The Exclusion Principle.—All we have said implies that save for its outermost shell there is a close-packed quality about the structure of a neutral many-electron atom in its lowest energy state. In spite of the grouping of electrons in rather widely separated shells the entire structure is as dense as its wave-mechanical quantum laws permit. These laws require the formation of the wide intershell spacings (in both radius and energy) and their essence is summed up in what is known as Pauli's principle of exclusion, which in one of its forms asserts that for no two electrons in an atomic structure can all of the quantum numbers required to describe their states be identical. Since space does not here permit a discussion of the detailed significance of the different quantum numbers, this form of Pauli's principle will be less significant to the reader than another one which has been used with great success by Fermi, Thomas and others when the electron swarm has to be treated statistically without detailed knowledge of the complicated force fields in which the electrons find themselves (their own fields and those of the nuclei). This statistical form of the statement must be made in terms of a phase space (a concept due to that great U.S. physicist, Josiah Willard Gibbs) of six dimensions: three, the position co-ordinates x, y, z of an electron; the other three, its momentum co-ordinates, p_x, p_y, p_z. Pauli's principle asserts that in such a space a small cell of volume $\Delta x\Delta y\Delta z\Delta p_x\Delta p_y\Delta p_z=h^3$ at the point x, y, z, p_x, p_y, p_z cannot contain more than two electrons (and this only if their spins are in opposite directions). The exclusion principle lays no restriction on the shape of the exclusion cell, only on its volume. The shapes are determined by the detailed mechanics of each particular case. The cell of volume h^3 is made up of the product of two factors, an ordinary and familiar spatial volume $\Delta x\Delta y\Delta z$, inside which the pair of electrons is supposed to be situated, and a momentum volume $\Delta p_x\Delta p_y\Delta p_z$ within which they also lie; meaning that in the momentum "hedgehog" (*see* above) the momentum arrow for that electron pair has its point inside the momentum cell in question so that its three momentum co-ordinates lie between p_x and $p_x+\Delta p_x$, p_y and $p_y+\Delta p_y$, p_z and $p_z+\Delta p_z$ respectively.[1] The presence of the position vector of the electron pair inside the first cell and the momentum vector inside the second cell excludes all other electrons from having their positions and momenta so located. Since the product of the volumes of the two cells is a universal constant, h^3, this means, in rough language, that if electrons are very densely packed in space they must be spread wider apart in momentum and vice versa, since their number density in the phase space is a constant. Consider the two electrons (with opposite spins) which have been packed into the *K* shell of helium where the classical dynamics plus the quantum laws require them to have high momenta (group velocities of the order of 1/68 that of light). When we increase the nuclear charge by one unit to form a lithium atom, not only does the *K* shell shrink, with increased orbital speed, but the additional electron must be placed in an *L* shell at considerably greater radial distance than the first two and at considerably lower momentum and kinetic energy than they, under the requirements of the phase exclusion principle.

Origin of Optical and X-ray Spectra Contrasted.—All the characteristic spectral lines emitted when atoms give off electromagnetic radiation are due to transitions of atomic electrons between the different initial and final stable electronic states.[2] In the case of optical lines, an outer electron (one in the outermost shell) has been, by additional energy supplied from some external source, raised to a quantum-mechanically-permitted (but not ordinarily occupied) energy level of value sharply defined by the wave-mechanical requirements. (The atom is said to be "excited".) Its "fall" from this energy level W_1 to the normal one W_2 is then accompanied by emission of a photon of radiation whose energy $h\nu$ just accounts for the difference W_1-W_2

$$W_1-W_2=h\nu \qquad (12)$$

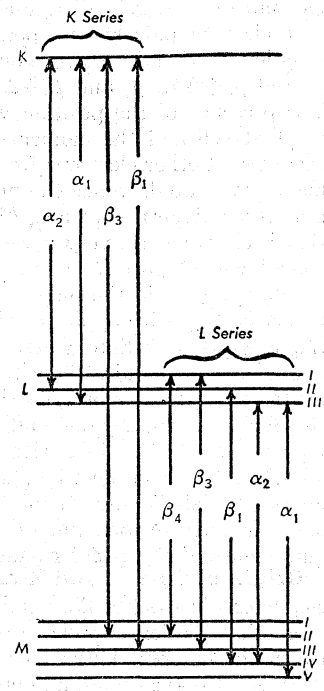
In the case of X-ray lines the atom is said to be "excited" when an electron in some inner shell is ejected completely from the atomic structure (by a supply from some external source of energy in amount equal to or greater than the energy of extraction). The atom is now left with a hole in its previously dense inner structure. The characteristic X-ray spectral line is then emitted when an electron from some shell outside the excited one "falls" into the hole or vacancy. Since it is the change in the total energy state of the entire atom which must be held accountable for the emission of the photon it turns out to be distinctly preferable to say that the hole in the structure has travelled upward to a new shell rather than to say that an electron from the new shell has fallen into the hole. (For clarity and brevity we shall use both descriptions in what follows as convenience dictates.) This process may occur in several steps before the hole reaches the outer surface. Eventually an electron from some external source will be picked up in the final vacancy and the atom will have returned to normal. In the process, characteristic spectral lines will have been emitted with definite frequencies determined by equations of the type of (12) for each of the discrete steps of readjustment. Note that in the X-ray case the

[1] This statement is only roughly true. A new shell is quite frequently started at somewhat earlier *Z* than the completion of its predecessor. The entire "rare earth" series is formed by the successive addition of electrons in an $N_{vi\ vii}$ shell, which process starts 21 atomic numbers later than the *O* shell outside it. Also with increasing *Z*, electrons are sometimes removed from outer shells and added to inner ones.

[1] This somewhat over-simplified language of cartesian co-ordinates implies that the cells are rectangular boxes, but no such restriction exists—their shapes are here undefined. In reality x, y, z, p_x, p_y and p_z should be regarded as generalized co-ordinates appropriate to the mechanics of the case.

[2] Certain very faint lines known as satellites are an exception to this statement. These however are accounted for by a similar but more complicated mechanism in atoms which have lost two or more electrons.

initial state of the atom, required for emission of a line, is one of ionization, creation of a hole. Now associated with this initial state there is a whole series of possible lines corresponding to electrons falling from different outer shells into that one vacancy. The most energetic of these lines (those of highest frequency) will be those that come from the remotest outer shells, those nearest the periphery of the atom. Such lines will approach in energy, $h\nu$, the energy of extraction of the electron removed when the hole was formed. The aggregate of all lines formed by such electron transitions from say the L, M, N, etc. shells into one ionized shell, say the K shell, is called a series, the K-series. The initial state of the atom characterizes the X-ray series. In optical spectra on the contrary it is the final state of the atom which characterizes a series of lines. Note, however, that in both cases if we think in terms of the "jump" the electron executes when the line is emitted, then it is the final level on which the electron lands which characterizes the series designation.



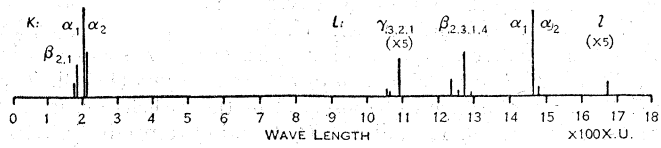
COURTESY, JESSE W. M. DUMOND

FIG. 6.—TYPICAL ARRANGEMENT OF THE HIGHER X-RAY ENERGY LEVELS OF AN ATOM

The vertical lines indicate the transitions or jumps between pairs of these levels which account for some of the stronger X-ray spectral lines as designated. Only K and L series lines are shown and by no means all of these. The magnitudes of the transitions are not shown to scale

X-Ray Energy Level Diagrams and X-Ray Spectra.—As we have already indicated, the extraction energy is not quite identical for all electrons in the same shell, the energy levels of the shells being said to have "a fine structure." For the detailed explanation of this the reader must consult more extended works. The accompanying small diagram, fig. 6, shows three principal atomic energy levels corresponding to an atom which has lost one electron from its K, L, or M shell. Since more energy is required to ionize a K-electron than an L or M-electron the K-level is plotted at the top. In such a diagram an electron falling from the L-shell into the K-shell appears to move upward but this is merely due to the convention used in plotting. It will be noted on this diagram that there is but one K-level while the L-levels are split into a triple fine structure and the M-shell has five distinct sublevels. It is the transitions of electrons as indicated by the lengths of the vertical lines which account for all of the frequencies of the characteristic spectral X-ray lines. (Except for certain very weak lines called "satellites" which are the result of multiply-ionized atoms, about which space does not permit us to elaborate.) Not all possible transitions occur with equal probability and some are so improbable as to have earned the name "forbidden." These transition probabilities control the relative intensities with which the various X-ray spectral lines are observed, for spectra must always come from a great multitude of excited atoms so that the probability of a radiative transition is statistically translated into the intensity of a line.

As a result of the spacing of the energy levels, large from K to L, relatively much less from L to M, relatively much less than the latter from M to N, etc.[1], the spectral lines of a given X-ray series form a rather compact group quite isolated from those of neighbouring series in the spectrum. As an example, we show in fig. 7 the K series and the L series lines of the spectrum of a tungsten target plotted against wave length, with the heights of the lines drawn to indicate roughly the relative intensities. If the value of $h\nu$ for the shortest wave length or highest frequency line in each group is computed, it is found to correspond almost



REDRAWN FROM RICHTMYER AND KENNARD, "INTRODUCTION TO MODERN PHYSICS," (MCGRAW-HILL BOOK CO.)

FIG. 7.—PLOT OF THE PRINCIPAL K AND L SERIES LINES OF TUNGSTEN AGAINST WAVE LENGTH

The relative intensities of the lines are indicated roughly by their heights save that the L γ and l lines are so weak that they are here magnified fivefold. The same line designations have been used as in fig. 6. Note the compactness of the pattern of lines of a given group (K or L) and the wide separation of groups

exactly (but not quite) to the extraction energy of the electron whose expulsion created the hole characterizing that series of lines. (Such extraction energies can be readily measured directly in a number of different ways as we shall see.)

We owe our first insight into atomic structure and the complexity of spectra in general to the simplicity of X-ray spectra, paucity and compactness of lines in a series, absence of overlapping of series, etc., as well as to the fact that the frequencies of the K series, the one first studied by Moseley, are chiefly determined by the energy levels of the K shells, those nearest the nucleus, as we pass from atom to atom. The K electrons are in the full attractive field of the nucleus itself with minimum screening by negatively charged electrons of the full nuclear positive charge Ze. It is this screening effect which accounts for the factor $(Z-1)^2$ instead of Z^2 in Moseley's equation (4) above. After excitation by removal of one K electron, the electrons of the outer structure (L, M, etc., shells) find themselves in the field of a nuclear charge Ze screened by one K electron, hence effectively $(Z-1)e$.

EXCITATION OF X-RAYS

Atoms can be excited to emit their characteristic X-rays (by expulsion of deep-lying electrons) in a number of ways as follows:

Electron Bombardment.—In this case the atom is ionized by collisions of fast electrons. (Of far greater total energy than the line spectrum from an X-ray tube, however, is the continuous spectrum generated directly by the impacts of the cathode electrons on the target, as explained below.) This is the method used in all X-ray tubes. As shown by experiments of W. Duane and F. L. Hunt and also of D. L. Webster, it is necessary that the colliding fast electrons have energy greater than the electron extraction energy W_e, the energy level of the series of X-ray lines to be excited. If V is the steady (D.C.) voltage applied in the tube to accelerate the electrons and e the electronic charge, then eV must equal or exceed W_e. The K series lines of silver, for example, just begin to make their appearance in the X-rays coming from the electronically bombarded silver target when, as we increase the voltage, we reach a value of 25,600 volts although the L series lines of silver are already strongly in evidence. At the critical voltage, all the K series lines appear at once. It is such behaviour that so strongly confirms the picture we have given of the atomic X-ray emission process. This critical value, 25,600 volts, is the extraction or ionization energy of silver K electrons expressed in "electron volts." The electron volt is a convenient unit of energy much used by physicists. It is equal to the energy possessed by one electron which has fallen through a difference of potential of one volt and is equal to about 1.601×10^{-12} ergs. A quantum $h\nu$ of radiation having this energy has a frequency of 242 million million cycles per second and a wave length $\lambda = 1.24\times10^{-4}$ cm. Energy, in quantum physics, can thus be expressed in ergs, volts, cycles per second, or wave length units. Convenient conversion relations from electron volts, V, to wave length λ in

[1] The reason for this rapidly decreasing energy level spacing is implicit in Bohr's original formula for the individual permitted energy levels of his orbits (*c.f.* Eq. 3). His permitted energy levels were given by

$$W_{nz}=\frac{2\pi^2me^4}{h^2}\frac{Z^2}{n^2}.$$

In an atom such as silver (Z=47), for example, the two K electrons are in a nuclear field of about 47 units; while the shielding of these places, the eight L electrons (also somewhat shielded by each other), in a field of somewhat less than 45 units. Also and more important, the quantum number. n=1, applies to the K while n=2 applies to the L electrons. Similar reasoning applied to the M, N, etc., shells will convince the reader of the rapid decrease in energy-level spacing.

centimetres and frequency ν in cycles per second are

$$\lambda=\frac{1.2378\times10^{-4}}{V};\quad \nu=2.4218\times10^{14}V \qquad (13, 14)$$

The original Crookes tube of fig. 1 used by Röntgen and the gas discharge tube of Sir Herbert Jackson, fig. 2, have been replaced by various forms of the "pure electron discharge" tube or "hard vacuum" tube invented by W. D. Coolidge of the Ameri-

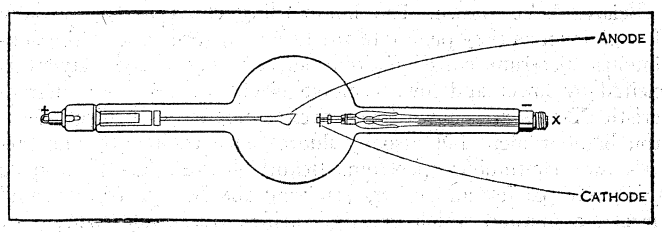


FIG. 8.—DIAGRAM OF THE STANDARD COOLIDGE X-RAY TUBE

Earlier tubes needed residual gas to sustain the electrical discharge but in the Coolidge tube the electrons forming the cathode rays are supplied by thermionic emission from an incandescent cathode

can General Electric company in 1913, of which an example is pictured in fig. 8. The electrically heated incandescent cathode emits electrons by a process analogous to the boiling of vapour from a liquid, first discovered by Thomas Edison but only well understood after much work on thermionics by many investigators, notably, Sir John Fleming and Owen Richardson. The target or anode may also be permitted to become incandescent, through the bombardment (this is not permissible however unless the tube is operated on a "rectified" supply so that the cathode is always negative); or if its substance is too easily melted, it may be kept cool by a supply of running fluid circulating in its interior. Such a tube must be evacuated of gas in the space surrounding cathode and anode to such an attenuation that the chance of an electron in the bombarding stream colliding with and ionizing an atom of the gas in its path from cathode to anode is very low indeed. We say the "mean-free-path" for electron collisions must be much longer than the cathode-anode separation. Pressures as low as of the order of 10^{-6} (one millionth) millimetre of mercury (or about one-billionth of an atmosphere) are required. The attainment of such vacuua was made possible by the invention of the diffusion pump by Irving Langmuir of the General Electric Co. and by the general development and improvement, in many laboratories, of high vacuum technique.

In another tube known as "Metalix," developed at the Philips laboratories, Eindhoven, Holland, and pictured in fig. 9, the disposition of the metal anode and cathode together with a cylindrical metallic section in the envelope of the tube is such that X-rays can only emerge through a small window thus obviating the necessity for large complicated and expensive external protective shielding.

Fluorescent Excitation of Characteristic X-Rays.—The second method whereby atoms can be excited to emit their characteristic X-rays consists in using radiation to supply the energy needed to extract one of the deeper electrons. In order for this to take place the photons of the exciting radiation (like the electrons in the previous method) must have energies, $h\nu$, equal to or greater than the work of extraction of the atomic electron whose removal accounts for the series of X-ray lines to be excited. Thus, in order to excite by fluorescence a sheet of silver to emit its K-series lines when exposed to a beam of monochromatic X-rays, it is necessary that the frequency of the X-ray beam exceed 6.2×10^{18} cycles per second (or, what is equivalent, that its wave length be less than 0.48×10^{-8} cm.). Both these figures are simply the quantum equivalents (computed from the formulae 13, 14) of the extraction energy, 25,600 electron volts, for the K electrons of silver. This is a striking example of the quantum or particlelike behaviour of X-radiation. Consider in detail how the event must take place:

A beam of X-rays from which has been selected a small bundle of monochromatic radiation of the required critical wave length either by reflection at a definite angle from a crystal surface or by diffraction from an artificial ruled grating or in any other way, falls on a sheet of silver. No matter how much the intensity of this beam is attenuated, either by distance of transmission, or by absorption in matter before reaching the silver, its photons will always possess the property of being able to eject K electrons from the silver (the ejected K electrons can be observed by appropriate means) and of exciting the silver sheet to emit the silver K spectrum of lines (easily observable by means of an X-ray crystal spectrometer). Weakening the intensity of the beam does not reduce the energy of the photons, it merely diminishes their number. Even the elementary process has been frequently observed, taking place in single isolated events. One photoelectron of the proper energy and one photon of the characteristic fluorescent X-rays were frequently observed simultaneously ejected from a copper plate when a beam of primary X-rays of sufficiently high $h\nu$ fell upon it by C. T. R. Wilson and others in cloud chamber experiments. The fluorescent photon gave evidence of itself by ejecting another photoelectron from a gas atom at some distance from the fluorescent copper and doing this with the proper energy.

Fluorescent excitation is rarely used for the production of characteristic X-rays. It does, however, furnish one method of chemical analysis applied with great success by G. Hevesy who, with D. Coster, in 1923 discovered the new element ($Z=72$), hafnium, by means of its characteristic X-rays.

Maurice de Broglie was the first to show that there is a class of photoelectrons ejected by X-rays of frequency ν whose kinetic energy, W_{kin}, accurately satisfies the equation

$$W_{kin}=h\nu-h\nu_q \qquad (15)$$

wherein $h\nu_q$ is the characteristic energy of extraction of some level of the irradiated matter.

The Continuous X-Ray Spectrum.—The characteristic line spectra we have described are not the only nor the most important X-radiation given off by X-ray tube targets when bombarded with electrons. There is also a smoothly spread, continuous spectrum of X-rays upon which the lines are superposed. The lines are very narrow, though they do have a finite measured width in wave length or frequency units and a very definite structure or profile which has been carefully studied. The X-ray energy in a section of continuous spectrum the same width as a line is much smaller, even in the most intense regions, than that in the stronger spectral lines. Nevertheless the lines are so narrow and the gaps between them so large that the total energy in the continuous spectrum far outweighs that in the lines. The bulk of the X-ray

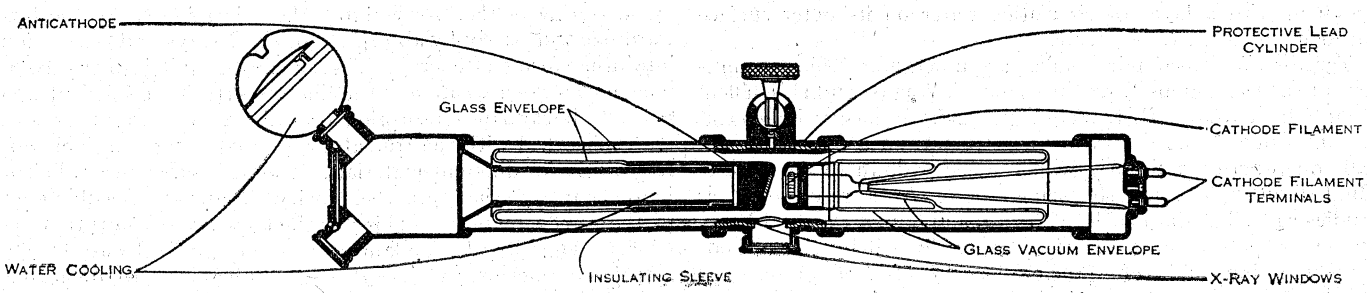

FIG. 9.—DIAGRAM OF THE "METALIX" X-RAY TUBE OF PHILIPS, SHOWING THE WATER-COOLED ANTICATHODE, THE TUBULAR METAL WAISTLINE WITH A THIN GLASS WINDOW AND THE OUTER PROTECTIVE LEAD JACKET

output of the tube is therefore in its continuous spectrum. Because of this it is chiefly the continuous spectrum which does the work in medical diagnosis and therapy.

The continuous spectrum has a sharp upper frequency limit beyond which it is absent altogether and which constitutes its most striking feature. If the X-ray tube is excited with a steady (D.C.) voltage V so that all electrons (of charge, e) impinging on the target have the same energy eV at all times then this highest frequency emitted ν_{max} satisfies the equation

$$h\nu_{max}=eV \qquad (16)$$

wherein h is Planck's constant. This important law, first observed about 1915 by D. L. Webster working in Duane's laboratory is usually called the Duane-Hunt law. It furnishes one of the important methods of measuring the ratio h/e from which, knowing e from other sources, Planck's constant h can be computed. The law asserts that no X-ray photon can be emitted from the X-ray tube with energy $h\nu$ greater than that of the impinging electrons which excite the X-rays. But it is the fact that some photons (even though relatively rarely) can be emitted with energies of this magnitude, which is the astonishing thing. This mechanism, especially in the case of complete conversion of electron energy into photon energy, is a difficult problem in quantum or wave mechanics (treated by A. Sommerfeld and others). It is closely related in classical analogy to sudden stoppages of the cathode ray electrons striking nearly "head-on" blows at the nuclei of the atoms of the target, accompanied with complete radiative loss of their energy. In this curious type of electron quantum transition the electron "falls" from the energy level of the free electrons emitted by the cathode to a final state as one of the conduction electrons of the target. In the wave-mechanical theory of Sommerfeld the free electron is envisaged as a positive energy state of a wave-mechanical atom, the positive energy states differing from the stable negative (total) energy states by forming a continuous rather than a discrete set of possible energies. In the mechanics of the solar system the analogue of an electron in a positive total energy state is a comet (possessing sufficient energy so that its return to the sun is not guaranteed) whereas the planets are analogous to electrons in negative energy states or bound electrons, save for the fact, of course, that the planetary negative energies do not have similar quantum restrictions on their permitted values.

The continuous spectrum from an X-ray tube is found to be partially polarized with its electric vector parallel to the direction of motion of the electrons impinging upon the target. The effect is more pronounced in thin targets and as one approaches the short wave-length limit of the spectrum.

At moderate electron voltages the direction of strongest emission is nearly at right angles to the direction of the impinging electrons but as we pass to higher voltages the maximum inclines toward the forward direction of the impinging electrons. At 24,000 volts the maximum emission is at about 70° to the forward direction of the cathode rays, at 38,000 volts it is at 64° while at 1,000,000 volts it is at about 25° only. The effect is best studied with a "thin" target consisting of a foil in which the X-ray absorption and cathode ray straggling are minimized. Because of this effect some very high voltage X-ray tubes have been constructed so as to utilize the X-rays transmitted directly through the target which is made appropriately thin for the purpose and provided with a layer of circulating water on its outer surface through which the rays emerge.

Targets of high atomic number are much more efficient emitters of the continuous X-ray spectrum, E. Wagner and H. Kuhlenkampff have shown that, plotted per unit frequency increment, the intensity in the continuous spectrum from a massive target falls off practically linearly with frequency down to the Duane-Hunt limit with some steepening there. As a result of their studies as well as those of R. T. Beatty and others, the total X-ray energy output of an X-ray tube target divided by the cathode ray energy input (therefore the efficiency ϵ of X-ray production) has been shown to be given by the approximate formula: $\epsilon=kZV$, wherein Z is the atomic number of the target material, V the voltage and k a constant probably about 1.1×10^{-9} according to S. K. Allison. (More recent elaborate theoretical calculations in 1945 by P. Kirkpatrick and L. Wiedmann indicate $K=1.4\times10^{-9}$. The formula obviously must fail long before $\epsilon=100\%$.) Thus a tungsten target ($Z=74$) bombarded at 100,000 volts would emit in all X-ray wave lengths about 0.8% of the electrical energy input. The other 99.2% of the input energy is converted into heat. The emission from massive X-ray targets is a very complex process as D. L. Webster, W. Hansen, P. Kirkpatrick and their associates have shown. The bombarding electrons are rapidly slowed down as they penetrate the target surface so that the continuous spectrum emission from successively deeper layers is excited by lower and lower voltage electrons. Also the characteristic X-rays are shown to be excited not only by direct electron bombardment but also by fluorescence excited by the target's own continuous spectrum. Beautiful work has been done by P. Kirkpatrick and others studying the X-rays from "thin" targets, a method which greatly clarifies the whole process of X-ray generation.

The emission from X-ray targets of radiation at the short wavelength limit of the continuous X-ray spectrum is an even more striking example of the particlelike behaviour of X-rays. Here we have almost literally the case (see *Particle-Wave Duality* above) of Compton's swimmer lifted up to the springboard by waves from a diver at a great distance. An electron in an X-ray tube strikes a target after having fallen a potential difference of 25,700 volts (the critical K extraction energy of silver plus 100 volts for good measure). The resulting X-rays falling on a silver surface will occasionally eject K electrons therefrom and the silver will (albeit weakly) emit its characteristic K spectrum, just as it would if it had been bombarded directly with 25,700 volt electrons in an X-ray tube. And this will happen no matter how far the X-rays have travelled to do it! Also the ejected photoelectrons will in some cases possess kinetic energies ranging all the way up to the extra 100 volts provided. Here on an atomic scale is radiant energy transmitted over great distances without any loss or diffusion at all! Yet there is not the slightest doubt that the same radiation has wavelike properties for it is by diffraction from crystal lattices and ruled gratings that we know the wave length of the short-wave limit of the very continuous X-ray spectrum of which we speak.

INTERACTIONS OF X-RAYS WITH MATTER

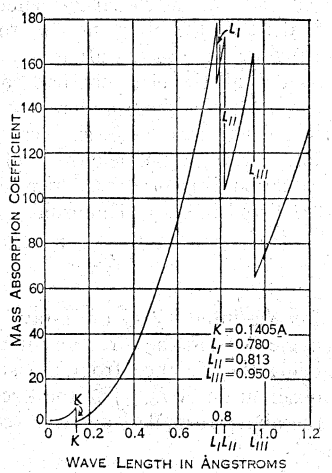
Photoelectric Absorption; The Effects upon the Radiation.—When a pencil of X-rays passes through a material-absorbing screen its intensity is reduced as an exponential function of the path length in the screen according to the law

$$I_x=I_0e^{-\tau x} \qquad (17)$$

Here I_x is the intensity after passage through x centimetres of screen, I_0 the initial intensity and τ is called the total linear absorption coefficient per cm. (An unfortunate lack of standardization exists in the use of the symbols τ and μ. Many physicists use μ to represent the total absorption and τ to represent the true absorption exclusive of scattering. It is experimentally difficult to separate true absorption from scattering in many cases.) It is clear that this law implies that each additional increment Δx of screen thickness removes the same fraction of intensity from the beam. This removal occurs partly by scattering of the X-rays into other directions than the forward one and partly by absorption of the X-rays and conversion into other forms of energy. Thus τ can be split into two components $\tau=\sigma+\mu$ where σ is the linear scattering coefficient and μ is the linear true absorption coefficient. We are at present only concerned with the true absorption coefficient μ. This differs widely for different materials. A more significant coefficient however is μ/ρ where ρ is the density (in grams per cubic cm.) of the screen material. This is called its mass absorption coefficient. Of still more fundamental significance is the atomic absorption coefficient, $\mu_{At}=(\mu/\rho)\,(A/N)$ wherein A is the atomic weight of the absorbing material and N is Avogadro's number. μ_{At} is the fraction of X-rays removed from an X-ray beam one

sq.cm. in cross section by each atom placed therein. It may be regarded as a cross section, the equivalent stopping area of the atom for the X-rays in question.

When μ/ρ or μ_{At} for a given absorbing screen is plotted as a function of λ, the wave length of a monochromatic beam of X-rays whose absorption coefficient is under investigation, certain very abrupt discontinuities are observed at well-defined values of λ which depend on the material of the screen. Such a curve is shown in fig. 10 as an example for the mass absorption coefficient of a lead-absorbing screen. The first, or K, discontinuity occurs at a wave length λ_K or frequency ν_K, for which the quantum energy (photon energy) of the radiation is just sufficient to eject K electrons from lead. There are three L discontinuities at wave lengths λ_L (or frequencies ν_L) such that the radiation just has the quantum energy to eject L electrons from the three different L levels of the lead atom. The sudden increase in absorption as the wave length is shortened in crossing one of these critical values, say the K, is caused by the fact that a new group of electrons in the lead atom (the K electrons), previously inactive, are now taking some extra energy from the beam (by being ejected from their atoms). Let us call the critical wave length values, λ_K, λ_L, etc.



REDRAWN FROM RICHTMYER AND KENNARD, "INTRODUCTION TO MODERN PHYSICS," (MCGRAW-HILL BOOK CO.)

FIG. 10.—MASS ABSORPTION COEFFICIENT CURVE OF LEAD IN THE WAVE LENGTH REGION OF THE K AND ALSO OF THE THREE L ABSORPTION DISCONTINUITIES

The sudden increase in absorption at each discontinuity as one passes toward shorter wave lengths λ or higher frequenole $\nu(=c/\lambda)$ is due to the fact that the quantum energy of the radiation has become sufficient to eject a new class of electrons, previously taking no part in the absorption process

In 1914 W. H. Bragg and S. E. Pierce showed that apart from the discontinuities, the coefficient μ/ρ approximately followed a law of the form

$$\frac{\mu}{\rho}=C\lambda^3Z^3 \qquad (18)$$

Z being the atomic number of the absorber. The coefficient C assumes a new value at each discontinuity. If we consider the absorption per atom, C is replaced by a constant, A' and the exponent of Z becomes 4 (since A is approximately proportional to Z).

$$\mu_{At}=A'\lambda^3Z^4 \qquad (19)$$

F. K. Richtmyer finds for the region $\lambda<\lambda_K$ that $A'=2.25\times10^{-2}$ and for the region $\lambda_K<\lambda<\lambda_L$, $A'=0.33\times10^{-2}$ when in both cases λ is in cm.[1]

The absorption discontinuities taken together with the characteristic X-rays emitted by the absorber give a complete verification of the picture we have formed of the absorption process and of the structure of atoms. As we diminish the wave length incident on the absorber, for example, in the range $\lambda_K<\lambda<\lambda_L$, the L series of lines is strongly emitted by the absorber but the K series is absent. But as soon as the wave length of the incident beam becomes shorter than λ_K, the entire K-series makes its appearance. All the K series lines are on the long wave-length side of the K edge, etc., because, to use rough figurative language, no energy of transition of an electron from a higher to a lower atomic level can exceed the work required to raise an electron from the lower of the two levels completely out of the atomic structure in the act of ionization, the essential preparation for the former transition. All this furnishes highly satisfactory confirmation of the picture we have formed of the atomic processes of absorption of radiation quanta when these have sufficient energy to eject a given class of electrons, and the concomitant process of emission of characteristic lines from the absorbing atom after the hole has been created by ejecting one of these electrons. The absorption edges furnish one of the best ways of determining the atomic extraction energies or energy levels. All the prominent X-ray spectral lines can be accounted for, as to their frequencies (photon energies $h\nu$) as the difference between two of these levels. Thus for example the $K\alpha_1$ line satisfies the equation

$$h\nu_{K\alpha_1}=h\nu_K-h\nu_{L_{III}} \qquad (20)$$

wherein ν_K and $\nu_{L_{III}}$ are the frequencies of the K and the third L absorption discontinuities. Moseley diagrams for the critical absorption frequencies (plotted between $\sqrt{\nu_A}$ and Z) are even more convincing than for the emission lines.

Although in the preceding discussion we have phrased our description of the process of ionization of an atom with subsequent emission of an X-ray line in the rough and forceful language of electrons jumping about, as it were, on the rungs of an energy ladder it is more accurate to regard such transitions as changes in the state of the total, densely-packed, atomic structure regarded as a unit. This calls for a rephrasing in terms of the motion not of an electron but of the hole in the atomic structure which the electron leaves as it were in its wake.

The Bragg-Pierce law of absorption is not rigorously accurate but is merely a good approximation. L. de Broglie and A. H. Kramers have constructed only partially successful theories to explain it.

It is important to note what an enormous range of atomic absorption the Z^4 law affords for a given X-ray wave length, in virtue of the 92 different atomic numbers. Thus if the law were rigorously true[1] an atom of uranium would absorb $92^4=71{,}639{,}296$ times as much radiation as an atom of hydrogen ($Z=1$). The process accounting for this true fluorescent absorption is not the only one whereby radiation acts on atoms. We still have the scattering coefficient σ to account for and still another process, the creation of electron pairs out of radiant energy, enters when the quantum energy of the incident radiation exceeds twice the rest-mass energy of the electron $2mc^2$ (about a million electron-volts). (*See* RADIATION, RAYS.)

Photoelectric Absorption, Effects Upon the Absorbing Atoms.—If we wish a rough classical analogue to the true fluorescent absorption process we must think of the electric vector of the incident electromagnetic waves as acting simultaneously on two members of an electric dipole, the positive consisting of the heavy nucleus and all but one of its attendant electrons, the negative consisting of one electron only of the outer structure, setting the latter (the lighter member of this dipole) into forced vibrations of increasing amplitude until practically the entire quantum energy of the incident photon has been transferred to the electron and the latter is ejected from the atom moving away as a "free" photoelectron with kinetic energy equal to the photon energy less the "work of ejection" just necessary to free it. The momentum given the photoelectron is balanced by an equal and opposite momentum given the heavy nucleus (and also the rest

[1] B. Walter (1927) gives the following results which may be slightly more reliable than Richtmyer's:

$\lambda<\lambda_K$; $\mu_{At}=2.64\times10^{-2}Z^{3.94}\lambda^3$, λ in cm.
$\lambda_K<\lambda<\lambda_L$; $\mu_{At}=8.52\times10^{-4}Z^{4.30}\lambda^3$, λ in cm.

[1] The figures we give here, while only approximate, do convey a correct idea of the orders of magnitude through which absorption coefficients can range.
E. Jönsson at Uppsala, Sweden, in 1928 in his thesis succeeded in formulating a universal law of absorption, designed to express the true atomic absorption coefficient for any element and any wave length. Jönsson bridges each of the absorption discontinuities by introducing, as one crosses each in the direction of decreasing wave length, a new multiplying coefficient equal to the ratio of the extraction energies for (1) the level just being excited and (2) its next lowest predecessor. By dividing the true atomic absorption coefficients by the atomic number Z he defines a new true absorption coefficient which might be called the electronic absorption coefficient and which in our notation would be

$$\mu_e=\mu_{At}/Z.$$

Jönsson's approximate universal rule may then be stated by saying that μ_e is a function of the product $(Z\lambda)$ only. This function is nearly but not exactly linear when $\log(\mu_e)$ is plotted against $\log(Z\lambda)$ and has been given as a curve in Compton and Allison's text, *X-Rays in Theory and Experiment*. Jönsson's rule is a better approximation at the higher atomic numbers and shorter wave lengths.

of its attendant electronic structure) which experiences a recoil like that of a gun when a bullet is fired. As might be expected from this picture, cloud chamber experiments with polarized radiation show that the ejected photoelectrons are most numerous in the direction of the electric vector of the radiation. There is also a slight statistical inclination of the ejected photoelectrons to move in the forward direction of the incident radiation which is a result of the fact that momentum, $h\nu/c$, is associated with the radiation itself—the photons. (The most probable forward momentum thus given to the photoelectron turns out however to be twice the momentum of the incident radiation. It is this momentum $h\nu/c$ which is associated with the pressure of light.) F. W. Bubb and also P. Auger and F. Perrin and A. Sommerfeld have discussed the process theoretically.

The velocities of the photoelectrons ejected by X-rays have been studied by H. Robinson, E. C. Watson, G. G. Kretschmar and many others in great detail by bending those coming from absorbing foils with known magnetic fields and also by observing their tracks in a Wilson cloud chamber (Auger and others) in which case the individual ejected electron tracks can be seen. It turns out that besides the primary photoelectrons already described, others appear which were ejected by the characteristic fluorescent X-ray lines emitted in the absorber. If these lines have characteristic frequencies ν_p and the work of extraction of a given electron is W_q then the energies of these electrons conform with the formula

$$\text{secondary photoelectron energy} = h\nu_p - W_q \qquad (21)$$

yielding another rich source of information as to energy levels and characteristic emission frequencies of the absorber in complete accord with the more directly observed values.

The X-ray ionization of gases and the effects of X-rays on living tissues have been shown to be due not to the direct action of the X-rays but to the photoelectrons which the X-rays eject from atoms of the gas or the tissue. These photoelectrons may, as we have explained, have energies (in volts) ranging practically all the way up to the energies of the electrons in the cathode ray stream of the X-ray tube where the radiation was generated. As the photoelectrons plough through a gas (or living tissue) they ionize many thousands of atoms in their paths, the average energy expended in ionizing an atom of air for example being only about 30 to 35 volts. The process is made indubitably clear in the Wilson cloud chamber. Of profound biological significance is the action of the photoelectrons in inducing mutations of the genes in living cells. It has been shown by M. Delbrück in such X-ray studies that the size of the molecular structure of a gene, the carrier throughout the ages of hereditary traits of amazing permanence, is of the order of that of a cube (or sphere) having only ten atoms in its linear dimensions! A book by the great physicist Erwin Schrödinger, *What Is Life,* reviews this evidence and suggests the most profound consequences to an understanding of biology and even perhaps of consciousness itself.

The Scattering of X-Rays.—The tremendously significant work of Arthur Compton dating from his discovery in 1923 of modified scattering, followed by the work of a long list of other investigators, has established that there are two important ways in which X-rays are "scattered" (deflected from their original paths) by atoms, called respectively modified and unmodified scattering. It was in this field that the particlelike behaviour of the photons of radiation was first driven home with telling force. As in the photoelectric process, here again there are two experimental aspects—the effect on the radiation and the effect on the atoms which scatter it.

It is the electrons in the atomic structure which are responsible for scattering X-rays. In unmodified scattering, which occurs the more frequently (for radiation of specified quantum energy) the higher the binding energy of the scattering electrons, the radiation is not changed in wave length at all by the scattering process—it is merely deflected into a new direction. Such unmodified scattering accounts for all of the selective diffraction phenomena in crystals and on ruled gratings which result in the formation of spectral lines. Each atom of the periodic structure reradiates the incident radiation without change of wave length in definite phase relationship to the primary exciting radiation. Since the photons lose none of their quantum energy $h\nu$ in the process, no net work is done on the atom, no electrons are removed or disturbed, and the final state of the atom is exactly like the initial state. It is as though all the electrons had co-operated in the reradiating process, each absorbing and re-emitting its share of the total $h\nu$, an insufficient amount in each case to equal the work of extraction.[1] For certain wave lengths and atomic numbers the amount of radiation thus scattered per electron approximates the amount predicted by J. J. Thomson's classical formula

$$I'_\phi = \frac{I}{r^2}\ \frac{e^4}{m^2c^4}\ \frac{1+\cos^2\phi}{2} \qquad (22)$$

for the intensity I'_ϕ of X-rays scattered per free electron at an angle ϕ from the direction of the incident beam of intensity I, r being the distance from the scattering electron to the point of observation of I'_ϕ. The total scattering in all directions given by the above formula leads to a scattering coefficient per electron

$$\sigma_e = \frac{8\pi}{3}\ \frac{e^4}{m^2c^4} = 6.66\times 10^{-25}\ \text{cm}^2. \qquad (23)$$

corresponding to a circle of radius 4.6×10^{-13} cm. When however the wave length of the radiation is long compared with the size of the atomic electron swarm there is a constructive interference of the radiation scattered by the individual electrons so that N of them instead of scattering N times the amount σ_e behave (in the limiting case of very long wave lengths) as though the charge e (raised to the fourth power in the formula) were first multiplied by N so that ten electrons become equivalent to $10^4 = 10{,}000$ independently scattering electrons. The presence of m^2 in the denominator, however, reduces the ratio by the divisor $10^2 = 100$ so that the net effect of ten electrons is one hundredfold that of one. All this is fairly reasonable according to classical concepts.

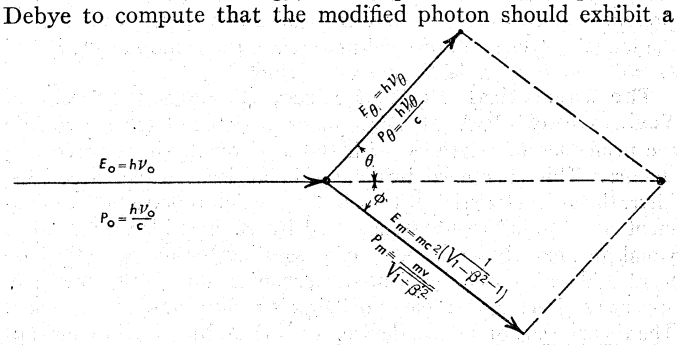
It has been possible, by study of the intensity of unmodified X-ray scattering as a function of scattering angle for gaseous atoms and also for atoms in crystal lattices, to learn a very great amount about the statistics of the spatial distribution of electrons around the atomic nuclei both in single atoms and in solid crystals, to reveal the sizes of the cloudlike electron shells and to map the regions of periodically varying electron density in crystals.

It is as the wave length becomes short, however, that our classical ideas of scattering break down completely and the scattering becomes very much lower than Thomson's formula predicts. The Compton effect here becomes pronounced.

The Compton Effect.—It had been observed by J. A. Gray (1920) that short wave-length radiation, after scattering from carbon and other low atomic number atoms, was somewhat more absorbable than the primary radiation. It is a simply demonstrable consequence of Maxwell's electromagnetic theory of radiation that when any quantity of radiant energy W is absorbed by a charged particle there will be exerted upon the latter an impulse (or quantity of momentum) in the direction of propagation, of magnitude W/c where c is the "velocity of light in vacuo." Thus a photon of energy $h\nu$ should carry with it the ability, if completely absorbed, to exert a momentum $h\nu/c$ on an electron (or any other charged particle). In 1923 Arthur Compton and simultaneously P. P. Debye proposed the daring hypothesis that a photon of X-rays might be regarded as a small projectile able to hit one and only one electron in the scattering atom (actually their initial theory envisaged as a first approximation only a free electron). The idea was that the photon bouncing off the electron (in the direction of scattering that was being studied) would deliver a blow giving, at the expense of some of its energy, a recoil velocity and a recoil energy to the electron in accord with the familiar laws of conservation of energy and

[1] The electrons must not be extracted by the radiation, their final energy states must be the same as their initial energy states before scattering the radiation in order that the latter shall not be modified in frequency. There is a finite chance according to ideas first enunciated by A. Smekal that this can occur even if the quantum energy $h\nu$ *exceeds* the energy of extraction. One may perhaps think of the electron as momentarily ejected and then immediately falling back to its original state.

momentum applicable to larger colliding masses. The energy so lost by the photon, initially of energy $h\nu_0$, would result in a new lowered frequency ν_θ corresponding to a lesser quantum energy, $h\nu_\theta$. Clearly the loss of energy should increase with increasing angle of scattering θ. The accompanying fig. 11 shows the simple vector momentum diagram with the help of which, together with the conservation of energy, it was possible for Compton and Debye to compute that the modified photon should exhibit a



REDRAWN FROM RICHTMYER AND KENNARD, "INTRODUCTION TO MODERN PHYSICS" (MCGRAW-HILL BOOK CO.)

FIG. 11.—VECTOR DIAGRAM SHOWING THE CONSERVATION OF MOMENTUM IN ITS TRANSFER FROM PHOTON TO ELECTRON IN THE COMPTON EFFECT

P_m is the momentum received by the recoiling electron. P_0 and P_θ are the momenta of incident and scattered photons. θ is the "scattering angle" through which the photon is deviated. Formulae for the energies E_0, E_θ and E_m are also given. The fundamental law of conservation of momentum requires that the vector sum of P_θ and P_m after the collision, that is to say the dotted diagonal of the parallelogram, shall be equal in magnitude and direction to the initial momentum of the radiation P_0 before the collision

shift toward longer wave lengths relative to the primary wave length and independent of the value of the latter given by

$$\lambda_\theta - \lambda_0 = (h/mc)(1-\cos\theta) = 0.0242\times 10^{-8}(1-\cos\theta) \text{ cm.} \quad (24)$$

Compton outdid Debye in that he immediately and quantitatively demonstrated this shift in wave length in the laboratory together with its dependence on the scattering angle θ. The effect on the entire world of physicists was electrifying. Confirmations followed almost immediately from many other laboratories, notably by P. A. Ross, J. A. Becker, S. K. Allison and W. Duane. The theory shows that the recoiling electron must have a forward velocity in an obvious well-specified direction and an energy E_r given by

$$E_r = h\nu_0 \frac{\xi(1-\cos\theta)}{1+\xi(1-\cos\theta)} \text{ wherein } \xi = \frac{h\nu_0}{mc^2} \quad (25)$$

Immediately following Compton's prediction of their existence, these "recoil" electrons were discovered in the laboratory by C. Wilson and by W. Bothe. Compton and Alfred W. Simon (1925) showed with fair quantitative accuracy in the Wilson cloud chamber that both the scattered photon and the recoil electron obey the required laws in individual scattering processes and A. A. Bless has checked their energy accurately by the method of the magnetic spectrograph.

E. Schrödinger (1927) proposed an alternate theory of the Compton effect based entirely on a wave picture in which the initially free recoiling electron must be replaced by its train of De Broglie waves, completely unlocalized in space, which act to reflect the X-radiation like the atomic layers in a crystal. The change in wave length, in this picture of the process, is to be ascribed to a Doppler effect caused by the velocity of recoil of the reflector. No basis for preference can be shown for either viewpoint, and we have here a striking example of the dual aspect of all nature. N. Bohr after very painstaking study of the entire duality principle resumed his work in what he calls the two principles of "complementarity" and "renunciation," *i.e.* the wave and the particle concepts are complementary aspects of the same phenomena (like the two sides of a coin which cannot both be seen at once) and we must renounce further efforts to reject either one or to harmonize them.

Evidence for Motion of Atomic Electrons.—The scattering electron in the original Compton-Debye theory was assumed free and initially at rest. P. A. Ross proposed and G. E. M. Jauncey, J. W. M. DuMond and H. Kirkpatrick have each analyzed the case where the electron possesses an initial velocity before the scattering process takes place. Thus not only does the photon deliver a blow upon the electron but the electron (like a baseball bat) may (1) either happen to hit back, thus decreasing somewhat the loss of photon energy, or (2) may recede as it receives the blow (as in "bunting") so as to increase the loss of photon energy. Now there is no such thing as a supply of free stationary electrons in nature to use as a scattering agent. All the electrons in sufficient numbers for this purpose are in the atoms of solids, liquids or gases. In monatomic gases the electrons may be expected to be in motion (to have momenta) quite rigorously as the wave mechanics predicts for single atoms. In solids or liquids, on the other hand, the electronic momenta will not be quite the same as for free atoms because of the perturbing effect of neighbouring atoms. In the case of metallic solids, conductors of electricity, a theory of A. Sommerfeld proposes as a first approximation that about one electron per atom in the metal crystal lattice is substantially unattached to any particular atom and wanders about freely so that the totality of all such electrons forms a "free electron gas" in the interspaces of the lattice. The quantum theory (principle of exclusion in phase explained above) requires the electrons of this "degenerate gas" to be in a state of extremely rapid motion at velocities on the average substantially higher than they would have as outer electrons in a free atom. (They are crowded into less volume in the crystal lattice than in the free atom and hence their "momentum hedgehog" must occupy more momentum space.) These electron velocities required by Sommerfeld's theory and the corresponding electronic energies are enormously greater at terrestrial temperatures than an equipartition of the ordinary thermal energy between the atoms and the electrons can alone account for.

These ideas would lead us to expect a considerable broadening of the Compton modified line as a statistical result of the individual shifted scattering processes from electrons rapidly moving in every conceivable direction, and exactly this was observed by DuMond and Kirkpatrick both with solid and with gaseous scatterers.[1] The structure and width of the broadened modified line is in complete accord with the magnitude and distribution of electron velocities predicted not only for single atoms and molecules (helium and hydrogen gases as scatterers) but also for the free electron gas in a solid electrically conducting crystal. We thus have quantitative experimental verification of the high velocity free electron degenerate gas in a conductor predicted by Sommerfeld, at least as concerns the velocities and the approximate number of electrons which belong to the class, and a refutation of the older statistical idea that such free electrons should on the average possess only the same energy as that associated with the thermal vibration of the atoms of the crystal lattice. The breadth of the modified line in wave-length units should diminish with decreasing scattering angle and also with decreasing primary wave length in a definite way and DuMond and Kirkpatrick have shown experimentally that it does, thus confirming the validity of the entire picture. The dynamic character of the electronic structure of the atom and of the electrons in solids is thus rather directly confirmed. Two figures, 1 and 2 on Plate III, are shown giving the spectra of (1) the K lines of molybdenum after scattering at three different angles from a block of graphite and (2) the K lines of molybdenum, silver and tungsten respectively each after scattering from graphite at about the same angle. In these spectra the modified α line is very clear but the modified β line can also be seen with less intensity. The sharp unmodified α and β lines formed by the unmodified scattering process are also clearly

[1] The first indubitable evidence of the broadening was in 1928 (*Proc.*, Natl. Acad. Sci., vol. 14, p. 875). It was not observed with certainty in the earlier work of Compton and many others because of the very low intensity of scattered X-rays which led earlier investigators to sacrifice spectral resolving power and accurate definition of the scattering angle in exchange for increased intensity. Compton, Ross and others had cautiously stated that their results led them to suspect such an effect but it was not proved and an index of this early uncertainty is the fact that even as late as 1930 N. Gingrich in Compton's laboratory reported the observation of very narrow modified lines in which he thought the $K\alpha$ doublet was clearly resolved, an observation which no one up to 1945 had been able to repeat. It was only after the development of an especial spectrometer permitting greatly increased intensity coupled with great homogeneity of the scattering angle that DuMond and Kirkpatrick were enabled to study the broadening with quantitative certainty.

visible. (The modified lines in the picture are designated α_c and β_c while the c is omitted in the subscript for the unmodified lines.) Figs. 1 and 2 obviously not only illustrate the effect of the broadening of the Compton line by the electronic motions and the variations of the breadth with scattering angle and primary wave length; they also clearly illustrate the Compton shift itself, its variation with scattering angle and its independence of primary wave length, all in perfect accord with the theoretical picture of the process.

In modified scattering the light pressure may be thought of as the agent which ejects the electron from the atom with the energy of recoil. The fact that the electron is initially bound to the atomic nucleus, which therefore shares slightly in the momentum transfer, introduces a slight correction to the Compton shift (in wave length). This correction, computed by F. Bloch, was verified in very careful and ingenious work by Ross and Kirkpatrick. In cloud chamber experiments with polarized X-radiation F. Kirchner has shown that the most probable direction of ejection of Compton recoil electrons is perpendicular to the electric vector as one would expect on the light-pressure ejection hypothesis. It is very clear that Compton modified scattering is an almost-private transaction between photons and single electrons in the scatterer.

If photons can be used as projectiles or probes to study the velocities of the electrons in matter, why not electrons? A. L. Hughes at St. Louis, Mo., has done exactly this. Certain classes of electrons after scattering from gas atoms exhibit modifications of their energies and momenta (or De Broglie wave lengths if we prefer) which yield information as to the atomic electron velocity or momentum distributions in completely satisfactory accord with the X-ray results of DuMond and Kirkpatrick. The method had not, in 1945, been extended to electrons in solids.

The Bohr-Heisenberg Uncertainty Principle (1930).—From this evidence that both radiation and matter act like particles, combined with the equally good proof that they have the characteristics of waves, there flows a consequence of the deepest philosophical and physical significance. This consequence is that there is a definite and fundamental limit placed upon the precision of prediction of the future actions of any object or system as based upon observations made with any form of radiation or matter. Space is not available to give here the interesting chain of reasoning leading to this conclusion. (*See* UNCERTAINTY PRINCIPLE.) This principle asserts that no physical experiment of any present known type can be devised which will simultaneously measure the momentum p_x and the position q_x of a system to precisions of order p_x and q_x respectively greater than the limits prescribed by the inequality

$$\Delta p_x \Delta q_x > h. \qquad (26)$$

A sufficient relaxation of precision in either factor, momentum or position, will permit any desired degree of precision in the other but the product of their uncertainties cannot be less than the constant, h. To predict the course of future events with certainty from present observations (the postulated ideal possibility of the determinists) we must have information other than the partially statistical data contained in the De Broglie-Schrödinger ψ-waves (not just their moduli $\psi\ \bar{\psi}$). Such information is physically inaccessible. To give an example of the far-reaching philosophical conclusions of a rigorous nature flowing from the uncertainty principle, a partial quotation from P. S. Epstein in *The Scientific Monthly* (1937) is given as follows:

"The views of modern physical science are incompatible with the doctrines of predestination and determinism which are no longer tenable. This statement should not be construed as an attack on religion and metaphysics; in fact it should be a boon to them. The metaphysicians were those who invaded the field of science by postulating as truth the religious equivalent of the law of causality, [thus creating] for themselves difficulties which they could not resolve. Science is now showing them the way out of the dilemma. . . ." [From the old point of view, determinism and free will were supposed tightly linked as mutually exclusive alternatives but this traditional linkage] "is converted into its opposite on the newly shifted ground of science. . . ." "The discoveries of physics [ringing the death-knell of mechanistic determinism] do not change in any way the status of the problem of free will. . . ." "The existence of free will is just as incompatible with the new non-deterministic physics as with the old deterministic. However, living organisms may be possessed of free will, if they are not completely controlled by the laws of physics. . . ." "Although, at present science cannot answer the question whether the laws of the human psyche and of dead matter are the same or not, *it will be able to answer it in the course of time.*"

The Theoretical Work of Dirac, Its Consequences and Verifications.—P. A. M. Dirac made an attempt (1928) to fuse the principles of relativity with those of quantum or wave mechanics. This succeeded brilliantly in at least three directions. First, the characteristics of the electron which required the assignment of a "spin" to it as suggested by G. E. Uhlenbeck and S. Goudsmit, namely its property of possessing both a magnetic moment and a definitely associated mechanical angular momentum, appear as direct consequences of Dirac's rather simple ingredients. The theory was, of course, devised with this objective in view, but its other successes are the more brilliant because they were unforeseen. Second, the theory predicts the existence of a positive counterpart of the negative electron (indicating that the two should have comparable[1] masses), and just such a particle was discovered four years later by C. Anderson in 1932 (verified by similar observations six months later by P. M. S. Blackett and G. P. S. Occhialini) in his studies of cosmic rays with the Wilson cloud chamber. *See* fig. 3 on Plate III. Third, Dirac's theory envisages the possibility of the "creation" and also "annihilation" of matter, in the form of pairs of positive and negative electrons, by the process of its conversion from or into radiant energy, and these processes have also both been firmly established as experimental facts. Colliding positive and negative electrons, say of equal velocities, can neutralize each other's charge and the total kinetic mass, $2m$, of the two particles, whose relativistic energy equivalent in ergs is $2mc^2$, can reappear as the mass of two photons of quantum energy $h\nu$ which, if no third body intervenes appreciably in the reaction, will satisfy the equation

$$2mc^2 = 2h\nu \text{ (equivalent to 1,022,000 electron volts).} \qquad (27)$$

Radiation of this type was first observed by C. Y. Chao (1930) and its explanation as "annihilation radiation" was established on a firm experimental basis by F. Joliot in 1933 and by J. Thibaud in 1934. Almost but not quite conversely a photon of energy $h\nu$ in the presence of a strong nuclear field can be converted into a positive and a negative electron, previously nonexistent, according to the equation

$$h\nu = m_1c^2 + m_2c^2 \qquad (28)$$

where m_1 and m_2 are the kinetic masses of the two electrons (m_1 and m_2 may differ slightly if the two oppositely charged electrons have somewhat different kinetic energies, a possibility which enters through the possible sharing of momentum with the nucleus). This creation of electron pairs was first observed by C. D. Anderson and S. H. Neddermeyer in 1933 (*see* fig. 4 on Plate III). These reactions are features quite appropriately to be classified under the nature of X-rays. The energy equivalent of the "rest mass" of the electron is about a half million volts, so that even before the advent of D. W. Kerst's "Betatron,"[2] it was not theoretically impossible to produce artificially X-radiation capable of materializing itself into electron "pairs."

Dirac's theory requires the conclusion that such a weird state of affairs as a particle with negative kinetic energy (and therefore imaginary[3] velocity) can be a physical reality. Indeed he formulates the supposition that what we call empty space is everywhere filled densely with negative electrons in negative kinetic energy states as closely packed as Pauli's principle of exclusion in phase

---

[1] At the time, Dirac was much troubled by the fact that the only elementary positively charged particle then known, the proton, was so much heavier than the negative electron.

[2] The Betatron, in 1945 a commercially available instrument, can give electrons a kinetic energy equivalent to 20,000,000 volts or more. Equipment capable of twenty- or thirtyfold this voltage by other methods is not beyond the realm of expectation.

[3] We mean here imaginary in the sense of the algebraic symbol $\pm\sqrt{-1}$.

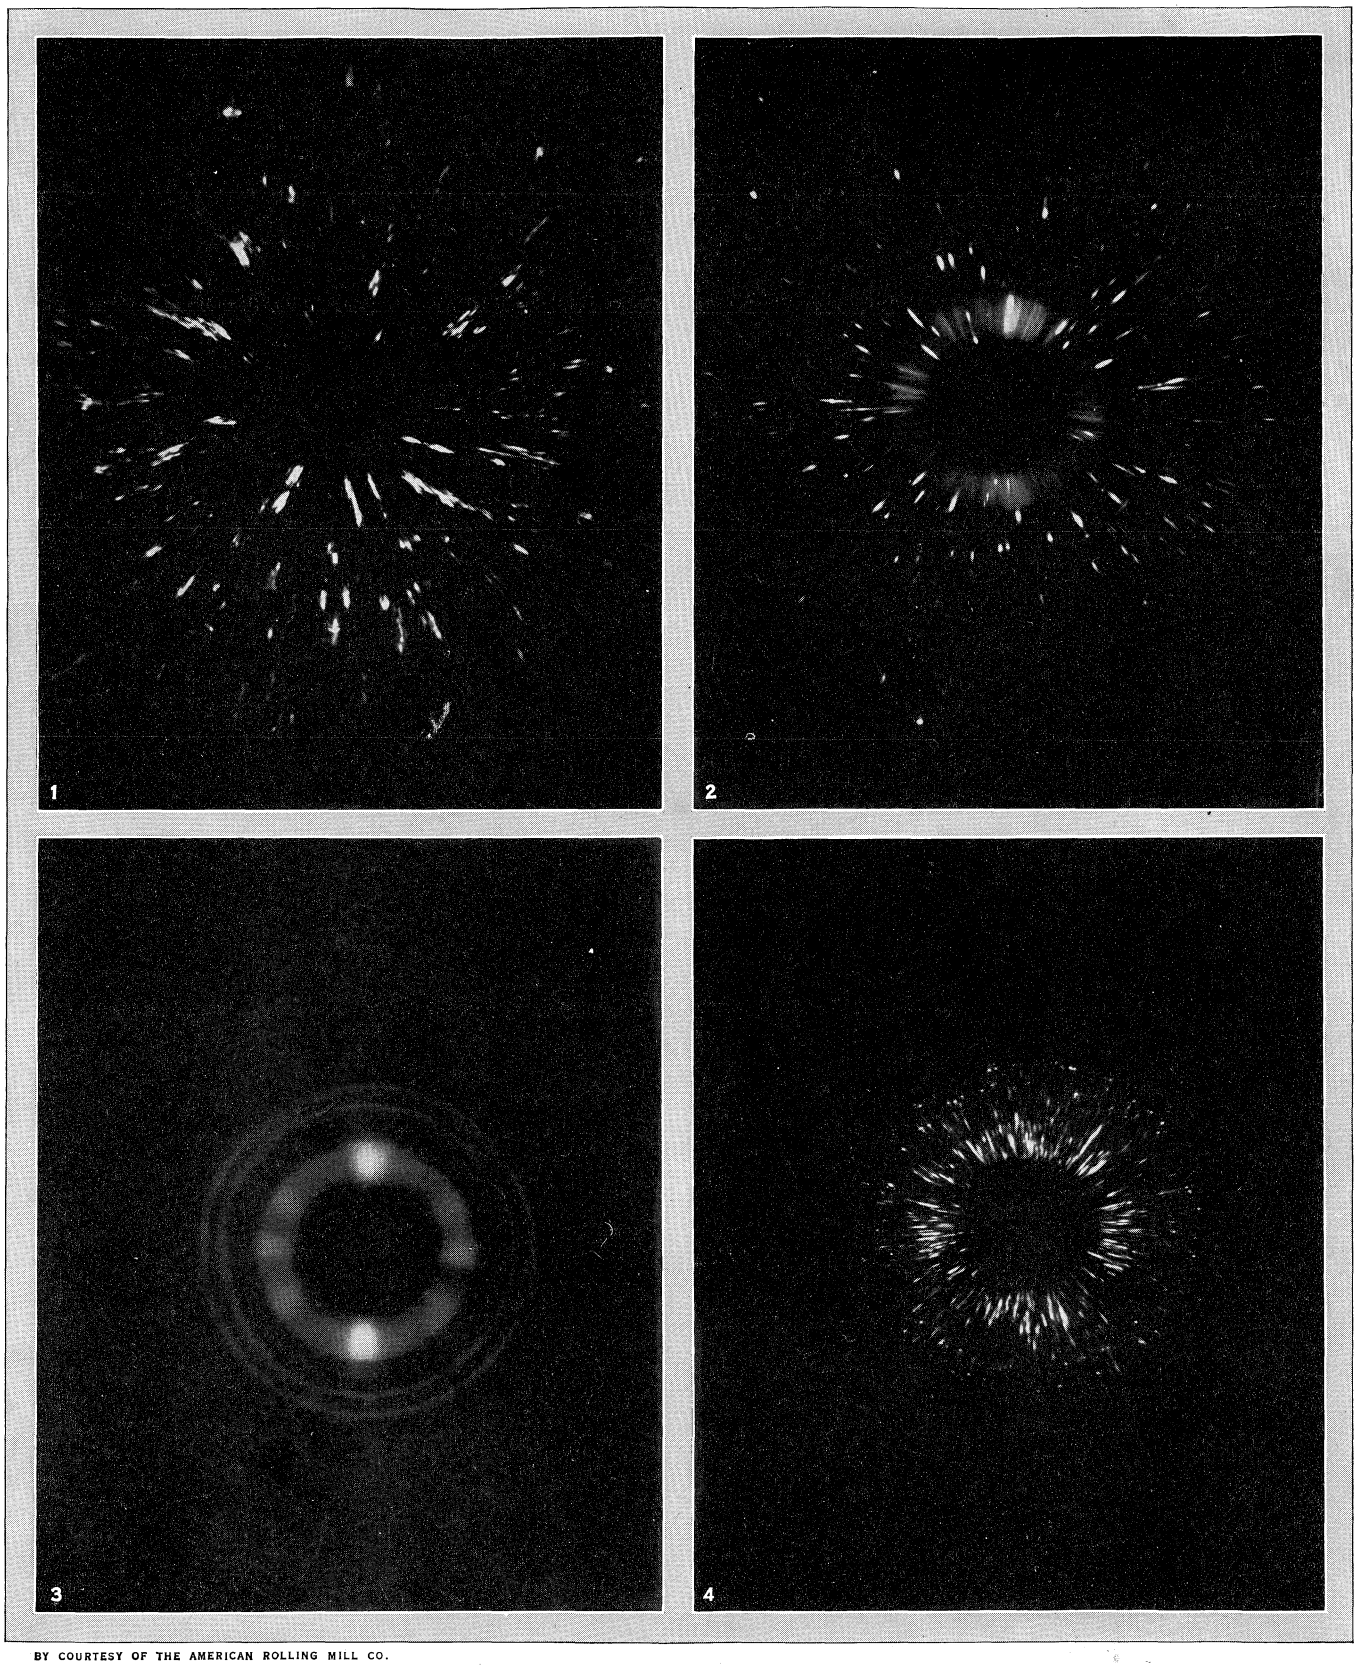
X-RAYS, NATURE OF



BY COURTESY OF THE AMERICAN ROLLING MILL CO.

X-RAY DIFFRACTION OF IRON AS IT PROGRESSES FROM THE INGOT TO ONE OF THE FINAL PROCESSES IN MANUFACTURE

1. Piece of ingot of typical cast structure photographed by the usual Laue procedure. The grains are quite large and have been very much strained in cooling
2. Thin bar from the continuous mill showing a considerable reduction in grain size, and amount of strain, as evidenced by the smaller and more uniform spots. The fine radial streaks near the center show the presence of some fragmentation of grains. The slight tendency towards the appearance of groups of spots on the central band indicates the beginnings of a preferred orientation of grains
3. Very fine grained structure of nicely oriented crystals in highly cold rolled iron. The absence of individual spots proves the smallness of the crystals, while the large spots on the various rings show the cubic iron crystals to be, to a very considerable extent, arranged in the sheet with a cube face parallel to the surface of the sheet and a face diagonal parallel to the rolling direction
4. The thoroughly annealed sheet, heat treated after the severe cold roll, is shown completely re-crystallized into slightly strained grains of quite uniform size. No crystal fragments are present and the preferred crystal orientation caused by the cold rolling has completely disappeared, leaving a structure with practically no directional properties

1. Spectra of molybdenum K-lines scattered by carbon at three different scattering angles θ illustrating both the Compton shift and the DuMond-Kirkpatrick broadening in their dependence on θ. The unmodified α_1, α_2 and β_1 lines of the molybdenum K spectrum are clearly visible and testify by their sharpness to the high resolving power. The broad shifted β_c and shifted α_c lines show increasing shift and increasing breadth as the scattering angle increases in complete quantitative accord with the theory as photometric measurements show. The broadening is evidence of the motion in the atom of the electrons which are the scattering agents. The shifted α_c line is a superposition of the shifted α_1 and shifted α_2 lines and is therefore a little broader than the shifted β_1 line

2. Spectra of scattered X-rays of three different wave-lengths λ scattered by carbon at about 155 degrees scattering angle θ, illustrating both the Compton shift and the DuMond-Kirkpatrick broadening in their dependence on λ. The wave-lengths in x-units are shown on the scales. The unmodified β and α lines can be clearly seen in the first (molybdenum) spectrum but with diminishing primary wave-length the unmodified scattering becomes too faint to be seen so that reference lines have been made on the edge of the tungsten spectrum by means of an auxiliary exposure with direct radiation to establish their positions. The broadened and shifted β and α lines of the scattered spectrum can be seen in all three cases. The constant shift and the diminishing broadening (in wave-length units) can be clearly seen and photometric measurements show both effects to be in good accord with the theory of the scattering process and of the motion of the scattering electrons in the atoms of the scattering substance

COURTESY OF (3, 4) CARL D. ANDERSON

3. A photograph of great historical interest made by C. D. Anderson in 1933 with the Wilson cloud chamber provided with a strong magnetic field capable of deflecting fast electrons. He inserted a 6-mm. thick lead septum horizontally across the chamber. In this picture the track is one left by a positron. This positron possessed an energy of 63,000,000 electron volts before entering the lead plate *from below* as shown by its curvature in the known magnetic field. After penetrating the plate its curvature shows that it proceeded with an energy of 23,000,000 electron volts. The change of energy, in good accord with the loss to be expected for such an electron in 6 mm. of lead, proves definitely the direction of motion of the particle and, therefore, with the known direction of the magnetic field enforces the conclusion that it is positively charged. The low specific ionization as attested by the density of the track and also the low energy loss in the lead exclude the possibility that the particle could be a proton. This was one of the first clinching evidences for the positron. This photograph is reproduced from Anderson's Nobel Prize lecture

4. The creation of an electron-positron pair in a lead plate by hard gamma rays from Th C'' shown in a Wilson cloud chamber photograph by C. D. Anderson. This photograph is reproduced from Anderson's Nobel Prize lecture. The two particles responsible for these tracks produce equal specific ionizations as judged by the track density and hence have the same mass. From the known direction and intensity of the magnetic field in which the chamber was operated (800 gauss) one concludes that the track of greater curvature was made by a negative electron of about 0.7 million electron volts energy while the track of lesser curvature was made by a positron of 0.8 million electron volts energy. Anderson and Neddermeyer have photographed thousands of similar examples of the same process wherein the hard gamma rays from Th C'' (of known quantum energy, $h\nu$=2.62 M.E.V.) falling on lead, aluminum or carbon produced the same result. In no case did the aggregate kinetic energies of pairs so produced exceed 1.6 M.E.V. thus leaving just the required margin of energy (1.02 M.E.V.) for the creation of the two masses. In this photograph the direct image is at the left; the right hand reversed image, taken with a mirror, is for stereoscopic observation. Stereoscopic viewing shows that the third track near the bottom of the picture is of entirely independent origin

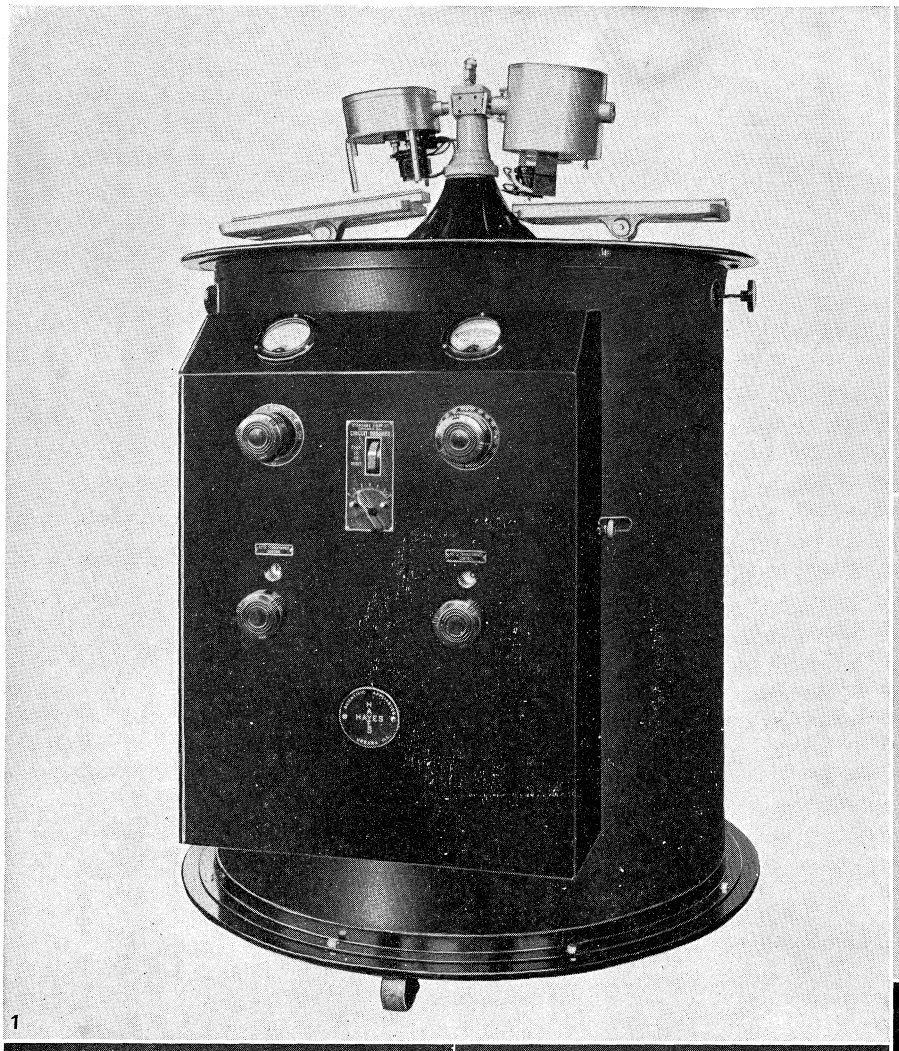
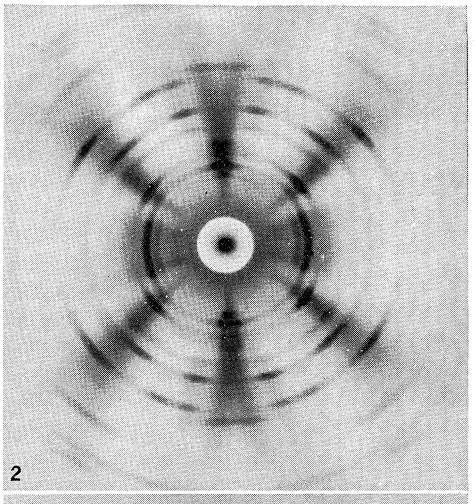
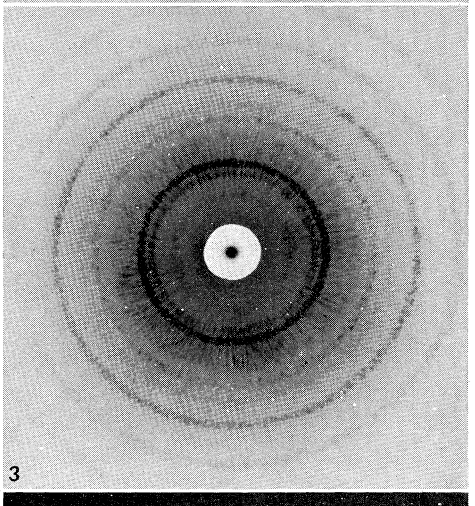
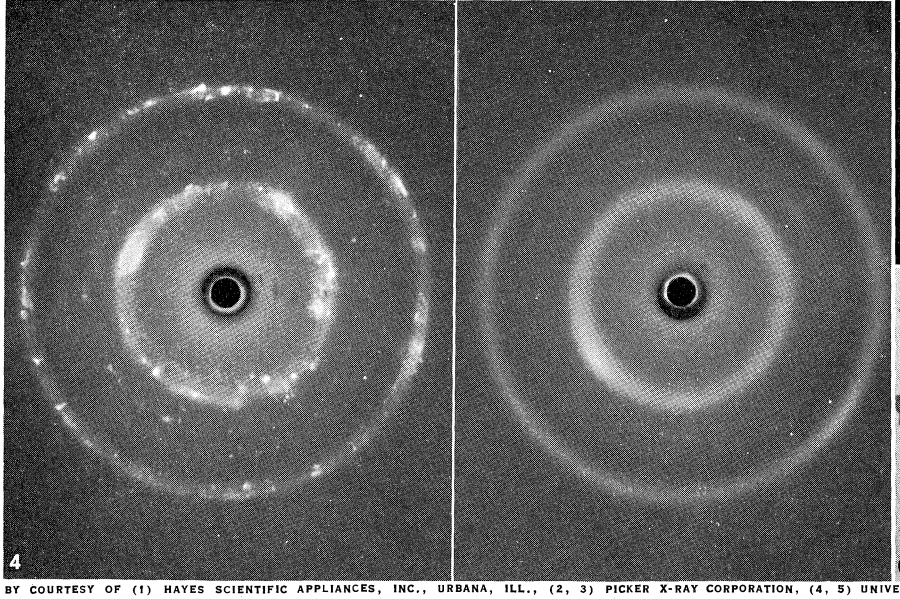
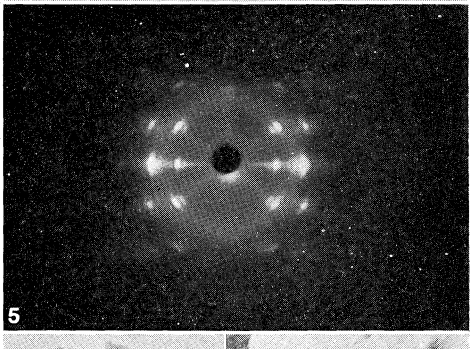
1. X-ray tube for operation at 2,000,000 volts producing beam capable of penetrating 12 inches of steel; and diagram of construction
2. Million-volt radiographic unit in use in plant of Babcock & Wilcox, Barberton, Ohio
3. X-ray examination of Gainsborough's "Blue Boy," showing (right) hidden painting of man with white stock above head in visible painting, which accounts for light shadow (pentimento)
4. Microradiographs of aluminum-copper alloy used in aircraft construction, compared with corresponding photomicrographs. Magnification, 100 diameters
5. Microradiograph of eye of common housefly. Magnification, 150 diameters
6. Radiographic classification and sorting of oranges; upper, juicy, high quality; lower, pithy, low quality

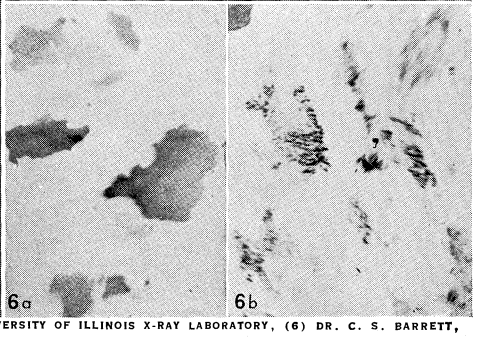












BY COURTESY OF (1) HAYES SCIENTIFIC APPLIANCES, INC., URBANA, ILL., (2, 3) PICKER X-RAY CORPORATION, (4, 5) UNIVERSITY OF ILLINOIS X-RAY LABORATORY, (6) DR. C. S. BARRETT, CARNEGIE INSTITUTE OF TECHNOLOGY

1. Multiple X-ray diffraction apparatus, showing two types of cameras supported from head of diffraction tube
2. Diffraction pattern of rolled aluminum sheet showing high degree of preferred orientation of crystal grains in sheet
3. Diffraction pattern of well annealed sheet steel with complete absence of preferred orientation introduced in rolling, and grain growth from spotted rings
4. Back reflection patterns from two sections of same aluminum alloy aeroplane motor castings, showing great difference in texture. With this method as a guide, casting techniques were improved until all sections, thin and thick, gave the same patterns and thus differential strains and failures were eliminated
5. Diffraction pattern of stretched rubber, showing crystallization and parallel arrangement of giant molecules; this behaviour has served as a guide in production of satisfactory synthetic rubber
6. Diffraction micrographs by new Barrett technique; A. individual grains in strain-free sheet of pure aluminum; B. effect of strain in grains introduced by 20% elongation of specimen

will permit (with no defined lower limit to this sea of negative energies). A few rare exceptions or holes in this close-packed array, created by photons after the general manner of the photo-electric effect are what appear to us, according to Dirac's picture, as positive electrons or "positrons."

The existence of negative kinetic energy states is not as fantastically "out of this world" as one might think. There seems to be experimental evidence that charged particles have a finite chance of penetrating potential barriers, if these latter are not too thick relative to the De Broglie wave length of the particle, even if the initial kinetic energy of the particle is inadequate to scale the barrier. The Ramsauer effect, in which atoms become surprisingly transparent to electrons of appropriate De Broglie wave length is of this nature, and E. U. Condon, R. W. Gurney and also G. Gamow explain the occasional escape of the constituent particles from radioactive nuclei also in this way. From the wave point of view this traversing of such otherwise insurmountable potential barriers is analogous to the fact that in physical optics the wave disturbance is to be found, albeit weakly and with penetration of the order of fractional wave lengths, in regions forbidden by geometrical optics. Now from the particle point of view, whose equal validity it seems unwise to contest, the corpuscle in its classically forbidden transit through the region of such potential barriers must have either (1) negative kinetic energy, or (2) energy borrowed temporarily from some unknown source, or (3) we must abandon the principle of conservation of energy. In 1945 these three possibilities seemed almost indistinguishable.

Inadequacies of Physical Theories.—We have tended in this review to stress the successes of the various theories which have been advanced to explain observed phenomena and which have frequently successfully predicted new phenomena later verified by experiment. The reader must not conclude however from this that any of these theories are in a satisfactory state. All are fragmentary, suffering from the fact that they have limited fields of applicability whose boundaries are ill defined. For example, J. C. Maxwell's theory of the electromagnetic field is very satisfactory indeed for the explanation of all the phenomena of radio waves. It starts to exhibit its weakness the moment the frequency reaches such values that the photon energy, $h\nu$, becomes comparable with characteristic energies in molecules or atoms. This is however not a well-defined boundary and there is no reason whatever to suppose that the nature of electromagnetic radiation has changed abruptly at some definite frequency or wave length. Even radio waves are undoubtedly quantized. There simply was no inclusive and satisfactory theory in 1945 for the electromagnetic field and its radiant energy. This state of affairs exists in every domain of physics. No satisfactory theory links gravitational and electrical phenomena. There is no satisfactory amalgamation of the theories of matter and of radiation. The mysterious ratios between the masses of the various fundamental particles and indeed nearly all the seemingly arbitrary relationships between the universal constants of nature are hardly understood at all. All physical theories are of the nature of half truths; they must have something right about them to claim our attention but improve them as we doubtless shall, it hardly seems likely they can ever escape from some incompleteness simply because nature proves to be so richly diverse and the number of new things to be explained seems always to keep pace with solutions. This is not in the least discouraging; quite the contrary, for it promises unlimited vistas of fascinatingly interesting human activity and we must never forget that the half truths we capture and incorporate into the scientific edifice are permanent gains. Relativity has not destroyed Newtonian mechanics; it has only refined and extended its predecessor without which as a starting point it would not have been possible. "The finest fate to which any theory can aspire is to become a special case of a better and more inclusive theory."

Conclusion.—Space limitations prevent inclusion in this article of a host of interesting subsidiary topics. Little or nothing has been said of the physical optics of X-rays such as: (1) M. Siegbahn's correction to the Bragg law necessitated by X-ray refraction; (2) total reflection of X-rays and the technique brought to astonishing accuracy by J. A. Bearden and others of their diffraction on artificial ruled gratings; (3) refraction of X-rays by prisms and prism spectra; (4) proof of their wave nature even down to $\lambda=8.3\times10^{-8}$ cm. by slit diffraction; (5) dispersion curves of X-rays near absorption edges; (6) polarization of X-rays by crystal reflection. The entire fascinating field of X-ray satellites explained by D. Coster and R. de L. Kronig and verified by F. Hirsh and by L. G. Parratt has been omitted as has also the evidence from the structure of absorption edges as to the less tightly bound or free electrons in solids. The enormous field of crystal structure study by a great number of methods has barely been mentioned. Nothing has been said of the technical means for supplying energy to X-ray tubes including the new Betatron of D. W. Kerst with electron energies of many millions of volts nor of the huge field of chemical, mineralogic and crystallographic applications. Many of these subjects are treated in other *Encyclopædia Britannica* articles and in the original research articles. The effort here has been: (1) to paint a thumbnail sketch of the unfolding of a complete branch of science from its inception, conveying if possible a little of the dramatic excitement it held for the participants, and the object lesson of their world-wide, free, spontaneous working co-operation as a result of the freedom of exchange of their information; (2) to thread the story on the most important news item it contains, namely the new concepts of radiation and matter and their fundamental duality, with their enormous implications; (3) to illustrate the primary importance of the search for truth and understanding, which at first always appear as "useless" knowledge, but inevitably open the door to all useful applications.

USE IN MEDICINE

The extraordinary value of Röntgen's discovery has been nowhere more in evidence than in medicine, and for a full discussion of the use of X-ray in medicine, *see* RADIOLOGY; RADIO-THERAPY; X-RAY TREATMENT.

MODERN INDUSTRIAL APPLICATIONS

The industrial applications of X-rays fall mainly into two divisions, the first being radiography, including the newly developed special technique of microradiography. Under this heading will also be considered visual examination by means of a fluorescent screen, which has obvious advantages over the photographic method in many instances. The second main division is concerned with the more difficult technique known as X-ray crystal analysis.

Radiography—The Examination of Gross Internal Structure.—In the science of engineering X-rays have been shown to have a most important place. Engineering materials must be constantly studied for weaknesses. Castings are always subject to flaws and cracks which very often are discovered only after expensive machining has been completed; they may then have to be scrapped and the work is wasted. If X-rays could be used to examine all castings, they might be universally employed, but unfortunately there is a limiting thickness of metal beyond which X-rays cannot penetrate. However, in the year 1945 this limiting thickness was nearly 12 in. of steel as a result of the development and commercial use of 1,000,000 and 2,000,000 volt X-ray tubes. (*See* figs. 1 and 2, plate IV.) Even greater thicknesses are penetrated by X-rays generated at 20,000,000 volts in the new commercial model of the electron accelerator or Kerst betatron. Metal ingots and castings below this thickness are all capable of X-ray inspection, although owing to the complicated shape of many castings, their examination by X-rays is not always practical. The plates give illustrations of radiographs of castings. The white lines and patches indicate flaws—places where the metal departs from its normal homogeneity. They represent either blowholes, inclusions or cracks.

It is well to remember that radiography is the production of a shadow picture. The shadows exist in the picture because X-rays are absorbed to different degrees by different media. If we were to radiograph a perfectly homogeneous piece of muscle or steel we should obtain a photographic plate quite uniformly blackened because the X-ray absorption would be uniform. The absorption of X-rays by any material depends, first, upon the material itself—in general, the higher its atomic weight the more absorbent it is—and second, upon the penetrating power or wave length of the X-rays. The latter condition depends, generally speaking, on the voltage which is applied to the terminals of the X-ray tube. Thus, remembering the first condition, lead is more absorbent than iron, iron more than aluminium, and aluminium more than organic substances such as flesh. At the same time, if we use an X-ray tube having a tungsten target, the X-rays will be more penetrating when generated by 200,000 volts than at

100,000 volts, and so on. If a beam of X-rays of suitable penetrating power is passed through an object of varying thickness or varying composition, the emerging rays (which affect the photographic plate) will have different intensities corresponding to the variations in the object, and the result will be a mixture of shadows of varying degrees of intensity. For example, a hidden cavity in a piece of metal means that the total thickness of the material is less at that particular place, and the X-ray absorption will also be less; therefore, we shall obtain more intense X-rays in that area, resulting in a darker patch on the negative. If, instead of a photographic plate, we are using a fluorescent screen, we shall see a brighter patch on the screen corresponding to the more intense radiation.

Unfortunately, of the energy represented by the X-rays that fall on the photographic film only a very small fraction (less than 1%) has any photographic effect; the remainder simply passes through the emulsion without affecting it. The photographic effect, however, may be increased by the use of suitable intensifying screens that absorb more of the rays and in consequence emit actinic rays which reinforce the photographic image. There are many details of correct technique for obtaining sharp radiographs revealing smallest defects, which must be learned from theory and experience. For example, specifications are rigidly set up by the U.S. army air forces and other agencies. These involve distance and size of focal spot of the X-ray tube, protection of the film from scattered and secondary radiation in the specimen, correct exposure charts, and stereoscopic exposures for locating the depth of a defect. When the object has very irregular edges it may be convenient to use a wax impregnated with lead or other heavy element. Another method is to immerse the specimen in a liquid having about the same coefficient of absorption as the specimen.

A certain number of patches or cracks may occur in a casting and still not be serious enough to entail its rejection. The actual significance of the X-ray picture in terms of mechanical strength is a matter for experience in interpretation. The positions and dimensions of metallic flaws may be calculated with great accuracy by stereoscopic methods, and the radiograph becomes an infallible guide as to the soundness of material.

The faults to which castings are subject demand continuous research in the actual process of casting various metals, and here again X-rays have become a most valuable adjunct to the conventional methods. The castings produced by a certain method are radiographed and weak places noted, the technique is then suitably modified, the resulting castings again radiographed, and so on. Among the castings and forgings being radiographed by 1945 on a routine service scale, were those for gun carriages, turbine shells and parts, oil stills, aeroplane parts, locomotive parts, high pressure steam installations, and expensive steel cylinders. The method is in general use in the U.S. and installations are in use for the same purpose in the factories and dockyards of the British government. The greatly expanded use during World War II of light aluminium and magnesium alloy castings was made possible to a large extent by radiographic control of soundness, both as a routine procedure and as a means of developing correct foundry practice.

Metallic welding affords another wide field of X-ray usefulness. All welding is subject to faults and even the best methods depend largely upon the skill and care of the individual workman. X-rays are the only method of testing a weld without destroying it. After extensive experience it is customary to estimate the mechanical strength of a weld by a mere examination of the radiograph. Inspection of the soundness of welds now ranges from spot welds of thin aluminium foil on aeroplane wings to welded Liberty ships and the giant penstocks of Boulder dam and similar structures.

Another X-ray application has its main expression in the inspection of assembled articles such as aircraft instruments, electronic tubes, electric relays and resistances, artillery shells, bombs and rockets (including the proper filling with explosive and incendiary materials and safe inspection of ammunition captured from the enemy) and fuses, where the finished product depends for its proper functioning on the completeness and correct assembly of its internal components. In such cases elaborate and expensive systems of inspection are often necessary. In many instances X-rays afford an accurate method of making such a check.

Wooden structures, such as aeroplane and glider parts, railway ties, telephone poles and lead storage battery separators also offer a suitable field for X-ray application. Worm holes, resin pockets, and graining may be determined with great exactness. X-ray inspection of the roof beams of the ancient Cathedral of St. Peter in York, England, disclosed in 1938 such a dangerous internal honeycombing from boring of death-watch beetles that immediate replacement was necessary.

In the course of a research of glued joints it was necessary to determine the disposition of the glue. By adding a small percentage of a heavy salt to the glue, thereby rendering it opaque to X-rays, the dispersion of the glue in the joint was shown with clearness in a radiograph. Much of the success of modern laminated wood as a light and strong structural material is the result of this technique. Motor tires may be examined by X-rays to determine the position of the cords and the bonding of rubber. Electric insulating materials, such as ebonite and built-up paper materials, may be examined for the presence of impurities and electrically conducting particles. Abrasive wheels have been examined for cracks, and fireclay pots used in the manufacture of glass have been inspected for the presence of harmful metallic impurities. X-rays have also been used by customs authorities to investigate the contents of sealed packages. Real pearls may be distinguished nondestructively from imitations by X-rays because the real pearl emits a visible fluorescence under the action of the rays. The real pearl also discloses a series of layers or growth rings from the centre outward, to distinguish it from the cultivated or Japanese pearl which has an artificial centre upon which is deposited a thin nacreous layer. Diamonds, which are very transparent to X-rays, may be distinguished from imitations, which as a rule are much more opaque. The use of X-rays to demonstrate the fit of shoes and boots is now a familiar sight in a shoe store. The exact measurement of the fit of screw threads is a matter that has given rise to a good deal of difficulty; X-rays are now being used for this purpose.

Entirely new is the "instantaneous" radiography developed by Westinghouse Electric corporation. A condenser discharge through a special tube provides an X-ray beam of such great intensity that an exposure of the order of a millionth of a second is possible. Thus objects in rapid motion may be radiographed. The most important application has been to the science of ballistics, since the course of bullets through various materials is easily followed.

Prior to 1928, Dr. J. Heilbron, of Amsterdam, conducted some very remarkable and beautiful experiments with X-rays on pictures painted by old masters. The pigments of modern painters are in general much less opaque to X-rays than those used many years ago. Dr. Heilbron was able to produce X-ray evidence of extraordinary alterations having been made to some pictures. One picture examined by Dr. Heilbron was by Cornelis Engelbrechtsen, where the X-ray picture showed the figure of a vested priest which had been covered at a later date by the painted portrait of a woman. This hidden feature of the original painting had been undiscovered for 400 years. Another picture, a representation of the Madonna by Geertgen van St. Jans, was shown by the X-ray picture to have originally included an infant in the arms of the figure, which had subsequently been painted out. This method was greatly extended by Alan Burroughs of the Fogg Art museum of Harvard university, F. I. G. Rawlins of the National Art gallery, London, and others with the result that an X-ray laboratory is an essential part of museum equipment. Even one of the most famous paintings in America. Thomas Gainsborough's "Blue Boy," in the Henry E. Huntington Art gallery, San Marino, Calif. has not escaped. Recently an area above the head appeared to have a peculiar light reflection (pentimento). Radiographic examination showed the figure of a man over which the "Blue Boy" had been painted. The light spot corresponded with the white stock around the neck of this underlying figure on a canvas which had been cut down for the "Blue Boy" (fig. 3, plate IV).

The development of X-ray apparatus has resulted in the production of small and portable equipment for various purposes, among which may be mentioned a set for the use of plumbers and builders to enable them to locate the position of wires and pipes in the walls and floors of buildings. Automatic equipment with moving belts permits quality classification of many products, usually by visual fluoroscopy, such as elimination of candy containing foreign bodies, separation of juicy from pithy citrus fruits, and detection of damaged or contaminated food products of many kinds (fig. 6, plate IV).

A logical extension of radiography is to the examination of very small objects, the image of which must be enlarged. Since there are no magnifying lenses for X-rays, it follows that recourse must be taken to enlargement of radiographs registered on very fine-grained photographic emulsion, such as the Lippmann. After 1938 this technique of microradiography was developed as the result of work of G. L. Clark and associates at the University of Illinois, Urbana, Ill., into a successful and important practical method, especially in the field of metallurgy. Each separate phase in a complex alloy having a different absorbing power for X-rays can be delineated; by a simple calculation from absorption coefficients the proper wave length may be selected for maximum differentiation between two or more phases in the most complex bronzes and other important commercial alloys. Biological materials of very small size can be similarly photographed depending simply on differences in density within the structure or following differential "staining" with absorbing materials. Figures 5 and 6 in plate I are microradiographs of a commonly used aluminium-copper alloy in which the copper appears as white streaks; and the eye of a common housefly. A recent accomplishment involved specification of steel for vitreous enamelling, since steels of the same composition and structure acted very differently, in some cases causing enamel to shatter. Microradiographs proved that microporous channels could cause diffusion of gases through the metal with disruption of the bond between steel and enamel.

X-Ray Diffraction.—The Analysis of Fine Structures of Materials.—The second great branch of X-ray science applied to industrial problems depends upon the fact that solid crystalline materials serve as diffraction gratings for X-rays by virtue of the regular arrangement in space of the ultimate atoms, ions or molecules, just as closely ruled lines on glass or metal serve as a diffraction grating and produce a spectrum of ordinary light. This interaction between X-rays and crystals was predicted and experimentally proved by Von Laue in 1912, and given its simplest expression in the familiar Bragg law: $n\lambda = 2d \sin\theta$, where n is an integer (the order of the spectrum),

λ is the X-ray wave length, d is the interplanar spacing or distance between two identical planes of atoms or molecules in the crystal, and θ is the angle of incidence of the X-ray beam on this set of planes. Thus every crystalline chemical element or compound produces a diffraction pattern which is uniquely characteristic of the particular kinds and arrangement of atoms or molecules which are the ultimate building blocks of the crystalline architecture.

The pattern may be used to identify the solid exactly as it is without solution in a liquid or other change. It is a comparatively simple matter to identify an unknown material if a library of standard patterns of known pure materials is available for matching. To this end the American Society for Testing Materials, in conjunction with the Physical Society of London, has issued a card index of X-ray patterns for about 10,000 compounds, based on the original Dow-Hanawalt tables. For this identification, the material is finely powdered and a so-called powder pattern or spectrogram of sharp lines is photographed. By rapid methods of comparing the three most intense lines with recorded values, the unknown may be readily discovered if there is a standard pattern for it in the index.

The practical industrial use is self-evident of identification without proceeding to the more difficult techniques of determining the actual crystalline architecture, or precise scheme of arrangement in space of atoms or molecules, or even of atoms within molecules, particularly for organic compounds.

There are a number of diffraction techniques and types of cameras. A carefully collimated train of parallel X-rays, usually with one wave length, is directed through, or reflected from, the surface of the specimen which may be a powder, aggregate, fibre or single crystal, which may be stationary, rotated or oscillated. The diffraction pattern is registered on a photographic film, stationary or moving, flat or curved, at a fixed distance from the specimen. In the U.S. four manufacturers produce largely for industrial use complete multiple diffraction units on which two or four patterns may be photographed simultaneously. (Fig. 1, plate V.)

Until recently, complete structure analyses were largely confined to academic laboratories from which came a growing new crystal chemistry. Suddenly the problems of identity and synthesis of quinine, penicillin, synthetic rubber, alloys, and a long list of essential materials have required the practical use of the ultimate analyses, culminating in an electron density contour map of a single molecule. Many of the newest industrial materials have been the direct result of the guidance of X-ray diffraction research and testing. Natural materials such as minerals, clays and soils, cellulose, proteins and other textile materials are frequently studied.

In addition to analysis of crystalline architecture, X-ray patterns have the important function of indicating texture—the actual condition of a specimen in terms of grain size, orientation, effects of rolling, drawing, fatigue, strain, annealing, aging and other processes. (Figs. 2 and 3, plate V.) During World War II hundreds of thousands of quartz plates for control of radio frequencies were properly cut and ground for the signal corps of the U.S. army by X-ray diffraction control in nearly automatic apparatus. Aeroplane motor castings were so improved by means of X-ray back reflection control (fig. 4, plate V) that strain was eliminated and horsepower safely doubled for the same weight of light alloys (*see* 1944 Mehl Award lecture, before Congress of Metals). Carbon blacks for rubber reinforcing, charcoal for gas masks, storage batteries (grids and active materials), explosives, chemicals, antiseptics and medicinals, waxes and coatings, welded Liberty ships, fluorescent materials, surgical sutures and membranes, rayons and synthetic textiles, elastic polymers and plastics, pigments, electroplatings, lubricants, instrument pivots, abrasives, adhesives, wood and lignin, boiler scale, glass, soaps, parts of V-1 and V-2 German bombs—these are but a short list of materials of industrial and wartime importance to which X-ray diffraction methods contributed fundamental research information and routine production control (Fig. 5, plate V.) These examples illustrate the fact that practical behaviour in use so frequently depends on the ultimate structure and texture.

In 1945, Dr. C. S. Barrett of the Carnegie Institute of Technology announced a new microscopy of potential value in physical metallurgy and in other fields, which depends on Röntgen ray diffraction. This new adaptation supplements optical and electron microscopy and microradiography. It differs from usual technique in employing a fine-grained photographic plate in contact with or very close to the specimen upon which a beam of characteristic X-rays strikes. The diffraction image is enlarged just as in the case of microradiography. These diffraction micrographs show the places where inhomogeneous strain is concentrated. Along planes where slip has occurred throughout the interior of crystals and polycrystalline grains there is a local bending or rotation of the crystal lattice. At such points the efficiency of Röntgen ray reflection is increased and a dark line is produced on the photographic plate. Measurement can be made of the amount of rotation (usually less than 0.1°) and the thickness of the distorted layer. (Fig. 6, plate V.) Thus strain, plastic deformation, twinning, distortion from scratches and cutting tools, annealing, recrystallization, coring, clustering of similarly oriented grains, age-hardening and super lattices are all subjects for investigation by the technique. Sizes and shapes of polycrystalline grains are shown in truly amazing photographs. Since these diffraction micrographs register the effects in individual grains (while ordinary diffraction patterns are the summation of effects from large numbers of grains) it is possible to identify microconstituents from the directions of diffracted rays measured with two films at different distances, and application of the Bragg law. Thus nondestructive microanalysis on individual particles is one of the useful applications. (*See* also SPECTROSCOPY, X-RAY; QUANTUM MECHANICS.) (G. L. CK.)

X-RAYS AND CRYSTAL STRUCTURE. The idea of a regular, underlying structure has always been at the back of scientific studies of crystals. It is suggested by their very appearance, and it becomes almost a necessity to explain the regularities of the laws of the arrangements of the external faces, and the physical properties of the crystals. Christiaan Huygens, in the 17th century, first put forward the idea that a crystal was essentially a regular piling of atoms or molecules similar on a minute scale to a pile of shot or to the blocks of the Great Pyramid. It was not until the beginning of the 19th century, however, that the Abbé Haüy gave it a firm mathematical footing. (*See* CRYSTALLOGRAPHY.)

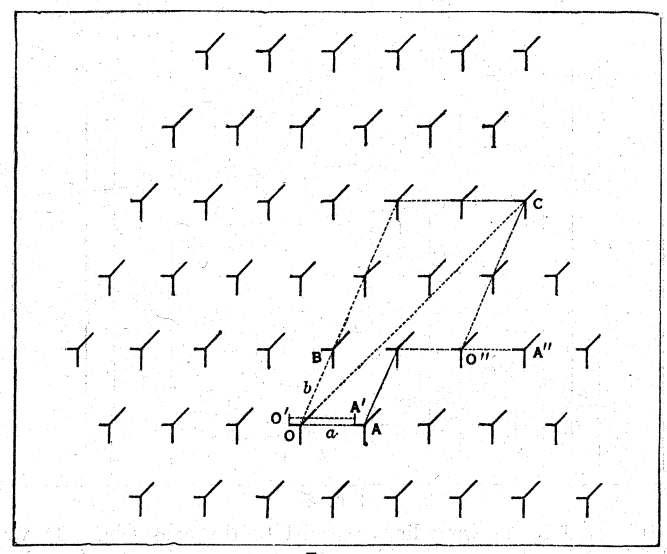

FIG. 1A

PART I. THE ANALYSIS OF STRUCTURE

The idea implicit in Haüy's work was that crystals consist of a regular ordering of exactly similar molecules in three dimensions.

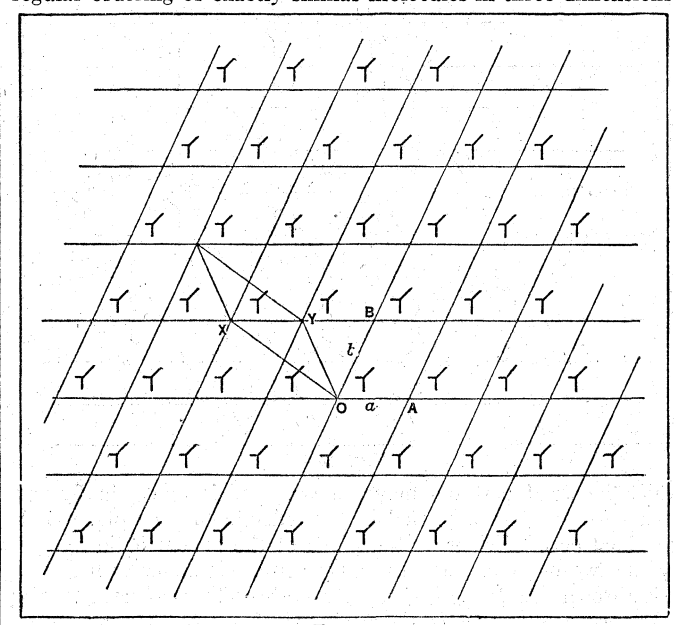

FIG. 1B

This is easiest to understand from its two dimensional analogue. In fig. 1A a set of similarly oriented identical patterns is shown, repeated, supposedly indefinitely. A certain movement O–A takes me from a point O of one pattern to a corresponding point A in

another. Now an exactly similar movement O′A′ would take me from any point of the pattern to the corresponding point, or from any point in any pattern O″ to a corresponding point on another A″. Similarly, the different movement O–B may be seen to have the same property. They are the so-called translations of the crystal. Now we can easily see that any translation O–C can be made up of a succession of translations O–A and O–B, so that O–A and O–B may be taken as the primitive translations or the axes *a, b* of the crystal. All the points derived in this way make up the

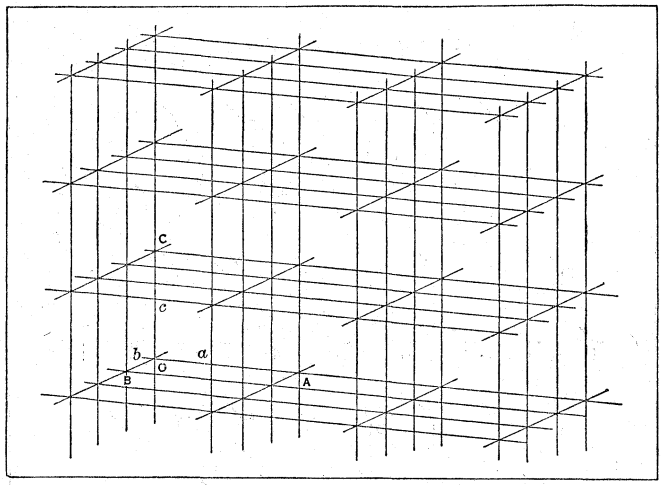

FIG. 2

lattice and by drawing lines parallel to the axes (fig. 1B) we define the cell of the crystal, the contents of all cells being identical. Of course, we might have chosen another set of axes, OX, OY instead, but the lattice is completely determined in either case by the lengths of the axes and the angle between them, and the whole crystal by the lattice and by the co-ordinates of each point in a single cell, referred to its axes as units. To extend this to three dimensions, we simply have to take another axis *c*, not in the plane of *a*–*b*, and the cells become parallelopipeds, extending in space in all directions. (*See* fig. 2.)

Symmetry.—Now there are other ways than translations in

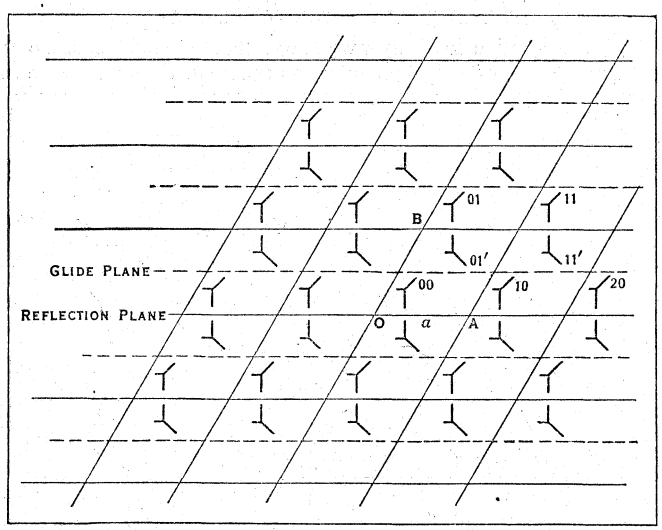

FIG. 3A

which identical patterns may appear. For instance, in fig. 3A each pattern is accompanied by its reflection in the plane O–A, imagined perpendicular to the plane of the paper; or in fig. 3B, by the two other patterns made by turning it about a three-fold axis through O. In fig. 3C we see both of these together. It is only necessary to specify the positions of one of the asymmetric patterns in the cell, and the nature of the symmetry, to define the crystal as completely as before. The elements of symmetry permitted in space lattices are essentially those of crystallography, that is, two, three, four and six-fold axes, centres of symmetry, reflection planes and axes of the second sort. (*See* CRYSTALLOGRAPHY.) But there is the important condition that all axes must be translations and all planes lattice planes, and in addition, there are glide planes and screw axes. In fig. 3A we have the two rows of patterns (marked $\begin{smallmatrix}01' & 11'\\ 00 & 10 & 20\end{smallmatrix}$), each of which can be seen to be a reflection of the other in a plane, but which has also been moved on a half translation of the cell. This is called a glide plane re-

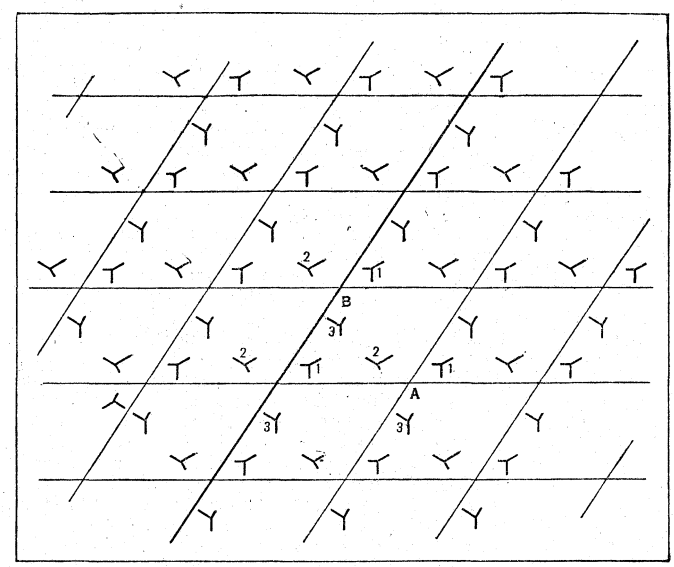

FIG. 3B

flection. An ordinary axis of symmetry is a pure rotation, but screw axes move the pattern a fraction ($\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{3}$ or $\frac{1}{6}$) of the lattice translation, parallel to the axis in each operation, so that at the end of a complete turn the pattern has moved through one translation, *e.g.*, three-fold screw axes perpendicular to the paper are shown in fig. 19. Screw axes may be right or left handed. In nature they are familiar as phyllotaxy, the arrangement of leaves on a stem.

The considerations of symmetry give us an ultimate method of classifying any regular arrangement of patterns in space. First we can divide the lattices into the fourteen types of Bravais

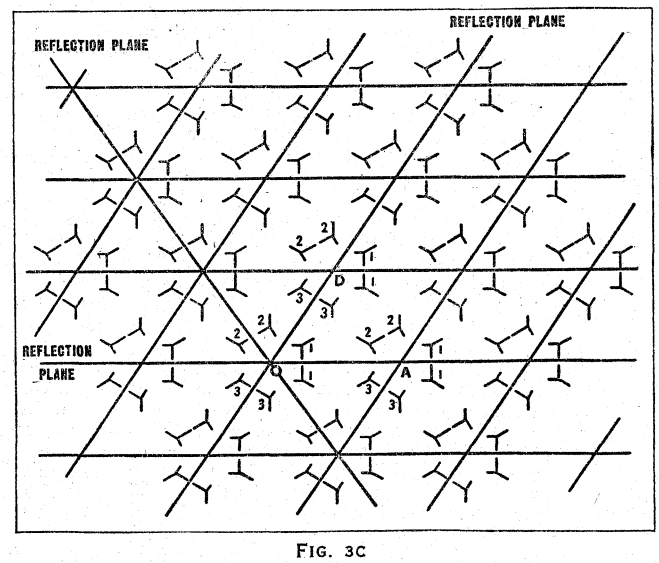

FIG. 3C

(1811–1863). (*See* fig. 4.) The seven systems of symmetry, cubic, tetragonal, hexagonal, rhombohedral, orthorhombic, monoclinic and triclinic, give rise to the simple lattices (i.) Γ_r, (iv.) Γ_t, (vi.) Γ_h, (vii.) Γ_{rh}, (viii.) Γ_o, (xii.) Γ_m, (xiv.) Γ_{tr}. But besides these there exist a number of face centred lattices [where the primitive translation is not from corner to corner of a rectangular face but to its midpoint]; one face centred (ix.) Γ_o', (xiii.) Γ_m', or all face centred (iii.) Γ_r'', (xi.) Γ_o'''. Lastly, there are the three

body centred lattices [where the primitive translation is to the centre of a rectangular parallelopiped rather than to its opposite corner]; (ii.) Γ_r', (v.) Γ_t', (x.) Γ_o''.

Next, we can divide the symmetry further, according to the nature of the axes and planes and the presence or absence of centres of symmetry into the thirty-two crystal classes. (*See* CRYSTALLOGRAPHY.) But the existence of glide planes and screw

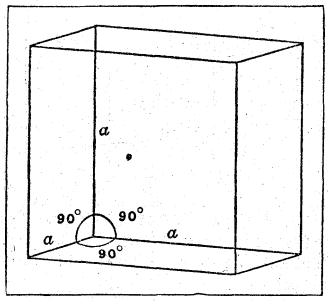

FIG. 4.—(I.) SIMPLE CUBIC LATTICE Γ_r equal axes of length ("a" at right angles)

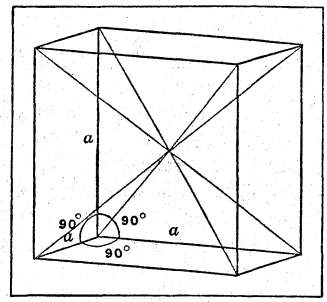

FIG. 4.—(II.) BODY CENTRED CUBIC LATTICE Γ_r' (equivalent point in centre of cube)

axes permits of still further divisions inside each class, and for each variety of lattice possible in that class. If these two are specified, the complete inner symmetry or space group of the crystal is given. The determination of the two hundred and thirty possible space groups was begun by Sonchke (1842–1897) and finished by Schoenflies, Fedorow and Barlow at the beginning of the present century.

Laue's Discovery.—But though the geometrical frame-work for the complete description of crystal structure had thus been worked out, there remained no way of applying it, for it was impossible to determine either the nature of the lattice, the existence of screw axes and glide planes or even the size of the cell, much less the positions of the atoms in it. Yet the labour of the mathematicians was not wasted. Soon after they were concluded, there was a controversy as to the nature of X-rays. Some maintained they were corpuscular and others that they were waves analogous to light. However, no one had then succeeded in diffracting them with a grating. (*See* LIGHT.) This seemed to show that if they were waves, their wave lengths must be much less than that of visible light, 10^{-5} cm. Now early in 1912 it occurred to von Laue, then a young physicist at Munich, who was in touch with the Crystallographic School of Groth, that the lattices of crystals, of which the little that was known indicated a periodicity of 10^{-8} cm., were of the right order to act as a grating for X-rays, and, if they were waves, to diffract them in definite directions. Friedrich and Knipping carried out the experiment of passing a narrow beam of X-rays through a crystal with a photographic plate behind it.

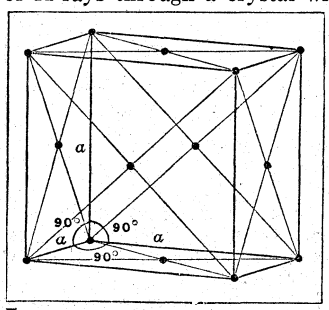

FIG. 4.—(III.) FACE CENTRED CUBIC LATTICE Γ_r'' (equivalent point at centres of cube faces)

The experiment was strikingly successful. The plate was covered with a regular pattern of spots, which was what von Laue had predicted. This experiment gave the key both to the nature of X-rays and the structure of crystals.

The Braggs' First Crystal Analyses.—The new discovery aroused immediate interest. In England it was taken up by Sir William Bragg and his son, W. L. Bragg, who in the same year determined the first crystal structures, those of rock salt and zinc-blende; and at the same time developed a method of analysis which was to be the basis of all further work. The way in which they accomplished the double task of determining the wave lengths of X-rays and the structure of crystals is told in their classic book, "X-rays and Crystal Structure." Here we will simplify it by assuming from the start that we can produce X-rays of single wave length λ (most easily from the fluorescent radiation of metals such as iron, copper and rhodium. *See* X-RAYS, NATURE OF).

Bragg's Law.—The action of X-rays on crystals is best dealt with as selective reflection from crystal planes. If a set of planes be drawn through corresponding points in a crystal (*see* fig. 5A), not necessarily in any relation to the superficial faces, these will be a constant interval apart. This is the spacing of the plane d_{hkl}; ([hkl] are the Millerian indices, that is, the reciprocals of the fractional intercepts on the axes. *See* CRYSTALLOGRAPHY). If a train of waves falls on such a set of planes p (*see* fig. 6) at a glancing angle θ, each plane will reflect a small part of the wave

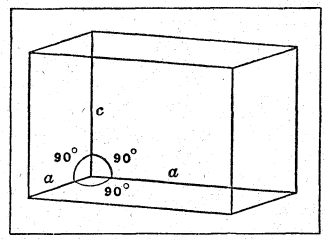

FIG. 4.—(IV.) SIMPLE TETRAGONAL LATTICE Γ_t (two equal axes "a" and "c" all at right angles)

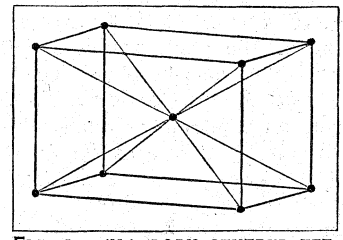

FIG. 4.—(V.) BODY CENTRED TETRAGONAL LATTICE Γ_t' (equivalent point in the centre of cell)

train regularly and let the rest through to the next plane. Now, in general, the reflected wave trains from successive planes will be out of phase with each other, will interfere and no reflection will result. (*See* LIGHT: *Interference.*) But if the path distance of the wave passing from plane to plane is a multiple of the wave length λ, all the reflected waves will be in phase and the train as a whole will be reflected by the crystal. This occurs when and only when

$$\sin\theta = n\lambda/2d.$$

This is the fundamental relation of crystal analysis known as "Bragg's Law." The integer n is the so-called order of the reflection. Thus the same plane will reflect at angles $\theta_1, \theta_2 \ldots \theta_n$, where $\sin\theta_1 = \frac{\lambda}{2d}$ $\sin\theta_2 = \frac{2\lambda}{2d}$ $\ldots$ $\sin\theta_n = \frac{n\lambda}{2d}$ for the same wave length. The higher the order or the smaller the spacing, the larger the angle of reflection. No plane whose spacing is less than half the wave length reflects at all. It is only necessary to measure θ, the angle at which X-rays of known wave lengths are reflected by a crystal, to know the spacing of its lattice planes.

But X-rays are able to give much more information than this. Consider a crystal with two scattering points in the cell of scattering powers A and B. (*See* fig. 5B.) Wave trains scattered from the A and B plane are now out of phase and necessarily interfere. If the B planes are xd from the A's, the resulting intensity of the nth order of reflection will be proportional to $(A+B\cos 2\pi nx)^2+B^2\sin^2 2\pi nx$. If, for instance, B was half way between two A's, $x=\frac{1}{2}$, this would become $(A+B)^2$ for the even orders and $(A-B)^2$ for the odd. The even orders would be strong and the odd weak, and these would vanish if A and B were equal, and the plane in this case is said to be halved. A crystal with more scattering points gives rise to a more complicated expression but it should be clear that the intensity of reflection is both an indication and a check on the positions of the scattering centres inside the cell.

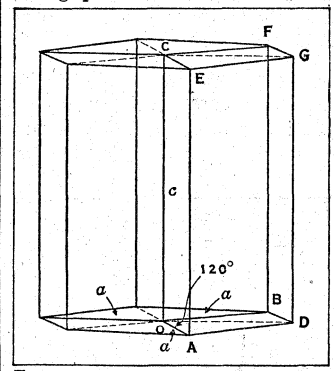

FIG. 4.—(VI.) HEXAGONAL LATTICE Γ_h (Three equal axes "a" at 120° and another "c" at right angles to them)

The chief experimental methods are therefore devised for a double purpose. Firstly, to find the glancing angles for the X-rays reflected by the different planes of the crystal, and secondly, to measure the intensity of the X-rays reflected. There are four chief experimental methods.

In the Bragg ionisation spectrometer (*see* fig. 7) the X-rays from the tube inside the lead box pass through the two slits

which limit them to a narrow beam, and meet the crystal mounted to rotate about a vertical axis. The reflection beam is received in an ionisation chamber, in which there is an absorbing gas such as methylene iodide, producing ions which charge the electroscope. The crystal and chamber are moved to record each reflection. Their angular position gives the glancing angle, while the ionisation current is a measure of the intensity. The Bragg spectrometer undoubtedly provides the most thorough method, but it is slow in action and suitable only for large crystals, so that methods depending on the photographic action of X-rays have also been developed.

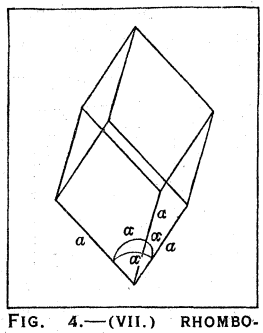

FIG. 4.—(VII.) RHOMBOHEDRAL LATTICE Γ_{rh}
Three equal axes (a) marking an angle (α) with each other

The Rotation Method.—For the rotation method originally due to de Broglie, an apparatus like fig. 8 is used. The X-rays from a tube (not shown) pass through the fine barrel aperture and fall on the crystal, which is rotated uniformly on the spindle, driven by the motor. As each crystal plane comes into a reflecting position, the reflected ray registers on the photographic plate, producing a pattern such as shown in fig. 9. Each plane reflects four times per revolution, giving the photograph a symmetrical appearance. From the position of the spot on the plate, the spacings or the indices of the planes can be calculated. An important property of the rotation method is that if the crystal is rotated about a translation a of the lattice, all the reflected rays lie on a set of cones ot angles ϕ_n where $\sin\phi = \frac{n\lambda}{\alpha}$ these cones intersect the plate in hyperbolae called layer lines (*see* fig. 9) and their distance apart is the best measure of the true axes of the crystal. It can be seen from the photograph that the spots are of very different intensities. These are usually estimated by eye, as strong, medium, weak, etc., so that the method is definitely inferior in this respect to the ionisation spectrometer.

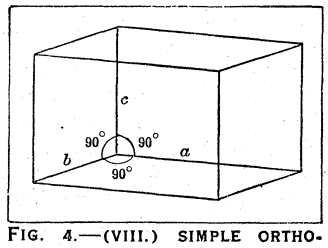

FIG. 4.—(VIII.) SIMPLE ORTHORHOMBIC LATTICE Γ_o
Three unequal axes a, b, c, at right angles

The Powder Method.—In the powder method, due to Debye and to Hull and Scherrer, a crystalline powder is used instead of a single crystal, depending on the fact that among so many grains some will be in the exact position to reflect. Consequently from the central beam diverge a set of cones each corresponding to the reflection from a single plane and forming circular rings on a plate (*see* fig. 10A) or so-called Debye curves on a film bent round a cylinder (*see* fig. 10B). Unfortunately, many planes often have the same or nearly the same spacings, which causes them to be confused and limits the method to simple crystals. However, as it is the only method for substances which cannot be obtained as single crystals, it is very useful, particularly for metals.

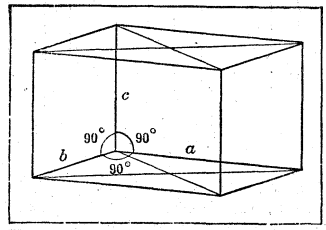

FIG. 4.—(IX.) ONE FACE CENTRED ORTHORHOMBIC LATTICE Γ_o' as (viii.) but with an equivalent point at the centre of one pair of faces

The Laue Method.—This depends on a different principle from the first three. Here the crystal is kept fixed, and a beam of white X-rays, that is with wave lengths ranging from between ·25 to ·5 A. (Ångström units $=10^{-8}$ cm.), is passed through it, usually parallel to a crystallographic axis. The apparatus used is the same as before (*see* fig. 8). For a great number of planes there will always be some wave length which is right for reflection and a spot is formed, the position of which depends only on the angular position of the reflecting plane. Thus the Laue method gives no information as to spacing. But, as can be seen from the photographs (*see* figs. 11a and 11b) it gives an excellent picture of the symmetry of the crystal and also of the relative intensities of a great number of reflecting planes.

Plainly, though any one of these methods but the last could be and has been used alone for crystal analysis, it is much better to use all to amplify and check each other's results. In this way we arrive at the experimental data for crystal analysis; *the spacings and intensities of the X-ray reflections of a number of planes of known indices.*

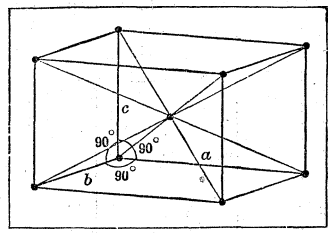

FIG. 4.—(X.) BODY CENTRED ORTHORHOMBIC LATTICE Γ_o'' as viii. but with an equivalent point in centre of cell

Stages in Structure Analysis.—With these data the actual analysis divides into two parts. It is carried out schematically as follows:

1. *Determination of Cell Size.* The lengths of the three axes, *a, b, c,* are found from rotation photographs or from the spacing of planes given by the formula

$$d_{hkl} = \frac{1}{\sqrt{\left(\frac{h^2}{a^2}+\frac{k^2}{b^2}+\frac{l^2}{c^2}\right)}}$$

for orthogonal crystals. For monoclinic and triclinic crystals it is more complicated and here the angles between the axes are usually obtained from the external crystal form. It is easiest to use the pinacoid spacings (100) (010) (001), which give the axes directly, but these may be halved, so for the true cell, one general plane (hkl) at least must be taken.

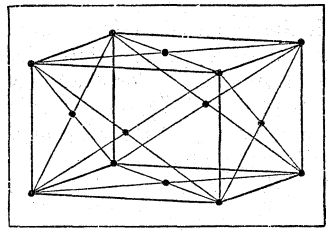

FIG. 4.—(XI.) FACE CENTRED ORTHORHOMBIC LATTICE Γ_o''' as (viii.) but with equivalent points in centres of all six faces

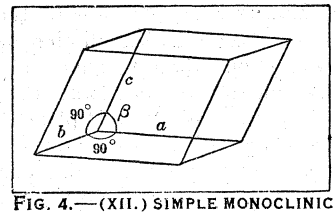

FIG. 4.—(XII.) SIMPLE MONOCLINIC LATTICE Γ_m
Two axes a and c making an angle β with each other and one axis b perpendicular to both of them

2. *Determination of the number of molecules per cell.* If D is the density of the crystal, and V its volume in cu.A. ($V=abc$ for an orthogonal cell), then the cell will contain Z molecules of molecular weight M, where $Z \times M \times 1{\cdot}66 = D \times V$. ($1{\cdot}66 \times 10^{-24}$ gm. being the weight of an atom of hydrogen.)

3. *Determination of the Lattice Type.* This is done by means of the halvings of planes of the type (hkl). In simple lattices there are no inner regularities and all kinds of planes appear, whereas in centred lattices, certain planes are inter-spaced identically so that they do not reflect in odd orders and are said to be halved. A halving when h+k is odd will, for instance, indicate an a c face-centred lattice Γ_m' (*see* fig. 4 [xiii.]).

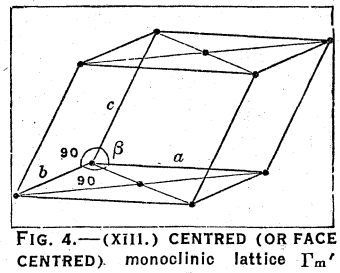

FIG. 4.—(XIII.) CENTRED (OR FACE CENTRED) monoclinic lattice Γ_m' (equivalent points in the centres of [a. b] faces)

4. *Determination of Space Group.* It is first necessary to know the crystal class. This must be done by the methods of ordinary crystallography. Laue photographs are useful in detecting axes, but unfortunately, X-ray methods cannot distinguish directly between crystals with or without a centre of symmetry. Next, screw axes and glide planes can be detected, for the former cause all orders of the plane normal to it to disappear except that corresponding to a multiple of the screw translation—*e.g.,* in quartz, owing to the trigonal screw axis, perpendicular to the c plane, only

the third, sixth, ninth, etc., orders of this plane reflect. Glide planes, on the other hand, halve whole sets of planes of the type (*hko*), where $h+k$ is odd. Space groups are usually found by the use of tables, of which those of Astbury and Yardley and Wyckoff are most used. They are denoted by a complex symbol, such as D^4_{6h}, where D_{6h} stands for the symmetry class and ^{4} is the ordinal number in a space group table, usually that of Schoenflies.

Once the space group is known and the number of molecules per cell, the symmetry of the individual molecule follows, which is in general lower than that of the crystal. Further, the conditions of symmetry fix the positions of the atoms within certain limits. If we designate the co-ordinates of the atom, referred to the axes *a b c* as *u v w*, the so-called parameters of the atom, then the symmetry conditions may fix the values of *u v w* within certain limits. If there are very few atoms of a particular kind in the cell, *u v w* may become o o o or 1/2 1/2 1/2, that is, the atom must be at a corner or in the centre of a cell. Or two parameters may be fixed, o o *v*, fixing the atom anywhere on the *c* axis; or o *v w*, fixing it anywhere in the *a* plane. However, it is only in the simplest cases that the symmetry positions fix all the atomic positions. Usually, a set of independent parameters are left undetermined, which may be only one, as in graphite, or twenty or more as in a silicate. The difficulty of fixing parameters leads to many crystals being left at this stage, but though it is indirect, the fixing of parameters by means of intensity considerations is far the most interesting part of crystal analysis.

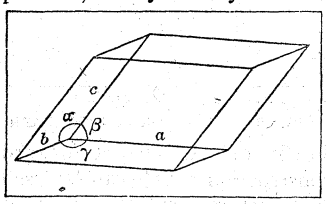

FIG. 4.—(XIV.) TRICLINIC LATTICE Γ_{tr}
Three unequal axes a, b, c, inclined at angles α, β, γ, to each other

The method consists in assuming certain values for the parameters and calculating from these the theoretical intensity of reflections from a set of planes. These are compared with the observed intensities, and the process repeated by trial and error, until the theoretical and observed intensities agree within the errors of the experiment. In many ways this method resembles the solution of a cross-word puzzle. The cell and space group provide the square and the pattern, the atoms the letters and the intensities the clues.

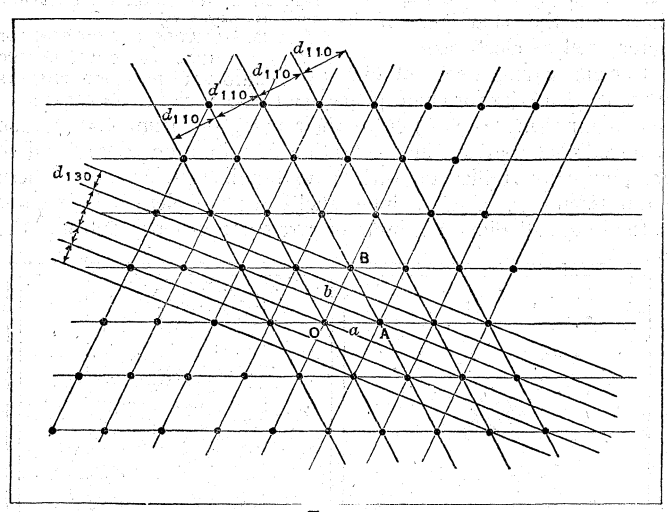

FIG. 5A

Atomic Structure Factors.—The amplitude of the reflection from the plane (*hkl*) of a crystal which has *n* atoms per cell with the parameters $u_1\ v_1\ w_1,\ u_2\ v_2\ w_2,\ \ldots\ldots\ u_n\ v_n\ w_n$ is given by

$$C_{(\theta)} \sum_{1\ldots n} F_{(r\theta)}\, e^{2\pi i(hu_r+kv_r+lw_r)}.$$

C_θ is the J. J. Thomson formula for the scattering from a single electron, which depends only on the angle of scattering θ. $F_1, F_2, \ldots\ldots F_n$ are the so-called structure factors of the different atoms. If the atoms scattered as points, $F_r = Z_r$ the total number of electrons in the atom. Actually, the electrons are diffused in space, so that their scattered radiations interfere, making *F* fall off very rapidly with the angle θ, particularly for light atoms. Structure factor curves giving F_θ can be found experimentally for each kind of atom or calculated from the wave mechanics distribution of electricity in the atom, as has been done by Pauling and Hartree. The exponential terms simply allow for the phase difference of the different atomic centres for the reflection of the plane (*hkl*). The observed intensity, before comparison with the calculated, must itself be corrected for absorption of the X-rays in the crystal, which is complicated by the fact that the very reflections of the X-rays increase the absorption differently for each plane. Corrections must also be made for temperature effects, as the atoms in a crystal vibrate more at higher temperatures, which reduces the reflection intensity.

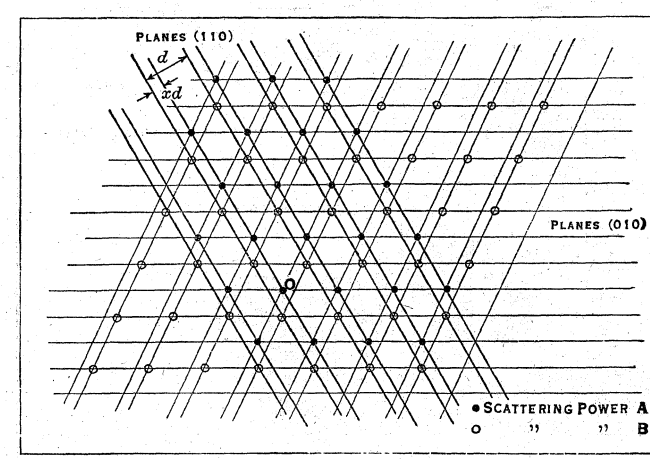

FIG. 5B

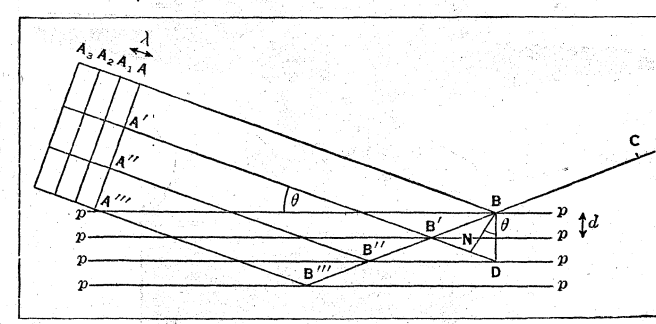
The calculation and comparison of intensities is a lengthy but straight-forward process, but the assigning of parameters is like solving a geometrical problem and always depends, in part, on intuition. Gradually, however, as more and more structures are being worked out, probable arrangements of atoms can be seen more easily, particularly by the use of the ideas of atomic diameters and co-ordination numbers (*see* Part II.). It was by the use of these that Pauling and West successfully and independently predicted the structure of topaz $Al_2SiO_4F_2$. But however the parameters are obtained, good intensity agreement absolutely confirms the structure as correct because the slightest change of atomic position causes such changes in intensity distribution between the different reflections as to wholly upset the agreement.



FROM BRAGG, "X-RAYS AND CRYSTAL STRUCTURE" (G. BELL & SONS)

FIG. 6

This completes our account of the methods of crystal analysis as far as the positions of the atoms are concerned. Unfortunately, to illustrate it with even a single example, would exceed the length of this article, and the reader must be content with the results of the analysis given in Part II. Strictly, however, merely to know the position of the centres of the atoms in a crystal, is only the beginning of a real knowledge of their structure. A complete knowledge must also include a quantitative account of the forces by which the crystal is held in equilibrium and of the dynamics of the crystal when it is acted on by mechanical or electrical

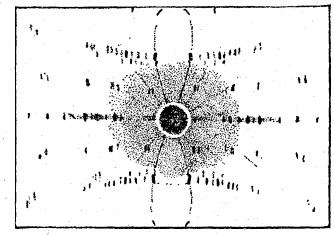
FIG. 8.—APPARATUS FOR ROTATION AND LAUE PHOTOGRAPHS ETC.

crystal analysis is only beginning, but already the work of Born, Landé, Leonard Jones, Joffé and several others has accounted quantitatively for the mechanical properties of simple ionic crystals, particularly of the rock salt type.

PART II. THE STRUCTURES OF CRYSTALS

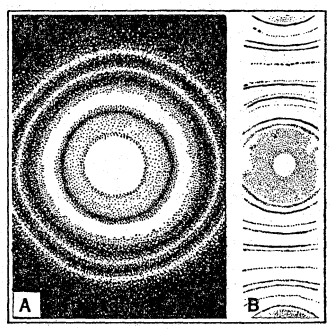
Crystal Chemistry.—By the methods outlined above, the structures of an ever increasing number of crystals have been worked out every year (1926 for instance, produced over three hundred papers on the subject) yet the field is so immense and the difficulties of analysis so considerable, that we can still only deal satisfactorily with the simpler types of crystal structure. Already, however, owing to the work of Sir William and W. L. Bragg, of Fajans, Wasatsjerna, Pauling and above all, V. M. Goldschmidt, we can put forward a theory of the mode of crystal construction which can be used to predict unknown structures, and structures and properties of new substances.



BY COURTESY OF J. M. ROBERTSON

FIG. 9.—ROTATION PHOTOGRAPH

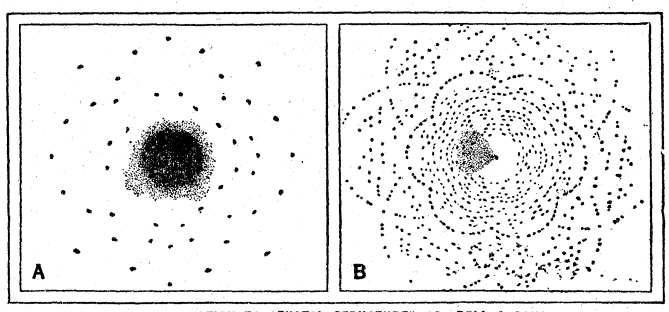
To understand the essence of this theory of crystal chemistry, we must start not from the crystal but from the atom. The most convenient form in which to represent the atom for this purpose is by Schrodinger's wave mechanics. Here each atom is pictured as a nucleus of positive electricity, surrounded by shells of diffuse negative electricity, growing denser towards the centre. Each shell corresponds to a set of Bohr orbits with the same chief quantum number in the classical quantum mechanics. These electron shells serve in the first place to give the atom a finite size (*see* fig. 12). This does not mean that the atom is a rigid sphere of definite radius. The wave mechanics atom must be considered as having a definite degree of compressibility and deformability. The chemical and crystallographic properties of an atom depend partly on the size but more on the character of its outer shell of electrons.



FROM BRAGG, "X-RAYS AND CRYSTAL STRUCTURE" (G. BELL & SONS)

FIG. 10.—POWDER PHOTOGRAPH OF (A) ALUMINIUM, (B) GOLD. (AFTER THE ORIGINAL PHOTOGRAPHS OF HALL AND DEBYE & SCHERRER)

Certain arrangements of electrons (2, 8, 18, 32 for chief quantum numbers 1, 2, 3, 4) have their inner quantum numbers so balanced that they are in a condition of minimum energy and so are physically stable and without external electric fields. These arrangements occur in the inner shells of most elements (but not in the iron, palladium, platinum or rare earth groups) but only the



FROM BRAGG, "AN INTRODUCTION TO CRYSTAL STRUCTURE" (G. BELL & SONS)

FIG. 11.—LAUE PHOTOGRAPH OF: (A) ROCK SALT, (B) BERYL

elements of the inert gas group have stable outer shells with 8 electrons. The other elements tend to fall into two groups. Those with one, two, or rarely up to four or five electrons more than the next lower stable grouping are the metals. They all tend to ionize, that is, to lose these spare electrons and assume a more stable configuration, acquiring a positive charge as a result; thus a sodium atom with eleven electrons loses one readily to become a singly charged sodium ion Na^+, with ten electrons in the configuration of the rare gas neon. The non-metallic type of atom is, on the other hand, one, two or three electrons short of the number required to

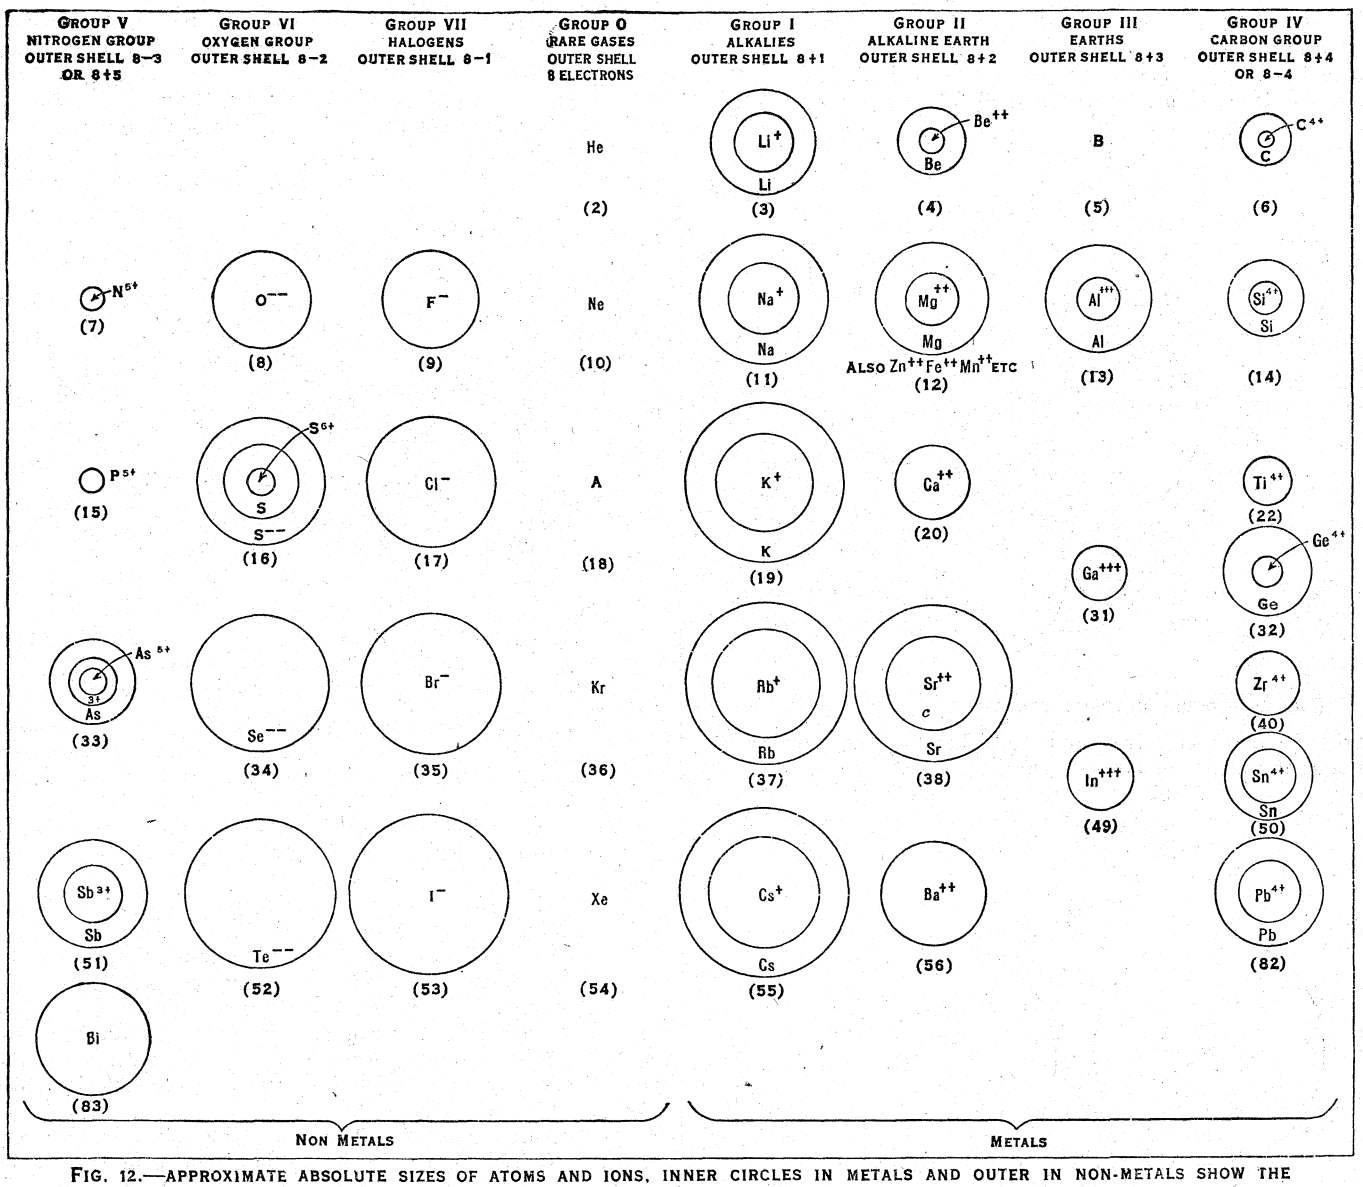


FIG. 12.—APPROXIMATE ABSOLUTE SIZES OF ATOMS AND IONS. INNER CIRCLES IN METALS AND OUTER IN NON-METALS SHOW THE IONIC STATE; NUMBERS IN () ARE ATOMIC NUMBERS (SCALE 50,000,000:1)

form the next stable configuration and tends to take up extra electrons to complete the shell, acquiring a negative charge in the process.

Isolated atoms and ions only exist at temperatures and pressures such as we find in stars and vacuum tubes. Under normal conditions they are always found combined. We know four such types of combination. These are called the heteropolar or ionic, the homopolar, the molecular and the metallic.

Ionic Combination.—Two ions such as Na^+ and Cl^- will attract each other with a force $\frac{e^2}{r^2}$ where r is the distance between them, and there will be an equilibrium when this force balances the repulsive force existing between their outer shells at close quarters. It is this repulsive force that gives the atoms their finite size. It is also electrical in origin but much more complex and expressible in such terms as $-\frac{c}{r^9}$. In the presence, however, of more Na^+ and Cl^- ions, it is easy to see that $\overset{+}{Na}\overset{-}{Cl}$ will become

$$\overset{+}{Na}\overset{-}{Cl} \quad \overset{-}{Cl}\overset{+}{Na} \qquad \text{and then} \qquad \overset{+}{Na}\overset{-}{Cl}\overset{+}{Na} \quad \overset{-}{Cl}\overset{+}{Na}\overset{-}{Cl} \quad \overset{+}{Na}\overset{-}{Cl}\overset{+}{Na}$$

and so on in three dimensions, each positive ion being surrounded by as many negative ions as possible and building up a crystal of rock salt (*see* fig. 13). Ions are of very different sizes (*see* fig. 12) and when a small, highly charged positive ion such as Be^{++} is close to a large, diffuse ion S^{--}, it not only attracts it but distorts its structure, attracting the electron shell and repelling the nucleus. This is called polarisation. Polarisation is particularly effective when the negative ion is unsymmetrically surrounded by positives, as in layer lattices (*see* fig. 29). A polarised heteropolar attraction can in this way build up a complex ion, such as $(Mg^{++}O_4^{--})^{6-}$.

Homopolar Combination.—In homopolar combination, two or more atoms with incomplete electron shells make up for their lack of stability by sharing electrons, thus achieving a completeness of outer shell for the combination which cannot exist for the individual. The simplest case is hydrogen. Individual hydrogen atoms, each with its one electron, are highly reactive because a one quantum shell is complete with two electrons, as in helium. Consequently two hydrogen atoms H combine to form the stable hydrogen molecule H_2, which spectrally and in many other ways resembles helium. In a similar way, by the sharing of a balanced pair of electrons, are formed the diatomic molecules F_2, O_2, N_2 of the non-metallic elements. An atom can share electrons with more than one other atom. Oxygen sharing electrons with two hydrogens forms the unsymmetrical water molecule $H\diagup O \diagdown H$, or carbon and two oxygens to form the symmetrical carbon diox-

ide O-C-O. The process, which can be extended indefinitely to form more and more complicated molecules, particularly those of organic chemistry (where the carbon atom possessing four two-electron bonds [co-valencies in modern chemical terms] which

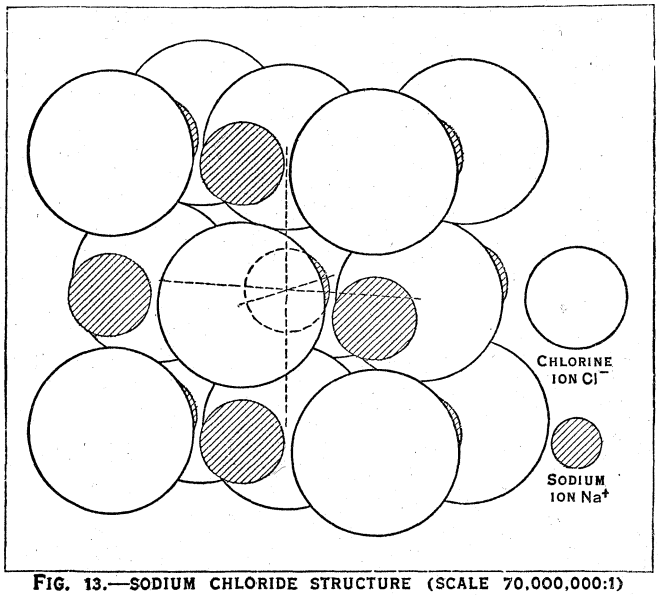

FIG. 13.—SODIUM CHLORIDE STRUCTURE (SCALE 70,000,000:1)

bring its outer shell from four to eight electrons) enables long chains of atoms to be formed as in the paraffins, or rings as in benzene derivatives. This reaches its ultimate limit when the linking is extended indefinitely in all directions and results, not in forming a molecule, but a crystal such as diamond (*see* fig. 23), which may

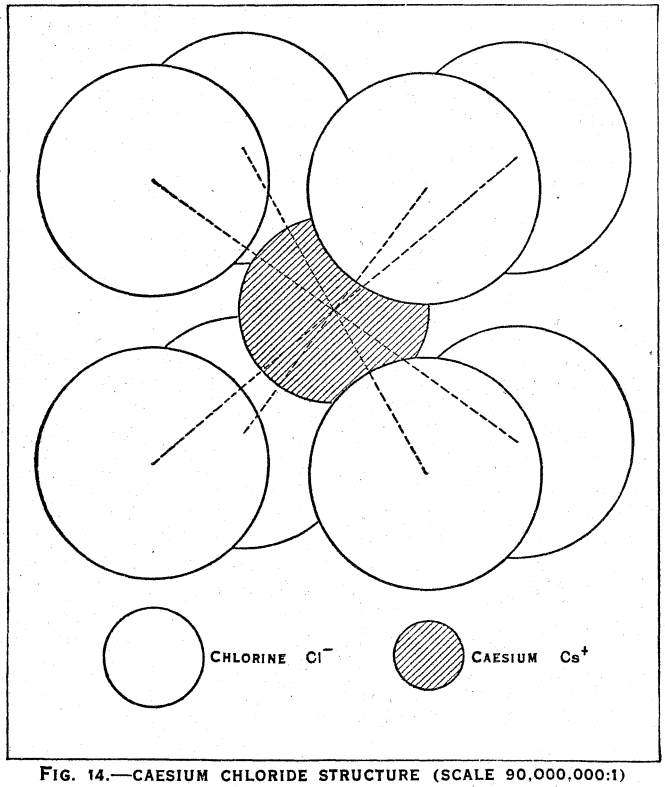

FIG. 14.—CAESIUM CHLORIDE STRUCTURE (SCALE 90,000,000:1)

be considered as one solid molecule. But homopolar bonds can also build up complex ions, such as the ammonium ion NH_4^+ with its ten electrons, which has the same relation to the neutral molecule CH_4 as the sodium ion Na^+ has to neon; or the series of negative ions ClO_4, SO_4, PO_4 and SiO_4.

