *De agric.* 141), where Mars's help is besought against disease and famine, not war. Three times the procession went round the land, reciting prayers and driving the victims to be sacrificed, viz., pig, sheep and ox (*suovetaurilia*), representing the farmer's most valuable stock. We can hardly doubt that in the state ceremony of the Ambarvalia, *i.e.,* the *lustratio* of the ager Romanus in its earliest form, the same god was invoked and the same ritual used (Fowler, *op cit.* p. 124 *seq.*). Again in the curious ritual of the sacrifice to Mars of the October horse (Oct. 15: Fowler *op. cit.* 241), though the animal was undoubtedly a war-horse, the head was cut off and decked with cakes, as we are told (Paul. Diac. 220) *ob frugum eventum.* Quirinus also is not without an association with agricultural perils, for it was his *flamen* who sacrificed the victims at the Robigalia on April 25, when the spirit of the mildew (Robigus) was invoked to spare the corn (Ovid, *Fasti,* 4. 901 *seq.*).[1]

The most reasonable conclusion seems to be that Mars, whatever his ultimate origin, became early a "high god" of the Italic peoples, and hence reflects their activities (1) in clearing forests (Mars Silvanus; *cp.* the fact that wolves and woodpeckers are sacred to him), (2) in agriculture, (3) in war.

See Roscher in *Myth. Lex. s.v.,* (bibl.); W. Warde Fowler, *Roman Festivals* (1908) and *Religious Experience* (1911); Wissowa, *Religion und Kultus der Römer* (1912). (W. W. F.)

MARS, in astronomy, the fourth planet in the order of distance



FROM "EARTH, MOON AND PLANETS," BY FRED L. WHIPPLE (THE BLAKISTON COMPANY)

OPPOSITIONS OF MARS FROM THE EARTH

From 1939 to 1971. The relative distances are shown by the straight lines joining the orbits. The seasonal dates on the earth are indicated. Mars is north of the equator for oppositions from September to March

from the sun, and the next outside the earth. To the naked eye it appears as a bright star of a decidedly reddish or lurid tint, which contrasts strongly with the whiteness of Venus. At opposition it is brighter than a first magnitude star, sometimes outshining even Sirius. It is by virtue of its position the most favourably situated of all the planets for observation from the earth. The eccentricity of its orbit, 0.0933, is greater than that of any other major planet except Mercury. The result is that at an opposition near perihelion Mars is markedly nearer to the earth than at an opposition near aphelion, the one distance being about 35,000,000 miles; the other 63,000,000. These numbers express only the minimum distances at or near opposition, and not the distance at other times. The time of revolution of Mars is 686.98 days. The mean interval between oppositions is 2 years 49½ days, but, owing to the eccentricity of the orbit, the actual excess over two years ranges from 36 days to more than 2½ months. Its period of rotation is 24 h. 37 m. 22.6 s.

Motions.—The accompanying diagram illustrates the order in which the oppositions of the planet follow each other. The outer circle represents the orbit of Mars, the inner that of the earth. Around the inner circle, representing the earth's orbit, are marked the months during which the earth passes through the different parts of the orbit. It will be seen that the distance of Mars at the time of any opposition depends upon the month in which opposition occurs. The least possible distance would occur in an opposition about the end of August, a little before Mars reached the perihelion, because the eccentricity of the earth's orbit throws our planet a little farther from the sun and nearer the orbit of Mars in July than it does in August. From the diagram it is seen that the points of opposition travel around the orbit in about 16 years, so that oppositions near perihelion, when Mars is therefore nearest the earth, occur at intervals of 15 or 17 years.

The axis of rotation of the planet is inclined between 23° and 24° to the pole of the orbit, and the equator of the planet has the same inclination to the plane of the orbit. The north pole is directed toward a point in longitude 355°, in consequence of which the projection of the planet's axis upon the plane of the ecliptic is nearly parallel to the line of our equinoxes. The aspect of the planet at opposition, especially the hemisphere which is visible, varies with the month of opposition, the general rule being that the northern hemisphere of the planet is entirely seen only near aphelion oppositions, and therefore when farthest from us, while the southern hemisphere is best seen near perihelion oppositions. The distances of the planet from the sun at aphelion and at perihelion are nearly in the ratio 6:5. The intensity of the sun's radiation on the planet is as the inverse square of this ratio. It is therefore more than 40% greater near perihelion than near aphelion. It follows from all this that the southern hemisphere is subjected to a more intense solar heat than the northern, and must therefore have a warmer summer season; but the length of the seasons is the inverse of this, the summer of the northern hemisphere being longer and the heat of the southern hemisphere shorter in proportion.

Diameter and Ellipticity.—The accurate determination of the diameter of Mars presents peculiar difficulties which have not as yet been satisfactorily resolved. Ordinary telescopic measurements of diameter give results which are too great as a consequence of several disturbing factors all of which act in a positive sense. Especially to be mentioned is irradiation, a subjective disturbance of vision which causes a bright object to appear larger than it is. The effects of most of these factors can be evaluated and allowed for, but there remains the influence of the planet's atmosphere, which possesses a certain amount of visibility, especially when it contains haze, and is seen in increased thickness at the planet's edge. This latter aspect of the problem has recently excited some discussion, and will be further alluded to in the subsection relating to photography by light of different colors. The equatorial diameter of Mars resulting from what are regarded as the most reliable telescopic measures is 6,740 km. (4,190 miles). Photographs made in yellow light by R. J. Trumpler give 6,820 km. (4,240 miles). Independent determinations of the solid surface by Trumpler and by W. H. Wright indicate a diameter approximately 180 km. (112 mi.) less than this. If this difference is interpreted in terms of the atmospheric overlayer it provides a value of 90 km. (55 mi.) for the atmospheric thickness, a result which

PHOTOGRAPHS, (6) E. E. BARNARD, BY COURTESY OF YERKES OBSERVATORY; (12-16) E. C. SLIPHER, LOWELL OBSERVATORY, (11) R. J. TRUMPLER, LICK OBSERVATORY; (1-5, 7-10) W. H. WRIGHT, LICK OBSERVATORY

TELESCOPIC PHOTOGRAPHS OF THE PLANET MARS

1–5. Show changes obtained by varying the colour of light employed in photographing: 1. was taken by ultra-violet light; 2, yellow; 3, red; 4, infra-red; 5, violet. Surface markings shown in varying strength in 2, 3. and 4. are not found in 1. and 5. Note clouds in 1. and 5

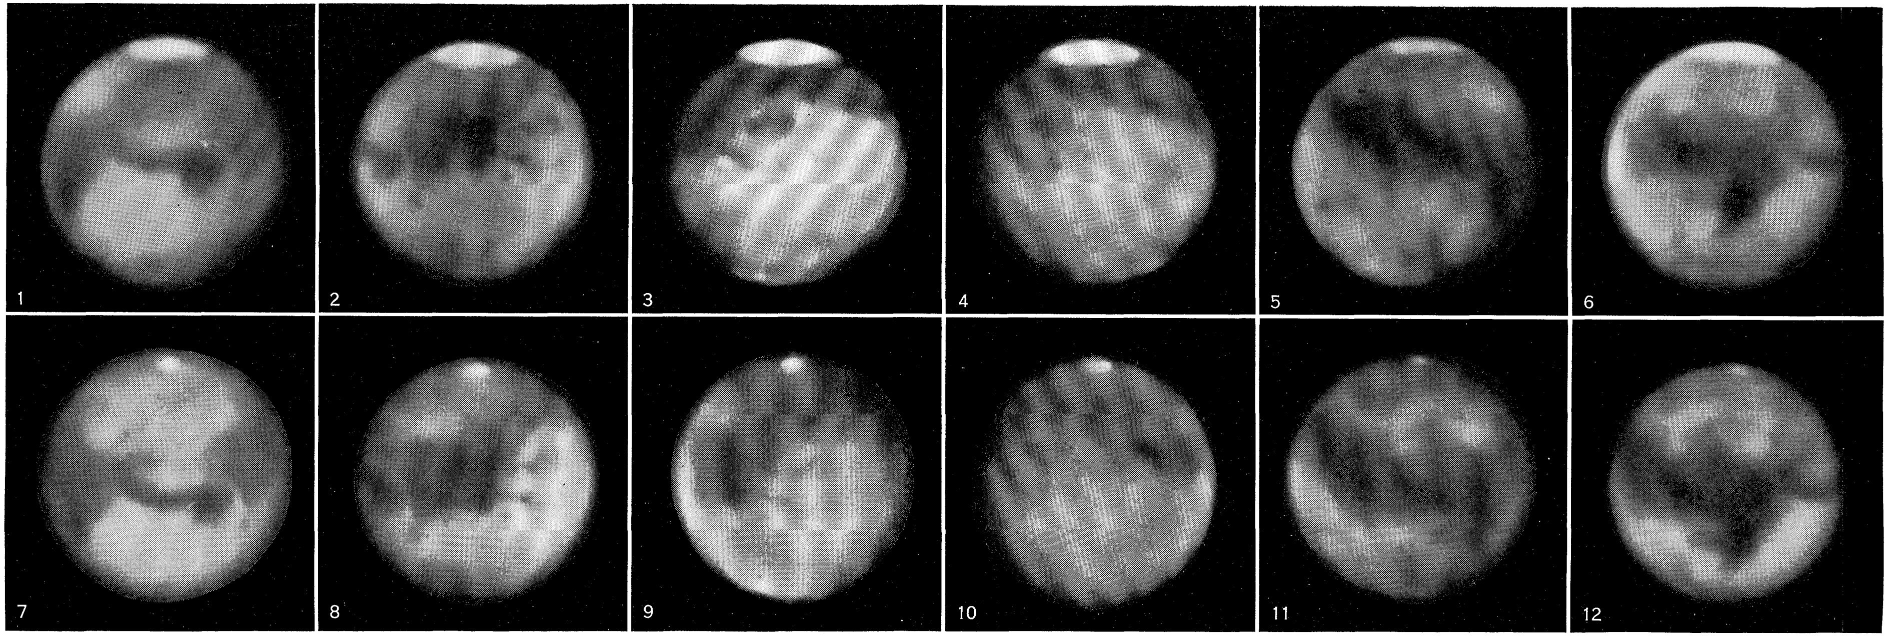
6–8. For full description see the text

9 and 10. Photographs of a terrestrial landscape using the same colours as for 4. and 5. above. Obscuration of the distant snow-covered mountains is caused by the earth's atmosphere, and the comparison suggests that obliteration of the surface markings in 5. is due to an atmosphere on Mars that is practically impenetrable by violet or ultra-violet light. Such an atmosphere explains the varying visibility of surface features in 2. to 4., also occurrence of clouds in 1. and 5.

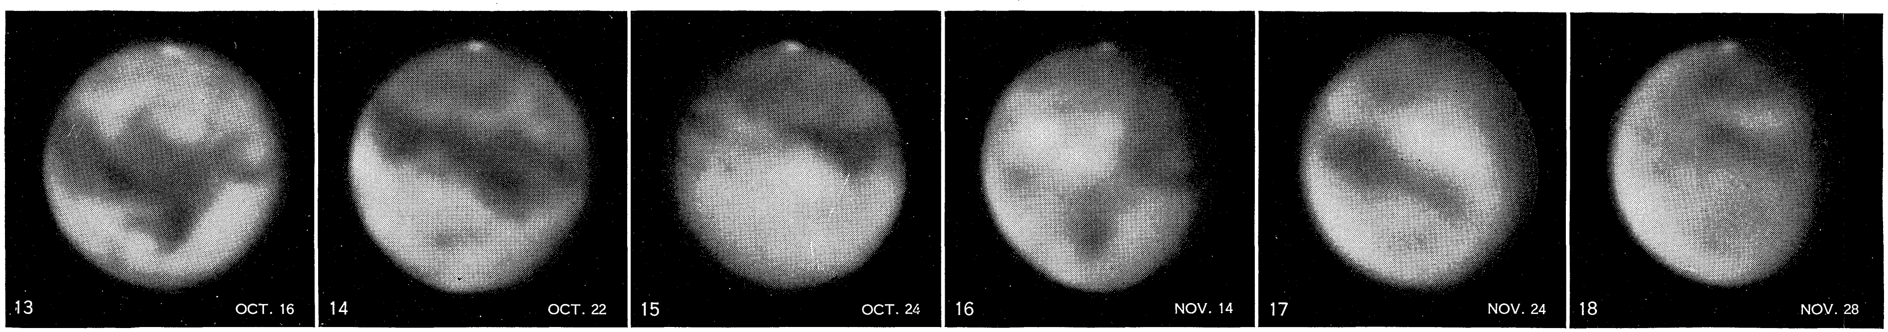
11. Chart of Mars at opposition of 1924. In comparing photographs with the chart the former should be viewed with the polar cap straight up. South is upward

12–16. Photographs of Mars showing seasonal changes during the progress of the planet's summer. The Martian seasonal dates are: 12., May 13; 13., May 29; 14., June 23; 15., July 31; 16., Aug. 20. Note the shrinking of the polar cap and darkening of the equatorial regions with advance of the season

PHOTOGRAPHS OF MARS



CLOUDS ON MARS



PHOTOGRAPHS BY COURTESY OF E. C. SLIPHER.

1–12. Photographs of Mars, showing various faces of the planet in 1939 (upper row figs. 1-6) and the same faces in 1941 (beneath figs. 7-12). In 1939 the southern hemisphere was in its springtime, in 1941 in its summer. (The 1939 photographs were made at Lamont-Hussey observatory, Bloemfontein, South Africa, the others at Lowell observatory)

13–18. Clouds on Mars. Photographs in 1941 displaying rare examples of widespread cloudiness in the atmosphere of Mars obscuring the familiar dark markings. Figures 13, 14, 15, show the planet normally clear, figures 16, 17, 18, taken within a few weeks of the same face of the planet, display the cloudy condition. Such Martian storms are often observed to move across the surface, but generally dissipate in a day or so may be very much in error, and is mentioned here principally for the purpose of illustrating a difficulty encountered in determining the diameter of the planet.

Measurements of the polar and equatorial diameters indicate an ellipticity of figure greater than can reasonably be accounted for by the planet's rotation, and greater also than seems compatible with the observed motion of the satellites. The usually adopted measure of ellipticity or "flattening" is the fractional excess of equatorial over polar diameter. This quantity, as derived from the measurements, is 0.010 (Trumpler, *Lick Obs. Bull.*, vol. 13, p. 31); and as calculated from the dynamical considerations just indicated, 0.005. It appears likely at the present time that the smaller, or calculated ellipticity is correct, and that the discrepancy in the observed value is to be ascribed to phenomena of the Martian atmosphere.

Some of the more important dynamical data not specified elsewhere in this article are:

Mean distance of Mars from the sun	228 million km. (141,650,000 mi.)
Mean orbital velocity	24.1 km. (15.5 mi.) per sec.
Mass	0.108 that of the earth.
Volume	0.150 that of the earth.
Density	4.0 times that of water.
Surface gravity	0.38 that of the earth.

The above are calculated for a mean Martian diameter of 6,770 km. If the diameter of the solid planet is taken to be 180 km. smaller (as explained above) the last three constants become: volume, 0.141; density, 4.2; gravity, 0.40.

Surface Features.—The fascination of the study of the Martian surface arises from a number of circumstances. Mars is the nearest and most favourably situated for observation of all the planets. Venus it is true comes closer to us, but at the time of its least distance the illuminated hemisphere is turned away, and consequently cannot be seen. Furthermore, Mars is one of the few heavenly bodies on which we see a solid surface, like that of the earth. Its solidity is shown by the substantial permanency of its configurations; the only other astronomical objects of consequence which present to our view surfaces of a like character are the Moon, and possibly Mercury; otherwise, perhaps with such inconsiderable exceptions as the asteroids and the satellites of planets, our telescopes reveal only fluid masses or bodies surrounded by clouds or impenetrable vapour. In the case of the Moon, the only real rival of Mars in the display of surface detail, we have the advantage of greater proximity, which enables us to distinguish mountains, plains and minor features of topography, but we encounter a sameness of aspect, due in part to its apparent rotational immobility and in part to the absence of an atmosphere, which is not altogether relieved by its phase variations. And whereas we see only slightly more than half the lunar surface, Mars—although its distance is such that, even at closest approach, the ultimate nature of its markings can only be inferred—has the advantage of rotation and all parts of the planet are therefore brought successively before us; it is, besides, surrounded by an atmosphere that provides diversified phenomena of climate and weather. Mars stimulates a unique and compelling interest, as a subject both of scientific investigation and popular theorizing.

In the telescope the planet presents a ruddy or orange coloured disk relieved by darker markings of a greenish blue hue which occupy about three-eighths of the area of the planet, and are, for the most part, distributed in a belt just south of the equator. There is one considerable projection into the northern hemisphere, known as the *Syrtis Major,* and a few isolated dark regions occur in the northern latitudes, as shown on the chart (*see* PLATE I, fig. 11). It should perhaps be explained, in respect to the charts and other illustrative material relating to astronomical subjects, that the usual practice is followed of placing them with the south side uppermost, to correspond with the appearance in the field of an inverting telescope. The dark markings of Mars are permanent features, although some of them undergo variations in size and appearance. Extending from the dark areas into the regions of greater brightness are a number of wisp-like filaments, the so-called and much discussed "canals." It seems to be generally agreed among observers who have the use of powerful telescopes that their occurrence is not limited to the bright regions (though they are, naturally, more easily seen there), but that they traverse the dark areas as well, forming a network which completely enmeshes the planet. At the poles of rotation are usually seen brilliant white patches, termed polar caps. These have not the quasi-permanent character of the dark markings, for each of them waxes and wanes with the coming and going of winter in the hemisphere to which it belongs, all but disappearing in the summer, as shown in figs. 12 to 16 of PLATE I. The striking parallelism between this phenomenon and the yearly variation of the winter areas of ice and snow in our higher terrestrial latitudes suggested to early observers that the Martian caps are polar snow-fields, and this view of their constitution appears to be the one most generally held at the present time, although an alternative explanation in terms of frozen carbon dioxide has been suggested. Another feature presented in the telescopic view of the planet is the so-called "limb light," a narrow band of bluish green tint that outlines the bright limb or fully illuminated edge of the planet.

The more conspicuous Martian phenomena have been known since the early days of telescopic observation. In 1610 the phases were observed by Galileo. The first sketches of surface detail were made by Huygens in 1659. Huygens suggested a rotation period of 24 hours, and Cassini seven years later independently estimated 24 hours and 40 minutes, which is very close to the actual value. The latter observer also described the polar caps. The drawings of Huygens and of Hooke (1660), though crude when judged by modern standards, have permitted the rotation period to be determined with a high degree of accuracy; the value $24^h\,37^m\,22.6^s$ for the sidereal revolution cannot well be in error as much as a tenth of a second. Little of value was accomplished for a century or more but in 1783 Sir William Herschel detected seasonal variation in the sizes of the polar caps, and determined the position of the axis of rotation. During the 19th century, especially its second half, with the increase in power and quality of telescopes, further details were revealed. In 1877 Asaph Hall discovered the two satellites. The outstanding observer of this period was G. V. Schiaparelli, who in 1877 made the first comprehensive triangulation of the surface, and added greatly to the number of known line-like markings which he was the first to designate "canals." Schiaparelli also reported a phenomenon with respect to the reality of which his successors have not been uniformly in agreement, namely, the "gemination" or doubling of the canals at certain seasons of the Martian year. Because of the pioneer nature of his work, the excellence of his observations and the philosophical character of his deliberations, Schiaparelli is undoubtedly to be regarded as the pre-eminent student of the Martian surface; in more recent years the names of E. E. Barnard, P. Lowell, E. M. Antoniadi, W. H. Pickering and many others have been associated with the telescopic study of Mars, and noteworthy photographs have been made, especially by E. C. Slipher at Lowell and by R. J. Trumpler at the Lick observatory. Finally, inquiries of two kinds, which may be regarded as departures from the traditional methods of telescopic observation, have been undertaken during recent oppositions. One of these has for its object the determination of the planet's temperature through analysis of its thermal radiation; the other consists in the study of the planet by light of different colours. Both will be discussed.

Before undertaking a more detailed description of the planet than is provided above it will be appropriate to refer to the Martian atmosphere, since it is through this gaseous envelope that the planet must be viewed, and some modification in appearance might reasonably be anticipated on this account. Photographic observations indicate that the effect of atmosphere on the visibility and appearance of the surface depends on the colour of light used in observation, and that for colours to which the eye is most sensitive (yellow and spectrally contiguous colours) modification of the appearance of the surface of Mars is not, except perhaps at the polar caps, very serious; so that it is permissible to approach the study of the planet by way of its telescopic appearance.

In fig. 6 of PLATE I is a photograph taken by Barnard with the great telescope of the Yerkes observatory. It was made by yellow light, a colour to which the eye is specially sensitive, and it illustrates, as well as a monochrome representation can, the appearance of the planet when seen in the telescope under good observing conditions. The south polar cap lies on the upper right edge of the disk. To the eye the cap is normally a brilliant white, while the remainder of the lighter toned area is deep yellow or orange; the dark parts are, as has already been said, normally of a bluish green tinge. The region shown is that of the Syrtis Major, the dark triangular portion resembling the Indian peninsula, extending downward to the left. On the chart (*see* PLATE I) the Syrtis will be found in long. 290°, lat. +10°. In correlating photograph and chart it is necessary to bear in mind that in the former the direction of the axis is inclined upward to the right, as is shown by the position of the polar cap. The lower of the two dark strips, which, on the photograph, reach out to the right, is the *Sabaeus Sinus,* approximately in long. 345°, lat. −7°. The small excrescence, or downward projection at the extremity of the strip, is the so-called forked bay; the bifurcation is not visible in the photographs because of the disadvantageous position near the planet's edge, but will be readily recognized on the chart. The meridian passing through the point of bifurcation has been arbitrarily chosen as the one from which areographic longitudes are measured (*"areographic,"* with respect to Mars, = "geographic" in relation to the earth; "areography" is Martian "geography").

The dark areas of the planet were regarded by the early observers as expanses of water, and were called *"maria"* or "seas." Even so recent an observer as Schiaparelli held this view, but it has now been generally abandoned, at least with respect to most of the dark markings, though a number of the smaller and more variable are by some observers still regarded as lakes. Despite this change in interpretation the names *mare* and "sea" have continued in general use as designations of the dark areas. Conclusive proof that these areas are not bodies of water is found in the fact that we do not see the reflection of the sun in them, as we certainly should, at times of proper presentation, if they exposed free surfaces of water; other indications are that the dark markings are far from uniform in strength, that detail is visible in them, and that some are subject to marked alterations, as may be seen by intercomparing the illustrations of groups 6 to 8 and 12 to 16 of PLATE I. The several photographs of each group were taken at approximately equivalent presentation, and either group provides ample proof of alteration in surface markings. For the purpose of discussing some of these alterations without dependence on the rather cumbersome classical names by which they are ordinarily designated, advantage will be taken of the suggestion which fig. 7 affords of the outline of a stag's head and antlers. The resemblance will be more apparent if the plate is turned to the left through a right angle. It will now be seen that the antlers in figs. 6 and 7 are conformable but that in fig. 8 the object which serves as the antler on the reader's left is not the comparatively erect one that functions in the first two cases. A closer examination of fig. 8 will reveal a vestige of the old antler (*Pandorae Fretum*), while the new one can be discerned in reduced strength in fig. 7, and as a trace in fig. 6. Other differences are found at the back of the stag's neck, and in the appendage to the chin (*Thoth*). In fact the disparities are so great that fig. 6 bears little resemblance to a head of any kind. It seems doubtful whether the earth would exhibit, to a planetary observer, alterations of surface features comparable in magnitude with those shown in these photographs. In drawing conclusions from such phenomena as these it is necessary to assure oneself that they are not the consequences of passing clouds, or of atmospheric obscurations of one kind or another, and fig. 7 shows, in fact, in the light spot at the stag's throat, what is in all likelihood a cloud, while temporary obscurations of one part or another of the surface have occasionally been observed that are most readily accounted for as effects of mists or other atmospheric abnormalities. There seems to be little ground, however, for doubting that much of the variation seen on Mars is real, and it becomes a matter of importance to inquire whether it synchronizes with the Martian seasons. Schiaparelli seems to have been the first to suspect seasonal variations, and, while evidence on this point can be supplied only by observations extending over many years, experienced observers consider that some of the changes are seasonal and others not, though the evidence is not altogether consistent (*Publ. Astron. Soc. Pacific,* vol. 39, 11, 108–109). Many observers of the planet, especially Lowell and members of the group of astronomers who were at one time or another associated with him at the observatory which he established, have reported seasonal alterations of a specific character. They find the dark areas to be stronger in the spring and summer of the hemisphere in which they are situated, the intensification starting in high latitudes, close to the shrinking cap, and working toward the equator, sometimes crossing it. They also report changes in shade or colour accompanying these alterations in intensity, the colour usually passing from bluish green to yellow, as the darkening is reduced, though a change from blue-green to chocolate-brown is stated to be characteristic of a certain region of the planet lying to the south of the *Syrtis Major.* The photographs in figs. 12 to 16 of PLATE I, taken by E. C. Slipher at the Lowell observatory, have kindly been provided by him to illustrate seasonal alterations in the strength of certain of the markings.[1] A seasonal effect, the significance of which has been emphasized in interpretations of the phenomena of the caps, is a dark margin said to surround the shrinking cap. This has been explained as flooding consequent upon the melting of the cap. The relationship of areographic mutation to the yearly cycle has been the subject of painstaking inquiry on the part of nearly every observer of the planet; the literature relating to it is, as a consequence, very voluminous, and from its nature, difficult to abridge or summarize; for fuller information the reader is referred to W. H. Pickering, *Popular Astron.* vol. 35, p. 195 (1927) and Antoniadi, *Bull. Soc. Astron. France,* vol. 38, p. 199; vol. 40, 278.

The generally bluish green colour of the dark markings, taken in conjunction with seasonal changes to which they appear to be subject, has provided the suggestion that they are areas of vegetation, an interpretation that has been accorded warm advocacy by certain astronomers, more especially, perhaps, those whose interest is centred in habilitating an hypothesis of close parallelism between organic phenomena on Mars and on the earth. While the present writer is, to borrow a phrase of Schiaparelli from a passage quoted elsewhere in this article, "very careful not to combat this supposition, which includes nothing impossible," he has recently pointed out that a high content of blue and violet light is to be expected in the image of dark surface areas, as a consequence of the superposition upon them of the Martian sky. That the planet's sky probably influences the colour and appearance of the surface has long been recognized, but the evidence of recent photographic observations, to be referred to later, suggesting as it does that a very large proportion of the blue and violet light from even the brighter parts of the planet is due to the overlying atmosphere, seems to require an alteration in the apparent colour (in the spectral direction green to blue) of surface markings, as a consequence merely of their darkness; in other words, the dark areas might be expected to appear bluish green whether that is their real colour or not. The change from blue-green to yellow, found to accompany the seasonal fading of the dark areas, would, according to this view, be merely a consequence of their fading; but changes from green to chocolate-brown, observed by Lowell in 1903 and 1905, cannot be so regarded.

The Canals.—If comment were confined to what is universally agreed upon with respect to the finer markings which pass under this designation very little could be said. That such markings exist there can be no question, and A. E. Douglass's discovery of similar features on the dark areas themselves appears to have been generally confirmed. Their visibility, like that of the seas, is variable, some appearing at one time and some at another, so that their appearance in the telescopic view is not to be inferred from

[1]The description sent by Mr. Slipher with the photographs is as follows: "Actual photographs of the planet Mars displaying the gradual decrease of the snow at the south pole and the darkening of the planet's tropics with the advance of Martian summer. This gradual darkening of certain regions of the planet in his summer season and their subsequent fading in winter seems best explained by assuming that these dark areas are due to vegetation." The responsibility for the interpretations rests, of course, with Mr. Slipher.

the network shown on one or another chart which usually includes all that have been seen, at least in a given season, by the person drawing it. Some observers report the canals as of sensible width, others as extremely fine, hair-like lines, while still others record canals of both descriptions. Schiaparelli, whose pioneer study of them is specially valuable, described them as straight, direct and continuous, and numerous observers have confirmed this impression of their appearance (Lowell, *Mars and its Canals,* p. 29), though astronomers of at least comparable skill and experience have reported deviations from rectilinearity, and have suggested that some of the more difficult of them may be merely the consequence of grouping by the eye of minute markings which are not separately visible, the apparent continuity being a subjective effect. (Pickering, *Mars,* chap. xiv; Trumpler, *Publ. Astron. Soc. Pacific,* vol. 39, p. 106; *Annual Rep. Mt. Wilson Obs.,* 1925, p. 103.) Schiaparelli reported a gemination, or doubling of certain of the canals at stated seasons, and very positive statements have been made in confirmation of this, notably by Lowell and his followers. On the other hand, skilled observers, among whom may be mentioned Barnard and Pickering, have failed to observe such conditions, despite long continued and careful scrutiny of the planet. These diverse findings would seem to prove that a study of the finer structure of the canals is beyond our present means of observation.

The impression of straightness and geometrical regularity made by the canals has stimulated the imaginations of certain astronomers to see in them the works of intelligent beings. Why this should be so is not altogether apparent. The remarkable systems of streaks which radiate from some of the craters of the Moon are not so interpreted, while the works of man which might be regarded as of sufficient magnitude to be visible to a well equipped celestial observer are not distinguished by geometrical regularity. A world-encompassing phenomenon suggests the action of geological forces, and Schiaparelli was among those to suggest the play of these in the formation of the canals. His reflections on the suggestion that they are the work of intelligent inhabitants of the planet are of interest, and we are indebted to a translation of one of his essays (*Mars,* pp. 92–94) by Prof. W. H. Pickering for the following passages:—

> Their [the canals'] singular aspect, and their being drawn with absolute geometrical precision, as if they were the work of rule or compass, has led some to see in them the work of intelligent beings, inhabitants of the planet. I am very careful not to combat this supposition, which includes nothing impossible. . . . Let us add further that the intervention of intelligent beings might explain the geometrical appearance of the gemination, but it is not at all necessary for such a purpose. The geometry of nature is manifested in many other facts, from which are excluded the idea of any artificial labour whatever. The perfect spheroids of the heavenly bodies and the ring of Saturn were not constructed in a turning lathe, and not with compasses has Iris described within the clouds her beautiful and regular arch. And what shall we say of the infinite variety of those exquisite and regular polyhedrons in which the world of crystals is so rich! In the organic world, also, is not that geometry most wonderful which presides over the distribution of the foliage upon certain plants, which orders the nearly symmetrical, starlike figures of the flowers of the field; as well as of the animals of the sea, and which produces in the shell such an exquisite conical spiral that excels the most beautiful masterpieces of gothic architecture? In all these objects the geometrical form is the simple and necessary consequence of the principles and laws which govern the physical and physiological world. That these principles and these laws are but an indication of a higher intelligent power, we may admit, but this has nothing to do with the present argument.

The remarkable paper from which this excerpt is taken contains a summary of Schiaparelli's views, and a complete reading of it is to be recommended.

Since Schiaparelli's time a number of astronomers both in Europe and America have been industrious observers of the canals, but it seems questionable whether the ground gained has been commensurate with the toll of labour its winning has exacted.

The surface of Mars is believed to be freer from topographical irregularities than that either of the earth or the Moon. This is an inference from the observed smoothness of the terminator, which would quite certainly present a more or less ragged appearance were irregularities comparable with terrestrial or lunar mountains upon or near it. It is, however, unreasonable to suppose that substantial differences in level do not exist, and the polar eccentricity and irregularity of outline of the southern cap, when shrinking, find a plausible explanation in the assumption that they are caused by local differences in the level of the ground. The relatively high temperatures of the dark areas, reported by Coblentz and Lampland, presently to be referred to, have led those observers to suggest that these areas lie at a lower level than the brighter ones. This is, however, an aspect of the Martian problem which is still in the speculative stage.

Atmosphere.—To a celestial observer of the earth the detection of its atmosphere would offer no difficulty whatever, since the clouds, which are a part of it, would continually be seen. The discovery of the Martian atmosphere was not so easy a matter, for clouds, in the ordinary sense of the word, are rare, and few evidences of the obstructive effects of an atmosphere are encountered in observing the planet with a telescope. Nevertheless, that Mars has an atmosphere of some kind has long been known from the phenomena of the polar caps; for while it is easy to understand how a cap could disappear simply by melting, its formation must quite certainly be the result of precipitation, and it was consequently inferred that there necessarily exists on the planet a considerable amount of vapour, the cap material, which would itself, even in the absence of other gases, constitute an atmosphere. Furthermore, projections from the terminator of Mars have occasionally been seen, for which the most satisfactory explanation known is that they are clouds at elevations of several miles. A cloud at such an altitude, illuminated by the rising or setting sun, would be seen in projection against an unilluminated part of the planet, a circumstance specially favourable for its observation. On other occasions temporary obscuration, partial or complete, of familiar surface markings has been interpreted in terms of obscuring mists, while, infrequently, very striking patches, whose mobility has left little doubt of their cloud-like nature, have been seen and photographed upon the planet. Thus, while the meteorological phenomena of Mars are not so conspicuous as those of the earth, their observation years ago gave ample proof of Mars's possession of an atmosphere. During recent oppositions a considerable amount of photographic evidence was obtained which appears to relate to the planet's meteorology.

Attempts have not been lacking to analyze the Martian atmosphere through spectroscopic examination of the planet's light. Since this light comes originally from the sun, and is merely deflected in our direction by the planet, a casual examination of the spectrum reveals merely the composition of the sun. However, the light, or more strictly speaking that part of it by which we see the planet's surface, must of necessity have traversed the planet's atmosphere both on entering and leaving, and some modification of the Fraunhofer, or dark line, spectrum might reasonably be anticipated as a consequence of this circumstance. Such modification is in fact known to be effected by the earth's atmosphere which adds to the numerous lines belonging properly to the spectrum of the sun a number of so-called "telluric" lines due to its own constituent gases. The presence of these lines of atmospheric origin adds enormously to the difficulty of a spectroscopic study of a planet's atmosphere, for they are precisely the lines that one would first seek in the planet's spectrum. Observations undertaken for the purpose of detecting on Mars any of the constituent gases of our own atmosphere therefore present peculiar difficulties, which have only partially been overcome by the adoption of very elaborate precautions. The observations of Huggins (1867) were for many years taken to indicate the existence of water vapour in considerable quantities in the atmosphere of Mars, and among later investigations those carried out under the auspices of the Lowell observatory by V. M. Slipher and F. W. Very are to the same effect. The latter observers estimated the Martian atmosphere to contain approximately 1.75 times as much water vapour, area for area, as existed in the atmosphere above their observing station at Flagstaff, Arizona, at the time of observation, that is to say 14 mm. of precipitable water for the Martian atmosphere. W. W. Campbell at the Lick observatory was however, unable to detect evidence of water vapour, and concluded that if any is present it does not exceed one fifth of the amount in the earth's atmosphere. Observations made with the powerful equipment of the Mount Wilson Observatory fail to show any trace of oxygen or water vapour in the spectrum of Mars. From his observations at Mount Wilson Dr. W. S. Adams estimated that an upper limit of one percent of the amount of terrestrial oxygen and water vapour would appear liberal for the Martian atmosphere.

From the most refined spectroscopic observations made thus far, it seems, therefore, that there is no appreciable effect of the atmosphere of Mars on the Fraunhofer spectrum. There is however a very marked change in the *distribution* of light through the spectrum. All observers agree that the more refrangible part of the spectrum is relatively weak, and to this fact is due the planet's ruddy colour. Exceptions are to be noted in the cases of the polar caps, and dark areas, for the spectrum of the caps continues in great strength into the ultra-violet, and the bluish green colour of the dark areas is due to the predominance of light of short wavelength. In view of the generally negative spectroscopic revelations of an atmosphere, and the ease with which features of the planet's surface, more especially the polar caps, are seen in the telescope, it would appear that the atmosphere of Mars is extremely tenuous. Evidence not altogether corroborative of this view is supplied by photographs taken by light of different colours.

Photographs by Light of Different Colours.—The study of Mars by the method just referred to involves a kind of analysis that has had some use in general scientific observation, and which may be said to occupy a place between precise spectroscopy, on the one hand, and the more versatile means of analysis provided through the perception of both form and colour by the eye, on the other. A series of photographs taken with approximately homogeneous light of distinct spectral regions has an advantage over the coloured presentation provided by ordinary visual perception in that its several images are separate, but its testimony, like ocular evidence, must be interpreted in the light of independently derived knowledge. Moreover, it is a matter of common knowledge that any object of diversified colour will suffer an apparent alteration in the contrasts of its several parts if the colour of the light by which it is viewed is changed. This is a natural consequence of the phenomenon of colour. Photography provides a specially suitable means for observing such alterations because it renders them in uniform terms of photographic density. Very marked differences are occasionally found when the colour used in photographing is altered, and it is sometimes possible, through a study of these differences, to learn something of the body under observation. Differences in the aspect of Mars when observed in this way appear first to have been described by de la B. Pluvinel and F. Baldet, and by G. Tikhoff, in 1909, but their important observations seem generally to have been overlooked. The phenomena were rediscovered and more completely described by later observers, especially on the planet's approach in 1924. A series of photographs, taken by light of five different regions of the spectrum, is shown in figs. 1 to 5 of PLATE I. The spectral positions of these regions are sufficiently well defined by the names of colours attached to the illustrations, except in the ultra-violet and infra-red, where the wave-lengths are approximately 3700A and 7600A respectively. The photographs are arranged in the order in which they were taken, which is, except in respect to fig. 5, also the spectral sequence of the colours used. It will be noted that there are progressive changes throughout the series 1 to 4. Those which relate to the position of the markings are readily recognized as being due to the planet's rotation on its axis. The axis passes upward to the right, and approximately through the centre of the polar cap, which is seen on some of the photographs as a small white dot on the planet's edge; and the effect of rotation is to displace the markings of successive images upward to the left. After allowing for these displacements, there remain differences of a more fundamental character which will now be considered. Figures 4 and 5 were taken so closely together in point of time that they provide substantially identical presentations of the planet, and the disparity in their appearance is one that it would be very difficult to explain as a consequence of the different colours of its several parts. Reduced contrast of markings against the bright background would be expected in a violet photograph because of their bluish green colour, but the total obliteration of all structure shown in the infra-red image, and the substitution of something of an entirely different kind, seems difficult to explain as a colour effect. Before attempting an interpretation it will be well to summarize some of the more remarkable peculiarities which pictures of this kind exhibit when taken, as during recent favourable approaches of the planet, with refined instruments and great precision of method.

(1) Excepting the polar caps and limb light, the familiar features of the planet are invisible in the ultra-violet photographs, but appear, and become increasingly conspicuous, as the wave-length of the light used in observation increases.

(2) The polar caps and limb light are, on the other hand, strong in the ultra-violet photographs, and weaken with increasing wave-length.

(3) Ultra-violet and violet photographs record at times whitish areas and mottlings which have been found to be temporary. These, like the polar caps and limb light, decrease in strength with increasing wave-length.

(4) When the planet is near opposition there is a pronounced fading, or darkening, at the limb in the red and infra-red images. The violet and ultra-violet images are, on the contrary, usually brightest at the limb.

(5) The ultra-violet and violet images are noticeably larger than those taken by red and infra-red light.

A tentative explanation of these characteristics has been made by W. H. Wright.

The theory may conveniently be approached through a consideration of figs. 9 and 10, which show small sections of a distant landscape photographed by light of the colours used in 4 and 5 directly above them. Obliteration of the distant part of the landscape in 10 is known to be due to the earth's atmosphere, and the comparison of the two pairs of photographs is suggestive of the presence of an atmosphere of considerable optical density on Mars. The light in the upper half of 10 comes from the atmosphere intervening between the camera and the distant snow-capped mountains. This part of the picture therefore is, in a sense, an image of the atmosphere, and if the analogy with the Martian pictures is correct the violet photograph, fig. 5, is an image of the Martian atmospheric shell. The infra-red photograph, fig. 4, is quite obviously one of the planet's surface. Under this interpretation the excess in size of the violet and ultra-violet images referred to in (5), is explained, because a shell must be larger than the body which it contains. Half of the difference between the diameters of the two images should obviously be the height of the Martian atmosphere, or rather the height to which it can be photographed, and this height has been provisionally estimated from the measures of the diameters as being of the order of 60 miles, though a discussion of all available material may greatly alter this estimate; indeed, a number of writers are averse to accepting so high an estimate of the atmospheric thickness (*see* Menzel, *Astrophysical Journ.*, vol. 63, p. 58, 1926; Fessenkoff, *Astrom. Nach.*, vol. 228, p. 25, 1926). The principal source of uncertainty in such a determination is encountered in the measurement of the infra-red image, which at the favourable time of opposition presents a very weak edge, especially if a dark marking falls on a part of it which may be selected for measurement. An implication of the foregoing theory, that has been seriously disputed, relates to the polar caps. These features are larger and stronger in the violet and ultra-violet photographs than in those taken by the infra-red light, and if the former are, in fact, pictures of the atmosphere, it seems difficult to escape the conclusion that the caps are in part, atmospheric phenomena. This is a conclusion that a number of excellent observers of the planet are unwilling to accept, for the reason that they regard it as incompatible with the telescopic appearance of the caps, and with their observed behaviour.

A word must be said about Martian clouds. These have been known for a great many years, but so much light has been shed upon them by the recent photographs that they may properly be discussed under this head. There is substantial evidence leading to the belief that Mars has clouds of two kinds. What we shall call the first kind (*see* figs. 1 and 5 of PLATE I) are specially conspicuous on photographs taken by light of the violet end of the spectrum, and are not seen on the red photographs; those of the second kind (*see* fig. 7 at the "stag's throat") have an exactly contrary behaviour, being strong in the red photographs and invisible in the violet. The term cloud is here used in a very general sense and is meant to designate merely an area of atmospheric unhomogeneity which registers a cloudlike impression on a photograph, though there is reason to believe that clouds of the second class may actually be aqueous clouds. The writer has suggested that clouds of the first class lie high in the Martian atmosphere, and those of the second at a lower level.

Temperature.—That the temperature on the surface of Mars is comparable with that of the earth was long ago inferred from the behaviour of the polar caps, under the supposition that the latter are composed of ice or snow; and this inference, whatever the validity of the premise from which it was drawn, has been corroborated by analyses of the planet's thermal radiation. The determination of the temperature of a planet through measurement of the heat it sends us presupposes a refinement of technique which, until recently, seemed quite unattainable, for small as is the amount of heat received, it consists of two parts, that which came originally from the sun and is reflected by the planet, and that which originates in the planet's own warmth. The second of these parts, called the planet's intrinsic radiation, is alone the index of the planetary temperature, and in order to be utilized as such it must either be isolated from the first part, or sufficiently separated from it to permit certain characteristics of thermal radiation to be recognized. The most practicable procedure that has until now been developed is to compare the total heat received from the planet with that part of it which falls within certain limited regions of the spectrum. The spectral limitations are secured by passing the beam through various substances, notably water, of known transmissive properties. The logic of the method will be suggested by the consideration that, since the bulk of the intrinsic radiation of a body well below the temperature of incandescence, such as a planet, lies far in the infra-red, a great falling off in the amount of heat received when this region is excluded by the interposition, for example, of a water cell, will indicate a substantial contribution by the planet itself, and therefore a relatively high temperature. The actual analysis, while it is not in its present approximate form very complex, involves many factors, and cannot be presented here. Of surpassing interest is the delicate electrical thermometer with which the heat measurements are made. The sensitive element is a thermo-couple of such small dimensions that the surface of the planet can be explored and the radiation of its several parts measured. These first successful measurements of planetary radiation from Mars were made in 1922 by W. W. Coblentz and C. O. Lampland at the Lowell observatory, but those undertaken at the Martian apparitions of 1924 and 1926 by these observers, and by E. Pettit and S. B. Nicholson of Mount Wilson, are of such superior quality that only they will be considered. Temperatures of several parts of the disk, depending on these measurements, are given in the table to the nearest 10°:

	Sunrise edge	Centre	Sunset edge	S. polar cap	N. polar region
(1924)* Mount Wilson	−10°C.	+30°C.	−10°C.	−70°C.	..
(1924)†Lowell	−20° to −60°	−10° to +20°	0°	0° to +10°	−70°
(1926)†Lowell	−20°	+20° to +30°	+10°	−10° to +10°	−30° to −40°

**Annual Report*, Mt. Wilson Obs.; Carnegie Inst. (Washington, 1925).
†*Sci. Papers Bureau Standards: No. 553* (Washington, 1927).

Considering the difficulty of the observations, the independent estimates by the Lowell and Mount Wilson observers are remarkably accordant, especially when it is remembered that the quantity determined is the absolute temperature (or temperature measured from the absolute zero point, −273° C.) and not the difference between this and the comparatively close number which has arbitrarily been chosen as the zero of the Centigrade scale. The fall in temperature from the centre to the edge of the disk is beautifully shown; and the polar temperatures as well as those at sunrise and sunset seem painfully low to dwellers on the earth. Two outstanding points of difference are presented by the estimates made at the two observatories. The Lowell observers find the Martian afternoons to be warmer than the mornings, as is indicated by higher temperatures at sunset than at sunrise. The Mount Wilson results on the other hand show equal temperatures for morning and afternoon. Our terrestrial experience is that it is usually warmer in the afternoon than in the morning, a fact which is due to the considerable water vapour content of the earth's atmosphere, and the Mount Wilson observers explain the symmetry of their morning and afternoon temperature curve to be a consequence of the known scarcity of water vapour in the atmosphere of Mars. The second discrepancy relates to the temperature of the south polar cap, which alone was visible at these oppositions. The Mount Wilson observations place the temperature at −70° C., those made at Lowell indicate approximately 0° C., the temperature of melting ice. This is a matter that bears critically on the question of the constitution of the polar caps. An interesting indication of the Lowell observations is that the dark parts of the planet are warmer than the bright ones, the estimated difference being 10° or 15° C., a fact which would appear to be better in accord with the supposition that they are merely areas of comparatively high optical absorption than that they are regions of vegetation. Optical absorption by a dark surface results in a rise of temperature, while expanses covered with vegetation are cooler than desert areas under like conditions.

