A return of bad harvests in 1879, however, brought new fears of famine, and the Land league was founded by Michael Davitt. The son of an evicted tenant, he had become a Fenian as a young labourer in England and had spent years in prison there. His Land league soon gathered wide support for its program of fixity of tenure, fair rents and free sale. **A** formidable agrarian agitation developed when Davitt was joined by Charles Stewart Parnell, a young landowner and member of parliament in the Home Rule party, which soon elected him as its leader in place of Butt. Parnell and Joseph Bigger had adopted a new policy of persistent obstruction at Westminster to compel attention to Irish needs. Their skilful and determined tactics brought parliamentary business to a standstill and galvanized the new popular agitation in Ireland. Gladstone was forced to introduce his Land act of 1881, which made large concessions; and its new rent tribunals soon insisted upon wholesale reductions of rent.

The Fenian revolutionary movement in the United States and in England agreed to support Parnell's dynamic leadership of the Home Rule party, which now aimed at forcing either Liberals or Tories to concede national government. In 1886 Gladstone introduced a home rule bill, but it was defeated and the Liberal party was split. Parnell, however, had created such a formidable movement, with widespread support from the United States and in England, that he seemed likely to succeed, until he was suddenly involved in divorce proceedings brought by his colleague Captain William O'Shea. Gladstone then announced that his nonconformist followers would not co-operate further if Parnell retained the leadership, and in Ireland the Catholic Church also insisted on his retirement. But Parnell refused to resign, and his party was bitterly divided when he died in Oct. 1891, fighting vehemently as leader of the minority.

The Nationalist Revival. — Gladstone introduced his second home rule bill in 1893; the house of commons passed it by 301 to 267, but the lords rejected it by 419 to 41. It became evident that the lords would always resist home rule, and nationalist hopes were further discouraged by the party split. Ireland's population had declined to 6,700,000 by 1891, and emigration continued to reduce it. But a new phase of nationalist revival now began, with a cultural and economic program. There was a revival of the Irish language, led by Douglas Hyde, and the co-operative movement in agriculture, fostered by Sir Horace Plunkett, coincided with a movement for Irish industrial develop-

ment and with a general policy of creating an Irish Ireland. Anti-English feeling and a concentration upon internal progress, without regard to Westminster, were fostered by the centenary of the 1798 rebellion and by the pro-Boer demonstrations during the South African War. A new party called Sinn Fein (Ourselves Alone) was founded in 1900 by Arthur Griffith, who ridiculed dependence upon the British parliament and demanded that the Irish members cease to attend it and form a national council in Ireland.

Conservative Reforms.—Around the close of the century Arthur Balfour had initiated a new Tory policy, designed to "kill home rule by kindness," by introducing constructive reforms in Ireland. The Congested Districts board carried out a general improvement of the uneconomic smallholdings in the west. A new department of agriculture and technical instruction gave much practical aid under Plunkett's direction. The Local Government act of 1898 abolished the grand juries and entrusted local affairs to elected councils. In 1903 George Wyndham, as Irish secretary, was enabled to carry the Land Purchase act. It offered generous inducements to the landlords to sell their estates to the Land commission, which was to collect terminable land annuities instead of rent. The response was immediate and overwhelming, and the Irish land question was settled at last by transferring ownership of the land to the occupying tenants on easy terms.

The Third Home Rule Bill.—In 1900 the two rival wings of the Nationalist party were at last reunited by consent, when John Dillon as leader of the larger section agreed to serve under the Parnellite John Redmond. But hopes of carrying home rule were still distant while the lords' veto remained, though the party continued to press for an Irish parliament, with increasing support in England and the dominions. The Liberals' triumph in 1906 revived hope, but it was soon disappointed by the meagre offer of an Irish councils bill, which was at once rejected. Other reforms, however, including the National University act of 1907, were obtained; and in 1909 Redmond seized his chance of demanding a home rule bill when Lloyd George's radical budget provoked a collision with the house of lords. H. H. Asquith promised home rule if the Nationalists would support his campaign against the lords, and iti 1910 the Parliament act appeared to leave the way open for the restoration of an Irish parliament. Popular enthusiasm had revived after years of despondency; a new generation, free from the inhibitions of old grievances and already accustomed to the responsibilities of local government, looked forward to a new era of opportunity in public service and in scope for employment at home. Nearly all the most important positions in the civil service and industry and commerce were still largely reserved for Englishmen or for members of the old Protestant ascendancy. Even in the professions advancement had usually been the reward of service to the Unionist party and to Dublin castle.

Redmond, however, had unexpectedly achieved the balance of power between the rival parties at Westminster which had been Parnell's ambition. The two elections of 1910 had each returned a Liberal ministry dependent upon Irish Nationalist support. But they had abolished the lords' veto, and home rule had become part of the Liberal and Labour programs in England. Under the Parliament act, the Home Rule bill of 1912 was apparently ensured of enactment after two years' delay if it passed the commons a second time during the same parliament.

Opposition in Ulster.—The Unionist party adopted unexpected methods to defeat its progress. Bonar Law replaced Balfour as its leader in 1911, and he gave full support to the threats of defying parliament by armed resistance in Ulster. Sir Edward Carson, as leader of the Ulster Unionists, announced that a provisional government would be formed there to defeat home rule. Both Carson and J. H. Campbell represented Dublin university at Westminster, but every other Irish constituency outside Ulster had returned a Nationalist, almost without an exception, for many years. Even in Ulster, 16 of the 33 members were Nationalists, and a by-election for Derry city in 1912 was won by a home ruler, so that the province had a majority against the union. The Ulster Unionists for some time proclaimed their intention of defeating home rule for all Ireland by defying its operation; but they gradually fell back on a demand for exclusion of all Ulster from its scope. Redmond's claim that there was "no Ulster question" implied that even among the Ulster members there was now a majority for home rule. But his claim hardened the Protestant and Unionist resistance in the heavily populated counties around Belfast. Down, Antrim, Armagh and Derry all contained large Unionist majorities and were predominantly Protestant or Presbyterian. Donegal, Cavan and Monaghan had strong home rule majorities, and Tyrone and Fermanagh each had a small total majority for home rule.

No serious consideration had been given to separate treatment for Ulster, but the Unionists now claimed exclusion for the whole province. They organized the Ulster volunteer force, for which the veteran Field Marshal Lord Roberts chose Gen. George Richardson as commander in chief. Arms for the Ulster volunteers were soon imported in defiance of the law, while Bonar Law and most of the leading English Unionists gave full encouragement to Carson's whirlwind campaign inciting to disorder. At Westminster Redmond had apparently won the political game by the accepted rules, but the Unionists were openly organizing defiance of parliament in Ulster. They were boasting of active sympathy among most of the serving officers in the army. Their boasts became formidable when all officers in the cavalry brigade at the Curragh, led by Gen. Sir Hubert Gough, suddenly announced in March 1914 that they would resign if called upon to move into Ulster. Mobilization orders had not even been issued, but there had been raids on war office depots in Ulster and reinforcements were needed, before Carson achieved a spectacular success in landing a large cargo of arms from Germany at Larne on April 24, 1914. The Curragh mutiny was followed by the resignation of Col. J. E. B. Seely as war minister, and Asquith personally assumed control.

The Irish Volunteers.—Before these sensational incidents, the Ulster volunteer movement had provoked inevitable countermeasures among the Nationalists. Faith in the efficacy of parliament had been rudely shaken by Carson's successful defiance. The younger Nationalists, especially in Ulster, considered Carson's aggressive realism more effective than Redmond's patient negotiations. In Nov. 1913 the Irish volunteers were launched in Dublin, to counteract the Ulster volunteers. They spread swiftly, especially in Ulster, and still more after the Curragh episode in March. Redmond was convinced that the Home Rule bill would become law that autumn and that only a European war could delay its operation. But the threats of civil war in Ulster were now reinforced by large cargoes of imported rifles, and the British army's readiness to enforce order in Ulster was seriously in doubt. The Irish volunteers were gaining such support among the younger Nationalists that Redmond found it necessary to assume control of an unconstitutional movement which he instinctively distrusted. In May 1914 the Irish volunteers agreed to expand their former provisional committee, which consisted mostly of unknown men, into a larger directorate composed chiefly of Redmond's supporters.

By the early summer Ireland was thus confronted with the prospect of civil war, while the rival volunteer forces collected arms wherever they could. The outlook was so menacing that in July the king convened a conference of leaders on both sides at Buckingham palace to find an agreed solution. Carson's earlier efforts to prevent an Irish parliament were now reduced to demanding exclusion of Ulster, and the issue had been narrowed to a definition of the area for exclusion. Redmond had agreed reluctantly to a strictly temporary exclusion of those counties which had Unionist majorities. He would not concede Tyrone or Fermanagh or Derry city, and he insisted on exclusion only for a short period. After several days the conference reached a deadlock and reported its failure to agree.

Meanwhile a small cargo of arms for the Irish volunteers had been bought in Belgium and was brought secretly into Dublin bay at Howth on July 26. A parade of Irish volunteers unloaded the cargo but was challenged by military and police on returning to Dublin. An armed collision on the Dublin quays resulted in many civilian casualties. The Ulster volunteers had run their cargo at Larne with impunity, and this discrimination against the National-

ists aroused fierce popular resentment. Redmond obtained the adjournment of the house of commons in protest, but events swiftly eclipsed the crisis in Ireland when the Germans invaded Belgium on Aug. 3.

World War I.—When Sir Edward Grey announced the declaration of war, Redmond intervened to promise full Irish sympathy. He made an immediate offer that the Irish volunteers of both forces (renamed the national volunteers) would defend the coasts of Ireland and that all troops could be withdrawn. Soon afterward he undertook an open campaign to encourage recruiting for the Irish regiments in the British army.

Great numbers of young Irishmen enlisted rapidly, and three new Irish divisions were recruited, one of them in Ulster. But Redmond's assurances that the Irish recruits would serve together soon led to bitter disappointment. Lord Kitchener, who had become war minister, had a deep distrust for Irish regiments, and he refused even a distinctive flag to the southern Irish divisions, though the Ulster division was allowed even to elect its own officers. Redmond's protests were unavailing, and the first enthusiasm for war service was soon deadened by official discouragement. But the flow of recruits continued steadily until it was computed that more than 200,000 had gone from Ireland without any measure of conscription.