Molecular Combination.—Between electrically neutral atoms and molecules which also have completed outer shells, there still exists a type of residual attraction which may be called molecular. In the simplest case of an inert gas atom, this residual attraction is only effective at very close distances and consequently, except at the lowest temperatures, the substance remains a gas. But at such temperatures it solidifies in a state of equilibrium between the attractive and repulsive forces, both probably due to distortions in the electronic structure. Very similar is the attraction

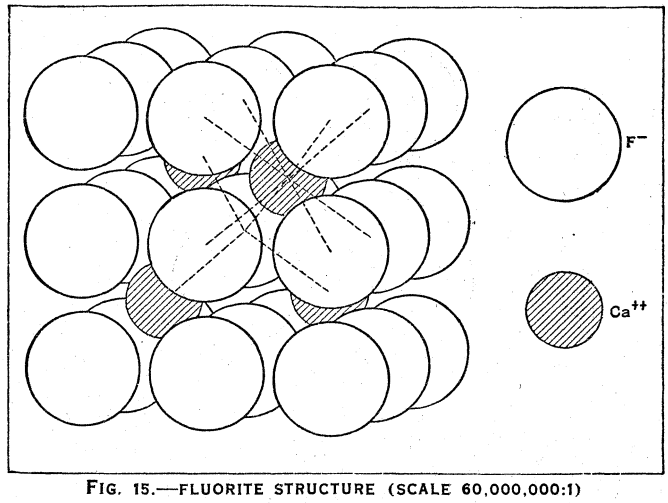

FIG. 15.—FLUORITE STRUCTURE (SCALE 60,000,000:1)

between non-polar molecules such as O_2 which also tend to have low melting points, but when a molecule is polar, that is, acts as an electric dipole or multipole, these poles attract others of opposite sign, with forces approaching those of ionic crystals.

Metallic Combination.—Metallic combination occurs when all the atoms tend easily to lose electrons. The positive ions thus formed cohere together, held by the electron gas, produced from the discarded electrons now no longer bound to particular atoms.

It is from such knowledge of the units of crystal structure, that is, atoms, simple and complex ions and molecules, and of the kind of forces holding them together, that we can see the physico-chemical meanings of the crystal structures which are found by the quite independent means of X-rays. But the process is two-sided. At the same time we learn from the structure much of the chemical and physical properties of atoms inaccessible by other methods.

Crystallised substances, that is to say, all solids with the exception of the glasses, may be divided into four main classes: the

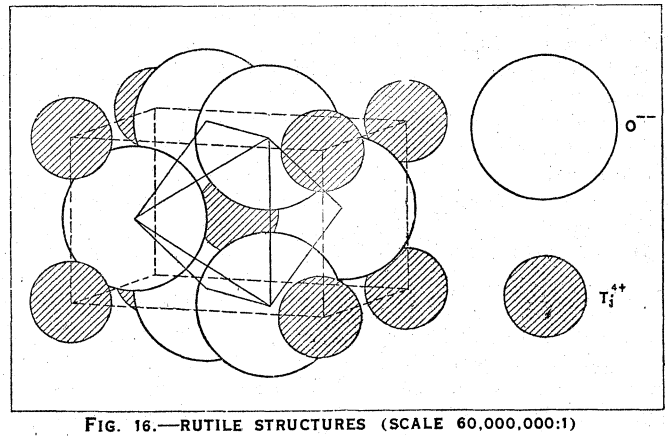

FIG. 16.—RUTILE STRUCTURES (SCALE 60,000,000:1)

ionic, the adamantine, the molecular and the metallic; and three prominent intermediate classes: the silicates, the layer lattices and the metalloids. The leading properties of these classes are shown in Table I.

Ionic Crystals.—These have been more studied than any of the other classes because the simple Coulomb electrical forces holding them together lead to simpler structures, of which it is sometimes possible to give a quantitative explanation. The first law of formation for ionic crystals was stated by Goldschmidt as follows:

Crystal type	Crystal units	Type of binding	Characteristic properties				Typical Crystals
			Optical	Electrical	Thermal	Mechanical	
Ionic	Simple and complex ions	Electrical attraction between ions of opposite signs, weak to moderate polarisation	Transparent, absorption: in visible (colour) if present is due to atoms; in short infra red is due to complexions; in long infra red is due to crystal lattice. Refractivity due to negative ions	Moderate insulators, in high fields conduct by transfer of ions. When polarisation is slight they dissolve with ionisation in ionising solvents (water); when stronger they are insoluble	Fairly high melting point, ionisation occurs in liquid and vapour	Hardness increasing with higher ionisation Tendency to fracture by cleavage	NaCl fig. (13) CaF_2 (15) $CaCO_3$ (21) K_2SO_4 $(NH_4)_2PtCl_6$ (20)
Silicate	O^{--} or F^- ions Si^{4+} or Be^{2+} or Al^{3+} and other positive ions				Very high melting points, glasses formed on cooling of melt	Very hard with tendency to cleave or fracture conchoidally	Olivine Mg_2SiO_4 (22) Cyanite Al_2SiO_5 Garnet $R''_3\,R'''_2Si_3O_{12}$ Spinel Al_2MgO_4 Corundum Al_2O_3
Adamantine	Atoms of the fourth group and groups on either side of it	Homopolar bonds throughout or strongly polarized ionic binding	Transparent with high refractivity or opaque metalloidal	Diamond is a perfect insulator. The others conduct metalloidally Very insoluble	Very high melting points with tendency to vapourise except in more metalloidal	Very hard Hardness less for metalloidal types	Diamond C (23) Zinc Blende ZnS Wurtzite ZnS (24) Carborundum CSi
Molecular	Inert gas atoms Non polar and polar molecules	Van der Waal's forces or residual electric fields between molecular poles	Transparent optical properties due to molecules and similar to gas and liquid phases	Insulators except when very polar; soluble in non-ionising (molecular) solvents except when polar	Melting point very low with neutral atoms, rises with heavier molecules and polar molecules	Very soft, hardness increasing with polarity of molecules. Deformation plastic	Argon A (31) CO_2 (25) Ice H_2O (18) Paraffins C_nH_{2n+2} (26) Calomel Hg_2Cl_2 (27)
Layer	Strongly polarising and easily polarised ions	In layers. Homopolar or polarised ionic Between layers Molecular	As Adamantine	Various. Similar both to molecular and adamantine	Various. Similar both to molecular and adamantine	Cleaving readily in layers which are soft and flexible	Graphite C (28) CdI_2 (29)
Metallic	Positive ions and electron gas	Electrical attraction between positive ions and electron gas?	Opaque (due to free electrons) with selective reflection in infra red	Conductors conductivity inversely proportional to number of free electrons Soluble in acids where H^+ ions absorb free electrons	Moderate to very high melting points. Long liquid interval	Moderate hardness increased by alloying. Elastic but yield by glide plane slipping when overstressed	Copper, Iron (30) Iron, Sodium (31) Zinc (32)
Metalloidal	Metal atoms and atoms of the sulphur and arsenic type	Mixture of homopolar ionic and metallic binding	Opaque metallic or transparent with high refractivity and colour	Medium to bad conductors Soluble only with decomposition	Tendency to vapourise or decompose at high temperatures	Moderately hard to soft. Properties a mixture of those of other types	Nickel Arsenide NiAs Fahlerz R''_2SbS_3 Pyrites FeS_2 (33)

"The crystal structure of a substance is determined by the size and polarisation properties of its components, which may be atoms, ions or atomic groups."

The size of an ion is, after its charge, its most important property. It varies very greatly for different ions. In fig. 12 is shown the size of a number of ions and atoms which illustrates their dependence on atomic number and charge. It can be seen that the size of a positive ion in the same group increases with the atomic number, while in the same series for positive ions, it decreases markedly with increasing charge, which acts by tightening the whole structure. But in negative ions, the increased size due to the repulsion of the extra electrons is counteracted by the greater fields they find themselves in, and consequently doubly charged negative ions are never greater than and sometimes smaller than singly charged. The way in which the increased charge tightens the structure is shown by the fact that in KCl, where both ions have eighteen electrons, the interatomic distance is 3·14 A; whereas in CaS, also with eighteen electrons each, but with quadruple electrostatic force, the corresponding distance has shrunk to 2·84 A.

The way in which atomic diameter influences structure can be seen from the simplest ionic structure of the type AX, with equal numbers of ions of opposite signs. The simplest of these is the structure of rock salt (*see* fig. 13), where sodium and chlorine ions occupy alternate corners of a cubic lattice. The co-ordination number is 6:6, that is, each sodium has six chlorine neighbours and vice versa. Actually, the chlorine ions are so large compared to the sodium that they form an octahedron that encloses it almost completely. Simple geometry shows that this can only be the case if R_A (radius of positive ion) : R_X (radius of negative ion) $< \cdot 73$. This relation holds for all halides of the alkaline metals with the exception of the chloride, bromide and iodide of caesium where the ratios $R_A:R_X$ are ·91, ·84 and ·75 respectively. Now these last three are the only alkaline halides which do not belong to the sodium chloride type but to the caesium chloride type. (*See* fig. 14.) Here the co-ordination number is 8:8 and there is, so to speak, more room for the larger caesium ion inside the cube of chlorine ions. Where $R_A:R_X$ is very small, the factor of polarisation comes in, and the structure becomes adamantine or molecular.

If we pass to the next simpler series, AX_2, a similar situation occurs. Where $R_A:R_X$ is greater than ·73, the structure is of the fluorite type. (*See* fig. 15.) Here the co-ordination number is 8:4, the calcium ions being surrounded by a cube of eight fluorine ions, just as the caesium by the chlorines. A great number of compounds belong to this type, which includes the chlorides of the alkaline earths and the oxides of zirconium, thorium and uranium. If $R_A:R_X$ lies between ·73 and ·41, a structure is formed

analogous to rock salt. This is the rutile structure. (*See* fig. 16.) Here the co-ordination number 6:3 cannot be satisfied in the cubic system and the octahedron of oxygen ions is placed on its

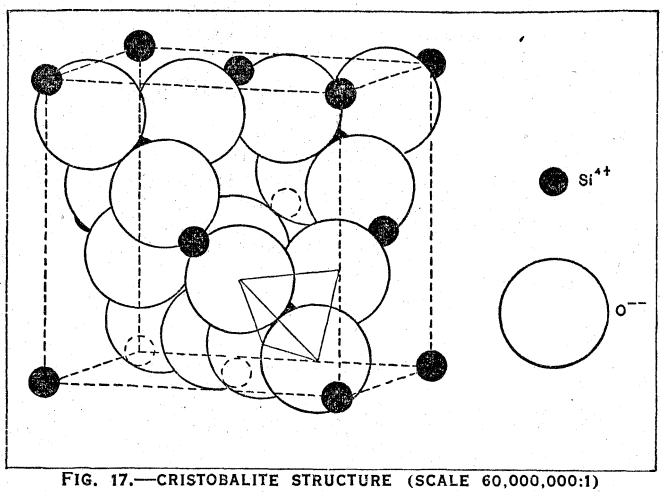

FIG. 17.—CRISTOBALITE STRUCTURE (SCALE 60,000,000:1)

side in a tetragonal structure. The two other forms of TiO_2, anatase and brookite, are also built with the same co-ordination but with the octahedra distorted and differently placed. A great number of substances belong to the rutile structure. The fluorides

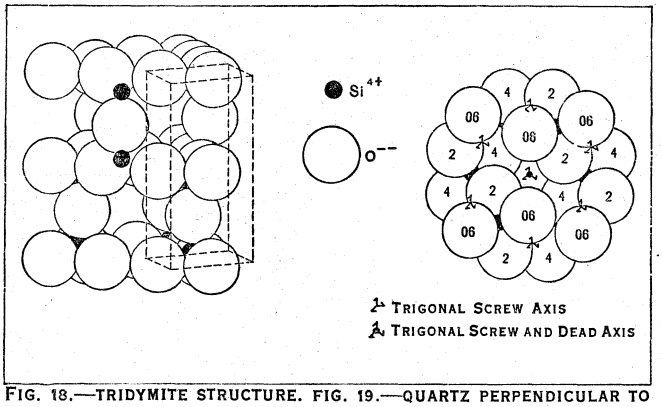

FIG. 18.—TRIDYMITE STRUCTURE. FIG. 19.—QUARTZ PERPENDICULAR TO THE TRIGONAL AXIS THE NUMBERS 0246 FOR THE O^{--} ATOMS AND 135 FOR THE Si^{4} ATOMS REFER TO DEPTHS BELOW PLANE OF PAPER (SCALE 30,000,000:1)

of Mg., Mn., Co., Fe., Ni., Zn. and the dioxides of Mn., Mo., Sn., W. and Pb., as well as several others.

When $R_A:R_X$ lies between ·41 and ·22, the co-ordination number is 4:2, which is approaching an adamantine structure. This is the

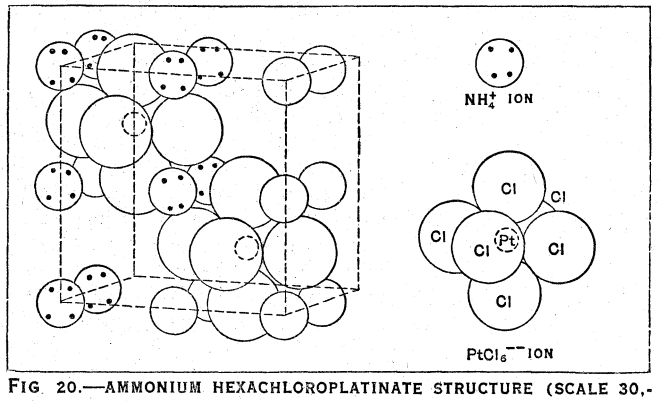

FIG. 20.—AMMONIUM HEXACHLOROPLATINATE STRUCTURE (SCALE 30,000,000:1)

case for the different forms of silica, SiO_2, Cristobalite, Tridymite and Quartz. These are shown in figs. 17, 18 and 19. Though apparently different, these structures have the essential point in common that they are built from silicon ions completely surrounded by four oxygens in a tetrahedron. Each oxygen is shared between two tetrahedra and the different forms of structure are merely due to different arrangements of these tetrahedra. Thus the polymorphism of silica is not due to any change in the molecule.

So far we have dealt only with crystals with simple ions, but those with complex ions are essentially similar. When the ion is

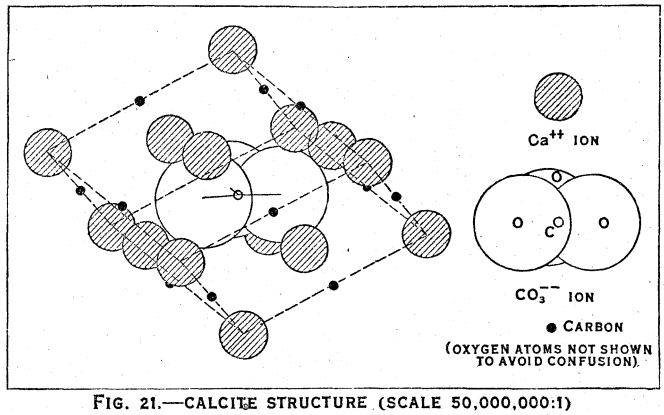

FIG. 21.—CALCITE STRUCTURE (SCALE 50,000,000:1)

approximately spherical, as is ammonium NH_4^+, or highly symmetrical as $Ni(NH_3)_6^{++}$,$PtCl_6^{--}$ it can take its place in a crystal exactly like a simple ion of the same size. Ammonium, NH_4^+, is practically indistinguishable in its compounds from Rb^+. Such

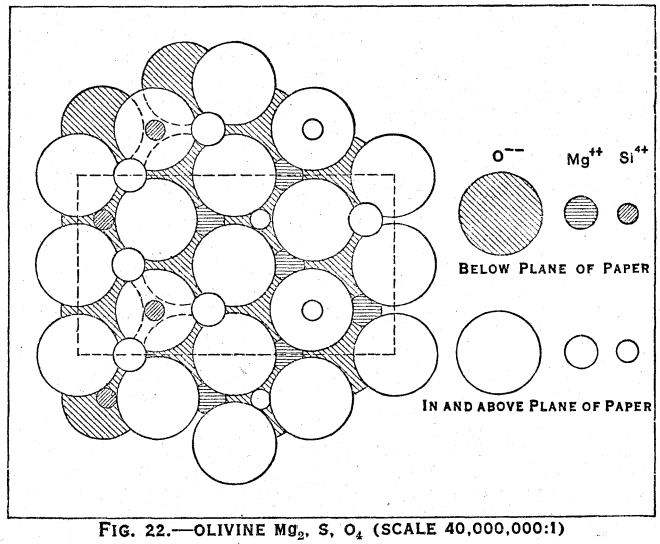

FIG. 22.—OLIVINE Mg_2, S, O_4 (SCALE 40,000,000:1)

a compound as $(NH_4)_2$ $(PtCl_6)$ (*see* fig. 20) is, except for its larger size, essentially the same as fluorite. When the compound ion is not nearly spherical, loss of symmetry results. In the case of calcite (*see* fig. 21), for instance, the ions are arranged very much as in rock salt, but owing to the flatness of the CO_3^{--} ion, one trigonal axis is shortened, leading to a rhombohedral crystal. A number of crystals, such as $FeCO_3$ and $NaNO_3$, belong to the calcite class. With ions of the type BX_4, such as BF_4^-, ClO_4^-, SO_4^{--}, PO_4^{---}, the structures are of even lower symmetry, though in all of these the tetrahedral arrangement of oxygen atoms is maintained.

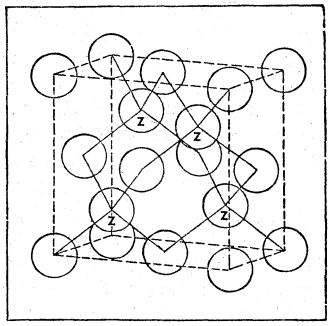

FIG. 23.—DIAMOND STRUCTURE; IF ATOMS MARKED Z ARE REPLACED BY ZINC AND THE REMAINING BY SULPHUR, ZINCBLENDE STRUCTURE IS GIVEN (SCALE 50,000,000:1)

Silicates.—There are a great number of ionic crystals which are neither of the simple ionic or complex ionic types, which may be grouped together as a silicate type, though not all contain silicon. The structure of the silicates are complex but, as W. L. Bragg has shown, they consist essentially of oxygen ions in a close-packed arrangement, either cubic or hexagonal (*See* figs.

31 and 33.) These ions are held together by strongly charged metallic ions, which occupy the spaces between them. In the tetrahedral spaces are found the smallest and most highly charged ions Si^{4+} Be^{++}. In the octahedral spaces larger ions with smaller charges, such as Ti_4^+, Al^{3+}, Mg^{++}, Fe^{++}. Still larger ions, such as Ca^{++} Na^+ or K^+, introduce distortions into the structure. The

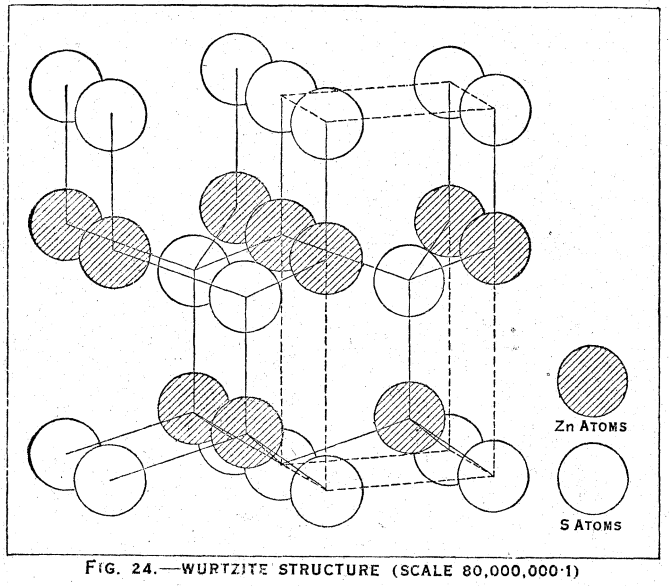

FIG. 24.—WURTZITE STRUCTURE (SCALE 80,000,000·1)

symmetry of the silicates adjusts itself to fit these ions with the minimum distortion, which leads to large and complicated cells, generally of low symmetry. One of the simplest of these olivine Mg_2SiO_4 is shown in fig. 22. Other silicates of known structure include cyanite Al_2SiO_5, phenacite Be_2SiO_4, beryl $Be_3Al_2Si_6O_{18}$ and

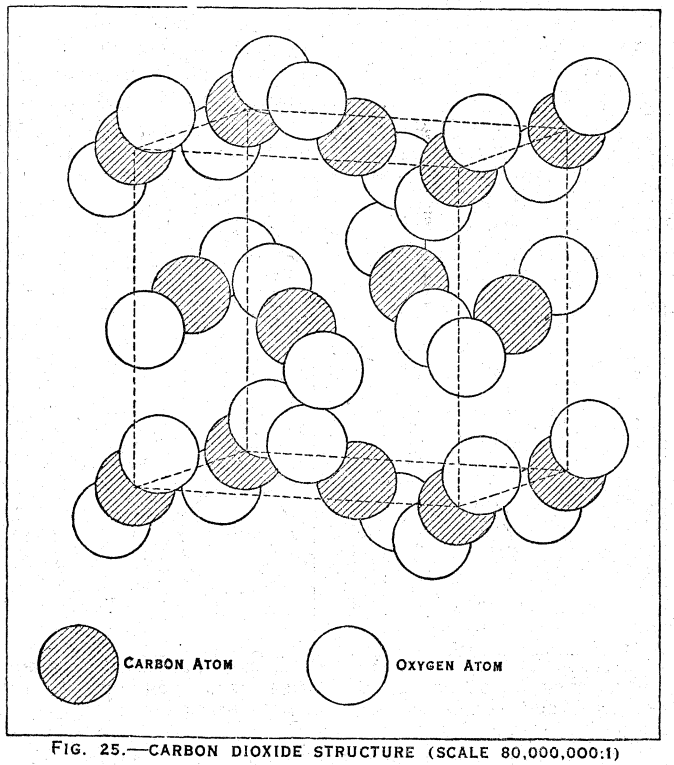

FIG. 25.—CARBON DIOXIDE STRUCTURE (SCALE 80,000,000:1)

the garnets $R_3''R_2'''$ Si_3O_{12}. Two non-silicate types are also built from close-packed oxygens, the corundum type Al_2O_3, including haematite Fe_2O_3 and $MgTiO_3$, and the spinel type Al_2MgO_4, including magnetite Fe_2FeO_4 and Ag_2MoO_4.

Adamantine Crystals.—In adamantine crystals the forces binding the whole crystal together are homopolar, so it may be considered that they are single molecules. The typical adamantine crystal is the diamond. (*See* fig. 23.) Here each carbon is joined to four others (co-ordination 4:4) by a homopolar electron sharing bond in a tetrahedral fashion, alternate tetrahedra pointing in opposite directions. If we replace alternate carbon atoms with zinc and sulphur, we arrive at the zinc blende structure, which is typical for adamantine compounds. Such compounds are chiefly found in the fourth group of the periodic table and in compounds between elements of the neighbouring groups on either side. For instance, we have

Compound	GeGe	GaAs	ZnSe	CuBr	
Atomic Numbers	32 32	31 33	30 34	29 35	
Interatomic dist.	2.43	2.435	2.45	2.46	A

all with diamond structure. It should be noticed that here, unlike the case of KCl and CaS, there is little change in interatomic distance. Another 4:4 is represented by Wurtzite (*see* fig. 24), the other form of zinc sulphide. The relations and the distances of neighbouring atoms are the same in both cases, but in Wurtzite, the symmetry is hexagonal instead of cubic. The three forms of carborundum represent a compound diamond-Wurtzite structure.

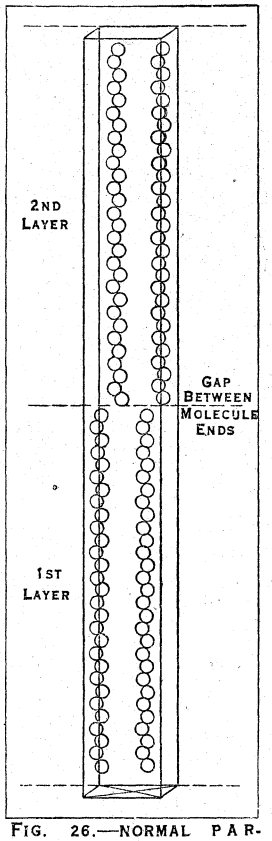

FIG. 26.—NORMAL PARAFFIN STRUCTURE (ONLY C ATOMS SHOWN) (SCALE 14,000,000:1)

Molecular Crystals.—In molecular crystals, the units of structure are neutral atoms or molecules, and as the forces are so much weaker, the determining factor is the shape of the molecules. The most ideally simple cases are the crystals of the inert gases, which are cubic close-packed. (*See* fig. 30.) The similar structures are found for symmetrical molecules such as CH_4, SnI_4 and more or less distorted for molecules N_2, O_2, I_2, NH_3 or CO_2 (*see* fig. 25), none of which are strongly polar. Another simple case is when the molecules are long, straight structures, such as those of the paraffins. (Fig. 26). Here they lie together like bundles of sticks, forming loosely connected layers. A study of compounds with benzene rings: benzene, naphthalene, hexamethylbenzene, shows that this ring of carbon atoms has a real existence and is probably plane, while studies of structures with quadruply substituted carbon atoms as tetraphenyl methane shows that the carbon bonds are arranged almost tetrahedrally.

If a molecule possesses unbalanced electrical poles, these arrange themselves in the crystal so as to neutralize each other as much as possible, either by polymerising or forming pseudionic crystals; thus ice formed from the strongly polar $_+H\diagup\overline{\underline{O}}\diagdown H_+$ has tridymite structure (*see* fig. 18), in which each oxygen is surrounded by four hydrogens, or calomel $\overset{-}{Cl}\overset{+}{Hg}\overset{+}{Hg}\overset{-}{Cl}$ (*see* fig. 27), in which the mercury atoms are surrounded by chlorines.

Layer Crystals.—A small but very interesting class are the layer crystals, in which the forces binding the atom extend only in two dimensions, forming large sheets which are held together by weaker molecular forces. The typical layer lattice is that of graphite. (*See* fig. 28.) Here the sheets are hexagons of carbon atoms, bound together in 3:3 co-ordination, 1·42 A, apart while the layers bound molecularly are 3·4 A apart. Another example is cadmium iodide. Here the polarisation of the large iodide ions prevents the normal ionic fluorite structure. To this type belong the hydroxides $Ca(OH)_2Mg(OH)_2$ and the sulphides ZrS_2, SnS_2.

Metals.—Metallic crystals differ from the previous classes by the presence of free electrons, the attraction between which and the positive ions gives the structure its stability. The basis of the

structure of pure metals and alloys is one of close packing, but the radii of atoms in metals are much greater than those of the corresponding ions in ionic crystals. (*See* fig. 12.) The pure metals have very simple structures: face centred cubic for Cu, Al, Feγ(*see* fig. 30); body centred cubic for Na, Feα, Feδ (*see* fig. 31) and close packed hexagonal cubic for Mg, Zn, W (*see* fig. 32). Several metals have phases with different structure. Iron, for instance, between the temperatures 1100° and 1425°, has a face centred cubic structure. Both above and below this temperature, its structure is body centred. Manganese has two forms with very complicated cubic structures, and tin, at low temperatures (grey tin) is like diamond, while at ordinary temperatures (white tin) it has a distorted diamond structure.

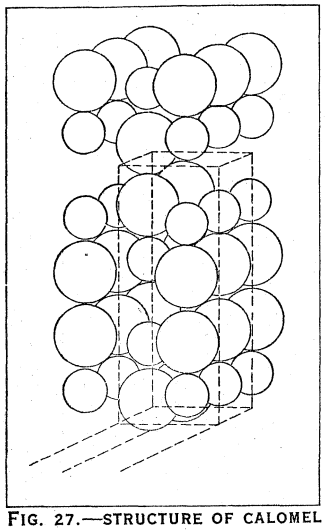

FIG. 27.—STRUCTURE OF CALOMEL Hg_2 Cl_2 (SEE FIG. 1) (SCALE 30,000,000:1)

Our knowledge of the real constitution of alloys is immensely furthered by X-rays. They are essentially of two types, solid solutions and compounds. In solid solutions, the atoms of one metal are replaced by another, distributed by chance throughout its structure. This is shown by an X-ray pattern similar to the pure metal but with a different size of cell. In inter-metallic compounds on the other hand, the atoms of the different metals have definite positions similar to those in ionic compounds, such as CuZn, which is like CsCl but usually more complicated, with a tendency to large cells of high symmetry. δ Bronze $Cu_{31}Sn_8$, for instance, has a cell of side 17·9 A. and 416 atoms. The laws of combination in metallic compounds are quite different from those of ordinary chemistry, but seem to depend on electron numbers.

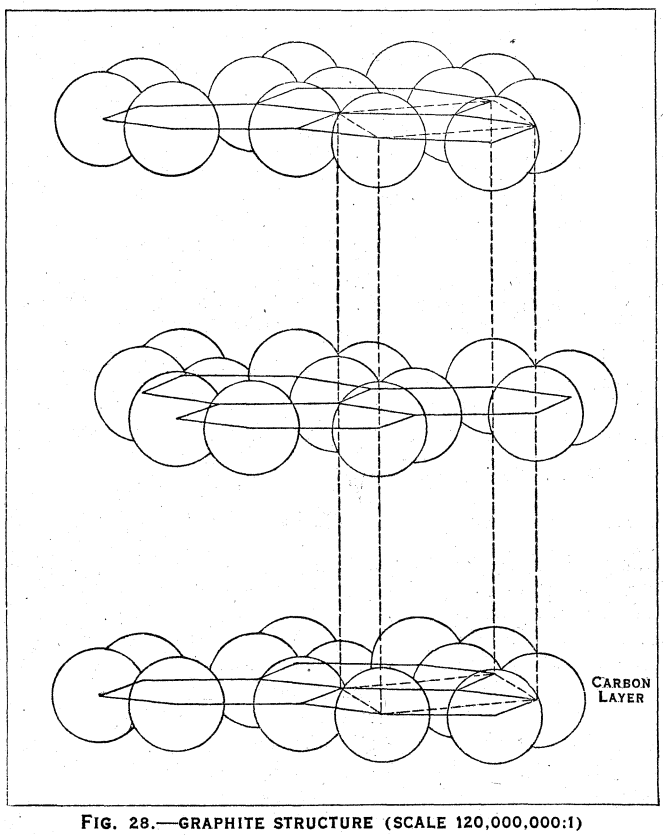

FIG. 28.—GRAPHITE STRUCTURE (SCALE 120,000,000:1)

Metalloidal Crystals.—There are a number of substances which show resemblances to both metallic, adamantine and ionic crystals. They may be roughly classed together as metalloidal These include the semi-metals Se, Te, As, Sb, Bi and a great number of simple and complex arsenides, antimonides, sulphides, selenides, etc. They resemble the metals in having free or loosely bound electrons, which makes them in a lesser degree opaque and conducting, and also by the complexity and indefinite composition of many compounds such as the fahlerz group, which contain Cu, Ag, Hg, Pb, Fe, As, Sb+S, in varying proportions The structures, however, are much less close-packed and resemble adamantine structures. Some, however, are more like ionic structures. Typical are pyrites (*see* fig. 33), which is a rock salt structure with Fe^{++} in the place of Na^+ and the complex ion S_2^{--} in that of Cl^-. Another is the nickel arsenide structure, hexagonal with 6:6 co-ordination, to which many substances belong.

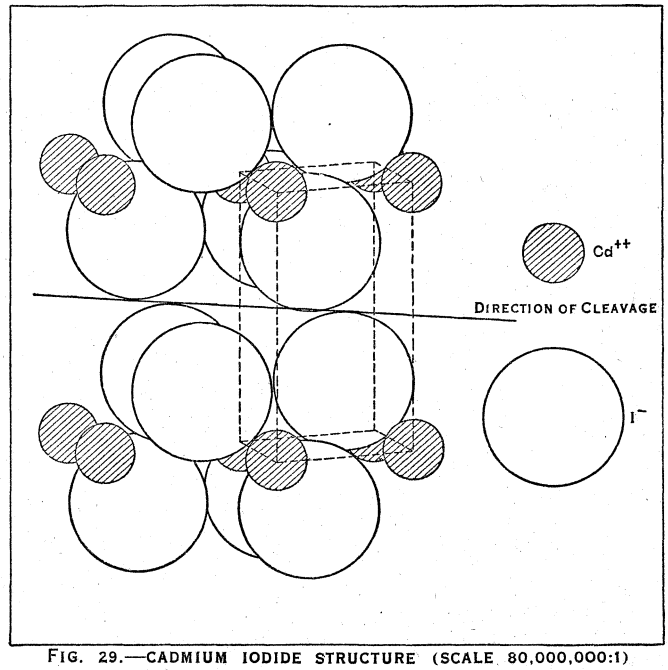

FIG. 29.—CADMIUM IODIDE STRUCTURE (SCALE 80,000,000:1)

Technical Applications.—This completes the systematic account of the structures of crystals, but X-rays have proved useful, not only in determining the positions of atoms in crystals, but of the arrangement of minute crystals in materials. It is possible by means of X-rays to find the position of the crystal axes of crystals far too small to be seen microscopically and to study their arrangement in relation to the properties of the material. This has been done in textiles, ceramics and metals.

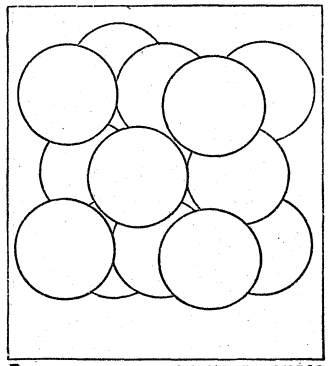

FIG. 30.—FACE CENTRED CUBIC STRUCTURE OF γ IRON AND COPPER AND OF ARGON (SCALE 60,000,000:1)

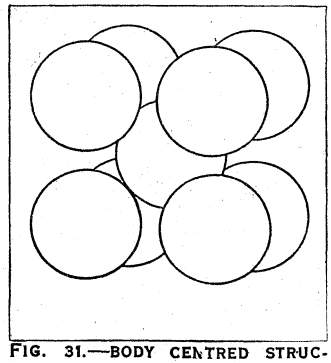

FIG. 31.—BODY CENTRED STRUCTURE OF α IRON (OR SODIUM) (SCALE 60,000,000:1)

Apart from their hardness, the chief mechanical property of metals is that of neither fracturing nor cleaving when overstressed, but deforming by the slipping of atoms along the glide planes, with consequent increase in hardness. This enables metals to be successfully worked, rolled, drawn, etc. Pure metals form

glide planes very easily, but the presence of another metal in solid solution interferes with the regularity of the lattice and makes gliding much more difficult, thus increasing hardness. The effect of alloying is greater, the more highly charged the alloying ion. Carbon has more effect, for instance, on iron than the same amount of cobalt. A piece of metal when cast has its small crystals of which it is composed oriented at random towards each other. On rolling or drawing, the crystals are not only elongated but they tend to take up positions with some crystallographic axis in the direction of the rolling. This is shown on a Debye diagram by the splitting up of the uniform rings into patches indicative of these preferred directions. On heating a rolled or a drawn metal, it recrystallises and the random orientation of the particles is restored. But at the same time, the hardness is lost. The explanation of these processes of hardening and annealing is energetically sought, largely by X-ray methods, and this has led to important technical results. The practical importance of X-ray analysis has only begun to be felt. *See* also SPECTROSCOPY; X-RAY; X-RAYS, NATURE OF; CRYSTALLOGRAPHY; SOLID STATE, THEORY OF.

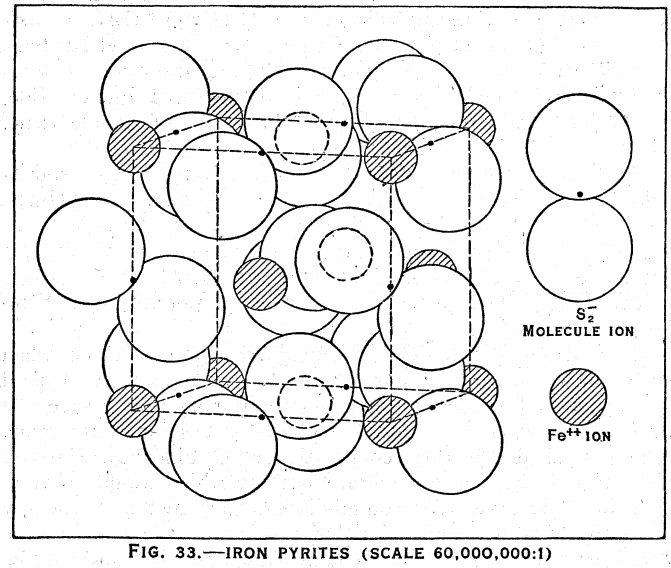

FIG. 33.—IRON PYRITES (SCALE 60,000,000:1)

X-RAY TREATMENT (*see* RADIOLOGY; RADIOTHERAPY). The X-rays are used extensively in medical treatment. They are valuable in many forms of skin disease, particularly those of a chronic character. They have a favourable influence upon enlargements of the lymphatic glands, of the spleen and of the thyroid gland. They give useful palliative effects in certain forms of malignant disease, and some permanent cures of cancerous conditions have been obtained by their use. In rodent ulcer, which presents features allied to cancer, there is no doubt of the efficacy of X-ray treatment for bringing about a complete cure in the majority of cases, provided that the disease has not advanced too deeply into the tissues.

The idea of using X-rays in the treatment of disease arose from recognition of the injurious effects which followed prolonged application of the rays for diagnostic purposes. Many early workers with X-rays noted the production of an inflammation of the skin, or a falling out of the hair over parts which had been subjected to X-rays, and Leopold Freund, of Vienna, has stated that his first attempts to utilize X-rays in treatment were made in 1896 to cure a hairy mole and were prompted by what he had read of such occurrences. A definite action of the rays upon the skin having been observed, their employment in the treatment of skin diseases followed as a natural corollary. Amongst the earliest investigators of the possible therapeutic effects of X-rays the names of Schiff, Freund, Kienböck, Holtzknecht, Sjögren and Stenbeck may be mentioned. In Great Britain C. R. C. Lyster, Sir Malcolm Morris, E. Dore and J. H. Sequeira were amongst the earliest investigators.

Therapeutic Dosage.—For operating successfully with an agent capable of producing decidedly harmful effects when given in large doses it is necessary to have a method of measurement, and the need for this quickly became apparent when X-rays were used for treatment. The results of X-ray photography had already shown that the tubes employed were capable of emitting radiations of varying powers of penetration, and that the tubes were by no means constant in this respect; and the question whether highly penetrating rays or rays of feeble penetration were to be preferred for therapeutic use became the subject of much discussion. It is now recognized that the choice depends upon the object of the treatment. So too the problem of measuring the quantity of rays emitted by a tube during a given time began to call for a solution. In 1901 Benoist designed an apparatus by which the quality of the rays emitted by a tube at any moment could be determined, and in 1902 Holtzknecht brought out the first quantitative device, a chromo-radiometer, which enabled the dose administered to a patient to be observed, and recorded for future guidance. Holtzknecht also drew up a scale of units by means of which the indications of his apparatus could be interpreted. The units of Holtzknecht are still used to express the dosage of X-rays, though his apparatus has been superseded. Holtzknecht's method of measurement consisted in observing the change of colour in certain pastilles when exposed to X-rays, and his apparatus consisted of a scale of tints, and a number of pastilles of a yellow tint which acquired a green colour during exposure. The composition of these was kept a secret, but analysis revealed in them the presence of potassium sulphate combined with celluloid or gelatine. The pastilles were laid upon the surface under treatment, and their change of colour was compared at intervals with the scale of standard tints.

Quantitative Measurement.—It was next thought that under suitable conditions the measurement of the current passing through the X-ray tube might serve as a guide to the quantity of X-rays emitted by the tube, but, although this is the case to a certain extent, the method of quantity measurement employed almost universally in X-ray treatment was that devised by Sabouraud and Noiré, and used with signal success by them in an enormous number of cases of ringworm, in which disease measurement of dose is of the most critical importance, for the following reason. The cure of ringworm by X-rays requires that all the hair of the affected region shall be caused to fall out, but, nevertheless, it is necessary for obvious reasons that the hair should grow again after the disease has disappeared. Now if the dose of X-rays be insufficient the hair does not come out and no cure results, while if the dose be too great the hair comes out but does not grow again; and the margin of safety is quite a narrow

one. The method of Sabouraud and Noiré which proved itself reliable for such critical measurements of dosage as are required for ringworm treatment, has to-day the universal acceptance of all X-ray workers for other forms of superficial X-ray treatment, although the use of their pastilles has certain disadvantages, notably that they react ill to highly penetrating or "hard" rays.

Sabouraud's pastilles consist of small disks of platino-cyanide of barium. This chemical compound has a bright yellow-green colour when freshly prepared, and changes through gradations of yellow to a brown colour when exposed to X-rays. The pastilles are supplied in a book with which a permanent tint of colour is supplied, to indicate the colour change in the pastille which corresponds with a quantity of X-rays equal to the maximum dose which the healthy skin will stand without inflammatory consequences. This is often spoken of as a "pastille dose." As the amount of irradiation needed to produce the change of colour is considerable, the salt is fixed, during the treatment, at a point halfway between the source of the rays and the skin surface under treatment. During an exposure the chemical salt, in the form of a small disk of the material on cardboard, is adjusted in the required position by means of a pastille holder, and it is examined at intervals during the course of the exposure, until it has reached the required tint. When in the holder the pastille must be protected from light, and should have a piece of metal as a backing.

In X-ray treatment some protection of the surrounding healthy parts is usually necessary. With this object various methods of shielding were devised, either covering the patient by impermeable materials, or enclosing the tube in an impermeable box with suitable windows for the passage of the pencil of rays which is to fall upon the part under treatment.

Effect on Tissues.—The effect of the rays on healthy tissues is in the main a destructive one, but some of the cells of the tissues are more sensitive to the rays than are others; and this permits of a selective effect being obtained, with the destruction of some cells and not of the whole tissue. Young cells, and actively growing cells, are the most susceptible, and for this reason it is possible to influence the glands of the skin and the papillae of the hairs with a dose which will not destroy the skin itself. The art of successful working with X-rays is based upon a careful adjustment of the dose so as to secure a selective destruction of the morbid elements, and to avoid wholesale damage to the part treated. The effects of excessive doses of X-rays is to produce an inflammation which may result in painful sores which obstinately refuse to heal for many weeks or months. In the case of "soft" rays a quantity up to double that of the usual maximum or pastille dose may be employed in urgent cases without risk of any serious inflammation. In the treatment of ringworm the exact pastille dose must not be exceeded or the fall of the hair is likely to be followed by permanent baldness.

The distance of the skin surface from the centre of the tube must be known, and the pastille arranged in place accordingly. Fifteen centimetres is a usual distance, and at this distance a tube working with a current of a milliampere should give the full therapeutic dose or "pastille dose" in about 15 minutes. In general X-ray treatment it is quite usual at the present time to proceed by the method of full doses at rather long intervals. From the experience obtained by Sabouraud in numerous cases of ringworm it has been found that a full dose must not be repeated until a month has elapsed.

Treatment of Abnormal Growths.—A great amount of work has been done with X-rays for the treatment of cancer, but it is now recognized that the X-rays do not cure a cancer, although they are of value for the relief of pain. Diminution of size in cancerous growths has frequently been observed, and in some instances sarcomatous tumours have completely disappeared under X-ray treatment. Sooner or later, however, the cancer or sarcoma returned either in the original site or elsewhere, and the patient died of the disease. How far the use of intensely hard X-rays produced by currents of some 150 KV, as in the Erlangen method of treating cancer, will prove effective, is doubtful.

X-ray treatment is of service for the treatment of enlarged "strumous" glands in the neck. When these glands are in the early stages, and there has not been any softening or breaking down of the gland tissue, the application of X-rays, a few times repeated in moderate doses, will determine the subsidence of the enlargement and may effect a complete cure.

In the massive glandular enlargements of lymphadenoma a great reduction of the tumours can be brought about by heavy doses of X-rays, but the results are to give a symptomatic rather than a real cure, for fresh glandular growths take place internally, and the usual course of the disease is not fundamentally modified

So too in leukemia, the symptom of excessive abundance of white cells in the circulating blood can be surprisingly altered for the better by X-rays, but generally without real cure of the underlying condition. The effect appears to be due to a direct destructive action upon the leucocytes of the blood.

The use of X-rays in fibroid tumours of the uterus has been advocated, particularly in France and in Germany. The action of the rays seems to be in part due to their influence upon the activity of the ovaries and in part to a direct effect upon the growing fibroids themselves, causing decrease of activity, relief of symptoms and reduction of the tumours. Not all varieties of fibroid are suitable for this kind of treatment. (H. L. J.)

XYLENE, the name given to certain hydrocarbons, the dimethylbenzenes, of which three forms exist with the same formula, $C_6H_4(CH_3)_2$ (*see* ISOMERISM); they occur in the light oil fraction of the coal tar distillate, but cannot be separated by fractional distillation owing to the closeness of their boiling points. The mixture can be separated by shaking with sulphuric acid, whereupon the ortho- and meta- compounds are sulphonated, the para- compound remaining unattached. The ortho and meta acids may be separated by crystallization of their salts or sulphonamides. The principal constituent of the light oil is *meta*-xylene, which is successively nitrated and reduced to commercial *m*-xylidine, (4-amino-1:3-xylene). From *para*-xylene a similar base, *p*-xylidine (2-amino-1:4-xylene), is prepared. Both xylidines are employed in colour making. *Keta*-xylene is also used in making artificial musk which is trinitro-*tert.*-butyl-*m*-xylene. (*See* PERFUMES.) Ortho-xylene is obtained from ortho-bromotoluene, methyl iodide and sodium as a colourless mobile liquid boiling at 142°, melting at −28°, and having a specific gravity of 0·8932 at 0°. Meta- or iso-xylene, the most important isomeride, has been obtained from Borneo petroleum (*see* TOLUENE), or by distilling with lime mesitylenic acid, $C_6H_3(CH_3)_2CO_2H$, an oxidation product of mesitylene, $C_6H_3(CH_3)_3$. Meta-xylene boils at 139°, melts at −54°, and has a specific gravity of 0·8812. Para-xylene obtained when camphor is distilled with zinc chloride, is best prepared from *para*-bromotoluene or dibromobenzene, methyl iodide and sodium.

The three xylenes are oxidized by nitric acid to the corresponding coluine acids. Further oxidation leads to ortho-, meta (iso)-, and para (tere)-phthalic acids. (*See* PHTHALIC ACIDS.)

XYLOPHONE, a small musical instrument, consisting of a graduated series of bars of wood, which are struck by a hammer.

XYSTUS, Greek term for the covered portico of a gymnasium.

X Y Z CORRESPONDENCE, the letters which when made public in 1798 nearly involved France and the United States in war. By orders of the French Directory fully a thousand U. S. vessels had been stopped on the high seas for examination. President Adams sent three commissioners, C. Pinckney, Marshall and Gerry, to France to negotiate a treaty which would do away with this annoyance. The commissioners were met in France by three agents who demanded a large sum of money before the Directory would receive the commission and also notified the commission that France would expect a loan from the United States if satisfaction of any other kind was to be given. The commissioners upon rejecting these overtures were ordered out of France. Their report was published at once in the United States and in it the French agents were labeled X, Y and Z, from which the correspondence took its name. The United States increased its army and navy, and hostilities were actually begun, when Talleyrand disavowed any connection with the agents and agreed to receive any minister the United States might send.

THE 25th letter of the modern alphabet dates only from Roman days in its present position. The Latin alphabet as adapted from the Chalcidic and Etruscan ended with X. The two final letters Y and Z were introduced after the conquest of Greece for use in Greek words transliterated and borrowed. Y was the form taken by the letter *upsilon* in the Ionic alphabet, which by the time of the Roman conquest had become generally used in Greece. The letter in the western or Chalcidic alphabet was in the form V in which form it had passed into Latin with the vocalic value of *u* and the consonantal value of modern English *w*. In the Greek *κοινή* based upon Attic the letter Y had the value of French *u* or German *ü*. This sound was unknown in the Latin language, and if pronounced in borrowed Greek words passed quickly into that of *i*.

In Old English and Middle English the letter was frequently used in place of *i*, e.g., in words such as *cyng*. In modern English its value is identical with that of *i* both long and short, its most frequent use being perhaps as final in the adverbial termination (e.g., *widely; strongly*). In addition it represents a palatal spirant most frequently when initial (*e.g.*, in words such as *yacht, yoke, young*). (B. F. C. A.)

YABLONOI or **YABLONOVOI** ("Apple Mountains"), known to the Mongols as *Dynze-Daban*, a range of the eastern part of Asiatic Russia. The range is really the eastern slope of a narrow north-northeast extension of the Malkan horst, which rises from eruptive rocks near Kiakhta. The Ingoda river flows along the foot of the range, which is 5,000–6,000 ft. above sea level, the highest point being Mount Sokhondo, near the Mongolian frontier. The descent of the Yablonoi to the trough of the Ingoda is 800 to 1,000 ft. and the slope is mainly rocky débris, with scattered patches of forest. The scarp cuts across the Archaean rocks, which strike to the east-northeast; all the horsts and ridges lying to the east of the Yablonoi are thus cut through by the Ingoda-Shilka valley, their waters flowing across the grain of the country in their course towards the Khingan range. The Yablonoi slope is part of the watershed between the Arctic-flowing and the Pacific-flowing streams and it also forms the boundary between the Siberian and the Daurian flora. The trans-Baikal railway crosses the range at 3,137 ft. above sea level.

YACHOW (YAAN, YACHOWFU), a city near the western borders of Szechwan, China, in 30° N., 103° E. Pop. about 30,000. It is situated on the banks of the river Ya, where tea is grown. The city is walled and is about 2 mi. in circumference. It is first mentioned during the Chow dynasty (1122–255 B.C.).

YACHT, a light and comparatively small vessel, propelled by sail or power and used for racing purposes or for pleasure exclusively. Boats propelled by oars or paddles are not considered as yachts. For sailing yachts *see* YACHTING. After the decade 1840–50, when steam began to replace sail in commercial vessels, this type of power, and later the internal combustion engine, was increasingly used in pleasure vessels. Large steam and power yachts were developed to a high degree and long-distance cruising became a favourite pastime of the rich. While the earliest power-driven yachts were paddle boats, this type of propulsion has been entirely abandoned in favour of the screw or propeller. In the transition from sail to power, steam auxiliaries carrying both sail and power were the fashion for many years. Steam engines were later replaced by the internal combustion engine and in the decade between 1930–40 practically all cruising yachts were auxiliaries, or else were strictly power yachts using gasoline or Diesel engines.

Among the early large auxiliary cruisers perhaps the highest development was reached in the "Valhalla," a ship-rigged auxiliary with triple expansion steam engines, built in 1892, of 1,490 tons Thames measurement. During the last decade of the 19th century there was a boom in the construction of large steam yachts, and conspicuous among these was the "Lysistrata" of 2,082 tons, and the "Mayflower" of 1,844 tons, which for a number of years was the official yacht of the president of the United States.

As internal combustion engines were developed they were built in increasingly larger sizes and good sized yachts were soon using them for power purposes. The development of the Diesel engine, using heavy oil for fuel, made great strides during World War I and in the decade that followed there was a boom in large power yacht building, which reached its climax about 1930 in the "Nourmahal" (1928), 1,969 tons, "Savarona" (1928), 2,076 tons, and "Orion" (1930), 3,097 tons. In the auxiliary fleet the largest yacht built during that period was the four-masted steel barque-rigged "Sea Cloud," of 2,323 tons, built in 1931.

The building of large power yachts began to decline after 1932. In the racing fleet the trend was toward classes of one-design sailing yachts not over 40 ft. in length; for cruising, auxiliaries of about 50 ft. became very popular, while in the straight power cruiser field, boats from 30 to 75 ft. in length were being turned out in ever increasing numbers. (H. L. ST.)

YACHTING, the sport of racing in yachts and also the pastime of cruising for pleasure in sailing, steam, or motor vessels. Yacht racing dates from the beginning of the 19th century; for, although there were sailing yachts long before, they were but few, and belonged exclusively to princes and other illustrious personages. During the reign of Elizabeth a pleasure ship was built (1588) at Cowes (Isle of Wight), so that the association of that place with the sport goes back a very long time. In 1660 Charles II was presented by the Dutch with a yacht named the "Mary," until which time the word "yacht" was unknown in England. He was fond of sailing, for he designed a yacht of 25 tons called the "Jamie," built at Lambeth in 1662, as well as several others later on. In that year the "Jamie" was matched for £100 against a small Dutch yacht, under the duke of York, from Greenwich to Gravesend and back, and beat her, the king steering part of the time—apparently the first record of a yacht match and of an amateur helmsman.

The first authentic record of a sailing club is in 1720, when the Cork Harbour Water club, now known as the Royal Cork Yacht club, was established in Ireland, but the yachts were small. Maitland, in his *History of London* (1739) mentions sailing and rowing on the Thames as among the amusements then indulged in; and Strutt, in his *Sports and Pastimes* (1801), says that the Cumberland society gave yearly a silver cup to be sailed for near London. The boats usually started from Blackfriars bridge, went up the Thames to Putney, and returned to Vauxhall, being no doubt mere sailing boats and not yachts or decked vessels. From the middle to the end of the 18th century yachting developed very slowly: although matches were sailed at Cowes as far back as 1780, very few yachts of any size, say 35 tons, existed in 1800 there or elsewhere. In 1812 the Royal Yacht squadron was established by 50 yacht owners at Cowes and was called the Yacht club, altered to the Royal Yacht club in 1820.

EARLY TYPES OF BRITISH YACHTS

Early English Yachts.—Among the earliest of which there is any record were the "Pearl," 95 tons, built by Sainty at Wyvenhoe near Colchester in 1820 for the marquess of Anglesey, and the "Arrow," 84 tons, originally 61 ft. 9½ in. long and 18 ft. 5¼ in. beam, built by Joseph Weld in 1822, which for many years remained a racing yacht, having been rebuilt and altered several times. The Thames soon followed the example of the Solent and established the Royal Thames Yacht club in 1823, the Clyde founding the Royal Northern Yacht club in 1824, and Plymouth the Royal Western in 1827. In this year the Royal Yacht squadron passed a resolution disqualifying any member who should apply steam to his yacht. In 1830 one of the largest cutters ever constructed was launched, viz., the "Alarm," built by Inman at

Lymington for Joseph Weld of Lulworth Castle, from the lines of a famous smuggler captured off the Isle of Wight. She was 82 ft. on the load line by 24 ft. beam, and was reckoned of 193 tons, old measurement, in which length, breadth and half-breadth (supposed to represent depth) were the factors for computation. Some yachtsmen at this time preferred still larger vessels and owned square-topsail schooners and brigs like the man-o'-war brigs of the day, such as the "Waterwitch," 381 tons, built by White of Cowes, in 1832, for Lord Belfast, and the "Brilliant," barque, 493 tons, belonging to J. Holland Ackers, who invented a scale of time allowance for competitive sailing. In 1834 the first royal cup was given by William IV to the Royal Yacht squadron. In 1836 the Royal Eastern Yacht club was founded at Granton near Edinburgh; in 1838 the Royal St. George's at Kingstown and the Royal London; in 1843 the Royal Southern at Southampton and the Royal Harwich; in 1844 the Royal Mersey at Liverpool and the Royal Victoria at Ryde. The number of vessels kept pace with the clubs, the 50 yachts of 1812 increasing nearly tenfold before the middle of the century.

First Alteration in Type.—In 1848, after J. Scott Russell had repeatedly drawn attention to the unwisdom of constructing sailing vessels on the "cod's head and mackerel tail" plan (*i.e.*, full bow and forebody and a long clean afterbody and run), and had enunciated his wave-line theory, Mare built at Blackwall an entirely new type of vessel, with a long hollow bow and a short afterbody of considerable fulness. This was the iron cutter "Mosquito," of 59 ft. 2 in. water line, 15 ft. 3 in. beam, and measuring 50 tons. Prejudice against the new type of yacht being as strong as against the introduction of steam, there were no vessels built like the "Mosquito," with the exception of the "Volante," 59 tons, by Harvey of Wyvenhoe, until the eyes of English yachtsmen were opened by the Americans three years later. About this period yacht racing had been gradually coming into favour in the United States. (*See* below.) John C. Stevens, who played a leading part in the development of boats for pleasure sailing and racing in the United States, commissioned George Steers of New York, builder of the crack pilot schooners, to construct a racing schooner to visit England in the year of the great exhibition, and the result was the "America," of 170 tons. She crossed the Atlantic in the summer of 1851, but failed to compete for the Queen's cup at Cowes in August, as her owner declined to concede the usual time allowance for difference of size, being desirous of obtaining a match race against only one yacht. The members of the Yacht squadron, not wishing to risk the reproach of denying the visitor a fair race, decided that their race for a cup given by the club, to be sailed round the Isle of Wight later in the same month, should be without any time allowance. The "America" entered and competed against 15 other vessels. The three most dangerous competitors being put out through accidents, the "America" passed the winning post 18 minutes ahead of the 47-ton cutter "Aurora," and won the cup; but, even if the time allowance had not been waived, the American schooner yacht would still have won by fully a couple of minutes. The prize was later given to the New York Yacht club and constituted a challenge cup, called "the America's cup," for the yachts of all nations, by the deed of gift of the owners of the winner. (*See* below for a complete account of these races.)

The First Great Era of Yacht Racing.—Between 1870 and 1880 there were some very notable additions to the racing fleet, including the schooners "Gwendolin," "Cetonia," "Corinne," "Miranda" and "Waterwitch"; the large cutters "Kriemhilda," "Vol au Vent," "Formosa," "Samoena" and "Vanduara," a cutter built of steel; the 40-tonners "Foxhound," "Bloodhound," "Myosotis"; and the yawls "Florinda," "Corisande," "Jullanar" and "Latona." The "Jullanar" may be noted as a specially clever design. Built in 1874 from the ideas of Bental, an agricultural implement maker of Maldon, Essex, she had no dead wood forward or aft, and possessed many improvements in design which were embodied and developed by the more scientific naval architects, G. L. Watson, William Fife, Jr., and others in later years. Lead, the use of which commenced in 1846, was entirely used for ballast after 1870 and placed on the keel outside.

No fewer than 400 matches took place in 1876, as against 63 matches in 1856, with classes for schooners and yawls, for large cutters, for 40-tonners, 20-tonners and 10-tonners. The Yacht-Racing association, established in 1875, drew up a simple code of laws for the regulation of yacht races, which was accepted by the yacht clubs generally. The association adopted the rule for ascertaining the size or tonnage of yachts which had been for many years in force, known as the Thames rule; but in 1879 they altered the plan of reckoning length from that taken on deck to that taken at the load water-line, and a few years later they adopted an entirely new system of calculation.

The Plank-on-edge.—These changes led to a decline in yacht-racing in England, the new measurement exercising a prejudicial effect on the sport, as it enabled vessels of extreme length, depth and narrowness, kept upright by enormous masses of lead on the outside of the keel, to compete on equal terms with vessels of greater width and less depth, in other words, smaller yachts carrying an inferior area of sail. The new type was known as the "lead mine" or plank-on-edge type.

Revival of Yacht-racing Under Length and Sail Area Rule.—Dixon Kemp in 1887 induced British yachtsmen to abandon the system of measuring yachts by tonnage and to adopt a new system of rating them by water line length and sail area. The new system contained no taxes or penalties upon beam or depth nor upon "over-all" length. The only factors measured were the water line and the area of the sails. All the old tonnage rules taxed the length and the breadth. This change of the system measurement crushed the plank-on-edge type completely.

Yachtsmen were greatly pleased with the broader and lighter types of yachts that designers began to turn out under the length and sail area rule. They were more comfortable and drier in a seaway than the old vessels. The first large cutters built with considerable beam were "Yarana" and "Petronilla" in 1888, and in 1889 the first of Lord Dunraven's "Valkyries" was a vessel that was much admired.

The Second Great Era in Yachting.—The seasons following 1892 are identified with the big cutter racing. The revival under the length and sail area rule had so far extended to "Iverna," "Tarana," "Petronilla," and "Valkyrie I" being built in the first class, but then there had been a pause of some years during which large numbers of 40-raters, 20-raters and the Solent classes had been built. Just when the critics were declaring that in the future no yachtsmen would build a class racer larger than a 40-rater (60 ft. L.W.L. with 4,000 sq.ft. of sail), the prince of Wales (afterward Edward VII) gave an order for the cutter "Britannia," while Lord Dunraven built "Valkyrie II," A. D. Clarke "Satanita" and Peter Donaldson "Calluna"; and in this same season (1893), an American yachtsman took the Herreshoff yacht "Navahoe" over the Atlantic. Yacht designing and building now became a science demanding the highest tax upon the skill and ingenuity of the naval architect. The cutter "Valkyrie II" visited the United States in 1893, but Lord Dunraven's vessel was beaten by the "Vigilant." Curiously enough, when the crack Herreshoff cutters "Navahoe" and "Vigilant" visited the British Isles they were severely beaten by the British yachts. During the years that followed the "Britannia" held a wonderful record.

After some years of designing to the length and sail area rule it became apparent that the "skimming dish" type the designers were producing under the rule would have no cabin accommodation or head room, and that the evolution of such type would be as bad for the sport as the development of the old plank-on-edge had been in 1885. It seemed strange that while the old tonnage rule had evolved the plank-on-edge ten years previously, the sail area measurement now evolved a plank-on-side, balanced by a fin. The fact was that designers had solved the problem. The rule measured only the length and the area of canvas. Taking the length of the vessel on the water line as constant, then the vessel with the smallest possible weight could be driven with less sail at the same speed as vessels with greater weight and greater sail. This solution of the problem was not apparent to designers from 1880 to 1885, because of the difficulty of obtaining stability. From 1880 to 1885 stability was obtained by means of very heavy keels. In 1895 the

stability was obtained by means of a light piece of lead placed at the bottom of a deep steel fin.

The First Linear Rating Rule.—To endeavour to check the tendency to build skimming dishes the Yacht-Racing association (Great Britain) introduced in 1896 a new system of measurement which was proposed by R. E. Froude. The novelty of this rule consisted of a tax upon the skin girth of the yacht, whereby a vessel with hollow midship section was penalized by her girth being measured round the skin surface. Froude's first system of rating began on Jan. 1, 1896, and ended at the close of the year 1900. The measurement of the yacht was obtained by the following formula:—

$$\frac{\text{Length L.W.L.} + \text{beam} + \frac{3}{4}\text{ skin girth} + \frac{1}{2}\sqrt{\text{(sail area)}}}{2} = \text{linear rating.}$$

This rule partially failed in its object. It was hoped that the skin-surface measurement would prevent the fin-bulb type being successful, but Froude and his colleagues had underestimated the possible developments of exaggerated pram bows, immense scow-shaped shoulders and stern-lines, all of which could be introduced into the skimming-dish type with great success. So, notwithstanding the small premium on displacement this rule contained, the dishes could still beat the full-bodied yachts.

The Second Linear Rating Rule.—This rule, also suggested by Froude, was introduced on Jan. 1, 1901. The Y.R.A. agreed to fix this rule for a period of seven years. The object of the rule was to ensure a big-bodied vessel. The formula was:—

$$\frac{\text{Length} + \text{breadth} + \frac{3}{4}\text{ girth} + 4\bar{d} + \frac{1}{2}\sqrt{\text{(sail area)}}}{2.1} = \text{linear rating.}$$

Now the novelty of this rule was the new tax $\bar{d}$. This $\bar{d}$ represents the difference in feet between the measurement of the girth of the yacht's hull taken round the skin surface and the girth at the same place measured with a string pulled taut. This measurement was taken $\frac{6}{10}$ the distance from the fore end of the water line. It is easy to see that in a full-bodied yacht $\bar{d}$ = a small unit, while in a hollow-bodied yacht $\bar{d}$ = a larger unit. Four times $\bar{d}$ being taken, it followed that hollow-bodied yachts were heavily penalized.

Class Racing, Handicapping and Cruiser Racing.—Yacht racing may be subdivided under these three heads. Yacht racing by rating measurement or tonnage, when either the first yacht to finish is the winner, or the yacht saving her time by a fixed scale of time allowance in proportion to the rating of the vessel and the length of the course, is called class racing, and it obviously tends to encourage the fastest possible vessel under the current rating rule to be produced. It has always been regarded as the highest form of the sport. It is naturally, however, the most expensive form, because only the most up-to-date and perfectly equipped vessels can keep in the first flight.

From time to time, chiefly from about the years 1884 and 1885 onwards, handicaps framed according to merits have been fashionable among yachtsmen. They were originally devised to afford amusement and sport to out-classed racers and cruisers. Owing to the expense of class racing, handicap racing thrived greatly during the period of the first and second girth rules. During these periods, too, the third style of yacht racing came into vogue, namely, cruiser racing; either very fast cruisers were built specially for the purpose of handicap racing, or a number of yachts of exactly similar design were built specially to the owner's orders for the purpose of racing in a class together. The fast handicap cruisers had the great advantage over class racers from 1896 up to 1906, inasmuch as they were much more strongly built.

The First International Rules Introduced.—In April 1904 B. Heckstall-Smith drew the attention of German, French and British yachtsmen to the fact that the yacht measurement rules (then different in the various countries) were generally due to terminate about the end of 1907, and suggested that many advantages would accrue if an international rule could be agreed upon. The Yacht-Racing association agreed to take the matter up, and at two international conferences, held in London in January and June 1906, an international rule of yacht measurement and rating was unanimously agreed to by all the nations of Europe. America alone did not attend the conference. R. E. Froude, a nephew of the historian, struck the keynote of the object of the conference by a statement that the ideal yacht should be a vessel combining "habitability with speed." Old plank-on-edge types under the tonnage rules were habitable but slow. Skimming dishes attained the maximum speed, but were uninhabitable. A good form was attained in 1901 with "Magdalen," but since that year the bane of light construction had become harmful to yachting. Hence the conference aimed at a rule which would produce a yacht combining habitability with speed. They adopted a form of linear rating comprising certain penalties upon hollow midship section (*i.e.*, Benzon's $\bar{d}$ tax) and also upon full pram (spoon shaped) bows. The following was adopted as the rule by which all racing yachts in Europe were rated:—

$$\frac{L + B + \frac{1}{2}G + 3\bar{d} + \frac{1}{3}\sqrt{S - F}}{2} = \text{rating in linear units, } i.e., \text{ either feet or metres.}$$

Where L = length in linear units.
" B = extreme beam in linear units.
" G = girth in linear units.
" $\bar{d}$ = girth difference in linear units.
" S = sail area in square units.
" F = freeboard in linear units.

The length L for the formula was the length on the water line, with the addition (1) of the difference between the girth, covering board to covering board, at the bow water line ending, and twice the freeboard at that point, and (2) one-fifth of the difference between the girth, covering board to covering board, at the stern water line ending, and twice the freeboard at that point. The additions (1) and (2) penalized the full overhangs and the bow overhang in particular. The girth, G, was the chain girth measured at that part of the yacht at which the measurement is greatest, less twice the freeboard at the same station, but there were certain provisions allowing the measurement of girth generally to be taken 0.55 from the bow end of the water line. The girth difference, $\bar{d}$ in the formula, was the difference between the chain girth, measured as above described, from covering board to covering board, and the skin girth between the same points, measured along the actual outline of the cross section.

For racing the yachts were divided into 11 classes. Class A for schooners and yawls only, above 23 metres (75.4 ft.) of rating, with a time allowance of four seconds per metre per mile. All the yachts in this class were classed A1 at Lloyd's. In racing, yawls sailed at their actual rating and schooners at 12% less than their actual rating. The other classes were ten separate classes for single-masted vessels only in which there was no time allowance.

The new rule produced the type of yacht desired—a vessel combining habitability with speed. Among the handsomest examples were the German emperor's schooner "Meteor IV" (1909), and the schooner "Germania" (1908), 400 tons or $31\frac{1}{2}$ metres measurement, Class A, both built by Krupp's at Kiel. German designed, German built and Germain rigged and manned, they demonstrated the wonderful strides made by Germany in yachting. A few years before there were not a dozen smart yachts in Germany, and, indeed, the Kaiserlicher Yacht club at Kiel was only founded in 1887. The "Germania" holds the record over the old "Queen's course" at Cowes, having in 1908 sailed it a quarter of an hour faster than any other vessel. Her time over the distance of about 47 to 48 nautical miles was 3 hours 35 min. 11 sec., or at the rate of 13.1 knots. The success of the international rule was remarkable. The Table on page 866 gives the racing yachts built under it in all countries from its foundation in 1907 to the outbreak of World War I in 1914.

The total does not include the big schooners of Class A, such as "Meteor IV," "Meteor V," "Germania," "Waterwitch," "Westward" and "Margherita," enormous vessels of 400 tons, and a number of small yachts built in Scandinavia and neutral countries early in the war, from 1915 to 1917, when the first international rule came to an end. There were thus upwards of 800 yachts built to this rule for international racing.

Much of the finest racing in the whole history of yachting took place from 1908 until 1914. The International Yacht Racing

Class in metres	Length in feet	Number of yachts built
23	75·4	3
19	62.3	6
15	49.2	19
12	39.4	35
10	32.8	54
9	29.5	25
8	26.2	174
7	23.0	86
6	19.7	328
5	16.4	41
Total	..	771

union was established under the chairmanship of the British Yacht Racing association and consisted of all the European nations and the Argentine republic. British yacht building was flourishing, German yachting was at its zenith under the kaiser. International regattas on a big scale were held at Spithead in 1911, at Kiel in 1912, at Le Havre in 1913, and in the Oslo fjord in 1914. America was attracted to European yachting, and in 1910 an American racing schooner came to Europe, the "Westward," 323 tons, designed and built by Herreshoff. She started in 11 races and won them all. Sir Thomas Lipton's 23-metre cutter "Shamrock" remained the best British cutter during these seasons.

The End of the First International Rule.—The yachting season of 1912 was notable for the appearance of a new 15-metre yacht, the "Istria," designed on novel lines by C. Nicholson for Sir Charles Allom, and the first of a series of yachts by the same clever designer which quickly began to defeat the purpose of the international racing rule. In 1912 and 1913 his great schooner "Margherita" and the cutters "Istria," "Pamela," "Paula III" and others were of an undesirable type, but so efficient as racers that they outsailed the yachts of all other designers.

The Second International Rule.—When World War I broke out in the summer of 1914, it put an end to all yacht racing in Great Britain, Europe and, later, in the United States, and the sport was only revived in 1919–20. At the end of the war, the Scandinavian nations purchased many of the best of the British racing yachts and the cost of building new yachts in Britain was prohibitive. But in 1919 the International Yacht Racing union was re-formed, and a new rating rule was adopted in 1920 by those countries which then adhered to that international racing body. This rule, with some modifications made at subsequent conferences, is the rule which has remained in force ever since, and which was adopted by the North American Yacht Racing union in 1927, after a meeting of its delegates and those of the International Yacht Racing union in London. It was essential in framing this rule to keep in view (1) Froude's ideals combining "habitability and speed" in the new yachts built for racing, and (2) the economy of labour in handling the yachts, *i.e.*, to reduce the sail area utilized to propel the hull. The object was to try to produce a habitable vessel of medium size which, instead of requiring enormous sails to drive the hull and that would require a crew of, say, eight men to work her, to produce a racing yacht with the equivalent accommodations that could be driven with one-third less canvas and would require a crew of, say, only four men. The international conferences of 1919, 1924 and 1926 framed two separate rules, one for yachts up to 12 metres and another for those above 12 metres. These were as follows:

Part I. For classes of 6-, 8-, 10- and 12-metres:

$$\frac{L+\frac{1}{4}G+2d+\sqrt{S}-F}{2.5}=\text{rating.}$$

Part II. For yachts above 12-metres:

$$\frac{L+\sqrt{S}-F}{2.3}=\text{rating.}$$

L = the "sailing length" being the length L.W.L. (length on water line) with certain additions, including measurements of the length of the overhangs at the bow and stern, and also the fullness or girth of the said overhangs.
G = the chain girth.
d = the difference between the skin and chain girths, but not taken round the bottom of the keel.
S = the sail area.
F = the freeboard.

A limit in each rule was placed upon draught of water and height of masts or sail plans.

Amendments adopted at subsequent International Conferences in London altered this measurement formula to the one that was in force in 1939 when the European War broke out, and again put a stop to yacht building and racing. This formula is, for the 6-, 8-, 10-, 12-, and 14½-metre classes:

$$\frac{L+2d+\sqrt{S}-F}{2.37}=\text{rating in linear units}$$

Where L = length in linear units.
" d = girth difference in linear units.
" S = sail area in square units.
" F = freeboard in linear units.

This, until altered, is the present (1944) international rule.

By far the most important innovation, however, in both rules was a limit upon the displacement of the yacht in proportion to her length. For many years there had been a "limit" or "penalty" upon the displacement of yachts under the universal rule in America. In 1919–20 the International Yacht Racing union of Europe adopted the American limit upon displacement. It has already been explained how, in the year 1895, the lack of displacement of the skimming dish fin and bulb raters killed the original English length and sail area rule, there being, of course, no limit upon the *minimum* displacement then permitted.

These new international rules are, in effect, nothing more nor less than length and sail area rules *plus* the all-important addition of a limit upon the minimum displacement. This is an actual fact, because L and S are the predominant factors of the rules, and the G, d and F amount to a very trifling percentage of the total.

The Bermudian Rig.—A direct outcome of the new international rule was the evolution of the Bermuda rig (*q.v.*).

The Development of Yachting After 1919.—Owing to the increased cost of the sport, the progress of yachting from 1919 until the year 1944 has been gradual. For a few years class racing for new yachts under the international rule was chiefly confined to the smaller classes of 12 metres and under. A 6-metre yacht built in 1914 cost about £500, and in 1928 it cost about £1,100. The 75-foot or 23-metre "White Heather" and "Shamrock," built in 1907 and 1908, cost about £9,000 or £9,500. The 23-metre yachts "Astra" and "Cambria," built in 1928, cost between £24,000 and £25,000. It is, therefore, not a matter for surprise that yachtsmen now cruise and race in yachts of smaller tonnage than in former times. Notwithstanding the cost of building, an enormous number of racing yachts were built to the second international rule from 1920 to 1928, as is shown by the following table:

Class in metres	Length in feet	Number of yachts built
23	75	3
12	39·3	24
10	32.8	20
8	26.2	60
6	19.7	200
Total	..	307

These yachts were built in Great Britain, Scandinavia, America, France, Italy, Belgium, Holland and Spain. The British 23-metres (built in 1928) are the "Astra," built by Nicholson for Sir Mortimer Singer, and the "Cambria," by Fife, for Sir William Berry. The most famous 12-metres was the "Vanity," built by Fife for J. R. Payne, and the "Norisca," built by Johan Anker at Oslo.

In the United States the 6-metre and 12-metre classes became popular, and in the latter class Olin J. Stephens designed the "Vim" for Harold S. Vanderbilt in 1938. In 1939 this yacht was taken to England where she raced with success in her class. In the 6-metre class international competition was spurred by the contests for the British-American cup, inaugurated in 1921 and sailed until 1924 between teams of British and American sixes. Each country was represented by four yachts selected to form its

2. A schooner yacht close hauled on the wind off Cowes, Isle of Wight, yachting centre of the south coast of England

team. The contests were sailed alternately in each country. Britain finally obtained the trophy by winning three of the four races. This was followed in succeeding years by international races for the Scandinavian gold cup and the Seawanhaka cup in the 6- and 8-metre classes. Under the second international rule, however, no individual country has carried off the palm. Norway, Sweden and the United States have shared the honours with Britain. For the first time in the history of yachting it appeared that yacht designers were unable to make certain of defeating an old yacht, under the rules, with a new vessel.

The King's Yacht "Britannia."—Encouragement was given to the pastime of yacht racing after 1920 by the king's taking the lead in the sport in British waters and refitting the old cutter "Britannia" for racing. This yacht, designed by G. L. Watson, and built in the year 1893, had a hull form very similar to that fostered and developed by the new rating rules of 1920. The chief difference between the "Britannia's" hull form and that of modern yachts was that the latter have greater freeboard, and are consequently able to develop higher speed when pressed by fresh wind. The form of modern yachts is also somewhat more elongated and more easily driven in light winds. Nevertheless, with the aid of a small handicap allowance in her favour, the "Britannia" was raced with much success from 1920 to 1935 when, after the death of King George V, at the end of a long and honourable career she was retired from racing and in 1936 taken out and sunk in the waters of the British channel. The "Britannia" thus had two distinct careers. First, from 1893 to 1897, and second, from 1920 to 1935. No other vessel in the world has won so many prizes or sailed so many races. The following is her complete record:

Year	Number of starts	Number of first prizes	Number of other prizes	Total
1893 to 1922	299	151	37	188
1923	26	11	11	22
1924	19	7	5	12
1925	36	6	6	12
1926	23	4	7	11
1927	24	8	8	16
1928	34	9	10	19
1930	26	5	5	10
1931	20	6	7	13
1932	32	9	14	23
1933	39	12	12	24
1934	27	3	7	10
1935	20	0	0	0
	625	231	129	360

The Speed of Sailing Yachts.—It may be said that the speed of sailing yachts of normal dimensions varies according to the square root of their length. In judging the speed of modern yachts a comparison thereof is usually made through the "rating measurement." A yacht of 20 metres or 65.6 rating length, in a strong wind can maintain a maximum speed of about 12 knots. The time allowance in seconds per mile between yachts of different "sizes," "ratings" or "lengths" is usually found by the formula:

$$\frac{2{,}160}{\sqrt{r}} - \frac{2{,}160}{\sqrt{R}}$$

where R is the rating length of the large yacht and r that of the smaller yacht.

It is interesting to recall some old records of speed over courses inside the Isle of Wight.

Date	Yacht	Distance	Time	Remarks
1858	The Arrow	45 miles	4 hr. 19 min.	Cutter|Same
1872	The Arrow	50 ,,	4 hr. 40 min.	Cutter/vessel.
1872	Kriemhilda	50 ,,	4 hr. 37 min.	Cutter.
1883	Marjorie	50 ,,	4 hr. 26 min.	Cutter.
1883	Samoena	50 ,,	4 hr. 15 min.	Cutter.
1885	Lorna	50 ,,	4 hr. 14 min.	Yawl.
1885	Irex	50 ,,	4 hr. 7 min.	Cutter.
1870	Egeria	50 ,,	4 hr. 27 min.	Schooner.
1875	Olga	50 ,,	4 hr. 25 min.	Schooner.
1879	Enchantress	50 ,,	4 hr. 18 min.	American schooner.
1902	Meteor	47 ,,	3 hr. 50 min.	American schooner.
1908	Cicely	46 ,,	3 hr. 43 min.	British schooner.
1908	Shamrock	47 ,,	4 hr. 0 min.	British cutter, only 75 ft. L.W.L.
1908	Germania	47 ,,	3 hr. 35 min.	German schooner.

The First Contest for the America's Cup.—This international trophy was originally a cup given by the Royal Yacht squadron at Cowes, Isle of Wight, on Aug. 22, 1851, for a race open to all yachts, with no time allowance of any kind, the course being "round the Isle of Wight, inside the No Man's buoy and Sand Head buoy and outside the Nab." Fifteen vessels took up their stations off Cowes and started from moorings. In the table following are the names of the competitors.

Yacht	Rig	Tons	Owner
Beatrice	Schooner	161	Sir W. P. Carew.
Volante	Cutter	48	J. L. Craigie.
Arrow	Cutter	81	T. Chamberlayne.
Wyvern	Schooner	205	The duke of Marlborough.
Ione	Schooner	75	A. Hill.
Constance	Schooner	218	The marquis of Conyngham.
Gipsy Queen	Schooner	160	Sir H. B. Hoghton.
Alarm	Cutter	193	J. Weld.
Mona	Cutter	82	Lord Alfred Paget.
America	Schooner	170	J. C. and E. A. Stevens, *et al.*
Brilliant	3-masted schooner	392	G. H. Ackers.
Bacchante	Cutter	80	B. H. Jones.
Freak	Cutter	60	W. Curling.
Eclipse	Cutter	50	H. S. Fearon.
Aurora	Cutter	47	T. Le Marchant.

The fleet started at 10 o'clock. Abreast of Ventnor the American schooner was a mile ahead of "Aurora," which was the last British craft to keep her in sight in a thick haze that blew up from the southwest late in the afternoon. At the Needles the wind dropped until it was very light, and the "America" was then some 6 mi. ahead of "Aurora," the time being about 6 P.M. The finish was:—

America (winner)	8.37 P.M.	Aug. 22
Aurora	8.55 P.M.	Aug. 22
Bacchante	9.30 P.M.	Aug. 22
Eclipse	9.45 P.M.	Aug. 22
Brilliant	1.20 A.M.	Aug. 23

The "America" was built at New York at the yard of William H. Brown, from the design of, or a model by, George Steers, for the special purpose of competing with British yachts. The principal dimensions of the "America" were: tonnage 170; registered length 94 ft.; on the keel 82 ft.; beam 22 ft. 6 in.; foremast 79 ft. 6 in.; mainmast 81 ft. (with a rake of $2\frac{7}{8}$ in. to the foot in each mast); hollow bowsprit 17 ft. outboard only; foregaff 24 ft.; maingaff 28 ft.; mainboom 56 ft., sail area 5,263 sq.ft. She was ballasted with pig iron; 21 tons of the iron were permanently built into the vessel and the rest stowed inside. Below deck she was comfortably fitted for the living accommodation of the owner, guests and crew, and a cockpit on deck was a feature that few English yachts of the period possessed.

The cup won at Cowes by the "America," although not originally intended as a challenge cup, was given to the New York Yacht club in 1857 by the owners of the "America" as a challenge trophy and named the "America's cup." In 1887 the sole surviving owner of the cup, George L. Schuyler, attached to the trophy a deed of gift which sets forth the conditions under which all races for the cup must take place. In brief the conditions are: (1) that the races must be between one yacht built in the country of the challenging club and one yacht built in the country of the club holding the cup; (2) that the size of the yachts, if of one mast, must be not less than 65 ft. L.W.L. and not more than 90 ft. L.W.L. If of more than one mast, not less than 80 ft. L.W.L. and not more than 115 ft. L.W.L.; (3) the challenging club must give ten months' notice of the race, and accompanying the challenge must be sent the name, rig and the following dimensions: length L.W.L., beam and draught of water of the challenging vessel (which dimensions shall not be exceeded) and, as soon as possible, a custom-house registry of the vessel; (4) the vessel must proceed under sail on her own bottom to the place where the contest is to take place. In addition, there was a clause in the deed of gift which allowed the holding and the challenging clubs to make, by mutual consent, any arrangements they might agree upon for the terms of the match, even to the waiving of the ten months' notice. Most of the races after 1920 were arranged through

this mutual consent clause, and many of the strict provisions and requirements of the deed have been waived. After the match of 1930 all the races have been sailed without time allowance. For results of these contests *see* table, p. 870.

HOW A YACHT IS SAILED

The method and principle upon which a yacht race is sailed may be described in a way easily understood by any landsman. The course is usually a triangle, to windward and return, or a square. Suppose the starting and finishing line is between the two mark boats X, Y (fig. 1); and suppose the start to be in an easterly direction. Suppose also the direction of the wind to be north. Then the course would be from the starting line round the marks or buoys placed at B, C, D, A, and back to finish across the line XY. The start of a yacht race is at a fixed hour, say 11 A.M. Two signal guns are fired, one at 10:55 to prepare, and the other at 11 A.M. to start. During the five minutes' interval between the guns, the yachts may sail about anywhere they like, "jockeying," so as to try to get into the best position as the second gun fires. The object of the steersman is to sail his yacht across the line XY at full speed immediately after the starting gun has fired.

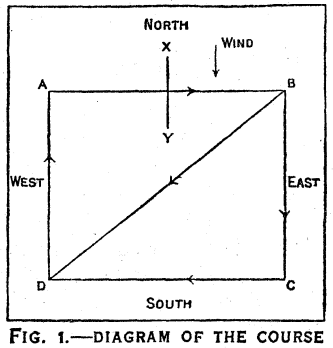

FIG. 1.—DIAGRAM OF THE COURSE OF A YACHT RACE

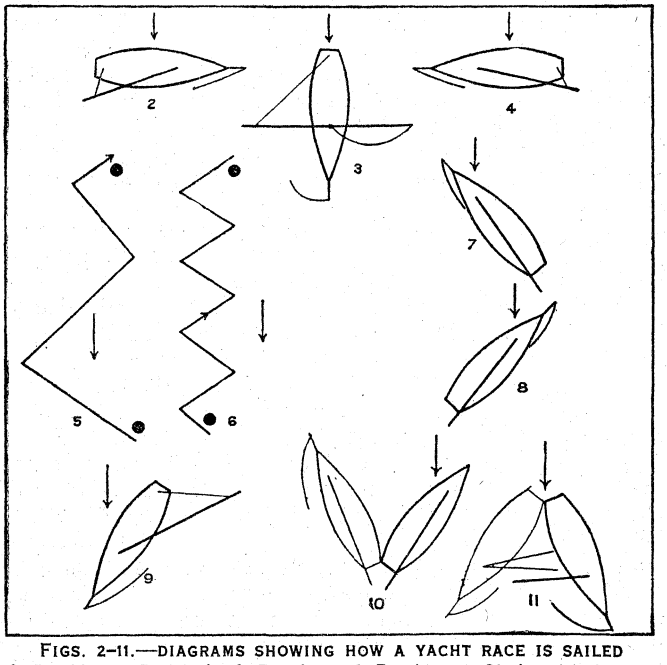
The first leg of the course is easterly, from the line XY to the point B. This is sailing at right angles to the wind and is called "reaching." The yacht sailing from XY to B is said to be "reaching on the port tack" because the wind is blowing upon her "port" or left-hand side. When reaching, the sails are trimmed as in fig. 2. The next course is from B to C. This is dead before the wind and is called "running." When the wind is dead aft, and the yacht is running before it, the balloon sail called the spinnaker is set. The spinnaker must be taken in before the yacht gets to C. When running, the sheets are eased right off as in fig. 3. The third course is from C to D; this is again reaching, as from A to B, but the yacht is now "reaching on the starboard tack" because the wind is blowing upon her "starboard" or right-hand side (fig. 4).



FIGS. 2–11.—DIAGRAMS SHOWING HOW A YACHT RACE IS SAILED
2. Reaching on Port tack. 3. Running. 4. Reaching on Starboard tack. 5 & 6. Course tacking to windward. 7. Starboard. 8. Port tack. 9. "A Quartering Wind." 10. Tacking. 11. Gybing

The yacht having reached to D, now has to sail from D to A. This is absolutely dead against the direction of the wind. The yacht cannot sail dead against the wind but only at an angle of rather less than 45° from it. The yacht, therefore, has to "tack to windward," or "turn to windward," making a zig-zag course. She may either make long tacks (fig. 5), or short tacks (fig. 6), whichever method will take her quickest from D to A. This turning to windward is the greatest test of the yacht's ability, and also of the ability of the helmsman. Much more distance and time may be gained or lost during the zig-zag than at any other period of the race. When sailing to windward the sheets are hauled in very close. In fig. 7 the yacht is close hauled on the starboard tack, and in fig. 8 she is close hauled on the port tack. Having arrived at A, the course is next a reach on the port tack, with the wind on the left side, from A to the finishing line XY. As the bowsprit (or mast) of the winning yacht crosses the finish line, her winning gun is fired. A gun is usually fired for the first three yachts. If the course had been a triangular course from the start to B, D, A and back to the finish, then the leg of the course BD would have been at an angle "between running and reaching." To sail off the wind from B to D in this manner is called "a free reach" or "a quartering wind," or to sail with "wind on the quarter." Sailing on a reach is usually the fastest point of sailing. With a quartering wind the sheets are trimmed as in fig. 9. A yacht is said to "tack" when she changes her course from port tack to starboard tack, or vice versa, when sailing toward the wind. Similarly, she is said to "gybe" when she changes her course from port tack to starboard tack, or vice versa, when sailing "off" or away from the wind. The boom in "tacking" and "gybing" passes from one side to the other, as in figs. 10 and 11. (B. H.-S.; H. L. St.)

YACHTING IN THE UNITED STATES

Early History.—Organized yachting and yacht racing in America began about 1840 with the formation of the first yacht or boat clubs for the promotion of pleasure-boating and the racing of yachts for sport. While a number of boats had been built in the United States and used solely for pleasure-sailing previous to that date, and hence could be classed as yachts, they were few in number, and in type they were more or less similar to the commercial or fishing craft of the same size in the locality in which they were to be used. The country, at that time, was too new and the people along the seaboard too busy in developing the trade and commerce of the newly formed states, and in opening up the land, to have either the leisure or the means for the development of pleasure-boating.

Yachts had been used in both Great Britain and Holland since the 17th century, and in the history of the Dutch colony of New Amsterdam, which later became the English colony of New York, there is mention of a yacht, or boat built for pleasure-boating, named the "Onrust" (Restless), which is claimed to be the first decked vessel built in America. She was about 44 ft. in length and followed the characteristics and proportions of the Dutch boats used in Holland. It is probable that this craft was used also for commercial purposes when not used for pleasure-sailing. While the "Onrust" was spoken of as a yacht, there is no authentic data relating to other yachts, or to the sport of racing boats, before the beginning of the 19th century. Except for the "Onrust," the earliest mention of a boat used exclusively for pleasure in New York waters was of a 20-ft. sailboat owned by John C. Stevens, named the "Diver," and built some time prior to 1809. The name of Stevens is one intimately connected with the development of yachting in America for many years.

On the New England coast, where the population was largely seafaring, there was built in 1801, for Captain George Crowninshield, a wealthy shipowner and merchant, a large sloop of 22 tons called the "Jefferson," which her owner used largely as a yacht until the War of 1812, when she was fitted out as a privateer and took several prizes. Later she was sold into the fisheries. Following this venture, Crowninshield had built in 1816 a vessel called "Cleopatra's Barge," intended solely for pleasure-cruising, and so luxuriously fitted and furnished as to entitle her to rank as a yacht even according to present standards. The builder of this

boat was Retire Becket, a well-known shipbuilder of Salem, Mass. In her, Crowninshield made a pleasure voyage to the Mediterranean and back in 1816–17, probably the first American yacht to go abroad. "Cleopatra's Barge" was 83 ft. long on the water, 23 ft. breadth of beam, and her tonnage was 191 tons.

It was in New York harbour, however, that most of the early yachting was done, and the first comprehensive attempt made to develop boats for pleasure-sailing and for racing. In this development the Stevens family, of which John C. Stevens was one of four brothers, played a leading part. Inheriting a love of the sea and mechanical tastes, they did much experimenting, and built successively larger yachts, following the "Diver" and the "Trouble." From 1830–40, sailing and racing boats for pleasure became common among men of means, and a good-sized, though mixed, fleet of boats was to be found in New York waters.

Organized Yachting.—It was not until yacht clubs were organized, bringing together those who were interested in the sport, that yachting and racing began to develop along lines that tended to make it a popular pastime, or that yacht design began to show much improvement. As early as 1811 the Knickerbocker Boat club of New York was formed, but it died the following year. After several other clubs, both in New York and Boston, had been formed and had died, the New York Yacht club was organized on July 30, 1844, aboard John C. Stevens' new schooner-yacht "Gimcrack," anchored off the Battery. Among its original members were most of the leading yachtsmen of New York, and it was the first club that survived. In its centennial year, 1944, the New York Yacht club was in point of age and prestige, the foremost yacht club in America, and much of the development of yachting can be traced to the influence of the club itself, or its members. In 1849 the Southern Yacht club, of New Orleans, was organized, followed in 1854 by the North Carolina Yacht club, and in 1857 by the Brooklyn Yacht club, but for 20 years the New York Yacht club was representative of American yachting and was the forerunner of the many yacht clubs that sprang up after the Civil War (1861–65) in all parts of the country wherever there was pleasure-sailing, until in 1944 there were over 800 organized yacht clubs in the United States and Canada.

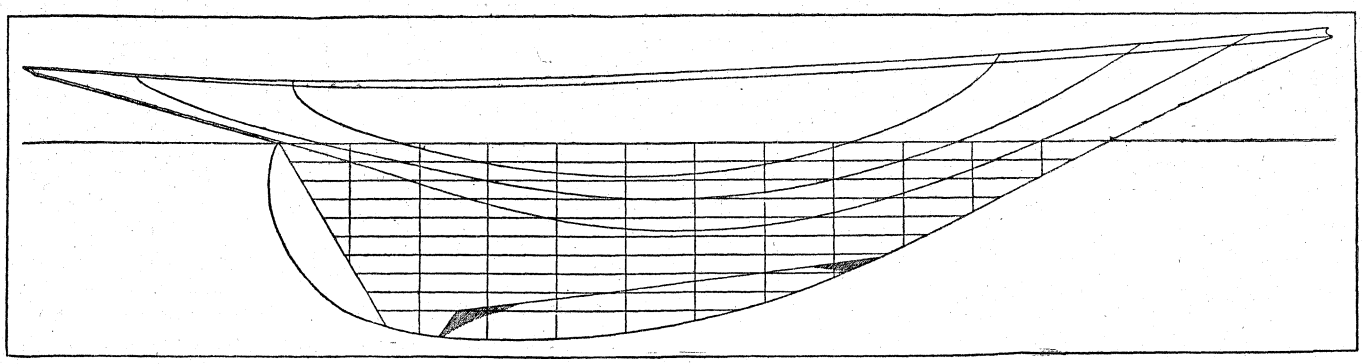
Development of Design.—At the time of the formation of the New York Yacht club, and for many years thereafter, the designing of yachts was not pursued as a science. Most of the yachts were turned out by local builders, working by "rule-of-thumb," each builder having his own particular fad or fancy for some particular type or model, these models being influenced largely by the environment and water conditions. With the shoal waters of the Atlantic coast, American yachtsmen as a whole preferred broad, shoal, centreboard craft, with great initial stability, which enabled them to carry a large spread of sail without a great amount of ballast. These boats were very fast in smooth water. The centreboard was an adaptation of the leeboards of Holland, but was lowered through the keel instead of over the side.

On New York waters, therefore, under the stimulus of the New York Yacht club, a large fleet of light draft centreboard yachts soon made its appearance, the boats being modelled by such noted builders as J. B. Van Deusen and "Pat" McGiehan, or such well-known boat sailors as Phil and Joe Ellsworth, or the Van Buskirks. These men had practical experience, but little technical knowledge of designing, and little real development was made during this period, it being an easier matter to rely on beam for stability and great sail area for speed, rather than on refinement of design. In New England, also, the centreboarder was becoming the popular type when speed was the consideration. All of the yachts of the period were then built on the accepted theory of full bow and fine, easy run, or the "cod's head and mackerel tail" principle, and design had not progressed as far as in England. Even very large yachts were centreboarders. In 1845 John C. Stevens built the "Maria," a centreboard sloop 92 ft. in length, which proved very fast.

During the winter of 1850–51, George Steers modelled for a syndicate of six American yachtsmen, headed by John C. Stevens, and all members of the New York Yacht club, a schooner of about 170 tons to go to England in the summer of 1851 and race there at the time of the world's fair of that year. The yacht, named the "America," won the Hundred Guinea cup at Cowes, in a Royal Yacht Squadron race around the Isle of Wight (*see* page 867). In 1857 the surviving owners presented the cup to the New York Yacht club to be held as a perpetual challenge cup for friendly competition between foreign countries. Under its new name, the America's cup became the most coveted yachting trophy in the world. Sportsmen from England and Canada have ventured forth with challenging yachts, but, as the table shown on p. 870 reveals, with no success.

In 1876, the advocates of the shoal-draft boat were given a rude jolt when the new 140-ft. centreboard schooner "Mohawk," built for Commodore W. T. Garner, of the New York Yacht club, was capsized off Staten Island, drowning her owner and several guests. She was lying at anchor with her sails up and sheets made fast when she was struck by a squall and heeled down on her beam ends, where she filled and sank. A few years after the "Mohawk" disaster, A. Cary Smith turned out the sloop "Mischief," called a "compromise sloop," a centreboard boat, but deeper than the skimming dishes, with more shape, and relying not alone on beam for stability. "Mischief," 67 ft. long, successfully defended the America's cup in 1881 against the Canadian centreboard challenger "Atalanta." That same year there arrived in New York from Scotland a little cutter that was to exert a powerful influence on the future of yacht design in America, and that strengthened the growing band of yachting enthusiasts who were looking for something better in design than the wide, shoal centreboarders. This was the "Madge," designed by George L. Watson, a young British designer, and owned by James Coats, of Paisley, who had recently lived in America. "Madge" was a typical British cutter, 46 ft. long over all, 38½ ft. on the water, and only 7 ft. 9 in. beam. She was shipped to New York. That first summer she won nearly all her races against the crack centreboarders, most of them being won without calling on her time allowance. The success of the "Madge" put centreboard advocates on the defensive.

The discussion was still acute when the next challenge for the America's cup was received, in 1885, from the British yacht "Genesta," a typical narrow cutter. There was much difference of



COURTESY OF "YACHTING"

Lines of "Gloriana," designed by Nathanael Herreshoff in 1891, in which the forefoot was cut away entirely, and the forward and after overhangs lengthened.

RECORD OF THE AMERICA'S CUP RACES

opinion in America as to what type to build to meet the challenger; but a group of Boston yachtsmen, less committed to shoal draft than those around New York, went to a young Boston naval architect, Edward Burgess, and commissioned him to design a large

sloop to defend the cup. Burgess was familiar with the cutter type, recognized its good points, and also knew the centreboard boats as they had developed around Cape Cod. Discarding all tradition, he decided to strike out in a radical way and design a yacht that to him appeared best suited to the conditions to be met, and combining the best points of the cutter with the wider beam and shoaler hull of the centreboard sloops. The result was the "compromise cutter," "Puritan," 81 ft. long on the water. On this length, "Puritan" had a beam of 22½ ft., draft of 8 ft. 8 in., and a centreboard. She had the plumb stem of the cutter and was deep enough to get a beautifully modelled underbody. "Puritan" proved most successful, beating the shoal-draft defender built in New York handily and defeating the cutter "Genesta," the challenger.

These victories made Burgess the most successful designer in America, and the type originated by him grew rapidly in popularity and soon became the recognized American type. "Puritan" was followed in the next two years by the "Mayflower" and the "Volunteer," both by Burgess and each a successful defender of the America's cup. Unfortunately, Burgess died in 1891, at the height of his career, and while still a comparatively young man.

The year that Burgess died, Nathanael G. Herreshoff, of Bristol, R.I., had turned out a yacht that focused the attention of American yachtsmen on the plant at Bristol, owned by him and his brother, John B. Herreshoff, and that was destined again to revolutionize yacht design and to bring fame to American yachts and to the Herreshoff family, which had been building boats on Narragansett bay since Civil War days. This yacht was "Gloriana," in which Herreshoff boldly cut away the forefoot, so that the profile showed an easy sweep from the stem head to the bottom of the keel.

When the next challenge for the America's cup (1893) was received from the Royal Yacht squadron, Herreshoff designed the successful defender, the sloop "Vigilant," 85 ft. on the water. While practically a keel boat, she carried a centreboard, which worked through a slot in the lead keel. After the "Vigilant," N. G. Herreshoff designed the successive defenders for the America's cup up to and including the contest in 1920, when the "Resolute" successfully defended, and Herreshoff became the foremost yacht designer in America, for either large or small yachts.

During this period the length and sail area rule $\frac{\text{L.w.l.}+\sqrt{\text{S.A.}}}{2}=$ rating was in use in America, but the same tendency was apparent in that country, as in England, to develop flat-bodied hulls with long overhangs and light displacement, producing an extreme skimming dish or scow type. This reached its limit in the America's cup defender "Reliance" (1903), which had 53 ft. of forward and after overhangs on a water-line length of 89 ft. Following this match, a conference of yachting organizations, under the lead of the New York Yacht club, adopted (1905) a rule which, while retaining length and sail area as the chief factors, used displacement in the formula and controlled overhangs, draught, freeboard, etc., by penalties. This was called the universal rule. This rule produced a much more wholesome vessel, and while it has been amended several times, it is still (1944) in use in the United States, and all of the America's cup matches since 1930 have been sailed under it. The formula is: 18% of the product of length multiplied by square root of sail area divided by the cube root of displacement = rating.

By 1930, N. G. Herreshoff had retired and the defender that year, "Enterprise," was designed by W. Starling Burgess, a son of Edward Burgess who designed the defenders of 1885, 1886 and 1887. The "Rainbow," successful defender of 1934, was also designed by W. Starling Burgess. When the 1937 defender was built, a young designer, Olin J. Stephens, was called upon to collaborate with Burgess, and the result of their collaboration, "Ranger," was the fastest Class J yacht that had been built up to that time.

The Scow Type and the Seawanhaka Cup.—On certain waters of Canada, notably the St. Lawrence river, and on the lakes of Minnesota and Wisconsin, where conditions are not suited to keel boats, the universal rule is not used, and in these localities the scow type has been developed to a very high state. These boats are extremely flat, drawing but a few inches, having two bilge boards instead of one centreboard, double rudders, and are sailed without ballast. On a reach they are exceedingly fast, and it is claimed that the larger boats sometimes attain a speed as high as 25 mi. per hour in a strong breeze and smooth sea. They are usually sailed in 28-ft., 32-ft. and 38-ft. classes.

The contests for the Seawanhaka cup between 1895 and 1912 did much for the development of the scow type. This trophy was put up by the Seawanhaka-Corinthian Yacht club, of Oyster Bay, in 1895, for international competition between small yachts, when the first race was sailed against an English challenger, "Spruce III," a "half-rater," the defender being the "Ethelwyn," designed by W. P. Stephens. The following year the cup was won by the Royal St. Lawrence Yacht Club of Canada, with an extreme scow named the "Glencairn," designed by G. Herrick Duggan, a young engineer who later became one of Canada's foremost designers. A long series of races followed between U.S., Canada, Great Britain and several European countries.

Later Development of Yacht Design.—During World War I there was very little yacht building in America, and no marked development in design. But following the readjustment period there was a marked increase in interest in all forms of yachting, and larger fleets were to be seen at the principal regattas than previously. In this development the small yacht predominated, due somewhat to the greatly increased cost of running large sailing craft, and to the fact that yacht racing was making a strong appeal to those who wanted to handle their own craft. Therefore, the smaller racing classes were promoted, principally the 31-rating (Class P), 25-rating (Class Q) and 20-rating (Class R) classes, and numerous one-design classes. About 1927 several international rule classes appeared in the United States, the most popular being the 6-metre and 12-metre classes.

One-Design Classes.—As early as the late '90s several racing classes in which the boats of each class were identical in design were formed, and proved popular, both because the boats were, theoretically, of equal speed, and because there was considerable economy in building many boats exactly alike at one time. Some of the earlier of these one-design classes were the Newport 30-ft. class of fin-keel sloops and the 70-ft. class of large sloops, both designed by Herreshoff. There followed, then, a great demand for such classes of yachts of one design. Among the important one-design racing classes in the first 40 years of the 20th century are:

Class	Load water line	Designer
	Feet	
Bar Harbor 31-footers	31	Herreshoff
New York Yacht Club 30-ft. class.	30	"
New York Yacht Club 50-ft. class.	50	"
New York Yacht Club 40-ft. class.	40	"
Larchmont O class	38	Wm. Gardner
Seawanhaka Schooner class	38	Cox & Stevens
Class S One-design	20½	Herreshoff
Victory class	21	Wm. Gardner
Interclub class	19	C. D. Mower
Star class (over 2,000 boats have been built to this class).	16	Wm. Gardner
Marblehead-Beverly (M-B) class	17½	Frank C. Paine
International One-designs	21½	B. J. Aas
10-metre class	36	Burgess & Morgan
Atlantic Class	21¼	Burgess & Morgan
New York Yacht Club 32-ft. Class	32	Sparkman & Stephens
Pacific Coast One-Design	21	G. W. Kettenburg, Jr.
And many smaller classes under 20-ft. water line length		

The North American Yacht Racing Union.—Legislation affecting yacht racing, the rules under which yachts were raced, and measurement rules, up to about 1900, had been in the hands of individual yacht clubs, or local yacht-racing organizations composed of a number of clubs in the same locality. There was thus great lack of uniformity in different sections of the country. At the time of the agitation for a new measurement rule to supersede the "length-and-sail-area" rule, the New York Yacht club took the lead and called a conference of yachting organizations of the Atlantic coast and the Great Lakes to find out what was wanted and to bring about uniformity by getting the other sections to adopt the new rule (the universal rule) that was then being formulated. This was a step forward, but the conference was not permanent in character, and there was no real governing body on yachting affairs in America. To remedy this situation, there was formed in 1925 a union of most of the local yacht-racing associations, and a number of prominent yacht clubs, the guiding spirits in the movement being Clifford D. Mallory and Commodore W. A. W. Stewart, of the Seawanhaka-Corinthian Yacht club. This organization, called the North American Yacht Racing union, was the first permanent legislative and governing body of national scope in America, and through it both the racing and measurement rules have been standardized, and an appeals body for its members formed. In 1927 delegates from this union met with delegates of the International Yacht Racing union, in London, to bring about closer co-operation internationally in yachting affairs. Sensing the value to the sport of international racing, the union recognized, in addition to the universal rule of measurement, the international rule used in European countries, with the result that several international classes such as the 6-metre, 8-metre, and 12-metre were built and became popular in the United States.

Development of Rig.—Probably no one thing has contributed more to the evolution of yachting and the speed of yachts than the development of rigs. Between 1920 and 1940 the science of aerodynamics was applied by naval architects to the design of sail plans, so that the period brought a revolutionary change in yacht rigs. Tall, narrow, triangular sail plans, with a long efficient leading edge, displaced the older gaff rig where the base was longer than the perpendicular. Mainsails became triangular in shape (called Bermudian or jib-headed) and were set on very tall masts with a ratio of hoist to foot of 2 or 2½ to 1. In the case of the Class J yachts (America's cup class), masts were as high as 165 ft. on a water line length of 80 ft. Large fore-triangles and overlapping head sails followed as a natural consequence, and tremendous jibs that overlapped the mainsail by as much as one-third the length of the boom, and were cut flat so as to be used on the wind, came into use. These were called Genoa jibs because the first one used was on a small Swedish yacht racing off Genoa, Italy. So efficient were the new rigs that yachts carrying from 25 to 40% less sail area would have as much or more

driving power and speed as with the larger sail spread. The new rigs were also easier to handle and required a smaller crew to work, while the elimination of the gaff, and the topmast with its fittings, saved weight aloft. Large, full spinnakers, cut like a parachute and with a lot of cloth in them, also replaced the smaller flatter spinnakers, and had tremendous pulling power. As an example of the efficiency of the new rigs, the 1937 America's cup yacht "Ranger" carried only 7,500 sq.ft. of sail, as against the 16,000 sq.ft. of the "Reliance" (1903), yet her average speed around a course was equal to or better than that of the larger yacht.

Cruising Yachts.—The development of cruising yachts in America has followed in a general way the development of the racing type. While no measurement rule had to be considered in their design, it was natural that in hull design the boats should take the same characteristics as the racing craft, especially as they were sailed on more or less protected waters, or along the coast where harbours were frequent. However, shortly after World War I, several designers, notably John G. Alden and William H. Hand, Jr., developed a type of small seaworthy yacht for cruising, embodying many of the characteristics of the New England fishing schooners. These boats were good offshore cruisers, and they quickly became popular, and were soon taking part successfully in long distance and ocean races, such as the one from New London to Bermuda, while several boats of this design, from 50 to 55 ft. long over all, made the Atlantic passage with safety and comfort. This led to the development by designers of a greatly improved type of yacht for ocean and coastwise cruising, with greater seaworthiness and speed.

Ocean Racing.—Long distance racing along the coast, and ocean races, were, until 1930, more popular among American yachtsmen than among those of the European yachting nations. The first transatlantic race was sailed in 1866, between three American schooners, in the month of December, one of them being a centreboarder, and the others keel yachts. The schooners were the "Henrietta," "Fleetwing" and "Vesta," the first winning in the fast time of 13 days 21 hr. and 45 min. The greatest ocean race ever sailed was in 1905, when 11 large yachts raced from Sandy Hook to Land's End, England, two being British, one German, and the rest American. It was won by the American three-masted schooner "Atlantic" in 12 days 4 hr. 1 min., for the course of 3,013 mi., still the record in 1944.

About 1905 ocean racing in small yachts was inaugurated by the late Thomas Fleming Day to demonstrate that small boats, properly designed, built and handled, could keep the sea with safety. He inaugurated the race from New York to Bermuda, and later, one to Havana for power craft. Interest lapsed after 1909, but in 1923 the Bermuda race was revived and was sailed every two years until World War II put a stop to ocean sailing. The race grew in popularity, and between 1930 and 1938 no fewer than 35 to 45 small yachts sailed in every race, including entries from Great Britain and several of the European countries. The race was responsible for the development of a special type of ocean-racing yacht, largely due to the success of "Dorade" and "Stormy Weather" designed by Olin J. Stephens, and to yachts of other designers who were turning out boats for these races that were both seaworthy and fast. The Cruising Club of America has been chiefly instrumental in fostering this type of racing in America, and has developed a measurement rule for ocean racers under which the yachts are rated. In Great Britain the Royal Ocean Racing club was formed in 1926 and the following year inaugurated a 600-mi. ocean race around Fastnet rock, off the southern coast of Ireland, called the Fastnet race, which did much to promote interest in the sport in that country. On the Pacific coast the principal ocean race, for which a permanent cup has been put up, is one from the California coast to Honolulu, Hawaiian Islands, a distance of about 2,200 mi. This is sailed every two years. In 1928 a transatlantic race from New York to Spain was sailed, with nine entries. In 1931 a race from the United States to Plymouth, England, brought out 10 entries under 72 ft. in length and was won by "Dorade," only 39 ft. long on the water, which made the phenomenal time of 17 days 2 hr. In 1935 a race from Newport to Norway was won by the "Stormy Weather," 40 ft. on the water, over a course of 3,118 mi. in 19 days 5 hr. During the decade 1930–1940 while interest in yacht sailing increased in all the yachting countries, those years saw a gradual change in the aspect of the sport, with a great increase in the popularity of the small yacht and the passing of the large yacht requiring a big professional crew. More and more the sport was becoming Corinthian in character and yachtsmen were sailing their own boats, dispensing as far as possible with paid hands on whom they were dependent to handle the yacht. The day of the large yacht has passed, and in its place many small or medium sized yachts up to some 70 ft. overall length are bringing many more men into the sport of both racing and cruising. Also, the day of the large steam and power driven yachts seems to have passed, and in the place of these expensive vessels yachtsmen are turning to smaller, standardized or custom-built power boats and cruisers, either diesel or gasoline (petrol) powered, that are economical to operate and seaworthy, and offer comfortable accommodations in small sizes. (H. L. St.)

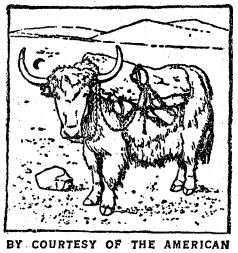
YAHGAN, an Indian tribe, now almost extinct, that occupies the south coast of Tierra del Fuego and the adjacent islands southward to Cape Horn. Hence they are the southernmost people in the world. That they have lived in the same region for many centuries is attested by great middens which cover their camping places. Yahgan life before the European settlement was extremely simple. In spite of the cold climate their chief garment was a single seal or other skin, which they wore on the windward shoulder. Their houses were usually small domed affairs of saplings covered with bark and grass or sealskins. Their canoes, peculiar for their high pointed ends and a fireplace amidships, were constructed of the bark from a beech tree. Their manufactures included baskets of several weaves, harpoons, spears, shell necklaces and simple tools. Their diet embraced shellfish, seal, whale, various birds, a few berries and several kinds of fungi. The Yahgan had no organized tribal life or recognized leaders. Each family, often including several wives, was a law unto itself, wandering at will and rarely camping in one place for more than a few days. At times, groups of relatives would assemble to perform elaborate initiation ceremonies for both the boys and the girls, who were forced to undergo various privations, to have their courage tested by masked apparitions, and to learn the tribal lore. It has been asserted that the Yahgan have no religion. However, they believe in evil spirits, who must be propitiated by their medicine men, and they also reverence a supreme God. Their mythology is surprisingly rich. (S. K. L.)

THE WILD YAK (BOS GRUNNIENS)

YAK, the wild (and domesticated) ox of the Tibetan plateau; a species allied to the bison group. The yak, *Bos grunniens,* is one of the largest of oxen, characterized by the growth of long shaggy hair on the flanks and under parts of the body and the well-known bushy tail. The wild species is black in colour. Domestic yaks are often black and white, and small-sized breeds exist. The magnificent half-tamed animals kept by the natives of the elevated Rupsu plateau, south of the Indus, afford the only means of transport by this route between Ladak and India. But even these are inferior to the wild yak, which stands nearly 6 ft. at the shoulder and is confined to the arid plateau of Tibet.

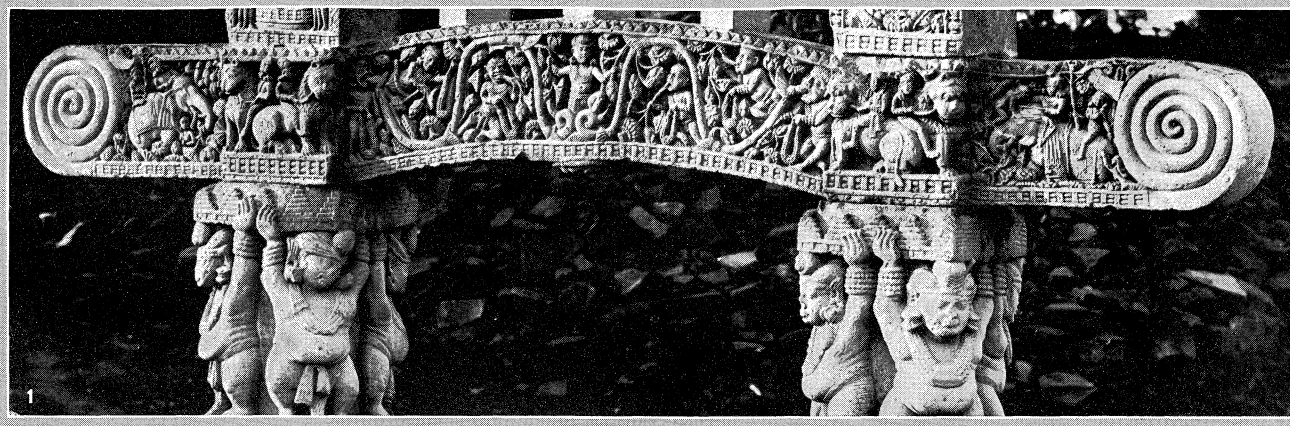


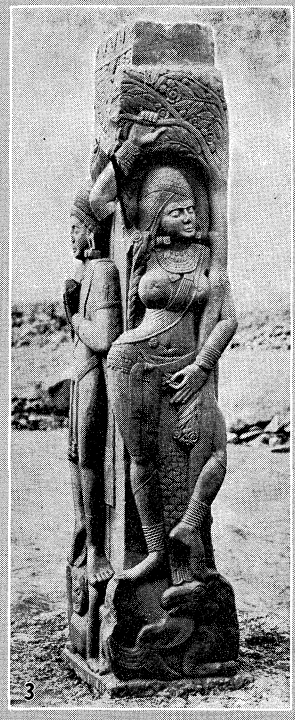
BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

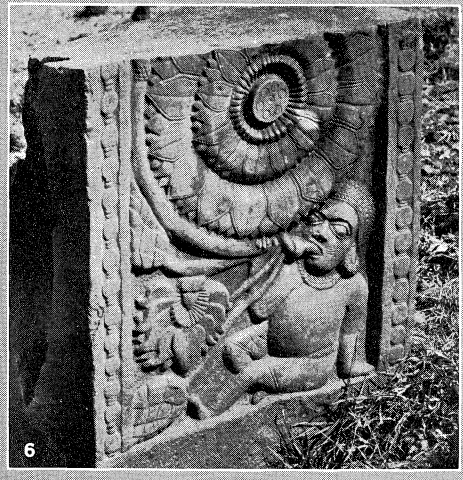
DOMESTICATED YAK

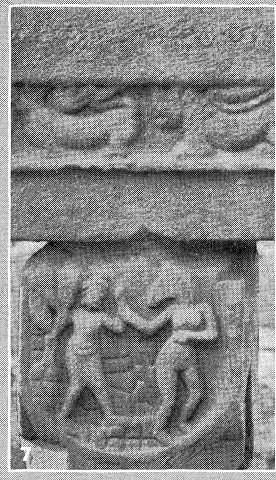
YAKIMA (yăk'ĭmą), a city of south-central Washington, U.S.A., on the Yakima river, at an altitude of 1,065 ft.; the county seat of Yakima county. It is on federal highways 97 and 410; has a municipal airport of 360 ac.; and is served by the Northern Pacific and the Union Pacific railways, and by electric interurban and motorcoach lines. Pop. 1940 by federal census 27,221 (92% native white). Yakima is the metropolis of a productive region of diversified agriculture, formerly a sagebrush desert, which owes its prosperity to reclamation by federal and private projects with 500,000 ac. under irrigation and an additional 72,000 ac. under construction. Apples and other fruits are leading crops, but potatoes, green vegetables, livestock, grain, hay and dairy products are also important. The ten-year average of farm and industrial products shipped out of Yakima county amounts to 48,000 carloads, valued at $38,000,000. The county has cold-storage facilities with a capacity for 12,000 carloads, and manufacturing industries including lumber

YAKṢAS









BY COURTESY OF (2) THE MUSEUM OF FINE ARTS, BOSTON, (8-10) A. K. COOMARASWAMY

STATUES OF YAKṢAS OR INDIAN DEITIES

1. Yakṣas, or deities, spouting lotus rhizome and flowers, and as Atlantes (Sāñcī 1st cent. B.C.). 2. Yakṣī, or dryad, under a tree (1st cent. A.D.—Museum of Fine Arts, Boston). 3. Chāndī Yakṣī (2nd cent. B.C.—Indian Museum, Calcutta). 4. Gangita Yakṣa (2nd cent. B.C.—Indian Museum, Calcutta). 5. Yakṣas Atlantes forming capital of column supporting arch of gate (Sāñcī 50 B.C.). 6. Yakṣa spouting lotus rhizome and flowers (from Bharhut 2nd cent. B.C.—Indian Museum, Calcutta). 7. Assamukhī Yakṣī (Bodhgaya 100 B.C.). 8. Kubera Yakṣa (1st–2nd cent. A.D.—Archaeological Museum, Mathurā). 9. Yakṣī carrying food and water (1st–2nd cent. A.D.—Archaeological Museum, Mathurā). 10. Yakṣa under tree (1st–2nd cent. A.D.—Archaeological Museum, Mathurā)

and canneries produce over 90 different commodities having an output during 1939 valued at $10,150,000. Bank clearings in 1940 totalled $57,975,277. The Central Washington District fair is held at Yakima annually in September. Ten miles south of the city is the northern border of the Indian reservation, and the entrance to Rainier national park is 50 mi. N.W. The city was incorporated in 1886 under the name of North Yakima. In 1900 the population was 3,154, and this increased to 14,082 by 1910. "North" was dropped from the name in 1917.

YAKṢAS. The Sanskrit designation *Yakṣa,* of uncertain derivation, is applied upon occasion to practically every Indian deity, and even to the Buddha, in an honorific sense. Later, in sectarian and especially in Buddhist literature, the Yakṣas are represented in the interests of edification either as devoted assistants and defenders of the faith, or as inferior beings of an ogre type. More generally we may say that Yakṣas are supernatural beings, deities of varying rank, who have once been men, and will be reborn again on earth. Generally speaking benevolent, they are closely connected with vegetation, human fertility and wealth; they are essentially tree spirits, others being more like gnomes; they possess magic powers, especially that of concealment.

The cult of Yakṣas seems to have been at one time the dominant aspect of popular religion in India; it may be described as an early form of devotional Hinduism, perhaps going back to a period in history contemporary with the Vedas. In the Atharva Veda and in certain Upaniṣads the Brahman itself is called "a great Yakṣa," and the indwelling spirit in Man a "self-like Yakṣa." The individual Yakṣas are for the most part local and tutelary deities; the Śākyas, for example, worshipped the Yakṣa Śākyavardhana. "He who prospers the Śākyas." Other Yakṣas are the guardian angels (*ārakkhadevatā*) of individuals. Others called Guhyakas are earth spirits who function as the bearers of vehicles and as supporters of buildings, like Atlantids. The chief of the Yakṣas is Kubera or Vaiśramaṇa, who is mentioned already in the Atharva Veda, and is best known as the great king who is regent of the north, where are his heaven, palaces and groves. He is essentially a god of wealth; his chief symbols are a lotus and a conch represented as fountains of money; as a tree-spirit he is associated with the banyan (*see* Plate, fig. 8). Another great Yakṣa is his generalissimo, Maṇibhadra. A group of 28 Yakṣa kings is mentioned in more than one place, but the total number of Yakṣas mentioned in the literature is very large. Many have come to be regarded as local manifestations of higher Brahmanical deities, especially Śiva. Kāmadeva, the god of love, belongs appropriately to the Yakṣa class; his symbol, the *makara* (mythical crocodile), represents the waters, or rather an essence in the waters, identical with the sap of trees, the water of life (*amṛta*).

YAKUB KHAN (1849–1923), ex-amir of Afghanistan, son of the amir Shere Ali, was born in 1849. He showed great ability at an early age, and was made governor of Herat by his father, but broke into open rebellion against him in 1870, and was imprisoned in 1874 in Kabul. However, when Shere Ali in 1878 fled before the British, he handed over the government to Yakub, who, on his father's death in the following February, was proclaimed amir, and signed a treaty of peace with the British at Gandamak. He agreed to receive a British resident, and was in turn to receive a subsidy and support against foreign attack. But in September of the same year his revolted troops attacked the British residency, and the resident, Sir Louis Cavagnari, and his staff and suite were cut to pieces. This outrage was instantly avenged, for in October Earl (then Sir Frederick) Roberts with a large force defeated the Afghans on the 6th and took possession of Kabul on the 12th. Yakub Khan thereupon abdicated, took refuge in the British camp, and was sent to India on Dec. 13. He died at Dehra in the United Provinces on Nov. 15, 1923.

YAKUTSK, an autonomous S.S.R. formed in 1922, stretching from the Krasnoyarsk territory on the west to the Khabarovsk territory on the east, and from the Arctic ocean on the north to about lat. 54° N.

It covers 1,169,927 sq.mi. and is therefore almost equal in size to European Russia, but its total population in 1939 was roughly 400,544.

The region is the least explored in the U.S.S.R., and has a tragic history of disaster overtaking many scientists whose efforts to investigate this inhospitable region have given us what information is available.

A geological expedition sent out to the Aldan watershed by the soviet government in 1926 nearly perished of starvation and records that the price of salt was 4 grams of gold for 400 grams of salt and that meat cost 30 to 40 grams of gold per kilogram.

Physical Features.—Much of Yakutsk is occupied by the basin of the Lena (*q.v.*). The Lena forms the eastern marginal river to that ancient block along the edge of which the Yenisei (*q.v.*) flows in the west.

It flows in a true valley of erosion of very great age and is not confined by mountains except near its mouth, where the Khara-ulakh range, a spur of the folded mountains of the Verkhoyansk arc, rises on its right bank and deflects its course, while subsidiary fold lines affect the lower courses of the Olenek and the Anabar to the west.

To the north lies a broad tundra belt sloping to the Arctic, from which rise four domes of basic eruptive rock.

Climate.—The soils of the republic are not favourable to cultivation; a broad belt south of the Arctic consists of dry clayey, stony tundra soil, merging southwards into forest tundra soil and then into the ash coloured alkali forest soils of the south, while there are belts of silty bog soils on the mountains. Along the banks of the Lena and Olekma, are strips and patches of fertile alluvial soils.

The climate is severe and extreme, and Verkhoyansk (67° 50′ N., 133° 50′ E.) has the greatest annual range of temperature in the world; its average January temperature is −59° F., absolute minimum −94° F., average July temperature 60° F., absolute maximum 93° F.

The fact that this cold pole lies so far east shows that the Atlantic has much more moderating influence than the Pacific, the latter being shut off by mountains, and also having strong prevailing off-shore winds. The change of temperature between the seasons is sudden and there is a drop of 40° F. between October and November.

At Yakutsk in lat. 62° 1′ N., winter is still extremely long and severe. The average January temperature is −46° F. and the river is frozen from Nov. 12 to June 10 in most years.

Occupations.—The Skoptsi, an exiled religious sect, settled in Yakutsk in the '60s of the 19th century and introduced agriculture in the neighbourhood of Olekminsk and Yakutsk. The clean, well-built Skoptsi villages are in striking contrast to the dirty Yakutsk settlements.

Barley occupies 53%, spring rye 27% and wheat 11% of the grain harvest. Potatoes, turnips and cabbages thrive and cultivation is slowly spreading in the alluvial patches of the Lena and Aldan, though the disturbed post-1917 conditions temporarily checked progress.

The limit of cultivation here extends to 63.5° N. and during 1898–1917 the sown area was trebled, many of the Yakuts sowing patches of grain.

Meadowland is important. Cattle and horse breeding is successful as far north as Yakutsk; both horses and cattle are short, long-haired and very hardy. The milk yield is small, but of good quality. There are no sheep or pigs.

North of this agricultural region is the region of the nomad reindeer breeders, relying entirely on their herds, while in some regions there is no reindeer-breeding and the natives rely on fish.

Ivory.—An important product is mammoth ivory. The mammoth (*Elephas primigenius*) existed in comparatively recent times in great numbers in the polar region of Siberia and entire carcasses, with flesh, skin, fur and congealed blood in the veins have

been found in the region.

Mammoth ivory is mentioned by Pliny and its existence was known to the Russians in 1582.

Mines.—Gold is the main product of the republic. It has been known to the Russians since the mid-19th century, when it was worked in the Olekma mines, later abandoned. The Aldan mines were re-opened in 1923. The gold here is easily worked, being on or near the surface, but there are great difficulties of transport and the miners are often unable to procure the necessities of life.

In 1914 a fresh source at Nyukhinsk was discovered.

Iron ore is worked in an entirely primitive way and smelted by the Yakuts to make hunting knives. They were capable smiths long before the coming of the Russians. Coal of recent origin and poor quality extends over a belt of 1,200 mi. north and south of Yakutsk, but is little used.

There is an area of curative mud on the Lena river with a high percentage of iron and aluminum, and a health resort is planned. Sulphur springs exist in many places, especially near Parsheva, and jasper and carneol are found below Zhigansk, where there is iron, coal and platinum.

Spars, amber, graphite, gypsum, crystal and emerald are reported, but unworked.

Population.—The Yakuts are a Turkic branch of the Ural-Altaic stock and their language closely resembles that of the Turks. A Yakut grammar by Boethlingk was published in 1851. They are thick set, brachycephalic, with dark eyes and hair, narrow foreheads, broad noses and long narrow eyes.

The Yakuts form 85% of the population, and the Russians, mainly in the Aldan mining region and in Yakutsk, form 11%. There are also Chinese and Koreans in the mining district. Half the population of the republic live in or near Yakutsk. In former times *brodyagi* or escaped convicts were a great terror in the district, and there has been much intermixture with Russian exiles, convicts and traders.

The Tungus are another branch of the Ural-Altaic group, as are the Lamuts.

The Yukaghir are a Palaeo-Siberian tribe, mainly found now between the Kolyma and Indigirka rivers and occupied in hunting and fishing. They are very short, with yellow or brown complexion, dark eyes and hair, and scanty beards. They are fast dying out, especially since the advance westwards of the Chukchee has lessened the number of wild reindeer. The latter tribe is spreading westward from the Khabarovsk territory (*q.v.*).

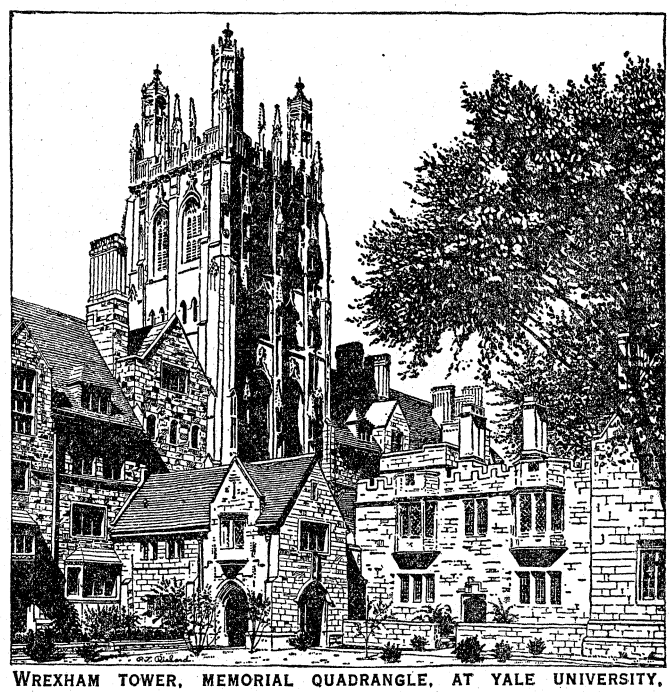
YAKUTSK, a town of Asiatic U.S.S.R., the administrative centre of the Yakutsk A.S.S.R., situated 2 mi. from the river Lena, here 9 to 11 mi. wide, on its left bank, in 62° 5′ N., 129° 4′ E. Pop. (1939) 23,000. The alluvial soil on which it is built is frozen all the year round, but thaws to a depth of 3 or 4 ft. in summer, when the streets become quagmires. Many mud huts exist, though there are some brick houses, and the schools, churches and official buildings are of brick; some wooden houses are built on high platforms as a protection against the June floods, when the ice breaks on the river, which remains open till November.

Winter sledge tracks radiate from the town to the sea of Okhotsk, Vilyuisk, the Kolyma and to Irkutsk (1,165 mi.). There are no good roads. Air communication with the town, however, lessened its isolation. Between the town and the Aldan are meadow lands with sandy sub-soil and scattered clumps of birch, willow and spruce.

The fort was founded in 1632, and the town later became a centre for the trade in furs, mammoth ivory, reindeer hides and cattle.

The policy of education in the vernacular has been encouraged.

YALE UNIVERSITY, the third oldest institution of higher education in the United States, situated at New Haven, Conn. In 1700 the needs of New England in the way of higher education were supplied by Harvard college, at Cambridge. Massachusetts Bay Colony was naturally the chief patron of Harvard, but Connecticut bore her full share in support of the enterprise. The two commonwealths, however, diverged to some extent in their theo-



WREXHAM TOWER, MEMORIAL QUADRANGLE, AT YALE UNIVERSITY, DESIGNED ON THE LINES OF WREXHAM CHURCH IN WALES, WHERE ELIHU YALE, FIRST DONOR TO THE COLLEGE, IS BURIED

logical and political development and there arose the desire for a separate college in Connecticut. The first distinct traces of this scheme appear in the early summer of 1701, in the neighbourhood of New Haven. The Rev. James Pierpont (Harvard, 1681), minister of the New Haven church, was the chief promoter.

The General Court of the Colony met at New Haven on Oct. 9, 1701, and a charter was granted (probably on Oct. 16) "for the founding, suitably endowing and ordering a Collegiate School within his Majesty's Colony of Connecticut." The founders chose the Rev. Abraham Pierson of their number as rector of the Collegiate school and it was at his parsonage in Killingworth that the first scholar sought admission in March 1702.

The school continued at Killingworth, with the annual commencements at Saybrook, until the death of Rector Pierson on March 5, 1707. From 1707 to 1716, although the commencement exercises were held annually at Saybrook, the students resided in the several towns where their tutors were established. It was not until a gift of nearly 1,000 volumes of great value was secured by Jeremiah Dummer, the agent for Connecticut at London, that a building for the school became necessary. After much argument it was decided to establish the institution at New Haven. A cargo of gifts for the Collegiate school, from Elihu Yale, former governor of Ft. St. George, Madras, India, and a native of Boston, including, besides books, East India goods which were sold in Boston for £562.12s., led the trustees to use the name Yale college at the first commencement (1718) in the completed college building.

President Clap secured the passage in 1745 of a new charter which legalized the name "Yale College" and in general provided a more explicit and liberal statement of powers and privileges conferred in 1701 and 1723. The organization of a College Church in 1757 provoked much criticism and revived the struggle to bring the college under the control of the legislature.

The charter drawn up by President Clap is still in force. In 1792 the governor and lieutenant governor of the State and six senior State senators were made *ex officio* members of the cor-

poration. In 1872 the six senators were replaced by six graduates, chosen by the alumni. The act authorizing the name Yale university was passed in 1887.

The curriculum of the college changed but little before the administration of Timothy Dwight the Elder (1795–1817), who expanded the usefulness of the college by the organization of professional schools. Benjamin Silliman, Sr. (1779–1864), was appointed to the first chair in chemistry, mineralogy and geology in the United States in 1802. In 1810 a medical department was established, and the theological and law departments were organized in 1822 and 1824.

Under the administration of Theodore Dwight Woolsey (1846–71) graduate courses were organized in 1846 and the Graduate school (under the title Department of Philosophy and the Arts) was established the following year. The degree of Doctor of Philosophy was first conferred in the United States by Yale in 1861. In 1847 courses in applied chemistry were offered and in 1852 instruction in engineering. Two years later these courses were distinguished as a separate section with the title "Yale Scientific School," which was changed in 1863 to "Sheffield Scientific School" in appreciation of the assistance of Mr. Joseph E. Sheffield, of New Haven, who endowed the school in 1860. From 1863 to 1892 this school was also the State college of agriculture and applied arts. The School of Fine Arts, established through the generosity of Augustus R. Street, was opened to students in 1869, the first of its kind to come within the scope of any university. The elective system of instruction in Yale college was substituted for the fixed curriculum in 1876.

During the presidency (1886–99) of Timothy Dwight, grandson of the former President Dwight, the institution more than doubled in resources, faculty and student enrolment. The School of Music was established in 1894, and its resources have been augmented through the patronage of Joseph Battell, Albert Arnold Sprague and his daughter, Mrs. Elizabeth Sprague Coolidge.

An outstanding feature of the administration of Arthur Twining Hadley (1899–1921) was the development of the university idea co-ordinating the various schools and departments. The School of Forestry, the oldest forest school in continuous operation in the United States, was founded in 1900, as the result of the gifts of James W. Pinchot and his family.

Under President James Rowland Angell (1921–37) the university expanded rapidly. A School of Nursing was established in 1923 by a gift from the Rockefeller foundation; in 1924 endowment was provided by Edward S. Harkness for a department of drama and a university theatre; the Institute of Human Relations was organized in 1929; and in 1932 the School of Engineering was re-established. In 1937 Pres. Angell resigned and was succeeded by Charles Seymour. The establishment in 1933 of residential colleges, designed to regain for undergraduates in a large university the educational and social advantages inherent in small groups of students, is the most important recent development at Yale. This was made possible by gifts from a Yale graduate, Edward S. Harkness. There are nine colleges (Berkeley, Branford, Calhoun, Jonathan Edwards, Pierson, Saybrook, Timothy Dwight and Trumbull), each providing accommodations for from 160 to 200 undergraduates during the last three years of the course. The Master of each college lives in a house attached to the college quadrangle. He is assisted in the work and life of the college by a group of faculty members who are Fellows of the college and have their studies and, if unmarried, their living quarters in the quadrangle. The Master and Fellows assist in guiding the undergraduate in his choice of courses, in his supplementary reading, and in general preparation for the examinations at the end of senior year.

The board of trustees, called the Yale corporation, consists of the president of the university, the governor and lieutenant governor of Connecticut, ten Fellows known as the successors of the original trustees, and six graduates elected for six-year terms. The corporation has five administrative officers, the president, provost, secretary, treasurer and associate treasurer and controller. The general administration of each school of the university is in the hands of a dean and a board of professors on permanent appointment, subject to the approval of the corporation. The teaching in the university is divided among 40 departments of study which serve the various schools. All members of these departments who are of professorial grade are grouped in four divisions: language, literature and the arts; history and the social sciences; mathematics and the natural sciences; and engineering. Courses of study in candidacy for degrees in course are offered in eleven schools: Yale College, Sheffield Scientific School, School of Engineering, Graduate School, School of Medicine, School of Law, Divinity School, School of the Fine Arts, School of Music, School of Forestry, School of Nursing.

The course of study in Yale College is designed to provide for substantial mastery of some one field of liberal arts together with an intelligent acquaintance with allied subjects. The Sheffield Scientific School provides for concentration in the principal fields of science, and the School of Engineering offers training in chemical, civil, electrical and mechanical engineering and metallurgy. In addition to preparation for the practice of medicine the School of Medicine offers courses leading to degrees in public health. The School of the Fine Arts offers four professional courses, architecture, drama, painting and sculpture, in which lectures are combined with technical practice. The School of Music admits those who intend to become musicians by profession, or to enter the field of musical criticism and literature of music. The curriculum of 32 months in the School of Nursing is open to women graduates of approved colleges and leads to the degree of Master of Nursing. Properly qualified women are admitted to all schools except the undergraduate schools and the School of Forestry.

The University library, including departmental collections, had a total (1936) of over 2,500,000 volumes and pamphlets. Besides gifts in the early years of the college, particular mention should be made of the Aldis collection of American *belles lettres,* the Elizabethan Club library of Shakespeare quartos and folios, the Henry R. Wagner collection of British and Irish economic and historical tracts, the William S. Mason collection of Benjamin Franklin and the Ezra Stiles manuscript diaries and itineraries. Other important collections are the Penniman library of education, the William A. Speck collection of Goetheana, the Albert S. Wheeler Roman law library, the Lowell Mason music library, the Frederick S. Dickson collection of Fielding's works, the Scandinavian library of Count Riant, the Curtius and Seymour libraries of classical literature, the Robert von Mohl library of political science, the Edward M. House collection of historical papers and the J. Sumner Smith Russian library. Among its rare volumes the library has a copy of the Gutenberg 42 line Bible.

The collections of the Gallery of Fine Arts include the Jarves collection of Italian primitives (13th to 17th centuries); the Trumbull collection of paintings and miniatures; the Rebecca Darlington Stoddard collection of Greek vases; *objects discovered at Gerasa and Dura-Europos;* the Mabel Brady Garvan collection of American arts and crafts; and the Achelis, Herr, and Callender collections of prints. The collections of the Peabody museum (1866) embrace the major fields of natural history.

The Yale university press was founded in 1908 for the publication of works having permanent interest and value. Since 1926 the Yale university press has published the *Yale Review* (1892), a national quarterly owned by the university. The university also publishes the *American Journal of Science* (1818), the oldest scientific publication in the United States, founded by Prof. Benjamin Silliman. The publications which are under the direction of students are the *Yale Law Journal; Yale Literary Magazine* (founded in 1836), the first undergraduate publication in the country; the *Yale Daily News* (1878), the oldest daily; the *Yale Record,* a humorous monthly; and the *Yale Scientific Magazine.*

In 1936 there were 865 officers and instructors and 732 assistants in instruction and administration. The students registered as candidates for degrees numbered 5,096; of this total 3,057 were undergraduates and 1,939 students in the graduate and professional schools. There were also 397 students who were not enrolled as candidates for degrees or certificates. The buildings number about 100. Connecticut hall (1752), a four-storey brick

building with gambrel roof, called South Middle college, is the only building remaining from the 18th century. The university funds on June 30, 1936, amounted to $99,993,785.21 ($21,181,302.17 in 1918), exclusive of land and buildings valued at $70,000,000 and of funds and property amounting to $1,082,488.30 held by the Sheffield trustees. The total income in 1935–36 was $6,769,371.46.

In 1936 there were 31,003 living degree holders and 11,906 non-graduates, the majority resident in the North Atlantic division, but other sections of the country were well represented, as well as foreign countries. The division according to occupations shows a preponderance in the fields of law, education, medicine, ministry, engineering, banking, industry and commerce.

YALU, BATTLE OF THE. This was the opening battle on land of the RUSSO-JAPANESE WAR, and is described under that heading. Fought on May 1, 1904, by Gen. Kuroki's I. Army, advancing from Korea, the Japanese success was a valuable moral tonic and created a profound impression in Europe.

YAM, a term usually applied to the tubers of various species of *Dioscorea* of the monocotyledonous family Dioscoreaceae. These are plants with thick tubers (generally a development of the base of the stem), from which protrude long, slender, annual climbing stems, bearing alternate or opposite, entire or lobed leaves and unisexual flowers in long clusters. The flowers are generally small and individually inconspicuous, though collectively showy. Each consists of a greenish, bell-shaped or flat perianth of six pieces, enclosing six or fewer stamens in the male flowers, and surmounting a three-celled, three-winged ovary in the female flowers. The ovary ripens into a membranous capsule, bursting by three valves to liberate numerous flattish or globose seeds. The species are natives of the warmer regions of both hemispheres.

D. sativa and *D. alata* are the species most widely diffused in tropical and subtropical countries. *D. esculenta,* grown in India, Cochin China and the South Sea islands, is one of the best kinds. *D. batatas,* the Chinese yam, or Chinese potato, is hardy in Great Britain, but the great depth to which its enormous tubers descend renders its cultivation unprofitable. It has deeply penetrating, thick, club-shaped, fleshy roots, full of starch (about 13% of the fresh weight) which when cooked acquire a mild taste like that of a potato; they grow 3 ft. or upwards in length, and sometimes weigh more than 1½ lb. The plant grows freely in deep sandy soil, moderately enriched. The tubers of *D. alata* sometimes weigh 100 lb. Most of the yams contain an acrid principle, which is dissipated in cooking. The only European species is *D. pyrenaica,* a native of the Pyrenees, a remarkable instance of a species growing at a long distance from all its congeners. In North America there is a single native species, *D. villosa,* called wild yam-root or colic-root. This is found from Rhode Island to Ontario and Minnesota and southward to Florida and Texas, but is of no economic value. True yams must not be confounded with the sweet potato, *Ipomoea batatas.* "Moist-fleshed" varieties of sweet potato are often erroneously called yams in the United States. True yams are rarely grown in the United States, and then only in the southernmost part.

For the history of the yam, and its cultivation and uses in India, *see* G. Watt, *Dictionary of the Economic Products of India,* iii. (1890).

YAMA, in Vedic Hindu mythology the twin of his sister Yamī, and with her the first human pair. Yama is king of the dead, and later, their judge. The word is Sanskrit for "twin."

YAMAGATA, ARITOMO, PRINCE (1838–1922), Japanese field-marshal, was born in Choshu. He began life as an ordinary *samurai* and rose steadily in reputation and rank, being created a count in 1884, a marquess in 1895 (after the war with China) and a prince in 1907 (after the war with Russia). He twice held the post of premier, and was the leader of Japanese conservatism, being a staunch opponent of party cabinets. He died at Odawara on Feb. 1, 1922.

YAMAMOTO, TATSUO, BARON (1856–), Japanese statesman, was born in Oita-ken, and educated at Keio. After some time in a business career he entered in 1890 the Bank of Japan of which he was appointed director and then governor (1898–1903). In 1910 he became governor of Hypothec Bank of Japan. He was made minister of finance in 1911–1912, minister of agriculture and commerce in 1913–1914, and again in 1918–1922. At that time he belonged to the Seiyukai Party, but in 1924 he seceded and established a new party, Seiyuhonto, with Tokonami, as leader, becoming himself the adviser to the party. When the Kenseikwai and Seiyuhonto parties united to form the Minseito, in 1927, he became adviser to the new party. He was made crown member of the house of peers in 1903, created baron in 1920, and was minister for home affairs (1932–34).

YAMBOL, a town of Bulgaria, on the river Tunja, 49 m. W. of Burgas by rail, and an important corn growing centre. Pop. (1934) 25,125. In the town are the remains of old fortifications, and the ruins of a fine mosque. Yambol is first mentioned in the 11th century, when it was known by the Byzantines as Hyampolis.

YAMETHIN, a town and district in the Mandalay division of Burma. The town has a station on the railway 275 m. N. of Rangoon on the main line to Mandalay. It is an important centre of trade with the Shan States. The district lies between the Shan States and the Meiktila, Magwe and Toungoo districts and comprises the Sittang valley in the centre, the Pegu Yomas on the west and the forested Shan hills on the east. Area, 4,196 sq.m.; pop. (1931) 390,820, showing an increase of 67,631 in the decade. The staple crop is rice, which is irrigated from tanks and canals. Millets and oil-seeds are grown in the north, where drought has more than once caused distress. Besides the chief town, Pyinmana and Pyawbwè, both also on the railway, carry on an active trade with the Shan States. Pyinmana has a forest school, and from Pyinmana a branch railway now crosses the forested Pegu Yomas to the Magwe district.

YANCEY, WILLIAM LOWNDES (1814–1863), American political leader, son of Benjamin Cudworth Yancey, lawyer of South Carolina, was born in Warren county, Ga., on Aug. 10, 1814. He attended Williams college for one year, studied law at Greenville, S.C., and was admitted to the bar. He was elected in 1841 to the State house of representatives, became State senator in 1843 and in 1844 was elected to the national House of Representatives to fill a vacancy, being re-elected in 1845. In 1846 he resigned his seat, and devoted himself to the resistance of anti-slavery aggression. In 1848 he secured the adoption by the State Democratic convention of the so-called "Alabama Platform," declaring that it was the duty of Congress not only to allow slavery in all the territories but to protect it, that a territorial legislature could not exclude it, and that the Democratic Party should not support for president or vice president a candidate not openly opposed to the exclusion of slavery from the Territories. When the Democratic convention in Baltimore refused to incorporate his ideas into the platform, Yancey with one colleague left the convention. He opposed the Compromise of 1850, and went so far as openly to advocate secession. In 1858 he advocated the appointment of committees of safety, the formation of a league of united southerners, and the repeal of the laws making the African slave-trade piracy. He attended the Charleston convention of the Democratic Party in April 1860, and again demanded the adoption of his ideas. Defeated, he again left the hall, followed by the delegates of Alabama, Mississippi, Louisiana, South Carolina, Florida, Texas and two of the three delegates from Delaware. On the next day the Georgia and a majority of the Arkansas delegation withdrew.

In the Baltimore convention of the seceders he advocated the nomination of John C. Breckinridge, and made a tour of the country on his behalf. When the South seceded, he delivered the address of welcome to Jefferson Davis on his arrival at Montgomery, but declined a place in President Davis's cabinet. On March 31, 1861, he sailed for Europe as the head of a commis-

sion sent to secure recognition of the Confederate government, but returned in 1862 to take a seat in the Confederate senate. On account of his failing health, he left Richmond early in 1863, and on July 27 died at his home near Montgomery.

Du Bose, "Yancey: A Study," *Gulf States Hist. Mag.*, vol. i., pp. 239–252, 311–324 (Montgomery, Ala., 1903); and G. Petrie, "What Will Be the Final Estimate of Yancey," *Alabama Hist. Soc., Reprint* No. 14 (1904).

YANGCHOW (KIANGTU), an important city in the province of Kiangsu on the Grand canal, north of the Yangtze river. Population about 100,000. The walls are between 3 and 4 mi. in circumference. It was the ancient capital of the Yang kingdom. It possesses an early historical connection with foreigners, for Marco Polo ruled over it for three years by appointment from Kublai Khan (?1282–85). It was a cultural rather than an industrial centre and was captured by the Japanese in 1938.

YANGTZE KIANG (Yahng-ts-Ke-ahng), the principal commercial river of China. This river, the length of which is estimated at some 3,000 miles, is known as the Yangtze by Europeans throughout its course, but among the Chinese this term indicates only the last three or four hundred miles where it flows through a region known in ancient times as "Yang." The ordinary official name for the whole river is Ch'ang Kiang or Ta Chiang, meaning the "long river" or the "great river." Popularly in the upper reaches every section has its local name. As it enters China it is known as the Kinsha Kiang (river of golden sand) and farther down as the Pai-shui Kiang; in Szechuan after its junction with the Min it is for some distance called the Min-kiang.