The estimates of temperature provided by these observations have been generally accepted with confidence, and there seems to be no ground for questioning their substantial accuracy in so far as the central part of the planet's disk is concerned. The calculations through which they were derived do not, however, take into account the properties of the Martian atmosphere, though the possible effects of an atmosphere were made the subject of conjecture by both groups of investigators. Whatever the magnitude of these effects, they must of necessity increase as the edge of the planet is approached, because of the greater amount of atmosphere intervening between us and the planet's surface at points remote from the centre. Furthermore the optical properties of the atmosphere are quite certainly affected by the lower temperature of the terminator, which at the most favourable time for general observation is close to the edge. That the atmosphere of Mars is not altogether negligible seems a fair inference from photographic evidence already discussed, but we are not in possession of sufficient knowledge of its optical properties to permit a reliable estimate to be made of its effect on the planet's radiation. For such reasons the temperatures derived for the polar caps and other parts of the edge are not regarded with the same confidence as those obtained for the centre. With these and other considerations in mind, Messrs. Coblentz, Lampland and Menzel have summed up their conclusions in the following words:

"We can say with some assurance that our measurements and deductions indicate that the temperature of the surface of Mars, under a noonday sun, rises considerably above the freezing point of water—a question that had been under discussion for years." (*Publ. Astron. Soc. Pacific*, vol. 39, p. 100; 1927).

Satellites and Pole.—At the opposition of Mars which occurred in Aug. 1877, the planet was unusually near the earth. Asaph Hall, then in charge of the 26-in. telescope at the Naval observatory in Washington, D.C., took advantage of this favourable circumstance to make a careful search for a visible satellite of the planet, and on the night of Aug. 11 found a faint object near the planet. Cloudy weather intervened, and the object was not again seen until the 16th, when it was found to be moving with the planet, leaving no doubt as to its being a satellite. On the night following an inner satellite much nearer the planet was observed. This discovery, apart from its intrinsic interest, is also noteworthy as the first of a series of discoveries of satellites of the outer planets. Hall named the outer satellite Deimos and the inner Phobos, from the horses that drew the chariot of the god Mars. A remarkable feature of the orbit of Phobos is that it is so near the planet as to perform a revolution in less than one-third that of the diurnal rotation of Mars. The result is that to an inhabitant of Mars this satellite would rise in the west and set in the east, making two apparent diurnal revolutions every day. The period of Deimos is only six hours greater than that of a Martian day; consequently its apparent motion around the planet would be so slow that more than two days elapse between rising and setting, and again between setting and rising. Lowell estimates the diameter of Deimos to be about 10 mi. and that of Phobos slightly more.

Long and careful series of observations have been made upon these bodies by other observers. At the very favourable oppositions of 1892 and 1894, observations were made by Hermann Struve at Poulkova, who later subjected all the data up to 1909 to a very careful discussion. He showed that the inclination of the planes of the orbits to the equator of the planet is quite small, thus making it certain that these two planes can never wander far from each other. The relations of the several planes can be best conceived by considering the points at which lines perpendicular to them, or their poles, meet the celestial sphere. By theory, the pole of the orbital plane of each satellite revolves round the pole of a certain fixed plane, differing less from the plane of the equator of Mars the nearer the satellite is to Mars. The observations of Lowell and Slipher, and of Trumpler, agree in placing the axis of Mars in position R.A. 316°.0; Dec. +54°.5 (Equinox of 1925). The tilt of the Martian equator to the Martian ecliptic calculated from this position is 23°.4.

Bibliography.—Camille Flammarion, *La Planète Mars,* etc. (2 vols., Paris, 1892–1909), a copious résumé of all publications and drawings of Mars up to 1901; W. H. Pickering, *Mars* (Boston, 1921), a collection of papers giving a brief account of the planet; Percival Lowell, *Mars and its Canals* (N.Y., 1911), a summary of this author's views of the planet; T. J. J. See, "Preliminary Investigation of the Diameter of Mars," *Astronomische Nachrichten,* vol. 157, 97 (1901), a condensed summary of the principal measurements made between 1651 and 1901; R. J. Trumpler, "Observations of Mars at the opposition of 1924," *Lick Obs. Bull.* vol. 13, p. 19 (Berkeley, Calif. 1927), a general discussion based principally on photographs, of its surface features, diameter and other constants, including the calculation of the diameter of the solid surface from timed measurements of the markings; Trumpler, "Visual and photographic observations of Mars made at the opposition of 1926," *Publ. Astron. Soc. Pacific,* vol. 39, p. 103 (1927); W. H. Wright, "Photographs of Mars made with light of different colours," three papers in *Publ. Astron. Soc. Pacific,* vol. 36, p. 239 (San Francisco, 1924), *Lick Obs. Bull.,* vol. 12, p. 48 (1925), and vol. 13, p. 50 (Berkeley, Calif., 1927); a discussion of marked variations in the appearance of Mars when photographed by light of different colours, with suggested explanation; among subjects dealt with are the atmosphere of Mars, some of its optical properties, its extent, the phenomena of clouds and those of the polar caps; E. Pettit and S. B. Nicholson, "Measurements of the Radiation of the Planet Mars," *Pop. Astron.,* vol. 32, p. 601, a radiometric determination of the temperature of Mars.

The temperature of Mars, as derived from radiometric observations made at the Lowell Observatory, is discussed in papers contributed individually or jointly by W. W. Coblentz, C. O. Lampland and D. H. Menzel to the *Journ. Franklin Institute,* vol. 199, p. 785; vol. 200, p. 103 (Philadelphia, 1925); *Sci. Papers,* Bureau of Standards, Nos. 512, 553 (Washington, 1925–26); *Astrophysical Journ.* vol. 63, p. 177 (1926); and *Publ. Astron. Soc. Pacific,* vol. 39, p. 97 (1927).

Among important sources of general information may be mentioned the *Monthly Notices and Memoirs* of the Roy. Astronom. Soc.; the *Journal and Memoirs* of the Brit. Astronom. Ass.; the *Bulletin* of the Soc. Astronom. de France, especially papers by E. M. Antoniadi. *Popular Astronomy* contains important articles by various authors, among which may be mentioned those by E. C. Slipher, and a series of reports by W. H. Pickering, beginning in vol. 22 (1914), and numbered consecutively; the latter constitute a running comment, with numerous references, on contemporary observations of the planet. Observations made at Lowell observatory are recorded in extenso in its *Annals* and *Bulletins.* Schiaparelli's memoirs are collected in *Le Opere di G. V. Schiaparelli* (Milano, 1929–30). *See* also E. M. Antoniadi, *La Planète Mars* (Paris, 1930); and F. L. Whipple, *Earth, Moon and Planets* (Philadelphia, 1941). (W. H. Wr.; X.)

MARSALA, seaport, Sicily, province of Trapani, 19 mi. by rail S. of Trapani. Pop. (1936) 24,650 (town), 62,171 (commune). It is situated on the low westernmost point of the island. The cathedral, dedicated to St. Thomas of Canterbury, contains 16 grey marble columns. The town trades in Marsala wine.

Marsala occupies the site of Lilybaeum, the principal Carthaginian stronghold in Sicily, founded by Himilco after the abandonment of Motya. Neither Pyrrhus nor the Romans were able to reduce it by siege, but it was surrendered to the latter in 241 B.C. In the later wars it was a starting point for the Roman expeditions against Carthage. The Saracens named it *Marsa Ali,* port of Ali. The harbour on the northeast was destroyed by Charles V to prevent its occupation by pirates. The modern harbour lies to the southeast. In 1860 Garibaldi landed at Marsala with 1,000 men and began his campaign in Sicily. Scanty remains of the ancient Lilybaeum, including fragments of the city walls, are visible. During World War II Marsala was heavily bombed by the Allies.

MARSCHALL VON BIEBERSTEIN, BARON ADOLF VON (1842–1912), German diplomatist, was born at Neuershausen, Baden, on Oct. 12, 1842. His grandfather, Karl Wilhelm, Baron Marschall von Bieberstein, ambassador of Baden in Stuttgart, represented Baden at the Congress of Vienna in 1815. Adolf was educated at Frankfort-on-Main, and at the universities of Heidelberg and Berlin. He held various administrative offices in the grand duchy of Baden, sitting from 1875–83 in the upper chamber of the Baden diet. In 1883 he was sent to Berlin as minister for Baden in the Federal council, and from 1884–90 he represented the council in the imperial insurance office. In 1890 he entered the imperial service, and succeeded Count Herbert Bismarck as state secretary for foreign affairs under Caprivi, continuing in that office under Prince von Hohenlohe; but he had incurred the enmity of Prince Bismarck by refusing his advice and the result was a fierce press campaign against him which finally obliged him to speak out when he appeared as witness at the trial of certain journalists in 1896 for *lèse-majesté.* He was opposed by the Agrarians for advocating the reduction of corn duties, and in 1897 resigned office, being appointed German ambassador in Constantinople, where he remained for nearly 15 years. He created a commanding position for himself and a growing ascendancy in Turkish affairs for his government. To him was largely due the promotion of the Baghdad railway. During his foreign secretaryship he took a strongly imperialist attitude. After the Krüger telegram, in the drafting of which Baron Marschall bore a leading part, it was he who declared in the reichstag that the maintenance of the independence of the Boer republics was a "German interest." He was an advocate of a strong naval policy for Germany. In 1907 he was principal German delegate in The Hague conference, and was the exponent of Germany's resolute and successful opposition to any practical discussion of the question of restriction of armaments. In May 1912 he succeeded Count Wolff-Metternich as ambassador to Great Britain, but his health broke down after a short time, and he died at Badenweiler on Sept. 24, 1912.

MARSCHNER, HEINRICH AUGUST (1795–1861), German composer and director, was born at Zittau, Saxony on Aug. 16, 1795. He studied music under Schicht at Leipzig, and in 1816 travelled to Pressburg and Vienna where he became acquainted with Košeluh and Beethoven. Weber produced his *Heinrich IV und Aubigné* at Dresden in 1820 and in 1824 Marschner was made musikdirector of the opera in that city. In 1827 he was appointed kapellmeister of the theatre in Leipzig, where he produced his highly successful romantic opera *Der Vampyr* in 1828, and in the following year his *Der Templer und die Jüdin.* In 1831 he became kapellmeister of the court at Hanover, and in May 1833, produced at Berlin his best and most successful opera, *Hans Heiling.* As a result of the performance of this work under his direction at Copenhagen in 1836, he was offered the position of musikdirector in Denmark. Marschner, however, returned to Hanover where, in 1859, he was given a pension and, after his death on Dec. 14, 1861, a monument was dedicated to his memory.

MARSDEN, WILLIAM (1754–1836), English orientalist, the son of a Dublin merchant, was born at Verval, Co. Wicklow, on Nov. 16, 1754. He was educated in Dublin, and having obtained an appointment in the civil service of the East India company went to Benkulen, Sumatra, in 1771. There he soon rose to the office of principal secretary to the government, and acquired

a knowledge of the Malay language and country. Returning to England in 1779 with a pension, he wrote his *History of Sumatra,* published in 1783. In 1795 Marsden was appointed second secretary and afterwards first secretary to the admiralty. In 1807 he retired and published, in 1812, his *Grammar and Dictionary of the Malay Language,* followed in 1818 by his translation of the *Travels of Marco Polo.* He was a member of many learned societies, and treasurer and vice-president of the Royal society. In 1834 he presented his collection of oriental coins to the British museum, and his library of books and oriental manuscripts to King's college, London. He died on Oct. 6, 1836. Other published works by him include *Numismata orientalia* (London, 1823–25), and *Catalogue of Dictionaries, Vocabularies, Grammars and Alphabets* (1796).

MARSEILLAISE, LA, the French national anthem, of a curiously fortuitous origin. It was composed—almost, it might be said, improvised—as to both words and music, in one night (April 24, 1792) by Claude Joseph Rouget de Lisle, a French captain of engineers who happened also to be a musical amateur. The need of a marching song for the French had been expressed by the mayor of Strasbourg, where de Lisle was then quartered, and the world-famous hymn was his patriotic response. It derived its name subsequently from the fact of its having been sung with indescribable enthusiasm by the troops on setting out from Marseille for Paris. Rouget de Lisle's actual authorship of the music was long disputed but may now be taken as established beyond dispute although his work undoubtedly underwent certain improvements at the hands of various composers (including Grétry and Gossec) before it reached its existing form.

MARSEILLES (Fr. MARSEILLE), a city of southern France, chief seaport of France and of the Mediterranean, 219 mi. S. by E. of Lyon and 534 mi. S.S.E. of Paris, by the P.L.M. railway. Pop. (1936) 814,679. It is capital of the department of Bouches-du-Rhône.

History.—The Greek colony of Massalia (Lat. *Massilia*) was founded by the mariners of Phocaea in Asia Minor, about 600 B.C.; probably Phoenicians settled at Marseilles before the Greek period. The name of the town is the Phoenician for "settlement." In 542 B.C. the fall of the Phocaean cities before the Persians probably sent new settlers to the Ligurian coast and cut off Massalia from close connection with the mother country. Isolated amid alien populations, the Massaliots made their way by prudence and by vigilant administration of their oligarchical government. Their colonies spread east and west along the coast from Monaco to Cape St. Martin in Spain, carrying with them the worship of Artemis; the inland trade, in which wine was an important element, can be traced by finds of Massalian coins across Gaul and through the Alps as far as Tirol. In the 4th century B.C. the Massaliot Pytheas visited the coasts of Gaul, Britain and Germany, and Euthymenes is said to have sailed down the west coast of Africa as far as Senegal. The great rival of Massalian trade was Carthage, and in the Punic Wars the city took the side of Rome, and was rewarded by Roman assistance in the subjugation of the native tribes of Liguria. In the war between Caesar and Pompey Massilia took Pompey's side and in A.D. 49 offered a vain resistance to Caesar's lieutenant Trebonius. In memory of its ancient services the city was left as a *civitas libera,* but her power was broken and most of her dependencies taken from her. From this time Massilia has little place in Roman history; it became for a time an important school of letters and medicine, but its commercial and intellectual importance declined. The town appears to have been Christianized before the end of the 3rd century, and at the beginning of the 4th century was the scene of the martyrdom of St. Victor. Its reputation partly revived through the names of Gennadius and Cassian, which give it prominence in the history of Semi-Pelagianism and the foundation of western monarchism.

After the ravages of successive invaders, Marseilles was repeopled in the 10th century under the protection of its viscounts. The town gradually bought up their rights, and at the beginning of the 13th century was formed into a republic, governed by a *podestat,* appointed for life, who exercised his office in conjunction with 3 notables, and a municipal council, composed of 80 citizens, 3 clerics and 6 principal tradesmen. Later in the middle ages, however, the higher town was governed by the bishop, and had its harbour at the creek of La Joliette which at that period ran inland to the north of the old town. The southern suburb was governed by the abbot of St. Victor, and owned the Port des Catalans. Situated between the two, the lower town, the republic, retained the old harbour, and was the most powerful of the three divisions. In 1245 and 1256 Charles of Anjou, count of Provence, whose predecessors had left the citizens a large measure of independence, established his authority above that of the republic. In 1423 Alphonso V of Aragon sacked the town. King René, who had made it his winter residence, however, caused trade, arts and manufactures again to flourish. On the embodiment of Provence in the kingdom of France in 1841, Marseilles preserved a separate administration directed by royal officials. Under Francis I. Charles de Bourbon vainly besieged the town with the imperial forces in 1524. During the wars of religion, Marseille took part against the Protestants, and long refused to acknowledge Henry IV. The loss of the ancient liberties of the town brought new disturbances under the Fronde, which Louis XIV came in person to suppress. He entered the town by a breach in the walls and afterwards had Fort St. Nicolas constructed. Marseilles repeatedly suffered from the plague, notably in 1720–1721.

During the Revolution the people rose against the ruling aristocracy. In the Terror they rebelled against the Convention, but were promptly subdued. The wars of the empire, by dealing a blow to their maritime commerce, excited the hatred of the inhabitants against Napoleon, and they hailed the return of the Bourbons and the defeat of Waterloo. The prosperity of the city received a considerable impulse from the conquest of Algeria and from the opening of the Suez canal. During World War I part of the harbour became a British base, and many Indian, Australian, and African troops passed through, and, after the armistice, an American embarkation camp was established.

The Town.—Marseilles is situated on the Golfe du Lion on the eastern shore of a bay protected to the south by Cape Croisette but open towards the west. The city is built on undulating ground and the south-western and most aristocratic quarter covers the slopes of the ridge crowned by a fort and the church of Notre-Dame de la Garde and projecting westward into the bay to form a protection for the harbour. The newest portion lies on the south-eastern slope of the ridge, which is better protected than most of the other quarters from the mistral, and where in summer the temperature is always a little lower than in the centre of the town. The old harbour of Marseilles opens on the west to the Golfe du Lion, the famous Rue Cannebière prolonged by the Rue Noailles leading east-northeast from its inner end. These two streets are the centre of the life of the city.

The old town of Marseilles is bounded west by the Joliette basin and the sea, east by the Cours Belsunce, south by the northern quay of the old port, and north by the Boulevard des Dames. It consists of a labyrinth of steep, dark and narrow streets inhabited by a seafaring population. The entrance to the old harbour is defended by Fort St. Jean on the north and Fort St. Nicolas on the south. Behind the latter is the Anse (Creek) de la Réserve. Beyond this again, situated in succession along the shore, come the Château du Pharo, which was given by the empress Eugénie to the town, the Anse du Pharo, the military exercising ground, and the Anse des Catalans. The harbour of Marseilles is deep enough for the largest vessels, and is being enlarged at the northern end, and a canal has been constructed to join the Rhone for inland traffic. A small port has been built at its opening into the Gulf of L'Estaque; land has been assigned for industrial development, and industrial suburbs are arising along the bank of the canal where, protected by embankments, it runs along the coast and reaches the Lave by a tunnel about 4½ mi. long. A new port was constructed at Etang de Berre. It is hoped that improved navigation on the Rhone, and the extension of the port to include the lake of Caronte, will bring a larger influx of trade to Marseilles.

In the roads to the southwest of the port lie the islands of

Ratonneau and Pomègue, united by a jetty forming a quarantine port. Between them and the mainland is the islet of Château d'If, in which the scene of part of Dumas' *Monte Cristo* is laid.

Marseilles possesses few remains of either the Greek or Roman periods of occupation and is poor in mediaeval buildings. The old cathedral of la Major (Sainte-Marie-Majeure), dating chiefly from the 12th century and built on the ruins of a temple of Diana, is in bad preservation. The chapel of St. Lazare (late 15th century) in the left aisle is early Renaissance. Beside this church and alongside the Joliette basin is the modern church begun in 1852, which has taken the place of the old Cathedral. It is a Byzantine basilica, in the form of a Latin cross, 460 ft. long built in green Florentine stone blended with white stone from the neighbourhood of Arles. The four towers which surmount it are roofed with cupolas. Near the cathedral stands the bishop's palace, and the Place de la Major. The celebrated Notre-Dame de la Garde, the steeple of which is surmounted by a gilded statue of the Virgin, 30 ft. in height, rises 150 ft. above the summit of the hill on which it stands. The present chapel is modern and occupies the site of one built in 1214.

On the south side of the old harbour near the Fort St. Nicolas stands the church of St. Victor, built in the 13th century and once attached to an abbey founded early in the 4th century. With its lofty crenellated walls and square towers built of large blocks of uncemented stone, it resembles a fortress. St. Victor is built above crypts dating mainly from the 11th century but also embodying architecture of the Carolingian period and of the early centuries of the Christian era. Tradition relates that St. Lazarus inhabited the catacombs under St. Victor; and the black image of the Virgin, still preserved there, is popularly attributed to St. Luke. The spire, which is the only relic of the ancient church of Accoules, marks the centre of Old Marseilles. Notre-Dame du Mont Carmel, also in the old town, occupies the place of what was the citadel of the Massaliots when they were besieged by Julius Caesar.

Of the civil buildings of the city, the prefecture, one of the finest in France, the Palais de Justice, and the Exchange, all date from the latter half of the 19th century. The Exchange, built at the expense of the Chamber of Commerce, includes the spacious hall of that institution with its mural paintings and gilding. The *hôtel-de-ville* (17th century) stands on the northern quay of the old harbour. The Palais Longchamp (1862–1870) is a museum and art gallery. The museum of antiquities, established in the Château Borély (1766–1778) includes a Phoenician collection (containing the remains that support the hypothesis of the Phoenician origin of Marseilles). The city also has a colonial museum and a laboratory of marine zoology. The triumphal arch of Aix, originally dedicated to the victors of the Trocadéro, was in 1830 appropriated to the conquests of the empire.

The *canal de Marseille,* constructed from 1837 to 1848, which has metamorphosed the town and its arid surroundings by bringing to them the waters of the Durance, leaves the river opposite Pertuis. It has a length of 97 miles (including its four main branches) of which 13 are underground, and irrigates some 7,500 acres. After crossing the valley of the Arc, between Aix and Rognac, by the magnificent aqueduct of Roquefavour, it purifies its waters, charged with ooze, in the basins of Réaltort. It draws about 2,200 gallons of water per second from the Durance, supplies 2,450 horse-power to works in the vicinity of Marseilles, and ensures a good water-supply and efficient sanitation to the city.

Marseilles is the headquarters of the XV Army Corps and the seat of a bishop and a prefect. It has tribunals of first instance and of commerce, a chamber of commerce, and a board of trade arbitration. The educational institutions include a faculty of science, a school of medicine and pharmacy, and a faculty (*faculté libre*) of law, these three forming part of the university of Aix-Marseilles and a school of navigation.

Trade and Industry.—Marseilles is the western emporium for the Levant trade and the French gate of the Far East. It suffers, however, from the competition of Genoa, which is linked with the Rhine basin by the Simplon and St. Gotthard railway routes, and from lack of communication with the inland waterways of France. In Jan. 1902 the chamber of deputies voted £3,656,000 for the construction of a canal from Marseilles to the Rhone at Arles. This scheme was designed to overcome the difficulties of egress from the Rhone and to make the city the natural outlet of the rich Rhone basin. Much of the activity of the port is due to the demand for raw material created by the industries of Marseilles itself.

The imports include wines, spirits, coal, tallow, copper, iron machinery, metals, cattle, sheep, copra, grain, cotton oil, palm oil, petroleum, oil seeds and nuts, coffee, cotton, hides, rice, maize and sugar. The exports include wines, spirits, liqueurs, tiles, bricks, metals, hides, ochre, oil cakes, soap, refined sugar, olive oil, dried vegetables, and glycerine.

The port is the centre for numerous lines of steamers which ply to the eastern Mediterranean, the east coast of Africa, Australia, India, Indo-China, Algeria, Tunis, Malta, Morocco, Antilles, as well as Great Britain and the French ports on the western coast. In addition many important foreign lines call at the port. Soap making was introduced in antiquity from Savona and Genoa and utilizes the products of the oil distilleries and of the chemical works, the latter being also an important adjunct to the manufacture of candles. A large quantity of iron, copper and other ores is smelted in the blast furnaces of Saint Louis and other foundries, and the Mediterranean Engineering Company and other companies have workshops for the construction or repair of marine steam engines, etc.

There are also important oil factories, flour mills, refineries, glassworks, tile works and tobacco factories, as well as the manufacturing of semolina, casks and rope, tanning, distilling, brewing, and State match factories.

Before World War I housing conditions were very bad, and manufacturers in consequence found it difficult to procure labour. During the war there was an influx of workers, and there was considerable industrial development, especially in the provision of foodstuffs and in metal manufacture.

MARSH, ADAM (Adam de Marisco) (d. *c.* 1258), English Franciscan, scholar and theologian, was born about 1200 in the diocese of Bath, and educated at Oxford under Grosseteste. Before 1226 Adam received the benefice of Wearmouth from his uncle, Richard Marsh, bishop of Durham; but between that year and 1230 he entered the Franciscan order. About 1238 he became the lecturer of the Franciscan house at Oxford. Roger Bacon, his pupil, speaks highly of his attainments in theology and mathematics. Consulted as a friend by Grosseteste, as a spiritual director by Simon de Montfort, the countess of Leicester and the queen, as an expert lawyer and theologian by the primate, Boniface of Savoy, he did much to guide the policy both of the opposition and of the court party in all matters affecting the interests of the Church. He shrank from office, and never became provincial minister of the English Franciscans, though constantly charged with responsible commissions. Henry III and Archbishop Boniface unsuccessfully endeavoured to secure for him the see of Ely in 1256.

In 1257 Adam's health was failing, and he appears to have died in the following year. He sympathized with Montfort as with a friend of the Church and an unjustly treated man; but on the eve of the baronial revolution he was on friendly terms with the king. He rebuked both parties in the state for their shortcomings, but he did not break with either.

See his correspondence, with J. S. Brewer's introduction, in *Monumenta franciscana,* vol. i. (Rolls ser., 1858); the biographical notice in A. G. Little's *Grey Friars in Oxford* (Oxford, 1892), where all the references are collected. On Marsh's relations with Grosseteste, see *Roberti Grosseteste epistolae,* ed. H. R. Luard (Rolls ed., 1861), and F. S. Stevenson, *Robert Grosseteste* (London, 1809). (H. W. C. D.)

MARSH, GEORGE PERKINS (1801–1882), American diplomatist and philologist, was born at Woodstock, Vt., on March 15, 1801. He graduated at Dartmouth college in 1820, was admitted to the bar in 1825, and practised law at Burlington, Vt., devoting himself also to philological studies. From 1843 to 1849 he was a Whig representative in Congress. In 1849 he was made United States minister resident in Turkey, returning to Vermont in 1854. In 1861 he became the first United States minister to the kingdom of Italy, and died in that office at Vallombrosa on July 23, 1882. Marsh was an able linguist, a scholar of great breadth, and a remarkable philologist for his day. His chief published works are: *A Compendious Grammar of the Old Northern or Icelandic Language* (1838); *The Camel, his Organization, Habits, and Uses, with Reference to his Introduction into the United States* (1856); *Lectures on the English Language* (1860); *The Origin and History of the English Language* (1862; revised ed., 1885); *Man and Nature* (1864); *The Earth as Modified by Human Action* (1874, 1885); and *Mediaeval and Modern Saints and Miracles* (1876).

See Mrs. C. Marsh's *Life and Letters of George Perkins Marsh* (1888).

MARSH, OTHNIEL CHARLES (1831–1899), American palaeontologist, was born in Lockport, N.Y., on Oct. 29, 1831. He graduated at Yale college in 1860, and studied geology and mineralogy in the Sheffield scientific school, New Haven, and afterwards palaeontology and anatomy in Berlin, Heidelberg and Breslau. Returning to America in 1866 he was appointed professor of vertebrate palaeontology at Yale college, and there began the researches of the fossil vertebrata of the western States, whereby he established his reputation. He was aided by a private fortune from his uncle, George Peabody, whom he induced to establish the Peabody Museum of Natural History (especially devoted to zoology, geology and mineralogy) in the college. In May, 1871, he discovered the first pterodactyl remains found in America, and in subsequent years he brought to light from Wyoming and other regions many new genera and families, and some entirely new orders of extinct vertebrata, which he described in monographs or periodical articles. These included remains of the Cretaceous toothed birds *Hesperornis* and *Ichthyornis*, the Cretaceous flying-reptiles (*Pteranodon*), the swimming reptiles or Mosasauria, and the Cretaceous and Jurassic land reptiles (*Dinosauria*) among which were the *Brontosaurus* and *Atlantosaurus*. The remarkable mammals which he termed Brontotheria (now grouped as Titanotheriidae), and the huge Dinocerata, one being the *Uintatherium*, were also brought to light by him. Among his later discoveries were remains of early ancestors of horses in America. He repeatedly organized and often accompanied scientific exploring expeditions in the Rocky mountains, and their results tended in an important degree to support the doctrine of evolution. He published many papers on these, and found time—besides that necessarily given to the accumulation and care of the most extensive collection of fossils in the world—to write *Odontornithes: A Monograph on the Extinct Toothed Birds of North America* (1880); *Dinocerata: A Monograph on an Extinct Order of Gigantic Mammals* (1884); and *The Dinosaurs of North America* (1896). His work is full of accurately recorded facts of permanent value. He was long in charge of the division of vertebrate palaeontology in the United States Geological Survey. He died in New Haven on March 18, 1899.

See obituary by Henry Woodward (with portrait) in *Geol. Mag.* (1899), p. 237; and Charles E. Beecher, "Memoir of Othniel Charles Marsh," *Bull. Geol. Soc. of Amer.*, vol. xi., pp. 531–537 (1900).

MARSH, an area of low-lying watery land. The significance of a marsh area lies in the peculiar chemical and physical results which accompany it, and in its ecological relations. Chemically it is productive of those transitory gases which arise from decomposing vegetation and also of hydrated iron oxide, which floats as an iridescent scum at the edge of rusty, marshy pools. This, sinking into the soil, forms a powerful cement to many sandstones, binding them into a hard local mass, while the surrounding sandstones remain loose and friable. Later, the former marsh area becomes the hard cap of a hill while the surrounding sandstones are more rapidly eroded. (*See* MESA.) Salt marshes characterise many low-lying sea-coasts and inland drainage areas.

MARSHAL, a title given in various countries to certain military and civil officers, usually of high rank. The origin and development of the meaning of the designation is closely analogous with that of constable (*q.v.*). Just as the title of constable is traceable to the style and functions of the Byzantine count of the stable, so that of marshal was evolved from the title of the *marescalci*, or masters of the horse, of the early Frankish kings. In this original sense the word survived down to the close of the Holy Roman empire in the titular office of *Erz-Marschalk* (arch-marshal), borne by the electors of Saxony. Elsewhere the meaning of office and title was modified. The importance of cavalry in mediaeval warfare led to the marshalship being associated with military command; this again led to the duty of keeping order in court and camp, of deciding questions of chivalry, and to the assumption of judicial and executive functions. The marshal, as a military leader, was originally a subordinate officer, the chief command under the king being held by the constable; but in the 12th century, though still nominally second to the constable, the marshal has come to the forefront as commander of the royal forces and a great officer of State. In England after the Conquest the marshalship was hereditary in the family which derived its surname from the office, and the hereditary title of earl-marshal originated in the marriage of William Marshal with the heiress of the earldom of Pembroke (*see* EARL MARSHAL). Similarly, in Scotland, the office of marischal (from the French *maréchal*), probably introduced under David I., became in the 14th century hereditary in the house of Keith. In 1485 the Scottish marischal became an earl under the designation of earl-marischal, the dignity coming to an end by the attainder of George, 10th earl-marischal, in 1716. In France, on the other hand, though under Philip Augustus the marshal of France (*marescalcus Franciae*) appears as commander-in-chief of the forces, care was taken not to allow the office to become descendible; under Francis I. the number of marshals of France was raised to two, under Henry III. to four, and under Louis XIV. to 20. Revived by Napoleon, the title fell into abeyance with the downfall of the Second empire.

In England the use of the word marshal in the sense of commander of an army appears very early; so Matthew Paris records that in 1214 King John constituted William, earl of Salisbury, *marescalcus* of his forces. The modern military title of field marshal, imported from Germany by King George II. in 1736, is derived from the high dignity of the *marescalcus* in a roundabout way. The *marescalcus campi*, or *maréchal des champs*, was originally one of a number of officials to whom the name, with certain of the functions, of the marshal was given. The marshal, being responsible for order in court and camp, had to employ subordinates, who developed into officials often but nominally dependent upon him. On military expeditions it was usual for two such marshals to precede the army, select the site of the camp and assign to the lords and knights their places in it. In time of peace they preceded the king on a journey and arranged for his lodging and maintenance. In France *maréchal des logis* is the title of superior non-commissioned officers in the cavalry.

Similarly at the king's court the *marescalcus aulae* or *intrinsecus* was responsible for order, the admission or exclusion of those seeking access, ceremonial arrangements, etc. Such "marshals" were maintained, not only by the king, but by great lords and ecclesiastics. The more dignified of their functions, together with the title, survive in the various German courts, where the court marshal (*Hofmarschall*) is equivalent to the English lord chamberlain. Just as the *marescalcus intrinsecus* acted as the vicar of the marshal for duties "within" the court, so the *marescalcus forinsecus* was deputed to perform those acts of serjeanty due from the marshal to the Crown "without." Similarly there appears in the statute 5 Edw. III. cap. 8, a *marescalcus banci regii*, or marshal of the king's bench, who presided over the Marshalsea court, and was responsible for the safe custody of prisoners bestowed in the Marshalsea prison. The office of marshal of the queen's bench survived till 1849 (*see* LORD STEWARD; and MARSHALSEA). The official known as a judge's marshal, whose office is of considerable antiquity, and whose duties consisted of making abstracts of indictments and pleadings for the use of the judge, still survives, but no longer exercises the above functions. He accompanies a judge of assize on circuit and is appointed by him at the beginning of each circuit. His travelling and other expenses are paid by the judge, and he receives an allowance of two guineas a day, which is paid through the Treasury. He introduces the high sheriff of the county to the judge of assize on his arrival, and swears in the grand jury. For the French *maréchaussée see* FRENCH LAW AND INSTITUTIONS.

In the sense of executive legal officer the title marshal survives in the United States of America in two senses. The United States marshal is the executive officer of the Federal courts, one being appointed for each district, or exceptionally, one for two districts. His duties are to open and close the sessions of the district and circuit courts, serve warrants, and execute throughout the district the orders of the court. There are United States marshals also in Alaska, Hawaii, Porto Rico and the Philippines. They are appointed by the president, with the advice and consent of the Senate, for a term of four years, and, besides their duties in connection with the courts, are employed in the service of the internal revenue, public lands, post office, etc. The temporary police sworn in to maintain order in times of disturbance, known in England as special constables, are also termed marshals in the United States. In some of the southern and western States of the Union the title marshal has sunk to that of the village policeman, as distinct from the county officers known as sheriffs and those of the justices' courts called constables.

In England the title of marshal, as applied to an executive officer, survives only in the army, where the provost marshal is chief of the military police in large garrisons and in field forces. Office and title were borrowed from the French *prévôt des maréchaux*, the modern equivalent of the mediaeval *praepositus marescalcorum* or *guerrarum.*

MARSHALL, ALFRED (1842–1924), British economist, was educated at Merchant Taylors' school and at St. John's college, Cambridge, where he read mathematics, being second wrangler in 1865, and elected to a fellowship in the same year. From mathematics he turned to the study of metaphysics, from that to ethics and finally to political economy, to which he himself was later to give the name economics. Having married in 1871, he had to vacate his fellowship, and he accepted the post of first principal of University college, Bristol, where he did a great deal of valuable administrative work, but had to resign in 1881 owing to ill-health. From 1883–85 he was a fellow and lecturer in political economy at Balliol college, Oxford; in the latter year he returned to Cambridge as professor of political economy in succession to Henry Fawcett. He was a member of the royal commission on labour from 1891–94 and subsequently rendered important services to a number of Government enquiries. In 1903, after years of struggle, he succeeded in calling into being an economics tripos at Cambridge, separate and distinct from the moral sciences tripos. He retired from the chair of political economy in 1908 and thenceforward gave himself up entirely to his writings until his death in 1924.

Marshall published the *Principles of Economics* in 1890, his first big work, and in many ways his most important contribution to economic literature. His next volume *Industry and Trade,* a realistic study of industrial organization, did not appear until 1918, but in the meanwhile he had devoted much time and energy to bringing out successive editions of his *Principles.* In 1923 he published his last volume, *Money, Credit and Commerce.* Marshall may be said to have been in the lineal descent of the great English economists—Adam Smith, Ricardo and J. S. Mill. Like their chief works, his *Principles of Economics* has become a classic. It was distinguished by its profound and systematic methods of analysis, and by the introduction of a number of new concepts, such as elasticity of demand, consumer's surplus, quasi-rent, the representative firm, etc., which have played a great rôle in the subsequent development of economics. Writing at a time when the economic world was hopelessly divided on the theory of value, he succeeded, largely by introducing the element of time as a factor in analysis, in reconciling the classical cost of production principle with the marginal utility principle formulated by Jevons (*q.v.*) and the Austrian school. He did much to rescue economics from the rigid dogmatism, which had alienated so many of the best minds of the 19th century, by insisting that economic reasoning and laws were not themselves a body of concrete truth, but an engine for the discovery of concrete truth.

Although so many years elapsed between the publication of the *Principles of Economics* and that of his next two works, much that was most important in them, especially in regard to the theory of money, had been transmitted orally in his lectures at Cambridge, and had appeared in the evidence which he gave before the gold and silver commission in 1887 and the Indian currency commission in 1899. In this way he had influenced thought far outside the confines of Cambridge, not only in England but also in foreign countries.

While Marshall never set himself to found a school of economic doctrine, his genius for stimulating the minds of a long succession of pupils, and the example of his methods of reasoning, had a profound effect upon the development of economics in England, the United States, and many European countries.

(C. W. G.)

MARSHALL, JOHN (1755–1835), American jurist, chief-justice of the U.S. Supreme Court, was born on Sept. 24, 1755, at Germantown (now Midland), in what four years later became Fauquier county, Va. He was of English descent, the son of Thomas Marshall (1732–1806) and his wife, Mary Isham Keith. Marshall served first as lieutenant and, after July 1778, as captain in the Continental army during the Revolutionary War. He resigned his commission early in 1781; was admitted to the bar after a brief course of study, first practised in Fauquier county, and after two years began to practise in Richmond. In 1786 we find him counsel in a case of great importance, *Hite* v. *Fairfax,* involving the original title of Lord Fairfax to that large tract of country between the headwaters of the Potomac and Rappahannock, known as the northern neck of Virginia. Marshall represented tenants of Lord Fairfax and won his case. From this time, as is shown by an examination of Call's *Virginia Reports* which cover the period, he maintained the leadership of the bar of Virginia. He was a member of the Virginia assembly in 1782–91 and again in 1795–97; and in 1788, he took a leading part in the Virginia convention called to act on the proposed Constitution for the United States, with Madison ably urging the ratification of that instrument. In 1795 Washington offered him the attorney-generalship, and in 1796, after the retirement of James Monroe, the position of minister to France. Marshall declined both offers because his situation at the bar appeared to him "to be more independent and not less honourable than any other," and his "preference for it was decided." He spent the autumn and winter of 1797–98 in France as one of the three commissioners appointed by President John Adams to adjust the differences between the young republic and the directory. The commission failed, but the course pursued by Marshall was approved in America, and with the resentment felt because of the way in which the commission had been treated in France, made him, on his return, exceedingly popular. To this popularity, as well as to the earnest advocacy of Patrick Henry, he owed his election as a Federalist to the House of Representatives in the spring of 1799, though the feeling in Richmond was overwhelmingly in favour of the opposition or Republican Party. His most notable service in Congress was his speech on the case of Thomas Nash, alias Jonathan Robbins, in which he showed that there is nothing in the U.S. Constitution which prevents the Federal Government from carrying out an extradition treaty. He was secretary of State under President Adams from June 6, 1800, to March 4, 1801. In the meantime he had been appointed chief-justice of the Supreme Court, his commission bearing date Jan. 31. Thus while still secretary he presided as chief-justice.

At the time of Marshall's appointment it was generally considered that the Supreme Court was the one department of the new Government which had failed in its purpose. John Jay, the first chief-justice, who had resigned in 1795, had just declined a reappointment to the chief-justiceship on the ground that he had left the bench perfectly convinced that the court would never acquire proper weight and dignity, its organization being fatally defective. The advent of the new chief-justice was marked by a change in the conduct of business in the court. Since its organization, following the prevailing English custom, the judges had pronounced their opinions seriatim. But beginning with the

December term 1801, the chief-justice became practically the sole mouthpiece of the court. For 11 years the opinions are almost exclusively his, and there are few recorded dissents. The change was admirably adapted to strengthen the power and dignity of the court. The chief-justice embodied the majesty of the judicial department of the Government almost as fully as the president stood for the power of the executive. That this change was acquiesced in by his associates without diminishing their good will towards their new chief is testimony to the persuasive force of Marshall's personality; for his associates were not men of mediocre ability. After the advent of Mr. Justice Joseph Story the practice was abandoned. Marshall, however, still delivered the opinion in the great majority of cases, and in practically all cases of any importance involving the interpretation of the Constitution. During the course of his judicial life his associates were as a rule men of learning and ability. During most of the time the majority were the appointees of Democratic presidents, and before their elevation to the bench supposed to be out of sympathy with the federalistic ideas of the chief-justice. Yet in matters pertaining to constitutional construction, they seem to have had hardly any other function than to add the weight of their silent concurrence to the decision of their great chief. Thus the task of expounding the Constitution during the most critical period of its history was his, and it was given to him to preside over the Supreme Court when it was called upon to decide four cases of vital importance: *Marbury* v. *Madison, M'Culloch* v. *Maryland, Cohens* v. *Virginia* and *Gibbons* v. *Ogden.* In each of these cases it is Marshall who writes the opinion of the court; in each the continued existence of the peculiar Federal system established by the Constitution depended on the action of the court, and in each the court adopted a principle which is now generally perceived to be essential to the preservation of the United States as a Federal State.

In *Marbury* v. *Madison,* which was decided two years after his elevation to the bench, he decided that it was the duty of the court to disregard any act of Congress, and, therefore, *a fortiori* any act of a legislature of one of the States, which the court thought contrary to the Federal Constitution.

In *Cohens* v. *Virginia,* in spite of the contention of Jefferson and the then prevalent school of political thought that it was contrary to the Constitution for a person to bring one of the States of the United States, though only as an appellee, into a court of justice, he held that Congress could lawfully pass an act which permitted a person who was convicted in a State court, to appeal to the U.S. Supreme Court, if he alleged that the State act under which he was convicted conflicted with the Federal Constitution or with an act of Congress.

In *M'Culloch* v. *Maryland,* though admitting that the Federal Government is one of delegated powers and cannot exercise any power not expressly given in the Constitution, he laid down the rule that Congress in the exercise of a delegated power has a wide latitude in the choice of means, not being confined in its choice of means to those which must be used if the power is to be exercised at all.

Lastly, in *Gibbons* v. *Ogden,* he held that when the power to regulate interstate and foreign commerce was conferred by the Constitution on the Federal Government, the word "commerce" included not only the exchange of commodities, but the means by which interstate and foreign intercourse was carried on, and therefore, that Congress had the power to license vessels to carry goods and passengers between the States, and an act of one of the States making a regulation which interfered with such regulation of Congress was, *pro tanto,* of no effect.

It will be seen that in the first two cases he established the Supreme Court as the final interpreter of the Constitution.

The decision in *M'Culloch* v. *Maryland,* by leaving Congress unhampered in the choice of means to execute its delegated powers, made it possible for the Federal Government to accomplish the ends of its existence. "Let the end be legitimate," said Marshall in the course of its opinion, "let it be within the scope of the Constitution, and all means which are appropriate, which are plainly adapted to that end, which are not prohibited, but consist with the letter and spirit of the Constitution, are constitutional."

If the decision in *M'Culloch* v. *Maryland* gave vigour to all Federal power, the decision in *Gibbons* v. *Ogden,* by giving the Federal Government control over the means by which interstate and foreign commerce is carried on, preserved the material prosperity of the country. The decision recognizes what the framers of the Constitution recognized, namely that the United States is an economic unit, and that business which is national should be under national, not State, control.

Though for the reasons stated, the four cases mentioned are the most important of his decisions, the value of his work as an expounder of the U.S. Constitution is not to be measured by these cases alone. In all he decided 44 cases involving constitutional questions. Nearly every important part of the U.S. Constitution as it existed before the amendments which were adopted after the Civil War, is treated in one or more of them. The Constitution in its most important aspects is the Constitution as he interpreted it. He did not work out completely the position of the States in the Federal system, but he did grasp and establish the position of the Federal legislature and the Federal judiciary. To appreciate his work, however, it is necessary to see that it was the work not of a statesman but of a judge. Had Marshall been merely a far-seeing statesman, while most of his important cases would have been decided as he decided them, his life-work would have been a failure. It was not only necessary that he should decide great constitutional questions properly, but also that the people of the United States should be convinced of the correctness of his interpretation of the Constitution. His opinions, therefore, had to carry to those who studied them a conviction that the constitution as written had been interpreted according to its evident meaning. They fulfilled this prime requisite. Their chief characteristic is the cumulative force of the argument. The ground for the premise is carefully prepared, the premise itself is clearly stated; nearly every possible objection is examined and answered; and then comes the conclusion. There is little or no repetition, but there is a wealth of illustration, a completeness of analysis, that convinces the reader, not only that the subject has been adequately treated, but that it has been exhausted. His style, reflecting his character, suits perfectly the subject matter. Simple in the best sense of the word, his intellectual processes were so clear that he never doubted the correctness of the conclusion to which they led him. Apparently from his own point of view, he merely indicated the question at issue, and the inexorable rules of logic did the rest. Thus his opinions are simple, clear, dignified. Intensely interesting, the interest is in the argument, not in its expression. He had, in a wonderful degree, the power of phrase. He expressed important principles of law in language which tersely yet clearly conveyed his exact meaning. Not only is the Constitution interpreted largely as he taught the people of the United States to interpret it, but when they wish to express important constitutional principles which he enunciated they use his exact words. Again, his opinions show that he adhered closely to the words of the Constitution; indeed no one who has attempted to expound that instrument has confined himself more strictly to an examination of the text. In the proper, though not in the historical, sense he was the strictest of strict constructionists, and as a result his opinions are practically devoid of theories of government, sovereignty and the rights of man.