Kitchener's attitude had also stimulated the more extreme Nationalist wing of the Irish volunteers, who had protested against Redmond's recruiting campaign, and they seceded as a separate force. Military repression, by censorship and by prosecutions for alleged seditious behaviour, soon increased disaffection. The original organizers of the Irish volunteers had consisted largely of recent recruits to the old Fenian Irish Republican brotherhood (I.R.B.), which had been lately revived in the United States. The Irish Republican brotherhood had discerned new prospects of anti-English intervention in case of war in Europe, and Carson's successful defiance of parliament had stimulated anti-English feeling in the United States. The supreme council of the Irish Republican brotherhood had decided, immediately after war broke out, that the long-delayed opportunity for an armed rising in Ireland must now be seized. Steps were taken to solicit help from Germany, and arrangements were made for regular secret instructions to Ireland from the United States. Membership of the secret Irish Republican brotherhood was very restricted, and its influence was not recognized until long afterward. Before the end of 1914 full plans had already been made for the revolutionary outbreak which took the country by surprise on Easter Monday, 1916.

Redmond's national volunteers were then almost moribund, because the more active members had either gone to war service or seceded. The republican Irish volunteers, more active though less numerous, had been drilling intensively with a view to serious action. They were ostensibly led by Eoin (John) MacNeill, though the I.R.B., which had planned an insurrection, kept him in ignorance. The I.R.B. had been in touch with Sir Roger Casement during his futile mission to Germany and knew that he had obtained only a small cargo of obsolete arms. When Casement was arrested in County Kerry after landing from a German submarine on April 21, 1916, and the German arms ship was sunk at sea, they had planned to rise on Easter Sunday, April 23. But MacNeill forestalled them by cancelling all mobilization orders, and only about 2,000 out of the small total force available were actually engaged on Easter Monday, when the general post office and other parts of Dublin were suddenly seized. For a week Dublin was paralyzed by street fighting until bombardment or fires compelled Padraic Pearse and his colleagues to surrender.

Asquith went at once to Ireland for a short visit, and announced openly that the former system of government there had completely broken down and a new departure was necessary. Lloyd George was appointed to attempt a final settlement by negotiating with both Irish parties. Each interpreted his offer differently and agreed to temporary concessions which were repudiated when the truth became clear. Redmond had persuaded the Ulster Nationalists to accept exclusion for six counties for six years only, while Carson had surrendered his claim to the three western counties of Ulster on condition that the rest got permanent exclusion. Bitter feeling had been aroused by the prolonged succession of executions and the deportation of a great number of political suspects. Redmond had vainly insisted that only a few exemplary sentences should be imposed, for what he described as an un-Irish conspiracy, inspired and financed by Germany. Lloyd George's part in the negotiations only strengthened the growing sense of betrayal, while the Home Rule act was still in abeyance. Sinn Fein candidates were now put forward at by-elections and received overwhelming support. Popular sympathy with Sinn Fein was immensely increased by Lloyd George's decision to apply conscription to Ireland early in 1918. A general surge of protest was supported by a resolution from the Irish bishops at Maynooth, who denounced conscription in Ireland as being morally unjust. When this protest prevailed, Sinn Fein gathered momentum everywhere. At the elections in Dec. 1918 it captured almost every seat which had formerly been held by Redmond's party.

The Growth of Republicanism.—Irish influence in the United States had grown steadily since the great famine, and bitter memories still inspired anti-English sentiment even during the war. The Nationalist revival in Ireland was being harshly repressed, and, though the Home Rule bill had been enacted late in 1914, a suspensory act delayed its operatian till the war ended. In a fast-changing world, Asquith's act seemed utterly inadequate. Sinn Fein was demanding an independent republic, claiming the right of national self-determination which Pres. Woodrow Wilson asserted to be the Allied war aim. Increasing pressure from the United States compelled Lloyd George to make new efforts; but the Irish convention which he appointed in 1917 to frame an Irish constitution by consent contained no representation of Sinn Fein. Many of the new members elected at the end of 1918 were then in prison for political agitation, and the Irish-Americans soon organized support for Ireland's representation at the peace conference at Versailles.

Agitation in Ireland intensified, and the Irish volunteers began to conduct guerrilla war against the military and armed police. As the Irish Republican army (I.R.A.) they soon engaged in widespread ambushes and attacks on barracks and convoys, and the government retaliated with ruthless reprisals. A large proportion of the Irish police resigned, and they were replaced by recruits from England, who became known as the Black and Tans, from their temporary uniforms. A new force of auxiliary police, recruited wholly from demobilized officers who lacked other employment, was organized under Gen. Hugh Tudor. They undertook a systematic campaign of reprisals, which culminated in setting fire to a large part of Cork city, after similar outbursts in Balbriggan and other towns.

This open competition in violence soon brought deep discredit upon British rule, and a wave of protest arose in England, as well as in the United States and the dominions. The Times of London joined vigorously in denouncing the excesses of the crown forces and put forward a constructive solution in proposing dominion status for a new Irish parliament. Lloyd George made yet another attempt by carrying the Government of Ireland act of 1920, which was to establish two Irish parliaments, with equal though very limited powers, one for southern Ireland and one for the six counties of northern Ireland. There was to be a joint council representing both Irish governments, which was to propose future extensions of independent authority when opportunity arose. But Sinn Fein refused to bring the southern parliament into operation, though it contested the elections and won 73 of the 102 Irish constituencies, including every seat outside Ulster except the four allotted to Dublin university. The Northern Ireland parliament was brought into being, though the Ulster Unionists protested that they preferred to remain within the union. King George V went to Belfast and formally opened the new parliament on June 22, 1921. He had been deeply concerned over the chaos in Ireland, and his speech contained a deliberate appeal for reconciliation. Gen. Jan C. Smuts and other dominion statesmen had been urging a settlement on the lines of offering dominion status and had gained the king's support. Within a week Lloyd George offered a truce to Eamon de Valera as the Sinn Fein leader and invited negotiations which were soon opened and resulted in the Anglo-Irish

treaty of Dec. 1921. For the subsequent history of Ireland see IRELAND, NORTHERN and IRELAND, REPUBLIC OF. (D. G.)

POPULATION

The population statistics for Ireland show some interesting and unusual features. Its population decreased by no less than half in the 100 years after the middle of the 19th century, in spite of a very high birth rate (about 20 per 1,000). Emigration became apparently a permanent and accepted characteristic of Irish life. It is normal for some of the young persons of both sexes to leave home permanently. Even in the most remote districts some members of nearly every family are settled in an overseas country. For many years most of them found homes in the United States and the British dominions overseas. When these lands limited immigration the numbers leaving Ireland quickly fell, and the main stream was directed toward Britain. During World Wars I and II and after World War II, the Republic of Ireland especially formed something of a reservoir of labour to be drawn upon by Britain when faced with a shortage of labour. The emigrants are drawn from every social grade. A curious feature is that, though most of them come naturally from rural environments, they become mainly town dwellers, largely employed on unskilled or semiskilled work in factory occupations. There is also of course the usual drain from the country toward the larger cities, notably to Dublin and Belfast, where many become, at least for a time, slum dwellers.

The distribution of the people over the land also shows some unusual features, perhaps more akin to those found in France than in other western countries. It is most dense where farming conditions are hardest; that is, along the Atlantic coasts. The general picture is of a widespread scattering of people on isolated farms with market centres (often quite small but all dignified with the name of town) at fairly regular intervals. The distance between these towns is probably determined by the length of the journey which can be undertaken by driven cattle and the time taken to return after their sale. Wide spaces without any population at all are found in the mountain areas, and there are numerous smaller unpopulated patches on the bog country of the lowlands.

The traveller in the coastal districts of the west is likely to be surprised by the unending series of small farmhouses along the roads. The associated farms reach back but a little way, however, to the mountain or bog which forms the limit to the occupied land. Many of them are of less than ten acres, and since each is occupied by a household of perhaps five persons on the average, the density on the useful land is evidently very high. These were the districts whose improvement was entrusted to the Congested Districts board in 1891. The density of rural population was as high as 400 per square mile in some of these areas. It is generally more than 100 in the country north of a line from Dundalk to Galway bay and in the southwest, and less than 100 in the south and east. In the big-farm country it falls to less than 30.

The census definition of a village in the republic is "a cluster of 20 houses or more." but in Northern Ireland the limit is raised to 50 houses. Yet even such small groups are few in number. Farmhouses and labourers' cottages are not usually grouped around a church, a few shops, an inn or two and a post office as in Great Britain. They generally occur in any sort of order along the highway or with each farm at the end of its own lane. Towns on the other hand may have as few as 200 people. Only ten have populations exceeding 20,000. No less than one-third the total population of Northern Ireland lives in Belfast, one-sixth that of the Republic of Ireland in Dublin. Nevertheless the tiny country towns play an essential part in the life of the country. They carry on the commercial life of the areas surrounding them. Most of them have monthly fairs; a few have weekly markets. There the farmer sells his young stock, eggs and poultry and some of his crops, or buys stock for fattening. There too he banks his savings and consults his solicitor or doctor. Their shops cater for the needs of both home and farm, and the inn provides for travellers.

Most of them have motor services for both goods and passengers, and the larger places have rail services too. The populations of such places are remarkably stable, nicely adjusted to the business of the areas they serve. Where some industry has been established they may rise to between 5.000 and 10,000, but there are still only about a score of this size in the whole country.

The church plays such an important part in the social and educational life of the country that religious adherence is recorded in the census returns. These show that the Republic of Ireland is predominantly Roman Catholic (2,786,033 as against 169,074 of other denominations in 1946), almost exclusively so over a quarter of its area. In Northern Ireland the Catholic element is in a minority (471,460 as against 899.461 in 1951), but the two groups are mixed throughout, with no regions exclusively of either kind.