The beginnings of the river are somewhat indefinite but may be located in the high and difficult country between Tibet, Sinkiang and Kuku-nor. The river flows in a southeasterly direction not far removed from some of the headwaters of the Hwang-ho. Proceeding southeastward the Yangtze follows one of those narrow longitudinal valleys separated from one another by lofty ridges that mark the bending southward of the eastern extensions of the Himalayan folds against the older core of southeast China. At Batang in this section of the course the river is 8,540 ft. above sea level. Its entrance into China proper is marked by bends in its course as it bursts through lines of weakness in the sides of the corridor valleys. The river then begins a long southwest to northeast course through the Red basin of Szechuan. As the Yangtze cuts across the longitudinal valleys it receives many tributaries (flowing in parallel valleys), all naturally on the left-hand bank. At Wa-Wu in Szechuan the height of the river is 1,900 ft. above sea level, a fall of about 8 ft. per mile from Batang. Through the Red basin of Szechuan the Yangtze flows at first with fairly low banks, but towards the east it becomes deeply encased and the rapids are many and dangerous. This is due to the fact that Szechuan is tilted down against the upthrust of the fault line of the west and thus the river cuts with ease through its western half but gets through on the east by means of deep gorges. (*See* SZECHUAN.) At Chungking, where the Kialing enters on the left, the river is only 630 ft. above sea level. After receiving the Wu-kiang on the right the river enters deep gorges and emerges at Ichang (130 ft. above sea level). In its subsequent course the river skirts the north side of the old land block of southeast China. Here the physical features are mostly set north-northeast to south-southwest or west-northwest to east-southeast. The Yangtze follows these directions alternately in successive sections. Below Ichang it is in the Hupeh basin, the Han flows in from the northwest and the basin focuses on Hankow (*q.v.*).

From Ichang to the sea, a distance of 1,000 miles, the fall of the river is exceedingly small, being as far as Hankow at the rate of $2\frac{1}{2}$ inches and from Hankow to the mouth at the rate of little more than 1 inch per mile. The last 200 miles of the Yangtze course are practically a dead level.

The drainage area in Szechuan and below is about 650,000 sq.mi., of which more than four-fifths lie above Hankow. The period of low water is from December to March. Melting snows in Tibet together with the summer monsoon cause an annual rise in the river of from 70 to 90 ft. at Chungking and from 40 to 50 ft. at Hankow. The mean volume of water discharged into the sea is estimated at 770,000 cu.ft. per second and the quantity of sediment at the mouth at 6,428 million cu.ft. per annum.

The Yangtze forms a commercial highway of first class importance. Except in winter low water, vessels of between 5,000–6,000 tons can reach Hankow. Sandbanks between Hankow and Ichang make navigation more difficult and above Ichang the gorges add to the dangers. But on the whole the Yangtze as a highway is the collecting and distributing centre of half the commerce of all China. Various "agreements" between China, Britain and other powers from 1898 have given Britain political influence over most of the Yangtze basin.

The great towns and centres of trade on the banks of the river are Chinkiang at the junction with the Grand Canal; Nanking; An-king; Hankow and Wuchang, Ichang, King-chow; Kwei-chow; Chungking, and Sui-fu.

YANKEE. The term means properly a citizen of New England, but by extension, chiefly by Europeans, it is often used to indicate any native of the United States. The origin of the word is uncertain, but according to a common statement the Massachusetts Indians are reported to have given the name, *Yenkees,* or *Yenghees,* to the English colonists, the term being a corruption of the word English; or as some think, a corruption of the French word, *anglais,* in which case the word must have originated in Canada, as the early Canadian Indians were the only ones in contact with the French. The British soldiers seem to have used it as a term of reproach for the New Englanders about 1775, who afterwards took up the word and used it in reference to themselves. During the Civil War the southerners used it in a derisive sense to indicate inhabitants of the northern states.

YANKTON, a city of South Dakota, U.S.A., on the high bank of the Missouri river, near the mouth of the James, 1,200 ft. above sea level, and 60 mi. from the S.E. corner of the state; the county seat of Yankton county. It is on federal highway 81 and is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific, and the Great Northern railways, and by motor coach lines to many points. Pop. 6,798 federal census 1940. In 1780 Pierre Durien reached the Indian village then occupying the site of Yankton, and married into the tribe. He guided the Lewis and Clark expedition from St. Louis to Yankton, and in 1811 his son accompanied the Astoria expedition up the river and on to the coast. In 1858 a permanent trading post was established there. The city was laid out in 1859, chartered in 1869, and in 1910 adopted a commission form of government. From 1861 to 1882 it was the capital of the territory of Dakota.

YAOS or **AJAWA,** a Bantu-Negroid people of east-central Africa, whose home is the country around the upper reaches of the Rovuma river, and the north of Portuguese East Africa. They have spread into the territory south of Lake Nyasa and throughout the Shiré districts. They are the tallest and strongest of the natives in the Mozambique country. They were formerly slave traders, but were reduced to submission by the English in 1896.

See Miss A. Werner, *The Natives of British Central Africa* (1906); Sir H. H. Johnston, *British Central Africa* (1897); H. L. Duff, *Nyasaland under the Foreign Office* (1903).

YAP. This island of the Caroline group, formerly owned by Germany, is situated in the Pacific ocean, south of Japan and east of the Philippines, and north of the equator, in lat. 9·35 N., long. 138·15 E. It has an estimated population of 6,652, almost entirely of Malay origin.

The importance of Yap arises from its cable connections, since it is a station on the direct line from the United States to the Dutch East Indies via Guam, while another cable runs from Yap to Shanghai. On May 7, 1919, Japan was given a mandate over the islands north of the equator previously owned by Germany, including Yap. The United States government protested, and asked for a reopening of the subject on the ground that at the Peace conference it had reserved the right to object to exclusive control of the cable landings by Japan and taken the position

that the island should be internationalized for cable purposes. Further, it was contended, the United States, not having ratified the Treaty of Versailles, was not bound by it. The supreme council of the Allies expressed its inability to reopen the matter. The controversy was finally disposed of at the Washington conference, Dec. 12, 1921, by an agreement between the two powers, wherein the United States recognized the Japanese mandate and Japan agreed that the United States should have free access to the island on a footing of entire equality with Japan or any other nation in respect to the Yap-Guam cable and any other cables which might be laid by the United States or its nationals, and also similar rights and privileges in regard to radio-telegraphic service. The United States was also granted free entry and exit for persons and property. The United States senate ratified the convention embodying this agreement March 1, 1922. (*See* WASHINGTON CONFERENCE.)

YAPOCK: *see* WATER-OPOSSUM.

YA'QŪBĪ [Aḥmad ibn abī Ya'qūb ibn Ja'far ibn Wahb ibn Wāḍiḥ] (9th century), Arab historian and geographer, was a great-grandson of Wāḍiḥ, the freedman of the caliph Manṣūr. Until 873 he lived in Armenia and Khurasan; then he travelled in India, Egypt and the Maghrib, where he died in 891. His history is divided into two parts. In the first he gives a comprehensive account of the pre-Mohammedan and non-Mohammedan peoples, especially of their religion and literature. For the time of the patriarchs his source is now seen to be the Syriac work published by C. Bezold as *Die Schatzhöhle*. In his account of India he is the first to give an account of the stories of Kalila and Dimna, and of Sindibad (Sinbad). When treating of Greece he gives many extracts from the philosophers (*cf.* M. Klamroth in the *Zeitschrift der deutschen morgenländischen Gesellschaft*, vols. xl. and xli.). The second part contains Mohammedan history up to 872, and is neither extreme nor unfair, although he inherited Shi'ite leanings from his great-grandfather.

Edition by T. Houtsma (2 vols., Leiden, 1883). Ya'qūbī's geography, the *Kitāb ul-Buldān*, contains a description of the Maghrib, with a full account of the larger cities and much topographical and political information (ed. M. de Goeje, Leiden, 1892). (G. W. T.)

YAQUI, the best known and sturdiest Indian tribe of Sonora, Mexico. Their language, generally called Cahita by older authors, belongs to the Piman division of the Uto-Aztecan family. The Yaqui were, and in part remain, settled agriculturists, but offered a stubborn resistance to the first Spanish invaders. They gradually came under mission influence, but in the 19th century Mexican encroachments on their lands and water rights led to a series of uprisings which were quelled with difficulty only to flare up anew, and since the final subjugation of the Apache, left the Yaqui the one unsubdued and feared tribe in North America. They pass as the best labourers in Sonora, and several thousand have recently settled in Arizona. They number about 30,000.

YĀQŪT or YAKUT (Yāqūt ibn 'Abdallah ur-Rūmī) (1179–1229), Arab geographer and biographer, was born in Greece of Greek parentage, but in his boyhood became the slave of a merchant of Hamah (Hamath), who trained him for commercial travelling and sent him two or three times to Kish in the Persian Gulf. After his master's death he became a bookseller, and he travelled in Persia, Syria, Egypt and visited Merv, Balkh, Mosul and Aleppo. About 1222 he settled in Mosul and worked on his geography, the first draft of which was ready in 1224. After a journey to Alexandria in 1227 he went to Aleppo, where he died in 1229. In his large geography, the *Mu'jam ul-Buldān* (ed. F. Wüstenfeld, 6 vols., Leipzig, 1866–73), the places mentioned in the literature or the stories of the Arabs are given in alphabetical order, with the correct vocalization of the names, an indication whether they are Arabic or foreign and their locality. A sketch of their history and of their monuments follows.

The parts of this work relating to Persia have been extracted and translated by Barbier de Meynard under the title *Dictionnaire géographique, historique et littéraire de la Perse* (1871). Yāqūt wrote a dictionary of geographical homonyms, the *Mushtarik* (ed. F. Wüstenfeld, Göttingen, 1846). Yāqūt also wrote an important dictionary of learned men, the *Mu'jam ul-Udabā'*. Vol i. has been edited by D. S. Margoliouth, *Irshād al Arib Il ā Ma'rifat al Adīb* (London, 1908).

YARKAND (Chinese name SOCHE), is the largest town in one of the two chief oases of the Tarim basin in the dominion of Sinkiang, 38° 25′ N. and 77° 16′ E., 3,900 ft. above sea level. The oasis lies along several rivers of the southwest part of the Tarim basin and, as these streams come from the glaciers of high Pamir, they are strong and give a good water supply. The Kashgar oasis lies to the northwest and the Khotan oasis (across a desert belt) to the southeast. In the Yarkand oasis irrigation is highly developed and the soil at the foot of the mountains is largely fertile loess, on which wheat, barley, rice, beans, and oil plants are grown, while there are also many fruit orchards. Among the mountains there is good pasture and large herds of camels, yaks, goats, sheep and cattle are kept. Cotton and silk (mulberry) are cultivated to some extent.

Marco Polo visited Yarkand between 1271 and 1275 and Goes went there in 1603. Schlagintweit passed through Yarkand a few days before he was killed at Kashgar in 1857.

The town is surrounded by a great earth wall with towers of Chinese type and has mosques and madrasas (colleges) of great fame, though less well known than those of Bukhara and Samarkand. Estimates of the population, all some years old, vary from 50,000 to 100,000, probably according to the extent to which suburbs have been reckoned with the city. There are several smaller towns in the Yarkand oasis: Tashkurgan on the Pamirs, Yangi-hissar, Posgam, Kargalyk, at the bifurcation of ways to Khotan and Ladakh, Sanju, Tagarchi, Kartchum, Besh-taryk and Guma: The city is a centre of caravan trade along routes from Cadakh, Khotan, Kansu and Trans-Caspian regions, as well as India and Russia generally. Horses, cotton, skins and leather and leather goods, carpets, silk, etc., are dealt in, and carpets as well as woven stuffs in silk, cotton and wool are made.

YARMOUTH, a seaport town and port of entry, Yarmouth county, Nova Scotia, Canada, on the Dominion Atlantic and Canadian National railways, 218 mi. from Halifax. Pop. (1941) 7,790. Steamers run to Boston, Mass., and to St. John, N.B., and Halifax. Fish and lumber are exported.

YARMOUTH, a port at the western extremity of the Isle of Wight, England, on the Solent, where the estuary of the Yare debouches. Pop. (1931) 948. Steamers connect it with the S.R. at Lymington on the mainland. It appears in the Domesday Survey of 1086 under the name of Ermud.

YARMOUTH (GREAT YARMOUTH), a municipal, county and parliamentary borough, watering-place, and seaport of Norfolk, England (with a small portion in Suffolk), 121 mi. N.E. from London by the L.N.E.R., served also by the M. and G.N.R. Pop. (1938) 53,780. Area 7 sq.mi.

Yarmouth (*Magna Gernemutha*), which lies near the site of the Roman camp of Garianonum, is believed to have been the landing-place of Cerdic in the 5th century. Not long afterward, the convenience of its situation having attracted many fishermen from the Cinque Ports, a permanent settlement was made, and the town numbered 70 burgesses before the Conquest. Henry I placed it under the rule of a reeve. The charter of King John (1208), which gave his burgesses of Yarmouth general liberties according to the customs of Oxford, a gild merchant and weekly hustings, was amplified by several later charters asserting the rights of the borough. In 1552 Elizabeth granted a charter of admiralty jurisdiction, afterward confirmed and extended by James I. In 1668 Charles II incorporated Little Yarmouth in the borough by a charter, which with one brief exception remained in force till 1703, when Anne replaced the two bailiffs by a mayor. In 1943 there were 12 aldermen and 36 councilmen. Yarmouth returned two members to parliament from 1300 to 1868 and one after 1885. Yarmouth claims to be the largest herring port in the world. This trade used to be carried on at an annual fair between Michaelmas and Martinmas.

Yarmouth lies on a long and narrow peninsula of sand between the North sea and the Breydon Water (formed by the rivers Yare and Waveney) and the river Bure. The old town of Great Yarmouth was built chiefly along the east bank of the Yare, but the modern town has extended beyond its ancient walls, of which some

remains exist, to the seashore. On the landward or Suffolk side of the estuary is the suburb of Southtown, and farther south that of Gorleston. The principal features of Yarmouth are the north and south quays, and the straight narrow lanes called "rows," 145 in number, running at right angles to them. The Haven bridge over the Yare between Yarmouth and Southtown, connecting Norfolk and Suffolk, was opened in 1930, replacing one built in 1854. The church of St. Nicholas, founded in 1101 by Herbert Losinga, and consecrated in 1119, was destroyed by incendiary bombs in 1942. It was the largest parish church in England. The town suffered greatly through air raids in World War II, and up to the end of 1941 about 11,500 houses had been damaged.

Yarmouth roads, off the coast, afford excellent anchorage except in E. or N.E. winds. The channel to the quays was made by Joost Jansen, a Dutch engineer, in 1567, and affords a depth at the bar of 12 ft. at low water. The herring industry is the most important, Yarmouth bloaters being famous, but there are numerous malting houses.

See *Victoria County History, Norfolk;* H. Swinden, *History of Great Yarmouth* (1772); C. J. Palmer, *History of Great Yarmouth* (1854): Marlowe, *People and Places in Marshland* (1927)

YARN. The derivation of this word from *"garn,"* a word common to the Scandinavian languages, meaning "guts," is interesting since today "cat-gut," which may be the drawn-out "guts" of the silk-worm, is a well-known commodity; and the same "guts" spun by the silk-worm itself into a fine filament are the basis of the best silk yarn produced. The silk-worm, however, in its "spinning" simply thins-out the silk fluid to a double microscopic strand some 500 to 1,000 yards long, several of which are combined by mechanical means to form a yarn; while the human spinner usually combines a number of much shorter fibres or filaments, also by mechanical means, into a continuous strand often much longer than the 1,000 yards filament of the silk-worm; and this also is spoken of as a yarn.

Materials.—The materials from which yarns are constructed or spun markedly influence the processes of production. In the case of the best silk yarn the worm itself does what is termed the spinning and the later running-together of several of the long silk filaments is not spoken of as spinning but as "throwing." In the case of a typical short fibre—say the cotton fibre ½″–2″ long—the spinning process is the binding together of many thousands of cotton fibres into a fine regular, continuous thread—usually spoken of as "yarn." Two or more of these threads or single yarns may be combined together by "twisting" to produce a thicker, stronger yarn. Of the true long fibres there are only two types, the natural silk reeled from the cultivated silk-cocoon and the synthetic artificial silks.

Of the short fibres there are many classes. The longest are the waste silks just mentioned; then come the animal fibres including hairs and wools up to 18″ long, short wools down to, say, 2″ long and broken-up wool fibres (variously termed shoddy, mungo, extract, flocks, etc., according to their source and manner of breaking up from the virgin wool clothes, knitted garments, etc.) which (it is popularly said) can be spun into yarn if they possess two ends; next come the "stem-fibres" such as flax (producing linen yarn), hemp, jute and china-grass which may vary in length from several inches down to fractions of an inch; lastly come the cotton fibres and cotton wastes often under one inch in length along with which should perhaps be ranked the mineral fibre asbestos, which may be spun into a yarn from which fireproof cloths are woven.

Structures.—Yarn structures may be considered from two points of view. In the first case particular fibres lend themselves only to particular "fibre combinations." Thus long silk filaments can only be "thrown" together with or without "twist." But the twisting of silk filaments is an art in itself. Thus several filaments may be reeled together from separate cocoons and these given a suitable "combining-twist" to produce what is known as singles; then several of these singles may be thrown together with little twist to produce almost a "paralleled-fibre" thread termed "tram," the most lustrous yarn known, or with much twist to produce a strong, fairly lustrous yarn termed "organzine" which is employed as "warp." On the other hand one inch cotton fibres after being drawn into a fairly fine "paralleled sliver" termed a "roving" can only be spun out into a fine thread by means of "supporting twist" which no doubt binds the fibres more or less concentrically in the thread or yarn: this is said to be the true form of spinning—draft (that is, drawing-out thinner) against twist.

Fancy Twists.—These naturally group themselves into three classes, viz., structural twists; colour twists; and structural-and-colour twists. Of the first class the two most important are the knop yarn—in which knops are formed at any required intervals on an otherwise level thread by holding one thread tightly and allowing the second thread to run in slackly to form knops of the required size, after which equal delivery of the two threads for the required length is followed again by the varied delivery to form the knop; and the curl yarn—in which a knop yarn is first formed and then this two-fold yarn twisted, in the opposite direction, with a third thread, this opening out the knops into loops which may be produced at more or less regular intervals or "spaced," *i.e.,* a length of the thread without loops and then a series of loops, which in turn are followed by a length of the thread without loops. Of fancy colour twists the simplest is the corkscrew twist which is formed by first twisting, say, a dark and a light thread in the normal manner and then twisting this two-fold yarn in the reverse direction, with a third dark thread, this producing the special appearance which gives its name to the yarn.

Other Fancy Yarns.—Fancy yarns of an effective character may also be produced with simple modification in the normal carding and spinning processes. Thus "knicker yarns" are produced by throwing little bits of highly coloured material into the last cylinders of the card so that instead of being broken up by carding they are carried forward as "knickers" into the spun thread. "Random yarns" are produced by feeding the card with alternate stripes of dark and light material and taking the condensed slivers off with a zig-zag or moving-laterally doffer which takes sections of the lengths of its slivers from first one and then the other stripes. "Marl yarns" are produced by running two differently coloured slivers together on the roving frame just prior to the worsted spinning process, so that the colours are "regularly irregularly" mixed together.

If on the other hand a very level mixture effect is required dark and light coloured tops are mixed together in the worsted drawing processes, or, better still, the "tops" are printed the required colours in bands and then passed through the worsted drawing processes this producing the extraordinary level mixture effect termed a "melange." Of the simple twofold yarns the best known is the "granderelle" in which a dark and light thread—usually of similar material, but not necessarily so—are finely twisted together as perfectly as possible. Another twofold twist termed a "spiral yarn" is formed by two single threads twisted in opposite directions being combined with twofold twist which necessarily shortens one of the threads by adding twist and markedly lengthens the other by taking out twist. Thus the slack thread "spirals" round the tight thread.

Yarn Effects and Special Properties.—The effects which may be produced by suitable selection of materials and yarn structure may be grouped into three classes, viz., light-reflective effects; form effects, and colour effects. Light reflection from the surface of a woven fabric depends upon the material or materials employed, upon the fibre arrangement in the thread, upon the thread interlacings and upon such modifications as may be introduced in the finishing processes. Thus some wools are lustrous—the Wensleydale wool, for example—and some are opaque and dull—the Down wools. Ordinary cotton is dull, mercerized cotton is lustrous. A lightly twisted net silk yarn ("tram") is the most lustrous yarn known, while a specially hard twisted net silk yarn (crape) is the dullest yarn produced. Tram silk yarn interlaced on the "satin" principle produces the most lustrous fabric and crape silk yarn interlaced on the "crape" principle produces the dullest fabric known.

Merino wool spun on the woollen principle when woven into a normal fabric gives a dull surface but if the fibres are "raised" from the surface and laid parallel in the "finishing" processes then

a brighter fabric may result than that produced from a merino wool spun on the worsted principle in which the fibres are laid parallel in the thread structure only.

The "form" effects will have been appreciated from the descriptions already given of knop, curl, spiral, etc., yarns. These yarns specially coloured as already described offer the designer the opportunity of producing a never-ending array of novel fabrics. Should specially white fabrics be required a "bleached" yarn is employed but it is more usual to bleach the material in the fabric state. Should a yarn which may be spun white but later—either in the yarn or cloth state—dyed two distinct colours be sought for, cotton may be blended with wool in the carding or in the drawing processes, or strands of wool and of cotton may be twisted together and dyed distinctive colours later.

Yarn Counting and Numbering.—The numbering or "counts" of varns, 30's, 40's, 80's, etc.—may be explained best by the counting of woollen yarns. The basic weight is the "wartern" of six lb. the "quartern" of the old 24 lb. stone. This appears to have been a convenient weight for the spinners to take away to their homes for hand or "jenny" spinning. If this weight was spun in 1,536 yd.—that is each dram spun out to one yard—it was termed "one skeins." If one dram was spun to 2 yd., it was termed "two skeins"; if to 20 yd., it was "twenty skeins." Later it was found more convenient to deal with the unit weight of 1 lb., so that it has come to be usual to reckon the woollen "skein" as 256 yd. and the number of skeins to which a pound of this material is drawn out as the "counts," spoken of as "skeins" in the woollen districts. Thus if 1 lb. is drawn out to 5,120 yards (256×20) the yarn is a "20 skeins." Unfortunately the woollen industry was spread over the whole of the known world before the unifying mechanical era dawned with the result that not only each country but each manufacturing district has adopted its own system of woollen yarn counting. Thus 200, 300, 420 yd. skeins are to be found and there is a still further complication in the United States where in one case the length is fixed and the count or skeins is given by the number of times the unit weight (the grain) is contained in this unit length. This method is that natural to the net silk industry in which the drams per 1,000 yards, or the deniers (or ½ deci-gram) per 450 metres gives the count spoken of as the "deniers."

The cotton spinning industry which started from England adopted from the first a hank (or skein) of 840 yards and the hanks per lb. as the "count" and this has obtained world-wide acceptance. The worsted industry, apparently an off-shoot of the cotton industry, taking a yard instead of a 1½ yard reel has adopted a hank of 560 yards and the hanks per lb. give the count. An attempt is now (1928) being made to adopt a universal system of counting yarns. The kilogram and the kilometre (or gram and metre) are suggested as the universal bases for everything excepting "thrown" silk and artificial silk yarns for which a base length of 500 metres is suggested and the weight of this in decigrams to give the "deniers" or "count."

The yards to which one pound of material may be spun naturally vary with the fineness and nature of the material. Thus cotton has been spun on a commercial basis to 588,000 yd. per lb., linen to 180,000 yd. per lb., worsted yarn to 56,000 yd. per lb., and woollen yarn to 15,000 yd. per lb.; while net silk yarns, if required, may even be thrown finer than the finest cotton.

Sometimes to obtain a fine, straight-fibred thread, wool is spun or twisted with cotton and later the cotton is "carbonized" by acid treatment. The reverse process may also be employed. Special note should be made that in twisting threads together the count number of the yarn will be lessened in proportion to the added weight of the thread or threads. Thus two threads of a 40's count twofolded give a 20's count—written 2/40's. There is, however, an exception to this in spun silk yarn in which a 2/40's yarn (often written 40/2) is a 40's but twofold, *i.e.*, two threads of 80's are twisted together giving a folded yarn with 40 hanks (each 840 yd.) to the pound. The twisting of varied count numbers is really simple but mystifying to the uninitiated. Thus a 10's count twisted with a 40's count does not give an intermediate count number (say 25's) but naturally a thicker count than 10's and consequently a lower count number, viz., 8's count; and this is true in whatever denomination the count may be stated—cotton, linen, woollen, worsted, etc. (A. F. B.)

YAROSLAVL, a region of the Russian S.F.S.R., surrounded by those of Kalinin, Vologda, Gorky (Nizhegorod), Ivanovo and Moscow. Area 23,507.4 sq.mi. Pop. (1939) 2,271,307 (rural 1,474,778; urban 796,529). Thick deposits of boulder clay, remains of the bottom-moraine of the ice-cap of the Glacial period, cover the Jurassic clays, and patches of Triassic "variegated marls" outcrop in some places, while Upper Carboniferous limestones crop out only in the north-west and towards the east. Coniferous forest, with firs predominating, occupies 39% of the region, and marshes are extensive, especially between the Sheksna and Mologa, and in the Rostov district. Dwarf birch, the Arctic raspberry (*Rubus arcticus*) and *Linnaea borealis* are widespread. The climate is severe, the rivers being frozen 118 to 183 days per annum, average January temperature 6.5° F., average July 61.5° F. The prevailing south-west and west winds make the rainfall heavier than in central Russia.

Of the land free from forest and marsh, only 25% is under plough culture, with rye (36.9%), oats (23.4%) and flax (7.4%). Potatoes, barley, grass, vegetables, chicory and herbs are grown, the latter especially in the Rostov district. Meadow and grassland prevail and the region has a flourishing dairy industry, with exports of butter and cheese. In the years 1926–27 a peat fuel electric station was opened at Liapinsk near Yaroslavl. Bog iron ores, copper sulphate and pottery clay are obtained and there are salt and mineral springs. The principal river is the Volga, which is connected with the Neva by the Mariinsk and Tikhvinsk canals through its tributaries the Sheksna and the Mologa. The Kotorost, flowing from Lake Nero to the Volga, is navigable in spring, and the Kostroma, flowing along the north-eastern boundary, is a channel for the export of timber and peat fuel. Of the rivers, 39% are available for steam navigation; the railway net is poor, and good roads are absent, except for the Moscow-Yaroslavl road. Yaroslavl and Rybinsk (*q.v.*) are the chief towns.

Yaroslavl, the chief town of the above region on the right bank of the Volga, at its confluence with the Kotorost, in 57° 38′ N., 39° 50′ E. Pop. (1939) 298,065. It is a productive centre with textile factories, and tobacco, leather and lacquer industries. Founded in 1026–36, it was the chief town of the principality from 1218 to 1417, when it was annexed by Moscow. The Uspenskiy cathedral was begun in 1215 and rebuilt 1646–48, and there are remains of 15th and 17th century monasteries.

YARROW, river and parish of Selkirkshire, Scotland. The river, issuing from St. Mary's Loch, flows for 14 mi. E. by N. to the Tweed, which it joins about 3 mi. below the county town. The stream and vale are famous in poetry. Pop. (1931) 459.

YARROW (*Achillea millefolium*), a plant of the family Compositae, also called milfoil, native or naturalized throughout the northern hemisphere. It has white or, rarely, rose-red flowers, borne in flat-topped clusters, and very finely divided leaves. Legend ascribes the discovery of its healing virtues to Achilles, in whose honour it was named. The leaves, anciently in great repute for use in the treatment of wounds, are said to be occasionally so employed in domestic medicine. In lawns it sometimes makes a solid turf, being more resistant to drouth than most lawn grasses. The closely allied *A. ptarmica,* the sneezewort or sneezewort yarrow, so named because of the use of the root for snuff, native to Europe and northern Asia and found in the British Isles, is naturalized in eastern North America.

YARURAN, a small group of tribes of South American Indians, constituting an independent linguistic stock. The Yaruros lived in Venezuela, on the Orinoco river between the Meta and the Capanaparo; in recent times they have spread somewhat further down stream to the Arauca and beyond.

See J. Chaffanjon, *L'Orenoque et la Caura* (Paris, 1889).

YATES, RICHARD (1818–1873), American political leader, born at Warsaw, Kentucky, Jan. 18, 1818. He graduated at the Illinois College at Jacksonville in 1838, was admitted to the bar, and entered politics as a Whig. From 1842 to 1845 and again in 1849 he served in the state House of Representatives. He was a

representative in Congress in 1851–1855, but having become a Republican, was defeated for a third term.

From 1861 to 1865 he was governor of Illinois, and was successful in enlisting troops and in checking the strong pro-Southern sentiment in the state. He was a member of the United States Senate in 1865–71, and was prominent in Reconstruction legislation. He died at St. Louis, Missouri, on the 27th of November 1873. His son Richard (b. 1860) was governor of Illinois from 1901 to 1905.

YAUCO, a prosperous and progressive town situated in the southwestern part of Puerto Rico. Its population by federal census of 1930 was 8,607; 1940, 9,985; the municipal district 1930, 27,787; 1940, 30,533. It is located on the main line of the belt line railroad and on the main highway which connects Ponce with Mayaguez. It is the southern terminus of a newly constructed highway connecting the town with Lares and other northern towns. The largest centre for the manufacture of cane-sugar is in this part of the island at the port of Guánica. This port was the first landing place of the American troops under command of Gen. Miles on July 25, 1898.

YAWS, the name in use in the British West Indies for a contagious inoculable tropical disease, running a chronic course and characterized by a peculiar eruption, together with more or less constitutional disturbance. It is known by various local names in different parts. The name *framboesia* was first given to the disease by Sauvages in 1759 from the likeness of the typical excrescences to a raspberry. Yaws was long thought to be peculiar to the African negro, but a disease the same in every respect has long been known in the East Indies, affecting the Malays rather than the negroes, its chief seats being Amboyna, Ternate, Timor, Celebes, Java and Sumatra. It has been identified by De Rochas and other observers in New Caledonia and Fiji.

The general course of the disease is as follows. In children (who form a large part of the subjects of yaws) there will probably be early rheumatic pains in the limbs and joints, in adults the eruption is often the first sign. The eruption begins as small pimples that have a whitish speck on their tops, grow rapidly and reach some half-inch in diameter. The pustules then break and a thick viscid ichor exudes and dries upon them as a whitish slough and around their base as a yellowish-brown crust. Beneath the slough is the raspberry excrescence or yaw proper, a reddish fungous growth with a nodular surface. The favourite seats of the eruption are the forehead, face, neck, arm-pits, groin, genitals, perinaeum and buttocks. Hairs at the seat of a yaw turn white. In young children or infants the corners of the mouth ulcerate, as in syphilis, and the perineal excrescences resemble condylomata.

Aetiology.—Yaws is a highly contagious disease. It is neither hereditary nor congenital. The disease spreads by contact with previously infected cases, and it has been proved by experiment that infection may be conveyed by flies, carrying infective material from a yaws sore to an ordinary ulcer. The virus must be introduced directly through a breach of the skin or mucous membrane; an attack in childhood gives a large degree of immunity for the rest of life. In 1905 Aldo Castellani demonstrated in yaws the presence of a slender spirillum, which he named the *Spirochaeta pertenuis* or *Spirochaeta pallidula.* It was also experimentally proved by him (1) that the material taken from persons suffering from yaws and containing the *Spirochaeta pertenuis* is infective to monkeys; (2) that when the *Spirochaeta pertenuis* is removed by filtration the material becomes inert; (3) that the injection of blood from the general circulation of a yaws patient gave positive results in monkeys; (4) by means of the Bordet-Gengou reaction it is possible to detect specific yaws antibodies and antigen.

The prophylaxis consists in the segregation of the patients suffering from the disease, the antiseptic dressing of the eruption, the application of a covering to protect it from flies, and the thorough cleansing and disinfection of infected houses and clothing, even the demolition of houses in endemic centres, and finally compulsory notification to the local sanitary authority.

As regards treatment, the malady in a person of good constitution runs its course and disappears in a few weeks. When the eruption is declared, iodide of potassium and arsenic are very beneficial. As external applications, weak lotions of zinc or carbolic acid may be used, and, if the excrescences are irritable, a watery solution of opium. In 7,157 West Indian cases treated in various hospitals there were only 185 deaths, a mortality of 25·8 per thousand (Nicholls).

YAZDEGERD ("made by God," *Izdegerdes*), the name of three Sassanid kings of Persia. (1) YAZDEGERD I., son of Shapur III., 399–420, called "the sinner" by the Persians, was a highly intelligent ruler, who tried to emancipate himself from the dominion of the magnates and the Magian priests. He punished the nobles severely when they attempted oppression; he stopped the persecution of the Christians and granted them their own organization. With the Roman Empire he lived in peace and friendship, and is therefore as much praised by the Byzantine authors (Procop. *Pers.* i. 2; Agath. iv. 26) as he is blamed by the Persians. After a reign of twenty years he appears to have been murdered in Khurasan. (2) YAZDEGERD II., was the son of Bahram V. Gor, 438–457. He persecuted the Christians and Jews, and had a short war with Rome in 441. He tried to extend his kingdom in the East and fought against the Kushans and Kidarites (or Huns). (3) YAZDEGERD III., a grandson of Chosroes II., who had been murdered by his son Kavadh II. in 628, was raised to the throne in 632 after a series of internal conflicts. He was a mere child and never really ruled; in his first year the Arabic invasion began, and in 637 the battle of Kadisiya decided the fate of the empire. Ctesiphon was occupied by the Arabs, and the king fled into Media. Yazdegerd fled from one district to another, till at last he was murdered at Merv in 651.

The Parsees, who use the old Persian calendar, continue to count the years from his accession (era of Yazdegerd, beginning June 16th, A.D. 632). (ED. M.)

YAZOO CITY, a city of western Mississippi, U.S.A., about midway between Memphis and New Orleans, on the (navigable) Yazoo river; the county seat of Yazoo county. It is on federal highway 49, and is served by the Illinois Central railroad. Pop. 5,244 in 1920 (52% Negroes); 7,258 in 1940 by the federal census. At the eastern entrance to the rich "Delta" between the Yazoo and the Mississippi rivers, it is an important market and shipping point. The city was founded about 1830.

YEAR-BOOK, a term applied to annual summaries either of events throughout the world during the previous year or of general or local progress in some one department of administration, art, science or industry. Examples are *The Britannica Book of the Year, The Statesman's Year-Book, Annual Register, Whitaker's Almanack, The World Almanac,* biographical records like *Who's Who,* genealogical records such as those of Debrett and Burke, and the Continental *Almanach de Gotha,* a scientific and scholastic publication of the type of the *Index Generalis,* and the innumerable specialized economic and industrial publications.

The English legal *Year Books,* described by Pollock as "our glory, for no other country has anything like them," are reports of cases covering the period 1292 to 1534, written in provincial French. Abridgments of these *Year Books* were made by Sir Anthony Fitzherbert in 1516 and by Sir Robert Brooke in 1568. The first systematic printer of them was Richard Pynson, from 1510; the principal publisher, from 1553, was Richard Tottell. In 1863 A. J. Horwood was commissioned by the then master of the Rolls to edit the unpublished *Year Books* of Edward I. This Rolls series was continued by L. O. Pike. The work has been supplemented by Maitland and others working for the Selden Society. The most convenient brief discussions of the *Year Books* are in *Holdsworth's History of English Law* (1903–09), vol. ii., pp. 444–462, and W. C. Bolland's *The Year Books* (1921). They are now thought to have had an official or even semi-official character.

YEAST. The botanist and microbiologist apply the term yeast to a group of plants many of which exhibit a marked ability to change sugar into alcohol and carbon dioxide. The characteristics of the group, which includes hundreds of species, are quite restricted. These, together with discussion of taxonomy,

are given under FUNGI and FERMENTATION. To the layman, untrained in botany, the term yeast suggests the cakes of pressed yeast available in almost every hamlet. The ability of certain yeasts to form carbon dioxide from sugar has caused some of them to be used for leavening bread. For centuries, other species have been used in the making of wine, alcohol, beer, etc.

Yeasts probably have as early origin as the bacteria. Grüss examined some fossil remains of Devonian plants and obtained striking evidence of the existence of budding fungi in this early age. This same investigator on examination of the sediment from a beer jar in Theban tomb of the XIth dynasty (2000 B.C.) isolated a yeast which was named *Saccharomyces Winlocki.* Examination of "beer bread" found among the offerings in other tombs also yielded the same yeast. It is now known that yeasts are widely distributed in nature and that those species concerned in fermentation pass the winter in the soil. They are disseminated by bees, dust and other agents in the spring.

The use of yeast in such fermentations as that of bread has made it convenient to have a constant supply of fresh active yeast. While in former days the by-product of certain fermentation industries was used, pressed (or compressed) yeast is now available to those who desire it. To this end the organism is grown in suitable media and the crop harvested when a sufficient crop of cells has appeared. The medium, according to an older method, consists of wort prepared from grains mashed in water. The mash prepared from grains is inoculated with lactic acid bacteria to "sour" it; the acid prevents putrefaction and also serves as food for the yeasts. The clear wort is passed into fermenters where it receives the seed yeast. The temperature is kept constant and rapid growth takes place. The yeast cells are then separated from the fluid in which they have grown by filter presses. They are mixed with starch and pressed into large cakes. These are sent to distributing centres, where they are cut and wrapped in the small size package commonly used in the home. In more recent times, yeast has been cultivated in mineral salt-sugar solutions instead of the wort described above. The cells are also incorporated in corn meal which is pressed into cakes.

Besides the application of yeasts in fermentology, they have been widely heralded as therapeutic agents. Their application to the cure of disease goes back to very early times. Many of the statements on the use of yeasts in this manner rest upon uncontrolled experiments, if indeed they may be called experiments. We are told that the monks used yeast for curing plague and that Hippocrates advised its use in leucorrhea. Since 1917 great interest was aroused by a publication of Hawk, et al. who reported beneficial results in furunculosis, acne vulgaris, constipation and certain other gastro-intestinal and cutaneous diseases.

YEATS, WILLIAM BUTLER (1865–1939), Irish author was born at Sandymount near Dublin on the 13th of June 1865. His father J. B. Yeats was a distinguished Irish artist and member of the Royal Hibernian Academy, his mother's family was from County Sligo. Soon after his birth his parents moved to London but his early years were largely spent in Sligo and even when, at the age of nine or ten, he went to school in London he returned to Sligo for his holidays and his early work is full of allusions to its mountains and little lakes, indeed this beautiful county has coloured all his writing. He studied painting for a short time but at the age of twenty-four published his first book of poems *The Wanderings of Oisin* (1889) and from that time forward gave his whole attention to literature. He was now living in London and a member of the group of young writers whose work appeared in *The Yellow Book.* A friend of William Morris and W. E. Henley and a frequent contributor to *The National Observer,* he was one of the founders of the Rhymer's Club and a close friend to Arthur Symons and Lionel Johnson. Years later he published two books, *Reveries over Childhood and Youth* (1915) and *The Trembling of the Veil* (1922)—now brought together in the volume called *Autobiographies*—and in these will be found the history, fascinatingly told, of the first thirty years of his life. In 1892 his first poetic play *The Countess Cathleen* was published; it was followed two years later by another play *The Land of Heart's Desire* and in the previous year appeared his first volume of essays *The Celtic Twilight.* With Edwin J. Ellis he edited the *Works of William Blake* (1893) and also edited *A Book of Irish Verse* (1895). Three books of prose appeared in 1897: *The Secret Rose, The Tables of the Law* and *The Adoration of the Magi;* the last two were published privately but subsequently appeared publicly. By 1897 he had become interested in the formation of an Irish theatre and with the help of Lady Gregory, Edward Martyn and other friends the first performance of the Irish Literary Theatre took place in Dublin in 1899. This Theatre gradually developed, attracting to itself writers such as Mr. George Moore and "A.E." and creating new writers such as J. M. Synge and Mr. Padraic Colum and by 1904 had established itself in the Abbey Theatre of which theatre Yeats was a Director until his death and contributed to its repertory many noble plays in verse and prose. Side by side with playwriting went the writing of lyrics and the rewriting of much of his early work—for he had always been his own harshest critic. After 1897 his most noteworthy volumes of poems are *The Wind among the Reeds* (1899), *Responsibilities* (1914), *The Wild Swans at Coole* (1917), *Later Poems* (1922) and *The Tower* (1927). His literary and critical essays are of importance, they are to be found in the volumes *Ideas of Good and Evil* (1903), *The Cutting of an Agate* (1912), *Per Amica Silentia Lunae* (1918) and a number of witty and profound essays on the art of the theatre now collected into the volume *Plays and Controversies* (1923). The private publication of a philosophic book *A Vision* (1925) must be noted. Owing to his habit of rewriting, versions of his work are many and various and the *Collected Edition* in eight volumes published in 1908 has long ago been superseded. The volumes at present published by Macmillan & Co. are practically a collected edition of the work which he wished to preserve, but in the opinion of many he had discarded or grievously altered many beautiful early poems. His first three plays in prose *Kathleen ni Houlihan* (1902), *The Pot of Broth* (1902) and *The Hour Glass* (1903) are entirely successful stage plays. It is difficult to speak with certainty of the stage success of his verse plays because, owing to the absence of a verse-theatre in England, the number of performances of them has not been large. He hoped in starting the Irish Literary Theatre to found amongst other things a verse-theatre in Ireland and during its early years a number of his verse plays were performed there but later the dramatic genius of Ireland emphatically declared itself to be realistic and not poetic and his dream of a verse-theatre had to be abandoned. But certainly *The Countess Cathleen* has proved itself a very successful stage play, the story is swift and dramatic, the incidents are full of variety, the verse is limpidly clear. The one-act play *The Land of Heart's Desire* (1894) is very popular and frequent performances of it are given by non-professional theatrical companies in England and America. His later plays demand great tragic acting, a demand met by Mrs. Patrick Campbell in her performance in *Deirdre* (1907) when the play showed itself to be of perfect construction and of intense passionate beauty. Given a great tragic actor *The King's Threshold* (1904) is as fine a stage-play as *Deirdre.* Other plays belonging to this period are *The Shadowy Waters* (1900), *On Baile's Strand* (1904) and *The Green Helmet* (1910). By this time he had despaired of finding a verse-theatre and his next play *The Player Queen* was in prose. It is a delightful phantasy and successful on the stage. Later still, influenced by the Japanese, he was to write four curious *Plays for Dancers* (1921) and, in the same mood, *The Cat and the Moon* (1924). Three of these plays have been performed and with success. He found in this unrealistic form freedom from stage conventions and an opportunity for phantasy.

In all probability these plays for dancers will never have popular appeal but to some they will seem the most beautiful work he has done for the stage. Considered as a poet his poetry falls into three periods, the early, the middle and the late. His early poetry was elaborate and richly wrought, influenced in some de-

gree by the Pre-Raphaelites, yet side by side with these possibly over-decorated poems can be found beautiful lyrics as simple as an Irish country ballad. By 1910 he had wearied of elaboration, he had been too much imitated, and he turned and attacked his own "embroideries." He had found, too, a new inspiration, a national one, and *Poems written in Discouragement* (1913) are the result of that inspiration. A year later with the publication of *Responsibilities* the new note in his verse is firmly struck, the last shred of embroidery for embroidery's sake has been discarded and the beauty of these poems is "like a tightened bow." He is struggling with a new, austere method, he has not entirely mastered it but he triumphantly emerges from the contest in his next volume *The Wild Swans at Coole* (1917). This book and each succeeding book mark his third period, the latest volume being *The Tower* (1927). Some poems in these volumes are obscure but only because they are part of his own difficult philosophy; if that be understood the poems are clear. The sweep and range of his art from *The Wanderings of Oisin* to *The Tower* are amazing and it is difficult to think of any other poet writing in English who is so varied and so developed. In 1928 appeared translations of Sophocles' *Oedipus the King* and *Oedipus at Colonus*. They are translations made specially for the Abbey Theatre; they are in prose and aim at simple, effective speech rather than meticulous verbal accuracy, the choruses are in rhymed verse. In 1929 he published a book of verse, *The Winding Stair;* his *Collected Poems* were published in 1933, and *Collected Plays* in 1934. As one of the founders of the Irish Literary Society Yeats had early shown his practical concern with the intellectual life of his country; and it was natural for the Government of the Irish Free State to nominate him in 1922 as one of its first Senators. He was awarded the Nobel Prize for literature for 1923. (L. Ro.)

YELLOWBIRD, a name applied in the United States to the American goldfinch (*Astragalinus tristis*) and to the yellow warbler (*Dendroica aestiva*). (*See* GOLDFINCH, WARBLER.)

YELLOW FEVER, a specific infective tropical fever, the virus of which is transmitted by a mosquito. The disease occurs endemically in certain limited areas. The area of distribution includes the West Indies, Mexico, part of Central America, the W. coast of Africa and Brazil.

The incubation period of yellow fever is generally four or five days, but may be as short as twenty-four hours. The illness usually starts like any other febrile attack. But there soon occurs a peculiar look of the eyes and face, which is characteristic: the face is flushed, and the eyes suffused at first and then congested or ferrety, the nostrils and lips red, and the tongue scarlet—these being the most obvious signs of universal congestion of the skin, mucous membranes and organs. There is high fever and albumen will nearly always be found in the urine. After two or three days the temperature falls below the normal; the pulse becomes slow and feeble, the skin cold and of a lemon-yellow tint, the act of vomiting effortless, the first vomit being clear fluid, but afterwards black from admixture of blood. This prostration may end in recovery, with copious flow of urine, which even then is very dark-coloured from the presence of blood or may increase and end in death. Much blood in the vomit and in the stools, together with all other haemorrhagic signs, is of evil omen.

The case mortality averages from 12 to 80%. In Rio in 1898 it reached the appalling height of 94·5%. In cities where it is endemic the case mortality is usually lower.

Modern Researches.—The dreaded "vomito negro" which for four centuries claimed more than 50% mortality among its victims, has been relegated to a place of secondary importance since the institution, in 1901, of the anti-mosquito campaign. Since 1910 no epidemic invasion of yellow fever into temperate regions has occurred, and some of the most noted endemic centres in Ecuador, Mexico and Brazil have been freed of the disease, probably forever; no case has been reported in the entire Western Hemisphere for many months. The use of oil for destroying mosquito larvae has now been practically abandoned in favour of placing in the tanks which serve as water supply for houses in the tropics one or two small fish, which eagerly devour the "wrigglers."

Connor, in Guayaquil, first used this method successfully in 1919, and it has since been used in other countries with excellent results. The fish must be of small size and able to withstand handling and transportation. Those chiefly used are the minnows, *Gambusia affinis, Dormitator latifrons* and *Fundulus heteroclitus* and the common "lefa" of South America (*Pygidium piurae C.*) some being top-feeding and others bottom-feeding fish.

Bacteriological Investigations.—While the transmitter of the yellow fever germ had been experimentally proved, by the American Army Board under Reed, to be the mosquito, *Aedes aegypti* (formerly known as *Stegomyia fasciata* or *S. calopus*), the microbe which produced the disease had remained unknown until 1918 when a minute spiral organism, subsequently named *Leptospira icteroides,* was isolated from the blood and organs of yellow fever patients, in Guayaquil, Ecuador. Inoculation of cultures of this organism reproduced all the characteristic symptoms and lesions of yellow fever in guinea pigs, marmosets and young puppies. Yellow fever was also transmitted directly to guinea pigs with blood taken from yellow fever patients and the same micro-organism from experimentally infected animals.

Investigations previously conducted by the American Army Board in Havana had demonstrated that the germ of yellow fever could pass through the pores of certain bacteria-proof filters (*see* FILTER-PASSING VIRUSES), and this fact alone had been sufficient to disprove the relation to yellow fever of a dozen or more different bacteria. *Leptospira icteroides,* on the other hand, proved to be a filter-passer and to conform with other well-known characteristics of the yellow fever virus; thermal death-point; transmissibility by *Aedes aegypti;* ability to produce typical fever, extensive haemorrhages into the gastro-intestinal tract, resulting in the "black vomitus" and melaena, severe nephritis, general jaundice and the characteristic changes of liver and kidney (fatty degeneration and necrosis). Another important proof that connects *Leptospira icteroides* with yellow fever is that this micro-organism is killed by the blood serum of persons who have just recovered from yellow fever but not by that of healthy persons or persons recovering from other diseases.

Leptospira icteroides was subsequently isolated from cases of yellow fever in Mexico, Peru and Brazil. It is actively motile, measures 4–9 μ long and 0·2 μ wide and there are two spirals for each micron. The ordinary microscope does not reveal its presence in the living condition, but it is easily seen by means of dark-ground illumination. It grows only on special culture media. The isolation of *Leptospira icteroides* has made it possible to prepare a preventive vaccine, similar in type to that in use for protection against typhoid fever, and a curative serum. While a given locality may be freed from yellow fever by destruction of mosquito larvae, this type of preventive work requires some months. Newcomers meantime are in danger, and protection, even of a temporary nature, is welcome. Injection of a small quantity of killed cultures of *Leptospira icteroides,* as first shown in experimental animals, confers temporary protection from the yellow fever infection, the inoculation taking effect within about two weeks. The results of prophylactic inoculation of 20,000 or more individuals since 1919 indicate that if persons are satisfactorily vaccinated they are protected against yellow fever for about six months. The curative serum has been tried in several hundred cases. When it has been used early in the disease, *i.e.,* before the fourth day of illness, the death-rate has been comparatively small (16% as compared with the usual 50% or more in yellow fever). It is without appreciable benefit when given later in the illness, when the micro-organisms have done irreparable injury to the liver and kidneys.

Since 1925 doubt has been thrown on the causal relationship of *Leptospira icteroides* to yellow fever by discovery of the fact that the common rhesus monkey (*Macacus rhesus*) and to a lesser degree the Indian crowned monkey (*M. Sinicus*) are very susceptible to the disease which may be transmitted to them by the bites of infected mosquitoes or inoculation with blood of a yellow fever patient. Material from such infected animals or from yellow fever cases is without effect upon guinea pigs which are extremely susceptible to *L. icteroides.* Since *L. icteroides* is serologically identi-

cal with *L. icterohaemorrhagia* it is thought probable that the organism described by Noguchi as the cause of yellow fever had been obtained from cases of Weil's disease or possibly from patients with a double infection. Working with a strain of yellow fever isolated in Senegal and rhesus monkeys A. W. Sellards and E. Hindle advanced matters further in favour of a filterable virus theory by showing that like some other filterable viruses yellow fever infective material is unaffected by cold and if frozen will maintain its virulence for at least twelve days.

YELLOW RIVER: *see* HWANG-HO.

YELLOWROOT, a small North American shrub (*Xanthorhiza simplicissima* or *Zanthorhiza apiifolia*) of the crowfoot family (Ranunculaceae, *q.v.*) found in woods from western New York to Kentucky and Florida. It has smooth stems, 1 to 2 ft. high, with yellow wood, long yellow roots, parsley-like leaves, and small purplish flowers in slender drooping clusters. It is sparingly planted for ornament. Yellowroot is also applied to the golden-seal (*Hydrastis canadensis*) and goldthread (*Coptis trifolia*).

YELLOWSTONE NATIONAL PARK, a national American public park, the first and most noted of a number of such national reserves set apart by the U.S. Government to preserve, for the benefit and enjoyment of the people, certain regions of extraordinary or unique natural grandeur and impressiveness. Yellowstone National Park includes about 3,350 sq.m.—62 m. long and 54 m. wide—lying largely in the north-west corner of Wyoming but extending a little over 2 m. northward into Montana. National forests surround the park on all sides—the Gallatin, Absaroka and Beartooth to the northward; the Shoshone to the eastward; the Teton and Targhee to the southward; and the Targhee, Madison, and Gallatin to the westward.

A broad volcanic plateau with an average elevation of 8,000 ft. occupies the centre of the park. The park is enclosed on its northern and north-western border by the Gallatin range, a bold picturesque sierra of which Electric peak, elevation 11,000 ft., constitutes the culminating crest. The Teton range, one of the most spectacular features of the northern Rockies, looms high upon the southern horizon, but only its bold spurs and foot-hills enter the park. East of the Tetons stretch the wild Gros Ventre and Wind river ranges well up toward the southern boundary of the park. The majestic Absaroka range, connected at the south with the Wind river range, forms an unbroken barrier along the whole eastern side of the park, its western side and many of its rugged peaks and canyon-grooved mountain masses lying within the park. A confused mass of mountains near the north-eastern part of the park connects the Absaroka with the Snowy range.

The general high elevation of the park is reflected in the climate, the mean annual temperature being considerably lower than that of the surrounding lower areas, and the amount of precipitation, both rainfall and snowfall, higher. At the Yellowstone Park weather station, elevation 6,200 ft., the mean temperature for the year is 38·7° F, ranging from 18·0° F in January to 61·3° F in July. The average annual snowfall at the Yellowstone Park station has been 100·5 in., varying from traces in July and August to 20·6 in. in January. The mean relative humidity varies from 53% at noon to 75% at 6 A.M. The annual percentage of sunshine is 56.

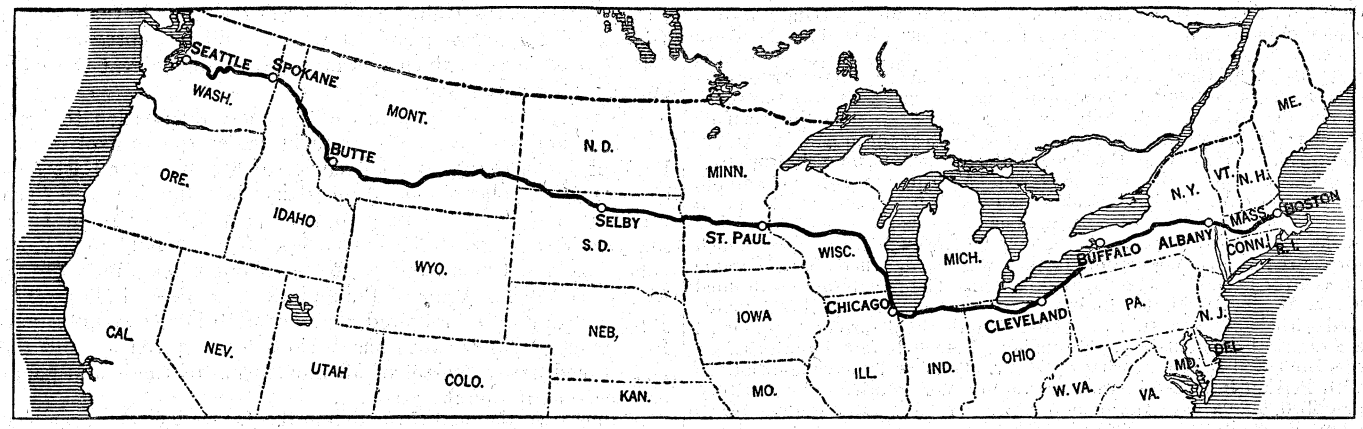
Such climatic conditions favour forest development and the growth of luxuriant grasses together with a varied alpine verdure. The whole of the park lies within the limits of the lodge-pole pine forest characteristic of the high Rockies though the higher slopes of the Absarokas and other high ranges are clothed with belts of spruce-fir forests and the crests of the mountains themselves are above timber line. The lodge-pole pine is a pioneer tree which invades terrain left open by other species, chiefly as the result of forest fires. Sunny, rocky slopes are in places occupied by the Douglas fir. Aspen and Engelmann spruce and a few limber pines are intermingled with the lodge-pole pines. Beautiful intermontane meadows where numerous grasses and sedges carpet the ground, and saxifrages, valerians, cinquefoils, senecios, orchises, betonies, gentians, grass of Parnassus and many other brilliant flowers blossom during the summer are interspersed with the rocky forest-clad ridges, while the banks of many pools, lakes and streams abound in water-lilies, buttercups, cresses, reeds and rushes. A few salt-loving plants grow about the hot springs and geysers, while in the hot waters issuing from them an interesting series of low plant forms is found.

The native fauna of the park area has been jealously guarded and preserved. Many elk and deer, a few antelope, bison, moose and mountain sheep; bears, foxes, coyotes, even wolves, lynxes and panthers; many species of squirrels, ground squirrels, mice, shrews, gophers, rabbits; the beaver, muskrat, otter, marten, skunk, weasel, badger, wolverene, marmot, mink; and several others less common wander in larger or fewer numbers into or about the park, though most of them may be encountered only in the remoter, less frequently visited, sections of the park. Proportionally as richly numerous and varied as the mammal life, the bird forms include over 200 species, some permanently resident, many only migrant. The streams are well stocked with fish, particularly trout, of which the native redthroat (*Salmo clarkii*) is one of the gamest and most eagerly sought.

Perhaps the most amazing spectacle of the park is its display of over 100 geysers and 4,000 hot springs. The geysers are concentrated in three adjoining groups upon the middle-west side, but hot springs occur everywhere at widely separated points, one steam jet even issuing from the Grand Canyon depths, more than 1,000 ft. below the rim. The most famous geyser is Old Faithful, which may be taken as typical. The regularity of its eruptions, the violence of its explosions, and the grace and beauty of its water column make it one of the most admired of the park geysers. The interval between eruptions averages 65 minutes, the period of eruption lasts 4½ minutes, and it throws into the air a column of water from 95 to 130 ft. in height. The Excelsior geyser, which ceased erupting in 1888, hurled aloft a greater volume of water with appalling fury of action. The Giantess geyser, when in action, is far more powerful than Old Faithful, but plays with less regularity, with intervals of nearly three weeks' duration. Another titanic geyser unexpectedly broke forth in 1928 with furious activity. It hurls water in all directions, some columns to a height of 100 feet. Two major eruptions every 24 hours form its schedule, each eruption lasting for three hours or more, with outbursts at 15 to 20 second intervals.

The Grand Canyon of the Yellowstone is also one of the truly wonderful features of the park. It is a magnificent and picturesque gorge penetrating deep into the volcanic rocks of the park plateau. It presents on a grand scale a remarkable picture of recent canyon cutting by the Yellowstone river, which, leaving Yellowstone lake at its broad outlet, flows northward through an open valley for about 15 m. and then plunges by two impressive falls, respectively 110 and 312 ft. in height, into the Grand Canyon. The walls of the canyon rise abruptly 800 to 1,100 ft. above the rushing turbulent stream which cuts the gorge. Much of the exquisite beauty and impressive grandeur of the region comes from the brilliantly-coloured canyon walls, with their bizarre bands and stripes of soft pink and salmon to blazing Indian red, deep orange in masses, and yellow and green blotches all gayly intermingled. Yellowstone lake is large—20 m. north to south, and 15 m. east to west—irregular in outline, and wooded to the water's edge.

The first recorded visit to Yellowstone Park was made by John Colter in 1810 when he took refuge there from hostile Indians. His story was wholly discredited, as was the story of the next visitor, Joseph Meek, a trapper who visited the region in 1829. The first description of the Firehole geyser basin was written by Warren Angus Ferres, a clerk in the American Fur Company, between 1830 and 1840, but not until 1852 was the region defined and described in its entirety by Father De Smet, the famous Jesuit missionary, who derived his information from the noted Indian scout and frontiersman, Jim Bridger. The first Government



THE YELLOWSTONE TRAIL

expedition sent out in 1859 under the command of Capt. W. F. Reynolds, brought back little authentic information regarding the section, and the reports of private explorers were discredited. Finally the well-equipped expedition under Henry D. Washburn and N. P. Langford, in 1870, established the facts and led to the creation of the Yellowstone National Park.

YELLOWSTONE TRAIL, an American highway leading from Plymouth Rock, on the Atlantic, to Seattle, on Puget sound. It is 3,400 mi. long. The roadway is paved or hard from Plymouth to Oshkosh, and improved over most of the rest, with some hard surfacing and pavement to the Pacific. This highway is one of the finest across the United States. It touches Albany and Buffalo, N.Y., Cleveland, O., Chicago, Ill., St. Paul, Minn., Selby, S.D., Butte, Mont., and Spokane, Wash.

YELLOW-THROAT, the name given to a species, with several sub-species, of North American birds of the Passerine family Mniotiltidae, the American wood warblers. The best known is the Maryland yellow-throat (*Geothlypis trichas*) which ranges over the greater part of the United States and southern Canada. About 5 in. long, this bird is olive green above, yellow below, with black forehead and cheeks in the male. Its sub-species the tule yellow-throat (*G. t. scirpicola*) is resident in southern California. The western yellow-throat (*G. t. occidentalis*) is found in southeastern California and southwestern Arizona.

YELLOWWOOD, AMERICAN (*Cladrastis lutea*), a handsome North American tree of the family Leguminosae, called also yellow locust, gopherwood and virgilia. Though somewhat rare in the wild state, being found only locally in rich soils, chiefly along mountain streams, from North Carolina to Missouri, it is widely cultivated for ornament. It has a short trunk branching into a graceful crown, sometimes rising 50 ft. high, with smooth bark, pinnate leaves, and fragrant, pea-like, white flowers, 1 in. long, borne in loose, drooping clusters, 10 in. to 20 in. long, blossoming in June. The hard strong wood yields a yellow dye.

YEMEN (*Yaman*), an extensive region forming the southwestern portion of Arabia. In 1934 Yemen lost its northern province 'Asir to Saudi Arabia; the boundary line lies north of the seaport Maidi and south of Samta. On the east its limits merge with the desert, while on the south they abut on Hadhramaut. Yemen may be looked upon as possessing two centres: the British protectorate of Aden (*q.v.*) in the south and the domains of the Imam Yahya, whose capital is Sana (*q.v.*).

The Imam Yahya is ruler of Yemen proper, and his lands include those abandoned by the Turkish power in 1918 and consequently the limits of his power are in line with those of the Anglo-Turkish boundary of 1902–04. He governs an area of some 75,000 sq.mi., with a population of some 1,600,000.

Ptolemy and the ancient geographers in general include the whole peninsula under the name of Arabia Felix (εὐδαίμων), in which sense they translate the Arabic *Yaman,* literally "right hand," for all Arabia south of the gulf of 'Aqaba was to the right from their standpoint of Alexandria; the Moslem geographers, however, viewing it from Mecca, confine the term to the regions south of Hejaz, including 'Asir, Hadhramaut, Oman and part of southern Nejd. Yemen occupies the uptilted edge of a block of ancient land forming Arabia.

The uptilted edge of the old block is known as the Jibal or highlands of Yemen, with an average height of 9,000 ft., the highest measured point being 12,336 ft.

The principal town of the Jibal is Ta'izz (pop. about 4,000). It was formerly a large city, and from its position in the centre of a comparatively fertile district at the junction of several trade routes it retained its importance. Some 30 mi. farther north are the small towns of Ibb (6,700 ft.) and Jibla, about 5 mi. apart, typical hill towns with their high stone-built houses and paved streets. Manākha produces the best coffee in Yemen. Another group of hill towns lies still farther north in the mountain mass between the Wadi Maur and Wadi Laja, where the strongholds of Dhāfir, 'Afār, Haja and Kaukabān have long been known for their independence. The last-named was once a city of 20,000 inhabitants, and the capital of a small principality which preserved its independence during the earlier Turkish occupation between 1536 and 1630. The lowland strip of Yemen is known as the Tihama and is hot and generally sterile. The lowland strip is from 20 to 30 mi. wide. There are oases, however, near the foot of the mountains, fertilized and irrigated by hill streams and supporting many large villages and towns. The most important of these are Zaidiya, Bait al Faqīh and Zabīd in the western Tihama, the latter a town of 20,000 inhabitants. Hudaida (*q.v.*) and Aden (*q.v.*) are the only ports of commercial importance, while Mokha is the old centre of the coffee trade. Beyond the crest of the uptilted edge of the old block stretches the third natural region of Yemen—the great desert. As it lies entirely to the east of the high crest, it has a smaller rainfall than the Jibal. Its general character is that of a steppe increasing in aridity towards the east where it merges in the desert, but broken in places by rocky ranges, some of which rise 2,000 ft. above the general level, and which in the Hamdan district north of Sana show evidence of volcanic action. It is intersected by several wadi systems, of which the principal are those in the north uniting to form the Wadi Najran, in the centre the Wadi Khārid and Shibwān running to the Jauf, and in the south the Wadi Bana and its affluents draining to the Gulf of Aden. The plateau has a gradual fall from the watershed near Yarim, 8,500 ft. above sea level, to less than 4,000 ft. at the edge of the desert.

The northern part nearly down to the latitude of Sana, is the territory of the Hāshid and Baqīl tribes, which never submitted to the Turks. Sa'da is an important town on the old pilgrim road 120 mi. N. of Sana, Khaiwan and Khamr. To the northeast, bor-

dering on the desert, lies the district of Najran, now in Saudi Arabia, a mountainous country with several fertile valleys including the Wadi Najran, Badr and Habuna, all probably draining northeast to the Rub' al-Khali. Farther south is the oasis of Jauf, a hollow or depression, as its name signifies, containing many villages. It was the focus of the old Minaean and Sabaean kingdoms, known to the ancients through their control of the frankincense trade of south Arabia. Ma'in, identified by Halévy as the seat of the former, is on a hilltop surrounded by walls still well preserved. Ma'rib, the Sabaean capital, had a great dam to whose breaking between A.D. 542 and 570 tradition ascribes the final decay of Yemen. The city was abandoned, probably owing to the deterioration of the country through desiccation, which forced the settled population farther westward, where Sana became the centre of the later Himyaritic kingdom. The Arhab district drained by the Wadi Khārid and Shibwān between Sana and the Jauf is covered with Himyaritic ruins, showing that the land formerly supported a large settled population. Throughout Yemen is found the *mijal*—a cemented well for the storing of water. These wells have associations with Persian influence in the 6th century A.D. South of the territory described above are 'Amran and Shibām on the road leading north from the capital Sana; Dhamar (the seat of an ancient university) and Yarim are on the road leading south to Aden; and two days' journey to the east is Rada.

The inhabitants of Yemen are settled, and for the most part occupied in agriculture and trade, the conditions which favour the pastoral or Bedouin type found in Hejaz and Nejd hardly existing. The people may be considered under four groups: (1) The Saiyids or Ashrāf, descendants of the prophet, forming a religious aristocracy; (2) the Qabail, or tribesmen, belonging to the Qahtanic or original south Arabian stock, who form the bulk of the population; (3) the trading class, and (4) a mixed group mostly of African descent and including a number of Jews.

In Sept. 1934, in the treaty between Britain with India, and the Yemen, the Zaidi Imam Yahya Ibn-Mohammed Ibn-Hamid-al-Din was acknowledged "king." On his defeat by Ibn Sa'ud in 'Asir, Yahya accepted on May 13, 1934, peace conditions and was left fully independent in Yemen.

YEN. The yen, monetary unit of the Japanese empire, is divided into 100 sen and 1,000 rin. Under the Gold Standard law of 1897 the yen has a theoretical gold content of 750 milligrams of fine gold, but Japan's gold reserves are valued under the Gold Reserve Revaluation law of 1937 on the basis of a gold content of 290 milligrams per yen. The obligation of the Bank of Japan to convert its notes into gold was suspended by the Gold embargo of Dec. 13, 1931, and repealed by the Law of the Bank of Japan of 1942.

The currency in circulation in the Japanese empire at the middle of 1945 consisted of banknotes in denominations of 1 yen or higher, and of state coins and bills in denominations of 50 sen or lower, as follows: (1) Bank of Japan notes, issued in accordance with articles 29 to 32 of the Law of the Bank of Japan of 1942, which had superseded the Convertible Bank Note law of 1884 and the law of 1941 concerning Extraordinary Exceptions from the Convertible Bank Note law; (2) Bank of Chosen notes, issued in accordance with articles 21 to 25 of the Law of the Bank of Chosen of 1911 as amended; (3) Bank of Taiwan notes, issued in accordance with articles 8 and 9 of the Law of the Bank of Taiwan of 1897 as amended; (4) coins of copper, tin, aluminum, nickel or silver, issued by the government in accordance with the Coinage law of 1897 and the Emergency Currency law of 1938 as amended; and (5) bills, issued by the government in accordance with imperial ordinance no. 202 of 1917 and the Emergency Currency law of 1938. State coins and bills were legal tender throughout the empire up to fixed amounts only. The privilege of issuing bank notes with legal tender character throughout the empire was reserved exclusively to the Bank of Japan. The Bank of Chosen notes constituted legal tender only in Korea, and the Bank of Taiwan notes only in Formosa. In addition, from 1938 on the Japanese government issued special notes, denominated in "military yen," for use by the Japanese forces in China; after 1941 their use was extended to Hongkong and other territories under Japanese military administration, where they circulated as legal tender side by side with the local currency. Similarly, United States forces operating in the Ryukyu Islands in 1945 were provided with a military currency, also denominated in yen, which was intended to supplement the local currency, but not to replace it.

From 1936 on, the extension of Japanese domination to parts of China and southeast Asia brought under the control of the Bank of Japan the various currencies of the "Greater East Asia Co-prosperity Sphere," and resulted in the formation of a "yen monetary bloc." At the time of its largest expansion, in 1944, the yen bloc included the currencies of "Manchoukuo," Mongolia, northern China, central and southern China, Indo China, Malay, Thailand, Burma, Philippines and East Indies. The Japanese authorities followed a policy of bringing about a uniform value (1:1) between the various local currencies and the yen through strict control of all movements of funds and goods between countries of the yen bloc.

In June 1941, the total circulation in the Japanese empire amounted to 5,900 million yen, consisting of: Bank of Japan—4,197 million, Bank of Chosen—509 million, Bank of Taiwan—198 million, state bills—363 million, and coins—600 million (est.). Bank of Japan notes in circulation reportedly had risen to more than 20 billion yen by March 1945. Externally, the yen was pegged to the pound sterling at 1*s.* 2*d.* from 1931 to 1939 and to the dollar at $0.234 from 1939 to 1941; after the outbreak of World War II the finance ministry fixed the official exchange rate of the yen at 0.989 Swiss franc, the equivalent of the former sterling and dollar bases. United States forces operating in the Ryukyu Islands in 1945 used a provisional rate of 1 yen=$0.10 for accounting purposes. (F. M. T.)

YENISEI (from a Tungus word meaning Great River), a river of Asiatic Russia, rising in Mongolia and flowing into the Arctic Ocean, having a total length of 2,700 mi. and a basin extending over a million square miles. It marks a structural boundary of great antiquity in the history of the continent. The western plain, extending from the Urals and covered by quaternary alluvial deposits, with a few isolated remnants of friable Tertiary sandstones, forms, apart from the smaller rivers of the Arctic tundra, a catchment area for the Ob. Near the left bank of the Yenisei there is a slight rise in the plain which deflects a few short tributaries to the Yenisei, but most of its drainage area lies to the right, on the ancient plateau remnant of Angara land, the middle of which forms a watershed, with drainage either to the Arctic, or to the east and west. Thus the Yenisei and the Lena are marginal rivers of an ancient block. Contrasts between the land to the west and that to the east of the Yenisei, north of Krasnoyarsk, are sharp, orographically, geologically, in soil formation and in climate, the winter isotherms curving southward on the higher land. The effects are that the plateau population is scanty, and that the limit of possible cultivation, which from the Urals to long. 50° E. remains considerably north of lat. 60° N., on the plateau lies considerably farther south. North of the Arctic circle, the difference disappears, the whole region being tundra.

Towards the south the plain forms an amphitheatre west of Lake Baikal; within it lie the courses of the Angara, the Stony or Middle Tunguska, the upper courses of the Lower Tunguska and of the Lena. It is bounded by the Archaean masses on the Middle Yenisei, cut off by a fracture along the river between the confluences of the Angara and the Stony Tunguska, and by the pre-Cambrian fold mountains to the south. Bogdanovich supposes that a great inland lake existed in the amphitheatre during the Angara epoch of the Mesozoic. The Yenisei is thus a mountain river of composite character. In Chinese Mongolia it flows through a longitudinal valley at the northern foot of the Tannu-ola; it then cuts through the western Sayan mountains and passes through portions of successive transverse valleys to Krasnoyarsk and its confluence with the Angara. It then flows along the western base of the Archaean range and finally enters the most northwesterly part of the Palaeozoic plateau. The Yenisei is formed by the junction of the Bei-kem and Chua-Kem streams in the Uryankhansk district of Chinese Mongolia, and is known as the Ulukem or Upper Yenisei. It receives the Kemchik river on the left and the town of Kemchik at the junction is much visited by Russian traders, who also have quarters in Krasniy at the junction of the Bei-kem and Chua-kem (or Little Yenisei).

After crossing the frontier it receives the Us on the right bank and there is a Russian settlement at Usinskoe. Eighty-two miles

north of the frontier are formidable rapids, the limit of raft navigation. This part of its course is through coniferous mountain forest, with some meadow land along the banks. Gold, asbestos, salt, coal, magnesia and iron occur in the mountains, but are little worked; the inhabitants are mainly nomad Finno-Tatar hunters, though Russian colonization is slowly spreading. The river now enters a prairie region, with the Abakan draining it on the left and the Tuba on the right. Minusinsk (*q.v.*) lies 8 m. from the confluence of the Abakan and Yenisei; and the Minusinsk black earth region, sheltered by the West Sayan mountains, the Siberian Urals and the Abakan range, is noted for its fertility and its mild climate and has been settled from prehistoric times. Gold and coal are found. Iron is found on the Irba, a tributary of the Tuba. At Novo-Selovsk 55° 5′ N., 91° 16′ E., the Chulim, a tributary of the Ob is only 6 m. distant, but canalization is impracticable owing to difference of level. At Krasnoyarsk (*q.v.*) the railway crosses the river, which here flows through a plain with mountains to the south and west, whose red sandstone and marl have given Krasnoyarsk its name.

South of the Pit mountains (the northern limit of corn growing land), the Angara or Upper Tunguska enters the Yenisei, after flowing 1,100 m. from Lake Baikal. The Selenga and the Angara were probably once united and Lake Baikal is of later formation. A rich gold-bearing region extends from the Angara to the Stony Tunguska, and the Pit enters the Yenisei on the right in this district. The Stony Tunguska, 1,000 m. long, is almost uninhabited, and here the deciduous forest merges into the coniferous. From the Stony Tunguska to Turukhansk is dense coniferous forest, with a few settlements on the right bank mainly. The Bakhta, north of the Stony Tunguska, flows through a marshy, uninhabited country. Above the confluence of the Stony Tunguska, the Yenisei broadens and reefs of rock known as the "Seventy Islands" rise above its waters.

The Lower Tunguska, 2,000 m. long, rising in lat. 57° N., 20 m. from the Lena, winds through a marshy forest country, with no settlements except in its upper course, where the villages are linked with the easily reached Lena. Coal, graphite and asbestos exist, but are not worked. The Turukhan enters from the left and is used by the Samoyedes to link with the Taz. The town of Turukhan, 10 m. from the Yenisei on the delta of the Turukhan, is now derelict and Monastir Turukhan (Troitskoe Monastir) on the right bank has replaced it. The Kureika river enters from the left and is linked with Obdorsk by a western track. There is unworked graphite in the Kureika valley. In lat. 69°–70° N., the scattered larches and birches give way to treeless tundra. There is a Russian trading settlement at Dudinsk, at the confluence of the Dudina and 60 m. E. coal of good quality is found in the Novil mountains, and platinum is reported. A scattered population, descendants of Russian exiles and natives, extends from Dudinsk to the Khatanga river. The Yenisei delta and gulf are not fully explored. The west is low and marshy and the east steep. Fish abound and native fishermen migrate north in summer. Golchikha, a Samoyede village on an island in the delta in 71° 45′ N., 84° E., has steamer communication with Krasnoyarsk and Minusinsk, fish and fur going upstream and corn, meat and manufactured goods downstream. Yenisei navigation is less important than that of the Ob, owing to the scantier population and more difficult environment. In winter the frozen river serves as a good road. At the delta the river is usually frozen from Oct. 30 to June 23; at Turukhansk, from Nov. 11 to June 8, at Krasnoyarsk from Dec. 5 to May 12; and at Minusinsk from Nov. 29 to May 11. There are floods in mid-May and mid-June, and huge blocks of ice collect in and near the mouth after the thaws.

Exploration and Settlement.—The Yenisei was first reached by Cossack bands in 1618 to 1620, who came from the Ob via the portage between the Ket tributary of that river and the Kaz tributary of the Yenisei which is now linked by canal. They met with much opposition from the Tungus and Buriat tribes and it was not till 1648 that the Russians penetrated to Lake Baikal via the Angara river. The exploration of the delta was much delayed, for though English and Russian navigators visited the Kara Sea in the 16th century, the upper course of the river, 6 m. wide near the delta, and with a delta opening into a gulf 40 m. wide, presents great difficulties when the warmer waters from the south undermine the ice and huge ice floes swell up and burst away, forming ice hills sometimes 50 to 60 ft. high on the banks, while the pack ice blocks on the current travel northwards at 20 m. an hour, crashing against one another with deafening reverberations.

After 1853, a wealthy Siberian, Sidoroff, agitated for 20 years to establish links between Europe and the mouths of the Arctic rivers of Siberia and in 1874 an English vessel reached the mouth of the Ob, while Nordenskjöld, the famous Swedish explorer, in 1875 entered the mouth of the Yenisei. In 1876 an English vessel reached Kureika on the Yenisei and in the following year Sidoroff reached the delta from Yeniseisk, and sailed to Leningrad. In 1878, the *Fraser* and *Express,* two ships of Nordenskjöld's "Vega" expedition ascended the Yenisei. A company was formed to establish trade via this route, but was unsuccessful and was dissolved in 1900. The project is now being revived and in 1928 a Kara Sea expedition, consisting of three British and five Norwegian vessels, set out from Hamburg on Aug. 1, sailing via the North Sea, Barents sea, through the Novaya Zemlya islands and the Kara sea to the mouths of the Ob and Yenisei, taking 15,000 tons of agricultural machinery, metals, drugs and coal, to exchange for timber, flax, cow-wool, hides and horsehair, brought down the rivers on barges towed by steamers.

BIBLIOGRAPHY.—Nordenskjöld, *The Voyage of the Vega,* 1881; P. Kropotkin, *Orographie de la Sibérie* (1905); Suess, *The Face of the Earth,* vol. III. (1908), with references to Russian articles, esp. by Obruchev; E. Argand, *La Tectonique de l'Asie* (1922, publ. 1924).

YENISEISK, a town in the Krasnoyarsk territory of the Russian S.F.S.R., in 58° 39′ N., 92° 4′ E., on the right bank of the Yenisei river at an altitude of 285 ft. It is a centre for fur trading and gold mining; pop. (1926) 5,957, about 50% of that in 1913. There is not much wharf accommodation, though there is regular steamer connection to Krasnoyarsk. The river at Yeniseisk is a mile wide and navigation opens about May 19 and closes about Dec. 1. The town was founded in 1618.

YEOMAN, a term meaning, first, a class of holders of land and second, a retainer, guard, attendant or subordinate official. The word appears in M.E. as *3eman, 3oman* and *yeman;* it does not appear in O.E. It is generally accepted that the first part is the same word as the Ger. *Gau,* district, province, and probably occurs in O.E. as *géa* in *Súðri-géa,* Surrey; *i.e.,* southern district, and other place-names. "Yeoman" thus meant a country-man, a man of the district, and it is this sense which has survived in the special use of the word for a class of landholders.

The extent of the class covered by the word "yeoman" in England has never been very exactly defined. One of the earliest pictures of a yeoman is that given by Chaucer in the Prologue to the *Canterbury Tales.* Here, represented as a forester, he follows the esquire as a retainer or dependant. The yeomen of later ages, however, are practically all occupied in cultivating the land, although, doubtless from its younger sons, the class furnished retainers for the great lords, men-at-arms and archers for the wars, and tradesmen for the towns. Medley (*Eng. Const. Hist.*) describes the yeomen of the 15th century as representing on the whole "the small freeholders of the feudal manor." Holinshed, in his *Chronicle,* following Sir T. Smyth (*De republica Anglorum*), and W. Harrison (*Description of England*), describes them as having free land worth £6 annually, and in times past 40s., and as not entitled to bear arms. They formed the intermediate class between the gentry and the labourers and artisans.

YEOMANRY, the name given to the volunteer mounted troops of the home defence army of Great Britain, ever since their original formation; it indicated that recruiting, organization and command were upon a county basis, the county gentlemen officering the force, the farmers and yeomen serving in its ranks, and all alike providing their own horses. Although the yeomanry was created in 1761, it was not organized until 1794. Under the stimulus of the French War recruiting was easy, and 5,000 men were quickly enrolled. A little later, when more cavalry were needed, the Provisional Cavalry Act was passed, whereby a sort of revived knight-service was established, every owner of ten

horses having to find and equip a horseman, and all who owned fewer than ten, grouped by tens of horses, similarly finding one. A great stimulus to yeomanry recruiting was given by an amending act which was soon passed by which yeomanry cavalry could be substituted for provisional cavalry in the county quota. At the peace of Amiens, the yeomanry was retained, although the provisional cavalry was disbanded. There was thus a nucleus for expansion when Napoleon's threatened invasion (1803–5) called out the defensive powers of the country, and as early as December 1803 there were in England, Scotland and Ireland, 44,000 yeomen. At the same time the limitations as to place of service in Great Britain were abolished.

From the extinction of Chartism to the South African War the history of the yeomanry is uneventful. The strength of the force gradually sank to 10,000. But when it became apparent that mounted troops would play a decisive part in the war against the Boers, the yeomanry again came to the front. Of its 10,000 serving officers and men, 3,000 went to South Africa in newly formed battalions of "Imperial Yeomanry," armed and organized purely as mounted rifles, and to these were added over 32,000 fresh men, for whom the yeomanry organization provided the cadres and training. In 1901 the yeomanry was remodelled; the strength of regiments was equalized on a four squadron basis, fresh regiments were formed and the strength of the force was more than trebled. In 1907 the yeomanry became part of the new Territorial Force.

At the outbreak of the World War in 1914, 53 regiments of yeomanry mobilized. The first to see active service was the Oxfordshire Yeomanry who accompanied the Royal Naval Division in the Antwerp campaign, but it was not until the spring of 1915 that the employment of yeomanry was seen on any considerable scale. In France four regiments of yeomanry were brigaded with regular cavalry in the cavalry corps and proved in every way worthy of this distinction.

Only in the Palestine campaign was opportunity found for the successful employment of large cavalry formations. Fourteen regiments of yeomanry, nine of which had formed part of an improvised dismounted force in Gallipoli, served in the various divisions of the Desert Mounted Corps and contributed very materially to Allenby's success. The actions of Huj and El Mughar following the third battle of Gaza, both executed entirely by yeomanry, provided classic examples of the employment of the mounted attack in mobile warfare. In the spring of 1918 eight of these regiments were grouped into machine gun battalions and sent to France.

One complete infantry division, the 74th, was formed in Palestine in early 1917 entirely from 18 yeomanry regiments, 12 of which had previously seen service in Gallipoli; it was first engaged as a division at the second battle of Gaza, served with considerable distinction till after the capture of Jerusalem and in the spring of 1918 was sent to France and Flanders. The Scottish Horse and Lovat's Scouts Brigade served as infantry in Gallipoli, Macedonia and France and Flanders. The remaining yeomanry regiments were employed as divisional cavalry.

After 1918 much attention was given to the territorial force, and on its reconstruction in 1920 (*see* TERRITORIAL ARMY) the greater portion of the yeomanry was mechanized. Of the 53 regiments, 25 were converted into units of the Royal Artillery, and 8 into Armoured Car companies of the Royal Tank Corps; one became a regiment of Cavalry Divisional Signals, and another an infantry regiment; while the 1st and 2nd Lovat's Scouts and the Scottish Horse with 14 other regiments were retained for their original purposes. This was the position when the territorials were merged into the regular army in September 1939. (E.F.LA.;X.)

YEOMEN OF THE GUARD, originally "Yeomen of the Guard of (the body of) our Lord the King"—"Valecti garde (corporis) domini Regis"—the title maintained with but a slight variation since their institution in 1485, of a permanent military corps in attendance on the sovereign of England, as part of the royal household, whose duties, now purely ceremonial, were originally those of the sovereign's personal bodyguard. They are the oldest existing body of the kind. The first warrants to individual "Yeomen of the Guard" date from Sept. 16, 1485, immediately after the victory of Henry VII. at Bosworth (Aug. 22).

The first official recorded appearance of the king's bodyguard of the Yeomen of the Guard was at the coronation of its founder Henry VII. at Westminster Abbey on Oct. 31, 1485, when it numbered 50 members. That number was rapidly increased, for there is an authentic roll of 126 attending the king's funeral in 1509. Henry VIII. raised the strength of the Guard to 600 when he took it to visit Francis I. of France at the Field of the Cloth of Gold (*q.v.*). In Queen Elizabeth's reign it numbered 200. The corps was originally officered by a captain (a post long associated with that of vice-chamberlain), an ensign (or standard-bearer), a clerk of the cheque (or chequer roll, his duty being to keep the roll of every one connected with the household), besides petty officers, captains, sergeants or ushers. In 1669 Charles II. reorganized the Guard and gave it a fixed establishment of 100 yeomen, officered by a captain, a lieutenant, an ensign, a clerk of the cheque and four corporals, which is the present organization and strength. The captaincy is now a ministerial appointment filled by a nobleman of distinction under the lord chamberlain, and the old rank of "corporals" has been changed to "exon," a title derived from "exempt," *i.e.*, exempted from regular regimental duty for employment on the staff. Formerly officers on the active list were given these appointments in addition to their own.

The original duties of the Guard were of the most comprehensive nature. They were the king's personal attendants day and night at home and abroad. They were responsible for his safety not only on journeys and on the battlefield, but also within the precincts of the palace itself. In Tudor times the Yeomen of the Guard alone were entrusted with the elaborate formality of making the king's bed. Another of their duties still retained is the searching of the vaults of the houses of parliament at the opening of each session, dating from the "Gunpowder plot," in 1605, when the Yeomen of the Guard seized Guy Fawkes and his fellow-traitors and conveyed them to the Tower.

The dress worn by the Yeomen of the Guard is in its most striking characteristics the same as it was in Tudor times. It has consisted from the first of a royal red tunic with purple facings and stripes and gold lace ornaments. Sometimes the sleeves have been fuller and the skirts longer. Red knee-breeches and red stockings (white in Georgian period only), flat hat, and black shoes with red, white, and blue rosettes are worn. Queen Elizabeth added the ruff. The Stuarts replaced the ruff and round hats with fancy lace and plumed hats. Queen Anne discarded both the ruff and the lace. The Georges reintroduced the ruff, and it has ever since been part of the permanent dress. Up to 1830 the officers of the Guard wore the same Tudor dress as the non-commissioned officers and men, but under William IV. the officers were given the dress of a field officer of the Peninsular period. The weapons of the Guard are a steel gilt halberd with a tassel of red and gold and an ornamental sword.

The real fighting days of the Guard ended with the Tudor period, but it was only with the final appearance of an English King in battle (Dettingen 1743) that the Guard's function of attending a sovereign on the battlefield ceased. For a brief period during the Georgian era the Guard lost to a certain extent its distinctive military character and a custom crept in of filling vacancies with civilians, who bought their places for considerable sums, the appointments being of great value. William IV. put a stop to the practice, the last civilian retired in 1848, and the Guard regained its original military character. Every officer (except the captain), non-commissioned officer, and yeoman must have served in the Home or Indian army or Royal Marines. They are selected for distinguished conduct in the field, and their pay is looked upon as a pension.

The nickname "Beef-eaters," which is sometimes associated with the Yeomen of the Guard, had its origin in 1669, when Count Cosimo, grand duke of Tuscany, was in England, and, writing of the size and stature of this magnificent Guard, said, "They are great eaters of beef, of which a very large ration is given them daily at the court, and they might be called 'Beef-eaters.'"

In 1509, Henry VIII., envying the magnificence of the body-guard of Francis I. of France, decided to have a noble guard of his own, which he accordingly instituted and called "The Gentlemen Speers." It was composed of young nobles gorgeously attired. In 1539 the guard was reorganized and called "Gentlemen Pensioners." That title it retained till William IV.'s reign, when the corps regained its military character and received their present designation, "The Honourable Corps of Gentlemen-at-Arms."

See *The History of the King's Body Guard of the Yeomen of the Guard,* by Colonel Sir Reginald Hennell, D.S.O., Lieutenant of the Yeomen of the Guard (1904).

YEOTMAL, a town and district of India in Berar. It stands on an elevated plain at about 1,400 feet. The population in 1931 was 20,967. It was formerly the headquarters of the Wun district but in 1905 the new district of Yeotmal was established, the old Wun district being renamed with additions from the district of Basim. Cotton ginning and pressing are the main industries. The town is also the chief trading centre of the district, being connected by a road, 29 miles long, with Dhamangaon on the G.I.P. railway, while a narrow gauge line recently constructed connects it through Darhwa and Karinja with Murtizapur on the main G.I.P. line.

The DISTRICT OF YEOTMAL has an area of 5,238 square miles. Yeotmal is a large cotton producing district, but its upland is less fertile than the average of Berar. The greater part of the district is drained by the Penganga River, which joins the Wardha in the south-east corner. There are large forest reserves in the south and south-east in which game abounds. There is a considerable aboriginal element of Gonds and Kalams in the wilder portions. The 1941 population was 887,738. There is coal at Pisgaon in the Wun *taluq* near the Wardha River. The climate in the uplands is cool and the rainfall (41″) plentiful.

YEOVIL, a market town and municipal borough in the Yeovil parliamentary division of Somersetshire, England, on the G.W. and S. railways, 127 mi. S.W. of London. Pop. (1938) 20,110. Area 3.5 sq.mi. The town lies on the river Yeo, and is a thriving place, with a few old houses. The town is famous for its manufacture of gloves (dating from 1565). It has also brick works, a brewery, and large engineering works. Its agricultural trade is considerable. Yeovil (*Gyoele, Evill, Ivle, Yeoele*) before the Conquest was part of the private domains of the Anglo-Saxon kings.

YERBA BUENA (*Micromeria chamissonis*), a pleasantly aromatic North American herb of the mint family (Labiatae, *q.v.*), found in woods from British Columbia to southern California. It is a slender perennial, with trailing stems ½ ft. to 2 ft. in length, roundish, short-stalked leaves, ½ in. to 1 in. broad, and delicate, two-lipped, white flowers, borne on hair-like stalks usually singly in the leaf-axils. Medicinal properties were ascribed to it.

YERBA MANSA (*Anemopsis californica*), a North American herb of the lizard's-tail family (Saururaceae), found in wet saline places from western Texas to central California and southward to Mexico. It is a perennial with upright stems, ½ ft. to 2 ft. high, springing from aromatic, creeping rootstalks, and astringent, slightly spicy foliage. The flowers are borne in terminal spikes, ½ in. to 1½ in. long, surrounded at the base by a circle of conspicuous white bracts; the fruit is a capsule, splitting open from the top. The Spanish-Californians used the plant medicinally.

YERBA MATÉ: *see* MATÉ.

YERBA SANTA (*Eriodictyon californicum*), a North American balsamic shrub of the water-leaf family (*Hydrophyllaceae*), native to dry slopes and mountain ridges from south central California to southern Oregon. It grows from 2 ft. to 8 ft. high, bearing narrowly lanceolate leaves, which are very glutinous-resinous above and densely white-woolly below, and bluish or white flowers in loose clusters. The Indians and early Spanish settlers made extensive medicinal use of the bitter-aromatic leaves; the Indians also chewed and smoked them.

YERSIN, ALEXANDRE ÉMILE JOHN (1863–1943), Swiss bacteriologist, was born at Rougemont, Switzerland, on Sept. 22, 1863, and studied at Lausanne, Marburg and Paris. He was associated with Roux in his researches on the diphtheria serum at the Pasteur institute, and then continued his researches in China and Indo-China, where he explored the Mois country. He introduced the culture of rubber into Indo-China. The plague bacillus was discovered by him in Hongkong in 1894, Kitasato simultaneously making the same discovery. The next year Yersin prepared a serum to combat the disease. Under the auspices of the Chinese government a branch of the Pasteur institute was founded by him at Canton. Yersin established a similar institution at Nha Nang, Annam, in the same year, of which he became director. Yersin was awarded le grand prix Leconte by the Paris Académie des Sciences in 1927. He died in Indo-China, March 2, 1943.

YEW (*Taxus baccata*), a tree which belongs to the family Taxaceae (*see* GYMNOSPERMS), in which the ordinarily woody

FROM COOPER AND WESTALL, "TREES AND SHRUBS OF THE BRITISH EMPIRE" (J. M. DENT & SONS, LTD.)

YEW (TAXUS BACCATA), TWIGS WITH (A) STAMINATE AND (B) CARPELLATE FLOWERS

cone of the pines and spruces is represented by a single seed surrounded by a fleshy berry-like cup. Usually it forms a low-growing evergreen tree of very diverse habit, but generally with dense spreading branches, thickly covered with very dark green linear leaves, which are given off from all sides of the branch, but which, owing to a twist in the base of the leaf, become arranged in two ranks.

The trees are usually dioecious, the staminate flowers being borne on one individual and the carpellate on another. The staminate and the carpellate flowers are placed each separately in the axil of a leaf, and consist of a number of overlapping scales. In the carpellate flower these scales surround a cup which is at first shallow, green and thin (the so-called aril), but which subsequently becomes fleshy and red, while it increases so much in length as almost entirely to conceal the single straight seed. It is clear that the structure of the carpellate flower differs from that of most conifers, from which it is separated in a distinct family, Taxaceae.

The poisonous properties, referred to by classical writers such as Caesar, Virgil and Livy, reside chiefly if not entirely in the foliage. This, if eaten by horses or cattle, especially when it has been cut and thrown in heaps so as to undergo a process of fermentation, is very injurious. As a timber tree the yew is used for cabinet-work and axle-trees, where strength and durability are required. It was once largely used for the English long-bow.

The European yew, *T. baccata,* is a native of Europe, north Africa, and Asia as far as the Himalayas and the Amur region. The yew is wild in Great Britain, forming a characteristic feature of the chalk downs of the southern counties and of the vegetation of parts of the Lake District and elsewhere. The evidence of fossil remains, antiquities and place-names indicates that it was formerly more widely spread in Europe than at the present day. The varie-

ties grown in the United Kingdom are numerous, one of the most striking being that known as the Irish yew—a shrub with the pyramidal or columnar habit of a cypress. The yew is a favourite evergreen tree, either for planting separately or for hedges, for which its dense foliage renders it well suited. Its dense growth when pruned has led to its extensive use in topiary work, which was introduced by John Evelyn and became very prevalent at about the beginning of the 18th century. In the United States and Canada the best known native yews are the American yew or ground hemlock (*T. canadensis*), a low, straggling shrub rarely over 5 ft. high, found in woods from Newfoundland to Manitoba and southward to Virginia and Iowa, and the western or Pacific yew (*T. brevifolia*), a tree sometimes 50 ft. high, with a trunk diameter of 2 ft., which grows from California to Alaska and eastward to Montana. The hard, heavy, very fine-grained, exceedingly durable wood of the Pacific yew, one of the best woods used by the Indians for making bows, is especially suitable for tool-handles and similar purposes. Two other North American species occur: the Florida yew (*T. floridana*), a rare tree of western Florida, and the Mexican yew (*T. globosa*), found in the mountains of Mexico. Numerous dwarf forms and leaf-colour variants of the Japanese yew (*T. cuspidata*), a tree sometimes 50 ft. high, native to northeastern Asia, are planted for ornament.

For further details *see* Elwes and Henry, *Trees of Great Britain and Ireland* (1906); C. S. Sargent, *Manual of the Trees of North America* (1905, new ed. 1933); L. H. Bailey, *Manual of Cultivated Plants* (1924); G. B. Sudworth, "Check List of the Forest Trees of the United States," *U.S. Dept. Agric. Misc. Cir. 92* (1927); W. Dallimore and A. B. Jackson, *Handbook of Coniferae* (1931).

YEZD or YAZD, a province and town of Iran. The former is bounded on the west by the province of Isfahan, on the north by Samnan-Damghan, on the east by Khurasan and on the south by Kerman and Fars. Much silk is produced in this district, but not sufficient for the requirements of the looms of Yezd, and quantities are imported from Gilan. Other products are opium, madder, almonds and grain, of which last, however, only one-third of the supply required for local consumption is grown, the surplus requirements being brought from the adjacent province of Khurasan. The eastern part of the province bordering on the Dasht-i-Lut (desert) is much exposed to moving sands.

Yezd, the chief town of the province, is in 31° 54′ N. and 54° 22′ E. at an elevation of 4,390 ft., 162 mi. S.E. of Isfahan and 192 mi. N.W. of Kerman; pop. est. 60,000. When the Arabs invaded Persia, many of the Zoroastrians fled toward Yezd and Kerman where they remained. The highest and lowest temperatures are respectively 106° F. in July and 20° in December. Commercially, Yezd occupies an important central position in Iran, whence a number of routes radiate: to Isfahan to Meshed on the N.E. via Tabas and the desert and to Kerman on the west and Zahidan on the S.E. connecting with the Indian railhead. There is also an important direct caravan track to Bandar Abbas.

Since Sassanian times Yezd has been famous for beautiful silk textiles, rivalled in later periods only by Kashan and Isfahan. It is still the most productive centre of silk weaving, with approximately 8,000 weavers. Besides part of the imposing city wall, built in the 12th and 14th centuries, the most interesting mediaeval fortifications surviving in Iran, there are many important mosques and mausolea, dating from the Duwaz dah Imam (1035). The Masjid-i-Jami (cathedral or Friday mosque) is distinguished by the highest minarets in Iran, mosaic faïence, a superb mihrab dated 1375, and two oratories, Gothic in appearance, with deep transverse vaults. Some of the other mosques and mausolea are decorated with extremely delicate and rich stucco relief or are polychromed with tones of pale blue, rose and yellow. The sky line is picturesque, with minarets and many tall towers devised to bring moving air down to the many small chambers which are a necessary refuge from the intense heat of summer.

See G. N. Curzon, *Persia and the Persian Question* (1892); E. G. Browne, *A Year amongst the Persians* (1893 and 1926); *Survey of Persian Art* (1938), for the monuments especially vol. iv, Pls. 273, 4; 438, 449 and vol. ii *passim*. Textiles, vol. iii, pp. 1995–2220 *passim*, and vol. vi, Pls. 1032–1106 *passim*. (P. Z. C.; X.)

YEZIDIS, a religious sect, numbering about 50,000 persons, dwelling chiefly in the neighbourhood of Mosul. Their own name for themselves is Dasni, but they are called by their neighbours Yezidi; the origin of both names is uncertain, but the latter is probably derived from the Persian *Yazdān,* God. Their religion was probably originally an offshoot of Mazdaism, but it has absorbed elements from Christianity and Islam, for they regard Christ as an angel in human form and recognize Mohammed as a prophet with Abraham and the other prophets, and practise circumcision and baptism. They regard the devil as the creative agent of the Supreme God, and seek to propitiate him as the author of evil; they avoid mentioning his name and represent him by the peacock. Their sacred books have been translated by F. Nau *Recueil de textes et de documents sur les Yézidis* (1918).

BIBLIOGRAPHY.—L. Menant, *Les Yézidis* (1892); R. Frank, *Scheich Adi, der grosse Heilige der Jezîdîs* (1911); R. H. W. Empson, *The Cult of the Peacock Angel* (1928, bibl.).

YEZO (HOKKAIDO), the most northerly of the five principal islands forming the Japanese empire, the five being Yezo, Honshu, Shikoku, Kyushu and Formosa. It is situated between 45° 30′ and 41° 21′ N. and between 146° 7′ and 139° 11′ E.; its coast line measures 1,423.32 mi., and it has an area of 30,148.41 sq.mi. On the north it is separated from Sakhalin by Soya strait (La Pérouse) and on the south from Nippon by Tsugaru strait. Its northern shores are washed by the Sea of Okhotsk, its southern and eastern by the Pacific ocean, and its western by the Sea of Japan. While Yezo is the old Japanese name, the correct modern designation is Hokkaido (Northern Sea circuit) as a separate administrative division, which however includes adjacent islands.

Orography.—The highest mountain in the island is Ishikari-dake (6,955 ft.) and the next in importance is Tokachi-dake (6,541 ft.). Yubari-take in Ishikari has a height of 6,508 ft., and in the province of Kushiro are O-akan-dake (4,470 ft.) and Meakan-take (4,500 ft.). Near Hakodate are two conspicuous volcanic peaks, Komaga-take (3,822 ft.) and Tokatsu-dake (3,800 ft.); and 24 mi. from Kushiro (by rail) is a volcano called Atosanobori, or Iwo-zan (sulphur mountain), whence quantities of first-rate sulphur are exported to the U.S. Rishiri, an islet on the extreme N.W., has a peak of the same name rising to 6,000 ft.

Rivers.—Yezo boasts the largest river in the Japanese empire, the Ishikari-gawa, which is estimated to measure 275 mi. Its other large rivers are the Teshio-gawa (192 mi.), the Tokachi-gawa (120 mi.), the Shiribeshi-gawa (88 mi.), the Kushiro-gawa (81 mi.), the Toshibetsu-gawa (64 mi.) and the Yubetsu-gawa (64 mi.). The valley of the Ishikari is the most fertile part of the island; the Tokachi is navigable to a point 56 mi. from its mouth, but the Teshio has a bar which renders its approach extremely difficult. Nearly all the rivers abound with salmon.

Lakes.—There are no large lakes, the most extensive—Toyako, Shikotsuko and Kushiroko—not having a circumference of more than 25 miles. Lagoons, however, are not uncommon. The largest of these—Saruma-ko in Kitami—is some 17 mi. long by 7 wide. It abounds with oysters nearly as large as those for which the much smaller lagoon at Akkeshi is famous, the molluscs measuring about 18 in. in length.

Climate.—The climate differs markedly from that of the main island of Japan, resembling the climate of the British Isles, though the winter is longer and more severe, and the atmosphere in the warm season contains a greater quantity of moisture. For five months the country is under snow, its depth averaging about 2 ft. in the regions along the southern coast and more than 6 ft. in the northern and western regions. An ice-drift, setting from the north and working south as far as Nemuro, stops all sea trade on the east coast from January through March, though the west coast is protected by the warm current of the Kuro-shiwo. Fogs prevail along the east coast during the summer months, and it is not uncommon to find a damp, chilly atmosphere near the sea in July, whereas, a mile inland, the thermometer stands at 80° or 90° F. in the shade, and magnolia trees are in blossom.

Fauna.—Tsugaru strait has been shown to form a line of zoological division. Pheasants and monkeys are not found on the Yezo side of this line, though they abound on Honshu, and, on the other hand, Yezo has grouse and solitary snipe which do not

exist in Honshu. The Yezo bear, too, is of a distinct species.

Population.—The island seems to have been originally peopled by semi-barbarous pit-dwellers, whose modern representatives are found in the Kuriles or their neighbours of Kamchatka and Sakhalin. These autochthons were driven out by the Ainu, who, in turn, succumbed to the Japanese. Yezo and 68 adjacent small islands included in the administrative area of Hokkaido had 3,272,718 people in 1940, largely due to emigration from Japan proper to Yezo. Yezo is divided into ten provinces, the names of which, beginning from the south, are Oshima, Shiribeshi, Ishikari, Teshio, Kitami, Iburi, Hidaka, Tokachi, Kushiro and Nemuro. Of these, Oshima, Shiribeshi and Ishikari are the most important. Three towns had a large 1940 population, viz., Hakodate (203,862), Sapporo, the seat of government (206,103) and Otaru (164,282).

Industries and Products.—Marine products constitute the principal wealth of Yezo. Great quantities of salmon, sardines and codfish are taken. The salmon are salted for export to Nippon and other parts of Japan; the sardines are used as an agricultural fertilizer and the codfish serve for the manufacture of oil. An immense crop of edible seaweed is also gathered and sent to Chinese as well as to Japanese markets. This *kombu,* as it is called, sometimes reaches a length of 90 ft. and a width of 6 in. The herring fishery, too, is a source of wealth, and the canning of Akkeshi oysters as well as of salmon gives employment to many hands. Vast tracts are covered with a luxuriant growth of ash, oak, elm, birch, chestnut and pine, but, owing to difficulties of carriage, this supply of timber has not yet been much utilized.

Communications.—The roads are few and in bad order, but there is a railway which, setting out from Hakodate in the extreme south, runs, via Sapporo and Iwamizawa, to the extreme N. with branches from Iwamizawa, S. to Muroran and E. to Poronai, and from Oiwake N.E. to the Yubari coal mines. There is also a line W. along the S. coast from Nemuro.

History.—Yezo was not brought under Japan's effective control until mediaeval times. In 1604 the island was granted in fief to Matsumae Yoshihiro, whose ancestor had overrun it, and from the close of the 18th century the east was governed by officials sent by the shogun, whose attention had been attracted to it by Russian trespassers. In 1871 the task of developing its resources and administering its affairs was entrusted to a special bureau, which employed U.S. agriculturists to assist the work and U.S. engineers to construct roads and railways; but in 1881 this bureau was abolished, and the government abandoned to private hands the various enterprises it had inaugurated. The modern government departments attend to the development of the island as an integral part of Japan proper; but the Japanese from the mainland do not like to settle there and its resources seem not to be fully exploited. *See* the *Annual Report* of the Japanese government.

YGGDRASIL, in Scandinavian mythology the mystical ash tree which symbolizes existence, binds together earth, heaven and hell, and is the tree of life, knowledge, fate, time and space. Its three roots go down into the realms—(1) of death, where, in the well Hvergelmer, the dragon Nidhug (Niðhöggr) and his brood are ever gnawing it; (2) of the giants; (3) of the gods, Asgard. Its stem upholds the earth, its branches overshadow the world and reach up beyond the heavens. Honey-dew falls from the tree, and on its topmost bough sits an eagle. G. Vigfusson and York Powell (*Corpus Poeticum Boreale,* Oxford, 1883) see in Yggdrasil not a primitive Norse idea, but one due to early contact with Christianity.

YIDDISH LANGUAGE AND LITERATURE. The word Yiddish is derived from the modern German *Jüdisch Deutsch* or Jewish German. It is the language spoken by the Polish and Russian Jews whose forbears, early in the middle ages, were invited to Poland from the Rhineland, to form a trading class in between the nobles and the serfs. They have kept their Low German tongue, writing and printing it in Hebrew characters to this day. Yiddish, though based on a Low German vocabulary and construction, was cut off from living German, whence its irregularities of grammar and spelling. It continued to absorb Hebrew and Aramaic words and expressions, together with Slav ones, Polish or Russian, and has a few of older Romance origin. The Hebrew and Aramaic came from the Hebrew Bible and its huge commentary the Talmud, which is largely Aramaic (*q.v.*). For the women, notably in the *Tzènah Urènah!* (Heb. "Come out and see!"), there were prayers and legends in Yiddish, or Màmelòshen (class. Heb. *lashòn*="tongue") or *Zhargòn,* in modern Hebrew: *Yehudīt*="Jewish" (*s.* Judith), *Yiddit, Zhargòn.* Yiddish is essentially a folk-tongue, it had no written grammar, it eludes all strict grammatical analysis, though efforts are now being made to bring about uniformity in its grammar and spelling in view of its continued existence among the Jews of east Europe.

Yiddish Literature is merely the reflection of the segregated, intense Jewish world of Eastern Europe which has been broken up, never to be reconstructed. It enshrines a distinct phase of Jewish history, one which began when the first Jews migrated to Poland from the Rhinelands in the middle ages, and which lately closed in a darkness still hard to penetrate. It is a literature rich in folksongs and tales. A wealth of folk-lore, still in course of discovery, gathered on the long road from Ur of the Chaldees to Pinsk and Minsk, passed into Yiddish from Talmudical and European sources. This legendary material remained common to the Jews of Poland and Germany.

The literature of the latter differed at all times little from that of their Gentile neighbours except for the Hebrew lettering. The Oppenheim collection in the Bodleian library contains many publications of these earlier periods. Across the Polish frontier the literary cleavage between Jew and Gentile was complete. Intercourse with Germany grew ever less. Yiddish literature came to mean one or two chapbooks of legends and the still familiar devotional work for women, the *Tzènah Urènah,* delightful in its renderings of Talmudical traditions.

Early in the 19th century the Haskalah, a movement for the enlightenment of the Jewish masses, initiated in Berlin by Moses Mendelssohn, began to creep across the Russo-Polish frontiers. The young Talmud student deciphered his first German book, frequently the poems of Schiller, in secret and in fear—woe betide him were he found with a volume of secular recreation, and in the tongue spoken by so many heretic Jews! Still he read and then came the wish to express his own feelings in Yiddish, to speak to the people in their every-day language. Lefin translated the Psalms and Ecclesiastes, Linetzki wrote his autobiography, the *Polish Boy,* J. L. Gordon his few powerful verses.

Revival in Russia.—Round the '60s and '70s, when Russian schools and culture were made accessible to Jewish youth, Yiddish literature suffered a decline. After the persecutions of the '80s it took on fresh life. The Jewish people, re-awakened to the fact that they were not Jewish Russians but Russian Jews, said in the words of Peretz: "We also want to bring our sheaf to the universal harvest." The people needed comfort and guidance. Spektor wrote his tales, sweet and simple in style, priceless in observation; Frug, till then a Russian poet, his melodious verse; J. Dienensohn his pathetic *Jossele.* Abramovitch laid aside his fluent Hebrew pen and wrote novels in a rich Yiddish, dealing with evil inside as well as outside the community; I. L. Peretz and "Sholem Alechem," both now dead, wrote abundantly. Peretz produced tales, poems and dramas. The two last have a spectral charm, but his *Stories and Pictures* is his great achievement. "Sholem Alechem," the humourist, is even more of a household word in the humblest home where Yiddish is spoken. His *Tovie der Milchiger* (Tobias the Milkman) is an immortal type. David Frishman is a distinguished critic. Among other later and gifted story-tellers, much of whose work was published in New York, are Sholem Asch, A. Reisin, Libin and Peretz Hirschbein.

Leo Wiener's *History of Yiddish Literature in the 19th Century* (1899), is invaluable to the student. Some English translations are: *Jewish Children* (Sholem Alechem), by Hannah Berman; *One Act Plays from the Yiddish,* by Etta Block; *A Lithuanian Village* (Leon Kobrin), by I. Goldberg, who has also translated the *Haunted Inn* of Peretz Hirschbein and other plays; *Stories and Pictures* (I. L. Peretz) and *Yiddish Tales* (20 different authors), by H. Frank. (H. F.)

BIBLIOGRAPHY.—Abramovitch, *Die Kliatshe, Fistike der Kàlike* (*The Cripple*), *Das kleine Menshele* (*The Little Man*), etc.; S. Asch, *Blätter* (*Leaves*), *Junge Johren* (*Youthful Years*); Frug, *Lieder* (*Poems*); Libin, *Gekliebene Skizzen* (*Selected Sketches*), *Modne Menshen* (*Queer Folk*); Opatosho, *Die Pölishe Wälder* (*The Polish Woods*) and other novels; I. L. Peretz, *Erzählungen und Bilder* (*Stories and*

Pictures); Reisin, *Collected Works;* Sholem Alechem, *Collected Works* (including *Stempenyu, Menachem Mendel* and *Tovie der Milchiger*); Spektor, *Collected Tales* including *Die zwei Chevertes (The two Companions)*; Yehoash, *Collected Poems* and *From New York to Rehovoth.*

The United States.—Yiddish literature in America developed under a combination of influences. On the one hand Russian literature—the writings of Tolstoi, Turgeniev, Dostoievski and Chekhov—played a decisive rôle in its growth for the obvious reason that nearly all Yiddish writers came from Russia and it was they who founded the Yiddish press, wrote the plays for the theatres, started weekly and monthly publications.

The distinctive contribution of the United States to Yiddish literature of the world has been the Yiddish language press. During the past four decades Yiddish journalism has swallowed up the ablest writers. There has never been a profitable market for Yiddish books in America on account of the poverty of the Jewish masses. Nine-tenths of the novelists, short story writers, poets, playwrights and critics have been obliged to eke out a livelihood as practising newspapermen. Hence the Yiddish press has been more than a purveyor of news and political comment. The man who has created modern Yiddish journalism is Abraham Cahan. From the founding of the *Jewish Daily Forward* in 1897 Cahan has been guide and mentor of the Yiddish press.

In addition to *The Forward* there are three other dailies in New York, viz., *Jewish Morning Journal, Day-Warheit* and *Freiheit.* The *Morning Journal* (edited by Peter Wiernik) is a conservative paper in politics no less than in religion. The *Day-Warheit* espouses the cause of Jewish nationalism, while *Freiheit* advocates communism. The total circulation of the several papers is in the neighbourhood of 400,000. Among the leading journalists in addition to those already mentioned are Zivion, Hillel Rogoff, Dr. A. Coralnik, M. Olgin, Dr. S. Margoshes, Jacob Fishman. The name of the late Louis E. Miller, one of the founders of *The Forward* and for years editor-publisher of *Warheit* and other publications, must be included in this list. Also S. Yanofsky, long the editor of *Freie Arbeiter Shtimme* (Free Workmen's Voice), an influential literary weekly of anarchist tendencies.

Much of the best modern Yiddish poetry has been written in the United States. Morris Rosenfeld was the most popular and most versatile poet produced in America. He was lyricist, satirist, polemicist. Yehoash, regarded by some as superior to Rosenfeld, was less popular. His poetry is cerebral, much of it obscure. Yehoash wrote magnificent nature poems; he translated Longfellow's "Hiawatha," devoted long years to the translation of the Old Testament from the original Hebrew into Yiddish and was the author of a *Dictionary of Hebraic Elements* in the Yiddish language, a pioneer work. A. Liesin, for years editor of the monthly magazine *Zukunft* (Future) is a poet of great power and originality as well as a foremost publicist. Excellent poetry has also been written by M. Winchevsky, Mani Leib, Rolnik, Joel Slonim, M. L. Halpern, Zisha Landau, Dilon, Nochem Yud.

The earliest writers of short stories were Z. Libin, Jacob Gordin and Leon Kobrin. Libin's career dates from the '90s. His sketches are full of a peculiar humour tinctured with sadness inspired by the hardships of life of the early immigrants. Libin has written extensively for the stage not without success. Kobrin was a prolific playwright and translator. Gordin's fame rests on the seventy-odd plays which he wrote for the stage during the last 20 years of his life rather than his earlier sketches. He was the reformer of the Yiddish stage in America.

Only two or three of the many plays which David Pinski has written proved successful on the stage, notably *Yekel the Blacksmith* and *The Treasure.* Some of his plays, short stories and a novel have been translated into English. Strongly under the influence of the Russian realists, Z. Levine occupies a unique position as a writer of grim stories unrelieved by humour. Highly esteemed by some critics, his reading public remains limited.

Along about 1914 and 1915 there emerged a group of young writers who challenged the supremacy of the older men. Fifteen years later, their position was being challenged by a still younger group. The most notable of the young writers were Opatosho, Ignatev and Raboi.

Many of the leading writers of Europe have lived in America for shorter or longer periods but have remained distinctly European writers for the most part. None of the sketches or poems which Reisin, for instance, has written in America are equal to his best European work. Asch, who is indubitably one of the two or three greatest living Yiddish writers, is the author of two novels of American life: *Uncle Moses* and *Lederer.* His fame, however, will rest on *Motke Ganef, Kidush Hashem, Gott fun Nekomah* and *Dos Shtetel*—all written in the old country.

Next to the press the stage has been the most potent cultural influence in the life of the Jewish immigrants. Long under the domination of Shomer, Lateiner and "Professor" Hurwich, it was devoted to the presentation of vapid musical comedies, operettas and blood-curdling melodramas. Jacob Gordin, and after him Libin, Kobrin, Asch, Pinski, Sackler, Gottesfeld and Leiwick, rescued the stage from the doldrums. Asch's *God of Vengeance,* though dealing with life in Warsaw, was first produced in New York and is perhaps the greatest single Jewish drama of modern times. Of plays dealing essentially with American conditions, Leiwick's *Shmattess* (Rags) ranks near the top. In recent years Gottesfeld has written delightful comedies of American life. Peretz Hirschbein's idyllic plays (*Dos Fervorfen Winkel, Grinne Felder,* etc.) have been extremely successful and have vastly enriched the repertoire of the American Yiddish stage. There are approximately 20 Yiddish theatres in the country, fully half of them in greater New York. Second avenue in New York is the Yiddish "Great White Way." (N. Z.)

YLANG-YLANG (*Cananga odorata*), a medium-sized tree of the custard-apple family (Annonaceae), found in southern India, Java and the Philippines and planted in warm regions for its exceedingly fragrant flowers, which yield the widely-prized perfume of the Pacific islands, known as ylang-ylang among the Malays. The tree has somewhat drooping branches; large, ovate, sharp-pointed leaves; numerous greenish or yellowish flowers, about 2 in. long, and oblong, greenish fruits about 1 in. long. It has been sparingly cultivated in southern Florida.

YOCHOW (YOYANG), a city in Hunan province, China, standing on high ground east of the outlet of Tungting lake. Population (1931) 4,800. The actual settlement is at Chinling-Ki, a village 5½ mi. below Yoyang and ½ mi. from the Yangtze. From Yoyang the cities of Changsha and Changteh are accessible, for steam vessels drawing 4 to 5 ft. of water, by means of the Tungting lake and its affluents the Siang and Yuan rivers. The district in which Yoyang stands is the ancient habitat of the aboriginal San Miao tribes who were deported into southwest China. The city, which was built in 1371, is about 3 mi. in circumference, and is surrounded by a wall. It was entered by the T'aip'ing rebels in 1853 and opened to foreign trade in 1899. The Japanese used it as a military centre for dominance of northern Hunan areas after 1938.

YODEL, a peculiar kind of singing consisting of alternations of high falsetto notes with ordinary chest tones. It is practised by the Swiss and Tirolese in the singing of their native melodies.

YOGA, "diversion of the senses from the external world, and concentration of thought within" (Sanskrit "yoking"). The Yoga system in Hindu philosophy is a branch of the Sankhya (*q.v.*), but loosely inserted into it is the conception of a personal God, who is indissolubly connected with the subtlest form of matter. Union with him was not the original object of *yoga.* By its practices of hypnotism and self-mortification the Yogi (mod. Jogi) could attain miraculous powers and control of nature itself. Siva (*q.v.*), was essentially the great Yogi.

YOKOHAMA, a seaport of Japan on the west shore of Tokyo Bay, 18 m. south of Tokyo by rail. It stands on a plain shut in by hills, one of which, towards the south-east, terminates in a promontory called Honmoku-misaki or Treaty Point. The temperature ranges from 95° to 43° F, and the mean temperature is 57·7°. The cold in winter is severe, owing to north winds, while the heat is great in summer, though tempered by southwest sea breezes. The rainfall is about 70 in. annually. Pop. (1940) 968,091. In 1859, when the neighbouring town of Kanagawa was opened to foreigners under the treaty with the United States,

Yokohama was an insignificant fishing village; and notwithstanding the protests of the foreign representatives the Japanese government shortly afterwards chose the latter place as the foreign settlement instead of Kanagawa. This settlement, which developed under the administration of foreign residents enjoying extraterritorial rights until 1899, formed the nucleus of a flourishing city, prospering with the growth of Japan's foreign trade and shipping. The harbour, which is a part of Tokyo bay, is good and commodious. It is somewhat exposed, but enclosed by two substantial breakwaters. The average depth in the harbour is about 46 ft. at high water, with a tide falling about 8 ft.

The city was almost obliterated by an earthquake in 1923, some 80% of its houses destroyed and many thousands of its inhabitants killed, mostly by fire.

Subsequent reconstruction under a comprehensive government plan had made good progress by 1930. The docks and the waterfront area, formerly known as the Bund, were much improved. Little now remains of the old foreign settlement.

Yokohama depended for its growth upon foreign trade and shipping, particularly the silk trade. The decline of the importance of silk in Japan's exports, together with a rapid growth of manufactures and foreign trade in other centres, notably Nagoya, Kobe and Osaka, tended to diminish the relative importance of Yokohama, and the city was showing signs of depression in the decade 1930–40.

YOKOHAMA SPECIE BANK, LTD., THE (*Yokohama Shokin Ginko*). This bank was founded in 1880 with an authorised capital of Yen 3,000,000 with the object of affording financial facilities in respect of the foreign trade of Japan. Subsequently, its capital was increased several times until it stood at Yen 100,000,000, all paid up by December 1920.

The business carried on by the bank consists of (1) foreign exchange, (2) inland exchange, (3) loans, (4) deposits of money and custody of articles of value, (5) discount and collection of bills of exchange, promissory notes and other securities, and (6) exchange of coins. The bank may also buy or sell public bonds, gold and silver bullion, and foreign coins, if so required by the condition of its business. It may also be entrusted with matters relating to foreign loans and with the management of public money for international account.

The head office of the bank is in Yokohama, and there are 44 branches, 7 of which are in Japan and the remainder distributed throughout China, Manchuria, Europe, North and South America, India, Australia and the East Indies. In March 1939, the subscribed and fully paid capital of the bank amounted to Yen 100,000,000, while there was a reserve fund of Yen 138,400,000.

(D. No.)

YOKOSUKA, a seaport and naval station of Japan, on the west shore of Tokyo Bay, 12 m. south of Yokohama. The town is connected by a branch line with the main railway from Tokyo. The port is sheltered by hills and affords good anchorage. The site was occupied by a small fishing village until 1865, when the shogun's government established a shipyard here. In 1868 the Japanese government converted the shipyard into a naval dockyard, and subsequently carried out many improvements. In 1884 it became a first-class naval station. Pop. (1940) 193,358.

YOLA, a native state of British West Africa, forming the major part of the province of Adamawa, Northern Nigeria. In the partition of Africa part of Adamawa fell to Germany and was included in the Cameroons. The British part was known as the province and emirate of Yola. In 1919 the former German part of Adamawa came under British mandate and was incorporated with Yola. In 1926 the name of the province and emirate was changed to Adamawa. By the people the Fula ruler is known as the Lamido of Adamawa. The capital is Yola, a town founded by the Fula conqueror Adama about the middle of the 19th century. The town is situated in 9° 12′ N., 12° 40′ E. and is built on the left or south bank of the Benue, 480 m. by river from Lokoja. It can be reached by shallow draught steamers when the river is in flood. The Niger Company had trading relations with Yola before the establishment of British administration in Northern Nigeria.

In 1903 an exploring expedition was sent up the Gongola, which coming from the north joins the Benue below Yola, and the navigability of the river for steam launches as far as Gombe at high water was demonstrated. The Gongola valley was in ancient times extensively cultivated and after the establishment of the British protectorate it again became a prosperous agricultural region. Cotton and food crops are cultivated.

Adamawa province has an area of 33,424 sq.m. and a pop. (1926) of 549,137.

See NIGERIA; ADAMAWA, and the *Annual Report* on the Northern Provinces, Nigeria (Kaduna), first issued in 1928.

YOM KIPPUR, Jewish sacred Day of Atonement, supposedly dates back to Moses. Its annual observance on the tenth day of the seventh month, the custom of fasting, and the elaborate ceremonies of supplication all date more directly from the religious revival beginning with Ezra. Some of the scriptural texts are Lev. XVI, XXIII: 26–32, XXV: 9, and Num. XXIX: 7–11.

YONGE, CHARLOTTE MARY (1823–1901), English novelist and writer on religious and educational subjects, daughter of William Crawley Yonge, 52nd Regiment, and Frances Mary Bargus, was born on Aug. 11, 1823 at Otterbourne, Hants. She was educated by her parents, and from them inherited much of the religious feeling and High Church sympathy which coloured her work. She lived at Otterbourne all her life, and was one of the most prolific writers of the Victorian era. Her first conspicuous success was attained with *The Heir of Redclyffe* (1853). *The Daisy Chain* (1856, repr. 1911) continued the success. Other popular books include *Heartsease* (1854), *Dynevor Terrace* (1857), *The Young Stepmother* (1861), *The Trial* (1864), and *The Clever Woman of the Family* (1865). She wrote over 120 volumes, including novels, tales, school manuals and biographies, and was for more than 30 years editor of the *Monthly Packet.* She died at Otterbourne on March 24, 1901.

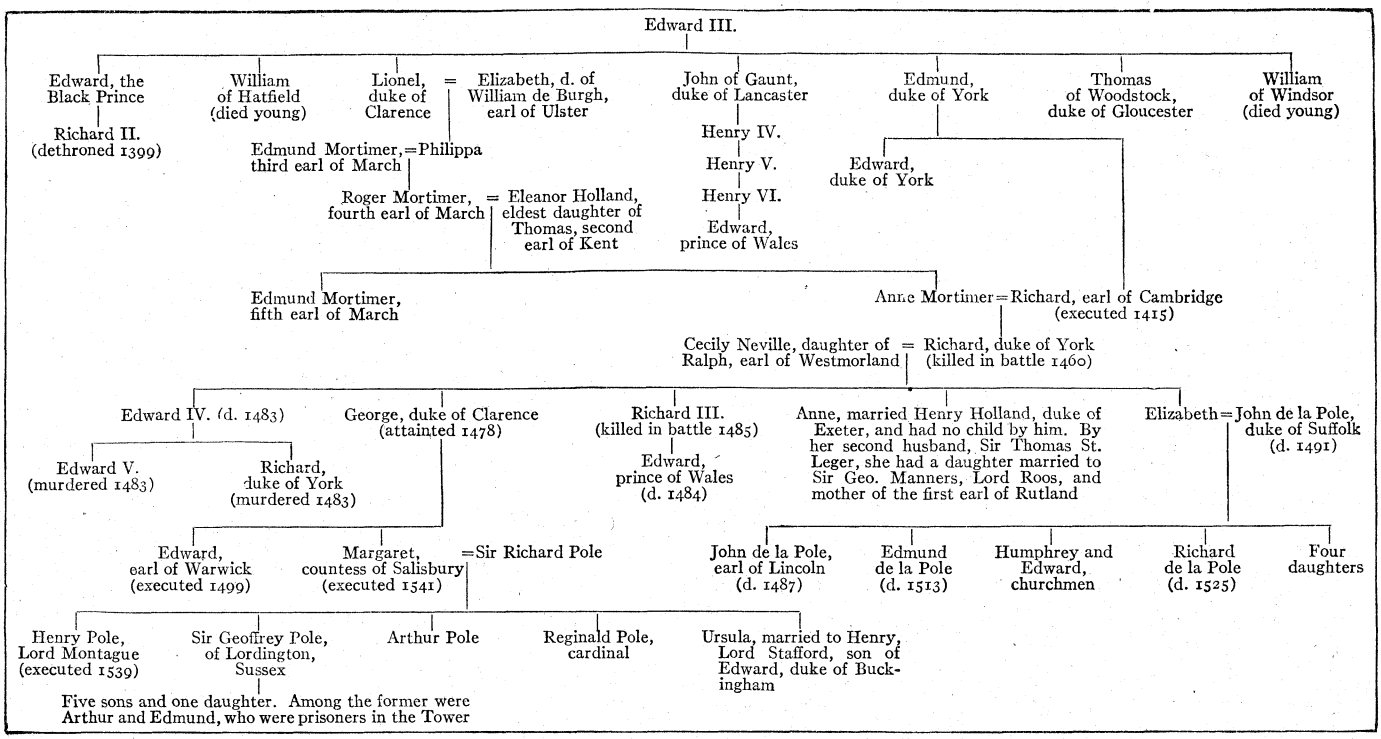
See E. Romanes, *Charlotte Mary Yonge: an Appreciation* (1908); and C. Coleridge, *Charlotte Mary Yonge, her Life and Letters* (1903).

YONKERS, a city of Westchester county, New York, U.S.A., on the east bank of the Hudson river, adjoining New York city on the north and facing the Palisades. It is served by the New York Central and electric railways, motor-bus lines, a ferry to Alpine, N.J., and river steamers. Pop. (1920) 100,176 (26% foreign-born white); 1940 U.S. census 142,598. Yonkers is an important manufacturing city as well as a popular residential suburb. There are many manufacturing establishments in the city.

In the heart of the business district stands the Philipse Manor-hall (built in 1682 and enlarged in 1745), one of the best examples of colonial architecture in America, now maintained as a State museum. In the northern part of the city (Glenwood) are the old Colgate mansion and the home of Samuel J. Tilden. There are many beautiful residential districts, commanding delightful views.

An Indian village (Nappeckameck) stood on the site of Yonkers, at the mouth of the Nepperhan creek, when the Dutch founded New Amsterdam, and the territory was within the "Keskeskick Purchase," acquired from the Indians by the Dutch West India company in 1639. In 1646 it was included in the large grant extending from the Hudson to the Bronx river, made to Adrian van der Donck, the first lawyer and historian of New Netherland. He encouraged settlers to come in, built a saw-mill near the mouth of Nepperhan creek (or Saw-Mill river), and soon the settlement came to be known as De Jonkheer's Land (the estate of the young lord), from which the name of Yonkers was gradually evolved. Later much of the estate passed into the hands of Frederick Philipse, who in 1682 built for his son the manor house mentioned above. This mansion was confiscated in 1779, as the Frederick Philipse of that time was suspected of Toryism. It came into the possession of Yonkers in 1867, and was used as the city hall from 1872 until it was bought by the State in 1908. Early in the Revolution Yonkers was occupied for a time by part of Washington's army and was the scene of several skirmishes. In 1854 the manufacture of elevators was begun in Yonkers by Elisha G. Otis. The village was incorporated in 1855 and in 1872 it became a city.

GENEALOGICAL TABLE OF THE HOUSE OF YORK



YONNE, a department of central France, formed partly from the province of Champagne proper (with its dependencies, Sénonais and Tonnerrois), partly from Burgundy proper (with its dependencies, the county of Auxerre and Avallonnais) and partly from Gâtinais (Orléanais and Île-de-France). It is bounded by Aube on the northeast, Côte-d'Or on the southeast, Nièvre on the south, Loiret on the west and Seine-et-Marne on the northwest. Pop. (1936) 271,685. Area 2,881 sq.mi. The highest elevation (2,000 ft.) is in the granitic highlands of Morvan. The department belongs to the basin of the Seine, except a small district in the southwest (Puisaye), which belongs to that of the Loire. The river Yonne flows through it from south to north-northwest, receiving on the right bank the Cure, the Serein and the Armançon, which water the southeast of the department. Farther north it is joined by the Vanne.

The department is served chiefly by the P.L.M. railway. The canal of Burgundy, which follows the valley of the Armançon, has a length of 57 mi. in the department, that of Nivernais, following the valley of the Yonne, a length of 33 miles. The department constitutes the archiepiscopal diocese of Sens, has its court of appeal in Paris, its educational centre at Dijon and belongs to the district of the VIII army corps. It is divided into 3 arrondissements (37 cantons, 486 communes), of which the capitals are Auxerre, also capital of the department, Avallon and Sens; these with Chablis, Vézelay (*qq.v.*) and St. Florentin are its chief towns. Pontigny has a Cistercian abbey, where Thomas Becket spent two years of his exile, with a 12th century church. Druyes has a 12th-century château. Villeneuve-sur-Yonne has a mediaeval keep and gateways and a church of the 13th and 16th centuries. The Renaissance châteaux of Fleurigny, Ancy-le-France, Tanlay and the château of St. Fargeau, of the 13th century, rebuilt by Mademoiselle de Montpensier under Louis XIV., are all noteworthy. At St. Moré there are remains of the Roman road from Lyons to Gallia Belgica and of a Roman fortified post. There are many megalithic monuments in the department.

YORCK VON WARTENBURG, HANS DAVID LUDWIG, COUNT (1759–1830), Prussian general field-marshal, was of English ancestry. He entered the Prussian army in 1772, but in 1779 was cashiered for disobedience. Entering the Dutch service, he took part in the operations of 1783–84 in the East Indies as captain. Returning to Prussia in 1785 he was, on the death of Frederick the Great, reinstated in his old service, and in 1794 took part in the operations in Poland. Five years afterwards Yorck began to make a name as commander of a light infantry regiment, being one of the first to give prominence to the training of skirmishers. In 1805 he was appointed to an infantry brigade, and in the Jena campaign played a successful part as a rearguard commander, especially at Altenzaun. He was taken prisoner, severely wounded, at Lübeck. In the reorganization of the Prussian army after the peace of Tilsit, Yorck took a leading part. At first major-general commanding the West Prussian brigade, afterwards inspector-general of light infantry, he was finally appointed second in command to General Grawert, the leader of the auxiliary corps which Prussia was compelled to send to the Russian War of 1812, succeeding to the command on Grawert's retirement. He conducted the advance on Riga with great skill; but his conviction that the French army was doomed led him at last to neutralize the Prussian army by the Convention of Tauroggen (Dec. 30). The step was intensely popular, and although it was officially proposed to court-martial Yorck, he was absolved when the Treaty of Kalisch ranged Prussia with the Allies. During 1813–14 Yorck led his veterans with success at Bautzen, Katzbach, Wartenburg (Oct. 4) and Leipzig (Oct. 18). In France, he distinguished himself at Montmirail and Laon. The storm of Paris was his last fight. In 1821 he was created general field-marshal. He had been made Count Yorck von Wartenburg in 1814. He died at his estate of Klein-Öls, the gift of the king, on Oct. 4, 1830.

See Seydlitz, *Tagebuch des Preussischen Armee Korps 1812* (1823); Droysen, *Leben des G. F. M. Grafen Yorck von Wartenburg* (1851).

YORK (HOUSE OF), a royal line in England, founded by Richard, duke of York (*q.v.*), who claimed the crown in opposition to Henry VI. His claim was, perhaps rightly, barred by prescription, the house of Lancaster having then occupied the throne for three generations; it was really owing to the misgovernment of Margaret of Anjou that it was advanced at all. The duke was descended from Lionel, the third son of Edward III., while the house of Lancaster came of John of Gaunt, the fourth son. The claim was derived (*see* the Table) through females; but this could not reasonably have been objected to after Edward III.'s claim to the crown of France; and the duke's claim was probably supported by the fact that he was descended from Edward III. both through his father and through his mother. (*See* Table.) The earldom of Ulster, the old inheritance of the De Burghs, had descended to him from Lionel;

the earldom of March came from the Mortimers, and the dukedom of York and the earldom of Cambridge from his paternal ancestry. Moreover, his own marriage with Cecily Neville, though she was but the youngest daughter of Ralph, 1st earl of Westmorland, allied him to a powerful family in the north of England, to whose support both he and his son were indebted.

The reasons why the claims of the line of Clarence had been so long forborne are not difficult to explain. Roger Mortimer, 4th earl of March, was designated by Richard II. as his successor; but he died the year before Richard was dethroned, and his son Edmund, the 5th earl, was a child at Henry IV.'s usurpation. Henry took care to secure his person; but the claims of the family troubled the whole of his own and the beginning of his son's reign. It was an uncle of this Edmund who took part with Owen Glendower and the Percies; and for advocating the cause of Edmund Archbishop Scrope was put to death. And it was to put the crown on Edmund's head that his brother-in-law Richard, earl of Cambridge, conspired against Henry V. soon after his accession. The plot was detected, being revealed, it is said, by the earl of March himself, who does not appear to have given it any encouragement; the earl of Cambridge was beheaded.

The popularity gained by Henry V. in his French campaigns secured the weak title of the house of Lancaster against further attack for forty years.

Richard, duke of York, seems to have taken warning by his father's fate; but, after seeking for many years to correct by other means the weakness of Henry VI.'s government, he first took up arms against the ill advisers who were his own personal enemies, and at length claimed the crown in parliament as his right. The Lords, or such of them as did not purposely stay away from the House, admitted that his claim was unimpeachable, but suggested as a compromise that Henry should retain the crown for life, and the duke and his heirs succeed after his death. This was accepted by the duke, and an act to that effect received Henry's own assent. But the act was repudiated by Margaret of Anjou and her followers, and the duke was slain at Wakefield fighting against them. In little more than two months, however, his son was proclaimed king at London by the title of Edward IV., and the bloody victory of Towton immediately after drove his enemies into exile and paved the way for his coronation.

After his recovery of the throne in 1471 he had little more to fear from the rivalry of the house of Lancaster. But the seeds of distrust had already been sown among the members of his own family, and in 1478 his brother Clarence was put to death—secretly, indeed, within the Tower, but still by his authority and that of parliament—as a traitor. In 1483 Edward himself died; and his eldest son, Edward V., after a nominal reign of two months and a half, was put aside by his uncle, the duke of Gloucester, who became Richard III. and then caused him and his brother Richard, duke of York, to be murdered.

But in little more than two years Richard was slain at Bosworth by the earl of Richmond, who, being proclaimed king as Henry VII., shortly afterwards fulfilled his pledge to marry the eldest daughter of Edward IV. and so unite the houses of York and Lancaster.

Here the dynastic history of the house of York ends. But a host of debatable questions and pretexts for rebellion remained. The legitimacy of Edward IV.'s children had been denied by Richard III. and, though the act was denounced as scandalous, the slander might still be reasserted. The duke of Clarence had left two children and the attainder of their father could not be a greater bar to the crown than the attainder of Henry VII. himself. Seeing this, Henry had kept Edward, earl of Warwick, a prisoner in the Tower of London. Yet a rebellion was raised in his behalf by means of Lambert Simnel, who was defeated and taken prisoner at the battle of Stoke in 1487. The earl of Warwick lived for 12 years later in confinement, and was ultimately put to death in 1499.

His sister Margaret married Sir Richard Pole (or Poole), and could give no trouble, so that Henry VIII. treated her with kindness. He made her countess of Salisbury, reversed her brother's attainder, created her eldest son, Henry, Lord Montague, and had one of her younger sons, Reginald, carefully educated. (*See* POLE, REGINALD and POLE, FAMILY.)

YORK, ALBERT FREDERICK ARTHUR GEORGE, DUKE OF (1895–): *see* GEORGE VI.

YORK, EDMUND OF LANGLEY, DUKE OF (1341–1402), fifth son of Edward III., was born at King's Langley in Hertfordshire on June 5, 1341. He accompanied his father on a campaign in France in 1359, was created earl of Cambridge in 1362, and took part in expeditions to France and Spain. After marrying Isabella (d. 1393), daughter of Peter the Cruel, king of Castile, he was appointed one of the English lieutenants in Brittany, whither he led an army in 1375. A second campaign in Brittany was followed in 1381 by an expedition under his leadership to aid Ferdinand, king of Portugal, against John I., king of Castile; but Edmund shortly returned to England as Ferdinand had concluded an independent peace with John. Accompanying Richard II. on his march into Scotland, he was created duke of York in Aug. 1385, and subsequently on three occasions acted as regent of England. He held a parliament in 1395, and he was again serving as regent when Henry of Lancaster landed in England in 1399. After a feeble attempt to defend the interests of the absent king, York joined the victorious invader; but soon retired from public life. He died at King's Langley on Aug. 1, 1402.

YORK, EDWARD PLANTAGENET, DUKE OF (*c.* 1373–1415), elder son of the preceding (Edmund of Langley), was created earl of Rutland in 1390. Being a friend of his cousin, Richard II, he became admiral of the fleet, constable of the tower of London and warden of the Cinque Ports. He accompanied the king to Ireland in 1394 and was made earl of Cork; arranged Richard's marriage with Isabella, daughter of Charles VI of France; and was one of the king's helpers in the proceedings against the "lords appellant" in 1397. He became constable of England and obtained the lands in Holderness previously belonging to Thomas of Woodstock, duke of Gloucester, together with other estates and the title of duke of Aumerle or Albemarle. He deserted Richard in 1399, and in Henry IV's first parliament he was denounced as the murderer of Gloucester. He was reduced to his former rank as earl of Rutland, and deprived of his recent acquisitions of land. It is uncertain what share Rutland had in the conspiracy against Henry IV in Jan. 1400, but he was probably not seriously involved. He served as royal lieutenant in Aquitaine and in Wales and became duke of York on his father's death in 1402. He was concerned in the scheme, concocted in 1405 by his sister Constance, for seizing the young earl of March and his brother Roger Mortimer and carrying them into Wales, and he was imprisoned in Pevensey castle. Released a few months later, he was restored to the privy council and regained his estates. York led one division of the English army at Agincourt, where, on Oct. 25, 1415, he was killed by "much hete and thronggid." He was buried in Fotheringhay church.

YORK, FREDERICK AUGUSTUS, DUKE OF (1763–1827), second son of George III., was born at St. James's Palace on Aug. 16, 1763. At the age of six months his father secured his election to the rich bishopric of Osnabrück. He became a knight of the Bath in 1767, a K.G. in 1771, and was gazetted colonel in 1780. From 1781 to 1787 he lived in Germany. He was appointed colonel of the 2nd horse grenadier guards in 1782, and promoted major-general and appointed colonel of the Coldstream Guards in 1784.

He was created duke of York and Albany and earl of Ulster in 1784, but retained the bishopric of Osnabrück until 1803. On his return to England he took his seat in the House of Lords, where, on Dec. 15, 1788, he opposed Pitt's Regency bill in a speech which was supposed to have been inspired by the prince of Wales. A duel fought on Wimbledon Common with Colonel Lennox, afterwards duke of Richmond, served to increase the duke of York's popularity. In 1791 he married Princess Frederica (b. 1767), daughter of Frederick William II. of Prussia. The princess was enthusiastically received in London, but the marriage was not happy, and a separation soon took place; the princess retired to Oatlands Park, Weybridge, where she died on Aug. 6, 1820.

In 1793 the duke of York was sent to Flanders in command

of the English contingent of Coburg's army. (*See* FRENCH REVOLUTIONARY WARS.) On his return in 1795 the king promoted him field-marshal, and on April 3, 1798, commander-in-chief. He then led the army sent to invade Holland in conjunction with a Russian *corps d'armée* in 1799. From the time of the duke's arrival with the main body of the army, disaster followed disaster until, on Oct. 17, the duke signed the convention of Alkmaar, by which the allied expedition withdrew after giving up its prisoners. Although unsuccessful as commander of a field army the duke devoted himself with the greatest vigour and success to reforms at home until his enforced retirement from the office of commander-in-chief on March 18, 1809. In the proceedings for bribery in connection with Mary Anne Clarke (*q.v.*) the duke was acquitted of having received bribes himself by 278 votes to 196. In May 1811, he was again placed at the head of the army by the prince regent, and rendered valuable services. He died on Jan. 5, 1827, and was buried at St. George's Chapel, Windsor.

A firm friendship existed between the duke and his elder brother, afterwards George IV., and he was also his father's favourite son. He founded the Duke of York's school for the sons of soldiers at Chelsea, and his name is also commemorated by the Duke of York's column in Waterloo place, London.

YORK, RICHARD, DUKE OF (1411–1460), was born on Sept. 21, 1411, the son of Richard, earl of Cambridge. He became duke of York in 1415, and on the death of Edmund Mortimer in 1425 he represented in the female line the elder branch of the royal family. He had been kindly treated by Henry V., and his name appears at the head of the knights made by Henry VI. at Leicester on May 19, 1426. York served in France (1430–31), and in 1432 he obtained livery of his lands and went over to Ireland to take possession of his estates there. In Jan. 1436 he was appointed lieutenant-general of France and Normandy. He showed vigour and capacity, and recovered Fécamp and other places in Normandy. He was not supported cordially by the home Government, and in 1437 applied to be recalled. York returned to England in the autumn of 1437. From this time he attached himself to Humphrey of Gloucester's party, in opposition to the Government under Cardinal Beaufort. By his marriage in 1438 to Cicely, sister of the earl of Salisbury, he allied himself to the rising family of the Nevilles. On July 2, 1440, York was again appointed to the French command. His previous experience made him stipulate for full powers and a sufficient revenue. He did not go to Rouen till June 1441. During his second governorship York maintained the English position in Normandy. Hampered by his political opponents at home, he was recalled in 1446 on the pretext that his term of office had expired.

The death of Humphrey of Gloucester in 1447 made York the first prince of the blood. Suffolk, now Henry's chief minister, found a convenient banishment for a dangerous rival by appointing York to be lieutenant of Ireland for ten years (Dec. 9, 1447). York, however, put off his departure for 18 months.

During his absence Jack Cade's rebellion occurred. In Sept. 1450 York landed in Wales, came to London with an armed retinue and forced himself into the king's presence. He declared that he desired only justice and good government. He took part in the punishment of Cade's supporters, and discountenanced a proposal in parliament that he should be declared heir to the crown. In March 1452 he came once more in arms to London, and endeavoured to obtain Somerset's dismissal. On a promise that his rival should be held in custody he disbanded his men, and, thus outwitted, found himself virtually a prisoner. However, a nominal agreement was concluded, and York accepted the king's pardon. The situation was changed by the birth of a prince of Wales and the king's illness in Oct. 1453. York secured his recognition as protector on March 27, 1454. But at the end of the year the king's sudden recovery brought York's protectorate to an end.

When it was clear that the queen and Somerset would proceed to extremities, York and his friends took up arms in self-defence. Even when the two armies met at St. Albans, York endeavoured to treat for settlement. The issue was decided by the defeat and death of Somerset on May 22, 1455. York used his success with moderation. He became constable of England, and his friends obtained office. This was no more than a change of ministers. But a return of the king's illness in Oct. 1455 made York again for a brief space protector. Henry recovered in Feb. 1456, and at Coventry, in October, the Yorkist officials were displaced. Still there was no open breach. York would not again accept honourable banishment to Ireland, but made no move till the queen's preparations forced him to act. In Sept. 1459 both parties were once more in arms. York protested that he acted only in self-defence, but the desertion of his best soldiers at Ludlow on Oct. 12 left him helpless. With a few followers he escaped to Ireland, where his position as lord-lieutenant was confirmed by an Irish parliament, and he ruled in full defiance of the English government. In March 1460 the earl of Warwick came from Calais to concert plans with his leader. York landed in England on Sept. 8, and marched on London. On reaching Westminster, he took up his residence in the royal palace, and formally asserted his claim to the throne in parliament. A compromise was arranged; Henry was to retain the crown for life, but Richard was to succeed him. On Nov. 8, he was accordingly proclaimed heir-apparent and protector. Early in December, Richard went north with a small force. On Dec. 30, he was hemmed in by a force of Lancastrians at Wakefield. Declaring that he had never kept castle in the face of the enemy, Richard rashly offered battle, and was defeated and slain. His enemies had his head cut off, and set it up on the walls of York adorned with a paper crown.

Richard of York was not a great statesman, but he had qualities of restraint and moderation, and might have made a good king. He had four daughters and four sons. Edmund, earl of Rutland, his second son, was killed at Wakefield. The other three were Edward IV., George, duke of Clarence, and Richard III.

YORK, a county and parliamentary borough, archiepiscopal city, county town of Yorkshire and county in itself, on the L.N.E.R., 188 mi. N.W. of London. Pop. (est. 1938) 100,800; area 10.9 sq.mi. It is situated in the low lying vale of York at the junction of the Ouse with the Foss. It lies at the crossing of the two most important natural routes of the region, the north-south waterway formed by the Ouse and the east-west landway on the York moraine ridge through which the river has cut a gap. The town is thus well above flood level, and at the head of the tidal part of the Ouse before the regulation of the river in the 18th century. The tides are now felt 7 mi. downstream from York. York may have been a British settlement. As Eboracum or Eburacum it was the military capital of Roman Britain, the fortress of Legio IX and later of Legio VI. Victrix being situated near the site of the cathedral on the defensive land between the Ouse and the Foss, a municipality (*colonia*) grew up on the opposite side of the Ouse. The emperor Hadrian visited York in 120 and, according to tradition, the body of the emperor Severus, who died there in 211, was burned on Severus hill near the city. After the death of Constantinus Chlorus, which also took place in York, his son, Constantine the Great, was inaugurated emperor there. In 314, a bishop of York is mentioned together with, and with precedence of, a bishop of London, as present at the council of Arles. Nothing is known of the history of the city from the time the Romans withdrew from Britain in 410 until 627 when King Edwin was baptized there, though two years earlier, Paulinus, the first archbishop, had been consecrated. York became the capital of the Angle kingdom of Northumbria and when in the 7th century Britain was divided into two archiepiscopal provinces, York was made the capital of the northerly one, and still remains the ecclesiastical capital of the northern province which now does not include Scotland. In the years 732 to 766, York became one of the most celebrated places of education in Europe. The Danish kingdom of York was formed from that part of Angle Northum-

bria to the south of the Tees and later, when the country was organized into shires by the West Saxon kings, the remoteness of this region hindered organization which was possible in the south and it became first a vassal state and later one shire. The city was taken by Harold Hardrada in 1066. The fortress built there by William the Conqueror in 1068 was stormed by the men of the north of England who put to death the whole of the Norman garrison. In revenge, the Conqueror burned the town and laid waste the country between the Humber and the Tees. York was an important calling place on the route to Scotland, and several councils were held there by the English kings, the first being that of 1175, when William the Lion, king of Scotland, did homage to Henry II. The Council of the North was established in York in 1537 after the suppression of the Pilgrimage of Grace. During the Civil War, York was garrisoned by Royalists. It was besieged by parliament in 1642 and surrendered after Marston Moor.

York is not mentioned in Domesday survey. The first charter, which is undated, was given by Henry II granting the citizens a merchant guild and all the free customs which they had in the time of Henry I. In 1194 Richard I granted exemption from toll throughout the kingdom and in 1200 King John confirmed the preceding charters and in 1212 granted the city to the citizens at a fee-farm of £160 a year. Richard II conferred the title of lord mayor in 1389, and in 1396 the city was made a county of itself and the burgesses were given power to elect two sheriffs. The town was incorporated in 1464, and in 1473 the citizens were directed to choose a mayor from among the aldermen. As this led to constant disputes, Henry VII arranged that a common council, consisting of two men from each of the more important guilds and one from each of the less important ones, should elect the mayor. The city is governed under a charter of Charles II confirming that of 1464. It was represented in parliament by two members from 1295 to 1918, when the number was reduced to one.