A single illustration of his avoidance of all theory and his adherence to the words of the Constitution will suffice. In the case of the *United States* v. *Fisher* the constitutional question involved was the power of Congress to give to the United States a preference over all other creditors in the distribution of the assets of a bankrupt. Such an act can be upheld on the ground that all governments have necessarily the right to give themselves priority. Not so Marshall. To him the act must be supported, if supported at all, not on any theory of the innate nature of the government, national or otherwise, but as a reasonable means of carrying out one of the express powers conferred by the Constitution on the Federal Government. Thus, he upholds the act in question because of the power expressly conferred on the Federal Government to pay the debts of the Union, and, as a necessary consequence of this power the right to make remittances by bills or otherwise and to take precautions which will render the transactions safe.

It is important to emphasize the fact that Marshall adhered in his opinions to the Constitution as written, not only because it is a fact which must be recognized if we are to understand the correct value of his work in the field of constitutional law, but also because there exists to-day a popular impression that by implication he stretched to the utmost the powers of the Federal Government. This impression is due primarily to the ignorance of many of those who have undertaken to praise him. During his life he was charged by followers of the State's rights school of political thought with upholding Federal power in cases not warranted by the Constitution. Later, however, those who admired a strong national Government, without taking the trouble to ascertain whether the old criticism by members of the State's rights party was just, regarded the assumption on which it was founded as Marshall's best claim to his country's gratitude.

As a constitutional lawyer, Marshall stands without a rival. His work on international law and admiralty is of first rank. But though a good, he was not a great, common law or equity lawyer. In these fields he did not make new law nor clarify what was obscure, and his constitutional opinions which to-day are found least satisfactory are those in which the question to be solved necessarily involves the discussion of some common-law concept, especially those cases in which he was required to construe the restriction imposed by the Constitution on any State impairing the obligation of contracts. His decision in the celebrated case of *Dartmouth College* v. *Woodward,* in which he held that a State could not repeal a charter of a private corporation, because a charter is a contract which a subsequent act of the State repealing the charter impairs, though of great economic importance, does not touch any fundamental question of constitutional law. The argument which he advances lacks the clearness and finality for which most of his opinions are celebrated. It is not certain with whom he thought the contract was made: with the corporation created by the charter, with the trustees of the corporation, or with those who had contributed money to its objects.

Of the wonderful persuasive force of Marshall's personality there is abundant evidence. His influence over his associates, already referred to, is but one example though a most impressive one. From the moment he delivered the opinion in *Marbury* v. *Madison* the legal profession knew that he was a great judge. Each year added to his reputation and made for a better appreciation of his intellectual and moral qualities. The bar of the Supreme Court during his chief-justiceship was the most brilliant which the United States has ever known. Leaders, not only of legal, but political thought were among its members; one, Webster, was a man of genius and commanding position. To a very great degree Marshall impressed on the members of this bar and on the profession generally his own ideas of the correct interpretation of the Constitution and his own love for the Union. He did this, not merely by his arguments but by the influence which was his by right of his strong, sweet nature. Statesmen and politicians, great and small, were at this time, almost without exception, members of the bar. To influence the political thought of the bar was to a great extent to influence the political thought of the people.

Though the direct influence of Marshall's constitutional arguments was largely confined to the members of the bar, the influence of his personality was felt by practically all classes of people. When he was appointed he was perhaps the most popular Federalist in the country. His supreme fitness for the judicial office was, however, probably not generally recognized until after the trial of Aaron Burr. Over this trial, the most dramatic in American history, he presided with a dignity, impartiality and ability never surpassed. Burr, himself brilliant, erratic, casts a certain fascination over each succeeding generation of historical students. In his character there is something alluring. Its dominant note is mystery. He was, next to Thomas Jefferson and perhaps James Madison, the leading Democrat of his day. When Jefferson became president he was elected vice-president, holding that office from 1801 to 1805. In 1804 he killed Alexander Hamilton, his great political antagonist, in a duel. Burr was the challenging party. His enemy's death ended his own political career in the United States. His restless energy and great ambition led him to organize an armed expedition which assembled on the Ohio in 1806 on Blennerhasset's island. Though Burr lived many years after the trial, and though everything in connection with his ill-starred expedition has been subjected to the most painstaking investigation, the real nature of his aims, whether to attack Mexico, or detach from the Union the portion of the United States west of the Alleghenies, or both, remains uncertain. To dream of conquest or of the dismemberment of the country is not treason. The Constitution provides that: "Treason against the United States shall consist only in levying war against them, or in adhering to their enemies, giving them aid and comfort." And it is also provided that: "No person shall be convicted of treason unless on the testimony of two witnesses to the same overt act, or on confession in open court." The trial took place in the Federal circuit court for the district of Virginia; the island, though in the Ohio river, being at that time, in the State of Virginia. It began on Aug. 10, 1807. Though Burr was indicted for treason on Blennerhasset's island, it was known to everyone that, at the time the alleged acts of levying war had been committed, Burr was not only not on the island, but hundreds of miles away in another State. The Government had evidence of a conspiracy to raise an armed force, perhaps to attack New Orleans, in which conspiracy Burr was the prime mover. It probably had evidence that, subsequent to the meeting on Blennerhasset's island, a small force under Burr had joined the small force which had previously assembled on the island, making in all about 100 men, and proceeded down the Ohio and Mississippi rivers to a few miles above Natchez, where Burr had voluntarily surrendered himself to George Mead, the acting governor of Mississippi, who, on the alarm created by the denunciation of Burr's plans, had assembled a small force of militia to oppose him. But the Government could not even prove that Burr had caused the force mentioned in the indictment to assemble on the island.

Looking back to-day, we see a succession of errors on the part of Jefferson that might have resulted in a drama ending in a tragedy—the execution of Burr as a result of a conviction for treason, which would probably have been improper in any event, certainly improper in view of the law, the wording of the indictment, and the character of the acts which the United States alleged it stood ready to prove. Jefferson had blundered in not arresting Burr and stopping his preparations when he first had evidence of the nature of his plans. His negligence had permitted those plans to go far towards maturity when he received a letter from Gen. Wilkinson, the commander at New Orleans, denouncing Burr as contemplating the detachment of the Western country from the Union. Instead of merely publishing the information and ordering Burr's arrest, Jefferson inflamed the popular mind by denouncing Burr as a traitor. From the moment this proclamation was issued, the president, instead of standing for the calm and efficient execution of the law, used his immense popularity in the country to excite the popular mind. By the time the prisoner was brought to trial, though he had become a hero to the few, the many had already made up their minds that only by legal chicanery could he escape the gallows. With one voice they clamoured for conviction. In Richmond, the local prejudice was so strong that it was impossible to secure an unprejudiced jury. Fortunate was it for Burr, but still more fortunate for the United States, that the trial was presided over by a man who combined as did Marshall, ability, courage and absolute control of nerves and temper.

More than one hundred years have elapsed since the curtain descended on the last scene of the trial. When we recall the trial, though we see Wirt, the able and eloquent attorney for the prosecution, and Luther Martin, the leader of Burr's forensic forces, drunken, rollicking, devoid of good taste, but as a lawyer unsurpassed; though the mind calls up before it the dignified figure of Aaron Burr, and fills in the background of the court-room with portraits more or less distinct of the other actors in those memorable scenes, the form which stands out as the central figure is that of the chief-justice, the one really great man in that brilliant throng. We feel the power of expression in his wonderful eyes and the calm dignity which emanated from his personality. As we read the following passage which practically closes his principal opinion, the opinion which, excluding all remaining testimony which the Government had to offer, necessarily brought the case to an end favourable to the prisoner, we seem to hear the even tones of his voice; and, realizing the excitement in the country, and the strain of the days that preceded, there comes to us as there came to his audience, the thrill of confidence in the man and pride in the majesty of the law.

"Much has been said in the course of the argument on points on which the court feels no inclination to comment particularly; but which may, perhaps not improperly, receive some notice.

"That this court dares not usurp power is most true.

"That this court dares not shrink from its duty is not less true. No man is desirous of placing himself in a disagreeable situation. No man is desirous of becoming the peculiar subject of calumny. No man, might he let the bitter cup pass from him without self-reproach, would drain it to the bottom. But if he have no choice in the case, if there be no alternative presented to him but a dereliction of duty, or the opprobrium of those who are denominated the world, he merits the contempt as well as the indignation of his country who can hesitate which to embrace."

Jefferson might rage as he read the opinions of the court; the excited inhabitants of Baltimore on learning the result of the trial might burn the judge in effigy along with Burr and his leading counsel, thus giving the latter the opportunity to deliver to them an immortal piece of sarcasm. But the brilliant throng which had crowded the rooms from day to day, had seen the judge whose calmness was in strange contrast to their half expressed excitement; moved by the impelling force of his personality, they had realized that this man held the scales of justice with impartial balance; that his known dislike and distrust of the president who wanted the conviction did not affect his judgment, any more than the fact that the prisoner at the bar had slain in the course of a career full of little but harm, one of his dearest friends. Furthermore, they had listened to his analysis of the legal questions arising in the case and with few exceptions they knew the result was correct. Thus, as they went out from the court-room to all parts of the country they carried with them the impress of the personality of the great judge.

In 1782 Marshall married Mary Willis Ambler, the daughter of the then treasurer of Virginia. They had ten children, six of whom grew to full age. For the greater part of the 48 years of their married life Mrs. Marshall suffered intensely from a nervous affection. Her condition called out the love and sympathy of her husband's deep and affectionate nature. Judge Story tells us: "That which, in a just sense, was his highest glory, was the purity, affectionateness, liberality and devotedness of his domestic life." For the first 30 years of his chief-justiceship his life was a singularly happy one. He never had to remain in Washington for more than three months. During the rest of the year, with the exception of a visit to Raleigh, which his duties as circuit judge required him to make, and a visit to his old home in Fauquier county, he lived in Richmond. His house on Shockhoe Hill is still standing.

On Christmas Day, 1831, his wife died. He never was quite the same again. On returning from Washington in the spring of 1835 he suffered severe contusions, from an accident to the stage-coach in which he was riding. His health, which had not been good, now rapidly declined and in June he returned to Philadelphia for medical attendance. There he died on July 6. His body, which was taken to Richmond, lies in Shockhoe Hill cemetery under a plain marble slab, on which is a simple inscription written by himself. In addition to his decisions Marshall wrote a famous biography of George Washington (5 vol., 1804–07; 2nd ed., 2 vol., 1832), which, though prepared hastily, contains much material of value.

Bibliography.—The principal sources of information are: Albert J. Beveridge, *Life of John Marshall* (1919); an essay by James B. Thayer (1904); *Great American Lawyers* (Philadelphia, 1908), ii. 313–408, an essay by Wm. Draper Lewis; and Allan B. Magruder, *John Marshall* (Boston, 1885), in the "American Statesmen Series." The addresses delivered on Marshall Day, February 4, 1901, are collected by John F. Dillon (Chicago, 1903). In the "Appendix" to Dillon's collection will be found the "Discourse" by Joseph Story and the "Eulogy" by Horace Binney, both delivered soon after Marshall's death. For a study of Marshall's decisions, the *Constitutional Decisions of John Marshall*, edit. by Joseph P. Collon, Jr. (1905), is of value.

(W. D. L.)

MARSHALL, STEPHEN (*c.* 1594–1655), English Nonconformist divine, was born at Godmanchester in Huntingdonshire, and was educated at Emmanuel college, Cambridge (M.A. 1622, B.D. 1629). After holding the living of Wethersfield in Essex he became vicar of Finchingfield in the same county, and in 1636 was reported for "want of conformity." He was a preacher of great power, and influenced the elections for the Short parliament of 1640. Clarendon esteemed his influence on the parliamentary side greater than that of Laud on the royalist. In 1642 he was appointed lecturer at St. Margaret's, Westminster, and delivered a series of addresses to the Commons in which he advocated episcopal and liturgical reform. He had a share in writing *Smectymnuus,* was appointed chaplain to the earl of Essex's regiment in 1642, and a member of the Westminster Assembly in 1643. He represented the English parliament in Scotland in 1643, and attended the parliamentary commissions at the Uxbridge Conference in 1645. He waited on Archbishop Laud before his execution, and was chaplain to Charles I. at Holmby House and at Carisbrooke. A moderate and judicious presbyterian, he prepared with others the "Shorter Catechism" in 1647, and was one of the "Triers" 1654. He died in November 1655 and was buried in Westminster abbey, but his body was exhumed at the Restoration.

MARSHALL, THOMAS RILEY (1854–1925), American politician, born at North Manchester, Ind., on March 14, 1854. He was educated at Wabash college (A.B. 1873; A.M. 1876), and was admitted to the bar in 1875. From 1876 to 1909 he practised law in Columbia City, Ind., and from 1909 to 1913 was governor of Indiana. He was nominated for vice-president on the ticket with Woodrow Wilson at the Democratic national convention in 1912 and was elected. He was again nominated with President Wilson in 1916 and elected for the term 1917–21. For almost two years after the outbreak of the World War he urged strict neutrality, but in 1918 publicly expressed regret for this attitude. In 1919 he welcomed the king and queen of Belgium on their visit to Washington during the illness of President Wilson. He was a strong advocate of the League of Nations, but did not favour woman suffrage. He served on the U.S. coal commission in 1922. He died in Washington, D.C., on June 1, 1925. His memoirs, *Recollections of Thomas R. Marshall,* were published posthumously in 1925.

MARSHALL, a city of southern Michigan, U.S.A., on the Kalamazoo river, federal highways 12 and 27 and the Michigan Central railroad; the county seat of Calhoun county. It has a municipal airport. The population was 5,019 in 1930 and 5,253 in 1940 by federal census. Its industries include a large automobile tappet factory, furnace factory and state highway garage plant.

The Michigan school system was founded there. The city was founded in 1831 and incorporated in 1837.

MARSHALL, a city of Missouri, U.S.A., 85 mi. E. of Kansas City, on the Salt Fork of La Mine river; the county seat of Saline county. It is on federal highway 65, and is served by the Alton and the Missouri Pacific railways. Pop. (1920) 5,200 (12% Negroes); 1930, 8,103; 1940, 8,533, federal census. There are salt springs, coal mines and stone quarries in the vicinity. The city has an aeroplane factory, flying school, shoe factory, milk condensing works and other industries. It is the seat of the Missouri Valley college (Presbyterian; 1888) and of the state colony for the feeble-minded and epileptic (1899). Marshall was founded and made the county seat in 1839, was incorporated as a town in 1866 and as a city in 1878.

MARSHALL, a city of eastern Texas, U.S.A., 38 mi. W. of Shreveport, on federal highways 59 and 80; the county seat of Harrison county. It is served by the Texas and Pacific railway.

Population (41% Negroes) in 1940, 18,410, by the federal census. It is the trade centre for agricultural products, including an annual cotton crop for the county of about 40,000 bales; and has railway shops employing 2,000 men and other important manufacturing industries, with an output in 1940 valued at approximately $6,000,000. The city's products include 50,000 car wheels, 30,000,000 brick, 3,000,000 baskets, 15,000 tons of cotton-seed and 6,000 tons of fertilizer annually; 70 different articles of stoneware; chairs and crates, powdered milk, butter, and deodorizing and decolorizing carbon made from lignite. There are three gas fields within 40 mi. of the city. Marshall is the home of the Central East Texas fair, and the seat of Bishop college (founded 1881) and Wiley college for Negroes, and the College of Marshall (1914), a junior Baptist college. Rosborough Springs (9 mi. S.) and Caddo lake (16 mi. N.E.) are popular resorts. Marshall was settled in 1842, incorporated in 1843, and chartered as a city in 1848. Since 1909 it has had a commission-manager form of government.

MARSHALL ISLANDS: *see* PACIFIC ISLANDS.

MARSHALLTOWN, a city of central Iowa, U.S.A., on the Iowa river and the Lincoln highway, at an altitude of 890 ft.; the county seat of Marshall county. It is served by the Chicago and North Western, the Chicago Great Western, and the Minneapolis and St. Louis railways. Pop. (1920) was 15,731 (88% native white), and 1940 federal census 19,240. It is the seat of the Iowa Soldiers home; has a large wholesale business; manufactures furnaces, engines, machinery, building trowels, automobile accessories, canned foods, and other commodities; and is an important market and shipping point for grain and livestock. The city was laid out in 1853, became the county seat in 1860, was incorporated as a town in 1863 and chartered as a city in 1868. County and city were named after Chief Justice Marshall of the U.S. supreme court.

MARSHALSEA, a prison formerly existing in Southwark and attached to the court of that name held by the steward and marshal of the king's house (*see* LORD STEWARD and MARSHAL). It existed as early as the reign of Edward III. It was consolidated in 1842 with the queen's bench and the Fleet, and was then described as "a prison for debtors and for persons charged with contempt of Her Majesty's courts of the Marshalsea, the court of the queen's palace of Westminster, and the high court of admiralty, and also for admiralty prisoners under sentence of courts martial." It was abolished in 1849. The Marshalsea prison is described in Charles Dickens' *Little Dorrit*.

MARSHFIELD, a city of Coos county, Oregon, U.S.A., on Coos bay, 220 mi. S.W. of Portland; a port of entry, with the largest natural harbour between the Columbia river and San Francisco. A rapidly growing commercial and industrial centre. It is on federal highway 101, and is served by the Southern Pacific railway lines, bus lines and by ocean steamers. Population 1930, 5,287; 1940, 5,259. Coos bay, with a fine natural harbour, had a traffic in 1940 amounting to 448,086 tons (chiefly lumber), valued at $5,152,000. The city has several sawmills and fish-packing plants, and manufactures veneer, battery separators, and in 1940 manufactured 947,523 lb. of cheese. Marshfield was founded in 1860 and incorporated in 1874.

MARSHFIELD, a city of Wood county, Wisconsin, U.S.A., in the central part of the state. It is on federal highway 10, and is served by the Chicago and North Western, the Chicago, St. Paul, Minneapolis and Omaha, and the Soo Line railways. Pop. (1920) 7,394 (85% native white); 1940 federal census 10,359. It is the trade centre and shipping point for a rich dairy region, and has numerous and varied manufactures (notably hardwood veneer) amounting to $4,250,000 annually in value. The site of Marshfield was in the tract granted by the United States to the Fox River Improvement company, organized to construct a waterway from the Mississippi river to Green Bay. It was settled about 1870; named after one of the original owners, Samuel Marsh, of Massachusetts; and chartered as a city in 1883.

MARSH GAS (methane), the first and simplest member of the paraffin hydrocarbons, owes its name to the fact that it is a constituent of the gas which arises in marshy districts from the decomposition of vegetable matter under the surface of water. It occurs also as a component of "fire damp" of coal mines. It is found in volcanic gases, in petroleum and in human intestinal gases, and is a product of the destructive distillation of complex organic matters (coal, lignite, bituminous shale, peat, wood, etc.) so that it is present to the extent of 30 to 40% in coal gas.

Methane, CH_4, is a colourless, inodorous gas of specific gravity 0·559 (air=1). At $-160°$ C it has been condensed to a colourless liquid, specific gravity 0·415 (water=1). It boils at $-164°$ C/736 mm. and freezes at $-186°$ C to white needles. One volume of water at $t°$ C absorbs $0{\cdot}05449-0{\cdot}001807t$ volumes of methane, and it is nearly ten times as soluble in alcohol.

The preparation of industrial methane is effected by passing a mixture of hydrogen with carbon dioxide or, preferably, carbon monoxide over a heated nickel catalyst. With the dioxide the reaction requires temperatures between 300° and 400° C, but with the monoxide the change proceeds to completion at 230–250° C. As the other product is steam, which can be condensed, the methane can be obtained almost pure.

Other methods of preparation are of scientific interest. Pure methane is obtained on decomposing aluminium or beryllium carbide with water (*see* CARBIDES) and also by the action of water on zinc dimethyl (E. Frankland) or on magnesium methyl iodide. (*See* GRIGNARD REAGENTS.) The removal of sulphur by red-hot copper from a mixture of sulphuretted hydrogen and carbon disulphide vapour leads to the formation of methane $CS_2+2H_2S+8Cu=4Cu_2S+CH_4$, and is a classical instance of an early organic synthesis (M. Berthelot, 1856). In the laboratory, methane is often prepared by heating dry sodium acetate with soda-lime but the product is contaminated with hydrogen and ethylene. Methane has been obtained by direct combination of carbon and hydrogen at 1,200° C (Bone, Jerdan, and Coward, 1897–98). Methane forms with air an explosive mixture of gas, the "fire damp" of the coal mines and a frequent cause of colliery explosions. (*See* Publications of the Safety in Mines Research Board, vol. ii., 1926, H.M. Stationery Office, London.)

The oxidation of methane may be caused to occur in stages, and methyl alcohol and formaldehyde have been identified as intermediate products of its combustion. Successive chlorination of methane leads to methyl chloride, methylene chloride, chloroform, and finally carbon tetrachloride.

MARSH MALLOW (*Althaea officinalis*), a European plant allied to the hollyhock (*q.v.*), found in Great Britain and sparingly naturalized in the eastern U.S.A. It grows in marshes, especially near the sea. Sweetmeats were formerly made from the root. In the U.S.A. a marshmallow is a confection of sugar, syrup, starch, and gelatin.

MARSHMAN, JOSHUA (1768–1837), English Baptist missionary and orientalist, was born on April 20, 1768, at Westbury Leigh, in Wiltshire. In 1799 he was sent by the Baptist Missionary Society to join their mission at Serampore. Here he translated the Bible into various dialects, and, aided by his son, established newspapers and founded Serampore college. He received the degree of D.D. from Brown university, U.S.A., in 1810. He died at Serampore on Dec. 5, 1837. Marshman translated into Chinese the book of Genesis, the Gospels, Romans and Corinthians; in 1811 he published *The Works of Confucius, containing the Original Text, with a Translation,* and in 1814 his *Clavis Sinica.*

See J. C. Marshman, *Life and Times of Carey, Marshman and Ward* (2 vols., 1859).

MARSH-MARIGOLD (*Caltha palustris*), a plant of the buttercup family (Ranunculaceae), the "winking Mary-buds" of Shakespeare (*Cymb.*, ii., 3), common in wet places on both sides of the Atlantic. In America it is usually called cowslip, and is often known as kingcup in Great Britain. The stem is thick and hollow; the leaves are shining and kidney-shaped; and the flowers, which bloom in March or April, have five yellow sepals. The early shoots and leaves are used like spinach and the flower-buds preserved in salted vinegar form a substitute for capers. A double-flowered variety is often cultivated and is occasionally found wild. *C. natus,* a large species with white or pink flowers, occurs in ponds from Minnesota north. *C. leptosepala,* with white or bluish, usually solitary flowers, native to the

Rocky Mountain region from Alaska to New Mexico, is an excellent potherb. The genus contains 20 species, confined to temperate climates. (*See* RANUNCULACEAE.)

MARSI, an ancient people of Italy, whose chief centre was Marruvium, on the eastern shore of Lake Fucinus. They are first mentioned as members of a confederacy with the Vestini, Paeligni, and Marrucini (Liv. viii. 29, *cf.* viii. 6, and Polyb. ii. 24, 12). They joined the Samnites in 308 B.C. (Liv. ix. 41), and became allies of Rome in 304 B.C. (Liv. ix. 45). They were renowned for their magicians, who had strange remedies for various diseases.

The Latin colony of Alba Fucens near the north-west corner of the lake was founded in the adjoining Aequian territory in 303 B.C., so that from the beginning of the 3rd century the Marsians were in touch with a Latin-speaking community, to say nothing of the Latin colony of Carsioli (298 B.C.) farther west. The earliest pure Latin inscriptions of the district seem to be *C.I.L.* ix. 3,827 and 3,848 from the neighbourhood of Supinum; their character generally is of the Gracchan period, though it might be somewhat earlier.

Mommsen (*Unteritalische Dialekten,* p. 345) pointed out that in the social war all the coins of Pompaedius Silo have the Latin legend "Italia," while the other leaders in all but one case used Oscan.

The chief record of the dialect or patois we owe to the goddess Angitia, whose chief temple and grove stood at the south-west corner of Lake Fucinus, near the modern village of Luco. She (or they, for the name is in the plural in the Latin inscription next cited) was widely worshipped in the central highlands (Sulmo, *C.I.L.* ix. 3,074, Furfo Vestinorum, *ibid.* 3,515) as a goddess of healing, especially skilled to cure serpent bites by charms and the herbs of the Marsian woods. Her worshippers naturally practised the same arts—as their descendants do (*see* A. de Nino's collection of *Usi e costumi abruzzesi*), their country being in Rome counted the home of witchcraft; *see* Hor., *Sat.* 1, 9, 29, *Epod.* 17, 28, etc.

The earliest local inscriptions date from about 300 to 150 B.C. and include the bronze of Lake Fucinus, which seems to record a votive offering to Angitia. The language of these inscriptions differs very slightly from Roman Latin of that date. The older form of the name of the tribe (dat. plur. *Martses* =Lat. *Martiis*) shows its derivation and exhibits the assibilation of *-tio-* into *-tso-* proper to many Oscan dialects (*see* OSCAN), but strange to classical Latin.

See R. S. Conway, *The Italic Dialects.*

MARSIGLI [MARSILIUS], **LUIGI FERDINANDO,** COUNT (1658–1730), Italian soldier and scientific writer, was born at Bologna on July 10, 1658. After a course of scientific studies in his native city he travelled through Turkey collecting data on the military organization and natural history. On his return he entered the service of the emperor Leopold (1682) and fought with distinction against the Turks, by whom he was wounded and captured in an action on the river Raab, and sold to a pasha whom he accompanied to the siege of Vienna. His release was purchased in 1684 and he afterwards took part in the war of the Spanish succession. In 1703 he was appointed second in command under Count Arco in the defence of Alt-Breisach. The fortress surrendered to the duke of Burgundy, and both Arco and Marsigli were court martialled; the former was condemned to death and the latter cashiered, although acquitted of blame by public opinion. Marsigli devoted the rest of his life to scientific investigations, in the pursuit of which he made many journeys through Europe, spending a considerable time at Marseilles to study the nature of the sea. In 1712 he presented his collections to his native city, where they formed the nucleus of the Bologna Institute of Science and Art. He died at Bologna on Nov. 1, 1730.

BIBLIOGRAPHY.—A list of his works, over twenty in number, is given in Niceron's *Memoirs;* his *Breve ristretto del saggio fisico intorno alla storia del mare* was published at Venice in 1711, and again at Amsterdam (in French) in 1725; the *Stato militare dell' impero ottomano* was published at Amsterdam and the Hague in Italian and French (1732), the *Osservazioni intorno al Bosforo Tracio* in Rome (1681) and the *Danubius pannonico-mysicus,* a large work in six volumes containing much valuable historic and scientific information on the Danubian countries, at the Hague (1725). *See* Fontenelle, "Éloge" in the *Mém. de l'acad. des sciences* (Paris, 1730); Quincy, *Mémoires sur la vie de M. le comte Marsigli* (Zurich, 1741), and Fantuzzi's biography of Marsigli (Bologna, 1770).

MARSILIUS OF PADUA [MARSIGLIO MAINARDINO] (1270–1342), Italian mediaeval scholar, was born at Padua, and went to Paris about 1311. He became rector of the university (for the first term of the year 1313). With the philosopher John of Jandun, he composed the famous *Defensor pacis* (1324,) one of the most extraordinary political and religious works which appeared during the 14th century. The work set out to demonstrate at a crisis in the quarrel between pope and emperor, the supremacy of the Empire, its independence of the Holy See, and the emptiness of the prerogatives "usurped" by the sovereign pontiffs—a demonstration naturally calculated to give them a claim on the gratitude of the German sovereign.

Marsilius denies, not only to the pope, but to the bishops and clergy, any coercive jurisdiction or any right to pronounce on their own authority excommunications and interdicts, or in any way to impose the observation of the divine law. He is not opposed to penalties against heretics, but he would have them pronounced only by civil tribunals. Desiring to see the clergy practise a holy poverty, he proposes the suppression of tithes and the seizure by the secular power of the greater part of the property of the church. The clergy, thus deprived of its wealth, privileges and jurisdiction, is further to be deprived of independence, for the civil power is to have the right of appointing to benefices, etc. The supreme authority in the church is to be the council, but a council summoned by the emperor. The pope, no longer possessing any more power than other bishops (though Marsilius recognizes that the supremacy of the Church of Rome goes back to the earliest times of Christianity), is to content himself with a pre-eminence mainly of an honorary kind, without claiming to interpret the Holy Scriptures, define dogmas or distribute benefices; moreover, he is to be elected by the Christian people, or by the delegates of the people, *i.e.,* the princes, or by the council, and these are also to have the power to punish, suspend or depose him. To overthrow the ecclesiastical hierarchy, to deprive the clergy of all their privileges, to reduce the pope to the rank of a kind of president of a Christian republic, which governs itself, or rather submits to the government of Caesar—such is the dream formed in 1324 by two masters of the university of Paris.

When the two authors of the book arrived at Nuremberg in 1326, Louis of Bavaria, king of the Romans, to whom the book was dedicated, and in whose cause it was written, was at first inclined to treat them as heretics. He soon changed his mind, however, and loaded them with favours. Marsilius accompanied Louis of Bavaria to Italy, where he preached or circulated written attacks against the pope, especially at Milan, and where he came within the sight of the realization of his wildest utopias. To see a king of the Romans crowned emperor at Rome, not by the pope, but by those who claimed to be the delegates of the people (Jan. 17, 1328), to see John XXII. deposed by the head of the Empire (April 18), and a mendicant friar, Pietro de Corbara, raised by an imperial decree to the throne of St. Peter (as Nicholas V.) after the sham of a popular election (May 12), all this was merely the application of principles laid down in the *Defensor pacis.* The two authors of this book played a most active part in the Roman Revolution. Marsilius, appointed imperial vicar, abused his power to persecute the clergy who had remained faithful to John XXII. In recompense for his services, he seems to have been appointed archbishop of Milan, while his collaborator, John of Jandun, obtained from Louis of Bavaria the bishopric of Ferrara.

Marsilius of Padua also composed a treatise *De translatione imperii romani,* which is merely a rearrangement of a work of Landolfo Colonna, *De jurisdictione imperatoris in causa matrimoniali,* intended to prove the exclusive jurisdiction of the emperor in matrimonial affairs. In an unpublished work preserved at Oxford, the *Defensor minor,* Marsilius completed and elaborated in a curious manner certain points in the doctrine laid down in the

Defensor pacis. In it he deals with ecclesiastical jurisdiction, penances, indulgences, crusades and pilgrimages, vows, excommunication, the pope and the council, marriage and divorce. Here his democratic theory still more clearly leads up to a proclamation of the imperial omnipotence.

Marsilius of Padua does not seem to have lived long after 1342. But the scandal provoked by his *Defensor pacis,* condemned by the court of Avignon in 1326, lasted much longer. Benedict XII. and Clement VI. censured it in turn; Louis of Bavaria disowned it. Translated into French, then into Italian (14th century) and into English (16th century), it was known by Wycliffe and Luther, and was not without an influence on the Reform movement.

See J. Sullivan, *American Historical Review,* vol. ii. (1896–97), and *English Historical Review* for April 1905; *Histoire littéraire de la France* (1906), xxxiii. 528–623; Sigmund Riezler, *Die literarischen Widersacher der Päpste zur Zeit Ludwig des Baiers* (Leipzig, 1874). There are numerous manuscripts of the *Defensor pacis* extant. We will here mention only one edition, that given by Goldast, in 1614, in vol. i. of his *Monarchia sacri imperii;* an unpublished last chapter was published by Karl Müller, in 1883, in the *Göttingische gelehrte Anzeigen,* pp. 923–925. Count Lützow in *The Life and Times of Master John Hus* (London and New York, 1909), pp. 5–9, gives a good abstract of the *Defensor pacis* and the relations of Marsilius to other precursors of the Reformation.

MARSIVAN or MERZIFON (anc. *Phazemon?*), a town in the Amasia vilayet of Turkey, situated at the foot of the Tavshan Dagh. Pop. (1940) 13,301. Before World War I, it was best known as a centre of American missionary and educational enterprise, and the seat of Anatolia college, a theological seminary, and schools.

MARS-LA-TOUR, a village of Lorraine, which formed part of the battlefield of Aug. 16, 1870. The battle is often called the battle of Mars-la-Tour, though it is alternatively named after Vionville or, by the French, after Rezonville. (*See* METZ; and FRANCO-GERMAN WAR.) At Mars-la-Tour occurred the destruction of the German 38th brigade.

MARSTON, JOHN (*c.* 1575–1634), English dramatist and satirist, eldest son of John Marston of Coventry, at one time lecturer of the Middle Temple, was born in 1575 or early in 1576. His mother was the daughter of an Italian physician, Andrew Guarsi. He entered Brasenose College, Oxford, in 1592, taking his B.A. degree in 1594. He married Mary Wilkes, daughter of one of the royal chaplains, and Ben Jonson said that "Marston wrote his father-in-law's preachings, and his father-in-law his sermons." His first work was *The Metamorphosis of Pigmalions Image, and certaine Satyres* (1598). "Pigmalion" is an erotic poem in the metre of *Venus and Adonis,* and Joseph Hall attached a rather clumsy epigram to every copy that was exposed for sale in Cambridge. In the same year Marston published, under the pseudonym of W. Kinsayder, already employed in the earlier volume, his *Scourge of Villanie,* eleven satires, in the sixth of which he asserted that Pigmalion was intended to parody the amorous poetry of the time. Both this volume and its predecessor were burnt by order of the archbishop of Canterbury.

The satires, in which Marston avowedly took Persius as his model, are coarse and vigorous. In addition to a general attack on the vices of his age he avenges himself on Joseph Hall who had assailed him in *Virgidemiae.* He had a great reputation among his contemporaries. John Weever couples his name with Ben Jonson's in an epigram; Francis Meres in *Palladis Tamia* (1598) mentions him among the satirists; a long passage is devoted to "Monsieur Kinsayder" in the *Return from Parnassus* (1606), and Dr. Brinsley Nicholson has suggested that *Furor poeticus* in that piece may be a satirical portrait of him.

On Sept. 28, 1599, Henslowe notices in his diary that he lent "unto Mr. Maxton, the new poete, the sum of forty shillings," as an advance on a play which is not named. Another hand has amended "Maxton" to "Mastone." The earliest plays to which Marston's name is attached are *The History of Antonio and Mellida. The First Part;* and *Antonio's Revenge. The Second Part* (both entered at Stationers' Hall in 1601 and printed 1602). These were written for the Paul's Boys, for whom he also probably revised the anonymous *Histriomastix,* and finally wrote *What you Will* (which was certainly written before 1607), while he was doubtless part author of *Jacke Drums Entertainment* (1600).

The melodrama and the exaggerated expression of these two plays offered an opportunity to Ben Jonson, who had already twice ridiculed Marston, and now pilloried him as Crispinus in *The Poetaster* (1601). The quarrel was patched up, for Marston dedicated his *Malcontent* (1604) to Jonson, and in the next year he prefixed commendatory verses to *Sejanus.* Far greater restraint is shown in *The Malcontent* than in the earlier plays. It was printed twice in 1604, the second time with additions by John Webster. *The Dutch Courtezan* (1605) and *Parasitaster, or the Fawne* (1606) followed. In 1605 *Eastward Hoe,* a gay comedy of London life, which gave offence to the king's Scottish friends, caused persons concerned in its production—Marston with others—to be imprisoned. (*See* JONSON, BEN.) In the preface to *The Wonder of Women, or the Tragedie of Sophonisba* (1606), Marston mocks at those authors who make a parade of their authorities and their learning, and the next play, *What you Will* (printed 1607; but probably written much earlier), contains a further attack on Jonson. Marston's undoubted dramatic work was completed in 1607. It is uncertain at what time he exchanged professions, but in 1616 he was presented to the living of Christchurch, Hampshire. He formally resigned his charge in 1631, and when his works were collected in 1633 the publisher, William Sheares, stated that the author "in his autumn and declining age" was living "far distant from this place." Nevertheless he died in London, in the parish of Aldermanbury, on June 25, 1634. He was buried in the Temple Church.

Marston's works were first published in 1633, once anonymously as *Tragedies and Comedies,* and then in the same year as *Workes of Mr. John Marston. The Works of John Marston* (3 vols.) were reprinted by Mr. J. O. Halliwell (Phillipps) in 1856, and again by Mr. A. H. Bullen (3 vols.) in 1887. His *Poems* (2 vols.) were edited by Dr. A. B. Grosart in 1879. For an account of the quarrel of Dekker and Marston with Ben Jonson *see* Dr. R. A. Small, *The Stage Quarrel between Ben Jonson and the so-called Poetasters;* in E. Koelbing, *Forschungen zur englischen Sprache und Litteratur,* pt. i. (1899). *See* also three articles *John Marston als Dramatiker,* by Ph. Aronstein in *Englische Studien* (vols. xx. and xxi., 1895), and "Quellenstudien zu den Dramen Ben Jonsons, John Marstons . . ." by Emil Koeppel (*Münchener Beiträge zur roman. und engl. Philologie,* pt. xi. 1895); also M. S. Allen, *The Satire of John Marston* (Columbia, 1920).

MARSTON, PHILIP BOURKE (1850–1887), English poet, was born in London on Aug. 13, 1850. His father, JOHN WESTLAND MARSTON (1819–1890), of Lincolnshire origin, the friend of Dickens, Macready and Charles Kean, wrote a series of metrical dramas which held the stage in succession to the ambitious efforts of John Tobin, Talfourd, Bulwer and Sheridan Knowles. The son, Philip Bourke, was born in a literary atmosphere. At his father's house near Chalk Farm he met authors and actors of his father's generation, and subsequently the Rossettis, Swinburne, Arthur O'Shaughnessy and Irving. Owing to an accident in infancy, he gradually became almost totally blind. Marston's verse became more and more melancholy. The idylls of flower-life, such as the beautiful "The Rose and the Wind" were succeeded by dreams of sleep and the repose of death. Melancholy pervades his three published collections, *Songtide* (1871), *All in All* (1875) and *Wind Voices* (1883). His popularity in America far exceeded that in his own country.

MARSTON MOOR, BATTLE OF, was fought on July 2, 1644 on a moor (now enclosed) seven miles west of York, between the Royalist army under Prince Rupert and the Parliamentary and Scottish armies under the earl of Manchester, Lord Fairfax and Lord Leven. For the operations that preceded the battle see GREAT REBELLION. Rupert had relieved York and joined forces with the marquess of Newcastle's army that had defended that city, and the Parliamentarians and Scots who had besieged it had drawn off south-westward followed by the Royalists. On the morning of July 2, however, Rupert's attack on their rearguard forced them to halt and deploy on rising ground on the south edge of the moor, their position being defined on the right and left by Long Marston and Tockwith and divided from the Royalist army on the moor by a lane connecting these two villages. The respective forces were—Royalists about 18,000, Parliamentarians and Scots about 27,000. The armies stood front to front. On the Royalist right was half the cavalry under Rupert; the infantry was in the centre in two lines and the left wing of cavalry was under General (Lord) Goring. The lane along the front was held by skirmishers. On the other side the cavalry of the Eastern Association under Lieut.-General Cromwell and that of the Scots under Major-General Leslie formed the left; the infantry of the Eastern Association under Major-General Crawford, of the Scots under Lord Leven, and of the Yorkshire Parliamentarians under Lord Fairfax was in the centre; and the Yorkshire cavalry under Sir Thomas Fairfax was on the right wing.

During the afternoon there was a desultory cannonade, but neither side advanced. At last, concluding from movements in the enemy's lines that there would be no fighting that day, Rupert and Newcastle strolled away to their coaches and their soldiers dismounted and lay down to rest. But seeing this Cromwell instantly advanced his wing to the attack (5 P.M.). His dragoons drove away the skirmishers along the lane, and the line cavalry crossed into the moor. The general forward movement spread along the Parliamentary line from left to right, the Eastern Association infantry being the first to cross the road. In Rupert's momentary absence, the surprised Royalist cavalry could make no head against Cromwell's charge, although the latter was only made piecemeal as each unit crossed the lane and formed to the front. Rupert soon galloped up with his fresh second line and drove back Cromwell's men, Cromwell himself being wounded, but Leslie and the Scots Cavalry, taking ground to their left, swung in upon Rupert's flank, and after a hard struggle the hitherto unconquered cavalry of the prince was broken and routed. Then, being unlike other cavalry of the time, a thoroughly disciplined force, the Eastern Association cavalry rallied, leaving the pursuit to the Scots light horse. On the Parliamentary right, Goring had swept away the Yorkshire horse, and although most of his troopers had followed in disorderly pursuit, Sir Charles Lucas with some squadrons was attacking the exposed right of Leven's infantry. At the same time the Parliamentary infantry had mostly crossed the lane and was fighting at close quarters and suffering severely, Newcastle's north-country "White-Coat" brigade driving back and finally penetrating their centre. Lord Leven gave up the battle as lost and rode away to Tadcaster. But the Scots on the right of the foot held firm against Lucas's attacks, and Cromwell and Leslie with their cavalry passed along the rear of the Royal army, guided by Sir Thomas Fairfax (who though wounded in the rout of his Yorkshire horse had made his way to the other flank). Then, on the ground where Goring had routed Fairfax, Cromwell and Leslie won an easy victory over Goring's scattered and disordered horsemen. The Eastern Association infantry had followed the horse and was now in rear of the Royalists. The original Parliamentary centre of foot, a remnant, but one containing only the bravest and steadiest men, held fast, and soon the Royalist infantry was broken up into isolated regiments and surrounded by the victorious horse and foot of the enemy. The White-Coats retreated into an enclosure and there defended themselves to the last man. The rest were cut down on the field or scattered in the pursuit and at nightfall the Royalist army had ceased to exist. Some of Rupert's foot regiments made their way to York, but the dispirited garrison only held out for a fortnight. Rupert rallied some six thousand of the men and escaped over the hills into Lancashire, thence rejoining King Charles in the south. But the Northern army, the main hope of the Royalist cause, was destroyed.

MARSUPIALIA, a subclass of Mammalia (*q.v.*) in which (with some exceptions) the young for some time after birth are kept in a pouch (marsupium) or bag of skin on the under side of the body of the female. Outstanding examples of the group are the kangaroos of Australia and the opossums of America. The marsupials are exceptionally important and interesting to the student of evolution for reasons which will appear later.

Discovery.—The South American opossums were seen and described by the first explorers of the New World, the Pinzons having taken a live one in Brazil in 1500, which was exhibited in Granada and described in a work by Trivigiano published in 1504. As to the North American opossums, Captain John Smith in his *Description of Virginia* (1612) states that: "An opossum hath a head like a Swine, and a taile like a Rat, and is of the bignesse of a Cat." Apart from the description by a Dutch voyager Pelsart (1629) of wallabies seen on islands off western Australia, the Australian marsupials remained practically unknown until Captain J. Cook's voyage. In 1770 Captain Cook saw kangaroos in the region now known as North Queensland. The kangaroo was at first regarded as a gigantic leaping rodent. The discovery of other Australian marsupials such as the marmot-like wombat, the rabbit-like bandicoot, the wolf-like thylacine, at first brought confusion into the gradual process of classifying the mammals of the world. Even Baron Cuvier did not at first realize that the marsupials formed an independent series, having only a general and superficial resemblance to the carnivorous, insectivorous and gnawing animals of the northern world, and separated from them by profound differences in the mode of reproduction. It remained for Henri M. D. De Blainville in 1816 and 1834 to take the steps of putting the marsupials by themselves in a subclass of mammals which he named Didelphia, co-ordinate in rank with the Ornithodelphia (the egg-laying mammals or monotremes) and with the Monodelphia, which are the placentals or ordinary mammals of the northern world.

Reproduction.—The most famous character of typical marsupials is the pouch in which the females carry their young. In its extreme form, as in the kangaroo, the pouch consists of a capacious elastic bag, lined with fur. The fold which grows up to form the pouch may be compared to a gigantic teat surrounding the entire mammary field. In some Australian dasyures the pouch-fold arises only around the front end of the mammary field; the presence of a scrotal pouch in the male thylacine shows how easily the abdominal wall sinks in. In its complete form the pouch has a circular aperture opening downward. As the number of nipples increases the mammary field becomes an elongate oval and the pouch gives place to low longitudinal ridges and finally disappears. It has been suggested that the lack of a pouch is really a primitive character and that we can trace many stages in the evolution of the pouch among living members of the group. Since the pouch is reduced or wanting in members of different families of marsupials, the foregoing hypothesis must assume also that when it is present the pouch has arisen independently in different families. However, before such an hypothesis can be seriously considered it would be necessary to disprove the older view that marsupials, like all other mammals, are subject to the occasional degeneration or loss of even highly evolved structures, that the pouch is normally an important part of the marsupial mode of caring for the young but that in special circumstances, such as a marked increase either in the number of young at a birth or in their size, the pouch becomes unnecessary and is reduced or eliminated. The newer view seems to rest in part also on the erroneous assumption that the banded anteater (*Myrmecobius*) is a little modified survivor of the Mesozoic mammals. In the marsupials of the polyprotodont division (*see* below) the pouch frequently opens downward or backward but in the kangaroos and phalangers, which rest in a sitting position, the pouch opens forward or upward.