ECONOMICS

Agriculture. — Ireland's main resource is its land. Two-fifths of its people look to farming for a livelihood, as against one-third depending on trade and manufactures. Good agricultural prices, primarily good prices in English markets, mean prosperity for the Irish people. Throughout its history Ireland has been a land of peasants, of people working the land mainly for their own sustenance and that of their near neighbours. The land hunger, typical of peasant communities everywhere, has been a constant factor in its social and political life. The tendency to invest surplus capital in land purchase is still strong. From mid-19th century, government action brought about the breakup of the old semifeudal estates so that the land became to an increasing degree the property of those who work it. Many of the old farm holdings, much too small to maintain the households living upon them and often consisting of scattered plots hopelessly uneconomic as working units, were combined to form more compact and larger farms. The governments of both the Republic of Ireland and Northern Ireland still maintain a lively interest in the welfare of their rural populations.

It is customary in Ireland to speak of holdings of less than 30 ac. as small farms, of 30–100 ac. as medium and of more than 100 ac. as large farms. These very descriptions in themselves suggest the small scale on which Irish farming is carried on. About 60% of all the farms fall into the first group, and together these cover nearly a quarter of the improved land. The large holdings occupy one-third the farmed acreage. Unimproved lands, in part used as rough pastures, include the mountains of the northwest, west and southwest, of Mourne and Wicklow, much of the bog country and the barren limestone plateaus of Clare. Bogs occur on all the uplands and over much of the central lowlands, more especially in the west. According to T. W. Freeman they cover probably not less than one-fifth of the country and form an important element in the rural economy. For centuries they have been the main source of fuel, providing in later years about 4,000,000 tons of peat annually. For the farmer they provide rough grazing for both sheep and cattle and bedding for stock under shelter. Sometimes the peat-cleared bog lands provide additional cultivable land, but often it is wet, infertile clay.

The small farm units are found in all parts of the country but are dominant in the north and west, particularly in east Connaught and in Armagh, Monaghan and Down. Those of the northern group are intensively worked, with half the land under crops. Flax growing and its first preparation for the mill is an important element in the farming economy and, combined with milk and egg production, provides a fair standard of living for the occupying household. The western farms support a much lower standard. Some of them, particularly those near the coast, provide only a precarious existence. Oats and potatoes, meadow and pasture, divide the acreage. Livestock include one or two cows and sheep, a few pigs and a fair number of poultry. It is usually necessary for some member or members of the household to become seasonal migrants, many going harvesting on the Scottish potato lands. On the edge of the lowlands conditions are a little better. Young cattle and butter are the main farm products, but home industry for the women and seasonal migration by the younger men are still necessary.

The medium-sized farm is more characteristic of the central lowlands of the south, though it frequently has as neighbour at least one farm of the higher category. A farm of this middle class is usually a family farm; that is, worked by members of one household. Besides fattening beef cattle, it supplies milk to the local creamery and grows a variety of crops — wheat for sale or barley for the local brewery where conditions permit, and such crops as oats, potatoes and turnips for feeding the stock. If it is within reach of one of the four sugar refineries, sugar beets may be included. In Northern Ireland flax will probably also appear. The variety of produce enables the owner to switch the emphasis from one product to another as the state of the markets suggests. Other variations are dictated by local facilities, as in the case of sugar beets or of fresh milk production near the larger town centres. The large farms are more specialized in their production. Notable types are those producing fat cattle for slaughter or export to Britain, dairy farms, horse breeding and training establishments and sheep farms on the borders of the uplands. The first of these is particularly important in Meath, Westmeath and Kildare, where there is a great concentration of the bigger farms, obviously related to the export trade of Dublin.

The great famine of 1846 shook the faith of the Irish fanner in arable farming, and thereafter pastoral farming was the principal type followed. During World War II a change took place, probably only temporary however. Much grassland was plowed up, partly in an attempt to compensste for the forced reduction of imported foodstuffs. The difficulty of procuring foreign feeding grain (mainly maize) and concentrates for stock fattening or dairying gave an additional impetus in the same direction by causing a reduction in the number of animals raised. Wheat production was increased, but the number of pigs fell to half the prewar figure. The trend was later reversed but without the 1939 position being quite recovered. Both climate and soil suit grass production and this, with the long period during which outdoor feeding is possible, obviously encourages dependence on grass feeding. Advice to increase the production of winter fodder in order to lengthen the period of butter manufacture seems to be oftener given than taken. More than three-quarters of the farm land remains untilled. Market gardening and fruit growing, for both of which conditions appear to be favourable, are certainly neglected.

The beef cattle trade has a characteristic organization. The small farms produce a surplus of calves which are sold in the western fairs. These are reared for a time on the medium-sized farms, sometimes on two or three in succession, before being passed on to the specialized big farms for finishing. At each sale the beasts move toward the ports — Dublin, Belfast or Londonderry. Dairying is chiefly developed in two areas, a northern belt through Leitrim and Fermanagh and a southern one from the Barrow valley to the Shannon estuary and Bantry. Its main product is butter, the creameries producing a standardized product on the Danish model. In the Republic of Ireland alone there were 4,504,026 cattle in 1954. The number of pigs in that year (958,321) was nearly double that in 1951. They are raised on all the small farms, mainly for home consumption, and in the creamery districts, where the waste milk is fed to them, to supply the bacon factories. In 1954, 3,112,842 sheep were raised, chiefly on the eastern uplands and the dry limestone areas of eastern Connaught.

Industry and Trade. — The character of Irish industry has been largely determined by two factors: (1) the strong tradition of self-sufficiency natural to the remote farm; (2) the absence of resources other than those derived from farming. In the 1950s they still affected both the nature and the distribution of manufactures in Ireland. The agricultural basis is evident in the great number of establishments producing butter and bacon, the breweries and distilleries, the newer meat packing and dried milk factories, the tanneries, the mills handling grain, flax and wool. The farm and its occupants still form the main market for the produce. Thus workshops and factories of small size are found in all the country towns. Lack of capital and narrow markets limit the size of these undertakings and check specialization. The industrial town or large village dependent on a single product, so common in

England, is virtually unknown in Ireland. The abundance of labour throughout the land and the lack of coal fields also remove some of the usual incentives to localize particular industries. It appears only in such simple forms as the preponderance of creameries and bacon factories in the dairying areas and of brewing and distilling near the barley-growing districts. Government action, too, encouraged both the scattering of industry and variety in its forms, though for different reasons in Northern Ireland and in the republic. The object in Northern Ireland is to reduce the dependence on linen and shipbuilding by creating a more diversified economy. In the Republic of Ireland the primary aims are to check the drift of population from the rural areas, whether overseas or to Dublin, and to raise living standards. Its strongly protectionist policy is also influenced by the ideal of creating a self-sufficient community.

Since the more modern industries depend very largely on imported raw materials they naturally tend to gather in the ports. The need for imported fuel has long had the same effect. Thus, in the Republic of Ireland, Dublin is the only place with any sort of claim to be regarded as an industrial city. It has great breweries and distilleries, fertilizer works treating imported phosphates, factories manufacturing biscuits, tobacco, soap, shoes and chocolate, and light engineering and assembly works. It remains, however, essentially a port and a capital city. Industry is far more important in Northern Ireland than in the republic. Belfast, though originally a market town, later a port and still later a centre of government, is essentially industrial in character. The making of linens was its first large industry and remains the most important. To it was soon added the making of cottons, and the manufacture of garments naturally followed. The improvement of its harbour and the reclamation of marsh land that accompanied it made possible the development of shipbuilding. It was this which finally changed the character of the city and quickened its growth. It works in well with the textile industry, employing almost entirely male labour whereas in the linen factories two-thirds of the workers are women. Subsidiary industries such as engineering and ropemaking followed in the wake of shipbuilding, and the later growth of aeroplane construction was yet another offshoot. Tobacco manufacture is of earlier establishment, but with the newer synthetic fibre factories adds to the demand for female labour. Other towns of east Ulster share in the linen trade but without creating any such industrial agglomerations as those of south Lancashire or the West Riding of Yorkshire.

IRELAND, CHURCH OF. The beginnings of Christianity in Ireland are difficult to trace, but there is no doubt that the first Christian missionary whose labours were crowned with any considerable success was Patrick (fl. c. 450), the patron saint of the country. Ireland was never conquered by the Romans and, chiefly for that reason, occupied a peculiar position in western Christendom for about six centuries. The church was mainly monastic, without parochial or diocesan divisions. Government was from the monasteries, and the powers of the bishops were limited to their purely spiritual functions. During this time missionaries went from Ireland to Britain and much of the continent of Europe; Irish scholarship was widely famous; and much evidence exists today of the devoted skill and craftsmanship of the Irish monks. (See IRELAND: History.)

The Norse invasions, beginning at the close of the 8th century, precipitated a decay in culture and learning. The weakness of an unco-ordinated ecclesiastical organization became evident, and the influence of Rome, through Canterbury, began to be felt for the first time. English bishops, chief among them Gilbert of Limerick, possessed themselves of the most important sees. About the year 1110 Gilbert held a synod at Rathbreasail which divided Ireland into 25 sees subject to the primacy of Armagh. Subsequently the pope sent legates to assist at the bringing of the Irish church into conformity with the rest of western Christendom, and the synod of Kells (1152) created four provinces with Armagh, Dublin, Cashel and Tuam as archbishoprics. The final step in the process of reform was taken at the synod of Cashel (1171), when obedience to Rome was accepted. There also regulations were made for marriage and baptism, tithes and papal tribute. The native liturgies were abandoned and the usage of the Church of England was adopted. With this began a period of subservience which was to last for 700 years.

The mediaeval history of the church in Ireland follows that of the country as a whole. Ireland was never completely conquered, but strategically important centres were developed and strengthened, and from these England exercised a measure of control. Most of the country was only at intervals made conscious of this overlordship, and the tribal kings continued to wield authority. In the church, Englishmen were appointed to the more important positions, the native orders were gradually replaced from abroad, but the mass of the secular clergy were Irish and retained something of the old Celtic spirit. It is possible that had this remnant of independence been considered and fostered at the Reformation the Church of Ireland might have become the church of the majority. In the event, a quite different course was followed. The native Irish were antagonized and came to look on the attempt at reformation as a political expedient and a weapon of conquest.