Numerous remains of Roman occupation have been found, including the Multangular tower whose base is of mingled stone and brick work. It was at the western corner of the fortress and formed part of the reconstruction of Constantine in about 300. In 1925 a systematic excavation was undertaken at the eastern corner of the fortress, which had been covered by a mound since Norman times. It proved to be of older date, the earliest finds dating back probably to 71. This corner formed probably the earliest building of the fortress and around it was placed a rampart of clay, surrounded by a wooden palisade. Remains of the clay rampart and some of the post holes of the palisade have been found and in the basement chamber of the corner tower part of the rampart is still visible. The fortress was first girded with a stone wall in about 105–108 and a fragment of this may be seen. There was possibly some reconstruction in 120. In 180 a great rising against the Romans took place in the north and among other forts York suffered. Great damage was done at the east corner and the old wall had to be rebuilt. Excavations also show that towers were built along the wall, probably at intervals of 45 yards. Remains of a Roman gateway have been found in the northeast rampart.

The cathedral of St. Peter, commonly known as the minster, is in the form of a Latin cross, consisting of nave with aisles, transepts, choir with aisles, a central tower and two west towers. It occupies the site of the wooden church in which King Edwin was baptized by Paulinus on Easter Day 627. Following his baptism, Edwin began to build a church in stone, but it was partly destroyed during the troubles which followed his death. It was repaired but suffered from fire in 741. At the time of the Norman invasion the Saxon cathedral with the archbishop's library perished in the fire by which the greater part of the city was destroyed, the only relic remaining being the central wall of the crypt. It was reconstructed in 1070–1100, but of this building few portions remain. The apsidal choir and crypt were rebuilt in 1154–81, the south transept in 1216–55, and the north transept and central tower in 1228–56. With the exception of the crypt the early English transepts are the oldest portions of the building now remaining. The south transept is the richest and most elaborate in its details, one of its principal features being the magnificent rose window; the north transept contains a famous series of lancet windows called the "Five Sisters," with specially fine glass. The foundation of the new nave was laid in the last years of the 13th century and the work was completed about 1340; the chapter house was built about the same period. The Lady chapel and presbytery were begun in the early Perpendicular style in 1361. The rebuilding of the choir was begun at the same period, but was not completed until about 1400. It is late Perpendicular, with a very fine great east window. During this rebuilding, the whole of the ancient Norman edifice was removed and the only Norman architecture now remaining is the east portion of the crypt of the second period. To correspond with the later alterations the central tower was recased and changed into a Perpendicular lantern tower in 1444. The southwest tower was begun in 1432, and the northwest tower in 1470, and with the erection of this tower, the church was completed as it now stands; it was reconsecrated on Feb. 3, 1472. The woodwork of the choir was burned in 1829 and in 1840 the southwest tower was reduced to a mere shell by fire.

The stained glass, both in the cathedral and in other churches of the city, is famous; its survival may be traced to the stipulation made by the citizens, when surrendering to parliament in the Civil War, that it should not be damaged. During World War I, when some of the most precious mediaeval glass was removed to a position of safety, it was found that owing to the corrosive effect of the atmosphere, it was necessary to clean each quarry; and lead lights now in many instances replace stone mullions. All the 109 stained glass windows were later renovated, including the 13th-century grisaille glass of the "Five Sisters" window, the cost of which was borne by the women of the country as a national memorial to the women of the empire who gave their lives in World War I.

St. Mary's abbey situated in the present museum gardens was founded for Benedictines in 1078; its head ranked as a mitred abbot with a seat in parliament. The principal remains of the abbey are the north wall and the ruins of the church in Early English and Decorated styles, and the principal gateway with a Norman arch. They lie outside the walls near the cathedral. The hospitium, built in the 14th and 15th centuries with its upper part of wood, houses the collection of Roman antiquities.

York also possesses a large number of churches of special architectural interest including All Saints, North street, Early English, Decorated and Perpendicular, with a spire 120 ft. in height; Christ church with south door in Decorated style, supposed to occupy the site of the old Roman palace; Holy Trinity, Micklegate, formerly a priory church, now restored, showing Roman masonry in its walls; St. Denis, Walmgate, with rich Norman doorway and Norman tower arches; St. Margaret's, Walmgate, celebrated for its curiously sculptured Norman porch and doorway; St. Mary the Elder, Bishophill, Early English and Decorated, with brick tower, rebuilt in 1659; St. Mary the Younger, Bishophill, with a square tower in the Saxon style, rebuilt probably in the 13th century; St. Mary, Castlegate, with Perpendicular tower and spire 154 ft. in height, the body of the church dating back to transitional Norman times; St. Martin's-le-Grand, fine Perpendicular; and St. Martin's-cum-Gregory, Early English and Perpendicular.

The ancient city is enclosed by walls dating in part from Norman times, but they are, in the main, of the 14th century. Their circuit is a little over $2\frac{1}{2}$ mi. and the area enclosed is divided by the river Ouse, the larger part lying on the left bank. On the east for a short distance the Foss takes the place of a wall. The walls are pierced by four principal gates or bars. On the southwest is Micklegate bar, a square tower built over a circular, probably Norman, arch, and with embattled corner turrets on which the heads of traitors were formerly exposed. Bootham bar, the main entrance from the north, also has a Norman arch. Monk bar on the northeast, at one time known as Goodramgate bar, has borne its present name since at least as early as 1370. Malmgate bar retains the barbican which was repaired in 1648.

Of the castle built by the Conqueror, in 1068, in the angle between the Ouse and the Foss, some portions were probably incorporated in Clifford's tower, the shell of which, showing an unusual ground plan of four intersecting circles, rises from an artificial mound. From 1826 to 1936 the castle was used as a prison, but many of the prison buildings have been demolished and others are used as a museum and offices.

St. William's college, near the minster, was founded in 1453 as a college for priests holding chantries in the minster; its restoration as a church house and meeting place for convocation was undertaken in 1906. The Merchant Adventurers hall (1357), a building with half-timbered work, has been restored. York is a great railway centre and has a distinguished railway museum. Damage caused by air raids in World War II included the destruction of the Guildhall (1446) and the church of St. Martin-le-Grand, and injury to St. Peter's and Bootham schools.

The county borough was created in 1888. The division of Yorkshire into three administrative counties has deprived York of its position as a civil capital. The city and the Ainsty (a district on the southwest included in the city bounds in 1449) are, for parliamentary purposes, in the North Riding; for registration purposes in the East Riding; and for all other purposes in the West Riding. The parliamentary borough extends into the East Riding. York is the headquarters of the northern command.

YORK, a town of York county, Maine, U.S.A., on the Atlantic coast, 45 mi. S.W. of Portland; served by motorbus lines connecting with the Boston and Maine railroad. Pop. (1930) 2,532; in 1940 it was 3,283. The town embraces the widely known summer resorts of York Beach and York Harbor and several other villages. The first settlement was made about 1624. In 1641 Sir Ferdinando Gorges made it the borough of Agamenticus, which in 1642 he chartered as the city of Gorgeana. In 1652, when Massachusetts extended her jurisdiction over Maine, it became the town of York. In 1692 most of the houses were destroyed by Indians and the inhabitants killed or taken captive. York was the shire-town of Yorkshire from 1716 to 1735; of the district of Maine from 1735 to 1760 (together with Falmouth, now Portland); and a county seat of York county from 1760 to 1832. In the 18th century York had a considerable trade with the West Indies and along the coast, and as late as the middle of the 19th century it had important fishing interests. Development as a summer resort began about 1873.

YORK, a city of southeastern Pennsylvania, U.S.A., the county seat of York county; on federal highways 30 (the Lincoln) and 111, 90 mi. W. of Philadelphia and 28 mi. S. by E. of Harrisburg. It is served by the Maryland and Pennsylvania, the Pennsylvania and the Western Maryland railways. Pop. (1920) 47,512 (94% native white); 1940 federal census (excluding contiguous boroughs) 56,712. The city's area of 4.1 sq.mi. is built up closely and there are populous industrial districts just outside the corporate limits in several directions. The streets in the central part of the city (laid out in 1741 in a bend of Codorus creek, by a surveyor for the Penns) bear such names as King, Queen, Duke, Princess and George, and the city itself was named after the English York. Penn common was set aside for the public in the original plan. The Quaker meeting house was erected in 1765, and there are several old burying grounds. The building used by Gen. Wayne for his headquarters while recruiting his brigade for the march on Yorktown still stands, in the heart of the city, and in Farquhar park there is a copy of the Provincial court house in which the Continental Congress held its sessions. The city's assessed valuation for 1940 was $48,876,000. Since 1912 it has had a commission form of government. York is the commercial centre of a rich agricultural region, and it has many large and diversified manufacturing industries. In 1936 the product of 226 factories in the city was valued at $67,437,000. Bank debits in 1940 aggregated $295,086,178.

York was the first permanent settlement in Pennsylvania west of the Susquehanna. It was laid out in 1741 in the centre of Springettsbury manor, a tract of 64,000 ac. granted to Springett Penn (a grandson of William Penn) in 1722. The first settlers were chiefly Germans from the Rhenish Palatinate (Lutherans, Reformed, Mennonites and Moravians), with some English Quakers and Scotch-Irish. The village was on the Monocacy road, the main route to the South and the South-west, and grew rapidly. When York county was erected in 1749 it was made the county seat, and by 1754 it had 210 houses and a thousand inhabitants. In 1777, when the British approached Philadelphia, the Continental Congress left the city, and after holding one day's session in Lancaster, crossed the Susquehanna to York and made it the national capital from Sept. 30, 1777, to June 27, 1778. In the old county court-house (built 1754–56 and torn down in 1849) the Congress passed the Articles of Confederation, received the news of Burgoyne's surrender, issued the first national Thanksgiving proclamation, received word from Franklin in Paris that France would aid with money, ships and men, received Von Steuben and Lafayette and commissioned them as major-generals. It was in York that the Conway Cabal was frustrated by Lafayette. Here $1,500,000 in silver, lent by France, was brought in Sept. 1778, and here Benjamin Franklin's printing press, moved from Philadelphia, issued $10,000,000 of Continental money. During the Civil War Confederate troops entered the town on June 28, 1863, and a small Federal force retreated before them. York was incorporated as a borough in 1787 and as a city in 1887.

YORKE, CHARLES (1722–1770), English lord chancellor, second son of Philip Yorke, was born in London on Dec. 30, 1722, and was educated at Corpus Christi college, Cambridge. In 1745 he published a treatise on the law of forfeiture for high treason; in 1746 he was called to the bar. Yorke obtained a sinecure appointment in the Court of Chancery in 1747, and became M.P. for Reigate. In 1751 he became counsel to the East India Company, and in 1756 solicitor-general. He resigned with Pitt in 1761, but in 1762–3 was attorney-general under Lord Bute. Resisting Pitt's attempt to draw him into alliance against the ministry he had quitted, Yorke maintained that parliamentary privilege did not extend to cases of libel; though he agreed with Pitt in condemning the principle of general warrants. Yorke became recorder of Dover in 1764, and in 1765 again became attorney-general in the Rockingham administration. He supported the repeal of the Stamp Act, while urging the simultaneous passing of the Declaratory Act. He drew up the constitution for Quebec. In 1767, Yorke resigned office. In 1770 he was invited by the duke of Grafton to take Camden's seat on the woolsack, but was pledged not to take office with Grafton. However, Yorke yielded to the king's entreaty, met the leaders of the Opposition on Jan. 17, and, overwhelmed with shame, fled to his own house, where he died on Jan. 20. The patent raising him to the peerage as Baron Morden had been made out, but his last act was to refuse his sanction to the sealing of the document.

YORKSHIRE, a north-eastern county of England, bounded by Durham, the North sea, the Humber estuary (separating it from Lincolnshire), Nottinghamshire, Derbyshire, Cheshire, Lancashire and Westmorland. It is the largest county in England, having an area of 6,089.7 sq.mi. and being more than double the size of Lincolnshire, which ranks next to it. In a description of the county it is constantly necessary to refer to its three great divisions, the North (2,127.4 sq.mi.), East (1,172.1 sq.mi.) and West (2,790.2 sq.mi.) Ridings.

Physical Features.—The county of Yorkshire can be divided into four upland tracts separated by lowland areas. These lie in the south-west, north-west, north-east and south-east quadrants of the county respectively. The great Yorkshire plain, drained by the Yorkshire Ouse (*q.v.*), stretches from the river Tees, which forms the northern boundary of the county, through the Vale of Mowbray, Vale of York and Vale of Ouse to the Trent basin in

the south. The Ouse divides the county into an eastern and a western division; whilst the "Aire Gap" separates the north Pennine moors from the south Pennine moors, and on the eastern side the Vale of Pickering separates the north Yorkshire moors from the Yorkshire Wolds. The north Pennine moors, which stretch northwards beyond the limits of the county, form a high moorland tract of Carboniferous limestone and Yoredale beds capped by millstone grit. The rocks have a very small dip eastward but are fractured by a series of faults, the most important being the Craven faults from Kirkby Lonsdale by Ingleton, Stainforth and Linton. There are also inliers of Ordovician and Silurian rocks at Horton and at Sedbergh.

The chief valleys are Teesdale, Swaledale, Wensleydale, Nidderdale, Wharfedale and Airedale. The chief peaks are Mickle Fell (2,591 ft.), Whernside (2,414 ft.), Ingleborough (2,373 ft.), Buckden Pike (2,302 ft.) and Penyghent (2,273 ft.). The "Aire Gap," which forms the gateway between north Lancashire and Yorkshire, has been followed by roads, railways and canals. The south Pennine moors are formed of millstone grit, which has been arched upwards approximately along the county boundary and the coal measures are preserved along the eastern and western flanks. The uplands are bleak grouse moors in which the feeders of the rivers Aire, Calder and Don, have carved out valleys across the northern portion of the Yorkshire, Derby and Notts coal-field. Between the Yorkshire plain and the Pennines there is a belt of magnesian limestone, which, lying across various members of the Carboniferous, forms a well marked scarp-face toward them in the southern half of the county. The country along this belt forms a marked contrast with the districts of Palaeozoic rocks on the west, for the limestone produces a rich soil, the effect of which is seen in a luxuriant vegetation.

On the south the alluvium-filled Vale of Pickering marks the site of an ancient lake and the river Derwent, which drains the vale, has broken its way through the Jurassic ridge of the Howardian hills to reach the Vale of York. In this south-eastern quadrant the chalk forms the Yorkshire Wolds and has a general dip towards the south-east thus forming scarp edges from Flamborough Head, along the south side of the Vale of Pickering and sweeping round in a broad arc toward Market Weighton. This ridge of higher ground is continued southward across the Humber into the Lincolnshire Wolds. The north Yorkshire moors rise immediately from the coast and form cliffs for the most part, whilst to the south of Flamborough Head the cliffs disappear beneath the low-lying drift-covered Holderness. There are several watering-places along the coast; the principal are Redcar, Saltburn-by-the-Sea, Whitby, Robin Hood's bay, Scarborough, Filey, Bridlington and Hornsea. There are numerous mineral springs in Yorkshire, the principal being at Harrogate.

Minerals.—The coal-field in the West Riding is one of the chief sources of mineral wealth in Yorkshire, the most valuable seams being the silkstone, which is bituminous and of the highest reputation as a house coal, and the Barnsley thick coal, the great seam of the Yorkshire coal-field, which is of special value, on account of its semi-anthracitic quality, for iron-smelting and engine furnaces. Associated with the upper coal measures are iron-ores, occurring in the form of nodules. Brick-clay, pottery-clay and fire-clay are also raised, as well as gannister and oil-shale. Middlesbrough is the most important centre of pig-iron manufacture in the kingdom. Lead-ore occurs in the Yoredale beds of the north Pennine moors, and flagstones are quarried in the Yoredale rocks. In the millstone grit there are several beds of good building stone, but that most largely quarried is the magnesian limestone of the Permian series.

Archaeology.—In spite of the importance of the Creswell caves in Derbyshire for Palaeolithic remains, Yorkshire has very little to show until the end of that stage, and remains which belong typologically to this period may actually date from a considerably later period. In this connection we note objects from the Victoria cave, Settle, and from Holderness. Petch has made special studies of the pigmy flints of south Yorkshire and has found large numbers of sites all above the 1,000 ft. contour line. (*See* J. A. Petch, *Early Man in the District of Huddersfield* [Huddersfield, 1924].) Implements of Late Neolithic type are found almost all over the county, and such implements, made of finely chipped flints, are especially characteristic of the district behind Scarborough and the Yorkshire Wolds, which henceforth stands out as an especially important region in prehistoric times. The Yorkshire Wolds are one of the chief regions of Britain for round barrows and Beaker pottery, while remains of the Bronze age abound both here and in the Aire gap. The north Yorkshire moors are in process of detailed study by Elgee. On the moors above Ilkley are interesting traces of an apparently megalithic culture, with large stones decorated with cup and ring markings, supposed swastikas, etc. Three decorated chalk drums from Folkton Wold are important, showing southern and probably Iberian influence. Jet ornaments are another feature. The rarity of Bronze age finds in the central Ouse basin is a noteworthy feature. The Yorkshire Wolds yield abundant evidences of early Iron age finds, and important settlements have been located near Arras and Hessleskar farms, 3 m. E. of Market Weighton. The finds in these regions show affinities with those of the period on the English plain and in north-eastern Gaul.

History.—By Roman times the Vale of York had become important and carried the north road. From Lindum (Lincoln) the main road ran north-west to Danum (Doncaster) and thence to Legiolium and Calcaria (Tadcaster), thence branching off to Eburacum (York, *q.v.*), the Roman capital of the north. The main road continued through the Vale of York from Calcaria past Isurium to Cataractorium (Catterick Bridge) and thence over the Tees to the north.

In the 6th century, an Anglian tribe having seized the promontory at the mouth of the Humber, named by the invaders Holderness, gradually subjugated the East Riding. The earliest settlements were chiefly confined to the rich valley of the lower Derwent, but the district around Weighton became the sacred ground of the kingdom which was named Deira, and Goodmanham is said to mark the site of a temple. Ella, the first king of Deira, extended his territory north to the Wear, and his son Edwin completed the conquest of the district which was to become Yorkshire. Traces of the "burhs" by which Edwin secured his conquests are perhaps visible in the group of earthworks at Barwick and on the site of Cambodunum, but the district long remained scantily populated. The defeat of Edwin at Hatfield in 633 was followed by a succession of struggles between Mercia and Northumbria for the supremacy over Deira. After the Danish conquest of Deira, Guthrum in 875 portioned the district among his followers, under whose lordship the English retained their lands. Cleveland came under Scandinavian influence, and the division into tithings probably originated about this date, the boundaries being arranged to meet at York, the administrative centre which, by A.D. 1000, had a population of over 30,000. At the battle of Stamford Bridge in 1066 Harold Hardrada, who had seized York, and Earl Tosti were defeated and slain by Harold of England.

For many years after the harrying of the country by the Conqueror all the towns between York and Durham lay uninhabited. In 1138 David of Scotland was defeated near Northallerton in the battle of the Standard. In the barons' wars of the reign of Henry II. Thirsk and Malgeard castles were captured and demolished. Robert Bruce in 1318 destroyed Northallerton, Boroughbridge, Scarborough and Skipton. In 1322 at the battle of Boroughbridge, the rebel barons were defeated by the forces of Edward II. In 1399 Richard II. was murdered in Pontefract castle. In 1408 the rebel forces of the earl of Northumberland were defeated at Bramham moor near Tadcaster. In 1453 a skirmish at Stamford Bridge was the opening event in the struggle between the houses of York and Lancaster; in 1460 the duke of York was defeated and slain at Wakefield; in 1461 the Lancastrians were defeated at Towton. The suppression of the monasteries roused deep resentment in Yorkshire, and the inhabitants flocked to join the Pilgrimage of Grace. On the outbreak of the Civil War of the 17th century, opinion was divided in Yorkshire. Sir William Savile captured Leeds and Wakefield for the king in 1642, and in 1643 Newcastle, having defeated the Fairfaxes at Adwalton moor, held all Yorkshire except Hull. In 1644, how-

ever, the Fairfaxes secured the East and West Ridings, while Cromwell's victory at Marston moor was followed by the capture of York, and in the next year of Pontefract and Scarborough.

On the redistribution of estates after the Norman Conquest, Alan of Brittany, founder of Richmond castle, received the honour of Richmond, and Ilbert de Laci the honour of Pontefract. Earl Harold's estate at Coningsburgh passed to William de Warenne, earl of Surrey, together with Sandal castle, which in the 14th century was bestowed on Edmund Langley, duke of York. Other Domesday landholders were William de Percy, founder of the abbey of Whitby; Robert de Bruce, ancestor of the royal line in Scotland; Roger de Busli; the archbishop of York enjoyed the great lordship of Sherburn, and Howdenshire was a liberty of the bishop of Durham.

The shire court for Yorkshire was held at York, but extensive privileges were enjoyed at various times by the great landowners. In the 13th century the diocese of York included in this county the archdeaconries of York, Cleveland, East Riding and Richmond. In 1541 the deaneries of Richmond were transferred to Henry VIII's new diocese of Chester. Ripon was created an episcopal see by act of parliament in 1836, and in 1888 the area of the diocese was reduced by the creation of the see of Wakefield, now consisting of the archdeaconries of Halifax and Pontefract, while the diocese of Ripon consists of the archdeaconries of Richmond and Leeds. The diocese of York includes the archdeaconries of York, East Riding and Cleveland. The bishoprics of Sheffield and Bradford were created in 1914 and 1919 respectively, the former containing the archdeaconries of Sheffield and Doncaster and the latter those of Craven and Bradford.

The woollen industry began after the Conquest, and historical details may be found under LEEDS, BRADFORD, etc. The time of the American Revolution marked the gradual absorption by Yorkshire of the clothing trade from the eastern counties. Coal appears to have been used in Yorkshire by the Romans, and was dug at Leeds in the 13th century. The early fame of Sheffield as the centre of the cutlery and iron trade is demonstrated by a line in Chaucer. In the 13th century forges are mentioned at Rosedale and at Gisburn. In the 16th century limestone was dug in many parts of Elmet, and Huddlestone, Hesselwood and Tadcaster had famous quarries; Pontefract was famous for its liquorice, Aberford for its pins, Whitby for its jet. Alum was dug at Guisborough, Sandsend, Dunsley and Whitby in the 17th century. Bolton market was an important distributive centre in the 17th century, and in 1787 there were 11 cotton mills in the county.

Architecture.—Of ancient castles Yorkshire retains many interesting examples. The fine ruins at Knaresborough, Pickering, Pontefract, Richmond, Scarborough and Skipton are described under their respective headings. Barden tower, picturesquely situated in upper Wharfedale, was built by Henry de Clifford (d. 1523). Bolton castle, which rises above Wensleydale, is a square building with towers, erected in the reign of Richard II by Richard Scrope; it was rendered untenable in 1647. Of Bowes castle near Barnard castle, there remains only the square keep. Cawood castle, near Selby, retains its gateway tower erected in the reign of Henry VI. Conisborough castle stands by the Don between Rotherham and Doncaster. The ruins of Danby castle are of various dates. Harewood castle in lower Wharfedale contains no portions earlier than the reign of Edward III. The keep of Helmsley castle was built late in the 12th century. Other remains are:—The fortress of Middleham, Mulgrave castle, Ravensworth castle, Sheriff Hutton castle, Spofforth castle, Tickhill castle, Whorlton castle, the fortress of Wressell, the mansions Gilling, Ripley, Skelton and the Elizabethan hall of Burton Agnes.

In ecclesiastical architecture Yorkshire is extraordinarily rich. At the time of the Dissolution there were 28 abbeys, 26 priories, 23 nunneries, 30 friaries, 13 cells, 4 commanderies of Knights Hospitallers and 4 preceptories of Knights Templars. The principal monastic ruins are described under separate headings and elsewhere. These are Bolton abbey (properly priory), a foundation of Augustinian canons; Fountains abbey, a Cistercian foundation, the finest and most complete of the ruined abbeys in England; the Cistercian abbey of Kirkstall near Leeds (*q.v.*); the Cistercian abbey of Rievaulx, and the Benedictine abbey of St. Mary, at York. Separate reference is also made to the ruins of Jervaulz (Cistercian) and Coverham (Premonstratensian) in Wensleydale, and to the remains at Bridlington, Guisborough, Malton, Whitby, Easby near Richmond, Kirkham near Malton, Monk Bretton near Barnsley, and Mount Grace near Northallerton. There are fine though scanty remains of Byland abbey, of Early English date, between Thirsk and Malton. There was a house of Premonstratensians at Egglestone above the Tees near Barnard castle. Other ruins are the Cistercian foundations at Meaux in Holderness, Roche, east of Rotherham, and Sawley in Ribblesdale; the Benedictine nunneries of Marrick, and Rosedale; and the Gilbertine house of Watton in Holderness.

Agriculture and Manufactures.—Nearly 87% of the East Riding was under cultivation in 1939, but of the North and West Ridings only about 60% and 58% respectively. The boulder-clay of Holderness forms the richest soil in Yorkshire, and the chalk wolds, by careful cultivation, form one of the best soils for grain crops. The central plains bear all kinds of crops excellently. Oats are grown in all three ridings, but wheat is the principal crop, though the area planted in the North Riding is less than half that in the east. Barley is extensively grown in the East and North Ridings. The bulk of the acreage under green crops is devoted to turnips and swedes, but potatoes form an important crop, especially in the West Riding. The next crop is sugar beet, grown most in the East Riding, the total acreage in 1939 being 27,158. Liquorice is cultivated near Pontefract. The proportion of hill pasture is greatest in the North Riding and least in the East, and the North and West are among the principal sheep-farming districts in England.

The industrial district of south Yorkshire is situated on the northern half of the Yorkshire, Derby and Notts coalfield. The West Riding is the chief seat of the woollen manufacture of the United Kingdom and has almost the monopoly in the production of worsted cloths. The early development of the industry was in part due to the rearing of sheep on the moors and to the abundance of water-power, while later the presence of coal further established it, but now most of the wool used is imported from abroad. The industry engages the most important towns. Almost every variety of woollen and worsted cloth is produced at Leeds; Bradford is especially concerned with worsted stuffs and alpacas; Batley with shoddy; Huddersfield with fancy goods; Halifax and Dewsbury with carpets and a varied class of woollens; and Keighley with yarns. Linen manufacture is the staple industry of Barnsley, though it is also carried on at Leeds. Cotton spinning is done at Huddersfield and Todmorden. The people of the industrial part of Yorkshire are noted for their singing, and choral societies are numerous, the Leeds festival chorus being one of the greatest in England. The woollen industry flourishes in the soft-water area and gives place to the iron and steel industry south of the Calder valley. Sheffield is especially famous for the finest grades of steel, for heavy machinery, hardware, fine metal work, cutlery and plated goods. The development of the iron ore deposits of Cleveland dates only from the middle of the 19th century. In addition to a large amount raised locally, the smelters of the Middlesbrough district ordinarily import large quantities of ore from Sweden and Spain. The attendant industries such as the production of steel, shipbuilding, etc., also flourish. The chemical industry is important both here and in the West Riding where also a great variety of other industries has sprung up, such as the great leather industry at Leeds, the manufacture of clothing, printing and bleaching, and paper-making. Besides coal and iron ore, much clay, limestone and sandstone are mined. Excellent building stone is obtained in the West Riding. The sea-fisheries are important, the chief fishing ports being Hull, Scarborough, Whitby and Filey. Leeds has become a great business centre and almost a metropolis for the woollen area of the West Riding.

Communication.—Two main lines traverse the county, the L.N.E. line from London, passing through Doncaster, Selby, York, Northallerton, to Durham and the north; the other, the L.M.S. line from London and Derby to Sheffield, Leeds, Skipton, Settle and on to Carlisle. In addition to these there is a perfect network

of lines, the L.N.E. serving for the most part the north and east of Leeds and the L.M.S. the West Riding. The Pennines are crossed by the L.M.S. from Huddersfield to Manchester, Halifax to Todmorden, as well as through the "Aire gap," and by the L.N.E. from Penistone to Manchester, Northallerton to Hawes Junction and across the north-west of the county from Barnard castle to Kirkby Stephen. In the East Riding in 1943 there were 2,204 mi. of county roads and in the West Riding 3,796 mi. A complete system of canals links the centres of the southern West Riding with the sea, east and west.

Population and Administration.—The areas of the three administrative counties of the East, North and West Ridings are 1,150, 2,116 and 2,517 sq.mi. respectively, with populations estimated in 1938 at 184,630, 333,500 and 1,502,523. Wartime population movements reduced the population of the whole county between Sept. 1939 and Feb. 1941, the North and West Ridings by 3% each and the East Riding by 10%. The distribution of the population may be inferred from the table below. The city of York (pop., est. 1938, 100,800) is situated where the three ridings meet in the Ainsty of York. It was formerly independent of the three ridings but now constitutes a wapentake in the West Riding, for civil purposes.

District	Parliamentary divisions, each returning one member	Parliamentary boroughs	Number of members returned by parliamentary boroughs	County boroughs	Municipal boroughs	Urban districts
York City	..	1	1	1	..	..
West Riding	19	10	24	10	11	57
East Riding	3	1	4	1	3	6
North Riding	4	1	2	1	4	10
Totals for County	26	13	31	13	18	73

The county and boroughs of Yorkshire return a total of 57 members to parliament. Of the area of the West Riding the south industrial district, considered in the broadest sense as extending between Sheffield and Skipton, Sheffield and Doncaster, and Leeds and the county boundary, covers rather less than one half. Although the three ridings are separate administrative counties, there is but one sheriff for the whole of Yorkshire. The county is divided among the dioceses of York, Ripon, Wakefield, Sheffield, and Bradford with small parts in those of Manchester, Blackburn, Southwell and Durham. York is the seat of the northern archdiocese. The National Trust owned 1,160 ac. in Yorkshire in 1942.

YORKSHIRE ELECTRIC POWER COMPANY. A group of men in the West Riding, interested in the woollen and colliery industries, promoted a bill in 1901 which incorporated The Yorkshire Electric Power company with an authorized share capital of £2,000,000. The concern was vested with powers of supplying over a large area in perpetuity and established at Thornhill, near Dewsbury, a generating station with a capacity of 4,500 kilowatts. A supply was made available in Dec. 1904, but for many years difficulties were experienced in consequence of the conservatism of manufacturers and the opposition of vested interests.

A second generating station was established at Barugh near Barnsley, where electricity is generated by means of surplus coke oven gas. A third station was started in 1927 at Ferrybridge. The three stations, which are selected stations under the Electricity Supply Act 1926, have been enlarged from time to time, and in 1939 their combined capacity was 229,000 kilowatts. It is of interest that the system of generation and supply adopted by the company in 1903, viz., 50 cycles, three-phase alternating current, has now become the British national standard.

A large number of collieries in the West Riding and many textile mills and engineering works are now supplied by the company, and in addition over 70 local authorities and other authorized distributors are taking a bulk supply for distribution in the towns and villages. This work has been greatly facilitated by associated companies, Electrical Distribution of Yorkshire Limited, formed in 1905, and the North Lincolnshire and Howdenshire Electricity Company Limited, formed in 1932. The original capital was increased by further acts in 1922 and 1927 to £6,000,000. In 1939 the capital expenditure of the company and its associated distribution companies was over £12,000,000. (L. C. M.; X.)

YORKTOWN, a town and county seat of York county, Virginia, U.S.A., on York river 10 mi. from its mouth, and about 60 mi. E.S.E. of Richmond. In 1940 the population of Nelson district, which includes Yorktown (pop., 521) was 1,175. It is served by a steamship line, and about 6½ mi. distant is Lee Hall, a station on the Chesapeake and Ohio railway. The town is now within the boundaries of Colonial National Historical park. In the main street is the oldest custom-house in the United States, and the house of Thomas Nelson (1738–1789), a signer of the Declaration of Independence. In commemoration of the surrender of Lord Cornwallis in October 1781, there is a monument of Maine granite (100ft. 6in. high) designed by R. M. Hunt and J. Q. A. Ward; its cornerstone was laid in 1881 during the centennial celebration of the surrender, and it was completed in 1883. Yorktown was founded in 1691, as a port of entry for York county. It became the county seat in 1696, and although it never had more than about 200 houses its trade was considerable until it was ruined by the Revolutionary War. In that war the final victory of the Americans and their French allies took place at Yorktown.

Baffled by Gen. Nathanael Greene in his campaign in the Carolinas, his diminished force (fewer than 1,400) sadly in need of reinforcement, and persuaded that the more southern colonies could not be held until Virginia had been reduced, Lord Cornwallis marched out of Wilmington, N.C., on April 25, 1781, arrived at Petersburg, Va., on May 20, and there, with the troops which had been under William Phillips and Benedict Arnold and with further reinforcements from New York, raised his army to more than 7,000 men. Facing him in Richmond was Lafayette, whom Washington had sent earlier in the year with a small force of light infantry to check Arnold, and who had now been placed in command of all the American troops in Virginia. Cornwallis's first attempt was to prevent the union of Lafayette and Gen. Anthony Wayne. Failing in this, he retired down the James in the hope, it is thought, of receiving reinforcements from Gen. Henry Clinton. While Cornwallis was marching from N. Carolina to Virginia, Washington learned that a large French fleet under De Grasse was to come up from the West Indies in the summer and for a brief period co-operate with the American and French armies. At a conference on May 21 at Wethersfield, Conn., with the French commanders, Washington favoured a plan for a joint attack on New York when De Grasse should arrive. An attack on the British in Virginia was, however, considered. The minutes of the conference with some suggestions from Rochambeau having been sent to De Grasse, he announced in a letter received on Aug. 14 that he would sail for the Chesapeake for united action against Cornwallis. About the same time Washington learned from Lafayette that Cornwallis was fortifying Yorktown. Sir Samuel Hood with 14 ships-of-the-line arrived at the Chesapeake from the West Indies three days ahead of De Grasse, and proceeding to New York warned Admiral Thomas Graves of the danger. Graves took command of the combined fleet, 19 ships-of-the-line, and on Aug. 31 sailed for the Chesapeake in the hope of preventing the union of the French fleet from Newport, under Count de Barras, with that under De Grasse. He arrived at the Chesapeake ahead of De Barras, but after an encounter with De Grasse alone (September 5), who had 24 ships-of-the-line, he was obliged to return to New York to refit, and the French were left in control of the coast. Leaving only about 4,000 men to guard the forts on the Hudson, Washington set out for Virginia with the remainder of his army immediately after learning of De Grasse's plan, and the French land forces followed. The allied army was transported by water from the head of the Chesapeake to the vicinity of Williamsburg, and on Sept. 28 it marched to Yorktown. Receiving, on the same day, a despatch from Clinton promising relief, and fearing the enemy might outflank him, Cornwallis abandoned his outposts during the following night and withdrew to his inner defences, consisting of seven redoubts and six batteries connected by intrenchments, besides batteries along the river bank.

The allies, 16,000 strong, took possession of the abandoned posts and closed in on the town in a semicircle extending from Wormley Creek below it to about a mile above it, the Americans holding the right and the French the left. On the night of Oct. 5–6 the allies opened the first parallel about 600yd. from the British works, and extending from a deep ravine on the north-west to the river bank on the south-east, a distance of nearly two miles. Six days later the second parallel was begun within 300yd. of the British lines, and it was practically completed on the night of the 14th and 15th, when two British redoubts were carried by assault, one by the Americans led by Alexander Hamilton and one by the French led by Lieut.-Colonel G. de Deux-Ponts. On the morning of the 16th Cornwallis ordered Lieut.-Colonel Abercrombie to make an assault on two French batteries. He carried them and spiked 11 guns, but they were recovered and the guns were ready for service again 12 hours later. On the night of the 16th and 17th Cornwallis attempted to escape with his army to Gloucester on the opposite side of the river, but a storm ruined what little chance of success there was in this venture. In grave danger of an assault from the allies, Cornwallis offered to surrender on the 17th; two days later his whole army, consisting of 7,073 officers and men, was surrendered, and American Independence was practically assured. The British loss during the siege was about 156 killed and 326 wounded; the American and French losses were 85 killed and 199 wounded.

In 1862 the Confederate defences about Yorktown were besieged for a month (April 4–May 3) by the Army of the Potomac under Gen. McClellan. There was no intention on the part of the Confederate commander-in-chief, Joseph Johnston, to do more than gain time by holding Yorktown and the line of the Warwick river as long as possible without serious fighting, and without imperilling the line of retreat on Richmond; and when after many delays McClellan was in a position to assault with full assistance from his heavy siege guns, the Confederates fell back on Williamsburg.

See T. N. Page, "Old Yorktown," in *Scribner's Magazine* (Oct. 1881); H. P. Johnston, *The Yorktown Campaign and the Surrender of Cornwallis* (New York, 1881); A. S. Webb, *The Peninsular Campaign* (New York, 1882); J. C. Ropes, *Story of the Civil War,* vol. ii. (1898); and Jean Henri Clos, *The Glory of Yorktown* (Yorktown, 1924).

YORUBA, a people inhabiting the Ilorin and Sokoto provinces of Northern Nigeria and the Abeokuta, Ijebu, Ondo and Oyo provinces, and the Lagos district, of Southern Nigeria, and comprising the following sub-tribes: Abori, Egba-Awori, Ekiti, Eko, Ijebu, Ijesha, Jekri and Oyo. The kingship was at first hereditary but later became elective, and there were numerous ministers, officials, and eunuchs. Each province, town or village also had its chief. They are divided into clans and extended family groups, but have no age-classes except among the Ekiti. Marriage is prohibited between those whose paternal or maternal kinship can be proved. Descent was formerly matrilineal but is now patrilineal, the widows being inherited by the sons, except in the case of their own mothers. The father's property is inherited by the sons, the mother's by the daughters. There are societies of a political and religious character, having secret rites, such as the *Egungun, Oro,* and *Ogboni.* The Yoruba are cultivators, and their religion is animist; they practise divination (*Ifa*).

See P. Amaury Talbot, *The Peoples of Southern Nigeria* (1926).

YOSEMITE, a deep valley forming a portion of the canyon of the Merced river, a tributary of the San Joaquin river, in central California. It lies due east of San Francisco at a distance of about 150 miles. The floor of the valley is approximately 4,000ft. above sea level, and its walls rise abruptly 3,000 to 4,000ft. to a rolling plateau region culminating in mountain peaks 10,000 to 13,000ft. in altitude. The valley itself is about seven miles long and from half a mile to a mile wide. In addition to its extraordinary form and its enormous monolithic cliffs and domes, it is remarkable for the variety and beauty of its waterfalls and for the enchanting loveliness of its woods and flowering meadows.

Principal features are the majestic rock forms—El Capitan, Three Brothers, Yosemite Point, Royal Arches, Washington Column, North Dome, Basket Dome, Cathedral Rocks, Cathedral Spires, Sentinel Rock, Sentinel Dome, Glacier Point and the superb Half Dome, which dominates the head of the valley; and the falls of clear, sparkling water which leap into the valley in spring and early summer—Bridalveil, Ribbon, Upper and Lower Yosemite, Illilouette, Vernal and Nevada. The Upper Yosemite fall has a drop of 1,430 feet. Mirror lake, a small body of water at the foot of Half Dome, where Tenaya canyon joins the valley, is famous for its reflections, especially at sunrise, although in recent years its beauty has become impaired by the accumulation of silt and debris brought down by flood and storm. The Happy isles, a little below Vernal fall, provide secluded spots from which to review the dancing rapids of the Merced river.

History.—Yosemite valley was undoubtedly seen in 1833 by members of Captain Joseph Reddeford Walker's party of trappers, but its existence was not made known to the world until 1851, when Major James D. Savage and members of his Mariposa battalion pursued marauding Indians into their secret refuge. Lafayette H. Bunnell, a young physician who accompanied the party, appears to be the only one of the group who was impressed with the magnificent scenery. He inquired of the friendly Indian guides the name of the place and was informed that it was called after the tribe that occupied it—a name which Bunnell understood to be "Yo-sém-i-ty," meaning "grizzly bear." The following year an Army officer, in writing a report, substituted *e* for *y* as the terminal letter, thinking perhaps that the name was of Spanish origin. Later visitors heard the word as "Yo-hám-i-te," or "Yo-hém-it-e." As a matter of fact, the Indians of the valley called the grizzly bear "Oo-hóo-ma-te" or "O-hám-i-te," while a neighbouring tribe called it "Oo-soó-ma-te" or "Uh-zú-mai-tuh." In a short time the name became established in print in its present form.

The first party to enter Yosemite valley solely for the purpose of viewing its marvels and enjoying its beauties was led by James M. Hutchings in 1855. For more than thirty years Hutchings was identified with the valley, as publicizer, hotelkeeper, and official guardian. An artist, Thomas Ayres, accompanied the 1855 party. Lithographs based on his sketches were published by Hutchings. They were the first representations of Yosemite scenery to reach the public and did a great deal to spread the fame of the valley throughout the world. Until 1874 the only access to Yosemite valley was by horseback or on foot over rough, steep trails. In that year two wagon roads were completed into the valley on the north side, from Big Oak Flat and Coulterville, respectively, and in 1875 the road from Mariposa brought wagons into the valley from the south. In 1907 the Yosemite Valley railroad was completed up the canyon of the Merced river as far as El Portal, where passengers and freight were transferred to stages and wagons for the remaining fifteen miles, an ascent of 2,000 feet. Although the first automobile entered the valley in 1900, it was not until 1913 that motor travel was authorized. Aeroplanes have, on a few occasions, landed on and taken off from the valley floor, but this is now prohibited. Travel to Yosemite has increased from a maximum annual number of visitors in the years up to 1885 of less than 3,000, to 8,850 in 1908, the first year of railroad travel by El Portal, to over 30,000 in 1915, to over 100,000 in 1922, and to over 400,000 annually since 1927. At the present time a large portion of the visitors come in private automobiles, but regular schedules are maintained throughout the year by motor stages connecting with the main railroad lines and with the Yosemite Valley railroad at El Portal. During the summer a stage connects Yosemite with Lake Tahoe and with the Owens Valley stage-lines by way of the Tioga road across the Sierra. Lodges, camps, and a hotel provide a variety of accommodations to the public the year round. In recent years winter travel to Yosemite has attained large proportions.

Geologic History.—The striking evidence of enormous dynamic forces of nature everywhere visible in Yosemite valley invariably prompts the question: How was the valley formed? The first discussions of this question by scientists developed widely divergent views. Josiah Dwight Whitney, head of the first State Geological Survey of California, proposed the theory that "the bottom of the valley sank down to an unknown depth, owing to its sup-

port being withdrawn from underneath, during some of those convulsive movements which must have attended the upheaval of so extensive and elevated a chain, no matter how slow we may imagine the process to have been."—*The Yosemite Guide-book,* 1869. It took years to eradicate this explanation from guide-books and other literature of the valley. At a time when Whitney and his pupil Clarence King were making the positive statements that the peculiar formation of the Yosemite was not due to the erosive action of ice and that there was no proof that glaciers had ever entered the valley, a young naturalist who had recently come to California and become enamoured of the orderly and pure beauty of the Yosemite and its surroundings, John Muir, proclaimed with enthusiasm that glacial erosion was, in fact, the key to the whole problem. As time went on Muir's views gained support, others elaborated upon them and modified them, until today the following statement by François E. Matthes, of the U.S. Geological Survey, represents the prevailing opinion: "In neither the Yosemite nor in any other valley of its type is there evidence of any dislocation of the earth's crust. In every one of these valleys, on the other hand, there is abundant proof of powerful glacial action such as Muir recognized. To be sure, the glaciers did not reach down to the foothills, nor did they excavate the canyons in their entirety, as Muir supposed. The ice age, it is now clear, was preceded in the Sierra Nevada by long periods of canyon cutting by the streams in consequence of successive uplifts of the range."—In *Sierra Club Bulletin,* 1938. Geologists of the present century have emphasized the importance of the structure of the rock, and have enormously lengthened the estimates of time involved in the erosion process. Matthes summarizes the theory as follows: "The story of the evolution of the Yosemite valley, then, is a story of several chapters—of successive periods of valley and canyon cutting by the Merced river, induced by successive uplifts of the Sierra Nevada; of vigorous glaciation, several times repeated, during the ice age, the quarrying action of the ice being controlled and guided locally by the varying structure of the granitic rocks and giving rise to exceptionally bold, clean-cut sculptural effects; and finally of a period of dismantling, resulting in greater detail and intricacy of sculpture, the production of slopes of rock waste, and the formation of level valley floors."—*Geologic History of the Yosemite Valley,* 1930.

Yosemite National Park.—Because very largely of the activities of Whitney and his associates of the State Geological Survey, Congress enacted a law in 1864 by which Yosemite valley and the Mariposa Big Tree grove were granted to the State of California with the stipulation that "the premises shall be held for public use, resort, and recreation. . . . inalienable for all time." The grant was accepted by act of the State Legislature in 1866, a step of inestimable value in the development of State and national parks. A second and even more important step was taken when Congress responded to the pleas of John Muir, Robert Underwood Johnson, of *Century Magazine,* and others, and by act of Oct. 1, 1890, reserved and withdrew from settlement a large area of forested and mountainous land surrounding the Yosemite valley grant. There was thus established a national park enclosing within its boundaries a State park. The dual administration continued until 1906, when Congress accepted the recession of the State grant enacted by the California Legislature in 1905. Since that date the entire area has constituted the Yosemite National park, which today, after several changes in boundaries, embraces over 1,100 square miles. From 1891 to 1914 the park was administered during the summer season by troops of United States Cavalry with an officer acting as superintendent. The most important duties during that period were the ousting of bands of sheep from the mountain ranges and the apprehension of poachers. Today, under the administration of the National Park Service, acting through a civilian superintendent, the duties are primarily concerned with making available to the public the opportunities for wholesome recreation and for education in natural history and science.

Most of Yosemite National park lies within the basins of the Merced and Tuolumne rivers. Outstanding features, in addition to Yosemite valley, are Little Yosemite, Merced lake and Lake Washburn at the head of the Merced; Tuolumne meadows, Benson lake, Tilden lake, Jack Main canyon; the canyon of the Tuolumne, with its Waterwheel falls; Hetch Hetchy valley, source of water and hydro-electric power for San Francisco, granted by special act of Congress in 1913; the Mariposa, Merced, and Tuolumne groves of big trees; and a galaxy of mountain peaks, including Lyell (13,090), Dana (13,050), Conness (12,556), Tower Peak (11,704), Cathedral Peak (10,933), Unicorn (10,849), Hoffmann (10,921), Clark (11,506), and Starr King (9,081). The park is crossed by the Tioga road, originally built as a wagon-road for access to mines, now regraded as a transmountain highway.

YOSHIHITO (1879–1926), 123rd emperor of Japan, third son of the Emperor Meiji (Mutsuhito), was born at Tokyo on Aug. 31, 1879. On the eighth anniversary of his birthday the prince was proclaimed heir-apparent, the first and second sons of the emperor Meiji having died in infancy. In Sept. 1887 the prince commenced attending the Peers' school, and on Nov. 3, 1889, entered the Army and was declared imperial crown prince. Two years later he left the school to continue his studies under private tutors. In 1897 he took his seat, in accordance with prescriptive right, in the house of peers. On May 10, 1900, the crown prince married Sadako, fourth daughter of the late Prince Michitaka Kujo, and on April 29, 1901, a son, Hirohito, was born, followed by a second son, Prince Yasuhito Chichibunomiya, on June 25, 1902, and a third, Prince Nobuhito Takamatsunomiya, on Jan. 3, 1905. On July 30, 1912, on the demise of his father, the crown prince ascended the throne, but owing to the national mourning the formal ceremony of enthronement did not take place until Nov. 1914. His reign was proclaimed as the era of Taisho (Righteousness). In the following year a fourth son, Prince Takahito Suminomiya, was born on Dec. 2. Owing to the indifferent health of the emperor, whose life was a constant struggle against disease, his son Hirohito became prince regent on Nov. 25, 1921. The emperor died on Dec. 25, 1926, of heart failure following bronchial pneumonia. The reign of Hirohito, who succeeded his father as emperor, is designated the period of Showa (Light and Peace).

Prince Chichibu (Yasuhito Chichibunomiya) went to England in 1925 and studied at Magdalen college, Oxford. He married Princess Setsuko, the eldest daughter of Ambassador Matsudaira, on Sept. 28, 1928.

YOSHIZAWA, KENKICHI (1874–), Japanese diplomat, was born in Niigata-Ken. He studied English literature for his degree in the Imperial university of Tokyo. He entered the diplomatic service, was consular assistant at Amoz, South China. After two years spent at Shanghai and in London he returned to the Foreign Office in Tokyo, and was sent as secretary to the Legation in Peking. This office he held until, in 1919, he became director of the Asiatic bureau, where his experience of Far Eastern people enabled him to adjust differences between his own country and other oriental Powers. He retained this post until 1923, and was again in Peking in an official capacity when the new Russo-Japanese alliance was broached in 1924. The treaty, though opposed by many Japanese, was signed in Jan. 1925. Yoshizawa was appointed ambassador to France in 1930.

YOUGHAL (pronounced *Yawl*), a seaport and watering-place of County Cork, Ireland, on the west side of the Blackwater estuary, and on the Cork and Youghal branch of the Great Southern railway, 26¾mi. east of Cork. Pop. (1936) 5,131. Youghal was a settlement of the Northmen in the 9th century, and was incorporated by King John in 1209. The Franciscan monastery, founded at Youghal by FitzGerald in 1224, was the earliest house of that order in Ireland. Sir Roger Mortimer landed at Youghal in 1317. The town was plundered by the earl of Des-

mond in 1579. In 1641 it was garrisoned and defended by the earl of Cork. Sir Walter Raleigh was mayor of Youghal in 1588–89, and is said to have first cultivated the potato here.

YOUNG, ARTHUR (1741–1820), English writer on agriculture and social economy, second son of the Rev. Arthur Young, was born Sept. 11, 1741. After being at a school at Lavenham, he was placed in a mercantile house at Lynn, but showed no taste for commerce. He published, when only 17, a pamphlet *On the War in North America,* and in 1761 went to London to start a periodical, *The Universal Museum.* He also wrote four novels, and *Reflections on the Present State of Affairs at Home and Abroad* in 1759.

In 1768 he published the *Farmer's Letters to the People of England,* in 1771 the *Farmer's Calendar,* which went through a great number of editions, and in 1774 his *Political Arithmetic,* which was widely translated. About this time Young acted as parliamentary reporter for the *Morning Post.* He made a tour in Ireland in 1776, publishing his *Tour in Ireland* in 1780. In 1784 he began the publication of the *Annals of Agriculture,* which was continued for 45 volumes. This work had many contributors, among whom was George III, writing under the nom de plume of "Ralph Robinson." Young's first visit to France was made in 1787. Traversing that country in every direction just before and during the first movements of the Revolution, he has given valuable notices of the condition of the people and the conduct of public affairs at that critical juncture. The famous book *Travels in France* appeared in 2 vols. in 1792. On his return home he was appointed secretary of the Board of Agriculture in 1793. His sight failed, and in 1811 he had an unsuccessful operation for cataract. He died on April 20, 1820. He left an autobiography in ms., which was edited (1898) by Miss M. Betham-Edwards.

YOUNG, BRIGHAM (1801–1877), Mormon leader, born at Whittingham, Vt. (U.S.A.), June 1, 1801. He moved to Mendon, N.Y., in 1829, and three years later joined the newly organized Mormon Church. (*See* MORMONS.) He was appointed an apostle in 1835, played a leading rôle in the removal of the Mormons from Missouri to Illinois, and in 1840 was sent to Liverpool to direct Mormon missionary work in England. There he organized branch missions, established emigrating agencies and began publication of the *Millennial Star.* He returned to America two months after the death of the prophet, Joseph Smith (*q.v.*), to take over the leadership of the church. The people of Illinois having demanded the removal of the Mormons, Young was faced with the Herculean task of leading them to a new country where they would be free from interference. After organizing the groups and planning every move in detail, the migration of nearly 5,000 people was gotten under way in 1846. Early in 1847 Young, leading the advance band, reached the valley of Great Salt Lake, and there decided to settle. He founded Salt Lake City, began the cultivation of crops by irrigation and directed the dispersal of the emigrant trains as they arrived. Both in moral and economic realms his word was law and he laid down the policies of the settlement. When the Territory of Utah was organized in 1850 he was appointed governor by President Fillmore and reappointed in 1854. Though not appointed again in 1858 because of his defiance of the United States in the so-called Mormon War, he continued to be the supreme power of the Territory. He encouraged agriculture, developed natural resources, established manufactures, founded Deseret University at Salt Lake City and Brigham Young Academy at Provo, built the Salt Lake Theatre, laid the foundations of the Mormon Temple, and created the Zion's Co-operative Mercantile Institution which grew into the largest institution of its kind in the West. His genius as a leader is generally recognized, the settlement of Utah being one of the best examples of organic colonization in history. He followed the doctrine of plural marriage and at his death at Salt Lake City Aug. 29, 1877, was survived by 17 wives and 47 children.

For bibliography *see* MORMONS.

YOUNG, EDWARD (1683–1765), English poet, author of *Night Thoughts,* son of Edward Young, afterwards dean of Salisbury, was born at his father's rectory at Upham, near Winchester, and was baptized on July 3, 1683. He was educated at Winchester College and New College, and Corpus Christi, Oxford. His first publication was an *Epistle to . . . Lord Lansdoune* (1713). It was followed by a *Poem on the Last Day* (1713), dedicated to Queen Anne; *The Force of Religion: or Vanquish'd Love* (1714), a poem on the execution of Lady Jane Grey and her husband, dedicated to the countess of Salisbury; and an epistle to Addison, *On the late Queen's Death and His Majesty's Accession to the Throne* (1714), in which he made indecent haste to praise the new king. About this time began his connection with Philip, duke of Wharton, whom he accompanied to Dublin in 1717, and with whom he had a lawsuit in 1740; the upshot was that Young was awarded an annuity of £100, but failed to secure a sum of £600 which he claimed. Meanwhile, his plays, *Busiris* and *Revenge,* were produced at Drury Lane in 1719 and 1721. Between 1725 and 1728 Young published a series of seven satires on *Love of Fame, the Universal Passion.*

Young was nearly fifty when he decided to take holy orders. In 1728 he was made one of the royal chaplains, and in 1730 was presented to the college living of Welwyn, Hertfordshire. He married in 1731 Lady Elizabeth Lee, daughter of the 1st earl of Lichfield. *The Complaint,* or *Night Thoughts on Life, Death and Immortality,* was published in 1742, and was followed by other "Nights." He died at Welwyn on April 5, 1765.

Other works by Young are: *The Instalment* (to Sir R. Walpole, 1726); *Cynthio* (1727); *A Vindication of Providence . . .* (1728), a sermon; *An Apology for Punch* (1729), a sermon; *Imperium Pelagi, a Naval Lyrick . . .* (1730); *Two Epistles to Mr. Pope concerning the Authors of the Age* (1730); *A Sea-Piece . . .* (1733); *The Foreign Address, or The Best Argument for Peace* (1734); *The Centaur not Fabulous; in Five Letters to a Friend* (1755); *An Argument . . . for the Truth of His* [Christ's] *Religion* (1758), a sermon preached before the king; *Conjectures on Original Composition . . .* (1759), addressed to Samuel Richardson; and *Resignation . . .* (1762), a poem.

YOUNG, MAHONRI MACKINTOSH (1877–), American sculptor, painter and etcher, was born at Salt Lake City, Utah, on Aug. 9, 1877. He studied with J. T. Harwood, Salt Lake City, at the Art Students' League, New York city, and in Paris. His works are characterized by simplicity, dignity and breadth of conception, united with exquisite workmanship. He is known chiefly through his statuettes, figures of labourers and cowboys, which exhibit close observation of nature and virile form. Among his best known works are "Man with Pick" in the Metropolitan Museum of Art; the Hopi and Apache groups in the Museum of Natural History, New York city; "A Labourer" and "The Rigger" in the free public library, Newark, N.J.; the "Sea-Gull" monument in Salt Lake City; "Rolling His Own" and "Monument to the Dead" (with Bertram Goodhue), in Paris.

YOUNG, OWEN D. (1874–), American lawyer and business man, was born at Van Hornesville, N.Y., on Oct. 27, 1874. He was educated at St. Lawrence university, N.Y. (A.B., 1894), and Boston university law school (LL.B., 1896). He commenced the practice of law in Boston (1896), being associated with and later a partner of Charles H. Tyler until 1912, when he retired in order to become general counsel for the General Electric company. In 1913 he was elected vice-president in charge of policy and in 1922 was elected chairman of the board of directors. He organized and became chairman of the board of the Radio Corporation of America. He was also a director of the Federal Reserve Bank of New York, General Motors corporation, the International General Electric company, and chairman of the American section of the international chamber of commerce.

Young was a member of President Wilson's second industrial conference, chairman of the committee on business cycles and unemployment appointed by President Harding, and chairman of the American group, international court of arbitration of trade disputes of the international chamber of commerce. In Dec. 1923, he accepted the invitation of the reparations commission to act as a member of the first committee of experts charged with the enquiry into the balancing of the German budget and the stabilizing of the German currency. Their ensuing report was accepted by the commission. Again by invitation Young became chairman of the second committee of experts which met in Paris in January 1929, to draw up a plan for the permanent settlement

of the reparations problem. This committee drafted the Young Plan (New Plan) which fixed the debt limit and term of years for payments, and established the Bank for International Settlements. The Young Plan went into effect May 17, 1930. During 1940–41 Young served as chairman of the advisory board for transportation study of the National Resources Planning board. (*See* also REPARATIONS.)

YOUNG, THOMAS (1773–1829), English man of science, belonged to a Quaker family of Milverton, Somerset, where he was born on June 13, 1773. At the age of fourteen he was acquainted with Latin, Greek, French, Italian, Hebrew, Arabic and Persian. He studied medicine in London, Edinburgh and Göttingen. In 1797 he entered Emmanuel College, Cambridge, and in 1799 he established himself as a physician in London. Appointed in 1801 professor of physics at the Royal Institution, in two years he delivered ninety-one lectures, which contain a remarkable number of anticipations of later theories. He resigned in 1803. In the previous year he was appointed foreign secretary of the Royal Society of which he had been elected a fellow in 1794. In 1816 he was secretary of a commission charged with ascertaining the length of the seconds pendulum, and in 1818 he became secretary to the Board of Longitude and superintendent of the National Almanac. He died in London on May 10, 1829.

Young is best known for his work in physical optics, as the author of a series of researches which did much to establish the undulatory theory of light, and as the discoverer of the principle of interference of light. (*See* LIGHT and INTERFEROMETER.) He gave the word "energy" its present scientific significance and gave his name to Young's modulus. In 1793 he explained the mode in which the eye accommodates itself to vision at different distances; in 1801 he described the defect known as astigmatism; and in his lectures he put forward the hypothesis, afterwards developed by H. von Helmholtz, that colour perception depends on the presence in the retina of three kinds of nerve fibres which respond respectively to red, green and violet light. In physiology he made an important contribution to haemadynamics in the Croonian lecture for 1808 on the "Functions of the Heart and Arteries." In another field of research, he was one of the first successful workers at the decipherment of Egyptian hieroglyphic inscriptions. Some of his conclusions appeared in the famous article on Egypt which he wrote in 1818 for the *Encyclopædia Britannica*.

His works were collected, with a *Life* by G. Peacock, in 1855.

YOUNGHUSBAND, SIR FRANCIS (EDWARD) (1863–1942), British soldier, explorer and author, was born at Murree, India, on May 31, 1863, and educated at Clifton and Sandhurst. He entered the army in 1882, and rose to the rank of lieutenant colonel in 1908. In 1886 he crossed the heart of central Asia, by crossing the Muztagh, the great mountain barrier between China and Kashmir. In 1890 he was transferred to the Indian political department, and in 1902 accompanied the British mission to Tibet, sent out to counteract the Russian influence on the dalai lama. The mission was ended by the treaty of Sept. 7, 1904, and Younghusband was made K.C.I.E. in the same year. His work during this period resulted in an extension of the Indian system of triangulation which finally determined the geographical position of Lhasa. He also proved that the Muztagh is the true water-divide west of the Tibetan plateau. Sir Francis returned to England in 1905 and was appointed Bede lecturer at Cambridge, but in 1906 he went to Kashmir as resident, remaining there until 1909. He travelled widely in India, Manchuria, China, Turkistan and South Africa. He was made K.C.S.I. in 1917. Sir Francis died July 31, 1942.

BIBLIOGRAPHY.—*Heart of a Continent* (1896); *Relief of Chitral* (1898); *South Africa of To-day* (1898); *Kashmir* (1909); *India and Tibet* (1912); *Within* (1912); *The Gleam* (1923); *Wonders of the Himalaya* (1924); *But in Our Lives* (1926); *The Epic of Everest* (1927); *The Light of Experience* (1927); *Life in the Stars* (1927); *Coming Country* (1929); *Dawn in India* (1930); *The Living Universe* (1933); *Modern Mystics* (1935); *A Venture of Faith* (1937); *The Sum of Things* (1939); etc.

YOUNG MEN'S CHRISTIAN ASSOCIATION, an organization for social and religious work among young men, founded in England in 1844 by George Williams (1821–1905). It grew out of meetings for prayer and Bible-reading which Williams held among his fellow-workers in a dry-goods business in the City of London. Similar associations had been founded earlier in Scotland. The distinctive feature of the movement was the combined interest in social and in religious welfare. It spread rapidly; branches were soon formed in France and Holland, and overseas in the United States, Canada, India and Australia. The first world conference was held in Paris in 1855.

The Y.M.C.A. expanded until, at the end of 1942, it was active in 56 countries, autonomously organized under the world committee at Geneva. There were more than 10,000 associations, employing almost 6,000 executive officers. The membership, according to the latest figures available in 1942, was 1,869,963, of whom 657,241 were boys. In the United States the Y.M.C.A. is usually regarded as a leading community institution, supported by citizens of all opinions. The value of its U.S. property and funds in 1942 was $259,740,300.

During World War II the Y.M.C.A.'s of most of the British empire and China were engaged in direct service among the fighting forces, but in the United States the association united with five other agencies under the United Service organizations in performing such service. Throughout the British empire, in China and in many neutral countries, the Y.M.C.A. in 1942 was conducting religious, educational and recreational programs among four to six million prisoners of war.

YOUNGSTOWN, a city of north-eastern Ohio, U.S.A., on the Mahoning river, about equally distant (65 m.) from Cleveland and Pittsburgh; the county seat of Mahoning county. It has a municipal airport; is served by the Baltimore and Ohio, the Erie, the New York Central, the Pennsylvania, the Pittsburgh and Lake Erie and the Lake Erie and Eastern railways, two industrial belt lines, inter-urban trolleys, motor-bus and truck lines; and is on the route of the proposed barge canal from Lake Erie to the Ohio river. Pop. (1920) 132,258 (26% foreign-born white); 1940 federal census 167,720.

The city occupies 34·5 sq.m., lying on both sides of the river, at an altitude of 858 ft. at the public square. It is on the watershed between Lake Erie and the Ohio river, and is surrounded by rolling hills. The adjacent country is a fine agricultural region, rich in mineral resources. Youngstown is the centre of the third largest iron and steel district of the country, producing $\frac{1}{6}$ of all the pig iron and $\frac{1}{8}$ of all the steel made in the United States, and using annually more than 8,500,000 tons of iron ore from the Lake Superior mines. Coal comes in over short hauls, and the limestone needed is quarried in the vicinity. The output of the city's industries is valued at more than $425,000,000 annually.

The public square (given in 1802 by the founder of the city) is still the centre of municipal life. Facing it, or near by, are several of the older churches, several banks, stores and office buildings, the Stambaugh memorial auditorium, the Reuben Mc Millan free library (named after the first superintendent of schools), and the beautiful Butler Art institute, of Georgia marble. The parks of the city cover 2,513 ac. The character of the chief occupations is reflected in the preponderance of men in the population (115 males to 100 females in 1920), the very small proportion of women employed (18·5% of all ten years of age and over) and the very small proportion of children 10 to 14 years of age working for wages (2·5% in 1920). The city's assessed valuation for 1940 was $267,000,000. Bank debits for 1940 aggregated $645,643,517.22.

Youngstown was named in honour of John Young (1763–1825) of New Hampshire, who in 1796 bought a tract of land in the Western Reserve, on which the city now stands, from the Connecticut Land Company. The first settlement was made in 1796 by William Hillman. A township government was organized in 1802, the town was incorporated in 1848 and in 1867 it was chartered as a city. In 1876 the county seat was moved from Canfield to Youngstown; in 1879, after litigation, the legality of the change was confirmed. Iron was mined in the vicinity in 1803 by Daniel Eaton, who in 1804 built the first blast furnace north of the Ohio and west of Pennsylvania and in 1826

the first one within the present limits of Youngstown. As late as 1860 the population of the city was only 2,759. By 1880 it had grown to 15,435 and by 1900 to 44,885. The 20th century has been the period of rapid development. Between 1900 and 1920 the population increased threefold, and the area was enlarged in about the same ratio.

YOUNG WOMENS CHRISTIAN ASSOCIATION, an organization founded in 1855 by two ladies simultaneously. In the south of England Miss Emma Robarts started a prayer union with a purely spiritual aim, and in London Lady Kinnaird commenced the practical work of opening homes and institutes for young women in business. In 1887 the two branches united in the Young Womens Christian association, which seeks to promote the all-round welfare of young women by means of residential and holiday homes, club and rest rooms, classes and lectures, and other useful departments. The association has spread all over the world, and the total membership is over half a million.

See article "Young Women's Christian Association," by Emily Kinnaird, in Hastings' *Encyclopaedia of Religion and Ethics,* vol. xii.

YPRES, JOHN DENTON PINKSTONE FRENCH, 1ST EARL OF (1852–1925), British soldier, was born at Ripple, Kent, on Sept. 28, 1852. The son of a naval officer, he entered the royal navy, in which he served as cadet and midshipman from 1866 to 1870. Joining the militia he passed from this into the army in 1874 and was gazetted to the 19th Hussars. He married Eleanora, daughter of R. W. Selby Lowndes in 1880. He served in the Nile expedition in 1884–5, and commanded his regiment from 1889 to 1893. After two years on the war office staff he commanded a cavalry brigade (1897–9), and on the mobilisation of the expeditionary force for S. Africa in 1899 he was chosen to command the Cavalry Division and was promoted major-general. Pending the assembly of this he served in Natal where he commanded the troops on the field at Elandslaagte and took part in the early combats near Ladysmith, but he proceeded to Cape Colony just before the place was invested. After a few weeks in charge of the force at Colesburg, he led the cavalry during Lord Roberts' advance from Cape Colony, relieved Kimberley, cut off the retreat of Cronje's army, and occupied Bloemfontein. During the subsequent advance into the Transvaal he was in command of the left wing, and at a later stage of the victorious campaign he played a prominent part in the move from Pretoria to Komati Poort. For these services he was given the K.C.B. During most of the second phase of the struggle he was in command of the forces operating against the enemy in Cape Colony, and he was on the conclusion of hostilities promoted lieutenant-general and was given the K.C.M.G.

He commanded at Aldershot from 1902 to 1907, in which year he was promoted general, and he then became inspector-general of the Forces for five years. He was appointed chief of the Imperial General Staff in 1912 and was promoted field-marshal in 1913. In April 1914 he vacated the post of C.I.G.S., owing to military troubles in Ireland in connection with Ulster, but four months later he was chosen to take charge of the Expeditionary Force on the outbreak of the World War, and he commanded the British Army on the Western Front from the outset of the struggle until the end of 1915. The terribly costly and somewhat fruitless advances of this year, culminating in Loos, provoked criticism at the time, and controversy has raged over French's share in them since. He certainly failed signally to harmonise with Kitchener at the War office. He resigned in December of that year, Sir D. Haig taking his place, and he returned to England, to be raised to the peerage as Viscount French of Ypres and High Lake. He then became commander-in-chief in the United Kingdom, and he held that appointment until May 1918, when he was selected to be lord lieutenant of Ireland. This position he occupied under most trying conditions until early in 1921. On resigning he was rewarded with an earldom. He died on May 22, 1925, at Deal Castle, Kent. At the end of the war, Lord French published his personal narrative under the title, *"1914."*

YPRES (Flemish *Yperen*), a town of Belgium in West Flanders, of which it was formerly considered the capital. Pop. (1939) 16,134. It is situated 35 mi. S. of Ostend and 12 mi. W. of Courtrai, on the Yperlée, a small river flowing into the Yser, both of which have been canalized. In the 14th century it ranked with Bruges and Ghent. Its fine Halles or cloth market, with a façade of over 150 yd., was begun in 1201, completed in 1304, and reduced to ruins in World War I. The cathedral of St. Martin dated from the 13th century, with a tower of the 15th century and was also ruined in 1914–18. Jansen, bishop of Ypres and the founder of the Jansenist school, is buried in the cathedral. For four war years (1914–18) the town was the centre of a salient of the British armies and was reduced to ruins, but was later largely rebuilt. The Menin Gate was built as a memorial to missing British soldiers. There are 40 cemeteries within two miles of Ypres.

YPRES, THE BATTLE OF, 1914, is the name given to the heavy but indecisive fighting near Ypres at the close of the "race to the sea" (Oct. 19 to Nov. 22, 1914). It is commonly spoken of as the First Battle of Ypres.

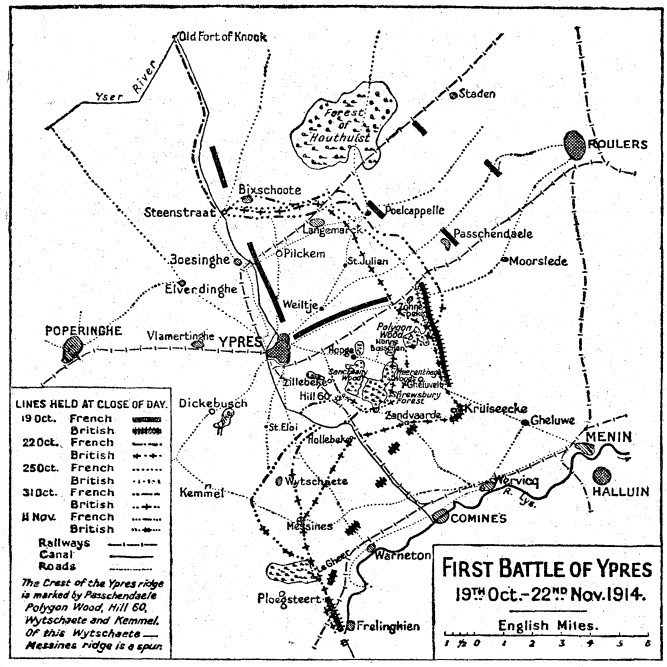
Genesis of the Battle.—When in Oct. 1914 the British Expeditionary Force under F.M. Sir John French left the Aisne front to be transferred to Flanders, its various corps, as they arrived in succession on the left of the Allied line, at once came into contact with the enemy, for each of the two belligerent forces was simultaneously extending its front northwards. Thus the II. Corps (Smith-Dorrien) on Oct. 10 began the "battle of La Bassée," and the III. Corps (Pulteney) and the Cavalry Corps (the 1st and 2nd Cavalry Divisions under Allenby), on Oct. 12–13, the battles of "Armentières" and "Messines." On Oct. 14–15 the IV. Corps (Rawlinson), the Belgian army and a French Marine brigade, falling back from Antwerp, and de Mitry's cavalry corps and two French Territorial divisions, coming up from the west between Ypres and the Belgians, completed the Allied line to the sea. Of this line, the British held the portion from the La Bassée canal to Langemarck, north of Ypres.

The co-ordination of the Allied operations in Flanders was placed by Gen. Joffre in the hands of Gen. Foch, and the general plan now adopted was for the British, supported by the French and Belgians, to advance from the neighbourhood of Ypres, break through the enemy's front, cut off any Germans between the gaps thus made and the sea, and then turn southward to roll up the German line.

The Opening of the Battle.—On Oct. 19, on the arrival behind Ypres of the I. Corps (Haig), Sir J. French sent forward Rawlinson's corps (consisting only of the 7th Division and the 3rd Cavalry Division) towards Menin, and directed Pulteney's and Allenby's corps to move down the Lys on both banks in the same direction. But on the day previous, the 18th, the enemy, with a general plan similar to that of the Allies, had also begun an advance, with a new IV. Army under Duke Albert of Württemberg, on a front from the Ypres-Gheluvelt (Menin) road to the sea. This army consisted of the new XXII., XXIII., XXVI. and XXVII. Reserve Corps composed of young volunteers with 25% of old soldiers and the III. Reserve Corps of three divisions which had besieged Antwerp. Thus, as the German VI. Army, under Crown Prince Rupprecht of Bavaria, south of the IV. Army, also attacked, battle was engaged on the 19th on the whole front from La Bassée to the sea. In the sector between the river Lys and the sea, the German XIX. Corps attacked the left wing of Wilson's division (4th) of Pulteney's corps; four German cavalry corps advanced against Allenby's two cavalry divisions; whilst of the 11 divisions of the German IV. Army, four were sent against Capper's division (7th) and Byng's cavalry division of Rawlinson's corps, two and one-half against the French north of Ypres, and four and one-half against the Belgians.

On Oct. 21, just as Haig's corps, which had been put in on the left of Rawlinson's, was making good progress towards Langemarck, the French on its left fell back before the enemy to the Ypres canal. Haig, with his flank thus exposed to the attack of the XXIII. Reserve Corps, whilst engaged with the XXVI. on his front, had to use his reserve to cover his left, and his advance, thus deprived of any fresh impetus, came to an end. Elsewhere, the British were opposed to at least double their numbers: Capper's division to the XXVII. Reserve Corps, the three British

cavalry divisions to eight German, and Wilson's division to the XIX. Corps. Nevertheless, they managed to hold their line unbroken on the 21st and 22nd. When on Oct. 23 the French IX. Corps (Gen. Dubois) reached Ypres and took over the Zonnebeke–Langemarck sector from Lomax's 1st Division of Haig's corps, a further slight advance was made; but the enemy was in superior numbers and had too much heavy artillery for any decisive success to be obtained. On the 24th Duke Albrecht equally abandoned any hope of a break-through until he could be reinforced; but desultory fighting continued, and on the 26th Capper's division lost the Kruiseecke salient, south-east of Gheluvelt. Meantime, the Belgians had been hard put to it and on Oct. 27 let in the sea at Nieuport to form an inundation in front of their line along the Yser.



The Second German Offensive.—On the same day, the 27th, Gen. von Falkenhayn, the chief of the German general staff, issued instructions for a new attack with increased forces. Six fresh divisions, brought from quiet parts of the line, to form under Gen. von Fabeck, the right of the VI. Army, were on the 30th to take the place of the four cavalry corps and attack Ypres from the south-east for the purpose of breaking through on the front Messines—Gheluvelt, which was held by two of the three cavalry divisions, now all united under Allenby's command, and Capper's division. At the same time, all the German troops north of the La Bassée canal were ordered to make a general attack. The addition of six divisions to the Ypres front gave, excluding cavalry, the Germans 15½ to the French and British six and one-half; but their artillery was even more overwhelming, for Fabeck, apart from what the other German commanders before Ypres possessed, was allotted over 250 heavy and super-heavy guns and howitzers, to which the Allies could only oppose 50, and of these more than half were of old and obsolete patterns.

There was some preliminary fighting on the 29th, when the British lost a little ground near Menin road. On this date, the eve of the second German offensive at Ypres, the line was held from the Lys to Zonnebeke by part of Wilson's division, the cavalry corps and the 7th, 1st and 2nd Divisions, all three since the 27th under Haig, who henceforward commanded in front of Ypres. Thence Dubois's IX. Corps and de Mitry's cavalry corps carried it on to the canal. The greater part of the Allied front maintained its ground on the 30th, but, under the heavy pressure of the six fresh German divisions, Allenby's cavalry divisions and Capper's division were forced back to the Messines-Wytschaete ridge, losing Zandvoorde and Hollebeke. Further danger in this sector was averted by Gen. Dubois, at Haig's request, sending his own reserve of four battalions and three batteries to the assistance of the British cavalry, and Gen. Haig himself despatching first two battalions and later three more, under Maj.-gen. E. Bulfin.

Gheluvelt, Oct. 31.—Matters, however, became more serious on the 31st, when, after a heavy bombardment, a convergent attack of five German divisions and three brigades on Haig's three divisions broke the line on a two battalion front at Gheluvelt, despite the desperate resistance of the 1st Battalion of the Queen's, which was annihilated. Elsewhere the front held, but at Messines part of the village was lost, and immediately south of the Menin road the line was pushed back. The situation was critical, and just at this time the staffs of Lomax's and Monro's divisions of Haig's corps were nearly all killed or disabled by a shell that struck Hooge Chateau.

A counter-attack ordered by Brig.-gen. H. Landon (3rd Brigade) drove back the Germans who had advanced from Gheluvelt along the Menin road; the village itself was recovered owing to the stout defence of the 1st South Wales Borderers north of the break, who held on to the park and chateau to the north of the village until a determined counter-attack of the 2nd Worcestershires initiated by Brig.-gen. C. Fitzclarence (1st Brigade) recaptured it; whilst south of the road a third counter-attack by the 2nd Royal Sussex, 1st Northamptonshire, and 2nd Gordon Highlanders, under the orders of Maj.-gen. E. Bulfin, regained all the ground that had been lost there, and more. At night, however, a retirement was made to a selected line east of Gheluvelt.

French Reinforcements.—On Nov. 1 the Germans continued to attack, and Messines was lost by Allenby's cavalry corps, but the French XVI. Corps (32nd, 39th and 43rd Divisions under Gen. Grossetti) arriving to relieve the cavalry, greatly strengthened the defence. Wytschaete and the rest of the ridge, however, were lost by the French next day. The Allied line was now held by the British and French alternately: from the Lys to opposite Messines by the British; thence as far as the Ypres-Comines railway by the French; thence along the front of Shrewsbury forest and Polygon wood to Zonnebeke by Haig's three divisions; and thence to the canal, by the French again; and this remained the distribution until the end of the battle. During Nov 3, 4 and 5 the German attacks somewhat died down; a composite division of Smith-Dorrien's II. Corps (under Maj.-gen. F. W. D. Wing) and the French 11th Division reinforced the Allies. But this assistance was counter-balanced by three out of five German divisions on the Belgian front being brought down against Ypres.

The Final German Effort.—The German supreme command now decided to attack the haunches of the Allied salient round Ypres from the north-east and south-east. Four more divisions, including a composite one of the Guard Corps, and the 4th (Pomeranian), one of the best in the whole army, were despatched to the sector with more heavy artillery. On the 4th, Crown Prince Rupprecht was given a definite order to break through south-east of Ypres, and whilst this offensive was in preparation to continue attacks all along the line, and the Duke of Württemberg was ordered to move against the north-east part of Ypres. During the 6th, 7th, 8th and 9th the Germans managed to make a little progress at several points; they gained Le Gheer on the edge of Ploegsteert wood, and Zwarteleen near Hill 60, barely 2m. from Ypres; but elsewhere they were repulsed with heavy loss, and Grossetti's corps recovered ground lost between Wytschaete and St. Eloi. On the 10th, after a long and desperate defence, Dixmude (13m. north of Ypres) was lost by the Belgians, and a very heavy attack was delivered against the French on the north-east and north of Ypres which gained a small amount of ground.

The Prussian Guard Attack on Nov. 11.—On Nov. 11 at 6:30 A.M., on a dark and misty morning, the German artillery opened a terrific fire, increasing in intensity as 9 A.M. approached, at which hour the German infantry, under cover of the mist, advanced to the assault on the Lys-Polygon wood front. The British were weary with three weeks' continuous fighting without reliefs, the French nearly as tired. But, in spite of the German numerical superiority—23 divisions to 9½, with cavalry in about the same proportion—the Allied line resisted the enemy's repeated assaults except at two places—just north of the Menin canal,

where a detachment of Dubois's IX. Corps was driven back, and just north of the Menin road. South of and across this road, where the German 4th Division and Winckler's Guard Division attacked, a front of about 2m., stood Wing's composite division of Smith-Dorrien's II. Corps, its battalions so weak that it was about the strength of a brigade, the 2nd K. O. Scottish Borderers on the right, then the 2nd R. Irish Rifles, 1st Gordon Highlanders, 1st Cheshire, 2nd Bedfordshire, 1st Lincolnshire, 1st Northumberland Fusiliers, 4th Royal Fusiliers, and 2nd Duke of Wellington's. North of the road was Fitzclarence's brigade of the 1st Division (the 1st Scots Guards, 2nd Cameron Highlanders and 1st Black Watch), 800 men in all, with the 1st King's of Monro's division in Polygon wood beyond them. By the mere weight of the advance of the German 2nd Guards Brigade (six battalions of the 1st and 3rd Foot Guards Regiments), the front and support lines of Fitzclarence's three Scots battalions were overwhelmed. The attack passed over them, but fire from the 1st King's in Polygon wood, from three strong points (small defended posts with all-round defence) which formed Fitzclarence's third line of defence, and from various battalion headquarters in farms put in a state of defence, then held the Germans up and took heavy toll of them. About 400 or 500, however, pressed on into the Nonne Bosschen (wood), only to be met by the point-blank fire of Haig's field artillery in action beyond it; and the rifle-fire of some artillery men and engineers, including cooks and grooms, hastily collected. The final discomfiture of the German Guards was completed by a counter-attack of the 2nd Oxfordshire and Buckinghamshire through the Nonne Bosschen.

The Close of the Battle.—On the next day, Nov. 12, the weather began to break and become wintry; nevertheless, on this and the following days the Germans made several further attacks against the French in the Wytschaete area and against Wing's division south of the Menin road. These did not alter the situation, and the fighting then died down, and both sides set about completing their defences. With the end of the First Battle of Ypres, on the 22nd, open warfare ceased, and the operations of siege warfare, so-called trench warfare, begun on the Aisne in September, prevailed along the whole western front.

Opposed to more than double its own numbers, the British Expeditionary Force had held its own by sheer good shooting and superior training, and the skilful use by Gen. Sir Douglas Haig of his very small reserve. But such heavy losses had been incurred in the five weeks' battle and in the fighting at La Bassée and Armentières, which went on during the same period, that of the original British Expeditionary Force of fully trained officers and men very few remained, and for the future the empire was dependent on three divisions from overseas garrisons, on Territorial and New Army divisions, and dominion troops.

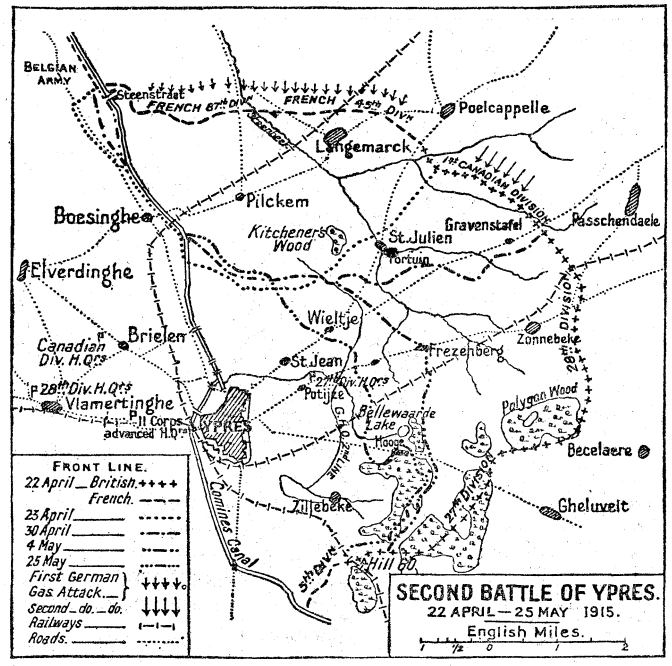
YPRES, THE BATTLES OF, 1915, commonly called the second battle of Ypres, comprise the period of severe fighting that took place in front of Ypres beginning on April 22 with the first gas attack and continuing to May 25, 1915. It resulted in heavy casualties and considerable loss of ground round the town of Ypres, the base of the Allied salient, measured along the Ypres canal, being reduced from 8m. to 5½m., and its maximum depth from 6m. to 2½ miles.

Phases of the Battle.—For the purposes of general description, the battle is best divided into five phases (*see* sketch map): (1) the first German attack on April 22 against the French, resulting in the loss of the Pilckem area; (2) the second attack on April 24 against the Canadian Division, resulting in the loss of the St. Julien-Gravenstafel area; (3) the fruitless British counter-attacks; (4) the British withdrawal to the Frezenberg line, abandoning the Zonnebeke area; and (5) the renewed German attacks (Frezenberg-Bellewaarde), resulting in further loss by the British of a narrow belt of ground.

The Situation Before the Battle.—During the winter of 1914–15 the German Supreme Command had decided to carry out an offensive against Russia in 1915, and to stand on the defensive in the western theatre, leaving only sufficient troops there to hold the line. No general attack at Ypres was contemplated. It was, however, desired to try a new weapon, gas, thoroughly in the field, and the Ypres front was selected for the purpose on the advice of the German meteorological experts. Duke Albrecht of Württemberg commanding the IV. Army, which held



the sector from the Comines-Ypres canal to the coast, proposed to turn the use of gas to local advantage, to improve his position. If he could obliterate the Ypres salient and drive the Allies beyond the canal, he would deprive them of a bridgehead which gave them facilities for attack. The duke's forces consisted of the XV. Corps, the four new Reserve Corps, XXVII., XXVI., XXIII. and XXII., and two *Ersatz* and two *Landwehr* brigades which had fought at the first battle of Ypres. The Marine Division guarded the Belgian coast.

The Allied line from the Comines canal northward was held by part of the 5th Division (Morland), as far as Hill 60; the 27th Division (Snow); the 28th Division (Bulfin); and the 1st Canadian Division (Alderson). The last three formed the II. Corps (Plumer) of the II. Army (Smith-Dorrien). The 27th and 28th Divisions had been formed of troops from Indian and overseas garrisons, but, having suffered heavily from the winter conditions in Flanders, contained in April a considerable proportion of partially trained reinforcements. The Canadian Division had reached England in Oct. 1914, and had embarked for France in Feb. 1915. After being in the line at Neuve Chapelle, it had, between April 15 and 17, relieved French troops covering Ypres. The front defences taken over by the II. Corps were poor, but there was a well-developed back line known as "the G.H.Q. Line." The left of the Canadians extended as far as the Ypres—St. Julien—Poelcappelle road, beyond which were two French divisions under Gen. Putz: the 45th Division, which had arrived on April 16, containing nine newly raised Zouave battalions and three battalions of African natives, these latter being in the line; and the 87th Territorial Division, a division of elderly reservists.

The First Gas Attack.—On April 22, after an afternoon of comparative quiet, suddenly at 5 P.M. a yellowish cloud—now known to have proceeded from chlorine gas released from cylinders in the trenches—was seen to form on the German front opposite the African troops and French Territorials. It blew slowly towards them, whilst the German artillery opened with every kind of gun, firing on the French troops with shrapnel and bombarding all the villages in the salient and the town of Ypres with high-explosive shell. The French infantry in the line fled beyond the canal, leaving their artillery to be captured, abandon-

ing a large area of ground and entirely exposing the British left flank (*see* sketch map). Fortunately for the Allies, the enemy had begun his attack so late in the afternoon that in the dusk he did not discover his immense success. Content with having secured Pilckem ridge and establishing outposts beyond it, about 7.30 P.M., according to plan, as it is asserted, but more probably in consequence of the stout defence put up by various small Canadian detachments, the Germans ceased any attempt to push into the gap, except at Steenstraat.

Gen. Plumer and his divisional commanders hurried what available troops they had to cover the gap, and when Gen. Putz in the course of the evening informed Gen. Smith-Dorrien that he meant to counter-attack at 4.30 A.M., and requested that the British should assist, arrangements were made to co-operate. But no movement of the French took place, nor were they in the succeeding days able to make any serious effort to recover the ground they had lost on the eastern bank of the canal.

Several counter-attacks were made by the British on April 23 to regain the ground lost by the French. They were carried out by the Canadians, the 13th Infantry Brigade, and Geddes's detachment—a temporary formation composed of six battalions of the 27th and 28th Divisions—without avail. The forces were too small, and there was not sufficient artillery or ammunition to support them. The Germans did no more than repel the counter-attacks on the 23rd, but from the 24th onward proceeded to follow two objectives: first to roll up the flank of the British line, aiming to get behind the troops still in position; secondly, to increase their gains across the canal near Steenstraat and separate the Belgians from the French and British. By the division of their forces, they failed to achieve either purpose.

The Second Gas Attack.—On April 24, at 4 A.M., the enemy released gas against the front of the 2nd and 3rd Canadian Brigades. In spite of having only extemporized means of protection (handkerchiefs, linen bandoliers, etc., dipped in water), they held fast for a time, but the enemy, after breaking in at one place, enlarged his gains, and the 3rd Canadian Brigade was gradually forced back, involving in the retirement through St. Julien the troops on the new left flank that had been built up. Gen. Snow, the only divisional general who had his headquarters east of the canal, at Potijze, took charge of the defence, and such reserves as could be hurried up were eventually placed by Gen. Plumer under his command, as communication across the canal between the headquarters of the other commanders and their troops was constantly interrupted. Although the Germans were driven out of St. Julien by a counter-attack of two battalions of the York and Durham Infantry Brigade of the Northumbrian (Territorial) Division, another large piece of the salient was lost, and after further German attacks on the 25th, Gravenstavel was abandoned, and the British line ran from the original left of the 28th Division past St. Julien, almost due west to the canal.

The British Counter-Attacks.—Counter-attack after counter-attack was now made by fresh troops hurried up to Ypres, the 11th Infantry Brigade (4th Division), the Lahore Division and the Northumberland Infantry Brigade (Northumbrian Division) with assistance on the left from the French. All were without success; they found the enemy well entrenched, and their only result was heavy casualties. In the operations of April 26, when some of the French 45th Division co-operated on the left of the Lahore Division, the Germans opened a few gas cylinders in defence, and broke the attack; whilst on the 27th gas shelling alarmed the African natives and caused them a second time to retreat in panic.

The position of the British troops in the narrow salient, projecting 6m. in front of Ypres and only some 3m. across was obviously untenable, as it was surrounded on three sides by the enemy and subject to constant bombardment. Gen. Smith-Dorrien proposed to withdraw to a line nearer Ypres. In consequence, however, of Gen. Foch's protests and promises that the French would regain the ground they had lost, and of the political desirability of not abandoning any more Belgian territory if it could be avoided, Sir John French agreed to leave his troops in their exposed position for some days longer. Gen. Joffre, having in preparation his great offensive which was to begin on May 9, near Arras, was not disposed to allow Gen. Foch to employ any more troops near Ypres; and the French attacks languished.

The Withdrawal from the Apex of the Salient.—When on May 1 the French infantry in a projected attack failed to leave their trenches, all hope of their recovering ground came to an end, and Sir John French directed Gen. Plumer, who by his orders was now in special charge of the operations near Ypres, to begin the retirement to the Frezenberg line, abandoning a zone some 2m. deep. This retirement was carried out with complete success by the infantry brigades of the 27th, 28th and 4th (which had replaced the Canadian) Divisions in the line on the nights of May 1–2, 2–3, and 3–4. The French now held the 1½m. of the left of the new semicircle round Ypres.

The Renewed German Attacks.—All hope of obtaining victory by gas attacks having disappeared, as the Allies were prepared for them, the Germans now tried by sheer weight of artillery to drive the British off their new position. After finally getting possession of Hill 60 on May 5–6, they made carefully prepared attacks on May 8 and on May 24. In spite of splendid defence and desperate British counter-attacks, in which the 4th, 27th, 28th, and Northumbrian Divisions and the Cavalry Corps troops were engaged, the enemy, dominating the situation with heavy artillery, gained a small amount of ground. Meanwhile, on the night of May 15–16, he had been compelled by the French to abandon his position on the western bank of the canal. On May 25, after the II. Corps had established itself on a strong line, the Germans brought the battle to a close.

The total British losses in the Ypres and Hill 60 fighting were 2,150 officers and 57,125 other ranks, the total killed being 10,519. The German losses on the Allied front were returned at 860 officers and 34,073 other ranks.

See "Military Operations, France and Belgium, 1915," *History of the Great War based on Official Documents,* vol. i., with a bibliography (1927); Palat, *Grande Guerre sur le front Occidental,* vol. ix. (1922); M. Schwarte, *Der deutsche Landkrieg,* vol. ii. (1923). The French and German official accounts are not yet available, but official information furnished in advance is included in the British account. (J. E. E.)

YPRES, BATTLES OF 1917. Almost continuous fighting took place in the Ypres-Yser region during many weeks in the summer and autumn of 1917, but the operations as a whole may be said to have consisted of two distinct phases. First came the brilliantly successful combat, lasting a few hours, which has come to be known as the battle of Messines. Then, after a lull, there came to be launched immediately north of the scene of the Messines victory a series of attacks at short intervals which lasted four months. This was not a battle, but rather a campaign, with the fighting more defined than the purpose—of the nature familiar in the military annals of Flanders and the Low Countries generally. Like its German forerunners of 1914 and 1915, it achieved little except loss—in which, again, it repeated the earlier history of this theatre of war. So fruitless in its results, so depressing in its direction was this 1917 offensive, that "Passchendaele" has come to be, like Walcheren a century before, a name of ill-omen and a synonym for military barrenness.

An offensive in this sector had formed part of Haig's original contribution to the Allied plan for 1917. Its actual inauguration had been postponed by the unfortunate turn of events elsewhere. When the ill-success of the opening offensive in the spring at Arras (*q.v.*) and in Champagne (*q.v.*) was followed by the threatened collapse of the French army as a fighting force, Haig's "first-aid" treatment was to allow the British offensive at Arras by the III. Army to continue for some weeks longer, with the general object of keeping the Germans occupied, and with the local object of reaching a good defensive line. When successive thrusts, against an enemy now fully warned and strengthened, failed to reach this line, Haig decided to transfer the main weight of this effort northward to Flanders, as he had originally intended. His loyalty to his Allies and his acute sense of the common interest, inspired him to press on with an offensive policy.

It is right to emphasise that in May Haig's opinion of the policy to pursue was reinforced by the Prime Minister, Lloyd George, who, having committed himself to the Nivelle gamble for victory.

was equally ardent to continue the offensive. It is true, however, that on cooler reflection he subsequently tried in vain to check the policy which he had countenanced.

British Objectives.—The aim was the occupation of the whole of the belt of high ground which extends from a point about three miles north of Armentières, to near Dixmude. It rises some 100 to 150 ft. above the great Flanders plain, and reaches a height of over 200 ft. at some points. In the spring of 1917 its southern portion enclosed to a great extent the Ypres salient, although the Allies' trenches gave them possession of the lower slopes of their side of the high ground. Farther to the north the enemy held the whole of the high ground. The general plan of operations was to begin at the southern end and to work thence northwards. The capture of the high ground was to be followed by an advance in the coast district. But the axis of the attack diverged from, instead of converging on, the German main communications, so that an advance could not vitally endanger the security of the enemy's position in France.

But, worse still, the Ypres offensive was doomed before it began—by its own destruction of the intricate drainage system in this part of Flanders. The High Command had persevered for over two years with the method of a prolonged preparatory bombardment, believing that quantity of shells was the key to success. The offensive at Ypres, which was finally submerged in the swamps of Passchendaele in October, threw into stronger relief than ever before the fact that such a bombardment blocked the advance for which it was intended to pave the way—because it made the ground impassable.

THE BATTLE OF MESSINES

The preliminary move is known as the Battle of Messines, and its purpose was to gain the high ground about Messines and Wytschaete as a flank bastion for the subsequent advance from Ypres. For while in German possession it gave the enemy complete observation of the British trenches and forward battery positions, enabled them to command the British communications up to the Ypres salient, and to take in enfilade, or even in reverse, the trench positions therein. General Plumer and his II. Army, who had been acting as wardens of the Ypres front for two years, had been selected to carry out this operation, while the V. Army under General Gough had been transferred from the Somme to hold the line north of the II. Army. Preparations for the undertaking had begun nearly a year before although their real development dated from the winter. Thus when Haig asked Plumer, on May 7, when he would be ready to deliver the attack Plumer was able to say, "a month from to-day," and to keep his promise.

Messines was to be a strict siege operation, the capture of a fortified salient at the minimum cost of lives by the maximum substitution of mind (care in preparation) and material for manpower. Mines, artillery, gas and tanks all contributed. But a contrary wind curtailed most of the scheme of gas projection, and the effect of the mines and artillery was so overwhelming that the tanks were hardly needed. On the centre corps front alone, of about three miles, a total of 718 guns and howitzers, 192 trench mortars, and 198 machine-guns was concentrated.

For the defence of this salient the Germans depended on two separate trench systems coinciding in trace with its arc, the more advanced one pushed down the forward slope of the high ground while the rear one followed its crest; they had also constructed two chord positions, stretching along the base of the salient on the reverse slope. The troops of the II. Army detailed for the enterprise were, from right to left, the II. Anzac Corps, with the Australian 4th Division in support, the IX. Corps with the 11th Division in support, and the X. Corps with the 24th Division in support. There were thus nine divisions in front line and three in support. The fact that the attack would converge against a salient increased its chances, but it complicated the staff, troop, and artillery organization of the attack. For the sectors of each attacking corps were of varying depths, and contracted more and more in width up to the final objective which was the chord of the arc forming the salient. As, however, it was a siege operation, without any attempt at exploitation or a break-through, it was easier to avoid the congestion which had occurred at Arras (*q.v.*). The problem was further simplified by the plan of allotting sectors so that five of the divisions had sectors of equal breadth from front to rear, while the four which filled the interstices had smaller tasks. Further, when the main ridge was captured, fresh troops were to "leap-frog" through to gain the final Oosttaverne line across the base of the salient. The first bombardment and "wire-cutting" began on May 21, were developed on May 28 and culminated in a seven days' intense bombardment, mingled with practice barrages to test the arrangements. The loss of surprise did not matter at Messines as it was a purely "limited" attack.

At 3.10 A.M. on June 7 the nineteen mines—one only had previously been blown by the enemy—were exploded, wrecking large portions of the Germans' front trenches. Simultaneously the barrage fell. When the débris and shock of the mines subsided, the infantry advanced and within a few minutes the whole of the enemy's front line system was overrun, almost without opposition. Resistance stiffened as the penetration was deepened, but the training of the infantry and the efficiency of the barrage enabled continuous progress to be made, and within three hours the whole crest of the ridge was secured.

The New Zealand Division had cleared the intricate fortifications of Messines itself—here the pace of the barrage was regulated to 100 yards in fifteen minutes instead of the general pace of 100 yards in three minutes. The garrisons of Wytschaete and the White Chateau held out for a time, but the first village was captured after a fierce struggle by troops of the 36th (Ulster) and 16th (Irish) Divisions in a combined effort—a feat of symbolical significance. Perhaps the most difficult sector was that of the 47th (London) Division, which had not only to overcome the highly fortified position of the White Chateau but had the Ypres-Comines canal as an oblique interruption across its line of advance. The Londoners, however, overcame both and by 10 A.M. the objective of the first phase was reached along the whole attacking line. While it was being consolidated, over forty batteries were moved forward to support the next pounce.

At 3.10 P.M. the reserve divisions and tanks "leap-frogged" through and within an hour almost the whole of the final objective was captured. Some 7,000 prisoners had been taken, apart from dead and wounded. The success had been so complete that only feeble counter-attacks were attempted that day. When the expected general counter-attack was launched on the whole front on the morrow, it failed everywhere against defences that had been rapidly and firmly organized, and in the recoil yielded the British still more ground.

THE MAIN OFFENSIVE

A long pause now occurred while preparations for carrying out the rest of Haig's programme were being completed. Although Plumer's victory of June 7 had put an end to the enemy overlooking Ypres from the south, the Germans still, in a measure, dominated the place from the east, from the north-east and from the north. Thus the preparations could not be concealed and the Germans knew that they were being made. The plan at the outset was that, while the II. Army stood fast, the V. Army under Gough on its left with the French I. Army still further to the left, should attack the enemy front from near Hooge to north of Steenstraat on the Yser canal.

Nearly two months passed before the preparations for the main advance were completed. This gave the Germans, amply warned, time to make counter-preparations of characteristic thoroughness and ingenuity. Having learnt by experience that a continuous system of trenches did not offer a satisfactory form of defence unless there was abundant underground cover, and realizing that the waterlogged soil of Flanders handicapped the creation of subterranean galleries, they had established a system of numerous disconnected trenches and strong points, arranged in depth rather than in breadth, together with numbers of concrete blockhouses armed with machine-guns. As their front line near Ypres had been in existence since 1915, they trusted to the old system to meet the first shock of attack, and it was rather in the

later offensive operations that the Allies found themselves confronted with these new defensive devices. A further new asset was the introduction of mustard gas which the Germans used to cause serious interference with the attackers' artillery.

On July 22 the bombardment opened, by 2,300 guns, to continue for ten days, until on July 31 the infantry advanced on a fifteen-mile front to the accompaniment of torrential rain. On the left substantial progress was made, Bixschoote, St. Julien, and the Pilckem Ridge being gained, and the line of the Steenbeke reached. But in the more vital sector round the Menin road the attack was repulsed.

The second blow, on Aug. 16, was a diminished replica of the first in its results. The left wing was again advanced across the shallow depression formed by the little valley of the Steenbeke and past the ruins of what had been Langemarck. But on the right, where alone an advance might have a strategic effect, a heavy price was paid for nought, and even the tally of prisoners shrank to a mere two thousand. Nor did men feel that the enemy's skilful resistance and the mud were the sole explanation of their fruitless sacrifice. Severe complaints against the direction and staff work were general, and their justness seemed to receive recognition when Haig extended the II. Army's front northward to include the Menin road sector, and thereby entrusted to Plumer the direction of the main advance towards the ridge east of Ypres.

It was a thankless task at the best, for the experience of war attested the futility of pressing on in places where failure had already become established, and it seemed heavy odds that the laurels earned by Messines must become submerged in the swamps beyond Ypres. Yet, in the outcome, the reputation of Plumer and the II. Army staff, headed by Harington, was enhanced—less because of what was achieved in scale than because so much more was achieved than could reasonably have been expected.

Bad weather and the need for preparation delayed the resumption of the offensive until Sept. 20, but that morning the II. Army attack, on a four-mile front, achieved success in the area of previous failure—on either side of the Menin Road. Fractions of six divisions, the 19th, 39th, 41st, 23rd, 1st and 2nd Australian advanced at 5.40 A.M.; by 6.15 A.M. the first objective was gained almost unopposed, and, with the exception of one or two strong points, the third and last objective was gained soon after midday, and the counter-attacks were repulsed by fire. A fresh spring on Sept. 26, and another on Oct. 4—the last a larger one on a six-mile front, by troops of the 37th, 5th, 21st, and 7th Divisions, the 1st, 2nd, and 3rd Australian Divisions, and the New Zealand Division—gained possession of the main ridge east of Ypres, with Gheluvelt, Polygon Wood, and Broodseinde, despite torrents of rain, which made the battlefield a worse morass than ever. On each occasion the majority of the counter-attacks had broken down under the British fire, a result which owed much to the good observation work of the Royal Flying Corps and the quick response of the artillery. Some 10,000 prisoners were swallowed in the three bites, and this frightened the enemy into modifying his elastic tactics and strengthening his forward troops—to their increased loss.

As a result of the operations begun on June 7 the crest of the long belt of high ground overlooking the Flanders plain had now, after four months of intermittent fighting, been secured from Messines northwards to within a few hundred yards of the Ypres-Roulers railway. And yet, regarding this Flanders offensive as a whole, the work was in reality only begun. The Houthulst forest, with the long line of high ground forming the quadrant of a circle beyond it, was still in the enemy's hands. Until the ridge had been secured to the vicinity of Staden it would be premature to embark upon the second part of the general scheme of operations—an attack on the German positions along the coast between Nieuport and Ostend, for which the IV. Army under General Rawlinson had been assembled on the extreme left.

Unhappily, the Higher Command decided to continue the pointless offensive during the few remaining weeks before the winter, and thereby used up reserves which might have saved the belated experiment of Cambrai (*q.v.*) from bankruptcy. Having wasted the summer and strength in the mud, where tanks foundered and infantry floundered, they turned in November to dry ground—where a decisive success went begging for lack of reserves.

At Ypres minor attacks on Oct. 9 and 12 advanced the line a trifle, and then, after an interval, a combined attack by the V. Army and the French was tried, with small result, on Oct. 22. On Oct. 26 the II. Army, in torrents of rain, as usual, made a fresh effort, which was less successful than before, owing to the exhaustion caused by pushing forward over a morass and to the fact that the mud not only got into and jammed rifles and machine-guns but nullified the effect of the shell-bursts. The trials of the attackers were augmented by the enemy's increasing use of mustard gas, and by his renewed adoption of his tactics of holding the bulk of his troops well back for counter-attack. Thus when, on Nov. 4, a sudden advance by the 1st Division and 2nd Canadian Division gained the empty satisfaction of occupying the site of Passchendaele village, the curtain was at last rung down on the pitiful tragedy of "Third Ypres." It was the long-overdue close of a campaign which had brought the British armies to the verge of exhaustion, one in which had been enacted the most doleful scenes in their history, and for which the only justification evoked the reply that, in order to absorb the enemy's attention and forces the Higher Command had chosen the spot most difficult for the defender and least vital for the attacker.

(B. H. L. H.)

YPSILANTI or HYPSILANTI, the name of a family of Phanariot Greeks claiming descent from the Comneni. ALEXANDER YPSILANTI (1725–1805) was dragoman of the Porte, and from 1774 to 1782 hospodar of Wallachia. He was again appointed hospodar just before the outbreak of the war with Austria and Russia in 1790. He allowed himself to be taken prisoner by the Austrians, and was interned at Brünn till 1792. Returning to Constantinople, he fell under the suspicion of the sultan and was executed in 1805. His son CONSTANTINE (d. 1816), who had joined in a conspiracy to liberate Greece and, on its discovery, fled to Vienna, had been pardoned by the sultan and in 1799 appointed by him hospodar of Moldavia. Deposed in 1805, he escaped to St. Petersburg, and in 1806, at the head of some 20,000 Russians, returned to Bucharest, where he set to work on a fresh attempt to liberate Greece. His plans were ruined by the peace of Tilsit; he retired to Russia, and died at Kiev. He left five sons, of whom two played a conspicuous part in the Greek war of independence.

ALEXANDER YPSILANTI (1792–1828), eldest son of Constantine Ypsilanti, accompanied his father in 1805 to St. Petersburg, and in 1809 received a commission in the Imperial Guard. He fought with distinction in 1812 and 1813, losing an arm at the battle of Dresden. He was one of Alexander's adjutants at the congress of Vienna. In 1820, on the refusal of Capo d'Istria to accept the post of president of the Greek *Hetairia Philike,* Ypsilanti was elected, and in 1821 he placed himself at the head of the insurrection against the Turks in the Danubian principalities. With other Greek officers in the Russian service he crossed the Pruth on March 6, announcing that he had the support of a "great power." There followed a series of humiliating defeats, culminating in that of Dragashan on June 19. Eventually he crossed the frontier into Austria in the hope of finding an asylum. He was immediately thrown into prison, where he remained for seven years. He died at Vienna on Jan. 31, 1828.

DEMETRIOS YPSILANTI (1793–1832), second son of Prince Constantine, fought as a Russian officer in the campaign of 1814, and in the spring of 1821 went to Morea, where the war of Greek independence had just broken out. In January 1822 he was elected president of the legislative assembly; but retired early in 1823. In 1828 he was appointed by Capo d'Istria commander of the troops in East Hellas. He succeeded, on Sept. 25, 1829, in forcing the Turkish commander Aslan Bey to capitulate at the Pass of Petra, which ended the active operations of the war. He died at Vienna on Jan. 3, 1832.

See the works cited in the bibliography of the article GREEK INDEPENDENCE, WAR OF, especially the *Δοκίμιονἱστορικὸν* of J. Philemon.

YPSILANTI (ĭp-sĭ-lăn'tĭ), a city of Washtenaw county, Michigan, U.S.A., on the Huron river, 713 ft. above sea-level,

30 mi. W. by S. of Detroit. It is on federal highway 112 and state highway 17 and is served by the New York Central railway and numerous truck and bus lines. The population was 7,413 in 1920 (83% native white) and was 12,121 in 1940 by the federal census. It is the seat of Michigan State Normal college (1849) and Cleary college (1883) with combined enrolment of 2,300. The city's assessed valuation for 1940 was $10,349,550 and the output of its 21 diversified manufacturing plants was valued at $4,140,000. Ypsilanti was laid out in 1823 and named after the Greek patriot. It was incorporated in 1832 and chartered as a city in 1858.

YPURINAN, a small group of tribes of South American Indians, forming an independent linguistic stock. The Ypurinas (Hypurinas) live in western Brazil, on the upper Purus and Acre rivers. They are forest rather than river Indians.

See W. Chandless, "Notes on the Tapajos, Purus and Aquiry" (*J. Roy. Geog. Soc.* vol. xxxvi., xxxix.); J. B. Steere, "Narrative of a visit to Indian Tribes of the Purus River, Brazil" (*U.S. Nat. Museum, Rep.* 1901).

YSAŸE, EUGÈNE (1858–1931), Belgian violinist, was born at Liége in 1858, where he studied with his father and under R. Massart, at the Conservatoire, until he was fifteen; he had some lessons from Wieniawski, and later from Vieuxtemps. In 1879 Ysaÿe played in Germany, and next year acted as leader of Bilse's orchestra in Berlin; he appeared in Paris in 1883, and for the first time in London at a Philharmonic concert in 1889. He was violin professor at the Brussels Conservatoire from 1886 to 1898, and instituted the celebrated orchestral concerts of which he was manager and conductor. Ysaÿe first appeared as conductor before a London audience in 1900, and in 1907 conducted *Fidelio* at Covent Garden. The sonata concerts in which he played with Raoul Pugno (b. 1852), the French pianist, became very popular in Paris and Brussels, and were notable features of several London concert seasons. As a violinist he ranks with the finest masters of the instrument, with extraordinary temperamental power as an interpreter. During the war he went to America, and for some time conducted the Cincinnati orchestra. He has received many orders and decorations, including the Legion of Honour. His compositions include *Poème élégiaque* for violin and orchestra and other pieces for violin, violoncello, etc. Ysaÿe died May 12, 1931. His brother THÉOPHILE YSAŸE (1865–1918), pianist and composer, was born at Verviers in 1865. He studied at Liége and in Berlin, and finally in Paris under César Franck.

YSER, a small coastal river, 78 km. long, of which 50 km. are in Belgian territory. It is famous as marking the point, in the World War (1914–18), at which the German advance towards Calais and the English coast was checked. On Oct. 10, 1914, the Belgian army, after being forced to evacuate Antwerp and Ghent, retreated on the Yser; on the 16th the battle of the Yser began, and the Allied troops fought desperately for 15 days. Eventually, assisted by the floods which, beginning on Oct. 29, reached Dixmude by Nov. 2, the allies succeeded in establishing themselves in an impregnable position on the left bank of the Yser.

YSER, BATTLE OF THE. On Oct. 10, 1914, the Belgian field army encamped on the west bank of the Ghent-Terneuzen canal (*see* ANTWERP, SIEGE OF). The British Naval Division, which had embarked at St. Gilles-Waes, regained Dunkirk except two battalions, which were cut off, and passed into Holland; the French Fusilier Marine Brigade, half of the British 7th Division and the 4th Belgian Brigade were holding Ghent and had repulsed an attack on that city by the 1st Res. Ersatz Brigade. Information had been received that a Bavarian cavalry division had advanced towards Deynze exploring between the Schelde and the Lys; that a column of 20,000 men had passed through Courtrai and Menin and that the German IV. Cavalry Corps was holding the region Tourcoing-Ypres-Poperinghe. The only way for the Belgian army to baffle the threat of envelopment on a large scale was an immediate march to the coast. It was decided to transport all the forces without delay to the region of Ostend-Thourout-Dixmude-Furnes, the infantry by rail, the artillery and transport by road, under the protection of all the cavalry and Rawlinson's Corps.

Plans of Opposing Commanders.—The "race to the sea" had in the meantime caused the Western Front to extend to La Bassée. The British army had been withdrawn from the region of the Aisne and was beginning to detrain west of Lille. A few French divisions, taken from other sectors, were given the same destination. It seemed to Gen. Joffre that the moment had come for bringing about the much-desired envelopment of the German right wing by a concentric offensive against Lille. The British army, the Belgian army and some French reinforcements would constitute, it was believed, under the high command of Gen. Foch, an *ensemble* capable of securing a decisive victory. Unfortunately, the assembling of the Allied troops by means of the Paris-Calais and Paris-Hazebrouck railways would take time. On the other hand, it was necessary to take in account that the Beseler Army Group would not fail to follow the Belgians.

The mission of the Belgian army was once again that of gaining time. The king, anxious to keep his left wing resting on the sea, and to preserve at all costs a fragment of national territory from invasion, thought best to entrench the army on the river Yser and the Ypres canal.

Events soon proved the wisdom of this decision. The British II. and III. and Cavalry Corps were stopped at the Lys by the German IV., VII. and XIII. Corps; Rawlinson's Corps found Menin in the hands of the XIX. Corps. Beseler's troops now entered Bruges and Ostend. It was known that numerous detrainments were taking place west of Brussels and that a new German IV. Army had installed its headquarters at Ghent. In fact Falkenhayn, the new chief of the German general staff, had anticipated the Allies' projects and like them, considered the moment for a decisive victory to have arrived.

With four new army corps, composed mainly of volunteers, the XXII., XXIII., XXVI. and XXVII. Res. Corps, Beseler's group and the artillery park from the siege of Antwerp, Prince Albert of Württemberg was charged to proceed to the Yser with his right resting on the sea, in order to attack in flank and in rear the Allied left, whose front the VI. Army was engaging between Arras and Armentières. Falkenhayn considered that: "The conquest of the coast was the sole means of frustrating the war of blockade which England contemplated and of retaliating through our destroyers, submarines, aeroplanes and Zepplins. . . . If we succeeded in driving the enemy out of the Yser valley and pursuing him at the point of the sword, there was no doubt that, having replenished our ranks and our stores, we should be in a condition to overthrow the western front."

Thus the Belgian army, which had only just moved into position in the general Allied line, found itself in focus for a new battle. It occupied a front of 40 km., from the sea to Boesinghe, with $4\frac{1}{2}$ divisions and $1\frac{1}{2}$ divisions in reserve behind the centre. The cavalry division was operating with de Mitry's French Cavalry Corps, east of the forest of Houthulst. On the army's right a French territorial division extended as far as Ypres and Rawlinson's Corps had entrenched itself along the line Passchendaele-Gheluvelt.

Opening of the Battle.—The battle commenced on the 18th with an attack by Beseler's corps (4th Ersatz and 5th and 6th Reserve Divisions) between the sea and Keyem. The Belgian outposts were only driven back after desperate fighting and the enemy did not even reach the Yser. On the morning of the 19th Ronarch's Marine Brigade and the 5th Division debouched from Dixmude on the flank of the III. Res. Corps. Beerst and Vladsloo were retaken; but the intervention of the XXII. Corps, coming from Thourout, and the XXIII. coming from Cortemarck, foiled the counter-attack. By the 20th the fighting had become general all the way from the sea to Gheluvelt between the Duke of Württemberg's $5\frac{1}{2}$ divisions on the one hand and the Belgian army, de Mitry's Cavalry Corps and Rawlinson's Corps on the other. After 48 hours of obstinate fighting the Belgian positions remained practically unchanged.

The attack of the 4th Ersatz Division on Nieuport had failed, partly on account of the flanking fire from Admiral Hood's flotilla; while that of the XXII. Corps against the bridgehead at Dixmude had been checked by Meiser's Brigade. But in the night

of the 21st–22nd the 6th Reserve Division made a surprise crossing of the Yser in the Tervaete salient and threw over 2½ battalions to the west bank. Concentrated artillery fire prevented the division from making any progress on the 22nd, but a gallant counter-attack, in which four battalions of grenadiers and carabineers faced death with superb indifference, broke down completely under their machine-gun fire, owing to the exposed nature of the ground. The following night the Germans passed a second regiment into the bend without, however, extending their ground.

On the 24th, the whole of the III. Reserve Corps and half of the 44th Reserve Division, covered by a bombardment from 10 heavy howitzer batteries and 150 field guns, broke through the front at St. Georges-Tervaete, only to find the Belgians deployed behind the Nieuport-Dixmude railway embankment, together with the French 42nd Division which had arrived in the meantime.

Finding themselves checked in this direction, the Germans renewed their attack on Dixmude. After a four hours' bombardment (in which 21 and 42 cm. howitzers were employed amongst others) which turned the town into a mass of burning ruins, the 43rd Reserve Division delivered its assault at midnight, driving its guns through the middle of—and even in advance of—its infantry. In spite of a threefold attempt it was completely repulsed by the 12th Belgian Regiment, assisted by some French companies of marines. A new attack on the night of the 25th–26th met with the same fate.

Opening of the Nieuport Sluices.—The battle had been in progress for eight days. Over a total of 48,000 rifles the losses amounted to 15,000 in all ranks. Many guns had been put out of action, by excessive use of rapid fire; the munitions were nearly exhausted, the men at the end of their tether. Neither the British nor the French, both hard pressed at Bixscoote, Langemarck and Zonnebeke, were able to send reinforcements. Having no reserves, the Belgian commander decided to call in the sea to his assistance.

On the 26th and 27th all the pioneers were set to stop up the 22 culverts of the Nieuport-Dixmude railway embankment so as to prevent the liberating tide from invading the Belgian positions. On the 27th at dawn a first attempt by the sluice of the Furnes canal, at high tide, failed to yield an effective result. Fresh attempts on the 28th and 29th proved that the inflow of water from this canal was too slight and too slow. Actually, another sluice, that of the Noordvaart, promised a larger delivery but as it lay in No Man's Land its utilization appeared hazardous. Fortunately, the Germans—also being weary—remained relatively quiet during that time. On the 29th, however, their artillery blazed forth again, and it seemed that a new attack was imminent. The Belgian command, acting on information from a waterman named Geeraert, determined on an audacious *coup*. During the night a party of pioneers opened the Noordvaart sluice under the noses of the enemy. Driven by a strong gale the sea water rushed through in a flood. At dawn on the 30th, the three divisions of Beseler's corps attacked along the line of the railway, taking possession finally of Ramscapelle and Pervyse; but the drains were now overflowing; the flooded meadows soon made it impossible for the Germans to advance or even to stay; no alternative was left to them but a hasty retreat. The battle of the Yser was won and the left flank of the Allies definitely saved. Checked along the coast line, the Germans moved the weight of their attack farther inland and made their desperate assault on Ypres. The Belgian army, in scrupulous observance of the spirit of the obligations of neutrality, had, from Aug. 4 to Oct. 31, 1914, gloriously defended its honour, paying the price with its blood and also with the loss of practically the whole of its territory. (*See* also YPRES, THE BATTLE OF, 1914.)

(R. VAN O.; X.)

YSTAD, a seaport of Sweden on the S. Baltic coast, in the district (*län*) of Malmöhus, 39 mi. E.S.E. of Malmö by rail. Pop. (1943) 11,537. Two of its churches date from the 13th century. Its artificial harbour, which admits vessels drawing 19 ft., is freer from ice in winter than any other Swedish Baltic port.

YTTERBIUM, a rare metallic element (symbol Yb, atomic number 70, atomic weight 173·5), of the rare-earth group, was first separated by Marignac in 1878. In 1907 G. Urbain split paleoytterbium into neoytterbium and lutecium. Von Welsbach also, independently, separated Marignac's ytterbium into its two component elements. The new ytterbium he named aldebaranium. The name ytterbium is reserved by most chemists for that portion of the mixture exhibiting the main characteristics of Marignac's element. Ytterbium is almost identical with lutecium in its properties. It possesses a very characteristic spectrum and has a higher magnetic susceptibility than lutecium. (*See* RARE EARTHS.)

(C. J.)

YTTRIUM, a metallic element (symbol Y, atomic number 39, atomic weight 89·0), belonging to the rare-earth group, was discovered by Gadolin in 1794 and further purified by Mosander in 1843. Only a few workers have prepared absolutely pure yttrium compounds. The common impurities are small amounts of holmium and erbium. The purity of yttrium compounds can best be determined by measuring the magnetic susceptibility, which for the oxide should be $-0{\cdot}12\times10^{-6}$. Traces of erbium and holmium cause the magnetic susceptibility to become strongly positive. Yttrium is one of the commoner rare earths found in the minerals gadolinite, xenotime, euxenite, etc. It may be separated from all others except erbium by the fractional crystallization of the bromates. The erbium may then be removed by boiling the nitrate solution with sodium nitrite, when the yttrium is the last to be precipitated. Yttrium oxide, Y_2O_3, is pure white and is rapidly attacked by most acids giving colourless solutions which show no absorption spectrum. The spark spectrum is very characteristic and strong. The pure metal has never been prepared. (*See* RARE EARTHS.)

(C. J.)

YUAN SHIH-K'AI (1859–1916), Chinese statesman, was born at Hsiang Cheng, a member of a family belonging to the smaller landed gentry of the province of Honan. His first important post was in Korea, where, as Imperial Resident and the trusted lieutenant of the Viceroy Li Hung-chang, he strove by adroit diplomacy to preserve China's shadowy suzerainty over the Hermit Kingdom and to check the steadily increasing ascendancy of Japan. After the Chino-Japanese war (1894–95) he held office as judicial commissioner, with military functions, under the viceroy Li, in Chihli, where he brought the troops to a remarkable standard of efficiency.

In Aug. 1898, the emperor Kuang Hsü, hoping to secure Yuan's services in support of his scheme to seize and imprison the empress dowager, summoned him to a special audience at the Summer Palace. The subsequent *coup d'état* by the empress dowager, which removed the emperor from the throne and replaced him under severe tutelage, owed its success to Yuan's betrayal of the emperor's confidence and to his active support of the conservative Manchu party. To the end of his unhappy career, the emperor never forgave Yuan's treachery, and on his death-bed (Nov. 1908) bade his brother, Prince Chun, see to it that he should not go unpunished.

Yuan received from the empress dowager the governorship of Shantung as reward for his services. In the summer of 1900, on the outbreak of the Boxer rising, he maintained order and protected foreigners throughout his jurisdiction. He had no sympathy with the empress dowager's anti-foreign policy. After the signature of the peace protocol (Peking 1901), as the aged Li Hung-chang desired to be relieved of further duty, Yuan was appointed to act in his place as viceroy of Chihli. At Li's death (Dec. 1901) the appointment was made substantive. Yuan now held the highest office in the gift of the Throne; at the same time he was made a Junior Guardian of the heir apparent. A month later the Yellow Jacket was conferred upon him, together with the appointments of consulting minister to the Government council and director general of the northern railway. In the following year he became a minister of the army reorganization council. During the five years of his viceroyalty, he raised and equipped six divisions of troops, greatly superior in every way to those of the Peking field force or the best provincial levies. But his rapid rise to place and power aroused much jealousy, and, in 1907, a cabal

against him, led by his old rival, the ex-Boxer Tatar general Tieh Liang, persuaded the empress dowager to transfer him from the Tientsin viceroyalty to the capital. He was made grand councillor and president of the Board of Foreign Affairs, which post he held until the death of the dowager and the emperor in Nov. 1908.

For a month after the death of the "Old Buddha," rumours were rife in the north concerning the regent's, Prince Chun's, vindictive intentions with regard to Yuan. But he merely deprived Yuan of office (Jan. 2, 1909) and ordered him into retirement at his native place in Honan. But on the outbreak of the revolution the regent, by an edict of Nov. 14, 1911, appointed him viceroy of Hunan and Hupeh, with a mandate to proceed south with his foreign-drilled troops and put an end to the insurrection. Yuan clearly foresaw and declared that if the monarchy were overthrown, the result would be chaos, "amidst which all interests would suffer and for several decades there would be no peace." Thus his avowed policy was to preserve a limited monarchy, pledged to systematic and practical reforms. Had he been loyally served by his representative, Tang Shao-yi, in the negotiations with the revolutionary leaders at Shanghai, above all, had he received the support which he was entitled to expect in the shape of a foreign loan, he might have won. As it was, he continued to fight on, practically singlehanded, against the forces of disruption, until Feb. 1912 when the terrified Manchu court decided to abdicate. Within two days of the issue of the abdication edict (Feb. 12), the southern revolutionaries, on the initiative of Sun Yat-Sen, exemplified the "unbroken continuity of immemorial tradition" in China by inviting him to stand for the presidency of the republic.

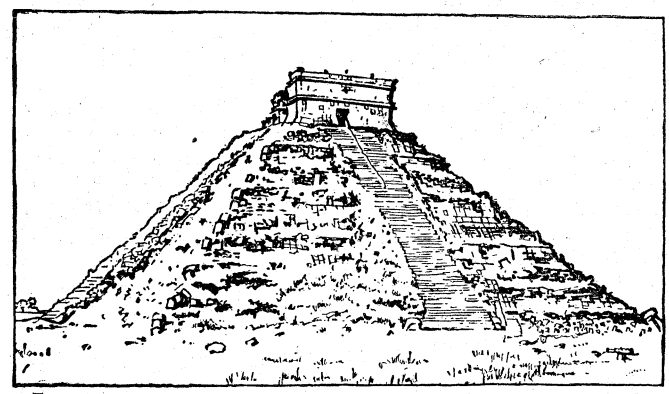
Yuan made a virtue of necessity, and on March 12 took the oath of office as president. Nevertheless, he continued to uphold the principles which he had publicly proclaimed in justification of his defense of the monarchy, and to insist upon maintenance of the continuity of the classical tradition of government and the preservation of the Confucian system. He was willing for a time to pay lip service to the republican formulas, but his actions proved clearly that he had no sympathy with Canton.

In the summer of 1913, a "war to punish Yuan" was started in the south by Sun Yat-Sen, Huang Hsing and other malcontents, but Yuan, having by this time secured a foreign loan and the moral support of the Powers, had no difficulty in retaining the venal "loyalty" of the chief military commanders in the provinces; the Cantonese insurrection came, therefore, to a swift and inglorious end. But Yuan dissolved and proscribed the Kuomintang, and with it made an end of its farce of parliamentary government and representative institutions.

The movement for the restoration of the throne organized by Yuan's adherents, began to take shape in the autumn of 1915. The leaders of the movement failed especially to perceive the danger created by Japan's 21 demands (May 1915), and to realize that the active opposition of the Japanese government would in all probability be fatal to Yuan's ambitions. In October the state council referred the question of the monarchy to the provinces. The result (a foregone conclusion) was a practically unanimous vote in favour of Yuan's accession. Meanwhile, however, the Japanese minister at Peking, supported by his British and Russian colleagues, had made friendly representations to the Chinese foreign office, deprecating the restoration of the monarchical system at this juncture. But on Dec. 12 the monarchy was proclaimed and the enthronement ceremony fixed for Feb. 9, 1916. A week after this announcement, an insurrection, led by one of Yuan's own nominees, broke out in Yunnan. The movement spread rapidly, one province after another declaring its independence. On Jan. 22 Yuan announced the postponement and the establishment of the monarchy. Toward the end of April he consented, while retaining the presidency, to surrender all civil authority to the cabinet, under the premiership of Tuan Chi-jui. He died on June 6, 1916. With him passed the last of the great viceroys of the old regime.

YUCATAN, a peninsula of Central America, which includes in its area of 55,400 sq.mi. the states of Campeche and Yucatan and the territory of Quintana Roo in Mexico, plus small parts of British Honduras and Guatemala. The natural boundary of the peninsula on the south is formed in part by the ridges extending across northern Guatemala, the line terminating in the east at the lower part of Chetumal bay, and in the west at Laguna de Terminos. From this base the land extends north and slightly east between the Gulf of Mexico and the Caribbean sea in nearly rectangular form for about 280 mi., with a mean breadth of about 200 mi., and a coast line of 700 miles.

Physical Features.—The coast on the north and west is low, sandy and semibarren. The outer shore line on the north for nearly 200 mi. consists of a narrow strip of low sand dunes, within



"THE CASTLE" AT CHICHEN ITZA, CAPITAL OF THE ANCIENT MAYA CIVILIZATION, SHOWING A CEREMONIAL TEMPLE ON TOP OF THE GREAT MOUND

which is a broad channel terminating to the east in a large lagoon. There are a number of openings through the outer bank and several small towns or ports have been built upon it. The eastern coast consists of bluffs, indented with bays and bordered by several islands, the larger ones being Cozumel (where Cortés first landed), Cancum, Mujeres and Contoy. There is more vegetation on this coast, and the bays of Chetumal, Espiritu Santo, Ascencion and San Miguel (on Cozumel island) afford good protection for shipping. It is, however, sparsely settled and has little commerce except in henequén, and in chicle, the basis for chewing gum.

The peninsula is almost wholly composed of a bed of coralline and porous limestone rocks, forming a low tableland, which rises gradually toward the south until it is merged in the great Central American plateau. It is covered with a layer of thin, dry soil, through the slow weathering of the coral rocks.

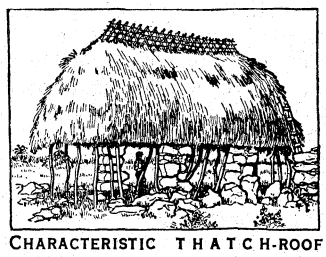
LOADING SISAL AT PROGRESO, YUCATAN, FOR SHIPMENT TO AN AMERICAN CORDAGE FACTORY

The climate of Yucatan is hot and dry and the absence of high mountainous ridges to intercept the moisture-bearing clouds from the Atlantic gives it a limited rainfall. The temperature ranges from 75° to 98° F. in the shade, but the heat is modified by cool sea winds which prevail day and night throughout the greater part of the year. The atmosphere is also purified by the fierce *temporales,* or "northers," which occasionally sweep down over the Gulf and across this open region. The dry season lasts from October to May, the hottest months appear to be in March and April, when the heat is increased by the burning of the corn and henequén fields.

All the northern districts, as well as the greater part of the Sierra Alta, are destitute of large trees; but the coastlands on both sides toward Tabasco and British Honduras enjoy a sufficient rainfall to support forests containing the mahogany tree, several valuable cabinet woods, vanilla, logwood and other dyewoods. Logwood forests fringe all the lagoons and many parts of the seaboard, which are flooded during the rainy season. The chief cultivated plants are maize, the sugar cane, tobacco, cotton, coffee and

especially henequén, which produces the so-called "sisal hemp."

History.—The modern history of Yucatan begins with the expedition of Francisco Hernandez de Cordova, a Spanish adventurer settled in Cuba, who discovered the east coast of Yucatan in Feb. 1517, when on a slave-hunting expedition. He followed the coast round to Campeche, but was unable to penetrate the interior. In 1518 Juan de Grijalva followed the same coast, but added nothing to the information sought by the governor of Cuba. In 1519 a third expedition, under Hernando Cortés, the conqueror of Mexico, came into collision with the natives of the island of Cozumel. In 1525 the inland part of the peninsula was traversed by Cortés during an expedition to Honduras. The conquest of the peninsula was undertaken in 1527 by Francisco de Montejo, who encountered a more vigorous opposition than Cortés had on the high plateau of Anáhuac. In 1549 Montejo had succeeded in establishing Spanish rule over barely one-half of the peninsula, and it was never extended further. The Spaniards found here the remains of a high aboriginal civilization which had already entered upon decline. There were deserted cities falling into ruins, and others, like Chichen-itza, Uxmal and Tuloom, which were still inhabited by remnants of their former Maya populations. (For details of the Maya civilization *see* CENTRAL AMERICA: *Archaeology* and *Ethnology;* also CHRONOLOGY: *Maya and Mexican.*



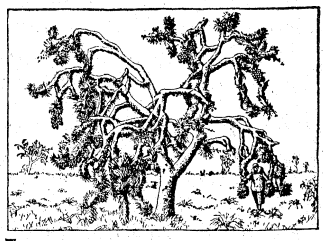
CHARACTERISTIC THATCH-ROOF DWELLING OF THE POORER CLASS IN YUCATAN

Since the Spanish conquest, the Mayas have clung to the semi-barren, open plains of the peninsula, and have more than once revolted. They seceded in 1839 and maintained their independence until 1843. In 1847 another revolt followed, and the Indians were practically independent throughout the greater part of the peninsula until near the beginning of the Diaz administration. In 1910 there was another revolt with some initial successes, such as the capture of Valladolid, but then the Indians withdrew to the unknown fastnesses of Quintana Roo.

The Mexican State of Yucatan occupies the northern part of the Yucatan peninsula, and is bounded east and south by the territory of Quintana Roo, and south and west by the State of Campeche. Its population in 1940 was 418,210 or a density of 28.2 per square mile. Area, 14,864 sq.mi. The capital is Merida.

Quintana Roo was separated from the State of Yucatan in 1902 and received a territorial government under the immediate supervision of the national executive, but its few remaining Indian tribes (pop. in 1940, 18,752 or 0.9 per sq.mi.) are practically independent. Area, 19,435 sq.mi.

YUCCA, a genus of the family Liliaceae (*q.v.*), containing about 30 species. The plants occur in greatest frequency in Mexico and the south-west United States, extending also into Central America, and occurring in such numbers in some places as to form straggling forests. They have a woody or fibrous stem, sometimes short, and in other cases attaining a height of 30 ft. to 40 ft., and branching at the top into a series of forks. The leaves are crowded in tufts at the ends of the stem or branches, and are generally stiff and sword-shaped, with a sharp point, sometimes flaccid and in other cases fibrous at the edges. The numerous flowers are usually white, bell-shaped and pendulous, and are borne in much-branched terminal panicles. The three-celled ovary is surmounted by a short thick style, dividing above into three stigmas, and ripens into a succulent berry in some of the species, and into a dry three-valved capsule in others. The flowers are fertilized entirely through the agency of certain moths. (*See* POLLINATION and YUCCA-MOTH.)



THE JOSHUA-TREE (YUCCA BREVIFOLIA), A TREE YUCCA OF THE SOUTHWESTERN DESERTS OF THE UNITED STATES, SOMETIMES 35 FT. HIGH

A coarse fibre is obtained by the Mexicans from the stem and foliage, which they utilize for cordage, and in the south-east United States the leaves of some species, under the name "bear-grass," are used for seating chairs, etc. The fruits of some species are cooked as food, and the roots of others contain a saponaceous matter used in place of soap.

Some 15 species of Yucca are native to the United States; of these nine attain the stature of small trees. Among the best known are the Spanishdagger (*Y. aloifolia*), the moundlily (*Y. gloriosa*) and the bear-grass or Adamsneedle (*Y. filamentosa*), of the south Atlantic and Gulf coast, all of which are planted for ornament. Among the most conspicuous are the Joshuatree (*Y. brevifolia*), sometimes 35 ft. high, and the Mohave yucca (*Y. schidigera*), 8 ft. to 15 ft. high. An almost stemless species (*Y. Whipplei*), called mission bells and Quixote-plant, which rears a stout flower-stalk, 12 ft. to 15 ft. high, bearing an immense cluster, 3 ft. to 6 ft. long, of fragrant, creamy-white, drooping bell-shaped flowers, is a strikingly handsome plant of the southern California chaparral (*q.v.*). The western Spanish-bayonet or Datil yucca (*Y. baccata*), found from New Mexico to California, bears a dark purple edible fruit.

YUCCA-MOTH, the name given to a genus of moths, *Tegeticula,* the various species of which are each adapted to a separate species of the yucca (*q.v.*). The moth emerges at the time of opening of the yucca flowers, which frequently remain open only for a single night. The female moth rolls together a ball of pollen, flies to another flower, lays four or five eggs in the pistil and inserts the pollen mass in the opening thus formed. Each larva, on hatching from the egg, requires about 20 seeds of the yucca plant as food. As the plant produces some 200 ovules, this leaves about 100 seeds over to perpetuate the plant. The yucca can be fertilized by no other insect. The larva of the yucca-moth can only live on its own species of yucca.

YUCHI, an Indian tribe, formerly on the Savannah river in Georgia and South Carolina to the number of 3,000–4,000, constituting a separate linguistic stock. They gradually joined the Creek confederacy and about 500, mixed with white and Negro blood, survive in the Creek area in Oklahoma. Their culture was marked by traits of Muskogi type.

See F. G. Speck, *Anthr. Publ. Mus. Univ. Penn.,* i. (1909).

YUDENICH, NIKOLAI NIKOLAEVICH (1862–1933), Russian soldier, was born July 18, 1862. He entered the army in 1879, and from 1887 to 1902 served on the general staff. In 1902 he became a regimental commander, in 1905 a general, an assistant chief of staff in 1907 and a chief of staff in 1913. At the beginning of the World War he commanded the II. Turkistan Corps, and was soon placed in command of all the military forces in the Caucasus, a post which he held till the arrival of the Grand Duke Nicholas in 1915. In March 1917 he resumed command, but further advance was rendered impossible by the increasing disorganisation of the Russian army. In 1919 Yudenich led anti-Bolshevik forces in an attempt against Petrograd (Leningrad). This venture was a failure, and Yudenich retired.

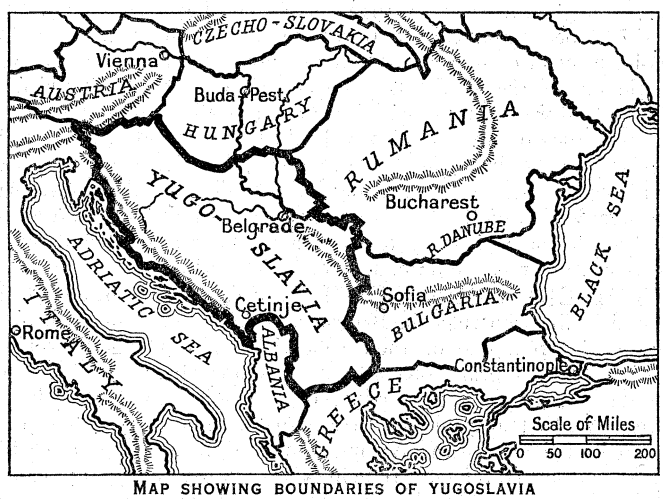
YUE-CHI or **YUEH-CHIH,** the Chinese name of a central Asiatic tribe who ruled in Bactria and India, are also known as Kushans (from one of their subdivisions) and Indo-Scythians (*q.v.*). They appear to have been a nomad tribe, inhabiting part of the present Chinese province of Kan-suh, and to have been driven W. by Hiung-nu (*q.v.*) tribes of the same stock. They conquered a tribe called the Wusun, who lived in the basin of the Ili river, and settled for some time in their territory (*c.* 175–140 B.C.). They then attacked another tribe known as Sakas (*q.v.*) and drove them to Persia and India. For about twenty years it would seem that the Yue-Chi were settled in the country between the rivers Chu and Syr-Darya, but here they were attacked again by the Hiung-nu, their old enemies, with whom was the son of the defeated Wusun chieftain. The Yue-Chi then occupied Bactria (*q.v.*), and little is heard of them for a hundred years. During this period they became a united people, having previously been a confederacy of five tribes, the principal of which, the Kushans (or Kwei-Shwang), supplied the new national name.

The chronology of this invasion and of the history of the

Kushans in India is uncertain; available evidence seems to show that a king called Kozulokadphises, Kujulakasa or Kieu-tsieu-k'io (? A.D. 45–85) united the five tribes, conquered the Kabul valley and annihilated the remnants of Greek dominion. He was succeeded, possibly after an interval, by Ooemokadphises (Himakapisa or Yen-kao-tsin-tai), who completed the annexation of N. India. Then followed Kanishka (*?c.* A.D. 123–53), who is celebrated throughout eastern Asia as a patron of the Buddhist church and convener of the third Buddhist council. He is also said to have conquered Kashgar, Yarkand and Khotan. His successors were Huvishka and then Vasudeva, who may have died *c.* A.D. 225. After Vasudeva's reign the power of the Kushans gradually decayed, and they were driven back into the valley of the Indus and N.E. Afghanistan. Here, according to Chinese authorities, their royal family was supplanted by a dynasty called Ki-to-lo (Kidara), who were also of Yue-Chi stock, but belonged to one of the tribes who had remained in Bactria when the Kushans marched to India. The subsequent migration of the Kitolo S. of the Hindu Kush was due to the movements of the Jwen-Jwen, who advanced W. from the Chinese frontier. Under this dynasty a state known as the Little Kushan kingdom flourished in Gandhâra (E. Afghanistan) about A.D. 430, but was broken up by the attacks of the Hûnas.

See Vincent Smith, *Early History of India* (1908); Hoernle and Stark, *History of India* (1905); Rapson, *Indian Coins* (1898); Gardner, *Coins of Greek and Scythian Kings in India* (1886); Franke, *Beiträge aus Chinesischen Quellen zur Kenntnis der Türkvölker und Skythen* (1904), and numerous articles by Cunningham, Fleet, A. Stein, Vincent Smith, Sylvain Levi, E. H. Parker and others in the *Journal of the Royal Asiatic Society, Asiatic Quarterly,* etc.

YUGOSLAVIA, a convenient name for the Serb, Croat, and Slovene state (*Kraljevina Srba, Hrvata, i Slovenaca*), which originated at the end of 1918 by the union of parts of the former Austro-Hungarian empire with Serbia and, at a slightly later date, with Montenegro. The declared basis of the union was ethnic, the desire being to group together all the South Slavs (Yugoslavs), though the actual frontiers represent a series of compromises. The inhabitants are mainly South Slav, but the new kingdom is, nevertheless, one of the most heterogeneous of the post-war states of Europe. Serbs constitute over one-third of the total population, and outnumber any other single element. But the Serbia of 1918 was not a unit, its frontiers having undergone notable changes since the outbreak of the Balkan wars. The Catholic Croats of Croatia-Slavonia and Dalmatia, the next largest group, number



MAP SHOWING BOUNDARIES OF YUGOSLAVIA

over three millions, but surpass the Serbs of Serbia both in culture and economic development. Serbia—or, more accurately, the Serbs of Belgrade, the only large town in the old kingdom—is however quite definitely the dominant partner.

The predominance of the Serbs of Belgrade is due both to political and geographical causes. Among the former we have to note that Belgrade, the capital of the old Serbian state as it is of the new Yugoslav one, possessed all the advantages of the presence of an organized national administration. No other part of the new state—apart from the small kingdom of Montenegro—had had any experience of complete self-government. Even when associated with numerical preponderance and military strength this might not have ensured concentration of power at Belgrade, had it not been for the outstanding position of the town at the convergence of great highways.

Divisions.—Yugoslavia has an area of 95,558 sq.mi., with a population in 1931 of 13,934,038, and an estimated population on Jan. 1, 1940, of 15,703,000. It is made up of the following 7 areas: (1) the Serbia of the treaty of Bucharest (1913) with some minor modifications; (2) the Montenegro of 1912; (3) Bosnia and Hercegovina; (4) Dalmatia, without the town of Zara and the islands of Lagosta and Pelagosa; (5) Croatia-Slavonia, without Fiume but with some minor additions; (6) Slovenia; (7) the Voyvodina or Duchy.

Of these the first two were independent South Slav states, Serbia having had its area nearly doubled and its population increased by one-half as the result of the Balkan wars. In both the Cyrillic alphabet is used, and the majority of the people belong to the Eastern or Orthodox church. But the new territories in the south, obtained by Serbia as the result of the Balkan wars, contain a considerable Muslim element, both in Old Serbia and in Macedonia. Bosnia and Hercegovina, nominally Turkish till the Austro-Hungarian annexation in 1908, had been administered by the Austro-Hungarian government since 1878. There is a large Muslim element in the population, Bosnia being the most northerly Muslim outpost in Europe.

Dalmatia was a purely Austrian province, with a mainly Catholic population. Italian influence was, however, strong in the coastal towns, particularly in Zara, which has been assigned to Italy. The Catholic Slavs of Dalmatia use the Latin alphabet and thus technically rank as Croats. Croatia-Slavonia (capital Zagreb) was formerly attached to Hungary, its port, Fiume, forming the chief Hungarian sea-outlet. To the Croatia-Slavonia which is included in Yugoslavia were added the commune of Kastav, on the peninsula of Istria to the west of Fiume, the island of Krk (Veglia), and a small area (Medjimurje) between the Mur and the Drava, with a Croat population. The port of Fiume, after long negotiation, went to Italy. Slovenia, the land of the Slovenes, is a name which has been given to a part of pre-war Austria inhabited by Slovenes and now attached to Yugoslavia: there has, however, never been a Slovene state since the early Middle Ages, and Slovenia is made up of fragments of former Austrian provinces. Thus it includes southern Styria, with the town of Maribor (Marburg), the greater part of Carniola, with the town of Ljubljana (Laibach), and a few communes only of Carinthia. To these has been added a small area (Prekmurje) north of the river Mur, formerly attached to Hungary but containing a Slovene population. The Slovenes are predominantly Catholics and highly westernized. Finally, the Voyvodina is similarly composed of scraps of territory, brought together because of the composition of the population and without any physical unity of its own. It includes the southern and often swampy part of the Hungarian plain, and both from the ethnic and the religious standpoint the population is exceedingly mixed. The Slav majority is due primarily to the flight of Balkan Serbs before the advancing Turk, for such low-lying lands were as a rule avoided by the early Slav settlers, who preferred wooded and hilly country. The considerable German and Magyar groups mostly owe their origin to a deliberate process of colonization, the Germans particularly having done much to drain and make habitable the swampy lands. The Rumanian element is due to migration from the hilly country to the east, especially during the 18th century. Many of the Slavs, particularly towards the east, belong to the Orthodox Church, while Catholics are in a majority to the west. There is also a Protestant element (German and Magyar).

The lands included are a part of the Baranja, the Mesopotamian area in the angle between the Danube and the Drava, the remainder of the Baranja being still attached to Hungary; the greater part of the Bačka, the area between the Danube and the Lower Tisa, the smaller part remaining Hungarian; the western part of the Banat, or area east of the Lower Tisa, the eastern part

being attached to Greater Rumania. The Voyvodina in this sense includes the town of many names now officially called Subotica (Ger. *Theresiopel,* Magyar *Szbadka*), a market town and a considerable centre of communication for the plain. Subotica (100,058) is the third largest town of the new kingdom.

Regional Division.—It has to be noted that while the lands briefly described above are those which were united together to form Yugoslavia, they ceased to exist as units. By a decree promulgated by the ministerial council in 1922, Yugoslavia was divided into 33 *oblasti* or regions, on a basis which has been stated to show "strong religious and political party influences"; which may be interpreted as meaning that they were intended to ensure Serb predominance. It is noteworthy that the old administrative or political river frontiers were sometimes preserved in the regions; as for example with the Drina (where it separated Bosnia and Serbia) and the Sava (where it separated Bosnia and Slavonia), and there they isolated from each other groups of different religious and political sympathies. But the old political frontier of the Danube was disregarded to allow the oblast of Belgrade to extend into the eastern part of the Bačka which had a considerable Orthodox element as well as many Catholics, and also into a part of the Banat where there was a similar mingling of creeds. The remainder of the Banat was included in a region (Podunavska or Danube) which also extended across the Danube. Here the solidly Orthodox element in that part of the oblast which lay in Serbia more than counter-balanced the Catholics which were intermixed with the Orthodox in the formerly Hungarian region on the left bank of the Danube.

Population.—The 1931 census showed that 10 million of the 13,934,038 inhabitants of Yugoslavia spoke Serbo-Croat, and over 1 million the Slovene language. Thus Serbs, Croats and Slovenes constitute together about 85% of the total population. The largest minority group is the German-speaking one, numbering over half a million. Most of the Germans inhabit the Voyvodina where they form about 23% of the population of that heterogeneous territory. There they live in compact agricultural colonies as well as forming a considerable part of the town population. The remainder live for the most part in Croatia-Slavonia and in Slovenia. In the latter area they are mainly urban. The Magyar-speaking element is only slightly less than the German-speaking one, and the Magyars constitute nearly the same percentage of the population in the Voyvodina as do the Germans. There they occur particularly in the neighbourhood of the river Tisa, often in compact groups. Elsewhere they occur chiefly in Croatia-Slavonia. The third considerable minority element is formed by the Albanian-speaking peoples. These are not much inferior to the Hungarians in numbers, and their proximity to the independent kingdom of Albania in Old Serbia and Serbian Macedonia gives a possibility of irredentist propaganda. Albanians are practically limited to this part of Yugoslavia. There are also about ¼ million Rumanian-speaking people, of whom the majority live in the Timok region of Serbia, or more accurately, between the river Timok, the Danube and Upper Mlava. Rather more than ¼ million people are registered as speaking Slav languages other than Serbo-Croat or Slovene. These include a certain number of Czechoslovaks in the Voyvodina and Croatia-Slavonia.

The density of pop. (1921) is highest in the Voyvodina (181 per sq. m.), a fact which reflects the productivity of this fertile agricultural region, well fitted for the growth of cereals. In Slovenia (169) and Croatia-Slavonia (162) the density is not greatly inferior. Here the causes are not only the presence of productive lands but the considerable degree of development of the economic resources, associated with marked urbanization. While Serbia has but one large town, and outside of that town has a population mainly of peasants, occupations in Croatia and Slovenia are diverse, mining and manufacturing having made a good deal of progress. Serbia as a whole has a density (111 per sq. mile) lower than that of Dalmatia (126), but the figure is reduced by the fact that the lands added in 1913 are undeveloped and thinly-peopled. In Bosnia and Hercegovina and particularly in barren Montenegro the density is low. For the whole kingdom the density is (1931) 145·8 per square mile.

Frontiers.—Yugoslavia is of trapezoidal shape, the long axis having a N.W.-S.E. direction. The south-eastward extension is narrowed by Albania, which separates Old Serbia and Serbian Macedonia from the Adriatic. The national seaboard extends from the river Fiumara, on which stands the Italian port of Fiume, to the river Bojana, which forms the frontier with Albania. Owing to the numerous islands and peninsulas, the latter with long bordering channels, the coast has a total length of nearly 1,000 miles.