Hardly less striking in appearance than the pouch are the pair of flat rod-like bones called the epipubic or marsupial bones, which lie in the deepest part of the muscular abdominal wall and are attached to the front or pubic border of the pelvis. These marsupial bones are present in both sexes and therefore are not exclusively related to the support of the female's pouch but seem rather to be remnants of the skeletal floor of the abdomen, which in primitive reptiles extends from the pubis to the sternum. Similar epipubic bones are found in the monotremes or egg-laying mammals. In some marsupials (including the thylacine or marsupial wolf) the epipubic bones are reduced to vestiges or completely lost.

At least in the larger marsupials the new-born animals are very small and in general poorly developed but it is remarkable that at this stage their fore-limbs are very large and tipped with strong claws, while the hind legs are hardly more than embryonic buds. In the case of the Virginia opossum, immediately after birth the young animal uses these large fore-limbs and claws in climbing along the under-side of the mother's body from the cloaca to the mammary field, where it attaches itself to one of the teats. The teat then swells and becomes fastened firmly in the mouth of the young; the windpipe of the young becomes prolonged upward and forward to fit into the back part of the nasal tunnel; thus the milk is prevented from getting into the windpipe and the air is delivered directly to the lungs. The teats vary in number from two in certain diprotodonts to 27 in *Monodelphis*.

The large size of the maternal teat and the prolonged attachment of the young to it may have crowded the tooth-forming part of the jaws to such an extent that the milk teeth are delayed in formation, only the hinder upper and lower premolars, at the back of the jaw, having room to develop in most marsupials, while even these milk teeth become reduced in size in the marsupial wolf (*Thylacinus*) and completely eliminated in the dasyures, wombats, koalas and marsupial anteaters. In this connection it is interesting to note that tiny vestiges of deciduous incisors and premolars, which never break through the gum, have been found in some marsupials.

At birth the young of the large forms are about an inch in length, entirely naked, blind, the ears hardly visible, the hind limbs small and the fore limbs more robust and with well-developed claws. The period of gestation in large kangaroos is about three weeks. At parturition the female sits with her tail brought forward between her legs and spends some of her time scratching at her pouch with the fore-paws and licking it. When the young animal emerges from the cloaca of the female it climbs by its clawed fore-limbs into the pouch, reaching the teats, one of which it eventually seizes with its mouth, the more easily as the teats at this time are pointed and rather turgid.

Shortly after the teat is received in the mouth of the young animal, lactation begins and the teat becomes somewhat flaccid. The body of the little kangaroo increases in size but the mouth that holds the teat does not at this time enlarge. The tip of the teat expands within the mouth so that the young cannot be released without rupturing the sides of its mouth. Numerous striated muscle fibres pass between the lobes of the mammary gland, indicating that the milk is forcibly expressed from it.

By the end of the Australian winter, September or October, the young kangaroo has grown considerably and is ready to leave the pouch. For some time before finally leaving the pouch it has been free from the teat and has eaten vegetation that it reached by leaning from the pouch while its mother was feeding.

The female reproductive organs of marsupials differ markedly from those of higher or placental mammals in the following respects: the vaginal tubes of the right and left sides always have at least a kink or sharp bend, one on each side, just above the place where the ureters pass downward to open into the bladder. These kinks usually join in the mid-line and from the point of junction is developed a cul-de-sac of varying lengths, leading backward toward the cloaca or short passage to the exterior. In females that have never produced young the median cul-de-sac ends blindly at the lower end. After the egg has passed down from the ovary into the oviduct it is fertilized by some of the sperm which has been kept in the vaginal caecum or kink above described. During parturition (in members of several families) the embryo passes down into the median cul-de-sac, which becomes prolonged backward, forming a median canal. A hole is formed in the median canal and the young escapes into the cloaca without going through the lateral canals. Thus the typical marsupials have a contorted vaginal canal with one median and two lateral passages, the median one being formed from the coalescence of part of the two laterals. In placental mammals, on the other hand, no traces of the three-way vaginal canal or of the kinks in the vaginal canals are ever formed but the lower part of the right and left oviducts tend to unite in a single median uterus. It is therefore inferred that the marsupial arrangement is a peculiar specialization not developed in the common ancestors of marsupials and placentals.

Another remarkable feature of the reproductive system of marsupials is the peculiar relation of the two sacks or outgrowths from the ventral wall of the embryo, either one of which forms the functional placenta or organ of contact of the embryo with the uterus. In certain marsupials a double contact with the uterine wall is formed both by the true or allantoic placenta and by the omphalopleure or yolk-sack wall. In the bandicoots the true or allantoic placenta forms an intimate relationship with the uterine wall, essentially like that in the true placental mammals. On the other hand, in *Dasyurus* the allantois is degenerate and the yolk-sack alone makes contact with the uterine wall. Essentially similar conditions are found in the American opossum (*Didelphis*). In the higher placental mammals, on the other hand, only the true placenta is of functional importance in supplying the growing embryo with maternal nutriment. Thus the marsupials specialized in the early and brief internal development of the embryo, which depends for food chiefly upon its own yolk-sack and which completes its development after birth while attached to the teat. The higher or placental mammals gave the young a longer and better uterine development and a more flexible system of nursing, with greater maternal responsibility.

EVOLUTION AND CLASSIFICATION

As the existing monotremes in many respects represent a specialized side-group of the earliest mammals, the marsupials, on the whole, are the most central group of the mammalian class; consequently the problem of the origin of the marsupials largely resolves itself into the problem of the origin of the mammals, which is treated more fully under MAMMALIA. Nevertheless we present here a short review of the palaeontologic data bearing on the possible relationships of the marsupials to the several Mesozoic orders with which they have been thought to be connected.

Origin of the Marsupials.—The cynodont reptiles, whose fossil skeletons have been found in the Permian formations of Russia and the Triassic of South Africa, may not have been in the direct line of mammalian ascent but they were certainly progressing in that direction and some of them, such as the smaller cynodonts of the family Galesauridae were approaching the carnivorous marsupials in the general appearance of the skull and jaws. The two minute fossil jaws from the Upper Triassic of Carolina named *Dromotherium* and *Microconodon,* which were regarded as basic Mammalia by H. F. Osborn are referred by G. G. Simpson, after careful study of the originals, to the group of cynodont reptiles.

The multituberculate or allotherian mammals (*see* MULTITUBERCULATA), which range in time from the Upper Triassic to the Lower Eocene, appear to have been a side branch of the primitive mammalian stock, paralleling the monotremes on the one hand and the diprotodont marsupials on the other but not closely related to either.

The fossil mammals called triconodonts from the Jurassic of England and Wyoming have usually been referred to the marsupials, but according to the recent studies by Simpson the triconodonts formed a special group of their own, with no valid claims to relationship with the marsupials. These were small predatory mammals, the largest about the size of a cat, with jagged cheek teeth, each molar crown comprising three cusps arranged in a longitudinal line. A braincase of *Triconodon* reveals an extremely primitive stage with large olfactory lobes and unexpanded forebrain. On the whole, the triconodonts stand on a lower level of evolution than any true marsupials.

Another Jurassic group, the Trituberculata, includes various small lower jaws, of which the most widely known has received the name *Amphitherium prevostii.* One of these jaws from Oxford was examined by Cuvier, who noted its resemblance to the jaw of the opossums but also noted that it had ten teeth on each side behind the canine, a greater number than that of any carnivorous marsupial. In 1888 H. F. Osborn pointed out that the lower molar teeth of *Amphitherium* consisted of two moieties: in front an elevated triangle of sharp cusps and behind a low heel or talonid; here clearly was a distinct prophecy of the famous "tuberculo-sectorial" lower molars of Eocene mammals. Whatever its precise relationships, the lower jaw of *Amphitherium* could be changed into that of a primitive marsupial by the inturning of the angular process, by the reduction in the number of the cheek teeth from ten to seven; and by the further development of the heel of the lower molars. Even less change would be required to transform it into the jaw of a generalized placental mammal, in which the angular process is not inflected.

The American Opossums.—The oldest known fossil which may be referred without any doubt to the group of marsupials is a fragmentary skull and lower jaw from the Upper Cretaceous of Montana, described by W. D. Matthew in 1916 as *Eodelphis browni;* this was discovered by Barnum Brown in association with the skull of a Cretaceous dinosaur. As Matthew pointed out, the pieces of the skull and the lower jaw match closely the corresponding parts of existing opossums, which thus take their place among the most primitive known mammals. Matthew has also traced the fossil history of the opossum family through several Eocene formations of Wyoming into the genus *Peratherium,* which is found in the Oligocene formations of western North America and France. In South America fossil opossums of the genera *Microbiotherium* and *Proteodidelphys,* date from the Lower Miocene and earlier formations. From these and similar facts Matthew has pointed out that the family of the opossums, like that of many other families of mammals, appears to have originated in North America and then to have spread on the one hand into Europe and on the other into South America. Possibly the common Virginia opossum, together with related genera in Mexico and Central America, may represent a reflux wave of immigrants coming from South America in Pliocene times.

T. H. Huxley, Dollo and R. A. Bensley have adduced much evidence tending to show that the common opossum (*Didelphis virginiana*) embodies nearly all the characters one might reasonably expect to find in the remote common ancestors of all the higher marsupials, since it retains all their primitive characters but has assumed few specializations of its own. This is not equivalent to saying, however, that American opossums are ancestral to the Australian marsupials. It probably means only that the American opossums are the survivors of an ancient and diversified group, which in some earlier geological epoch was spread perhaps as far east as Asia and which gave rise on the one hand to the American marsupials and on the other to the Australian carnivorous marsupials and later groups.

The tree-climbing habits of the opossum are expressed in its muscular prehensile tail and especially in the grasping power of its hands and feet, each with five fully developed toes; the "friction pads" on the sole of the foot also are well developed. The forearm can be freely twisted on the upper arm and the collar-bones (clavicles) are well developed, as in most climbing mammals. In the hind-limbs the great toe is set off widely from the others, the feet are plantigrade and capable of being freely turned inward.

The braincase of a large opossum is relatively small and unexpanded in keeping with its low type of brain. The muzzle is large and in its interior the delicate bones that support the membranes of the sense of smell are well-developed; the bony orbits or sockets for the eyes are rather small, as are the eyes themselves; the inner ear-bones are relatively small and the same is true of the resonating chamber of the middle ear. All these and many similar facts suggest that the opossum is not an intelligent animal, that it pursues its prey chiefly by the sense of smell, and depends for safety upon hiding in the daytime and prowling about at night.

In conformity with its carnivorous-omnivorous habits, the skull of a large opossum recalls those of other carnivorous mammals in its stout cheek arches and in its high median and occipital crest, all for the support of the stout jaw muscles. The dentition also tells plainly that the opossum is primarily a flesh-eating animal, which however has not acquired highly specialized shearing teeth like those of a cat but has retained certain primitive features. The general outline of an upper molar crown of an opossum is that of a scalene triangle with the apex on the inner side, the shorter leg being in front, the longer one behind. From the general surface of this triangle two small, V-shaped cusps project: a very small one in front (the paracone) and a much larger one behind (the metacone). Between any two adjacent upper molars are empty embrasures or openings, each like an inverted V with the tip pointing outward. Into these embrasures fit the elevated V-shaped forepart of the lower molars, surmounted by three blade-like cusps, the apex of this V pointing outward. The inverted V of a lower molar shears past the large V of an upper molar; while the inwardly projecting apex of an upper molar fits into a concave projection constituting the rear half of a lower molar. Thus the upper and lower molars of the opossum present fundamentally the same combination of shearing V's and piercing projections and sockets which is to be found in the most primitive mammals of the Cretaceous and Eocene ages.

In the opossum, as in all primitive marsupials, there are on each side four upper molars and four lower, also three upper premolars and three lower premolars. The upper premolar crowns have a single high tip, equivalent to the highest cusp on the crown of the molars. Thus there are in all seven teeth on each side, above and below, behind the canines. The same number of postcanine teeth is to be found in primitive placental mammals, but in the latter there are four premolars and three molars. The canine teeth, both upper and lower, of the opossum have long-curved, sharp-tipped crowns, well fitted for fighting and killing. The incisor teeth are small and numerous with simple crowns, five on each side in the upper jaw and four in the lower jaw; of these the first upper incisors are somewhat larger and have downwardly directed points, while the first lower incisors are somewhat inclined forward. Here then is the first hint of the nipping or prehensile development of the incisors which becomes pronounced in the diprotodont group of marsupials. Accordingly the dental formula, showing the number of different kinds of teeth in the upper and lower jaws of the common opossum may be written as follows: (incisors $\frac{5}{4}$ canines $\frac{1}{1}$ premolars $\frac{3}{3}$ molars $\frac{4}{4}$) $\times 2 = 50$. From this as a starting-point the dental formulae of all other marsupials appear to have been derived either by reduction and loss of teeth or, in the case of *Myrmecobius,* by the secondary increase in number of the molar teeth. As in all typical marsupials, only the hinder or third premolars of the adult dentition are preceded by deciduous teeth.

The precise arrangement of the lateral and median vaginal canals varies widely in different individuals and species of the opossum family. In some, the lateral canals are completely separate and there is hardly a beginning of the median cul-de-sac; in other species, however, it is very well developed and in still others transitional conditions are found. The attachment of the embryo to the wall of the uterus is by the yolk-sack, there being no true placenta.

Some of the smaller species of opossums have a large number of young at a birth, together with a large number of teats (rarely, as many as 27) and a reduction or loss of the pouch. It is very doubtful, however, whether these are primitive characters; they seem more like retrogressive specializations within the family.

The common opossum (*Didelphis virginiana*) may reach a total length of 37 inches, the head and body being 22 inches long, while at the other extreme, in the shrew-opossum of Brazil (*Monodelphis*) the length of the head and body is less than 3 inches. The murine opossum (*Marmosa*) of Central America and Brazil includes mouse-like insectivorous forms in which the pouch is absent. The water opossum or yapok (*Chironectes*) of Panama and Guiana is the only known marsupial adapted to a partly aquatic life. The toes of the hind feet are webbed and it resembles an otter in habits. The pouch is present.

The Australian Dasyuroids.—Under the name dasyuroids we may include a series of Australian forms ranging from the tiny "pouched mice" to the wolf-like *Thylacinus.* They are frequently referred to collectively as "carnivorous marsupials." The ordinary "pouched mice" of the genus *Phascogale* are extremely active little animals with the blood-thirsty habits of shrews. They live mostly in the bush or forest. They differ profoundly from true mice not only in their internal anatomy but especially in their dentition, which is of the carnivorous-insectivorous type. In his excellent work *The Mammals of South Australia* F. Wood Jones writes: "The Yellow-footed Pouched Mouse is an animal of great interest from a zoological point of view, since in the whole of its anatomy it shows itself to be a remarkably generalized animal. It represents a marsupial base form, its general anatomy being but little modified from a basal mammalian plan, and it stereotypes the simple creature that could be considered ancestral to most of the marsupial radiations." Although too specialized in certain details, such as the reduction of the first toe of the hind foot and the loss of the caecum of the intestine, to be the direct ancestors of the diprotodont or herbivorous marsupials, the pouched mice of the genus *Phascogale* are at least structurally near to the diverging lines leading to the jumping pouched mice, to the dasyures, to the Tasmanian devil and other peculiar forms.

In the fat-tailed pouched mouse (*Sminthopsis crassicaudata*) the hind foot is much elongated and this feature is carried to an extreme in the jerboa pouched mouse (*Antechinomys*), which shows a maximum adaptation to the jumping habit, including a complete loss of the first digit of the hind foot. As in many other desert-living animals, the ears are very large and the bony shells covering the chambers of the middle ears are greatly enlarged. The animal is insectivorous and probably leaps after insects.

One of the most remarkable members of the pouched mouse group is the mulgara or crest-tailed pouched mouse (*Dasycercus cristicauda*) of South Australia. This sturdily-built, short-limbed little animal is a typical desert form, which has multiplied in an astonishing manner during the passage of a mouse plague across cultivated districts and is a fearless predatory animal.

The carnivorous adaptations of the mulgara are carried further in the so-called native cats or dasyures, which are about as large as true cats but have pointed muzzles. The blades on the upper molars are relatively longer and more obliquely directed than in the mulgara and the third upper premolar is now completely eliminated. The skull bears heavy crests and well developed cheek arches for the support of the powerful muscles. The general form of body is like that of a marten. In the spotted-tailed native cat (*Dasyurus maculatus*) the first digit of the hind foot is retained and the foot pads are striated in conformity with its tree-climbing habits; but in the common native cat (*Dasyurus viverrinus*) the first digit of the hind foot is lost and the foot pads are granular. It formerly inhabited treeless rocky country as well as cultivated districts and was a fearless predatory animal.

The Tasmanian devil (*Sarcophilus ursinus*) is a short-bodied burly dasyurid with a broad muzzle, an enormous, broad and massive skull and most powerful jaws. There are strongly developed blades on the upper and lower molar teeth, which resemble those of such extinct placental carnivores as *Oxyaena*. The inner projections of the upper molar crowns are reduced and the planes of the inner surfaces of these blades now point more obliquely backward than those in the more primitive pouched mice.

In the marsupial wolf or tiger (*Thylacinus*) the general habitus is somewhat wolf-like, except that the feet are shorter and the hinder part of the body gradually tapers into the tail. Broad transverse black stripes over the back and tail give the animal its common name of "tiger." The thylacine (*q.v.*) is a wolf-like derivative of the dasyuroid stock, specialized for long-distance running. Its skull is elongate, in contrast with the very broad short skull of *Sarcophilus*. The molar teeth, although adapted for shearing flesh, differ markedly from those of the dasyures and *Sarcophilus*. The upper molars have lost the accessory cusps on the outer side of the crown, the internal spurs of the upper molars are subcircular, the two main external cusps are more or less approximated. In the lower molars the hinder spur or talonid is reduced, while the front part consists of two large blade-like cusps, the metaconid or hinder inner cusp being totally wanting. The nearest resemblances in dentition and skull are found not in any other Australian forms but among the extinct borhyaenids of the Patagonian Miocene. On the other hand, *Thylacinus* agrees closely with the Australian dasyuroids in many important details, so that there seems little doubt of its derivation from an Australian dasyuroid stock. The further significance of these facts will be discussed below. The thylacine formerly inhabited the mainland of Australia, its fossil remains having been found in caves; but during historic times it has lived only in Tasmania. As it was destructive to sheep it has been almost exterminated and survives only in the mountains.

Under the Australian dasyuroid series we include the banded anteater (*Myrmecobius*) or wombat of South and West Australia. This very rare animal is now almost extinct. In general appearance it strongly recalls other small dasyuroids, having a long pointed muzzle and long ears, somewhat like *Antechinomys*, a transversely striped back, recalling *Thylacinus* and certain bandicoots, a bushy tail, like that of the brush-tailed pouched mouse. Moreover it is pouchless and the large foetuses are carried on the nipples, exposed as in *Dasycercus*. The high number of molars (sometimes rising to five in the upper and six in the lower jaws) may be regarded as a secondary increase in number correlated with reduction in size and spreading out of the teeth, in connection with an elongate, cylindrical extensible tongue, and a backwardly prolonged palate. A comparative study of the entire skeleton of *Myrmecobius* leads to the conclusion that it is thoroughly dasyuroid in type. A fossil lower jaw from the basal Eocene of Montana, named *Myrmecoboides montanensis*, helps us to visualize the process by which more normal insectivorous lower molars could readily be modified into the *Myrmecobius* type by suppression of the main outer cusps on the lower molars and of the inner cusps of the upper molars, this producing what I. W. Gidley has well named a "pseudotriconodont" type. The fossil jaw itself, however, is probably not at all related to *Myrmecobius*, since it agrees with the extinct placental insectivores of the family Lepticitidæ in its dental formula and in the family characters of the teeth.

A most highly aberrant dasyuroid is the pouched mole (*Notoryctes*) of South and Western Australia. The general appearance is like that of the African golden mole (*Chrysochloris*). In adaptation to its digging habits the conical head ends in front in a horny shield over the nose and evidently the head must be pushed into the soil. The neck vertebrae are fused to give it a firm support. The hands are provided with two enormous claws on the third and fourth fingers, the first and second fingers bearing much smaller claws which are opposable to the inner surfaces of the large outer claws. The fifth finger is very short and capped with a horny boss. The body is thick and cylindrical and the tail very short and covered with horny rings. The hind feet are short and spreading, with long digging claws. The eyes are degenerate, almost vestigial, and there are no external ears. The upper molar crowns, like those of the Cape golden mole, consist of very narrow V's, probably derived by degeneration from a more normal, less compressed type; in the lower molars the talonids or hinder spurs are lost. A pouch is present and opens backward. A comparative study of the skeleton has shown that the marsupial mole resembles the Cape golden moles, which are true placental mammals, only in its "habitus," while its "heritage" is unmistakably that of other marsupials.

The Australian Bandicoots.—The largest of these animals somewhat resemble rabbits both in appearance and habits, since they have large ears and dig holes in the ground. They are therefore often called "native rabbits." But they are none the less true marsupials.

The hind feet are remarkably like those of kangaroos and have what was originally the fourth toe much elongated; the first toe, if present, is small; all the remaining toes have large pointed claws for scratching and digging. The hind foot also resembles those of kangaroos and other herbivorous marsupials in the fact that the toes corresponding to the second and third of the normal mammalian foot are very slender, much smaller than the fourth toe, and so closely appressed to each other that they appear to be united at their bases. Each, however, is a complete digit with its own claw and separate muscles. These two digits serve as a comb by which the animal removes from its fur biting lice or other unwelcome objects. This peculiar syndactylous specialization of the hind feet is found also throughout the series of diprotodont or herbivorous marsupials of Australia but not in any of the polyprotodont families (American opossums, Australian dasyuroids, etc.).

The bandicoots have front teeth of the carnivorous-insectivorous or polyprotodont type, essentially like those of the American opossums and the dasyuroids, while their molar teeth, although peculiar, show traces of derivation from some form in which the accessory cusps on the outer sides of the molar were strongly developed. The bandicoots, while chiefly insectivorous, frequently have the molar teeth much ground down by wear, which may indicate that their food gets mixed with a certain amount of grit. Apparently in adaptation to this condition, the molar teeth tend to acquire high crowns, like those of many rodents. Bandicoots are pugnacious little animals which leap up in the air and strike each other with their long-clawed hind-feet. In the forms with very long hind-feet this extraordinary leaping ability is probably useful not only in escaping enemies but in capturing insects. All the species are now rapidly becoming rare. The family (Peramelidae) ranges from New Guinea and adjacent islands on the north to Tasmania on the south.

The Australian Diprotodonts.—Under the term Diprotodontia are generally included all the primarily herbivorous marsupials of Australia, in which the median pair of lower incisor teeth are more or less enlarged and inclined forward, so as to oppose one or more pairs of upper incisors, thereby functioning either as nippers or cutters. All known diprotodonts have the syndactylous relations of the second and third toes described above in the bandicoots. The diprotodont division includes a large number of species of highly diversified size and form, from the tiny dormouse phalanger to the almost elephantine extinct *Diprotodon,* and from the most agile pygmy "flying-squirrel" to the powerful and clumsy wombat.

Australians usually call the phalangers "opossums," but they are not closely related to the American animals. This mistake arises from the facts that both animals are pouched mammals, both live in trees, both have pointed muzzles and strongly grasping hands and feet and prehensile tails. But in many other important characters the American opossum and the Australian "opossum" differ widely. The former belongs to the polyprotodont division, having the incisors and canines disposed as in other carnivorous mammals, the latter have diprotodont front teeth, adapted for cutting vegetable fibre, and crested molar teeth adapted for grinding. Very striking is the contrast in the dental formulae of the two animals:

American opossum (*Didelphis*): $(\mathrm{i.}\frac{5}{4}\ \mathrm{c.}\frac{1}{1}\ \mathrm{p.}\frac{3}{3}\ \mathrm{m.}\frac{4}{4}) \times 2 = 50$

Australian "opossum" (*Trichosurus*): $(\mathrm{i.}\frac{3}{2}\ \mathrm{c.}\frac{1}{0}\ \mathrm{p.}\frac{2}{2}\mathrm{m.}\ \frac{4}{4}) \times 2 = 36$ (or less)

The polyprotodont American opossums have no trace of the syndactylous specialization of the hind feet which, as described above, is so characteristic of the Australian "opossum" and there are many striking differences in the skulls and other parts of the anatomy. The Australian phalangers as a group live in close ecologic relations with the eucalyptus trees that dominate the landscape in all but the dryest regions of the interior. Many eat eucalyptus leaves and the "native bear" (*Phascolarctos*) normally lives on nothing else. To overcome the aromatic essence of these leaves and extract nutriment from this highly indigestible material the phalangers have a long intestine and a greatly enlarged caecum. In locomotor habits the phalangers range from the sloth-like native bear, which clings tenaciously to the branches with its large hands and feet, to the highly active flying phalangers, including several quite different genera, which have a skimming membrane on the sides of the body and between the limbs. In one division of the family, including *Pseudochirus* and *Phascolarctos,* the upper molar teeth each bear two sharp V's or crescents. In another subfamily, which includes the Australian "opossum" (*Trichosurus*), the two V's of the upper molars are modified into cross-crests. The last lower premolar of the typical phalangers has a compressed cutting crown, with more or fewer vertical grooves and ridges. In the phalangers, however, these cutting premolars are not as elongate as they are in the smaller kangaroos. These cutting premolars, both in the upper and lower jaws, became greatly enlarged in the extinct "marsupial lion" (*Thylacoleo*), in which the molars were reduced and the front teeth became enlarged and piercing. Sir Richard Owen was of the opinion that *Thylacoleo* was a fierce carnivorous creature but others have demurred from this opinion on various grounds and think the animal sheared some unknown kind of fruit. In widest contrast to the shearing-toothed *Thylacoleo* is the tiny long-snouted phalanger (*Tarsipes*) of West Australia, which is said to live on the honey and insects found in long-tubed flowers, into which it sticks its long muzzle and extensile tongue.

The kangaroos doubtless represent a ground-living group descended from arboreal ancestors; in the most primitive living type, the musk-kangaroo (*Hypsiprymnus*), the hind-foot still bears the stamp of the foot of the tree-living phalanger, in which the fourth digit is much enlarged, the second and third digits are reduced and syndactylous, the first digit is still present, and separate friction pads are retained under the digits. In the more advanced kangaroos the first digit is lost and so are the friction pads. For further evolution of this family *see* KANGAROO.

The wombats (*Vombatus*) are sometimes called "native badgers" on account of their robustness and burrowing habits, but they far excel the true or placental badgers in strength and in ability to dig deep tunnels with great rapidity. Their skulls are rodent-like in so far as they have only a single pair of long curved incisors in the upper jaw as well as in the lower; their molar teeth also have long-curved crowns and widely open roots. Each upper molar crown consists essentially of a pair of V's in tandem and this arrangement appears to be derivable from the double-V molars of the Koala (*Phascolarctos*) with which the wombats are in many ways rather closely related.

Fossil Marsupials of Australia.—During the Pleistocene or glacial epoch when northern Europe and northern North America were repeatedly covered by continental glaciers, Australia remained free of glaciers except in the vicinity of its highest mountains. While the mastodon, the mammoth, the cave-bear and other animals dominated Europe, Australia had her own peculiar mammalian fauna which has left its bones in cave deposits of eastern Australia and in ancient lake basins of the interior. In the cave fauna are the scattered bones of giant kangaroos of many extinct species, of the lion-like *Thylacoleo,* of the marsupial wolf and many others. Around the margins of the lakes, however, lived still stranger beasts, the clumsy diprotodonts and nototheres. In general body form these resembled huge rodents; the name "marsupial rhinoceros" applied to one notothere seems highly inappropriate even if the animal did have a hump on its nasal bones. In general the molar teeth of the diprotodonts each bear two sharp cross-crests, not unlike those of the extinct proboscidean *Dinotherium.* They appear to be an offshoot of the phalanger stock, distantly related to the kangaroos, wombats and native bears. The fossil diprotodont *Wynyardia,* described by Sir Baldwin Spencer from the Tertiary beds of Table Cape, Tasmania, was formerly regarded as of Oligocene age but is now known to be much younger (Pliocene). The skull is thoroughly phalangerid in type.

Fossil Marsupials of South America.—We have already noted that the family of American opossums, appearing late in the Cretaceous in North America, and continuing there well into Oligocene, somehow found its way into South America at least by Lower Miocene and possibly earlier. But along with these purely American fossils there have been found in the Santa Cruz (Lower Miocene) formation of Patagonia the fossil representatives of two families that have a strangely Australian appearance.

The first are unquestionably carnivorous marsupials, the several genera ranging from the size of a large opossum to that of a hyaena. Of these the largest and most famous form, called *Borhyaena,* figured in scientific literature as a kind of link between the extinct creodonts of the Eocene epoch of North America and the existing marsupial wolf of Australia. But in every fundamental feature they are true carnivorous marsupials. W. D. Matthew even holds that the special resemblances between the Patagonian borhyaenids and the Australian carnivorous marsupials are likewise due in part to parallel evolution, the borhyaenids being predatory derivatives of the American opossum stock, the Australian thylacines of the related Australian dasyurid stock, both derived ultimately from Cretaceous opossums of the northern hemisphere. But H. E. Wood has shown that, apart from the rather close resemblances in the borhyaenid dentition to that of the Australian thylacines, there are several curious resemblances in the backbone, pelvis and limbs, which tend to link borhyaenids with thylacines and contrast them both with opossums, so that to attribute this all to parallelism, plus descent from a common didelphid ancestor, seems to be essentially a *petitio principii,* especially as the now rather numerous known opossums from Cretaceous to Recent times show not the slightest tendency to vary in the borhyaenid-thylacine direction.

The second family of South American marsupials which seem to have a distinctly Australian appearance are the caenolestids. These little animals were long known from a few fragmentary fossils (*Epanorthus, Abderites,* etc). In 1895 Oldfield Thomas announced that this supposedly extinct family was actually represented in the living mammalian fauna of Ecuador and Bolivia by a small shrew-like animal, which he called *Caenolestes* and pointed out that it resembled certain of the extinct Patagonian epanorthids in its dentition, also that it resembled in other respects certain of the Australian phalangers, with the important exception that its hind feet were devoid of the syndactyl specialization of the second and third toes. Since that time a number of species of *Caenolestes* have been found in the mountains of the Andean parts of South America and the anatomy of the animal has been thoroughly studied, especially in the recent monograph by W. H. Osgood. From all this it appears that *Caenolestes* exhibits a highly confusing mixture of resemblances with the Australian bandicoots and diprotodonts, but that it contrasts widely with the opossums except in a few details, such as the construction of Jacobson's organ in the interior of the nose; in this it shows strong resemblances both to the opossums and the bandicoots. The general impression left by a careful consideration of the evidence is that, in spite of the somewhat phalanger-like features of its dentition, *Caenolestes* is not a true diprotodont but merely a phalanger-like offshoot of a primitive marsupial stock that was perhaps more nearly allied with the bandicoots than with the American opossums.

How then did the extinct borhyaenids and the extinct and recent caenolestids, both apparently more nearly related to Australian stocks than to the American opossums, ever get into South America? Are they derived from two as yet undiscovered northern ancestral stocks which also gave rise respectively to the Australian dasyuroids and to the Australian bandicoots and diprotodonts, or did they come into Patagonia from the south, after crossing some long-sunken archipelago connecting Patagonia with the once flourishing continent of Antarctica? Matthew has shown that in a great many other cases relict forms of the southern land masses have been derived from northern ancestors and this may eventually prove true in the case of the borhyaenids and caenolestids. Nevertheless, the more direct evidence so far brought forward by recent authors leaves the impression that the American opossums are not closely related either to the borhyaenids or to the caenolestids and that the latter two are more nearly related respectively with the dasyuroid and perameloid stocks of Australia in spite of their wide geographic separation.

Classification of Families.—The famous classification of the marsupials into two suborders, Polyprotodontia and Diprotodontia, based upon the number and arrangement of the front teeth, seems at the present time to be a rather misleading simplification of a complex situation. The "polyprotodont" bandicoots, for example, appear to be more nearly related to the Australian true diprotodonts than to the American polyprotodont opossums, while the functionally "diprotodont" caenolestids appear to be more nearly related to the polyprotodont bandicoots than to the true diprotodonts. No less objectionable is the old grouping into Diadactyla and Syndactyla recently revived by Wood Jones, which is based solely upon the presence or absence of the syndactylous specialization of the second and third toes of the hind foot. However, the bandicoots, which resemble the kangaroos in possessing the syndactylous type of foot, differ profoundly from them in many other respects. From a comparative study of the dentition we may even affirm with B. A. Bensley that both bandicoots and kangaroos, along with all other Australian families, must be derived from primitive Australian polyprotodonts much resembling the pouched mice (*Phascogale*). In short, in the present state of knowledge it seems advisable to abandon the old larger groups and to group the families into the following series of superfamilies:

1. Superfamily Didelphoidea. North America, Cretaceous to Recent; Europe, Oligocene; South America, Oligocene to Recent. Primarily arboreal with strongly grasping hind feet, the great toe (hallux) large and divergent. Second and third digits not syndactylous. Snout pointed. Insectivorous-carnivorous, with unreduced dentition; polyprotodont. Dental formula typically i.$\frac{5}{4}$ c.$\frac{1}{1}$ p.$\frac{3}{3}$ m.$\frac{3}{3}$, seldom reduced. Upper molars triangular, with strongly developed metacones (main posteroexternal cusps) and various developed accessory marginal cusps; internal cusps large. Lower molars primitive, tuberculo-sectorial. Auditory process of alisphenoid small or moderate, not covering tympanic cavity below. Jacobson's organ well developed. Nipples numerous (5–27). Pouch variable, if present opening forward or downward. Paired vaginal canals separate or partly united in a variable median cul-de-sac. Allantoic sack abortive, not forming a placenta.

Family Didelphiidae. North America, Cretaceous to Oligocene, Recent; South America, Oligocene (?), Lower Miocene, Recent.

2. Superfamily Dasyuroidea. Australian Region,-Pliocene to Recent; One family in South America,-Miocene. Terrestrial or slightly arboreal, with narrow or variously elongated hind feet, the hallux more or less reduced. Snout pointed to blunt. Insectivorous to extremely carnivorous dentition, polyprotodont, often with reduced premolars. Upper molars triangular to shearing. Internal cusps often small. Lower molars tuberculo-sectorial to shearing. Auditory process of alisphenoid much inflated. Nipples usually numerous (4–10). Pouch variable, often reduced or absent; if present, marsupial bones sometimes absent; typically opening backward. Median vaginal canal temporarily pierced at parturition. Allantoic sack abortive.

Family Dasyuridae. Australia, Pleistocene and Recent. Pouched mice, native cats, Tasmanian devil, Tasmanian wolf.

Family Borhyaenidae. Patagonia, South America, Lower Miocene.

Family Myrmecobiidae. Australia, Recent. Banded anteater.

Family Notoryctidae. Australia, Recent. Marsupial mole.

3. Superfamily Perameloidea. Australian Region. Terrestrial, with kangaroo-like hind limbs, longer than fore limbs, adapted for scratching, digging and leaping. Hallux reduced, fourth digit much enlarged, second and third syndactylous. Snout very long, projecting, pointed. Dentition insectivorous-omnivorous, polyprotodont. Dental formula: (i.$\frac{5 \text{ or } 4}{3}$ c.$\frac{1}{1}$ p.$\frac{3}{3}$ m.$\frac{4}{4}$)$\times 2=48$ or 46. Incisor teeth with flattened, not pointed, crowns. Upper molars more or less quadrangular, long-crowned, main outer cusps probably representing much enlarged marginal cusps of primitive dasyuroids. Auditory process of alisphenoid inflated. Jacobson's organ well developed. Nipples six to eight. Pouch present, opening downward and somewhat backward. Median vaginal cul-de-sac moderately developed, young at least occasionally delivered *via* lateral vaginal canals. Allantoic placenta well developed.

Family Peramelidae. Australia and New Guinea, Pleistocene, Recent. Bandicoots.

4. Superfamily Caenolestoidea. Andean South America, Miocene to Recent. Terrestrial shrew-like forms with narrow non-syndactylous hind feet with slender hallux. Snout elongate. Insectivorous, functionally more or less diprotodont but with polyprotodont. Dental formula: (i.$\frac{4}{3 \text{ or } 4}$ c.$\frac{1}{1}$ p.$\frac{3}{3}$ m.$\frac{4}{4}$)$\times 2=46$ or 48. First and second upper molars more or less quadrangular, short crowned; lower molars modified tuberculo-sectorial with large talonids. Last lower premolars sometimes compressed, grooved (*Abderites*). Auditory process of alisphenoid moderate. Jacobson's organ very well developed, essentially as in polyprotodonts. Teats four. Pouch absent in adults. Marsupial bones well developed. Median vaginal canal essentially as in Didelphiidae.

Family Caenolestidae. Patagonia, Miocene to Recent.

5. Superfamily Phalangeroidea. Australian region, Pliocene to Recent. Primarily arboreal, secondarily terrestrial and derived

forms; the primitive arboreal type with strongly grasping hind feet, the hallux large and divergent, second and third digits markedly syndactylous. Snout typically rather short and thick. Dentition primarily herbivorous, diprotodont; dental formula reduced, typically $(i.\frac{3}{2}\ c.\frac{1}{0}\ p.\frac{2}{2}\ m.\frac{4}{4})\times 2=36$. Upper and lower molars typically bicrescentic or bilophodont. Last premolars compressed, in primitive forms grooved. Auditory process of alisphenoid usually well inflated, typically bridging petrous bone below and joining paroccipital process. Nipples usually four, rarely two. Pouch well developed, opening forward. Marsupial bones well developed. Median vaginal canal well developed, the young delivered through a temporary pseudo-vaginal opening. Allantois not forming a placenta.

Family Phalangeridae. Australian Region, Pliocene to Recent. Phalangers, native bears.
Family Thylacoleontidae. Australia, Pleistocene.
Family Macropodidae. Australia, Pliocene to Pleistocene. Kangaroos.
Family Diprotodontidae. Australia, Pliocene to Recent.
Family Vombatidae. Australia, Pliocene to Recent. Wombats.

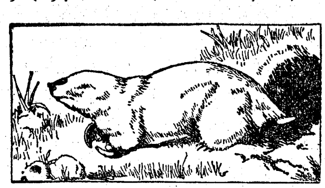
MARSUPIAL MOLE (*Notoryctes typhlops*), a polyprotodont from central South Australia, constituting a family (Notoryctidae). This small burrowing animal is of a pale golden-yellow colour, with long silky hair, a horny shield on the nose, and a stumpy leathery tail. The feet are five-toed, and the third and fourth toes of the front pair are armed with enormous claws for digging. Neither ear conches nor eyes are visible externally. There are but three pairs of incisor teeth in each jaw, and the upper molars are tricuspid. Being a marsupial, it is not a relative of the true moles, but the resemblance of the two forms is due to convergence.



MARSUPIAL MOLE (NOTORYCTES TYPHLOPS), OF SOUTH AUSTRALIA

MARSUPIAL MOUSE, any small member of the family Dasyuridae (*see* Marsupialia); most belong to the genus *Phascogale.* There are over a dozen species, none larger than a rat. Females of several species have pouches, but there are only folds of skin around the mammae in other forms. Marsupial mice are found throughout Australia and on Tasmania, New Guinea and the Aru Islands.

MARSUS, DOMITIUS, Latin poet, friend of Virgil and Tibullus, and contemporary of Horace. He survived Tibullus (d. 19 B.C.), but was no longer alive when Ovid's catalogue of poets (*Ex Ponto,* iv, 16) was written (A.D. 12). He was the author of a collection of epigrams called *Cicuta* ("hemlock") from their bitter sarcasm. According to others the name was derived from a reed-pipe made of the stalks of hemlock; the reading *scutica* ("whip") has also been proposed. He also wrote an epitaph on the death of Tibullus; elegiac poems, an epic poem *Amazonis;* and a prose work on wit (*De urbanitate*).

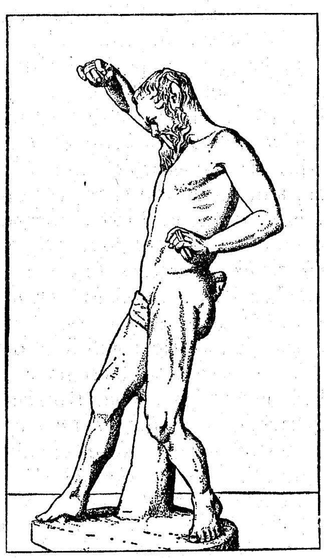
MARSYAS, a daimon or silenus of Anatolian origin, but adopted by Greek legend. According to it Athena had invented the oboe (αὐλός) and threw it away in disgust because it distorted the features. Marsyas found it, and having acquired great skill in playing it, challenged Apollo to a contest with his lyre. Midas, king of Phrygia, who had been appointed judge, declared in favour of Marsyas, and Apollo punished Midas by changing his ears into ass's ears. In another version, the Muses were judges and awarded the victory to Apollo, who tied Marsyas to a tree and flayed him alive. In Rome, a statue of Marsyas, a favourite art-subject (*cf.* Greek Art), stood in the Forum, and this was imitated by Roman colonies and came to be considered a symbol of autonomy.

See Jessen in Roscher's *Lexikon,* art. "Marsyas" (bibl.).

MARTABAN, a town in the Thaton district of Lower Burma, on the right bank of the Salween, opposite Moulmein. It is said to have been founded in A.D. 573, by the first king of Pegu, and was once the capital of a powerful Talaing kingdom; but it is now little more than a village. Martaban is frequently mentioned by European voyagers of the 16th century; and it has given the name of "Martavans" to a class of large vessels of glazed pottery, also known in India as "Pegu jars." It was twice captured by the British, in 1824 and 1852.

MARTELLO TOWER, a kind of tower formerly used in English coast defence. The name is a corruption of Mortella. The Martello tower was introduced in consequence of an incident of the French revolutionary wars. In September 1793 a British squadron of three ships of the line and two frigates was ordered to support the Corsican insurgents. In 1794, an assault was planned upon a tower on Cape Mortella commanding the Gulf of San Fiorenzo. On Feb. 7, 1,400 troops were landed, and the tower was attacked by land and sea on the 8th. The "Fortitude" and "Juno" kept up a cannonade for 2½ hours and then hauled off, the former being on fire and having 62 men killed and wounded. The fire from the batteries on shore produced no impression until a hot shot set fire to the "bass junk with which, to the depth of 5ft., the immensely thick parapet was lined." The garrison of 33 men then surrendered. The armament was found to consist only of two 18-pounders and one 6-pounder. The strong resistance offered by these three guns seems to have led to the conclusion that towers of this description were specially formidable, and Martello towers were built in large numbers, and at heavy expense, along the shores of England, especially on the southern and eastern coasts, which in certain parts are lined with these disused towers at short intervals. They are structures of solid masonry, containing vaulted rooms for the garrison, and providing a platform at the top for two or three guns, which fire over a low masonry parapet. Access is provided by a ladder, communicating with a door about 20ft. above the ground. In some cases a ditch is provided around the base. The defect of the tower was its weakness against vertical fire. The French *tours modèles* were somewhat similar to the Martello.

MARTEN, HENRY (1602–1680), English regicide, was born at Oxford where he entered University College. He first became prominent in 1639 when he refused to contribute to the general loan for the Scottish War, and in 1640 he was returned to parliament as a member for Berkshire. There he spoke in favour of the proposed bill of attainder against Strafford, and used such frank language about the king that Charles demanded his trial for high treason. When rebellion broke out Marten did not take the field, although he was appointed governor of Reading, but in parliament he was very active. In 1643, on account of some remark about extirpating the royal family, he was expelled from parliament, but in the following year was made governor of Aylesbury. Allowed to return to parliament in 1646, Marten again spoke against the king, and attacked the Presbyterians, and, supporting the army against the parliament, signed the agreement of Aug. 1647. He was one of the most prominent of the king's judges and signed the death warrant. In 1649 he was chosen a member of the council of state, but he took no part in public life during the Protectorate. Having resumed



MARSYAS, FROM A COPY OF MYRON'S GROUP, ABOUT 450 B.C., FOUND ON THE ESQUILINE HILL, ROME, NOW IN THE LATERAN MUSEUM, ROME his seat in the Long Parliament in 1659, Marten surrendered himself as a regicide in June 1660. He was imprisoned at Chepstow Castle where he died on Sept. 9, 1680. Although a leading Puritan, Marten was a man of loose morals. He published several pamphlets, and in 1662 *Henry Marten's Familiar Letters to his Lady of Delight,* containing letters to his mistress, Mary Ward.

See J. Forster, *Statesmen of the Commonwealth* (1840); M. Noble, *Lives of the English Regicides* (1798); S. R. Gardiner, *History of the Great Civil War* and *History of the Commonwealth and Protectorate,* and *Dict. Nat. Biog.* for further bibliography.