The Reformation period began with the passing of the Irish Supremacy act in 1537. This asserted the English king's supremacy in the Irish as in the English church. No attempt was made to win the mass of the Irish people to Reformation principles, and they were ignorant of and unaffected by the religious controversies which had been raging in Europe and Great Britain for many years. Nor were the differences of religious outlook of succeeding English sovereigns brought home to them as they were to the people of England. At Mary's accession five bishops either abandoned or were deprived of their sees; but the Anglo-Irish who remained faithful to the Reformation were not subjected to persecution such as would have been their fate on the other side of the channel. Again, under Elizabeth, while two bishops were deprived far open resistance to the new order of things, and while stern measures were taken to suppress treasonable plotting against the constitution, the uniform policy of the government in ecclesiastical matters was one of toleration. James I caused the Supremacy act to be rigorously enforced, but on political rather than on religious grounds. The episcopal succession was unbroken at the Reformation, and the Church of Ireland claims to be the direct and legitimate successor of the church of the 14th and 15th centuries. The continuity of that church with the church of pre-Norman times is not easily demonstrated, however.

On the accession of Charles II, the church was strengthened by the translation of John Bramhall (the most learned and zealous of the prelates) from Derry to the primatial see of Armagh and by the consecration of 12 other bishops, among whom was Jeremy Taylor. But though the church had now been reformed for more than a century, it had made little progress; and the tyrannical provisions of the penal code introduced by the English government during 1702–15 made it more unpopular than ever. The clergy, finding their ministrations unacceptable to the great mass of the population, were tempted to indolence and nonresidence; and, although bright exceptions could be named, there was much that called for reform. To William King (1650–1729), bishop of Derry and subsequently archbishop of Dublin, was mainly attributable the reorganization of the work of the church, and the impulse which he gave it was felt all through the 18th century. In 1800 the Act of Union was passed by the legislature, and thenceforward, until disestablishment, there was but one "United Church of England and Ireland." The dissatisfaction felt by the majority of Irishmen because of the continued existence of the established

church in a privileged position became increasingly plain as the years passed. Discontent was increased by the fact that the church drew its tithes largely from Roman Catholic tenant farmers. In the 1830s the agitation against this privilege became strong enough to be known as the tithe war. The census of 1861 showed that out of a total population of 5,798,967, only 693,357 belonged to the established church, 4,505,265 being Roman Catholics; once this had been made clear, the passing of the Act of Disestablishment was only a question of time. Introduced by W. E. Gladstone, and passed in 1869, it became law on Jan. 1, 1871.

The church was thus suddenly thrown on its own resources and called on to reorganize its ecclesiastical system as well as to make provision for its future clergy. This challenge met with a magnificent response from both clergy and laity. The spirit of the church of that time is shown by the fact that in 1865, with disestablishment imminent, the foundation stone was laid in Cork of an elaborate cathedral for that diocese. Many other cathedrals and parish churches were restored and adorned during the 20 years following the passing of the act.

A convention of the bishops, clergy and laity was summoned in 1870, and its first act was to declare the adherence of the Church of Ireland to the ancient standards and its determination to uphold the doctrine and discipline of the Catholic and Apostolic Church, while reaffirming its witness, as Protestant and Reformed, against the innovations of Rome. Under the constitution then agreed on, the supreme governing body of the church is the general synod, consisting of the bishops and of 208 clerical and 416 lay representatives of the several dioceses, whose local affairs are managed by diocesan synods. There are two primatial sees, Armagh and Dublin, the archbishops being chosen by the bishops from their own number. The number of dioceses was reduced by amalgamations to 14. Bishops are elected by a two-thirds majority of each order of the diocesan synod. Failing such majority, appointment passes to the house of bishops. Private patronage of benefices is almost nonexistent, and appointments are made by boards of nomination composed of diocesan and parochial nominators meeting under the chairmanship of the bishop. Most of the clergy receive their training for the ministry in the divinity school of Trinity college, Dublin.

The Book of Common Prayer was twice revised after 1662—in 1878 and in 1924. Changes were slight, but criticism was directed against the "Constitutions and Canons Ecclesiastical" by which are forbidden the placing of the cross on the altar, the making of the sign of the cross by clergy or laity, except where ordered in the baptismal office, and bowing to the altar. There is a high degree of uniformity in ceremonial throughout the church.

The finances are controlled by the Representative Church Body, to which a sum sufficient to provide life annuities for the existing clergy (2,043 in number) was handed over by the Church Temporalities commissioners in 1870, together with £500,000 in compensation for private endowments. The annuities provided were subsequently commuted for a capital sum. So skilfully was this fund administered, and so generous were the contributions of clergy and laity, that the total assets of the Representative Church Body amounted by the latter 1950s to more than £13,000,000. Church of Ireland membership was approximately 500,000.

IRELAND, NATIONAL UNIVERSITY OF. The National University of Ireland had its beginning in the Queen's university, incorporated in 1850. In 1880 the Queen's university was superseded by the Royal University of Ireland. It in turn was dissolved on Oct. 31, 1907, giving place to the National university. Of the rhree Queen's colleges, founded in 1845 at Belfast, Cork and Galway, which had formed the constituent colleges of its two predecessors. Belfast became a separate university, Cork and Galway were taken over as constituent colleges, while a new college was projected in Dublin and Maynooth was added as a recognized college. The headquarters of the university are in Dublin.

University representation in *dail eireann* was discontinued on June 14, 1937; the *Seanad* Electoral (University Members) act, 1937, entitled the university to three representatives in *seanad eireann.* Faculties include arts, philosophy and sociology, Celtic studies, science, medicine (including dentistry), engineering and architecture, law, commerce, general agriculture, dairy science and veterinary science. In 1951–52 there were 5,274 students, including 1,242 women. *(See* also UNIVERSITIES.)

See *Calendar of the National University of Ireland* (annual).

IRELAND, NORTHERN, a part of the United Kingdom of Great Britain and Xorthern Ireland, with a certain measure of local self-government. It comprises the counties of Antrim, Armagh, Down, Fermanagh, Londonderry and Tyrone and the county boroughs of Belfast and Londonderry. The area is 5,459 sq mi. It is bounded by the sea on the north and east, where there is a seaboard of 245 mi., and on the south and west by the Republic of Ireland, with which it has a common frontier zoo mi. long. The geology, physical geography and archaeology of Northern Ireland are described in the article IRELAND. The modern Northern Ireland is roughly similar in extent to the ancient province of Ulster and is often called Ulster. It is almost identical with the distribution area of the Ulster megalithic culture of the horned cairn, and it contains six of the nine counties defined as constituting Ulster at the beginning of James I's reign. Four of the counties of Northern Ireland were included in the colonization scheme known as the Plantation of Ulster in the early 17th century. Even larger bodies of British colonists settled in Antrim and Down, which were omitted from that scheme.

HISTORY

The first parliament of Northern Ireland was opened by King George V on June 22, 1921, the first prime minister being Sir James Craig, who took office at the head of a Unionist government. The new government had to deal with a disturbed country, troubied by bombings, shootings and incendiarism. From the close of 1921 there was civil war in the Irish Free State, and this overflowed into Northern Ireland, making the years 1922 and 1923 very disturbed. During 1922, in the course of these disturbances, 232 persons were killed in Northern Ireland, including two Unionist members of parliament, and nearly 1,000 were wounded. Enormous damage was done to property.

In accordance with the agreement which the United Kingdom government had made with the Free State, a boundary commission was established to investigate possible frontier changes between the Free State and Northern Ireland. The commission failed to agree and presented no report; negotiations were then opened between the governments concerned. A tripartite agreement was signed in 1925 between the governments of the United Kingdom, the Free State and Northern Ireland, agreeing to maintain and respect the existing frontier.

A new phase in political affairs opened in 1932 with the advent of Eamon de Valera to power in the Free State. Tension arose in Northern Ireland with his policy of growing dissociation from the United Kingdom and the commonwealth and his substantial repudiation of the binding character of the 192j agreement. His policy of tariffs also made the frontier between Northern Ireland and the Free State into a formidable economic barrier and rendered any possibility of being merged in the Free State extremely alarming to many interests and classes of people in Northern Ireland whose prosperity depended upon a flourishing export trade. The government of Eire, as the Free State then came to be called, made emphatic irredentist claims upon Northern Ireland.

During the same period Northern Ireland suffered from serious industrial depression and recession of export trade. Unemployment remained in the neighbourhood of 70,000 over long periods.

The Unionist party, standing for the maintenance of the union with Great Britain, gained a strong majority at every general election in Northern Ireland, whether for the parliament of Northern Ireland or for the province's representation at Westminster. Though united on this issue, the Unionist party allowed and experienced differing opinions in its ranks on a good many other issues. Sir James Craig (later Viscount Craigavon) held office as prime minister until his death on Nov. 24, 1940, when he was succeeded by John Miller Andrews, formerly minister of finance. In May 1943 Andrews was succeeded by Sir Basil Brooke (who was created Viscount Brookeborough in 1952).

The strategic importance of Northern Ireland, covering Britain's main shipping route, providing a landing place for the U.S. forces and filling the gap created by Eire's neutrality, was very great and was emphasized by Winston Churchill, Gen. Dwight D. Eisenhower and other war leaders. In addition the agricultural and industrial resources of the province were very valuable. Belfast constructed 600,000 tons of merchant shipping, a tenth of the output of the whole United Kingdom, as well as doing extensive admiralty work, including the building of six aircraft carriers, three cruisers and several other large ships, making a total of 140 warships of all sizes and 123 merchant ships. Among other wartime products of the province were 1,500 heavy bombers. 2,000,000 parachutes, 200,000,000 yd. of cloth for service use, 90% of the service shirts for British forces and one-third of the ropes required by the war department, as well as considerable quantities of tanks, guns and ammunition. Because of its industrial importance Belfast was the target of several destructive air raids.

In the period following the war, Northern Ireland adopted schemes of social insurance, free health services and other aspects of the welfare state as they were introduced in Great Britain. Though a policy of nationalization was denied, steps were taken to unify a number of public services under newly created public authorities. Road transport had already been treated in this way in 1933, and the principle was extended to rail transport and electricity. As new types of public service came into being it became necessary to amend the Government of Ireland act, 1920, in the United Kingdom parliament. New legislation was necessary to empower the government of Northern Ireland to proceed with its scheme of social insurance and state health services. But the essential principles of the 1920 act remained, and this amendment was only a natural development of the original principle that the government of Northern Ireland should control its own local affairs and welfare services.