Of the four sides of the trapezium the northern one abuts, from west to east, on Austria, Hungary and Rumania. Strategically it is the weakest of all the frontiers, but this means that there is easy communication with the adjacent states and with Central Europe in general. The Hungarian section (353 m.) of this frontier is the longest, and is traversed by the most important lines of rail. The Austrian frontier (160 m.) is short but is again traversed by important railway lines. The Rumanian section (337 m.) falls into two parts, the old Danube frontier with Serbia and the new one in the Banat.

To the east Yugoslavia marches with Bulgaria, and this frontier (283 m.) is strategically the strongest of all. Strategic changes have been made in the old Serbo-Bulgarian frontier in four places. In the north, in the Timok region, a slight rectification had for its object the affording of greater protection to the railway which follows the Timok valley from Knjaževac and Zaječar to Negotin and thus to the Danube below the obstacle of the Iron Gate. Formerly this railway was close to the frontier. The other changes have been made in the region of Caribrod, where the Niš-Sofia railway line crosses the frontier; to the east of Vranje; and in the Strumica region.

To the south the frontier with Greece (152 m.) remains that agreed upon between Greece and Serbia in 1913. The Albanian part (277 m.) of the western frontier is similarly in essentials that laid down by the Conference of Ambassadors at London in 1913.

The north-western frontier with Italy (132 m.) has only been settled with a considerable degree of difficulty, particularly in the Fiume region, where only the small port of Baros with the delta region remains to Yugoslavia. The frontier is not drawn on a linguistic basis, large numbers of Croats and Slovenes being included within the borders of enlarged Italy.

Within these boundaries Yugoslavia has an extreme range in latitude of from 41°–47° N., and in longitude of from about 14°–23° E.

Communications.—A section of the main European highway passes through Belgrade, branching at Niš for Constantinople and Salonika respectively. Thus the new state had not to improvise a national system from the cut fragments of routes which converged on centres outside the national territories, for a main trunk line was already present.

In the northern area Yugoslavia obtained in the first place that part of the Belgrade-Budapest route which runs via Novi Sad to Subotica. This section was already linked to an important east-west trunk line, with many branches, which follows broadly the Sava valley. Thus Zagreb (185,581) the second city of the kingdom, lying in the Sava valley, had direct connection with Belgrade (238,775), as had also Ljubljana farther west. Zagreb was also connected, if by a somewhat difficult route, to the Hungarian port of Fiume, and directly to Budapest. Ljubljana (59,767) had similarly railway connections both to Fiume and to Trieste and directly to Vienna through Maribor.

Further, southern Hungary had an excellent system of waterways, and just as Belgrade was linked to the Hungarian railway net because of its position, so also that position makes it the centre of the waterways. Navigation is possible on the R. Sava to Sišak, south-east of Zagreb; on the Danube; on the Tisa; and on the Drava as far as Barcs on the left or Hungarian bank of the river. In addition the Voyvodina contains a number of canals, constructed to function both as means of irrigation and as waterways. Again, the navigable Sava receives a number of powerful tributaries from forested Bosnia, well fitted for floating timber.

Conditions are different in Bosnia where Austrian policy in railway construction was determined by political motives. It was not to Austria's interest to facilitate communication between

Turkish lands and Bosnia, and there is not even now any railway through what used to be the *sanjak* of Novipazar. From Skoplje in Serbian Macedonia a railway runs towards Novipazar, but this line ends "in the air" at Mitrovica. Again, since the Bosnians, whether Muslims or not, are Slavs, it was contrary to Austria's interest to permit of any direct connection being made between Serbia and Bosnia. A possible route does, however, occur between the Morava valley and Sarajevo (78,173). The Morava has a large left-bank tributary, the Western or Serbian Morava, which flows in a generally west-to-east direction, and opens up a line of communication into western Serbia. A Serbian railway was built from the Belgrade-Niš route along this valley line, which ended blindly at Užice, near the Serbian-Bosnian frontier. Within Bosnia feeders of the River Drina made it easy to construct a line from Sarajevo of similar direction. This line, however, stopped at Višegrad, a short distance from the frontier. By filling up the Užice-Višegrad gap Yugoslavia was able to connect Sarajevo to the main Belgrade-Niš line. Further, there is a connection from Paraćin on that line to Zaječar in the Timok valley, already mentioned. Since the Zaječar line runs down to the Danube near Negotin there is thus a transverse connection from Sarajevo to the navigable section of the Danube below the Iron Gate and thus to the Black sea.

Sarajevo was linked to Austria by a line through the Bosnia valley which joined the Sava valley trunk-line at the town of Brod. The Austrians also connected Sarajevo with the Dalmatian coast by a narrow-gauge line, which has a rack-and-pinion section and is quite unsuited for heavy traffic. It was largely a tourist line, Austria having done much to develop the Dalmatian coast as a tourist resort.

During the Austrian period Dalmatia may be said broadly to have had no railways of any account apart from this line. The multitude of small ports made coastal traffic easy, and the population is chiefly centred in the towns on the fertile parts of the shore—for the coast is not uniformly productive. Dalmatia was not effectively linked with the interior, and without such links there was no hope of finding outlets on the national seaboard. The problem has not yet been solved, despite a certain amount of railway construction. During the post-war period when feeling ran high between Italy and Yugoslavia all sorts of obstacles were put in the way of Italian coastal steamer services, and since Yugoslavia found it impossible to organize an effective national service, trade and the revival of tourist traffic were seriously hampered. Such facts are of importance because they give reasons for the intensity of the political feeling between Serbs and Croats, and the danger of a policy so centralized at Belgrade as to be out of touch with local needs. Railway construction in Dalmatia has led to the two ports of Sebenico (Šibenik) and Spalato (Split) being connected via Knin and Gospic to Ogulin on the main route between Zagreb and Fiume. A branch line from Knin goes by a very indirect route via Prijedor to the main Sava valley line. Even if it were possible to build a number of railway lines between Dalmatian ports and the interior, the long and expensive haul would complicate their use. Further, the ports are not equipped for dealing with heavy traffic. It would appear, therefore, as though Yugoslav maritime trade must continue to use foreign ports, especially Salonika, where there is a Free Zone, and Fiume.

NATURAL REGIONS

Three great types of land-forms are represented in Yugoslavia: — (1) the western mountain belt which is a continuation of the Alpine folding; (2) the Danubian plains, or Pannonian basin of Austrian geographers, with their southern hilly rim; (3) the much disturbed belt of country, with alternating hills and small plains, separating the western mountains from the crust-block of old rocks which forms the core of the Balkan peninsula; this is best called the Morava-Varder depression, from the great valley which traverses it from north to south. Speaking broadly, we may say that (1) includes the Slovene lands, the western and south-western part of Croatia-Slavonia, Dalmatia, a large part of Bosnia, Hercegovina and Montenegro. The extreme eastern edge of the Slovene lands, the eastern part of Croatia-Slavonia, the northern part of Bosnia and Serbia, with the whole of Voyvodina, fall into (2), while a large part of Serbia is included under (3).

Of these three types, however, the mountain belt in particular is too complex to be regarded as a unit. In the first place the mountains of the north-west show some striking contrasts to the Dinaric Alps which margin the west coast of the Balkan Peninsula proper. The former are made up of the Julian Alps (Terglav, 9,400 ft.), the Karawanken, the Steiner Alps (Grintovec, 8,395 ft.) and some smaller ranges, all with a general west to east direction. This means that the intervening valleys open towards the Danubian plains. North of the Karawanken lies the valley of the Upper Drava, of which, however, only a comparatively small part lies in Yugoslavia. The river may be said to emerge from the mountain to the plain section at the town of Maribor. Between the Karawanken and the Julian Alps lies the roughly parallel Upper Sava valley, of which a larger part falls within the state. Here the considerable (25 m. by 6 m.) basin in which lies the town of Ljubljana may be said to mark the end of the mountain section.

Farther south the mountain belt differs greatly in character. The fold-lines take on a south-easterly direction, parallel to the coast-line, and three distinct zones can be recognized. The coastal ranges have been largely submerged beneath the sea to form the chain of islands and the characteristic peninsulas. Here, particularly in the islands and occasionally in narrow strips on the mainland, there are areas with a considerable depth of fertile soil, enjoying a Mediterranean type of climate, despite the blasts of the bora, or cold northerly wind. Water occurs in the form of springs, often of great force, with, on the mainland, rivers which sometimes mingle their waters with the sea within a mile or two, or even a few hundred yards, of their sources in the limestones, but occasionally reach a considerable length. This coastal belt, with its characteristic products, form a distinct natural region, and is separated by steep limestone cliffs or hills from the barren karst behind. The karst area of massive limestones extends from Carniola, south of the Ljubljana basin, through western Croatia, the interior of Dalmatia, a part of western Bosnia, the greater part of Hercegovina and western Montenegro to the Albanian frontier. It includes ridges such as the Great and Little Kapela and the Velebit, the Uskok Mts. west of Zagreb and other hilly areas, with intervening basins and depressions of varying sizes, much of the surface being below 2,000 ft. above sea-level.

Farther inland, however, especially to the south, in Bosnia, the extreme east of Hercegovina and eastern Montenegro, the elevation increases notably, outstanding heights being Durmitor (8,234 ft.) in north-west Montenegro and Majlić (7,840 ft.) on the frontier between Montenegro and Hercegovina. This elevated area is the Planina region of the Slavs, planina being the precise equivalent of alp (mountain pasture) in the Alps proper. In the Planinas or high mountain region then, upland pastures and forests re-appear.

The Five Natural Regions.—We may therefore recognize five natural regions in Yugoslavia, falling into three groups. Of these (1) the Pannonian basin in the wide sense is by far the most important economically, and with it may be associated (2) the Slovene Alps, which are linked to it by the Drava and Sava valleys. (3) The Morava-Vardar depression forms a unit by itself. In the west, despite the difficulties of communication (4) the coastal belt may be associated with (5) the Dinaric karst and mountain belt.

1. **The Pannonian Basin.**—This obtains its name from the old Roman province of Pannonia, the name being applied by geologists to a great depression between the Alps on the west and the Transylvanian Mts. on the east which was flooded by water during the Tertiary period. The water was finally drained off by the Danube as it cut its way through the encircling mountain rim by the gorge which forms the Iron Gate. Northwards the plain left by the ebbing of the waters extends beyond the limits of Yugoslavia; southwards, beyond the plain which fringes the Sava-Danube, it gives place to an undulating platform which seems to represent the shore of the old lake. This hill country forms part of northern Bosnia and northern Serbia, extending in the latter country southwards to the hills west of Niš, notably the Jastrebac and Kopaonik ranges.

That part of this productive Tertiary hill country which extends

eastwards from the Kolubara to the Morava and is bounded to the south by the valley of the Western Morava, forms the Šumadija of the Serbs and constituted the heart of modern Serbia. Originally thickly forested—Šumadija means forest—the woods have been largely cleared except on the island-like mountains of older rock, such as Rudnik, which rise from the general surface. In Bosnia, however, much of the original woodland remains.

The whole region, including plains, river valleys, hill country and isolated mountains and uplands, constitutes economically the most important part of the state, and has a considerable variety of resources. In Serbia the characteristic occupation is mixed farming carried on by peasants on small holdings. The cereals include maize, wheat, barley and oats. A great variety of vegetables is grown for local use, and there are numerous orchards, the characteristic plum being accompanied by all the usual temperate fruit-trees. Local advantages of climate and soil account for certain special crops, such as tobacco (especially near Užice in the valley of the Western Morava); the vine for table grapes or wine in the more sheltered areas, especially near Smederevo in the Morava valley and in the lower Timok valley; sugar beet in the Morava valley; flax, especially in the Drina and Kolubara valleys; mulberry for silkworm-rearing in the Morava valley, and so on. Of stock animals the pig is particularly important but cattle and horses are reared, with many sheep on the uplands.

In the Voyvodina conditions are broadly similar, but cereal production, especially of wheat, is more important, and the farming is of a more advanced type. There is a correspondingly greater development of the industries using local raw material, such as flour-milling, sugar-extraction, brewing and distilling, rope-making from local hemp, the making of linen and silk goods, etc., and as a consequence towns are more numerous and larger. The greater variety of the surface in Croatia-Slavonia, again, brings certain modifications. Orchards are numerous, and to the plums, vines, apples, pears, etc., of Serbia are added walnuts and chestnuts. Stock-rearing is extensively practised, and the fact that there are large forested areas results in a great development of industries based on wood and wood products.

The part of Bosnia included within the region may be said to resemble a more backward Serbia. Maize is the most important cereal, and since there has been less clearing for agriculture here extensive and valuable forests remain. As in Serbia the plum is by far the most important fruit-tree.

2. **The Slovene Alps.**—The essential features of this region have been described. From the economic standpoint it has to be noted that, on account of the limited amount of arable land, there is not only no surplus of cereals, such as is found in (1), but an actual deficiency, so that additional supplies have to be obtained especially from Slavonia, Bačka and the Banat. On the other hand the well-organized dairying industry permits of a considerable export of dairy products. Ljubljana and Maribor are not only centres of this trade but also of a number of minor industries similarly dependent on the extensive rearing of live stock, such as meat-packing, the making of margarine, soap, candles and so forth. Further, the valleys and the margins of the basins yield fruit, including walnuts and chestnuts, the vine, especially in the Drava valley where Maribor carries on a considerable trade in wine of good quality, as well as small fruits.

Forests are not only extensive but include both conifers and such hardwoods as beech, oak, chestnut, etc., and industries dealing with timber are important. Since water-power is abundant and coal also occurs, while the forests are widely distributed, many of the industries are of old standing and of the small, scattered type rather than commercialized undertakings. The products, notably furniture, show the influence of localized skill and tradition and had a ready sale in the old Austria-Hungary. Minerals, in addition to coal, are of some importance, though many of the industries based upon them have suffered from the drawing of the new frontiers.

3. **The Morava-Vardar Depression.**—This not very appropriate name may be given to the region which extends from the southern margin of the Šumadija to the Greek frontier. It is traversed by a series of basins strung along the Morava and Vardar systems, and affording a continuous route from north to south. Structurally the region is remarkably complex, for it represents the zone of weakness where the fold-mountains of the west and north-east abut upon the central crust-block of the peninsula. Instead of the continuous and extensive depression which gave rise to the Pannonian basin to the north, earth movements were limited and localised, producing numerous small basins, originally flooded by water but now largely drained by river action. These basins are floored by soft deposits and are in consequence fertile, containing arable land. With them alternate great mountain masses, such as the Kopaonik, Golja, Crna Gora, Šar and others. The Crna Gora marks the limit between Old Serbia or Raška to the north and Serbian Macedonia (*see* MACEDONIA) to the south.

Among the more important rivers may be noted the Nišava, a right-bank tributary of the Morava which allows of the passage of the railway from Niš to Sofia and Constantinople. The Toplica, a left-bank tributary of the Morava, drains a very fertile valley. The long stream of the Ibar has a small headstream, the Sitnica, which drains a part of the productive Kosovo polje, or plain of the blackbirds, with the town of Priština. The Ibar itself passes through a wide valley containing the towns of Mitrovica and Raška and enters the western Morava. In a side valley to the west lies the town of Novipazar, which is extremely "Turkish" in appearance and has a large Muslim element.

As regards resources the arable plains and basins produce a considerable variety of crops, becoming more and more southern in type as the Greek frontier is approached. The mountains and uplands allow for a notable development of the live stock industry, the area in earlier days having furnished a considerable part of the meat supplies of Constantinople, to which the sheep could be driven by successive stages. Finally the mineral resources are considerable, especially round Skoplje, Veles and Kumanovo. Coal, copper, silver-lead, chrome ore, iron and antimony all occur.

Among the products of the live stock industry is wool of good quality, particularly from the sheep reared on the eastern uplands. This forms the basis of the celebrated carpet industry of Pirot, in the upper Nišava valley, the carpets being noted for their excellent colours and designs. Round Lake Dojran the camel is present.

The crops of Old Serbia are generally similar to those of the Šumadija, but in Macedonia they are more varied. Thus the Bregalnica valley near Kočane is famous for its rice fields and near Štip for opium poppy yielding a high percentage of opium, exported from Salonika. In the Strumica valley farther south cotton, rice, sesame, tobacco, with much fruit and a variety of other crops, all occur. Gevgeli, the frontier station on the Skoplje-Salonika line, is famous for its silk production and silk factories.

4. **The Coastal Belt.**—The general geographical interest of this region far exceeds its economic one. Even the name is somewhat deceptive, for parts of the coast are as barren and arid as the karst lands of the interior. Characteristic Dalmatian landscapes are best seen in such areas as the Riviera of the Seven Castles, which stretches from Spalato to Trau (Trogir), forming a narrow, fertile strip about 10 m. in length, watered by short, spring-fed streams and backed and sheltered by bare and waterless limestone hills; or round Ragusa, one of the most perfect examples of the Mediterranean city-state in miniature. The olive grows round Spalato, but olive oil is imported from Italy.

The coastal belt is for the most part unsuited to cereals, which are grown in the poljen of the interior. But the marshy area round the mouth of the river Narenta forms an exception to the general statement. Wine is made and exported largely to France to be mingled with locally-produced kinds. Special products of some interest are the liqueur maraschino, distilled from cherries at Spalato and Sebenico (Šibenik); insect powder made from locally-grown and wild pyrethrum, and a variety of substances obtained from the aromatic plants of the maquis. Among the last rosemary (especially from the islands of Lesina [Hvar] and Lissa [Vis]), sage and noble laurel may be named. Apart from the shrubs, wood is rare.

Minerals are not very important, but large beds of cement-stones occur near Spalato and form the basis of a considerable industry using the water-power of the short river Jader, which

gushes out of the limestone near by. The water power of the river Kerka near Sebenico and of the river Cetina near Almissa (Omiš) is also used for such industries as the making of calcium carbide and cyanamide. These industries were mainly established with Italian capital. Fishing is of some importance, especially on the islands, where Lissa has a canning industry. The catch includes tunny, sardines, mackerel and crabs and lobsters.

5. **The Dinaric Karst and Mountain Region.**—If the coast of Dalmatia is apt to be estimated too highly, precisely the reverse is true of this region which is less unproductive than it appears at first sight. From the human standpoint the contrasts are very striking, for if Ragusa and Spalato are western and Latin, with many evidences of a great past, towns like Sarajevo, Mostar, Trebinje and Cetinje are thoroughly eastern in appearance, and the rural population is in many ways highly primitive and backward. The area owes its Slav population to the Turkish advance, to the same cause, that is to say, as that which led ultimately to the decay of the coastal towns. The Slavs of the interior fled, at various times, before the advancing Turk, and were constrained to occupy and use poor land.

Montenegro is particularly well fitted for livestock rearing because of the appearance of schists in the mountain belt which lies east of the Zeta valley. There is a better and more permanent water supply and a richer growth of grass there.

Cereals, especially maize, with wheat and barley, tobacco and wine are produced in the depressions of the mountain region.

HISTORY

The Adriatic Dispute at Paris.—At the Paris Conference there was from the first a deadlock in the Adriatic dispute. (*See* SERBIA.) Clemenceau and Lloyd George found themselves between two irreconcilable standpoints—between Sonnino, who claimed the literal fulfilment of their treaty pledges, with the addition of the port of Fiume, and Wilson, who refused all cognizance of the secret treaties and regarded them as abrogated by the Allies when they accepted his successive Notes as the basis of the Armistice. The three Western Powers were in the impossible position of judges in a dispute to which one was a party, while two were accessories. On Feb. 11, 1919, the Yugoslavs offered to submit the whole dispute to the arbitration of President Wilson, and on April 16 to leave the settlement of frontiers to a plebiscite.

But these proposals were rejected by the Italians, who even withdrew for a time from Paris; and Wilson's public manifesto on the Adriatic question (April 23) so far from improving matters, actually stiffened Italian resistance. The problem was left unsolved during the final stages of the negotiations on the German treaty, and was still being postponed when, on Sept. 12, D'Annunzio and his Arditi, with official Italian connivance, seized Fiume and proceeded to create a *fait accompli.* On Dec. 9, 1919, the Supreme Council made a definite proposal to Italy on the basis of a slight modification of the so-called "Wilson Line," Fiume as a buffer State, a special régime in Zara, Valona in full sovereignty and an Italian mandate in Albania.

Late in April the Yugoslavs consented to direct negotiations with Italy, but the Nitti cabinet fell before any decision could be reached, and it was not till Nov. 12, 1920, that the Treaty of Rapallo was signed. By it Italy acquired a frontier considerably farther east than the Wilson line, the watershed of the Julian Alps as far as Snježnik (Monte Nevoso), almost all Istria with Abbazia and Volosca, and a narrow strip of shore connecting it with Fiume, which was to become an independent unit under the League of Nations, while the Croat suburb of Sušak was to remain in Yugoslavia and the Baroš Port was added as an outlet for Yugoslav trade. Zara became a free city under Italian sovereignty, but as a tiny island isthmus without hinterland or islands. Italy renounced all claim to Dalmatia, and of all the islands retained only Lussin and Cherso. Special linguistic and other privileges were assured to the tiny Italian minority in the Dalmatian towns, but no corresponding charter was granted to the 400,000 to 500,000 Slovenes and Croats annexed to Italy. One practical result of the treaty was that Italy tacitly abandoned the cause of King Nicholas and accepted as inevitable Montenegro's incorporation in Yugoslavia. Unhappily Italy allowed the treaty to remain a dead letter as regards Fiume, which was firmly held by D'Annunzio's irregulars, to the utter ruin of its trade and prosperity. The final liquidation of the Adriatic dispute was postponed till Jan. 27, 1924, when Mussolini and Pašić (Pashitch) concluded the so-called "Pact of Rome" guaranteeing the Peace Treaties of St. Germain, Trianon and Neuilly and promising neutrality if either should be attacked by a third party. A supplementary agreement recognized Italy's annexation of Fiume, but left to Yugoslavia the Baroš Harbour and also a free commercial zone in Fiume itself, with proper railway access.

The New Frontiers.—In five other directions also the regulation of the new frontiers was a slow and difficult process.

1. The frontier between Yugoslavia and Rumania rests on a decision of the Peace Conference, published on June 13, 1919. Rejecting equally the frontier fixed by the secret treaty of 1916, under the terms of which Rumania entered the war, and the line up to which the Serbs had been allowed to occupy after the Armistice, the Allies divided the Banat on a mainly ethnographic basis. At the last moment they drove two awkward salients into Rumanian territory, in order to include Vršac and Bela Crkva in Yugoslavia, thereby blocking the railway outlet of Timişoara and Arad towards the Danube at Bazias.

2. The regulation of the Austro-Yugoslav frontier was decided according to a plebiscite supervized by an inter-Allied Commission at Klagenfurt. After a keen contest between rival Slovene and Pan-German propagandists, voting took place in Oct. 1920 and resulted in a majority of 12,747 for Austria in Zone A (the more southerly section in dispute), whereupon Zone B also was automatically assigned to Austria.

3. By the Treaty of Neuilly (Nov. 27, 1919), Bulgaria was forced to cede to Yugoslavia (*a*) the Strumnica salient, which threatened the Vardar railway from the east, (*b*) the district of Kočana and the Bregalnica and (*c*) the town and district of Tsaribrod, which places Sofia strategically at the mercy of her neighbour.

4. The Albanian frontier remained in suspense till 1921, when the Supreme Council sanctioned the line laid down by the Council of Ambassadors in the winter of 1913, thus putting an end to the disreputable design favoured in some quarters of an Italo-Yugoslav "deal" on the lines of "Scutari for Fiume."

5. The frontier with Hungary was the last to be regulated. By the Treaty of Trianon the Banat (save a small Magyar triangle opposite the city of Szeged) was divided between Rumania and Yugoslavia, while the latter received the whole Bačka (except Baja and district), part of the Baranya (forming the angle between Drave and Danube) and the Medjumurje (between Drave and Mur). Thus, in order to secure the town of Subotica (Szabadka) with its large Bunjevac (or Catholic Serb) population, she was allowed to annex not less than 250,000 Magyars.

Internal Politics.—So long as these vital frontier disputes were outstanding, the Government hesitated to hold new elections, and the new united parliament rested on a highly irregular basis, the Serbian mandates having actually expired in June 1914, and the delegates from most of the new provinces owing their positions to membership in the numerous revolutionary committees which sprang up in Oct. 1918. The chaotic party conditions slowly crystallized into a keen struggle between the Radicals, who still possessed the best party machine and stood for a narrowly Serbian as opposed to a Yugoslav programme, and the new Democratic party, which absorbed most of the Opposition groups in Serbia, the old Serbo-Croat coalition of Croatia and the Slovene Liberals. In Aug. 1919 Protić was replaced by Davidović, the Democratic

leader, but at the elections to the Constituent Assembly (November 1920) no party secured an absolute majority. Pašić again became premier in January 1921, and was able to steer through parliament a new Constitution on extreme centralist lines. This caused immediate ill-feeling, and drastic measures "for the defence of the state," including the annulment of the mandates of the 53 Communist Deputies.

Having broken openly with the Democrats, Pašić formed a purely Radical cabinet. Davidović replaced him in 1924, but soon after Pašić resumed power, supported by Pribičević. Radić, meanwhile, had been making political visits to Western Europe, Vienna and Moscow. In 1925 he suddenly recognised the constitution, dynasty and army, and entered the Government, but withdrew his support the next year. After a long deadlock, a Government coalition was formed in 1927 between the Radicals, Democrats, Slovenes, Clericals and Muslims. Radić and Pribičević united to organise among the Prečani (former subjects of Austria-Hungary) a campaign against centralist inefficiency and corruption. This was waged with increasing violence until on June 20, 1928, a Montenegrin Radical Deputy named Puniša Račić fired in the Skupština on the Croat Deputies, mortally wounding Stephen Radić and killing his nephew and a colleague outright. The Croats withdrew to Zagreb. Efforts to find a new Parliamentary modus proved unavailing.

The coup d'état of January 1929.—On January 6, 1929, King Alexander suspended the Constitution and established a personal dictatorship with the declared objects of improving administration, eliminating corruption and inefficiency and bringing about national unity. When those objects had been achieved, constitutional life—it was expressly promised—should be restored. The King's first premier was General Živković, commander of the Royal Guard, and the cabinet included both Serbs and Croats.

Considerable administrative and financial reforms were at first introduced. The King's most important measures were, however, those promulgated on October 3, 1929. The official name of the State was changed from the Serb-Croat-Slovene kingdom to Yugoslavia; and the historic subdivisions vanished altogether, the country being re-partitioned into 9 "Banovinas," called after their main rivers, and generally arranged (except in the case of the Drave Banovina, which corresponded to the old Slovenia) so as to strengthen the centralist elements. The Governors of the Banovinas were appointed by the Crown.

These steps were highly unpopular in Serbia itself, but the more obvious discontent was in Croatia, where it was fanned by the numerous arrests and political trials, including that of M. Maček, Radić's successor. Many Croat leaders—extremists and some moderates—fled abroad. Other political leaders from all parties were interned. The dictatorial regime continued throughout 1930. On September 3, 1931, a new Constitution was promulgated, but existing repressive measures remained in force, voting was open and no parties or other associations resting on a basis of religion, race or district were allowed. The opposition urged their adherents to boycott the elections, which returned a parliament mostly composed of Serbs, nearly all men quite unknown to the public. In fact, although General Živković retired from the premiership on April 4, 1932, the civilian ministers who succeeded him (Dr. Marinković, M. Srskić and M. Uzunović) were all representatives of the King's strongly personal and centralist policy, the "Yugoslav" tendency of which was still incomprehensible to most of the public. The widespread discontent was fostered by great economic difficulties, due mainly to the world crisis and to the fall in prices of agricultural produce; and by rumours of corruption in Government circles.

Foreign Policy.—In foreign affairs the King remained faithful to the policy of the Little Entente, strengthened by the signature in 1933 of its new Organisation Pact. Certain differences of policy were, however, to be noted in Yugoslavia's very friendly attitude towards Germany, which caused it to be widely believed that she would not oppose the Anschluss of Austria to Germany, preferring German influence in Austria to Italian. For the rest, Yugoslav foreign policy was pacific, and the King himself made notable and very successful endeavours after 1930 to improve relations with Bulgaria. He was unable to secure Bulgaria's participation on the Balkan Pact, signed in February, 1934, under which Rumania, Yugoslavia, Greece and Turkey mutually guaranteed each other's Balkan frontiers; but he brought about a genuine rapprochement with Bulgaria, whose capital he courageously visited in 1934. Relations with Italy and Hungary remained strained.

The Assassination of the King.—On October 9, 1934, King Alexander visited France, and on arriving at Marseilles, was assassinated by a Macedonian émigré. The assassins had had some connections in Italy and particularly Hungary, and relations with those two countries became increasingly difficult. A worse conflict was averted by the mediation of the League of Nations. The effect was greatly to strengthen the feeling of national unity. King Alexander's heir was his son, Peter II.; but the regency was entrusted to a Council of Three, consisting of Alexander's cousin, Prince Paul, and two Croats, Dr. Stanković and Dr. Perović. It was hoped that the centralist regime would now be relaxed, but although a few concessions were made, M. Uzunović kept in the main to the old centralising policy. His successor M. Yevtić, began with some concessions to the Croats, but the elections held in May 1935, although the opposition was allowed to contest them, proved a disappointment to those who expected a real change of methods. A new cabinet under M. Stoyadinović made certain further concessions; but the situation remained unsatisfactory.

THE STRUGGLE FOR YUGOSLAVIA

The Royal Dictatorship.—The royal coup d'état of Jan. 6, 1929, by which the constitution had been suspended and parliament dissolved, had pursued one aim: to overcome the difficulties inherent in the fact that Yugoslavia was a heterogeneous state made up of three main elements of population, the Serbs, the Croats and the Slovenes, who though closely related by descent and language were different in their national temperament and in their historical traditions. King Alexander despaired of the effort to work out by patient parliamentary means a modus vivendi which would establish an ever more intimate relationship between the different constituent groups of the triune kingdom of the Serbs, Croats and Slovenes. Instead of that, he wished to force the amalgamation of the three elements in a united and unitarian Yugoslav kingdom, regarding himself as the great unifier of the southern Slavs. The new division of the kingdom into nine banovinas, named after rivers and following entirely geographic lines, was to obliterate the historical lines of division. Their names were: Dravska, Savska, Vrbaska, Primorska, Drinska, Zetska, Dunavska, Moravska and Vardarska. But King Alexander's experiment could be carried on only against the dissatisfaction of large parts of the population. The Serbs, by temperament and tradition a deeply democratic people, politically highly conscious and vocal, a nation of small independent sturdy peasants, protested against the dictatorial methods involved in the coup d'état. The Croats, by their history a much more peaceful and tractable people but sharing in the democratic attitude peculiar to the awakened Balkan peasantry, resented the dictatorial form of the regime and, even more, the attempt to divest them of their character as a separate nationality with its own deeply ingrained cultural traditions, and were afraid that the new regime would perpetuate the predominance of Belgrade instead of creating a more flexible federal constitution for which they had hoped.

The years of the dictatorship were, therefore, years of tension and trouble. King Alexander, in his plans for the new national state, looked to the fascist dictatorships for some idea as to how to strengthen national unity. Among others he accepted the idea of creating official youth organizations to inspire the young people with the spirit of national unity and loyalty to his regime. The famous athletic organization, the Sokol, or "falcon," which had been established among the Yugoslavs after the Czech example, on a voluntary basis of democratic patriotism, was to be incorporated officially into the new state. Like all other parties, the Croat Peasant party led by Dr. Vladimir Maček had been dissolved, but terrorist actions in Croatia led to the persecution and trial for sedition of Dr. Maček and some of his collaborators. He and most of his codefendants were acquitted. The internal tension was heightened by a threat of war with Italy, by corresponding military preparations and by the growing economic crisis which reached Yugoslavia in 1930 and made itself severely felt in all agrarian countries of southeastern Europe.

It was not only Croatian discontent which caused concern; it was also the discontent of the Macedonians in those parts of Serbia which had been annexed after the Balkan War in 1913. The revolutionary Macedonian organization kept alive the unrest in the provinces bordering on Bulgaria. The Yugoslav government tried hard to improve relations with Bulgaria. Bulgarians are southern Slavs like the Serbs

and the Croats, an agrarian democratic people, and there is much feeling of kinship among them. There have been repeated efforts for a union of all southern Slavs, but the rivalry between the Bulgarian and the Yugoslav royal houses made such a union impossible, though undoubtedly it would have been in the common interest and welcomed by the population. But in the years following 1930 serious attempts were made to arrive at a reconciliation between the two branches of the southern Slavs who in the last decades had been estranged by several wars between them and by their mutually exclusive claims to Macedonia with its inextricably mixed population groups.

On Sept. 3, 1931, King Alexander proclaimed a new constitution, which formally put an end to the existing dictatorship. But this constitution retained all the decisive powers in the hands of the king, strengthened the tendency toward centralization, and thus was far from satisfactory to the democratic and autonomist aspirations of the different parts of the population. It was accused of being a mere screen for the continuation of the royal dictatorship. The new constitution recognized the rights of the three official languages of the kingdom, Serb, Croat and Slovene, guaranteed the individual liberties and freedom of religion and of the press, but it did not allow the formation of any parties on ethnic or regional bases, and so made the formation of the Croat Peasant party and similar parties impossible. The electoral law of Sept. 12 made certain the victory of the government candidates, who represented the National Yugoslav party, a unitarian group somewhat aspiring to become the only Yugoslav party, like the Fascist party in Italy. But the deep democratic traditions and the proud sense of independence of the Serbs never allowed the transformation of the regime into anything approaching a fascist dictatorship. Demands for the restoration of a true democratic and representative government did not cease but gained in momentum, and were coupled with demands for the establishment of a federal state in which the different ethnic and regional groups would enjoy a large autonomy. This discontent led on April 4, 1932, to the resignation of the cabinet of Gen. Živković, who as the king's man had headed the Yugoslav cabinet after the coup d'état of 1929. He was followed by a number of civilians, who, however, continued to be straw men for the king's will. None of them lasted for more than a few months; first Dr. Voyislav Marinković, then Dr. Milan Srškić tried to include in their cabinets as many representatives of the Croats and of the Slovenes as possible, but that in no way reconciled the Croats. On May 30, 1932, bombs were thrown at the king's palace and at other points in Belgrade, and Croat nationalists carried on guerrilla warfare against Serbian authorities. Communist agitation and financial difficulties caused by the poor crops and the decline in foreign trade complicated the situation. On Nov. 14 an executive committee of a coalition formed of Serbian democratic opposition and Croatian Peasant leaders issued a manifesto demanding a return to democracy.

The new parliament elected under the new constitution did not meet with any favourable response. According to the constitution the parliament consists of two houses. The members of the senate were elected for six years, half of them to be re-elected every three years, and a corresponding number to be nominated by the king. Only citizens over 40 years of age can become senators. The chamber of deputies or Skupština was elected by public and verbal elections, in which every male citizen of over 21 years could participate. The lack of secrecy and the verbal character of the vote, however, gave the authorities complete control over the election results. Deputies were elected for a period of four years, one for every 50,000 inhabitants. At the elections held on Nov. 8, 1931, all deputies elected organized themselves into one party adhering to the government policies.

Meanwhile, with the accession of Hitler to power in Germany, the situation of the Little Entente, to which Yugoslavia belonged together with Czechoslovakia and Rumania, had become more critical. Incidents in Dalmatia had again aroused the spectre of a conflict with Italy; a proposed customs union between Italy and Albania had increased Yugoslavia's fears. There were even rumours current that the three "revisionist" powers, Italy, Germany and Hungary, might unite to divide Yugoslavia, Rumania and Czechoslovakia among themselves. Italian influence was very strong in Hungary and Bulgaria, and all that was felt as a threat to Yugoslavia who tried to rely partly upon her understanding with the Little Entente and with the newly formed Balkan Entente, comprising Turkey, Greece, Rumania and Yugoslavia —but partly also upon a rapprochement with Germany against which apparently Yugoslavia felt no aversion. Some Yugoslav circles were of the opinion that the German domination of Austria might be more advantageous to Yugoslavia's security than Italy's preponderant influence there.

To counteract the economic crisis, a number of new trade agreements were concluded in 1933, and an effort was made to implement the political co-operation of the Little Entente by economic co-operation. In spite of the growing seriousness of the international situation, the internal tension between Croats and the government showed no relaxation, though Croat and Serb leaders collaborated in their demands for the restoration of democracy.

The Tragedy of Marseilles.—In the internationally tense situation the French foreign minister, Louis Barthou, one of the most agile of French statesmen, tried to re-establish closer ties between France and her eastern allies, and especially to arrange for an understanding between Yugoslavia and Italy. On Oct. 9, 1934, King Alexander landed in Marseilles, where he was greeted by M. Barthou. On their way through the streets of the French port they were both assassinated. It was proved that the assassination had been inaugurated by a Croat revolutionary organization under Dr. Ante Pavelić, the head of the terrorist Ustashi, and his fellow worker Sladko Kvaternik. A French court sentenced them to death in absentia for the murders. Both were living in Italy, where apparently they were on the best of terms with the fascist government. The Ustashi movement also had a training farm at Janka Puszta in Hungary near the Yugoslav border, where the terrorists were trained and educated in fascist principles. The Yugoslav government charged that the Hungarian government had been aware of this activity and had supported it.

The eleven-year-old son of King Alexander, Peter II, became king under the regency of his uncle Prince Paul, as chief regent, with Dr. Radenko Stanković, a Slovene, and Dr. Ivo Perović, a Croat, as members of the regency council. All three had been appointed by the late king in his last will.

The death of the king introduced a more conciliatory spirit into the administration, but the new cabinet under Bogoljub Yevtić was in no way ready to accept the demands of the opposition. New elections in May 1935, did not change the composition of the parliament. The Croats refused to collaborate. In 1936 Milan Stojadinović became prime minister. He tried to alleviate the economic crisis by diversification of agriculture and industrialization of the country. The basis for a heavy industry was not lacking, as sufficient ore was found in the country. But the most important event under the new cabinet consisted in the attempt to reorient Yugoslavia's foreign policy. Mr. Stojadinović was favourably inclined toward the fascist dictatorships. Thus the ties binding the countries of the Little Entente were loosened, and especially cordial relations were established with National Socialist Germany.

Toward a Serb-Croat Understanding.—On Sept. 15, 1937, Dr. Maček met with the leaders of the Serb Radical party, the Serb Democratic party and the Serb Agrarian party at Zagreb, the Croatian capital. His own party, which represented the overwhelming majority of the Croat people, and the three Serb parties, which could speak for the overwhelming majority of the Serb people, reached complete agreement and demanded the abolition of the semidictatorial constitution, free elections to a constituent assembly which would elaborate the new constitution and finally the formation of a coalition ministry containing representatives of all major parties. Thus the foundation was laid for a Serb-Croat understanding. But the government of Stojadinović did not wish to reintroduce democracy, the more so because it knew that the Serbs and the Croats were for complete and close co-operation with the democratic peoples, while Mr. Stojadinović followed more and more openly a policy of close collaboration with the Rome-Berlin Axis. As a result of this policy he in no way opposed Germany's annexation of Austria, though this act brought the German army to the borders of Yugoslavia. He trusted Mr. Hitler, who solemnly pledged the inviolability of Yugoslavia's frontiers. Nor did the Yugoslav government help its nominal ally Czechoslovakia when Germany threatened that country. The sympathies of the Yugoslav population were outspokenly and enthusiastically for Czechoslovakia, but the government did not heed popular opinion and pursued unflinchingly its pro-National Socialist policy, which also helped to establish the economic domination of Germany in Yugoslavia.

The year 1937 saw also much agitation of the Orthodox church against a proposed concordat of the government with the Roman Catholic church. The patriarch of the Orthodox church died during the controversy.

The year 1938 was marked by continued co-operation between the Croats and the Serbs. Dr. Maček visited Belgrade on Aug. 14. Both peoples were united in their demands for democracy and in their opposition to a profascist foreign policy. Meanwhile Prime Minister Stojadinović visited Italy and Germany and was everywhere most warmly received. His policy led also to a rapprochement with Hungary and Bulgaria. On Dec. 11, 1938, new elections were held, in which all opposition parties, Serbian and Croation, joined in a common front against the government. The government succeeded in receiving a slight majority of votes. The only outright fascist party, the Zbor, received only 30,310 votes, or less than 1% of the votes cast. The great triumph of the opposition at the polls indicated the instability of the regime. In spite of all the pressure exercised by the government and in spite of the method of open and oral ballots, the government succeeded in getting—according to its own official figures which were subject to doubt—only 1,643,783 votes as against 1,364,524 for the opposition.

As a result, Stojadinović resigned on Feb. 4, 1939. He was followed by Dragisha Cvetković. Minister of foreign affairs in the cabinet was Aleksander Cincar-Marković; minister of war was Gen. Milutin Nedić. The new government mitigated the pro-Axis course in foreign policy in agreement with public opinion, though the sympathies of the foreign minister were known to be profascist. But a serious attempt was made to solve the Croat-Serb problem. After long negotiations, agreement was reached on Aug. 25, 1939. Two of the banovinas, Savska, and Primorska, were united into a single administrative unit called Banovina Croatia, comprising about one-fifth of the total area of the state and having a population of 4,500,000 or about a third of the country. Croatia was to enjoy a large autonomy and to

have its own Diet at Zagreb. Mr. Subasitch was appointed ban of autonomous Croatia. These measures were regarded as only the first step toward the complete reconstruction of Yugoslavia, the autonomous constitution of further units and the reintroduction of parliamentary democracy based upon free elections as the centre of the government. The outbreak of European war in the fall of 1939 postponed the realization of these plans.

Yugoslavia and the War.—With the outbreak of World War II, the Yugoslav government proclaimed its neutrality. As the year 1940 developed, the government, despite the outspoken sympathies of the large majority of the people, showed a pronounced tendency toward rapprochement with Germany. Efforts to establish closer co-operation and an antifascist bloc among the Balkan countries through the medium of the Balkan entente proved futile. Each of the nations was split into pro and antifascist cliques; this divisory spirit among the Balkan governments worked to the advantage of the axis. Furthermore, within Yugoslavia itself, the ill feeling existing between the Croats, who sought more representation in the government, and the reigning Serbs complicated that country's position.

Meanwhile, the government rulers moved closer toward the axis and on Feb. 26, 1941, Yugoslavia signed a friendship pact with Hungary. This step of the Yugoslav administration toward tighter bonds with the axis was facilitated by Hitler's bloodless and successful occupation of Rumania. The adherence of Hungary, Rumania and Bulgaria to the axis pact left Yugoslavia little choice. The alternative was to resist Germany in co-operation, if possible, with Greece and Turkey. However, the government was predisposed toward the axis and in the early months of 1941, the prime minister, Dragisha Cvetkovitch, and the foreign minister, Alexander Cincar-Markovitch, visited Hitler in Berlin. While they seemed politically inclined toward the fascist orbit, they had legitimate reason to fear that the Yugoslav people might revolt against an alliance with Germany and Italy. Thus Cvetkovitch and Cincar-Markovitch dallied in their negotiations with Hitler until March 22, 1941, when, yielding finally to a German ultimatum, they decided to join up with Hitler and Mussolini. On March 25, Cvetkovitch and Cincar-Markovitch affixed their signatures in Vienna to the axis pact.

This proved to be a fatal mistake of the Cvetkovitch government. Two days later, the people and elements of the army who had objected to this surrender to fascist pressure overthrew the government. Gen. Dusan Simovitch, Yugoslav chief of aviation became prime minister and King Peter II assumed the government amid unprecedented scenes of public rejoicing by the Serb people, who saw their liberty saved and in a lesser degree by the Croats. Under Gen. Simovitch, Dr. Vladimir Maček continued as vice-premier. Prince Regent Paul fled to Greece and Cvetkovitch and Cincar-Markovitch were arrested.

The Yugoslav decision to make a fight rather than submit to the axis came too late. The country already was hemmed in by German troops and as the preceding government was inclined to appeasement, it had not prepared the army and its mobilization sufficiently. Thus, when the wehrmacht struck from several directions on April 6, 1941, it defeated the courageous Yugoslav army in two weeks.

Promptly thereafter the axis powers partitioned Yugoslavia. Croatia was brought under the "protection" of the Italian crown. Italy also annexed important parts of the Dalmatian coast and divided Slovenia with Germany. For their assistance, Bulgaria and Hungary also received shares of Yugoslavia.

After the collapse of his armies, King Peter II fled to London where he set up a government-in-exile. At home, Yugoslav guerrilla armies emerged; within Serbia, Gen. Draja Mikhailovitch organized the Chetniks who, at one time, claimed a membership of 250,000. A rival group, the partisans, was headed by Marshal Josip Broz (Brozovitch), a Croat communist, more widely known as Tito. Mikhailovitch's army consisted chiefly of Serb factions loyal to King Peter. Tito's forces were more representative in character and welcomed volunteers from men of all races, parties and classes.

After 1942, Tito's forces vastly overshadowed the Chetnik movement in size and importance and the British, who had been supporting Mikhailovitch switched their support to the partisans.

Then, on Dec. 4, 1943, Tito's Yugoslav Committee of National Liberation announced that it had set up a provisional government in opposition to the existing *émigré* regime in London. Tito's assumption of power was opposed by the Chetniks and clashes between the two forces were frequent. As a result of the émigré government's failure to disavow Mikhailovitch, Tito deprived the London regime of all rights and openly accused Mikhailovitch, who had been named war minister in the royal government, of organizing civil strife.

At first King Peter refused to recognize the Tito government; later, he endorsed the formation of a new cabinet for the London regime by Dr. Ivan Subasitch (July 7, 1944), who was empowered to confer with Tito and to work out a solution of the dispute. Tito and Subasitch agreed on formation of a regency for rule of Yugoslavia. This agreement was reluctantly recognized by King Peter on Jan. 29, 1945.

As World War II drew to its end, Tito's partisans in Yugoslavia and Allied forces in northern Italy engaged in a race for occupation of the Venezia Giulia department of Italy. In May 1945, a Yugoslav partisan force entered Trieste but was prevented from assuming complete control of the port by the almost simultaneous arrival of British and U.S. troops.

Tito's efforts to win control of Trieste and surrounding areas resulted in sharp and acrimonious exchanges with the U.S. and British. But on June 20, a compromise agreement was reached whereby a joint occupation of the disputed Italo-Yugoslav border area by U.S., British and Yugoslav troops was provided until final disposition of the territory at the peace conference.

The Republic.—On Aug. 7, 1945, Marshal Tito appealed to the national congress meeting in Belgrade to support a republican form of government and he denounced the monarchical regime. Tito's views were upheld in the national elections for a constituent assembly, Nov. 11, when about 6,500,000 Yugoslavs voted their approval of his policies while 700,000 cast ballots against him. The rightist opposition refused to participate in the elections on grounds that they were neither free nor democratic. Tito, however, declared (Nov. 16) that the results of the vote proved conclusively that the people of Yugoslavia rejected any "return to the old state of affairs." On Nov. 29, a republic was proclaimed by the constituent assembly meeting in Belgrade and the monarchy was abolished. On hearing the news, King Peter in London asserted that the decision was unfairly reached, alleging that Tito had forbidden the people to express their own wishes on the issue of retaining the monarchy.

The new constitution was adopted by the constituent assembly (Jan. 31, 1946) and Tito was asked to form a new government. In its post-war foreign policy, the Tito government was decidedly pro-Russian and anti-British. Tito made renewed demands for Istria and that part of Slovenia containing Trieste.

The Russians were disposed to support Tito's claims while the British rejected them. Tito also suspected that the Allied armies in northern Italy might be used for a possible thrust into Yugoslavia. The Allies on the other hand feared that Tito's communism would spread into Italy if their forces did not bar the way. These conflicting views were mirrored in the Allied-Yugoslav dispute on the presence of Yugoslav royalist and anti-Russian Polish forces in Italy and in the Allied occupation zones of Germany. On Feb. 16, the Tito government, through the medium of the Russian delegate to the United Nations, charged that the Polish forces in Italy had been moving closer toward the Yugoslav border and were a "possible future threat to peace." This accusation was categorically denied two days later by Ernest Bevin, the British foreign secretary.

The U.S. state department announced April 18, 1946, that it would recognize the new republic, although with some reservations as to Tito's domestic policies.

In the spring of 1946, Draja Mikhailovitch, who had been captured by Yugoslav forces (March 13), was on the way to becoming an international *cause célèbre*. The Tito government's announcement that Mikhailovitch would be tried on charges of collaboration with the axis provoked an outcry from anti-Tito elements in the U.S. and Britain who expressed doubt that the Chetnik leader would receive a fair hearing.

A U.S. state department request that some U.S. airmen who had been rescued during the war by the Chetniks be permitted to testify for Mikhailovitch was rejected by the Yugoslav government (April 5, 1946). The trial took place between June 10 and July 15, 1946, when Mikhailovitch was declared guilty of treason and collaboration with the axis and sentenced to death. He was shot on July 17. (*See* also WORLD WAR II.) (H. Ko.; X.)

DEFENSE

The first shots in World War I were fired by Austrian guns bombarding Belgrade on July 29, 1914. After a gallant resistance the Serbian army was overpowered by its northern adversaries in October 1915, and forced into a disastrous retreat across Albania as the result of a sudden blow struck from the right rear by the old adversary Bulgaria. After being reconstituted in Greek territory (Corfu) the Serbian troops joined the Allied army at Salonika, and those troops formed the nucleus of the Yugoslavian army of 1939. In October 1918, when the resistance of the central powers was on the point of collapse and the Bulgarians had already thrown up the sponge, the Serbian army numbered 63,050 combatants, with a ration strength of 110,550. It was organized in six infantry divisions and one of cavalry, with 289 field guns. Its battle casualties had exceeded 331,000, a figure which included 45,000 killed and over 133,000 wounded in action. Such was the war record of the Serbian troops in what was later the army of Yugoslavia.

The Army of 1939: Recruitment and Service.—The territory of the Serbs, Croats and Slovenes was divided into 5 army areas, each of these containing three or four divisional areas subdivided into military districts. Military service was obligatory for all physically fit citizens between the ages of 21 and 40 with the active army and subsequently with the reserve up to the age of 50. With the sanction of the cabinet, the war minister could also call up youths of ages from 18 to 20 and all men under 55 years. Service with the colours was for 18 months from the year in which the 21st birthday falls.

Yugoslavia was divided into areas for 16 infantry and 3 cavalry divisions. The infantry divisions included also artillery, while the cavalry divisions included horse artillery. On the whole there were in 1939, 53 infantry regiments, 10 cavalry regiments and 33 artillery regiments. In addition there were independent heavy artillery formations and pioneer and engineering regiments. The budget for the year 1939–40 comprised a sum of 2,928,166,000 dinars for army and navy.

In Yugoslavia the ministry of war controls the army, the air force and the navy.

The Yugoslav air force in 1939 counted 8 regiments with 48 squadrons and 2 hydroplane regiments with 7 squadrons. The small navy, destined exclusively for coastal defence, comprised 1 cruiser, 1 flotilla leader, 3 destroyers, 6 torpedo boats, 8 motor torpedo boats, 4 submarines and 35 different auxiliary units. (X.)

ECONOMIC AND FINANCIAL POSITION

Agriculture and Livestock.—Agriculture occupies about 80% of the total population of Yugoslavia. The different provinces vary greatly in climate, soil, configuration and methods of cultivation. The coastal districts and the high Karst land immediately behind them are mountainous and often barren, and present great difficulties of communication. The most fertile districts are the Voivodina (Banat and Bačka), Slavonia and northern Serbia (especially the Mačva, Morava and Timok districts) and portions of Croatia, Slovenia and Bosnia. The principal crops are maize and wheat (40% of both being produced in the Voivodina), sugar beet, hemp and hops (also in the north), opium (in Macedonia) and tobacco (chiefly in Macedonia and Hercegovina). Other important crops are beans, potatoes, flax, clover and lucerne.

Areas Sown and Productions in 1938

Crop	Acreage	Tons
Wheat	5,262,393	3,029,037
Barley	1,026,235	421,259
Rye	627,178	227,102
Oats	894,051	326,526
Maize	6,801,742	4,755,873
Vines	540,264	4,672,157*

*Hectolitres

Admirable wines are produced in Dalmatia and Hercegovina in Syrmia (of the Hungarian type) and along the Danube in Serbia (Smederevo). The fruit industry is important, notably in the Sumadija district of Serbia and in the east of Bosnia. In an average year some 750,000 tons of fresh plums are produced, and 40,000 to 50,000 tons of dried plums and pulp are exported. There were eight sugar factories, two state-owned, the rest in the hands of foreign banks and companies.

In 1938 there were in Yugoslavia 1,264,470 horses, 142,323 mules and asses, 4,267,339 cattle, 10,137,357 sheep, 3,450,884 pigs and 1,890,386 goats. The forests cover 7,500,000 hectares of land, of which all save 2,000,000 is old forest. Timber is a main article of export, Italy, Egypt and the Levant being the best customers. The most important state forests are in Bosnia, beech, fir and oak being the commonest trees. The Slavonian oak (known abroad as "Austrian oak") is valuable and of high quality. In Serbia 60% of the forests are beech. At Teslić there is a wood-distilling factory, which is the largest in Europe, and produces methylated spirit, alcohol, formaldehyde and acetone.

Mining and Mineral Resources.—The mineral resources of Yugoslavia have for the most part lain idle since Roman and mediaeval times, but offer very great possibilities. Iron ore of good quality occurs in enormous quantity and near the surface at Ljubija, in Bosnia, where it is mined by the state mining authorities and sold for exportation. Another iron mine worked by the state exists at Vareš, in Bosnia, and is worked in conjunction with a coal mine and iron-smelting establishment and the ironworks at Zenica. The metallurgical works here are on a primitive scale, their production being pig iron and small castings. The ironworks at Jesenice (Slovenia), which have a capacity of 70,000 tons per annum, produce bar iron, iron and steel sheets, steel rails up to 22 kilograms per metre (as used on the Bosnian narrow-gauge railways), rolled iron, drawn iron and wire nails. Bar iron is manufactured at Store, near Celje, in Slovenia; steel and steel springs at Guštanj, on the Maribor-Klagenfurt railway, and highly silicated foundry iron is produced at Sopusko in Slovenia. Large deposits of brown coal and lignite occur in many parts of Yugoslavia, but there is no coking coal. Copper is produced at Bor and Majdanpek in Serbia.

In 1938 the output of iron ore was 606,884 metric tons, of copper ore 762,066 metric tons and of lead-zinc ore 882,892 metric tons. Of chrome ore 58,470 metric tons were produced, and of brown coal and lignite 5,737,193 metric tons.

Principal exports in 1939, valued in thousands of dinars

	1938	1939
Eggs	157,455	160,313
Wheat	208,811	375,101
Cattle	74,865	107,659
Maize	480,873	99,082
Swine	376,954	484,161
Fresh meat	236,589	282,521
Timber	676,275	853,102
Copper ore	406,062	441,428

Foreign Trade.—The total exports in 1939 amounted to 5,521,187,370 dinars—the principal items being shown in the table in the first column. The chief countries of destination are shown in the table below.

Chief countries of destination

Country	Value in thousands of dinars	
	1938	1939
Germany	1,813,864	1,762,003
Great Britain	485,133	366,698
Czechoslovakia	398,361	769,203
Belgium	336,843	348,304
Italy	324,297	583,516
United States	255,860	280,736
Hungary	215,377	289,246
Greece	130,250	135,382
Netherlands	108,788	103,388
Switzerland	83,741	167,529

Imports during 1939 amounted to 4,757,381,947 dinars, the most important items being cotton and cotton goods (690,740,000 dinars), iron and iron goods (576,461,000 dinars), wool and woollen goods (415,169,000 dinars) and machinery (388,303,000 dinars). Germany took first place on the list of countries supplying Yugoslavia's imports.

Revenue and Expenditure.—For the year 1939–40, the expenditure was estimated at 12,942,000,000 dinars, and the revenue at the same figure. The principal sources of revenue were (in millions of dinars): direct taxes, 3,025; indirect taxes, 2,304; state enterprises, 4,253; monopolies, 2,215; and various, 44.

The Yugoslav dinar was originally equal to a franc. On May 8, 1931, a stabilization loan was concluded in Paris to help in the legal stabilization of the dinar. As a result the dinar was stabilized at a value of 26.5 mg. of gold, or 11 dinars corresponding to 1 gold franc, 100 dinars to $1.76 in gold.

Public Debts.—On July 1, 1939, the public external debt of Yugoslavia comprised the most various items, partly prewar debts, going as far back as 1888, war debts to the British government, to the United States and to the French government, and finally postwar debts. The internal debt amounted on April 1, 1939, to 8,613,000,000 dinars. (H. Ko.)

YUKON, the largest river in Alaska, and the fifth largest in North America. With its longest tributaries not in Alaska, the Lewes and the Teslin (or Hootalinqua), its length is about 2,300 mi., in the form of a great arc, beginning in the Yukon district of British Columbia, near the Pacific ocean, and ending at the Bering sea coast. Its catchment area is about 330,000 sq.mi., more than one-half of which lies in Canada. The Lewes river rises in Lake Bennet, or, more accurately speaking, Lake Lindeman, on the northern slope of the coast range just over the Dyea pass up from Lynn canal (at the head of Chatham strait). It flows north through a chain of lakes with connecting streams until it is joined by the Hootalinqua about 30 mi. below the last of these lakes (Lebarge). Its confluence with the Pelly river, at Selkirk, Yukon district, about 120 mi. due east of the Alaskan-Canadian boundary, forms the headwaters of the Yukon proper. Flowing thence north-west, the Yukon turns abruptly to the south-west near Ft. Yukon, Alaska, on the Arctic Circle, and continues nearly at right angles to its former course to a point south of the head of Norton sound, where it turns again and flows in a north-west direction, emptying into the sound from its south shore.

The Yukon valley comprises four sub-provinces, or physiographic divisions, called the "Upper Yukon," "Yukon flats," "Rampart region" and "Lower Yukon." The "Upper Yukon" valley is about 450 mi. long and from 1 to 3 mi. broad, and is flanked by walls rising to the plateau level from 1,500 to 3,000 ft. above the stream. In this part of its course the Yukon receives from the south the Selwyn river (about 40 mi. below the junction of the Lewes and Pelly rivers); from the west the White river (about 60 mi. below the Selwyn); from the north the Stewart river (about 10 mi. below the White), one of the largest tributaries of the Yukon; from the east the Klondike river (near 64° N. lat.); from the west Forty-mile creek (about 40 mi. above the Alaskan-Canadian boundary line), and many other smaller streams. The "Yukon flats" flank the river for about 200 mi. and are from 40 to 100 mi. wide. Here the stream varies in width from 10 to nearly 20 mi., and involves a confused network of constantly changing channels. Here, too, the river makes its great bend to the south-west, and its channels are constantly changing. The "flats" are monotonous areas of sand bars and low islands, thickly wooded with spruce. The principal tributaries here are the Porcupine river (an important affluent, which enters the main stream at the great bend about 3 mi. N. of the Arctic Circle); the Chandlar river, also confluent at the great bend, from the north, and, near the west edge of the flats, the Dall river, also

from the north. The "Rampart region" begins near 66° N. lat., where the "flats" end abruptly, and includes about 110 m. of the valley, from 1 to 3 m. wide, and extending to the mouth of the Tanana. No large tributaries are received in this part of the river. At the west edge of the Ramparts the Yukon receives the Tanana river, its largest tributary lying wholly within Alaska. The Tanana valley is about 450 m. long, nearly parallel to the Yukon from about due west of its head waters to the great bend, and drains about 25,000 square miles. Its sources lie in the glaciers on the north slopes of the coast, or St. Elias range, and it receives many tributaries. The Lower Yukon includes that portion between the ramparts and the sea, a stretch of about 800 m. At the mouth of the Tanana (which enters the main stream from the south) the gorge opens into a lowland from 15 to 20 m. wide. Along the north-west boundary of the valley are low mountains whose base the Yukon skirts, and it continues to press upon its north bank until the delta is reached. The valley is never less than 2 or 3 m., and the river has many channels and numerous islands; it has walls nearly to the head of the delta, though about 100 m. above the delta the south wall merges into the lowland coastal plain; the relief is about 1,000 feet. The Yukon delta begins near 63° N. lat. Here the main stream branches into several channels which follow north or north-west courses to Norton sound. The northernmost of these channels is the Aphoon pass, and the most southerly is Kwikpak pass; their outlets are about 75 m. apart on the coast, and from 40 to 50 m. from the head of the delta. Between them is a labyrinth of waterways, most of the intervening land being not more than 10 ft. above low tide.

The Yukon river is unique among rivers, in that it rises within 15 m. of tidal waters in the Dyea inlet on the Pacific coast, whence it flows in a north-westerly direction nearly 1,000 m., just crossing the Arctic Circle, where it turns south-west through the middle of Alaska, and then flows more than 1,200 m. until it reaches the ocean within sight of which it rose; for we may properly call Bering sea a part of the Pacific ocean. This grand stream is also surprising in the length of navigation way it gives in proportion to its length, for less than 15 m. N. from where its tiniest streamlets trickle from the crest of Dyea pass lies Lake Bennet, whose head is the true beginning of steamboat navigation on this noble stream. From the starting-point of those same streamlets one can look down on other streamlets beginning their steep descent of the Dyea pass to the waters of the Lynn canal. The nearest harbour for ocean-going vessels is a poor one at St. Michael's island, about 60 m. north-east of the delta; here freight and passengers are transferred to flat-bottomed river steamers. These enter the delta and the river by the Aphoon pass, which is about 4 ft. deep at mean low water, the current varying from 1½ to 4 m. an hour. The Lewes is navigable as far as White Horse rapids, which with Miles cañon obstruct the river for a few miles. Above them the stream is again navigable to its source, about 100 m. beyond. The White pass and Yukon railway from Skagway to White Horse (111 m.) overcomes these obstructions, however, for traffic and travel. The Stewart river, seldom less than 150 yd. wide, is navigable by light-draught steamers to Frazer falls, a distance of nearly 200 miles. The Tanana is navigable for about 225 m. to the mouth of the Chena, and above the mouth of the Chena it again becomes navigable for more than 250 m., including its principal upper tributary, the Nebesna. The Koyukuk, the second largest tributary, entering the Yukon about 600 m. up from its mouth, is navigable for 570 m. (Camden). Altogether the Yukon proper with its principal tributaries embraces more than 3,500 m. of navigable waters. The system is open to navigation from May until September.

Cantwell, R.C.S., *Report of the Operations of the U.S. Revenue Steamer Nunivak of the Yukon River Station, Alaska, 1899–1901* (Washington); W. Ogilvie, *Early Days on the Yukon* (Ottawa); A. H. Brooks, "The Geography and Geology of Alaska," *U.S. Geol. Survey, Doc. No. 201* (Washington, 1906).

YUKON TERRITORY, the most westerly of the northern territories of Canada, bounded south by British Columbia, west by Alaska, north by the Arctic ocean and east by the watershed of Mackenzie river. It has an area of 205,346 sq.mi. (excluding water). The territory is chiefly drained by the Yukon river and its tributaries, though at the southeast corner the headwaters of the Liard river, flowing into the Mackenzie, occupy a part of its area. The margins of the territory are mountainous, including part of the St. Elias range with the highest mountains in Canada at the southwest corner, Mount Logan (19,850 ft.) and Mount St. Elias (18,008 ft.), and the north extension of the Rocky mountains along the south and northeast sides; here, however, not very lofty. The interior of the territory is high toward the southeast and sinks toward the northwest and may be described as a much dissected peneplain with low mountains to the south. The most important feature of the hydrography is the Yukon (*q.v.*) and the rivers which flow into it. The Klondike gold mines are reached by river boats coming down 460 mi. from White Horse, the terminus of the White Pass railway, 111 mi. long, from Skagway on an inlet of the Pacific. The Trans-Canada Airlines have branch services to the Yukon from Edmonton. The Alaska-Canada highway of 1942 connects railhead at Dawson Creek, B.C., with the Yukon and Alaska.

Before the discovery of gold on the Forty Mile and other rivers flowing into the Yukon the region was inhabited only by a few Indians, but the sensational finds of rich placers in the Klondike (*q.v.*) in 1896 brought in a vigorous population centred in the mines and at Dawson, which was made the capital of the newly constituted Yukon territory. With the decline of the gold-mining industry, the population decreased from 27,219 in 1901 to 4,157 in 1921, with 4,914 (males 3,153) in 1941. The Yukon is administered by an appointed (dominion) commissioner and a Territorial Council of three, elected for three years from the Dawson, White Horse and Mayo districts. Law and order are enforced by members of the Royal Canadian Mounted Police. The Yukon is represented in the dominion parliament by one member in the house of commons. Placer gold, originally the principal output, is now quite subordinate to lode mining. Gold output, 1941, 70,939 fine oz. The Yukon has also been a steady producer of silver and in 1940 yielded 2,259,343 fine oz., mostly from Keno and Galena Hills, in the Mayo district. A concentrator has been installed at Keno Hill. The wide distribution of the ores of gold, copper, silver and lead indicate enormous mining possibilities. Coal, of which there are large reserves, is being mined. Large game and fur-bearing animals abound.

Though so near the Pacific the Yukon territory has a rigorous continental climate with very cold winters seven months long, and delightful sunny summers. Owing to the lofty mountains to the west the amount of rain and snow is rather small, and the line of perpetual snow is more than 4,000 ft. above sea-level, so that glaciers are found only on the higher mountains; but the moss-covered ground is often perpetually frozen to a depth of 100 or 200 ft. Vegetation is luxuriant along the river valleys, where fine forests of spruce and poplar are found, and the hardier grains and vegetables are cultivated with success.

YUMA, a city near the south-western corner of Arizona, U.S.A., on the Colorado river, at the mouth of the Gila river; it is the county seat of Yuma county. It is on Federal highway 80; has a municipal airport; and is served by the Southern Pacific and the Yuma Valley railways. Pop. (1940) 5,325.

YUMAN, a speech stock of American Indians, named from the Yuma tribe, living about the lower Colorado river and occupying a distinctly desert habitat. The groups that belong are the Havasupai, Walapai and Yavapai of the mountains of western Arizona; the Mohave (*q.v.*), Yuma, Kamia and Cocopa (*q.v.*) in the Colorado river bottomlands; the Maricopa (*q.v.*), Halchidhoma, Kohuana, Halyikwamai, once on the river but driven out and the remnants, except the Maricopa, lost to tribal identity; the Diegueño to the rear of San Diego in California; and the Akwa'ala, Yukiliwa, Cochimi and other groups known under varying local names in Mexican California. Of these tribes, the most advanced were those on the Colorado, who have changed little since their discovery by Alarcon in 1540. They have always been warlike and turbulent, but chiefly among one another. They are agricultural, marking the north-western frontier in the continent of the native practice of maize farming. They make pottery but no basketry. They are divided into totemic patrilineal clans

YUNCAN, a group of tribes of South American Indians, forming an independent linguistic stock. The Yuncas (known also as Chimus and Muchic) occupied originally the arid coastal region of northern Peru comprised within the valleys of Trujillo, Chicama, Jequetepeque, Lambayeque and Morope; later, by conquest, they extended the area controlled north as far as Tumbez and southward to Chancay. In the 15th century they were conquered, after stubborn resistance, by the Incas and their territory included within the Inca empire. Their most important centre was the great city of Chan Chan (Gran Chimu), which was situated near the present Trujillo.

The Yuncas were a city-dwelling, agricultural people with highly developed agriculture, growing manioc, maize and sweet potatoes. While the houses of the poorer people were doubtless of reeds and matting or thatch, the better dwellings and all the important structures were built of sun-dried brick. The temples were stepped pyramids, raised on high platforms, and containing burial chambers within. Some of the palaces were decorated with elaborately executed stucco relief patterns in geometric style derived from textiles, and reminiscent of the stone mosaics of Mitla in Mexico. The Yuncas were wide traders along the coast, using reed and log balsas or rafts, and constructed regular harbour works at their ports. They were expert textile makers and raised cotton for the purpose; were very skilful workers in gold, of which great amounts have been excavated by treasure-hunters; and were also makers of very fine pottery, of which three sequent styles may be distinguished. They would appear to have had a rather elaborate social and governmental organization, with kings or chiefs of considerable power. In their religion they venerated the moon more than the sun (in contrast to their Inca conquerors), and also held sea deities in high esteem.

Uhle, "Die Ruinen von Moche," *J. Soc. Americanistes de Paris,* (ms.) vol. x., pp. 95–119; A. L. Kroeber, "The Uhle Collection from Moche," *Univ. of California, Pub. Amer. Arch. Ethnol.,* vol. xxi., pt. 5.

YUNNAN (*South of the Clouds*), a southwest province of China, bounded north by Szechwan and Sikang, east by Kweichow and Kwangsi, south by Annam and Burma, and west by Burma and Assam; area 155,861 sq.mi. The population was 10,853,359 in 1939, but increased due to wartime migration from Japanese-occupied China. The inhabitants include many races beside Chinese, such as Shans, Lolos and Miaotze. The Mosos, in northwest Yunnan, once formed an independent kingdom which extended into East Tibet. Some of the inhabitants are staunch Moslems. The west and northwest have high mountain ranges and deep gorges of the Kinsha-kiang (upper Yangtze-kiang), the Mekong and the Salween; the ridges have peaks over 16,000 ft. high, the slopes are often heavily forested. The Burma road, built in 1939, leads from Kunming via Paoshan and Lungling to Lashio with a branch road via Tengyueh to Bhamo. The southeast includes the upper basin of the Songkoi or Red river, and of the Pata-ho (upper Si-kiang); the former becomes navigable near Man-hao, just before it leaves Yunnan for Tonkin. This region has rich valleys and open, undulating country. The northeast, near the Yangtze-kiang's right bank, is not very high, though higher than Kweichow, over the border, but it is deeply dissected and sparsely peopled. There are a few lakes, especially near the capital, Kunming. The mean monthly temperature of Kunming varies from 47° F. in December to 69° F. in July, the warm season being April to August and the rainy season March to August, with the maximum in June (13.34 in.). The total annual fall is 37 to 38 in. Yunnan under its native governor, Lung Yün, had been practically autonomous. But war conditions after 1937 reintegrated the province with the national government. The province became an important communications link between Chungking, Chengtu, Kweiyang and Burma. Following an Anglo-Chinese agreement in 1941, finally delimiting the Sino-Burmese border, railway construction was begun for a Kunming-Lashio railway as the railway to Japanese-controlled Indo-China had been torn up. The fall of Lashio to the Japanese in 1942 closed the Burma road. The Japanese continued their advance into Yunnan province as far as the Salween river occupying Tengyueh and Lungling. In 1944 a Chinese counteroffensive aimed at clearing the province and reopening the Burma road in connection with the Sino-American upper-Burma offensive. The war greatly stimulated the industrial and agricultural development of the province. The mineral resources in tin, coal, iron, tungsten, antimony, copper and gold were being developed, and private factories in metallurgy, machinery, electrical equipment, textiles, rubber, cement and other productions were established. In food and textiles progress has been made toward provincial self-sufficiency. Yunnan, long independent, was subdued by Kublai Khan, but was not finally incorporated in the empire until the 17th century. It was the principal centre of the great Mohammedan rebellion, which lasted 16 years and was suppressed in 1872.

See H. R. Davies, *Yunnan, the Link between India and the Yangtze* (Cambridge, 1909); A. Little, *Across Yunnan* (London, 1910); Rev. J. M'Carthy, "The Province of Yunnan," in *The Chinese Empire* (London, 1907); L. Richard, *Comprehensive Geography of the Chinese Empire* (Shanghai, 1908).

YUN-NAN-FU (KUNMING), the capital of Yunnan province, China, about 500 mi. by rail N.N.W. of Haiphong, Tonkin. It is centrally placed at a focus of ways within the province. The plain near by is fertile and well populated. The city has a strong Mohammedan colony and suffered during the Mohammedan rising in 1855. The opening of the French railway from Tonkin in 1910 brought a development with French interests. However, Kunming, pop. about 50,000, remained a provincial city with inefficient electric light and telephone systems. The population and importance greatly increased (pop. to over 150,000) during 1940–41 with the completion of the Burma road with Kunming as terminus. The railroad to Japanese-controlled Indo-China was torn up and French influence ended. Kunming became a centre of tin, steel, copper, cement, rubber, textile and other industries and the communications and cultural centre of the southwest.

YURIEV: *see* TARTU.

YUROK, a tribe on the lower Klamath river, asserted but also disputed to be of Algonkin speech lineage, is perhaps the nuclear group of the N.W. California Indian culture, principal others being the Hoḳan Karok upstream, the Athabascan Hupa (*q.v.*) of Trinity, the Chilula of Redwood, the Tolowa of Smith river; and the Algonkin (?) Wiyot of Humboldt bay. The Yurok once numbered about 2,400 in more than 50 villages; 500 remain.

YURUCAREAN, a small group of tribes of South American Indians, constituting an independent linguistic stock. The Yurucares live in Bolivia on the eastern slopes of the Andes and the lowlands along the Chaparé, Isiboro and Securé rivers, tributaries of the Mamoré. They are a tall, well-built folk, slightly lighter in colour than the Quechua of the highlands, who gave them the name by which they are known, signifying "white men." Their dress consisted of a poncho-like garment, without sleeves, of bast, decorated with geometric patterns, printed by means of large wooden dies. The Yurucares are sedentary agriculturalists and hunters, living in open thatched shelters.

See A. D'Orbigny, *L'Homme Americain* (Paris, 1839); L. E. Miller, The "Yurucare Indians of Eastern Bolivia" (*Geog. Review,* 1917, pp. 450–464).

YUSAFZAI, a large group of Pathan tribes, originally immigrants from the neighbourhood of Kandahar, which includes those of the Black Mountain, the Bunerwals, the Swatis, the people of Dir and the Panjkora valley, and also the inhabitants of the Yusafzai plain in Peshawar district of the North-West Frontier Province of India. Three sections of the tribe, the Hassanzais, Akazais and Chagarzais, inhabit the W. slopes of the Black Mountain, and the Yusafzai country extends to the Utman Khel territory.

YVERDON (1,437 ft.), a town in the canton of Vaud, Switzerland, and on the south-western corner of Lake Neuchatel, at the mouth of the Thièle. It is situated on the site of the small Roman town of Eburodunum. Population (1941) 10,856, French-speaking and mostly Protestant. At the beginning of the 19th century its castle was the home of Pestalozzi's school. It has an historical museum and several industries. It is a well-known spa with warm and sulphurous springs.

YVES, SAINT, OF BRITTANY (1253–1303), was born in 1253 at Kermartin, near Tréguier, Brittany. His father was Héloury, seigneur of Kermartin, and his mother Azou de Quenquis. In 1267 he went to Paris to study law, and ten years later to Orléans to study canon law. On returning to Brittany he was appointed ecclesiastical judge under the archdeacon of Rennes. In 1285 he was ordained priest and appointed first to the parish of Trédrez, and afterwards to Louannec, where he died on May 19, 1303. He was buried in the cathedral of Tréguier, and was canonized by Clement VI. in 1347. As a lawyer and judge he was famed for his rectitude and wisdom and for his zeal in defending the cause of widows and orphans. His feast is celebrated on May 19. He is the patron saint of lawyers for he was "advocatus et non latro, res miranda populo" (a lawyer and not a thief, a marvel to the people).

YVETOT, a town of north France, in the department of Seine-Inférieure, 24 mi. N.W. of Rouen on the railway to Le Havre. Pop. (1936) 6,565. Cotton goods and hats are made; also trade in agricultural products. The lords of Yvetot bore the title of king from the 15th till the middle of the 16th century, their petty monarchy being popularized in one of Béranger's songs. In 1592 Henry IV here defeated the troops of the League.

Z THIS letter together with Y was adapted by the Romans from the Greek alphabet after the conquest of Greece for use in Greek words borrowed or transliterated. It was the seventh letter of the Greek alphabet and had the form or . It was not taken over by the Latins from the Chalcidic alphabet with the rest of the letters as the sound it represented did not occur in Latin. Its place in the alphabet was filled by the letter G adapted from C to represent the voiced velar stop. The letter corresponded to Semitic (*zain*).

The minuscule letter has generally retained the form of the majuscule, though in certain hands the form has developed.

The sound represented by the letter in Greek is not precisely known. It was, at least in certain cases, a double sound and probably varied in separate dialects as well as in different words between *z, ž, zd, dz,* or *dž.* In Latin it was probably the voiced fricative corresponding to *s* and this value it has retained till modern times. (B. F. C. A.)

ZABERN: *see* SAVERNE.

ZABRZE: *see* HINDENBURG.

ZACATECAS, a state of Mexico. Its area is 28,117 sq.mi.; pop. (1940) 565,437. It belongs wholly to the great central plateau of Mexico, with an average elevation of about 7,700 ft. The state is somewhat mountainous, traversed in the west by lateral ranges of the Sierra Madre Occidental, and by numerous isolated ranges in other parts—Mazapil, Norillos, Guadalupe and others. There are no large rivers, only the small headstreams of the Aguanaval in the north, and of the Guazamota, Bolanos and Juchipila in the west, the last three being tributaries of the Rio Grande de Santiago. As the rainfall is light this lack of streams suitable for irrigation is a drawback to agriculture. The climate is dry and generally healthful, warm in the valleys and temperate in the mountains. The agricultural products are cereals, sugar and maguey; the first depends on the rainfall which often fails altogether, the second on irrigation in the lower valleys, and the third doing best in a dry climate on a calcareous soil with water not far beneath the surface. A natural product is *guayule,* a shrub from which rubber is extracted and which attracted considerable attention in the U.S. after the outbreak of war in the Pacific in 1941 cut off the normal sources of rubber supply. Mining for silver, gold, mercury, copper, iron, zinc, lead, bismuth, antimony and salt is carried on. The state's mineral wealth was discovered soon after the conquest, and some of its mines are among the most famous of Mexico, dating from 1546. Zacatecas is traversed by the Mexican National railway. Manufactures are limited chiefly to the reduction of mineral ores; extraction of rubber from *guayule,* making of sugar, rum, mescal, pulque, woollen and cotton fabrics; and some minor industries of the capital. The capital is Zacatecas. Other principal towns are: Sombrerete, pop. (1940) 5,628, an important silver-mining town 70 mi. northwest of the capital (elevation 8,430 ft.); Villa Garcia, pop. (1940) 1,922; Concepción del Oro, 4,847; Tlaltenango, 4,627; and the silver-and-copper-mining centre at Fresnillo, 24,614.

ZACATECAS, a city of Mexico, capital of the state of Zacatecas, 442 mi. by the Mexican National railway northwest of Mexico City. Pop. (1940) 21,846. It is built in a deep, narrow ravine, 8,050 ft. above sea level, with narrow, crooked streets climbing the steep hillsides, and white, flat-roofed houses of four and five stories overtopping each other. The city is well drained and has a fine aqueduct for its water supply. The cathedral is an elaborately carved red-stone structure with unfinished towers and richly decorated interior. Overlooking the city from an elevation of 500 ft. is the Bufa Hill, which is crowned by a chapel and is a popular pilgrimage resort.

Zacatecas was founded in 1546 and was built over a rich vein of silver discovered by Juan de Tolosa in the same year. This and other mines in the vicinity attracted a large population, and it soon became one of the chief mining centres of Mexico. It was made a city in 1585 by Philip II.

ZACCONI, LUDOVICO, Italian musical theorist, was born about the middle of the 16th century at Pesaro, the years of his birth and death being unknown. He made his home in Venice, where he became an Augustine monk and was appointed *maestro di cappella* at the church of his Order. After a short time spent in the service of Wilhelm, duke of Bavaria in 1592, and a longer period in Vienna with the archduke Charles, he returned in 1619 to Venice. Zacconi's fame is based on a single monumental work, the *Prattica di musica utile et necessaria si al compositore . . . si anco al cantore* (2 pts., Venice, 1596 and 1619). It is one of three standard theoretical works of the Polyphonic period, the others being the *Dodecachordon* of Glaureanus and the *Musicae activae Micrologus* of Ornithoparcus; Zacconi's work, being the latest of the three, treats of the methods of the ripest period of the Polyphonic school.

Complete copies of the *Prattica di Musica* are in the British museum and the Royal College of Music, London. *See* the article by W. S. Rockstro in Grove's *Dictionary of Music;* also F. Batielli, *Un musicista pesarese nel seccolo* xvi (1905) and *Notizie su la vita e le opere di L. Zacconi* (1912); H. Kretzschmar, *Ludovico Zacconi's Leben auf Grund seiner Autobiographie* (1910).

ZACHARIAE VON LINGENTHAL, KARL SALOMO (1769–1843), German jurist, was born on Sept. 14, 1769, at Meissen in Saxony, the son of a lawyer, and was educated there and at Leipzig university. He was professor of law at Wittenberg (1798), and at Heidelberg from 1807 till his death on March 27, 1843. In 1820 he was member for his university in the new parliament of Baden, and in 1825, after the revision of the constitution, for the district of Heidelberg. Throughout his parliamentary career he was a strong Conservative, and it was the growth of liberalism that induced him to retire in 1829, and devote himself entirely to juridical work. The German universities still had their old jurisdiction in legal questions of international importance, and Zachariae had referred to him such points as the claim of Sir Augustus d'Este to the dukedom of Sussex, and the dispute about debts due to the elector of Hesse-Cassel, confiscated by Napoleon. He was ennobled in 1842.

His writings deal with almost every branch of jurisprudence, and relate to Roman, Canon, German, French and English law. The first book of much consequence which he published was *Die Einheit des Staats und der Kirche mit Rücksicht auf die Deutsche Reichsverfassung* (1797), a work on the relations of church and state, with special reference to the constitution of the empire. In 1805 appeared *Versuch einer allgemeinen Hermeneutik des Rechts;* and in 1806 *Die Wissenschaft der Gesetzgebung,* an attempt to find a new theoretical basis for society in place of the opportunist politics which had led to the French Revolution. This basis he seemed to discover in something resembling Bentham's utilitarianism. Zachariae's last work of importance was *Vierzig Bücher vom Staate* (1839–42), to which his admirers point as his enduring monument. It has been compared with Montesquieu's *L'Ésprit des lois,* and covers no small part of the field of Buckle's first volume of the *History of Civilization.*

For an account of Zachariae and his works, *see* Robert von Mohl, *Geschichte u. Literatur der Staatswissenschaften* (1855–58), and Charles Brocher, *K. S. Zachariae, sa vie et ses oeuvres* (1870); also his biography in *Allgem. Deutsche Biographie* (vol. 44) by Wilhelm Fischer, and Holtzendorff, *Rechts-Lexicon, Zachariae von Lingenthal.*

His son, KARL EDUARD ZACHARIAE (1812–1894), also an eminent jurist, was born on Dec. 24, 1812, and studied at Leipzig, Berlin and Heidelberg. Having made Roman and Byzantine law his special study, he visited Paris in 1832 to examine Byzantine mss., went in 1834 to St. Petersburg (Leningrad) and Copenhagen for the same purpose, and in 1835 worked in the libraries

of Brussels, London, Oxford, Dublin, Edinburgh and Cambridge. In 1837 he went in search of materials, to Italy and the East, visiting Athens, Constantinople and the monasteries of Mount Athos. Having a taste for a country life, and none for teaching, he gave up his position as extraordinary professor at Heidelberg, and in 1845 bought an estate in the Prussian province of Saxony. He died on June 3, 1894.

For a list of Zachariae's works, see *Allgem. Deutsche Biogr.*

ZACHARIAS, ST., pope from 741 to 752, was a Greek by birth, and appears to have been on intimate terms with Gregory III., whom he succeeded (November 741). Contemporary history dwells chiefly on his great personal influence with the Lombard king Luitprand, and with his successor Rachis; it was largely through his tact in dealing with these princes in a variety of emergencies that the exarchate of Ravenna was rescued from becoming part of the Lombard kingdom. A correspondence, between Zacharias and St. Boniface, the apostle of Germany, is still extant, and shows how great was the influence of this pope on events then passing in France and Germany; he encouraged the deposition of Childeric, and it was with his sanction that Boniface crowned Pippin as king of the Franks at Soissons in 752. Zacharias is stated to have remonstrated with the emperor Constantine Copronymus on the part he had taken in the iconoclastic controversy. He died on March 14, 752, and was succeeded by Stephen II.

The letters and decrees of Zacharias are published in Migne, *Patrolog. lat.* lxxxix. p. 917–960.

ZAGAZIG (Zaḳāzīḳ), a town of Lower Egypt, capital of the province of Sharkia. Pop. (1937) 59,793. It is built on a branch of the Fresh Water or Ismailia canal, and on the Al-Mo'izz canal (the ancient Tanitic channel of the Nile), and is 47 m. by rail N.N.E. of Cairo. Situated on the Delta in the midst of a fertile district, Zagazig is a great centre of the cotton and grain trade of Egypt. It has large cotton factories and the offices of numerous European merchants. About a mile south of the town are the ruins of Bubastis (*q.v.*).

ZAGHAWA: *see* NUBA.

ZAGHLUL, SAAD (1860–1927), Egyptian patriot, came of fellahin stock in the district of Ibian, Gharbia Province. He was educated at the village school and at the university of El Azhar, in Cairo. In 1880, he became editor of the *Official Journal.* Later he was nominated a Moawin under the Ministry of the Interior and eventually became Chief of the Contentieux for the province of Giza. Involved in the Arabi revolt, he was one of the many notables detained on the occupation of Egypt by British troops in 1882. In 1884 he began to practise at the bar, and in 1893 became a judge in the native court of appeal. He became Minister of Education in 1906, and in 1910 Minister of Justice. At the Ministry of Justice he made a charge of corruption against the Khedive Abbas Hilmi, and was asked (1912) by Lord Kitchener to resign. Zaghlul's evidence was insufficient, but he was thought to have been fundamentally justified, and his fierce opposition to British domination was undisguised from that time onwards. He then became vice-president of the Legislative Assembly.

On the signing of the Armistice (Nov. 1918) Zaghlul, who had for long been considered the principal spokesman of the Nationalist party, appealed to the Residency in Cairo for the recognition of Egyptian independence, basing his demand on President Wilson's self-determination policy and the British proclamation defining the status of the other countries liberated from Turkish rule by the World War. His proposal that he, with other representative Nationalists, should visit London to press their views was refused by the Government, and his attitude was so hostile that he and three others were arrested on March 8, 1919 and deported to Malta. This was the signal for a murderous outbreak in Egypt and serious disturbances (*see* EGYPT: *History*). Zaghlul and his friends were later released by Lord Allenby, and a special mission under Viscount Milner was sent to Egypt in Nov. 1919 to report on the situation.

Zaghlul returned to Egypt early in 1921, where he represented the extreme Nationalist party in opposition to the more moderate ministry under the presidency of Adly Pasha. At the end of the year, when trouble again broke out in Egypt, Zaghlul was arrested once more and deported, first to Aden and then to the Seychelles. In Sept. 1922 he was transferred to Gibraltar, whence he was released on April 4, 1923, on the grounds of ill-health. After the promulgation of the new constitution, martial law was abolished and Zaghlul was free to return to Egypt. He was enthusiastically received, and in the elections of Jan. 1924 his supporters gained an overwhelming majority. Yehia Ibrahim Pasha resigned and Zaghlul formed a ministry. Conversations to secure a settlement between England and Egypt took place in London (Sept. 25—Oct. 3) between Zaghlul and Ramsay Macdonald; Zaghlul refused to modify his intransigent attitude, and no agreement was reached. On Nov. 19, 1924 Sir Lee Stack, the Sirdar, was assassinated and Zaghlul was forced to resign. Nevertheless he became president of the new Chamber of Deputies. From that time the history of Zaghlul Pasha is the history of Egypt (*q.v.*).

Zaghlul died at Cairo on Aug. 23, 1927. His health had long been failing, but he was to the end the life and soul of Egyptian nationalism.

ZAGHOUAN, a small town of Tunisia, French North Africa, 35 mi. S. of Tunis by rail, 275 ft. above sea-level. Pop. (1936) 4,100. It occupies the site of an ancient town (perhaps Onellana) of which nothing remains but a monumental entrance gate. Below the rocky mass known as the Djebel Zaghouan (over 4,000 ft.) are the openings which were used for the Roman aqueduct of Carthage; they were directed into an oval basin, behind which was a hemicycle 100 ft. wide; in the centre of the curve stood the temple of the protecting nymph or divinity.

ZAGREB, the capital of Croatia-Slavonia, Yugoslavia (German, *Agram*), lies on the Sava, with a background of mountains and surrounded by vineyards and country houses. Pop. (1931) 185,581. In 1910 it was only 79,083, but the influx of officials and business men after the formation of the state of Yugoslavia more than outweighed the exodus of Magyars and Germans. Zagreb is the second city of Yugoslavia and its commercial and financial centre, with many important trade associations. It was also the headquarters of one of the five army provinces. The older part of the town, with narrow, winding streets, contains the 15th century Gothic cathedral and the bishop's palace, while the newer part, with wide streets, open squares, a park and botanical gardens, contains the business and industrial quarters. Here too are the palace of justice, the South Slavonic academy, the university, a synagogue, and a Protestant church. Roman Catholic schools and churches are numerous, and there is also a School of Music. Tobacco, leather, linen, carpets, war material, hats and caps, boots, paper, chemicals, varnish and oil-colours are made.

Modern excavations have shown that a settlement existed at Zagreb in Roman times, and though the Croats probably built a town there in the 7th century, the first written record of the city occurs in 1093 when King Ladislaus of Hungary made it the see of a bishop. The older part of Zagreb, known as the Kaptol, contains the bishop's palace and the 15th century Gothic cathedral surrounded by the towers of the 11th century fortress. In 1242 a walled town, now called the Upper Town, arose on a neighbouring hill, and was raised to the rank of a royal free town by King Bela of Hungary.

For centuries a bitter feud raged between the Kaptol and the Upper Town, until these rivals were forced to join hands against the Turks.

Zagreb, already the political centre of Croatia-Slavonia, was selected as the capital in 1867. It suffered severely from earthquakes in 1880 and 1901. It became the home of an aristocracy and a seat of culture on a level with more famous European centres.

It was also the centre of the Yugoslav movement before 1918, and in that year a national assembly met there and proclaimed Croatia's adhesion to the kingdom of the Serbs, Croats and Slovenes. Soon, however, serious differences arose between Croat national aspirations for autonomy and Serb tendencies toward centralization. Zagreb became the seat of the Croat autonomists. When in April 1941, after the partition of Yugoslavia, an independent Croatia was created, Zagreb became its capital.

ZAHAROFF, SIR BASIL (1849–1936), financier and politician, was born in Mughla, Anatolia, of Greek parents, on October 6, 1849. Little is known of his early years except that he was educated in London and Paris. In fact a veil of mystery enshrouded most of his life. He was reputed to be one of the world's richest men, his fortune being built up from munition plants, shipbuilding, oil and other enterprises. He exerted a strong if indirect influence during World War I and at the Paris conference, being a close friend and political adviser of Lloyd George, Venizelos, Clemenceau and Briand. During this period he extended very considerable financial aid to the British and French governments, and later was honoured by these countries for his war services. He is said to have given Greece $2,500,000 a year during the Balkan War, and half that sum during World War I. To the American Near East Relief fund for refugee relief projects in Greece he contributed several thousand pounds and he gave 1,000,000 francs to France for the "save the franc fund." He established chairs of aviation at the universities of Paris, Petrograd, and London and endowed the Marshal Foch professorship of French literature at Oxford university and the Field-Marshal Haig chair of English literature at Paris university. He died Nov. 27, 1936.

ZAHN, ERNST (1867–), Swiss novelist and poet, was born at Zürich on Jan. 24, 1867. Long associated with his father in the management of the railway restaurant at Göschenen, at the entrance to the St. Gotthard tunnel, he became in turn councillor, judge and president of the diet of Canton Uri; but he has latterly devoted himself wholly to literature. His first book was *Kämpfe* (Zurich, 1893), a romance; his most popular novel is *Lukas Hochstrassers Haus* (Stuttgart and Leipzig, 1907). Other notable volumes are: *Blancheflur* (Stuttgart, 1924), *Frau Sixta* (Stuttgart, 1926), and two collections of short stories, *Helden des Alltags* (Stuttgart, 1906) and *Das Licht* (Stuttgart, 1912). *Herrgottsfäden* (Stuttgart, 1901), dealing with the St. Gotthard tunnel, has been translated into English under the title of *Golden Threads* (1908).

See a study by H. Spiero, *Ernst Zahn* (Stuttgart, 1927).

ZAILA or **ZEILA,** a town in British Somaliland, on the African coast of the Gulf of Aden, 124 mi. S.W. of Aden. Pop. (1933) about 5,000 Somali, Arabs, Indians, Greeks, Jews and a few British. The town has the sea on three sides; landward the country is unbroken desert for some 50 miles.

Zaila owed its importance to its proximity to Harar, the great entrepôt for the trade of southern Abyssinia. Its trade received, however, a severe check on the opening (1902) of the railway to Dire Dawa, near Harar, from the French port of Jibuti, which is 35 mi. N.W. of Zaila. Some trade with Harar survived, and about 10% of the imports and 15% of the exports of British Somaliland pass through Zaila. Zaila was captured by Italians Aug. 5, 1940, but was retaken in March 1941.

ZAÏMIS, ALEXANDER (1855–1936), Greek statesman, was born in Athens Oct. 28, 1855, and came of a family of politicians. Entering public life rather from duty than ambition, Zaïmis became the "utility man" of Greek politics; thus he was first appointed prime minister in Oct. 1897, to clear up the aftermath of the disastrous Graeco-Turkish War. Resigning in 1899, after having accomplished that task, he again became premier after the "Gospel Riots" had caused the fall of Theotokes in Nov. 1901, but succumbed to the majority which supported his uncle, Deliyannes, in 1902. In Sept. 1906 he was appointed high commissioner of the Powers in Crete, a post which he held until 1911. In 1913 he was appointed governor of the National Bank. He became premier for the third time in Oct. 1915, but returned to the Bank after a month's office, emerging, however, to resume the premiership in June 1916. He became for the fifth time premier in 1917, and announced to King Constantine the decision of the three Protecting Powers that he must abdicate. He then retired again to the National Bank, but was removed on the restoration of King Constantine. After the king's second abdication, Sept. 1922, Zaïmis refused a sixth premiership, and was talked of as a possible president. On Dec. 4, 1926, he became premier of an Oecumenical Government of three republican ex-premiers and the two Royalist leaders, and remained at the head of the two coalition cabinets, which succeeded it in Aug. 1927 and Feb. 1928. From 1929 to 1935 he was president of the Greek Republic. (W. M.)

ZAIMUKHT, the name of a small Pathan tribe who inhabit the hills between the Miranzai and Kurram valleys.

ZAIRE, a Portuguese variant of a Bantu word (*nzari*) meaning river, a name by which the river Congo was formerly known. In the 16th and 17th centuries the powerful native kingdom of Congo possessed both banks of the lower river, and the name of the country was in time given to the river also. Until, however, the last quarter of the 19th century "Zaire" was frequently used to designate the stream. It is so called by Camoens in the *Lusiads.* (*See* CONGO, river.)

ZAISAN ("Noble"). (1) A lake of Asiatic Russia, situated in a valley between the Altai range on the north-east and the Tarbagatai on the south, at an altitude of 1,355 feet. Its area is 707 sq.m., and its surface is dotted with islands; it is 60 to 65 m. long and 10 to 20 m. wide and receives the drainage of ten rivers, including the Black Irtysh and the Kendyrlyk; the White Irtysh forms the north-western outlet of the lake. Roach, perch, carp, trout, *nyelma* and sterlet abound during the fishing season, May to August. The lake has a depth of 50 ft. and is navigable for steamers; and barges ascend the Black Irtysh into Mongolia.

(2) A town in the Kazakstan A.S.S.R., in 47° 32′ N., 84° 56′ E., situated on a route into Mongolia, at an altitude of 2,200 feet. It lies south-east of Lake Zaisan and south of the Black Irtysh. Population 8,130. Its tanning and leather industry is important and it is a centre for trade between Kazakstan and Mongolia. Topolni Mis, on Lake Zaisan, acts as a port for it.

ZAKOPANE, a town of Poland in the province of Cracow, situated amid superb scenery in the heart of the Tatra mountains; a great health resort both in summer and winter; the most frequented holiday resort of Polish tourists and rock climbers. It has important thermal springs. The town lies 1,000 metres above sea-level and has an alpine climate. Pop. (1931) 17,703. Zakopane was occupied by Germany in Sept. 1939.

ZALEUCUS, of Locri Epizephyrii in Magna Graecia (*fl. c.* 660 B.C.), Greek lawgiver, is said to have been the author of the first written code of laws amongst the Greeks. The story has some familiar features. The Locrians were distressed at their own lawlessness; they commissioned Zaleucus a slave, to draw up a code, and he did so under divine inspiration. The code was a severe one of the Draconic type which remained unchanged for centuries. The story ends with the episode (*cf.* Charondas) of the lawgiver committing suicide on discovering that he had inadvertently broken one of his own laws.

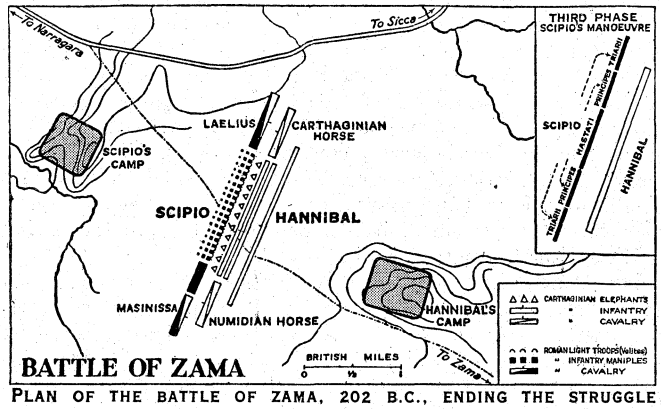
See Bentley, *Dissertation on the Epistles of Phalaris;* F. D. Gerlach, *Zaleukos, Charondas, Pythagoras* (1858); G. Busolt, *Griechische Geschichte* (1885–1904).

ZALMOXIS or ZAMOLXIS, a semi-mythical social and religious reformer, regarded as the only true god by the Thracian Getae. According to Herodotus (iv. 94), the Getae, who believed in the immortality of the soul, looked upon death merely as going to Zalmoxis. It is probable that Zalmoxis is Sabazius, the Thracian Dionysus or Zeus; Mnaseas of Patrae identified him with Cronus. In Plato (*Charmides,* 158 B) he is mentioned with Abaris as skilled in the arts of incantation. No satisfactory etymology of the name has been suggested.

ZAMA, BATTLE OF, 202 B.C. One of the most decisive battles in military history in its military result, Zama ranks above any, save perhaps Waterloo, for its decisive effect on the course of world history. For the defeat of Hannibal, the first and only true defeat in his career, left Carthage naked, and her surrender put an end to the long struggle between Rome and Carthage (*see* PUNIC WARS) for the mastery of the Mediterranean World.

The prologue to Zama had been the invasion of Africa by Scipio (*q.v.*), almost in defiance of the Roman senate which wished him instead to attack Hannibal, who still stood unconquerable in Southern Italy. In Africa Scipio's brilliant series of victories over less formidable generals had forced Carthage to sue for peace before Hannibal could answer the summons of recall. But while the peace negotiations were being conducted in Rome, Hannibal landed at Leptis, whereupon the Carthaginians broke the

truce, and Scipio's military position was gravely compromised—isolated on hostile soil and with part of his force detached to assist his ally Masinissa in securing his new kingdom of Numidia. Instead of awaiting Hannibal near Carthage, Scipio cut himself off from his base and marched on a divergent path into the interior. Security lies often in calculated audacity, and an analysis of the military problems makes it highly probable that his march inland



PLAN OF THE BATTLE OF ZAMA, 202 B.C., ENDING THE STRUGGLE BETWEEN ROME AND CARTHAGE FOR MASTERY OF THE MEDITERRANEAN WORLD

up the Bagradas valley was aimed, by its menace to the rich interior on which Carthage depended for supplies, to force Hannibal to push west to meet him instead of north to Carthage. By this clever move he threatened the economic base of Carthage and protected his own, also luring Hannibal away from his military base—Carthage. A complementary purpose was that this line of movement brought him progressively nearer to Numidia, shortening the distance which Masinissa would have to traverse with his expected reinforcement of strength.

It had the intended effect, for the Carthaginians sent urgent appeals to Hannibal to advance towards Scipio and bring him to battle, and within a few days he marched west, and arrived by forced marches at Zama. He then sent out scouts to discover the Roman camp and its dispositions for defence—it lay some miles farther west. Almost coincidently Masinissa arrived with 6,000 horse and 4,000 foot, and Scipio then broke up his camp and moved to a fresh site near the town of Narragara, his position being well chosen tactically, and having water "within a javelin's throw." Hannibal also moved his camp forward to meet him.

A parley between the two commanders led to no result, and both thereupon prepared to decide the issue by arms. The dispositions made by the rival leaders have several features of note. Scipio placed his heavy Roman foot—he had probably two legions—in the centre; Laelius with the Italian cavalry on the left wing; and on the right wing Masinissa with the whole of the Numidians, horse and foot. The heavy infantry were drawn up in the normal three lines: first, the *hastati;* then the *principes;* and finally, the *triarii.* But instead of adopting the usual chequer formation, with the maniples of the second line opposite to and covering the intervals between the maniples of the first line, he ranged the maniples forming the rear lines directly behind the respective maniples of the first line—thus forming wide lanes between each two cohorts.

The Carthaginian had eighty elephants, more than in any previous battle, and in order to terrify the enemy he placed them in front of his line. Supporting them, in the first line, were the Ligurian and Gallic mercenaries, intermixed with Balearic and Moorish light troops. In the second line were the Carthaginian and African levies, their combined strength probably exceeding that of the first line. Finally, Hannibal's own troops from Italy formed the third line, held back more than 200 yards distant from the others, in order evidently to keep it as an intact reserve. On the wings Hannibal disposed his cavalry, the Numidian allies on the left and the Carthaginian horse on the right. His total force was probably in excess of 50,000, perhaps 55,000. The Roman strength is less certain, but if we assume that each of Scipio's two legions was duplicated by an equal body of Italian allies, and add Masinissa's 10,000, the complete strength would be about 36,000.

The battle opened, after preliminary skirmishing, with Hannibal's order to the drivers of the elephants to charge the Roman line. Scipio promptly countered by a blast of trumpets along the whole line. The strident clamour so startled and terrified the elephants that many of them at once turned back on their own troops. This was especially the case on the left wing, where they threw the Numidians, Hannibal's best cavalry wing, into disorder just as they were advancing to the attack. Masinissa seized this golden opportunity to launch a counter-stroke, which inevitably overthrew the disorganized opponents. With Masinissa in hot pursuit, they were driven from the field, and so left the Carthaginian left wing exposed. The remainder of the elephants wrought much havoc among Scipio's *velites,* caught by their charge in front of the Roman line. But the foresight that had provided the "lanes" and laid down the method of withdrawal was justified by its results. For the elephants took the line of least resistance, penetrating into the lanes rather than facing the firm-knit ranks of the heavy infantry maniples. Once in these lanes the *velites* who had retired into the lateral passages, between the lines, bombarded them with darts from both sides. Their reception was far too warm for them to linger when the door of escape was held wide open. While some of the elephants rushed right through, harmlessly, and out to the open in rear of the Roman army, others were driven back out of the lanes, and fled towards the Carthaginian right wing. "It was at this moment that Laelius, availing himself of the disturbance created by the elephants, charged the Carthaginian cavalry, and forced them to headlong flight. He pressed the pursuit closely, as likewise did Masinissa." Both Hannibal's flanks were thus stripped bare.

In the meantime the infantry of both armies had slowly advanced on each other, except that Hannibal kept his third line back. At first the Gauls and Ligurians had the balance of advantage, through their personal skill in skirmishing and more rapid movement. But the Roman line remained unbroken, and the weight of their compact formation pushed the enemy back despite losses. Another factor told, for while the leading Romans were encouraged by the shouts from the rear lines, coming on to back them up, Hannibal's second line—the Carthaginians—failed to support the Gauls, but hung back in order to keep their ranks firm. Forced steadily back, and feeling they had been left in the lurch by their own side, the Gauls turned about and fled. When they tried to seek shelter in the second line they were repulsed by the Carthaginians, who deemed it essential to avoid any disarray which might enable the Romans to penetrate their line. In a short time the relics of the first line had dispersed completely, or disappeared round the flanks of the second line. The latter, however, showed their fighting quality by thrusting back the Roman first line—the *hastati.* In this they were helped by a human obstacle, the ground encumbered with corpses and slippery with blood, which disordered the ranks of the attacking Romans. Even the *principes* had begun to waver when they saw the first line driven back so decisively, but their officers rallied them, and led them forward in the nick of time to restore the situation. This reinforcement was decisive. Hemmed in, because the Roman formation produced a longer frontage and so overlapped their line, the Carthaginians were steadily cut to pieces. The survivors fled back on the relatively distant third line, but Hannibal continued his policy of refusing to allow the fugitives to mix with and disturb an ordered line.

The curtain now rose on what was practically a fresh battle. The Romans "had penetrated to their real antagonists, men equal to them in the nature of their arms, in their experience of war, in the fame of their achievements. . . ." Livy's tribute is borne out by the fierceness and the long uncertain issue of the subsequent conflict, which refutes the suggestion that Hannibal's "Old Guard" was but a shadow of its former power—in the days of Trasimenus and Cannae. The Romans had the moral advantage of having routed two successive lines, as well as the cavalry and elephants, but they had now to face a compact and fresh body of probably 24,000 veterans, under the direct inspiration of Hannibal. And no man in history has shown a more dynamic personality in infusing his own determination in his troops. The Romans, too, had at last

a numerical advantage, not large, however—the forces were "nearly equal in numbers" according to Polybius—and in reality still less than it appeared. For while all Hannibal's third line were fresh, on Scipio's side only the *triarii* had not been engaged, and these represented but half the strength of the *hastati* or *principes*. Further, the *velites* had been so badly mauled that they had to be relegated to the reserve, and the cavalry were off the field, engaged in the pursuit. Thus it is improbable that Scipio had at his disposal for this final blow more than 18,000 or 20,000 infantry, less the casualties these had already suffered.

His next step is characteristic of the man—of his cool calculation even in the heart of a battle crisis. He sounded the recall to his leading troops, and then, in face of an enemy at hardly more than a bow-shot distance, he not only reorganized his troops but reconstructed his dispositions. His problem was this: against the first two enemy lines the Roman formation, shallower than the Carthaginian phalanx and with intervals, had occupied a wider frontage, and so enabled him to overlap theirs. Now, against a body double the strength, his frontage was no longer, and perhaps less, than Hannibal's. His appreciation evidently took in this factor, and with it two others. First, that in order to concentrate his missile shock power for the final effort it would be wise to make his line as solid as possible and this could be done because there was no longer need for or advantage in retaining intervals between the maniples. Second, that as his cavalry would be returning any moment there was no advantage in keeping the orthodox formation in depth and using the *principes* and *triarii* as a direct support and reinforcement to his front line. The blow should be as concentrated as possible in time and as wide as possible in striking force rather than a series of efforts. He, therefore, made his *hastati* close up to form a compact centre without intervals. Similarly he closed each half of his *principes* and *triarii* outwards, and moved them forward to extend the flank on either wing. He now once more overlapped the hostile front. The rôle of Scipio's infantry in the final phase was to fix Hannibal's force ready for the decisive manoeuvre to be delivered by the cavalry. For this rôle violence and wideness of onslaught was more important than sustenance. Scipio made his redistribution deliberately and unhurriedly—the longer he could delay the final tussle, the more time he gained for the return of his cavalry. It is not unlikely that Masinissa and Laelius pressed the pursuit rather too far, and so caused an unnecessary strain on the Roman infantry and on Scipio's plan. For Polybius tells us that when the rival infantries met, "the contest was for long doubtful, the men falling where they stood out of determination, until Masinissa and Laelius arrived providentially at the proper moment." Their charge, in the enemy's rear, clinched the decision, and though most of Hannibal's men fought grimly to the end, they were cut down in their ranks. Of those who took to flight few escaped.

The completeness of the victory left no room for a strategic pursuit, but Scipio did not linger in developing the moral exploitation of his victory. An immediate move on Carthage achieved its object, a bloodless capitulation.

ZAMBEZI, the fourth in size of the rivers of Africa, and the largest of those flowing eastwards to the Indian ocean. Its length (taking all curves into consideration) is about 2,200 m. The area of its basin, according to Dr. Bludau, is 513,500 sq.m., or rather less than half that of the Nile. The main channel is clearly marked from beginning to end. The river takes its rise in 11° 21′ 3″ S., 24° 22′ E. The source lies in British territory in a depression of an undulating country 5,000 ft. above the sea, covered with bracken and open forest. The water, like that of all the rivers of the neighbourhood, issues from a black marshy bog. Eastward of the source the water-parting between the Congo and Zambezi basins is a well-marked belt of high ground, falling abruptly north and south, and running nearly east and west between 11° and 12° S.

The Upper River.—The infant Zambezi, after pursuing a south-westerly course for about 150 m., turns more directly south and, receives on either side numerous small tributaries. A few miles above Kakengi (in 12° 24′ S.), the Zambezi, narrow, picturesque and tortuous, suddenly widens from 100 to 350 yd. Below Kakengi are a number of rapids ending (13° 7′ S.) in the Suapuma cataracts. At this point the river flows tumultuously through a rocky fissure.

The first of its large tributaries to enter the Zambezi is the Kabompo, a left-hand affluent. It joins the main stream in 14° 26′ S. A little lower down (in 14° 18′ S.) the Zambezi receives from the west the waters of a much larger stream than the Kabompo, namely, the Lungwebungu. The land, from 5,000 ft. at the source, falls gradually to 3,600 ft. at Kakengi—a distance of 220 m. From this point until the Victoria Falls are reached—500 m.—the level of the Zambezi basin is very uniform, the fall being in this distance 600 ft. only. Twenty miles below the confluence of the Lungwebungu the country becomes flat, and in the rainy seasons is largely covered by floods. From the east the Zambezi continues to receive numerous small streams, but on the west is without tributaries for 150 m., when the great river formerly misnamed the Chobe, but known to the natives as Kwando or Linyante, joins it (in 17° 47′ S.).

The Middle Zambezi.—The Victoria Falls are reached some 60 m. below the Kwando confluence. The surrounding country is formed of horizontal flows of basic lavas, which are traversed by two well marked sets of joints. Along these the river, following an extremely angular course, has eroded a great cañon, about 400 ft. deep and in many places, with vertical sides. (*See* Victoria Falls.) Into the cañon the river plunges over a vertical wall of rock. The narrow gorge can be traced more or less continuously along its course for about 40 miles. The middle course of the river may be said to extend for 800 m. below the Victoria Falls to the Kebrabasa Rapids, where the Zambezi crosses the great East African escarpment, and enters the coastal belt.

The Lower River.—The lower Zambezi—400 m. from Kebrabasa Rapids to the sea—presents no obstacles to navigation save the shallowness of the stream in many places in the dry season. This shallowness arises from the different character of the river basin. Instead of, as in the case of the middle Zambezi, flowing mainly through hilly country with well-defined banks, the river traverses a broad valley and spreads out over a large area. Only at one point, the Lupata Gorge, 200 m. from its mouth, is the river confined between high hills. Here it is scarcely 200 yd. wide. Elsewhere it is from 3 to 5 m. wide, flowing gently in many streams. The river-bed is sandy, the banks are low and reed-fringed. At places, however, and especially in the rainy season, the streams unite into one broad swift-flowing river. About 100 m. from the sea the Zambezi receives the drainage of Lake Nyasa through the river Shiré. On approaching the ocean, which it reaches in 18° 50′ S. the Zambezi splits up into a number of branches and forms a wide delta. Each of the four principal mouths—Milambe, Kongone, Luabo and Timbwe—is obstructed by a sand-bar.

Mileage of Navigable Water.—As a highway into the interior of the continent the Zambezi, like all other large African rivers, in greater or less degree, suffers on account of the bar at its mouth, the shallowness of its stream, and the rapids and cataracts which interrupt its course. Nevertheless its importance to commerce is great, as the following recapitulation of its navigable stretches will show: (1) From the sea to the Kebrabasa Rapids, 400 m. (2) From Chikoá (above Kebrabasa) to within 140 m. of the Victoria Falls, 700 m. (3) From the rapids above the Victoria Falls to the Katima Molilo Rapids, 100 m. (4) Above the Gonye Falls to the Supuma cataract, 300 m. (5) Above the Supuma cataract, 120 m. Thus for 1,620 m. of its course the Zambezi is navigable for steamers with a draught up to 28 in.

Several of the Zambezi affluents are also navigable for many miles. The Lungwebungu, which enters the upper river, is navigable for a long distance, thus supplying communication with the extreme north-west corner of the Zambezi basin. Parts at least of the Luena, Kafukwe, Loangwa and the Kwando tributaries are also capable of being navigated. The Shiré is also navigable for a considerable distance. The sum of such navigable reaches within the Zambezi basin as exceed 100 m. is nearly 4,000 m.

Exploration of the River.—The Zambezi region was known to the mediaeval geographers as the empire of Monomotapa and

the course of the river, as well as the position of Lakes Ngami and Nyasa, were filled in with a rude approximation to accuracy in the earlier maps. These were probably constructed from Arab information. The first European to visit the upper Zambezi was David Livingstone in his exploration from Bechuanaland between 1851 and 1853. Two or three years later he descended the Zambezi to its mouth and in the course of this journey discovered the Victoria Falls. During 1858–60, accompanied by Dr. (afterwards Sir) John Kirk, Livingstone ascended the river by the Kongone mouth as far as the Falls, besides tracing the course of its tributary, the Shiré, and discovering Lake Nyasa. For the next 35 years practically no additions were made to our knowledge of the river system. In 1889 the entrance of vessels from the sea was much facilitated by the discovery by D. J. Rankin of the Chinde channel north of the main mouths of the river. Major A. St. Hill Gibbons and his assistants, during two expeditions, in 1895–96 and 1898–1900, ably continued the work of exploration begun by Livingstone in the upper basin and central course of the river. Of non-British travellers Major Serpa Pinto examined some of the western tributaries of the river and made measurements of the Victoria Falls (1878).

See David and Charles Livingstone, *Narrative of an Expedition to the Zambesi and its Tributaries* (1865); A. de Serpa Pinto, *How I Crossed Africa* (1881); D. J. Rankin in *Proc. R.G.S.* (March 1890); A. Sharpe, *ibid.* (December, 1890); H. S. Bivar, "Curso medio do Zambeze," *B.S.G. Lisboa,* vol. xxiv. (1906); G. W. Lamplugh in *Geo. Jnl.,* vol. xxxi. (1908); F. Coillard, *On the Threshold of Central Africa* (London, 1897), and A. St. H. Gibbons, *Africa from South to North through Marotseland* (2 vols., London, 1904). (F. R. C.)

ZAMBOANGA, a municipality (with administrative centre and 60 *barrios* or districts) and capital of Zamboanga province, and an important port of entry, of Mindanao, Philippine Islands, situated at the south extremity of the Zamboanga peninsula on Basilian strait. Pop. (1939) 131,455, of whom 69,066 were males and 204 were white. A native settlement had long existed on the site when the Spanish town was founded in 1635. It soon became a centre for Spanish activity in their long contest with the Moros. Its climate is said to be cooler than that of Manila. The surrounding forests contain valuable timber, and the agricultural products include palay (rice), copra, abacá (Manila hemp), sugar, tobacco and sweet potatoes. There was a flourishing trade until the Japanese invasion of Dec. 1941, as the shipping facilities were good and exports of copra and abacá were extensive. There is a meteorological station, a modern water system and an electric lighting plant. Of the inhabitants aged 6-19 inclusive, 26.8% were reported in 1939 as attending school, and 40.2% of the population 10 years old and over was reported as literate. (C. S. L.)

ZAMIA, a genus of cycads which comprise about 30 species of small fern-like plants, native to tropical and sub-tropical America. They have a turnip-like, mostly underground stem surmounted by a crown of leaves, 1 ft. to 2 ft. long, surrounding large fruiting cones. The crushed stems yield starch used for food, after washing to extract an alkaloid. Two species, *Z. floridana* and *Z. pumila,* known as coontie or comfort-root, occur in southern Florida.

ZAMINDAR or **ZEMINDAR,** an Indian landholder (from Persian *zamin*-"land"). In official usage the term is applied to any person, whether owner of a large estate or cultivating member of a village community, who is recognized as possessing some property in the soil, as opposed to the ryot (*q.v.*), who is regarded as having only a right of occupancy, subject in both cases to payment of the land revenue assessed on his holding.

ZAMINDAWAR, a district of Afghanistan, situated on the right bank of the Helmund river to the north-west of Kandahar, bordering the road which leads from Kandahar to Herat via Farah. Zamindawar is a district of hills, and of wide, well populated and fertile valleys watered by important affluents of the Helmund. The principal town is Musa Kala, which stands on the banks of a river of the same name, about 60 mi. N. of Girishk. The whole of this region is a well-known hotbed of fanaticism, the headquarters of the Achakzais, the most aggressive of all Durani tribes.

ZAMORA, an inland province of Spain, one of the three into which the former province of León was divided in 1833; bounded W. by Portugal and Orense, N. by León, E. by Valladolid, S. by Salamanca. Pop. (1940) 298,722; area 4,082 sq.mi. Zamora is traversed from east to west by the river Duero or Douro (*q.v.*); the Tormes also skirts the southwestern boundary for some 25 miles. Except in the northwest, where it is entered by two outlying ridges of the Cantabrian mountains, the Sierra de la Culebra and Sierra de Peña Negra, the surface is a level or slightly undulating plateau; its lowest point is 1,070 ft. Its plains, especially the valley of the Esla, yield much grain and pulse; wine and flax are also produced; and on the higher grounds many merino sheep and goats are reared. Three railway lines, from the north, south and east, traverse the province and meet at the city of Zamora. Other towns include Benavente (7,713) and Toro (7,881). Spanish nationalists occupied Zamora in 1936.

ZAMORA, an episcopal city, and the capital of the Spanish province of Zamora; on the right bank of the river Duero (Douro), and at the junction of railways from Salamanca, Medina del Campo and Astorga. Pop. (1940) 29,036 (mun., 32,388). In the early period of the Christian re-conquest Zamora was a place of considerable strategic importance. Ferdinand I of Castile and Leon in 1061 gave it to his daughter Doña Urraca. After his death in 1065 his son Sancho II disputed possession with Urraca and laid siege to the city, but without success, although the famous Cid Ruy Diaz de Bivar was among his warriors. Zamora became subject to Alphonso VI in 1073. Zamora occupies a rocky height overlooking the Duero, a little below its confluence with the Valderaduey. The river is crossed by a fine 14th-century bridge of sixteen pointed arches. The citadel of Zamora dates from the 8th century. The small but beautiful Romanesque cathedral, one of four 12th-century churches, was completed about 1175.

ZAMOYSKI, JAN (1541–1605), Polish statesman, was the son of Stanislaw, Castellan of Chelm, and Anna Herburtowna, a noble Polish lady. After completing his education at Paris, Strasbourg and at Padua, where as rector of the academy he composed his celebrated work *De senatu romano* (Venice, 1563), he returned home in 1565, one of the most consummate scholars and jurists in Europe, and at once entered politics. He played a leading part, after the the death of Sigismund II., in remodelling the Polish constitution and procuring the election of Henry of Valois. After the flight of that prince Zamoyski seems to have aimed at the throne himself, but quickly changed his mind and supported Stephen Báthory, whose election he prepared and whose foremost counsellor he became. Appointed chancellor on May 1, 1576, immediately after the coronation, as *wielki hetman,* commander-in-chief, in 1580, Zamoyski strenuously supported Stephen during his long struggle with Ivan the Terrible. He also enabled the king in 1585 to bring the traitorous Samuel Zborowski to the scaffold. On the death of Stephen, the Zborowski recovered their influence and did their utmost to keep Zamoyski in the background. At the election diet of July 9, 1587, however, Zamoyski triumphed over his rivals, and rejecting an offer from the Habsburgs of the title of prince, with the Golden Fleece and 20,000 ducats, procured the election of Sigismund of Sweden, son of Catherine Jagiellonica (Aug. 19). The opposite party immediately elected the Austrian Archduke Maximilian, but Zamoyski routed and captured the archduke at Byczyna (Jan. 24, 1588).

From the first there was a certain coldness between the new king and the chancellor, Sigismund desiring an alliance with the Habsburgs, which Zamoyski feared. Friction became acute when Sigismund appointed an opponent of Zamoyski vice-chancellor, and made other ministerial changes which limited his authority; though ultimately, with the aid of his partisans and the adoption of such desperate expedients as the summoning of a confederation to annul the royal decrees in 1592, Zamoyski recovered his full authority. In 1595 Zamoyski, in his capacity of commander-in-chief, at the head of 8,000 veterans dethroned the anti-Polish hospodar of Moldavia and installed in his stead a Catholic convert, George Mohila. On his return he successfully sustained in his camp at Cecora a siege by the Tatar khan. Five years later (Oct. 20, 1600) he won his greatest victory at Tirgoviste, over Michael the Brave, hospodar of Walachia and Moldavia. But

beyond securing the Polish frontier Zamoyski would never go. He refused to wage war with Turkey even under the most favourable circumstances, nor could he be drawn into the Holy League against the Ottomans in 1600, making conditions for Poland's co-operation which her allies could not possibly accept. Statesman though he was, Zamoyski cannot, with all his genius and valour, be called a true patriot. Sigismund was undoubtedly right when he attempted to reform the Polish constitution in 1605 by strengthening the royal power and deciding all measures in future by a majority of the diet. These reforms Zamoyski strenuously opposed. The last speech he delivered was in favour of the anarchic principle of free election. He died suddenly at Zamosc, June 3, 1605.

ZANESVILLE, a city of south-eastern Ohio, U.S.A., the county seat of Muskingum county; on the Muskingum river at the mouth of the Licking, 55 mi. E. of Columbus. It is on Federal highways 40 and 22; and is served by the Baltimore and Ohio, the New York Central, the Pennsylvania, the Wheeling and Lake Erie and motorbus and truck lines and river packets to Parkersburg and Pittsburgh. Pop. (1920) 29,569; (1930) 36,440; (1940) it was 37,500. The city lies on both sides of both rivers, at an altitude of 700 feet. A "Y" bridge (the only one of the type in the United States) crosses the Muskingum, its two arms running on either side of the Licking. The present concrete structure (erected 1901) replaced a covered wooden bridge of the same plan which had stood for 68 years. Zanesville is one of the principal centres in the country for the manufacture of clay products, notably encaustic and mosaic tile, art pottery and stoneware. Other important manufactures are cement, glass containers, bottles, steel products, cast-iron radiation and electric transformers. In 1935 the product of 44 factories was valued at $17,038,390. There were a few pioneers on the site of the city of Zanesville when "Zane's Trace" was cut through from Wheeling (under an act of Congress of 1796) by Ebenezer and Jonathan Zane and Ebenezer's son-in-law, John McIntire, who received for this service three sections of land. Jonathan Zane and McIntire chose their sections at the point where the new road (now the national highway) crossed the Muskingum river. The town was planned in 1800, incorporated in 1814 and in 1850 was chartered as a city. It was made the county seat when Muskingum county was created in 1804, and from Dec. 1810, until May 1812, it was the capital of the State. Zanesville was an important station on the old national road. The population was 9,229 in 1860.

ZANGWILL, ISRAEL (1864–1926), Jewish man of letters, was born in London on Feb. 14, 1864. His early childhood was spent in Plymouth and at Bristol, where he received his first schooling. He was in his ninth year when his parents settled in Spitalfields, and he entered the Jews' Free School, where eventually ne became a teacher, working at the same time for his university degree. He had written a clever fantastic tale entitled *The Premier and the Painter* with Louis Cowen, when he gave up teaching for journalism. He founded and edited *Ariel, The London Puck,* and did much miscellaneous work on the London press. He made his literary reputation with a novel, *The Children of the Ghetto* (1892), which was followed by *Ghetto Tragedies* (1893); *The Master* (1895); *Dreamers of the Ghetto* (1898); *The Mantle of Elijah* (1901); and other tales and novels of great interest dealing with Jewish life. *Children of the Ghetto* was produced as a play in New York with success in 1899, and has since been extensively played both in English and Yiddish. He was greater as a playwright than as a novelist, and did admirable work both in light comedy and in serious plays. *Merely Mary Ann* (Duke of York's, 1904) and *Too Much Money* (1917) represent his lighter gift; *The Melting Pot* (1908), *The War God* (1911) and *The Next Religion* (1914), banned by the censor, all deal with serious social problems. Zangwill was an outstanding personality in the Jewish world. He was at one time president of the Jewish Territorial Organization for the Settlement of Jews within the British Empire, and later an advocate of the Zionist movement. He died on Aug. 1, 1926.

ZANTE (anc. *Zacynthus*), southernmost of the Ionian Islands, west of Greece, 25 mi. long, about 12 broad, and 64 mi. round, with an area of 277 sq.mi., and a population in 1928 (last census before World War II) of 40,492. Zante lies 8 mi. S. of Cephalonia, forming with it, Leucas and Ithaca a crescent-shaped group, the crest of a submerged limestone ridge facing the Gulf of Patras. Zante is of somewhat irregular oval shape, indented by a deep inlet at its south end. A wide fertile central plain is skirted on the west by bare limestone hills 1,000 to 1,200 ft. high, which fall gently landwards, but with steep sea cliffs culminating northwards in Mount Skopos (ancient *Elatos,* 1,600 ft.). On the east the plain is also limited by a low ridge. These hills are still densely clothed to the summit with olives, figs, myrtles, laurels, oranges, aloes, vines and other sub-tropical plants. The central plain is an almost continuous stretch of gardens and vineyards, with a few cornfields and pastures. The peculiar dwarf vine, the "currant" (from Corinth) of commerce, is the staple export of Zante, as of the neighbouring mainland: it grows to 3 ft., begins to yield in seven years and lasts a century. Earthquakes are frequent and at times disastrous. During recent times the most destructive were those of 1811, 1820, 1840 and 1893. Other volcanic indications are the oil springs on the coast, and in the bed of the sea near Cape Skinari on the north, and especially the bituminous wells in a swamp near the coast village of Chieri, mentioned by Herodotus (iv. 195). These still yield pitch.

Zante, capital and seaport, on the east side, with a population of 11,609, occupies the site of ancient Zacynthus, said to have been founded, like the neighbouring citadel of Psophis, by Zacynthus, son of Dardanus, a legendary Arcadian chief.

Traditionally Zacynthus belonged to Ulysses, king of Ithaca, and was peopled by settlers from Achaea or Arcadia. It figures occasionally in history as a base for belligerents. Thus during the Peloponnesian War and again in 374 B.C. the Athenians used it; in 357 it was the headquarters of Dion on his expedition against Syracuse; in 217 it was seized by Philip V of Macedon. The Romans captured it in 211, but restored it temporarily to Philip; in 191, to keep it out of the hands of Greek powers, they annexed it themselves. In 86 it was raided by Mithradates' admiral Archelaus. Under the Roman Empire, Zante was included in the province of Epirus. In the 11th century it passed to the Norman kings of Sicily; after the Fourth Crusade it belonged at various times to the despots of Epirus, the emperors of Constantinople, and the Orsini counts of Cephalonia. After remaining from 1357 to 1482 in the hands of the Tocco family it became a Venetian possession. In 1797 it was ceded to France, and after a short occupation by the Russians was brought under British protection; in 1864 it was ceded with the other Ionian islands to Greece. In 1941, during World War II, it was occupied by Italy.

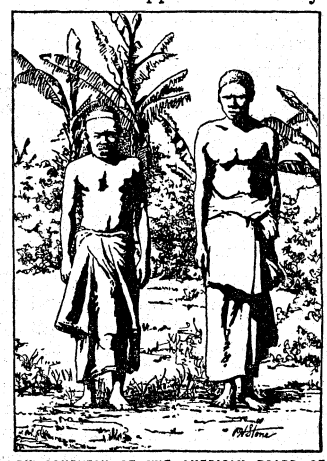
The long Venetian occupation is reflected in the appearance, character, and to some extent even the language and religion of the Zantiots. Nearly all the aristocracy claim Venetian descent; most of the upper classes are bilingual, speaking both Greek and Italian; and a considerable section of the population are Roman Catholics. Even the bulk of the people, although mainly of Greek stock, form in their social usages a connecting link between the Hellenes and the western nations.

See B. Schmidt, *Die Insel Zakynthos* (Freiburg, 1899).

ZANZIBAR, a sultanate and British protectorate of East Africa. The sultanate, formerly of much larger extent (see *History*) is now reduced to the islands of Zanzibar and Pemba, some adjacent islets and the nominal sovereignty of a strip of coastland—10 mi. deep—forming the protectorate of Kenya (*see* KENYA COLONY). The collective area of the sultanate (Zanzibar and Pemba) is 1,020 sq.mi. The island of Zanzibar, in 6° S. latitude, is separated from the mainland by a channel 22½ mi. across at its narrowest part. The largest coralline island on the African coast, it is 50 mi. long by 24 mi. broad (maximum measurements), and has an area of 640 sq.mi.

Topography.—Pemba (*q.v.*), lying 25 mi. to the northeast, and the more distant Mafia (to the south), which is part of Tangan-

yika Territory, form with Zanzibar an independent geological system, resting on a foundation of coralline reefs, and constituting a sort of outer coast-line, which almost everywhere presents a rocky barrier to the Indian ocean. All three are disposed parallel to the mainland, from which they are separated by shallow waters, mostly under 30 fathoms, strewn with numerous reefs dangerous to navigation, especially in the Mafia channel opposite the Rufiji delta. Some 6 mi. off the N.W. coast of Zanzibar and forming part of the coral reef is the small, densely wooded island of Tumbatu. Zanzibar island, called Unguja in Kiswahili, is not exclusively of coralline formation, several heights of reddish ferruginous clay rising in gentle slopes 400 to 450 ft. in the centre, and to double that height in the north. The forests which formerly covered the island have largely disappeared; the western part has been cleared for cultivation, and the eastern half is mostly covered with low scrub.



BY COURTESY OF THE AMERICAN BOARD OF FOREIGN MISSIONS

SWAHILI NATIVES OF ZANZIBAR

The great heat and excessive moisture of the atmosphere render the climate trying to Europeans. The year is divided into two seasons, according to the direction of the monsoons. The northeast monsoon sets in about the end of November, the southwest monsoon in April. The "hot season" corresponds with the northeast monsoon, when the minimum readings of the thermometer often exceed 84° F. In June to September the minimum readings drop to 76°, the mean annual temperature being about 80.5°. Rain falls in every month of the year. December, April and May are the rainiest months, August to October the driest. The average annual rainfall (45 years' observations) is 61.47 in. (In 1859 as much as 170 in. were registered.)

Inhabitants.—On the east side of Zanzibar island the inhabitants, a Bantu-speaking race of low development, probably represent the aboriginal stock. They are known as Wahadimu and are noted as good fishermen, cattle raisers and skilled artisans. In the west, and especially in the capital (for which, *see* below), the population is of an extremely heterogeneous character, including full-blood and half-caste Arabs, Hindus, Goanese, Parsis, Persians, Baluchs, Swahili of every shade, and representatives of tribes from many parts of East Africa. The Arabs number about 11,500; the Indians and other Asiatics 13,000; and Europeans less than 300. Pop. of the sultanate (1931 census) 235,428 (Zanzibar 137,741 and Pemba 97,687); 1941 est. 250,000 (Zanzibar 150,000, Pemba 100,000). Besides the port of Zanzibar there are no large towns. Chwaka is a health resort facing the Indian ocean.

HISTORY

From the earliest times of which there is any record the African seaboard from the Red sea to an unknown distance southwards was subject to Arabian influence and dominion. Egyptians, Chinese and Malays also appear to have visited the coast. At a later period the coast towns were founded or conquered by Persian and Arab Mohammedans who, for the most part, fled to East Africa between the 8th and 11th centuries on account of the religious differences of the times, the refugees being schismatics. Various small states thus grew up along the coast, Mombasa seeming to be the most important. These states are sometimes spoken of as the Zenj empire, though they were never, probably, united under one ruler. Kilwa (*q.v.*) was regarded as the capital of the "empire." The seaboard itself took the name of *Zanquebar* (corrupted to Zanzibar by the Indian traders), the Bilad ez-Zenj, or "Land of the Zenj" of the Arabs, a term which corresponds to the Hindu-bar, or "land of the Hindu," formerly applied to the west coast of India. By Ibn Batuta, who visited the coast in 1328, and other Arab writers the Zenj people are referred to in a general way as Mohammedan Negroes; and they are no doubt still represented by the Swahili or "coast people," in whose veins is a large admixture of Asiatic blood. The Zenj "empire" began to decline soon after the appearance of the Portuguese in East African waters at the close of the 15th century. To them fell in rapid succession the great cities of Kilwa with its 300 mosques (1505), Mombasa the "Magnificent" (1505), and soon after Malindi and Mukdishu the "Immense" (Ibn Batuta). The Portuguese rule was troubled by many revolts, and towards the end of the 16th century the chief cities were ravaged by the Turks, who came by sea, and by the Zimbas, a fierce Negro tribe, who came overland from south of the Zambezi. On the ruins of the Portuguese power in the 17th century was built up that of the Imams of Muscat. Over their African dominions the Imams placed *valis* or viceroys, who in time became independent of their overlord. In Mombasa power passed into the hands of the Mazrui family. The island of Zanzibar, conquered by the Portuguese in 1503–08, was occupied by the Arabs in 1730, and in 1832 the town of Zanzibar, then a place of no note, was made the capital of his dominions by the Sayyid Said of Muscat, who reconquered all the towns formerly owing allegiance to the Imams, Mombasa being taken by treachery in 1837. On the death of Said in 1856 his dominions were divided between his two sons, the African section falling to Majid, who was succeeded in 1870 by his younger brother Bargash ibn Said, commonly known as sultan of Zanzibar. At that time besides the islands of Zanzibar, Pemba and Mafia, the sultan's dominions extended along the East African coast from Cape Delgado northwards to and including some of the Somali ports, with an undefined extension inland. Bargash, however, lived to witness the dismemberment of his dominions by Great Britain, Germany and Italy (*see* AFRICA) and in March 1888 left to his successor, Sayyid Khalifa, a mere fragment of the territories over which he had once ruled. The mainland territories were divided, Italy acquiring the northern part, Great Britain the central part (now the Kenya protectorate) and Germany the southern part (now Tanganyika Territory) as well as Mafia island. The division was first by lease; subsequently Germany and Italy purchased the sovereign rights in their respective areas. The Sayyids Majid and Bargash acted largely under the influence of Sir John Kirk (*q.v.*) who from 1866 to 1887 was consular representative of Great Britain at Zanzibar. Had an offer by Bargash been accepted the whole of his mainland dominions would have been leased to a British company in 1877. By Sir John's efforts a treaty for the suppression of the slave trade in the sultanate was concluded in 1873.

British Protectorate.—On Nov. 4, 1890, what was left of the sultanate was proclaimed a British protectorate, in conformity with conventions by which Great Britain on her part ceded Heligoland to Germany and renounced all claims to Madagascar in favour of France. On the death of the then sultan, Sayyid Hamoud bin Thwain, in Aug. 1896, his cousin, Sayyid Khalid, proclaimed himself sultan, and seized the palace. The British government disapproved, and to compel Khalid's submission the palace was bombarded by warships. Khalid fled to the German consulate, whence he was removed to German East Africa, and Hamoud bin Mohammed, brother of Hamoud bin Thwain, was installed sultan by the British representative (Aug. 27, 1896). The government was reconstituted under British auspices in Oct. 1891, when Sir Lloyd Mathews was appointed prime minister, a title afterwards changed to first minister. In 1897 after a long agitation the legal status of slavery was abolished, compensation being given to the slave owners, mostly Arabs, who had used slave labour for the clove plantations. In 1913 the control of the protectorate was transferred to the colonial office. At first the British agent and consul general in Zanzibar also administered the East Africa protectorate (Kenya colony). This arrangement ceased in 1904; the colonial office (in 1913) made the governor of the East Africa protectorate high commissioner for Zanzibar, local affairs being entrusted to a British resident, who took over the functions of first minister. With abolition of the office of high commissioner in 1925 the British resident became directly responsible to the colonial office. An advisory council was then created, only to be replaced in 1926 by a nominated legislative council.

Although the administration was controlled by the British resident the sultan continued to exercise much authority. Sayyid Khalifa bin Harud (born 1879), who became sultan in 1911, was a great-nephew of Bargash. He worked in full agreement with the British and as the leading Moslem prince in East Africa his moderating influence did much to steady Moslem opinion in that part of Africa during World War I. The most dramatic incident of the war, for Zanzibar, was the sinking of the ancient British cruiser "Pegasus" by the German cruiser "Königsberg" on Sept. 20, 1914, the "Pegasus" being at the time at anchor in Zanzibar roadstead, undergoing repairs. During World War I, in 1917, the Sayyid Khalid, who had lived in German East Africa since his attempt to seize the throne, surrendered to the British. He was deported to St. Helena, but in 1921 was allowed to live in Mombasa, where he died in 1927.

Administration.—The government is administered by the British resident. Questions of importance are referred to an executive council (of four officials *ex officio* and three officials appointed by the sultan), over which the sultan presides. The legislative council consists of four officials *ex officio* (including the resident, who is president) and five official and six unofficial members, both the latter appointed by the sultan. Legislation consists of the decrees of the sultan and certain British statutes of general application; the sultan's decrees, when countersigned by the resident, are binding upon all persons. The Mohammedan law, which in civil matters is the fundamental law of the sultanate, controls in some measure personal relationship and land tenure among the Islamic population. There is a British court for British and foreign subjects and for all cases where one of the parties is a non-native.

Economic Conditions.—The modern development of Zanzibar dates from the occupation of the islands by the Muscat Arabs about 1830. In addition to the cultivation of cloves (made compulsory under the Sayyid Said), Zanzibar had a large transit trade in ivory, slaves, cotton goods and rice. Many merchants from India settled in Zanzibar—and apart from the traffic carried on by dhows with Arabia—trade fell largely into their hands. In 1873 the highly profitable slave trade was declared illegal, though illicitly it was carried on for the next 25 years. The Arab-owned clove and other *shambas* (plantations) were worked by domestic slave labour, but the legal status of slavery was abolished in 1897 and slavery in the sultanate finally ceased in 1907. Many Arabs failed to adapt themselves to the new conditions and their shambas passed into the hands of natives. In course of time nearly half of the adult male population was either clove plantation owners or peasant proprietors. The protectorate produces more than 80% of the world's supply of cloves, the exports of which, in 1940, amounted to 217,836 cwt.; at that period some 48,000 ac. were under clove cultivation. Coco-nuts are the second most important economic crop, and limited quantities of tobacco and citrus fruits are also exported. Manufacture of agricultural products is confined to the distillation of oil from clove buds and stems and the expression of edible oil from copra and from imported groundnuts and sesame seeds. The principal imports are rice and grain, and cotton piece goods. In 1940 the exports of the sultanate were valued at £1,158,474, and the imports at £875,697. The East African Currency board shilling (of 100 cents) became the standard coin in 1936, when the rupee of British India ceased to be legal tender. Indian and South African banks have branches in Zanzibar.

Communication.—The port of Zanzibar is well served by British and other European shipping companies, as well as by those of India, Japan and the United States; vessels of the Zanzibar government maintain a service to Pemba and to Dar-es-Salaam. Cable communication is provided by Cable and Wireless, Ltd. Prior to World War II there was a bi-weekly aeroplane service from Zanzibar to Dar-es-Salaam, Tanga, Mombasa and Nairobi, connecting with the London-to-Cape Town service. There are no railways in the island, but nearly 250 mi. of roads suitable for motor traffic.

Education.—The education of Arabs and Africans devolves almost entirely on the government, for Islamic influence is supreme. Elementary education is free, and compulsory for subjects of the sultan. In 1940 there were, for boys, 15 elementary rural schools, a rural boarding school, two urban central schools and a secondary school; for girls (provision for whose education began in 1928), there were two elementary schools and an urban school. The three missions operating in the sultanate (the Universities' Mission to Central Africa, the Society of the Holy Ghost, and the Friends' Industrial) restrict their educational activities to mainland adults and children resident in Zanzibar.

Ingrams, *Chronology and Genealogies of Zanzibar Rulers* (1926) and *Zanzibar: Its History and Its People* (1931); Government Printer, *A Guide to Zanzibar* (1939); R. E. Moreau and R. H. W. Pakenham, "Faunistics and Ages of the East African Islands," *Nature* (Oct. 1940); S. W. T. Lee, "Health of Zanzibar," *Nature* (April 1941); annual *Blue Book* and *Colonial Report*.

ZANZIBAR, an East African seaport, capital of the island and sultanate of the same name, in 6° 9′ S., 39° 15′ E. Pop. (1931 census) 45,276; 1941 est. about 65,000. The town is situated on the western side of the island 26 mi. N.E. of the mainland port of Bagamoyo. Zanzibar is built on a triangular-shaped peninsula, about 1½ mi. long, which runs from east to west, forming a safe and spacious roadstead, with a minimum depth of water exceeding five fathoms. In addition to this anchorage, there is a concrete wharf 800 ft. long, capable of berthing ships alongside up to 400 ft.; the wharf is fitted with five electrically operated cranes, and transit sheds are provided for exports and imports. Viewed from the sea, the town—which has a thoroughly oriental aspect—presents a pleasant prospect. Certain sections of the narrow bazaar street are surfaced with precast concrete slabs, and there are 9 mi. of waterproofed roads other than bazaar streets. Characteristic of the streets are the carved and massive wooden doors, whose blackness contrasts with the white stone of the houses, and the bright red of the acacias in the garden enclosures. The bazaar is a great centre of attraction. The Anglican cathedral (built 1873–79), a semi-Gothic coral building, occupies the site of the old slave market, which was closed in 1873. The Roman Catholic cathedral is a fine building in the Renaissance style.

The motley population of Zanzibar—the chief elements are Arab, Indian and Negro—is indicative of the commercial importance of the city. Its geographical position made it the key of East Africa from Cape Guardafui to Delagoa Bay. "When you play on the flute at Zanzibar" (says an Arab proverb) "all Africa as far as the lakes dances." The Americans were the first among white merchants to realize the possibilities of the port, and a United States consulate was established as early as 1836. The name Merikani, applied to cotton goods and blankets on the east coast, is a testimony to the enterprise of the American trader. The city was the headquarters of the Arabs who ravaged East Africa for slaves and ivory during the major part of the 19th century, and was described by Henry Drummond in *Tropical Africa* (1888) as a "cesspool of wickedness oriental in its appearance, Mohammedan in its religion, Arabian in its morals." Nevertheless, Zanzibar in those days was the focus of all exploring and missionary work for the interior.

ZAPARAN, a group of tribes of South American Indians forming an independent linguistic stock. The Zaparos live in the region of the Peruvian-Ecuadorian border, on the Curary and Napo rivers and the lower Aguarico. They are a tall, robust people, rather light in skin colour, with prominent noses and are said sometimes to have blue eyes. The men wear a tree-bast poncho-like garment, ornamented with painted designs. The women wear only a small fringed apron. Their houses are merely thatched shelters with no sides. Their weapons are bows, spears and blowguns, poison being used on the darts for the latter and for their arrows. They depend mainly on hunting and fishing for food, although growing some sweet potatoes and bananas.

See A. Simpson, "Notes on the Zaparos," *Journ. Anthrop. Inst. Gr. Brit. and Ire.*, vol. vii, pp. 502–510; G. Osculati, *Esplorazione delle Regioni Equatoriali, etc.* (Milano, 1854); Reinburg, "Folklore amazonien," *J. Soc. Americanistes de Paris* (n.s.) vol. xiii, pp. 11–17.

ZAPOROZHE (formerly Alexandrovsk), a town of the Ukrainian S.S.R., in 47° 51′ N., 35° 10′ E., on the left bank of the

Dnieper river. Pop. (1939) 289,188. Its name means "beyond the rapids," and it is situated south of the falls on which the Dnepropetrovsk hydraulic station was constructed. There is a motor factory and five factories produce agricultural machinery; the town is also a railway junction. Zaporozhe is opposite to Khortitsa Island, a former camp of the Zaporozhian Cossacks and kurgans (tumuli) are numerous in the district.

Zaporozhe was captured by the Germans in 1941 and was retaken by soviet troops in 1943.

ZAPOTEC, a south Mexican nationality, the most important of a group comprising also Mixtec and half a dozen other peoples, all speaking tonal languages, and occupying a territory roughly coterminous with the state of Oaxaca. The population in this area of the so-called Zapotecan family, of which the Zapotec proper held the south-eastern part, is still overwhelmingly Indian in blood and largely native in speech. The ancient Zapotec were an important people, who probably served as intermediaries of culture between the Maya and the Nahua, but also developed traits of their own. They excelled in finely modeled figure jars of pottery. Their calendar appears to have been that of the Maya and Aztec; their glyphs have not been read. Two important groups of ruins in Zapotec territory lie at Monte Alban and at Mitla. The former, which appear to be the earlier, comprise terraces and pyramids on a hill, and inscribed stelae and tablets. Mitla has long stone buildings, sunken or on low platforms, with stone columns, veneers of stone cut into geometric patterns, and pictographic frescoes. The population speaking Zapotec numbered 231,000 in 1895; that speaking idioms of Zapotec family, about 450,000.

ZARA, a town on the east coast of the Adriatic, formerly the capital of Dalmatia but now attached to Italy, and included in Venezia Giulia. Italian territory includes an adjacent belt with a total area of 42 sq.mi., and a population of 20,055, of whom 12,838 lived within the town in 1936. Zara in this sense forms a small enclave on the coast of the Yugoslav *oblast* of Split. The town is placed on the north-west end of a small, low-lying peninsula separated by the Canale di Zara from the islands of Ugliano and Pasman. It is about 73 m. N.W. of Split and about 92 m. N. of E. from Ancona, with which it is connected by steamer. The space between the peninsula on which the town stands and the adjacent mainland forms a natural, deep-water harbour, the entrance to which was in Venetian times blocked by a chain. Surrounded on three sides by the sea the town was rendered still more secure, after its capture by the Venetians in 1409, by the digging of a deep ditch on the fourth side, so as to convert the tip of the peninsula into an island. When the fortifications were reconstructed by Sanmicheli in the 16th century, a gate, the Porta di Terraferma, was erected to guard the single entrance across the ditch on the landward side.

At the end of the 10th century Zara passed for the first time under Venice. For four centuries it was bandied about from Venice to Hungary and back again. Finally, in 1409 it was sold by the King of Hungary to the Republic and remained Venetian till the Republic ceased to exist. It was then ceded to Austria, passed temporarily into French possession, forming part of the short-lived Illyrian kingdom, till in 1814 the French were driven out and it remained Austrian till the end of World War I. Its transference to Italy, when the rest of Dalmatia became Yugoslav, was justified by the large Italian element in the population and the continuity of Latin culture and speech.

Of the churches one of the oldest is the secularized S. Donato, probably dating from the early 9th century, and recalling S. Vitale at Ravenna. The cathedral dates from the 13th century and its treasury contains some good examples of Dalmatian silver work.

See T. G. Jackson, *Dalmatia, the Quarnero and Istria* (1887) and G. Dainelli, *La Dalmazia* (with atlas, 1918).

ZARHON, a mountain in Morocco, altitude 3,600 feet, 9½ m. N. of Meknes; it is covered with olive-trees and vines, and has numerous villages; it is one of the most picturesque and smiling regions of Morocco. On the flanks of the Zarhon is the town Mulai Idrīs Zarhoon, so called after Mulai Idrīs I., the founder of the Moorish empire, who was buried there in A.D. 791. The whole town is considered as a sanctuary. Not far from Mulai Idrīs are the ruins of the Roman town of Volubilis (Oulili). *See* L. Chatelain, *Les fouilles de Volubilis* (Casablanca, 1915).

ZARIA, a province occupying a central position in the Northern Provinces of the British protectorate of Nigeria. It has an area of 23,695 sq.m. and a population (1926) of 1,031,567. The province was enlarged in 1926 by the transference to it of the Katsina emirate from Kano province (*see* KATSINA). The province, of which a great portion consists of open rolling plains, is watered by the Kaduna affluent of the Niger and its many tributaries, and is generally healthy. There is an area of high land (2,000 ft. and over) in the centre of the province which in the south consists of parksland—"orchard brush." In the north the country is more open and becomes semi-desert where the Katsina emirate adjoins the French Niger colony. The chief towns are Zaria, the capital of the emirate, 87 m. S.W. of Kano, and Kaduna, the capital of the Northern Provinces. Both Zaria and Kaduna are in direct railway communication with Kano, Lagos and Port Harcourt, the Western and Eastern railways of Nigeria having their junction at Kaduna. There is also a railway from Zaria to the Bauchi tin-fields, and another railway goes N.W. from Zaria towards Sokoto. There are over 1,000 m. of motor roads in the province. Cotton is very extensively grown.

The ancient state of Zaria, also called Zeg-Zeg by the geographers and historians of the middle ages, was one of the original seven Hausa states. It suffered all the fluctuations of Hausa history, and in the 13th and early 14th centuries seems to have been the dominating state of Hausaland. At later periods it submitted in turn to Kano, Songhoi and Bornu. At the end of the 18th century it was an independent state under its own Mohammedan rulers, but, like the rest of northern Hausaland, it was conquered in the opening years of the 19th century by the Fula. It remained a Fulani emirate up to the period of the British occupation of Nigeria. The emir of Zaria professed friendliness to the British, and in March 1902 the province was taken under British administrative control. It was found that, notwithstanding his friendly professions, the emir of Zaria was intriguing with Kano and Sokoto, then openly hostile to Great Britain, while he continued to raid for slaves and to perpetrate acts of brutal tyranny and oppression. He was deposed in the autumn of 1902, and after the Sokoto-Kano campaign of 1903, which assured the supremacy of Great Britain in the protectorate, another emir, Dan Sidi, was appointed to Zaria.