MARTEN, the name originally applied to the pine marten (*Martes martes*) but now used for all members of this genus of carnivorous mammals (*see* CARNIVORA). Martens are confined to the temperate and subtropical parts of the northern hemisphere, save for one species which extends to Java. They inhabit wooded and rocky localities and climb trees with facility. They are largely carnivorous in diet and have a blood-thirsty disposition. All the species yield valuable fur, but those from the far north are the most esteemed, especially when caught in winter, since the fur is then longer and denser. They are usually captured in "deadfall" traps, in which a log of wood is so arranged as to fall on the victim when it interferes with the bait.

The pine marten is a rich dark brown in colour, reddish-grey beneath, with a yellow breast spot. It varies in length from 2–2½ ft., inclusive of the tail, and is distributed throughout northern Asia and Europe, including the British Isles, where, however, it is very rare. The beech or stone marten (*M. foina*) is lighter in colour and more southern in range. The sable (*M. zibellina*), very like the pine marten, is the most valuable fur-bearer of the group. It inhabits eastern Siberia. The North American marten (*M. americana*) is closely related to the pine marten and sable, which it resembles in habits and appearance. The pekan or fisher (*M. pennanti*) is larger and more stoutly built than its relatives, reaching a length of about 3 feet. The yellow-throated marten (*M. flavigula*) ranges from India and China to Java; it is light brown on the shoulders, becoming blackish on the rump and has an orange chest. The Japanese marten (*M. melampus*) resembles the last species but is golden brown or dark brown above, with blackish feet. (J. E. HL.)

MARTENS, FRÉDÉRIC FROMMHOLD DE (1845–1909), Russian jurist, was born at Pernau in Livonia. In 1868 he entered the Russian ministry of foreign affairs, and in 1872 was professor of public law in the Imperial School of Law and the Imperial Alexander Lyceum. In 1874 he started special juristic work for the Russian government. His book on *The Right of Private Property in War* appeared in 1869, and was followed in 1873 by *The Office of Consul and Consular Jurisdiction in the East.* These were the first of a series of studies which won for their author a world-wide reputation, and raised the character of the Russian school of international jurisprudence. First amongst them must be placed the great *Recueil des traités et conventions conclus par la Russie avec les puissances étrangères* (13 vols., 1874–1902). This collection, published in Russian and French in parallel columns, contains not only the texts of the treaties but valuable introductions dealing with the diplomatic conditions of which the treaties were the outcome. These introductions are based largely on unpublished documents from the Russian archives. Of Martens' original works his *International Law of Civilized Nations* is perhaps the best known. More openly "tendencious" in character are such treatises as *Russia and England in Central Asia* (1879); *Russia's Conflict with China* (1881), *The Egyptian Question* (1882), and *The African Conference of Berlin and the Colonial Policy of Modern States* (1887).

Martens was repeatedly chosen to act in international arbitrations. Among the controversies which he helped to adjust were that between Mexico and the United States—the first case determined by the permanent tribunal of The Hague—and the difference between Great Britain and France in regard to Newfoundland in 1891. He played an important part in the negotiations between his own country and Japan, which led to the peace of Portsmouth (Aug. 1905) and prepared the way for the Russo-Japanese convention. He was employed in laying the foundations for The Hague Conferences. He was one of the Russian Plenipotentiaries at the first conference and president of the fourth committee—that on maritime law—at the second conference. His visits to the chief capitals of Europe in 1907 were an important preliminary in the preparation of the programme. He was judge of the Russian supreme prize court established to determine cases arising during the war with Japan. He died suddenly on June 20, 1909.

See T. E. Holland, in *Journal of the Society of Comparative Legislation* for October 1909, where a list of the writings of Martens appears.

MARTENS, GEORG FRIEDRICH VON (1756–1821), German jurist and diplomatist, was born at Hamburg on Feb. 22, 1756. Educated at the universities of Göttingen, Regensburg and Vienna, he became professor of jurisprudence at Göttingen in 1783 and was ennobled in 1789. In 1814 he was appointed privy cabinet-councillor (*Geheimer Kabinetsrat*) by the king of Hanover, and in 1816 went as representative of the king to the diet of the new German Confederation at Frankfort, where he died on Feb. 21, 1821.

Of his works the most important is the collection of treaties *Recueil des traités,* etc. from 1761 onwards. Of this the first seven vols. were published at Göttingen (1791–1801), followed by four supplementary volumes partly edited by his nephew Karl von Martens. These were followed by *Nouveau recueil,* of treaties subsequent to 1808, in 16 vols. (Göttingen, 1817–42), of which G. F. von Martens edited the first four, the fifth being the work of K. von Martens, the others (6–9) by F. Saalfeld and (10–16) F. Murhard; a *Nouveau Supplément* in 3 vols. was also published by Murhard (Göttingen, 1839–1842). The series has been continued since under other editors.

MARTHA'S VINEYARD, an island of south-eastern Massachusetts, five miles across Vineyard sound from the "heel" of Cape Cod. It comprises about 100sq.m., its greatest length being 19¼m. and its greatest width, from north to south, 9⅜ miles. It figured largely in the whaling industry and merchant trade of former times; now it is chiefly a summer resort, although its many and diverse fisheries continue to be of importance and increasing value. Martha's Vineyard has characteristic insular temperatures. Its topography, of glacial origin, includes picturesque hills, as high as 311ft., strewn with boulders; broad, undulating plains cut by great ponds with many fingerlike coves; deeply indented harbours with contrasting coast lines; and extensive wooded areas. Gay Head, its western peninsula, ends in a stretch of cliffs, 6,000ft. in length and as high as 145ft., of brilliantly coloured sands and clay. Bartholomew Gosnold visited and named Martha's Vineyard in 1602. (It may also have been the Straumey of the Norsemen and the Luisa of Verrazano.) The first settlement was at Great Harbour (Edgartown), sent out by Thomas Mayhew, an English merchant of Watertown, in 1642. The island was controlled by New York until 1692. With the Elizabeth islands it constitutes Dukes county, so named with Kings and Queens, on Long Island, by the New York provincial assembly in 1683.

The six towns of Martha's Vineyard, with population in 1940, are as follows: Tisbury (1,966) is principally the village of Vineyard Haven, called Holmes Hole until 1871. Its fine harbour, of great beauty, made it an historic refuge and port of call for ships. Oak Bluffs (1,584) is the site of camp meetings, held annually, save for a single year, since 1835. Becoming a populous summer town it was incorporated as Cottage City in 1880 and renamed in 1907. Edgartown (1,370) was one of the important whaling centres, serving as the port for Nantucket for many years. It retains much of its atmosphere. West Tisbury (260) was separated from Tisbury in 1892. Chilmark (226) includes the fishing village of Menemsha and the small island of Nomans Land (named after Tequenoman, an Indian). It was founded as Tisbury Manor, with feudal lords, in 1671. Gay Head (127), never relinquished by the Indians, has been an Indian town since 1870. Its men, peculiarly skilled as harpooners, played a noted part in whaling history.

MARTIAL (MARCUS VALERIUS MARTIALIS) (b. between A.D. 38 and 41, died *c.* A.D. 102), Roman epigrammatist, was born at Bilbilis (Bambola), in Spain (Mart. i. 61. 11 Te, Liciniane, gloriabitur nostra Nec me tacebit Bilbilis). The date of his birth is inferred from his own words in x. 24, where he celebrates his 57th birthday on March 1 (*cf.* x. 92. 10, Martem mearum principem Kalendarum). The poems of Bk. x. belong to the years 95–98.

Life at Rome.—In 64 he came to Rome, where, apart from a brief visit to Cisalpine Gaul (*cf.* iii. 1, iii. 4) in A.D. 88, he made his home for 34 years. Living at first in rather humble circumstances (i. 117, 7 scalis habito tribus sed altis), he gradually made headway and was able to have, in addition to his town house on the Quirinal (x. 58. 10), a small country place at Nomentum (ii. 38, vi. 43, xii. 57) in the Sabine territory. He won the ear of the Court and received from Titus and Domitian the *ius trium liberorum* (ii. 91–92, ix. 97, 5, tribuit quod Caesar uterque ius mihi natorum), a privilege which permitted a person to hold a public office before his 25th year and be exempted from public burdens. Though, strictly, it belonged to the father of three legitimate children, it was frequently conferred on those who had fewer than three children, or even none at all (*cf.* Plin. *Ep.* ii. 13). He also obtained a military tribuneship and the dignities of an *eques Romanus* (iii. 95, 9). In A.D. 98 he finally left Rome to return to his native Bilbilis (xii. 18), where he lived on an estate presented to him by his friend Marcella (xii. 31.7, post septima lustra reverso Hos Marcella lares parvaque regna dedit). Here he wrote and published the last (xii.) book of his Epigrams and soon after died.

Literary Friendships.—At Rome he seemed to have enjoyed the friendship of all the leading literary men of his time. Pliny the Younger (*Ep.* iii. 21) describes his feelings on hearing of the poet's death: "I hear that Valerius Martial has died and I am grieved. He was a man able, acute and keen, who in his writing had wit and pungency and not less of candour. When he was leaving Rome I presented him with his travelling expenses (*viaticum*), a tribute to friendship, a tribute also to the lines he wrote about me." The lines in question are in our texts x. 19, of which Pliny, in his letter, quotes the last ten lines. Quintilian is addressed in ii. 90:

> O chiefest ruler of our wayward youth, Quintilian, glory of the Roman gown, I crave thy pardon if still young nor yet made useless by the years I haste to live True life, which no man hastes enough to live. Howbeit if any is fain to gather wealth Beyond his fathers and to crowd his halls with busts of mighty men, his ancestors, He may defer the day of life, but me the hearth and halls that scorn not sooty smoke Delight, the living spring, the simple grass. Give me my well-fed servant and a wife. No more than needful learnéd, sleep o' nights, And days untroubled by the law's delays.

Lucan is the theme of vii. 21–23, the first and the last of these epigrams being addressed to Polla, Lucan's widow. Juvenal, with whom Martial deprecates comparison (vii.24), is addressed in xii. 18. Silius Italicus is addressed in iv. 14 and mentioned in vi. 64. 10, vii.63.1, xi.48.1, xi.49.3 *seq.*, while i.76, iv.42, iv.49 are addressed to Valerius Flaccus, who is referred to also in i.61.4. There appears to be no reference to Statius either by name or by implication.

Works.—Martial's work consists of: (1) The so-called *Liber Spectaculorum* (33 epigrams), written in connection with the opening of the Colosseum, an amphitheatre in the middle of the city which had been begun by Vespasian (Sueton. *Vesp.* 9) and was finished by Titus (Suet. *Tit.* 7) in A.D. 79. (2) Two books of epigrams (in modern editions Bks. xiii. and xiv.) entitled *Xenia* and *Apophoreta,* two-line inscriptions for presents, published at the Saturnalia of 84. (3) Twelve books of epigrams, of which i. and ii. were published in 86 and iii.-xi. between then and 98. Bk. x. was first published under Domitian, but the revised edition (our present text) belongs to 98. Bk. xii. was written after his final return to Bilbilis. The prose prefaces to Bks. i., ii., viii. (dedication to Domitian), xii. are of considerable interest.

A comparison of Martial with the Greek Anthology suggests three points worthy of notice. (1) By *epigram* the Greeks normally understood a short poem in elegiac couplets, and the overwhelming majority of the epigrams in the Greek Anthology conforms to that definition. We do, indeed, though very rarely, find other metres used, *e.g.,* hendecasyllables, A.P. v. 308, etc., iambic trimeter, A.P. vi. 107, etc., pure hexameters, A.P. v. 109, etc. But in Martial, though the elegiac still constitutes the normal type, other metres occupy a very considerable place. The metres other than elegiac which Martial uses are: (1) hendecasyllables, *e.g.,* x.9.1. Undenis pedibusque syllabisque, (2) pure hexameters, i. 53, etc., (3) iambic trimeter scazon, *e.g.,* vii.26.1, Apollinarem conveni meum, scazon, (4) iambic trimeter alternating with iambic trimeter, *e.g.,* i. 49 Vir Celtiberis non tacende gentibus Nostraeque laus Hispaniae, (5) iambic trimeter scazon alternating with ordinary iambic dimeters, *e.g.,* i.61 Verona docti syllabas amat vatis Marone felix Mantua est, (6) pure iambic trimeters, *e.g.,* vi. 12 Iurat capillos esse quos emit suos. This feature of Martial is probably due, like much else in Martial, to the influence of Catullus, who again was much influenced by the Alexandrines. (2) Whereas the typical epigram of the Greek Anthology does not exceed some eight lines, in Martial 20 to 30 lines is not unusual—iii. 58 extends to 51 lines. Ep. vi. 64 is in pure hexameters and extends to 32 lines. It is followed by a defence in vi. 65. "I know that Tucca says 'you write epigrams in hexameters': Tucca, it is a usual practice and lastly it is legitimate. 'But this is long': that also, Tucca, is usual and legitimate (*solet licetque*). If you approve of shorter epigrams, you should read only distichs. Let's make a bargain—that I be allowed to write long epigrams, you to skip them." (3) The typical epigram in Martial depends for its effect on some witty turn at the end, a "sting" in the tail. This is again a departure from the Greek model, but the development can easily be traced from Alexandrine times. Martial's own point of view may be gathered from vii. 25, where he indicates that epigrams without point and pungency are food only for babes.

Character of His Epigrams.—The subject-matter of the epigrams embraces the whole range of the life of a man about town, and from this point of view their value to the student of Roman life and manners is inestimable. They bear witness alike to the nobler aspects of that life and to the more ignoble. The ugliest feature of Martial's work is the gross indecency—with no plea or palliation of comic effect—which disfigures some—not relatively a large proportion—of his epigrams. It is difficult to imagine the tone of a society which could not merely tolerate but even applaud such language. Martial defends himself on the ground of traditional usage. "I should have apologized," he says (pref. to Bk. i.), "for the lascivious frankness of speech, the language, that is, of my epigrams, had I been setting the example; but it is thus that Catullus writes, thus Marsus, thus Pedo, thus Gaetulicus, thus every author whose work is read to an end. If however any one is so ostentatiously austere that in his presence one can in no page speak Latin, he may content himself with this letter, or even with the title. The Epigrams are written for those who are accustomed to see the Festival of Flora. Let Cato not enter my theatre, or, if he enter, let him look on." Two things may be noted: (1) Martial considered himself in this matter superior to the generality. In x. 9. 2 he describes himself as known "for much wit and that not wanton" (Et multo sale nec tamen protervo), and in xii.43.11 he protests to one who had recited to him eloquent lines on libidinous topics—*Tanti non erat esse te disertum,* Your eloquence was too dearly purchased at such a price. In the dedication to Domitian prefixed to Bk. viii. he writes: "Although men the most austere and of the highest rank have written epigrams affecting a liberty of language appropriate to *mimes,* yet I have not permitted mine to speak so frankly as is usual." (2) Martial protests that licence in speech does not imply licentiousness of life: Lasciva est nobis pagina, vita proba (i.4.8). In any case his candour disarms criticism: Non potes in nugas dicere plura meas Ipse ego quam dixi. . . . Nos haec novimus esse nihil (xiii.2).

Emotional Quality in Poems.—Among the more pleasant features of his poetry are his genuine feeling for the simpler aspects of country life, which reveals itself in many charming pictures (i.49, i.55, iii.58, etc.); the tenderness which shows itself in his sepulchral epigrams, some of which are worthy to stand beside the best Greek examples, such as those on Alcimus (i.88) and Canace (xi.91) or this—one of several—on Erotion, a little slave girl who died in infancy:

Here, ah! too soon, Erotion takes her sleep,
Whom Death's fell scythe ere her sixth year did reap.
O whoso henceforth shall this land possess,
If thou be kind this little grave to dress,
Long may thy tenure be, and through the years
May thy heart know no other place for tears! (x.61).

and finally his affection for his native Bilbilis, to which "after four and thirty harvests" the tired exile returns, having known fame and friends, but also having suffered the disillusion which suggests that sad and sober philosophy of friendship, enunciated long before in Euripides (*Hippol.* 253 *seq.*) and Sophocles (*Aj.* 678 *seq.*): Nulli te facias nimis sodalem, Gaudebis minus et minus dolebis (xii.34.10 *seq.*).

See also Edwin Post, *Selected Epigrams of Martial* (1908) with introduction and notes; G. Thiele, *Die Poesie unter Domitian,* Hermes 51 (1916); the translation into English verse by Elphinston (London, 1782) is famous for its absurdity, which drew an epigram from Burns.

(A. W. Ma.)

MARTIALIS, QUINTUS GARGILIUS, a Latin writer on horticultural subjects. He has been identified by some with the military commander of the same name, mentioned in a Latin inscription of A.D. 260 (*C. I. L.* viii. 9047) as having lost his life in the colony of Auzia (*Aumale*) in Mauretania Caesariensis. Considerable fragments of his work (probably called *De hortis*), which treated of the cultivation of trees and vegetables, and also of their medicinal properties, have survived, chiefly in the body of and as an appendix to the *Medicina Plinii* (an anonymous 4th century handbook of medical recipes based upon Pliny, *Nat. Hist.* xx.–xxxii.). Extant sections treat of apples, peaches, quinces, almonds and chestnuts. Gargilius also wrote a treatise on the tending of cattle (*De curis boum*), and a biography of the emperor Alexander Severus is attributed by two of the Scriptores historiae Augustae (Aelius Lampridius and Flavius Vopiscus) to a Gargilius Martialis, who may be the same person.

Bibliography.—*Gargilii Martialis . . . fragmenta,* ed. A. Mai (1846); *Plinii secundt quae fertur medicina,* ed. V. Rose (1876); *De curis boum,* ed. E. Lommatzsch (1903) with Vegetius Renatus's *Mulomedicina,* "Gargilius Martialis und die Maurenkriege," C. Cichorius in G. Curtius, *Leipziger Studien.* x. (1887), where the inscription referred to above is fully discussed; *see* also Teuffel-Schwabe, *Hist. of Roman Literature* (Eng. trans.), § 380.

MARTIAL LAW. "Martial Law" is a much misunderstood term, the use of which has given rise to a great deal of speculation.

Definition.—Much of the confusion and doubt about its meaning and the powers exercisable in its name would have been avoided if modern writers had been careful to confine the term to its original meaning as used by Hale and Coke, namely, the law applied to the army and nothing else, the law known as "military law." Modern writers have appropriated the term "martial law" to the assumption of arbitrary powers by the Executive, in time of civil disturbances, over civilians, and have then proceeded to read earlier authorities by the light of its rays. The result is to darken their counsel and beget a gross anachronism. Hale (*History of the Common Law,* pp. 36–42) says of martial laws that "the necessity of good order and discipline *in the army* is that *only* which can give these laws countenance." He accordingly held that it could not apply to civilians in any circumstances.

The term was used in the same sense as Hale uses it in the famous Petition of Right, which forbade martial law in time of peace. The "Petition" did not thereby, either expressly or impliedly, legalize it in time of war. The contemporary debates in the House of Commons show that the men of those days did not contemplate the legality of martial law, as applied to civilians, under any circumstances. In objecting to martial law they were objecting to commissions issued by the king to try civilians as though they were soldiers subject to military law and triable by court-martial. As for soldiers themselves, the contemporary view was that at common law, even they were not, in time of peace, subject to martial law, *i.e.,* to military law, except by statute (a view which now finds countenance in the necessity of the annual Army Act), although in the field, in time of war, they were so subject. Or to put it another way, martial law was pure military law, and as such unknown to the common law, and only came into existence with the outbreak of war and even then was confined to troops.

THE EXERCISE OF MARTIAL LAW

Cockburn, C. J., was unquestionably right in holding (*see* his observations in the *Queen* v. *Nelson,* Finlasson's edition, p. 66) that the Petition of Right condemned the exercise of martial law against the subject "under any circumstances," whether in "war" or in "peace," and even as against soldiers except in the case of armies in time of war. The promoters of the Petition of Right were solely concerned to assert the supremacy of the common law. Even a rebel, they argued, taken with arms in his hands, had a right to be tried by the ordinary common law courts. If he could not be so tried, the law was then altogether suspended. They did not trouble themselves with the question with which modern lawyers are so greatly vexed, namely as to whether there could exist a kind of qualified "state of war" under which the courts might still be sitting, but in circumstances of military indulgence such as would bind them not to interfere. This modern view has helped to give a colour of legality to martial law which would have been incomprehensible to the Stuart generation, denying, as they did, the very existence of the thing except within the determinate limits of military law.

Early Views.—The 17th century view as to the position of the ordinary courts was clear and unequivocal. It was that if the civilian situation was such that the courts were able to sit at all, the judges were free to examine every arbitrary act of the military on its merits. If the civil situation was so "warlike"—the term "war," in connection with martial law, does not mean war in the international sense, but war in the sense of rebellion or civil strife, as in the Statute of Treasons where it is declared to be treason for a subject to "levy war" against the king in his realm—that the courts could not sit, the king's writ did not run, and the sheriffs and ministers of justice could not levy execution, then such facts constituted a state of war (*cf.* Coke, *Institutes I.,* 249 *b*). But the existence of such facts must be proved to the satisfaction of the courts, if and when they were able to sit. The courts could thus, either *at the time or after,* decide whether the military measures taken to suppress the civilian commotion exceeded the necessity of the case, in precisely the same way as the courts always decide how far civilians and police are justified in using force to encounter and suppress force. The mere fact that the military, for the more instant suppression of the disturbances or the rebellion, have "tried" the rebels by court-martial in no way implies that those "trials" are lawful or that any law has been administered. A trial by martial "law" is a purely executive act. It is for this reason that the civil courts have no jurisdiction to review the "judgments" of such bodies by *way of appeal*—the memorandum of their proceedings is not the record of a court of justice (cf. *A. G.* v. *Van Reenen* [1904], A.C. 117). The so-called courts-martial, convened to try civilians under martial law, cannot, as two law officers long ago pointed out (*see* Forsyth, *Cases and Opinions in Constitutional Law,* p. 555), be properly described as courts at all. The way to seek relief from a sentence of such a tribunal is not by writ of prohibition or by appeal, but by an application for a writ of Habeas Corpus (*cf.* Lord Sumner in the recent Irish case *Re Clifford and O'Sullivan* [1921], 2 A.C. 570).

MARTIAL AND COMMON LAW

The truth of the matter is that the term martial law is really an anachronism and legally means nothing at all. Martial law is simply, as Fitzjames Stephen put it, "the assumption by the officers of the Crown of *absolute power* exercised by military force for the suppression of an insurrection and the restoration of order and lawful authority." It should never be resorted to for punishment except in so far as immediate punishment is necessary for suppression of the disturbance. The moment the disturbance is over, the prisoners should be handed over to the civil power. The very fact that it means the assumption of "absolute power" renders it subject to the control of the courts *ab initio*. A mere "proclamation" of martial law by the Crown has, of itself, no legal validity whatsoever. A proclamation is not necessary to justify resort to martial law nor is the resort to martial law justified by it. It is all a question of fact. One must thus carefully distinguish between the prerogative of the Crown to declare war with a foreign country and the alleged prerogative—there is none—to declare the realm internally in a state of war, *i.e.*, a state of rebellion. The former is absolute and binding on the courts (*see* PREROGATIVE) who cannot question it; the latter is not binding on the courts at all and they may, whenever the Crown proclaims a "state of war" within the country, go behind the proclamation and enquire (1) whether, as a question of fact, there is such a state of affairs and (2) whether the acts done by the authorities in putting down such war, if it exists, are justified. There can be no doubt about this, but it is still a matter of some dispute whether, once they are satisfied that a state of war exists, the courts, if sitting, can, during the actual continuance of disturbance, interfere with the action of the military authorities.

In the famous *Marais* case, A.C. (1902) 109, the Privy Council, discarding Coke's doctrine that the fact that the courts were still able to sit did not establish *ipso facto* the absence of the state of war, went on to lay down that the courts should not interfere with the discretion of the military authorities, *e.g.*, by granting a writ of Habeas Corpus, to anyone detained by them, while war was actually raging, but that they might enquire afterwards into the validity of the acts done by the military. To the writer of this article, the distinction seems untenable. It amounts to the paradoxical contention that the common law is, for the time being, neither quick nor dead but merely passive; the "necessity" of the moment is held to be too overwhelming to permit of a contemporaneous enquiry but not so overwhelming as to forbid a retrospective one; "we cannot interfere now"—such appears to be the argument—for, to do so, would be to assume responsibility for and lend countenance to the acts of the military authorities, but we reserve our right to do so afterwards." If this view is to prevail, it would make it possible for the military authorities to contract and expand the geographical area of their martial law jurisdiction at will, with the common law courts merely looking on.

STANDARD CASES

The older doctrine, which received statutory countenance in American cases (cf. *Ex parte Milligan* [1866], 4 Wallace 2, and the dissentient judgment of Mr. Justice Woodbury in *Luther* v. *Borden* [1849], 7 How. 1), was that nothing short of the complete suppression of civil authority and the closing of the courts—in other words, such overwhelming necessity as silences the voice of justice altogether—could establish martial law. The view taken in the *Marais* case seems to proceed on the assumption that the judiciary exists by sufferance of the Executive; it goes very near a repudiation of jurisdiction altogether, and in that respect is perilously like the discredited doctrine of "act of state." It is difficult, if one accepts the doctrine of the *Marais* case, to escape the conclusion in the American case of *Luther* v. *Borden* (although that case be turned on a different point): "If this right [of interference] does not reside in the courts when the conflict is raging, and if the judicial power is, at that time, bound to follow the decision of the political, *it must equally be bound when the contest is over;* it cannot, when peace is restored, punish, as offences and crimes, the acts which it before recognized and was bound to recognize as lawful." In other words, it seems more reasonable to hold that the common law persists throughout the disturbances and that the courts can interfere at any stage. Whether they should do so must depend on the merits of the particular case. They certainly should not interfere if, in the particular situation, their interference is calculated to hamper, delay and embarrass the military authorities in the suppressing of the rebellion, and thereby to prolong it. During the Irish disturbances of 1920–1922, the Irish courts, however, followed and applied the doctrines of the *Marais* case (cf. *Higgins* v. *Willis* [1924], 2 Irish Rep. K.B.D. 386; *R.* v. *Portobello Barracks C.O. Ex parte Erskine Childers* [1923], 1 Irish Rep. 5, and *R.* v. *Strickland* [1921], 2 Irish Rep. 317).

The whole subject of martial law—or rather the extent to which its enforcement is justified—provoked a blaze of excitement in the year 1919, as the result of the action of Gen. Dyer on April 13 of that year in ordering his troops to fire, with decisive results, on a bloodthirsty mob who, for several days, had been terrorizing the peaceful inhabitants of Amritsar in the Punjab province of India. As the result of the agitation of the Indian extremists, a committee of enquiry was appointed, whose constitution and procedure were, in the language of Lord Finlay, "most unseemly." As the result of the committee's report, the India Office, which acted with gross cowardice, removed Gen. Dyer from the army. The whole matter subsequently came under review in a debate in the House of Lords (41 H.L. Deb. 5 s. 222), which, by a large majority, approved the action of Gen. Dyer. Later on in the case of *O'Dwyer* v. *Nair* (unreported) an English jury, after a masterly summing up by Mr. Justice McCardie, vindicated the action of Gen. Dyer, which was one of the points at issue, and awarded heavy damages to Sir Michael O'Dwyer, the lieutenant governor of the Punjab under whose authority Gen. Dyer acted, against the defendant who had written a book describing the action of both these distinguished public servants as an "atrocity." The main point at issue in all this was whether Gen. Dyer used "unnecessary force," and the view was strongly expressed in the House of Lords by Lord Sumner that under modern conditions, with all their possibilities of rapid propaganda and equally rapid communication, a soldier, placed like Gen. Dyer, was entitled to take into account the possibility—and in this case the extreme probability—of a general rising if he did not take stern measures. Public opinion, when not clouded by political considerations, has entirely endorsed this view and it is widely held that the action of Sir Michael O'Dwyer and Gen. Dyer "saved India."

MARTIAL LAW AND THE WORLD WAR

A somewhat paradoxical situation arose with the outbreak of the World War. England was at war with Germany, but there was no "state of war" in England, in other words, no internal disturbance such as would justify resort to martial law. On the other hand, it was obviously necessary that the Executive should be armed with extensive powers to secure the safety and defence of the realm, such as the power, which at common law it did not possess, to suppress the publication of information likely to be of use to the enemy, to secure the safety of communications, and a thousand other things. The difficulty was met by the enactment of the famous Defence of the Realm Acts and the regulations thereunder, the effect of which was, among other things, to introduce a kind of statutory martial law and to abridge the common law rights of the subject in every direction. So far did this departure go that by the Consolidation Act, Nov. 27, 1914, provision was made for trial and punishment by court-martial of any civilian, committing offences against the regulations, "as if he were a person subject to military law"—in other words a soldier—"and had committed the offence on active service." It was further provided that if the offence were committed with the intention of assisting the enemy, "he should be punishable with sentence of death." This tremendous and unprecedented extension of military law to the civil population was severely criticized in the House of Lords, and, four months later, in March 1915, an amending act was passed restoring the right to trial by jury in the case of a British subject, while leaving the alien subject to this military jurisdiction. The mere fact that all this "Dora" legislation was necessary illustrates the strict limitations to which the assumption of despotic power, known as martial law, is subject in English law. The same may be said of the Emergency Powers Act of 1920, giving the Crown power by proclamation, subject always to the positive approval of parliament within 10 days, to take various measures to deal with industrial disturbances threatening the supply of the necessaries of life to the population. (*See* also MILITARY LAW.)

UNITED STATES

In the United States, martial law, as distinguished from military law, is the temporary government and control, under a body of principles or doctrines, by the military authorities, of a Territory or a State in which, by reason of war, or overwhelming public disturbance, the Territory or State is unable to preserve order or enforce its law. (*In re Kemp,* 16 Wis. 309, 368, and *Ex parte Milligan,* 1866, 4 Wallace 2.) Its authority depends upon a state of complete insurrection and terminates when the insurrection ends, or a reasonable time thereafter. (*In re Moyer,* 85 Pac. 192; *Boon* v. *Aetna Insurance Company,* 40 Conn. 575, 584.) Martial law is not provided for in the U.S. Constitution, except by inference, but is rather a means of preserving the Constitution. It is the law of necessity and asserts itself.

Where the civil courts are open and able to exercise their functions, with the aid of the military if necessary, there can be no exercise of martial law. (But see *State Ex Rel. Mays* v. *Brown,* 45 L.R.A., N.S. 996.) When martial law prevails martial-law courts, provost courts, military commissions or other courts of the military commands may punish those guilty of acts which obstruct the military in its enforcement of order. This authority ends with the cessation of hostilities. Martial law may be exercised in time of war only, and within the theatre of war, and where the civil courts are wholly unable to exercise their functions. It found its use in the United States in New Orleans in 1815, in the border States in 1861–65, and during the World War. The use of the military forces to aid the civil power has its justification in law, while martial law finds its justification in necessity.

See Fairman, *Law of Martial Rule* (1930); "Lieber's Justification of Martial Law Theory," *North American Review* (1896); Winthrop, *Military Law and Precedents;* Birkhimer, *Military Government and Martial Law;* W. E. Hall, *International Law.* (F. W. Ha.)

MARTIGNAC, JEAN BAPTISTE SYLVERE GAY, Vicomte de (1778–1832), French statesman, was born at Bordeaux on the 20th of June 1778. In 1798 he acted as secretary to Sieyès; then after serving for a while in the army, he turned to literature, producing several light plays. Under the Empire he practised with success as an advocate at Bordeaux, where in 1818 he became advocate-general of the *cour royale.* In 1819 he was appointed *procureur-général* at Limoges, and in 1821 was returned for Marmande to the Chamber of Deputies, where he supported the policy of Villèle. In 1822 he was appointed councillor of state, in 1823 he accompanied the duc d'Angoulême to Spain as civil commissary; in 1824 he was created a viscount and appointed director-general of registration. In contact with practical politics his ultra-royalist views were gradually modified in the direction of the Doctrinaires, and on the fall of Villèle he was selected by Charles X. to carry out the new policy of compromise. On the 4th of January 1828 he was appointed minister of the interior, and, though not bearing the title of president, became the virtual head of the cabinet. He succeeded in passing the act abolishing the press censorship, and in persuading the king to sign the ordinances of the 16th of June 1828 on the Jesuits and the little seminaries. He was exposed to attack from both the extreme Left and the extreme Right, and when in April 1829 a coalition of these groups defeated him in the chamber, Charles X., who had never believed in the policy he represented, replaced him by the prince de Polignac. His last public appearance was in defence of Polignac in the Chamber of Peers in December 1830. He died April 3, 1832.

Martignac published *Bordeaux au mois de Mars 1815* (1830), and an *Essai historique sur les révolutions d'Espagne et l'intervention française de 1823* (1832). *See* also E. Daudet, *Le Ministère de M. de Martignac* (1875).

MARTIGUES, a port of south-eastern France, department of Bouches-du-Rhône, on the south shore of the lagoon of Berre, and at the eastern extremity of that of Caronte, by which the former is connected with the Mediterranean. Pop. (1936) 6,415. Built in 1232 by Raymond Bérenger, count of Provence, Martigues was made a viscountship by Joanna I., queen of Naples. Henry IV. made it a principality, in favour of a princess of the house of Luxembourg. It afterwards passed into the hands of the duke of Villars. Martigues is 23 m. W.N.W. of Marseilles by rail. It is divided into three quarters by canals. It has a harbour (used by coasting and fishing vessels), marine workshops, and oil and soap manufactures. A dainty, *boutargue,* is prepared from the roes of the grey mullet caught in the salt lagoons and is said to rival Russian caviare, though the flavour is quite different. Owing to its canals and numerous bridges the town has sometimes been called "the Venice of Provence."

MARTIN, ST. (*c.* 316–400), bishop of Tours, was born of heathen parents at Sabaria (Stein am Agger) in Pannonia, about the year 316. When ten years old he became a catechumen, and at 15 he reluctantly entered the army. While stationed at Amiens he divided his cloak with a beggar, and on the following night had the vision of Christ making known to his angels this act of charity to Himself on the part of "Martinus, still a catechumen." Soon afterwards he received baptism, and two years later, having left the army, he joined Hilary of Poitiers, who wished to make him a deacon, but at his own request ordained him to the humbler office of an exorcist. On a visit home he converted his mother, but his zeal against the Arians roused persecution against him, and for some time he lived an ascetic life on the desert island of Gallinaria near Genoa. Between 360 and 370 he was again with Hilary at Poitiers, and founded in the neighbourhood the monasterium locociagense (Licugé). In 371–372 the people of Tours chose him for their bishop. He did much to extirpate idolatry from his diocese and from France, and to extend the monastic system. To obtain privacy for the maintenance of his personal religion, he established the monastery of Marmoutier-les-Tours (Martini monasterium) on the banks of the Loire.

At Trèves, in 385, he entreated that the lives of the Priscillianist heretics should be spared, and he ever afterwards refused to hold ecclesiastical fellowship with those bishops who had sanctioned their execution. He died at Candes in the year 400, and is commemorated by the Roman Church on Nov. 11.

He is the patron of the cities of Mainz and Würzburg. The *Life* by his disciple Sulpicius Severus is practically the only source for his biography, but it is full of legendary matter and chronological errors. Gregory of Tours gives a list of 206 miracles wrought by him after his death; Sidonius Apollinaris composed a metrical biography of him. The Feast of St. Martin (Martinmas) took the place of an old pagan festival, and inherited some of its usages (such as the *Martinsmännchen, Martinsfeuer, Martinshorn* and the like, in various parts of Germany); by this circumstance is probably to be explained the fact that Martin is regarded as the patron of drinking and jovial meetings, as well as of reformed drunkards.

See A. Dupuy, *Geschichte des heiligen Martins* (Schaffhausen, 1855); J. G. Cazenove in *Dict. chr. biog.* iii. 838; C. A. Bernoulli, *Die heiligen der Merowinger* (1900); C. H. von Rhin, *Martin von Tours* (1912).

MARTIN (Martinus), the name of several popes.

Martin I. succeeded Theodore I. in June or July 649. He had previously acted as papal apocrisiarius at Constantinople. Almost his first official act was to summon a synod (the first Lateran) for dealing with the Monothelite heresy. It met in the Lateran church, was attended by one hundred and five bishops (chiefly from Italy, Sicily and Sardinia, a few being from Africa and other quarters), held five sessions or "secretarii" (Oct. 5–31, 649), and in twenty canons condemned the Monothelite heresy, its authors, and the writings by which it had been promulgated. In this condemnation were included, not only the *Ecthesis* or exposition of faith of the patriarch Sergius for which the emperor Heraclius had stood sponsor, but also the Typus of Paul, the successor of Sergius, which had the support of the reigning emperor (Constans II.). Martin published the decrees of his Lateran synod in an encyclical, and Constans replied by enjoining his exarch to seize the pope and send him prisoner to Constantinople. Martin was arrested in the Lateran (June 15, 653), hurried out of Rome, and conveyed first to Naxos and subsequently to Constantinople (Sept. 17, 654). He was ultimately banished to Cherson, where he arrived on March 26, 655, and died on Sept. 16 following. His successor was Eugenius I.

A full account of the events of his pontificate will be found in Hefele's *Conciliengeschichte,* vol. iii. (1877).

MARTIN II. and III., *see* MARINUS I. and II.

MARTIN IV. (Simon Mompitié de Brion), pope from Feb. 22, 1281, to March 28, 1285, should have been named Martin II. He was born about 1210 in Touraine. He became a priest at Rouen and canon of St. Martin's at Tours, and was made chancellor of France by Louis IX. in 1260 and cardinal-priest of Sta. Cecilia by Urban IV. in 1261. As papal legate in France he conducted the negotiations for the assumption of the crown of Sicily by Charles of Anjou, through whose influence he succeeded Nicholas III., after a six-months' struggle between the French and Italian cardinals. The Romans at first declined to receive him, and he was consecrated at Orvieto on March 31, 1281. His excommunication of the emperor Michael Palaeologus (Nov. 1281), who stood in the way of the French projects against Greece, weakened the union with the Eastern Christians, dating from the Lyons Council of 1274. He unduly favoured his own countrymen, and for three years after the Sicilian Vespers (March 31, 1282) he employed all the resources of the papacy on behalf of his patron against Peter of Aragon. He was driven from Rome by a popular uprising and died at Perugia. His successor was Honorius IV.

His registers have been published in the *Bibliothèque des écoles françaises d'Athènes et de Rome* (Paris, 1901).

See A. Potthast, *Regesta pontif. roman.,* vol. 2 (Berlin, 1875); K. J. von Hefele, *Conciliengeschichte,* Bd. 6, 2nd ed.; F. Gregorovius, *Rome in the Middle Ages,* vol. 5, trans. by Mrs. G. W. Hamilton (London, 1900–02); H. H. Milman, *Latin Christianity,* vol. 6 (London, 1899); W. Norden, *Das Papsttum u. Byzanz* (Berlin, 1903); E. Choullier, "Recherches sur la vie du pape Martin IV.," in *Revue de Champagne,* vol. 4 (1878); *Processo istorico dell' insurrezione di Sicilia dell' anno 1282,* ed. by G. di Marzo (Palermo, 1882).

MARTIN V. (Otto Colonna) (1417–1431) was elected at Constance on St. Martin's Day, in a conclave composed of twenty-three cardinals and thirty delegates from the five different "nations" of the council. Having become a cardinal under Innocent VII., he had seceded from Gregory XII. in 1408, and together with the other cardinals at Pisa, had taken part in the election of Alexander V. and afterwards of John XXIII. At Constance, his rôle had been chiefly that of an arbiter; he was a good and gentle man, leading a simple life, free from intrigue. While refraining from making any pronouncement as to the validity of the decrees of the fourth and fifth sessions, which had seemed to proclaim the superiority of the council over the pope, Martin V. nevertheless soon revealed his personal feelings by having the constitution read in consistory which forbade any appeal from the judgment of the sovereign pontiff in matters of faith (May 10, 1418).

Martin V. himself settled a great number of points, which had been raised at the council, and then passed a series of special concordats with Germany, France, Italy, Spain and England. Though this was not the thorough reform of which need was felt, the council itself gave the pope a *satisfecit.* When the council was dissolved Martin V. made it his task to regain Italy. After staying for long periods at Mantua and Florence, where the deposed pope, Baldassare Cossa (John XXIII.), came and made submission to him, Martin V. was enabled to enter Rome (Sept. 30, 1420). He set to work to repair the damage done by the Great Schism, to enter into negotiations, unfortunately unfruitful, with the Greek Church also with a view to a return to unity, to organize the struggle against heresy in Bohemia; to interpose his pacific mediation between France and England, as well as between the parties which were rending France; and, finally, to welcome Bernardino of Siena and Francesca Romana, foundress of the nursing sisterhood of the Oblate di Tor de' Specchi (1425).

Martin V., after an interval of five years, summoned a new council, which was almost immediately transferred from Pavia to Siena, in consequence of an epidemic (1423). It was quickly dissolved. Pending the reunion of the new council which had been summoned at Basel, Martin V. himself endeavoured to effect a reformation in certain points, but he died (Feb. 20, 1431), just as he had designated the young and brilliant Cardinal Giuliano Cesarini to preside in his place over the council of Basel.

Valois, *La Crise religieuse du xv^e^ siècle; le pape et le concile* (1909), vol. i. p. i.–xxix., 1–93.

MARTIN, FRANÇOIS XAVIER (1762–1846), American jurist and author, was born in Marseille, France, on March 17, 1762. An immigrant to North Carolina during the Revolution, he supported himself by teaching French and working as a printer. Meanwhile he studied English and law to such good purpose that he became a member of the general assembly in 1806 and was commissioned a judge of the superior court of the Territory of Mississippi in 1809. The following year he assumed a similar position in Louisiana. In 1813 he became attorney general of the newly established State of Louisiana, in 1815 a judge of the supreme court, and from 1836 to 1846 the presiding judge. His work in publishing in English and French *A General Digest of the Acts of Legislatures of the Late Territory of Orleans and of the State of Louisiana* (1816) and in publishing reports of decisions of the superior and supreme court (20 vol., 1811–30), particularly valuable in view of the tangle of French, Spanish and English laws, won him the title of "father of Louisiana jurisprudence." His *History of Louisiana from the Earliest Period* (2 vol., 1827–29) made him a pioneer in this field also, but his work, though accurate, partakes of some of the dryness of his legal studies and lacks entirely the glow of Gayarré's histories. Martin was also the author of a *History of North Carolina* (2 vol., 1829) and of various other legal books published in, or concerned with, that State. He died in New Orleans on Dec. 10, 1846.

See memoirs by H. A. Bullard in B. F. French, *Historical Collections of Louisiana* (vol. ii., 1850) and by W. W. Howe in the 1882 edition of Martin's *History.*

MARTIN, HENRI (1810–1883), French historian, was born at St. Quentin (Aisne), where his father was a judge. With Paul Lacroix ("le Bibliophile Jacob"), he planned a history of France, to consist of excerpts from the chief chroniclers and historians, with original matter filling up gaps in the continuity. His *Histoire de France,* 15 vols. (1833–36), was the result. This *magnum opus,* rewritten and further elaborated (4th ed., 16 vols. and index, 1861–65) gained for the author in 1856 the first prize of the Academy, and in 1869 the grand biennial prize of 20,000 francs. A popular abridgment in seven volumes was published in 1867. This, together with the continuation, *Histoire de France depuis 1789 jusqu'à nos jours* (6 vols., 1878–83), gives a complete history of France, and supersedes Sismondi's *Histoire des Français.* Martin sat in the *assemblée nationale* as deputy for Aisne in 1871, and was elected life senator in 1878, but he left no mark as a politician. He died in Paris on Dec. 14, 1883.

See Hanotaux, *Henri Martin; sa vie, ses oeuvres, son temps* (2nd ed., 1898).

MARTIN, HOMER DODGE (1836–1897), American artist, was born at Albany (N.Y.) on Oct. 28, 1836. A pupil for a short time of William Hart, his earlier work followed the lines of the Hudson river school. He was elected as associate of the National Academy of Design, New York, in 1868, and a full academician in 1874. During a trip to Europe in 1876 he was captivated by the Barbizon school, and from 1882–86 he lived in France, spending much of the time in Normandy. At Villerville he painted his "Harp of the Winds," now at the Metropolitan Museum of Art, New York. Among his important canvases are "Westchester Hills," "Adirondack Scenery," "The Cinqueboeuf Church," "Sand Dunes," and "A Newport Landscape." Martin is generally spoken of as one of the great trio of American landscape artists, the others being Inness and Wyant, and examples of his work are in most of the important American collections. He died at St. Paul (Minn.) on Feb. 2, 1897.

MARTIN, JOHN (1789–1854), English painter, was born at Haydon Bridge, near Hexham, on July 19, 1789. His first picture, "Sadak in Search of the Waters of Oblivion," was exhibited in the Royal Academy of 1812. His most famous work was "Belshazzar's Feast," exhibited in 1821, and reproduced in many media. Other popular works were "Joshua" (1816), "The Fall of Babylon" (1833), the "Eve of the Deluge" (1841), and a series of other Biblical and imaginative subjects. In 1832–1833 Martin drew and engraved a fine series of designs to Milton, and with Westall he produced a set of Bible illustrations. He died in the Isle of Man on Feb. 17, 1854.

See M. L. Hendered, *John Martin, Painter* (1923).