In 1949 Eire, as the Republic of Ireland, withdrew from the commonwealth. To meet various legal problems arising from this, the United Kingdom parliament passed the Ireland act, 1949. This act contained the following provision: "It is hereby declared that Northern Ireland remains part of His Majesty's Dominions and of the United Kingdom and it is hereby affirmed that in no event will Northern Ireland or any part thereof cease to be part of His Majesty's Dominions and of the United Kingdom without the consent of the Parliament of Northern Ireland." Northern Ireland thus acquired something in the nature of federal status within the United Kingdom. Incidents connected with nationalist activities occurred sporadically, and in 1954 army barracks in Armagh and Tyrone were raided by members of the illegal Irish Republican army.

Limited self-government as a distinct entity within the United Kingdom intensified an Ulster regional self-consciousness. Attention was drawn to the province's high output of talent in many fields—particularly in the military, where it was represented by such figures as Viscount Alanbrooke, Earl Alexander of Tunis, Sir John Dill and Sir Gerald Templer. Efforts were made to create in Northern Ireland those cultural and other institutions which governments, when bestowing them on Ireland in the past, had always located in Dublin. A regional radio station also heightened this self-consciousness. The province was meanwhile represented in literature by Forrest Reid, St. John Ervine, Robert Lynd, C. S. Lewis, Louis MacNeice, H. Montgomery Hyde and Stephen Gilbert and in art by Sir John Lavery, Paul Henry, Frank McKelvey, Rosamond Praeger, J. Humbert Craig, William Conor, Maurice Wilks, John Luke and Colin Middleton. Music and drama received attention as never before.

POPULATION

More than two-thirds of the modern population of Northern Ireland is located in the eastern part of the province, in the city of Belfast and the adjacent counties of Antrim and Down. Belfast has a very restricted county borough boundary, and a "greater Belfast" extends considerably into Antrim and Down. More than half the population lives in cities or towns. Belfast is by far the largest city, Londonderry being the only other with populations of more than 10,000 at the 1961 census: Newtownabbey (37,440), Bangor (23,865), Portadown (18,605), Lurgan (17,873), Lisburn (17,691), Larne (16,341), Ballymena (14,740), Newtownards (13,090), Newry (12,450), Coleraine (11,912) and Carrickfergus (10,211).

Distribution of Area and Population of Northern Ireland, 1961 Census

Counties and county boroughs	Area (sq.mi.)	Urban	Per cent of total	Total	Density per sq.mi.
Antrim	1,176	113,353	41.4	273,923	232.9
Armagh	512	49,379	42.0	117,580	229.6
Belfast county borough	26	416,094	100.0	416,094	16,003.6
Down	952	82,600	30.9	267,013	280.5
Fermanagh	715	7,438	14.4	11,613	722
Londonderry (excluding county borough)	814	20,186	18.1	111,565	137.1
Londonderry county borough	3	53,744	100.0	53,744	17,914.6
Tyrone	1,261	27,353	20.4	133.930	106.2
Total	5,459	770,147	54.0	1,425,462	261.1

Religion. — The religious professions of the population at the 1951 census were as follows: Roman Catholic 471,460, Presbyterian 410,215, Church of Ireland 353,245, Methodist 66,639, other 69,362. Thus, roughly two-thirds of the population was Protestant and one-third Roman Catholic.

Education. — The county and county borough councils, through their respective education committees, act as education authorities in their areas. They carry on primary, grammar, secondary intermediate and technical schools. But a majority of the primary schools, a third of the secondary intermediate schools and most of the grammar schools are under voluntary management, by denominational bodies, boards of governors or other organizations. Primary schools provide for children under 11; after 11 the majority attend intermediate schools, but those who show that they can benefit by a more academic education go into grammar schools. Education in the early 1950s was free and compulsory up to the age of 15, and this was to be raised to 16. There are many scholarships in higher education. Extensive technical education facilities are also available. There are two training colleges for teachers. Queen's university, Belfast, is a self-governing university. It receives parliamentary grants and also grants from local government authorities. It has about 3,000 students. Magee university college, Londonderry, is a teaching body which prepares students for the arts examinations of Dublin university.

GOVERNMENT AND ADMINISTRATION

British antecedents, Protestant religion and economic interest caused a large proportion of the population of Ulster to resist all schemes for Irish self-governmerit in the later 19th and early 20th centuries. The Government of Ireland act, 1920, was an attempt to give a measure of self-government to Ireland but at the same time to give the Ulster community guarantees against being placed under the rule of the predominantly Roman Catholic and nationalist majority. The act set up two legislatures, one in Dublin for the 26 counties of southern Ireland and one in Belfast for the 6 counties of Northern Ireland. These two subordinate governments were to deal with purely local affairs, and all Ireland was to remain within the United Kingdom and was to continue to send representatives to the United Kingdom parliament at Westminster. A common council of representatives from both north and south was to provide a link between Northern and southern Ireland and a means of discussing matters of common interest and extending co-operation.

This scheme was accepted as a compromise in Northern Ireland but was rejected in southern Ireland, which ultimately received dominion status as the Irish Free State in 1922. With modifications appropriate to these changed circumstances, the Government of Ireland act, 1920, continued to be the basis of the constitution of Northern Ireland.

Constitution. — The essential feature of the constitution of Northern Ireland is that the province forms an integral part of the United Kingdom of Great Britain and Northern Ireland. Northern Ireland elects 12 members to the United Kingdom parliament; but within the province a large range of legislative and administrative functions is delegated to the government of Northern Ireland. The head of that government and the representative of the sovereign within the limits of the Northern Ireland constitution is the governor. The governor summons, prorogues and dissolves the parliament of Northern Ireland, gives the final assent to its legislation and fulfils other functions which are fulfilled by the sovereign within the larger field of the United Kingdom constitution.

The parliament of Northern Ireland consists of two houses. There is a house of commons of 52 members elected by universal adult franchise from single-member constituencies, with the exception of the university constituency, which is not single-member; and there is a senate or upper house of 26 members, of whom 24 are elected by the house of commons on the principle of proportional representation. Each elected senator holds office for eight years, and half the seats in the senate are vacated every four years. The two other senators are the lord mayor of Belfast and the mayor of Londonderry, who become senators ex officio. The house of commons has a maximum life of five years. Members of parliament receive salaries. Each house elects its own speaker. Legislation going through the Northern Ireland parliament takes a course similar to that in the United Kingdom parliament, with the usual readings and committee stage in each house; but a finance bill can be passed by the commons alone. In the event of a deadlock between the houses they can meet together in joint session, but this has never occurred.

There is a prime minister of Northern Ireland and a small cabinet of ministers. A minister is permitted to introduce business, answer questions or make a statement in either house, but he can vote only in the house in which he has a seat. Ministers represent the following departments: finance, home affairs, labour and national insurance, education, agriculture, commerce and health and local government. The functions of these departments indicate the range of functions delegated to the parliament of Northern Ireland. A wide range of other subjects is entirely reserved for control and legislation by the United Kingdom parliament, including problems affecting the crown and succession, decisions about peace, war or neutrality and the armed services, relations with foreign powers or with other parts of the commonwealth and empire, titles of honour, treason, extradition, naturalization, aliens, foreign trade, navigation by sea or air, post office, submarine cables, radio, lighthouses, coinage, weights and measures, trade-marks, copyright and patents. In these and some other matters, unless the exclusion of Northern Ireland is specially provided for, the province is legislated for in the United Kingdom parliament like any other part of the United Kingdom. Northern Ireland, for example, came under all food rationing regulations which applied to the rest of Great Britain during and after World War II.

Public Finance. — The taxation of Northern Ireland is the same as that of the rest of the United Kingdom, and the taxation revenue of the province goes into the United Kingdom exchequer. A deduction is then made for the full cost of all services carried on in Northern Ireland under direct control of the United Kingdom government, such as the post office and the inland revenue and customs and excise services. A further sum is deducted to meet Northern Ireland's share of certain liabilities remaining from before 1921. Out of the revenue that remains after these deductions, a sum is handed over to the government of Northern Ireland to meet the cost of services directly administered by it.

The size of the annual allocation of funds to the government of Northern Ireland for the purpose of carrying on the public services delegated to it is decided by the Joint Exchequer board, consisting of a chairman appointed by the crown and a representative each from the United Kingdom treasury and from the ministry of finance, Sorthern Ireland, on the principle that Northern Ireland shall have equality with other parts of the United Kingdom in social services and, so far as possible. equality in other services also. In the early 1950s this sum annually amounted to about £35,000,000. In addition to this sum, the Northern Ireland government is in direct control of a small range of local taxes, including death duties, stamp duties and motor vehicle duties, which usually amount to about 10% of its total revenue.

The amount of Northern Ireland taxation revenue still remaining in the United Kingdom exchequer after all these deductions and payments represents Northern Ireland's contribution to the general services of the United Kingdom as a whole, including the armed services, the national debt and other general Cnited Kingdom liabilities. This is called the "imperial contribution." It has varied considerably in size according to conditions and taxation levels. The highest sum in any one year was 536.300 ooo in 1944–45. The size of the imperial contribution also depends on the decision of the Joint Exchequer board. The purpose of this board is to ensure that Northern Ireland does not pay too much or too little in relation to its own needs and taxable capacity. This is brought about automatically in the case of other parts of the United Kingdom by the complete pooling of taxation, but it requires administrative action in the case of Northern Ireland, nhose finances form a special segregated transaction within the larger system of the United Kingdom's public finances.

Local Government. — There are five main types of local government authority in Northern Ireland. There are the two corporations of the county boroughs of Belfast and Londonderry; nine borough councils in Ballymena, Bangor, Carrickfergus, Coleraine, Enniskillen, Larne, Lurgan. Newtownards and Portadown; 24 urban district councils for various smaller towns; six county councils; and 32 rural district councils. These bodies are elected by householders and owners of property in the areas which they serve. With the exception of rural district councils, they have power to levy rates. They work under the supervision of the ministry of health and local government.

Other Administrative Bodies and Public Services. — In addition to the local government bodies, there is a variety of boards and authorities established to do special administrative work or to organize public utility services. Most of these work under the supervision of one of the ministries. Thus the attention of the ministry of commerce is given to several administrative bodies, including the Ulster Transport authority, which is responsible for carrying on the whole road and rail transport system of the province, with the exception of municipal passenger transport, the work of private carrying firms in Belfast and Londonderry and certain railways which cross the frontier; the Northern Ireland Electricity board, which provides electricity supplies over the greater part of the province; and the Tourist board, which supervises tourist and hotel accommodation.