ZARLINO, GIOSEFFO (1517–1590), Italian musical theorist, surnamed from his birthplace ZARLINUS CLODIENSIS, was born at Chioggia, Venetia, in 1517 (not 1540, as Burney and Hawkins say). Studying in his youth for the Church, he was admitted to the minor orders in 1539 and ordained deacon in 1541 at Venice; but he soon devoted himself entirely to the study of music under the guidance of Adrian Willaert, then choirmaster at St. Mark's. Willaert, dying in 1562, was succeeded by Cipriano di Rore, on whose removal to Parma in 1565 Zarlino was elected choirmaster. Though now remembered chiefly as the earliest advocate of a system of equal temperament for fretted and keyed instruments and for his invaluable contributions to the theory of music, he was both a practical musician and a composer. His printed works consisted of a volume entitled *Modulationes Sex Vocum* (Venice, 1566) and a few motets and madrigals scattered through the collections of Scotto and other contemporary publishers, but he also produced and superintended the public performance of some important pieces in the service of the republic. The only example we possess of his compositions on a grand scale is a ms. mass for four voices, in the library of the Philharmonic Lyceum at Bologna. He died at Venice on Feb. 14, or, according to some Feb. 4, 1590.

Zarlino's first theoretical work was the *Istitutioni Armoniche* (Venice, 1558; reprinted 1562 and 1573). This was followed by the *Dimostrationi Armoniche* (Venice, 1571; reprinted 1573) and by the *Sopplimenti Musicali* (Venice, 1588). Finally, in a complete edition of his works published shortly before his death Zarlino reprinted these three treatises, accompanied by a *Tract on Patience,* a *Discourse on the True date of the Crucifixion of Our Lord,* an essay on *The Origin of the Capuchins,* and the *Resolu-*

tion of Some Doubts Concerning the Correction of the Julian Calendar (Venice, 1589).

The *Istitutioni* and *Dimostrationi Armoniche* deal, like most other theoretical works of the period, with the whole science of music as it was understood in the 16th century. The earlier chapters, treating chiefly of the arithmetical foundations of the science, differ but little in their line of argument from the principles laid down by Pietro Aron, Zacconi, and other early writers of the Boeotian school; but in bk. ii. of the *Istitutioni* Zarlino boldly attacks the false system of tonality to which the proportions of the Pythagorean tetrachord, if strictly carried out in practice, must inevitably lead.

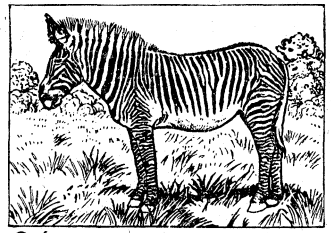
Again, Zarlino was in advance of his age in his classification of the ecclesiastical modes. These scales were not wholly abolished in favour of our modern tonality in the 17th century. Eight of them, it is true, fell into disuse; but the mediaeval Ionian and Hypo-ionian modes are absolutely identical with the modern natural scale of C; and the Aeolian and Hypo-aeolian modes differ from our minor scale, not in constitution, but in treatment only. Mediaeval composers, however, regarded the Ionian mode as the least perfect of the series and placed it last in order. Zarlino thought differently and made it the first mode, changing all the others to accord with it. His numerical table, therefore, differs from all others made before or since, prophetically assigning the place of honour to the one ancient scale now recognized as the foundation of the modern tonal system.

These innovations were violently opposed by the apostles of the monodic school. Vincenzo Galilei led the attack in a tract entitled *Discorso Intorno alle Opere di Messer Gioseffe Zarlino,* and followed it up in his famous *Dialogo,* defending the Pythagorean system in very unmeasured language. It was in answer to these strictures that Zarlino published his *Sopplementi.*

ZAUSCHNERIA, a genus of North American plants of the evening-primrose family (Onagraceae), comprising several species native to California and adjacent Mexico. They are low, slightly shrubby perennials, with small narrow or ovate leaves and large scarlet, fuchsia-like flowers. *Z. californica,* known as California fuchsia and Mexican balsamea and found on mountain slopes, is planted in flower gardens.

ZEALAND (Dan. *Sjaelland*), the largest island of the kingdom of Denmark 2,709 sq.mi. in area, lying between Fyn (11 mi. distant) on the west, and southern Sweden (only 3 mi. distant at the sound) on the east. The surface is undulating, but little above sea-level, and the outline very irregular. On the island are the old cathedral city of Roskilde, the Danish capital, Copenhagen, and the historic port of Helsingfors (Helsinki). Pop. (1940) 1,406,232. (*See* DENMARK.)

ZEBRA, the name for the African striped members of the horse tribe. The true or mountain zebra (*Equus zebra*) maintains a precarious foothold in the mountainous region of Cape Colony and also inhabits Angola. It stands about 4ft. at the shoulder, with fairly long ears, a tail scantily clothed with hair, and a short mane. The ground colour is white and the stripes, absent only on the abdomen and inside of the thighs, are black. The lower part of the face is brown. The stripes on the haunch do not reach the median dorsal stripe and there are a number of transverse short stripes on each side of the midline. These are absent in Burchell's zebra (*E. burchelli*), which has broader stripes, often with shadow stripes between them. The typical race is extinct, but other races of this species are common from the Transvaal to Uganda. The ground colour is pale buff, the stripes, which in the southern race do not extend to the lower limbs, dark brown or black. The East African race (*E.b. boemi*) has the lower parts striped and shadow stripes are usually lacking. The closely related quagga (*q.v.*) is extinct. Grévy's zebra (*E. grevyi*) of Somaliland, northern Kenya and parts of Ethiopia, is distinguished by its long head, large ears and numerous narrow stripes. Zebras occur in large herds and are preyed upon chiefly by lions. They have been crossed with the domestic horse but the resultant hybrid is not as valuable as the horse, mule and ass. Fossil horses, with teeth closely resembling those of zebras, have been found in the Pleistocene of North America. (*See* HORSE; EQUIDAE.) (J. E. HL.)



GRÉVY'S ZEBRA (EQUUS GREVYI) DISTINGUISHED BY ITS NUMEROUS STRIPES AND ASSLIKE EARS

ZEBU (*Bos indicus*), an Indian species of ox, characterized by light colour and a hump. The sacred bulls of India belong to this species, which is used for draught work, and supplies milk. In many places it is crossed with domestic cattle. (*See* CATTLE.)

ZEBULON, a tribe of Israel, named after the sixth son borne by Leah to Jacob (Genesis xxx. 20). The fertile territory occupied by the tribe lay roughly north-east of the plain of Jezreel, but the boundaries between it and the neighbouring territories of Naphtali, Asher and Issachar are ill-defined. The somewhat obscure text of Genesis xlix. 13 seems to imply that at one time Zebulon extended to the sea-coast and marched with Phoenician territory. The tribe appears to have furnished valiant warriors, and receives special mention in the Song of Deborah for its martial exploits (Judges v. 14, 18).

ZECHARIAH, the eleventh in order of the "minor prophets" of the Old Testament. He was associated with Haggai (*q.v.*) in stimulating the re-building of the temple at Jerusalem, begun in 520 (Ezra iv. 24) and completed in 516 (Ezra vi. 15). A previous attempt made by returned exiles in 537 (Ezra i. 1 *seq.,* iii. 1 *sqq.*) seems to have been checked by local opposition and not renewed owing to economic pressure. In 520, however, the political disturbances of the Persian empire (of which the Jewish community in Palestine was a negligible part) were interpreted by these two prophets as a sign that the Messianic expectations were now to be realized, and that the "Day of Yahweh" was at hand. Haggai gave the first impulse to the new attempt; two months later, Zechariah joined him in encouraging the faint-hearted. His prophecies, exactly dated in 520 (i. 1, 7) and 518 (vii. 1), are to be found in the first eight chapters of the book now bearing his name. Their central feature is a series of "night-visions" (i. 8, iv. 1), intended to show Yahweh's immediate and effective intervention on behalf of His people. They are arranged with literary art in connected sequence, beginning with the vision of horsemen who report that the expected Messianic crisis has not yet come (i. 11, *cf.* Hagg. ii. 21 *seq.*), and culminating in the vision of Yahweh's war-chariots despatched to execute His vengeance upon the heathen, especially on Babylonia (vi. 8). The six intervening visions (all the eight are ascribed to a single night) reveal in succession four horns, representing the heathen powers of the four quarters of the earth, cast down by four craftsmen (i. 18–21), a man with a measuring line, whose narrow ideas of the future city are replaced by the conception of a city without walls because of its great extent, to which Yahweh's protection will be a wall of fire (ii. 1–5), the formal acquittal and restoration of Joshua the high-priest, representing the community (iii. 1 *seq.*), the seven-branched lampstand, representing Yahweh's watchful eyes, with two olive-trees, representing Joshua and Zerubbabel (iv. 1–14, but see the commentaries), the flying roll which brings its ubiquitous curse on evil-doers (thieves and false-swearers), and so cleanses the land of moral evil (v. 1–4), the woman carried off in an ephah, representing the removal of guilt (v. 5–11). These visions are now prefaced by a call to repentance and the promise of forgiveness (i. 2–6), in which Zechariah's appeal to "the former prophets" (like the detail of an interpreting angel in the visions themselves) reminds us that the great prophetic period (8th–6th centuries) lies in the past, and that the conception of revelation itself has lost something of its original simplicity and spontaneity.

The "night-visions" are followed, two years later (vii. 1), by a divine oracle which directs that the fasts kept throughout the exile should now become festivals (viii. 18 *seq.*). The enquiry which led to the oracle (vii. 3) is made the occasion of warning against the externality of fasting, of appeal for true conduct, and of an idyllic picture of the happiness of the coming Mes-

sianic age (note especially viii. 4, 5). In this happy future the prophet expected that Zerubbabel would be the Messiah, and the bringing of an offering of gold and silver from Jews in Babylon led Zechariah to crown him symbolically in the name of Yahweh (vi. 9–15; *see* the commentaries for the original text). The darkness that falls on Jewish history with the completion of the second temple suggests that these words and deeds may have thrust Zerubbabel into a dangerous political prominence, leading to his removal by the Persian authorities, and the eclipse of Messianic expectations.

The remainder of the present book of Zechariah (ix.–xiv.) is of an altogether different character, and is now generally admitted to belong to a period later than the Persian (as indeed the direct reference to Greece in ix. 13 implies). This portion of the book is divided by the titles in ix. 1, xii. 1. ("The burden of the word of Yahweh"), into two distinct collections, each of which it seems necessary to divide again, so that we have four groups of prophecies, distinguished by their subject-matter. The first (ix.–xi. 3) deals with the recovery of Palestine by Yahweh's victories over Syria, Phoenicia and Philistia (ix. 1–8), the coming of the Messianic king to the restored and victorious Israel (ix. 9–17), the overthrow of the (foreign) "shepherds" or rulers, and the gathering of exiled Israelites (x. 1–12), closing with a figurative dirge over the fall of these "shepherds" (xi. 1–3). The second group (xi. 4–17, with the misplaced xiii. 7–9) describes the rejection of the prophet, representing a worthy shepherd, and the accursed doom of a worthless one, a purified third of the people alone remaining. The third (xii., xiii. 1–6) pictures an attack of the nations upon Jerusalem, in which Judah is first a foe and then a victorious friend to the mother city; this is followed by elaborate mourning for an unnamed martyr (xii. 10, R. V. mg.), and the cleansing of Jerusalem from idolatry and *prophecy*. The fourth division (xiv.) describes the delivery of Jerusalem from the heathen, that it may become the metropolis of religion for all the world. The last two of these divisions are of a markedly eschatological character, and even the first two could be so regarded (so Sellin). These writings are perhaps the most obscure of the Old Testament, chiefly because we have no sufficient clue to the historical allusions, such as the cutting off of three shepherds in one month (xi. 8), the pierced martyr (xii. 10) and the antagonism of Judah and Jerusalem (xii. 2, xiv. 14). By some scholars these chapters have been brought down as late as the Maccabean age, the events of which are supposed to explain these and other allusions. But the fact is that we are almost wholly ignorant of Jewish history during the earlier part of the Greek period (from 331 B.C.), to which these writings might equally well belong.

BIBLIOGRAPHY.—For commentaries *see* S. R. Driver in *Century Bible* (1906); H. G. Mitchell in *Internat. Crit. Comment.* (1912); W. E. Barnes in *Cambridge Bible*, (1917); R. H. Kennett in *Peake's Commentary* (1919). (H. W. R.)

ZEDEKIAH, son of Josiah, and the last king of Judah (2 Kings xxiv, 17 *sqq.*; 2 Chron. xxxvi, 10 *seq.*). He was appointed king by Nebuchadrezzar after the capture of Jerusalem (597 B.C.) and held his position under an oath of allegiance. After three years he began an intrigue with Moab, Edom, Ammon, Tyre and Sidon, and it is possible that he was summoned to Babylon to explain his conduct. Nevertheless, relations were maintained with Egypt and steps were taken to revolt. The Babylonian army laid siege to Jerusalem in 588 B.C., and a vain attempt was made by Pharaoh Hophra to cause a diversion. After six months a breach was made in the city, Zedekiah was captured and taken to Nebuchadrezzar at Riblah. His sons were killed, and he was blinded and carried to Babylon in chains where his predecessor, Jehoiachin was already a captive.

ZEEBRUGGE, ATTACK ON: *see* BELGIAN COAST OPERATIONS.

ZEEHAN, a town of Montagu county, Tasmania, 225 mi. N.W. of Hobart, on the Little Henty river. It is a railway centre and focus of the silver-lead mining of the neighbourhood. It is about halfway along the railway between the copper mines at Mount Lyell and the tin mines of Mount Bischoff. In 1938 Tasmania produced silver-lead worth £268,000, mostly from Zeehan. Pop. for locality (1933), 1,002.

ZEELAND, the most southerly North sea maritime province of the Netherlands, consists mainly of six deltaic islands between the Grevelingen (the southern sea-exit of the Waal-Maas) and De Hont or Western Schelde sea-channel, together with a strip of the Flanders mainland lying south of De Hont. Belgium borders it on the south; the Dutch provinces of North Brabant, east, and South Holland, north, are its other neighbours. It is 609 sq.mi. in area, and of the other ten Dutch provinces only Utrecht is smaller. Very little of its entire surface is above sea-level. Formed of the accumulated alluvium from the great rivers and with little natural protection against the encroaching waves, its life has been marked by inundation catastrophes and by the long, slow winning back of territory in the lee of successive ranks of many miles of artificial dikes. (*See* HOLLAND: *Dikes.*)

Above a gateway of the old mint of the counts of Holland in Middelburg a sculptured lion of Zeeland rises through stone waves and his "Luctor et emergo" is one of the most apposite of the provincial mottoes. Its pop. (est. 1938) 254,565, is, with the exception of Drente, the lowest of any province in Holland. However, its fertile soil favours the cultivation of cereals, wheat, rye and barley and of root crops. Its famous black and white cattle and dairy produce are important exports.

The constituent islands are Walcheren to the south-west with North Beveland and South Beveland in close proximity to the east. North of the fairly wide waterway Ooster Schelde, which at the eastern end has the significant name of Verdronken (Drowned) Land, are Schouwen-en-Duiveland (westward), and the smaller Tholen and still smaller St. Philipsland. All the islands preserve archaic customs and costumes. Walcheren, though not the largest island, is the most densely populated and nearest to England with which Flushing (Vlissingen), its largest town, has regular passenger and mail boat services *via* Harwich and Queenborough. Flushing (pop. 21,716) is not only a sea and canal port, but also a gay resort. It is the railhead for the line which in 1866 first crossed the great railway dam between Walcheren and South Beveland and now runs to Roosendaal (North Brabant) the great railway junction for Belgium, Germany and north Holland. The ship canal from Flushing divides Walcheren into two unequal parts and passes Middelburg en route for Veere, while steam trams connect Flushing and Middelburg with Domburg. Domburg is a small seaside resort built over and round a much older settlement with civic rights dating back to the 13th century; in addition, numerous Roman antiquities found locally suggest a still earlier origin. South-west of Domburg is the famous Westkapelle dike. Middelburg, the capital of the province, is but little smaller than Flushing. It is and has long been the real focus of Dutch life in Zeeland and has many interesting buildings.

The small industries of Walcheren include ship-building, distilling, brewing and spinning, but it deservedly ranks as the flower garden of Zeeland; in latter days it is cultivating a great variety of products from hemp to the opium poppy and its orchards are important. South Beveland and its small neighbour North Beveland are even more important for fruit which, in their case, is largely exported as jam. South Beveland has suffered much from inundations, particularly in the south-west; here, during the 16th century, the island of Borsselen was submerged but has been gradually recovered. North Beveland, destitute of ship canal or railway has no large settlements; it is intensively cultivated and shares with Schouwen and South Beveland an important oyster-breeding industry, Yerseke on the north-east coast of South Beveland being particularly famed. Goes (pop. [1940] 9,669) is the largest town of North Beveland, Schouwen contains the greatest amount of elevated land in Zeeland and the well-wooded tract along the western seaboard introduces a less usual scenic feature. The former natural seaway between Schouwen and Duiveland has been closed by the damming of the Dykwater but a canal still follows its line. On this is the old port of Zierikzee which has probably retained more of its mediaeval features than any other Zeeland town.

In the north of Schouwen is Brouwershaven, established as a port by the brewers and wine merchants of Middelburg. Here the English supporters (under Jacquelin of Bavaria) were defeated by the troops of Philip of Burgundy. St. Philipsland is rather inaccessible and has little of interest; Tholen, only little easier of approach, has on its east coast a small ancient circular town of the same name, noted for oysters and onions. In the still smaller village of St. Maartensdyk little remains of its once mighty 14th-century castle—the home of the Borsseles—but the village church contains a tomb of Floris van Borssele. Stavenisse on the west coast is modern and ugly. The strip of Zeeland-Flanders gives the Dutch command of both banks of the Lower Schelde. Here the busiest town is Terneuzen at the sea-end of the canal (1825–27), running due south to Ghent; south-east of it lies Axel, formerly fortified but now noted only for the peculiar costumes of its peasant women. Zeeland played an important role in the battle of Holland in May 1940, as it was able to hold out for about 10 days longer than the other provinces in the battle against the German invaders. Most of its capital, Middelburg, was destroyed by enemy bombing. (W. E. WH.; X.)

ZEEMAN, PIETER (1865–1943), Dutch physicist, was born at Zonnemaire, Zeeland, on May 25, 1865. He studied at Leyden, where he was successively assistant in physics (1890–94), *Privat-dozent* (1894–97) and lecturer (1897–1900). In 1900 he was appointed professor of physics at Amsterdam, and in 1908 director of the Physical institute in that city. Zeeman's best known work in physics is the so-called Zeeman effect (*q.v.*), the splitting up of spectral lines in a magnetic field, which he discovered in 1896. The theoretical explanation was first given by Hendrik Antoon Lorentz soon after the effect was observed. The phenomenon has been used by astronomers for the detection of magnetic effects at the surface of the sun. Later Zeeman worked on the propagation of light in moving media. He made observations in water, quartz and flint; the bodies were given an oscillatory motion and instantaneous photographic methods were applied, the exposure being made when the velocity was at a maximum. The results of these observations are collected in *Archives Néerlandaises des Sciences Exactes* (vol. x, 1927). Zeeman was a member of many learned societies and was the recipient of many awards, including the Nobel prize, which he won jointly with Lorentz in 1902. He was the author of several books on magneto-optics, which were translated into English and German. He died in Amsterdam, Oct. 9, 1943.

ZEEMAN EFFECT, named after its discoverer, is the term used to describe the phenomena produced in spectroscopy (*q.v.*) by a magnetic field. When a substance, which emits a line spectrum, is placed in a strong magnetic field, every line is split up into several components each of which has a characteristic change of frequency and characteristic polarization and intensity. Magnetism produces many curious effects in matter (change of electrical resistance, "Hall" effect, etc.), but the Zeeman effect has an importance immensely greater than the rest because it has proved to be one of the most powerful means of discovering the nature of the forces in the atom. The first indication of a connection between light and magnetism was due to Faraday, who discovered the magnetic gyration of light in 1845; *i.e.*, when plane polarized light goes through transparent matter in a magnetic field the plane of polarization is rotated. With extraordinary insight he conjectured that there ought to be a corresponding effect in the emission of light, and almost the last experiment of his life was to seek for it. He failed to detect it since the technique both of spectroscopes and of magnetic fields was insufficiently developed, but modern theory entirely bears out the correctness of his conjecture. In 1896 Zeeman made a similar attempt and was successful. When a source of light, such as a metallic arc, was placed between the poles of a powerful electromagnet, the lines of its spectrum were split into components, some displaced to the red and some to the blue, and each of these was polarized in a characteristic way.

The experimental study of the Zeeman effect calls for little comment. Even in the strongest magnetic fields available (say 30,000 gauss) the extreme components into which a line is split are never more than about 1 Å. U. apart, and there may well be a dozen or so components between them, so that it is not only necessary to have a powerful magnet, but also a spectroscope of high resolving power. The consequent difficulties are very great, but are not peculiar to the Zeeman effect. The polarizations of the various components are shown by the ordinary methods used for polarized light, and their intensities by means of an opaque wedge according to the usual photometric practice, and only one point calls for comment. Light passing through a diffraction grating has its intensity differently affected according as it is polarized along or across the lines of the grating, and this might entirely vitiate the comparison of the intensities of lines polarized in these two ways. The difficulty is avoided by the use of a quartz plate, which rotates the planes of polarization so that both types are at 45° to the lines of the grating. It was only after this was done that it was found possible to obtain correct values for the intensities, with important consequences for the general theory of spectra.

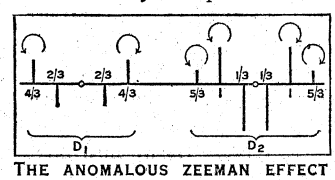
The Normal Zeeman Effect.—Almost immediately after Zeeman had made his discovery, Lorentz showed how it would fit into the classical electric theory. His explanation has been superseded in the light of later knowledge, but it still furnishes a convenient description of the simpler features of the effect. It explains what is called the "normal effect," though, as so often happens with scientific nomenclature, it turns out that the normal effect is of rather rare occurrence and is not in fact the most primitive type. Lorentz supposed that the atom contains an electron which describes free vibrations about a centre. The restraining force is proportional to the distance from the centre and is the same for all directions, so that the free period is independent of the orbit of the electron. Such an electron will emit light of its own frequency and with polarization completely determined by its orbit. When there is no external magnetic field the orbits of the various atoms in the source are orientated at random, and their average effects give unpolarized light.

When an electron is placed in a magnetic field, it experiences a force at right-angles to the direction of the field and also at right-angles to its line of motion, and this force is to be superposed on the other forces acting on the electron. The effect is most conveniently described by Larmor's theorem which asserts that the field is equivalent to a rotation. This means that the actual motion of the electron in the field is the same as the apparent motion it would have without the field, but now as seen by an observer who is himself rotating at a suitable speed about an axis in the direction of the magnetic force. The angular velocity of the Larmor rotation is $eH/2mc$, where H is the strength of the field, e and m the charge and mass of the electron and c the velocity of light. Compared to ordinary standards this is a very high speed even for quite weak fields (for the earth's magnetic field is about a million rotations a second), but it is much smaller than the speed with which it is to be compared, the electron's motion in the atom.

The equivalence of magnetism and rotation is true whatever other forces may act on the electron. In our case the effect can best be seen by considering three special types of orbits; the general motion is merely a superposition of these. The first is a motion along the line of the magnetic field, and this is evidently unaffected by the rotation. The others are circular motions, both in a plane perpendicular to the field, but in opposite directions. The Larmor rotation must be added to one of these, and subtracted from the other. If the original frequency was ν there will now be three frequencies, ν and $\nu \pm eH/4\pi mc$, and we conclude that the magnetic field will split one line into three. Moreover each of the three will have a characteristic polarization, associated with the corresponding motion of the electron. These polarizations vary according to the position of the observer, and are most easily described by saying that the light-vector (electric force) behaves like the perspective view that the observer has of the motion of the emitting electron. Thus the light of frequency ν corresponds to the electron vibrating along the line of the field. Viewed from anywhere it appears to describe a straight line, and so the associated light is plane-polarized. From the poles (in the

direction of the magnetic field) the electron will appear motionless, and so no light is emitted in this direction. At the equator the apparent motion is a maximum and the light is polarized with vector in the same direction as the field; for this reason the component is called *parallel*. Next consider one of the circular motions; on the same principle it emits circularly polarized light towards the poles, and plane-polarized light towards the equator where the electron's motion is seen edgewise. From the direction of its polarization at the equator this component is called *perpendicular*. One of the first tasks of Zeeman was to examine the light in the polar direction, for, by finding whether the bluer component gives right- or left-handed circularly polarized light, it is possible to fix the sign of the Larmor rotation, and so to determine the sign of the electron's charge *e*. Once this is done it is most convenient to observe the effect from the equator, since in that direction all three components are plane-polarized, and this is much more convenient for investigation.

The Anomalous Zeeman Effect.—The experiments on some spectral lines (in particular on the chief cadmium lines which are used as fundamental standards of wave-length) entirely bore out Lorentz's theory and gave a measure of e/mc, which in magnitude and sign was in agreement with the value determined for free electrons. This result, however, proved to be quite exceptional; nearly all lines were found to give much more complicated splitting and this in many different ways, which are collectively referred to as the *anomalous Zeeman effect*. There are usually many more than the three lines of Lorentz's theory, and often none in the positions predicted by it; but the scale of the pattern is still proportional to the magnetic force and the polarizations still fall into the three classes described, the central ones being *parallel* and the outer *perpendicular* of the two types. Moreover the displacement always bears a simple numerical ratio to that given by the simple theory. The general rules are very complicated and we may be content to describe a single example, the yellow lines, D_1 and D_2, of sodium. These two lines break up into 4 and 6 components respectively, in the manner shown in figure. This is the simplest case of the anomalous effect, and theory now shows it to be the most primitive effect of all, much more so than the normal Lorentz triplet.



THE ANOMALOUS ZEEMAN EFFECT FOR THE D LINES OF SODIUM

The anomalous Zeeman effect is connected with another important phenomenon, called the Paschen-Back effect after its discoverers. As the magnetic field is increased, the components get further apart, and for a strong enough field those of D_1 and D_2 ought to overlap one another. This does not occur, but a complicated rearrangement takes place; some lines weaken in intensity and disappear, others melt together and finally, when the magnetic field is very strong indeed, a totally new pattern is observed in the form of a *single* Lorentz triplet. A trace of the original two lines remains, in that each component has a fine structure and is not a simple line. The actual transition to the Paschen-Back effect cannot be observed for the D-lines, because it would need quite unattainable strengths of field, but it is safely inferred from the behaviour of other lines of the same type which are originally much closer together. Though we have only described one particular example, it is universally true that in very strong fields every *multiplet* of a spectrum is replaced by a single Lorentz pattern.

The disentangling of the very complicated patterns was made possible by the quantum theory of spectra, according to which there is a spectrum of *levels* underlying the spectrum of lines. Every line is given in frequency by the difference in "height" between two levels, and the levels have much simpler characteristics than the lines. The analysis was worked out with the help of quasi-dynamical models, and its result was to express the displacement, polarization and intensity of every line algebraically in terms of the *quantum numbers* which describe the two associated levels. From this analysis it emerged that in the atom there are two kinds of system, one exhibits the Larmor rotation, while the other shows a rotation just twice as great. By the interaction of the two systems it is possible to explain both the anomalous Zeeman effect and the Paschen-Back effect. For some time the existence of this doubled rotation was mysterious, but it was finally traced to the electron itself; the electron in addition to its electric charge is a magnet and rotates in the magnetic field with twice the Larmor speed. Even this is not the last word, for it has been shown that it is only possible to make a picture of electrical phenomena which rigorously reconciles the quantum theory with the theory of relativity by endowing the electron with magnetism in just the way required for the Zeeman effect. Einstein's conception of relativity was developed to explain a totally different category of phenomena, and it is one of the most remarkable syntheses in the history of physics that it should be possible to make it responsible for the intricacies of the Zeeman effect.

We have described the most interesting aspect of the Zeeman effect, and need only touch on a few others. There is the *inverse Zeeman effect* where light is absorbed by matter in a magnetic field; this follows exactly the same rules as the direct effect. Faraday's magnetic gyration (*see* LIGHT) is another aspect of the same thing. The theory of the effect is still very incomplete for band spectra, and indeed for some classes of line spectra. In conclusion we may refer to a more practical use to which the Zeeman effect has been put: by its means it is known that there are very powerful magnetic fields in sun-spots, and also that the sun as a whole has a magnetic field like the earth. *See* also SPECTROSCOPY; OPTICS; LIGHT; QUANTUM MECHANICS.

(1928).

(C. G. D.)

ZEITZ, a town in the extreme south of the Prussian province of Saxony, Germany, on the Weisse (White) Elster, 28 mi. by rail S.S.W. of Leipzig on the line to Gera, and with branches to Altenburg and Weissenfels. Pop. (1939) 36,131. Zeitz is an ancient place of Slavonic origin. From 968 till 1028 it was the seat of a bishopric, afterwards removed to Naumburg, and styled Naumburg-Zeitz. In 1564 the last Roman Catholic bishop died, and his dominions were thenceforward administered by princes of Saxony. From 1653 till 1718 Zeitz was the capital of the dukes of Saxe-Zeitz. It thereafter remained in the possession of the electors of Saxony until 1815, when it passed to Prussia.

ZELLER, EDUARD (1814–1908), German philosopher, was born at Kleinbottwar in Württemberg on Jan. 22, 1814, and educated at the University of Tübingen and under the influence of Hegel. In 1840 he was *Privatdozent* of theology at Tübingen, in 1847 professor of theology at Bern, in 1849 professor of theology at Marburg, migrating soon afterwards to the faculty of philosophy as the result of disputes with the Clerical party. He became professor of philosophy at Heidelberg in 1862, removed to Berlin in 1872, and retired in 1895. His great work is his *Philosophie der Griechen* (1844–52). He was one of the founders of the *Theologische Jahrbücher,* a periodical which acquired great importance as the exponent of the historical method of David Strauss and Christian Baur. Like most of his contemporaries he began with Hegelianism, but later he saw the necessity of going back to Kant in the sense of demanding a critical reconsideration of the epistemological problems which Kant had made but a partially successful attempt to solve. None the less his merits as an original thinker are far outshone by his splendid services to the history of philosophy, in spite of the fact that his view of Greek thought is somewhat warped by Hegelian formalism. He died on March 19, 1908. Among his other works are: *Platonische Studien* (1839); *Gesch. d. christlich. Kirche* (1898); *Gesch. d. deutsch Philos. seit Leibniz* (1873, 1875); *Staat und Kirche* (1873); *Über Bedeutung und Aufgabe d. Erkenntniss-Theorie* (1862); *Über teleolog. und mechan. Naturerklärung* (1876); *Philosoph. Aufsätze* (1887).

The *Philosophie der Griechen* was translated into English (2 vols., 1881) under the editorship of S. F. Alleyne. The *Philosophie* appeared in an abbreviated form as *Grundriss d. Gesch. d. Griech. Philos.* (1883; 5th ed. 1898); Eng. trans. by Alleyne and Evelyn Abbott (1866), under the title, *Outlines of the Hist. of Gk. Philosophy.*

ZEMARCHUS (*fl.* 568), Byzantine general and traveller. The Turks, by their conquest of Sogdiana in the middle of the 6th century, gained control of the silk trade which then passed through Central Asia into Persia. But the Persian king, Chosroes Nushirvan refused to allow the old commerce to continue, and the Turks in 568 sent an embassy to Constantinople to form an alliance with the Byzantines and "transfer the sale of silk to them." The offer was accepted by Justin II., and in Aug. 568, Zemarchus the Cilician, "General of the cities of the East," left Byzantium for Sogdiana. The embassy was under the guidance of Maniakh, "chief of the people of Sogdiana," who had himself come to Byzantium to negotiate the "Roman alliance." On reaching the Sogdian territories the travellers were offered iron for sale, and solemnly exorcised; Zemarchus was made to "pass through the fire" (*i.e.*, between two fires), and strange ceremonies were performed over the baggage of the expedition. The envoys then proceeded to the camp of Dizabul (or rather of Dizabul's successor, he having just died) "in a hollow encompassed by the Golden Mountain," apparently in some locality of the Altai. They found the khan surrounded by astonishing barbaric pomp—gilded thrones, golden peacocks, gold and silver plate and silver animals, hangings and clothing of figured silk. They accompanied him some way on his march against Persia, passing through Talas or Turkistan in the Syr Darya valley.

Near the river Oēkh (Syr Darya?) he was sent back to Constantinople with a Turkish embassy and with envoys from various tribes subject to the Turks. Halting by the "vast, wide lagoon" (of the Aral sea?), Zemarchus sent off an express messenger, one George, to announce his return to the emperor. George hurried on by the shortest route, "desert and waterless," apparently the steppes north of the Black sea; while his superior, moving more slowly, marched 12 days by the sandy shores of "the lagoon"; crossed the Emba, Ural, Volga and Kuban (where 4,000 Persians vainly lay in ambush to stop him); and passing round the western end of the Caucasus, arrived safely at Trebizond and Constantinople. For several years this Turkish alliance subsisted, while close intercourse was maintained between Central Asia and Byzantium; but from 579 the friendship rapidly began to cool. All this travel does not seem to have corrected the misapprehension that the Caspian was a gulf of the Arctic ocean.

Graec.*, vol. cxiii., Paris, 1864); H. Yule, *Cathay*, clx.–clxvi. (Hakluyt Society, 1866); L. Cahun, *Introduction à l'histoire de l'Asie*, pp. 108–118 (1896); C. R. Beazley, *Dawn of Modern Geography*, i. 186–189 (1897). (C. R. B.)

ZEMGALS, GUSTAV (1871–1939), president of the republic of Latvia (1927–30), was born in Courland on Aug. 12, 1871. Educated in Riga, he studied law at the University of Moscow. Up to the time of his election as president of the republic he was a well known lawyer and notarius publicus in Riga, and took an active part in the Co-operative movement. He was vice-president of the Latvian National Council in 1918, and this council was recognized by the Western European Powers as being the legitimate representative body of the Latvian nation. It was he who proclaimed the independence of Latvia on Nov. 18, 1918, in the absence of Monsieur Tschakste, the president of the Latvian National Council.

He was elected president of the republic of Latvia for three years on April 8, 1927, in succession to the late J. Tschakste, the first president of the republic of Latvia. President Zemgals was elected by a great majority, receiving about 80 votes out of a possible 100 in the Latvian parliament. He held office until April 8, 1930, when he was succeeded by Albert Kviesis. He enjoyed remarkable popularity among all classes of the population, as he was keenly interested in the life and the progress of the people of the country. He was a member of the Constituent Assembly of Latvia and had a seat in the first parliament (Saeima). He was lord mayor of Riga and was minister of war from 1921–23. He died Jan. 7, 1939.

ZEMUN, a town of Croatia-Slavonia, Yugoslavia (German *Semlin*), on the Danube opposite Belgrade. Pop. (1931) 28,083, the majority being Serbs. Zemun is the seat of an Orthodox bishop; but most of the inhabitants are Roman Catholics. Zemun has an important transit trade in grain, fruit, livestock and timber. On a hill overlooking the Danube are the ruins of the castle of Hunyadi Janos, who died here in 1456. Until 1881 the town belonged to the military frontier of Austria-Hungary. In April 1941, the town passed under German occupation.

ZENÁGA, a Berber tribe of southern Morocco who gave their name to Senegal, once their tribal home. With other tribes under Yusef bin Tashfin, they crossed the Sahara and gave the Almoravide dynasty to Morocco and Spain. The Zeirid dynasty which supplanted the Fatimites in the Maghrib and founded the city of Algiers was also of Zenága origin. The Zenága dialect of Berber is spoken in southern Morocco and on the banks of the lower Senegal, largely by the negro population.

ZENATA or ZANATÀ, a Berber tribe of Morocco in the district of central Atlas. Their tribal home seems to have been south of Oran in Algeria, and they early claimed an Arab origin, though the Arabs called them descendants of Goliath, *i.e.*, Philistines or Phoenicians (Ibn Khaldun, vol. iii. p. 184 and vol. iv. p. 597). They were formerly a large and powerful confederation, and took a prominent part in the history of the Berber race. The Beni-Marin and Wattasi dynasties of Zenata origin, reigned in Morocco from 1213 to 1548.

ZEND-AVESTA, the original document of the religion of Zoroaster (*q.v.*), still used by the Parsees as their bible and prayer-book. The name "Zend-Avesta" has been current in Europe since the time of Anquetil Duperron (*c.* 1771), but the Parsees themselves call it simply *Avesta, Zend* (*i.e.*, "interpretation") being specially employed to denote the translation and exposition of a great part of the Avesta which exists in Pahlavi. The origin and meaning of the word "Avesta" (or in its older form, *Avistāk*) are alike obscure; it cannot be traced further back than the Sassanian period. The term is now applied both to the collection of writings and also to the language in which they are composed. The Avesta is a work of but moderate compass (comparable, say, to the *Iliad* and *Odyssey* taken together), but no single manuscript gives it in entirety.

Contents.—As we now have it, the Avesta consists of the following parts:—

1. The *Yasna,* the principal liturgical book of the Parsees, in 72 chapters (*hāiti, hā*), contains the texts read by the priests at the solemn yasna (Izeshne) ceremony, the general sacrifice in honour of *all* the deities. The arrangement of the chapters is purely liturgical, although their matter in part has nothing to do with the liturgical action. It falls into three sections of about equal length:—(*a*) The introduction (chap. 1–27) consists mainly of invocations. Yet it includes some interesting texts, *e.g.*, the *Haoma* (*Hom*) Yasht (9, 11) and the ancient confession of faith (12), which is of value as a document for the history of civilization. (*b*) The Gāthās (chap. 28–54) contain the discourses, exhortations and revelations of the prophet, written in a metrical style and archaic language. The Gāthās proper, arranged according to the metres in which they are written, fall into five subdivisions (28–34, 43–46, 47–50, 51, 53). Between chap. 34 and chap. 43 is inserted the so-called Seven-Chapter Yasna (*haptanghāiti*), a number of small prose pieces not far behind the Gāthās in antiquity. (*c*) The so-called Later Yasna (*Aparō Yasnō*) (chap. 5–72) consists mainly of invocations. Special mention ought to be made of the *Sraosha* (*Srōsh*) Yasht (57), the prayer to fire (62), and the great liturgy for the sacrifice to divinities of the water (63–69).

2. The *Vispered,* a minor liturgical work in 24 chapters (*karde*), is alike in form and substance completely dependent on the Yasna, to which it is a liturgical appendix. The name *Vispered,* meaning "all the chiefs" (*vispē ratavō*), has reference to the spiritual heads of the religion of Ormuzd, invocations to whom form the contents of the first chapter of the book.

3. The *Vendidad* the priestly code of the Parsees, contains in 22 chapters (*fargard*) a kind of dualistic account of the creation (chap. 1), the legend of Yima and the golden age (chap. 2), and in the bulk of the remaining chapters the precepts of religion with

regard to the cultivation of the earth, the care of useful animals, the protection of the sacred elements, such as earth, fire and water, the keeping of a man's body from defilement, together with the requisite measures of precaution, elaborate ceremonies of purification, atonements, ecclesiastical expiations and so forth. Yet in spite of an exaggerated casuistry the whole of Zoroastrian legislation is subordinate to one great point of view: the war—preached without intermission—against Satan and his noxious creatures, from which the whole book derives its name; for "Vendīdād" is a modern corruption for *vī-daēvō-dātem*—"the anti-demonic Law." The three concluding chapters are devoted to sacerdotal medicine.

4. The *Yashts, i.e.,* "songs of praise," except those inserted in the Yasna, form a collection by themselves. They contain invocations of *separate* Izads, or angels, number 21 in all, and are of widely divergent extent and antiquity. The great Yashts—some nine or ten—are impressed with a higher stamp, and represent the religious poetry of the ancient Iranians. They resemble the Rig-Veda hymns, and are a rich source of mythology and legendary history. Side by side with full, vividly coloured descriptions of the Zoroastrian deities, they frequently interweave, as episodes, stories from the old heroic fables. The most important of all, the 19th Yasht, gives a consecutive account of the Iranian heroic saga in great broad lines, together with a prophetic presentment of the end of this world.

5. The *Khordah Avesta, i.e.,* the Little Avesta, comprises a collection of shorter prayers designed for all believers—the laity included—and adapted for the various occurrences of ordinary life.

There are also a considerable number of fragments from lost books, *e.g.,* the *Nīrangistān,* as well as quotations, glosses and glossaries.

The Larger Avesta and the Twenty-one Nasks.—In its present form, however, the Avesta is only a fragmentary remnant of the old priestly literature of Zoroastrianism. Native tradition, carrying us back to the Sassanian period, tells of a larger Avesta in 21 books called *nasks* or *nosks,* as to the names of which we have several more or less detailed accounts, particularly in the Pahlavi Dīnkard (9th century A.D.) and in the Rivāyats. From the same sources we learn that this *larger* Avesta was only a part of a yet more extensive *original* Avesta, which is said to have existed before Alexander. But even of the remains of the Avesta, as these lay before the author of the 9th century, only a small residue has survived to our time. Of all the nasks one only, the 19th, has come down on us intact—the Vendidad.

It would be rash summarily to dismiss this old tradition of the 21 nasks as pure invention. The number 21, being a sacred number, points, indeed, to an artificial arrangement of the material. In the enumeration of the nasks we miss the names of the books we know, like the Yasna and the Yashts. But we must assume that these were included in such or such a nask, as the Yashts in the 17th or *Bakān* Yasht; or, it may be that other books, especially the Yasna, are a compilation extracted for liturgical purposes from various nasks. Further, the author of the Dīnkard appears to have had before him the text of the nasks, or at all events of a large part of them: for he expressly states that the 11th nask was entirely lost, so that he is unable to give the slightest account of its contents. And, besides, in other directions there are numerous indications that such books once really existed. The numerous other fragments, the quotations in the Pahlavi translation, the many references in the *Bundahish* to passages of this Avesta not now known to us, all presuppose the existence in the Sassanian period of a much more extensive Avesta literature than the mere prayer-book now in our hands. The existence of a larger Avesta, even as late as the 9th century A.D., is far from being a mere myth, and we may well believe the Parsees themselves, when they affirm that their sacred literature has passed through successive stages of decay, the last of which is represented by the present Avesta.

Origin and History.—While all that Herodotus (i. 132) has to say is that the Magi sang "the theogony" at their sacrifices, Pausanias is able to add (v. 27. 6) that they read from a book. Hermippus, in the 3rd century B.C., is said by Pliny to have explained the doctrine which Zoroaster had composed in 20 times 100,000 verses. According to the Arab historian, Ṭabari, these were written on 12,000 cow-hides, a statement confirmed by Mas'ūdī, who further says that the book consisted of 21 parts, and that Zartusht, who invented "the writing of religion," wrote it in Old Persian. These assertions sufficiently establish the existence and great bulk of the sacred writings. Parsee tradition adds a number of interesting statements as to their history. According to the Dīnkard, there were two copies, of which one was burned, while the second came into the hands of the Greeks. One of the Rivāyats relates how after the villainy of Alexander, several high-priests collected all the fragments that could be found. As to this re-collection and redaction of the Avesta the Dīnkard gives various details. One of the Arsacid kings, Vologeses (I. or III.?), ordered the scattered remnants of the Avesta to be carefully preserved and recorded, and under several of the Sassanian kings in the 3rd and 4th centuries the new redaction was completed.

The Avesta, as we now have it, belongs to the Sassanian period, but it cannot be said to be of Sassanian origin. From the remnants and heterogeneous fragments at their disposal, the diasceuast or diasceuasts composed a new canon from the materials of the old. In point of detail, it is now impossible to draw a sharp distinction between that which they found surviving and that which they themselves added or revised. It may reasonably be supposed, not only that they constructed the external framework of many chapters, and also made some additions of their own, but also that they fabricated anew many formulae and imitative passages on the model of the materials at their disposal. All the grammatically correct texts, together with those portions of the Avesta which have intrinsic worth, the Gāthās and greater Yashts, especially the metrical passages, are indubitably authentic and taken *ad verbum* from the original Avesta. Opinions differ greatly as to the precise age of the original texts. According to some, they are pre-Achaemenian; according to Darmesteter's former opinion, they were written in Media under the Achaemenian dynasty; according to some, their source must be sought in the east, according to others, in the west of Iran. But it is more correct to say that the Avesta was worked at from the time of Zoroaster down to the Sassanian period. Its oldest portions, the Gāthās, proceed from the prophet himself. This conclusion is inevitable for every one to whom Zoroaster is an historical personality. The rest of the Avesta, in spite of the opposite opinion of orthodox Parsees, does not even claim to come from Zoroaster. As the Gāthās now constitute the kernel of the most sacred prayer-book, viz., the Yasna, they were the nucleus of a religious literature.

The Avesta now in our hands is but a small portion of the book as restored and edited under the Sassanians. The larger part perished under the Mohammedan rule and under the more barbarous tyranny of the Tatars, when through conversion and extermination the Zoroastrians became a mere remnant. The understanding of the older Avesta texts began to die away at an early period. The need for a translation and interpretation became evident; and under the Later Sassanians the majority of the books, if not the whole of them, were rendered into the current Pahlavi. For the interpretation of the older texts the Pahlavi is of great value where they are concerned with the fixed, formal statutes of the church. But when they pass beyond this narrow sphere, as particularly in the Gāthās, it becomes defective and unreliable. The Parsee priest, Neryosangh, subsequently translated a portion of the Pahlavi version into Sanskrit.

The manuscripts of the Avesta are, comparatively speaking, of recent date. The oldest is the Pahlavi Vispered in Copenhagen, dated 1258. Next come the four manuscripts of the Herbad Mihirāpān Kaī Khusro at Cambay (1323 and 1324), two Vendidads with Pahlavi in London and Copenhagen, and two Yasnas with Pahlavi in Copenhagen and Oxford. The earliest mss. are the best, though careful 17th and 18th century transcripts come from Kirman and Yazd in Persia.

The first European scholar to direct attention to the Avesta was Hyde of Oxford, in his *Historia Religionis Veterum Persarum eorumque Magorum* (1700), which, however, failed to awake any

lasting interest in the sacred writings of the Parsees. The merit of achieving this belongs to the enthusiastic orientalist Anquetil-Duperron, the fruit of whose prolonged stay in India (1755–61) and his acquaintance with the Parsee priests was a translation (certainly very defective) of the Zend-Avesta. The foundation of a scientific exegesis was laid by Burnouf. The interpretation of the Avesta is one of the most difficult problems of oriental philology. Up to the present no kind of agreement has been reached by conflicting schools, even upon some of the most important points. Opinion is divided also as to the significance of the Avesta in the literature of the world. Upon the whole, the Avesta is a monotonous book. The Yasna and many Yashts in great part consist of formulae of prayer which are as poor in contents as they are rich in verbiage. The book of laws (*Vendidad*) is characterized by an arid didactic tone; only here and there the legislator clothes his dicta in the guise of graceful dialogues and tales, or of poetic descriptions and similitudes; and then the book of laws is transformed into a didactic poem. Nor can we deny to the Yashts, in their depiction of the Zoroastrian angels and their presentment of the old sagas, a certain poetic feeling, at times, and a pleasant diction. The Gāthās are quite unique in their kind. As a whole, the Avesta, for profundity of thought and beauty, stands on a lower level than the Old Testament. But as a religious book—the most important document of the Zoroastrian faith, and the sole literary monument of ancient Iran—the Avesta occupies a prominent position in the literature of the world. At the present day its significance is decidedly underrated. (For works on the theology of the Avesta *see* ZOROASTER.)

EDITIONS.—*Zend-Avesta,* ed. by N. L. Westergaard (Copenhagen, 1852–54), complete; F. Spiegel, *Avesta* (Vienna, 1853–58), only Vendidad, Vispered and Yasna, but with the Pahlavi translation; K. Geldner (Stuttgart, 1886–96). Translations.—Anquetil-Duperron, *Zend-Avesta, Ouvrage de Zoroastre* (Paris, 1771); Fr. Spiegel (Leipzig, 1852–63); both completely antiquated. *Avesta* traduit par C. de Harlez, ed. 2 (Paris, 1881); *The Zend-Avesta, Part I, Vendidad, Part II, Sīrōzahs, Yashts and Nyāyish,* tr. by J. Darmesteter, *Part III, Yasna, Vispered,* etc. by L. H. Mills (Oxford 1880–87), in the *Sacred Books of the East; Le Zend-Avesta,* traduction nouvelle par J. Darmesteter (Paris, 1892–93) (*Annales du Musée Guimet*).

ZENGER, JOHN PETER (1697–1746), U.S. printer, was born in Germany and went to the U.S. in 1710. From 1711–19 he served an apprenticeship with the printer William Bradford. In 1720 he settled in Chestertown, Md., remaining there for two years. For a short time he worked in partnership with Bradford, but in 1726 established himself in his own printing business. On Nov. 5, 1733, he published the first issue of the *New York Weekly Journal,* a newspaper which was founded solely as a political organ by a group of New York citizens who opposed the policies of the colonial governor, William Cosby. For a year the paper contained in almost every issue scathing attacks on the governor until, in Nov. 1734, unable any longer to endure them in silence, Cosby issued a proclamation condemning the "divers scandalous, virulent, false and seditious reflections" which the *Journal* had published and offering a reward for the apprehension of their author. On Nov. 17, 1734, Zenger was arrested for libel and until the following August remained in prison, continuing to edit the *Journal* from his cell. His case finally came to trial on Aug. 4, 1735, his defense being handled by the noted lawyer Andrew Hamilton. Hamilton began by offering to prove the truth of the statements which had appeared in Zenger's paper but, in accordance with English law, the judge, a supporter of the administration, refused to allow this procedure, instead instructing the jury simply to decide whether the statements in question had actually been printed and to leave the decision as to whether they were libelous to the court. Hamilton, however, urged the jury to consider itself competent to make that decision itself and stated Zenger's cause so eloquently that the jury returned a verdict of not guilty. Zenger subsequently served as public printer in both New York and New Jersey. His account of the trial was published in 1736 in the *Journal* and was widely circulated both in the U.S. and in England. He died July 28, 1746. Zenger's case established the first important victory for freedom of the press in the colonies. With juries given the right to decide not only whether statements said to be libelous had been published but also whether they actually were libelous, the press was freed from censorship by a biased judiciary, and although this principle was not for many years established as a legal precedent, it was for the first time recognized as valid in the Zenger case.

ZENITH TELESCOPE, a form of telescope specially devised for the accurate determination of the latitude of a station. It is used both in geodetic surveys and also at fixed stations for measuring the variation of latitude. The usual form of instrument consists of a telescope which can be clamped at any angle to a vertical axis and rotated about the vertical. Two stars of known declination δ_1 and δ_2 are chosen which transit within a few minutes of one another, the one north and the other south of the zenith at nearly equal zenith distances. If ϕ is the latitude the respective zenith distances are $\delta_1-\phi$ north and $\phi-\delta_2$ south, so that the small difference between them is $\delta_1+\delta_2-2\phi$. Settings of a micrometer wire are made on each star in turn, the telescope being of course rotated from the north to the south direction between the two observations: the small distance that the wire has to be moved measures the quantity $\delta_1+\delta_2-2\phi$ and hence determines ϕ. This method, known as the Talcott method, depends on securing accurate rotation about the vertical; usually delicate spirit levels attached to the telescope are used to determine the correction for imperfect fulfilment of this condition. In a floating zenith telescope devised by B. Cookson and now employed for latitude variation at Greenwich observatory, rotation about the true vertical is obtained by floating the whole instrument in mercury. The observations are made photographically; the trails of the pair of stars are shown close together on the plate, and the distance between them (equivalent to $\delta_1+\delta_2-2\phi$) is measured with a suitable micrometer.

ZENO, East Roman emperor from 474 to 491, was an Isaurian of noble birth. Of his early life nothing is known; after his marriage to Ariadne, daughter of Leo I, in 468 he became patrician and commander of the imperial guard and of the armies in the east. In 474 Leo I died after appointing as his successor Leo, the son of Zeno and Ariadne; Zeno, however, succeeded in getting himself crowned also, and on the death of his son in the same year became sole emperor. In the following year, in consequence of a revolt fomented by Verina in favour of her brother Basiliscus, he was compelled to take refuge in Isauria. The growing misgovernment of Basiliscus ultimately enabled Zeno to re-enter Constantinople unopposed (476); his rival was banished to Phrygia, where he soon afterwards died. The remainder of Zeno's reign was disturbed by numerous other less formidable revolts. Since 472 the aggressions of the two Ostrogoth leaders Theodoric had been a constant source of danger. In 487 he induced Theodoric, son of Theodemir, to invade Italy and establish his new kingdom. In ecclesiastical history the name of Zeno is associated with the *Henoticon* or instrument of union, promulgated by him and signed by all the eastern bishops, with the design of terminating the Monophysite controversy.

See J. B. Bury, *The Later Roman Empire* (1889), i, pp. 250–274; E. W. Brooks in the *English Historical Review* (1893), pp. 209–238; W. Barth, *Der Kaiser Zeno* (Basel, 1894).

ZENOBIA (Gr. Ζηνοβία), queen of Palmyra, one of the heroines of antiquity. Her native name was Septimia Bathzabbai. This remarkable woman was well fitted to be the consort of Odainatti (*see* ODAENATHUS) in his proud position as Dux Orientis; during his lifetime she actively seconded his policy, and after his death in A.D. 266–267 she determined to surpass his position and make Palmyra mistress of the Roman empire in the east. Wahab-allath or Athenodōrus (as the name was Graecized), her son by Odainath, being still a boy, she took the reins of gov-

ernment into her own hands. Under her general-in-chief Zabdā, the Palmyrenes occupied Egypt in A.D. 270 under the pretext of restoring it to Rome; and Wahab-allath governed Egypt in the reign of Claudius as joint ruler. In Asia Minor Palmyrene garrisons were established as far west as Ancyra in Galatia and Chalcedon opposite Byzantium. When Aurelian became emperor in 270 he quickly realized that the policy of the Palmyrene queen was endangering the unity of the empire and instantly took measures; Egypt was recovered for the empire by Probus (270), and the emperor himself prepared a great expedition into Asia Minor and Syria. Towards the end of 271 he marched through Asia Minor and, overthrowing the Palmyrene garrisons in Chalcedon, Ancyra and Tyana, he reached Antioch, where the main Palmyrene army under Zabdā and Zabbai, with Zenobia herself, attempted unsuccessfully to oppose his way. The queen was defeated at Emesa (now Homs) and fell back upon Palmyra, where Aurelian followed her and laid siege to the city. The queen and her son fled to seek help from the Persian king, but were captured on the bank of the Euphrates, and the Palmyrenes, losing heart, capitulated (A.D. 272). Zenobia probably closed her days at Tibur, where she lived with her sons the life of a Roman matron. A few months after her fall Palmyra revolted again; Aurelian unexpectedly returned and destroyed the city.

Among the traditions relating to Zenobia may be mentioned that of her discussions with the Archbishop Paul of Samosata on matters of religion. It is probable that she treated the Jews in Palmyra with favour; she is referred to in the Talmud as protecting Jewish rabbis (Talm. Jer. *Ter.* viii, 46 b).

The well-known account of Zenobia by Gibbon (*Decline and Fall,* i, pp. 302–312 Bury's edition) is based upon the imperial biographers (*Historia Augusta*) and cannot be regarded as strictly historical in detail. *See* A. P. Caussin de Perceval, *Essai sur l'hist. des Arabes,* ii, 28 f., 197 f. (3 vols., 1847–48); Tabari, i, 757 f. *See* further PALMYRA.

(G. A. C.; X.)

ZENOBIUS, a Greek sophist, who taught rhetoric at Rome during the reign of Hadrian (A.D. 117–138). He was the author of a collection of proverbs in three books, still extant in an abridged form, compiled, according to Suïdas, from Didymus of Alexandria and Lucillus of Tarrha. Zenobius is also said to have been the author of a Greek translation of Sallust and of a birthday poem (γενεθλιακόν) on Hadrian.

Editions by T. Gaisford (1836) and E. L. Leutsch-F. W. Schneidewin (1839), and in B. E. Miller, *Mélanges de littérature grecque* (1868); *see* also W. Christ, *Griechische Literaturgeschichte* (1898).

ZENODOTUS, Greek grammarian and critic, pupil of Philetas (*q.v.*) of Cos, was a native of Ephesus. He lived during the reigns of the first two Ptolemies, and was at the height of his reputation about 280 B.C. He was the first superintendent of the library at Alexandria and the first critical editor (διορθώτης) of Homer. Having collated the different mss. in the library, he expunged or obelized doubtful verses, transposed or altered lines, and introduced new readings. He divided the Homeric poems into books (with capitals for the *Iliad,* and small letters for the *Odyssey*), and possibly was the author of the calculation of the days of the *Iliad* in the Tabula Iliaca. He is further called an epic poet by Suïdas. There appear to have been at least two other grammarians of the same name: (1) Zenodotus of Alexandria, surnamed ὁ ἐν ἄστει; (2) Zenodotus of Mallus, the disciple of Crates, who like his master attacked Aristarchus.

See F. A. Wolf, *Prolegomena ad Homerum,* s. 43 (1859 ed.); H. Düntzer, *De Zenodoti studiis Homericis* (1848); A. Römer, *Über die Homerrecension des Zenodotus* (Munich, 1885); F. Susemihl, *Geschichte der griechischen Literatur in der Alexandrinerzeit,* i, p. 330, ii, p. 14; J. E. Sandys, *Hist. of Class. Schol.* (1906).

ZENO OF ELEA, son of Teleutagoras, born probably towards the beginning of the 5th century B.C. The pupil and the friend of Parmenides, he sought to recommend his master's doctrine of the existence of the One by controverting the popular belief in the existence of the Many. In virtue of this method of indirect argumentation he is regarded as the inventor of "dialectic," that is to say, disputation having for its end not victory but the discovery of truth. In Plato's *Parmenides,* Socrates, "then very young," discusses with Parmenides and Zeno, "a man of about forty," but it may be doubted whether such a meeting was chronologically possible. Plato's account of Zeno's teaching (*Parmenides,* 128 *seq.*), however, is presumably accurate. In reply to those who thought that Parmenides's theory of the existence of the One involved inconsistencies, Zeno tried to show that the assumption of the existence of a plurality of things in time and space, carried with it more serious inconsistencies. In early youth he collected his arguments in a book, which, according to Plato, was put into circulation without his knowledge.

Of the paradoxes used by Zeno to discredit the belief in plurality and motion, eight survive in the writings of Aristotle and Simplicius. They are commonly stated as follows: (1) If the Existent is Many, it must be at once infinitely small and infinitely great—infinitely small, because its parts must be indivisible and therefore without magnitude; infinitely great, because, that any part having magnitude may be separate from any other part, the intervention of a third part having magnitude is necessary, and that this third part may be separate from the other two the intervention of other parts having magnitude is necessary, and so on *ad infinitum.* (2) In like manner the Many must be numerically both finite and infinite—numerically finite, because there are as many things as there are, neither more nor less; numerically infinite, because, that any two things may be separate, the intervention of a third thing is necessary, and so on *ad infinitum.* (3) If all that is is in space, space itself must be in space, and so on *ad infinitum.* (4) If a bushel of corn turned out upon the floor makes a noise, each grain and each part of each grain must make a noise likewise; but, in fact, it is not so. (5) Before a body in motion can reach a given point, it much first traverse the half of the distance; before it can traverse the half of the distance, it must first traverse the quarter; and so on *ad infinitum.* Hence, that a body may pass from one point to another, it must traverse an infinite number of divisions. But an infinite distance (which the paradox does not distinguish from a finite distance infinitely divided) cannot be traversed in a finite time. Consequently, the goal can never be reached. (6) If the tortoise has the start of Achilles, Achilles can never come up with the tortoise; for, while Achilles traverses the distance from his starting point to the starting point of the tortoise, the tortoise advances a certain distance, and while Achilles traverses this distance, the tortoise makes a further advance, and so on *ad infinitum.* Consequently, Achilles may run *ad infinitum* without overtaking the tortoise. (This paradox is virtually identical with [5], the only difference being that whereas in [5] there is one body, in [6] there are two bodies, moving towards a limit. The "infinity" of the premise is an infinity of subdivisions of a distance which is finite; the "infinity" of the conclusion is an infinity of distance.) (7) So long as anything is in one and the same space, it is at rest. Hence an arrow is at rest at every moment of its flight, and therefore also during the whole of its flight. (8) Two bodies moving with equal speed traverse equal spaces in equal time. But, when two bodies move with equal speed in opposite directions, the one passes the other in half the time in which it passes it when at rest. These paradoxes are probably properly regarded as dilemmas advanced in refutation of specific doctrines attributed to the Pythagoreans.

Important as these paradoxes of plurality and motion were in stimulating speculation about space and time, their direct influence upon Greek thought was less considerable than that of another paradox—strangely neglected by historians of philosophy—the paradox of predication. Plato says (*Parmenides,* 127 D) that "the first hypothesis of the first argument" of Zeno's book above mentioned ran as follows: "If existences are many, they must be both like and unlike (unlike, inasmuch as they are not one and the same, and like, inasmuch as they agree in not being one and the same [Proclus, *On the Parmenides,* ii, 143]). But this is impossible; for unlike things cannot be like, nor like things unlike. Therefore existences are not many."

When in the second decade of the 4th century the pursuit of truth was resumed, it was plain that Zeno's paradox of predication must be disposed of before the discussion of the problems of knowledge and the problem of being could be resumed. Accordingly, in bk. 7 of the *Republic,* Plato directs the attention

of studious youth primarily, if not exclusively, to the concurrence of inconsistent attributes; and in the *Phaedo*, 102 B–103 A, taking as an instance the tallness and the shortness simultaneously discoverable in Simmias, he offers his own theory of the immanent idea as the solution of the paradox. Simmias, he says, has in him the ideas of tall and short. Again, when it presently appeared that the theory of the immanent idea was inconsistent with itself, and moreover inapplicable to explain predication except where the subject was a sensible thing, so that reconstruction became necessary, the Zenonian difficulty continued to receive Plato's attention. Thus, in the *Parmenides*, with the paradox of likeness and unlikeness for his text, he inquires how far the current theories of being (his own included) are capable of providing, not only for knowledge, but also for predication, and in the concluding sentence he suggests that, as likeness and unlikeness, greatness and smallness, etc., are relations, the initial paradox is no longer paradoxical; while in the *Sophist*, Zeno's doctrine having been shown to be fatal to reason, thought, speech and utterance, the mutual *κοινωνία* of *εἴδη* which are not *αὐτὰ καθ' αὐτά* is elaborately demonstrated.

In all probability Zeno did not observe that in his controversial defence of Eleaticism he was interpreting Parmenides's teaching anew. While Parmenides had recognized, together with the One, which is, and is the object of knowledge, a Many, which is not, and therefore is not known, but nevertheless becomes, and is the object of opinion, Zeno plainly affirmed that plurality, becoming and opinion are one and all inconceivable. In a word, Parmenides's tenet "The Ent is, the Non-ent is not," was with Zeno a declaration of the Non-ent's absolute nullity. Thus, just as Empedocles developed Parmenides's theory of the Many to the neglect of his theory of the One, so Zeno developed the theory of the One to the neglect of the theory of the Many. With the severance of its two members Eleaticism proper, the Eleaticism of Parmenides, ceased to exist.

Russell, *Principles of Mathematics* (1903) and F. Cajou, *Hist. of Zeno's Arguments against Motion* (1915).

ZEOLITES, a family of minerals consisting of hydrated silicates of alumina with alkalis or alkaline earths or both. The water they contain is readily lost, and before the blowpipe it is expelled with intumescence; hence the name zeolite, from the Greek *ζεῖν* (to boil) and *λίθος* (a stone). In some other characters, as well as in their origin and mode of occurrence, they have points in common. Several species have been distinguished, of which the following are the more important:—

Heulandite Group	Heulandite	$H_4CaAl_2(SiO_3)_6+3H_2O$.
	Brewsterite	$H_4(Sr, Ba, Ca)Al_2(SiO_3)_6+3H_2O$.
	Epistilbite	$H_4CaAl_2(SiO_3)_6+3H_2O$.
Stilbite Group	Wellsite	$(Ba, Ca, K_2)Al_2Si_3O_{10}+3H_2O$.
	Phillipsite	$(K_2, Ca)Al_2(SiO_3)_4+4H_2O$.
	Harmotome	$H_2(K_2, Ba)Al_2(SiO_3)_5+5H_2O$.
	Stilbite	$CaAl_2(SiO_3)_6+6H_2O$.
	Gismondite	$CaAl_2(SiO_3)_4+4H_2O$.
	Laumontite	$H_4CaAl_2Si_4O_{14}+2H_2O$.
Chabazite Group	Chabazite	$(Ca, Na_2)Al_2(SiO_4)_2+4H_2O$, etc.
	Gmelinite	$(Na_2, Ca)Al_2(SiO_3)_4+6H_2O$.
	Levynite	$CaAl_2Si_3O_{10}+5H_2O$.
	Analcite	$NaAl(SiO_3)_2+H_2O$.
Natrolite Group	Natrolite	$Na_2Al_2Si_3O_{10}+2H_2O$.
	Mesolite	$(Ca, Na_2)Al_2Si_3O_{10}+2H_2O$.
	Scolecite	$CaAl_2Si_3O_{10}+3H_2O$.
	Edingtonite	$BaAl_2Si_3O_{10}+3H_2O$.
	Thomsonite	$(Na_2, Ca)Al_2(SiO_4)_2+2\frac{1}{2}H_2O$.

Some of the chemical formulae given above are only approximate, since in some species the composition varies between certain limits and can be best expressed by the isomorphous mixing of different molecules. They are all readily decomposed by hydrochloric acid, usually with the separation of gelatinous silica. By the action of various reagents several substitution products have been prepared artificially: thus, crystallized products, in which the alkalis or alkaline earths are replaced by ammonium or silver, etc., have been obtained.

The zeolites are often beautifully crystallized, and belong to several crystal-systems. The crystals usually show evidences of twinning, and when examined in polarized light they frequently exhibit optical anomalies and a complex structure. The hardness (3·5–5·5) and specific gravity (2·0–2·4) are comparatively low, and so are the indices of refraction and the double refraction.

The water of zeolites presents many points of interest. Laumontite loses water on exposure to air, and the crystals soon crumble to powder unless they are kept in a moist atmosphere. All the zeolites lose a portion of their "water of crystallization" in dry air (over sulphuric acid), and a considerable portion at a temperature of 100° C, increasing in amount to 200° or 300°; the actual amount lost depending not only on the temperature, but also on the tension of aqueous vapour in the surrounding atmosphere. In some species the remaining water is expelled only at a red heat, and is therefore to be regarded as "water of constitution." With the progressive loss of water there is a progressive change in the optical characters of the crystals. When a partially dehydrated and opaque crystal is exposed to moist air the water is reabsorbed, the crystal becoming again transparent and regaining its original optical characters. Not only may water be reabsorbed, but such substances as ammonia, hydrogen sulphide and alcohol may be absorbed in definite amounts and with an evolution of heat. The water of zeolites may therefore be partly driven off and reabsorbed or replaced by other substances without destroying the crystalline structure of the material, and it would thus seem to differ from the water of crystallization of most other hydrated salts.

Zeolites are minerals of secondary origin and in most cases have resulted by the decomposition of the felspars of basic igneous rocks: in fact their chemical composition is somewhat analogous to that of the felspars with the addition of water. Nepheline and sodalite are often altered to zeolites. They usually occur as crystals lining the amygdaloidal and other cavities of basalt, melaphyre, etc. Usually two or more species are associated together, and often with agate, calcite and some other minerals. Less frequently they occur in cavities in granite and gneiss, and in metalliferous veins (*e.g.*, harmotome); while only exceptionally are they primary constituents (*e.g.*, analcite) of igneous rocks. Several species have been observed in the Roman masonry at the hot springs of Bourbonne-les-Bains: and phillipsite has been dredged from the deep sea. (L. J. S.)

ZEPHANIAH, the ninth of the minor prophets in the Bible. His ancestry is traced to his great-grandfather Hezekiah, who may, in spite of 2 Kings xx. 18, xxi. 1, be the well-known king of Judah (*c.* 720–690). This would agree fairly with the title (i. 1) which makes the prophet a contemporary of King Josiah (*c.* 637), and this in turn appears to agree (*a*) with the internal conditions (i. 4–6, *cf.* 2 Kings xxiii. 4, 5, 12) which, it is held, are evidently earlier than Josiah's reforms (621); (*b*) with the denunciation of the royal household, but not of the (young) king himself (i. 8, iii. 3); (*c*) with the apparent allusion in ch. i. to the invasion of the Scythians (perhaps *c.* 626), and (*d*) with the anticipated downfall of Assyria and Nineveh (ii. 13, 612 B.C.).

Although one single leading motive runs through the book of Zephaniah there are abrupt transitions which do not depend on modern subjective considerations of logical or smooth thought, but are material and organic changes representing different groups of ideas. The instruments of Yahweh's anger (ch. i.) are not so real or prominent on the political horizon as, for example, in Isaiah, Jeremiah or Habakkuk. The Scythian inroad and its results for Judah and Philistia are less important when it is observed that the doom upon Philistia, the vengeance upon Moab and Ammon, and the promises for Judah (ch. ii.), belong to a large group of prophecies against certain historic enemies (Edom included) who are denounced for their contempt, hostility and intrusion. The prophecies are in large measure associated tradition-

ally with the fall of Jerusalem, and to some such calamity, and not to the inroad of the Scythians, the references to the "remnant" and the "captivity" refer. The anticipation of future events is of course conceivable in itself; but the promises (in ch. ii.) *presuppose* events other and later than those with which the Scythians were connected. On the other hand, a prophecy relating to Scythians may have been re-shaped to apply to later conditions, and on this view it is explicable why the indefinite political convulsions should be adjusted to the exile and why the gloom should be relieved by the promise of a territory extending from the Mediterranean to the Syrian desert (ii. 7, 9). After a period of punishment (*cf.* book of Lamentations) Yahweh's jealousy *against* the semi-heathen Judah has become a jealousy *for* his people, and we appear to move in the thought of Haggai and Zechariah, where the remnant are comforted by Yahweh's return and the dispersed exiles are to be brought back (*cf.* Zech. i. 14–17, viii. 2–17). But in ch. iii. other ideas are manifest. Israel's enemies have been destroyed, her own God Yahweh has proved *his* loyalty and has fulfilled *his* promises, but the city remains polluted (*vv.* 1–7, *cf.* Isa. lviii. *seq.;* Malachi). Once more doom is threatened, and once more we pass over into a later stage where Yahweh has vindicated *his* supremacy and Zion is glorified. Instead of the realities of history we have the apocalyptical feature of the gathering of the nations (*v.* 8); the thought may be illustrated from Zech. xii. 1.–xiii. 6, where Jerusalem is attacked, purged and delivered, and from Zech. xiv. where the city is actually captured and half the people are removed into captivity (*cf.* Zeph. iii. 11 purging, 15 removal of the enemy, 18–20 return of the captivity). The goal is the vindication of Israel and of Israel's God, and the establishment of universal monotheism (ii. 11, iii. 9 *seq.*). The foe which threatened Judah has become the chastiser of Ethiopia and Assyria (ii.) and the prelude to the golden age (iii., *cf.* Ezek. xxxviii. *seq.*).

If Jer. iv. 5–vi. 30 originally referred to the Scythians, it has been revised to refer to the Chaldeans; also in Ezek. xxxviii. *seq.* a northern foe becomes associated with the great world-judgment. Also, in Isaiah and Zechariah, notably, older and later *groups* of prophecies are preserved, whereas here the new preludes and new sequels suggest that the original nucleus has passed through the hands of writers in touch with those vicissitudes of thought which can be studied more completely elsewhere. It is not to be supposed that the elimination of all later passages and traces of revision will give us Zephaniah's prophecies in their original extent. In fact the internal religious and social conditions in i. 4–6 or iii. 1–4 do not compel a date before Josiah's reforms. The doom of Cush is still in the future in Ezek. xxx. 4; and if the impending fall of Nineveh (ii. 13) implies an early date, yet it is found in writings which have later additions (Nahum), or which are essentially later (Jonah, *cf.* Tobit xiv. 4 [LXX.], 8, 10, 15); *cf.* also the use of Assyria for Babylon (Ezra vi. 22) or Syria (Zech. x. 10). Historical references in prophecies are not always decisive (Ezek. xxxii., for example, looks upon Edom and Sidon as dead), and while the continued revision of the book allows the presumption that the tradition ascribing its inception to the time of Josiah may be authentic, it is doubtful how much of the original nucleus can be safely recognized.

ZEPHYRINUS, ST., bishop of Rome from about 198 to 217, succeeded Victor I. The controversies on doctrine and discipline that marked his pontificate are associated with the names of Hippolytus and of Calixtus, his principal adviser and afterwards his successor.

ZEPHYRUS, in Greek mythology, the west wind, son of the Titan Astraeus and Eos, the dawn. He was the husband of Chloris, the goddess of flowers, by whom he had a son, Carpus, the god of fruit (Ovid, *Fasti,* v. 197).

See also FLORA; HARPIES; HYACINTHUS.

ZEPPELIN, FERDINAND, COUNT VON (1838–1917), German airship inventor, was born at Constance, Baden, on July 8, 1838. He was educated for the army and received a commission at the age of 20. He served, as a volunteer, in the Federal army during the American Civil War and whilst in America made his first balloon ascent. Returning to Germany he saw active service in the Austrian War of 1866 and in the Franco-German War of 1870. In 1891 he retired from the army with the rank of general and thenceforth devoted his energies to the study of aeronautics. In 1900 he built an airship, which rose from the ground and remained in the air for 20 minutes, but was wrecked in landing. In 1906 he made two successful flights at a speed of 30 m. an hour, and in 1907 attained a speed of 36 miles. From that time onwards his airship construction made steady progress and many Zeppelin airships took part in the World War, though with heavy losses under attack. (*See* AIRSHIP.) He died at Charlottenburg on March 8, 1917.

See *Eine Festgabe zu seinem 75. Geburtstag von Luftschiffbau Zeppelin* (Stuttgart, 1913).

ZERBST, a town of Germany, in the *Land* of Anhalt, situated on the Nuthe, 11 mi. N.W. of Dessau and 27 mi. S.E. of Magdeburg by railway. Pop. (1939) 23,725. Zerbst is an ancient town, mentioned in 949, which in 1307 came into the possession of the Anhalt family. It is still surrounded in part by old walls and bastions. It contains five churches, one of which (St. Nicholas), built in 1446–88, is a good example of the late Gothic style as developed in Saxony, with its spacious proportions, groined vaulting, and bare simple pillars. The town hall dates from about 1480, but it was disfigured by additions in the beginning of the 17th century. The palace (1681–1750) has been used as a depository of archives since 1872. There are several quaint old houses, with high gables, in the market-place, in the middle of which stand a Roland column, of about 1445, and a bronze figure known as the *Butterjungfer* (butter-girl), of uncertain origin and meaning. There were here formerly a Franciscan monastery, with fine cloisters, founded in 1250, a Cistercian nunnery of 1214, and an Augustinian monastery of 1390, a hospital since 1525.

ZERMATT, a mountain village (5,315 ft. above sea-level) at the head of the Visp valley and at the foot of the Matterhorn, in the canton of the Valais, Switzerland. It has about 960 permanent inhabitants, German-speaking and Roman Catholics. It is $22\frac{1}{4}$ mi. by rail from Visp in the Rhône valley, and there is also a railway from Zermatt past the Riffel inns to the very top of the Gornergrat (10,289 ft.). Formerly Zermatt was called "Praborgne," and this name is mentioned in the Swiss census of 1888. Its originally Romance population seems to have been Teutonized in the course of the 15th century, the name "Matt" (now written "Zermatt," *i.e.,* the village on the meadows) first occurring at the very end of that century.

See E. Whymper, *Scrambles in the Alps* (1871).

ZERO, the figure 0 in the Arabic notation for numbers meaning nought, or cipher. The Sanskrit name for the figure was *śūnya* (void), and this term passed over into Arabic as *aṣ-ṣifr,* or *ṣṣifr.* The old Latin writers on arithmetic translated or transliterated the Arabic word as *zephyrum;* this in Ital. took on such forms as *zeuero, zepiro,* and became contracted to *zero,* borrowed by F. *zéro,* whence it came late into English. The Spanish form *cifra,* more closely resembling the original Arabic, gave O.Fr. *cifre,* mod. *chiffre,* also used in the sense of monogram, and English "cipher" which is thus a doublet. Although no character for zero is found in India before the 9th century, there is literary evidence for the belief that it was known much earlier. In the Maya inscriptions in Central America there appears a character for zero, but only in connection with the calendar.

ZEROMSKI, STEPHEN (1864–1925), Polish novelist, poet and dramatist, was born at Strawczyn on Nov. 14, 1864. Banished from Poland by the Russian Government early in his life, he first attracted attention by a collection of tragic tales entitled *The Ravens and the Crows are Picking us to Pieces* (1895, Eng. trans. 1906). In the publication of *The Homeless* (1900) Zeromski supplied a generic name for all his Polish heroes. His pessimistic philosophy finds expression in the novel *Aryman takes Revenge* (1904), while the triumph of evil over good is vividly treated in *The Story of Sin* (2 vol., 1906) describing the slow and terrible

downfall of a woman of culture. In his epic poem *Ashes* (2 vol., 1904) he delineates the minds of the Polish people after the Partition and their efforts to liberate their country by serving in the Napoleonic legions. During the World War Zeromski published his great trilogy *The Fight with Satan—The Conversion of Judas* (1916), *The Blizzard* (1918), *Charitas* (1919)—a kind of epilogue and synthesis of his previous work and at the same time an autobiography of his own life. After the achievement of national independence, Zeromski wrote his drama, *The Broken Spell* (1924) in which the hero dedicates himself to the services of a resuscitated Poland. He died on Nov. 20, 1925.

See S. Brzozowski, *O Stefan Zeromski* (Warsaw, 1905); W. Jampolski, *Stefan Zeromski, the Spiritual Leader of the Race* (Lwów, 1918).

ZETKIN, KLARA (1857–1933), German communist, was born on June 5, 1857, at Wiederan, Saxony, and educated at the university of Paris, becoming a school teacher. She presently became editor of *Gleichheit,* the organ of the Social Democratic Party for women. Klara Zetkin was a member of the Communist Party from its foundation in 1919, and was one of its most fiery orators. She became a member of the Reichstag in 1920.

ZETLAND, 2ND MARQUESS OF: *see* RONALDSHAY, LAWRENCE JOHN LUMLEY DUNDAS.

ZEUGLODON or **BASILOSAURUS,** a genus of extinct late Eocene whales up to 65 ft. in length. Smaller relatives of *Basilosaurus* are the oldest known Cetacea (*q.v.*).

ZEUS, the Greek counterpart of the Roman god, Jupiter (*q.v.* for the etymology of the name). It is probable that Zeus had already been conceived as a personal and pre-eminent god by the ancestors of the leading Hellenic tribes before they entered the peninsula, which became their historic home. In the first place, his pre-eminence is obviously pre-Homeric; for Homer attests for us the supremacy of Zeus in his day, say 950 B.C.; and appreciating how slow was the process of religious change in the earlier period, we shall believe that the god had won this position long before the Homeric age. In the next place, we cannot trace the origin of his worship back to any special stock or particular locality; his unquestionable association with Olympus and Thessaly is only what we should expect, seeing that many at least of the Greeks must have entered Greece that way.

To appreciate the Homeric Zeus, we must distinguish the lower mythologic aspect of him, in which he appears as an amorous and capricious deity lacking often in dignity and real power, and the higher religious aspect, in which he is conceived as the all-father (*see* GREEK RELIGION). In fact, later Greek religion did not advance much above the high-water mark of the Homeric, although the poets and philosophers deepened certain of its nobler traits. But Homer we now know to be a relatively late witness in this matter. Yet traces of a pre-deistic and animistic period survived here and there; for instance, in Arcadia we find the thunder itself called Zeus (Ζεὺς κεραυνός) in a Mantinean inscription, and the stone near Gythium in Laconia, on which Orestes sat and was cured of his madness, evidently a thunder-stone, was named itself Ζεὺς καππώτας, which must be interpreted as "Zeus that fell from heaven" (Pausan iii. 22. 1.); we here observe that the personal god does not yet seem to have emerged from the divine thing or divine phenomenon.

The day is now past when scholars could discover in the ritual of Zeus *Lukaios* (*see* LYCAON), or the Dipolia, the cult of a wolf —or ox-totem—somehow blended with Zeus; but certainly a characteristic of his earliest ritual was human sacrifice. We find it again in the story of the house of Athamas and in the worship of *Zeus Laphustios* ("Zeus the Glutton"), of Thessaly (Herod. vii. 197), and other examples are recorded. The cruel rite had ceased in the Arcadian worship before Pliny wrote, but seems to have continued in Cyprus until the reign of Hadrian. It was found in the worship of many other divinities of Hellas in early times, and no single explanation can be given that would apply to them all. A hypothesis favoured by Frazer, that the victim is usually a divine man, a priest-king incarnating the god, may be well applied to the Athamantid sacrifice and to that of King Lycaon; for he derives his name from the divinity himself, and according to one version (Clemens, *Protrept* p. 31 P.) he offers his own child; and the legend presents one almost unique feature, which is only found elsewhere in legendary Dionysiac sacrifice, the human flesh is eaten, and the sacrifice is a cannibalistic-sacrament, of which the old Mexican religion offers conspicuous example. Yet it is in this religion of Zeus that we see most clearly the achievement of progressive morality; Zeus himself punishes and abolishes the savage practice.

We can now consider the special attributes of the anthropomorphic god. His character and power as a deity of the sky, who ruled the phenomena of the air, so clearly expressed in Homer, explains the greater part of his cult and cult-titles. More personal than Ouranos and Helios—with whom he has only slight associations—he was worshipped and invoked as the deity of the bright day (*Amarios*), who sends the rain, the wind and dew (*Ombrios, Huetios, Ourios*), and such a primitive adjective as *diipetēs* applied to things "that fall from heaven," attests the primeval significance of the name of Zeus. But the thunder was his most striking manifestation, and no doubt he was primevally a thunder-god, (*Keraunios, Astrapaios*). Much of his ritual was weather-magic; the priest of Zeus *Lukaios* in time of drought, was wont to ascend Mt. Lycaeum and dip an oak-bough in a sacred fountain, and by this sympathetic means produce mist (Pausan. viii. 38, 3). A god of this character would naturally be worshipped on the mountain-tops, and that these were very frequently consecrated to him is shown by the large number of appellatives derived from the names of mountains. But probably in his earliest Hellenic period the power of Zeus in the natural world was not limited to the sky. A deity who sent the fertilizing rains would come to be regarded as a god of vegetation, who descended into the earth and whose power worked in the life that wells forth from the earth in plant and tree. Homer calls the god of the lower world *Zeus Katachthonios* (*Iliad,* ix. 457), and the title of *Zeus Chthonios,* which was known to Hesiod, occurred in the worship of Corinth (Hesiod, *Works and Days,* 456; Pausan. ii. 2, 8).

A glimpse into a very old stratum of Hellenic religion is afforded us by the records of Dodona. A Dodonean liturgy has been preserved which, though framed in the form of an invocation and a dogma, has the force of a spell-prayer—"Zeus was and is and will be, O great Zeus: earth gives forth fruits, therefore call on Mother Earth" (Pausan. x. 12, 10). Zeus, the sky-god, is seen here allied to the earth-goddess, of whom his feminine counterpart, Dione (*q.v.*), may have been the personal form. And it is at Dodona that his association with the oak is of the closest. His prophet-priests, the *Selloi,* "with unwashed feet, couching on the ground" (Homer, *Iliad,* xvi. 233), lived about the sacred oak, which may be regarded as the primeval shrine of the Aryan god, and interpreted its oracular voice, which spoke in the rustling of its leaves or the cooing of its doves. Zeus, we may believe, long remained at Dodona such as he was when the Hellenic tribes first brought him down from the Balkans, a high god supreme in heaven and in earth.

We may also believe that in the earliest stages of worship he had already acquired a moral and a social character. The Homeric view of him as the all-father is a high spiritual concept, but one of which many savage religions of our own time are capable. The family, the tribe, the city, the simpler and more complex organisms of the Hellenic polity were specially under his care and direction. In spite of the popular stories of his amours and infidelities, he is the patron-god of the monogamic marriage, and his union with Hera (*q.v.*) remained the divine type of human wedlock.

He was also the tutelary deity of the larger organization of the phratria; and the altar of *Zeus Phratrios* was the meeting-point of the *phrateres,* when they were assembled to consider the legitimacy of the new applicants for admission into their circle (Demosth. *Contra Macartatum,* 1078, i.).

His religion also came to assist the development of certain legal ideas, for instance, the rights of private or family property in land; he guarded the allotments as *Zeus Klarios* (Pausan. viii. 53, 9), and the Greek commandment, "thou shalt not remove thy neighbour's landmark," was maintained by *Zeus Horios,* the god of boundaries, a more personal power than the Latin Iuppiter Terminus (Plato, *Laws,* 842 E).

His highest political functions were summed up in the title *Polieus*, a cult-name of legendary antiquity in Athens, and frequent in the Hellenic world.

His consort in his political life was not Hera, but his daughter Athena Polias. He sat in her judgment court ἐπὶ Παλλαδίῳ, where cases of involuntary homicide were tried (Corp. Inser. Attic. iii. 71 and 273). With her he shared the chapel in the council-hall of Athens dedicated to them under the titles of *Boulaios* and *Boulaia*, "the inspirers of counsel," by which they were worshipped in many parts of Greece (Antiphon vi. p. 789; Pausan. i. 3. 5; *cf. Corp. Inser. Attic.* iii. 683). The political assembly and the law-court were consecrated to *Zeus Agoraios*, and being the eternal source of justice he might be invoked as *Dikaiosunos* "The Just." As the god who brought the people under one government he might be worshipped as *Pandemos* (*Corp. Inser. Attic.* iii. 7); as the deity of the whole of Hellas, he became *Panhellenios*, perhaps about the time of the Persian wars, when thanksgiving for the victory took the form of dedications and sacrifice to "Zeus the Liberator" *Eleutherios* (Simonides, *Frag.* 140 [Bergk]; Strab. 412). Finally, in the formulae adopted for the public oath, where many deities were invoked, the name of Zeus was the master word.

It remains to consider briefly certain moral aspects of his cult. The morality attaching to the oath, so deeply rooted in the conscience of primitive peoples, was expressed in the cult of *Zeus Horkios*, the god who punished perjury (Pausan. v. 24. 9). The whole history of Greek legal and moral conceptions attaching to the guilt of homicide can be studied in relation to the cult-appellatives of Zeus. The Greek consciousness of the sin of murder, only dimly awakened in the Homeric period, and only sensitive at first when a kinsman or a suppliant was slain, gradually expands till the sanctity of all human life becomes recognized by the higher morality of the people; and the names of *Zeus Meilichios*, the dread deity of the ghost-world whom the sinner must make "placable," of *Zeus Hikesios* and *Prostropaios*, to whom the conscience-stricken outcast may turn for mercy and pardon, play a guiding-part in this momentous evolution.

But it was in the poets and philosophers that this evolution attained its end. Most of them were believers in a supreme power, present always and everywhere, and some of them—Empedocles, Aeschylus, Plato—gave to this supreme power the name of Zeus. "Zeus, whosoever he is,—if this name be pleasing unto him, by this name do I call him,—weighing all things in the balance, nought can I conjecture save only Zeus." (Aeschylus, *Agamemnon*, 160 *et seq.*; *cf.* frag. 70, Naucks 2nd ed.). He is the spirit of the world, the law of the universe, the universal reason, and all other gods are only parts or manifestations of him (*cf.* Diog. Laert. vii. 147). Moreover, as we may see from the "hymn" of Cleanthes (frag. 48), and from St. Paul's quotation from it or Aratus (Acts xvii., 28—Arat., phaen. 5), he was conceived by the Stoics as the father of the human race, who "alone of mortal things that live and move upon the earth" were created in his image.

ZEUXIS, one of the best known Greek painters, flourished about 420–390 B.C., and described himself as a native of Heraclea, probably the town on the Black Sea. He was, according to one account, a pupil of Demophilus of Himera in Sicily, the other statement being that he was a pupil of Neseus of Thasos. Afterwards he appears to have resided in Ephesus. His known works are—

1. Zeus surrounded by Deities.
2. Eros crowned with Roses.
3. Marsyas bound.
4. Pan.
5. Centaur family.
6. Boreas or Triton.
7. Infant Heracles strangling the serpents in presence of his parents, Alcmena and Amphitryon.
8. Alcmena, possibly identical with 7.
9. Helena at Croton.
10. Penelope.
11. Menelaus.
12. Athlete.
13. An old Woman.
14. Boy with grapes.
15. Grapes.
16. Monochromes.
17. Plastic works in clay.

In ancient records we are told that Zeuxis, following the initiative of Apollodorus, had introduced into the art of painting a method of representing his figures in light and shadow, as opposed to the older method of outline, with large flat masses of colour for draperies, and other details, such as had been practised by Polygnotus and others of the great fresco painters. The new method led to smaller compositions, and often to pictures consisting of a single figure, on which it was more easy for the painter to demonstrate the various means by which he obtained perfect roundness of form. The effect would appear strongly realistic, as compared with the older method, and to this was probably due the origin of such stories as the contest in which Zeuxis painted a bunch of grapes so like reality that birds flew towards it.

ZHITOMIR or **JITOMIR,** a town in the Ukrainian S.S.R., in 50° 19′ N., 28° 40′ E., on the Teterev river, a left bank tributary of the Dnieper, and at the terminus of a branch railway from Berdichev (1939) 66,306. Pop. (1939) 95,090. There are iron-smelting works, and a brewing industry, in connection with which a hop fair is held in early September. Its position on the road west from Kiev gave it early importance and it dates back to the time of the Scandinavian expansion (9th century). The Tatars plundered it in the 13th, 14th and 17th centuries. In 1320 it became part of Lithuania, but was afterwards annexed by Poland and when the Cossacks rose against their chief Bogdan Chmielnicki (1648) they sacked the town. Russia occupied it, along with the rest of the Ukraine, in 1778. During World War II Zhitomir was captured by the Germans in 1941 but was subsequently reoccupied by soviet troops in 1943.

ZHOB, a valley and river in the north-east of Baluchistan, India. The Zhob is a large valley running from the hills near Ziarat first eastward and then northward parallel to the Indus frontier, till it meets the Gomal river at Khajuri Kach. Its importance is due to its being the shortest route between the North-West Frontier Province and Quetta; it dominates all the Pathan tribes of Baluchistan by cutting between them and Afghanistan. Up to the year 1884 it was practically unknown to Europeans, but the Zhob Valley Expedition of that year opened it up, and in 1889 the Zhod Valley and Gomal Pass were taken under the control of the British Government. The Zhob Valley was the scene of punitive British expeditions in 1884 and 1890. In 1890 Zhob was formed into a district or political agency, with its headquarters at Fort Sandeman. It was much disturbed during the third Afghan war of 1919. The district has an area of 9,626 sq.m.; pop. (1921) 56,668, mostly Pathans of the Kakar tribe.

See A. W. C. McFall, *With the Zhob Field Force* (1895); R. Bruce, *Forward Policy* (1900); T. H. Holdich, *Indian Borderland* (1901); *Zhob District Gazetteer.*

ZHUKOVSKY, VASILI ANDREYEVICH (1783–1852), Russian poet, born in the government of Tula, on Jan. 29, 1783, was the earliest of the Russian poets of the golden age of Russian poetry, and a precursor of Pushkin. The volume of his original work is small, consisting of a few beautiful lyrics and elegies. His greatest work was the opening up of the knowledge of English and German poetry in Russia by a series of translations. Brückner (*Gesch. v. Russ. Lit.*) calls him "the most original translator in the world's literature." He began by a translation of Gray's *Elegy;* he went on to the more famous poems of the English romanticists, and it has been asserted that in some cases his versions have greater poetic power than their originals. He turned Fouque's *Undine* into Russian verse. His last great work was a version of the *Odyssey* (1847). Zhukovsky was tutor to Alexander II., and he used his favour at court to help both Pushkin and Gogol. His last years were spent in Germany, and he died at Baden-Baden in 1852.

ZIEM, FÉLIX FRANÇOIS GEORGE PHILIBERT (1821–1911), French painter, was born at Beaune (Côte d'Or) in 1821. He studied at the art school of Dijon, where he gained the *grand prix* for architecture. In 1839 he went to Rome and

from 1845 to 1848 travelled in the south of France, Italy and the East, where he found the glowing sunlight and the rich colour peculiarly suited to his temperament. Many of his paintings are in American private collections, but two of his finest pictures, "The Doge's Palace in Venice" (1852), and a marine-painting, are at the Luxembourg museum, and a "view of Quai St. Jean, Marseilles" at the Marseilles gallery.

See *Félix Ziem,* by L. Roger-Milès (*Librairie de l'art,* Paris).

ZIETEN, HANS JOACHIM VON (1699–1786), Prussian general-field-marshal, began his military career as a volunteer in an infantry regiment. In 1741 Frederick the Great made him colonel of the newly formed hussar regiment, and his promotion was rapid. He served with distinction in the first Silesian War, and still more in the second. His hussars, reorganized in the short interval of peace, were considered the best of their arm in Europe. Zieten fought the brilliant action of Moldau Tein almost on the day he received his commission as major-general. In the next campaign he led the famous *Zietenritt* round the enemy's lines to deliver the king's order to a distant detachment. When the Seven Years' War broke out in 1756 Zieten had just been made lieutenant-general. At Reichenberg and Prag he held important commands. At the disastrous battle of Kolin (June 18, 1757) his left wing of cavalry was the only victorious corps of troops, while at Leuthen he was brilliantly successful. Almost the only error in his career of battles was his misdirection of the frontal attack at Torgau, but he redeemed the mistake by his brilliant assault on the Siptitz heights. At the peace, he retired, and died in 1786.

ZIGGURAT, in architecture, a common temple form in Chaldea and ancient Babylonia and Assyria, which consists either of a stepped pyramid or of a somewhat similar shape in which the flat terraces of the ordinary stepped pyramid are replaced by an inclined plane ascending spirally from the ground to the summit. Ziggurats were usually great mounds of sun-dried brick with the exterior walls faced with a coating of burned, glazed brick or tile. On the summit there was frequently a shrine to the deity to whom the temple was erected. It is probable that the ziggurat form originated in the attempt to obtain high observatories from which the stars, so important in Chaldean religion and magic, might be observed.

ZIGZAG, in architecture and the decorative arts, an ornament formed by a succession of chevrons. It usually takes the shape of a band, changing direction at points equidistant from each other by angles usually acute, in such a manner that alternate segments are parallel to each other. The zigzag is one of the most primitive ornamental forms, both on pottery and in textiles. In Egyptian work it is frequently used for tomb ceilings and walls, evidently imitating matting or cloth decorations. Its most important architectural use is in some of the Romanesque styles, especially the Norman work in France and England.

ZIMBABWE, a Bantu name, probably derived from the two words *zimba* ("houses") and *mabgi* ("stones"), given to certain ruins in south-east Africa. The mediaeval Portuguese applied it as a generic term for the capital of any considerable chief and to several distinct places. From about 1550 onwards the Zimbabwe generally referred to by Portuguese writers was at a spot a little north of the Afur district, not far from the Zambezi. Before this the capital of the Monomotapa was situated much farther south, and it may plausibly be identified with the extensive ruins near Victoria (Mashonaland), now generally called Zimbabwe.

These ruins, discovered by Adam Renders in 1868 and explored by Karl Mauch in 1871, became well known to English readers from J. T. Bent's account of the *Ruined Cities of Mashonaland.*

The explorations conducted in 1905 proved that the mediaeval objects were necessarily contemporaneous with the foundation of the buildings, and that there was no super-position of periods of any date whatsoever. The plan and construction of Zimbabwe are by no means unique, and this site only differs from others in Rhodesia in respect of the great dimensions and the massiveness of its individual buildings. It may therefore be dated to a period not earlier than the 14th or 15th century A.D., and attributed to the same Bantu people the remains of whose stone-fenced *kraals* are found between the Limpopo and the Zambezi.

The three distinct, though connected, groups of ruins at Zimbabwe are commonly known as the "elliptical temple," the "acropolis," and the "valley ruins." The first is doubly misnamed; it is not a temple and its contour is too unsymmetrical to be described properly as elliptical. It is an irregular enclosure over 800ft. in circumference, with a maximum length of 292ft. and a maximum breadth of 220ft., surrounded by a dry-built wall of extraordinary massiveness. This wall is in places over 30ft. high and 14ft. wide, but is erratic in outline and variable in thickness. On the south and south-east, the wall is decorated by a row of granite monoliths beneath which runs a double line of chevron ornament. The interior has been much destroyed by the ravages of gold-seekers and amateur excavators. The scheme was a combination of such a stone *kraal* as that at Nanatali with the plan of a fort like those found about Inyanga. The only unique feature is the occurrence of a large and a small conical tower at the southern end.

The "Acropolis" is a hill rising 200ft. to 300ft. above the valley, fortified with the minutest care and with extraordinary ingenuity. The principles of construction, the use of stone and cement, are the same as in the "elliptical" *kraal;* there is no definite plan, the shape and arrangement of the enclosures being determined solely by the natural features of the ground. Between this and the "elliptical" *kraal* are the "valley ruins," consisting of smaller buildings, perhaps the dwellings of traders who bartered the gold brought in from distant mines. Zimbabwe was probably the distributing centre for the gold traffic carried on in the middle ages between the Monomotapa and the Mohammedans of the coast.

Hall, *Great Zimbabwe* 1905); *Prehistoric Rhodesia* (1909).

ZIMMERMANN, ARTHUR (1859–1940), German diplomat was born May 8, 1859, at Frankenstein. After having been vice-consul at Shanghai and acting consul in 1900 at Tientsin, he entered the Foreign Office in 1902 and rose by 1910 to be a director of the political section. In 1911 he was appointed under-secretary, and in Nov. 1916 secretary of state in succession to Von Jagow. In this capacity he addressed to America the note of Jan. 31, 1917, on the subject of U-boat warfare. He was also the author of the invitation of Jan. 19, 1917, to Mexico to enter into alliance with Germany and to sound Japan as to her willingness to co-operate. For Mexico the price of this alliance was to be the American States of New Mexico, Texas and Arizona. This proposal, which was sent through the medium of Von Eckhardt, the German minister to Mexico, was intercepted in America and President Wilson was in a position to publish it on March 1, 1917. The disclosure was one of the primary causes resulting in America's declaration of war upon Germany. Zimmermann retired on Aug. 5, 1917, shortly after the resignation of Bethmann Hollweg.

ZINC, a metallic chemical element (symbol Zn, atomic number 30, atomic weight 65·38). Zinc as a component of brass had currency in metallurgy long before it became known as an individual metal. The word zinc (in the form *zinken*) was first used by Paracelsus, who regarded it as a bastard or semi-metal; but the word was subsequently used for both the metal and its ores. Moreover, zinc and bismuth were confused, and the word *spiauter* (the modern spelter) was indiscriminately given to both these metals. In 1597 Libavius described a "peculiar kind of tin" which was prepared in India, and of which a friend had given him a quantity. From his account it is quite clear that this metal was zinc, but he did not recognize it as the metal of calamine. It is not known to whom the discovery of isolated zinc is due; but we do know that the art of zinc-smelting was practised in England from about 1730. The first continental zinc-works were erected at Liége in 1807.

Occurrence.—Zinc does not occur free in nature, but in combination it is widely diffused. The chief ore is zinc blende, or sphalerite (*see* BLENDE), which generally contains, in addition to zinc sulphide, small amounts of the sulphides of iron, silver and

cadmium. It may also be accompanied by pyrites, galena, arsenides and antimonides, quartz, calcite, dolomite, etc. It is widely distributed, and is particularly abundant in Germany (the Harz, Silesia), Austro-Hungary, Belgium, the United States and in England (Cumberland, Derbyshire, Cornwall, North Wales). Second in importance is the carbonate, calamine (*q.v.*) or zinc spar, which at one time was the principal ore; it almost invariably contains the carbonates of cadmium, iron, manganese, magnesium and calcium, and may be contaminated with clay, oxides of iron, galena and calcite; "white calamine" owes its colour to much clay; "red calamine" to admixed iron and manganese oxides. Calamine chiefly occurs in Spain, Silesia and in the United States. Of less importance is the silicate, $Zn_2SiO_4{\cdot}H_2O$, named electric calamine or hemimorphite; this occurs in quantity in Altenburg near Aix-la-Chapelle, Sardinia, Spain and the United States (New Jersey, Pennsylvania, Missouri, Wisconsin). Other zinc minerals are willemite (*q.v.*), Zn_2SiO_4, hydrozincite or zinc bloom, $ZnCO_3{\cdot}2Zn(OH)_2$, zincite (*q.v.*) or red zinc ore, ZnO, and franklinite, $3(Fe,Zn)O{\cdot}(Fe,Mn)_2O_3$.

Production.—Until about 1833 the supply of zinc was almost entirely obtained from Germany, but in this year Russia began to contribute about 2,000 tons annually to the 6,000 to 7,000 derived from Germany. Belgium entered in 1837 with an output of about 2,000 tons; England in 1855 with 3,000; and the United States in 1873 with 6,000 tons. The last country now produces about one-third of the world's supply. The present state and general trend of the industry is shown by the following statistics for output of smelter and electrolytic zinc (in metric tons) for the chief producing countries and for the world's production.

Year	1933	1935	1937
U.S.A.	278,669	381,591	505,212
Belgium	137,300	181,740	225,579
Canada	83,412	135,645	143,964
Poland	82,705	84,606	107,174
Australia	54,822	68,752	70,869
France	51,958	47,443	60,427
Germany*	50,867	123,198	163,200
United Kingdom*	41,717	61,433	63,138
World output	983,000	1,332,000	1,621,000

*Some secondary metal included. "Minerals Yearbook 1938," U.S. Bureau of Mines.

Properties.—Zinc is bluish white, with a high lustre when fractured. It fuses at 419° C and under ordinary atmospheric pressure boils at 918° C. Its vapour density shows that it is monatomic. The molten metal on cooling deposits crystals belonging to the hexagonal system, and freezes into a compact crystalline solid, which may be brittle or ductile according to circumstances. If zinc be cast into a mould at a red heat, the ingot produced is laminar and brittle; if cast at just the fusing-point, it is granular and sufficiently ductile to be rolled into sheet at the ordinary temperature. According to some authorities, pure zinc always yields ductile ingots. Commercial "spelter" always breaks under the hammer; but at 100° to 150° C it is susceptible of being rolled out into a very thin sheet. Such a sheet, if once produced, remains flexible when cold. At about 200° C, the metal becomes so brittle that it can be pounded in a mortar. The specific gravity of zinc cannot be expected to be perfectly constant; according to Karsten, that of pure ingot is 6·915, and rises to 7·191 after rolling. The coefficient of linear expansion is 17×10^{-6} between 20° and 100°. The specific heat is 0·0929 from 18° to 100°. Compact zinc does not tarnish much in the air. It is fairly soft, and clogs the file. If zinc be heated to near its boiling-point, it catches fire and burns with a brilliant light into its powdery white oxide, which forms a reek in the air (*lana philosophica*, "philosopher's wool"). Boiling water attacks it appreciably, but slightly, with evolution of hydrogen and formation of the hydroxide, $Zn(OH)_2$. A rod of perfectly pure zinc, when immersed in dilute sulphuric acid, is so very slowly attacked that there is no visible evolution of gas; but, if a piece of platinum, copper or other more electro-negative metal be brought into contact with the zinc, it dissolves readily, with evolution of hydrogen and formation of the sulphate. The ordinary impure metal dissolves at once, the more readily the less pure it is. Cold dilute nitric acid dissolves zinc as nitrate, with evolution of nitrous oxide. At higher temperatures, or with stronger acid, nitric oxide, NO, is produced besides or instead of nitrous oxide. Zinc is also soluble in soda and potash solutions, but not in ammonia.

Applications.—Zinc is largely used for "galvanizing" iron, sheets of clean iron being immersed in a bath of the molten metal and then removed, so that a coat of zinc remains on the iron, which is thereby protected from atmospheric corrosion. For the same purpose zinc may be sprayed on to other metals, or it may be deposited electrolytically. It is also a constituent of many valuable alloys; brass, Muntz-metal, pinchbeck and tombac are examples.

Zinc forms only one oxide, ZnO, from which is derived a well-characterized series of salts. It is chemically related to cadmium and mercury, the resemblance to cadmium being especially well marked; one distinction is that zinc is less basigenic. Zinc is capable of isomorphously replacing many of the bivalent metals, *e.g.*, magnesium, manganese, iron, nickel, cobalt and cadmium, in certain salts.

Zinc Oxide, ZnO, is manufactured for paint by two processes —directly from the ore mixed with coal by volatilization on a grate, and by oxidizing the vapour given off by a boiling bath of zinc metal. The oxide made by the latter method has generally a better colour, a finer texture, and a greater covering power. It is an infusible solid, which is intensely yellow at a red heat, but on cooling becomes white. This at least is true of the oxide produced from the metal by combustion; that produced from the carbonate, if once made yellow at a red heat, retains a yellow shade permanently. Crystalline zinc oxide is obtained by heating the nitrate, or by heating the chloride in a current of steam. It is insoluble in water, but dissolves readily in all aqueous acids, with formation of salts. It also dissolves in aqueous caustic alkalis, including ammonia, forming "zincates" [*e.g.*, $Zn(OK)_2$]. Zinc oxide is used in the arts as a white pigment (zinc white); it has not by any means the covering power of white lead, but offers the advantages of being non-poisonous and of not becoming discoloured in sulphuretted hydrogen. It is used also in ointments, as a polish for glass, and in dental cements.

Zinc Hydroxide, $Zn(OH)_2$, is prepared as a gelatinous precipitate by adding a solution of any zinc salt to pure aqueous caustic potash. It is a white powder, is insoluble in water, but soluble in excess of alkali and in acids.

Zinc Peroxide, obtained from zinc sulphate and barium peroxide, or by electrolysis of neutral zinc chloride solutions in the presence of hydrogen peroxide, is a valuable antiseptic, being odourless and non-irritant; it is much used for skin troubles under various proprietary names (*e.g.*, dermogen), and as produced commercially contains about 50% of ZnO_2 together with hydroxide and moisture.

Zinc chloride, $ZnCl_2$, is produced by heating the metal in dry chlorine gas, or by heating a mixture of zinc sulphate and sodium chloride. It condenses as a white translucent mass, boiling at about 700°. Its vapour density at 900° C corresponds to $ZnCl_2$. It is extremely hygroscopic and is used in synthetical organic chemistry as a condensing agent. It dissolves in a fraction of its weight of even cold water and in any proportion of boiling water, forming a syrupy solution. A solution of zinc chloride is easily produced from the metal and hydrochloric acid; it cannot be evaporated to dryness without considerable decomposition of the hydrated salt into oxychloride and hydrochloric acid, but it may be crystallized as $ZnCl_2{\cdot}H_2O$. A concentrated solution of zinc chloride converts starch, cellulose and a great many other organic substances into soluble compounds; hence the application of the fused salt as a caustic in surgery and the impossibility of filtering a strong $ZnCl_2$ solution through paper. (*See* CELLULOSE.) The solution is also used as a flux in soldering.

Zinc chloride solution readily dissolves the oxide with the formation of oxychlorides, some of which are used as pigments, cements and for filling teeth in dentistry. A solution of the oxide in the chloride has the property of dissolving silk, and hence is employed for removing this fibre from wool.

Zinc sulphide, ZnS, occurs in nature as blende (*q.v.*), and is artificially obtained as a white precipitate by passing sulphuretted hydrogen into a neutral solution of a zinc salt. It dissolves in mineral acids, but is insoluble in acetic acid.

Zinc sulphate, $ZnSO_4+7H_2O$, or white vitriol, is prepared by dissolving the metal in dilute sulphuric acid, concentrating, and cooling the solution. The hydrated salt crystallizes out on cooling, forming colourless orthorhombic prisms, usually small and needle-shaped. They are permanent in the air. According to Poggiale, 100 parts of water dissolve respectively of ($7H_2O$) salt, 115·2 parts at 0°, and 653·6 parts at 100°. At 39° C the crystals lose one, and at 100° six of their molecules of water; the remaining molecule goes off at 250°. The anhydrous salt, when exposed to a red heat, breaks up into oxide, sulphur dioxide and oxygen. An impure form of the salt is prepared by roasting blende at a low temperature. In the arts it is employed in the preparation of varnishes, and as a mordant for the production of colours on calico. A green pigment known as *Rinmann's green* is prepared by mixing 100 parts of zinc vitriol with 2·5 parts of cobalt nitrate and heating the mixture to redness, to produce a compound of the two oxides. Zinc sulphate, like magnesium sulphate, unites with the sulphates of the potassium metals and of ammonium into crystalline double salts, $ZnSO_4{\cdot}R_2SO_4+6H_2O$, isomorphous with one another and with the magnesium salts.

Zinc Carbonate, $ZnCO_3$, occurs in nature as the mineral calamine (*q.v.*), but has never been prepared artificially, *basic carbonates,* $ZnCO_3{\cdot}xZn(OH)_2$, where x is variable, being obtained by precipitating a solution of the sulphate or chloride with sodium carbonate; the basic salt is used as a pigment.

Of zinc phosphates we notice the minerals hopeite, $Zn_3(PO_4)_2{\cdot}4H_2O$, and tarbuttite, $Zn_3(PO_4)_2{\cdot}Zn(OH)_2$, both found in Rhodesia.

Analysis.—From neutral solutions of its salts zinc is precipitated by sulphuretted hydrogen as sulphide, ZnS—a white precipitate, soluble, but by no means readily, in dilute mineral acids, but insoluble in acetic acid. In the case of the acetate precipitation is quite complete; from a sulphate or chloride solution the greater part of the metal goes into the precipitate; in the presence of a sufficiency of free HCl the metal remains dissolved; sulphide of ammonium precipitates the metal completely, even in the presence of ammonium salts and free ammonia. The precipitate, when heated, passes into oxide, which is yellow when hot and white after cooling; and, if it be moistened with cobalt nitrate solution and re-heated, it exhibits a green colour after cooling.

Zinc may be quantitatively estimated by precipitating as basic carbonate, which is dried and ignited to zinc oxide. It may also be precipitated as zinc ammonium phosphate, NH_4ZnPO_4, which is filtered on a Gooch crucible and dried at 105°. Volumetric methods have also been devised.

PHARMACOLOGY AND THERAPEUTICS

Zinc chloride is a powerful caustic, and is prepared with plaster of Paris in the form of sticks for destroying warts, etc. The salt is a corrosive irritant poison when taken internally. The treatment is to wash out the stomach or give such an emetic as apomorphine, and, when the stomach has been emptied, to administer demulcents such as white of egg or mucilage. Numerous other salts of zinc, used in medicine, are of value as containing this metal. Certain others are referred to in relation with the important radical contained in the salt. Those treated here are the sulphate, oxide, carbonate, oleate and acetate. All these salts are mild astringents when applied externally, as they coagulate the albumen of the tissues and of any discharge which may be present. In virtue of this property they are also mild haemostatics, tending to coagulate the albumens of the blood and thereby to arrest haemorrhage. *Lotio Rubra,* the familiar "Red Lotion," a solution of zinc sulphate, is widely used in many catarrhal inflammations, as of the ear, urethra, conjunctiva, etc. There are also innumerable ointments.

These salts are extensively employed internally especially in the treatment of the more severe and difficult cases of nervous disease. The sulphate is an excellent emetic in cases of poisoning, acting rapidly and without much nausea or depression. For these reasons it may also be given with advantage to children suffering from acute bronchitis or acute laryngitis. *See* also *Zinc peroxide* (above).

Gregory and Mrs. M. S. Burr) (1926); Smith, *The Zinc Industry* (1918); for statistics and technological advances, *see* G. A. Roush and A. Butts, *The Mineral Industry* (annually). (X.; A. D. M.)

ZINC PRODUCTION

The United States is the principal producer of both zinc ore and spelter. The Joplin area in Missouri has long been the principal mining region, but large deposits are worked in the Upper Mississippi region, Franklin Furnace (New Jersey) and, since the application of improved methods of zinc concentration, in the western States. Australia is next to the United States as a zinc producer, most of the ore being obtained from the Broken Hill district (New South Wales). Tasmania also has important deposits and occurrences are known in Australia.

In Canada, the most important deposits of the metal occur in British Columbia and Quebec, these two provinces sharing practically the whole of the Canadian production in the proportions of four-fifths and one-fifth respectively. The principal countries in Europe participating in the zinc industry are Germany, Italy, Poland and Spain. For many years Germany ranked second only to the United States. Her most important deposits were in Upper Silesia, which yielded about three-fourths of the total German production. Before the World War the European industry was almost wholly controlled by the German zinc convention.

In Italy the chief mines now worked are in Sardinia, though occurrences of ore are found in Lombardy, Piedmont and Tuscany. During the post-War period Poland produced more zinc ore than any other European country, her richest mines being situated in Silesia; her exports in 1923 amounted to 80,000 long tons. In Spain the chief zinc-mining centres are in the provinces of Santander and Murcia. The ores of Santander are mainly calamine, while those of Murcia are principally blende and galena. Mention should be made of the zinc-ores mined in the United Kingdom. These are almost invariably blende associated with galena, and occur chiefly in North Wales, the north of England, the Isle of Man and at Dumfries in Scotland.

In the following table the production of zinc in the principal countries of the world is set out for the three years, 1918, 1923 and 1925.

	Long Tons		
	1918	1923	1925
United States	462,435	455,745	511,559
Australia	9,444	41,153	45,698
Canada	11,227	26,972	34,358
Germany	232,000	39,400	57,705
Italy	1,169	3,622	6,374
Poland	..	90,000	112,507
Spain	15,644	10,746	140,300
United Kingdom	50,000	33,000	42,000
Belgium	9,096	144,677	179,130
France	18,052	48,541	70,000
Japan	39,203	13,671	14,000*
Netherlands	..	16,185	20,778
Yugoslavia	..	2,400	2,196†
Sweden	..	1,194	4,598
Norway	..	3,722	6,698

ZINCITE, a mineral consisting of zinc oxide (ZnO), crystallizing in the hemimorphic-hemihedral class of the hexagonal system. Distinct crystals are of rare occurrence; they have the form of a hexagonal pyramid terminated at one end only by a basal plane. There is a perfect cleavage parallel to the basal plane, and usually the mineral is found as platy foliated masses. The blood-red colour and the orange-yellow streak are characteristic features. The hardness is 4·5, sp.gr., 5·6. Some manganese is usually present replacing zinc. It is known only from Sterling Hill and Franklin Furnace in Sussex county, N.J.

ZINDER, a town on the northern margin of the central Sudan. Pop. (1939) 10,400, of whom 100 were Europeans. It forms part of the French colony of Niger, of which the capital, at first Zinder, was in 1926 moved to Niamey. Its ruler was formerly subordinate to Bornu, but with the decline of that kingdom he shook off the yoke of the sultan, and on the conquest of that country by Rabah (*q.v.*) seems to have maintained his independence. The country of which Zinder is the capital is known as Damerghu. It is semi-fertile, and supports considerable numbers of horses and sheep, besides troops of camels. By the Anglo-French agreement of June 1898 it was included in the French sphere. The town was occupied in July 1899, after a slight resistance. A French post (named Fort Cazemajou) was built outside the town on a mound of huge granite blocks. Zinder was the first point in the Sudan reached by F. Foureau after his great journey across the Sahara *via* Air in 1899. Subsequently Commandant Gadel, from his headquarters at Zinder, mapped and pacified the surrounding region, and sent out columns of *meharistes* (camel-corps) which occupied the oasis of Air and Bilma in 1906. Zinder is a large and fine town surrounded with high earthen walls, very thick at the base and pierced with seven gates.

See Cazemajou, in *Bul. Com. de l'Afrique Française* (1900); F. Foureau, in *La Géographie* (December 1900), *D'Alger au Congo par le Tchad* (Paris, 1902); Joalland, in *La Géographie,* vol. iii. (1901); E. Arnaud and M. Cortier, *Nos Confins Sahariens* (Paris, 1908); C. Jean, *Les Touareg du Sud-Est* (Paris, 1909).

ZINGARELLI, NICCOLO (1752–1837), Italian composer, was born at Naples on April 4, 1752, the son of Riccardo Tota Zingarelli, a singing-master and soloist. His first dramatic work, *I quattro Pazzi,* was produced at the conservatorio in 1768. He then gave violin lessons for a time, but in 1781 produced his first opera, *Montesuma,* at the San Carlo and afterwards in Vienna, where it was highly commended by Haydn. He finally settled in Milan, with introductions to the viceregal court, and over a period of eleven years produced a series of operas for the Scala, an oratorio of the Passion, and several cantatas. In 1789 he went to Paris to write an opera for the Académie royale de musique. This work, *L'Antigone,* for which Marmontel provided the libretto, was performed on April 30, 1790, but Paris was no place for Zingarelli during the Revolution, and he fled into Switzerland and returned to Milan early in 1791.

In 1792 he won the appointment, by open competition, of master of the chapel at the cathedral. He first achieved an international reputation by a series of comic operas, beginning with *La Secchia rapita* in 1793. His finest work was, however, *Romeo and Juliet,* played at the Scala in 1796. From 1794–1804 Zingarelli was master of the chapel at Loreto, and during this time, although he also wrote operas, he was chiefly inspired to compose sacred music, contributing largely to the enormous collection of manuscript works, the property of the church, known as the *Annuale di Loreto.* In 1804 he went to Rome as master (maestro di capella) of the Sistine chapel and in 1805 produced one of his most successful works, "The Destruction of Jerusalem," which held the stage for five years. His last opera, *Berenice,* received a hundred consecutive performances.

At the "King of Rome" celebrations, when Napoleon ordered a Te Deum to be sung in Rome, Zingarelli's principles did not allow him to undertake the performance, and on his refusal he was arrested and brought before the emperor in Paris. But Napoleon at once released him and provided him with a pension. Zingarelli's post in Rome had been taken by Fioravanti, but in 1813 he was appointed director of the Real Collegio di Musica at Naples and in 1816 maestro di cappella at the cathedral. Zingarelli's gift for melody was remarkable. He was a deeply religious man and was rigorous in his exclusion of secular music from church performances. He died in 1837.

ZINGIBERACEAE, a family of monocotyledonous plants, chiefly tropical, characterized by its irregular flowers. The various parts of the plants are usually more or less aromatic. Forty genera and about 900 species are recognized. Among the economic species are ginger (*q.v.*) (*Zingiber officinale*), cardamoms (*q.v.*) (*Elettaria cardamomum* and *Amomum cardamomum*), grana-paradisi (*Aframomum*) and turmeric (*q.v.*) (*Curcuma longa*), the latter used in making curry powder. Various species of *Alpinia, Hedychium, Phaeomeria* and other genera are cultivated for ornamental purposes. *See* K. Schumann, "Zingiberaceae," *Pflanzenreich,* 20 (iv 46): 1–459, fig. 1–52 (1904).

ZINNIA, a genus of the family Compositae, containing about a dozen species of tender annual or perennial herbs or undershrubs, found wild from the southern United States and Mexico to Chile. The numerous single and double garden forms are mostly derived from *Zinnia elegans,* and grow about 2 ft. high, producing flowers of various colours, the double ones being about the size of asters, and very handsome. The colours include white, yellow, orange, scarlet, crimson and purple. Zinnias do best in a rich deep loamy soil, in a sunny position. They should be sown on a gentle hotbed at the end of March and planted out only after settled warm weather.

ZINOVIEV, GRIGORY EVSEEVICH (1883–1936), Russian politician, was born in Sept. 1883 at Elisavetgrad (Zinovievsk). He studied chemistry and later law at Bern. He was a revolutionary before he was 20, and in 1903 met Lenin. He was head of the Bolshevik party in Bern and during 1903–4 started Bolshevik propaganda in South Russia. Apart from his activities abroad, he came into prominence in Russia during 1906–8 as a member of the Bolshevik St. Petersburg committee of the R.S.D.P., by his organization of the attempted Kronstadt rising after the dispersal of the first Duma, his editorship of the Bolshevik paper *Vpered* (Forward), and of *The Social Democrat,* the central organ of the party. In 1908 he was arrested and imprisoned but was released. He went abroad and did not return until the revolution in 1917. During these nine years Zinoviev worked hard for his party. He was a member of the central committee, co-editor of the principal Bolshevik publications, and representative of the party at the Copenhagen congress of the International. In 1912 he went with Lenin to Galicia to control from the nearest possible point the growing labour movement in Russia. In Galicia he founded the foreign bureau of the central committee, which guided the party work in Russia and the activities of the Bolshevik group in the Duma. Zinoviev edited with Lenin *Against the Tide,* a work of propaganda against World War I; and at the Zimmerwald conference (1915) they began to organize the Communist International. On the outbreak of the March revolution (1917) they returned to Russia and began to prepare the way for the revolution. Zinoviev was co-editor of *Pravda* and, after its suppression, of *The Proletarian* and *The Worker.* He thus became one of the leading figures in Russia. In 1919 he was elected president of the Communist International, and after the death of Lenin in 1924 was one of the most zealous upholders of pure "Leninism." But in 1926 he was expelled from the political bureau, and in 1927 from the Communist party. He was readmitted in 1929; but in Jan. 1935 he and Kamenev (*q.v.*) were exiled for counter-revolutionary activities. On Aug. 25, 1936, convicted of high treason together with Kamenev and 14 others, he was shot. His alleged letter to English communists was a factor in the British general election of Oct. 1924.

ZINOVIEVSK, Ukrainian S.S.R.: *see* KIROVOGRAD.

ZINZENDORF, NICOLAUS LUDWIG, COUNT OF ZINZENDORF AND POTTENDORF (1700–1760), German religious and social reformer, was born on May 26, 1700, at Dresden. Both

his parents belonged to the Pietist circle, and the lad had Philipp Jakob Spener for his godfather. His school days were spent at Halle amidst Pietist surroundings, and in 1716 he went to the University of Wittenberg, to study law and fit himself for a diplomatic career. Three years later he was sent to travel in Holland, in France, and in various parts of Germany. During a lengthened visit at Castell he fell in love with his cousin Theodora; but her mother objected to the marriage, and Theodora married Count Henry of Reuss. Zinzendorf took this rebuff as a call to special work for God, and he now resolved to settle down as a Christian landowner, spending his life on behalf of his tenantry at Berthelsdorf. His intention was to carry into practice the Pietist ideas of Spener.

The "band of four brothers" (Rothe, pastor at Berthelsdorf; Melchior Schäffer, pastor at Görlitz; Francis von Wattewille, a friend from boyhood; and himself) set themselves to create a revival of religion. From the printing-house at Ebersdorf large quantities of books and tracts, catechisms, collections of hymns and cheap Bibles were issued; and a translation of Johann Arndt's *True Christianity* was published for circulation in France. Zinzendorf seems to have doubted the wisdom of Spener's plan of not separating from the Lutheran Church, and began to think that true Christianity could be best promoted by free associations of Christians, which in course of time might grow into churches with no State connection. Zinzendorf offered an asylum to a number of persecuted wanderers from Moravia (*see* MORAVIAN BRETHREN), and built for them the village of Herrnhut on a corner of his estate of Berthelsdorf. The refugees who came to this asylum (between 1722 and 1732—the first detachment under Christian David) from various regions where persecution raged, belonged to more than one Protestant organization. Zinzendorf devoted himself to them.

Gradually Zinzendorf was able to organize his refugees into something like a *militia Christi,* based not on monastic but on family life. He established a common order of worship in 1727, and soon afterwards a common organization, which has been described in the article MORAVIAN BRETHREN. He travelled widely on behalf of the Moravians, visiting America in 1741–42 and spending a long time in London in 1750. Missionary colonies had by this time been settled in the West Indies (1732), in Greenland (1733), amongst the North American Indians (1735); and before Zinzendorf's death the Brethren had sent from Herrnhut missionary colonies to Livonia and the northern shores of the Baltic, to the slaves of North Carolina, to Surinam, to the negro slaves in several parts of South America, to Travancore in the East Indies, to the Copts in Egypt and to South Africa.

In 1752 Zinzendorf lost his only son, Christian Renatus, whom he had hoped to make his successor; and four years later he lost his wife Erdmute, who had been his counsellor and confidante in all his work. Zinzendorf remained a widower for one year, and then (June 1757) contracted a second marriage with Anna Nitschmann. He died on March 9, 1760, leaving John de Wattewille, who had married his eldest daughter Benigna, to take his place at the head of the community.

Kirchenthum seiner Zeit* (Leipzig, 1886); H. Römer, *Zinzendorf's Leben und Werken* (Gnaudau, 1900), and other literature mentioned under MORAVIAN BRETHREN.

ZION, a city of Lake county, Illinois, U.S.A., on Lake Michigan, 45 m. N. by W. of Chicago. It is served by the Chicago and North Western and the Chicago, North Shore and Milwaukee railways. Pop. 5,580 in 1920, 20% foreign-born white, and was in 1940, 6,555 by the federal census. It is the centre of a fruit-growing, truck-gardening and dairying district, and has a variety of manufacturing industries. Zion City (as it was called at first) was founded in 1901 by John Alexander Dowie (*q.v.*) to be the headquarters of the "Christian Catholic Apostolic Church in Zion." It was chartered as a city in 1902.

ZION, originally the name of the Jebusite stronghold at Jerusalem captured by David (2 Samuel v.). This was probably on the southern part of the eastern hill. Above it was built the temple, and later the name was extended to the whole hill. Finally it became a synonym for the city of Jerusalem, whose inhabitants are personified as "the daughter of Zion." *See* JERUSALEM.

ZIONISM is the lineal heir of the attachment to Zion which led the Babylonian exiles under Zerubbabel to rebuild the Temple, and which flamed up in the heroic struggle of the Maccabees against Antiochus Epiphanes.

During the middle ages, though the racial character of the Jews was being transformed by their Ghetto seclusion, the national yearning suffered no relaxation. The nationalist spirit of the mediaeval Jews is sufficiently reflected in their liturgy, and especially in the works of the poet, Jehuda Halevi.

The strength of the nationalist feeling was practically tested in the 16th century, when a Jewish impostor, David Reubeni (*c.* 1530), and his disciple, Solomon Molcho (1501–1532), came forward as would-be liberators of their people. Throughout Spain, Italy and Turkey they were received with enthusiasm by the bulk of their brethren. In the following century the influence of the Christian Millennarians gave a fresh impulse to the national idea. Menasseh ben Israel (1604–1657) co-operated with English Millennarians to procure the resettlement of the Jews in England as a preliminary to their national return to Palestine. In 1666 a leader appeared at Smyrna, in the person of a Jew named Sabbatai Sebi (1626–1676), who proclaimed himself the Messiah. The news spread like wildfire, and despite the opposition of some of the leading rabbis, the Jews everywhere prepared for the journey to Palestine. Throughout Europe the nationalist excitement was intense. Even the downfall and apostasy of Sabbatai were powerless to stop it. The bulk of the people refused for a whole century to be disillusioned.

The reaction arrived in 1778 in the shape of the Mendelssohnian movement. The growth of religious toleration, the attempted emancipation of the English Jews in 1753, and the Judeophilism of men like Lessing and Dohm, showed that a new era was at hand. Moses Mendelssohn (1729–1786) sought to prepare his brethren for their new life as citizens of the lands in which they dwelt, by emphasizing the spiritual side of Judaism and the necessity of Occidental culture. His efforts were successful. The nationalist spirit showed signs of yielding before the hope or the progress of local political emancipation. In 1806 the Jewish Sanhedrin convened by Napoleon virtually repudiated the nationalist tradition. The new Judaism, however, had not entirely destroyed it. It had only reconstructed it on a different foundation. Mendelssohnian culture, by promoting the study of Jewish history, gave a fresh impulse to the racial consciousness of the Jews. From this race consciousness came a fresh interest in the Holy Land. It was an ideal rather than a politico-nationalist interest—a desire to preserve and cherish the monuments of the ancient national glories. It took the practical form of projects for improving the circumstances of the local Jews by means of schools, and for reviving something of the old social condition of Judea by the establishment of agricultural colonies. In this work Sir Moses Montefiore, the Rothschild family, and the Alliance Israélite Universelle were conspicuous. More or less passively, however, the older nationalism still lived on—especially in lands where Jews were persecuted—and it became strengthened by the revived race consciousness and the new interest in the Holy Land. Christian Millennarians also helped to keep it alive. Lord Ashley, afterwards Lord Shaftesbury, Col. Gawler, Walter Cresson, the United States consul at Jerusalem, James Finn, the British consul, Laurence Oliphant and many others organized and supported schemes for the benefit of the Jews of the Holy Land on avowedly Restoration grounds. Another vivifying element was the re-opening of the Eastern Question and the championship of oppressed nationalities in the East by the Western Powers. In England political writers were found to urge the re-establishment of a Jewish State under British protection as a means of assuring the overland route to India (Hollingsworth, *Jews in Palestine,* 1852). Lord Palmerston was not unaffected by this idea (Finn,

Stirring Times, vol. i pp. 106–112), and both Lord Beaconsfield and Lord Salisbury supported Laurence Oliphant in his negotiations with the Porte for a concession which was to pave the way to an autonomous Jewish state in the Holy Land. George Eliot's *Daniel Deronda,* which appeared in 1876, was a striking illustration of the sympathy with which Jewish national aspirations were regarded by cultivated western minds.

In the middle of the 19th century, Zionism, or what the next generation of Jews was to know as Zionism, was already being preached in western Europe by Moses Hess (1812–1875) and in eastern Europe by Hirsch Kalischer (1795–1874) and Perez Smolenskin (1842–1885). A powerful impetus was given to the movement by the rise and spread of anti-Semitism, which, in one form or another, began to harass the Jews and embitter their lives in nearly every part of Europe. In Russia it reached its climax in 1882, when murder and pillage raged unchecked through the Jewish pale of settlement. It was in this fateful year that the immediate precursor of Theodor Herzl, the founder of the Zionist organization, appeared in the person of Leo Pinsker of Odessa (1821–1891), whose "auto-emancipation" was a plea for the solution of the Jewish problem by the re-establishment of a Jewish nation living its own life on Jewish soil. The "back to Zion" movement soon began to assume a practical form. A society known as *Choveve Zion* ("Lovers of Zion") was formed for the purpose of promoting Jewish colonization in Palestine.

A new chapter opened in 1896 with the publication of a pamphlet entitled *The Jewish State* by Theodor Herzl (*q.v.*). In his "Jewish state" he elaborated in detail a scheme for the establishment of an autonomous Jewish commonwealth in Palestine under the suzerainty of the sultan. This scheme secured a large amount of popular support throughout Europe and in 1897 the first international Zionist congress met at Basle. The congress established the Zionist Organization for the purpose of giving effect to the following program: "Zionism strives to create for the Jewish people a home in Palestine secured by public law. The congress contemplates the following means to the attainment of this end: (1) The promotion on suitable lines of the colonization of Palestine by Jewish agricultural and industrial workers. (2) The organization and binding together of the whole of Jewry by means of appropriate institutions, local and international, in accordance with the laws of each country. (3) The strengthening and fostering of Jewish national sentiment and consciousness. (4) Preparatory steps towards obtaining government consent where necessary to the attainment of the aim of Zionism."

In 1901 and again in 1902 Dr. Herzl had audiences with the sultan, Abdul Hamid, but the negotiations led to nothing. He now sought from the British government a grant of territory on an autonomous basis in the vicinity of the Holy Land, which would provisionally afford a refuge and a political training-ground for persecuted Jews. A site was suggested in the Sinai peninsula, but owing to the waterless character of the country the project was given up. Then Joseph Chamberlain suggested the uninhabited highlands of the East Africa Protectorate, and in 1903 the British government made the Zionist Organization a provisional offer of an area of 6,000 sq.mi. in the Guas Ngishu plateau. This offer was warmly appreciated as a mark of British goodwill, but it gave rise to sharp differences of opinion between a minority who urged its acceptance and a much larger body of Zionists who were alarmed at any suggestion of the diversion of Zionist energies from Palestine. In the end the project was shelved by the seventh Zionist congress (1905).

Meanwhile Zionism had suffered an irreparable blow by the death of Dr. Herzl (1904). He was succeeded by David Wolffsohn, a banker of Cologne. The movement was further shaken by the dissensions which followed the rejection of the East African project. Israel Zangwill led an influential minority which combined with certain non-Zionist elements to found a rival organization under the name of the ITO (Jewish Territorial Organization) with a view to taking over the East African offer or establishing an autonomous place of refuge elsewhere. On the other hand, the Zionist Organization had now dedicated itself irrevocably to Palestine, and under the auspices of Wolffsohn fresh negotiations were opened with the Porte. These, however, were rendered hopeless by the Turkish revolution, which postulated a united Ottoman nationality, and resolutely set its face against any extension of the racial and religious autonomies under which the integrity of the empire had already severely suffered.

A Zionist bibliography has been published by the Federation of American Zionists. Besides the works already cited in the body of this article, *see,* on the early nationalist movement Graetz, *Geschichte der Juden,* under the heads of the various pseudo-Messiahs and their adherents. Jewish agricultural colonies will be found discussed very fully in *The Jewish Encyclopedia,* vol. i pp. 240–62. For early Zionist projects see *Publications of the American Jewish Historical Society,* No. 8, pp. 75–118; Laurence Oliphant, *Land of Gilead;* Mrs. Oliphant, *Life of Laurence Oliphant,* pp. 168 *et seq.* The Zionist movement since 1895 is fully recorded in its official organ, *Die Welt* (Vienna). For proceedings of the congresses *see* the *Official Protocols* published for each year by the society "Erez Israel" of Vienna; also Herzl, *Der Baseler Congress* (Vienna, 1897). On the movement generally, *see* Herzl's *Zionistische Schriften,* edited by Dr. Leon Kellner; *Ten Years of Zionism* (Cologne, 1907); Nordau, *Zionism, Its History and Its Aims* (1905); J. de Haas, *Zionism, Jewish Needs and Jewish Ideals;* also articles by I. Zangwill in *Cosmopolis* (Oct. 1897), *Contemporary Review* (Oct. 1899) and *Fortnightly Review* (April 1910); Dr. Gaster in *Asiatic Quarterly Review* (Oct. 1897); H. Bentwich in *Nineteenth Century* (Oct. 1897), and *Fortnightly Review* (Dec. 1898); Reich in *Nineteenth Century* (Aug. 1897); Lucien Wolf, "The Zionist Peril," *Jewish Quarterly Review* (Oct. 1904). On the ITO *see* pamphlets and leaflets published by the Jewish Territorial Organization; also the *Report of the Commission on Cyrenaica* (1909). (L. W.; X.)

LATER PERIOD

As the prospects of obtaining a charter from the sultan gradually receded, sharp differences of opinion developed within the Zionist ranks. The "practical" Zionists, who included most of the Zionist leaders in Russia, pressed for an immediate start to be made in Palestine. The "political" Zionists, whose strength was in western and central Europe, still clung to the charter as an essential prerequisite, protesting that Zionist resources should not be dissipated on petty colonization. The "practical" Zionists won their first important success in 1908, when a Zionist agency was established at Jaffa. The political field was not abandoned, but the movement now began to throw itself more and more vigorously into the actual settlement of Jews on the soil of Palestine. For this purpose its main financial instrument was the Jewish National fund, which in 1914 owned property in Palestine to the value of £144,000, as compared with £35,000 in 1909 and £11,000 in 1907, when its active operations began. The marked quickening of the pace which dates from 1910 reflects the change in the direction of Zionist policy, though the resources of the movement were still small in comparison with those which were lavished upon the Jewish settlements in Palestine by Baron Edmond de Rothschild. It was Baron Edmond who came to the assistance of the struggling colonists in 1883, and it was due mainly to him that a number of Jewish agricultural colonies were already in existence in Palestine when his efforts began to be supplemented by those of the Zionist Organization. In 1914 Palestine had a Jewish population of about 90,000, including about 13,000 settlers in 43 agricultural colonies. The total number of Jewish immigrants between 1882 and 1914 has been estimated at about 45,000. In the period immediately before World War I, the Zionist Organization showed a growing tendency to interest itself in the revival of Hebrew culture in Palestine as well as in the settlement of Jews on the land. In 1913 the eleventh Zionist congress, while approving an ambitious program of rural colonization, also resolved that steps should be taken towards the early establishment in Jerusalem of a Hebrew university.

The outbreak of World War I, followed almost immediately by the intervention of Turkey on the side of the Central Powers, brought Zionist work in Palestine to a standstill. A new world was in the making, and it was now at least conceivable that the Zionists might secure something like the charter on which they had originally staked their hopes. Political Zionism was again in the ascendant. The initiative was taken by a group of Zionists in Great Britain, headed by Dr. Chaim Weizmann of Manchester university. The Zionists now proposed that Great Britain should make it part of its policy to provide in the peace settlement for the establishment in Palestine of a national home for the Jews.

The Balfour Declaration.—Meanwhile, a new situation was developing in the eastern theatre of war, and a British conquest of Palestine was becoming a possibility of the near future. At the same time, the hour of decision was approaching in the United States, where there was a Jewish population of over 3,000,000, while Russia, where the Jews were still more numerous, was steadily drifting into chaos. A declaration in favour of Zionism would help to rally Jewish opinion throughout the world to the side of the Allies. Further, the settlement in Palestine of a Jewish population attached to Great Britain by ties of interest and sentiment might well be of value in guaranteeing the permanent security of the approaches to the Suez canal. To these practical motives was added a genuine desire to contribute towards the solution of the Jewish problem, in which British statesmen had shown themselves sympathetically interested long before the war.

All these considerations played their part in bringing the British government into closer relations with the Zionist leaders. With Sir Mark Sykes as the principal intermediary, an exchange of views began in Feb. 1917, with the result that on Nov. 2 the foreign secretary, Mr. Balfour, wrote to Lord Rothschild:—

"Dear Lord Rothschild—I have much pleasure in conveying to you on behalf of His Majesty's Government the following declaration of sympathy with Jewish Zionist aspirations, which has been submitted to and approved by the Cabinet: 'His Majesty's Government view with favour the establishment in Palestine of a national home for the Jewish people, and will use their best endeavours to facilitate the achievement of this object, it being clearly understood that nothing shall be done which may prejudice the civil and religious rights of existing non-Jewish communities in Palestine or the rights and political status enjoyed by Jews in any other country.' I should be grateful if you would bring this Declaration to the knowledge of the Zionist Federation."

The Balfour Declaration, as it has come to be called, was the act of Great Britain, but it was issued with the knowledge and concurrence of the Allied Powers. France formally associated itself with the declaration in Feb. 1918, and Italy in the following May. As for the United States, President Wilson had personally intervened to make it clear that he would welcome a British pronouncement in favour of Zionism, and soon after the declaration was issued, he publicly expressed his satisfaction. In 1922 resolutions associating the United States with the policy embodied in the declaration were unanimously adopted by both houses of congress.

British Mandate for Palestine.—In Dec. 1920, the proposed terms of the Palestine mandate were submitted by the British government to the League of Nations for confirmation by the council. There was a succession of unforeseen delays, but a slightly modified draft was eventually approved by the council at its meeting in London on July 24, 1922. A few weeks earlier, the British government had issued a statement of British policy in Palestine, in which it interpreted the Balfour Declaration as meaning, "not the imposition of a Jewish nationality upon the inhabitants of Palestine as a whole, but the further development of the existing Jewish community, in order that it may become a centre in which the Jewish people, as a whole, may take, on grounds of religion and race, an interest and a pride." The mandate came into full operation on Sept. 29, 1923. In its final form, it recites the Balfour Declaration in the preamble, and includes among its provisions various articles dealing with Jewish immigration.

Zionism at Work.—The return to normal conditions was marked by the San Remo decision of April 1920, which was followed by the establishment in Palestine of a civil administration in the following July. Subject to the general control of the government, the Zionist Organization was for the first time in a position to bring in immigrants and to purchase land. Between 1918 and 1936 about 280,000 Jews immigrated to Palestine, of whom 61,854 entered in 1935. During the same period there were about 30,000 Jewish emigrants, of whom about 25,000 were post-war settlers, leaving a net immigration of about 255,000. The Jewish population, which was about 95,000 in 1914, was reduced during the war to about 55,000. It was returned at 84,000 at the census of Oct. 1922, was officially estimated at 108,000 in March 1925, and had risen to nearly 400,000 at the end of 1936. The area of land in Jewish possession rose from 177 sq.mi. in 1914 to 545 sq.mi. in 1936, and the total Jewish population of the rural areas from 13,000 to 90,000. With the exception of about 30 sq.mi. of state and waste lands, all the land acquired after World War I was bought, often at inflated prices, in the open market, and in addition to the heavy expenditure in which they have thus been involved, the Jewish National fund and other Jewish bodies have had to sink large amounts of capital in improvements, including in particular the drainage of marshes. There has been a considerable increase, which has been particularly marked since 1924, in the Jewish population of Jerusalem and Haifa. In the neighbourhood of Jaffa, the Jews have built up the rapidly expanding urban settlement of Tel Aviv, which had in March 1937 a population of 140,000, as compared with 13,000 in Dec. 1922, and 2,000 in Aug. 1914. The rapid growth of the towns is connected with the industrial development of Palestine, which in turn is largely due to the influx of private Jewish capital. In 1933 it was estimated that since 1920, 4,055 industrial enterprises had been established in Palestine, representing in the aggregate an investment of £4,500,000, which was predominantly Jewish. An important factor in the industrial and general development of Palestine is the Palestine Electric corporation, which has been largely financed from Jewish sources and which is supplying Jaffa and Haifa with electric light and power.

Education.—Since World War I, the Jewish organizations have largely extended the scope of their educational work in Palestine. At the end of 1935 they controlled 492 schools of various grades and categories with 51,314 pupils. Public health work on a large scale is done by the Hadassah Medical organization, the Jewish National council and other Jewish bodies. A Jewish technical institute was opened at Haifa in Feb. 1925 and the Zionist Organization also maintains an agricultural institute at Tel Aviv.

In April 1925, Lord Balfour formally inaugurated the Hebrew University of Jerusalem, consisting, in its first stages, of three research institutes, devoted respectively to chemistry, microbiology and tropical medicine, and Jewish and oriental studies.

In all these institutions the language is Hebrew, which has already become the Jewish vernacular in Palestine and is the mother-tongue of the whole of the new generation. (L. St.; X.)

ZIONISM 1929–39

The Unrest of 1929.—Jewish immigration to Palestine had reached its first peak in 1924–25, to fall off sharply immediately thereafter. The following years witnessed large Jewish unemployment in Palestine and an emigration surpassing the number of immigrants. In 1929, at the Zionist congress at Zurich, a Jewish Agency composed of Zionists and non-Zionists was formed with strong American participation. At the same time the long smouldering Arab discontent with Zionism and with the British policy supporting it came to a head in violent outbreaks. Religious agitation had centred for some time around the respective Jewish and Mohammedan rights of the western wall (the Wailing Wall) of the Herodian Temple. But what had started as a religious conflict soon became a national conflict, Christian Arabs uniting with the Mohammedans. The new revolt surpassed by far the former open outbreak of Arab discontent in 1921. The British government sent out a commission of inquiry. Its report thought the disturbances caused by the Arab fear of a Jewish majority and of dispossession of their land. A British White Book on Oct. 20, 1930, accepted the recommendations of the commission regarding restrictions of immigration and land purchase. It was violently attacked by the Zionists and was reinterpreted in a way favourable to Zionist aspirations in a letter by the prime minister, Ramsay MacDonald, to the president of the Zionist Organization, Dr. Weizmann, on Feb. 13, 1931.

The New Prosperity and the New Unrest.—The wave of anti-Semitism rising in Germany with Hitler's advent to power and its spread to neighbouring countries increased rapidly Jewish immigration to Palestine after 1934. Most of the new immigrants came from Poland and Germany; some brought considerable capital with them, which they invested in new industries and in building developments, especially in Tel Aviv and Haifa. The highest official figure for Jewish immigration in Palestine in any single year was reached in 1935 with 61,854. Tel Aviv grew in population to more than 150,000, and the number of Jews in the whole of Palestine was estimated at 500,000, or a third of the country's total population. Yet it was this growing realization of Zionist hopes which increased the fears and resentment of the Arab population. The unrest which the events of 1936 provoked in the whole near east expressed itself in a revolu-

tion of the Palestine Arabs against Zionism and Great Britain, which assumed serious proportions and surpassed by far the preceding Arab revolts, not only in duration and scope but also in leadership and in the support which it found in all Arab countries, including Egypt.

The outbreak occurred in April 1936. Material damages and loss of human life were great. The British government dispatched in Nov. 1936 a royal commission under the chairmanship of Earl Peel to Palestine which reported in July 1937. In its findings it expressed great sympathy for Zionist aspirations and a warm recognition of the splendid Zionist achievements, but stressed at the same time the genuine character of Arab nationalism and of Arab fears. Palestine was an A mandate like Iraq or Syria and the inhabitants were thus entitled to democratic self-government and felt their expectations frustrated by Zionism. The aspirations of Zionism and of the Arabs being, as the commission declared, mutually exclusive and irreconcilable, it suggested the partition of Palestine into a smaller Jewish state which would comprise the fertile plains along the Mediterranean shore and the land of Galilee, while the Arabs would receive the hills and the deserts of the interior. Both states should be made independent and should enter into treaty relations with Great Britain which would retain Jerusalem and Bethlehem and a strip of land connecting these cities with the sea as a mandated territory. The Zionist congress meeting in Zurich in 1937 accepted, though reluctantly, the principle of partition but expressed the hope for a larger Jewish share. The Arabs opposed the idea of partition and were supported by the whole Arab world and its governments which made the issue of the future of the Palestinian Arabs one of the strongest causes uniting the Arab world.

New violence flared up in the summer of 1937 and was met this time by very strong government measures. The leading Arab committee was outlawed, its members deported or imprisoned, while its recognized leader, the mufti of Jerusalem, fled abroad. Military courts were instituted and vast military operations for the control of the country undertaken. Nevertheless the revolt continued unbroken during 1938 and gained even in intensity, especially after Zionist extremists, the Revisionists, resorted to terrorist acts of retaliation. By the fall of 1938, in spite of all the energetic countermeasures of the government and the large number of Arab victims, great parts of the country were under rebel control, who took over the functions of government; cities like Hebron, Bethlehem and Ramallah were in their hands and all normal traffic throughout the country was suspended. The revolt began only to subside in 1939.

During these years the development of Zionism had been affected in various ways by the events in the country. A heavy crisis in the citrus industry, the spread of the disorders, the political uncertainty, all that combined to create, after a period of great prosperity, a period of relative economic depression. Jewish immigration was reduced to about 12,000 yearly. Nevertheless, partly with the help of the government, the number of Jewish unemployed was kept small. Political attention was centred largely in London and in the United States, where the active sympathy of wide and influential circles was enlisted for Zionism. Meanwhile a commission appointed by the government under the chairmanship of Sir John Woodhead to report on the proposed partition submitted its report in Oct. 1938. Its members could not agree on any definite proposal. Under these circumstances the government declared in Nov. 1938 that it would drop the partition scheme and try to promote an understanding between the Arabs and the Zionists by direct negotiations in London.

By the beginning of 1939 the British government met in London with delegates of the Jewish Agency and of the Arabs. The case of the latter was supported with certain vigour by delegates from Egypt, Iraq and Saudi Arabia who proposed an independent Arab Palestine with full minority rights for the Jewish national home. Thus no common ground between Zionist and Arab aspirations could be found. The proposals made by the government in March 1939 were rejected by both sides. The British government saw itself now forced to suggest a solution of its own in its White Paper of May 17, 1939, which rejected the idea of a Jewish state as contrary to British obligations to the Arabs, and foresaw an independent Palestine which would safeguard the essential interests of Arabs and Jews alike. This independent state should come into existence after a transitional period of ten years. Meanwhile a Jewish immigration of 75,000 should be allowed over the next five years, while after that further Jewish immigration would depend upon Arab agreement. Measures for the regulation of the sale of land were also introduced. These British proposals were rejected by the Arabs and by the Zionists. The Jews in Palestine answered with a general strike and their more radical elements resorted to terrorism. Meanwhile immigration of Jews went on, often illegally. The Zionist congress at Geneva in the summer of 1939 voiced a protest against any restriction of Jewish immigration and against the policy expressed in the statement of May 1939.

World War II, which broke out in Sept. 1939, threw its shadow over Palestine, especially after Italy's entry into the war. As in World War I, the future of Palestine seemed again open for international deliberations, and the attention of Zionist circles was devoted to enlisting public opinion, especially in the United States, for a Zionist solution of the Palestinian and of the Jewish problem.

ZIRCON, a mineral composed of zirconium silicate, sometimes used as a gem stone. It is believed that the name comes from the Arabic *zargun,* and is essentially the same as "jargoon," the name given to certain varieties of zircon. The mineral crystallizes in the tetragonal system, generally in combinations of square prisms and square pyramids (figs. 48 and 49, CRYSTALLOGRAPHY). It is isomorphous with cassiterite and rutile, and like these may form geniculated twins. There is no distinct cleavage, and the mineral breaks with a conchoidal fracture. The hardness is about 7·5. The specific gravity has a very wide range, extending from 4·0 to rather more than 4·7, being thus greater than that of any other gem stone. Rarely colourless, zircon is usually brown or red, sometimes orange, yellow, green or blue, and occasionally parti-coloured or zoned. While common zircon is opaque, the gem varieties are transparent.