MARTIN, LUTHER (1748–1826), American lawyer, was born in New Brunswick, N.J., on Feb. 9, 1748. He graduated at the college of New Jersey (now Princeton university) in 1766, and removed to Maryland, teaching at Queenstown in that colony until 1770. He was admitted to the bar in 1771, and became recognized as one of the ablest lawyers in the United States. From 1778 to 1805 and again in 1818–22 he was attorney-general of Maryland. He was one of Maryland's representatives in the constitutional convention of 1787 at Philadelphia, but opposed the constitution and refused to affix his signature. He subsequently allied himself with the Federalists, and was an opponent of Thomas Jefferson, who in 1807 spoke of him as the "Federal Bull-Dog." His ability was shown in his famous defence of Judge Samuel Chase (*q.v.*) in the impeachment trial before the United States Senate in 1804–05, and in his defence of Aaron Burr (*q.v.*) against the charge of treason in 1807. Though he received a large income, he was so improvident that he was frequently in want. Martin died at the home of Aaron Burr in New York on July 10, 1826.

See the biographical sketch by Henry P. Goddard, *Luther Martin, the Federal Bull-Dog* (Baltimore, 1887), No. 24 of the "Peabody Fund Publications," of the Maryland Historical Society.

MARTIN, SIR THEODORE (1816–1909), British man of letters, the son of a solicitor, was born at Edinburgh on Sept. 16, 1816, and educated at the Royal High school and the University. He practised for some time as a solicitor in Edinburgh, but in 1846 went to London, where he joined a firm of parliamentary agents, eventually becoming senior partner. He contributed in Edinburgh to *Fraser's Magazine* and *Tait's Magazine*, under the signature of "Bon Gaultier," and in 1855, with W. E. Aytoun (*q.v.*), he published the famous *Bon Gaultier Ballads*. In 1858 he published, also with Aytoun, a volume of translations of the *Poems and Ballads of Goethe*. In 1861 he married Helena Faucit (*q.v.*). While engaged upon a memoir of Aytoun (1867) Martin was requested by Queen Victoria to undertake the *Life of His Royal Highness the Prince Consort* (5 vols., 1874–76). A knighthood was then conferred upon him. Among his other works may be mentioned *Queen Victoria as I Knew Her* (1908). Sir Theodore Martin died on Aug. 18, 1909.

MARTIN, VIOLET FLORENCE (1862–1915) ("Martin Ross"), was born at Ross House, Co. Galway, from which she took her pen-name, on June 11, 1862, of an old Irish family. From the time of her father's death in 1872, she spent her childhood in Dublin, and was educated privately and at Alexandra college, Dublin. The greater part of her life was spent in Ireland, but she often travelled abroad with her cousin Edith Oenone Somerville, with whom she collaborated. Their books give vivid and sympathetic pictures of Irish life, and their love of hunting (Miss Somerville was for 12 years master of the West Carbery foxhounds) gave rise to the series of books of which *Some Experiences of an Irish R.M.* is perhaps the best known. Their novels include *The Real Charlotte* (1894), their first serious work; *Mount Music* (1919), and *The Enthusiast* (1921). The two latter were published under joint authorship, although after Miss Martin's death, as they were largely her work. Her qualities can best be seen in two volumes of essays, autobiographical in character, *Some Irish Yesterdays* (1906) and *Stray-Aways* (1920). She died at Cork on Dec. 21, 1915.

MARTIN, SIR WILLIAM FANSHAWE (1801–1895), British admiral, son of Admiral of the Fleet Sir Thomas Byam Martin, comptroller of the navy, was born on Dec. 5, 1801. He entered the navy when twelve, and secured rapid promotion, becoming lieutenant in 1820, commander of the "Fly" sloop in 1823, commodore commanding the Channel squadron in 1849–52, rear-admiral in 1853 and for the next four years superintendent of Portsmouth dockyard. He was made vice-admiral in February 1858 and, after a year as a lord of the admiralty, was appointed commander-in-chief in the Mediterranean. He had no war service, and, beyond the Italian disturbance of 1860–61, no opportunity for showing diplomatic ability. He became an admiral in Nov. 1863 and on Dec. 4 succeeded to the baronetcy which had been conferred on his grandfather. His last appointment was the command at Plymouth, 1866–69. In 1878 he was made rear-admiral. He died at Upton Grey, near Winchfield, on March 24, 1895. He is remembered as a reformer of discipline and the originator of a system of steam manoeuvres.

MARTIN, a name applied to the well-known European and American birds, the house martin (*Delichon urbica*), sand martin (*Riparia riparia*) and the purple martin (*Progne subis*). Others occur all over the world, except in New Zealand.

The house martin, like its ally the swallow (*q.v.*) is a migrant, arriving in Europe and western Asia in spring from its winter quarters in South Africa and India. It is a smaller bird than the swallow, lacking the latter's forked tail; the plumage is black above and white beneath. The nest, a half hemisphere of mud and straw, lined with feathers, is built under the eaves of houses; occasionally nests are found on cliffs, which must have been the original site. Two broods are usual.

The sand martin is smaller than the last and has a brownish tinge to the upper parts. It is the earliest of the British Hirundinidae to arrive. The nest is placed at the end of a horizontal burrow in a sandy bank or the face of a quarry. It ranges from Ireland to the Sea of Okhotsk and thence right across North America, where it is called the bank swallow. In winter, it reaches the Transvaal, India and Caiçara in Brazil. The larger purple martin of Canada and the United States normally builds in hollow trees, but readily adapts itself to nesting-boxes, but leaves when house sparrows are abundant. It ranges from southern Mexico to within the Arctic Circle. The rock-martin (*Riparia rupestris*) of Europe builds a bottleshaped nest of mud. All the martins feed on insects, which they capture as they fly. The eggs are usually white. The kingbird (*q.v.*) is known as bee martin.

MARTIN OF TROPPAU or **MARTIN THE POLE** (d. 1278), chronicler, was born at Troppau, and entered the order of St. Dominic at Prague. Afterwards he went to Rome and became papal chaplain under Clement IV. and other popes. In 1278 Pope Nicholas III. appointed him archbishop of Gnesen, but he died at Bologna whilst proceeding to Poland to take up his new duties. Martin wrote some sermons and some commentaries on the canon law; but more important is his *Chronicon pontificum et imperatorum*, a history of the popes and emperors to 1277, which is untrustworthy, but was much used by subsequent chroniclers.

The Latin text is printed, with introduction by L. Weiland, in Band XXII. of the *Monumenta Germaniae historica* (Hanover and Berlin, 1826 *seq.*). *See* G. Waitz, H. Brosien and others in the *Neues Archiv der Gesellschaft für ältere deutsche Geschichtskunde* (Hanover, 1876 *seq.*); W. Wattenbach, *Deutschlands Geschichtsquellen*, Band II. (Berlin, 1894); and A. Molinier, *Les Sources de l'histoire de France*, Tome III. (1903).

MARTINEAU, HARRIET (1802–1876), English writer, was born at Norwich, where her father was a manufacturer, on June 12, 1802. The family was of Huguenot extraction (*see* MARTINEAU, JAMES) and professed Unitarian views. The atmosphere of her home was industrious, intellectual and austere; she herself was clever, but weakly and unhappy; she had no sense of taste or smell, and moreover early grew deaf. At fifteen she was sent on a prolonged visit to her aunt, Mrs. Kentish, who kept a school at Bristol. Here her life became happier. In 1821 she began to write anonymously for the *Monthly Repository*, a Unitarian periodical, and in 1823 she published *Devotional Exercises and Addresses, Prayers and Hymns*.

In 1826 her father died, leaving a bare maintenance to his wife and daughters. Harriet's eldest brother and her lover both died about the same time. Then the Martineaus lost all their money.

Harriet began to write for her living. She met with moderate success only until she found (1831) a publisher for the series of tales known as *Illustrations of Political Economy.* In 1832 she moved to London, where she numbered among her acquaintance Hallam, Milman, Malthus, Monckton Milnes, Sydney Smith, Bulwer, and later Carlyle. In 1834 Harriet Martineau paid a long visit to America. Her open adhesion to the Abolitionist party, then small and very unpopular, gave great offence, which was deepened by the publication, soon after her return, of *Society in America* (1837) and a *Retrospect of Western Travel* (1838). An article in the *Westminster Review,* "The Martyr Age of the United States," introduced English readers to the struggles of the Abolitionists.

In 1839, during a visit to the Continent, Miss Martineau's health broke down. She retired to solitary lodgings in Tynemouth, and remained an invalid until 1844. Besides a novel, *The Hour and the Man* (1840), *Life in the Sickroom* (1844), and the *Playfellow* (1841), she published a series of tales for children containing some of her most popular work: *Settlers at Home, The Peasant and the Prince, Feats on the Fiord,* etc. During this illness she for a second time declined a pension on the civil list, fearing to compromise her political independence. Her letter on the subject was published, and some of her friends raised a small annuity for her soon after. She removed to Ambleside, where she built herself "The Knoll," the house in which the greater part of her after life was spent. In 1845 she published three volumes of *Forest and Game Law Tales.* In 1846 she made a tour with some friends in Egypt, Palestine and Syria, and on her return published *Eastern Life, Present and Past* (1848). This work showed that as humanity passed through one after another of the world's historic religions, the conception of the Deity and of Divine government became at each step more and more abstract and indefinite. The ultimate goal Harriet Martineau believed to be philosophic atheism, but this belief she did not expressly declare.

In 1851 Miss Martineau alienated many of her friends by the publication of *Letters on the Laws of Man's Nature and Development.* She contributed regularly from 1852 to 1866 to the *Daily News.* In the early part of 1855 Miss Martineau found herself suffering from heart disease. She now began to write her autobiography, but her life, which she supposed to be so near its close, was prolonged for twenty years. She died at "The Knoll" on June 27, 1876. She cultivated her tiny farm with success, and her poorer neighbours owed much to her. The verdict which she records on herself in the autobiographical sketch left to be published by the *Daily News* has been endorsed by posterity.

See her *Autobiography, with Memorials by Maria Weston Chapman* (1877); Mrs. Fenwick Miller, *Harriet Martineau* (1884, "Eminent Women Series"); Janet E. H. Courtney, *Free Thinkers of the Nineteenth Century* (1920); Theodora Bosanquet, *Harriet Martineau* (1927); and F. S. Marvin, "Harriet Martineau: Triumph and Tragedy," *Hibbert Jour.,* vol. xxv., pp. 631–640 (1928).

MARTINEAU, JAMES (1805–1900), English philosopher and divine, was born at Norwich, of Huguenot ancestry, on April 21, 1805, the seventh child of Thomas Martineau and Elizabeth Rankin, the sixth, his senior by almost three years, being his sister Harriet (*see* above). James was educated at Norwich Grammar school and at the private academy of Dr. Lant Carpenter at Bristol. On leaving he was apprenticed to a civil engineer at Derby, but in 1822 entered Manchester college, then lodged at York with a view to entering the Unitarian ministry.

On leaving the college in 1827 Martineau taught for a time in his old school at Bristol. From 1828 to 1832 he was junior minister of a Presbyterian church in Dublin, but resigned on a matter of conscience. He was then called to Liverpool, and there for a quarter of a century he exercised extraordinary influence as a preacher. In 1840 he was appointed professor of mental and moral philosophy and political economy in Manchester New college, now removed to Manchester. This position he held for 45 years (until 1885). In 1853 the college removed to London, and four years later Martineau followed. In 1858 he became minister of Little Portland street chapel in London. Martineau received many academic honours. He died in London on Jan. 11, 1900.

Martineau's most characteristic and stimulating works are his sermons, published as *Endeavours after the Christian Life* (1st series, 1843; 2nd series, 1847); *Hours of Thought* (1st series, 1876; 2nd series, 1879); the various hymn-books he issued at Dublin in 1831, at Liverpool in 1840, in London in 1873; and the *Home Prayers* in 1891. Martineau just escaped the active period of the old Unitarian controversy. But its presence is felt in his *The Rationale of Religious Enquiry* (1836), and later in his *Types of Ethical Theory* (1885) and *The Study of Religion* (1888) and, in some measure, in *The Seat of Authority in Religion* (1890).

Martineau's theory of the religious society or church was that of an idealist rather than of a statesman or practical politician. He stood equally remote from the old Voluntary principle, that "the State had nothing to do with religion," and from the sacerdotal position that the clergy stood in an apostolic succession, and either constituted the Church or were the persons into whose hands its guidance had been committed. He hated two things intensely, a sacrosanct priesthood and an enforced uniformity. He may be said to have believed in the sanity and sanctity of the state rather than of the Church. Statesmen he could trust as he would not trust ecclesiastics. And so he even propounded a scheme, which fell still-born, that would have repealed uniformity, taken the church out of the hands of a clerical order, and allowed the coordination of sects or churches under the state. Not that he would have allowed the state to touch doctrine, to determine polity or discipline; but he would have had it to recognize historical achievement, religious character and capacity, and endow out of its ample resources those societies which had vindicated their right to be regarded as making for religion. His ideal may have been academic, but it was the dream of a mind that thought nobly both of religion and of the state.

See *Life and Letters* by J. Drummond and C. B. Upton (2 vols., 1901); J. E. Carpenter, *James Martineau, Theologian and Teacher* (1905); J. Crawford, *Recollections* of James Martineau (1903); A. W. Jackson, *James Martineau, a Biography and a Study* (Boston, 1900); H. Sidgwick, *Lectures on the Ethics of Green, Spencer and Martineau* (1902); and J. Hunt, *Religious Thought in England in the 19th Century.*

MARTINET, a military term (more generally used in a disparaging than in a complimentary sense) implying a strict disciplinarian or drill-master. The term originated in the French army about the middle of Louis XIV.'s reign, and was derived from Jean Martinet, who as lieutenant-colonel of the King's regiment of foot and inspector-general of infantry drilled and trained that arm in the model regular army created by Louis and Louvois between 1660 and 1670. Martinet seems also to have introduced the copper pontoons with which Louis bridged the Rhine in 1672. He was killed, as a *maréchal de camp,* at the siege of Duisburg in the same year, being accidentally shot by his own artillery while leading the infantry assault. His death, and that of the Swiss captain Soury by the same discharge gave rise to a *bon mot,* typical of the polite ingratitude of the age, that Duisburg had only cost the king a martin and a mouse.

The "martin" as a matter of fact shares with Vauban and other professional soldiers of Louis XIV. the glory of having made the French army the first and best regular army in Europe. Great nobles, such as Turenne, Condé and Luxemburg, led this army and inspired it, but their fame has obscured that of the men who made it manageable and efficient. It was about this time that the soldier of fortune, who joined a regiment with his own arms and equipment and had learned his trade by varied experience, began to give place to the soldier regularly enlisted as a recruit in permanent regiments and trained by his own officers. The consequence of this was the introduction of a uniform, or nearly uniform system of drill and training. Thus Martinet was the forerunner of Leopold of Dessau and Frederick William, just as Jean Jacques de Fourilles, the organizer of the cavalry, who was forced into an untimely charge at Seneffe (1674) by a brutal taunt of Condé, and there met his death, was the forerunner of Zieten and Seydlitz. These men, while differing from the creators of the Prussian army in that they contributed nothing to the tactics of their arms, at least made tactics possible by the thorough drilling and organization they imparted to the hardly coherent elements of an army.

MARTINEZ DE CAMPOS, ARSENIO: *see* CAMPOS, ARSENIO MARTÍNEZ DE.

MARTINEZ DE LA ROSA, FRANCISCO DE PAULA (1787–1862), Spanish statesman and dramatist, was born at Granada and educated at the university there. He won popularity with a series of epigrams on local celebrities published under the title of *El Cementerio de momo*. During the struggle against Napoleon he took the patriotic side, was elected deputy, and at Cadiz produced his first play, *Lo que puede un empleo,* a prose comedy in the manner of the younger Moratin. *La Viuda de Padilla* (1814), a tragedy modelled upon Alfieri, was less acceptable to the Spanish public. Meanwhile, the author became more and more engulfed in politics, and in 1814 was banished to Africa, where he remained till 1820, when he was suddenly recalled and appointed prime minister. During the next three years he was the most unpopular man in Spain; denounced as a revolutionist by the Conservatives and as a reactionary by the Liberals, he alienated the sympathies of all parties, and his rhetoric earned for him the contemptuous nick-name of *Rosita la Pastelera.* Exiled in 1823, he took refuge in Paris, where he issued his *Obras literarias* (1827), including his *Arte poética,* in which he exaggerated the literary theories already promulgated by Luzán. Returning to Spain in 1831, he became prime minister on the death of Ferdinand VII, ambassador at Paris in 1839–40, and at Rome in 1842–43. Martinez de la Rosa never rose above mediocrity either as a statesman or as a writer though the production of his *La Conjuración de Venecia* (April 23, 1834), entitled him to be called the pioneer of the romantic drama in Spain. The play is more reminiscent of Casimir Delavigne than of Victor Hugo; but it was unquestionably effective and smoothed the way for the bolder essays of Rivas, Garcia Gutiérrez and Hartzenbusch.

MARTINEZ RUIZ, JOSÉ: *see* AZORÍN.

MARTINEZ SIERRA, GREGORIO (1881–), Spanish novelist and dramatist, was born at Madrid on May 6, 1881. Martínez Sierra writes a slightly alembicated prose in *Sol de la tarde* (1904), *Tú eres la paz* (1907) and other novels. As a dramatist he has won considerable popularity by plays of an almost feminine delicacy, of which *Canción de Cuna* (1911) is the most typical example. His *Reino de Dios* (1915) was translated into English in 1924 and acted in London in 1927 under the title of *The Kingdom of God.*

MARTINI, FERDINANDO (1841–1928), Italian author and statesman. Born at Monsummano in Tuscany on July 30, 1841, he took to journalism at an early age to earn his living, and after a short period as a normal school teacher at Pisa, he joined the staff of the *Fanfulla* of Rome, and afterwards founded the *Fanfulla della Domenica,* to which Carducci, Bonghi, Verga, Panzacchi and other eminent writers contributed. In 1874 he was elected to parliament for Monsummano, and soon made a name for himself as a brilliant and witty speaker. He became minister of education in the first Giolitti cabinet (1892–93), and in 1898 he was appointed on the suggestion of King Umberto first civilian governor of Eritrea, a position which he held for ten years. He reorganized the colony, reduced its budget from 17 to 5 millions, built roads and a railway, and constructed the new capital at Asmara. He accepted the post of minister of the colonies offered him by Salandra (*q.v.*) in 1914, and on the outbreak of World War I he at once became an active interventionist, and resigned with Salandra in 1916. At the elections of 1919 he failed to be re-elected owing to the strong pressure of Nitti. In 1922 he was created a senator on the proposal of Mussolini, but took little part in public life on account of his feeble health. Besides numerous articles, many of which are collected in a volume *Fra un sigaro e l'altro,* which ran through several editions, he wrote short stories and novels (*Chi sa il giuoco non l'insegni, Il bacio dato non è mai perduto, Il peggior passo,* etc.). His *Confessioni e Ricordi,* published in 1922, enjoyed a wide popularity. His writings are not deep or of the highest literary merit, but witty, brilliant and racy, as was his conversation. Among other works may be mentioned *Al teatro* (1908), *Cose africane* (1896), and *Nell 'Africa italiana* (1891).

MARTINI, GIOVANNI BATTISTA (1706–1784), Italian musician, was born at Bologna on April 24, 1706. He was received as a Minorite on Sept. 11, 1722. In 1725 he became chapel-master in the Franciscan church at Bologna, where he opened a school of composition at which several celebrated musicians were trained. He consistently declared his preference for the traditions of the old Roman school of composition. Padre Martini was a zealous collector of musical literature, and possessed an extensive musical library which passed at his death to the Imperial library at Vienna, and the city of Bologna; Burney estimated the collection at 17,000 volumes. He died at Bologna on Aug. 4, 1784. His *Elogio* was published by Pietro della Valle at Bologna in the same year.

Martini's father, Antonio Mario Martini, a violinist, had taught him the elements of music, and he had later learned singing and harpsichord playing from Padre Pradieri and counterpoint from Antonio Riccieri. His education in classics he received from the fathers of the oratory of San Filippo Neri. Most contemporary musicians speak of Martini with admiration, and Mozart's father consulted him with regard to the talents of his son. Abt Vogler, however, makes reservations in his praise, condemning his philosophical principles as too much in sympathy with those of Fox, which had already been expressed by P. Vallotti.

The Liceo of Bologna possesses the mss. of two oratorios; and a requiem, with some other pieces of church music, are now in Vienna. *Litaniae atque antiphonae finales B. V. Mariae* were published at Bologna in 1734, as also twelve *Sonate d'intavolatura;* six *Sonate per l'organo ed il cembalo* in 1747; and *Duetti da camera* in 1763. Martini's most important works are his *Storia della musica* (Bologna, 1757–81) and his *Saggio di contrapunto* (Bologna, 1774–75). His celebrated canons, published in London, about 1800, edited by Pio Cianchettini, show him to have had a strong sense of musical humour.

MARTINI, JOHANN PAUL AEGIDIUS (1741–1816), German musician, sometimes also known as Martini Il Tedesco, was born in Freistadt, Germany, Sept. 1, 1741. When he was only 10 he became organist at the Jesuit seminary at Neustadt and at 17 held the same position at the Franciscan convent at Freiburg. He soon determined to remove to France, however, and first settled at Nancy. There he changed his family name, Schwartzendorf, to Martini, by which he was known thereafter, and entered the service of King Stanislaus I of Poland, then living in France. After the king's death, Martini went to Paris, where he remained for the rest of his life. He published his highly popular opera, "L'Amoureux de quinze ans" in 1771. For a time, he served as conductor of the Théâtre Feydeau, and later became inspector of the Paris conservatory, following which he was made professor of composition there. He was forced to retire in 1802, but when Louis XVIII came to power in 1814 he made Martini superintendent of court music. Martini died in Paris, Feb. 10, 1816. Besides his considerable output of music, both secular and religious, he wrote *Mélopée moderne,* a study of vocal music.

MARTINI, SIMONE (*c.* 1284–1344), Sienese painter, probably a pupil of Duccio, from whom he inherited his love of harmonious colour, to which he added a grace of line and delicacy of interpretation beyond anything to be found in his master's works. The beings he created move in a world of beauty, of grace and restfulness, and seem to embody the knightly ideals of the later middle ages.

The first known fresco of Simone is in the hall of the Palazzo Pubblico in Siena—the "Madonna Enthroned, with the Infant and a number of angels and saints" (1315). In S. Lorenzo Maggiore, of Naples, he painted a life-sized picture of King Robert crowned by his brother, St. Louis of Toulouse (1317). In 1320 he painted for the high altar of the church of S. Caterina in Pisa the Virgin and Child between six saints; above are archangels, apostles and other figures. The compartmented portions of this work are now dispersed, some of them being in the Museum of Pisa, others in the seminary. Towards 1321 he executed for the church of S. Domenico in Orvieto a picture of the bishop of Savona kneeling before the Madonna, attended by saints, now in the museum of the cathedral. In 1328 he produced for the sala del consilio in Siena a striking equestrian portrait of the victorious general, Guidoriccio Fogliani de' Ricci.

Simone had married in 1324 Giovanna, the daughter of Memmo (Guglielmo) di Filippuccio. Her brother, named Lippo Memmi, was also a painter and was frequently associated with Simone in his work; and this is the only reason why Simone has come down to us with the family name Memmi. They painted together, in 1333, the "Annunciation," which is now in the Uffizi gallery. From 1333 to 1339 Simone worked at Assisi, where he decorated the chapel of St. Martin in the Lower church with scenes illustrating the life of the saint. In the arch between this chapel and the nave he painted figures of eight saints. These frescoes are among his finest works. Four small panels, two at Antwerp, one in Berlin, and one in the Louvre, are ascribed to this period. They represent scenes of the Passion, and the artist here displays a taste for tragic, realistic effects. In 1339 he settled at the papal court in Avignon, where he made the acquaintance of Petrarch, and he painted for the poet a portrait of Laura, which gave occasion for two of Petrarch's sonnets in which Simone is eulogized. He is also said to have illuminated for the poet a copy of the commentary of Servius upon Virgil, now preserved in the Ambrosian library of Milan. One of his latest productions (1342) is the picture of "Christ Found by his Parents in the Temple," now in the Liverpool gallery. Simone died in Avignon in July 1344. He was the most important painter of the Sienese school in the 14th century, and his influence in Siena was great; while, outside his native city, important groups of adherents were formed at Naples, Pisa, Orvieto and to some extent in France; and to them was due the propagation of the Sienese style.

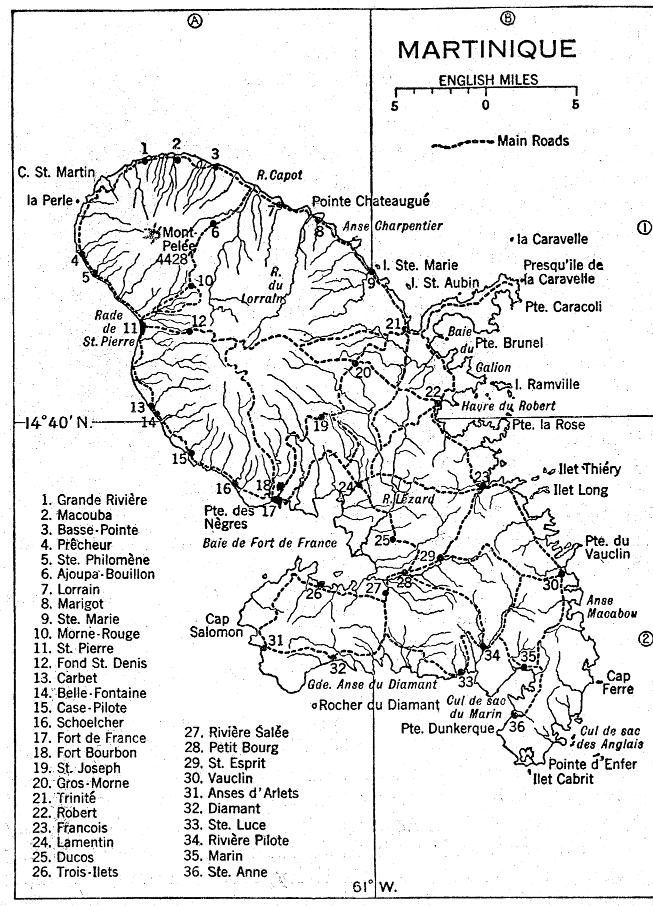
MARTINIQUE, an island of the West Indies, a French colony in the chain of the Lesser Antilles, 25 mi. S. of Dominica and 20 mi. N. of St. Lucia, both British islands, about 14° 40′ N., 61° W. Length 40 mi., greatest width 21 mi.; area 427 sq.mi. A cluster of volcanic mountains in the north, a similar group in the south, and a line of lower heights between them, form the backbone of the island. Its deep ravines and precipitous escarpments are clothed in forest. The massif of Mont Pelé in the north is the culminating point (4,430 ft.); that of Carbet reaches 3,963 ft., the mountains in the S. are much lower.

Of the numerous streams which traverse the strip between the watershed and the sea (the longest radiating from Mount Carbet), about seventy-five are of considerable volume, and in the rainy season often become destructive torrents. On the north-west and north the coast is elevated; on the south a lateral range, branching from the backbone of the island, forms a blunt peninsula bounding the low-shored bay of Fort de France. Another peninsula, Caravelle, projects from the middle part of the east coast, and south of this the coast is low and fretted, with many islets, cays and coral reefs. Plains, most numerous and extensive in the south, make up about one-third of the total area of the island.

Mean annual temperature, 80° F in the coast region, the monthly mean for June being 83°; for January 77°. Annual rainfall, 87 in. August has the heaviest share (11·3 in.), though the rainy season extends from June to October; March, the driest month, has 3·7. The low coastal districts are not very healthy for Europeans in the hotter months, but there are numerous sanatoria in the forest region at an elevation of about 1,500 ft., where the average temperature is some 10° F lower. The north winds which prevail from November to February are comparatively fresh and dry; those from the south (July to Oct.) are damp and warm. From March to June easterly winds prevail.

Population (1936) 246,712. In 1905, shortly after the first eruption of Mont Pelé, the population was only 182,024. The bulk of the population consists of negroes, coloured people of various grades, ranging from the "Saccatra," who has retained hardly any trace of European blood, to the so-called "Sangmêlé," with only a suspicion of negro commixture. The capital of the island is Fort de France, on the bay of the same name, with a fine harbour defended by three forts, and a population of 43,338. Other principal centres of population are, on the west coast Lamentin, on the same bay as the capital, and on the east coast Le François and Le Robert. The colony is administered by a governor and a general council, and returns a senator and two deputies. There are elective municipal councils. The island is



served by French, British, Canadian and American steamship lines, and local communications are carried on by small coasting steamers and by subsidized coaches on excellent roads. In 1925 the total value of the exports (mainly sugar, rum, coffee, cocoa and vanilla) was fr. 154,871,706, France taking by far the greater part. Imports were valued at fr. 132,566,419, of which more than two-thirds by value came from France, the United States of America being the next principal importing country.

Martinique, the name of which may be derived from a native form Madiana or Mantinino, was probably discovered by Columbus on June 15, 1502; although by some authorities its discovery is placed in 1493. It was inhabited by Caribs who had expelled or incorporated an older stock. On June 25, 1635, possession was taken of the island in the name of the French *Compagnie des Îles d'Amérique.* Actual settlement was carried out by Pierre Belain, Sieur d'Esnambuc, captain-general of the island of St. Christopher. In 1637 his nephew Dyel Duparquet became captain-general of the colony, now numbering seven hundred men, and subsequently obtained the seigneurie of the island by purchase from the company under the authority of the king of France. In 1654 three hundred Jews, expelled from Brazil, landed, and by 1658 there were at least five thousand people exclusive of the Caribs, who after much fighting, were exterminated. Purchased by the French government from Duparquet's children for 120,000 livres, Martinique was assigned to the West India Company, but in 1674 became part of the royal domain. The *habitants* (French landholders) at first cultivated cotton and tobacco; but in 1650 sugar planting was begun, and in 1723 the coffee plant was introduced. Slave labour was an early feature (there were 60,000 blacks in the island by 1736), but was abolished in 1860. In 1666 and 1667 the island was attacked by the British, but hostilities were terminated by the treaty of Breda. The Dutch made similar attempts in 1674, and the British again in 1693. Captured by Rodney in 1762, Martinique was next year restored to the French; but after the conquest by the British in 1793 it was retained for eight years; and, seized again in 1809, it was not surrendered till 1814. The island was the birth-place of the Empress Josephine.

BY COURTESY OF THE CUNARD STEAMSHIP CO., LTD.

NATIVE WOMAN OF MARTINIQUE

Martinique has suffered from occasional hurricanes, as in 1767, when 1,600 persons perished, and in 1839, 1891, 1903 and 1928. Earthquakes have also been frequent, but the most terrible natural disaster was the eruption of Mont Pelé in 1902, when St. Pierre, formerly the chief commercial centre of the island, was destroyed. Early in the year manifestations of volcanic activity had occurred; on April 25 there was a heavy fall of ashes, and on the 2nd and 3rd of May a heavy eruption destroyed extensive sugar plantations north of St. Pierre, and caused a loss of some 150 lives. A few days later news that the Souffrière in St. Vincent was in eruption reassured the inhabitants of St. Pierre, as it was supposed that this outbreak might relieve the volcano of Pelé. But on May 8 the final calamity came without warning; a mass of fire swept over St. Pierre, destroying the ships in the harbour, among which, only one, the "Roddam" of Scruttons, escaped. A fall of molten lava and ashes followed the flames, accompanied by dense gases which stifled those who had escaped. The total loss of life was estimated at 40,000. Consternation was caused not only in the West Indies, but throughout the world, and at first it was seriously suggested that the island should be evacuated, but no countenance was given to this proposal by France. Relief measures were undertaken and voluntary subscriptions raised. The material losses were estimated at £4,000,000; but, besides St. Pierre, only one-tenth of the island had been devastated, and although during July there was further volcanic activity, causing more destruction, the economic situation recovered more rapidly than was expected.

Anderson (November 20, 1902), who investigated the eruptions on behalf of the Royal Society; *cf.* T. Anderson, "Recent Volcanic Eruptions in the West Indies," in *Geographical Journal*, vol. xxi. (1903).

MARTINSBURG, a city of north-eastern West Virginia, U.S.A., the county seat of Berkeley county; 80 m. N.W. of Washington, on federal highway 11, and served by the Baltimore and Ohio and the Pennsylvania railways. The population was 12,515 in 1920 (91% native white) and was 15,063 in 1940 by the federal census. It lies 435 ft. above sea level, at the entrance to the beautiful and historic Shenandoah valley, and is surrounded by apple and peach orchards and farms. There are large deposits of limestone, clay and shale in the vicinity. The county ships 2,161,958 bushels of apples each year, and the city's plants can 1,500,000 gallons and make 3,000,000 gallons of cider vinegar. Martinsburg has the largest apple by-product plant in the U.S.A. and the largest mill making men's hosiery. Other important manufactures are woollen goods, women's garments, cement, amesite, brick and paper boxes. The Baltimore and Ohio has large repair shops here. Martinsburg was laid out by General Adam Stephen and was named after Colonel Thomas Bryan Martin. It was chartered as a city in 1778. During the Civil War it was occupied at different times by several Union and Confederate forces.

MARTINS FERRY, a city of Belmont county, Ohio, U.S.A., on the Ohio river, nearly opposite Wheeling, with which it is connected by a bridge. It is served by the Baltimore and Ohio, the Pennsylvania and the Wheeling and Lake Erie railways. Pop. (1920) 11,634 (82% native white); 14,729 in 1940 by the federal census. The city lies on two plateaus, the lower occupied chiefly by factories, the upper by dwellings. It is an important coal-mining and manufacturing centre.

Tin, sheet iron, stoves and structural steel are leading products. The first settlement (1785) was abandoned on account of trouble with the Indians. In 1795 a town (called Jefferson) was laid out by Absalom Martin, and it was abandoned because it was not made the county seat. In 1835 Ebenezer Martin, son of Absalom, again laid out the town. It was incorporated in 1865 and chartered as a city in 1885.

MARTINSVILLE, a city of central Indiana, U.S.A., 30 mi. S.W. of Indianapolis, on the Big Four and the Pennsylvania railways; the county seat of Morgan county, and a health resort with several hotels and sanatoria utilizing the mineral water from artesian wells. The population was 4,895 in 1920 (99% native white) and 5,009 in 1940 by federal census.

MARTINSVILLE, a city of the first class in southern Virginia, U.S.A., the county seat of Henry county; on federal highways 58 and 220, at an altitude of 980 ft., and is served by the Danville and Western and the Norfolk and Western railways. The population was 7,705 in 1930; and 10,080 in 1940 by the federal census. Martinsville and Henry county, Va., have a total annual pay roll of $10,000,000, the principal industries being furniture factories, cotton and hosiery mills, knitting mills, nylon (Du Pont) plant, and tobacco (leaf and manufactured). The city was founded in 1830 and incorporated in 1873.

MARTINUZZI, GEORGE [GYÖRGY UTIEŠENOVIĆ] (1482–1551), Hungarian statesman, known in Hungarian history as FRATER GYÖRGY or simply THE FRATER, was born at Kamičic, Croatia, the son of Gregory Utiešenović, a Croatian gentleman. His mother was a Martinuzzi, a Venetian patrician family. From his eighth to his twentieth year he was attached to the court of John Corvinus; subsequently he saw something of warfare under John Zapolya but, tiring of a military life, he entered the Paulician Order in his twenty-eighth year. His historical career began when his old patron Zapolya, now king of Hungary, forced to fly before his successful rival Ferdinand, afterwards the emperor Ferdinand I., sent him on a diplomatic mission to Hungary. It was due to his tact and ability that John recovered Buda (1529), and henceforth Frater György became his treasurer and chief counsellor.

In 1534 Martinuzzi became bishop of Nagyvarád (Grosswardein); in 1538 he concluded with Austria the peace of Grosswardein, which left Zapolya with the royal title and most of Hungary. On Zapolya's death (1540) Martinuzzi acted as guardian and regent for his infant son John Sigismund, for whom on Dec. 29, 1541 he concluded the Treaty of Gyula with the Sultan, which left an enlarged Transylvania as an independent principality under Turkish suzerainty. For a time Martinuzzi kept Transylvania neutral and on friendly terms with both Austria and the Porte. In 1550, however, the Queen-Mother Isabella, who hated him, contrived against him with the hospodars of Moldavia and Wallachia and the Turks. Martinuzzi defeated all his enemies and concluded a composition confirmed by the diet of Kalozsvár (1551) whereby Isabella renounced her rights over Transylvania, in her son's name, to Ferdinand of Austria.

The Frater retained the governorship of Transylvania, and was subsequently consecrated Cardinal and archbishop of Esztergom. Thus Hungary was once more reunited, but the inability of Ferdinand to defend it against the Turks, as promised, forced the Frater to resume payment of tribute to the Porte in December 1551. Ferdinand, however, suspecting the cardinal's loyalty, had him assassinated at Alvinczy (Dec. 17, 1551). Ferdinand took the responsibility of the murder on himself. He sent to Julius III. an accusation of treason against the Frater in eighty-seven articles, and after long hesitation, and hearing one hundred and sixteen witnesses, the pope exonerated Ferdinand of blame.

1715); O. M. Utiešenović, *Lebensgeschichte des Cardinals Georg Utiešenović* (Vienna, 1881); *Codex epistolaris Fratris Georgii 1535–1551*, ed. A. Károlyi (Budapest, 1881); also M. Jókai's historical romance, *Brother George* (Hung.) (Budapest, 1893).

MARTIUS, CARL FRIEDRICH PHILIPP VON (1794–1868), German botanist and traveller, was born on April 17, 1794, at Erlangen, where he graduated M.D. in 1814. He afterwards devoted himself to botanical study, and in 1817 was sent to Brazil by the king of Bavaria. In 1820 he was appointed conservator of the botanic garden at Munich, and in 1826 professor of botany in the university; he held both offices until 1864.

His chief publications include: *Nova Genera et Species Plantarum Brasiliensium* (1823–32, 3 vols.), *Icones selectae Plantarum Cryptogamicarum Brasiliensium* (1827), *Historia Palmarum* (3 vols., 1823–50), and an account of his travels in Brazil (3 vols., 1823–31). In 1840 he began the *Flora Brasiliensis,* with the assistance of other botanists. He died at Munich on Dec. 13, 1868.

MARTOS, CRISTINO (1830–1893), Spanish politician, was born at Granada on Sept. 13, 1830. As a student, he narrowly escaped being expelled from Madrid university for his share in demonstrations against the government of Queen Isabella. He joined O'Donnell and Espartero in 1854, turned against O'Donnell to assist the Democrats and Progressists in the unsuccessful movements of 1866, and, driven to go abroad, returned to take his seat in the Cortes (1869). Throughout the revolutionary period he represented the advanced Radical tendencies of the men who wanted to give Spain a democratic monarchy. After the abdication of Armadeus, Martos played a prominent part in the proclamation of the Federal republic. In May 1874, he returned to the bar. He sat in several parliaments under Alphonso XII. and the queen-regent Christina. Failing to form a rival party against Sagasta, he sank into political insignificance, despite his great talent as an orator and debater, and died in Madrid on Jan. 16, 1893.

MARTOS, a town of Spain, in the province of Jaén, 16 mi. W.S.W. of Jaén, by the Jaén-Lucena railway. Pop. (1940), 17,-206 (mun., 27,127). Martos is on an outlying western peak of the Jabalcuz mountains. It possibly stands on or near the site of the *Tucci* of Ptolemy, which was fortified and renamed *Colonia Augusta Gemella* by the Romans. It was taken from the Moors in 1225 by Ferdinand III and given to the knights of Calatrava. The brothers Carvajal were executed here in 1312 by order of Ferdinand IV. In the neighbourhood are sulphurous springs with bathing establishments.

MARTYN, HENRY (1781–1812), English missionary to India, was born on Feb. 18, 1781, at Truro, Cornwall. He was educated at Truro grammar school and St. John's college, Cambridge, and was senior wrangler and first Smith's prizeman in 1801. In 1802 he became a fellow of his college. He had intended to go to the bar, but the stories of the missionaries William Carey and David Brainerd decided him to seek a missionary career. He obtained a chaplaincy under the East India Company and left for India on July 5, 1805. He translated the whole of the New Testament into Hindi, and into Persian twice, and the Psalms into Persian, the Gospels into Judaeo-Persic, and the Prayer-book into Hindustani. Ordered by the doctors to take a sea voyage, he went to Persia to correct his Persian New Testament, whence he wished to go to Arabia, and there compose an Arabic version. He set out from Bombay in January 1811 for Bushire, bearing letters from Sir John Malcolm. After an exhausting journey from the coast he reached Shiraz, and was soon plunged into discussion with the disputants of all classes. Having made an unsuccessful journey to Tabriz to present the shah with his translation of the New Testament, he fell ill with fever, and had to seek a change of climate. On Sept. 12, 1812, he started with two Armenian servants, crossed the Araxes, rode from Tabriz to Erivan, from Erivan to Kars, from Kars to Erzerum, from Erzerum to Chiflik, urged on from place to place by a thoughtless Tatar guide, and, though the plague was raging at Tokat (near Eski-Shehr in Asia Minor), he was compelled by prostration to stop there. On Oct. 6, he died.

See his *Journals and Letters* (1837) ed. Samuel Wilberforce. *See* also *Lives* by John Sargent (1819; new ed. 1885), and G. Smith (1892).

MARTYN, JOHN (1699–1768), English botanist, was born in London on Sept. 12, 1699. Originally intended for a business career, he abandoned it in favour of scientific studies. He was one of the founders (with J. J. Dillen and others) and the secretary of a botanical society which met for a few years in the Rainbow Coffee-house, Watling Street; he also started the *Grub Street Journal*, a weekly satirical review, which lasted from 1730 to 1737. He held a professorship of botany at Cambridge, 1732–62, and at the same time practised as a physician at Chelsea, where he died Jan. 29, 1768. His reputation chiefly rests upon *Historia plantarum rariorum* (1728; 3rd ed., 1797; Eng. ed., 1728–32), and his translation, with valuable agricultural and botanical notes, of the *Eclogues* (1749) and *Georgics* (1741) of Virgil.

See memoir by Thomas Martyn reprinted in *Memoirs of John Martyn and Thomas Martyn*, by G. C. Gorham (1830), and *Dict. Nat Biog.* for a complete list of his works.

MARTYR, a word meaning literally "witness" (Gr. μάρτυρ or μάρτυς), and often used in that sense in the New Testament, *e.g.,* Matt. xviii. 16; Mark xiv. 63. During the conflict between Paganism and Christianity when many Christians "testified" to the truth of their convictions by sacrificing their lives, the word assumed its modern technical sense. The beginnings of this use are to be seen in such passages as Acts xxii. 20; Rev. ii. 13. During the first three centuries the fortitude of these "witnesses" won the admiration of their brethren. The zeal of Ignatius (*c.* 115), who begs the Roman Church to do nothing to avert from him the martyr's death, was natural enough in a spiritual knight-errant, but with others in later days, especially in Phrygia and North Africa, the passion became artificial. Fanatics sought death by insulting the magistrates or by breaking idols, and in their enthusiasm for martyrdom became self-centred and forgetful of their normal duty. None the less it is true that these men and women endured torments, often unthinkable in their cruelty, and death rather than abandon their faith. The same phenomena have been witnessed, not only in the conflicts within the Church that marked the 13th to the 16th centuries, but in the different mission fields, and particularly in Madagascar and China.

See A. J. Mason, *The Historic Martyrs of the Primitive Church* (1905); H. B. Workman, *Persecution in the Early Church* (1906); Paul Allard, *Ten Lectures on the Martyrs* (1907); Foxe's *Book of Martyrs;* Mary I. Bryson, *Cross and Crown* (1904).

MARTYROLOGY, a catalogue or list of *martyrs* or, more exactly, of *saints,* arranged in the order of their anniversaries. This is the now accepted meaning in the Latin Church. In the Eastern Church the nearest equivalent to the martyrology is the Greek Synaxarium. As regards form, we should distinguish between simple martyrologies, which consist merely of an enumeration of names, and historical martyrologies, which also include stories or biographical details. As regards documents, the most important distinction is between local and general martyrologies. The former give a list of the festivals of some particular Church; the latter are the result of a combination of several local martyrologies. The most important ancient martyrology preserved to the present day is in the form (mainly) of an enumeration of names, and was falsely attributed to St. Jerome. In its present form it goes back to the end of the 6th century. It is the result of the combination of a general martyrology of the Eastern Churches, a local martyrology of the Church of Rome, some general martyrologies of Italy and Africa, and a series of local martyrologies of Gaul. The task of critics is to distinguish between its various constituent elements. Unfortunately, this document has reached us in a lamentable condition. Of the best known historical martyrologies the most famous is that of Usuard (*c.* 875), on which the Roman martyrology was based. The first edition of the Roman martyrology appeared at Rome in 1583. The third edition, which appeared in 1584, was approved by Gregory XIII., who imposed this martyrology upon the whole Church.

MARUTS, the storm-gods of Hindu mythology, prominent in the *Rig-Veda* which makes them sons of Rūdra, but associates them with Indra, the goddesses Indrānī and Saraswati, and more closely, with Rodasi, their beauteous bride. Yet they are sometimes hostile to Indra and rend Vritra, the "drought," in pieces. In the epic era they appear to be the Māruta, the winds, sons of the benevolent earth-goddess, Aditi.