Other administrative bodies are associated with the work of the ministry of health and local government. Three are concerned with health services: the General Health Services board, the Hospitals authority and the Tuberculosis authority. The Northern Ireland Housing trust builds workers' houses throughout the province and co-operates with local authorities or acts as agent for them in the building of houses. It is financed by advances of capital from the ministry of finance. Other public administrative bodies include the Belfast Harbour commissioners and the Belfast City and District Water commissioners. Several public bodies established under the United Kingdom government also operate in Sorthern Ireland, including the British Broadcasting corporation and British European Airways. A number of steamship routes from Northern Ireland to Great Britain are operated by British railways.

Justice and **Police.**—The superior courts in Northern Ireland, including the supreme court and the court of criminal appeal, are under the jurisdiction of the United Kingdom parliament. The

supreme court has two main divisions, the high court of justice and the court of appeal, the former having in turn the three divisions of queen's bench, chancery and assize courts. From the court of appeal there is possibility of further appeal to the house of lords in certain matters, including, by leave of the court, certain cases regarding the validity of acts passed by the parliament of Northern Ireland.

The inferior courts, dealing with minor civil and criminal matters, are under the jurisdiction of the parliament of Northern Ireland and are the concern of the ministry of home affairs. There are five county court judges, two of whom act as recorders of Belfast and Londonderry. Quarter sessions courts are held in 29 towns. Petty sessions courts are normally composed of a single resident magistrate, except in a few cases where two must adjudicate. In 1935 the judicial functions of honorary justices of the peace were abolished and those functions altogether transferred to a full-time professional magistrature.

The police force, the royal Ulster constabulary, is under the ministry of home affairs. It is not permitted by law to exceed 3.000 and has a normal strength somewhat below that number. There is a special constabulary with a small full-time establishment and its ranks filled by citizens doing part-time service. Its total strength is usually about 10,000.

Social Services.—Health.—The general medical and dental services are administered by the General Health Services board. It makes available to every resident in the province general practitioner and specialist services and attendance, a dental service and pharmaceutical services. These services are available without charge, except in certain cases where charges are also made in Great Britain. A hospital service is also available, administered by the Northern Ireland Hospitals authority.

Health authority services, including maternity services, immunization, aftercare and health education, are operated by county and county borough health authorities, who work in co-operation with the Hospitals authority and General Health Services board. The Tuberculosis authority specializes in prevention, discovery, care, aftercare and education with respect to tuberculosis.

Welfare.—The eight county and county borough councils also act as welfare authorities in their respective areas. They provide residential accommodation for old people and others and are responsible for care of children, the blind and other handicapped persons. They co-operate with voluntary organizations and with the National Assistance board. The Assistance board gives grants and supplements pensions and unemployment benefit to prevent destitution and administers a number of welfare schemes.

Social Insurance.—A comprehensive scheme of social insurance operates in Northern Ireland. Although separately financed, the scheme is the same as that operating in Great Britain in nearly every particular. The scheme provides industrial insurance, unemployment benefit, sickness benefit, maternity benefits, retirement pensions and other allowances and grants. The rates of payment are the same as in Great Britain. The scheme is administered by the ministry of labour and national insurance. Family allowances and noncontributory old-age pensions are also provided.

ECONOMICS

Northern Ireland is not rich in natural resources. There is almost no coal, and the extensive deposits of iron and bauxite are not sufficiently rich or accessible to compete economically with ores brought from elsewhere. There is, however, much good agricultural land; there are many streams and rivers useful in connection with the textile industries; there is a considerable quarrying industry; and there are substantial deposits of diatomic earth. Although there are many hills and much of the land is above the 500-ft. contour, the streams are not well suited to provide hydroelectric resources capable of economical development on a big scale. The province has thus to conduct some of its industries by meeting a high import of raw materials with a high production of goods and also a slightly diminished profit margin in some industries. The province's natural beauty and the opportunities it offers for sports and pleasures of many kinds have given it a considerable and thriving tourist industry.

Agriculture and Fisheries—The land is divided into small family farms, and there are nearly 90,000 agricultural holdings. There is a tendency for holdings gradually to become fewer and larger. Mixed farming is the general custom. A large proportion of the crops grown are used to feed livestock and poultry, and the greater part of the income of farmers comes from sale of livestock and livestock products, including dairy produce. Oats are the chief cereal crop. There is a big production of potatoes, particularly of high-quality seed potatoes, and seed hay is a popular crop. Flax is grown by about 25% of the farmers. In suitable districts, particularly in County Armagh, fruit is grown.

From 1924 onward a series of schemes was introduced and enforced by law for the inspection, grading, packing and marketing of agricultural produce, and Northern Ireland farm produce has gained a high reputation for quality and reliability. Most of it is sent to Britain. The chief agricultural exports are fat and store cattle, eggs, potatoes, poultry, bacon, milk products, grass seed, seed potatoes and apples. A proportion of the produce of the land goes through the province's many food-processing and canning factories.

Great progress has been made in agricultural education and in improved methods, mechanization and electrification, and this was speeded by wartime and postwar need for increased production. Under the ministry of agriculture financial and technical assistance is given for improvement of land and equipment. The ministry has also undertaken extensive reafforestation schemes and gives grants to encourage planting of trees by private owners.

Salmon fishing is carried on in the tidal portions of the Foyle, Bann and Bush and at several stations along the seacoast. Trout and pollan are caught in Lough Neagh, and there are eel fisheries on the Bann. Herring fleets operate from Ardglass, Portavogie, Kilkeel and Annalong.

Industry.—Textiles.—The linen industry gives employment to nearly one-fifth the gainfully occupied population in Northern Ireland. The mills of the province contain about 800,000 spindles, and the weaving factories contain about 25,000 looms. The industry is carried on in all parts of the province but chiefly within a 30-mi. radius of Belfast. Clothing and cotton goods are also extensively manufactured and there is a flourishing shirt industry in Londonderry. Various types of synthetic fabrics are also produced. Textiles, textile goods and clothing account for nearly a third of Northern Ireland's exports.

Shipbuilding and Other Industries.—The Belfast shipyards have long been the largest single establishment of their kind in the world, and their annual tonnage output of new ships has often run far into six figures. There is also a big volume of repair work. Though Belfast has a great tradition in the building of passenger liners, the main output is cargo vessels, particularly tankers. A considerable number of passenger liners has also been launched, and much work has been carried out for the admiralty, including the building of aircraft carriers of the largest size.

In 1937 a large industry for the manufacture of aircraft was established at Belfast. Many engineering industries also operate in Belfast and district, some specializing in textile machinery or machinery for other local industries. There is a tea-processing plant and ventilating machinery is produced. Belfast is also the site of a large ropemaking industry and possesses the largest ropeworks in the world.

Tobacco, whisky and mineral waters are long-established industries in the province.

In 1955 a Northern Ireland Development council was set up to attract new industries in order to help solve the unemployment problem. The inducements include the leasing of government-built factories, advances of capital, relief from rates and special co-operation from the Housing trust and other bodies.

Trade.—The total volume of trade in visible exports and imports is usually more than £500,000,000. Total exports in 1955 were £267,475,000 and total imports were £295,327,000.

IRELAND, REPUBLIC OF. The republic occupies four-fifths of the island of Ireland and is bounded on the northeast by Northern Ireland. Its total area is 27,136 sq.mi. For details of its topography and for the country's history up to 1921 *see* IRELAND.

The Republic of Ireland, as an independent state divorced from its former association with the British crown, came into operation under the Republic of Ireland act as from April 18, 1949. The interparty government, headed by John A. Costello, thereby repealed the External Relations act of 1937, which had already diminished the connection with the commonwealth. *Dail eireann* approved the decision without a single dissentient, and the British government acknowledged the right of Eire as a dominion to secede. This secession without active opposition from the British government was the climax of a rapid process of political separation within the previous years.

HISTORY

Establishment of the Irish Free State. — The intensive conflict which took place during and after World War I and is known in Ireland as the Anglo-Irish war resulted in the Irish peace agreement, which was signed in London by British and Irish plenipotentiaries on Dec. 6, 1921. The agreement provided that Ireland should thenceforward have the "same constitutional status in the Community of Nations known as the British Empire" as had the dominions of Canada, Australia, New Zealand and South Africa; "with a Parliament having powers to make laws for the peace, order and good government of Ireland and an Executive responsible to that Parliament." The new dominion was to be known as the Irish Free State. This peace agreement was ratified by the British parliament on Dec. 16, 1921, and became operative when it had also been passed on Jan. 15, 1922, by a meeting of the parliament of southern Ireland convened by Arthur Griffith. The new state included only 26 of the 32 Irish counties, as the northeastern area, known as Northern Ireland, was to decide whether or not it would accept inclusion in the dominion.

The peace agreement had been concluded between the British government and the representatives of an Irish government which it had previously refused to recognize. The Irish representatives held their authority from *dail eireann* (the assembly of Ireland), which had come into existence in Jan. 1919. The general elections held at the end of 1918 had resulted in an overwhelming majority for Sinn Fein as the party which declared for an Irish republic. All members elected for any Irish constituency were invited to attend an assembly in Dublin on Jan. 21, 1919, but in fact only the Sinn Fein members attended. Acting as a constituent assembly for all Ireland, they then proclaimed the Irish republic in existence, and they elected a president and ministers. Eamon de Valera was then in prison in Lincoln jail, but was regarded as president designate. He was to be both national president and chief executive, as in the United States. But the immediate concern of *dail eireann* in Jan. 1919 was to present Ireland's claim to national independence at the international peace conference which was then assembling at Versailles.

In the period of acute Anglo-Irish conflict which ensued, *dail eireann* regarded itself as the constitutional legislature of Ireland. The British government did not accept that claim until it signed the treaty of Dec. 6, 1921, and agreed to the establishment of the Irish Free State. The negotiations had been begun in July between De Valera and David Lloyd George, but were soon entrusted to plenipotentiaries, who were appointed by De Valera but required to consult closely with him while the negotiations proceeded. The final agreement was reached in Downing street only after Lloyd George had delivered an ultimatum threatening "immediate and terrible war" if the terms were not accepted at once. Griffith, Michael Collins and E. Duggan then agreed to sign, and Robert Barton and Gavan Duffy added their signatures under protest. Their chief objections were to the prescribed oath of allegiance to the British crown and to the provisions which allowed Northern Ireland to remain outside the new state.