The effect of heat on zircon is remarkable. Most coloured zircons, exposed to a high temperature, either change or lose their colour, but this loss is attended by a gain in brilliancy. The "Matura diamonds" of Ceylon are zircons which have been thus artificially decolorized. Certain zircons when heated in a Bunsen-flame glow with an orange incandescence, while others may emit an orange glow when ground on a copper wheel fed with diamond dust. Some zircons when heated undergo remarkable changes in specific gravity and refractive indexes, and the suggestion has been made that there are at least three modifications of zirconium silicate. Zircon is used as a source of zirconia in various preparations, for incandescent gas mantles, etc. It was in this mineral that zirconia was originally discovered by M. H. Klaproth in 1789, while it has been found to contain small amounts of hafnium.

When fit for use as a gem stone it is often known as "noble" or "precious zircon." The red and orange stones are termed hyacinth (*q.v.*) and jacinth, while those of all other colours, as also the colourless transparent zircons, are called jargoons (*q.v.*). The gem varieties are found in detrital deposits, especially in Ceylon, New South Wales, Queensland and Siam, with sapphire, etc.

Zircon is an accessory constituent of many rocks, especially granite, and it forms an important constituent of the zircon-syenite of Norway. Being but little subject to alteration, it is common in secondary deposits, as in auriferous and other sands, occurring usually in small characteristic crystals.

ZIRCONIUM, a metallic chemical element, so called from the identification of its oxide, zirconia, by Klaproth (1789) in the mineral zircon (symbol Zr, atomic number 40, atomic weight 91·2). It was first isolated by J. J. Berzelius in 1824, who heated potassium zirconifluoride, K_2ZrF_6, with potassium and obtained an iron gray powder, which was, however, impure.

Preparation.—Preparation of the pure metal is difficult, owing to the facility with which zirconium combines with hydrogen, oxygen, nitrogen, boron, carbon and silicon and forms alloys with such metals as aluminum and magnesium. Specimens containing more than 99·6% of zirconium were obtained by pressing the impure metal into rods which could be used as electrodes. When an electric arc was struck across such electrodes in an atmosphere of hydrogen or ammonia under 11 mm. pressure, the metal of the positive electrode fused and fell in iron gray drops on the negative electrode. This procedure is allied to the method for obtaining pure zirconium by heating its hydride or nitride *in vacuo.* By electrical heating of zirconium tetrachloride with sodium in an evacuated bomb, ductile metal was produced which when fashioned into rods gave a shiny surface on burnishing and a similar product was obtained in the reduction of zirconia by metallic calcium. Pure zirconium is deposited on a heated tungsten filament when the vapour of zirconium iodide is passed over the filament. Colloidal zirconium has been obtained by dialysis of the reduction product of potassium zirconifluoride with potassium. The melting point of zirconium has been variously given as 1,530° C. and 1,700° C. Its specific gravity is 6·4.

COMPOUNDS

Ferrozirconium (20% Zr), employed as a scavenger in steel castings, is made by heating zirconia and ferric oxide with aluminium in graphite crucibles. The addition of about 0·34% of zirconium to armour plating steel containing 3% of nickel adds to the tensile strength of the metal.

Hydrofluoric acid, even when dilute, hot concentrated sulphuric acid and aqua regia attack zirconium energetically, whereas hydrochloric and nitric acids dissolve it very slightly. It is oxidized on fusion with alkali hydroxides or nitre. At red heat zirconium reduces boric oxide, silica, titania and metallic oxides such as chromic oxide. Its great affinity for oxygen explains the employment of zirconium and its alloys as cleansing agents (scavengers for oxygen and nitrogen) in metallurgy. The commercially important zirconium minerals are (1) baddeleyite (brazilite), the native zirconia found in large quantities in Brazil (São Paulo and Minas Geraes); (2) zirkelite, a mixture of brazilite with zircon silicates, also found in Brazil; (3) zircon, $ZrSiO_4$, mined in Colorado. Following on their discovery of hafnium (*q.v.*) Coster and Hevesy report (1923) that most zirconium ores contain very appreciable quantities of this new element, the amount rising in certain instances to 10 or 20%.

Crystallised zirconia, ZrO_2, is obtained in colourless quadratic crystals by heating zirconium tetrafluoride with boric oxide. Owing to its refractory character and high melting point (given as 2,653±10° C or as 3,000° C) it has been recommended for furnace linings, crucibles, muffles and pyrometer tubes. It has also been used in enamels and in porcelain and opaque glasses. The first incandescent mantles made by A. v. Welsbach consisted principally of zirconia but this oxide is now superseded by thoria and ceria. In the Nernst lamp the incandescent body is chiefly zirconia (85%) with yttrium oxides (15%). Zirconium tetrafluoride, ZrF_4, obtained by heating zirconia with ammonium fluoride in highly refracting crystals, dissolves in water to form the hydrate, $ZrF_4,3H_2O$, and combines with alkali fluorides to yield several types of double fluorides employed in the isolation of the metal by reduction with potassium or sodium. The commonest type is exemplified by the potassium salt, K_2ZrF_6.

Zirconium tetrachloride, prepared by passing chlorine saturated with the vapour of carbon tetrachloride over zirconia heated in a silica tube at 600° C, is a white crystalline sublimate volatilising at 300° C and hydrolysed by water to zirconyl chloride, $ZrOCl_2$, which forms a crystalline octahydrate. Zirconium sulphate, $Zr(SO_4)_2,4H_2O$, forms colourless crystals prepared by dissolving zirconia in concentrated sulphuric acid and diluting slightly with water. It is also regarded as a zirconyl acid sulphate, $[ZrO(SO_4)_2]H_2,3H_2O$.

Other Salts.—Many other zirconyl salts are known including the nitrate which crystallises from aqueous solutions as $ZrO(NO_3)_2,2H_2O$. Zirconium tetra-acetylacetone, $Zr\{CH(CO\cdot CH_3)_2\}_4,10H_2O$, obtained by the interaction of zirconyl nitrate, acetylacetone and aqueous sodium carbonate, crystallises from alcohol or acetylacetone in anhydrous colourless prisms melting at 193–195° C. When zirconium tetrachloride reacts with acetylacetone, benzoylacetone or dibenzoylmethane in anhydrous media, compounds are obtained of the general formula $[ZrDk_3]Cl$, where Dk is the univalent diketone radical (G. T. Morgan and A. R. Bowen, 1924).

Zirconium carbide, ZrC, a hard metallic substance, produced from zirconium and carbon in the electric furnace (H. Moissan and Lengfeld, 1896) is used as an abrasive and for cutting glass. A mixture of this carbide (90%) with ruthenium (10%) has been suggested as a filament for incandescent lamps.

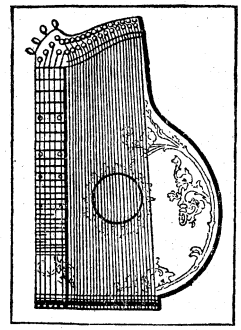
(G. T. M.)

ZITHER, a name applied in modern Germany to the ancient cithara (*q.v.*), to the cittern (*q.v.*), and to a derived instrument which is a kind of psaltery, consisting of a shallow, horizontal sound-chest with strings stretched above it which are plucked and thrummed, with plectrum and fingers, by the performer. (*See* illustration.) Zithers, which are made in various sizes, are the favourite instruments of the peasants in the Swiss and Bavarian highlands, and are sometimes heard also in the concert halls in Germany. The *Streichzither,* or bowed zither, is another variety of the instrument. There are four strings corresponding to those of the violin or viola, but the tone is nasal and glassy.



FROM GROVE, "DICTIONARY OF MUSIC" (MACMILLAN)

THE ZITHER, OR CITHARA, AN ANCIENT MUSICAL INSTRUMENT HAVING 36, 38 OR 42 STRINGS

ZITTAU, a town of Germany, in the extreme south-east of the *Land* of Saxony, on the left bank of the Mandau, near its confluence with the Neisse, by rail 48 mi. E.S.E. of Dresden and at the junction of lines to Reichenberg, Hermsdorf, Görlitz, Oybin and Löbau. Pop. (1939) 38,271. Zittau is of Wendish origin (Chytawa is its Wendish name), and was made a town by Ottocar II. of Bohemia. It was one of the six towns of the Lusatian League (1346), at which period it belonged to Bohemia. It suffered severely in the Hussite wars and in the Thirty Years' War.

ZIWAR, AHMAD PASHA (1864–1945), G.C.M.G. (1925), Egyptian statesman, was born at Alexandria on Nov. 14, 1864, the son of Ziwar Bey. He was educated at the college of Lazarists, Alexandria, and at the Jesuit university of St. Joseph, Beirut. He studied law at Aix-en-Provence, and held office as supreme judge at the Cairo court of appeal from 1899 to 1913, when he became governor of Alexandria. From 1918 to 1924 he held various government offices, being for a time minister of education and also minister plenipotentiary in Rome.

At the end of 1924 Ziwar Pasha formed a ministry in succession to the Zaghlul ministry, which had been compelled to resign in November after the murder of Sir Lee Stack. Ziwar Pasha reestablished good relations with Great Britain and took action to prevent political agitation among young students. He also came to an agreement with the British government on the rights of Egypt in the waters of the Blue Nile. In the elections of February-March, 1925 the parties opposed to Zaghlul obtained a very small majority of 6, and Ziwar Pasha then formed a coalition cabinet, which proved to be short-lived, for the new chamber immediately chose Zaghlul as its president. Ziwar Pasha thereupon immediately resigned and advised the king to dissolve parliament. But the elections had to be postponed owing to the need of framing a new electoral law. Ziwar withdrew his resignation, and continued to direct the government. He spent some months in Europe, and on his return proceeded to reconstruct his cabinet. Ziwar resigned on June 5, 1926. He died Aug. 21, 1945.

ŽIŽKA, JOHN (*c.* 1376–1424), Bohemian general and Hussite leader, was born at Trocnov in Bohemia. He lost an eye in the civil wars under Wenceslaus IV. Connected with the court from his youth, he held the office of chamberlain to Queen Sophia. The Hussite movement first brought him into prominence. When a temporary armistice was concluded between the partisans of King Sigismund and the citizens of Prague, Žižka joined the advanced Hussites at Tabor, helped to organize the new military community and became one of the four "captains of the people" (*hejtmane*) at its head. On receiving an appeal from the citizens of Prague to help against Sigismund, king of the Germans and king of Hungary, who had invaded Bohemia, claiming the crown as the heir of his brother Wenceslaus, the Taborites marched to Prague and on July 14, 1420, largely through Žižka's heroism, repulsed an attack by Sigismund's forces, on their position on the Vitkov hill, where the suburb of Žižkov now stands, forcing Sigismund to raise the siege. On Aug. 22, 1420, the Taborites left Prague and returned to Tabor.

Žižka was now engaged in constant, and invariably successful, warfare with the partisans of Sigismund, particularly with the powerful Romanist, Ulrich of Rosenberg. At the meeting of the Estates of Bohemia and Moravia at Caslav (June 1, 1421), Žižka was elected member for Tabor to the provisional government. He summarily suppressed some disturbances by the

Adamite sect, continued his campaigns against the Romanists and adherents of Sigismund, and, having captured a small castle near Litoměřice (Leitmeritz), retained possession of it—the only reward for his great services that he ever received or claimed. According to Hussite custom, he gave the biblical name of "Chalice" to this new possession, and henceforth adopted the signature of "Žižka of the Chalice." In 1421, while besieging the castle of Rábi, he lost the use of his remaining eye. Though now totally blind, he retained his command, and on Jan. 6, 1422, severely defeated Sigismund at Nebovid, Kutna Hora, and again at Německy Brod (Deutschbrod) on Jan. 10. Early in 1423 internal dissensions among the Hussites led to civil war. Žižka, as leader of the Taborites, defeated the men of Prague and the Utraquist nobles at Hořic on April 27, and when the armistice of Konopist (June 24) was followed by renewed civil war, he once again defeated the Utraquists, under Borek, at Strachov, near Králové Hradec (Aug. 4, 1423).

Žižka now made a brilliant, although unsuccessful attempt to invade Hungary, which was under the rule of his old enemy King Sigismund. In 1424, civil war having again broken out in Bohemia, Žižka decisively defeated the Praguers and Utraquist nobles at Skalic (Jan. 6), and at Malesov (June 7). In September he marched on Prague, but on the 14th of that month peace was concluded between the Hussite parties who agreed to make a combined attack on Moravia, part of which was still held by Sigismund's followers. Žižka was given the command, but before reaching the frontier, he died of the plague at Pribyslav (Oct. 11, 1424).

See Count Lützow, *Bohemia: an Historical Sketch* (1896); Louis Léger, *Jean Žižka* in *"Nouvelles études Slaves," deuxième série* (1886).

ZLATOUST, a town in the Chelyabinsk region of the Russian S.F.S.R., 1,925 ft. above sea level on the Ai, a tributary of the Ufa river, in 55° 10′ N., 59° 40′ E., on the Ufa-Chelyabinsk railway. Pop. (1939), 99,272. The town has smelting works and manufactures machinery; there is a meteorological and magnetic observatory.

ZLOTY, post-war monetary unit of Poland. Following the collapse of the Polish mark, instituted immediately after the World War, the zloty was substituted in 1924. It was then made equivalent to the gold franc, at a parity of 25.22 zlotys to the pound sterling, and was backed partly by gold and gold exchange, and partly by other forms of security. Events soon showed that the new currency had been introduced before the country was ready to support it, and during 1925 and 1926 renewed depreciation set in. In 1927 a second attempt at stabilization was made. A foreign stabilization loan was issued, and the proceeds used to give a gold exchange backing to the new zloty, the value of which was fixed at 43.38 to the £1 sterling; in 1938 it fluctuated between 24¼ and 26¾ to the £1. (*See* CURRENCY.)

ZNAIM: *see* ZNOJMO.

ZNOJMO (*Znaim*), in Moravia, on the Dyje. A settlement is believed to have existed here from prehistoric time. The present town was founded in 1226 on the site of the old capital, destroyed in 1145. Lying at the junction of old granites and tertiary strata Znojmo manufactures clay products and stoneware. It is also famous for its extensive fruit and vegetable farms, which supply bottling factories. Among its old buildings are a 12th century Romanesque castle chapel (the Heiden-Tempel) a 14th century Gothic church and a 15th century town hall with Gothic tower (250 ft.). Population 24,952, mostly German.

ZOBEIR RAHAMA (1830–1913), Egyptian pasha and Sudanese governor, came of the Gemaab section of the Jaalin, and was a member of a family which claims descent from the Koreish tribe through Abbas, uncle of Mohammed. He was the most energetic and intelligent of the Arab ivory and slave traders who about 1860 established themselves on the White Nile and in the Bahr-el-Ghazal. Nominally a subject of Egypt, he raised an army of several thousand well-armed blacks and became a dangerous rival to the Egyptian authorities. At the height of his power Zobeir was visited (1871) by Georg Schweinfurth, who found him "surrounded with a court which was little less than princely in its details" (*Heart of Africa,* vol. ii., chap. xv.). In 1869 an expedition sent from Khartum into the Bahr-el-Ghazal was attacked by Zobeir and completely defeated, its commander being slain. Zobeir represented that he was blameless in this matter, received a "pardon," and was himself appointed governor of the Bahr-el-Ghazal, where he was practically independent. In 1873 he attacked the sultan of Darfur, and the khedive Ismail gave him the rank of bey and sent troops to co-operate. After he had conquered Darfur (1874), Zobeir was made a pasha, but he demanded the governor-generalship of the new province, and went to Cairo in the spring of 1876 to press his title. The Egyptian authorities prevented his return, though he was allowed to go to Constantinople at the outbreak of the Russo-Turkish War. In 1878, however, his son Suleiman, having got possession of the Bahr-el-Ghazal, defied the authority of General Gordon, the new governor-general. Gordon sent Romolo Gessi against Suleiman and his ally Rabah (*q.v.*), who was subdued after an arduous campaign and executed.

During the campaign Zobeir offered, if he were allowed to return to the Sudan, to restore order and to pay a revenue of £25,000 a year to the khedive. Gordon declined this help, and subsequently, for his instigation of the revolt, Zobeir was condemned to death, but the trial was a farce, the sentence was remitted, and he remained at Cairo, now in high favour with the khedival court. In March 1884, Gordon, who had been sent to Khartum to effect, if possible, the relief of the Egyptian garrisons in the Sudan, astonished Europe by requesting that Zobeir, whose son he had overthrown and whose trade he had ruined, should be sent to Khartum as his successor. Zobeir, described by Sir Reginald Wingate, who knew him well, as "a quiet, far-seeing, thoughtful man of iron will—a born ruler of men" (*Mahdiism and the Egyptian Sudan,* book v.), might have been able to stem the mahdist movement. But to reinstate the notorious slave-dealer was regarded in London as too perilous an expedient, even in the extreme circumstances then existing, although Colonel Stewart (Gordon's companion in Khartum), Sir Evelyn Baring and Nubar Pasha in Cairo, and Queen Victoria and Mr. Gladstone, all favoured such a course. In March 1885 Zobeir was arrested in Cairo by order of the British government for treasonable correspondence with the mahdi and other enemies of Egypt, and was interned at Gibraltar. In August 1887 he was allowed to return to Cairo, and after the reconquest of the Sudan was permitted (1899) to settle in his native country. He established himself on his estates at Geili, some 30 m. N. of Khartum, where he died on Jan. 5, 1913.

See GORDON, CHARLES GEORGE, and the authorities there cited.

ZODIAC, in astronomy and astrology, a zone of the heavens within which lie the paths of the sun, moon and principal planets (ὁ ζωδιακὸς κύκλος from ζῴδιον "a little animal"). It is bounded by two circles equidistant from the ecliptic, about 18 degrees apart; and it is divided into 12 signs, and marked by 12 constellations. These 12 constellations, with the symbols of the signs which correspond to them, are as follows:—

Aries, the Ram	♈	Libra, the Balance	♎
Taurus, the Bull	♉	Scorpio, the Scorpion	♏
Gemini, the Twins	♊	Sagittarius, the Archer	♐
Cancer, the Crab	♋	Capricornus, the Goat	♑
Leo, the Lion	♌	Aquarius, the Water-carrier	♒
Virgo, the Virgin	♍	Pisces, the Fishes	♓

In the technical sense of the word the 12 "signs" are geometrical divisions 30 degrees in extent counting from the position of the sun at the vernal equinox. In the time of Hipparchus the signs corresponded fairly closely with the constellations; that is to say, the first sign (called Aries) corresponded with the constellation Aries. Owing to precession there is now a discrepancy amounting to the breadth of a whole sign, so that the sign Aries is occupied by the constellation Pisces. (*See* CONSTELLATION.)

ZODIACAL LIGHT, a faint illumination of the sky, surrounding the sun and elongated in the direction of the ecliptic on each side of the sun. It is lenticular in form, brightest near the sun, and shades off by imperceptible gradations, generally becoming invisible at a distance of 90° from the sun. Until a recent

time it was never observed except in or near the zodiac; hence its designation. The most favourable time for evening observation in the northern hemisphere is during the months of February and March. In the tropics, where the ecliptic is nearly perpendicular to the horizon, it may be seen after the end of twilight on every clear evening, and before twilight on every clear morning, unless blotted out by moonlight. It then presents a nearly vertical wedge-shaped form, the base of which extends 15° or 20° on each side of the point at which the ecliptic intersects the horizon. The point of the wedge is quite indefinite, the extremely diffuse light gradually fading into invisibility at a height which may range from 50° to 70° or even more, according to the keenness of the observer's vision.

It is clear that the light proceeds from a region surrounding the sun, lenticular in form, the axis of the lens being nearly perpendicular to the ecliptic, while the circumference extends at least to the orbit of the earth. The hypothesis which best explains all the phenomena is that the light is that of the sun reflected from an extremely tenuous cloud of particles having the form and extent described, and becoming more and more tenuous as the earth's orbit is approached until, immediately outside the orbit, it fades into complete invisibility. It has been shown by Fath that the spectrum is identical with that of sunlight.

Intimately connected with the zodiacal light is the *Gegenschein,* or counter-glow, a faint illumination of the sky in the region opposite the sun, which may generally be seen by a trained eye when all the conditions are favourable. The Milky Way renders it invisible during the months of June, July, December and January. Its light is so faint and diffuse that it is impossible to assign dimensions to it, except to say it covers a region of several degrees in extent. Barnard, the most successful observer, assigns diameters of 5° or even 10° or more. The explanation is uncertain.

ZOFFANY, JOHANN (1733–1810), British painter, whose father was architect to the prince of Thurn and Taxis, was born in Frankfort-on-Main. He ran away from home at the age of 13 and went to Rome, where he studied art for nearly 12 years. In 1758 he left for England, and after undergoing some hardships was brought into fashion by royal patronage, and in 1769 was included among the foundation members of the Royal Academy. He went to Florence in 1772 with an introduction from George III. to the grand duke of Tuscany, and remained until 1779. He lived (1783 to 1790) in India, executing some of his best-known paintings; but the last 20 years of his life were spent in England. He died in 1810 and was buried in Kew churchyard.

ZOG 1, Ahmed (1895–), King of the Albanians, was head of the Zogolli, one of the four ruling families of the Mati district and was educated at a military school at Monastir and in Constantinople. He first distinguished himself as a supporter of the prince of Wied in 1914. During the World War he fought for the Austrians. He became minister of the interior (Jan.–Nov. 1920), and organized resistance to the Yugoslav incursions during the autumn. He was commander-in-chief of the national forces under the "Sacred Union" cabinet (Oct.–Dec. 1921), and again distinguished himself against the Yugoslavs. As minister of the interior in Djafer Ypi's cabinet (Dec. 1921–Dec. 1922), he suppressed a serious insurrectionary movement in March 1922, and disarmed the lowlanders. Becoming prime minister, Dec. 1922, he governed with ability, pursuing a sound anti-irredentist and constructive policy. Towards the end of 1923 he was accused by the Democratic party of obstructing various progressive and agrarian reforms. Following an attempt upon his life he resigned in Feb. 1924, but his influence remained. A revolt against him and his colleagues took place in June, and he sought refuge in Yugoslavia. But skilfully turning to his advantage Yugoslavian policy, he returned to Albania in Dec. 1924 and ousted his successor, Archbishop Fan Noli. His election as president of the Albanian republic on Feb. 1, 1925, ushered in a period of internal tranquillity. He was proclaimed king at Tirana on Sept. 1, 1928. On April 27, 1938, he married Countess Geraldine Apponyi of Hungary; a son being born to them on April 5, 1939. Three days later, on the Italian occupation of Albania, the King and Queen became exiles. (*See* Albania.) (J. Sw.)

ZOÏLUS (*c.* 400–320 B.C.), Greek grammarian of Amphipolis in Macedonia. Zoïlus appears to have been at one time a follower of Isocrates, but subsequently a pupil of Polycrates. Zoïlus was chiefly known for the acerbity of his attacks on Homer (which gained him the name of Homeromastix, "scourge of Homer"), chiefly directed against the fabulous element in the Homeric poems. Zoïlus also wrote against Isocrates and Plato, who had attacked the style of Lysias of which he approved. The name Zoïlus came to be generally used of a spiteful critic.

See U. Friedländer, *De Zoilo aliisque Homeri Obtrectatoribus* (Königsberg, 1895); J. E. Sandys, *History of Classical Scholarship* (2nd ed. 1906).

ZOISITE (named after Baron Zois who first observed it), a rock-forming mineral of the composition of $HCa_2Al_3Si_3O_{13}$, crystallizing in the rhombic system. Crystals are usually prismatic, deeply striated parallel to their length and have a perfect 010 cleavage. Two varieties are optically distinguishable; in α-zoisite the plane of the optic axes is parallel to the cleavage (010), while in β-zoisite it is normal to this plane. The resemblance to the monoclinic clinozoisite of the same chemical composition (*see* Epidote) is revealed when the crystallographic orientation of zoisite is adjusted so that the plane of cleavage is basal (001) and the zone of elongation and striation the *b* axis. The colour of the mineral is white or grey, but a manganiferous variety (thulite) is pink and pleochroic. The hardness is 6·5 and the sp.gr. 3·3.

Zoisite is characteristically a product of dynamic metamorphism and is an essential constituent of saussurite, the zoisite of this aggregate being derived from the anorthite molecule of plagioclase. It is chiefly developed in crystalline schists.

Thulite occurs with blue vesuvianite at Telemarken in Norway and with withamite gives the red colour to the well known *porfido rosso antico* or hornblende-porphyrite of Djebel Dokhan in Egypt. Zoisite has not been prepared synthetically. (C. E. T.)

ZOLA, ÉMILE ÉDOUARD CHARLES ANTOINE (1840–1902), French novelist, was born in Paris on April 2, 1840, his father being an engineer, part Italian and part Greek, and his mother a Frenchwoman. The father seems to have been an energetic, visionary man, who, dying while his only son was a little lad, left to his family no better provision than a lawsuit against the municipality of the town of Aix. It was at Aix, which figures as Plassans in so many of his novels, that the boy received the first part of his education. Thence he proceeded, in 1858, to Paris. His first book, *Contes à Ninon,* appeared on Oct. 24, 1864, and attracted some attention, and in Jan. 1866 he determined to abandon clerking and take to literature. Vigorous and aggressive as a critic, his articles on literature and art in Villemessant's paper *L'Événement* created a good deal of interest. So did the gruesome but powerful novel, *Thérèse Raquin* (1867). Meanwhile, with characteristic energy, Zola was projecting something more important: the creation of a world of his own, like that of Balzac's *Comédie Humaine*—the history of a family in its various ramifications during the Second Empire. The history of this family, the Rougon-Macquart, was to be told in a series of novels containing a scientific study of heredity—science was always Zola's *ignis fatuus*—and a picture of French life and society. The first novel of the series, *La Fortune des Rougon,* appeared in book form at the end of 1871. It was followed by *La Curée* (1874), *Le Ventre de Paris* (1874), *La Conquête de Plassans* (1875), *La Faute de l'Abbé Mouret* (1875), *Son Excellence Eugène Rougon* (1876)—all books unquestionably of immense ability, and in a measure successful, but not great popular successes. Then came *L'Assommoir* (1878?), the epic of drink, and the author's fortune was made. Edition followed edition. He became the most discussed, the most read, the most bought novelist in France—the sale of *L'Assommoir* being even exceeded by that of *Nana* (1880) and *La Débâcle* (1892). From the *Fortune des Rougon* to the *Docteur Pascal* (1893) there are some 20 novels in the *Rougon-Macquart* series, the second half of which includes the powerful novels *Germinal* (1885) and *La Terre* (1888). In 1888 Zola departed from his usual vein in the idyllic story of *Le Rêve.* Zola also wrote a series of three romances on cities, *Lourdes, Rome, Paris* (1894–98), novels on the "gospels"

of population (*Fécondité*) and work (*Travail*), a volume of plays, and several volumes of criticism.

Zola played a very important part in the Dreyfus affair, which convulsed French politics and social life at the end of the 19th century. At an early stage he came to the conclusion that Dreyfus was the innocent victim of a nefarious conspiracy, and on Jan. 13, 1898, with his usual intrepidity, he published in the *Aurore* newspaper, in the form of a letter beginning with the words *J'accuse,* a terrible denunciation of all those who had had a hand in hounding down that unfortunate officer.

Zola's object was a prosecution for libel, and a judicial inquiry into the whole *affaire,* and at the trial, which took place in Paris in February, a fierce flood of light was thrown on the case. The chiefs of the army put forth all their power, and Zola was condemned. He appealed. On April 2, the Cour de Cassation quashed the proceedings.

A second trial took place at Versailles, on July 18, and without awaiting the result Zola, by the advice of his counsel and friends, and for reasons of legal strategy, abruptly left France and took refuge in England. Here he remained in hiding, writing *Fécondité,* until June 4, 1899, when, immediately on hearing that there was to be a revision of the first Dreyfus trial, he returned to Paris.

On the morning of Sept. 29, 1902, Zola was found dead in the bedroom of his Paris house, having been accidentally asphyxiated by the fumes from a defective flue. He received a public funeral, at which Captain Dreyfus was present. Anatole France delivered an impassioned oration at the grave. At the time of his death Zola had just completed a novel, *Vérité,* dealing with the incidents of the Dreyfus trial. A sequel, *Justice,* had been planned, but not executed.

Zola's literary position would have more than qualified him for the French academy. He was several times a candidate in vain. (F. T. M.)

ZONARAS, JOANNES (JOHN), Byzantine chronicler and theologian, flourished at Constantinople in the 12th century. Under Alexius I Comnenus he held important official positions, but in the succeeding reign he retired to Hagia Glykeria (one of the princes' islands), where he reluctantly yielded to the pressure of his friends to compose a profane history. This work, Ἐπιτομὴ Ἱστοριῶν (compendium of history), in 18 books, extends from the creation of the world to the death of Alexius (1118). Zonaras is chiefly valuable for preserving in his work the first 21 books of Dio Cassius (Zon. 7–8).

Complete edition in Migne, *Patrologia Graeca,* cxxxiv, cxxxv, cxxxvii. Translation in Cary's *Dio Cassius,* Loeb Classical Library.

ZONE, EQUISIGNAL, a term in radio denoting the region in which the two distinctive signals from an equisignal radio beacon (*q.v.*) are received with equal intensity.

ZONING. The zoning of cities has had considerable influence on their architecture and on the preservation of their amenity. As practised in modern times it is a new movement and is still in the experimental stage.

Zoning in Europe.—What has come to be called zoning in English-speaking countries had its first inspiration and derived its name from the building regulations applied in Central Europe before 1909. After 1875 German and Swedish cities applied zoning regulations to the zones around their built areas, with a view to controlling the heights and densities of buildings in town extensions. The effect of the German laws, and of the fairly rigid control exercised under them, has been to procure a greater spaciousness and uniformity of development than would have occurred under ordinary building regulations.

When the Town Planning act was passed in England in 1909, it had for its general object the control of the development of land likely to be used for building purposes. In so far as it provided for regulation of heights, densities and uses of buildings it related primarily and almost solely to entirely new building development. The fact that it is so limited has prevented it from being an effective instrument in procuring architectural control. But part of its object is to provide such control over new developments. Section 59 (2) in the original act of 1909 was as follows:

"Property shall not be deemed to be injuriously affected by reason of the making of any provisions inserted in a town planning scheme, which, with a view to securing the amenity of the area included in the scheme or any part thereof, prescribe the space about buildings or limit the number of buildings to be erected, or prescribe the height or character of buildings, and which the Ministry of Health, having regard to the nature and situation of the land affected by the provisions, consider reasonable for the purpose."

It is noteworthy that the purpose for which the restrictions in an English scheme are imposed is to secure the "amenity of the area." For the reason given, the law has not influenced the redevelopment of built-upon areas. Being primarily intended to regulate residential buildings it has had little effect also on the architecture of other buildings. It has introduced into England a spacious type of development for the cottages of the working classes. On the whole, it has improved cottage architecture and introduced a better arrangement and grouping of buildings.

In town planning schemes public authorities may take power to approve or disapprove the elevation of, and the materials to be used in, buildings. For the purpose of exercising this power the authority must constitute a special advisory committee of those members of which one shall be an architect nominated by the Royal Institute of British Architects.

Zoning in the United States.—Contrary to what has happened in England zoning in the United States has been too limited in its application to undeveloped areas and has been chiefly applied to areas already built upon.

In New York zoning has exercised a greater influence on architecture than in any other city. New York was the first city in the western continent to impose zoning regulations. Its Zoning resolution was passed in 1916 and had for its object the restriction of the height and bulk of buildings and the regulation of their uses. It did not directly attack the problem of density, except by restricting height and bulk.

New York was zoned just when the steel frame and the elevator had begun to have a profound influence on building and architecture (*q.v.*). After the passing of the act enormous changes took place in the city, and an extensive rebuilding program was carried out.

The zoning law in New York is intended to relieve street congestion, for, other things being equal, it is obvious that such congestion is directly proportionate to the bulk of the buildings flanking the street. The Paris law limits the straight vertical height to 20 metres; above that, additional storys must remain within the arc of a circle of fixed radius. The London regulations permit of 80 ft. vertical height and two supplementary storys which must remain behind a sloping line of 75 deg. from the horizontal. In New York the vertical height is now determined by the width of the street, but varies according to the "zone" or district in which the given property is situated. These districts are classified as follows: "One-time" districts, "one-and-one-half-time" districts, "two-time" districts and "two-and-one-half-time" districts. That is to say, the straight vertical height may be equal to the width of the street in residence zones; it may be one-and-one-half times the width of the street in certain residence and business zones; twice the width in the principal business centres and two-and-one-half times in the Wall street financial section. For the purpose of the law, no street is considered less than 50 ft. or more than 100 ft. wide. Additional storys above the vertical

height must remain back of a line drawn from the centre of the street through a point on the top front of the vertical height.

The salient feature of New York is its towers, and it was considered wise, in framing the zoning law, to permit the erection of a tower, which may rise to an indefinite height (limited only by structural possibilities and economic conditions), upon 25% of the total lot area. This has resulted in a very surprising and interesting form of architecture (*q.v.*). In Paris certain buildings of a monumental nature, either religious or governmental, may exceed the height limit. In London, towers purely for architectural embellishment but not for human occupancy, may pass the legal height. In New York no restriction is made as to occupancy of the tower provided that the building remains within the given "envelope." Furthermore, the so-called "dormer" permit allows certain portions of the front of each building to rise slightly in excess of the maximum vertical height to give variety of outline. Above this the buildings are usually stepped back, forming a pyramidal series of terraces which vie with the storied magnificence of the hanging gardens of Babylon. The law has produced two other interesting results: first, the virtual elimination of interior light courts, these being cut in the side in order to preserve a base for the central tower; second, the tendency to assemble larger and larger plottage so that the 25% tower will be large enough to warrant construction of a great number of tower stories.

The example of New York has been followed in hundreds of U.S. cities, where no part of city planning has been so popular as zoning. No effect of zoning has impressed itself on the public consciousness more than its effect on the architectural treatment of buildings. The important needs in connection with the further development of zoning, as a means of promoting art and amenity in connection with city building, whether directly owing to extended power under restrictive legislation, or indirectly by further use of existing powers, are: the inclusion of zoning as part of comprehensive city plans so that it will deal constructively with building expansion and reconstruction of complete urban areas comprising all parts of a city or a region; the further extension of zoning in regard to restriction of density, parallel with further strengthening of provisions in regard to heights and uses, so as to secure more light and air in buildings, a better display of buildings and less congestion on adjacent streets than at present. Further restriction on height should be based on the principle that the primary need is to obtain adequate spaces about buildings of all heights, and not to obtain lower buildings as an object in itself. (*See* also TOWN AND CITY PLANNING.)

ZOOLOGICAL COLLECTING. The techniques of zoological collecting and preparation or preservation of specimens differ radically for the various groups of animals, and special directions, and special apparatus, may be needed. The means of collecting marine animals fall into the province of oceanography (*see* OCEAN AND OCEANOGRAPHY), and are dealt with in a separate section below. Fresh water collecting, in the interests of limnology, may require many of the oceanographic techniques. The study of the animal life of the high seas and of the deep sea requires elaborate apparatus and an ocean-going vessel, and thus falls into the province of organized scientific expeditions or of special institutes.

The preservation of invertebrate animals requires so great a variety of techniques that the reader must be referred to the bibliography at the end of this article. This applies also to the collecting of insects, for which excellent and inexpensive pamphlets of directions are available. Insect collecting forms one of the best of introductions to natural science.

VERTEBRATES

In the pioneer 18th century zoological collecting was so much focused on birds and mammals and large reptiles that the early manuals of taxidermy all include the collection of museum specimens of fishes and insects as a matter of course, and refer to the preparation of mammals and birds as mounted specimens as a part of museum collecting. The divergence between the collection of specimens for study and the preparation of museum exhibits had its origin in the reorganization of the British museum collections in the 1880s under the direction of William Flower. The exhibition series was segregated in halls open to the public from the reserve material intended for study and research, properly referred to as the study series or as the reference collection. The reference collection, not on public exhibition, being the principal means of research by the scientific staff, became the special charge of the curators. If the curator's interest lay in education, the reference collection was a necessary accessory to the preparation of exhibits. If his interest lay in the increase of knowledge in systematic zoology, the reference collection would become his principal if not his exclusive concern. In the large modern museums, the reference collection in the biological departments is vastly greater than the exhibition series.

The nature of the museum specimens used in the study of birds and mammals brings their preparation more directly into the field of taxidermy, and the museum taxidermist may be charged with collecting such specimens as well as specimens required for exhibition. It will fall to the province of museum taxidermists to aid in the preparation, repair and conservation of the bird and mammal skins preserved for study.

It is especially desirable to call the attention of young people who are attracted by taxidermy to the preparation of study specimens as an alternative. Taxidermy *per se* leads into a limited field requiring artistic talent for success. Collecting of study specimens of birds and mammals leads into scientific studies, and is an excellent preparation and accessory for a career in any field of biology, whether in research or in teaching.

The accumulation of private collections of bird skins is discouraged by the necessary protection of song birds from indiscriminate and wanton killing. Certain birds, however, like the English sparrow and starling and the various game birds, which can be hunted under legal restrictions, serve excellently for the amateur who wishes to learn to make a study skin. The use of borax as a preservative avoids the necessity of using the dangerous white arsenic. The essential requirement for such skins is accuracy of record—the locality, date, collector's name, colours of eye, bill, any bare skin, feet, breeding condition and any other notes that contribute to the natural history of the species. The essential data are placed on a label attached to the skin; a good collector will keep a catalogue record of his specimens with additional notes. A considerable series of specimens of each species of bird is a necessity, as the plumages of male and female vary with age and with the season. Nestlings, if collected, should be preserved in alcohol; they should never be collected unless positively identified as to species.

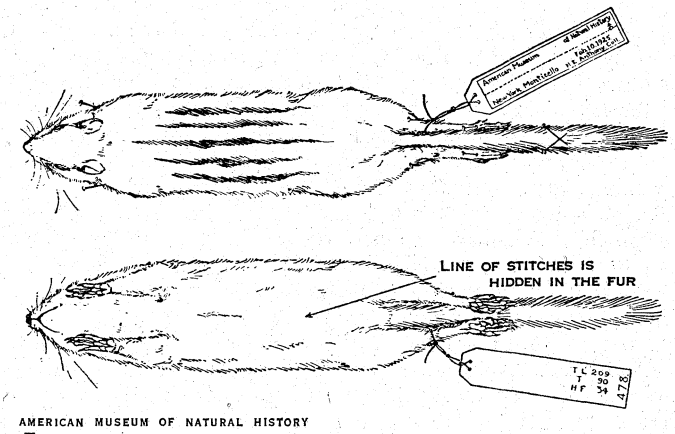
AMERICAN MUSEUM OF NATURAL HISTORY

FIG. 1.—STUDY SKIN OF A BIRD, PREPARED FOR A MUSEUM COLLECTION

Birds' eggs were formerly greatly in vogue for private collections. All migratory birds in the United States and Canada are now strictly protected by state and federal laws against the collecting of their eggs, which may be taken only by special permit for scientific purposes. Even with such permits, egg collecting is to be discouraged, since large collections exist in almost every museum, and additional specimens are not required for scientific studies.

No restrictions apply to the collecting of small mammals such as mice, gophers, moles and shrews; and the larger game mammals and the fur bearers can also be collected during the legal season for hunting them, which varies from state to state. The study specimen of a mammal includes the cleaned skull with the prepared study skin, and a system of numbered tags required to identify the associated skulls and skins properly. In the study of mammals, specimens preserved in alcohol or formalin may supplement the dry skin and skull, and such specimens are especially important in the bat group, in which the peculiar skin characters of

the head and wing membranes are largely lost in drying. Juvenile specimens, especially the newborn young, should be similarly preserved rather than skinned. Skeletons also form a desirable supplement for any adequate study of a species of mammal, and are essential for the use of the taxidermist in the preparation of a mounted specimen. Thus an adequate representation of a single species of mammal, as for birds, will require a considerable series of specimens. For small mammals and birds, powdered borax, liberally applied to the inside of the skin while skinning, will be sufficient as a preservative.



AMERICAN MUSEUM OF NATURAL HISTORY

FIG. 2.—FINISHED STUDY SKIN OF A SMALL MAMMAL FROM ABOVE AND BELOW

The collecting of mammals involves a great variety of techniques of hunting and trapping. For all small forms the ordinary spring mousetrap is the most essential equipment, but it is essential to use the over-size "museum special," as the ordinary trap is quite certain to strike the animal across the skull and ruin this most essential part of the specimen. Shooting, snaring, capture in live traps, pitfalls and other methods, limited only by the ingenuity of the hunter, will be required for the collection of mammals of different sizes and varying habits.

Fishes, amphibians and reptiles collected for study, except for skeletal material (and except for very large specimens), are preserved by placing the entire animal in alcohol or formalin. For permanent storage it is essential that all formalin specimens be transferred to alcohol. Labelling may consist of numbered tags of metal (pure tin or aluminum), of special waterproof paper, or of parchment. Such numbers must be accompanied by a carefully kept catalogue for the corresponding information about locality, etc. Field labels written with soft pencil on slips of bond paper, if wrapped with the specimens so that they cannot rub, are satisfactory. The principal attention required for good preservation of such specimens is that the body cavity and thick muscular parts of the body must either be injected with the preservative, with a large hypodermic needle, or must be opened by means of ample cuts to permit the fluid to enter. Specimens immersed in preservative must be examined for the first few days until they are firm; any portion that remains soft will require further opening or transfer to fresh preservative.

Skulls and skeletons of such large creatures as crocodiles and alligators, large turtles and of large reptiles in general are especially desired by museums. For field collecting such material needs only to have most of the flesh removed, the brains extracted from the skull, and the roughed out skeleton or skull dried. Protection from flies and from offensive decay is accomplished by rapid drying, but in wet climates thorough soaking in borax solution or rubbing with dry borax, drying over fire and packing into sealed containers may be essential. Paper labels for such material must be protected from rubbing.

Persons interested in natural history, especially if travelling in foreign countries, or stationed in a foreign region, should correspond with any one of the larger museums about animals of special interest to be looked for on their routes or near their stations. Such letters usually receive courteous and even enthusiastic attention; the unpacking of small incoming lots of material from miscellaneous sources forms one of the attractive elements of museum work.

MARINE COLLECTING

Marine collecting presents a number of special problems because of the vastness of the sea, the great depth at which many of the animals live and the difficulty of caring properly for many of the delicate forms while in the field. The marine collecting area comprises about 71% of the earth's surface, and most parts can be reached only by sea-going vessels. About 77% of the bottom area is covered by water over 9,800 ft. (nearly 2 mi.) in depth, and the greatest depth is over 6 mi. Animal life is found not only on the bottom but also to some extent throughout the entire water mass, hence collecting on the high seas must be adapted to all of these circumstances, and it is therefore an undertaking for specially organized and equipped expeditions. However, a most important part of marine collecting can be done with simple equipment in the intertidal zone or in shallow coastal waters. Fortunately, also, it is here that the greatest abundance and variety of plant and animal life is produced. The great depths are relatively barren.

Early systematic collecting of bottom (benthic) animals was limited to the intertidal and shallow water zones and it was believed (E. Forbes, 1843) that no animals lived at depths greater than about 300 to 700 metres. Before this time some collections had been reported by Sir John Ross (1819) from depths of 1,800 metres, but these were discredited as being uncertain. However, in 1860 undisputed collections of marine animals were made from a submarine cable which, in being repaired, was raised from a depth of 2,160 m. where the animals had attached and grown. Thus, interest was stimulated in collecting and exploring the great depths to determine what mysteries of life might lie hidden in this forbidding environment and to learn the factors controlling life in the sea. Likewise, the vast abundance and importance of the planktonic or floating life was not realized until about 1846 when J. Müller is said to have used for the first time a fine-meshed cloth net drawn through the water as a collecting device.

The earliest large-scale marine collecting expedition was that of H.M.S. "Challenger" 1873–76, during which time vast areas of the Atlantic and Pacific were explored. Since then much marine collecting has been done by research ships of various nations, and animal life has been collected and studied from many positions in all oceans, but vast coastal and oceanic areas are still unexplored by collectors. In all of these expeditions the collecting has usually not been an end in itself but rather a necessary part in gathering data of importance to fisheries or to general marine biology (*q.v.*).

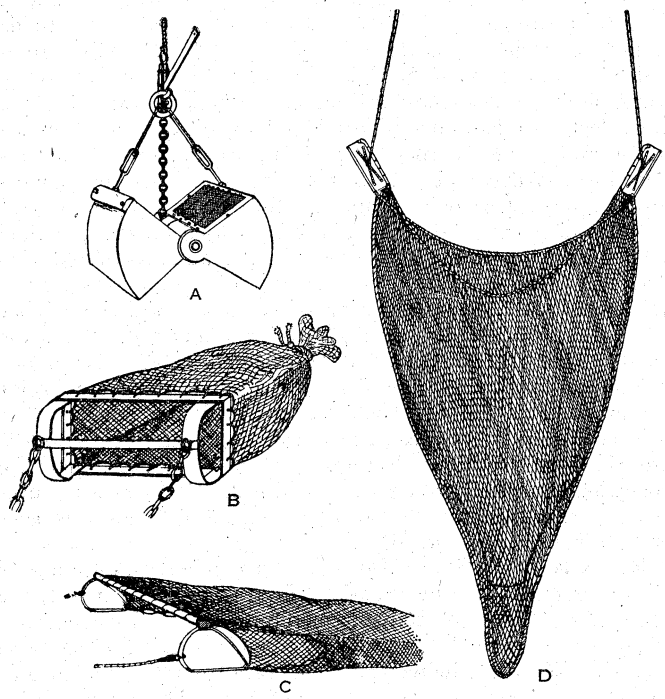
Methods and Gear Used in Collecting.—Collecting is either for qualitative or quantitative purposes. The first is the simpler because the objective is merely to obtain the organisms, whereas in the second it is necessary to know as nearly as possible how many species or individuals were taken from a definite area of the bottom or from a known volume of water. This requires careful collecting in order that the numbers can be correlated with other ecological data bearing on the distribution and biology of the organisms.

Intertidal and shallow-water collecting for bottom-living animals requires only simple equipment. Where the bottom is composed of mud and sand, a long-handled shovel or rake is needed for digging out the burrowing forms and a screen for sieving out the smaller animals from the loose material. A mixture of mud and sand usually yields more animals than does a beach of pure sand. The latter, however, is not without its characteristic type

of life and sometimes in surprising numbers, especially certain worms (*Thoracophalia,* for example), the little sand crabs (*Emerita,* etc.), the wedge shells *Donax* and, at high-tide level, the sand hoppers. The animals that are found on mud-sand bottoms are numerous and varied. Commonly they are of the burrowing types, such as clams and worms, and their presence is revealed to the collector by little characteristic mounds, holes or markings on the surface of the mud. The best collecting for variety of forms is, however, on rocky or coral reefs. Here a strong chisel-edged bar is useful for prying loose limpets, mussels, sea stars and many other forms that are attached to the rocks, or for breaking up old coral and shell encrustations or for rolling over rocks to expose retreats that usually teem with life. The tide pools left by the receding tide yield many additional forms including nudibranchs, fishes and cephalopods. The attached algal plants should be searched for the many animals that attach to or hide among their fronds. Eel grass (*Zostera*) beds in shallow water are favorite collecting places. Here attached to or living among the leaves can be found an abundance of hydroids, bryozoa, skeleton shrimp and such characteristically eel-grass inhabitants as the sea anemone *Epiactis,* and the sessile jellyfish *Haliclystus.* Dip nets or hand seines drawn through the disturbed eel grass are sure to capture a variety of small fish and invertebrates.

Among the more profitable of collecting places are the submerged portions of wharf piles or floats where fouling organisms and the animals associated with them can be scraped off with rakes or dip nets. Here the wood too should be examined for the destructive wood-boring forms such as the shipworm *Teredo* and the gribble *Limnoria.*

Shallow-water benthic animals are often cast up on the beach by action of waves during storms, and sometimes also pelagic forms normally found only on the high seas are drifted ashore in this way. The collector takes advantage of this and also watches



FROM SVERDRUP, JOHNSON, AND FLEMING, "THE OCEANS" (PRENTICE-HALL)

FIG. 3.—GEAR FOR BIOLOGICAL COLLECTING: (A) PETERSEN GRAB. (B) DREDGE. (C) BEAM TRAWL. (D) OTTER TRAWL

for the many small animals that he can find among the rootlike holdfasts of deep-growing seaweeds that have been torn loose from the bottom and drifted onto the beach.

Deep-water collecting for benthic animals requires special equipment operated from boats provided with winches for reeling in line. The standard equipment includes dredges or trawls (fig. 3, B,C,D). The dredge consists of a strong iron frame to which a bag or net of strong web or wire screen such as hardware cloth is attached. This bag retains the animals that are scooped up from the bottom by the edge of the dredge frame as it is dragged forward over the bottom by a long wire cable or rope operated from a winch aboard a slowly moving ship. The edge of the frame may be constructed with flares or teeth to dig into the bottom. Usually the frame is rectangular and is about 2 to 5 ft. in length, depending upon the size of boat and winch facilities. The trawl, a modification of the dredge, is designed to fish free in the water or to skim over the bottom rather than to dig into it. There are three main types: the beam, the Agassiz and the otter trawls. In the beam trawl the mouth of the net is held open by a beam of iron or wood so arranged as to glide over the bottom on sledlike runners, while a lead line holds the lower lip of the net in contact with the bottom. The Agassiz trawl is a modification of the beam trawl. In it the mouth of the net has both upper and lower lead lines, hence it fishes properly no matter which side of the trawl is applied to the bottom. For scientific collecting a 10 or 15-ft. beam is ample but for commercial fishing the beam may be much longer. In the otter trawl the mouth of the net is held open by means of otter boards so arranged that they are forced apart by the water when being towed forward by a line attached to each.

The trawls are more efficient than are the dredges for collecting active animals such as fish or shrimps. They are not practicable for collecting on rocky bottoms. Dredging and trawling in very deep water is a laborious operation, sometimes requiring as much as 12 hours for one haul at a depth of 3000 fathoms. Often only a few animals are caught at these depths but these are of exceptional interest because of their strange habitat.

Dredges and trawls are most useful for qualitative collecting because it is difficult to know accurately how much bottom has been covered in sampling. For quantitative collecting of small sessile animals in shallow water the Petersen grab is used (fig. 3, A). It consists of hinged heavy iron jaws that are held open by a mechanism that is released when the instrument strikes the bottom. Upon being lifted from the bottom the jaws close over a definite area (usually 0.1 sq. metre) of the bottom, scooping up the bottom material together with the contained animals.

The collecting of pelagic animals may be considered in two parts: (1) the floating animals (zooplankton) and (2) the strong-swimming animals (nekton).

The zooplankton, composed mainly of such feeble swimmers as copepods, euphausiids, chaetognaths, various larvae, and the dinoflagellates, is collected in various ways all of which utilize some type of screening device, such as the plankton tow net. In simple form the tow net (fig. 4) consists of a ring to which is attached a conical bag of gauze, usually of silk bolting cloth which is so woven that the screening apertures are uniform and not readily changed in size. When the net is drawn through the water, the organisms are screened out and concentrated in a bottle or jar fastened into the apex of the net. There is a great range in size of plankton organisms, hence the fineness of the net used is determined by the minimum size of the animals to be caught. For general zooplankton collecting a No. 8 type bolting cloth with screening apertures of about 0.205 mm. is practicable, though many of the smallest organisms escape. Some protozoan forms, for example the smaller ciliates and dinoflagellates, pass through the finest nets. To obtain a quantitative estimate of these small members of the plankton, it is necessary to collect them by means of centrifuging a known quantity of sea water.

For collecting planktonic animals from subsurface levels, closing nets are used. These can be lowered to the desired depth and there opened by means of a special mechanism operated by a "messenger" which glides down the towing wire. When the tow is completed the net can again be similarly closed to prevent any further fishing while it is being hoisted to the surface.

Some quantitative nets are provided with a small cyclometer which records the amount of water that has flowed through the net. George H. Clark and D. F. Bumpus (1940) developed a plankton sampler of this type which can be used in series, thus collecting plankton from several water strata simultaneously.

A. C. Hardy (1939) devised a continuous plankton recorder which collects quantitatively at a given depth (10 m.) along the route of a ship back of which the recorder may be towed for many miles.

For collecting fishes and other nektonic animals, nets, seines, hooks and harpoons are used, but these are best considered under fisheries (*q.v.*), nets and seining.

The use of lights for attracting and collecting swimming animals at night sometimes yields many forms not readily collected during the daytime. Even some bottom living forms may swim to the surface where they can be scooped up with hand nets.

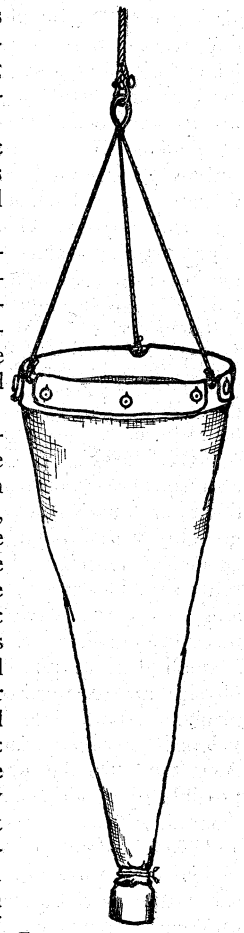


FIG. 4.—PLANKTON TOW NET

Care of Material Collected.—A definite part of the task of collecting is the care of the material while in the field or en route to its destination in the laboratory, museum, or aquarium. Unless means are available for a steady or frequent change of fresh sea water in which to keep the animals, most of them soon die. Benthic animals when crowded into a bucket, as is often done, usually survive best if covered with wet seaweed rather than with water which soon becomes warm and exhausted of its oxygen or charged with metabolic wastes. If the animals are of a flabby type and need the support of water, a quantity of sea lettuce (*Ulva*) kept in the bucket with them is of aid. Intertidal and tidepool animals are the hardiest and should be collected for aquarium specimens in preference to the more delicate forms of deep water. On expeditions or on long collecting trips most or all of the material will need to be preserved in a manner consistent with its future use for study or display. Alcohol, 70%, is the best general preservative, but formalin is more economical and serves as well where some hardening of the tissues is not deleterious. Five parts formalin to 95 parts sea water is suitable to preserve most small animals. Basic formalin may be used for organisms such as the foraminifera and echinoderm larvae with delicate calcareous skeletons if alcohol is not available.

ZOOLOGICAL GARDENS (Zoos), institutions in which live animals are kept in captivity. The custom of keeping collections of living wild animals is as old as recorded history. In ancient China, Wen, the first king of the Chou dynasty, in the early part of the 12th century B.C. maintained near his palace a "garden of intelligence" in which were exhibited specimens from the various provinces in the empire. In ancient Egypt menageries were kept as adjuncts to the temples, but the Empress Hatasu in the 18th dynasty had a "garden of acclimation" and sent a fleet to the land of Punt (the first expedition for live animals), that brought back dogs, monkeys, leopards and giraffes. There is an obelisk in the British museum describing the capture of animals by Ashur Akbar, one of the early kings of Nineveh. These were brought to the capital, and "by each animal was placed its name." Solomon had his monkeys and peacocks, and Nebuchadrezzar his lions. Ancient Greeks maintained collections of birds, and later, of mammals; Aristotle kept a collection of live things secured for him by the men of Alexander's army. The Romans had collections far exceeding in numbers anything of today, with hundreds of lions, tigers and leopards. Most of these were used in the arenas in gladiatorial and other combats. In 29 B.C. Octavius Augustus, himself quite an amateur of natural history, maintained a collection of 420 tigers, 260 lions, 600 African animals including cheetahs, panthers and other carnivores, 1 rhinoceros, 1 hippopotamus, several seals, bears, elephants, eagles, 36 crocodiles, and "1 serpent 25 metres long." During mediaeval times zoos were again restored, sometimes as civic institutions as in Florence, but more often as private menageries of the nobility. In 797 the caliph of Baghdad, Haroun el Raschid, sent an elephant and some monkeys to the Emperor Charlemagne. In the 13th century Marco Polo reported the collection of lions, tigers, leopards, hippopotamus and wild asses in Kubla Khan's palace at Xanadu, and another menagerie with stables for elephants and rhinoceros. Henry I (1100–35) established a royal menagerie at Woodstock, Oxfordshire, England. Later this was transferred to the Tower of London. In 1829 the animals were taken over by the Royal Zoological society, and this collection was the origin of the famous zoo at Regent's park, London. Rulers in continental Europe maintained royal menageries at Madrid, Vienna, Versailles and elsewhere. Pope Leo X had a menagerie in the Vatican. Monkeys and civet cats are listed, and he received an elephant as a present from Manuel I of Portugal. Zoos were established in 1554 by the elector Augustus I at Dresden, by Frederick William in 1640 at Potsdam, by Prince Eugene of Savoy at Belvedere, Austria, in 1716; and in 1752 the imperial menagerie was founded at Schönbrunn, Vienna. Louis XIV appropriated £5,400 a year for the upkeep of his menagerie at Versailles, which received presents of animals from numerous French emissaries abroad. Louis XV had little interest in the zoo, although in 1770 a two-horned rhinoceros arrived, the first seen in Europe since Roman times. In 1793 the Jardin des Plantes was established in Paris in connection with the museum of natural history. In the 19th century zoos were established in numbers throughout the world.

Africa.—The zoological garden at Giza, Cairo, consists of a beautiful park and a large collection, chiefly of African mammals, maintained by the government. The zoological garden at Khartoum is maintained by the municipality and is one of the few old world zoos to which admission is not charged. The game department of the Sudan controls the collection and from time to time supplies fine specimens to other institutions. The large zoo at Pretoria is supported by the government, and there is an excellent collection also at Johannesburg.

North America.—In 1945 there were more than 30 zoos in Mexico, Canada and the United States, a number of them of considerable size. In Canada, the Quebec Zoological society exhibits a collection made up chiefly of Canadian species; Toronto includes numerous exotic species, and at the annual Toronto exposition a children's zoo is one of the most attractive features. In Mexico, kings of the Aztecs had zoological collections before the Spanish conquest, and a zoo is still maintained at Chapultepec. In the United States, nearly all large cities have zoological gardens, the first of these having been established at Philadelphia in 1874; Cincinnati followed. Some of the larger zoos are in the Bronx, New York, St. Louis, Detroit, Chicago—one in Lincoln park and a magnificent display at Brookfield—and San Diego. These exhibit some of their collections in open-air, barless pits of the type originated by the Hagenbecks at Stellingen, Germany. These zoos are supported by grants from their respective cities and from funds of local zoological societies. Some charge admission, the proceeds of which are devoted to the institution. The profits from refreshment stands are sometimes used for the purchase of animals. The United States National Zoological park in Washington was established in 1890 by congress "for the advancement of science and the education and recreation of the people," and is supported by the United States government. The park itself consists of 175 acres of hills and woods with Rock creek flowing through. It contains several modern buildings and a large collection of specimens.

South America.—At Buenos Aires there is an extensive collection maintained by the federal district. There are other notable good zoos at Concepción and Santiago in Chile and a small but beautiful zoological-botanical garden at Belém, Para, Brazil, specializing in Amazonian birds and animals.

Asia.—The zoo at Alipore, Calcutta, was established in 1875 by the government of Bengal and is the largest in India. There is an outstanding zoo at Bombay, and an excellent one at Karachi; and many of the native princes maintain private collections. Singapore, Batavia and especially Surabaya have interesting zoos. There is a good collection at Fort de Kock on the west coast of Sumatra, and another at Johore Bahru, property of the crown prince. In Japan there are a dozen zoological collections, large and small, as well as numerous private aviaries. Notable ones are at Tokyo, Nagoya, Kyoto, Osaka and Kobe, the last-named situated on a hill overlooking the city and harbour. The zoo in Shanghai, though small, contains some interesting Chinese animals.

Australia and New Zealand.—There are large zoological gardens at Sydney, Melbourne, Adelaide and Perth; smaller ones at Brisbane and at Wellington and Auckland, New Zealand. The one at Wellington has a well selected group of New Zealand fauna.

Europe.—Zoological gardens are favourite public institutions in many cities of Europe. In France a modern and model zoo was built at Vincennes for the Paris exposition in 1937. The Jardin d'Acclimatation was founded in 1858 in the Bois de Boulogne. The old Jardin des Plantes in Paris was improved between 1918 and 1939, with some new buildings and an outstanding vivarium for the smaller creatures. Switzerland has two zoos, one at Basle and one at Zurich, the latter attractively arranged in a series of terraces. In Germany, in the years between World Wars I and II, a great deal of development was done in approximately 20 zoos, the larger ones being Berlin, Frankfurt-on-Main, Munich (the Geo-Zoo, so-called because the animals were grouped according to continent of origin), Dresden, Leipzig and Cologne. The Hagenbeck Garden at Stellingen became an outstanding show place and animal distributing centre. Smaller but attractive zoos are at Düsseldorf, Elberfeld and Hanover. Several of these were destroyed by bombs during World War II. Vienna boasts of the Schönbrunn, one of the oldest zoos in Europe. Budapest maintained an attractive collection with especially fine groups of European birds. At Antwerp a large menagerie was founded by the Royal Zoological society in 1843. In England the most notable zoo is of course the garden of the London Zoological society in Regent's park. The park is small but the collection has always been one of the finest. The society also has a large open-air zoo at Whipsnade, where herds are maintained rather than individual specimens. Manchester and Clifton have smaller zoological parks. The Edinburgh zoo, beautifully situated in hilly terrain, has long been famous for its extensive collection of penguins. The zoo in Dublin is famous for its lions, having had more than 100 born there during the 19th century. In both Amsterdam and Rotterdam important zoological gardens were established, the former being larger and with a magnificent collection from the East Indies, as well as a fine aquarium. The Skansen zoo in Stockholm is built on an elevated area reached by an escalator, and limits its exhibits to the fauna of northern Europe. At Moscow is the largest zoo in the U.S.S.R., with superb collections of northern animals and a good representation also of exotic species. This zoo is divided into two parts, one of small enclosures, and the other with large paddocks for herds of ruminants. Most of the cities and large towns in Europe have some sort of zoological collection maintained by the cities, by local societies or sometimes as commercial enterprises. In Rome there is a large and very popular zoo with a number of barless pits. Lisbon has a city zoo, small but attractive. In Madrid there remain only parts of the original royal menagerie.

Management of Zoos.—The first object of a zoological garden is the exhibition of its collection to the public. A few animals well shown are immensely more attractive than great numbers inadequately housed and cared for. Considerable research has been done on conditions leading to the welfare of these animals. Studies in diet, ventilation, lighting, heating, artificial sunlight, glass penetrated by ultra-violet rays, and air conditioning have improved conditions in many zoos. Some maintain biological laboratories for research on various phases of animal life and diseases of animals in captivity, and many volumes of natural history have been based on studies made in zoos. As the welfare of animals depends in general upon the same conditions as the welfare of human beings, some of these studies have been of value to medical science. A great deal of work has been done in zoos on experimental animal behaviour. Some zoos are associated with museums that receive and preserve animals which die in the zoo. Many species new to science have been described from captive specimens.

BIBLIOGRAPHY.—C. V. A. Peel, *The Zoological Gardens of Europe* (1903); G. Loisel, *Histoire des Ménageries de L'Antiquité à Nos Jours* (1912); S. S. Flower, *Reference List of the Zoological Gardens of the World* (1914); *Zoological Parks and Aquariums*, vol. I (1932); Guide books and annual reports of zoological societies and gardens are published by nearly all zoos. (W. M. MN.)

ZOOLOGICAL GEOGRAPHY. Zoological distribution, also known as zoogeography, is the science dealing with the distribution of animals over the surface of the globe. It is concerned not only with present conditions but also with those of former geological periods and with the mode in which the present arrangement has arisen. The study of the present distribution of animals may be of two extreme types, whose fields overlap. It is possible to investigate the details of the occurrence of a species in a small district, relating the facts discovered not only to the physical and chemical conditions of its environment but also to its neighbours both plant and animal. Such a study (still very undeveloped) is called ecology (*q.v.* and *see* also DISTRIBUTION OF ANIMALS). On the other hand, it has long been known that it is possible to divide the land of the world into regions separated from other land masses either entirely, as in the case of Australia and New Zealand, or very nearly, as in the case of Africa. Such regions may possess characteristic faunas and the investigation of the nature of these and an elucidation of the resemblances and differences that they present, form the subject matter of the aspect of zoological distribution dealt with here. To those early naturalists who believed in the independent creation of all the species of animals, their irregular distribution over the world must either have presented no problem or have been inexplicable. When, however, Charles Darwin showed that the existing distribution received a ready explanation on the theory of the evolutionary origin of species, and that its details might be used to throw light on the mechanism that had brought about evolution, the whole subject acquired a new interest. The division of the world into zoological regions established by P. L. Sclater in 1858 received much attention and was the subject of much discussion in the light of natural methods of dispersal through geologic time.

The differences that separate the faunas of the zoological regions are not dependent on climate or temperature. For example, the mammal fauna of North America is, on the whole, very similar to that of northern Asia and Europe, while the faunas of Patagonia and Australia, which present a similar range of climatic conditions, differ completely not only from those of the northern areas but also from each other. Furthermore, the mammal fauna of South America is in some respects a unit, although that continent stretches throughout the tropics and into the antarctic regions of Tierra del Fuego. Thus the factors that have led to the distribution of existing animals into regions are not discoverable in present day conditions but must lie in the past, and they can only be discovered by an investigation of the history of the animals that compose the fauna, and of the changes in the distribution of land and water that have taken place during geological time.

The zoogeographical regions at present recognized are as follows:—

1. Palaearctic, including Europe and Iceland; Asia, including Japan, north of the Himalayas and of the Yangtze-kiang watershed; Iran and Asia west of the Indus; and Africa north of the Sahara, including the Azores.

2. Nearctic, comprising the whole of America north of Mexico.

These two regions are conveniently grouped as Holarctica.

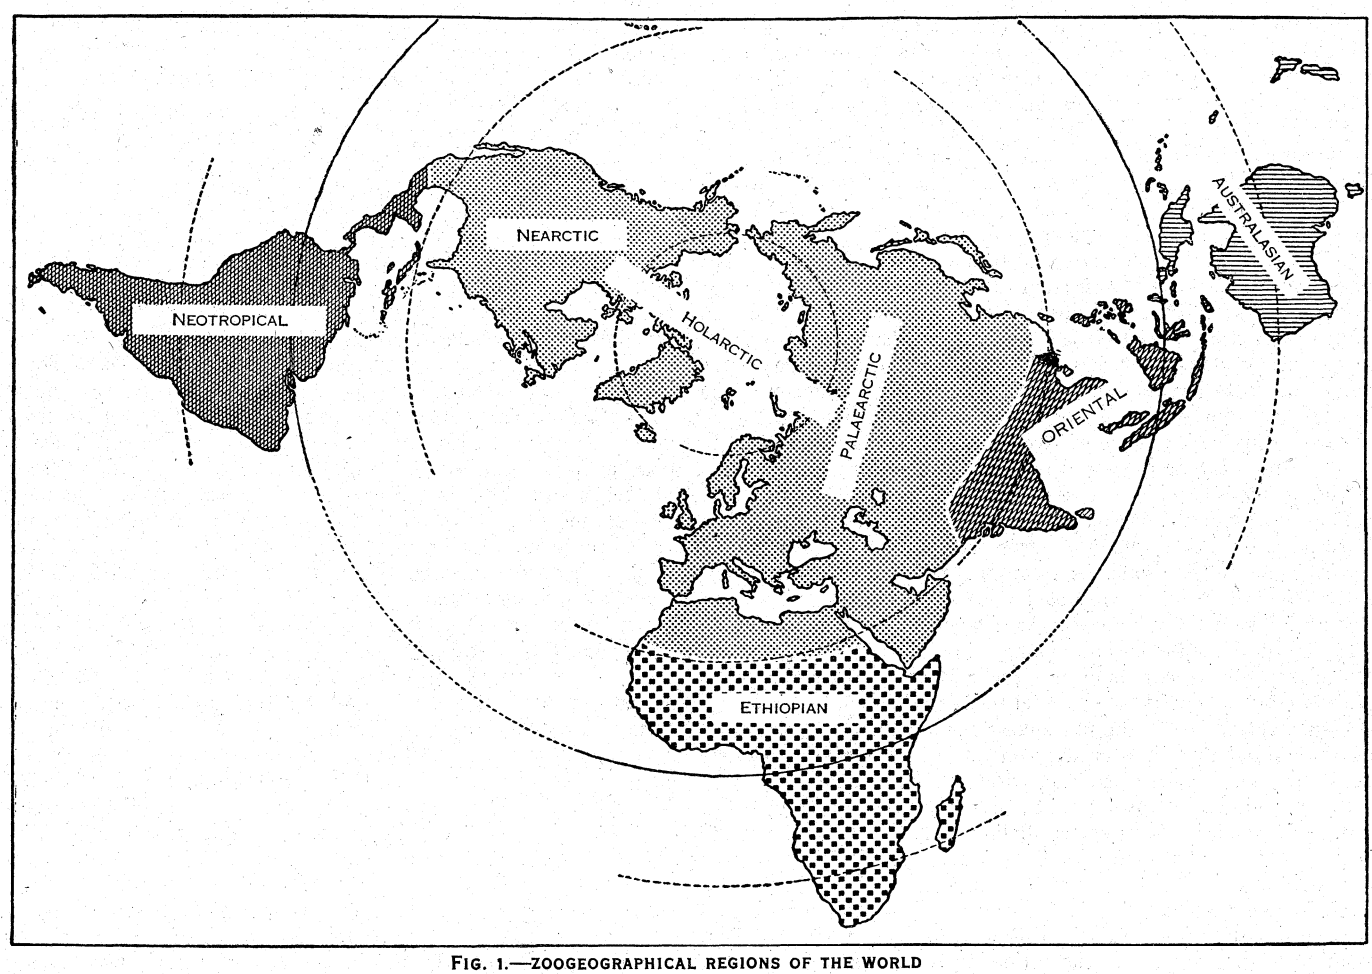

FIG. 1.—ZOOGEOGRAPHICAL REGIONS OF THE WORLD

To the south of Palaearctica lie two distinct regions, each a peninsula projecting from the great northern land mass into the wide seas of the southern hemisphere. They are:

3. The Ethiopian region, comprising the whole of Africa south of the Sahara, with Madagascar and the Mascarene islands.

4. The Oriental region, comprising India and Ceylon, Siam and southern China, and the Malay archipelago.

Bearing a somewhat similar relation to the Nearctic region is:—

5. The Neotropical region, comprising the whole of America from the Mexican escarpment southward, and the Antilles.

Finally more isolated than any is:—

6. The Australasian region, including Australia with Tasmania and New Guinea, New Zealand, and the islands of the Pacific.

Many minor modifications of these regions have been suggested which, although they may be useful, especially in the study of certain groups, are not of great significance. Thomas Huxley, Max Weber and others have grouped these six regions into three main realms, as follows:—

1. Arctogaea comprising Holarctica, the Ethiopian and Oriental regions.

2. Neogaea, comprising the Neotropical region.

3. Notogaea, comprising the Australasian region.

This arrangement has the merit of emphasizing the distinctness of the Neotropical and Australasian regions. All of these terms correspond to natural faunal distinctions and retain their usefulness in descriptive animal geography.

NOTOGAEA AND NEOGAEA

Notogaea.—Notogaea is by far the most distinct of the three realms. That portion of the area which alone is inhabited by mammals (New Guinea, Australia and Tasmania) is the home of the only monotremes known; *Proechidna* restricted to New Guinea, and *Echidna* and *Ornithorhynchus* in the other two areas. The great majority of the other mammals are marsupials. One of the two natural divisions of the marsupial group is confined to Australia; the other is shared by Australia with the Americas. The only higher mammals found in Notogaea are rodents and bats, together with a pig in New Guinea, the native dog or dingo in Australia, and man himself throughout the realm. There is every reason to believe that the pig and dog were introduced by man. The bats present no special features; some of them indeed belong to forms with a world-wide range. The rodents on the other hand are often of peculiar genera not found elsewhere, but are all members of the family Muridae, which have unusual powers of dispersal. Thus Notogaea so far as its mammal fauna is concerned is remarkable not only for the presence of many animals entirely peculiar to it, but also by the absence of all representation of the higher eutherian orders. There are no insectivores, carnivores, armadillos, pangolins, hoofed animals, or primates, types of mammals whose members are to be found in all other regions. The absence of these forms receives a simple and complete explanation if Notogaea has been separated from all other land-masses since a period that preceded the evolutionary development of these orders, or indeed of the primitive mammalian stem from which they arose. Existing palaeontological evidence suggests that this period cannot have been later than the end of the Cretaceous times, and it may be necessary to set it back at least as far as the end of the Lower Cretaceous if certain Mongolian discoveries be correctly interpreted.

The Australian polyprotodont marsupials form a series, the more primitive of which are small mammals of insectivorous and commonly arboreal habits. These forms have their headquarters in Australia, in which the majority of forms are found, but some of them extend on into New Guinea and into the Aru and neighbouring islands. From this primitive group have arisen forms (*Myrmecobius*), which have very small teeth and are committed to a diet of ants; others (the bandicoots), which are in part herbivorous, although they certainly also eat animal food.

One of them is a little hopping animal, superficially recalling the jerboas. On the other hand there is a series of forms that become progressively more and more highly specialized for a carnivorous diet, resulting finally in *Thylacinus,* an animal as large as the collie dog, capable of killing and eating sheep. This group of marsupials is represented in the Americas by the various types of opossums in tropical America and by the curiously primitive *Caenolestidae* of the Andean region. During early Tertiary times, opossums similar to those now living in North America ranged over North America and Europe, and a perfectly typical member of the same family is known from the Upper Cretaceous rocks of North America. Thus the possession in common of Polyprotodonta by Arctogaea and Neogaea on the one hand and Notogaea on the other, does not necessarily imply that these realms were connected with one another after the end of the Cretaceous. The fact that the polyprotodonts of Notogaea have radiated into such diverse forms whilst those of Arctogaea are restricted essentially to one type, may be explained by the absence of the competition of higher mammals in one case, and its presence in the other.

The diprotodont marsupials are peculiar to Notogaea. The diprotodonts as a group are herbivorous. The most primitive family, that of the phalangers, contains many animals all essentially arboreal in habit, varying in size from that of a mouse to that of a cat. They take in Australia much the same place that is occupied by the squirrels and monkeys in other parts of the world, and they often present, as in the development of a flying or rather gliding habit, a remarkable parallel to the flying squirrels. An interesting derivative of the phalangers is the koala or native bear, a large animal that lives entirely on the leaves of the eucalyptus trees. From the same group has arisen the wombat, a large, very powerfully-built, burrowing animal, strictly herbivorous in habit, with a remarkable dentition paralleling that of the larger rodents such as the capybara, in its adaptations. Finally the kangaroos and their allies form a very distinct group of terrestrial animals fitted by their elongated hind legs and long tail for a progression by a series of jumps. Their dentition is so arranged as to allow them to crop grass as do the artiodactyls and as they occur in large numbers in relatively open country, they are similar to this group in their general diet and habits.

Thus the Australian marsupials have experienced an adaptive radiation that has fitted them for most of the modes of life known among the more modern types of mammals of other parts of the world and the fact that no diprotodont, either living or extinct, is known from any other part of the world, is a clear indication that the evolution of the group took place in Australia and that it was made possible by the absence of the competition of higher mammals.

It should be possible to establish the truth of the above view by studies of the Australian fossil marsupials. At present, however, except for a single specimen, which is clearly a diprotodont marsupial, and probably a phalanger, from the Upper Miocene of Wynyard, Tasmania, no pre-Pleistocene mammals are known. The Pleistocene mammals include an interesting human skull presenting the characters of the living Australian aborigines, the dingo, some rodents of Australian type and a very large series of marsupials, including representatives of extinct animals. It is an interesting feature that in Pleistocene time the large carnivorous Tasmanian wolf and Tasmanian devil, at present restricted to Tasmania, occurred widely spread in Australia, and it is customary to attribute their disappearance on that continent to competition with the dingo, that animal having never reached Tasmania.

The large carnivorous marsupial, *Thylacoleo,* found in Pleistocene deposits all over Australia is remarkable in that it is related not to the carnivorous polyprotodonts but to the otherwise exclusively herbivorous diprotodonts. Of this order several gigantic forms are found, a kangaroo, *Macropus titan,* perhaps 12 feet in height, *Diprotodon* and its allies, not closely related to any living forms, but as large and heavily built as a rhinoceros, and the giant wombat, *Phascolomus,* which attained a similar size. Thus what little is known of their fossil history emphasizes still more the peculiarity of the Australian marsupials.

It is clear that man did not arise in Australia and that he is as certainly an immigrant into that continent as he is in those Pacific islands, where the date and manner of his coming are recorded. From the occurrence of a fossil human skull in the Pleistocene of Queensland, we know that the human immigration took place as early as Pleistocene times, and from the fact that this skull belongs to the species *Homo sapiens,* which is not known in the early or indeed the middle Pleistocene, it follows that the human immigration was in late Pleistocene times.

Neogaea.—The mammal fauna of Neogaea, that is of South America, is less peculiar than that of Notogaea. It contains no monotremes but there are many living marsupials, the most abundant being the opossums of the family Didelphidae; the other forms, belonging to two genera of which *Coenolestes* is the more important, have ancestors in the Miocene deposits of South America and were certainly evolved in that region and have never spread beyond it. A few shrews are found in Central America, no insectivores at all on the South American continent, and one peculiar family, the Solenodontidae, is restricted to certain islands of the West Indies. It belongs to the suborder Zalambdodonta, which has living representatives in Africa and Madagascar and has been found fossil in a perfectly typical form in the Basal Eocene of North America. The most characteristic South American mammals are, however, the "edentates" belonging to the group Xenarthra. These fall into three groups, the sloths, the anteaters and the armadillos, none of which, except for the occurrence of an armadillo in Texas, is living outside the region. The rodents of South America, which are numerous, belong in the main to peculiar families; the cavies, chinchillas and agoutis are not found elsewhere, while another important group, the octodonts, are represented by forms both in South America and in Africa. There are also representatives of the Myomorpha and tree-porcupines. The Carnivora include dogs, bears and cats, together with many raccoons peculiar to the area. The perissodactyls are represented only by the tapir, while the artiodactyls include the peccaries and llamas, which are now primarily South American, together with certain deer related to North American forms. The Primates are represented by the group Platyrrhina, which is restricted to South America, and by man.

It is clear from this account that the South American mammal fauna is sharply marked off from all others by the possession of groups of animals peculiar to it, but that it is linked with the North American fauna by the presence of deer, raccoons, bears, cats and dogs. The condition of South America differs from that of Australia in the increased number and variety of those animals which may be regarded from the existence of their relatives elsewhere, as immigrants into an area which has long been separated. The abundance and varied nature of those mammal groups peculiar to South America, such as the sloths, armadillos and anteaters, and the platyrrhine monkeys, would suggest that these animals had undergone their evolution in isolation as had the Australian marsupials. It is possible to test the truth of this idea by an investigation of the fossil history of these and other forms, and in South America, unlike Australia, it is possible to do this not only for one horizon but for the whole Tertiary period.

In Pleistocene times South America was inhabited by a fauna far more varied in character and including much larger animals than those now living there. Of the groups that appear to be of South American origin, the Xenarthra were represented not only by armadillos of modern type, but also by the giant armoured glyptodonts and the enormous ground-sloths; each of these groups being sufficiently varied to be divided into three families. The rodents are of the same types as those now living and the Platyrrhina are present. Extinct groups of hoofed mammals are found, falling within the Notoungulata and including most varied animals. There are the following groups: *Typotheria,* the Pleistocene form being an animal about as large as a pig with a gnawing dentition; *Toxodontia,* with a skull 2 feet in length and a dentition not unlike that of the typotheres; and the order Litopterna with a Pleistocene form about as large as a camel.

Living alongside these native animals were carnivores including not only the ancestors of those forms that still exist but also a sabre-toothed tiger, *Smilodon;* and a bear, *Arctotherium,* now ex-

tinct. The perissodactyls include horses, in part belonging to the modern genus *Equus,* and in part to four extinct genera. Proboscidea are represented by several forms less advanced in structure than true elephants and commonly referred to as mastodons.

Thus except that it is richer both in the number of groups represented and in the size of the individuals, the Pleistocene fauna of South America resembles the recent one in that it contains a mixture of mammals that had originated *in situ* with immigrants from the north. When we pass backward to Miocene times, as represented in the Santa Cruz beds, we find an even fuller and more varied representation of the true South American groups, and a complete absence of those that we had assumed to be immigrants. It is natural to believe that the continents of North and South America became connected by a land-bridge sometime between the Miocene and the Pleistocene, and the truth of this conclusion is established by the fact that giant ground sloths and glyptodonts first appear in the North American fauna in Pliocene times.

The mammal fauna of the Miocene of South America contains the following elements. The marsupials include not only opossums essentially of modern type, but also a variety of carnivorous animals closely similar to the Tasmanian wolf, but some like *Borhyaena,* greatly exceeding that animal in size. Relatives of the living *Coenolestes* occur. There is an animal *Necrolestes,* which is supposed to be an insectivore related to the Zalambdodont golden moles of South Africa. All the rodents, which are extremely numerous and varied, belong to the South American families of tree-porcupines, cavies, chinchillas and agoutis. There are a few unmistakable platyrrhine monkeys. Among the Xenarthra, no representatives of the living sloths and anteaters have been found, probably because these animals are restricted to tropical forests and the known mammal fauna is that of the more open, less well watered and considerably colder plain. The armadillos are very varied; the glyptodonts, small compared with their descendants of Pleistocene times, to some extent bridge the gap between the normal armadillos from which they sprang and the later glyptodonts. The ground-sloths, of relatively small size, include the ancestors of the later forms and the three families into which these creatures are divided can already be recognized. The Notoungulata include an immense range of animals adapted to very varied habits. The Typotheria, then small forms which filled the place occupied at present by rabbits, fall into three distinct families, while the Toxodontia include an abundance of forms smaller than their Pleistocene successors. The Entelonychia include a remarkable animal, *Notioprogonium,* with stilted fore-legs and digging claws. The Litopterna, another extinct family represented by a single type in Pleistocene times, included forms which parallel the horses in the reduction of the toes in foot and hand to one. Yet another extinct order, Astrapotheria, includes gigantic creatures unlike any other forms.

Thus the South American fauna of the Miocene is seen to include essentially only those elements most characteristic in the modern fauna, the indicators of the Neogaean realm. The forms of Holarctic origin, some of which, like the tapirs, camelids and various carnivores, now appear to be equally peculiar to South America, are absent in the South American mid-Tertiary, and are known to be present and undergoing rapid evolution in the same era in North America.

Certain of the early types of marsupials in South America, such as the wolflike *Borhyaena,* have been thought to be so closely allied to existing Australian types as to indicate interchange of faunas between Australia and South America by a direct land route or via connections with the Antarctic continent. The resemblance between *Borhyaena* and *Thylacinus* is now interpreted as caused by convergent development from different ancestral stocks. The negative evidence, in the obviously independent course of evolution of the fauna of Neogaea as a whole, seems to be overwhelmingly against any land connections of South America with any continent throughout most of Tertiary time, with reestablishment of the Panama bridge with North America in the Pliocene.

MODERN ARCTOGAEA

The remaining realm, Arctogaea, is much more extensive and less compact than those that we have considered, and it is most convenient to begin its discussion by a consideration of the existing distribution of animals in the various regions of which it is composed.

Nearctic Region.—Covering as it does the whole of North America except the lowlands of Mexico, the Nearctic region exhibits extreme variations in geographical qualities. In the extreme north there is a completely snow-covered arctic area, to the south of which there is a continuous belt of coniferous forest extending from Alaska to New England. In the extreme south lies the Sonoran region which has a warm temperate climate and is largely composed of great treeless plains, although at the mouth of the Mississippi it includes much forest, and in California passes into deserts where the day temperature may be extraordinarily high, reaching in the Mohave desert 120° F.

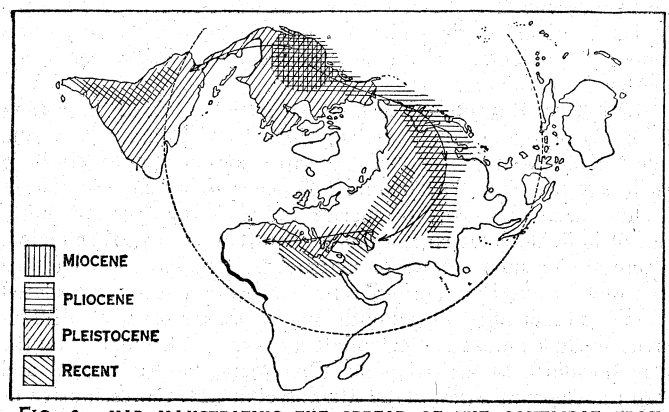

FIG. 2.—MAP ILLUSTRATING THE SPREAD OF THE CAMELIDAE FROM THEIR EVOLUTIONARY HOME IN NORTH AMERICA

In the Arctic zone there are polar bears, arctic foxes, musk oxen, reindeer, lemmings and arctic hares, all of these animals extending round the north pole over the northern lands of Asia and Europe as well as those of North America.

The wooded region includes shrews and the American moles among insectivores; the Canadian porcupine, chipmunks, muskrats, woodchucks, lemmings, beavers and hares among rodents. The carnivores are represented by pumas and lynx, the grey wolf, foxes, bears, otters, skunks, raccoons, wolverines, marten, weasels and the American badger. The artiodactyls are deer of types found in Asia and in Europe—the wapiti corresponds to the red deer, the moose to the European elk and the caribou to the reindeer; mountain sheep and the peculiar Rocky mountain goat; bison extremely close to those of Europe, and various peculiarly American types of deer.

The southern part of the nearctic region exhibits faunal elements much more different from the modern Palaearctic. Such elements include the opossum, apparently not a re-entrant from South America, as might be expected; the neotropical re-entrants, like the armadillo and many types of birds unknown in the old world; and a great variety of iguanid lizards in the southwest. The southeastern forest in the United States appears to be a remnant of a forest widespread in the northern hemisphere in the Cretaceous, as shown by its floral relations with eastern Asia, and by numerous faunal elements, such as the alligator, hell-bender, and various genera of snakes. The most characteristic of the North American mammals is the prongbuck, the "antelope" of common speech in the United States, which represents a distinct type of artiodactyl, nearly intermediate between the Bovidae proper and the deer in the nature of the horns.

Palaearctic Region.—The Palaearctic region greatly resembles the Nearctic in the general character of its mammalian fauna. It contains no monotremes, marsupials, armadillos, hyracoids, Proboscidea, or Primates over the greater part of its area, though representatives of some of these groups occur in the Mediterranean region, which forms a transition between the Palaearctic and the Ethiopian regions. The following groups of animals are common

to Palaearctic and Nearctic areas:—hares and picas, beavers, marmots, ground squirrels, voles and lemmings; martens and weasels, wolverines, brown bears, wolves and foxes; elk (*i.e.*, moose), reindeer, wapiti, bison, big-horned sheep and musk ox either in identical or closely allied species. On the other hand the Palaearctic area includes certain wild sheep, goats, saiga antelope, chamoix, many peculiar deer, camels and true pigs not known in America. It possesses also a number of horses and asses, though no other perissodactyls. The desmans and some other insectivores are peculiar to the old world, as are the dormice, hamsters and jerboas among the rodents, and the tiger and the giant and lesser panda among the carnivores.

Ethiopian Region.—The fauna of Africa south of the Sahara is on the whole strikingly unlike that of the Palaearctic region, and the intervening Mediterranean area does comparatively little to bridge the gap. The mammal fauna is remarkable in that it includes a great variety of species and probably a greater number of individuals of large animals than that of any other region. There are no monotremes or marsupials. The aardvark and the pangolin (*Manis*) are curious forms, probably not closely related to one another nor to the South American anteaters. The Insectivora include among the Zalambdodonta the golden moles and the Potamogalidae known from no other regions of the world, and also the elephant shrews (the Macroscelididae), representative of a group, the Menotyphla, of which the other forms are the tree-shrews of the Malayan subregion. There are many peculiar rodents, the springhaas (*Pedetes*), molerats (Bathyergidae), crested rats (*Lophiomys*) and cane-rats together with many members of the Muridae and true hares. The Carnivora include true dogs, the hunting dog (*Lycaon*) and the long-eared fox (*Otocyon*), spotted hyaenas and the Manhaar jackal (*Proteles*), etc. There are several mongooses and civets. The cats are represented by the lion, leopard and cheetah in addition to very numerous smaller forms; ratels, zorillas and otters represent the Mustelidae. There are elephants of a distinct type, and hyraxes, of two genera which spread northward into Syria but are otherwise exclusively Ethiopian. The perissodactyls are represented by zebras and wild asses, together with two species of rhinoceroses. Among the artiodactyls there is found a remarkable variety of pigs. The hippopotamus is widely distributed throughout the region, while a dwarf form is restricted to the west coast in the neighbourhood of Liberia. The Giraffidae, including true giraffes and okapis, are restricted to the region; the chevrotains of the genus *Dorcatherium* are similar to those found in Malaysia. Deer are completely absent but the hollow-horned ruminants include not only buffaloes but also an extraordinary number of peculiar genera of antelopes. Sheep and goats penetrate into the region only in the mountains of Abyssinia.

The Primates of the Ethiopian region include lemurs belonging to two groups, the Lemuriformes, which are restricted to Madagascar and the Lorisiformes, which do not occur there but are represented by the galagos and pottos, allied to animals living in the Oriental region. Monkeys belonging to the two sub-families of Cercopithecinae and Semnopithecinae occur throughout the forested regions. The most characteristic members of the latter are the typical baboons with short tails and elongated muzzles; these animals are terrestrial in habit and usually live in large tribes; they are at present confined to Africa and Arabia. The dense forests of western equatorial Africa are the home of the giant apes, the chimpanzee and gorilla, which are restricted to the region.

Oriental Region.—The Oriental region proper includes the whole of India south of the Himalayas, Ceylon, Malaysia and the Malay archipelago, including Java, Sumatra, Borneo and Celebes. The region contains no monotremes and marsupials are represented only by the cuscus, which reaches Celebes. The single genus *Manis* represents the pangolins. The Zalambdodont insectivores are unrepresented, while the dilambdodonts include as special forms *Gymnura* and *Hydromys*, which are essentially spineless hedgehogs, and a variety of shrews of the genus *Soriculus*. The Menotyphla are represented by tree-shrews, *Tupaia* and *Ptilocercus*. Galaeopithecus represents a distinct order. The rodents include among many forms of wide distribution certain endemic genera of which the flying squirrels are perhaps the most striking. The carnivores include lions (now only in northwestern India), leopards, tigers, cheetahs and many smaller cats; bears, wolves, foxes and dholes; striped hyaenas, civets and mongooses. The perissodactyls include two species of rhinoceroses belonging to different genera than those in Africa, and a tapir restricted to the forests of the Malayan subregion. Pigs belonging to several species, and chevrotains of the genus *Tragulus* are not found elsewhere. Certain deer are peculiar to the region, the few antelopes include the nilghai and black buck, and there are many and unusual forms of oxen, the buffalo, the gaur and in Celebes the dwarf buffalo *Anoa*. In the mountains the tahr, gorals and takin are curious forms whose relatives are to be met with in the Palaearctic region and possibly in the Rocky mountain goat of North America. Two groups of lemurs occur within the area, the Lorisiformes, including the slender and slow lorises; and the Tarsiiformes with the single living genus, *Tarsius*. Monkeys are widely distributed, though baboons are absent from this region.

The gibbons (*Hylobates*) and siamangs (*Symphalangus*) are found only in the Malayan subregion, and the orang occurs in Borneo and Sumatra.

ANCIENT ARCTOGAEA

Inspection of the foregoing lists, which represent the existing fauna of the various zoogeographical regions, will show that although they are distinct from one another and mingle only incompletely in the transition regions, certain animals such as the tapirs, may occur in widely separated areas not now connected by a practicable land-bridge. The whole distribution of these mammals is inexplicable on the basis of the present distribution of land, water and mountain ranges; it can only be understood in the light of the history of the evolution of mammals, now known through the work of three generations of palaeontologists in very considerable detail. Perhaps the simplest method of explaining this history is to take the mammalian orders in succession and discuss the time and place of origin of their more important families and genera.

Monotremata.—It is clear that the monotremes are a group of very ancient origin, probably Triassic, but that the existing forms are highly specialized and closely related to one another. The only fossil forms known are Pleistocene and belong to the existing genera.

Marsupialia.—Polyprotodont marsupials of the family Didelphidae occur in the Upper Cretaceous of North America. Their remains are found in Eocene, Oligocene and Miocene of North America and Europe and they have inhabited South America throughout the Tertiary. The South American carnivorous borhyaenids appear to be autochthonous, while the Australian dasyurids have no relatives outside Notogaea. The pseudo-diprotodonts, the coenolestids, are represented in South America from the Oligocene to the present day, and have no other relatives. The true diprotodonts have always been Australian; *Wynyardia* from the Middle Miocene of Tasmania is the oldest known form.

Xenarthra.—In older classifications the essentially South American armadillos, anteaters and sloths were united with various old world forms as the "Edentata," a term which proves to be meaningless, since the forms in question—the pangolins, and the aardvarks—are clearly independent orders of mammals. The earliest certainly known Xenarthra are found in the Eocene *Notostylops* beds of South America. Forms in the North American Eocene appear to be related, and it is the most probable hypothesis that South America received its original stock of mammals from the northern continent via land connection in the earliest Tertiary or perhaps even Cretaceous times.

Tubulidentata.—The aardvarks of Africa include only the single genus *Orycteropus*. These have a most peculiar tooth structure, and like the pangolins and anteaters, they are really termite eaters. The range of the order extended to Europe and Persia in the Pliocene, but the earlier Tertiary history is as yet unknown.

Pholidota.—The peculiar ant and termite-eating forms known as the pangolins, covered with large overlapping scales, are found in tropical Asia and in Africa. Their fossil history is still unknown.

Insectivora.—The order Insectivora includes a large number

of forms only distantly related to one another. The Menotyphla at present represented by the elephant shrews of Africa and the tree-shrews of Malay, probably also covers a number of forms whose remains are found in Europe, Mongolia, and North America in rocks of various ages from the Basal Eocene into the Oligocene. It must be admitted however, that the evidence on which these forms are referred to the group, is very slender. Modern classifications tend to emphasize the close relations of this group with the ancestral primates.

The Zalambdodontidae, including the solenodons of the Antilles, *Potamogale* and the golden moles of Africa, together with the Madagascan tenrecs, include not only a perfectly characteristic skull from the Basal Eocene of North America but other forms extending as high as the Oligocene. At any rate the group is of such antiquity that its members have had the whole Tertiary period in which to wander over the world and could then reach any part of it that has been connected by land within that period.

The remaining insectivores, the Dilambdodonta, are first found in the Lower Eocene; the living families are comparatively modern. The erinaceoids first appear in the Oligocene of Europe, North America and Mongolia. The shrews and moles have a similar distribution, while the primitive family of lepticids is confined to the Oligocene and Eocene of North America. Thus the Dilambdodonta appear originally to have been of northern origin, occurring throughout the whole of Arctogaea and entering the southern peninsulas at some late period. *Galeopithecus* has perhaps ancestors in the Eocene of North America and of Europe.

Carnivora.—In Basal Eocene times Europe and North America were inhabited by primitive carnivores belonging to sub-orders the majority of which were not related to any living form. These extinct groups, the Acreodi and pseudo-Creodi, are represented in Europe, Mongolia, and North America in the Eocene and Oligocene, and one or two members of the latter group reached northern Africa in Oligocene times. One form at any rate lived on in India to the Miocene but none ever reached South America. The ancestors of the true carnivores, which fall within the family Miacidae, occur in Basal Eocene and Eocene rocks in Europe, Mongolia and North America. From this family there arose a whole series of forms from which the civets (Viverridae), raccoons (Procyonidae), dogs (Canidae) and Mustelidae arose.

The Viverridae are represented in the Eocene of Europe although not in that of America. They have a long history in the European Tertiary and appear in the Upper Miocene and later deposits of northern India: from a viverrid stock the Hyaenidae seem to have originated. The first forms known, both of the existing genus itself and of the intermediate genus *Ictitherium*, occur in the Pontian Lower Pliocene fauna, which stretches with minor modifications in its character from China to Portugal: no member of the group reached America.

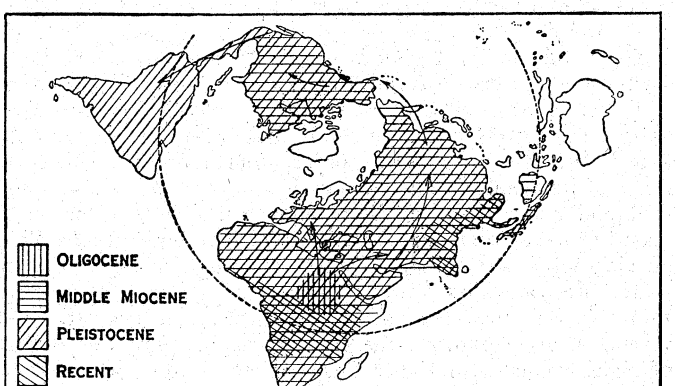

FIG. 3.—MAP ILLUSTRATING THE SPREAD OF THE PROBOSCIDEA FROM THEIR ORIGINAL HOME IN AFRICA

The mustelids first appear in exceedingly similar forms of weasels in the Oligocene of Europe, Mongolia and North America. During its later history the group appears to have been European and North American, the otters and badgers being old world and occurring in later Miocene or Pontian times in the Oriental region.

The Canidae (dogs) have a long, very elaborate and still incompletely understood evolutionary history both in the old and new worlds. One interesting feature is an early separation of the dholelike dogs from the others, dating from Oligocene times. The Oligocene forms of this group are entirely North American, but a single member at any rate seems to occur in the Upper Miocene of Europe. The living representatives are South American, African and oriental, regions which were certainly not inhabited by members of this group until late Tertiary times.

The amphicyonine dogs, which are represented in the Oligocene of North America, occur during Miocene times in both Europe and North America; from this group the Ursidae (bears) appear to have arisen, *Ursavus* being from the Middle Miocene of France and possibly related forms occur in Europe, India, China and North America. They first appear in South America in Pleistocene times.

The Procyonidae are first represented by Lower Miocene forms in North America, and no members of the group appear to have reached Mongolia or Europe. An apparent exception is provided by two animals, *Aelurus* (the panda), now living in the Himalaya, first known from Upper Pliocene deposits in west Europe, and *Aeluropus* (the giant panda), living in Tibet, found fossil in the Pleistocene of Burma. The ancestry and affinities of these forms are however still uncertain.

The Felidae (cats) belong to two independent groups, the Machaerodontinae (sabre-tooth cats) and the Felinae (true cats). Both families occur in the Oligocene of North America and Europe, and their descendants are found in these localities at every horizon between that and the Pleistocene. At this stage the former became extinct, while the latter has living representatives in both subregions. The Middle Miocene of central Africa contains the remains of a feline, and the Oriental region has been inhabited by both sabre-tooth and true cats since Miocene times. Cats of both types first appear in South America in Pliocene deposits. The group appears to be of northern origin and to have colonised the southern projections of Arctogaea during the Miocene at a time when many migrations were taking place.

The Proboscidea first appear in Upper Eocene rocks in Egypt as a small animal, *Moeritherium*, which presents the first traces of their characteristic specialisations. In the Lower Oligocene of Egypt this animal is still found and is there accompanied by its descendant *Palaeomastodon*. This genus gave origin to the later Proboscidea, its immediate descendants being included under the somewhat vague term "mastodon." Mastodons appear in the Lower Miocene of North Africa, Baluchistan and Europe and by mid-Miocene times had reached China and North America. Subsequently in Upper Pliocene times mastodons of special type migrated southward and lived on into Pleistocene times in South America.

The true elephants arose from the mastodons, and their earliest representatives are found in the Pliocene of India. Then they migrated outward, reaching Europe in the Pliocene and North America in Pleistocene times, but they never reached South America.

All the Holarctic members of the order died out at the end of Pleistocene times, one of them, the mammoth, which became adapted to Arctic conditions, living along the front of the great ice-cap which covered northern Europe and North America, until the ice finally disappeared, perhaps about 8000 B.C.

Hyracoidea.—The Lower Oligocene rocks of Egypt which contain the remains of *Palaeomastodon* yield also several genera of large hyracoids. The next representatives of this order are very small animals found in Middle Miocene rocks near Victoria Nyanza, and in South West Africa. In the Lower Pliocene Pontian fauna of Samos and Pikermi near Athens, they are rarely represented by a very large form. The existing animals are Ethiopian, except for a few individuals found in Syria and Arabia. The order thus appears to have arisen and carried out its evolution in Africa. The Lower Oligocene of Egypt also contains the remains of two orders, the Barytheria and Embrithopoda, no representatives of which are found elsewhere. Its fauna

is therefore very isolated and contains only certain creodonts and anthracotheres of northern origin.

Notoungulata.—This extinct order of herbivorous mammals was until recently known only from South America, where it exhibits a number of evolutionary series. Most of these series can be traced upwards from the Eocene (Notostylops beds) of Patagonia into the Miocene or Pleistocene, although it has to be recognized that most of such series are only approximate. A single lower jaw of a member of this order has been found in the Lower Eocene of North America, and more abundant remains of a different genus occur in rocks (the Gashato beds in Mongolia) whose age is not certainly known but is probably Basal Eocene. This animal appears to be the most ancient member of the family yet discovered, and suggests that the group was of northern origin, although its later evolution took place entirely in Neogaea.

Condylarthra.—The Basal Eocene of North America contains numerous remains of small animals that appear to represent a primitive group from which various types of hoofed animals have arisen. The descendants of some of these forms lived on into the Lower Eocene and in a modified form, as the Amblypoda, even to the Upper Eocene. These latter forms had their headquarters in North America, but a single representative of them, of Upper Eocene age, has been found in Mongolia. The Basal and Lower Eocene of Europe contain a few animals which are probably condylarthrans, and the earliest Eocene members of the Litopterna (a group restricted to South America) are essentially identical in structure. Thus this group gives a further indication of the uniformity of the Basal Eocene fauna throughout the Palaearctic region, and of the probable derivation of the South American fauna from members of this widespread group of animals, which, becoming isolated about the beginning of Tertiary time, and not being exposed to the competition of the northern groups, carried on an adaptive radiation, leading to the evolution of many very peculiar groups.

Perissodactyla.—Perissodactyls first appear at the bottom of the Lower Eocene in Europe and North America as small animals, presenting a very uniform structure and including the ancestors of the half-dozen families into which the group becomes divided.

The first of these, the Equidae (horses), is represented in North America at every stage of the Tertiary from the Lower Eocene to the Pleistocene. The remains of these animals provide the longest and most complete evolutionary series known. It is therefore very remarkable that no remains of horses have been found below the Lower Pliocene in Mongolia and China. Horses extremely similar to those of North America, but forming a less complete evolutionary series, are found in Lower, Middle and Upper Eocene rocks in western Europe, and this region possesses the only representatives of a small group, the palaeotheres, which, derived from a horse-stock, reached a large size and very peculiar structure as early as the Upper Eocene, becoming extinct in Lower Oligocene times.

No representatives of the true horses are found in Europe in the Oligocene, and the single form, *Anchitherium,* in the Middle and Upper Miocene, belongs to an aberrant group of forest animals also represented from the Middle Miocene to the Lower Pliocene in North America and in the Lower Pliocene of China. Only in the Lower Pliocene Pontian fauna from China to Portugal and in India, do we again meet with typical members of the horse family in individuals of the genus *Hipparion.* The living genus *Equus*, which is not a descendant of *Hipparion,* appears suddenly in the Upper Pliocene of India and western Europe. South America received its horses in Pliocene times from North America, the peculiar genera of that continent having arisen from a North American Pliocene genus.

The Tapiridae have a probable ancestor in the Lower Eocene of North America and unquestionably ancestral tapirs occur in the Oligocene of Europe and North America. The group appears to have survived in North America until Pleistocene times, reaching South America after the two continents became connected in the Pliocene. In Europe and Japan a Lower or Middle Miocene form is known, and the living genus is represented in Upper Miocene and Lower, Middle and Upper Pliocene deposits. A gigantic form twice the size of the existing ones occurs in the Pleistocene of China. No representatives of this family appear to have been discovered in the Tertiary rocks of India, but it is clear that the existing Bornean form must have reached that region from the Palaearctic region.

The lophiodonts, a group allied to the tapirs but restricted to Eocene and Oligocene times, include cursorial forms, and occur not only in North America and Europe but also very abundantly in Mongolia.

The rhinoceroses present a very complicated evolutionary story not yet fully understood. One primitive group of animals, the amynodonts, somewhat hippopotamus-like in their adaptations, occur in Eocene and Oligocene rocks in Europe, Mongolia, Burma and North America. The cursorial hyracodonts are known only from the Eocene and Oligocene of North America and Mongolia, whilst their associates of such genera as *Diceratherium* occur both in Europe and North America. The evolution of the more normal rhinoceroses is still so little understood that it is impossible to discuss their dispersal; it is however clear that creatures essentially ancestral to the living Sumatran rhinoceroses occur widely spread in the Upper Pliocene and Pleistocene of Europe, in association with forms allied to the African rhinoceroses. The living Indian rhinoceros has apparently been derived from forms present in that area in Pliocene times. One remarkable extinct rhinoceros, *Elasmotherium,* found in the Lower Pleistocene of Russia and Siberia, and very rarely in Germany, has an ancestor in the Pliocene of China.

The Titanotheriidae is a small family of perissodactyls whose first representatives are found at the top of the Lower Eocene of North America. They underwent a very rapid evolution in that continent, soon attaining a gigantic size and a very highly specialised character. In the Middle Eocene of Transylvania a single lower jaw has been found. In the Upper Eocene of Mongolia typical members of American genera of similar age are to be found; fragments of very nearly allied animals have been described from Upper Eocene rocks in Burma, and in the Lower Oligocene of North America and Mongolia their remains are abundant. A few fragments have occurred in presumably Oligocene rocks in eastern Europe, but none have been found in the thoroughly explored deposits of this age in western Europe.

The only remaining group of perissodactyls, the chalicotheres, has a possible ancestor in the Middle Eocene of the United States. It then occurs in the Oligocene both of Europe and North America, is found in Middle Miocene times in India, and is a member of the Pontian fauna of southern Europe. It occurs in the Pleistocene of Central Africa after it had died out in other parts of the world.

The history of the Perissodactyla is of very great importance for the study of geographical distribution as so many fossil forms of the group are well known that relationships existing between the various members can be established with greater certainty than is the case in any other order of mammals. Furthermore many of its members were strange looking animals whose abundant and unmistakable fossil remains make the evidence with regard to its distribution during past times of peculiar reliability. Judging solely from the perissodactyls, it would appear that in Lower Eocene times Europe, Mongolia and North America formed a continuous land-surface, presenting such a variety of vegetation as to allow of the free passage of forest as well as of plains animals. In Upper Eocene times Europe became partially separated from North America, so that certain groups, the palaeotheres and the titanotheres, which are swamp and forest forms, were unable to emigrate freely from one region to the other. Horses however still occurred in very similar forms in the two regions. In Oligocene times this differentiation of fauna became exaggerated, the two areas becoming completely separated from one another. The intense earth movements of Miocene times so altered the geography of the world as to reunite the Palaearctic and Nearctic regions and many forms are common to the two regions at this period. In the succeeding Lower Pliocene

rhinoceroses are very abundant and varied in the Palaearctic and Oriental regions, while they are much more seldom found in America. Oligocene Africa had no perissodactyls but by mid-Miocene times a rhinoceros had reached that continent. South America was colonized by horses and tapirs in Upper Pliocene times, but no member of the group ever reached Notogaea.

Artiodactyla.—General discussion of the past distribution

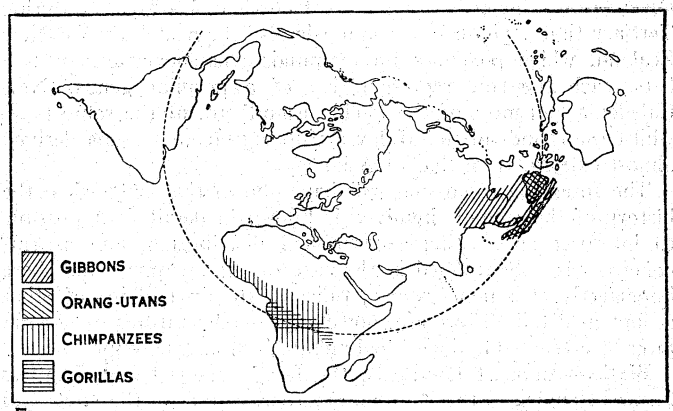

FIG. 4.—MAP OF THE WORLD SHOWING THE DISTRIBUTION OF THE LIVING GREAT APES

of the artiodactyls is rendered difficult by the uncertainty which exists as to the classification of that group.

In the Lower Eocene of North America and Europe occur the most primitive forms, and their successors in the Middle and Upper Eocene are similar in these two regions, but in Upper Eocene times certain special groups make their appearance which are restricted to one or other of the two continents. In North America the ancestors of the camels are found at this time and the entirely American family of the oreodonts is represented. In Europe the Anoplotheriidae take the place of these latter forms, and the long-lived family of the Anthracotheriidae appears as small animals.

In the Oligocene the descendants of all these groups are found and a strange creature *Elotherium*, resembling a gigantic long-legged pig, is represented by very similar forms from both sides of the Atlantic. In this period both in Europe and North America there are peccarylike creatures, and perhaps true pigs in Europe: the anthracotheres reached America at this time but only one of the very large number of European and Indian genera ever reached that continent.

In the Lower Miocene in Europe and Baluchistan there was an amazing variety of anthracotheres ranging from forms as small as a sheep to great creatures as big as a hippopotamus. The last representative of the anthracotheres occurs in rocks of probable Upper Pliocene age in India and Tunis.

It is quite possible that the hippopotamus arose from the anthracotheres. The animal is clearly of Oriental origin, reaching north Africa and Europe in the Upper Pliocene, and widespread over Java, India, Europe, Africa and Madagascar in Pleistocene times.

The camels carried out the whole of their evolution in North America, where they are now extinct. They first left that continent in Lower Pliocene times, a large member of the group occurring in the Lower Pliocene of China, and in India in rocks perhaps of somewhat later date. The llamas reached South America in the Pliocene and a llamalike form survived in North America into Pleistocene times.

The higher artiodactyls (Pecora) are represented in the Upper Eocene of Europe and North America by small animals resembling the existing tragulines. This group of primitive artiodactyls includes one animal *Archaeomeryx* from the Upper Eocene of Mongolia, which is the earliest known form capable of being regarded as a direct ancestor for the Pecora. In Oligocene deposits in Europe, and in Lower Miocene times in Europe and North America occur the remains of animals which are more certainly deer. Deer have a continuous representation in both continents from that time to the present day but the earlier American forms appear to be related to the Virginian deer and its allies, the typical genera being of Asiatic and European origin. The antelopes and their allies first appear in the Lower Miocene of Europe, and the group appears to be definitely of old world origin. It is abundantly represented in the Pontian fauna from China to Spain and is now the most conspicuous element in the Ethiopian region. Antelopes first appear in North America in the Upper Miocene, but are extremely rare there. The history of the group is however still uncertain. The true oxen are clearly derivatives of the antelopes, and the earliest known and most primitive forms occur in the Lower Pliocene of India: they reached Europe in Upper Pliocene times and America only in the Pleistocene. The ancestry of the goats and sheep is still uncertain but the first definite members of the group appear in the Pliocene of India. In North America from the Middle Miocene to the present day there occurs a distinct family of Pecora, the Antilocapridae, represented now only by the prong-horned antelope. No member of the group has ever been found elsewhere.

According to Pilgrim, the earliest known relative of the giraffe is found in the Lower Miocene of Baluchistan: in the Lower Pliocene the group is represented by very varied forms, some gigantic, some indistinguishable from the living giraffes and others nearly similar to the okapi. These occur throughout the entire distribution of the Pontian fauna from China, Persia, South Russia, Samos and Pikermi. Their remains are not found in German deposits of the same age. No fossil giraffes are known from Africa, the only continent at present inhabited by the family, nor did any member of the group ever reach North America.

Primates.—The lowest division of the Primates, the Lemuroidea, is first recognised with certainty in rocks of Lower Eocene age in North America and Europe. These remains belong to two very distinct groups, the Lemuriformes, with a complete dentition and a comparatively elongated face, and the Tarsiiformes, in which the tooth-row is shortened, the eyes are large, the olfactory region and face very small, and the lower jaws meet in front at an acute angle. Representatives of these two groups are found in the Middle and Upper Eocene in Europe and America, and both continue in the Oligocene of Europe, but disappear at this period in North America. The two groups are then unknown in the northern hemisphere, but the Lemuriformes reappear in the Pleistocene of Madagascar in a most varied series of forms, and the Tarsiiformes are represented by the single living genus *Tarsius* in the East Indies. Nothing is certainly known of the remaining group of lemurs, the Lorisiformes, but it is conceivable that *Pronictycebus* from the Upper Eocene of France represents their ancestor.

The higher Primates fall into two completely separate divisions: the platyrrhine and catarrhine apes respectively. Of these the platyrrhines are first found in the Miocene of Patagonia, and none of them occur outside that continent. The first catarrhine is *Parapithecus* from the Egyptian Oligocene, a primitive form presenting distinct points of resemblance to the tarsioids. Associated with this animal is *Propliopithecus*, which is beyond question a member of the highest family, the anthropoid apes. The earliest members of the lower families of old world apes occur in the Lower Pliocene throughout the range of the great Pontian fauna. Their distribution presents one or two points of interest, *e.g.*, the typical baboon is known from the Pleistocene of India, and another strange form closely allied to the living gelada has been found in the east African Pleistocene. The giant apes have a more complete representation as fossils, a fact which is remarkable when the relative rarity of the living groups is taken into account. *Pliopithecus* from the Middle and Upper Pliocene of Europe appears to be essentially an ancestor of the gibbons, whilst the genus *Dryopithecus* has a wide distribution in Europe and Asia in the Middle Miocene and in somewhat later rocks. The closely allied *Sivapithecus* has been claimed as a human ancestor but really presents no definite evidence of such affinities. From *Dryopithecus* and its immediate allies the living giant apes certainly arose, and such evidence as exists is consonant with the view that man also came from the same stock.

CONDITIONS OF DISTRIBUTION

The outline of the history of land-mammals contained in the preceding pages shows that the present distribution of a mammal may tell us nothing whatsoever about the place of its origin, or the time at which it came into its existing habitat. All the great land-masses of the world except Australia and Madagascar have been continuous with one another at some time during the Tertiary period and representatives of all the higher orders have been enabled to cross the bridges between them. The fact that each continent none the less has a distinctive fauna, is because of the extinction which has overtaken the members of every group in some portions of its former range, the differences in the period at which the union of the continents took place, and the peculiarities in the geographical conditions of the bridges which made them available to certain forms whilst they could not be crossed by others. The geographical conditions which may act as barriers to the free dispersal of mammals are very varied. A wide strait of sea cannot be crossed by most mammals but there is evidence that certain creatures have in fact reached islands by some rare and casual mode of distribution not available to most forms.

Madagascar.—Perhaps the best evidence of the possibility of such transference is afforded by Madagascar. Taking the Pleistocene and recent faunas of that island together, we find that it is inhabited by very many genera of lemuriform lemurs, varying in size from animals no bigger than a squirrel to a form with a skull more than a foot in length. Although all the living and the majority of the extinct forms are strictly arboreal some of the larger lemurs were terrestrial and even perhaps aquatic in their habits. There is however no doubt that all these forms despite their very varied appearances are extremely closely related and that they may all have arisen from a form resembling *Lemur* itself.

The only other important element in the Madagascan fauna is the group of many genera included in the Zalambdodont insectivores. All these belong to the single family Centetidae and may have arisen from a single form. The carnivores are represented by a few genera of Viverridae, all extremely peculiar in their structure; the largest and most interesting is the fossa, an animal whose true relationships are obscure. There is another viverrid, *Eupleres,* with very small widely-separated teeth like those of an insectivore, and finally there is a much more typical viverrid, perhaps belonging to *Viverrus* itself. The rodents are included in the single family Nesomyidae, peculiar to the island. The only other forms are bats, including the fruit-bat *Pteropus* not found in Africa, a pig of the genus *Potamochoerus* and a pigmy hippopotamus now extinct.

This fauna is clearly quite different from that of any other part of the world and gives a sound basis for the establishment of Madagascar as an independent region. We know that *Hippopotamus* only came into existence about at the end of the Miocene times and that it first reached Africa in the Pliocene: it is therefore clear that it must be a relatively recent immigrant. If it had crossed over a land-bridge it would necessarily have been accompanied by those other elements of the African fauna which live in close association with it. We should in fact expect to find in Madagascar representatives of those antelopes which live in the forests or swamps which border rivers, the Cape buffaloes and elephants, true monkeys, and an assemblage of carnivores which prey upon them. The complete absence of such forms implies that the hippopotamus did not cross on dry land and it is probable that it reached Madagascar by swimming. The pig is also a water-loving form and may also have swum across. It is clear from their many peculiarities that the viverrids have lived longer in Madagascar: they cannot have crossed on land because of the absence of any associates, and it is most improbable that they swam. The lemurs represent a group well established in Eocene times and their wide radiation again implies a long residence. Finally the centetids are known to have existed in North America in the Basal Eocene. Neither group could have crossed land-bridges without bringing with them other forms, so that it seems clear that they were transported by some other method, the only plausible suggestion is that they crossed on rafts of tangled vegetation washed down from the great rivers, forerunners of the Limpopo and Zambezi, which drained Africa throughout Tertiary times.

Madagascar, in the absence from its fauna of most ungulates and carnivores, is representative of all those islands which have never been connected with the great northern land-masses during Tertiary times. Of such "oceanic islands" the next largest is New Zealand, which possesses no mammals whatsoever except two bats, each the sole representative of a peculiar genus. New Caledonia and most of the Pacific islands are of the same type, whilst the islands of the Malay archipelago have a fauna derived almost entirely from that of Asia.

The foregoing discussion will have shown that only when the history of the animals involved is known in detail, is it possible to interpret an existing geographical distribution, and as this condition is only fulfilled in the case of the mammals and there imperfectly, it is unnecessary to discuss the distribution of other groups in detail. There are, however, certain features of general interest presented by individual members of other groups.

Birds.—Amongst the birds, the large cursorial and flightless forms belonging to the Ratitae, are represented by the emus and cassowaries of Notogaea, the rheas of South America and the ostrich of Africa and Arabia. Extinct ostriches were abundant in Pleistocene times in China and Mongolia, and have been found in the Upper Tertiary of India and the Lower Pliocene of Samos, in association with that great fauna which we have seen to include the ancestors of the living African animals. In addition, in the Pleistocene of Madagascar, there is a series of birds (*Aepyornis*) one of which is the largest known bird, standing some 12 ft. high, with an egg with a capacity of 2 gal. A similar group of forms, very variable as to size and proportions, lived in New Zealand long enough to be hunted by the Maoris, and filled in that island the rôle more normally assumed by ungulates. The occurrence of these giant flightless birds in continental areas is interesting because flightless representatives of other groups are generally restricted to islands where they were not exposed to the attacks of carnivorous mammals: of such forms the most familiar is the dodo, probably allied to the pigeons, which formerly lived in Mauritius, whilst a similar form occurred in Rodriguez. The Chatham islands were inhabited by a whole series of flightless rails.

Reptiles.—The reptiles present an example of a group of animals whose modern distribution is limited by temperature while the broad features of their distribution exhibit much more ancient origins and dispersals than do the mammals. The European reptilian fauna is much impoverished. The British Isles are very nearly at the extreme northern limit of reptile existence, and are inhabited by very few forms; the mud tortoise, *Emys,* which lives in Belgium, is incapable of maintaining itself in England.

While the majority of the orders and families of reptiles are circumtropical or are limited to the tropics in one or more of the tropical regions, there are notable examples of what appear to be relicts of southward dispersal and of dispersal via the Alaskan Holarctic connection. The occurrence of the amphisbaenid lizards, for example, in lower California and Florida, with fossil finds from Mongolia and South Dakota, is such an indication, as is the linking of the two species of true alligators, one in the southeastern United States and one in eastern China by numerous extinct species in western North America.

Amphibia.—The distribution of Amphibia presents some interesting and puzzling features. The caecilians, probably the most archaic group, are strictly confined to the Tropics and occur in the Neotropical, Ethiopian and Oriental regions. The salamanders, a very ancient group, are not now represented in Notogaea. They are at present most abundant and varied in the temperate zone of eastern Asia and North America. The distribution of frogs cannot be intelligently discussed owing to our lack of knowledge of the history of the group.

Fresh-water Fishes.—The distribution of fresh-water fish does not fall easily into the zoo-geographical regions established for

the mammals, a fact which is remarkable because the bony fish are in the main a Cretaceous and Tertiary group. The most archaic of living vertebrates, the lung-fish *Neoceratodus,* now lives solely in two small rivers in southern Queensland, but remains of the same genus have been found in the Pleistocene of South Australia. *Ceratodus* itself is a Triassic form found widely spread all over the world in fresh-water deposits. It is clear that the present restricted distribution has resulted from the extinction of this fish over the greater portion of its former range. The other two dipnoans, *Lepidosiren* of South America and *Protopterus* of tropical Africa, are very closely related to one another, but differ materially from *Ceratodus*. A specimen of *Protopterus* has been found in the Oligocene of Egypt, proving that the group is an ancient one, and its present distribution must depend on factors incapable of analysis. *Polypterus* and its close relative *Calamoichthys,* which are the much modified descendants of the Palaeozoic Palaeoniscidae, are now restricted to tropical Africa, but isolated scales perhaps of the same type occur in the Eocene of Egypt. The sturgeons, belonging to a group which first appears in the Lower Jurassic, are remarkable for their restriction to the temperate waters of the northern hemisphere, where are found all the members of the two existing families. That the only two other living ganoids, the bowfin and the garfish, live in temperate parts of North America, and that both are known from the Eocene of Europe, shows yet again how present distribution may give no clue to former extent of range.

One peculiar family of bony fish, the cichlids, extraordinarily abundant in the great lakes of equatorial Africa, is represented in equal numbers in tropical America, a phenomenon which with the similar distribution of lungfishes and octodont rodents has led to a belief that South America and Africa were connected by a land-bridge until late in Tertiary times. The distribution of mammals makes this view untenable, and when the fossil history of the cichlids comes to be known, it will probably be found either that they once occurred in the northern hemisphere or that the African and American forms are not really closely related. It is impossible to deal in this article with the distribution of invertebrates but the matter is dealt with in the articles dealing with individual groups.

Marine Animals.—The distribution of marine animals depends on many factors. To a considerable extent it is controlled by temperature, many marine forms being capable of life and reproduction only within a narrow range of temperature variation. The seas may be divided into the open oceans and the shallow waters into which detritus derived from the land is carried by rivers.

In the ocean, animals may inhabit three regions; they may live in the surface layers (40 fm.) to a depth where the light intensity becomes negligible and growths of plants is no longer possible: or they may inhabit the midwaters (roughly 40–2,000 fm.) depending ultimately for their food-supply on the remains of dead animals and plants from the surface: or they may live on the ocean bottom even at depths approaching 3,000 fathoms. The fauna of the sea-bottom lives under remarkably uniform conditions; light is absent, the temperature is not far above freezing point, all the food which reaches this region has fallen from the surface of the sea and the bottom is usually soft mud. The abyssal fauna is nearly uniform over the whole world: it includes the great majority of known species of the primitive hexactinellid sponges, and most of the phyla of the animal kingdom are represented, often by forms peculiar in structure and belonging to groups restricted to deep water. Although a more detailed study shows that species and genera may range over only comparatively small areas of the ocean floor, the abyssal fauna is nevertheless remarkably distinct from all others, nearly all its members being recognizable as such at sight.

The free-swimming fauna of the mid-water includes certain radiolarians and medusae. The Crustacea are represented by many forms of prawns, usually bright red in colour, and by a gigantic ostracod. The Mollusca include pteropods and cuttle-fish, but the most abundant forms are fish, very characteristic in their possession of light-producing organs, their black, and in shallower water, silvery colour, and the presence of very large or excessively small eyes.

The pelagic fauna of the surface layers of the ocean consists mainly of transparent animals of delicate structure; it includes the foraminiferan *Globigerina* and many radiolarians, innumerable representatives of the dinoflagellates, some brilliantly phosphorescent, medusae and the floating siphonophores, familiar as the "Portuguese man-of-war." The arrow-worm *Sagitta* is often abundant and certain polychaet worms are of universal occurrence. The Crustacea include immense numbers of copepods, usually very small forms living on diatoms. Other small Crustacea belonging to the Ostracoda are plentiful, while of the higher Crustacea, the schizopods may form a large proportion of the catch. The pelagic molluscs belong largely to the pteropods:

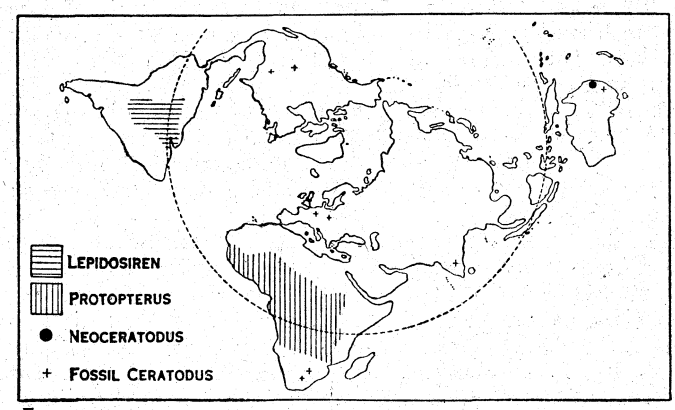

FIG. 5.—MAP OF THE WORLD SHOWING THE DISTRIBUTION OF THE DIPNOI AND THE PLACES WHERE EXTINCT MEMBERS OF THE GENUS CERATODUS HAVE BEEN FOUND

lamellibranchs are absent and gastropods represented by a few special forms. Cephalopods probably form an important element in the pelagic fauna and tunicates belonging to the appendicularians, salps and *Pyrosoma* occur abundantly. The oceanic surface fishes include forms allied to the herrings, with many representatives of the mackerels, flying-fishes and gar-fishes.

The distribution of those animals living near the coast depends very largely on local features such as the nature of the bottom, the salinity, the acidity of the water, the temperature and temperature range, the nature of the currents, and other factors which can only be determined in each individual case. It is therefore impossible to deal with them in this article, but an account will be found in the article DISTRIBUTION OF ANIMALS.

The faunal realms, regions and provinces of the ocean as a whole are far less sharply defined and have received much less attention than has the corresponding zoogeographic partition of the animal life of the land. The distribution of fishes and other animals of commercial importance, however, has been much studied. The subject as a whole has been summarized by A. E. Ortmann (1896) and Sven Ekman (1935).

The primary partitions of the life of the sea, like those of the life of the world as a whole, are essentially ecological. Before geographic distributions can be compared, it is essential to sort the animals into the benthic (bottom-dwelling) types and the pelagic types of the open sea. Within these ecological types, it is useful to distinguish the littoral from the abyssal benthic forms, and to make a similar distinction between the surface zone pelagic forms and the free-swimming forms of the deep sea.

Within these limitations of comparison of faunae, striking geographic features of distribution appear. The secondary partition of the oceanic faunae is clearly dominated by the temperature zones of the sea, modified and confused as they are by the great ocean currents. Arctic, north temperate, tropical, south temperate and antarctic zones are distinguished, often characterized by species and genera rather than by families and orders as is the case with the main faunal divisions of the land.

The tropical belt, with the coral reef habitat strictly limited to it, has a vastly more diverse animal life than have the colder zones. This tropical belt is sharply isolated into the Atlantic and

the Indo-Pacific segments by the land barriers set by the American continents and by Africa and the Isthmus of Suez. It is at first glance extremely astonishing to find that the American land barrier is not the principal partition of the tropical zone at all. The two coasts of Central America prove to be inhabited by distinct faunas between which direct and close relations, species by species, may be traced. For the most part the species of the two coasts form related pairs, the so-called "germinate species." These are of course readily explainable as the result of the long continued Tertiary connection of the Pacific and Atlantic in the Central American region, plus the subsequent species divergence with isolation after the elevation of the Panama connection of the two continents. The marine relations accordingly corroborate the evidence of the South American land fauna.

The major break in the tropical zone is the great area of open ocean between the Americas and the Marquesas and Hawaiian Islands. The maximum wealth of benthic life is centered in the Australasian region, in the shallow island-rich waters between Australia and southeastern Asia. The rich paleontological record of the Mediterranean region indicates that the absence of a large part of this fauna from the Atlantic is the result of progressive extinction and impoverishment during the climatic vicissitudes of the Tertiary.

In the foregoing account it has been assumed that the great continents have been stable in the sense that they contain within themselves great areas, such as Mongolia, eastern Canada, west Australia and south and central Africa, which have been dry land for a period vastly greater than that within which the adaptive radiation and distribution of the mammals has taken place. The truth of this assumption is abundantly demonstrated by geological observations, but the further belief that these old land masses have always occupied the same positions with respect to one another and to the poles has been seriously questioned by A. Wegener.

Wegener holds that in Upper Carboniferous times the whole of the dry land of the world was concentrated into one great continent, subdivided to some extent into independent areas by shallow seas, but essentially continuous. The south pole lay within this land mass in what is now Portuguese West Africa.

The present continents are thought to have arisen from this mass by an actual horizontal displacement, the present coasts, or more accurately the margins of the continental shelfs which face one another across the Atlantic and Indian oceans having formerly been in actual contact. By such drift the Americas were torn away from the western coast of Europe and Africa. Australia and Asia drifted away from Africa on the other side, and the island festoons, New Zealand, the Antilles, Madagascar, etc. have been detached from the neighbouring coast of a continent. These great movements naturally produced great pressures on those continental margins which lay in the direction of motion, and led to the uprising of the coastal mountain ranges which are a marked feature of the earth's morphology.

The continental drift did not take place freely, the large land masses twisted round with respect to one another and became deformed, so that their margins in many cases no longer fit accurately, and small land bridges between the continents persisted long after the main masses had become widely separated.

This remarkable view has been accepted by some geologists and has geological evidence behind some of its basal assumption. Jefferys, however, points out that on geophysical grounds any movement of the continents at all should result in the accumulation of the land masses in the equatorial belt.

Wegener was first led to the proposal of his theory by a consideration of the evidence from the distribution of animals for the former existence of a land bridge between Africa and Brazil. Wegener's view has the very great merit of explaining simply the remarkable facts of the distribution of that peculiar flora, the Glossopteris flora, which in South America, the Falkland Islands, South Africa, Madagascar, India and Australia occurs in late Carboniferous and Permian rocks, usually in association with boulder clays and other evidences of an ice-bound land and arctic climate. It accounts for similarities in the Triassic reptilian faunas of Brazil and South America regions and the extreme resemblance between the land and shallow sea faunas of North America and Europe in Carboniferous times.

But a continuation of these and other land bridges into late Tertiary times, which has been suggested on the evidence of the present distribution of land snails, earthworms and similar groups, seems to be negatived by the distribution of mammals, in which, as W. D. Matthew has shown, the existing distribution of land masses together with a few former land bridges, such as that connecting Asia and America through the Aleutian Islands, are sufficient to account for all the observed facts. The evidence of mammals far outweighs in value that of every other group, because for them alone have we any considerable knowledge of the history of the individual groups.

ZOOLOGICAL NOMENCLATURE is the system by which names in Latin form are applied to the various divisions of the animal kingdom, especially those of genera and species. Names of higher groups, such as orders, classes and phyla, are relatively few in number and are often determined by common consent rather than strict rules. Although essentially the same in principle and largely in practice, zoological nomenclature is independent of botanical nomenclature. Therefore, the use of a name in botany does not preclude the acceptance of the same name in zoology. The system is binary and (with rare exceptions) binomial, following its first consistent use by Linnaeus in the 10th edition (1758) of his *Systema Naturae*. Prior to that date animals were designated by single words or by descriptive phrases, the so-called polynomials. The advantages of a two-name system were at once recognized; one name for the genus and one for the species. Thus the genus *Felis* included various kinds of cats, such as *Felis leo, Felis tigris,* etc. With increased knowledge and refinements of classification, a third name was approved, that of the subspecies or variety to indicate a subdivision (usually geographic) of a species. This produced the trinomial, as *Felis leo senegalensis*.

In spite of the apparent simplicity of the Linnaean system there was much confusion in its early use, and in 1842 there was issued a set of rules (Stricklandian code) sponsored by the British Association of Science. This laid down certain principles which were still followed in 1945, but complications arose and practice was far from uniform. Other codes appeared, notably those of the Sociéte Zoologique de France and the American Ornithologists' union, the last extensively followed in the United States. The Americans fixed the date 1758 (Linnaeus, 10th ed.) as the beginning of nomenclature, whereas the British used 1766 (12th ed.), thus causing a lack of uniformity.

The need for world-wide agreement was seriously considered at the first International Congress of Zoology (Paris, 1889), but it was not until 1902 that an international code of zoological nomenclature was adopted and published by the congress, following the unanimous recommendation of a commission which had been appointed, consisting of 15 members (later increased to 18) representing ten different nations. The president of the original commission was the French zoologist, R. Blanchard, and the secretary the American, C. W. Stiles. The code was something of a compromise, and power to alter it was restricted to the congress with the commission limited mainly to recommendation and interpretation, but various congresses down to that at Lisbon (1935) made a few amendments, and the powers of the commission were

somewhat increased. Zoologists of all countries supported the code and followed its rules so far as possible, but many cases proved so equivocal that they were submitted to the commission, which began to issue a series of "Opinions" (more than 150 by 1945), most of which were accepted and given the force of law. In special cases, the commission was empowered to make arbitrary decisions, and it began the compilation of an official list of generic names which was to be inviolate. A serious difficulty has been the delay in obtaining decisions because of the infrequency of meetings of the congress.

The basis of the rules is the law of priority: "The name of a genus or species can only be that name under which it was first designated." With the re-examination of literature and the changing concepts of zoological groupings, the rigid application of this law has been difficult and elimination of long current names has often been necessary. However, it has been the spirit of the rules that no name be changed except upon convincing evidence. Personal opinion or preference has been largely outlawed and it has been necessary to disregard inferences as to an author's intention and to make judgment solely on his printed record.

The law of priority is not strictly applied to family names, but they are always formed by adding *idae* to the root of the name of the typical genus, and subfamily names by adding *inae*, as Felidae and Felinae from *Felis*. A subgeneric name is governed by the same rules as those applying to generic names, but when written is enclosed in parentheses after the generic name, *e.g., Felis (Lynx) canadensis*. A proper name following a specific name is that of the authority or first proposer of the specific name; if his name be in parentheses it indicates that the species was originally described under a generic name different from the one now combined with it; *e.g., Psittacus linnaei* (Wagler).

ZOOLOGY, the study of animals. The science of zoology embraces all conceivable modes of study, not only of individual animals but of entire faunas and of the relations of animals with one another, with plants, and with the nonliving environment. Because of its vast scope, zoology is usually broken up into several subsidiary subjects of which the chief ones are: morphology or anatomy, histology and cytology, embryology, palaeontology, taxonomy or systematics, genetics and evolution, ecology and physiology. As special articles under these names will be found in the encyclopaedia, only a brief survey can be attempted here of the main findings in the various fields of zoology, with special emphasis on morphology and classification. Although animal physiology, strictly speaking, is a branch of zoology, it is usually considered an independent science and will not be treated here.

MORPHOLOGY

The study of zoology undoubtedly had its origin from the observation that there are many different kinds of animals. The more obvious and easily discovered characters that distinguish animals from one another are the external ones: differences in body shape, size and colour, character of the skin and its derivatives as scales, hair and feathers, presence of prominent sense organs, such as eyes and ears, and presence of legs or other appendages. But it soon became clear to zoologists that external appearances alone will not provide understanding of the animal kingdom, thus they were driven to a study of internal structure. Anatomical investigations of this character were carried out at first entirely by dissection of the animal's carcass with knives, scissors and other instruments, a technique that, in skillful hands, can yield an astonishing amount of accurate information but which is necessarily incapable of revealing many structures, either because they are too small to be seen or are otherwise undiscoverable. Progress in anatomical investigation, therefore, had to await the introduction of the microscope (toward the end of the 16th century). The possibility of magnifying an animal at once greatly extended the scope of zoology, since it enabled the structure of very small animals to be investigated and, indeed, revealed the existence of an immense variety of microscopic animals previously unknown because they were too small to be seen with the unaided eye.

Cellular Structure of Animals.—The most important revelation of microscopical study was the discovery, through the efforts of a number of workers toward the end of the 18th century and during the first half of the 19th, that animals (and plants) do not consist of a continuous mass of material, but that their substance is partitioned off by walls and membranes into an immense number of minute units, the cells. The cells of an animal are not all alike, but occur as a number of different kinds with appropriate functions, a condition known as differentiation. Cells also do not in general occur singly; but many of one kind are united in masses or sheets termed tissues. Organs such as the stomach or liver consist of two or more kinds of tissues closely associated. Thus, the body of an animal consists of cells combined to form tissues and organs.

During the last half of the 19th century great progress was made in the study of cells. It was discovered that cells have affinities for dyes similar to those used in dyeing cloth, and that with the aid of such dyes the details of cell structure are made much more visible and apparent for microscopical examination. Because only very thin objects can be studied with the microscope, methods and a machine, the microtome, were devised by which small animals or pieces of larger ones could be sliced into a series of exceedingly thin sections, and these mounted serially on glass plates for microscopical examination. By the application of such methods an understanding was attained of the internal structure of a great variety of animals. That branch of zoology which concerns itself with the kinds of cells that go to make up an animal is termed histology (*q.v.*), and that which studies the fine details of structure within the cells is called cytology (*q.v.*).

The discovery and study of the cellular structure of animals and plants resulted in the last half of the 19th century in a philosophy termed the cell theory. This theory exaggerated the importance of cells and considered them to be the vital units in which were vested all of the phenomena of life. An animal was regarded not as a functioning whole but merely as a collection of cells and its properties merely as the sum of the properties of the cells. Following a wide acceptance, this theory began to be questioned and discarded by the leading thinkers among zoologists, and is being replaced by the organismal conception, which maintains that the cells are simply constituent parts of an animal and that such phenomena as growth, form, reproduction, development, heredity and evolution are clearly manifestations of the animal as a whole, and cannot be understood merely by studying its cells.

Grades of Structure.—All combined methods of studying the structure of animals show that animals exist in several grades of structure ranging from simple to complex. Such arrangements are, of course, more or less artificial but they assist in enabling one to understand the animal kingdom.

In the first place it was soon discovered that animals are divisible into two great groups, those that are made of cells and those that are not. The latter group comprises a host of microscopic animals whose substance is not partitioned into cells, and which are thus regarded simply as consisting of one cell. These one-celled or unicellular animals are known as Protozoa. In reality, they are not equivalent to a single cell of other animals but constitute complete little organisms capable of all the functions that distinguish larger animals. Their bodies may be far more elaborately organized than any of the cells of higher animals and may contain contractile and neuroid fibrils, supporting plates and fibres of a skeletal nature and elaborate food-catching mechanisms. Although sexual processes also occur among the Protozoa, practically all of them can reproduce simply by dividing into two or more parts.

All other animals are composed of cells, although in some cases the cell walls may more or less disappear as the animal matures. These multicellular animals are termed Metazoa. They are not only composed of cells, but their cells are differentiated into a number of different kinds and are associated into tissues and organs for the performance of different functions. A metazoan animal is an individual, a unit whose cells are subordinated to the whole and are not in general capable of an independent existence or of performing all of the necessary functions as is the case with the protozoan cell.

It follows, as a necessary concomitant of the cellular differentiation of the metazoan body, that all such animals must undergo a process of development (*see* EMBRYOLOGY) during which this complication gradually arises. Although there are a number of cases among the Metazoa in which reproduction occurs by division or budding much as in Protozoa, the Metazoa generally reproduce sexually, giving rise to female sex cells or eggs, and male sex cells or sperm. The egg is large, provided with food supplies

in varying amounts and nonmotile. The spermatozoan is relatively very small and slender and provided with a locomotory apparatus for reaching the egg. When the egg is fertilized by a spermatozoan, *i.e.,* fuses with it, it starts upon a process of development during which it divides to make many cells, and these undergo differentiation. However, many Protozoa also produce eggs and sperm and undergo some degree of development so that the contrast between Protozoa and Metazoa is not as great as assumed during the heyday of the cell theory. There are, further, types of colonial Protozoa that approach the metazoan condition.

Among the Metazoa it is customary to set off one group, the sponges or Porifera, from the others because of their lowly grade of organization and many peculiarities of structure. Sponges are little more than loose aggregations of cells covered over by an epithelium. Although the cells of sponges show some degree of differentiation, they are mostly variants of amoeboid types and each can perform a number of different functions. Furthermore, sponges have no mouth or proper digestive cavity; they are permeated by systems of canals through which a continuous water current is maintained. On these grounds sponges are separated as a branch Parazoa from other metazoans which are then called Eumetazoa or Metazoa proper.

The Eumetazoa all have a proper mouth and digestive tube; they present many grades of structural complexity of which the lowest is represented by the group Coelenterata (*q.v.*). The Coelenterata illustrate the structural plan on which the Eumetazoa are based and from which the more complex members can be theoretically derived. The coelenterates are composed essentially of tissues; *i.e.,* they represent a tissue grade of construction. They consist of two epithelia back to back with some sort of cement or connective tissue between. The outer epithelium, the ectoderm, or better, epidermis, has protective, nervous and sensory functions, and the inner epithelium, the entoderm, or better, gastrodermis, forms a primitive digestive tube. Epidermis and gastrodermis meet at the mouth. Both epithelia may give off muscle fibres that lend the animal a considerable degree of motility. It is characteristic of animals of the tissue grade of construction that they are built on the plan of radial symmetry or some variant thereof (*see* MORPHOLOGY). Consequently they may be termed radiate animals or Radiata.

All other Eumetazoa are constructed on the plan of bilateral symmetry, and hence may be collectively termed Bilateria. They show definite differentiation into anterior and posterior ends, and dorsal and ventral surfaces (*see* MORPHOLOGY). Their tissues are also more or less aggregated into organs so that they may be considered to be of the organ-system grade of construction. Between their outer or ectodermal epithelium and inner or entodermal epithelium they have a mass of mesodermal tissue that gives rise to muscles, connective tissues, and reproductive, circulatory and excretory systems (*see* EMBRYOLOGY).

It is customary to group the Bilateria on the basis of the number and kinds of internal cavities. The lowest Bilateria, the Platyhelminthes or flatworms, have the same solid construction as the Coelenterata; *i.e.,* there is only one internal cavity, the digestive cavity. In the flatworms the space between epidermis and digestive epithelium is filled with tissues and organs of mesodermal origin. Bilateria having this kind of solid construction are called acoelomate.

The remaining Bilateria have an extra space between the digestive tube and the body wall, but it appears that this space is not necessarily the same as to embryonic origin in different groups. When this space is formed by the parting of the mesoderm so that it has mesoderm on both sides of it, the space is considered a true coelom. When, however, this space is a remnant of the blastocoel (*see* EMBRYOLOGY) and has mesoderm on only one side or on neither side of it, it is considered a false coelom or *pseudocoelom.* The Bilateria, therefore, exist in acoelomate, pseudocoelomate and coelomate grades.

It is likewise characteristic of all Bilateria, except the Platyhelminthes, that the digestive tube has a rear opening, the anus. The presence of an anus greatly increases the efficiency of the digestive tube, for there is then no mixing of food in various stages of digestion as must be the case where the digestive tube has but one opening, serving for both ingestion of food and ejection of indigestible remnants. Further, in coelomate animals part of the mesoderm attaches to the digestive epithelium, furnishing muscle layers to the latter and conferring motility upon the digestive tube.

A feature seen in three groups of higher Bilateria (Annelida, Arthropoda and Chordata) is the segmentation of the body, *i.e.,* the division of the body along its main axis into a series of equal joints or segments, each of which contains a representative of the various body systems (*see* further, article MORPHOLOGY).

Organ Systems.—As already intimated all of the Bilateria are provided with organ-systems, *i.e.,* associations of organs for the performance of specific functions. The organ-systems of the higher Bilateria are the following: integumentary, muscular, skeletal, nervous, sensory, digestive, excretory, reproductive, circulatory, respiratory and hormonal. These systems appear gradually in the lower Metazoa and attain their full complexity and functional specialization only in the higher ones.

The integumentary system comprises the skin and its derivatives such as cuticle, scales, feathers, hair and armour (exoskeleton). The essential purpose of this system is protection against the external world and against drying out of internal parts.

The muscular system consists primitively of a layer of muscle fibres running in two or more directions situated just beneath the external covering. Such a system is incapable of complicated movements but serves to shorten and extend the animal and to allow it to bend in various directions. In higher animals the muscle fibres aggregate into definite bundles or muscles that permit much more varied and exact movements.

The skeletal system is closely associated with the muscular system, being in fact derived from the same embryonic source, and functions chiefly as a support for the musculature. The skeleton, properly speaking, is an internal structure and is best illustrated in the vertebrates with their internal assemblage of cartilage and bones. Among the invertebrates, skeletal structures such as the shells of molluscs are chiefly external, and, therefore, really belong to the integumentary system. Such exoskeleton also serves for muscle attachment as well as for protection.

The nervous system is a derivative of the surface covering (epidermis) and functions for the correlation of body activities by means of its power of rapid transmission. It consists essentially of nervous tissue aggregated into masses (ganglia) and strands (nerves). It is characteristic of the nervous system of vertebrates that it is dorsal and hollow whereas that of invertebrates is ventral and solid. In the evolution of animals the nervous system gradually shifts from a superficial position immediately under the epidermis to a deeper position, to the inner side of the muscle layer.

The sensory system is that part of the nervous system that responds to external factors and transmits these responses to the central nervous system where appropriate action is initiated. The sensory system consists of a variety of nerve endings and sensory organs designed to be affected by particular external factors such as light, sound waves, odours, temperature, etc. Whereas the essential sensory part is microscopic, numbers of such parts may be aggregated with accessory structures to form conspicuous organs such as the eye, ear, etc.

The digestive system consists in its earliest form, as seen in coelenterates, simply of the inner epithelial tube and has only one opening, the mouth. In the metazoan series, the digestive tube becomes separated from the body wall by the formation of either a pseudocoelomic or a coelomic cavity and at the same time acquires a rear opening, the anus. In coelomate animals part of the mesoderm attaches to the digestive tube, forming muscle layers for the latter which then becomes capable of motility. Various functional regions become differentiated along the digestive tube in different animals, as a crop for storing food, gizzard for grinding hard food, stomach for the main processes of digestion, intestine for absorption, etc.; glands that secrete digestive enzymes or other substances involved in digestion occur either in the wall of the digestive tube or attached to it. Among the vertebrates

the liver and the pancreas are conspicuous glands that embryologically are formed from the lining epithelium of the digestive tube.

The foregoing systems occur in all the Eumetazoa, but the following ones are found only in the Bilateria. The excretory system has the function of regulating the water content of the body and secondarily of removing the useless products of body chemistry, especially nitrogenous products. The system consists primitively of secretory tubules that have either closed inner ends or open at their inner ends into body spaces. At first the tubules obtain their excretory material directly from body spaces but with the increasing size and complexity of the animal they obtain it from the blood and the internal openings then close up. In vertebrates the tubules are aggregated into organs known as kidneys, which extract water and nitrogenous waste products from the blood.

Although sex cells occur in all groups of animals, including some Protozoa, a definite reproductive system with ducts and other differentiated parts is first seen in the lowest Bilateria (flatworms) and is characteristic of the Bilateria in general. Although very simple reproductive systems are seen in many Bilateria, in others the system reaches inexplicable complexity. The complexity is associated with internal fertilization, *i.e.*, the passage of sperm from the male to the female, and seems to indicate that such fertilization is more desirable than the mere shedding of sex cells into the water.

The circulatory system consists of a set of tubes for distributing respiratory gases and food, and collecting waste materials; there is also usually one or more pumping organs to aid the process. Such a system is obviously necessary only to animals of some size and complexity because in small animals physical diffusion is adequate. Hence, the circulatory system is found only in the larger and higher Bilateria and reaches a complex development only in the vertebrates. The circulatory system is filled with a fluid, the blood, that may or may not be red, and that travels in a circuit passing through respiratory organs for the exchange of gases, and close to the excretory organs for the emission of wastes. The red colouring matter found in vertebrate (and some invertebrate) bloods is concerned with the exchange of gases (*see* RESPIRATION).