See E. W. Hopkins, *Epic Mythology* (Strasbourg, 1915).

MARVELL, ANDREW (1621–1678), English poet and satirist, son of Andrew Marvell and his wife Anne Pease, was born at the rectory house, Winestead, in the Holderness division of Yorkshire, March 31, 1621. In 1624 his father exchanged the living of Winestead for the mastership of Hull grammar school. He also became lecturer at Holy Trinity church and master of the Charterhouse in the same town. Thomas Fuller (*Worthies of England,* ed. 1811, i. 165) describes him as "a most excellent preacher." The younger Marvell was educated at Hull grammar school and at Trinity college, Cambridge. He contributed two poems to the *Musa cantabrigiensis* in 1637, and in the following year he received a scholarship at Trinity college, and took his B.A. degree in 1639. His father was drowned in 1640 while crossing the Humber in company with the daughter of a Mrs. Skinner, almost certainly connected with the Cyriack Skinner to whom two of Milton's sonnets are addressed. Marvell travelled for four years on the Continent, visiting Holland, France, Italy and Spain. In Rome he met Richard Flecknoe, whom he satirized in the amusing verses on "Flecknoe, an English priest at Rome."

Although Marvell ranks as a great Puritan poet his sympathies were at first with Charles I., and in the lines on "Tom May's Death" he found no words too strong to express his scorn for the historian of the Long Parliament. He himself was no partisan, but had a passion for law and order. He acquiesced, accordingly, in the strong rule of Cromwell, but in his famous "Horatian Ode upon Cromwell's Return from Ireland" (1650) he inserts a well-known tribute to the courage and dignity of Charles I. In 1650 he became tutor to Lord Fairfax's daughter Mary, afterwards duchess of Buckingham. During his life with the Fairfaxes at Nunappleton, Yorkshire, he wrote the poems "Upon the Hill and Grove at Billborow" and "On Appleton House." Doubtless the other poems on country life, and his exquisite "garden poetry" may be referred to this period.

Marvell was acquainted with Milton, probably through their common friends, the Skinners, and in Feb. 1653 Milton recommended him as assistant to himself in his duties as foreign secretary. The appointment was, however, given at the time to Philip Meadows, and Marvell became tutor to Cromwell's ward, William Dutton, at Eton, in the house of John Oxenbridge, then a fellow of the college, but formerly a minister in the Bermudas. No doubt the well-known verses, "Bermudas," were inspired by intercourse with the Oxenbridges. He was employed by Milton in 1654 to convey to Bradshaw a copy of the *Defensio secunda.* When the secretaryship again fell vacant in 1657 Marvell was appointed, and retained the appointment until the accession of Charles II. During this period he wrote many political poems all of them displaying admiration for Cromwell.

Marvell's connection with Hull had been strengthened by the marriages of his sisters with persons of local importance, and in Jan. 1659 he was elected to represent the borough in parliament. He was re-elected in 1660, again in 1661, and continued to represent the town until his death. According to Milton's nephew, Edward Phillips, the poet owed his safety at the Restoration largely to the efforts of Marvell, who "made a considerable party for him" in the House of Commons. From 1663 to 1665 he acted as secretary to Charles Howard, 1st earl of Carlisle, on his difficult and unsuccessful embassy to Muscovy, Sweden, and Denmark; and this is the only official post he filled during the reign of Charles. With the exception of this absence, and of short visits to Holland on private business, Marvell was constant in his parliamentary attendance to the day of his death. He looked after the special interests of the port of Hull. He was a member of the corporation of Trinity House, both in London and Hull, and became a younger warden of the London Trinity House. His correspondence with his constituents, from 1660 to 1678, some 400 letters in all, first printed by Dr. Grosart (*Complete Works,* vol. ii.) forms a useful source of information.

When in 1667 the Dutch fleet sailed up the Thames, Marvell expressed his wrath at the gross mismanagement of public affairs in the broadside, "Last Instructions to a Painter." He had no scruples in the choice of the weapons he employed in his warfare against the corruption of the court, which he paints even blacker than do contemporary memoir writers; and his satire often descends to the level of the lampoon. The most inexcusable of his scandalous verses are perhaps those on the duchess of York. In the same year he attacked Lord Clarendon, evidently hoping that with the removal of the "betrayer of England and Flanders" matters would improve. But in 1672 when he wrote his "Poem on the Statue in the Stocks-Market" he had no illusions left about Charles, whom he describes as too often "purchased and sold," though he concludes with "Yet we'd rather have him than his bigoted brother." "An Historical Poem," "Advice to a Painter," and "Britannia and Raleigh" urge the same advice. These and other equally bold satires were probably handed round in ms., or secretly printed, and it was not until after the Revolution that they were collected with those of other writers in *Poems on Affairs of State* (3 pts., 1689; 4 pts., 1703–07). Marvell's controversial prose writings are wittier than his verse satires, and are free from the scurrility which defaces the "Last Instructions to a Painter." A short and brilliant example of his irony is "His Majesty's Most Gracious Speech to both Houses of Parliament" (printed in *Grosart,* ii. 431 seq.), in which Charles is made to take the house into the friendliest confidence on his domestic affairs.

Marvell was among the masters of Jonathan Swift, who, in the "Apology" prefixed to the *Tale of a Tub,* wrote that his answer to Samuel Parker could be still read with pleasure, although the pamphlets that provoked it were long since forgotten.

His *Mr. Smirke, or the Divine in Mode . . .* (1676) was a defence of Herbert Croft, bishop of Hereford. *An Account of the Growth of Popery and Arbitrary Government in England, more particularly from the Long Prorogation of Parliament . . .* (1677) was written in the same outspoken tone as the verse satires, and brought against the court the indictment of nursing designs to establish absolute monarchy and the Roman Catholic religion at the same time. A reward was offered for the author, and it is said that Marvell was in danger of assassination. He died on Aug. 16, 1678, in consequence of an overdose of an opiate taken during an attack of ague. He was buried in the church of St. Giles-in-the-Fields, London. Joint administration of his estate was granted to one of his creditors, and to his widow, Mary Marvell.

Marvell had friends among the republican thinkers of the times. Aubrey says that he was intimate with James Harrington, the author of *Oceana,* and he was probably a member of the "Rota" club. He kept his political virtue unspotted. There is a story that his old schoolfellow, Danby, was sent by the king to offer the incorruptible poet a place at court and a gift of £1,000, which Marvell refused with the words: "I live here to serve my constituents: the ministry may seek men for their purpose; I am not one."

Among Marvell's works is also a *Defence of John Howe on God's Prescience . . .* (1678), and among the spurious works fathered on him are: *A Seasonable Argument . . . for a new Parliament* (1677), *A Seasonable Question and a Useful Answer . . .* (1676), *A Letter from a Parliament Man . . .* (1675), and a translation of *Suetonius* (1672). Marvell's satires were no doubt first printed as broadsides, but few are extant in that form. Earlier editions of his works were superseded by Dr. A. B. Grosart's laborious work, *The Complete Works in Verse and Prose of Andrew Marvell, M.P.* (4 vols., 1872–75) in the "Fuller Worthies Library," and by the Oxford edition of the *Poems and Letters,* edited (1927) by H. M. Margoliouth. *See* also the admirable edition of the *Poems and Satires of Andrew Marvell . . .* (2 vols., 1892) in the "Muses' Library," where a full bibliography of his works and of the commentaries on them is provided; *The Poems and some Satires of Andrew Marvell* (ed. Edward Wright, 1904); *Andrew Marvell* (1905), by Augustine Birrell in the "English Men of Letters" series; and W. H. Bagguley, *Andrew Marvell, 1621–1675 Tercentenary Tributes* (1922).

MARX, KARL HEINRICH (1818–1883), German socialist and philosopher, and head of the International Working Men's Association (*see* INTERNATIONAL) was born on May 5, 1818, in Treves (Rhenish Prussia). His father, a Jewish lawyer, in 1824 went over to Christianity, and he and his whole family were baptized as Protestants.

The son went to the high grammar school at Treves, and from 1835 to the universities of Bonn and Berlin. He studied first law, then history and philosophy, and in 1841 received the degree of doctor of philosophy. In Berlin he had close intimacy with the brothers Bruno and Edgar Bauer and their Hegelian circle, the so-called "Freien."

Beginnings.—His Radical views made a university career out of the question, and he joined the staff of the *Rheinische Zeitung*, which expounded the ideas of the most advanced section of the Rhenish Radical *bourgeoisie*. In Oct. 1842 he became one of the editors of this paper, which, however, was suppressed in the beginning of 1843. In the summer of this year Marx married Jenny von Westphalen, the daughter of a high government official. Through her mother Jenny von Westphalen was a lineal descendant of the earl of Argyle, who was beheaded under James II. She was a most faithful companion to Marx during all the vicissitudes of his career and died on Dec. 2, 1881; he outliving her only 15 months.

Already in the *Rheinische Zeitung* there appeared some socialist doctrine couched in a somewhat philosophical strain. Marx, though not accepting these views, refused to criticize them until he had studied the question thoroughly. For this purpose he went in the autumn of 1843 to Paris, where the socialist movement was then at its intellectual zenith, and where he, together with Arnold Ruge, the well-known literary leader of Radical Hegelianism, was to edit a review, the *Deutsch-französische Jahrbücher,* of which, however, only one number appeared. It contained two articles by Marx—a criticism of Bruno Bauer's treatment of the Jewish question, and an introduction to a criticism of Hegel's philosophy of the law. The first contended that the social emancipation of the Jews could only be achieved together with the emancipation of society from Judaism, *i.e.* commercialism. The second declared that in Germany no partial political emancipation was possible; there was now only one class from which a real and reckless fight against authority was to be expected—namely, the proletariat. But the proletariat could not emancipate itself except by breaking all the chains, by dissolving the whole constituted society, by recreating man as a member of the human society in the place of established states and classes. "Then the day of German resurrection will be announced by the crowing of the Gallican cock."

Both articles thus relegated the solution of the questions then prominent in Germany to the advent of socialism, and so far resembled in principle other socialist publications of the time. But the way of reasoning was different, and the final words of the last quoted sentence pointed to a political revolution, to begin in France as soon as the industrial evolution had created a sufficiently strong proletariat. In contradistinction to most of the socialists of the day, Marx laid stress upon the political struggle as the lever of social emancipation. In some letters which formed part of a correspondence between Marx, Ruge, Ludwig Feuerbach, and Mikhail Bakunin, published as an introduction to the review, this opposition of Marx to socialistic "dogmatism" was enunciated in a still more pronounced form: "Nothing prevents us," he said, "from combining our criticism with the criticism of politics, from participating in politics, and consequently in real struggles. We will not, then, oppose the world like doctrinarians with a new principle: here is truth, kneel down here! We expose new principles to the world out of the principles of the world itself. We don't tell it: 'Give up your struggles, they are rubbish, we will show you the true war-cry.' We explain to it only the real object for which it struggles, and consciousness is a thing it *must* acquire even if it objects to it."

In Paris Marx met Friedrich Engels (1820–1895) (*q.v.*), from whom the *Deutsch-französische Jahrbücher* had two articles—a powerfully written outline of a criticism of political economy, and a letter on Carlyle's *Past and Present.* The first result of the collaboration of Marx and Engels was the book *Die heilige Familie oder Kritik der kritischen Kritik, gegen Bruno Bauer und Konsorten,* a scathing exposition of the perverseness of the high-sounding speculative radicalism of Bauer and the other Berlin "Freie." By aid of an analysis which, though not free from exaggeration and a certain diffuseness, bears testimony to the great learning of Marx and the vigorous discerning faculty of both the authors, it is shown that the supposed superior criticism—the "critical criticism" of the Bauer school, based upon the doctrine of a "self-conscious" idea, represented by or incarnated in the critic—was in fact inferior to the older Hegelian idealism. The socialist and working-class movement in Great Britain, France and Germany are defended against the superior criticism of the "holy" Bauer family.

In Paris, where Marx had very intimate intercourse with Heinrich Heine, who always speaks of him with the greatest respect, and some of whose poems were suggested by him, he contributed to a Radical magazine, the *Vorwärts*; but at the request of the Prussian government, nearly the whole staff got orders to leave France. Marx now went to Brussels, where he shortly afterwards was joined by Engels. In Brussels he published his second great work, *La Misère de la philosophie,* a sharp rejoinder to the *Philosophie de la misère ou contradictions économiques* of P. J. Proudhon. In this he deals with Proudhon, whom in the former work he had defended against the Bauers, not less severely than with the latter. It is shown that in many points Proudhon is inferior to both the middle-class economists and the socialists, that his somewhat noisily proclaimed discoveries in regard to political economy were made long before by English socialists, and that his main remedies, the "constitution of the labour-value" and the establishment of exchange bazaars, were but a repetition of what English socialists had already worked out much more thoroughly and more consistently. In justice to Proudhon, it must be added that it is more often his mode of speaking than the thought underlying the attacked sentences that is hit by Marx's criticism. In Brussels Marx and Engels also wrote a number of essays in which they criticized the German literary representatives of that kind of socialism and philosophic radicalism which was mainly influenced by the writings of Ludwig Feuerbach, and deduced its theorems or postulates from speculations on the "nature of man." They mockingly nicknamed this kind of socialism "German or True Socialism," and ridiculed the idea that by disregarding historical and class distinctions a conception of society and socialism superior to that of the English and French workers and theorists could be obtained. Some of these essays were published at the time, two or three by one of the attacked writers in his own magazine; one, a criticism of Feuerbach himself, was in a modified form published by Engels in 1885, but others have remained in manuscript. They were at first intended for publication in two volumes as a criticism of post-Hegelian German philosophy, but the revolution of 1848 postponed for a time all interest in theoretical discussions.

In Brussels Marx and Engels came into still closer contact with the socialist working-class movement. They founded a German workers' society, acquired a local German weekly, the *Brüsseller deutsche Zeitung,* and finally joined a communistic society of German workers, the "League of the Just," a secret society which had its main branches in London, Paris, Brussels and several Swiss towns. For this league, which till then had adhered to the rough-and-ready communism of the German workman Wilhelm Weitling, but which now called itself "League of the Communists" and became an educational and propagandist body, Marx and Engels at the end of 1847 wrote their famous pamphlet, *Manifest der Kommunisten.* It was a concise exposition of the history of the working-class movement in modern society according to their views, to which was added a critical survey of the existing socialist and communist literature, and an explanation of the attitude of the Communists towards the advanced opposition parties in the different countries.

Cologne and London.—Scarcely was the manifesto printed when, in Feb. 1848, the Revolution broke out in France, and "the crowing of the Gallican cock" gave the signal for an upheaval in

Germany such as Marx had prophesied. After a short stay in France, Marx and Engels went to Cologne in May 1848, and there with some friends they founded the *Neue rheinische Zeitung,* with the sub-title "An Organ of Democracy," a political daily paper on a large scale, of which Marx was the chief editor. They took a frankly revolutionary attitude, and directed their criticism to a great extent against the middle-class democratic parties, who, by evading all decisive issues, delayed the achievement of the upheaval. When in November 1848 the king of Prussia dissolved the National Assembly, Marx and his friends advocated the non-payment of taxes and the organization of armed resistance. Then the state of siege was declared in Cologne, the *Neue rheinische Zeitung* was suspended, and Marx was put on trial for high treason. He was unanimously acquitted by a middle-class jury, but in May 1849 he was expelled from Prussian territory. He went to Paris, but was soon given the option of either leaving France or settling at a small provincial place. He preferred the former, and went to England. He settled in London, and remained there for the rest of his life.

At first he tried to reorganize the Communist League; but soon a conflict broke out in its ranks, and after some of its members had been tried in Germany and condemned for high treason, Marx, who had done everything to save the accused, dissolved the Communist League altogether. Nor was a literary enterprise, a review, also called the *Neue rheinische Zeitung,* more successful; only six numbers of it were issued. It contained, however, some very remarkable contributions; and a series of articles on the career of the French Revolution of 1848, which first appeared there, was in 1895 published by Engels in book form under the title of *Die Klassenkämpfe in Frankreich von 1848* "by Karl Marx." Carlyle's *Latter Day Pamphlets,* published at that time, met with a very vehement criticism in the *Neue rheinische Zeitung.* The endeavours of Ernest Jones and others to revive the Chartist movement were heartily supported by Marx, who contributed to several of the Chartist journals of the period, mostly, if not wholly, without getting or asking payment.

He lived at this time in great financial straits, occupying a few small rooms in Dean street, Soho, and all his children then born died very young. At length he was invited to write letters for the *New York Tribune,* whose staff consisted of advanced democrats and socialists of the Fourierist school. For these letters he was paid at the rate of a guinea each. Part of them, dealing with the Eastern Question and the Crimean War, were republished in 1897 (London, Sonnenschein). Some were even at the time reprinted in pamphlet form. The co-operation of Marx, who was determinedly anti-Russian, since Russia was the leading reactionary power in Europe, was obtained by David Urquhart and his followers. A number of Marx's articles were issued as pamphlets by the Urquhartite committees, and Marx wrote a series of articles on the diplomatic history of the 18th century for the Urquhartite *Free Press* (Sheffield and London, 1856–1857).

When in 1859 the Franco-Austrian War about Italy broke out, Marx denounced it as a Franco-Russian intrigue, directed against Germany on the one hand and the revolutionary movement in France on the other. He opposed those democrats who supported a war which in their eyes aimed at the independence of the Italian nation and promised to weaken Austria, whose superiority in Germany was the hindrance to German unity. Violent derogatory remarks directed against him by the well-known nationalist Karl Vogt gave occasion to a not less violent rejoinder, *Herr Vogt,* a book full of interesting material for the student of modern history. Marx's contention, that Vogt acted as an agent of the Bonapartist clique, seems to have been well founded, whilst it must be an open question how far Vogt acted from dishonourable motives. The discussions raised by the war also resulted in a great estrangement between Marx and Ferdinand Lassalle. Lassalle had taken a similar view of the war to that advocated by Vogt, and fought tooth and nail for it in letters to Marx.

In the same year, 1859, Marx published as a first result of his renewed economic studies the book *Zur Kritik der politischen Ökonomie.* It was the first part of a much larger work planned to cover the whole ground of political economy. But Marx found that the arrangement of his materials did not fully answer his purpose, and that many details had still to be worked out. He consequently altered the whole plan and sat down to rewrite the book, of which in 1867 he published the first volume under the title *Das Kapital.*

The International.—In the meantime, in 1864, the International Working Men's Association was founded in London, and Marx became in fact though not in name, the head of its general council. All its addresses and proclamations were penned by him and explained in lectures to the members of the council. The first years of the International went smoothly enough. Marx was then at his best. He displayed in the International a political sagacity and toleration which compare most favourably with the spirit of some of the publications of the Communist League. He was more its teacher than an agitator, and his expositions of such subjects as education, trade unions, the working day, and co-operation were highly instructive. He did not hurry on extreme resolutions, but put his proposals in such a form that they could be adopted by even the more backward sections, and yet contained no concessions to reactionary tendencies.

But this condition of things was not permitted to go on. The anarchist agitation of Bakunin, the Franco-German War, and the Paris Commune created a state of things before which the International succumbed. Passions and prejudices ran so high that it proved impossible to maintain any sort of centralized federation. At the congress of The Hague, Sept. 1872, the general council was removed from London to New York. But this was only a makeshift, and in July 1876 the remains of the old International were formally dissolved at a conference held in Philadelphia. That its spirit had not passed away was shown by subsequent international congresses, and by the growth and character of socialist labour parties in different countries. They have mostly founded their programmes on the basis of its principles, but are not always in their details quite in accordance with Marx's views. Thus the programme which the German socialist party accepted at its congress in 1875 was very severely criticized by Marx. This criticism, reprinted in 1891 in the review *Die neue Zeit,* is of great importance for the analysis of Marx's conception of socialism.

The dissolution of the International gave Marx opportunity of returning to his scientific work. He did not, however, succeed in publishing further volumes of *Das Kapital.* In order to make it —and especially the part dealing with property in land—as complete as possible, he took up, as Engels tells us, a number of new studies, but repeated illness interrupted his researches, and on March 14, 1883, he passed quietly away. He lies buried in Highgate cemetery.

Of his six children only three girls grew up: Jenny, who married Charles Longuet; Laura, who married Paul Lafargue; and Eleanor, who lived for many years an unhappy life with Edward Aveling. (E. Bn.)

Marxist Theory.—The starting point of Marx's theory of Socialism is his doctrine of the class struggle. This provides the clue to the two doctrines chiefly associated with his name—the materialist conception of history and the theory of surplus value. The former of these, though it underlies all his thinking, is nowhere systematically expounded in his books. The latter is the main theme of his chief work, *Das Kapital.*

Marx's materialist conception of history has been often misunderstood. It is far from being merely the doctrine that economic forces are predominant in the direction of social affairs, though this is involved in it. Still less is it the doctrine that individual men act only from material motives, and this is not even involved in it at all. Marx's theory must be confounded neither with the views of writers like Buckle on the effect of physical environment on the course of history, nor with the utilitarian doctrines of Bentham and his followers. In essence, Marx contended that there exist, in any society, certain material "forces of production" and a certain knowledge of their use in man's service. These form the "conditions of production," and for their employment there is required an arrangement of the powers of society, implying a certain relationship among the members, and the establishment and maintenance of appropriate social institutions. If, for example, at a particular stage of development the "forces of production" are to be fully exploited, certain forms of private property must be recognized and secured, and certain members of society endowed with authority both over the material means of production and over the other members, who must accept the subordinate rôle assigned to them by the dictates of economic circumstance. This recognition and this authority imply and require a power able to enforce them; and this power is found in the State, which takes its special form from the character of the economic institutions it exists in order to uphold. Political and social institutions are thus dependent upon and derive their special forms from the underlying economic circumstances of the society in which they exist. Political power is a derivative power, depending for its validity and survival on its correspondence with the needs forced on men by the conditions of production.

These underlying conditions are, however, flexible because of changes both in the forces of production at men's command and in the knowledge of their use. It follows that the superstructure —the arrangement of social classes and the political institutions by which the existing order is maintained—must also change as the conditions of production are modified. But institutions, once established, are highly resistant to modification. The class-structure of society and its political and social institutions therefore tend to lag behind the movement of economic change, until the accumulated disharmony forces drastic readjustment by the method of revolution. Then the entire superstructure is brought crashing down, and a new arrangement of classes and a new set of institutions in harmony with the new economic order arise.

Hegelianism.—The mechanism by which this process is carried into effect is the class-struggle. At this point Marx brings to his aid the Hegelian dialectic in which he had been trained. For Hegel, the history of the world is real only as a history of ideas. Each idea, as it is affirmed as truth, brings with it the idea that is its negation. The ideas do battle, and out of their conflict a new and higher idea arises, to be fought and conquered in its turn. For this battle of ideas Marx substitutes a battle of economic forces, waged by means of the social classes which are the product of these forces. One set of economic forces raises a particular class to power, and this class makes a State in its own image, for the enforcement of its decrees upon the society as a whole. But no class can rule without bringing an antagonistic class into play.

Thus, modern capitalism cannot develop its powers without calling into being a proletariat—a working class depending solely on its wages for the means of life. This proletariat, moreover, must be gathered together in factory and mine, and organized into a co-operative force labouring to produce wealth for the capitalist. Thus concentrated and organized, it becomes a power, and develops a will of its own, contrary to the will of its capitalist masters. In time, it develops far enough to be able to dispense with these masters, and organize the changing and ever expanding forces of production in a new way. It turns upon its masters, and in the fulness of time overthrows them, and sets up a new social and political superstructure corresponding to the new needs of the productive forces. This conception of the method of social and political change underlies the fierce invective of the *Communist Manifesto* of 1847, and indeed all Marx's writings on the practical strategy of socialism and revolution. It has also been the theoretical driving force behind the Communism of modern Russia, and finds dogmatic expression in the writings of Nikolai Lenin.

Marx's only general account of the Materialist Conception of History is found in a few pages of the Preface and Introduction to his *Critique of Political Economy,* the germ of his larger work, *Capital.* But the *Communist Manifesto* is mainly an application of it, while the historical chapters of the first volume of *Capital* (13–15 and 26–32) are in essence an attempt to work out its bearing on the origin and growth of the capitalist system. The pamphlet *Historic Materialism,* by Marx's close collaborator and editor, Friedrich Engels, states the doctrine in a more systematic, if cruder form.

Surplus Value.—The doctrine of surplus value, which is the main theme of *Capital,* is best understood in close relation to Marx's doctrine of historical development and the class struggle. According to the latter, the capitalist class is the exploiter and the labouring class the exploited which will in due time overthrow its rulers. The extraction of surplus value from the workers is the means by which this exploitation is accomplished. In seeking to prove that this exploitation exists, Marx takes his text from the classical economists of his own day, and especially from Ricardo and his less subtle populariser, M'Culloch. According to the classical doctrine, the value of commodities depends on the amount of labour involved in their production, and incorporated in them as finished products. Socialist writers before Marx, such as William Thompson and Thomas Hodgskin, had used this Ricardian doctrine as the basis for an assertion of the workers' "right to the whole produce of labour," and had treated the reward of the capitalists (rent, interest and profits) as sheer extortion, filched from the workers by means of the capitalists' social power.

Marx refines upon this view, and seeks to show that the extortion is made possible because, whereas all commodities sell at their value (apart from temporary market deviations) there is one peculiarity about the worker's only commodity, his labour-power, that marks it off from all others. For this commodity alone has the power, in producing other commodities, to produce a value greater than it possesses itself. The value of the commodity, labour-power, is determined, like that of all other commodities, by the quantity of labour required for its production, or in other words, by the amount of labour required to enable the labourer to subsist and reproduce his kind. But the labourer produces by a day's work more than enough for his subsistence and the subsistence of his family. The capitalist, after paying him a subsistence wage, is able to keep for himself the rest of the labourer's product. This residue, the fund from which rent, interest and profits are drawn, Marx calls "surplus value." Suppose, he says, the labourer works 12 hours a day, and only 6 hours are needed for his subsistence. The capitalist can then filch in the form of surplus value the product of 6 hours' labour. The rate of surplus value is 100% of the labourer's wage, and 50% of the total product.

This doctrine is elaborately worked out in the massive volumes of *Capital.* Marx admits, of course, that all kinds of labour are not of equal value. The skilled workman produces more value than the unskilled, and he also receives higher wages. How are these differences measured? By the differing costs of producing and maintaining the supply of skilled and unskilled workers. The training of the skilled worker is a cost of producing him, and the maintenance of the supply of skilled labour involves additional costs. The "labour" whose amount is the measure and determinant of the value of commodities is not the actual labour time of the workers, irrespective of their skill and quality, but an "abstract, undifferentiated human labour" of which skilled labour is to be regarded as a multiple. One hour's labour of a skilled man may count as two or more hours of this "simple labour"; but the difference is not arbitrary. It is measured by the relative costs of producing the different types of labour.

Equally, not all labour, but only useful labour, is productive of value. Useless labour produces no value at all; and even useful labour produces value only in so far as it is of average, or ordinary, efficiency. A slow worker, who takes two hours to do what an ordinary, or average, worker would do in an hour, produces in two hours only one hour's value. This is Marx's conception of "socially necessary labour."

The Social Right.—While asserting that the worker is exploited by the extraction of surplus value, Marx throws overboard completely the notion that each worker ought to receive the full value of his own product. Modern production, he points out, is essentially a social and co-operative process, in which it is impossible to say what, or how much, any single individual has produced. The "right to the whole produce" thus becomes, not a right of any worker to his own product, but a social right of all the workers to the whole product of their combined and co-operative labour. The entire economic system is essentially one: it is no more possible to draw a line between factory and factory, or industry and industry, than between individual workers.

If then, Marx claims the entire product for the whole body of producers, and treats all surplus value as filched from them by extortion, what allowance does he make for the labour of organising and managing production, and of distributing the products? He is ready to allow that the brain-worker engaged in production is a producer of value equally with the manual worker. But he denies that the processes of distribution, the merchanting and trading processes of industry, are productive of value. This is not to say that they are unnecessary. They are necessary expenses of production, and cause deductions from the amount of surplus value left for division as rent, interest and profits to the exploiters. The workers engaged in distribution have clearly to be paid as well as the directly productive workers. The capitalist also may be doing useful work; but in addition to his own share in the social product he is filching the workers' surplus value.

This surplus value is divided into rent, interest and profits. In discussing the principles on which this division takes place Marx makes few original contributions to economic theory, following in the main the orthodoxy of his own day. But in discussing the allocation of profits (*Capital,* Vol. III.) he incidentally modifies in a vital fashion the impression created by his treatment of the question of value in Volume I. Profits in different employments, he points out, are equalized by the competition of capitalists one with another. If the profits in one employment are high, fresh competitors enter the field, and lower prices until profits fall to the average level.

Capital and Value.—How does this doctrine square with Marx's general theory, borrowed from the orthodox economists, that value depends on the amount of labour incorporated in a commodity, and surplus value on the capitalists' success in prolonging the duration or intensity of labour beyond what is needed in order to provide the labourers' subsistence? According to Marx, surplus value is produced only by labour. Capital itself, spent on machines or materials, can transfer its value to the finished product, but can create in the process no additional value. Thus, if two capitalists have each £1,000, and one spends £700 on machines and materials and £300 on labour, and the other £500 on each, the one has only £300, and the other £500, of capital in a form capable of yielding surplus value. Marx calls this "variable capital," and all capital expended in any way except on the purchase of labour he calls "constant capital"—a distinction fundamentally different from the customary division of capital into "fixed" and "circulating," which Marx also employs. The capitalist with the larger variable capital will, on the face of it, secure a proportionately larger "surplus value." But he will not, according to Marx, secure a larger profit; for the averaging process mentioned above, operating through the prices of the commodities produced by the two capitalists, will bring their profits to a common level.

What follows? It has been tacitly assumed, throughout Volume I., that, apart from temporary marked deviations due to supply and demand, all commodities tend to sell at their value. But it now appears that they do not. They sell at prices which will yield to each capitalist the appropriate profit, and owing to the differing "compositions" of the various capitals employed, as between "constant" and "variable" capital, these prices cannot coincide with the values determined by the amount of abstract labour incorporated in each commodity. Marx's "value," unlike that of the orthodox economists, thus turns out to have no necessary relation to the price of any particular commodity, but to be a property intrinsic to the commodity and wholly distinct from its market price. On this showing, much of the criticism directed against Marx's theory of value is irrelevant; for it has been largely based on the assumption that "value" is equivalent to "normal price." And Marx himself appears to assume this in the first volume.

Marx's explanation would probably have been that, throughout *Capital,* he is dealing, not with the actual phenomena of any particular capitalist society, but with the abstract and unqualified working of a pure capitalist system treated as a unified whole. In this rarified atmosphere, all labourers are one huge exploited class, all capitalists one exploiting class, all values one unified social value. The divergence between particular values and prices does not arise, because the totals of all values and all prices, in which alone the abstract working of the system can be seen, necessarily coincide. The values of particular commodities can no more be separately determined than the contribution of any individual labourer to their production. It is only in the total system that the working of the social process can be clearly seen. This point is of vital importance to the understanding of the highly abstract method followed throughout the first two volumes of *Capital.* The third, put together by Engels after Marx's death from scattered notes, is not wholly in the same vein. It often comes far nearer to a discussion of concrete phenomena.

Subsidiary Doctrines.—There are, of course, many subsidiary doctrines in *Capital,* and some of them are of great importance (*e.g.,* the theory of commercial crises) for the understanding of Marx's place in the history of economic thought. But it has seemed better, in this article, to concentrate upon a careful exposition of his fundamental doctrines than to attempt to cover a wider field. Something must, however, be said in conclusion of his contribution to the problem of Socialist strategy, since round this point centre the most lively controversies among modern Marxists.

We have seen that Marx represents the State as a part of the political superstructure whose form is, in the long run, governed by the character of the productive forces. Its function is to uphold the dominant productive system, and the social relationships which are essential for its working. It is "an executive committee for managing the affairs of the governing class as a whole." Accordingly, when a new governing class is brought to power by a revolution in the productive forces, it becomes necessary for the new class to re-make the State in its own image. It cannot simply take over the State from its old masters, and use it for its own ends; for it will not be adapted for those ends. It must smash the old State, and make a new one for itself. It is on this part of Marx's doctrine that the modern Communists base their policy, quoting in support of their views Marx's famous discussion of the Paris Commune of 1871, first issued as a manifesto of the International Working Men's Association, and now known as *The Civil War in France.* On the other hand, the Social Democrats of Germany, and indeed most European Socialist Parties, profess to be Marxist, and yet work for the constitutional conquest of political power by peaceful capture of the existing State machine. They mean to modify the machine, but not to smash it or build up a new State on a purely proletarian foundation.

The doctrine of the "dictatorship of the proletariat," emphasized by the modern Communists, is based directly on Marx's theory of the State. The dictatorship is the means by which the proletariat makes, and exerts the authority of, a new State of its own. But this stage is conceived as purely transitional. The dictatorial proletarian State is a necessary instrument for the crushing of counter-revolution and the firm establishment of the new order. But, when once this is accomplished, the need for it disappears. There is no longer a proletariat to dictate; for exploitation has been abolished, and all classes are merged in one. The apocalyptic vision of the closing chapter of Volume I. of *Capital* has come true. The State, in Lenin's phrase, "withers away": the problem of government is replaced by that of social administration in a classless society in which all economic antagonisms have been resolved. Thus Marxian socialism, like all socialism, ends in the proclamation of a Utopia. But this Utopia is not, for Marx, the end; it is the opening of a new chapter in the record of mankind. At this point, with the final disappearance of class distinctions and the exploitation of man by man, "pre-history ends, and history begins."

No attempt has been made in this article to criticise or evaluate the Marxian doctrine as a whole. It has been confined to an attempt to state clearly the main outlines of the Marxian system, in so far as this is possible in face of the incompleteness of Marx's published work. In the note below, mention has been made of books both favourable and unfavourable to the Marxian standpoint. (G. D. H. C.)

BIBLIOGRAPHY.—LIVES—by F. Mehring (in German—English translation announced), by John Spargo (1910), and (slight but good) by Max Beer (*Life and Teaching of Karl Marx* 1921). Additional matter in D. Riazanov, *Marx and Engels* (1927); W. Liebknecht, *Karl Marx, Biographical Memoirs* (Eng. tr. 1901) and Engels' account of Marx in the *Handbuch der Staatswissenschaften.* BOOKS ON MARXISM—K. Kautsky, *The Economic Doctrines of Karl Marx* (and many other works); A. D. Lindsay, *Karl Marx's "Capital"*; H. J. Laski, *Communism;* Böhm-Bawerk, *Karl Marx and the Close of his System* (reply by R. Hilfferding); H. W. B. Joseph, *Marx's Theory of Value;* J. Borchardt, *The People's Marx;* E. Aveling, *The Student's Marx;* A. Loria, *Karl Marx;* B. Croce, *Historical Materialism and the Economics of Karl Marx;* N. Lenin, *The State and Revolution;* L. B. Boudin, *Theoretical System of Karl Marx;* M. Eastman, *Marx, Lenin and Revolution.*

WRITINGS.—An exhaustive bibliography of Marx and Engels' writings is given in vol. 1 of *Archiv* (in Russian and German) published by the Marx-Engels Institute, Moscow, which has also begun the issue of a collected edition of their writings in 42 vols.

MARX, WILHELM (1863–), German politician, was born at Cologne Jan. 15, 1863. He entered the political branch of the Civil Service and became a judge. In 1899 he was elected to the Prussian Diet and in 1910 entered the German Reichstag, where he soon became prominent among the leaders of the Centre. He was elected president of the Centre party in 1921, and on Nov. 30, 1923 succeeded Stresemann as chancellor of the Reich. In Aug. 1924 he took part in the Conference of London which determined the acceptance of the Dawes Plan. (*See* GERMANY.) In the autumn of 1924 Marx dissolved the Reichstag in the hope of getting a government majority, and after the elections retired from the post of chancellor. In Feb. 1925 he became Prussian Minister-President for a short period. After the death of Ebert he stood as candidate for the post of president of the Reich, but was defeated by Hindenburg. In Jan. 1926 he became Minister for Justice and Occupied Territories in the second Luther Cabinet and later in the same year succeeded Luther as Chancellor. He remained Chancellor through the reshuffle on the entry of the German National Party representatives into the cabinet, but resigned on June 13, 1928, partly owing to ill health.

MARY, the mother of Jesus. At the time when the gospel history begins, she had her home in Galilee, at the village of Nazareth.

Of her parentage nothing is recorded in any extant historical document of the 1st century, for the genealogy in Luke iii. (*cf.* i. 27) is manifestly that of Joseph.

In early life she became the wife of Joseph (*q.v.*) and the mother of Jesus Christ; that she afterwards had other children is inferred by some from Matt. i. 25.

The few incidents mentioned in Scripture about her show that she followed our Lord to the very close of His earthly career with unfailing motherliness, but the "Magnificat" assigned to her in Luke i. is the only passage which would distinctly imply on her part a high prophetic appreciation of His divine mission. It is however doubtful whether Luke really intended to assign this hymn to Mary or to Elizabeth (*cf.* especially *Niceta of Remesiana* by A. E. Burn, Cambridge, 1905; Harnack's "Das Magnificat der Elizabeth" in the *Sitzungsberichte* of the Berlin Academy for 1900, and Burkitt's "Who spoke the Magnificat?" in the *Journal of Theological Studies,* Jan. 1906). The original text of Luke probably mentioned no name in introducing the Magnificat; scribes supplied the ambiguity by inserting, some Mary, others Elizabeth. It is doubtful which represents the intention of the writer: there is perhaps more to be said for the view that he meant to assign the Magnificat to Elizabeth. The Fourth Gospel records that Mary was present at the Crucifixion, where she was commended by Jesus to the care of the Apostle John (John xix. 26 f.), Joseph having apparently died before this time. Mary is mentioned in Acts i. 14 as having been among those who continued in prayer along with the apostles at Jerusalem during the interval between the Ascension and Pentecost. There is no mention in the New Testament of the time or place of her death.

The subsequent growth of ecclesiastical tradition, legend and belief regarding Mary will be traced most conveniently under the separate heads of (1) her perpetual virginity, (2) her absolute sinlessness, (3) her peculiar relation to the Godhead, which specially fits her for successful intercession on behalf of mankind.

(1) Her Perpetual Virginity.—This doctrine was, to say the least, of no importance in the eyes of the evangelists, and so far as extant writings go there is no evidence of its having been anywhere taught within the pale of the Catholic Church of the first three centuries. On the contrary, to Tertullian the fact of Mary's marriage after the birth of Christ is a useful argument for the reality of the Incarnation against gnostic notions, and Origen relies upon the references to the Lord's brethren as disproving the Docetism with which he had to contend. The ἀειπαρθενία, though very ancient, is in reality a doctrinc of non-Catholic origin, and first occurs in a work proscribed by the earliest papal *Index librorum prohibitorum* (attributed to Gelasius) as heretical—the so-called *Protevangelium Jacobi,* written, it is generally admitted, within the 2nd century. According to this very early romance, which seems to have formed the basis of the later *Liber de infantia Mariae et Christi salvatoris* and *Evangelium de nativitate Mariae,* the name of Mary's father was Joachim (in the *Liber de infantia* a shepherd of the tribe of Judah, living in Jerusalem); he had long been married to Anna her mother, whose continual childlessness had become a cause of much humiliation and sorrow to them both. The birth of a daughter was at last angelically predicted to each parent separately. From her third to her twelfth year "Mary was in the Temple of the Lord as a dove that is nurtured; and she received food from the hand of an angel." When she became of nubile age a guardian was sought for her by the priests among the widowers of Israel "lest she should defile the sanctuary of the Lord"; and Joseph, an elderly man with a family, was indicated for this charge by a miraculous token. Some time afterwards the annunciation took place; when the Virgin's pregnancy was discovered, Joseph and she were brought before the high priest, and, though asserting their innocence in all sincerity, were acquitted only after they had been tried with "the water of the ordeal of the Lord" (Num. v. 11ff.). Numerous details regarding the birth at Bethlehem are then given. To Jerome the perpetual virginity not only of Mary but even of Joseph appeared of so much consequence that while a young man he wrote (387) the long and vehement tract *Against Helvidius,* in which he was the first to broach the theory (which has since gained wide currency) that the brethren of our Lord were children neither of Mary by her husband nor of Joseph by a former marriage, but of another Mary, sister to the Virgin and wife of Clopas or Alphaeus. At last the epithet of ἀεὶ παρθένος was authoritatively applied to the Virgin by the council of Chalcedon in 451, and the doctrine implied has ever since been an undisputed point of orthodoxy both in the Eastern and in the Roman Churches, some even seeking to hold the Anglican Church committed to it on account of the general declaration (in the *Homilies*) of concurrence in the decisions of the first four general councils.

(2) Her Absolute Sinlessness.—While much of the apocryphal literature of the early sects in which she is repeatedly spoken of as "undefiled before God" would seem to encourage some such doctrine as this, many passages from the acknowledged fathers of the Church could be cited to show that it was originally quite unknown to Catholicism. Even Augustine repeatedly asserts that she was born in original sin (*De gen. ad lit.* x. 18); and the *locus classicus* regarding her possible immunity from actual transgression, on which the subsequent doctrine of Lombardus and his commentators was based, is simply an extremely guarded passage (*De nat. et grat.* ch. 36), in which, while contradicting the assertion of Pelagius that many had lived free from sin, he wishes exception to be made in favour of "the holy Virgin Mary, of whom out of honour to the Lord I wish no question to be made where sins are treated of—for how do we know what mode of grace wholly to conquer sin may have been bestowed upon her who was found meet to conceive and bear Him of whom it is certain that He had no sin." A writer so late as Anselm (*Cur deus homo,* ii. 16), declares that "the Virgin herself whence He (Christ) was assumed was conceived in iniquity, and in sin did her mother conceive her, and with original sin was she born, because she too sinned in Adam in whom all sinned," and the same view was expressed by Damiani. For the growth of the modern Roman doctrine of the immaculate conception from the time in the 12th century, when the canons of Lyons sought to institute a festival in honour of her "holy conception," and were remonstrated with by Bernard, *see* IMMACULATE CONCEPTION. The epithets applied to her in the Greek Church are such as ἀμόλυντος, πάναγνος, ἁγία, παναγία; but in the East generally no clear distinction is drawn between immunity from actual sin and original sinlessness.

(3) Her Peculiar Relation to the Godhead, which Specially Fits Her for Successful Intercession on Behalf of Mankind.—It seems probable that the epithet θεοτόκος ("Mother of God") was first applied to Mary by theologians of Alexandria towards the close of the 3rd century; but it does not occur in any genuine extant writing of that period, unless we are to assign an early date to the apocryphal *Transitus Mariae,* in which the word is of frequent occurrence. In the 4th century it is met with frequently, being used by Eusebius, Athanasius, Didymus, and Gregory of Nazianzus,—the latter declaring that the man who believes not Mary to have been θεοτόκος has no part in God (*Orat.* li. p. 738). If its use was first recommended by a desire to bring into prominence the divinity of the Incarnate Word, there can be no doubt that latterly the expression came to be valued as directly honourable to Mary herself and as corresponding to the greatly increased esteem in which she personally was held throughout the Catholic world, so that when Nestorius and others began to dispute its propriety, in the following century, their temerity was resented, not as an attack upon the established orthodox doctrine of the Nicene creed, but as threatening a more vulnerable and more tender part of the popular faith. It is sufficient in illustration of the drift of theological opinion to refer to the first sermon of Proclus, preached on a certain festival of the Virgin at Constantinople about the year 430, or to that of Cyril of Alexandria delivered in the church of the Virgin Mary at the opening of the council of Ephesus in 431. In the former the orator speaks of "the holy Virgin and Mother of God" as "the spotless treasure-house of virginity, the spiritual paradise of the second Adam; the workshop in which two natures were welded together . . . the one bridge between God and men"; in the latter she is saluted as the "mother and virgin," "through whom (δι' ἧς) the Trinity is glorified and worshipped, the Cross of the Saviour exalted and honoured, through whom Heaven triumphs, the angels are made glad, devils driven forth, the tempter overcome, and the fallen creature raised up even to heaven." The response which such language found in the popular heart was sufficiently shown by the shouts of joy with which the Ephesian mob heard of the deposition of Nestorius, escorting his judges with torches and incense to their homes, and celebrating the occasion by a general illumination. The causes which in the preceding century had led to this exaltation of the Mother of God in the esteem of the Catholic world are not far to seek. On the one hand the solution of the Arian controversy, however correct it may have been theoretically, undoubtedly had the practical effect of relegating the God-man redeemer for ordinary minds into a far away region of "remote and awful Godhead," so that the need for a mediator to deal with the very Mediator could not fail to be felt. Perhaps it ought to be added that the comparative colourlessness with which the character of Mary is presented, not only in the canonical gospels but even in the most copious of the apocrypha, left greater scope for the untrammelled exercise of devout imagination than was possible in the case of Christ, in the circumstances of whose humiliation and in whose recorded utterances there were many things which the religious consciousness found difficulty in understanding or in adapting to itself. At all events, from the time of the council of Ephesus, to exhibit figures of the Virgin and Child became the approved expression of orthodoxy, and the relationship of motherhood in which Mary had been formally declared to stand to God was instinctively felt to give the fullest and freest sanction of the Church to that invocation of her aid which had previously been resorted to only hesitatingly and occasionally. Previous to the council of Ephesus, indeed, the practice had obtained complete recognition, so far as we know, in those circles only in which one or other of the numerous redactions of the *Transitus Mariae* passed current. There we read of Mary's prayer to Christ: "Do Thou bestow Thine aid upon every man calling upon, or praying to, or naming the name of Thine handmaid"; to which His answer is, "Every soul that calls upon Thy name shall not be ashamed, but shall find mercy and support and confidence both in the world that now is and in that which is to come in the presence of My Father in the heavens." But Gregory of Nazianzus also, in his panegyric upon Justina, mentions with incidental approval that in her hour of peril she "implored Mary the Virgin to come to the aid of a virgin in her danger." Of the growth of the Marian cultus, alike in the East and in the West, after the decision at Ephesus it would be impossible to trace the history, however slightly, within the limits of the present article. Justinian in one of his laws bespeaks her advocacy for the empire, and he inscribes the high altar in the new church of St. Sophia with her name. Narses looks to her for directions on the field of battle. The emperor Heraclius bears her image on his banner. John of Damascus speaks of her as the sovereign lady to whom the whole creation has been made subject by her son. Popular devotion gradually developed the entire system of doctrine and practice which Protestant controversialists are accustomed to call by the name of Mariolatry. With reference to this much-disputed phrase it is always to be kept in mind that the directly authoritative documents, alike of the Greek and of the Roman Church, distinguish formally between *latria* and *dulia,* and declare that the "worship" to be paid to the Mother of God must never exceed that superlative degree of *dulia* which is vaguely described as *hyperdulia.* But it does not seem unfair to hold the Roman Church responsible for the natural interpretations and just inferences which may be drawn even from apparently exaggerated expressions in such works as the well-known *Glories of Mary* and others frequently quoted in controversial literature. There is a good *résumé* of Catholic developments of the cultus of Mary in Pusey's *Eirenicon.*

MARY, known as MARY MAGDALENE, a woman mentioned in the Gospels, first in Luke viii. 2, as one of a company who "healed of evil spirits and infirmities . . . ministered unto them (Jesus and the apostles) of their substance." It is said that seven demons were cast out of her. Mary came from Magdala (el-Mejdel, 3m. N.W. from Tiberias: in Matt. xv. 39 the right reading is not Magdala but Magadan). She went with Jesus on the last journey to Jerusalem, witnessed the Crucifixion, followed to the burial, and returned to prepare spices. John xx. gives an account of her finding the tomb empty and of her interview with the risen Jesus. Mary of Magdala has been confounded (1) with the unnamed fallen woman who in Simon's house anointed Christ's feet (Luke vii. 37); (2) with Mary of Bethany, sister of Lazarus and Martha.