During the interval between the assembling of the first *dail eireann* in Jan. 1919 and the conclusion of the treaty in Dec. 1921, the British parliament had in 1920 passed an act to establish two Irish legislatures, one for the 6 counties of Northern Ireland and the other for the remaining 26 counties. Both parliaments and their executives were to possess identical powers, much more restricted than had been conceded under the prewar Home Rule bill, which had been enacted in Sept. 1914, though its operation was indefinitely suspended. But under this Government of Ireland act of 1920, general elections were held in Ireland so that the two Irish parliaments should be brought to life. In the 26 counties every constituency except Dublin university returned a Republican candidate; and even in Northern Ireland some seats were also won by Republicans. All except the four members for Dublin university refused to bring the southern Ireland parliament into operation, and it consequently never functioned. But the same Republican members who had been elected in 1920 assembled for the first time on Aug. 16, 1921, in the Dublin Mansion house, after the truce had brought an end to military hostilities. They then constituted themselves the second *dail eireann,* and all members took the oath of allegiance to the Irish republic while negotiations were proceeding between De Valera and Lloyd George. Soon afterward plenipotentiaries, led by Griffith and Collins, were appointed by De Valera to conclude the peace agreement, which eventually fell short of the full Republican demands.

The Provisional Government. — Although the British parliament ratified the peace agreement on Dec. 16, De Valera immediately repudiated it, on the ground that the plenipotentiaries had departed from their instructions. In *dail eireann* a long and bitter debate developed, and on Jan. 8, 1922, ratification was passed by a majority of only 64 to 57. De Valera at once resigned the presidency, and Griffith was elected to replace him, but by a majority of only two votes. A provisional government was then appointed under article 17 of the treaty, by a meeting to which all members elected in 1920 for the southern Ireland constituencies were summoned. Those who had opposed the treaty refused to come, and the provisional government was composed largely of men who were little known in public life. Griffith as president remained outside the government, as did Gen. Richard Mulcahy, who now became minister for defense. Collins, who had attained an almost legendary reputation and great popularity by his daring and energy during the Anglo-Irish war, was appointed head of the provisional government. The only minister whose name was well known was Eoin (John) MacNeill, who had long been prominent in the Gaelic league and as founder of the Irish volunteers. The others were still young men. In opposition to the government were De Valera and most of the active leaders of Sinn Fein. The armed forces were still nominally the army of the republic, and their allegiance was divided. The old police force was disbanded, and a new force, the civic guard, was formed at once; but it was to be unarmed.

Griffith and Collins desired an immediate general election to obtain a verdict for the treaty. But De Valera anticipated them by convening a full convention of Sinn Fein delegates, and in the interests of maintaining national unity Collins then agreed to delay the election. There was still a dim hope of inducing Northern Ireland to come into the new dominion, and an attempt was made by the provisional government to negotiate with Sir James Craig (later Lord Craigavon), the Northern Ireland prime minister. But in Belfast fierce sectarian riots were raging, and these approaches had no success. In the meantime defiance of the provisional government began to spread, and De Valera proclaimed openly that only the Republican *dail* had legitimate authority. Many of his followers were calling for renewed military action

against the British government. Incidents of open defiance and violence became frequent, but Collins was always determined to avoid taking punitive action, though Griffith was believed to consider it necessary. Collins reached an agreement with De Valera, which was announced on May zo, that elections should be held on a basis of putting forward candidates representing both sides in the same proportion as in the existing *dail.* A coalition government would then be formed after the elections, in which De Valera would have four seats and the protreaty party five. All parties were urged to refrain from proposing candidates other than those selected from this joint panel. Moreover, the election was not to be regarded as a verdict for or against the treaty. But this arrangement was out of touch with general feeling in the country. The Irish Labour party gave a lead in putting forward its own candidates. Many others also came forward, and at the elections on June 16, 34 members were elected who were not on the joint list, all of them being in favour of accepting the treaty. Of the panel candidates who were elected, 58 were protreaty and 36 Republican.

Although faced with this decisive defeat, the Republicans maintained that the republic was still in existence and refused to recognize any other authority than the Republican minority of the second *dail.* The Irish Republican army (I.R.A.) soon took the law into its own hands, and large areas in the south and west were more or less under its control. Acts of violence and arson became more frequent, and the British government was soon accused in England of having let loose conditions of anarchy without protecting its friends. A crisis arose when Field Marshal Sir Henry Wilson was shot dead on June 22, on his own doorstep in London, by two Irishmen who had served in the British army during World War I. Drastic action to restore order in Ireland was demanded from London, and an open conflict became inevitable on June 28. The Republicans in Dublin seized the assistant chief of staff of the Irish army as a hostage and imprisoned him in the Four Courts, which they had occupied. The provisional government demanded his immediate release and besieged the courts. Serious fighting in Dublin ensued for a week, until Rory O'Connor, who had occupied the courts, blew them up before surrendering. British military equipment and munitions had been supplied to assist the government, and the conflict was assuming a new phase. Meanwhile De Valera, who had escaped to the southwest, was openly supporting the insurgents. Griffith and Collins decided that there could be no further compromise, and Collins assumed charge of the army as commander in chief. The strain had told so heavily upon Griffiththat he died suddenly on Aug. 12. Then Collins rashly left Dublin to inspect the military operations in the south. On Aug. 22 he ran into an ambush in west Cork and was shot dead.

The provisional government had thus lost its two most prominent leaders within a fortnight, while De Valera was openly heading the insurgents in the west. The surviving ministers could not even appear openly without armed protection and were obliged to live at the central government offices which had been established in the college of science. Under the treaty the newly elected *dail* was required to frame its constitution before Dec. 6, 1922, and the new constitution had then to be ratified also by the British government. The new *dail* was therefore summoned to meet on Sept. 9, in the building of the Royal Dublin society, Leinster house, which later became the seat of both the *dail* and senate. The building was for some time kept closely guarded.

Its first business was to elect a new president in place of Griffith. None of the acting ministers had yet attained a national reputation, but W. T. Cosgrave was older than most of the others, with active experience as a member of the Dublin corporation, and he had shown great competence and energy as minister for local government during the Anglo-Irish war. He was now chosen as president, and the *dail* also elected a team of 11 ministers whom he proposed. It then had to pass the clauses of the constitution defining relations between the Irish Free State and the crown, and questions of imperial defense, which Griffith had already settled with the British government. In the absence of the Republican deputies, who refused to recognize the new *dail,* the work proceeded swiftly, and the constitution was ratified both in Dublin and in London by Dec. 6.

Open conflict between the armed forces of the Republicans and of the Free State had ceased by the autumn, but public order and security were still being widely violated in many districts. Courts had not yet been formally constituted, and the new police, or civic guard, had to be organized and trained under great difficulties. Kevin O'Higgins, as minister for justice, insisted that the police must be unarmed, in contrast with the old royal Irish constabulary. They were consequently at a grave disadvantage in restoring public order while irregular Republican forces were still active. The government had to rely on military forces, which were hurriedly recruited until they exceeded 50,000 men. Under such conditions, trial by jury could not be expected to obtain convictions. The *dail* authorized trial by court-martial, with drastic punishments. But the prisons were already filled with men awaiting trial for reasons which usually had some political pretext. Attacks upon life and property were still widespread, and agrarian outrages were reoccurring. The government decided that the unauthorized possession of firearms must be resolutely punished, and in November it was solemnly announced that four men had been tried, convicted and executed on the sole charge of having revolvers without licence. Other similar trials soon followed, and Robert Erskine Childers (*q.v.*) was likewise executed after he had been found to have a revolver. These executions were fiercely resented by the Republicans and embittered Irish politics for years afterward.

The Cosgrave Ministries. — By Dec. 6 the new Irish constitution had been ratified, both by the *dail* and at Westminster. The new ministry had to test its own powers while labouring to restore confidence and good order. A crisis arose on Dec. 8, when the *dail* met to choose a senate under the new constitution. One member of the *dail* was shot dead and another wounded on their way to the meeting. The government decided upon immediate reprisals against the Republican leaders, and on the following day four of the principal insurgents, one from each province, were shot in prison without trial. They included Rory O'Connor, who had seized the Four Courts in June. Republican opposition to the government became more bitter than ever, but there was soon a lessening of organized resistance. More than 10,000 prisoners had been placed under restraint, and there had been about 50 executions. In May 1923 De Valera openly appealed to the Republicans to cease fighting and to conceal their arms. Soon afterward it was found generally possible to hold public meetings.

Confronted with the problems of civil war and with responsibility for reorganizing the country's normal life, the young ministers under Cosgrave's leadership displayed remarkable ability and energy. They were untrained either by office or by public experience, and they were regarded by their former Republican comrades as having betrayed their oath to the republic. But they received more encouragement than had been expected both from the conservative elements in Ireland and from the British government. At the outset they had applied to London, with success, for the appointment of an Irish nationalist as the first governor general of the Free State. They suggested T. M. Healy, a veteran of Charles Stewart Parnell's agitation who in later years had shown his active sympathy with Sinn Fein. In approving his nomination, the British government went far toward creating a sense of co-operation and mutual confidence. It also showed its willingness to admit the wider implication of dominion independence, which the Irish ministers soon found other opportunities to press forward. But the first necessity was to restore public order and to bring the new constitution into operation.

The first senate was duly created, and Cosgrave gave generous representation to the former Unionists when he had to nominate half its membership. It elected as its first chairman Lord Glenavy, who as Sir James Campbell had been Sir Edward Carson's principal colleague in the campaign to resist home rule before World War I. But the Northern Ireland government was now headed by Sir James Craig, since Carson's retirement, and it had formally notified the British government that it would not join in the Irish Free State. By April 1923 the Free State had consequently been obliged to establish a customs system along the border of Northern

Ireland and also in the Irish ports. Cosgrave was still finance minister, as well as head of the government, and the British financial system was still being operated, though preparations were being made for protective tariffs.