The respiratory system is concerned with the exchange of respiratory gases and also occurs only in the larger and more complex Bilateria since such exchange takes place by diffusion in smaller forms. Animals obtain energy for their life processes by means of oxidation; therefore, they must continually absorb oxygen or they die. Carbon dioxide is emitted as a result of the oxidation process. A respiratory system is a device for facilitating the absorption of oxygen and the emission of carbon dioxide, and is not itself the seat of the oxidation process. Its essential features are a large exposure of surface to the gases and thin walls to permit easy passage of gases. Hence, a respiratory organ is a greatly folded structure of spongy, feathery or booklike appearance. It may project to the outside and is then known as a gill, or it may project into the interior, forming a lung. Gills get their gases from the surrounding medium, usually water, and lungs get theirs from the air. There are often accessory mechanisms for causing water to flow over the gills or for causing air to pass into and out of the lungs. Such respiratory mechanisms should not be confused with the true process of respiration, which consists of the utilization of oxygen by the body cells.

The hormonal system consists of a number of glands or gland-like bodies that have no ducts and hence secrete their products directly into the blood, for which reason they are also called endocrine glands or glands of internal secretion. They are best known in vertebrates where they include the pituitary body of the brain, the thyroid, parathyroid, the islets of Langerhans in the pancreas, the adrenal glands near the kidneys and the sex glands. The secretions of these glands are necessary for the normal growth and health of the body and for the initiation and maintenance of sexual reproduction. The substances that they secrete are known as hormones. Hormone-secreting structures also occur in invertebrates but are less well-known.

CLASSIFICATION

The knowledge gained through anatomical and microscopical studies, plus the results accumulated in the fields of embryology (*q.v.*) and palaeontology (*q.v.*), has enabled zoologists to classify the animal kingdom. Classifications were of course attempted long before the necessary knowledge was available, but only after 1850 had considerable agreement been reached about the main subdivisions of the animal kingdom. Classification consists essentially of grouping together animals of like structure, in much the same manner as one would separate a mixed lot of grains into wheat, corn, oats, etc. Although seemingly simple in principle, zoological classification is exceedingly difficult in actual practice and depends largely on the personal judgment of zoologists. The usual difficulty consists in deciding when a degree of difference is sufficient to justify the making of a different category. The classification of so-called aberrant forms, *i.e.*, individuals or small groups of animals that do not seem to fit into any of the established groups, also raises great difficulty. As a consequence, no two zoologists or zoological texts agree in all details on the scheme of classification, although a considerable amount of agreement will be found. The branch of zoology that deals especially with classification is termed taxonomy or systematics but so vast is the number of animals (probably approaching 2,000,000) that any one zoologist must limit himself to the taxonomy of a single group.

The Species.—Classification begins by separating animals into different kinds. Thus, anyone can see that the common horse is very much alike throughout the world and that it is different from the cow. This difference is expressed by regarding the entire population of horses as constituting one category, termed the species; the same is done for cows, and for other animals. Although an exact definition of the species concept has given zoologists much trouble, for practical purposes a species may be defined as a population or populations of animals that are alike in the details of their structure within close but variable limits, and that breed together, or can do so.

In the early days of classification when relatively few specimens were available for study, species seemed to be easily distinguishable from each other. But as more and more specimens were collected, and as zoologists began to study actual populations as they exist in nature, it became apparent that the majority of species do not constitute a uniform population, but comprise a number of geographically distributed populations that differ from each other in minor details. Thus, the species in many cases really consists of a few too many geographic races or variants, usually termed varieties or subspecies, many of which were formerly considered distinct species, because of insufficient collecting. It is therefore evident that to determine the content of a species and to distinguish species from each other, extensive collecting over the entire range of distribution is necessary. The interbreeding test should be applied when possible, although it is often obviously impractical. The breeding test is not, however, conclusive since individuals belonging to what taxonomists regard as distinct species do sometimes interbreed in nature.

It is believed by most zoologists (although denied by some), that the geographical variants of a species represent incipient species, and that they will become distinct species whenever they cease to breed together either because of morphological divergence of their copulatory organs or because of behaviouristic divergence.

The Genus.—The next taxonomic category above the species, referred to as the genus, embraces a number of species of sufficiently similar morphology. In short, after the species are defined and delimited they are grouped together according to similarity and each group of similar species constitutes a genus. It is clear that whereas the species has a real existence in nature, the genus is a more or less arbitrary conception. How much species must resemble each other to justify their grouping into one genus, and how much they must differ to justify separating them into different genera are obviously matters of judgment on the part of the taxonomist. As a result, there is a continuous process in taxonomy of transferring species from one genus to another.

The Scientific Name.—Since the days of Carolus Linnaeus, who invented the system, it has become obligatory upon zoologists to combine the generic with the specific name to form the accepted scientific name of the animal. This procedure is termed the binomial system of nomenclature. The generic name is capitalized; the specific name begins with a small letter. The scientific name has to be constructed in Latinized form and hence is understandable throughout the world, whereas common names are confusing and inexact, and vary with language. The scientific name is, therefore, a very useful tool, since each scientific name can designate only one kind of animal; what is meant by that name is apparent to zoologists throughout the world.

Higher Taxonomic Categories.—By using more and more important characters as a basis for deciding resemblance, larger and larger taxonomic divisions can be constructed. The most important ones in common use are family, order, class and phylum. A family is composed of those genera having certain characters in common; an order is made up of families of similar construction, etc. If considered desirable in any particular case, these categories can be subdivided to form subfamilies, suborders, etc., or grouped as superfamilies, etc. Like the scientific name, the names of all taxonomic categories are constructed in Latinized form, usually of Greek and Latin roots. The names of families and subfamilies must be constructed from the name of their principal genus and must end in *idae* and *inae,* respectively. No rules govern the formation of names higher than family although they generally terminate in *a.*

The Phylum.—The highest taxonomic category of all is termed the phylum, which thus constitutes the primary division of the animal kingdom. Each phylum is sharply characterized by a plan of structure in the adult peculiar to it and differing from that of other phyla in such ways that in general phyla are not derivable from each other. However, as all animals are related to each other by descent (*see* EVOLUTION), it is evident that at some time in its past history each phylum must have been derived from some pre-existing phylum, and one of the favourite "arm-chair" occupations of zoologists, especially in the past, was the surveying of available evidence for indications of phyletic relationships, a field of zoology termed phylogeny. The evidence most useful in such phylogenetic speculation is that drawn from embryology (*q.v.*) and palaeontology (*q.v.*). The facts, however, are so scanty that the various schemes of interphyletic relationships that have been advanced must be regarded merely as suggestive. At the present time in the earth's history the different phyla of animals are widely separated from each other in structural plan, and no intermediates between phyla are known except in the case of the phyla Annelida and Arthropoda.

Identification of Animals.—Through his knowledge of the structural characters on which the taxonomic divisions are based, a zoologist when confronted with an unknown animal can usually place it at least to order after a brief examination. However, the determination of the genus and species to which an animal belongs is generally a matter that calls for prolonged study, often with the aid of microscopic examination, because the characters that separate genera and species are usually minute and detailed. In general, only a specialist in the group to which the animal belongs is competent to identify it to genus and species, and identifications should not be attempted by others. The correct identification of an animal is of great importance in zoological research so that zoologists all over the world may know what animal is under discussion. Very often in the history of zoology, heated arguments have arisen over differing research results that in reality were caused by the fact that different species were being used. Experience has shown that results obtained with one species cannot safely be assumed to be applicable to another, even closely related, species. Correct identification is also of great importance in the economic relations of zoology, being the first necessary step in the understanding and control of pests and parasites, and in the encouragement of useful animals.

THE PHYLA OF THE ANIMAL KINGDOM

The question of the division of the animal kingdom into phyla is one of the greatest importance to the zoologist because such division really expresses the state of his knowledge of animal structure, development and relationships. In the beginning of the era of modern zoology, roughly from the times of Linnaeus, the divisions proposed were highly erroneous, being based chiefly on external appearances. As discussed above, a correct knowledge of animal structure is attained only through dissection and microscopical examination. Embryological studies also are of the greatest importance (*see* below). As knowledge from these sources accumulated, the phyletic arrangement was continuously altered by a succession of zoologists, and cannot be said to have attained a stable condition even to this day. The reasons for this are, first that embryological and morphological information is still far from complete, and, second, that opinions differ as to what characters are the most important in defining phyla. Some zoologists tend to lump groups together so as to make a few very inclusive phyla and others tend to separate off various small groups as independent phyla. Consequently any published arrangement of phyla must be understood to represent merely some zoologist's opinion.

The following scheme leans towards the separation of small groups as independent phyla. It is based on the grades of structure discussed above, presence or absence of an anus, kind and number of body spaces, etc.

KINGDOM ANIMALIA

Subkingdom I. Protozoa. Animals consisting of one cell or of colonies of like cells.

Phylum 1. Protozoa.
Class 1. Flagellata
Class 2. Rhizopoda
Class 3. Ciliata
Class 4. Sporozoa

Subkingdom II. Metazoa. Animals composed of unlike cells that may lose their boundaries in the adult state.

Branch A. Mesozoa. Parasitic animals composed of a surface layer of epithelial cells inclosing reproductive cells.

Phylum 2. Mesozoa

Branch B. Parazoa. Animals composed of several kinds of differentiated cells somewhat arranged in tissues; without organ systems or mouth; porous.

Phylum 3. Porifera, the sponges
Class 1. Calcarea
Class 2. Hexactinellida
Class 3. Demospongiae

Branch C. Eumetazoa. Metazoa with cells arranged in tissues; usually also with organ systems; with mouth and digestive tract except when lost by parasitic degeneration; not porous.

Grade I. Radiata. With primary radial symmetry; of the tissue grade of construction.

Phylum 4. Cnidaria or Coelenterata, the coelenterates. Radiata with nematocysts; no ciliated plates.
Class 1. Hydrozoa
Class 2. Scyphozoa
Class 3. Anthozoa

Phylum 5. Ctenophora, the comb jellies. Without nematocysts; with eight rows of ciliated plates.
Class 1. Tentaculata
Class 2. Nuda

Grade II. Bilateria. Eumetazoa with bilateral symmetry or secondary radial symmetry; with organ systems.

Section a. Acoelomata. No space between digestive tube and body wall.

Phylum 6. Platyhelminthes, the flatworms. No anus.
Class 1. Turbellaria
Class 2. Trematoda
Class 3. Cestoda

Phylum 7. Nemertina or Rhynchocoela, the nemertine worms. With anus; with a protrusible proboscis above the digestive system.

Section b. Pseudocoelomata. With pseudocoelom between digestive tract and body wall; usually with anus; body clothed with cuticle.

Phylum 8. Acanthocephala, the spiny-headed worms. Parasitic worms with spiny protrusible anterior end; without mouth or digestive tract.

Phylum 9. Aschelminthes. Without spiny proboscis, or if so, not parasitic; nearly always with mouth and digestive tract.
Class 1. Rotifera, the rotifers
Class 2. Gastrotricha
Class 3. Kinorhyncha or Echinoderida

Class 4. Nematoda, the round worms
Class 5. Nematomorpha or Gordiacea, the gordian worms
Phylum 10. Entoprocta. Anterior end bears circle of ciliated tentacles, inclosing mouth and anus.

Section c. Eucoelomata. With true coelom; with anus and organ systems.

1. With a lophophore, a circular, crescentic, or double spirally coiled ridge bearing ciliated tentacles.
Phylum 11. Phoronida. Wormlike.
Phylum 12. Bryozoa, the moss animals. Colonial with gelatinous, chitinous or calcareous encasements.
Phylum 13. Brachiopoda, the lamp shells. Inclosed in a bivalve shell.

2. Without a lophophore; coelom a schizocoel, formed by a mesodermal split.

a. Body not segmented.
Phylum 14. Mollusca. Visceral mass covered by a body fold, the mantle, that secretes an external shell of one or more pieces; coelom usually reduced.
Class 1. Solenogastres
Class 2. Placophora
Class 3. Gasteropoda
Class 4. Scaphopoda
Class 5. Pelecypoda
Class 6. Cephalopoda
Phylum 15. Sipunculoidea. Wormlike, with eversible proboscis, anus anterior, dorsal.
Phylum 16. Priapuloidea. Similar, anus at posterior end.
Phylum 17. Echiuroidea. Similar, without eversible proboscis.

b. Segmented.
Phylum 18. Annelida, the annelids. Worms, with long jointed bodies, but without jointed appendages.
Class 1. Archiannelida
Class 2. Chaetopoda
Class 3. Hirudinea
Phylum 19. Arthropoda, the arthropods. Mostly not wormlike, body bears jointed appendages.
Class 1. Onychophora
Class 2. Crustacea
Class 3. Arachnida
Class 4. Pentastomida or Linguatulida
Class 5. Pycnogonida or Pantopoda
Class 6. Pauropoda
Class 7. Diplopoda
Class 8. Symphyla
Class 9. Chilopoda
Class 10. Insecta

3. Without a lophophore; coelom an enterocoel, formed by outpouchings of the digestive tube.

a. With secondary, usually pentamerous radial symmetry; with a water-vascular system.
Phylum 20. Echinodermata, the echinoderms.
Class 1. Asteroidea
Class 2. Ophiuroidea
Class 3. Echinoidea
Class 4. Holothuroidea
Class 5. Crinoidea

b. Bilateral symmetry retained throughout life.
Phylum 21. Chaetognatha, the arrow worms. Wormlike, without gill slits or endoskeleton.
Phylum 22. Hemichordata. Wormlike with gill slits.
Phylum 23. Chordata. Not wormlike, adults with gill slits or vertebral column or both.
Subphylum 1. Urochordata or Tunicata.
Subphylum 2. Cephalochordata or Acrania.
Subphylum 3. Vertebrata or Craniata.
Class 1. Agnatha
Class 2. Placodermi
Class 3. Chondrichthyes
Class 4. Osteichthyes
Class 5. Amphibia
Class 6. Reptilia
Class 7. Aves
Class 8. Mammalia

The above omits two groups of very uncertain position, the Tardigrada, or water bears, and the Myzostomida, a group of flat, disc-shaped animals ectoparasitic on echinoderms. These groups seem to be intermediate between Annelida and Arthropoda with closer affinities to the former. The systematic position of the groups Onychophora and Pentastomida is also disputed. For further information about the phyla, special articles in the encyclopaedia should be consulted.

EMBRYOLOGY AND THE HOMOLOGY OF THE GERM LAYERS

Animals in general develop from a single cell, the egg, which, after being stimulated by fusion with a sperm, enters upon a remarkable process of embryonic development in which the definitive characters gradually make their appearance. When this process was studied in many diverse animals, zoologists began to realize that certain similarities obtain throughout the animal kingdom. First the egg undergoes cleavage, dividing up into a ball of many cells. A two-layered condition, the gastrula, follows, in which the embryo consists of an outer epithelium, the ectoderm and an inner epithelium or, in some cases, a solid mass, the entoderm. The manner of origin of the entoderm is varied, but great importance has been attributed by some zoologists, notably Ernst Haeckel, to one particular method, that of invagination, or the bending inward of the outer epithelium. Haeckel, and after him most zoological texts, considered invagination to be the original and primary method and other methods derived and secondary. This proposition is open to grave doubt, but it is probably impractical to ascertain what was the original method of entoderm formation.

Following the establishment of the gastrula stage, the next general step in development is the formation of a tissue between the ectoderm and the entoderm, termed the mesoderm. Here again varied modes of formation of mesoderm are seen in different animal embryos, but most prominence was given in zoological theory to one particular method, the enterocoelous method, in which the mesoderm arises by the out-pushing of pockets from the entoderm. Again the primary nature of the enterocoelous method may be seriously questioned, but the determination of the original mode of mesoderm formation is probably an impossibility.

Ectoderm, entoderm and mesoderm are known as the germ layers, and from them all of the tissues and organs of the adult animal are derived, chiefly by processes of folding and migration. Their role in the production of adult structure is generally much the same throughout the animal kingdom. The ectoderm furnishes the surface covering of the animal (epidermis), and also the nervous system and the nervous part of the sense organs. The entoderm furnishes the lining epithelium (gastrodermis) of the digestive tract and the epithelial cells of various outgrowths of the digestive tract, such as the liver, pancreas and other glands. All the tissues and organs between the epidermis and gastrodermis are of mesodermal origin, *i.e.*, the muscles and connective tissues, the bones and cartilages of the skeleton, and the circulatory, excretory and reproductive systems. In coelomate animals, the mesoderm separates into a somatic part, which furnishes the muscles of the body wall and also the skeleton, and a splanchnic part, which attaches to the viscera and provides their muscular layers. The space between the somatic and splanchnic mesoderm is the coelom.

These facts are certainly very striking and have led to an important zoological theory termed the *homology of the germ layers*. This theory states that development by means of germ layers is fundamental throughout the multicellular animals; that the germ layers were originally (if not now) formed in the same way throughout the Metazoa; that each of them produces the same organs wherever found; and that in short there is complete morphological correspondence between the same germ layers in different animals. Different grades of construction are regarded as representing different stages in germ-layer formation. The coelenterate or tissue-grade corresponds to the gastrula or two-layered stage of development; the acoelomate or flatworm stage corresponds to the stage after the mesoderm has arisen but has not yet divided into somatic and splanchnic layers, etc.

Germ-layer theory prevails in embryological teaching to the present time and certainly constitutes an orderly method of presentation of the subject. The theory has, however, been subject to severe criticism in recent years, and it is not yet clear to what extent it will survive. In regard to early embryonic stages, it must be admitted that the actual modes of formation of the germ layers and the processes of early development are extremely

varied, and it is impossible on the available facts either to affirm or deny some original uniform method of germ-layer formation. There is, however, undoubtedly, a marked similarity in the later developmental stages and the manner of formation of many organs among the Bilateria.

The main criticisms of the germ-layer theory come from the field of experimental embryology (*q.v.*). Transplantation experiments have shown that in early embryonic stages of many animals, pieces of germ layers when transplanted into appropriate sites may be caused to develop into organs that would normally come from some other germ layer. As development proceeds, this is no longer possible, for the fate of embryonic regions becomes more and more fixed and in the case of some animals is fixed at very early stages. These experiments cannot, therefore, be regarded as overthrowing the germ-layer theory. They confirm what observation had shown, namely, that the early stages are labile and do not conform in different animals but that the later stages do show the uniformity of development demanded by the theory. It therefore seems probable that the germ-layer theory in its broader aspects will remain a permanent part of zoological science.

EMBRYOLOGY AND THE THEORY OF RECAPITULATION

The similarity of embryological processes throughout the Bilateria suggests some underlying principle, and this principle is to be found in the phenomenon of evolution (*q.v.*). The resemblance between lower animals and the embryos of higher ones had, however, been noted long before Charles Darwin enunciated the theory of evolution in 1859, especially by J. F. Meckel, 1821, A. E. R. A. Serres, 1842 and Karl Ernst von Baer, 1828. Von Baer formulated his observations on development in four "laws," of which the fourth one states that the young stages of higher animals resemble the young stages of lower ones. Following the publication of Darwin's book, *The Origin of Species,* the concept of evolution as an explanation of the embryonic stages through which higher animals pass was first advanced by Fritz Müller, 1864, and strenuously advocated by Ernst Haeckel, beginning in 1866. Haeckel had a gift for trenchant phrases, and zoology has become thoroughly imbued with his formulations of the relation between evolution and development. Haeckel's generalization is, in effect, that an animal in its development passes through stages representing the ancestors it had during its evolution from lower animals. This doctrine is termed recapitulation or the *biogenetic law,* and was epitomized by Haeckel in such phrases as "ontogeny repeats phylogeny," and "phylogeny is the mechanical cause of ontogeny," etc.

As already noted, the general resemblance of embryonic stages among animals is not to be doubted, and is particularly marked among the members of a given phylum; neither is it to be doubted that evolution, *i.e.,* descent from a common ancestor, is the explanation of this resemblance. However, there has been a great deal of argumentation as to the correctness of Haeckel's theory of recapitulation, *i.e.,* as to whether it is true or not that embryonic stages represent *adult* ancestors. The accumulated facts and arguments indicate that the relation between evolution and embryology does not follow any one rule but is a combination of several different kinds of rules. In some cases development follows ancestral stages up to a very late period, then adds on a new stage that makes the animal different from its ancestors. This type of development most nearly conforms to Haeckel's recapitulation. In many other cases, however, the development diverges from the ancestral pattern at an earlier time, sometimes very early in development. Or, ancestral stages may be omitted at the end or in the middle or even very early in development. The order of development may also be altered so that events may occur in a different order in the descendant than they did in the ancestor. Finally, many embryos exhibit adaptive structures that have no relation to any ancestor but are concerned in embryonic life.

It appears clear enough that Haeckel's formulation was altogether too narrow, and it is probable that no embryonic stage ever represents an exact duplication of an adult ancestor, although very considerable resemblance may obtain in some cases. It is more common for embryonic stages of the descendant to resemble embryonic stages of the ancestor. Phylogeny is not the cause of ontogeny but rather phylogenetic progress, *i.e.,* the evolution of new types, is brought about by deviation from the ancestral pattern during the course of embryonic development.

Ancestral reminiscence during development is then a general zoological principle; commonly this reminiscence concerns the embryonic or larval stages of the ancestor rather than the ancestor itself. Ancestral reminiscence has been of the greatest value in working out relationships especially among the invertebrates. In vertebrates there is an extensive fossil record and fossil findings have given zoologists a fairly complete story of the evolution of the main vertebrate groups. But invertebrates often have no hard parts preservable as fossils and in general palaeontology has been of little value in determining relationships among invertebrates. Hence, embryology is the chief tool for elucidating phylogenetic problems in the invertebrates. It is in fact a truism that a group is not understood in its relations to other invertebrate groups until the embryology of several members has been thoroughly worked out. Many examples could be cited of the solving of the taxonomic position of aberrant forms by means of their embryology. Thus *Sacculina* and related forms are very degenerate parasites of crustaceans, being reduced in the adult state to a nearly structureless sac with rootlike extensions into the host's tissue. It would be impossible to determine the taxonomic position of these parasites by study of their anatomy; but when it is found that their development closely follows that of barnacles, no doubt remains that they are degenerate barnacles.

VARIATION, HEREDITY, AND EVOLUTION

As seen above, hereditary factors play an important role in embryonic development; but as shown by the work in experimental embryology (*q.v.*), environmental influences are also operative. The study of the roles of heredity and environment in the production of the characters of the species and the mechanism of such production constitutes one of the most important and flourishing branches of zoology, generally termed genetics. The end and aim of genetics may be stated to be an understanding of the mechanism of heredity (*q.v.*) under specific environmental conditions, and thereby of evolution (*q.v.*).

Variation.—No two animals, even belonging to the same brood, are alike; although exhibiting a close similarity to their parents and to one another, each will differ from all others to a small extent or sometimes they may vary considerably in one or many respects. Such differences between individuals of the same species or variety is termed variation and the investigation of the nature and causes of these variations and of the manner and the extent to which they are passed on from one generation to the next is the main subject matter of genetics. The inheritance of variations is studied by breeding experiments; variation as it exists in a given population is studied by mathematical methods of the type known as biometrical. Measurements are made of various characters in a large number of individuals of a population and the data so obtained are tabulated to show the number of individuals exhibiting each of certain measurements. Such tabulations can then be graphed and a curve obtained. This curve of variation usually conforms to a definite symmetrical shape, rising to a peak and descending again. Such a normal curve of variation means that most of the individuals of a population fall within certain measurements, as length, for instance, and that especially long or short individuals are few in number. The normal curve of variation implies that the variations it records are due to chance events. Deviation from such a normal curve indicates that some factor is operative to distort the curve, or that the population being studied is not uniform but consists of two or more groups. Such studies of animal populations, termed biometry, are of great value both in pure and in applied science.

Types of Variation.—It is necessary for the geneticist and the systematist to evaluate properly the variations within a

population and to differentiate those associated with age, sex or habitat from hereditary variations that occur by chance without relation to obvious factors. There are in general two sorts of variation: those that do not involve an hereditary alteration, termed phenotypic variation, and those that result from hereditary alteration, termed genotypic.

Phenotypic Variation.—This may concern various stages in the life cycle, seasonal variations in the same individuals, and changes impressed on the individual during its life by environmental conditions. Examples of these may be given. Many animals at birth or hatching bear little resemblance to their parents, and in the past were often regarded as distinct species until the life history of the animal in question was worked out and the juvenile or larval form traced to the adult condition. For instance, the common fresh-water eel, *Anguilla,* passes through a transparent ribbonlike oceanic stage termed *Leptocephalus. Leptocephalus* was considered to be a distinct kind of fish, whose relationship to eels was not suspected, until Johannes Schmidt of Denmark discovered that *Leptocephalus* is a juvenile stage of *Anguilla.* Crawling caterpillars bear no resemblance to the butterflies or moths into which we know they develop. Parasitic worms may have as many as four different juvenile stages in different hosts. As these juveniles bear no or little resemblance to the adults, mere study of them does not suffice to determine to what adults they belong and such information is assembled only by laborious isolation studies and feeding of juveniles to appropriate parasite-free hosts.

The colours and colour patterns of many animals change with age and sexual maturity. The soft down of feathers or hair at birth or hatching gives way first to the juvenile and later to the adult plumage or pelage, differently coloured or patterned. Some plumage or pelage colour changes result from the wearing off of feather or hair tips. Many male animals assume a resplendent nuptial dress during their breeding season and may also develop structural features that are lost again in the off-season, as the horns of mammals, and thickened skin areas termed pearl organs of fishes.

Seasonal changes in colours and shape are of common occurrence. Where several broods are born within a year as in insects, broods produced at different seasons may differ so much as to be originally regarded as distinct species. Many small animals of open waters have summer and winter forms of different shape; commonly the summer form shows increased body surface as compared to volume and the winter form shows the reverse effect. Thus, water-fleas such as *Daphnia* and *Bosmina* tend to develop taller shapes with longer spines in summer, more rounded heads and shorter spines in winter. The factors operative are believed to be quantity of food, and changes in the density and viscosity of the water, requiring new shapes to insure body stability. Seasonal colour changes are well-known in arctic animals, such as the varying hare, ermine, ptarmigan and arctic fox that are white in winter, brownish during the summer. Much seasonal variation is related to temperature. Thus the Himalayan rabbit is white except for black ears, feet and tail. If hair is plucked from the white parts and the animal placed in the cold while the new fur is growing out, this comes out black, not white. Conversely, hair plucked from the black parts grows out white if these parts are kept warm by bandages. It is known that fishes tend to have more vertebrae and more scales along the lateral line in the colder parts of their range. The experiments of Dr. Mordecai Gabriel have shown that if the eggs of the fish *Fundulus* from the same batch are reared at different temperatures, the number of vertebrae formed is greater the lower the temperature. This result probably comes from a slowing down of development by the cold at a critical time.

Members of the same species may show much variation throughout their range as a result of local conditions. This is very true of corals, for instance, since the same species may grow into tall branching shapes in still water, massive rounded shapes in surf. Molluscs also show great variation of shell form in different environments. These variants, termed *ecophenotypes,* were formerly regarded as of taxonomic worth and often very many scientific names were created for what are now known to be merely phenotypic variants of the same species.

In the above examples identity of genetic constitution is assumed. The changes recorded are phenotypic changes of the same genotype, that is, of the same hereditary constitution. Whether a given change is phenotypic or not can, however, be determined only by breeding experiments under varieties of environment.

Genotypic Variation; Mendelian Inheritance.—Genotypic variations are new alterations that are inheritable. Whether a given variation is genotypic or not cannot be determined by mere inspection of the animal but only by painstaking breeding experiments under controlled environmental conditions. Forty years of intensive breeding experiments on various plants and animals have led to the conclusion that hereditary characters are vested in the chromosomes of the nucleus, in the submicroscopic particles termed genes of which these chromosomes are constituted (*see* HEREDITY). It is these genes that are directly transmitted to the offspring in the nuclei of the egg and the sperm whose fusion begins the new individual. The characters that are represented by these genes are inherited, but they do not come to expression unless the environmental conditions are right for their appearance. Among the better known inheritable characteristics of animals transmitted by genes are eye colour, hair colour, hair shape, skin colour, body form and proportions, length of limbs, hands, feet, tail, and various diseases and defects, as well as varying degrees of immunity to disease.

The manner of inheritance of such characters and of genotypic variations in general is that termed Mendelian because it was first formulated by Gregor Mendel, an abbot of Brünn, Austria, in 1865 as a result of his experiments in crossing garden plants in the garden of the monastery. His experiments remained unappreciated until 1900 when they were simultaneously repeated by several biologists. Since that time an enormous amount of work has been done on Mendelian inheritance, for the details of which *see* the articles HEREDITY; VARIATION. A very striking part of the Mendelian work was the elucidation of the mechanism of sex differentiation. It was found that there is a chromosomal difference between the sexes. In some animals two kinds of eggs and in others two kinds of sperm, as to their chromosomal content, are produced, and whether a given fertilization will result in a male or a female offspring is determined at the time of fertilization by whatever chromosomal combination happens to ensue (for complete explanation *see* articles SEX; CYTOLOGY; CHROMOSOME).

Bisexual reproduction is of the greatest importance in increasing the variability within populations. Geneticists are agreed that nearly all genetic factors are located in the chromosomes and that normal individuals of sexually reproducing species have two chromosome sets, one from each parent; *i.e.,* each chromosome occurs in duplicate as a result of the fertilization process. During the formation of the sex cells of an individual the duplicate chromosomes and duplicate genes become segregated in a chance manner into the sex cells, for these have only one chromosome set (*see* CYTOLOGY; CHROMOSOME). Thus an indefinite number of gene combinations is possible. In reference to man with his two sets of 24 chromosomes it is said that exactly the same genic constitution has never appeared in two individuals, except in the case of identical twins that come from one egg.

Heredity and Environment.—Every character of an organism is the product equally of its inheritance and of the environment under which the character develops and matures. Some characters reappear regularly in successive generations because the stimuli necessary for their appearance are always operative in their environment. Often certain temperatures are required for the appearance of both phenotypic and genotypic characters. What is really transmitted is the ability to respond to given environmental factors; but the specific response that occurs in a given case is determined by the hereditary constitution.

For exact studies of environmental effects in the individual's life it is necessary to start with material of identical genetic

constitution. Some of the best information on the heredity-versus-environment question has been accumulated in recent years by the study of identical human twins reared apart from early life. Identical human twins come from the same fertilized egg, hence have the same genic constitution. Data were collected by H. H. Newman of the University of Chicago on 50 pairs of identical twins reared together and 20 pairs reared apart. Twins reared apart were, on the average, no more different in measurable physical characters than those reared together, except for body weight which was found to depend on food, health and amount of physical exercise. A different result ensued when mental differences were studied. The average difference in the I.Q. of twins reared together was 5.3 points and for twins reared apart 8.2 points, an excess of nearly 3 points. The average difference in scholastic achievement for twins reared apart was more than twice as great as for twins reared together, an indication that achievement tests register differences in schooling more accurately than do ability tests. Newman found much evidence that differing environments had resulted in marked personality differences despite identical genetic constitution. These results, although only preliminary, give great encouragement in the direction of human improvement through educational and environmental means.

Inheritance of Acquired Characters.—Since ancient times there has been a general popular belief in the theory that characters acquired during the lifetime of an individual can be inherited, and that thereby an improvement or alteration in a desired direction is possible. This theory is termed Lamarckism because it was expounded particularly by Lamarck in 1815, although not exactly original with him. Lamarckism states that every animal tends to change its structure and habits during its individual existence in such ways that it becomes better fitted for life under the conditions to which it is subjected. If the characters so acquired be transmitted to offspring which in turn become modified in the same direction, there will in time arise a group of individuals differing from the original progenitor and better adapted than it was for the conditions in question. The theory thus particularly seeks to explain the origin of adaptive characters.

Adaptation is certainly an outstanding phenomenon of nature; that environment can alter the structure and habits of animals within their lifetime is also an established fact and comes under the head of phenotypic variation discussed above. The difficulty of the theory centres around the possibility of the inheritance of such environmentally induced alterations. At the present time such inheritance is believed to be impossible; therefore, the theory of the inheritance of acquired characters has been abandoned by practically all biologists.

Mutations.—Inheritable alteration is now believed to be entirely of the nature of mutation, which is another name for genotypic variation. Mutations, in the present sense of the word, are caused by change, probably chemical, in a single gene, or by chromosomal changes such as losses, multiplications, rearrangements of genes, recombinations, etc. Mutations occur in all degrees from those so slight as to be unnoticeable in ordinary genetic work to conspicuous variations. The cause of mutation is not known, although mutations have been induced by the action of x-rays and other radiations on organisms at critical periods in the ripening of their germ cells. It is firmly believed by geneticists that mutations are of chance nature and that they have no direct relation to environmental factors. *See* further, article VARIATION.

Evolution; Natural Selection.—The principle of evolution is the most important contribution of zoology to general science and to civilization. Evolution is the doctrine that all organisms are related to each other through common descent and that the differences that now exist between the many species of animals and plants have arisen through hereditary alteration of pre-existing forms. Evolution is defined by Theodore Dobzhansky as a change in the genetic composition of populations so that dissimilarities develop between the ancestral and the descendant populations. Evolution as a constant process of nature is supported by such innumerable facts that it is unanimously accepted by biologists as a fundamental principle of biological science. The principle of evolutionary change has also been incorporated into almost every field of human thought and endeavour, and everywhere has acted as a clarifying leaven.

It is necessary to distinguish clearly between evolution as a phenomenon of nature and the mechanism by which evolution takes place. Too often there is confusion in the popular mind between these two matters. Evolution is regarded by biologists as an established fact, but the mechanism by which it occurs is still under investigation. Indeed, such investigation is particularly intensive at the present time, nearly 100 years after Darwin published his epoch-making investigations and conclusions.

Although the idea of evolution had been expressed by a long chain of his predecessors, it was first clearly expounded by Darwin in 1859 in his book *The Origin of Species*. Darwin was concerned primarily with finding a mechanism by means of which evolution could occur, and by analogy with selection practised by man in breeding domestic animals, Darwin postulated a selective action of nature. Darwin based his theory of evolution by natural selection on the observed facts of variation and of excessive reproduction in nature. As already noted, every species tends to vary within limits; also, every species tries to reproduce in unlimited numbers so that if unchecked, even slowly-reproducing animals would in a relatively short time populate the earth. As this does not occur, there must be factors limiting the survival of offspring, and these factors consist of competition for food and space, depletion by enemies and parasites, etc. In this struggle for existence it seemed to Darwin that variations, even slight ones, might play a decisive role in preserving some individuals while others perished. Any (genotypic) variation that is at all advantageous will have survival value and the individual possessing it will have more chance to live and to pass on its advantageous variation to its offspring than will individuals lacking such variation. In this way there is an accumulation of variations, and this eventually leads to the establishment of new varieties and species, providing isolation occurs to prevent the wiping out of the new characters by cross-breeding with the old population. By isolation is meant any factor that prevents cross-breeding. Such isolation may consist of physiographical features such as mountains or water courses that form barriers against interbreeding; or it may consist of variations in the sexual apparatus or in sexual behaviour that make mating physically or psychologically impossible.

After the theory of evolution by natural selection had suffered some decline, selection has again come into prominence as a factor in evolution. Acceptable evidence has been found of the actual operation of natural selection in wild populations. Natural selection operating on chance genotypic variations remains the best explanation of adaptation. The modern view of evolution holds that it is the joint product of mutation and selection plus isolating mechanisms (ecological, geographical or sexual) that prevent the new gene patterns from being swamped by interbreeding with the old. In recent years population size has also been shown to be an important factor, and restricted populations appear to be most favourable for progressive evolution. The study of population dynamics is rapidly becoming of increasing interest and importance in the fields of genetics and evolution. (*See* further, EVOLUTION.)

ECOLOGY

What is generally termed natural history or observation of the habits and behaviour of animals in nature has undoubtedly interested man from the dawn of civilization. But toward the end of the 19th century this type of zoological study more or less fell into disrepute as not sufficiently scientific. Zoologists were more or less divided into two camps: those that studied morphology and taxonomy, and those that were experimentalists subjecting animals or their parts to laboratory study. The latter increased rapidly at the expense of the former and neither left much room for natural history in its old form. At the beginning of the 20th century there emerged, however, ecology (also called

bionomics), which has been defined as scientific natural history and which has progressively increased in importance. (*See* ECOLOGY.)

Ecology is the study of animals as they exist in their natural environment. The subject naturally divides itself into two parts: the study of the environment and the study of the animal in its environment.

Environments.—Evidently the complete study of environments is a complicated matter, depending in many cases on the availability of appropriate methods and apparatus. The environment is composed of physical, chemical, geological, geographical and meteorological factors as well as biological factors in the form of other plants and animals and their products. These factors require to be studied not only at any one time but also through daily, seasonal and annual cycles.

Environments are broadly classifiable into marine, fresh-water and terrestrial; each of these of course comprises numerous subsidiary environments. The study of the marine environment has reached the status of a branch of zoology, termed oceanography (*q.v.*). It involves such matters as currents and circulation, depths and bottom contours, types of bottom, temperature at various regions and depths, penetration of light with reference to depth, dissolved gases at various depths, salinity and chemical composition in general, and variations of organic substances or material produced by biological action. Many of these changes need to be followed through daily, seasonal and annual cycles. The animal life of the ocean is divisible into the pelagic forms living free in the water and the benthonic forms inhabiting the bottom. Each of these is again subdivisible on the basis of depth. Thus the pelagic animals fall into epipelagic, inhabiting surface waters to moderate depths, and bathypelagic, or deep water, categories. The ocean bottom is usually divided into the littoral zone (shore to 200 metres), the archibenthal (200 to 1,000 metres), and the abyssal zone or deep bottom.

Brackish water or water of lowered salinity at the mouths of rivers offers special ecological problems. Animals inhabiting such areas must be able to endure great changes of salinity and osmotic pressure. Study of the mechanism of such adjustment may throw light on how marine animals were able to enter fresh waters and establish themselves therein.

Fresh-water habitats are of two general types, standing or lentic waters and running or lotic waters. The former embraces the large lake, small lake, pond, swamp, pool series, and the latter the brook, stream, river series. Here, too, of course there are numerous localized environments as a rapids in a stream. Seasonal changes are of particular importance in the lentic series and many fresh-water animals show marked annual cycles that contrast with the uniformity of existence in the sea.

Terrestrial environments are more varied and present more difficult conditions for animals than do aquatic environments, and vegetation plays a predominant role in them. In fact, the subdivisions of land faunas practically coincide with those of the flora, and the latter in turn depend upon climatic and physiographical features, notably temperature, rainfall and quality of the soil. Land habitats vary from bare areas such as sand dunes, rock outcrops, snowfields and glaciers, the arctic and antarctic circles, and alpine summits, through areas of scant vegetation such as deserts, subalpine zones, high latitudes and treeless areas (grasslands, prairies, plains, steppes), to regions of small trees (thornbush, etc.) and forests. Each terrestrial habitat is of course zoned horizontally into such strata as the air, taller vegetation, shorter vegetation, ground surface and subterranean stratum.

Faunas.—The sum total of the animals inhabiting an area is termed the fauna. The ocean has the richest and most varied fauna, presumably because of the uniformity of conditions therein. The fauna of the ocean is broadly characterized by an inability to withstand extreme changes of conditions, by the lack of protective devices against exposure, such as cysts, by the frequency, especially among pelagic animals, of a delicate, transparent construction, and by the frequent production of free larval stages. Fresh-water animals must be able to withstand much greater ranges of conditions than do marine animals, especially temperature, evaporation, and alterations of acidity and alkalinity. Further, the fresh-water medium has a lower osmotic pressure than that of the body fluids of fresh-water animals, and means must be present to prevent excessive hydration of the body. Fresh-water animals provide against extremes of temperature and drought by protective devices such as encystment or production of hard-shelled eggs or other reproductive bodies, or by habits of hibernation or estivation; free larval stages are in general absent from the reproductive cycle. Air-breathing types are common among fresh-water animals but rare in the ocean. Fresh-water animals also experience greater turbidity and more concentrated organic decay than do the marine fauna, and many are adapted for living in muck practically devoid of oxygen. Conditions encountered by the land fauna are even more difficult, despite the advantage of abundant oxygen. The great danger is that of water loss so that land animals, unless they live in very humid places, must be protected against evaporation; hence the characteristic coverings of scales, hairs, fur, etc., or the hardened exterior as in insects. They must also be adjusted to a wide range of temperature or else have developed a mechanism for maintaining constant body temperature; habits of hibernation and estivation also play a role in temperature adaptation. Lacking the support of water, terrestrial animals must have a generally stronger build than aquatic ones, and they are also capable of efficient types of locomotion depending upon stronger build, such as walking, running, leaping and flight. Although the terrestrial fauna is less rich in species and groups than are aquatic faunas, it displays a much greater variety of associations, many strikingly adapted.

Animal Communities.—The fauna of a restricted area throughout which very similar conditions prevail, such as a meadow or a pond, forms an animal community or association. Such an association usually consists of large numbers of individuals of one or a few species, that form the dominant animals, and small numbers of a considerable number of other species. Many of the animals of an association show striking structural and behaviouristic adaptations to the conditions of the habitat. Very complex relations generally obtain between the members of a community. These are usually in the nature of food relationships, and in general every community contains herbivorous, carnivorous and scavenging animals. In a community each species generally occupies a particular part of the habitat and of the food chain; such a position in the community is termed an ecological niche.

The animals of the same kind of habitat are usually of different species or are even quite different taxonomically in different parts of the world, but they generally show ecological similarity, *i.e.*, structural and behaviouristic resemblance. Such corresponding forms have been termed ecotypes. Thus, the animals of steppes and prairies are generally long-legged, swift-running types, as the bison and pronghorn of the Great Plains of North America, the zebras and various kinds of antelopes of the African plains, and the deer of the Argentine pampas.

Ecological Succession.—The old adage that nothing is permanent except change is peculiarly applicable to ecological study because environments change and with them the flora and fauna also alter. Under ordinary conditions, *i.e.*, in the absence of cataclysms of nature, these changes follow an orderly arrangement, and this is termed ecological succession. Succession is naturally chiefly a phenomenon of fresh-water and land habitats and the littoral zone of the ocean. Thus, ponds fill and become meadow, meadow becomes invaded by shrubs and eventually trees, and finally a forest occupies the site of the original pond. In general all fresh-water and land habitats tend towards a certain floral association that is termed the climax. The climax formation varies in different areas of the earth, primarily in association with rainfall and temperature.

Animal Behaviour.—The reactions and activities of an animal in its environment is termed animal behaviour. This field at first was part of the subject of psychology, and experiments on animal behaviour were carried out chiefly in psychological laboratories. The setups employed in these laboratories were mostly

without relation to the natural habitat of the animal and the object was more or less anthropomorphic—to discover the learning abilities, intelligence and reasoning power of the lower animals, chiefly birds and mammals other than man, and the effect upon these powers of operations on the central nervous system. The animal was frequently set to solve problems that were remote from its normal life. At the same time ecologists were studying the behaviour of animals, chiefly invertebrates and cold-blooded vertebrates, from a different angle, that of subjecting the animal in turn to single factors of its environment such as light, temperature, etc. This procedure usually made use of a gradient tank or box in which the intensity of the factor being investigated was uniformly graded from one end to the other of the apparatus. Animals were placed in the apparatus and the part of the gradient in which the majority of the animals came to rest after random wanderings was considered to represent the intensity of the factor most suitable to the animal, and the one affecting its distribution in nature.

Although valuable results were yielded by both types of inquiry, their artificial nature has gradually become recognized, and there is a decided return at present to studies of the type of the old natural history but more exact, critical and better controlled. Field observations are supplemented by observations in the laboratory in conditions that simulate the natural surroundings, and problems are set that are more in harmony with the animal's anatomical equipment and the conditions of its existence in nature. (*See* ANIMAL BEHAVIOUR.) Studies of mass behaviour and social relations among animals are also receiving increased attention today.

Limiting Factors.—The study of animal behaviour by means of the gradient setup mentioned above showed that a given animal tends to avoid certain intensities of surrounding factors and to seek others. The distribution of a given animal in nature is therefore limited by responses of this type. Thus, an animal that avoids bright light and dryness may be expected to occur in nature in dark humid places as under stones or logs. Such an animal will obviously be limited in its distribution by the availability of this kind of habitat. By these reactions of avoidance animals come to occupy and to remain in certain small niches of a given environment.

Zoological Distribution.—As noted above, animals of similar but geographically separated ecological regions exhibit similarity of appearance and behaviour but are usually taxonomically different. This suggests that the fauna of each part of the world is peculiar to that region and that it might be possible to divide up the world into zoological regions, each with its own set of species. Various attempts of this sort have been made of which the most accepted scheme recognizes the following regions: palaearctic, including Europe, most of Asia, and Africa north of the Sahara; nearctic, comprising North America; neotropical, comprising South and Central America and the West Indies; Ethiopian, Africa south of the Sahara and Madagascar; oriental, southern Asia, Malay Archipelago, and some islands of the East Indies; and Australian, including Australia, New Zealand and the rest of the East Indies. (*See* ZOOLOGICAL GEOGRAPHY.) Each of these areas does in fact have a characteristic fauna. As is well known, the Australian region is characterized by its primitive mammals, such as the duckbill, kangaroo, and other marsupials, and curious birds like the kiwi, emu and cassowary, none of which are found elsewhere. However, many facts of animal distribution are not explained on the basis that each part of the world has its own peculiar constellation of species, for the reason that animals have not necessarily evolved in the region that they now occupy. Although isolation or inability to emigrate because of water or other barriers account for some facts of distribution like the peculiarities of the Australian fauna, emigrations, both recent and in past geological ages, are also an important factor in explaining present distribution. In fact, the distribution of animals constitutes important evidence for the existence of land connections in the past that have later vanished. Emigrations over land bridges later eliminated by geologic change account for the occurrence of closely related animals in distant parts of the earth with no representatives in the intervening area. Such facts can also be explained on the assumption of an originally wide distribution with the wiping out of relatives in intermediate areas through geologic and climatic changes. (*See* further, ZOOLOGICAL GEOGRAPHY.)

Animal Interrelationships.—Study of the relationships between animals constitutes an important part of ecological research. Such relationships within a species vary all the way from the relation of sexual pairs in courtship, mating and rearing of young to studies of populations. Here belongs also competition between the individuals of a species for mates, living and breeding places, and food. Relationships between animals of different species, apart from such general matters as competition for food and space, mostly fall into three categories: relationships of predator and prey, relations of mutual assistance and relations of one-sided benefit. Many animals are provided with protective or defensive devices, such as armour, horns, hoofs, stings, spines, venoms, or exhibit protective behaviour, as hiding, burrowing, rolling up into a ball, or playing dead, as a means of avoiding being captured and eaten by carnivorous animals; conversely, the predator often has special structural devices or exhibits special behaviour enabling it to capture other animals as food, often specific animals. One common mode of avoiding capture is through resemblance to surroundings (protective resemblance) or through resemblance to some other animal that is distasteful (mimicry). Volumes have been written on the questions whether protective resemblance or mimicry actually protect and how they have come about. It now appears quite certain that they do have protective value, and natural selection acting on chance variations is the accepted explanation of their origin.

Associations of animals of different species with mutual benefit is termed mutualism. Many examples of such relationship, often intimate, are known. Thus, ants protect and care for aphids and in return get a sweet fluid secreted by the aphids. Hermit crabs carry anemones on their backs, securing the protection afforded by the stinging bodies of the anemone and furnishing the latter with free transport and better oxygenation. Many such relationships are extremely intimate, in that one partner may live inside the other, as in the case of the termites and their intestinal Protozoa; the former protect the latter and the protozoans digest cellulose for the termites.

Relations of one-sided benefit range all the way from harmless association (commensalism) to parasitism. Small animals may habitually live in or on or near larger ones or accompany them, for protection or to obtain bits of food. Ant-hills and other types of burrows frequently harbour other animals, usually of specific kinds, termed inquilines or guests; these get protection and steal bits of the host's food, but are probably otherwise harmless. Such habits, however, gradually lead to parasitism, a relation in which one animal benefits and the other is harmed. Parasites are divisible into ectoparasites such as lice, mites and ticks, that live on the surface of animal bodies, eating hair, feathers, or bits of skin or sucking blood; and entoparasites that inhabit interior organs, sucking blood or body fluids or devouring cells, or, in case they lack a digestive tract, imbibing nutriment through the surface. Entoparasites include worms of various kinds and protozoans. Parasitism leads to extensive structural changes in the parasite: reduction of sense organs and the nervous system; loss of locomotory organs; reduction and eventual loss of mouth and digestive system; development of clinging organs such as hooks and suckers; excessive development of the reproductive system with production of immense numbers of eggs; and complicated life cycles involving some stage adapted for spreading the parasite.

ECONOMIC ZOOLOGY

This name is applied to the utilization of zoology in the interests of human welfare. The breeding of domestic animals is a great industry that has been extraordinarily successful in producing breeds of sheep, cattle, horses, dogs, poultry, etc., fitted for all conditions and uses. Practiced in the past mainly by empirical methods, animal breeding has in recent years been greatly ad-

vanced by the application of modern genetics. Among recent trends is the practice of artificial insemination by which the semen of fine male horses, cattle, etc., may be shipped considerable distances for the improvement of stock. Fisheries present numerous complex problems falling within the province of the zoologist, such as the study of variations of the catch from season to season, depletions of breeding stock, development of new fishing grounds, and the improvement of pisciculture. Work of this type involves not only fishes but other aquatic food animals such as oysters, shrimp and lobsters.

The damage that animal pests, especially insects, do to crops is tremendous; these ravages can be controlled only by methods laid down by zoologists. The establishment of these methods depends on a full investigation of the life history and habits of the pest, and of all the factors in its surroundings that influence it, such as climatic conditions, alternative sources of food, the efficiency and mode of application of poisons, parasites, and diseases of the pest, and the discovery of animals that prey upon it. Some of the greatest triumphs of economic entomology have been achieved through finding a suitable predator to prey upon a particular insect pest. (*See* ENTOMOLOGY.)

The investigation and control of animal-borne diseases of man such as malaria, yellow fever, etc., is a zoological matter as is also the study of the animal parasites of man, their taxonomic position, life histories and methods of control.

A present important trend in economic zoology concerns conservation which aims towards the preservation of animals beneficial to man and in general towards restoring the balance of nature that has been upset by human activities. Through ignorance and greed man has succeeded in destroying many useful animals and in seriously depleting the stocks of others. The destruction of any one species may have far-reaching effects because of the complicated interrelationships of animals, especially as regards food cycles. These food cycles always involve plants, so that a whole train of evil consequences may result. Thus, elimination of predators such as the mountain lion or birds of prey permits the excessive increase of herbivorous animals that serve as their prey and are normally kept in check by them; and this results in overgrazing of grasslands and forests. Only intensive studies of plant and animal interrelationships can teach man how to avoid wholesale destruction and interference with natural balance that, if continued, will also destroy him.

ZORILLA, the name of several African carnivorous mammals belonging to the weasel family, the genera *Ictonyx, Poecilictis* and *Poecilogale*. Superficially they resemble skunks, being black with white stripes. (*See* CARNIVORA.) (J. E. HL.)

ZORN, ANDERS (1860–1920), Swedish artist, was born at Mora, in the province of Dalecarlia, Sweden, on Feb. 18, 1860. He began his artistic career as a water-colourist, adopting the style and tastes of Egron Lundgren under whom he studied. He became well-known in Sweden through the exhibition in 1880 of a small girl's head, entitled "Mourning," now in the National Museum, Stockholm. An increasing reputation brought him orders for many portraits and he earned the means to travel. His first trip to Spain greatly advanced his work through contact with vivid colourings in nature and in life. In the three years following he maintained a studio in London and afterwards travelled in eastern Europe and in Algiers. These years saw the best of his water-colours, such as "Our Daily Bread," "Gipsy Forge," "Caique Rower," "Algiers Harbour," "Lapping of the Waves," "En première," "The Fish Market at St. Ives" and "Rositi Mauri." From 1887 to 1893 he lived chiefly in Paris, though making long visits to Sweden in the summer. In these years he took up oil painting. Also he abandoned the realist manner and became primarily an impressionist and colourist. In 1893 he made his first visit to the United States as Swedish commissioner accompanying that country's art exhibit at the Columbian Exposition in Chicago. He made six subsequent trips, and painted portraits of many American millionaires as well as of Cleveland, Taft, Roosevelt, Hanna, Hay and others. After 1896 he began to spend more of his time in Mora, where he loved and encouraged the Dalecarlian peasant life and customs. He died there on Aug. 22, 1920.

As a painter Zorn is an excellent example of the matured impressionistic group. He won renown for his characteristic and picturesque portraits in which, owing to his sensitive study of values, he gives proper play to light and half-tones. In addition to millionaires, international celebrities, and members of royal families, he painted red-cheeked Swedish girls, country peasant women, and old artisans at their work, and some of his best pictures, such as the studies of his mother in "Mona," of the watchmaker "Djos Mats," the smith "Bosl Anders," and the fiddler "Hins Anders," belong in the latter categories. He loved the nude, especially the play of water on or around the body. "Naked," "After Bathing," "En première," "Renaissance," "By Lake Siljan," "Improvised Bath," and "Mother and Daughter" are among the best of these. In later years he turned more and more to Dalecarlian peasant subjects of which should be mentioned "Midsummer Dance," "Dance at Gopsmor," "Vallkulla," "Early Christmas Service" and "Watering the Horses."

Zorn's status as an etcher is still in controversy between those who would rank him among the masters and those who feel he has been over-rated. He learned the art from his fellow-countryman, Axel Haig, in 1882, but did not do important work in the medium until 1889. At his best, especially in the series of etched portraits of Renan, Anatole France, Proust, Rodin and Verlaine in France, of the Scandinavians Strindberg and Carl Larsson, of Grover Cleveland, Henry Marquand and Senator Mason in America, of the old artisans of Mora in "Djos Mats," "An Old Soldier," and "Vicke," and in "Mona" and "The Toast," he shows genius of the highest sort. Of his nudes "Early Morning," "My Model and My Boat," "Edö," "Precipice," "Wet," "Sappho," all enjoyed favour, but he pursued the theme until it became monotonous, and many of his later plates were quite common in conception. Zorn also won fame as a sculptor, one of his most popular pieces in Sweden being the statute of Gustavus Vasa at Mora (1901). The "Faun and Nymph," "Morning Bath" and "Broken Pitcher" also show his high ability in this field.

ZORNDORF, a village of Prussia, Germany, in the Oder valley, N.E. of Cüstrin. It is famous as the scene of a battle in which the Prussians under Frederick the Great defeated the Russians under Fermor, on Aug. 25, 1758 (*see* SEVEN YEARS' WAR).

ZOROASTER, the founder of the national religion of the Iranian people from the time of the Achaemenidae to the close of the Sassanian period. The name (Ζωροάστρης) is the corrupt Greek form of the Iranian *Zarathustra* (new Persian, *Zardushi*). Its signification is obscure. Zoroaster was famous in antiquity as the founder of the wisdom of the Magi. His name occurs first in a fragment of Xanthus (29), and in the *Alcibiades* of Plato (i. p. 122), who calls him the son of Oromazdes. Occidental writers sometimes call him a Bactrian, sometimes a Median or

Persian (*cf.* Jackson, *Zoroaster,* 186). According to Pliny (*Nat. Hist.* vii. 15), he laughed on the very day of his birth—a statement found also in the *Zardusht-Nāma*—and lived in the wilderness upon cheese (xi. 97). Plutarch speaks of his intercourse with the deity, and compares him with Lycurgus and Numa (*Numa,* 4). Dio Chrysostom, Plutarch's contemporary, declares that neither Homer nor Hesiod sang of the chariot and horses of Zeus so worthily as Zoroaster, of whom the Persians tell that, out of love to wisdom and righteousness, he withdrew himself from men, and lived in solitude upon a mountain. The mountain was consumed by fire, but Zoroaster escaped uninjured and spoke to the multitude (vol. ii. p. 60). Plutarch, drawing partly on Theopompus, speaks of his religion in his *Isis and Osiris* (cc. 46–47). He gives a faithful sketch of the doctrines, mythology and dualistic system of the Magian Zoroaster.

Agathias remarks (ii. 24), with truth, that it is no longer possible to determine with any certainty when he lived and legislated. "The Persians," he adds, "say that Zoroaster lived under Hystaspes, but do not make it clear whether by this name they mean the father of Darius or another Hystaspes. But, whatever his date, he was their teacher and instructor in the Magian religion, modified their former religious customs, and introduced a variegated and composite belief."

He is nowhere mentioned in the cuneiform inscriptions of the Achaemenidae, although Darius and his successors were Zoroastrians. The Avesta, our principal source for the doctrine of Zoroaster, is comparatively reticent; on the subject of his person and his life with regard to his date it is, naturally enough, absolutely silent. The 13th section, or *Spend Nask,* which was mainly consecrated to the description of his life, has perished; while the biographies founded upon it in the 7th book of the *Dinkard* (9th century A.D.), the *Shāh-Nāma,* and the *Zardusht-Nāma* (13th century) are full of wonders and fabulous histories and miraculous deliverances.

The personality of Zoroaster is historic, but in the later Avesta, and in writings of more recent date, he is presented in a legendary light and endowed with superhuman powers. At his appearing all nature rejoices (*Yasht,* 13, 93); he enters into conflict with the demons and rids the earth of their presence (*Yasht,* 17, 19); Satan approaches him as tempter to make him renounce his faith (*Vendidad,* 19, 6).

The Gāthās alone within the Avesta claim to be the *ipsissima verba* of the prophet, and are expressly called "the Gāthās of the holy Zoroaster" (*Yasna,* 57, 8), his actual expressions in presence of the assembled congregation, the last genuine survivals of the doctrinal discourses with which—as the promulgator of a new religion—he appeared at the court of King Vīshtāspa.

The person of the Zoroaster in these hymns is a mere man, standing always on the solid ground of reality, whose only arms are trust in his God and the protection of his powerful allies. He had to face forms of outward opposition, the unbelief and lukewarmness of adherents, even his own misgivings as to the truth and final victory of his cause. The range of the emotions which find their immediate expression in these hymns is wide and the whole breathes originality, is psychologically accurate and just, so that in the Gāthās we have the beginnings of the Zoroastrian religion. They give no historical account of the life and teaching of their prophet, but are general admonitions, asseverations, solemn prophecies, directed to the faithful or to the princes, and are generally dialogues with God and the arch-angels, whom he repeatedly invokes as witnesses to his veracity with many allusions to personal events which later generations have forgotten. Their extent is limited and their meaning is frequently dubious and obscure.

The Person of the Prophet.—As to his birthplace the testimonies are conflicting. According to the Avesta (*Yasna,* 9, 17), Airyanem Vaējō, on the river Dāitya, the old sacred country of the gods, was the home of Zoroaster. There on the river Dāreja, if the passage (*Vend.,* 19, 4) is correctly interpreted, stood the house of his father; and the *Bundahish* (20, 32 and 24, 15) says expressly that the river Dāreja lay in Airan Vej, on its bank was the dwelling of his father, and that there Zoroaster was born. According to the *Bundahish* (29, 12), Airan Vej was situated in the direction of Atropatēne, and consequently Airyanem Vaējō is generally identified with the district of Arrān on the river Aras (Araxes), close by the north-western frontier of Media. Other traditions make him a native of Rai (Ragha, Ῥάγαι). According to *Yasna,* 19, 18, the *zarathushtrōtema,* or supreme head of the Zoroastrian priesthood lived in Sassanian times, in Ragha. The Arabic writer Shahrastānī endeavours to reconcile the two traditions by the theory that his father lived at Atropatēne, while the mother was from Rai. In his home he is said to have enjoyed the celestial visions and the conversations with the arch-angels and Ormazd mentioned in the Gāthās. There, too, according to *Yasht,* 5, 105, he prayed that he might convert King Vīshtāspa. He then appears to have quitted his native district. On this point the Avesta is wholly silent; an obscure passage (*Vasna,* 53, 9) intimates that he found an ill reception in Rai. Finally, in the person of Vīshtāspa, a prince resident in east Iran, he gained the powerful protector and faithful disciple of the new religion whom he desired—after almost superhuman dangers and difficulties, which the later books depict in lively colours. In the epic legend, Vīshtāspa was king of Bactria; in the later Avesta he became a half-mythical figure, the last in the series of heroes of east Iranian legend. In the Gāthās he appears as a quite historical personage; to his power and good example the prophet is indebted for his success. In *Yasna,* 53, 2, he is spoken of as a pioneer of the doctrine revealed by Ormazd. In the relation between Zoroaster and Vīshtāspa lies the germ of the state church which afterwards became subservient to the dynasty and sought its protection from it.

Among the grandees of the court of Vīshtāspa were two brothers, Frashaoshtra and Jāmāspa, both, according to the later legend, vizirs of Vīshtāspa. Zoroaster's wife, Hvōvi, was the daughter of Frashaoshtra, and the husband of his daughter, Pourucista, was Jāmāspa. The rôle of intermediary was played by the pious queen Hutaosa. Apart from this, the new prophet relies especially upon his own kindred (*hvaētush*). His first disciple, Maidhyōimāongha, was his cousin: his father was, according to the later Avesta, Pourushaspa, his mother Dughdōvā, his great-grandfather Haēcataspa, and the ancestor of the whole family Spitama, for which reason Zarathushtra usually bears this surname. His sons and daughters are repeatedly spoken of. His death is nowhere mentioned in the Avesta; in the *Shāh-Nāma* he is said to have been murdered at the altar by the Turanians in the storming of Balkh.

As to the date of Zoroaster; King Vīshtāspa has no place in any historical chronology, and the Gāthās give no hint on the subject. According to the Arda Vīrāf, 1, 2, Zoroaster taught some 300 years before the invasion of Alexander. Assyrian inscriptions relegate him to a more ancient period. Eduard Meyer (see *Ancient Persia*), conjecturally puts the date of Zoroaster at 1000 B.C., with Duncker (*Geschichte des Altertums,* 4, 78). This may be too high: but, in any case, Zoroaster belongs to a prehistoric era. Probably he belonged to the old school of Median Magi, and appeared first in Media as the prophet of a new faith, but met with sacerdotal opposition, and turned his steps eastward. In the east of Iran the novel creed first acquired a solid footing, and subsequently reacted with success upon the West.

Zoroastrianism.—Zoroaster taught a new religion rooted in the old Iranian—or Aryan—folk-religion, of which we can form some representation by comparison with the religion of the Veda. The Aryan folk-religion was polytheistic. Worship was paid to popular divinities, such as the war-god and dragon-slayer Indra, to natural forces and elements such as fire, but the Aryans also believed in the ruling of moral powers and of an eternal law in nature. On solemn occasions the inspiring drink soma (*haoma*) was consumed by the devout. Numerous coincidences with the Indian religion survive in Zoroastrianism, side by side with astonishing diversities.

In the Avesta the evil spirits are called *daēva* (Modern Persian *dīv*), while the Aryans of India gave the name of *dēva* to their good spirits, the spirits of light. An alternative designation for deity in the *Rig-Veda* is *asura.* In the later hymns of the *Rig-*

Veda and in later India, only *evil* spirits are called *asuras,* while in Iran the corresponding word *ahura* was, and is, the designation of God the Lord. *Ahura* indicates the more sublime and awful divine character, for which man entertains reverence and fear: *daēva* denotes the kind gods of light, the anthropomorphic deities. Zoroaster elevated the conception of the *Ahura,* and he degraded the daivas (*daēvas*) to the rank of malicious powers and devils. In one *Ahura,* he concentrated the whole of the divine character, and conferred upon it the epithet of "the wise" (*mazdāo*). The Wise Lord (*Ahurō Mazdāo*—later *Ormazd*) is the primaeval spiritual being, the All-father, who was existent before ever the world arose. From him that world has emanated, and its course is governed by his foreseeing eye. His guiding spirit is the Holy Spirit, which wills the good: yet it is not free, but restricted, in this temporal epoch, by its antagonist and own twin-brother (*Yasna,* 30, 3), the Evil Spirit (*angrō mainyush, Ahriman*), who in the beginning was banished by the Good Spirit by means of the famous ban contained in *Yasna,* 45, 2, and since then drags out his existence in the darkness of Hell as the principle of ill. In the Gāthās the Good Spirit of Mazda and the Evil Spirit are the two great opposing forces in the world, and Ormazd himself is to a certain extent placed above them both. Later the Holy Spirit is made directly equivalent to Ormazd; and then the great watchword is: "Here Ormazd, there Ahriman!" The very *daēvas* are only the inferior instruments, the corrupted children of Ahriman, from whom come all that is evil in the world. The *daēvas,* attacked by Zoroaster as the enemies of mankind, are still, in the Gāthās, the perfectly definite gods of old popular belief—the idols of the people. Zoroaster regarded them as spurious deities, and their priests and votaries as idolaters and heretics. In the later, developed, system the *daēvas* are the evil spirits in general, and their number has increased to millions. Some have names; and among them the old Aryan divinities emerge here and there, *e.g.,* Indra and Nāonhaitya. With some, of course, such as the god of fire—the connection with the good deity was indissoluble. Other powers of light, such as Mitra the god of day (Iranian *Mithra*), survived in popular belief till the later system incorporated them in the angelic body. The authentic doctrine of the Gāthās had no room either for the cult of Mithra or for that of the Haoma. Beyond the Lord and his Fire, the Gāthās only recognize the archangels and certain ministers of Ormazd, who are personifications of abstract ideas. The essence of Ormazd is Truth and Law (*asha*=Vedic *rta*): this quality he embodies, and its personification (though conceived as sexless) is always his constant companion. The essence of the wicked spirit is falsehood: and falsehood, as the embodiment of the evil principle, is more frequently mentioned in the Gāthās than Ahriman himself.

Zoroaster says that he had received from God a commission to purify religion (*Yasna,* 44, 9) from the grossly sensual elements of *daēva* worship. This self-contained theory of the universe and logical dualistic principle were destined to terminate in monotheism. Later sects sought to rise from it to a higher unity in other ways. Thus the Zarvanites represented Ormazd and Ahriman as twin sons proceeding from the fundamental principle of all—*Zrvana Akarana,* or limitless time.

Ethically, too, the new doctrine stands on a higher plane, and represents, in its moral laws, a superior civilization. It is the religion of the settled grazier and the peasant, while the ruder *daēva*-cult holds its ground among the uncivilized nomadic tribes, who sacrificed the cow, the gift of Ormazd to man, a sacred animal.

The Doctrine of Zoroaster may be summarized as follows:—

At the beginning of things there existed the two spirits who represented good and evil (*Yasna,* 30, 3). Both spirits possess creative power, which manifests itself positively in the one and negatively in the other. Ormazd is light and life, and creates all that is pure and good—in the ethical world of law, order and truth. His antithesis is darkness, filth, death and produces all that is evil in the world. Until then the two spirits had counterbalanced one another. The ultimate triumph of the good spirit is an ethical demand of the religious consciousness and the quintessence of Zoroaster's religion.

The evil spirit with his wicked hosts appears in the Gāthās much less endowed with the attributes of personality and individuality than does Ahura Mazda. Within the world of the good Ormazd is Lord and God alone. In this sense Zoroastrianism is often referred to as the faith of Ormazd or as Mazdaism. Ormazd in his exalted majesty, the ideal figure of an Oriental king, has in conjunction with himself a number of genii—for the most part personifications of ethical ideas. These are his creatures, his instruments, servants and assistants. They are comprehended under the general name of *ameshā spentā* ("immortal holy ones") and are the prototypes of the seven *amshaspands* of a later date. These are—(1) Vohu Manō (εὔνοια), good sense, *i.e.,* the good principle, the idea of the good, the principle that works in man inclining him to what is good; (2) Ashem, afterwards Ashem Vahishtem (Plutarch's ἀλήθεια), the genius of truth and the embodiment of all that is true, good and right, upright law and rule—ideas practically identical for Zoroaster; (3) Khshathrem, afterwards Khshathrem Vairīm (εὐνομία), the power and kingdom of Ormazd, which have subsisted from the first but not in integral completeness, the evil having crept in like tares among the wheat: the time is yet to come when it shall be fully manifested in all its unclouded majesty; (4) Ārmaiti (θοψία), due reverence for the divine, *verecundia,* spoken of as daughter of Ormazd and regarded as having her abode upon the earth; (5) Haurvatāt (πλοῦτος), perfection; (6) Ameretāt, immortality. Other ministering angels are Gēush Urvan ("the genius and defender of animals"), and Sraosha, the genius of obedience.

As soon as the two separate spirits (cf. *Bundahish,* 1, 4) encounter one another, their creative activity and at the same time their permanent conflict begin. The history of this conflict is the history of the world. All creation divides itself into that which is Ahura's and that which is Ahriman's.

In the soul of man is the object of the war. Man is a creation of Ormazd, who therefore has the right to call him to account. But Ormazd created him free in his determinations and in his actions, wherefore he is accessible to the influences of the evil powers. Man takes part in this conflict by all his life and activity in the world. By a true confession of faith, by every good deed, word and thought, by continually keeping pure his body and his soul, he impairs the power of Satan and strengthens the might of goodness, and establishes a claim for reward upon Ormazd; by a false confession, by every evil deed, word and thought and defilement, he increases the evil and renders service to Satan.

The life of man falls into two parts—its earthly portion and that which is lived after death. The lot assigned to him after death is the result and consequence of his life upon earth. On the works of men here below a strict reckoning will be held in heaven (according to later representations, by Rashnu, the genius of justice, and Mithra). All the thoughts, words and deeds of each are entered in the book of life as separate items—all the evil works, etc., as debts. Wicked actions cannot be undone, but in the heavenly account can be counterbalanced by a surplus of good works. Only in this sense can an evil deed be atoned for by a good deed. Of a real remission of sins the old doctrine of Zoroaster knows nothing, whilst the later Zoroastrian Church admits repentance, expiation and remission. After death the soul arrives at the *cinvatō peretu,* or accountant's bridge, over which lies the way to heaven. Here the statement of his life account is made out. If he has a balance of good works in his favour, he passes forthwith into paradise (*Garō demāna*) and the blessed life. If his evil works outweigh his good, he falls finally under the power of Satan, and the pains of hell are his portion for ever. Should the evil and the good be equally balanced, the soul passes into an intermediary stage of existence (the *Hamēstakāns* of the Pahlavi books) and its final lot is not decided until the last judgment. This court of reckoning is called *ākā.* The course of law cannot be turned aside by sacrifice, nor by the grace of God.

In the Gāthās Zoroaster speaks usually in general terms of the divine commands and of good and evil works, of the renunciation of Satan, adoration of Ormazd, purity of soul and body, and care of the cow. Ceremonial worship is hardly mentioned. The Gāthās contain revelations concerning the last things and the future lot, whether bliss or woe, of human souls, promises

for true believers, threatenings for misbelievers, and Zoroaster's firm confidence as to the future triumph of the good.

Zoroaster believed that the calling of a prophet took place precisely when it did with special reason. It was, he held, the final appeal of Ormazd to mankind at large. The fulness of time was near, the kingdom of heaven was at hand. Through the whole of the Gāthās runs the pious hope that the end of the present world is not far distant. He himself hopes, with his followers, to live to see the decisive turn of things, the dawn of the new and better aeon. Ormazd will summon together all his powers for a final decisive struggle and break the power of evil for ever; by his help the faithful will achieve the victory over their detested enemies, the *daēva* worshippers. Thereupon Ormazd will hold a general ordeal. Forthwith begins the one undivided kingdom of God in heaven and on earth. This is called, sometimes the good kingdom, sometimes simply the kingdom. Here the sun will for ever shine, and all the pious and faithful will live a happy life, which no evil power can disturb, in the eternal fellowship of Ormazd and his angels. Every believer will receive as his guerdon the inexhaustible cow and the gracious gifts of the Vohu Manō.

Later Development.—For most of the people Zoroaster's doctrine was too abstract. In the later Avesta are Mithra and popular divinities like the angel of victory, Verethraghna, Anāhita (Anāitis), the goddess of the water, Tishrya (Sirius), and other heavenly bodies, invoked with special preference. The Gāthās know nothing of the belief in the *Fravashi,* or guardian angels of the faithful. *Fravashi* properly means "confession of faith," and when personified comes to be regarded as a protecting spirit.

With the new teaching arose a widely spread priesthood (*āthravanō*) who systematized its doctrines, organized and carried on its worship, and laid down the minutely elaborate laws of the Vendidad for the purifying and keeping clean of soul and body, such as the numerous ablutions, bodily chastisements, love of truth, beneficial works, support of comrades in the faith, alms, chastity, improvement of the land, arboriculture, breeding of cattle, agriculture, protection of useful animals, as the dog, the destruction of noxious animals, and the prohibition either to burn or to bury the dead. These are to be left on the appointed places (*dakhmas*) and exposed to the vultures and wild dogs. In the worship the drink prepared from the *haoma* (Indian *soma*) plant had a prominent place. Worship in the Zoroastrian Church was devoid of pomp; it was independent of temples. Its centre was the holy fire on the altar. The fire altars afterwards developed to fire temples. In the sanctuary of these temples the various sacrifices and high and low masses were celebrated. As offerings meat, milk, show-bread, fruits, flowers and consecrated water were used. The priests were the privileged keepers and teachers of religion. They only performed the sacrifices (Herodotus, i. 132), educated the young clergy, imposed the penances; they in person executed the ceremonies of purification and exercised a spiritual guardianship and pastoral care of the laymen. Every young believer in Mazda, after having been received into the religious community by being girt with the holy lace, chose a spiritual guide (*ratu*).

In eschatology a change took place. The last things and the end of the world are relegated to the close of a long period of time (3,000 years after Zoroaster), when a new Saoshyant is to be born of the seed of the prophet, the dead come to life, and a new incorruptible world begins.

Zoroastrianism was the national religion of Iran, and was professed by Turanians as well. The worship of the Persian gods spread to Armenia and Cappadocia and over the whole of the Near East (Strabo, xv. 3, 14; xi. 8, 4; 14, 76). Of the Zoroastrian Church under the Achaemenides and Aeracides little is known. After the overthrow of the dynasty of the Achaemenides a period of decay set in. Yet the Aeracides and the Indo-Scythian kings as well as the Achaemenides were believers in Mazda. The national restoration of the Sassanides brought new life to the Zoroastrian religion and long-lasting sway to the Church. Protected by this dynasty, the priesthood developed into a completely organized state church, which employed the power of the state in enforcing strict compliance with the religious law-book hitherto enjoined by their unaided efforts only. The head of the Church (Zarathushtrōtema) had his seat at Rai in Media and was the first person in the state next to the king. The formation of sects was at this period not infrequent (*cf.* MANICHAEISM). The Mohammedan invasion (636), with the persecutions of the following centuries, was the death-blow of Zoroastrianism. In Persia itself only a few followers of Zoroaster are now found (in Kerman and Yezd). The PARSEES (*q.v.*) in and around Bombay hold by Zoroaster as their prophet and by the ancient religious usages, but their doctrine is a pure monotheism.

ZORRILLA, JOSÉ (1817–1893), Spanish poet and dramatist, was born at Valladolid and read law at the University of Toledo, but after a year of idleness there, he fled to Madrid and started a paper which was suppressed by the Government. He then fell into great poverty, but was brought into notice by an elegiac poem, declaimed at Larra's funeral in Feb. 1837. His *Cantos del trovador* (1841), a collection of national legends versified with infinite spirit, secured for the author the place next to Espronceda in popular esteem. National legends also supply the themes of his dramas, though in this department Zorrilla somewhat compromised his reputation for originality by adapting older plays which had fallen out of fashion. For example, in *El Zapatero y el Rey* he recasts *El montañés Juan Pascual* by Juan de la Hoz y Mota; in *Don Juan Tenorio* he adapts from Zamora's *No hay denda que no se pague, y Convidado de piedra,* and from the elder Dumas's *Don Juan de Marana* (which itself derives from *Les âmes du purgatoire* of Prosper Mérimée). But his rearrangements usually contain original elements, and in *Sancho García, El Rey loco,* and *El Alcalde Ronquillo* he apparently owes little to any predecessor. In 1855 he emigrated to Mexico where he was protected by the Emperor Maximilian. He returned in 1866 to find himself a half-forgotten classic. His old fertility was gone, and new standards of taste were coming into fashion. He was always poor, and for some 12 years after 1871 he was in the direst straits. A small pension secured him from actual want in his old age, and the reaction in his favour became an apotheosis. In 1889 he was publicly crowned at Granada as the national laureate.

ZOSIMUS, bishop of Rome from March 18, 417 to Dec. 26, 418, succeeded Innocent I. and was followed by Boniface I. For his attitude in the Pelagian controversy, *see* PELAGIUS. He took a decided part in the protracted dispute in Gaul as to the jurisdiction of the see of Arles over that of Vienne, but without settling the controversy.

ZOSTEROPS, a genus of birds inhabiting various parts of the Old World and especially common in Australia and New Zealand. In New Zealand, the most familiar species (*Z. caerulescens*) is called white-eye or blight-bird, the last an allusion to its clearing the fruit-trees from blight.

ZOUAVE, the name given to certain infantry regiments in the French Army. The corps was first raised in Algeria in 1831 with one and later two battalions, and recruited solely from the Zouaves, a tribe of Berbers, dwelling in the mountains of the Jurjura range (*see* KABYLES). In 1838 a third battalion was raised and the regiment thus formed was commanded by Lamoricière. Shortly afterwards the formation of the *Tirailleurs algériens,* the Turcos, as the corps for natives, changed the enlistment for the Zouave battalions, and they became, as they

now remain, a purely French body. Three regiments were formed in 1852, and a fourth, the Zouaves of the Imperial Guard, in 1854. The Crimean War was the first service which the regiments saw outside Algeria. There are now six regiments, of three battalions each, stationed in North Africa.

The Papal Zouaves were formed in defense of the Papal states by Lamoricière in 1860. After the occupation of Rome by Victor Emmanuel II in 1870, the Papal Zouaves served the government of national defense in France during the Franco-Prussian War, and were disbanded during the siege of Paris.

ZOUTPANSBERG, a district forming part of the Low Veld of the northern Transvaal. It is, for the most part, low-lying undulating country, bounded on the north by the Limpopo river. The principal hills are the Zoutpansberg, which consist of three parallel ranges, which are due to the dislocation of Waterberg rocks with strike faults. Copper is mined at Messina, near the Limpopo, and gold has been found at several places. Owing to its isolation and malaria, the district has been little developed, and the population was regarded as typical "backveld Boers." A railway has been built, linking Messina with the Transvaal system, and with Lourenço Marques. Area 10,698 sq.mi., pop. (1936) 237,414 (7,878 white).

ZUCCARELLI, FRANCESCO (1702–1788), Italian painter, was born at Pitigliano in Tuscany, and studied in Rome under Morandi, and Nelli. He was a foundation member of the Royal Academy and had the patronage of royalty and of many wealthy English collectors, for whom he executed his principal works—generally landscapes with classic ruins and small figures.

ZUCCARO, the name of two Italian painters.

I. Taddeo Zuccaro (1529–1566), one of the most popular painters of the so-called Roman mannerist school, was the son of Ottaviano Zuccaro, an almost unknown painter at St. Angelo in Vado, where he was born in 1529. He was employed by popes Julius III. and Paul IV., by Della Rovere, duke of Urbino, and other patrons. His best frescoes were a historical series painted on the walls of a palace at Caprarola, built for Cardinal Alessandro Farnese, for which Taddeo also designed rich decorations in stucco relief after the style of Giulio Romano and other pupils of Raphael. Nearly all his paintings were in fresco, very large in scale, and often in *chiaroscuro*. He died in Rome in 1566.

II. Federigo Zuccaro (*c.* 1539–1609) was in 1550 placed under his brother Taddeo's charge in Rome, and worked as his assistant; he completed the Caprarola frescoes. Federigo was perhaps the most popular artist of his generation. Probably no other painter has ever produced so many enormous frescoes crowded with figures on the most colossal scale, extravagant in attitude. His first work of this sort was the completion of the painting of the dome of the cathedral at Florence in 1579; the work had been begun by Vasari but left unfinished at his death. Federigo was recalled to Rome by Gregory XIII. to continue in the Pauline chapel of the Vatican the scheme of decoration begun by Michelangelo during his failing years, but he left Italy owing to a quarrel with members of the papal court. He visited Brussels, and there made a series of cartoons for the tapestry-weavers. In 1574 he went to England, where he received commissions to paint the portraits of Queen Elizabeth, Mary, queen of Scots, Sir Nicholas Bacon, Sir Francis Walsingham, Lord High Admiral Howard and others. Federigo was soon recalled to Rome to finish his work on the vault of the Pauline chapel. In 1585 he accepted an offer by Philip II. of Spain to decorate the new Escorial at a yearly salary of 2,000 crowns. He returned to Rome in 1588 and there founded in 1595, under a charter confirmed by Sixtus V., the Academy of St. Luke, of which he was the first president. Its organization suggested to Sir Joshua Reynolds the plan for the English Royal Academy.

He also wrote on art, see *L'Idea de' Pittori, Scultori, ed Architetti* (Turin, 1607), and two volumes (Bologna 1608) describing his visit to Parma and a journey through central Italy. He died at Ancona in 1609.

ZUG, the smallest undivided canton of Switzerland, is centrally situated. Of its 92·6 sq.m., 83·6% are productive, forests covering 20·1 sq. miles. Of the unproductive area, 12·6 sq.m. are covered by lakes, 2·8 by the Aegeri See (wholly within the canton), and the balance by part of the Lake of Zug. The pear-shaped Rossberg mass, with its central summit (Wildspitz, 5,193 ft.) thrusts its pointed end (Zugerberg, 3,261 ft.) north-north-west into the canton. Its steep western flanks fall to the Lake of Zug, the less steep eastern slopes descend to the basin and waters of the Aegeri See. Still eastwards, the land rises to the Hohe Rone mass (4,055 ft.) near its eastern boundary. From Aegeri a gorge carries the river Lorze to the low land at the north end of the Zugerberg, round which it curves to enter the lower end of the Lake of Zug. The Lorze leaves this lake slightly west of its point of entrance and flows north-north-west, over fertile lowlands, to its junction with the river Reuss—the latter stream forming the north-west boundary of the canton. Zug thus holds a strategical position at the entrance to the higher land. Railways connect the capital both with Lucerne and with Zürich, while lines running along the shores of the Lake of Zug join at the Arth-Goldau station of the St. Gotthard railway. (*See* Schwyz.) An electric railway connects Zug and Oberaegeri; $2\frac{3}{4}$ m. distant, on the south-east of the lake, is Morgarten, the site of the great victory of the Confederates over the Habsburgs (1315). In 1941 the population was 36,744; in 1930, 34,395, of whom 32,897 were German-speaking, 1,001 Italian-speaking, and 294 French-speaking, while 29,211 were Catholics, 5,015 Protestants, and 46 Jews. Since 1928 the canton has formed part of the diocese of Basle. All towns are small. Zug (pop. 12,316) is the largest; north of it is Baar, and west-north-west is Cham, which are merely large villages. The canton forms a single administrative district and contains 11 communes. By the Constitution of 1814 the "Landsgemeinde," or primitive democratic assembly, which had existed since 1376, became an electoral body to choose a cantonal council. In 1848 the remaining functions of the Landsgemeinde were abolished.

The 1873–76 Cantonal Constitution was largely replaced by the present one in 1894.

The legislature (*Kantonsrat*) of 78 deputies has one member to every 450 inhabitants, and the seven members of the executive (*Regierungsrat*) are elected directly by popular vote.

The earlier history of the canton is closely linked with that of its capital, Zug (*see* below); subsequently violent disputes about the distribution of the French pensions took place (1728–38). In 1798 its inhabitants opposed the French, and during the period of the Helvetia republic it was one of the districts of the huge canton of the Waldstätten, but became a separate canton again on the fall of the republic (1803). As one of the six Catholic cantons, it joined the Sonderbund (1845) and shared in the war of 1847. In 1848, and again in 1874, it voted against the acceptance of the proposed Federal Constitution.

ZUG, capital of the Swiss canton of that name, a picturesque little town at the N.E. corner of the lake of Zug, and at the foot of the Zugerberg (3,255 ft.), which rises gradually, its lower slopes thickly covered with fruit trees. Pop. (1941) 12,316, mainly German-speaking and Roman Catholic.

The town, first mentioned in 1240, is called an *oppidum* in 1242, and a *castrum* in 1255. In 1273 it was bought by Rudolph of Habsburg from Anna, the heiress of Kyburg. After this it was governed by a bailiff, appointed by the Habsburgs, and a council, and was much favoured by that family. Several country districts (Baar, Menzingen, and Aegeri) had each its own "Landsgemeinde" but were governed by one bailiff, also appointed by the Habsburgs; these were known as the "Aeusser Amt," and were always favourably disposed to the Confederates. On the 27th of June 1352 both the town of Zug and the Aeusser Amt entered the Swiss Confederation; but in September, 1352, Zug had to acknowledge its own lords again, and in 1355 to break off its connection with the league. About 1364 the town and the Aeusser Amt were recovered for the league by the men of Schwyz, and from this time Zug took part as a full member in all the acts of the league. In 1379 the German king Wenceslaus exempted Zug from all external jurisdictions, and in 1389 the Habsburgs renounced their claims, reserving only an annual payment of twenty silver marks, and this came to an end in 1415. In 1385 Zug joined the league of the Swabian cities against Leopold of Habsburg,

and shared in the victory of Sempach. Between 1379 (Walchwil) and 1477 (Cham) Zug had acquired various districts in her own neighbourhood, principally to the north and the west, which were ruled till 1798 by the town alone as subject lands. At the time of the Reformation Zug clung to the old faith and was a member of the "Christliche Vereinigung" of 1529. In 1586 it became a member of the Golden League.

ZUG, LAKE OF, one of the minor Swiss lakes, north of that of Lucerne. It is formed by the Aa, which enters the southern extremity of the lake. The Lorze enters at its northern end, but $1\frac{1}{4}$ m. further W. issues from the lake to pursue its course towards the Reuss. The lake has an area of about 15 sq.m., is about 9 m. long, $2\frac{1}{2}$ m. wide, and has a maximum depth of 650 ft., while its surface is 1,368 ft. above sea-level. Most of the lake is in the canton of Zug, but $3\frac{3}{4}$ sq.m. at the southern end is in Schwyz, while $\frac{3}{4}$ sq.m., to the N. of Immensee is in Lucerne.

ZUHAIR [Zuhair ibn Abī Sulmā Rabī' a ul-Muzanī] (6th century), one of the six great Arabian pre-Islamic poets. Of his life practically nothing is known save that he belonged to a family of poetic power; his stepfather, Aus ibn Hajar, his sister, Khansā, and his son, Ka'b ibn Zuhair, were all poets of eminence. He is said to have lived long, and at the age of one hundred to have met Mohammed. His home was in the land of the Banī Ghatafān. His poems are characterized by their peaceful nature and a sententious moralizing. One of them is contained in the *Moallakāt*.

As a whole his poems have been published by W. Ahlwardt in his *The Diwans of the six Ancient Arabic Poets* (London, 1870); and with the commentary of al-A'lam (died 1083) by Count Landberg in his *Primeurs arabes* (Leiden, 1889). (G. W. T.)

ZUIDER ZEE (Zoi'dur zā), a shallow gulf, penetrating far into the northern Netherlands, communicating with the North Sea but almost cut off from it at low water by the Frisian islands (Texel, etc.) and the sandbanks of the Wadden Zee. It is probable that in the middle ages the coast line to the north of the Zuider Zee was an almost continuous series of dunes, but, before the 14th century the Zuider Zee acquired something of its present form. The greater part of the water-covered area has a depth of less than 15ft. at low water. An area of over 12,000ac. of rich land was reclaimed from Lake Y in the neighbourhood of Amsterdam, at the time of the building of the North Sea ship canal in the middle of the 19th century, by the construction of a sea-dike and locks cutting off Amsterdam from the Zuider Zee. The earliest plans for reclaiming the Zuider Zee date from the 17th century but it was not until 1918 that the sanction of the Netherlands legislature was obtained to the carrying out of a vast scheme of reclamation commenced in 1920. (*See* COAST PROTECTION AND LAND RECLAMATION; HOLLAND.) (N. G. G.)

The Zuider Zee originally covered an area of about 3,570 square kilometres. When drained, there will remain a fresh-water lake covering 1,450 square kilometres. The reclaimed land, divided into four polders by the new lake (to be called Yssel lake), and the mouths of the Amstel and the Yssel, will cover an area of almost 2,112 square kilometres. Of this land, 1,950 sq.km., will consist of exceedingly fertile soil. To render this drainage possible, the Zuider Zee had to be separated from the North sea by a dike, completed in 1932 at a cost of £10½ millions. The dike is 29.3 kilometres long, and six metres high above the water level. The top is only two metres in width. On the inside berm, however, there will be room for a road 17 metres wide, over which a double-track railway will run. The dike will be equipped with 30 discharge sluices, each 10 metres wide and five metres deep. Further, there will be two locks, respectively 10 and 6 metres wide. These sluices and locks will maintain communication between the Yssel lake and the North sea. It is hoped that the northwestern polder, covering an area of 220 sq.km., will be completed at the same time as the dike and that all four polders will be in exploitation by 1958.

ZULA, a small town near the head of Annesley bay on the African coast of the Red sea. Ruins in its vicinity are supposed to mark the site of the ancient emporium of Adulis ('Αδουλῖς, 'Αδουλεί), the port of Aksum (*q.v.*) and chief outlet in the early centuries of the Christian era for the ivory, hides, slaves and other exports of the interior. Cosmas Indicopleustes saw here an inscription of Ptolemy Euergetes (247–222 B.C.); and it is conjectured that the town may have been the Berenice Panchrysus of the Ptolemies.

In 1857 an agreement was entered into by Dejaj Negusye, a chief of Tigré, in revolt against the Negus Theodore of Ethiopia, to cede Zula to the French. Negusye was defeated by Theodore, and the commander of a French cruiser sent to Annesley Bay in 1859 found the country in a state of anarchy. No further steps were taken by France to assert its sovereignty, and Zula, with the neighbouring coast, passed nominally to Egypt in 1866. Zula was the place where the British expedition of 1867–68 against Theodore disembarked. The road made by the British from Zula to Senafé on the Ethiopian plateau is still in use. The authority of Egypt having lapsed, an Italian protectorate over the district of Zula was proclaimed in 1888, and in 1890 it was incorporated in the colony of Eritrea (*q.v.*).

ZULOAGA, IGNACIO (1870–1945), Spanish painter, was born at Eibar in the Basque country on July 26, 1870, the son of the metal-worker and damascener Placido Zuloaga, and grandson of the organizer and director of the royal armoury in Madrid. He was intended for an architect, and to this end was sent to Rome, where he at once followed his strong impulse to become a painter. After six months' work he completed his first picture, which was exhibited at the Paris Salon of 1890. Continuing his studies in Paris, he was strongly influenced by Gauguin and Toulouse-Lautrec. But his true style developed after his return to Spain, when he had studied the work of Velazquez, Zurbaran, El Greco and Goya. His own country was slow in acknowledging the young artist whose strong, decorative, rugged style was the very negation of the aims of such well-known modern Spanish artists as Fortuny, Madrazo and Benlliure. It was in Paris, and then in Brussels and other continental art centres, that Zuloaga was first hailed by the reformers as the regenerator of Spanish national art and as the leader of a school. He is represented in almost every great continental gallery.

Two of his canvases are at the Luxembourg, one at the Brussels Museum ("Avant la Corrida"), and one ("The Poet Don Miguel") at the Vienna Gallery. The Pau Museum owns an interesting portrait of a lady, the Barcelona Municipal Museum the important group "Amies," the Venice Gallery, "Madame Louise"; the Berlin Gallery, "The Topers." Other examples are in the Budapest, Stuttgart, Ghent and Posen galleries and in many important private collections.

A fully illustrated account of the artist and his work, by M. Utrillo, was published in a special number of *Forma* (Barcelona, 1907).

ZULULAND, a region in southeast Africa, forming the northeastern section of the province of Natal in the Union of South Africa. It was incorporated with Natal in Dec. 1897, from which time until the formation of the union it was known as the province of Zululand. It lies between 26° 50′ and 29° 15′ S. and 30° 40′ and 33° E. and is bounded on the southeast by the Indian ocean, on the north and northeast by the Utrecht and Vryheid districts of Natal and by Swaziland. The region has an area of 10,427 sq.mi. including Amatongaland, Zaambauland and Ingwavuma District, territories not part of the former Zulu domains. Population (1936) 362,421 of which 352,437 are natives; 6,159 Europeans; 2,600 Asiatics; and 1,225 coloured. European settlement has been restricted by the prevalence of malaria and of the tsetse fly. For an account of physical features, geology, climate, flora, fauna and general geography *see* under NATAL and SOUTH AFRICA, UNION OF.

Crown reserves of land for native use, although considerably reduced, form about three-fifths of Zululand, 3,882,000 acres having been set aside in 21 districts as the Zululand native trust. Large areas in Zululand have been planted to sugar cane. Completion of the Swazi border railway opened up much country for the cultivation of cotton. The completion of the Empangeni-Nkwaleni railroad should aid in the development of large and fertile areas. The important irrigation scheme at Mkuzi should further facilitate agriculture, as should also a similar project, estimated to cost £250,000, on the Pongola river. Coal deposits, believed to underlie much of the southern sections of Zululand,

have not been fully exploited. (P. W. I.)

History.—At what period the Zulu (one of a number of closely allied septs) first reached the country to which they have given their name is uncertain; they were probably settled in the valley of the White Umfolosi river at the beginning of the 17th century, and they take their name from a chief who flourished about that time. By certain shipwrecked Europeans they were described as very proud and haughty, careful in the preparation of food, very cleanly in person and keeping strict watch over their women. That was in 1756. At the close of the 18th century the Zulu were an unimportant tribe, numbering a few thousands only. At that time the most powerful of the neighbouring tribes was the Umtetwa (mTetwa or Aba-Tetwa), which dwelt in the country northeast of the Tugela. Its ruler was a chief who had had in early life an adventurous career and was known as Dingiswayo (the Wanderer). He divided the young men of his tribe into *impis* (regiments), and the Umtetwa became a formidable military power. In 1805 he was joined by Chaka (Tshaka, born *c.* 1783), the son of the Zulu chief Senzangokona; on the latter's death in 1810 Chaka, through the influence of Dingiswayo, was chosen as ruler of the Ama-Zulu, though not the rightful heir. About 1812 Dingiswayo was captured and put to death by Zwide, chief of the Undwandwe clan.

Chaka and Dingaan.—After Dingiswayo's death the Umtetwa army then placed themselves under Chaka, who not long afterward conquered the Undwandwe. By the incorporation of these tribes Chaka made the Zulu a powerful nation. He strengthened the regimental system adopted by Dingiswayo and perfected the discipline of his army. A new order of battle was adopted—the troops being massed in crescent formation, with a reserve in the shape of a parallelogram ready to strengthen the weakest point. This order of battle was not, however, entirely new to the Bantu and probably Chaka's greatest innovation was the introduction of the stabbing assegai. At the same time the size of the shield was increased, the more completely to cover the body of the warrior. Military kraals were formed for the warriors.

Chaka had but two ways of dealing with the tribes with whom he came in contact; either they received permission to be incorporated in the Zulu nation or they were attacked. In the latter case the only persons spared were young girls and growing lads. About 1820, after the Zulu had conquered Natal, Mosilikatze (properly Umsilikazi), a general in the Zulu army, having incurred Chaka's wrath by keeping back part of the booty taken in an expedition, fled with a large following across the Drakenberg. Mosilikatze was not of the Zulu tribe proper, and he and his followers became known as the Matabele. Chaka's own dominions coincided almost exactly with the limits of Zululand and Natal.

Chaka seems to have first come into contact with Europeans in 1824, when he was visited by F. G. Farewell and a few companions. To them he made a grant of the district of Port Natal. Chaka, who was cured of a wound by the skill of one of Farewell's companions, showed himself friendly to Europeans. He wished to send an embassy to England, but the Cape government turned back his envoy. Again Chaka sent chiefs to Capetown, but before their arrival he had been murdered (Sept. 23, 1828) at a kraal on the Umvote, about 50 miles from Port Natal. Chaka was a victim to a conspiracy by his half-brothers Dingaan and Umthlangana, while a short time afterwards Dingaan murdered Umthlangana and made himself king.

Bloodstained as had been Chaka's rule, that of Dingaan appears to have exceeded it in wanton cruelty. In 1835 Dingaan permitted the British settlers at Port Natal to establish missionary stations in the country in return for a promise made by the settlers not to harbour fugitives from his dominions. In 1836 American missionaries were also allowed to open stations; in Nov. 1837 Dingaan received Pieter Retief, the leader of the first party of Boer immigrants to enter Natal. The story of Retief's mission, the massacre of the Boer leader and the fighting which followed is told in the article NATAL. In the result Dingaan's army was totally defeated on Dec. 16, 1838 ("Dingaan's Day"), by a Boer force under Andries Pretorius. A year later he was overthrown, the Boers in Natal (Jan. 1840) supporting his brother Mpande (usually called Panda) in rebellion against him. Dingaan passed into Swaziland in advance of his retreating forces, and was there murdered, while Panda was crowned king of Zululand by the Boers.

Panda and Cetywayo.—When in 1843 the British succeeded the Boers as masters of Natal they entered into a treaty with Panda, who gave up to the British the country between the upper Tugela and the Buffalo rivers, and also the district of St. Lucia bay (which, however, was not then occupied). Less warlike than Chaka and Dingaan, Panda remained throughout at peace with the government of Natal. Bishop Schreuder, a Norwegian missionary long resident in Zululand, gave Sir Bartle Frere the following estimate of the three brothers who successively reigned over the Zulu:—"Chaka was a really great man, cruel and unscrupulous, but with many great qualities. Dingaan was simply a beast on two legs. Panda was a weaker and less able man, but kindly and really grateful, a very rare quality among Zulus. He used to kill sometimes, but never wantonly or continuously." In 1856 war broke out between two of Panda's sons, Cetywayo and Umbulazi, who were rival claimants for the succession. A battle was fought between them on the banks of the Tugela in Dec. 1856, in which Umbulazi and many of his followers were slain. The government of Natal in 1861 obtained the formal nomination of a successor to Panda; and Cetywayo was appointed. Panda died in Oct. 1872 and Cetywayo succeeded in 1873.

Border disputes with the Transvaal Boers were fairly frequent during Panda's reign. The Boers had obtained from Panda in 1854 a cession of the Utrecht district; in 1860 they tried to get from the king a road to the sea at St. Lucia bay. In 1861 a quarrel arose between Cetywayo and another of his brothers, Umtonga (who had been originally designated by Panda as his successor). Umtonga fled to Utrecht; Cetywayo offered the Boers a strip of land if they would surrender his brother. This they did on condition that Umtonga's life was spared. The Boers got their strip of land and beaconed it off in 1864. When, however, in 1865 Umtonga fled to Natal, Cetywayo declared that he had lost his part of the bargain, for he feared that Umtonga might be used to supplant him. He thereupon caused the boundary beacons to be removed and put forward a claim to certain lands north of the Pongola, ceded by the Swazi to the Lyndenburg Boers in 1855, on the ground that the Swazi were the vassals of the Zulu and had no right to part with any of their territory.

Cetywayo's Rule.—Such was the position when by his father's death Cetywayo (*q.v.*) became absolute ruler of the Zulu. As far as possible he revived the military methods of his uncle Chaka. His rule over his own people was tyrannous. By Bishop Schreuder he was described as "an able man, but for cold, selfish pride, cruelty and untruthfulness worse than any of his predecessors." The tension between Cetywayo and the Transvaal over border disputes continued and when in 1877 Great Britain annexed the Transvaal the disputes were transferred to the new owners of the country. A commission appointed by the lieutenant governor of Natal reported in July 1878, and found almost entirely in favour of the Zulu on the boundary disputes. Sir Bartle Frere, then high commissioner, thought the award "one-sided and unfair to the Boers" (Martineau, *Life of Frere,* ii, xix). Frere, moreover, was convinced that it was necessary in the interests of South Africa that the power of Cetywayo be curtailed. In furtherance of this general plan a British resident was to be accepted. These demands were made to Zulu deputies on Dec. 11, 1878, a definite reply being required by the 31st of that month.

The Zulu War.—Cetywayo returned no answer, and in Jan. 1879 a British force under Gen. Thesiger (Lord Chelmsford) invaded Zululand. Chelmsford had a force of 5,000 Europeans and 8,200 natives; Cetywayo an army of fully 40,000 men. Chelmsford divided his force into three columns—their entry was unopposed—which were to converge on Ulundi, the royal kraal. On Jan. 22 the centre column (1,600 Europeans, 2,500 natives), which had advanced from Rorke's Drift, was encamped near Isandhlwana; on the morning of that day Chelmsford moved out with a small force to support a reconnoitring party. After he had left, the camp, in charge of Col. Durnford, was surprised by a Zulu army nearly 10,000 strong. The British were overwhelmed and

almost every man killed, the casualties being 806 Europeans (more than half belonging to the 24th regiment) and 471 natives. The reconnoitring party returned to find the camp deserted; next day they retreated to Rorke's Drift, which had been the scene of an heroic and successful defense. After the victory at Isandhlwana several impis of the Zulu army had moved to the Drift. The garrison stationed there, under Lieuts. Chard and Bromhead, numbered about 80 men of the 24th regiment, and they had in hospital between 30 and 40 men. Late in the afternoon they were attacked by about 4,000 Zulus. On six occasions the Zulus got within the entrenchments, to be driven back each time at the bayonet's point. At dawn the Zulus withdrew, leaving 350 dead. The British loss was 17 killed and 10 wounded.

In the meantime the right column under Col. Pearson had reached Eshowe from the Tugela; on receipt of the news of Isandhlwana most of the mounted men and the native troops were sent back to Natal, leaving at Eshowe a garrison of 1,300 Europeans and 65 natives. This force was hemmed in by the enemy. The left column under Col. Evelyn Wood, which had advanced from Utrecht, found itself obliged to act on the defensive.

News of Isandhlwana reached England on Feb. 11 and on the same day about 10,000 men were ordered to South Africa. The first troops arrived at Durban on March 17. On the 29th a column under Chelmsford, consisting of 3,400 Europeans and 2,300 natives, marched to the relief of Eshowe, entrenched camps being formed each night. On April 2 the camp was attacked at Ginginhlovo, the Zulu being repulsed. Their loss was estimated at 1,200, while the British had only two killed and 52 wounded. The next day Eshowe was relieved. Wood, who had been given leave to make a diversion in northern Zululand, on March 28 occupied Hlobane (Inhlobane) mountain. The force was, however, compelled to retreat owing to the unexpected appearance of the main Zulu army, which nearly outflanked the British. There were 100 casualties among the 400 Europeans engaged. At midday next day the Zulu army made a desperate attack, lasting over four hours, on Wood's camp at Kambula; the enemy—over 20,000 strong—was driven off, losing fully 1,000 men, while the British casualties were 18 killed and 65 wounded.

By the middle of April nearly all the reinforcements had reached Natal, and Chelmsford reorganized his forces. The 1st division, under Maj. Gen. Crealock, advanced along the coast belt and was destined to act as a support to the 2nd division, under Maj. Gen. Newdigate, which, with Wood's flying column, an independent unit, was to march on Ulundi from Rorke's Drift and Kambula. Owing to difficulties of transport it was June before Newdigate was ready to advance. On the 1st of that month the prince imperial of France (Louis Napoleon), who had been allowed to accompany the British troops, was killed while out with a reconnoitring party. On July 1 Newdigate and Wood had reached the White Umfolosi, in the heart of the enemy's country. On the 4th they crossed the river, the force numbering 4,200 Europeans and 1,000 natives. Within a mile of Ulundi the British force, formed in a hollow square, was attacked by a Zulu army numbering 12,000 to 15,000. The battle ended in a decisive victory for the British, whose losses were about 100, while of the Zulu some 1,500 men were killed (*see* ULUNDI). Sir Garnet Wolseley had been sent out to supersede Chelmsford and reached headquarters on July 7.

Cetywayo's Downfall.—After Ulundi the Zulu army dispersed, most of the leading chiefs tendered their submission, and Cetywayo became a fugitive. On Aug. 27 the king was captured and sent to Capetown. His deposition was formally announced to the Zulu, and Wolseley drew up a new scheme for the government of the country. The Chaka dynasty was deposed and the Zulu country portioned among 11 Zulu chiefs, John Dunn, a white adventurer, and Hlubi, a Basuto chief, who had done good service in the war. A resident was appointed who was to be the channel of communication between the chiefs and the British government. This arrangement was productive of much bloodshed and disturbance, and in 1882 the British government determined to restore Cetywayo to power. In the meantime, however, blood feuds had been engendered between two chiefs of the royal house, Usibepu (Zibebu) and Hamu, and the tribes who supported the ex-king and his family. Cetywayo's party (who became known as Usutus) suffered severely at the hands of the two chiefs. When Cetywayo was restored Usibepu was left in possession of his territory, while Dunn's land and that of the Basuto chief (the country between the Tugela and the Umhalatuzi, *i.e.*, adjoining Natal) was constituted a reserve. Before very long this new arrangement proved as futile as had Wolseley's. A collision soon took place; Usibepu's forces were victorious and, on July 22, 1883, led by a troop of mounted whites, he made a sudden descent upon Cetywayo's kraal at Ulundi, which he destroyed, massacring such of the inmates of both sexes as could not save themselves by flight. The king escaped, though wounded, into the reserve; he died in Feb. 1884.

Cetywayo left a son, Dinizulu, who sought the assistance of some of the Transvaal Boers against Usibepu, who was defeated and driven into the reserve. These Boers, led by Lukas Meyer, claimed as a reward for their services the greater and more valuable part of central Zululand. On May 21 the Boer adventurers had proclaimed Dinizulu king of Zululand; in August following they founded the "New Republic," carved out of Zululand. The British government intervened, and in Dec. 1884 took formal possession of St. Lucia bay, caused the Boers to reduce their territorial demands, and in its truncated form recognized the New Republic—which was in 1888 incorporated in the Transvaal and has since 1903 formed the Vryheid division of Natal. (F. R. C.)

Zululand Annexed.—The British government annexed Zululand in 1887 and placed it under a commissioner responsible to the governor of Natal. In the following year Dinizulu rebelled. After a sharp campaign (June–Aug. 1888), Dinizulu fled into the Transvaal. He surrendered to the British in November; in April 1889 he and two of his uncles were found guilty of high treason and were exiled to St. Helena.

Under the administration of Sir Melmoth Osborn, the commissioner, and his successor Sir Marshal Clarke, and the district magistrates, the Zulu became reconciled to British rule.

At the close of 1897 Zululand, in which Tongaland had been incorporated, was handed over by the imperial government to Natal. In 1898 Dinizulu was allowed to return and was made a "government induna." Officially one of several chiefs he was, in fact, regarded by most of the Zulu as the head of their nation.

In 1905 a poll tax of £1 on all adult males was imposed by the Natal legislature; this tax was the ostensible cause of a revolt in 1906 among the natives of Natal. After a hard campaign the rebellion was crushed by July 1906. In all about 3,500 Zulus were killed and about 3,000 taken prisoners, the majority of them being released in 1907. (*See* further, NATAL: *History.*) Zululand remained, however, in a disturbed condition, and a number of white traders and officials were murdered. In Dec. 1907 the Natal government felt justified in charging Dinizulu with high treason, murder and other crimes. A military force entered Zululand and Dinizulu surrendered without opposition. He was brought to trial in Nov. 1908 and in March 1909 was found guilty of harbouring rebels. The more serious charges against him were not proved. Sentenced to four years' imprisonment, he was released on the establishment of the Union in 1910 by Gen. Botha. Dinizulu was settled on a farm in the Transvaal, where he died in Oct. 1913.

No disturbance of public order occurred from 1907 to 1945. European influence has greatly modified native life, consequent upon opening of the country to cotton and sugar planters. The Zulus, because of their traditions as a dominant military people, have shown reluctance to enter industrial employment, although they have not been disinclined to enter domestic service. Numbers of the male population have been obliged to seek livelihoods off the native reserves, with consequent deterioration of the native communities. Many aspects of the tribal systems, however, continue to be important, including the patriarchical social organization, the system of regulating inheritance of personal property (consisting chiefly of cattle), and regulation of marriage. Considerable pressure for further reduction of the native reserves is exerted by the fact that additional land suitable for sugar plantations under European ownership can be found only in the native reserves where the density is already 33.7 per sq.mi. as compared with 20.7 in the union.

About 80 native chiefs, as provided in the act of annexation of Zulu-

land to Natal, hear native criminal and civil cases, under a supervisory staff of magistrates. A court of appeals has been established. The Natal Code of Native Law, with revisions, has been extended to Zululand. It is also proposed to set up a native Bunga, a consultative and deliberative council, along the lines of that set up in the Transkei.

ZUMALACÁRREGUI, TOMÁS (1788–1835), Spanish Carlist general, born at Ormaiztegui, Navarre, Dec. 29, 1788. In his youth he served under Gaspar de Jauregui, one of the minor guerrillero leaders. He then entered the army, but was disgraced for his support of Don Carlos.

Appointed commander-in-chief in Navarre by Don Carlos, he escaped from Pamplona on the night of Oct. 29, 1833, and took command the next day in the Val de Araquil of the few hundred ill-armed and dispirited guerrilleros that constituted his whole force. In a few months Zumalacárregui had organized the Carlist forces into a regular army. Whether as a guerrillero leader, or as a general conducting regular war in the mountains, he proved unconquerable. By July 1834, he had made it safe for Don Carlos to join his headquarters. The pretender, bigoted and narrow-minded, was afraid of Zumalacárregui's personal influence with the soldiers, and Zumalacárregui was hampered by the intrigues of the court. Yet by June 1835 he had made the Carlist cause triumphant to the north of the Ebro: had he been allowed to march on Madrid, he might well have put Don Carlos in possession of the capital. He reluctantly obeyed the order to besiege Bilbao, was wounded in the leg on June 14, 1835, attended by Don Carlos's physicians, and died on June 24, 1835—not without suspicion of poison.

ZUMPT, the name of two German classical scholars. KARL GOTTLOB ZUMPT (1792–1849) was born on April 1, 1792 in Berlin, and died at Karlsbad on June 25, 1849. He was professor of Latin literature at Berlin University. His chief work was his *Lateinische Grammatik* (1818). He edited Quintilian's *Institutio oratoria* (1831), Cicero's *Verrines* and *De officiis* (1837), and Curtius. He also published *Annales veterum regnorum et populorum* (3rd ed. 1862), a work in chronology down to A.D. 476, and other antiquarian studies. His nephew, AUGUST WILHELM ZUMPT (1815–1877), was born on Dec. 4, 1815, at Königsberg, and died on April 22, 1877, and was professor in the Friedrich Wilhelm Gymnasium. He is known chiefly in connection with Latin epigraphy, his papers on which (collected in *Commentationes epigraphicae*, 2 vols., 1850–54) brought him into conflict with Mommsen. His works include *Monumentum Ancyranum* (with Franck, 1847) and *De monumento Ancyrano supplendo* (1869); *Studia Romana* (1859); *Das Kriminalrecht der röm. Republik* (1865–69); *Der Kriminalprozess der röm. Republik* (1871); editions of Namatianus (1840), Cicero's *Pro Murena* (1859) and *De lege agraria* (1861). Ihne incorporated materials left by him in the 7th and 8th vols. of his *Römische Geschichte* (1840).

ZUNI, a native town on the Zuni river, an affluent of the Little Colorado, in western New Mexico, sole remnant of a Pueblo population of wholly distinct speech and unknown origin. First seen by Niza in 1539; the then seven Zuni towns were entered by Coronado in 1540 after the storming of Hawikuh, one of the chief of them. A mission was established in 1629; in 1670 Hawikuh was destroyed by the Apache; in 1680, on the outbreak of the Pueblo rebellion, only three towns remained, at one of which, Halonawa, the reconquered Zuni population was concentrated around a mission, now in ruins. About this rose the congested pueblo in tiers up to four and five stories of masonry. The population was 2,252 as of Jan. 1, 1941, the largest resident population of any Pueblo. Like the other pueblos, the Zunis have maintained much of their traditional customs and religion. While their culture is thus closely bound up with soil and seasons, their government is on an elective democratic basis. The Zuni ritual best known to non-Indians is the Shalako dance, a house-blessing ceremony held annually in December.

(1883–96), *Zuñi Folk Tales*, 1901, *Zuñi Breadstuff* (Indian Notes and Monographs, vol. viii., 1920); A. L. Kroeber, *Am. Mus. Nat. Hist. Anthr. Pap.*, vol. xviii. (1917); E. C. Parsons, *Am. Anthr. Ass. Mem.*, vol. iv. (1917).

ZUNZ, LEOPOLD (1794–1886), Jewish scholar, was born at Detmold in 1794, and died in Berlin in 1886. He was the founder of what has been termed the "science of Judaism," the critical investigation of Jewish literature, hymnology and ritual. His *Gottesdienstliche Vorträge der Juden, i.e.*, lays down principles for the investigation of the Rabbinic exegesis (Midrash, *q.v.*) and of the prayer-book of the synagogue.

Zunz's other principal works are *Synagogale Poesie des Mittelalters* (1855); and *Literaturgeschichte der Synagogalen Poesie* (1865, supp. vol. 1867).

ZURBARAN, FRANCISCO DE (1598–?1669), Spanish painter, was born at Fuente de Cantos in Estremadura, and baptized on Nov. 7, 1598. His parents belonged to the agricultural labouring class, but, discovering their son's talent, sent him at the age of 16 to study under a painter called Diego Perez Villanueva; he then worked under Juan de Roélas at Seville. He soon developed an independent realistic style, with solid modelling, and strongly contrasted light and shade, and acquired the name of the "Spanish Caravaggio." A series of "Scenes from the life of St. Peter" and a great altarpiece painted for the cathedral at Seville in 1625 established his reputation and in 1629 he was nominated town painter of Seville. Other important works of the early period are four pictures representing "Scenes from the Life of St. Buenaventura" now in the Louvre, Berlin, and Dresden museums; "the Vision of Alonso Rodriguez" (1630 in the Academy, Madrid) which is, perhaps, his masterpiece; the grand altarpiece representing "the Apotheosis of St. Thomas of Aquinas" (1631, Seville museum); to the year 1629 belong the series of pictures out of the Merced Calzada, representing scenes from the life of S. Pedro Molaxo (Seville Cathedral and Prado Madrid). The paintings in the monastery of Guadelupe were executed ten years later. Through his friendship with Velasquez he was nominated "Painter to the king" in 1638. It was, however, not until 1650, that he moved to the capital where he was commissioned to decorate a room of the palace of Buenretiro with the "Labours of Hercules." Of this series only four panels (now in the Prado) were completed. The date of Zurbaran's death is unknown. He was still alive on Feb. 28, 1664, when he was called upon to value some paintings at Madrid. Other important works of the master are at Seville, Cadiz, Jerez and in the museums of Budapest, London, in the Gardner collection, Boston, and with the Hispanic Society, New York, and elsewhere.

Zurbaran's principal pupils were Martinez de Granadille, Bernabe de Ayala, and the brothers Polanco. In the 19th century Courbet, who, like Zurbaran, was a son of the soil, professed a great admiration for the Spaniard's works in the Louvre and, to some extent, formed his style thereon.

See Narcisso Sentenach y Cabanas, *Painters of the School of Seville* (Eng. trans., 1911); José Cascales y Munoz, *Francesco de Zurbaran* (Madrid, 1911); C. Justi, *Diego Velazquez und sein Jahrhundert* (Bonn, 1903). (I. A. R.)

ZÜRICH, the canton of north-eastern Switzerland and which ranks officially first in the Confederation. Its total area is 667·4 sq.m., of which the high proportion of 90·4% is reckoned as "productive" (forests, 184·9 sq.m., and vineyards 4·6 sq.m., the latter showing a rapid decrease during the 20th century, and now ranking much below Valais [*q.v.*]). Of the rest, 27·8 sq.m. are occupied by lake waters, chiefly part of the Lake of Zürich, but wholly within the canton are the Lakes of Greifen (3¼ sq.m.) and Pfäffikon (1¼ sq.m.). The canton, though not one of the ancient three, joined the Confederation in 1351. Its irregularity of shape arises from its continued growth, up to 1803, by the additions of acquisitions made by the capital. As far back as 1362 the

whole of the lower part of the lake was added, and by the purchase of Winterthur (1467) from the Habsburgs, it reached the Rhine. To-day it extends from its enclave in Baden, on the right bank of the Rhine (above the Thur junction to below the Töss junction) to some 8 m. S.W. of Pfäffikon See. It consists essentially of shallow river valleys draining Rhinewards and separated from one another by north-west to south-east ridges. The most important valley is that of the Linth, which expands into the Lake of Zürich and is continued as the Limmat; the ridge to the east is low and then successively eastwards are the valley of the river Aa-Glatt, which flows through the Greifen See; a higher ridge separating it from the more gorge-like Töss valley, and finally the highest ridge along the east boundary separating the Töss from the Toggenburg (*q.v.*). On the last ridge, Hornli reaches 3,727 feet. West of the Lake of Zürich is the strikingly parallel valley of the Sihl, bounded farther west by the Albis range, with Albishorn (3,012 ft.) as its highest point. All the valleys are occupied by railway lines and the Limmat (Zürich to Baden) carried the first line opened (1847) in Switzerland. From the town of Zürich standard lines and mountain railways radiate in all directions; of the latter, one (south-west) is for Uetliberg (2,864 ft.) the north buttress of the Albis range and one (north-east) is for Zürichberg (2,285 ft.), on the ridge between the Limmat and the Glatt. Pop. (1941) 671,714.

In 1930 the population was 617,706, of whom 585,501 were German-speaking, 17,192 Italian-speaking, 9,350 French-speaking, and 1,716 Romansch-speaking, while there were 458,307 Protestants, 141,568 Catholics and 6,081 Jews. The capital of the canton is Zürich (pop. 1941, 333,829), but Winterthur (59,192) is the only other considerable town. Uster (10,588), east of Greifen See, is an industrial town, while Thalwil (7,943), Horgen (9,358) and Wädenswil (9,501), all on the western shore of the Lake of Zürich, are of note as industrial centres. Though the land is highly cultivated, yet the canton is essentially a great manufacturing area, especially of machinery and railway rolling-stock. Silk weaving and cotton weaving are widely spread, and the products of the former industry have a large foreign market. The canton is divided into 11 administrative districts containing 186 communes. In 1869 the cantonal Constitution was revised, and no material changes have been made since. There is an executive (*Regierungsrat*) of seven members and a legislature (*Kantonsrat*) of 180 deputies (distributed among the electoral circles on a population basis, which varies from census to census). Each body holds office for four years and is elected by a method making use of the principle of proportional representation. The compulsory referendum exists, and all laws and all financial decisions involving a total sum over 250,000 frcs., or an annual sum of 20,000 frcs., must be submitted to a popular vote. Any 5,000 voters can employ the "initiative" to force the government to submit to the people any legislative or constitutional matter. Both members of the Federal *Ständerat* and the 28 members of the Federal *Nationalrat* are elected simultaneously by a popular vote and hold office for three years. (*See* SWITZERLAND.) (W. E. WH.)

ZÜRICH, the capital of the Swiss canton of the same name (Fr. *Zurich;* Ital. *Zurigo;* Lat. *Turicum*). It is the most populous, the most important, and on the whole the finest town in Switzerland, and till 1848 was practically the capital of the Swiss Confederation. In 1941, after an extension of boundaries (1934), its population was 333,829. In 1930 it was 249,820, and with its suburbs 309,541. Of the city's population 160,621 were Protestants, 75,291 Roman Catholics and 5,742 Jews, while 230,209 were German-speaking, 6,633 French-speaking, 8,850 Italian-speaking, and 1,082 Romansch-speaking.

Zürich is built on both banks of the Limmat as it issues from the lake of Zürich, and also of its tributary, the Sihl. That portion of the town which lies on the right bank of the Limmat is called the "Grosse Stadt" and that on the left bank the "Kleine Stadt." Till 1893 the central portion of the town on either bank of the Limmat formed the "city" and ruled the outlying communes or townships that had sprung up around it. But at that time the eleven outer districts (including Aussersihl, the workmen's quarter on the left bank of the Sihl) were incorporated with the town. Much land has been rescued from the lake, and is the site of fine quays, stately public buildings, such as the Civic Theatre and the Concert Hall, and splendid private villas. The older quarters are still crowded; but the newer quarters which stretch up the slope of the Zürichberg (above the right bank of the Limmat) have broad streets and fine buildings.

There were numerous pile dwellings on the sides of the lake and Zürich was a pre-Roman settlement, probably an "oppidum." About the middle of the first century A.D. a Roman "castellum" and customs station existed on the Lindenhof.

Of the old buildings the finest and most important is the Gross Münster (or Propstei), on the right bank of the Limmat. This was originally the church of the king's tenants, and in one of the chapels the bodies of Felix, Regula and Exuperantius, the patron saints of the city, were buried. The present building was erected at two periods (*c.* 1090–1150 and *c.* 1225–1300), the high altar having been consecrated in 1278. The towers were first raised above the roof at the end of the 15th century and took their present form in 1779. The chapter consisted of twenty-four secular canons; it was reorganized at the Reformation (1526), and suppressed in 1832. On the site of the canons' houses stands a girls' school (opened 1853), but the fine Romanesque cloisters (12th and 13th centuries) still remain. There is a curious figure of Charlemagne in a niche on one of the towers; to him is attributed the founding or reform of the chapter. On the left bank of the Limmat stands the other great church of Zürich, the Frau Münster (or Abtei), founded for nuns in 853, by Louis the German. The high altar was consecrated in 1170; but the greater part of the buildings are of the 13th and 14th centuries.

Of the other old churches may be mentioned St. Peter's, the oldest parish church, though the present buildings date in part from the 13th century only (much altered in the early 18th century), and formerly the meeting-place of the citizens; the Dominican church or Predigerkirche (13th century), in the choir of which the cantonal library was stored after 1873; the church of the Austin friars (14th century), now used by the Old Catholics, and the Wasserkirche. The last-named church is on the site of a pagan holy place, where the patron saints of the city were martyred; after 1631 it housed the Town Library. In 1916 the various libraries were united into a central library of some 700,000 books, 12,000 mss. including letters of Zwingli, of Bullinger and his friend Lady Jane Grey, of Schiller, etc. This is near the Predigerkirche which is now the repository of the archives of Zürich. The building itself was erected from 1479 to 1484, and near it is a statue of Zwingli, erected in 1885. The existing town hall dates from 1698, while the gild houses were mostly rebuilt in the 18th century. One of the most magnificent of the newer buildings is the Swiss National Museum, which was opened in 1898, and contains a wonderful collection of Swiss antiquities of all periods and art treasures of all kinds.

The town is noted for its numerous clubs and societies, and is the intellectual capital of German-speaking Switzerland. The University of Zürich (*see* below) ordinarily has students of many nations and is housed in new buildings with several outlying institutes. It was opened in 1833, no doubt as a successor to the ancient chapter school at the Gross Münster, said to date back to Charlemagne's time, and hence called the Carolinum, which was reorganized at the Reformation and suppressed in 1832. The Federal Polytechnic school, opened in 1855, is one of the best known institutions of its type and had more than 2,000 students in 1941. Near it is the observatory (1,542 ft.). There are excellent primary and secondary schools and many institutions for special branches of education, *e.g.,* music, silk-weaving, etc. The Pestalozzium, with educational exhibits and Pestalozzi's study, occupies a new building near the Urania bridge.

The position of Zürich as a meeting-point of international trade gives it a cosmopolitan character. Cotton spinning, furniture-making, the manufacture of machinery, the electrical industry and the silk industry are leading activities. The silk-weaving industry flourished in Zürich in the 12th and 13th centuries, but disappeared about 1420; it was revived by the Protestant exiles from Locarno (1555) and by the Huguenot refugees from France (1682 and 1685). Zürich is the banking centre of Switzerland.

History.—The earliest inhabitants of the future site of Zürich were the lake dwellers. Later, the Helvetii (a Celtic tribe) had a settlement on the Lindenhof, where the Romans established a custom station. The Romans called it Turicum. The district was later occupied by the Alamanni.

The beginnings of the mediaeval town of Zürich date from the 9th and 10th centuries. In the 13th century Zürich was already an important imperial city; in the 16th century she became the centre of the Swiss Reformation and in modern times, though she lost the dominion over the country-side, she remained the capital of the canton and developed as a commercial, industrial intellectual and educational centre of the first importance.

Three stages in the constitutional development of the town may be distinguished. First comes the city's fight for freedom from foreign powers. The burghers were originally under the rule of a *Reichsvogt*, the representative of the emperor (who had a castle on the Lindenhof), but they obeyed also the orders of the abbess of the Fraumünster, a Benedictine convent (endowed in 853 by the Emperor Louis the Pious) which had acquired extensive rights and privileges over the people who had settled round about it. When the council of the abbess, which was composed of the noblemen and rich merchants of the town, became the trusted representation of the townspeople, power actually passed from the abbey to the town (13th century). The *Reichsvogtei*, which had been in the hands of the most powerful dynasty in the country, was in the same period entrusted to some nobleman of the town and was later (1400) bought off altogether from the emperor. Thus the city had acquired independence.

The second stage is characterized by the struggle for admittance of the craft guilds to a share with the patricians in the government of the town. Naturally, in the age of industrial development and of democratic tendencies in the towns, the guilds tried to secure for themselves a share in the city's councils. They found a leader in Rudolf Brun, a nobleman, who after being elected burgomaster introduced a new constitution (1336) which divided the functions of government between the patricians (the *Constafel*) and the representatives of the 13 guilds. The *Constafel* still retained a privileged position; the head of the *Constafel* was to be the burgomaster, and in the Little Council the *Constafel* members alone were invested with the functions of government.

In 1393, however, power passed from the Little Council into the hands of the Great Council (about 200 members) and the guild members got the majority on the Little Council with a title to have the burgomaster chosen out of their own ranks. From the 13th to the 15th century Zürich fought for the possession of a considerable dominion—the Zürich country district (which later became the canton). For a long time the town hesitated between a pro-Habsburg and a pro-Swiss policy. Brun had induced his followers to join in the Swiss League, which was then (1353) only beginning to develop. When, by purchase or right of succession, Zürich had become the ruler of the adjoining lake district, she came in conflict with the territorial aspirations of Schwyz. The "Old Zürich War" (1436–50) broke out between Zürich and all the other members of the Swiss League; Zürich, however, had the assistance of Austria, the old enemy of the League. The war ended with the defeat of Zürich who gave up the Austrian alliance. The authority of the Swiss League was much strengthened. In 1467 Zürich enlarged her dominion by acquiring from the Habsburgs the town of Winterthur. Zürich gained the military leadership in the League under her great burgomaster Hans Waldmann, who led the Swiss to victory in the Burgundian war at Morat (1476). He also fought with the gild masters against the *Constafel* party. A true adventurer by nature, he was a great reformer, did much to strengthen the administration of the town against the Church and the country districts, and helped to make Zürich a great commercial centre.

Another great figure, but of an entirely opposite character, was Huldreich Zwingli (*q.v.*), the leader in the Swiss Reformation. He obtained quite an exceptional influence over the decisions of the council. Zürich was later to become the capital of a reformed Swiss League and for the realization of this aim he renewed the fight against the conservative Forest districts of the Swiss League. This war ended again with defeat for Zürich and it deprived the whole Evangelical party in Switzerland for nearly two centuries of its preponderant position.

The fight of the country districts for the grant of equal political rights with the burghers of the ruling class marks the third stage in the history of Zürich. Originally the people in the country had retained a number of political privileges, which had been confirmed by the town herself and in the Reformation period were even enlarged. In the 17th and 18th centuries, however, there was a tendency to limit the privileges of burghership to the actual holders. The reserved rights of the country population were disregarded, the administration centralized, the country ruled solely by deputies from the town. The Great Council came to be mainly chosen by a small committee of members actually sitting in the Council and each gild had the right to fill by itself the seats becoming vacant by decease of its members. Trade was a privilege of the burghers alone. A country man was not allowed to have a business of his own; he could only work in the pay of a burgher as his employee. Some particular crafts were altogether reserved to the townspeople; an attempt was even made to deprive the town of Winterthur of its flourishing silk trade.

Occasional opposition from the country folk was severely punished. In 1794 some inhabitants of Stäfa (a rich village on the lake) claimed the restoration of their old privileges (Stäfner articles), but it was not until 1798, when the Helvetic Republic was founded, that political and economical liberty was extended to the country districts. In 1803 certain privileges of the town were restored by giving the town proportionally a much larger representation in the new council than the country. Under the cantonal constitution of 1814 matters became even worse, for the town with about 10,000 inhabitants had 130 representatives in the Great Council, while the country districts with about 200,000 inhabitants had only 82. Reaction lasted till 1830, when a great popular meeting at Uster proposed a radical reform to abolish inequality between town and country. The democratic reform was accepted by the majority of the voters. The following period has rightly been called the "Regeneration Period"; administration was completely reorganized, the school-system reformed and crowned by the establishment of a cantonal university. The last great change in the cantonal constitution occurred in 1867–69, when the rights of the legislative council were reduced in favour of a more truly democratic system. The cantonal Government was to be elected by the people, the power of parliament was reduced by the people's privilege of referendum (*i.e.* the right to accept or reject bills proposed by parliament) and initiative (*i.e.* the right to propose bills of its own).

A particular task fell yet on the city proper: the assimilation of the new population which—owing to the rapid development of the town—had by far outgrown the number of the old privileged class and had partly settled in the outlying districts. The town began to open her schools to the newcomers and then facilitated the entrance into burghership. The work was crowned by the incorporation into the town of 11 outlying districts in 1893. A further expansion of 1934 in which a number of other suburbs were incorporated brought the city's area to within the size of some of the biggest European cities.

(M. St.)

Zürich University (*see* UNIVERSITIES) was founded in 1833. Its buildings are nearly all new, with modern equipment, among the most outstanding being its central university library, and its clinics for diseases of the eye, ear and throat. The language of the university is German, and there are faculties of evangelical theology, law and political sciences, medicine and dentistry, veterinary medicine, science and letters. It has made important developments in bacteriology and hygiene, and in the study of living oriental languages and in the thought and history of Islam. Though during World War I and immediately afterwards its numbers fluctuated considerably, its usual attendance is about 1,600 regular students and 700 non-matriculated. In 1919 it received 1,274,052 fr. for the Julius Claus Foundation for social anthropology racial hygiene. (A. L. Wi.)

ZÜRICH, LAKE OF, a Swiss lake, extending south-east of the town of Zürich. Its basin was formed by glacial erosion and it shows interesting phases of damming by moraines. The river Linth flows into it and the Limmat out of it. Its area is about 34 sq.m., extreme length 25 m., greatest breadth 2½ m., greatest depth 469 ft., surface 1,342 ft. above sea level. The greater portion is in the canton of Zürich, but 8¾ sq.m. S.E. is in Schwyz, and 4 sq.m. N.E. in St. Gall. The great dam of masonry, carrying the railway line and motor road from Rapperswil to Pfäffikon, cuts off the extreme eastern part of the lake and is passed only by small boats; steamers do not go beyond the dam, as the part beyond is shallow. West of this dam is the island of Ufenau, where in 1523 Ulrich von Hutten took refuge and died. Zürich stands at the north end of the lake. On the west shore are Thalwil, Horgen, Wädenswil, Richterswil, Pfäffikon, and Lachen. On the opposite shore are Meilen (near which the first lake dwellings were discovered in 1853–54), Stäfa, and Rapperswil, the castle of which shelters a Polish museum. Schmerikon and Uznach are near the eastern end.

ZUTPHEN or ZUTFEN, a town in the province of Gelderland, Holland, on the right bank of the Ysel at the influx of the Berkel, and a junction station 18 mi. N.N.E. of Arnhem by rail. Pop. (1940) 21,490. In the middle ages it was the seat of a line of counts, which became extinct in the 12th century. Having been fortified, the town stood several sieges, specially during the wars of freedom waged by the Dutch, the most celebrated fight under its walls being the one in September 1586 when Sir Philip Sidney was mortally wounded. Taken by the Spaniards in 1587, Zutphen was recovered by Maurice, prince of Orange, in 1591, and except for two short periods, one in 1672 and the other during the French Revolutionary Wars, it then remained a part of the United Netherlands. German troops occupied it in World War II.

The most important building is the *Groote Kerk* of St. Walpurgis, which dates from the 12th century and contains monuments of the former counts of Zutphen, and other objects of interest. The chapter-house contains a pre-Reformation library which includes some valuable mss. and *incunabula*. There are some remains of the old town walls. The place has an active trade, especially in grain and in the timber floated down from the Black forest by the Rhine and the Ysel; the industries include tanning, weaving, and oil and paper manufactures. About 3 mi. to the north of Zutphen is the agricultural colony of Nederlandsch-Mettray, founded by a private benefactor for the education of poor friendless boys in 1851. At 3 mi. distance, in the picturesque "Achterhoek," are the mediaeval castles of Ruurloo and Vorden.

ZUTUHIL, an Indian tribe inhabiting the territory south of Lake Atitlan in Guatemala. Their tongue, one of the "metropolitan" Maya dialects, is spoken to-day in Atitlan, San Pedro la Laguna, San Lucas Tolimán, and San Antonio Suchitepéquez. They number about 14,000.

The part the Zutuhil played in the wars with the Quiché and Cakchiquel is described in the annals of those tribes, which make it clear that the Zutuhil were only slightly less powerful than these enemy neighbours, and they appear never to have been completely subdued. The Zutuhil capital was picturesquely located above Lake Atitlan. Near by stood a strongly fortified position, reduced by the Spaniards under Pedro de Alvarado in 1525 only with the greatest difficulty. To-day the Zutuhil work, often under a system of peonage, on the big coffee estates. Their costumes, of local cotton covered with embroidery, are noted for their brilliant colours.

ZWEIBRÜCKEN, a town of Germany, in the Bavarian Palatinate, on the Schwarzbach, and on the railway between Germersheim and Saarbrücken. Pop. (1939) 33,430.

Zweibrücken ("two bridges") is the Latin *Bipontinum;* it appears in early documents also as *Geminus Pons,* and was called by the French *Deux-Ponts*. The independent territory was at first a countship, half of which Count Eberhard sold in 1385 to the count palatine of the Rhine, holding the other half as his feudatory. Louis (d. 1489) founded the line of the dukes of Zweibrücken which became extinct in 1731, when the duchy passed to the Birkenfeld branch. At the peace of Lunéville Zweibrücken was ceded to France; on its reunion with Germany in 1814 the greater part of the territory was given to Bavaria, the remainder to Oldenburg and Prussia. Zweibrücken was known to scholars for its early editions of the Greek and Latin classics. Its war factories were bombed in World War II.

ZWICKAU, a town of Germany, in the *Land* of Saxony, situated on the left bank of the Zwickauer Mulde, 41 mi. S. of Leipzig and 20 mi. S.W. of Chemnitz on the main line of railway Dresden-Hof and at the junction of several other lines. Pop. (1939) 85,484.

Zwickau is of Slavonic origin, and is mentioned in 1118 as a trading place. Zwickau was an imperial possession, but was pledged to Henry the Illustrious, margrave of Meissen. It passed to the electors of Saxony, as successors of the margraves of Meissen. The discovery of silver in the Schneeberg in 1470 brought it much wealth. The Anabaptist movement of 1525 began at Zwickau under the inspiration of the "Zwickau prophets." Robert Schumann (*q.v.*) was born here.

Among the nine churches, the Gothic church of St. Mary (1451–1536 and restored 1885–91) is remarkable. Other noteworthy buildings are the town-hall of 1581, with the municipal archives, including documents dating back to the 13th century and an autograph ms. of the works of Hans Sachs, and the late Gothic *Gewandhaus* (cloth merchants' hall), built 1522–24 and now in part converted into a theatre. The manufactures of Zwickau include spinning and weaving, machinery, chemicals, porcelain, paper, glass, dyestuffs, wire goods, aluminum, lacquer, embroidery, stockings and curtains. The adjacent coalfield has only been actively worked since 1823, during which time the population has increased more than tenfold.

ZWINGLI, HULDREICH (1484–1531), Swiss reformer, was born on Jan. 1, 1484, at Wildhaus in the Toggenburg valley, St. Gall, Switzerland. He came of a free peasant stock, his father being *amtmann* of the village; his mother, Margaret Meili, was the sister of the abbot of Fischingen in Thurgau. His uncle, Bartholomew Zwingli, afterwards *dekan* or *superintendent* of Wesen, had been elected parish priest of Wildhaus. He went to school at Wesen, then at Basle, and finally at Berne, where his master, Heinrich Wölflin, inspired him with an enthusiasm for the classics. In 1500 he was sent to the university of Vienna to study philosophy. He then returned to Basle, where he graduated in the university and taught classics in the school of St. Martin's church. At twenty-two Zwingli was ordained by the bishop of Constance and elected parish priest of Glarus. The ten years which Zwingli spent at Glarus laid the foundations of his work as a reformer. He there began the study of Greek that he might "learn the teaching of Christ from the original sources," and gave some attention to Hebrew. He read also the older Church Fathers and his skill in

the classics led his friends to hail him as "the undoubted Cicero of our age." He entered into correspondence with Erasmus, and received a somewhat chilling patronage; whilst the brilliant humanist, Pico della Mirandola (1463–94), taught him to criticize Catholic doctrine. His first publications, which appeared as rhymed allegories, were political rather than religious; they were directed against the Swiss practice of hiring out mercenaries in the European wars. In 1521 he prevailed upon the authorities of the canton of Zürich to renounce the practice altogether. Especially did he oppose alliances with France; but the French party in Glarus was strong, and it retaliated so fiercely that in 1516 Zwingli was glad to accept the post of people's priest at Einsiedeln. He dated his arrival at evangelical truth from the three years (1516–19) which he spent in this place. There he studied the New Testament in the editions of Erasmus and began to found his preaching on "the Gospel," which he declared to be simple and easy to understand.

Reform Propaganda.—Zwingli began to preach "the Gospel" in 1516, but a contemporary says that he did it so cunningly (*listiglich*) that none could suspect his drift. He began his work without saying much about corruptions in the Roman Church, and it was his political denunciation of the fratricidal wars into which the pope, not less than others, was drawing his fellow-countrymen, that first led to rupture with the papal see. Three visits which he had paid to Italy as army chaplain opened his eyes to the worldly character of the papal rule, and he began to attack at Einsiedeln the superstitions which attended the great pilgrimages made to that place. Zwingli denounced the publication of plenary indulgence to all visitors to the shrine. When in August 1518 the Franciscan monk Bernardin Samson appeared in Switzerland with a commission to sell indulgences, Zwingli persuaded the council to forbid his entrance into Zürich.

Zwingli now became (1518) people's priest at the Great Minster of Zürich. In the beginning of 1519 he began a series of discourses on St. Matthew's Gospel, the Acts of the Apostles, and the Pauline epistles; and with these it may be said that the Reformation was fairly begun in Zürich. His correspondence of this year shows him jealous of the growing influence of Luther. He claimed to have discovered the Gospel before ever Luther was heard of in Switzerland. Towards the end of September he fell ill with the plague; his illness sobered his spirit and brought into his message a deeper note than that merely moral and common-sense one with which, as a polite humanist, he had hitherto been content. He began to preach against fasting, saint worship and the celibacy of priests. People were found eating flesh in Lent, and the bishop of Constance accused them before the council of Zürich. Zwingli was heard in their defence and the accusation was abandoned. His first Reformation tract, April 1522, dealt with this subject: *Von Erkiesen und Fryheit der Spysen.* The matter of the celibacy of the clergy was more serious. Zwingli had joined in an address to the bishop of Constance calling on him no longer to endure the scandal of harlotry, but to allow the priests to marry wives, or, at least, to wink at their marriages. Pope Adrian VI. interfered and asked the Zürichers to abandon Zwingli, but the reformer persuaded the council to allow a public disputation (1523), when he produced sixty-seven theses and vindicated his position so strongly that the council decided to uphold their preacher and to separate the canton from the bishopric of Constance. Thus legal sanction was given in Zürich to the Reformation. In 1522 Zwingli produced his first considerable writing, the *Architeles,* "the beginning and the end," in which he sought by a single blow to win his spiritual freedom from the control of the bishops, and in a sermon of that year he contended that only the Holy Spirit is requisite to make the Word intelligible, and that there is no need of Church, council, or pope in the matter.

Victory of Reform.—There was a strong opposition to the Reformation, especially in the five Forest Cantons: Lucerne, Zug, Schwyz, Uri and Unterwalden; and the Zürichers felt it necessary to form a league in its defence. They were especially anxious to gain Berne, and Zwingli challenged the Romanists to a public disputation in that city. The pleadings began on Jan. 2, 1523 and lasted nineteen days. Zwingli and his companions undertook to defend the following propositions:—

(1) That the Holy Christian Church, of which Christ is the only Head, is born of the Word of God, abides therein, and does not listen to the voice of a stranger; (2) that this Church imposes no laws on the conscience of people without the sanction of the Word of God, and that the laws of the Church are binding only in so far as they agree with the Word; (3) that Christ alone is our righteousness and our salvation, and that to trust to any other merit or satisfaction is to deny Him; (4) that it cannot be proved from the Holy Scripture that the body and blood of Christ are corporeally present in the bread and in the wine of the Lord's Supper; (5) that the mass, in which Christ is offered to God the Father for the sins of the living and of the dead, is contrary to Scripture and a gross affront to the sacrifice and death of the Saviour; (6) that we should not pray to dead mediators and intercessors, but to Jesus Christ alone; (7) that there is no trace of purgatory in Scripture; (8) that to set up pictures and to adore them is also contrary to Scripture, and that images and pictures ought to be destroyed where there is danger of giving them adoration; (9) that marriage is lawful to all, to the clergy as well as to the laity; (10) that shameful living is more disgraceful among the clergy than among the laity.

The result of the discussion was that Berne was won over to the side of the reformer. He had maintained that the congregation, and not the hierarchy, was the representative of the Church; and he sought to reorganize the Swiss constitution on the principles of representative democracy so as to reduce the disproportionate voting power of the Forest Cantons.

On April 2, 1524 the marriage of Zwingli with Anna Reinhard was publicly celebrated in the cathedral. In August of that year Zwingli printed a pamphlet in which he set forth his views of the Eucharist. They proved the occasion of a conflict with Luther which was never settled, but more attention was attracted by Zwingli's denunciation of the worship of images and of the Roman doctrine of the mass. These points were discussed at a fresh congress where about 900 persons were present, and where Vadian (Joachim von Watt, the reformer of St. Gall) presided. It was decided that images are forbidden by Scripture and that the mass is not a sacrifice. Images were removed from the churches, and many ceremonies and festivals were abolished. Zürich was threatened with exclusion from the union, and she began to make preparations for war.

Divergence from Luther.—At this point the controversy between Luther and Zwingli became more serious. In March 1525 Zwingli brought out his *Commentary on the True and False Religion.* He declined to accept Luther's teaching that Christ's words of institution required the belief that the real flesh and blood of Christ co-exist in and with the natural elements. He declared that Luther was in a fog, and that Christ had proclaimed that by faith alone could His presence be received in a feast which He designed to be commemorative and symbolical. The landgrave of Hesse brought the two Reformers together in vain at Marburg in October 1529, and the whole Protestant movement broke into two camps. At home the long-felt strain between opposing cantons led at last to civil war. In February 1531 Zwingli himself urged the Evangelical Swiss to attack the Five Cantons, and on Oct. 10 there was fought at Kappel a battle, disastrous to the Protestant cause and fatal to its leader. Zwingli, who as chaplain was carrying the banner, was struck to the ground, and was later despatched in cold blood. His corpse was quartered by the public hangman, and burnt with dung by the soldiers. A great boulder, roughly squared, standing a little way off the road, marks the place where Zwingli fell. It is inscribed, " 'They may kill the body but not the soul': so spoke on this spot Ulrich Zwingli, who for truth and the freedom of the Christian Church died a hero's death, Oct. 11, 1531."

Zwingli's theological views are expressed succinctly in the sixty-seven theses published at Zürich in 1523, and at greater length in the *First Helvetic Confession,* compiled in 1536 by a number of his disciples[1]. They contain the elements of Reformed as distinguished from Lutheran doctrine. As opposed to Luther, Zwingli insisted more firmly on the supreme authority of Scripture, and broke more thoroughly and radically with the mediaeval Church. Luther was content with changes in one or two fundamental doctrines; Zwingli aimed at a reformation of government

[1] P. Schaff, *Creeds of the Evangelical Protestant Churches,* p. 211.

and discipline as well as of theology. Zwingli held that there should be no government in the Church separate from the civil government which ruled the commonwealth. All rules and regulations about the public worship, doctrines and discipline of the Church were made in Zwingli's time, and with his consent, by the council of Zürich, the supreme civil authority in the State. This was the ground of his quarrel with the Swiss Anabaptists, for the main idea in the minds of these greatly maligned men was the modern thought of a free Church in a free State. Like all the Reformers, he was strictly Augustinian in theology, but he dwelt chiefly on the positive side of predestination—the election to salvation—and he insisted upon the salvation of infants and of the pious heathen. His most distinctive doctrine is perhaps his theory of the sacrament, which involved him and his followers in a long and, on Luther's part, an acrimonious dispute. He held that the Eucharist was not the *repetition* of the sacrifice of Christ, but the faithful *remembrance* that that sacrifice had been made once for all. His theological opinions were set aside in Switzerland for the somewhat profounder views of Calvin. The publication of the Zürich Consensus (*Consensus Tigurinus*) in 1549 marks the adherence of the Swiss to Calvinist theology.

Zwingli's most important writings are—*Von Erkiesen und Fryheit der Spysen* (April 1522); *De Canone Missae Epichiresis* (September 1523); *Commentarius de Vera et Falsa Religione* (1525); *Vom Touf, vom Wiedertouf, und vom Kindertouf* (1525); *Ein klare Unterrichtung vom Nachtmal Christi* (1526); *De Providentia Dei* (1530); and *Christianae Fidei Expositio* (1531). For a full bibliography *see* G. Finsler, *Zwingli-Bibliographie* (Zürich, 1897).

Works.—Collected editions, 4 vols. (Zürich, 1545, 1581); by M. Schuler and Joh. Schulthess, 8 vols. (Zürich, 1828–42, with "supplementorum fasciculus," 1861); by E. Egli and G. Finsler in "Corpus Reformatorum" (Berlin, 1905 *sqq.*).

Lives.—O. Myconius (1532); H. Bullinger's *Reformationsgeschichte* (ed. Hottinger and Voegli, 1838); J. M. Schuler (1818); R. Christoffel (1857, Eng. tr. by J. Cochran, Edinburgh, 1858); J. C. Moriköfer, 2 vols. (Leipzig, 1867–69); R. Stähelin, 2 vols. (Basle, 1895–97); S. M. Jackson in *Heroes of the Reformation* (New York and London, 1901); Prof. Egli's articles in Hauck-Herzog's *Realencyklopädie für prot. Theologie u. Kirche,* and *Zwingliana,* published at Zürich.

S. M. Jackson's book gives a chapter on Zwingli's Theology by Prof. F. H. Foster, and also full details of further information on the subject, together with a list of modern English translations of Zwingli's works.

ZWITTERION. In chemistry, a molecule containing both acidic and basic groups may be expected to neutralize itself with the production of an internal salt or, as it is commonly called, a zwitterion (from the German *Zwitter,* hybrid or hermaphrodite, plus *ion*). Thus glycine (*q.v.*) may be expected not to have the amino-acid structure I, with the acidic carboxyl group COOH and the basic amino group NH_2, but rather the zwitterionic structure II. In general amino acids

$$\underset{\text{I}}{H_2N.CH_2.COOH} \qquad \underset{\text{II}}{H_3\overset{+}{N}.CH_2.COO^-}$$

and proteins (*q.v.*) at their isoelectric points, as well as betaines (*q.v.*), exist largely if not entirely in the form of zwitterions.

ZWOLLE, the capital of the province of Overysel, Holland, on the Zwarte Water, and a junction station 24½ mi. N.E. of Harderwyk. Pop. (1939), 42,136. It is the centre of the whole northern and eastern canal systems, and by means of the short canal, the Willemsvaart, which joins the Zwarte Water and the Ysel, has regular steamboat communication with Kampen and Amsterdam.

Three miles from Zwolle on the Agnietenberg, once stood the Augustinian convent in which Thomas à Kempis spent the greatest part of his life. Zwolle has a considerable trade by river, a large fish market and the most important cattle market in Holland after Rotterdam.

ZYGADENUS, a genus of plants of the lily family (Liliaceae, *q.v.*), containing about 12 species, all North American except one found in Siberia. They are smooth perennial herbs, springing mostly from coated bulbs, with erect stems, usually ½ ft. to 4 ft. high, very narrow leaves and conspicuous flowers in terminal clusters. Some 10 species occur in the United States and Canada. The smooth zygadene (*Z. elegans*), with greenish flowers, is found from New Brunswick to Alaska and southward to New Mexico. The poisonous zygadene or death camas (*Z. venenosus*) with yellow flowers, occurs in the northwestern and Pacific states.

ZYGOPHYLLACEAE, a family of dicotyledonous plants, 26 genera and about 225 species being recognized. The various genera and species are characteristic of the drier parts of both temperate and tropical regions in both hemispheres, and include herbs, shrubs and trees. Large genera are *Fagonia,* in the Mediterranean region with about 40 species, southern North America and Chile, and *Zygophyllum* with 80 species in the drier parts of Asia, Africa and Australia. *Guiacum* of tropical America produces the very hard wood known as lignum vitae, the resin of which is also used in the practice of medicine. The South American species of *Bulnesia* also yield a very hard wood. For a consideration of the genera *see* A. Engler, "Zygophyllaceae," in Engler and Prantl, *Die Natürlichen Pflanzenfamilien,* ed. 2, vol. 19a, pp. 144–184, fig. 70–87 (1931). (E. D. Mᴇ.)

ZYGOTE, the biological term for the fertilized egg or ovum. (*See* Fertilization; Embryology.)