MARY I., queen of England (1516–1558), unpleasantly remembered as "the Bloody Mary" on account of the religious persecutions which prevailed during her reign, was the daughter of Henry VIII. and Catherine of Aragon, born in the earlier years of their married life, when as yet no cloud had darkened the prospect of Henry's reign. Her birth occurred at Greenwich, on Monday, Feb. 18, 1516, and she was baptized on the following Wednesday, Cardinal Wolsey standing as her godfather. She seems to have been a precocious child, and is reported in July 1520, when scarcely four and a half years old, as entertaining some visitors by a performance on the virginals. When she was little over nine she was addressed in a complimentary Latin oration by commissioners sent over from Flanders on commercial matters, and replied to them in the same language "with as much assurance and facility as if she had been twelve years old" (Gayangos, iii. pt. 1, 82). Her father was proud of her achievements. About the same time that she replied to the commissioners in

Latin he was arranging that she should learn Spanish, Italian and French. A great part, however, of the credit of her early education was undoubtedly due to her mother, who not only consulted the Spanish scholar Vives upon the subject, but was herself Mary's first teacher in Latin.

When Mary was two years old she was proposed in marriage to the dauphin, son of Francis I. Three years afterwards the French alliance was broken off, and in 1522 she was affianced to her cousin the young emperor Charles V. by the Treaty of Windsor. Not many years passed away before Charles released himself from this engagement and made a more convenient match. In 1526 a rearrangement was made of the royal household, and it was thought right to give Mary an establishment of her own along with a council on the borders of Wales, for the better government of the Marches. For some years she accordingly kept her court at Ludlow, while new arrangements were made for the disposal of her hand. She was now proposed as a wife, not for the dauphin as before, but for his father Francis I., who had just been redeemed from captivity at Madrid, and who was only too glad of an alliance with England to mitigate the severe conditions imposed on him by the emperor. Wolsey, however, on this occasion, only made use of the princess as a bait to enhance the terms of the compact, and left Francis free in the end to marry the emperor's sister.

It was during this negotiation, as Henry afterwards pretended, that the question was first raised whether his own marriage with Catherine was a lawful one. But this story is proved to be untrue by the strongest evidence, for we have pretty full contemporary records of the whole negotiation. On the contrary, it is clear that Henry, who had already conceived the project of a divorce, kept the matter a dead secret, and was particularly anxious that the French ambassadors should not know it, while he used his daughter's hand as a bait for a new alliance. The alliance itself, however, was actually concluded by a treaty dated Westminster, April 30, 1527, in which it was provided, as regards the Princess Mary, that she should be married either to Francis himself or to his second son Henry duke of Orleans.

During the next nine years the life of Mary, as well as that of her mother, was rendered miserable by the conduct of Henry VIII. in seeking a divorce. During most of that period mother and daughter seem to have been kept apart. Possibly Queen Catherine had the harder trial; but Mary's was scarcely less severe. Removed from court and treated as a bastard, she was, on the birth of Anne Boleyn's daughter, required to give up the dignity of princess and acknowledge the illegitimacy of her own birth. On her refusal her household was broken up, and she was sent to Hatfield to act as lady-in-waiting to her own infant half-sister. Nor was even this the worst of her trials; her very life was in danger from the hatred of Anne Boleyn. Her health, moreover, was indifferent, and even when she was seriously ill, although Henry sent his own physician, Dr. Buttes, to attend her, he declined to let her mother visit her. At her mother's death, in January 1536, she was forbidden to take a last farewell of her.

But in May following another change occurred. Anne Boleyn, the cause of her miseries, fell under the king's displeasure and was put to death. Mary was then urged to make a humble submission to her father as the means of recovering his favour, and after a good deal of correspondence with the king's secretary, Cromwell, she actually did so. The terms exacted of her were bitter in the extreme, but there was no chance of making life tolerable otherwise, if indeed she was permitted to live at all; and the friendless girl, absolutely at the mercy of her father who could brook no contradiction, at length subscribed an act of submission, acknowledging the king as "Supreme Head of the Church of England under Christ," repudiating the pope's authority, and confessing that the marriage between her father and mother "was by God's law and man's law incestuous and unlawful." Henry was now reconciled to her, and gave her a household in some degree suitable to her rank. During the rest of the reign we hear little about her except in connection with a number of new marriage projects taken up and abandoned. Her privy purse expenses for nearly the whole of this period have been published, and show that Hatfield, Beaulieu or Newhall in Essex, Richmond and Hunsdon were among her principal places of residence. Although she was still treated as of illegitimate birth, it was believed that the king, having obtained from parliament the extraordinary power to dispose of the crown by will, would restore her to her place in the succession, and three years before his death she was so restored by statute, but still under conditions to be regulated by her father's will.

Under the reign of her brother, Edward VI. she was again subjected to severe trials, which at one time made her seriously meditate escaping abroad. Edward himself indeed seems to have been personally kind to her, but the religious revolution in his reign assumed proportions such as it had not done before, and Mary, who had done sufficient violence to her own convictions in submitting to a despotic father, was not disposed to yield an equally tame obedience to authority exercised by a factious council in the name of a younger brother not yet come to years of discretion. Besides, the cause of the pope was naturally her own. In spite of the declaration formerly wrung from herself, no one regarded her as a bastard, and the full recognition of her rights depended on the recognition of the pope as head of the Church. Hence, when Edward's parliament passed an Act of Uniformity enjoining services in English and communion in both kinds, she insisted on having Mass in her own private chapel under the old form. When ordered to desist, she appealed for protection to the emperor Charles V., who, being her cousin, intervened for some time not ineffectually, threatening war with England if her religious liberty was interfered with.

But Edward's court was composed of factions of which the most violent eventually carried the day. Lord Seymour, the admiral, was attainted of treason and beheaded in 1549. His brother, the Protector Somerset, met with the same fate in 1552. Dudley, duke of Northumberland, then became paramount in the privy council, and easily obtained the sanction of the young king to those schemes for altering the succession which led immediately after his death to the usurpation of Lady Jane Grey. Dudley had, in fact, overawed the rest of the privy council, and when the event occurred he took such energetic measures to give effect to the scheme that Lady Jane was actually recognized as queen for some days, and Mary had to fly from Hunsdon into Norfolk. But the country was devoted to her cause, as indeed her right in law was unquestionable, and before many days she was royally received in London, and took up her abode within the Tower.

Her first acts at the beginning of her reign displayed a character very different from that which she still holds in popular estimation. Her clemency towards those who had taken up arms against her was remarkable. She released from prison Lady Jane's father, Suffolk, and had difficulty even in signing the warrant for the execution of Northumberland. Lady Jane herself she fully meant to spare, and did spare till after Wyatt's formidable insurrection. Her conduct, indeed, was in every respect conciliatory and pacific, and so far as they depended of her personal character the prospects of the new reign might have appeared altogether favourable. But her position was one of peculiar difficulty, and the policy on which she determined was far from judicious. Inexperienced in the art of governing, she had no trusty councillor but Gardiner; but she was naturally led to rely even more on the advice of her cousin, the emperor, who had been her mother's friend in adversity, and had done such material service to herself in the preceding reign. Following the emperor's guidance she determined almost from the first to make his son Philip her husband, though she was eleven years his senior. She was also strongly desirous of restoring the old religion and wiping out the stigma of illegitimacy upon her birth.

Restoration of the old religion might deprive the new owners of abbey lands of their comfortable acquisitions; and it was only with an express reservation of their interests that the thing was actually accomplished. A declaration of her own legitimacy necessarily cast a slur on that of her sister Elizabeth, and cut her off from the succession. But the marriage promised to throw England into the arms of Spain and place the resources of the kingdom at the command of the emperor's son. The Commons sent her a deputation to entreat that she would not marry a foreigner, and when her resolution was known insurrections broke out in different parts of the country. Suffolk, whose first rebellion had been pardoned, proclaimed Lady Jane Grey again in Leicestershire, while Wyatt raised the county of Kent and, though denied access by London Bridge, led his men round by Kingston to the very gates of London before he was repulsed. In the midst of the danger Mary showed great intrepidity, and the rebellion was presently quelled; after which she married Philip, restored the old religion, and induced Cardinal Pole to absolve the kingdom from its past disobedience to the Holy See.

It was a more than questionable policy thus to ally England with Spain—a power then actually at war with France. By the treaty, indeed, England was to remain neutral; but the force of events, in the end, compelled her to take part in the quarrel. Meanwhile the country was full of faction, and seditious pamphlets of Protestant origin inflamed the people with hatred against the Spaniards. Philip's Spanish followers met with ill-usage everywhere, and violent outbreaks occurred. A year after his marriage Philip went over to Brussels to receive from his father the government of the Low Countries and afterwards the kingdom of Spain. To Mary's distress, his absence was prolonged for a year and a half, and when he returned in March 1557 it was only to commit England to the war; after which he went back to Brussels in July, to return no more to England.

Hostilities with France were inevitable, because France had encouraged disaffection among Mary's subjects, even during the brief truce of Vaucelles. Conspiracies had been hatched by English refugees in Paris, and an attempt to seize Scarborough had been made with the aid of vessels from the Seine. But perhaps the strangest thing about the situation was that the pope took part with France against Spain. It was this war with France that occasioned the final calamity of the loss of Calais.

The persecution of the Protestants, which has cast so much infamy upon her reign, was not due, as commonly supposed, to inhumanity on her part. When the kingdom was reconciled to Rome and absolved by Cardinal Pole, it followed, almost as a matter of necessity, that the old heresy laws should be revived, as they were then by Act of Parliament. Serious doubts were felt as to the result even from the first; but the law having been once passed could not be relaxed.

No doubt there were milder men among the heretics, but as a class their stern fanaticism and ill-will to the old religion made them dangerous, even to the public peace. Rogers, the first of the martyrs, was burnt on Feb. 4, 1555. Hooper, bishop of Gloucester, had been condemned six days before, and suffered the same fate upon the 9th. From this time the persecution went on uninterrupted for three years and three quarters, numbering among its victims Ridley, Latimer and Cranmer. It came to an end at last on the death of Mary. Nearly three hundred victims are known to have perished at the stake; and their fate created a revulsion against Rome that nothing else was likely to have effected.

Mary was of weak constitution and subject to frequent illnesses, both before and after her accession. One special infirmity caused her to believe a few months after her marriage that she was with child, and thanksgiving services were ordered throughout the diocese of London in November 1554. The same delusion recurred in March 1558, when though she did not make her expectation public, she drew up a will in anticipation of the dangers of childbirth, constituting her husband regent during the minority of her prospective heir. To this she added a codicil on Oct. 28 following, when the illness that was to be her last had set in, showing that she had ceased to have much expectation of maternity, and earnestly entreating her "next heir and successor by the laws" (whom she did not name) to allow execution of the instrument. She died on Nov. 17, 1558.

Her name deserved better treatment than it has generally met with; for she was far from cruel. Her kindness to the poor is undoubted, and the severe execution of her laws seemed only a necessity. Even in this matter, moreover, she was alive to the injustice with which the law was usually strained in behalf of the prerogative; and in appointing Sir Richard Morgan chief justice of the Common Pleas she charged him "not to sit in judgment otherwise for her highness than for her subjects," and to avoid the old error of refusing to admit witnesses against the Crown (Holinshed III. 1112). Her conduct as queen was governed by the best possible intentions; and it is evident that her very zeal for goodness caused most of the trouble she brought upon herself. Her subjects were entirely released, even by papal authority, from any obligation to restore the confiscated lands of the Church. But she herself made it an object, at her own expense, to restore several of the monasteries; and courtiers who did not like to follow her example, encouraged the fanatics to spread an alarm that it would even yet be made compulsory. So the worldly minded joined hands with godly heretics in stirring up enmity against her.

MARY II. (1662–1694), queen of England, wife of king William III., elder daughter of James, duke of York, afterwards King James II., by his first wife, Anne, daughter of Edward Hyde, 1st earl of Clarendon, was born in London on April 30, 1662. She was educated as a Protestant, and as it was probable that she would succeed to the English throne after the deaths of her uncle, Charles II., and her father, the choice of a husband for her was an important political event. About 1672 the name of William, prince of Orange, was mentioned in this connection; and after some hesitation on both sides caused by the condition of European politics, the betrothal of William and Mary took place in October 1677, and was quickly followed by their marriage in London on Nov. 4. Mary's married life in Holland does not appear to have been a happy one. She soon became very popular among the Dutch, but she remained childless. Her troubles were not diminished after her father became king of England in 1685. James had treated his daughter very shabbily in money matters; and it was increasingly difficult for her to remain loyal to both father and husband when they were so divergent in character and policy. Mary shared heartily in the events which immediately preceded William's expedition to England in 1688. After the success of the undertaking she arrived in London in February 1689; and by her faithful adherence to her promise made a satisfactory settlement of the English crown possible.

William and Mary were together proclaimed king and queen of England, and afterwards of Scotland, and were crowned on April 11, 1689. During the king's absence from England the queen, assisted by a committee of the privy council, was entrusted with the duties of government, duties which she performed faithfully, but which she gladly laid down on William's return. In these times of danger, however, she acted when necessary with courage and promptitude, as when in 1690 she directed the arrest of her uncle Henry Hyde, 2nd earl of Clarendon; but she was constantly anxious for William's safety, and unable to trust many of her advisers. She was distressed by a quarrel with her sister Anne in 1692 following the dismissal of Marlborough, and this event somewhat diminished her popularity, which had hitherto been one of the mainstays of the throne. Weak in body and troubled in mind, the queen died at Kensington Palace from small-pox on Dec. 28, 1694, and was buried in Westminster Abbey.

Mary was a woman of a remarkably modest and retiring disposition, whose outstanding virtue was perhaps her unswerving loyalty to William. Burnet has passed a remarkable panegyric upon her character. She was extremely pious and charitable; her blameless private life was in marked contrast with her surroundings, both in England and Holland; without bigotry she was greatly attached to the Protestant faith and to the Church of England. Greenwich Hospital for Seamen was founded in her honour.

MARY (1867–), Queen Consort of George V, daughter of the Duke of Teck and Mary Adelaide, daughter of Adolphus, duke of Cambridge, seventh son of George III., was born at Kensington Palace May 26, 1867, and was baptised as Victoria Mary Augusta Louise Olga Pauline Claudine Agnes. She was affianced in 1891 to Albert Edward, Duke of Clarence, eldest son of Edward VII., who died Jan. 14, 1892. On July 3, 1893, she married George, Duke of York, and when he succeeded to the throne, on the death of Edward VII., was crowned with him in Westminster Abbey June 22, 1911. Both as Princess of Wales and as queen she took a prominent part in public life, showing special and well-informed interest in all that concerned the welfare of women and children. This was particularly notable at the outset of the World War, when the organization of relief, as well as the promotion of the women's part in public service, claimed and received her constant attention. By the universal testimony of those who came into direct contact with her through those anxious years, no one showed a more practical appreciation of the problems to be solved than the queen. In the first month of the war she inaugurated (Aug. 20) the "Queen's Work for Women Fund" to provide employment for as many as possible of the women thrown out of work by the outbreak of war. Over 70 special relief workrooms were opened, through which about 9,000 women passed before Feb. 1915; after that date, the need became less as the women were gradually absorbed into munition making and other industries. On Aug. 10, 1914, the queen also inaugurated "Queen Mary's Needlework Guild" for the purpose of "organizing a collection of garments for those who will suffer on account of the War." On March 11, 1921, the queen showed her sympathy with the higher education of women by visiting the women's colleges at Oxford and responding generously to their appeal for funds. The interest shown by the queen in the hospitals and the nursing profession was signalized when she opened the new College of Nursing (the gift of Lord and Lady Cowdray) in London on May 31, 1926. On June 23, 1936, Queen Mary was created Dame Grand Cross of the Victorian Order, being the first woman admitted into the Order. (*See* GEORGE V; EDWARD VIII.)

MARY (1496–1533), queen of France, daughter of Henry VII. of England and Elizabeth of York. The treaty of Calais (Dec. 21, 1507) arranged for her marriage with Charles of Austria (Charles V.) when the prince reached the age of 14, and the wedding was celebrated by proxy in 1508. The contract was renewed (1513) by Henry VIII., but the emperor Maximilian I. was now in treaty for a marriage with Renée of France (with Brittany as a dowry) for his son, and evinced an intention to withdraw from the contract. He was forestalled by Wolsey, who arranged, by the peace of 1514, the marriage of Mary with Louis XII. of France. The marriage was celebrated at Abbeville on Oct. 9. The bridegroom was a broken man of fifty-two; the bride a beautiful, well-educated and charming girl of eighteen, whose heart was already engaged to Charles Brandon, duke of Suffolk, her future husband. The political marriage was, however, no long one.

Mary was crowned queen of France on Nov. 5, 1514; on Jan. 1 following King Louis died. Mary had only been induced to consent to the marriage with Louis by the promise that, on his death, she should be allowed to marry the man of her choice. But the dukes of Lorraine and Savoy were mentioned as possible suitors, and meanwhile the new king, Francis I., was making advances to her. Suffolk himself was at the head of the embassy which came from England to congratulate the new king, and he used the opportunity to win the hand of the queen. Mary feared opposition, and, in spite of Suffolk's promise to the king to delay any action until after his return, she persuaded him to marry her secretly before he left Paris. Suffolk was ultimately pardoned through Wolsey's intercession, on payment of a heavy fine and the surrender of all the queen's jewels and plate. The marriage was solemnized at Greenwich on May 13, 1515. Mary died on June 24, 1533. By the duke of Suffolk she had three children: Henry, born on March 11, 1516, created earl of Lincoln (1525), who died young; Frances, born on July 16, 1517, the wife of Henry Grey, marquess of Northampton, and mother of Lady Jane Grey (*q.v.*); and Eleanor.

MARY (QUEEN OF SCOTS)[1] (1542–1587), daughter of King James V. and his wife Mary of Lorraine, was born at Linlithgow in Dec. 1542, a few days before the death of her father. In July 1543 a treaty for the betrothal of the infant to Edward, heir of Henry VIII. of England, was made by the regent Arran, but Henry's obvious ambition to annex the crown of Scotland at once to that of England aroused instantly the general suspicion and indignation of Scottish patriotism. The marriage treaty was denounced by the Scots at the end of the same year, Henry retaliated by invasions of Scotland, and the Scots renewed their ancient alliance with France. In 1548 the queen of five years old was betrothed to the dauphin Francis, and set sail for France, where she arrived on Aug. 15. For the next ten years, the child was under the care of her mother's relatives, the Guises. In April 1558 she was married to the dauphin, and in November of the same year Elizabeth became queen of England. In the eyes of Roman Catholic Europe, Elizabeth's birth was illegitimate, and Mary was *de jure* queen of England. Henry II. of France ordered his son and daughter-in-law to challenge Elizabeth's claim by assuming the royal arms of England. Civil strife broke out in Scotland between John Knox and the queen-dowager—between the self-styled "congregation of the Lord" and the adherents of the regent—and Elizabeth retaliated by helping the insurgent Protestants against the queen-dowager and her French troops. The war ended with the death of Mary of Lorraine in June 1560. Francis and Mary, who had become king and queen of France, had no efficient representative in Scotland, and the Protestant leaders were in control of the situation. On Aug. 25 Protestantism was proclaimed and Catholicism suppressed in Scotland by a parliament which was assembled without the assent of the absent queen.

On Dec. 5 Francis II. died; in Aug. 1561 his widow left France for Scotland. The queen arrived in safety at Leith. On Aug. 21 she first met the only man able to withstand her; and their first passage of arms left, as he has recorded, upon the mind of John Knox an ineffaceable impression of her "proud mind, crafty wit and indurate heart against God and His truth." And yet her acts of concession and conciliation were such as no fanatic on the opposite side could have approved. She assented, not only to the undisturbed maintenance of the new creed, but even to a scheme for the endowment of the Protestant ministry out of the confiscated lands of the Church. Her half-brother, Lord James Stuart, shared the duties of her chief counsellor with William Maitland of Lethington, the keenest and most liberal thinker in the country. By the influence of Lord James, in spite of the earnest opposition of Knox, permission was obtained for her to hear mass celebrated in her private chapel—a licence to which, said the reformer, he would have preferred the invasion of ten thousand Frenchmen.

[1]In a letter dated April 4, 1882, referring to the publication of his drama *Mary Stuart,* Swinburne wrote to Edmund Clarence Stedman: "*Mary Stuart* has procured me two satisfactions which I prefer infinitely to six columns of adulation in *The Times* and any profit thence resulting. (1) A letter from Sir Henry Taylor . . . (2) An application from the editor of the *Encyclopædia Britannica*—who might, I suppose, as in Macaulay's time, almost command the services of the most eminent scholars and historians of the country—to me, a mere poet, proposing that I should contribute to that great repository of erudition the biography of Mary Queen of Scots. I doubt if the like compliment was ever paid before to one of our 'idle trade.'" The present article is based on the biography consequently written by the poet for the 9th edition, after revision by Prof. R. S. Rait.

Through all the first troubles of her reign the young queen steered her skilful and dauntless way with the tact of a woman and the courage of a man. An insurrection in the north, headed by the earl of Huntly, gave Lord James, whom she created earl of Murray, the opportunity of destroying the influence of the most powerful Catholic nobleman in Scotland (1562).

The question of the queen's second marriage was, meanwhile, occupying the attention of both English and Scottish statesmen. The chief aim of the diplomacy of Mary and Maitland of Lethington was a recognition by Elizabeth of the Scottish queen's claim to succeed her, in default of heirs of Elizabeth's own body. A marriage between Mary and a Habsburg prince was rendered impossible by Elizabeth's threat that, if Mary married a foreign prince, she would be debarred from the English succession. Elizabeth proposed as a suitor to the queen of Scots her own favourite, Lord Robert Dudley, the widower if not the murderer of Amy Robsart; but she permitted Mary's cousin, Henry, Lord Darnley, to make a visit to Scotland. Darnley's mother, the countess of Lennox, was the daughter of Margaret Tudor, widow of James IV., by her second husband, the earl of Angus, and therefore the next heir to the English throne after Mary herself. She had been born and brought up in England, and had married the earl of Lennox, an exiled Scottish traitor of Mary's minority. Elizabeth knew that a marriage which would unite the two claims to the succession was a probable result of Darnley's visit, but she protested against the marriage. Mary, who had already married her kinsman, in secret, at Stirling Castle, with Catholic rites celebrated in the apartment of David Rizzio, her secretary for correspondence with France, assured the English ambassador, in reply to the protest of his mistress, that the marriage would not take place for three months, when a dispensation from the pope would allow the cousins to be publicly united without offence to the Church. On July 29, 1565, they were accordingly remarried at Holyrood. Protestant feeling was aroused, and Murray raised a rebellion. He entered Edinburgh with his forces, but failed to hold the town against the guns of the castle, and fell back upon Dumfries before the advance of the royal army, which was joined by James Hepburn, earl of Bothwell, on his return from a three years' outlawed exile in France. Another new adherent was the son of the late earl of Huntly, to whom the forfeited honours of his house were restored a few months before the marriage of his sister to Bothwell. In Oct. 1565 the queen marched an army of 18,000 men against the malcontents; their forces dispersed in face of superior numbers, and Murray, on seeking shelter in England, was received with contumely by Elizabeth, whose half-hearted help had failed to support his enterprise, and whose intercession for his return found at first no favour with the queen of Scots. But the conduct of the besotted boy on whom, at their marriage, she had bestowed the title of king, began at once to justify the enterprise and to play into the hands of all his enemies alike. His father set him on to demand the crown matrimonial, which would at least have assured to him the rank and station of independent royalty for life. Rizzio, hitherto his friend and advocate, induced the queen to reply by a reasonable refusal to this hazardous and audacious request. Darnley who professed to be jealous of Rizzio's intimacy with his wife, at once threw himself into the arms of the party opposed to the policy of the queen and her secretary, and the destruction of Rizzio was planned.

On March 9 the palace of Holyrood was invested by a troop under the command of Morton, while Rizzio was dragged by force out of the queen's presence and slain without trial in the heat of the moment. A parliament which had been summoned for the attainder of Murray and his fellow-conspirators was discharged by proclamation issued in the name of Darnley as king; and in the evening of the next day the banished lords returned to Edinburgh. On the day following they were graciously received by the queen, who undertook to sign a bond for their security, but delayed the subscription till next morning under plea of sickness. During the night she escaped with Darnley, whom she had already seduced from the party of his accomplices, and arrived at Dunbar on the third morning after the slaughter of her favourite. From thence they returned to Edinburgh on March 28 guarded by 2,000 horsemen under the command of Bothwell, who had escaped from Holyrood on the night of the murder, to raise a force on the queen's behalf with his usual soldierly promptitude. The slayers of Rizzio fled to England, and were outlawed; Darnley was permitted to protest his innocence and denounce his accomplices.

A reconciliation between husband and wife followed the birth of their son, James, on June 19, 1566, but it was only temporary. Darnley refused to be present at the baptism of the prince in October, and soon afterwards, while suffering from a serious illness, he went to stay with his father in Glasgow. He had earned his doom at all hands alike, and if his wife and Bothwell were by this time plotting against him, his death was not to be the result of a mere domestic conspiracy, for Bothwell had other accomplices than the queen. On Jan. 22, 1567, Mary visited her husband at Glasgow and proposed to remove him to Craigmillar Castle, where he would have the benefit of medicinal baths; but instead of this resort he was conveyed, on the last day of the month, to the lonely and squalid shelter of the residence known as Kirk-of-Field. On the evening of Sunday, Feb. 9, Mary took her last leave of the miserable boy who had so often and so mortally outraged her as consort and as queen. That night the whole city was shaken out of sleep by an explosion of gunpowder which shattered to fragments the building in which he should have slept and perished; and the next morning the bodies of Darnley and a page were found strangled in a garden adjoining it, whither they had apparently escaped over a wall, to be despatched by the hands of Bothwell's confederates.

Three months and six days after the murder of her husband Mary became the wife of her husband's murderer. On Feb. 11 she had written to the bishop of Glasgow, her ambassador in France, announcing her providential escape from a design upon her own as well as her husband's life. A reward of £2,000 was offered by proclamation for discovery of the murderer. Bothwell and others, his satellites or the queen's, were instantly placarded by name as the criminals. Gracefully and respectfully, with statesmanlike, yet feminine dexterity, the demands of Darnley's father for justice on the murderers of his son were accepted and eluded by his daughter-in-law. On March 28 the Privy Council, in which Bothwell himself sat, appointed April 12 as the day of his trial. Bothwell was acquitted in default of witnesses against him, and his wealth and power were enlarged by gift of the parliament which met on the 14th and rose on April 19—a date made notable by the subsequent supper at Ainslie's tavern, where Bothwell obtained the signatures of its leading members to a document affirming his innocence, and pledging the subscribers to promote the marriage by which they recommended the queen to reward his services and benefit the country. On the second day following Mary went to visit her child at Stirling, where his guardian, the earl of Mar, refused to admit more than two women in her train. It was well known in Edinburgh that Bothwell had a body of men ready to intercept her on the way back, and carry her to Dunbar—not, as was naturally inferred, without good assurance of her consent. On April 24, as she approached Edinburgh, Bothwell accordingly met her at the head of 800 spearmen, assured her (as she afterwards averred) that she was in the utmost peril, and escorted her, together with Huntly, Lethington and Melville, who were then in attendance, to Dunbar Castle. On May 3 Lady Jane Gordon, who had become countess of Bothwell on Feb. 22 of the year preceding, obtained a separation on the ground of her husband's infidelities. Mary and Bothwell returned to Edinburgh with every prepared appearance of a peaceful triumph. Lest her captivity should have been held to invalidate the late legal proceedings in her name, proclamation was made of forgiveness accorded by the queen to her captor in consideration of his past and future services. Bothwell, as a conscientious Protestant, refused to marry his mistress according to the rites of her Church, and she, the chosen champion of its cause, agreed to be married to him by a Protestant.

On May 12 Bothwell was created duke of Orkney and Shetland and the marriage was solemnized three days later. The confederate lords almost immediately took up arms and seized the town and the castle of Edinburgh. Proclamations were issued in which the crime of Bothwell was denounced, and the disgrace of the country, the thraldom of the queen and the mortal peril of her infant son, were set forth as reasons for summoning all the lieges of the chief cities of Scotland to rise in arms on three hours' notice and join the forces assembled against the one common enemy. On June 15, one month from their marriage day, the queen and Bothwell, at the head of a force of fairly equal numbers, but visibly inferior discipline, met the army of the confederates at Carberry hill, some 6m. from Edinburgh. Du Croc, the French ambassador, obtained permission, through the influence of Maitland, to convey to the queen the terms proposed by their leaders—that she and Bothwell should part, or that he should meet in single combat a champion chosen from among them. At last it was agreed that the queen should yield herself prisoner, and Bothwell be allowed to retire in safety to Dunbar, with the few followers who remained to him.

In the evening she was taken to Holyrood, and thence to the port of Leith, where she embarked under guard, with her attendants, for the island castle of Lochleven. On the 20th a silver casket containing letters and French verses, miscalled sonnets, in the handwriting of the queen, was taken from the person of a servant who had been sent by Bothwell to bring it from Edinburgh to Dunbar. (*See* CASKET LETTERS.) Three days after this discovery Lord Lindsay, Lord Ruthven and Sir Robert Melville were despatched to Lochleven, there to obtain the queen's signature to an act of abdication in favour of her son, and another appointing Murray regent during his minority. She submitted, and a commission of regency was established. After an imprisonment of 11 months, in the course of which Elizabeth intervened on her behalf, and sent Mary a letter and a ring in token of her protection, a young member of the household at Lochleven, Willie Douglas, aged 18, succeeded on May 2 in assisting her to escape by a postern gate to the lake-side, and thence in a boat to the mainland, where George Douglas, Lord Seton and others were awaiting her. Thence they rode to Seton's castle of Niddry, and next day to Hamilton Palace, round which an army of 6,000 men was soon assembled. The queen's forces made for the castle of Dumbarton, marching 2m. south of Glasgow, by the village of Langside. Here Murray, with 4,500 men, met and defeated his sister's army on May 13. Mary fled 60m. from the field of her last battle before she halted at Sanquhar, and for three days of flight, according to her own account, had to sleep on the hard ground, live on oatmeal and sour milk, and fare at night like the owls, in hunger, cold and fear. On the third day from the rout of Langside she crossed the Solway and landed at Workington in Cumberland, May 16, 1568. On the 20th Lord Scrope and Sir Francis Knollys were sent from court to carry messages and letters of comfort from Elizabeth to Mary at Carlisle. Her fateful choice of England instead of France was determined by her thirst for victory. She believed that Elizabeth's horror of rebellion would lead the English queen to assist her to regain her crown, and she knew no such help could be expected from France, embroiled in the wars of religion. On July 15, after various delays interposed by her reluctance to leave the neighbourhood of the border, where on her arrival she had received the welcome and the homage of the leading Catholic houses of Northumberland and Cumberland, she was removed to Bolton Castle in north Yorkshire. During her residence here a conference was held at York between her own and Elizabeth's commissioners and those appointed to represent her son as a king of Scots. These latter, of whom Murray himself was the chief, privately laid before the English commissioners the contents of the famous casket. On Oct. 24 the place of the conference was shifted from York to London, where the enquiry was to be held before Queen Elizabeth in council. Mary was already aware that the chief of the English commissioners, the duke of Norfolk, was secretly an aspirant to the peril of her hand; and on Oct. 21 she gave the first sign of assent to the suggestion of a divorce from Bothwell. On Oct. 26 the charge of complicity in the murder of Darnley was distinctly brought forward against her, in spite of Norfolk's reluctance and Murray's previous hesitation. On Jan. 10, 1569, the judgment given at the conference acquitted Murray and his adherents of rebellion, while affirming that nothing had been proved against Mary—a verdict accepted by Murray as equivalent to a practical recognition of his office as regent for the infant king. This position he was not long to hold; and the fierce exultation of Mary at the news of his murder gave reason to fear, if her liberty of correspondence and intrigue were not restrained, the likelihood of a similar fate for Elizabeth. On Jan. 26, 1569 she had been removed from Bolton Castle to Tutbury in Staffordshire, where proposals were conveyed to her, at the instigation of Leicester, for a marriage with the duke of Norfolk, to which she gave a graciously conditional assent; but the discovery of these proposals consigned Norfolk to the Tower, and on the outbreak of an insurrection in the north Mary, by Lord Hunsdon's advice, was again removed to Coventry, when a body of her intending deliverers was within a day's ride of Tutbury. In October Cecil had an interview with Mary at Chatsworth, when the conditions of her possible restoration to the throne in compliance with French demands were debated at length. The queen of Scots, with dauntless dignity, refused to yield the castles of Edinburgh and Dumbarton into English keeping, or to deliver up her fugitive English partisans then in Scotland; upon other points they came to terms, and the articles were signed Oct. 16. On the same day Mary wrote to Elizabeth, requesting the favour of an interview which might reassure her against the suggestion that this treaty was a mere pretence. On Nov. 28 she was removed to Sheffield Castle, where she remained for the next 14 years in charge of the earl of Shrewsbury. The detection of a plot, in which Norfolk was implicated, for the invasion of England by Spain on behalf of Mary, who was then to take him as the fourth and most contemptible of her husbands, made necessary the reduction of her household and the stricter confinement of her person. On May 28, 1572, a demand from both houses of parliament for her execution as well as Norfolk's was rejected by Elizabeth, who, however, entered into negotiations with successive Scottish regents for Mary's delivery into their hands and her immediate execution.

In 1581 Mary accepted the advice of Catherine de' Medici and Henry III. that she should allow her son's title to reign as king of Scotland conjointly with herself when released and restored to a share of the throne. This plan was but part of a scheme including the invasion of England by her kinsman, the duke of Guise, who was to land in the north and raise a Scottish army to place the released prisoner of Sheffield beside her son on the throne of Elizabeth. After the overthrow of the Scottish accomplices in this notable project, Mary poured forth upon Elizabeth a torrent of pathetic and eloquent reproach for the many wrongs she had suffered at the hands of her hostess, and pledged her honour to the assurance that she now aspired to no kingdom but that of heaven. In the spring of 1583 she retained enough of this saintly resignation to ask for nothing but liberty, without a share in the government of Scotland; but Lord Burghley not unreasonably preferred, if feasible, to reconcile the alliance of her son with the detention of his mother. In the autumn of 1584 she was removed to Wingfield Manor under charge of Sir Ralph Sadler and John Somers, who accompanied her also on her next removal to Tutbury in Jan. 1585. On Christmas Eve, 1585, she was removed from the hateful shelter of Tutbury to the castle of Chartley in the same county. Her correspondence in cipher from thence with her English agents abroad, intercepted by Walsingham and deciphered by his secretary, gave eager encouragement to the design for a Spanish invasion of England under the prince of Parma. In 1585 Anthony Babington was induced to undertake the deliverance of the queen of Scots by the murder of the queen of England. In the conduct and detection of her correspondence with Babington, traitor was played off against traitor, and spies were utilized against assassins, with as little scruple as could be required or expected in the diplomacy of the time. In August the conspirators were netted, and Mary was arrested at the gate of Tixall park. At Tixall Mary was detained till her papers at Chartley had undergone thorough research. Her secretaries were examined in London, and one of them gave evidence that she had first heard of the conspiracy by letter from Babington, of whose design against the life of Elizabeth she thought it best to take no notice in her reply, though she did not hold herself bound to reveal it. On Sept. 25 she was removed to the castle of Fotheringay in Northamptonshire. On Oct. 6 she was desired to answer the charges brought against her before certain of the chief English nobles.

On Oct. 14 and 15, 1586, the trial was held in the hall of Fotheringay Castle. Mary conducted the whole of her own defence with courage incomparable and unsurpassable ability, insisting on the production of proof in her own handwriting as to her complicity with the project of the assassins, who had expiated their crime on the 20th and 21st of the month preceding. Elizabeth determined to adjourn the judgment and transfer the place of it to the star-chamber. Here, on Oct. 25, the commissioners again met; and one of them alone, Lord Zouch, dissented from the verdict by which Mary was found guilty of having, since June 1 preceding, compassed and imagined divers matters tending to the destruction of Elizabeth. This verdict was conveyed to her, about three weeks later, by Lord Buckhurst and Robert Beale. She wrote to Elizabeth and the duke of Guise two letters of almost matchless eloquence and pathos, admirable especially for their loyal and grateful remembrance of all her faithful servants.

Elizabeth was uncertain how James VI., then 20 years of age, might take the execution of his mother. When Elizabeth discovered that James was much more interested in the succession to the English throne than in his mother's life, and that, if he was assured that her trial and condemnation would not prejudice his claim to the succession, he would (in his own words) "digest" his resentment, she rejected the intercessions made by France and Scotland, and on Feb. 1, 1587, she signed the death-warrant. On Feb. 7 the earls of Shrewsbury and Kent arrived at Fotheringay with the commission of the council for execution of the sentence. Mary received the announcement with majestic tranquillity, expressing in dignified terms her readiness to die, her consciousness that she was a martyr for her religion, and her total ignorance of any conspiracy against the life of Elizabeth. At eight next morning she entered the hall of execution, having taken leave of the weeping envoy from Scotland, to whom she gave a brief message for her son; took her seat on the scaffold, listened with an air of even cheerful unconcern to the reading of her sentence, solemnly declared her innocence of the charge conveyed in it and her consolation in the prospect of ultimate justice, rejected the professional services of Richard Fletcher, dean of Peterborough, lifted up her voice in Latin against his in English prayer, and when he and his fellow-worshippers had fallen duly silent prayed aloud for the prosperity of her own Church, for Elizabeth, for her son, and for all her enemies; then, with no less courage than had marked every hour and every action of her life, received the stroke of death from the wavering hand of the headsman.

Five months after Mary's death her body was buried at Peterborough, whence in 1612 it was removed to King Henry VII.'s chapel in Westminster Abbey. It still lies there in a sumptuous tomb erected by her son, James VI.

Mary Stuart was in many respects the creature of her age, of her creed, and of her station; but the noblest and most noteworthy qualities of her nature were independent of rank, opinion or time. Even the detractors who defend her conduct on the plea that she was a dastard and a dupe are compelled in the same breath to retract this implied reproach, and to admit, with illogical acclamation and incongruous applause, that the world never saw more splendid courage at the service of more brilliant intelligence, that a braver if not "a rarer spirit never did steer humanity." A kinder or more faithful friend, a deadlier or more dangerous enemy, it would be impossible to dread or to desire. Passion alone could shake the double fortress of her impregnable heart and ever-active brain. The passion of love, after very sufficient experience, she apparently and naturally outlived; the passion of hatred and revenge was as inextinguishable in her inmost nature as the emotion of loyalty and gratitude. Of repentance it would seem that she knew as little as of fear, having been trained from her infancy in a religion where the decalogue was supplanted by the creed. Adept as she was in the most exquisite delicacy of dissimulation, the most salient note of her original disposition was daring rather than subtlety. Beside or behind the voluptuous or intellectual attractions of beauty and culture, she had about her the fresher charm of a fearless and frank simplicity, a genuine and enduring pleasure in small and harmless things no less than in such as were neither. In 1562 she amused herself for some days by living "with her little troop" in the house of a burgess of St. Andrews "like a burgess's wife," assuring the English ambassador that he should not find the queen there,—"nor I know not myself where she is become." From Sheffield lodge, 12 years later, she applied to the archbishop of Glasgow and the cardinal of Guise for some pretty little dogs, to be sent her in baskets very warmly packed,—"for besides reading and working, I take pleasure only in all the little animals that I can get." For her own freedom of will and of way, of passion and of action, she cared much; for her creed she cared something; for her country she cared less than nothing. She would have flung Scotland with England into the hell fire of Spanish Catholicism rather than forgo the faintest chance of personal revenge. Elizabeth, so shamefully her inferior in personal loyalty, fidelity and gratitude, was as clearly her superior on the one all-important point of patriotism. (A. C. S.; R. S. R.)

Bibliography.—The biography of Mary Stuart being virtually the history of Scotland during the period covered by her life, with which the history of England at the same period is also largely concerned, the chief events in which she figured are related in all the general *Histories* of both countries. The most important original authorities are the voluminous *State Papers* of the period, with other ms. documents preserved at the British Museum, the Cambridge University Library, Hatfield and elsewhere. *See* especially the *Reports* of the Hist. MSS. Commission; *Calendar of State Papers relating to Scotland and Mary Queen of Scots* (Scottish Record Publ., 1898); *Calendar of Letters and State Papers relating to English Affairs, principally in the Archives at Simancas* (vols. i.-iv., 1892–1899); and the *Calendars of State Papers: Domestic Series, Edw. VI.–James I.; Foreign Series, Elizabeth; Venice Series.*

The most important unofficial contemporary works are the *Histories* of John Knox, Bishop John Lesley, George Buchanan, and Robert Lindsay of Pitscottie; the *Diurnal of Remarkable Occurrents from the death of James IV. till 1575* (Bannatyne club, 1833); Robert Birrell's "Diary," in Sir. J. G. Dalzell's *Fragments of Scottish History* (Edinburgh, 1798), etc. Much of Mary's own correspondence will be found in Prince A. Labanoff's *Lettres inédites, 1558–87* (1839), and *Lettres, instructions, et mémoires de Marie Stuart* (7 vols., London, 1844), selections from which have been translated into English by W. Turnbull in *Letters of Mary Queen of Scots* (1845), and by Agnes Strickland in *Letters of Mary Queen of Scots and Documents connected with her Personal History* (3 vols., 1842). Recently the following three publications have added to our knowledge of original sources: Conyers Read: *Bardon Papers* (published by the Royal Historical Society in its Camden Society Series); J. Pollen, *The Babington Conspiracy* (Scottish History Society); and M. Wood, *Balcarres Papers* (Scottish History Society).

Among recent works may be mentioned F. A. MacCunn, *Mary Stuart* (1905); Andrew Lang, *The Mystery of Mary Stuart* (1900); R. S. Rait and A. T. Cameron, *King James's Secret; Negotiations relating to the Execution of Mary, Queen of Scots* (1927).

MARY (1457–1482), duchess of Burgundy, only child of Charles the Bold, duke of Burgundy, and his wife Isabella of Bourbon, was born on Feb. 13, 1457. As heiress of the rich Burgundian domains her hand was eagerly sought by a number of princes. When her father fell upon the field of Nancy, on Jan. 5, 1477, Louis XI. of France took possession of the duchy of Burgundy as a fief lapsed to the French crown, and also of Franche Comté, Picardy and Artois. He was anxious that Mary should marry the Dauphin Charles and thus secure the inheritance of the Netherlands for his descendants. Mary declined the French alliance, and married the archduke Maximilian of Austria, afterwards the emperor Maximilian I., at Ghent on Aug. 18, 1477. She died, of a fall from her horse, on March 27, 1482. Three children had been the issue of her marriage, and her elder son, Philip, succeeded to her dominions under the guardianship of his father.