At the end of August, when order was generally restored and De Valera had instructed his followers to abandon armed resistance, the fourth *dail* was elected, on a basis of adult suffrage for men and women. De Valera retained his personal following, and his party won 44 seats out of 128. Cosgrave's party did not secure half the total of seats; but as the Republicans refused to sit in the new *dail,* Cosgrave had a majority among those who did attend, and on many issues he had general support from Labour and the others. The absence of any effective opposition party greatly strengthened the power of the new government to carry measures quickly, and it displayed great energy in the following years. In September the government sent its official representatives to attend the council of the League of Nations, and soon afterward the Irish ministers, headed by Cosgrave, took part in the Imperial conference in London. These contacts soon led to co-operation with several other dominions in pressing for a more definite recognition of sovereign rights. Partly under pressure of criticism from the Republicans outside the *dail,* and partly in the direct tradition of Irish nationalist aspirations, the government concentrated steadily upon the expansion of dominion status.

An executive council of seven ministers with four other "extern" ministers was established after the elections of Aug. 1923. Ernest Blythe now became finance minister, and in December he succeeded in floating the first national loan of £10,000,000 at 5%, repayable in 20 years, which was quickly oversubscribed. Conditions had improved immensely during the year, but there had been a bad harvest and unemployment was inevitably increased when the government decided to reduce the army, which was costing £14,000,000 a year. Blythe courageously faced the unpopular task of collecting arrears of taxes and land annuities which had been withheld during the years of unrest. He reduced old-age pensions and made other unwelcome cuts in expenditure, and by introducing a protective tariff he caused new dislocation of trade which could not be expected to produce immediate benefits in increased employment. But the government had a great advantage in being free from effective opposition in the *dail,* so long as De Valera's followers refrained from attending it.

Reconstruction and Progress.—Patrick Hogan, as minister for agriculture, had already completed land purchase by the tenant farmers. He introduced a licensing system for the export of butter and eggs which soon resulted in higher prices when it was found that a high standard was enforced and that regular deliveries could be ensured. He also provided long-term credits to farmers. His energy and knowledge of Irish agriculture, combined with great gifts of popular appeal, produced remarkable results, which were hastened by the skilful assistance of John Dulanty as trade commissioner in London. Other economic developments were inspired by bolder conceptions than had ever been attempted under British rule. Plans for providing hydroelectric power for the Dublin area were already in preparation when the government was offered assistance by the Siemens company in Germany for introducing electric power on a national scale by harnessing the river Shannon. P. McGilligan as minister for industry and commerce accepted early in 1925 the German company's offer to undertake a full survey at its own expense on condition that Siemens would get the contract if the work proved economically desirable. Its report, after approval by an independent committee of international experts, was then adopted. The Shannon scheme provided for utilizing three lakes in stages, as reservoirs to meet future requirements. All three were brought into operation much sooner than had been foreseen, and the Shannon power was later supplemented by other similar sources. Another new enterprise was the introduction of beet sugar factories, under a scheme which provided a government subsidy of more than £1,000,000 to a Belgian firm which undertook to organize the industry. Various other important industries were also encouraged, and before long many factories mere being organized in Ireland by British and other enterprises which undertook to produce goods in Ireland for the Irish market. The new system of protective tariffs became a powerful inducement, and the government soon insisted that the Irish companies so constituted should be under the control of a majority of Irish shareholders.

Reconstruction proceeded vigorously in other directions also. Political control of the elected corporations in Dublin and Cork, and of some county councils, led to such conflicts with the government that it boldly suppressed the corporations, in disregard of their long association with the nationalist agitation. City managers were appointed, and they soon removed old abuses and reduced the prevalent corruption while introducing useful reforms. District councils were abolished and their powers transferred to the county councils; and the central government exerted its authority with increasing disregard for local objections. Many good results followed, though it was clear that the government was often exercising its power to override political opposition.

O'Higgins, the young minister for justice, was particularly high-handed in carrying out his reforms, and he enforced drastic and unpopular restrictions on the drink trade. He had created an efficient, though unarmed, civic guard, which replaced the old royal Irish constabulary with a much smaller and less expensive force. The unpaid justices of the peace were abolished and district justices for each area were appointed instead. The high court judges ceased to go on circuit, and circuit judges were appointed. Many of these judges were young men of outstanding ability who brought integrity and enthusiasm to their work. In former days judges had been appointed largely for their political services while they were barristers. Most of the senior judges had retired on the generous pensions offered to them under the treaty settlement, but among the appointments to replace them the government had included a large proportion of former Unionists.

The Ulster Boundary Crisis.—One overriding problem had clouded the whole prospect since the new state began to function. The Republicans, who still held more than 40 seats in the *dail,* had repudiated the treaty mainly because it allowed Northern Ireland to remain separate. Collins had been convinced in his negotiations with Lloyd George that the treaty supplied a solution, by providing under article 12 that if Northern Ireland did not come into the Free State there must be a boundary commission to decide what areas were to remain excluded. Two of the six excluded counties, Tyrone and Fermanagh, contained clear, though small, majorities in favour of union with Ireland; and on the southern side of both Down and Armagh were substantial areas which had for years returned nationalist members. Collins, like most Irish nationalists, had assumed that when a boundary commission was set up these areas would all be withdrawn from Northern Ireland and that the remaining territory would be too small to continue as the basis of an independent legislature and government.

On these assumptions Cosgrave's ministry was soon criticized for delay in demanding the appointment of a boundary commission. In 1924 Ramsay MacDonald's Labour government had taken office, and soon Cosgrave demanded that the commission be set up to "determine in accordance with the wishes of the inhabitants, so far as may be compatible with economic and geographical considerations, the boundaries between Northern Ireland and the rest of Ireland." The Northern Unionists quickly organized preparations to resist any interference, and Craig was soon threatening to revive the Ulster volunteers. Attempts to obtain a settlement by consent failed, and when Eoin MacNeill was appointed to represent the Free State on the boundary commission the Northern government refused to appoint a representative. The dispute was referred to the judicial committee of the privy council, which decided that legislation was necessary if a representative of Northern Ireland were to be appointed by the imperial government. An act for that purpose was accordingly passed, and MacDonald appointed a well-known Ulster barrister, T. R. Fisher, to represent Northern Ireland. As chairman, Judge Richard Feetham was brought from the Union of South Africa. During 1925 the commission conducted its inquiry in secret, but in November a London newspaper published a detailed anticipation of its report which suggested that the alterations would be small and even adverse to

the Free State in important areas. MacNeill resigned at once from the commission and also from the government, protesting his disagreement with the newspaper report. But Irish disappointment was so great that Cosgrave's ministry was in real danger of defeat.

MacDonald then called a conference in London, which Craig attended, and a new agreement was made which left the existing boundaries intact in consideration of large financial concessions. Under article 5 of the treaty, Ireland had accepted liability for part of the United Kingdom's public debt in 1921, to be determined "in such proportion as may be fair and equitable, having regard to any just claims on the part of Ireland by way of set off, or counterclaims." This article, as well as article 12, was now cancelled, while Ireland agreed to pay a revised claim in compensation for war damages, estimated at less than £5,000,000.

Removal of this uncertain but great financial liability was an immense help to the Irish government, but the agreement involved surrender of all hopes of compelling Ulster to come in. The agreement was vehemently opposed by the Labour party, as the *dail* had not been consulted before it was made. The Republicans renewed their accusations that Ireland's national integrity had been surrendered, and even the supporters of the treaty were shaken in their confidence. But the danger of collision with the Northern Ireland government was removed, and it at once disbanded two of the three branches of the Ulster special police force. Meanwhile the Irish ministry had found that the British government was disposed to be actively helpful in overcoming difficulties, and the approach of another Imperial conference gave opportunities to press for fuller independence. Ireland was already actively participating in the League of Nations, and both at Geneva and in the Imperial conference collaboration with other dominions was pursued, to develop greater freedom from imperial control. Passports for Irish citizens were now issued from Ireland; the authority of the governor general in regard to diplomatic and other appointments was subjected to increasing restrictions; and the right of appeal from Irish courts to the judicial committee of the privy council was strongly contested. These and other matters affecting the implications of dominion status were considered, with growing support from Canada and South Africa.

Republicans in the **Dail.**—By the spring of 1927, five years of intensive work had produced striking progress. Blythe's new budget reduced the estimate of normal army expenditure by £500,000, and income tax was now lowered below the English rate to 3*s.* in the pound. The fourth *dail* alone had passed nearly 200 acts, and a sense of security had been achieved. But there was a natural desire for change, and when general elections were held in June the smaller parties increased their strength. Cosgrave's party was reduced from 57 seats to 46 and could no longer command a majority, even while the Republicans remained outside the *dail.* But Cosgrave agreed to form a new ministry to continue its own course with support from other groups until it was outvoted. Among the other ministers, Hogan, McGilligan and Blythe had shown great abilities, but O'Higgins had made the strongest mark, especially at the Imperial conference and in Geneva. He was now vice-president of the executive council, the ablest debater and most decisive character in the government. But his sardonic wit and provocative speeches had incurred intense resentment during the civil war. The old feuds were suddenly revived when he was murdered by gunmen outside his house on Sunday, July 10, 1927.

The Republicans at once disclaimed all sympathy with his murder, but Cosgrave denounced it as a deliberate attack on the state. He took drastic powers by carrying the Public Safety act, which proclaimed all revolutionary societies as treasonable and gave power to arrest or deport suspected persons. The Republicans still refused to enter the *dail* and continued their efforts to discredit the government from outside. Cosgrave decided to force them to come in by introducing a bill which prescribed an oath of willingness to enter the *dail,* and also an oath of allegiance to the constitution, for every candidate at future elections. De Valera did his utmost to defeat the bill but found it impossible to hold out. He decided that he and his party would subscribe to the oath, but only after proclaiming that they regarded it as an "empty formula" which would have no binding force. He then led his followers into the *dail,* and an agreement was reached with T. Johnson's Labour party, and with Capt. W. A. Redmond's National league, that they would outvote the government on a motion of no confidence. Johnson was to assume office with the support of the Republicans. The motion was debated on Aug. 16, but one member absented himself and Cosgrave's ministry was saved by the speaker's casting vote. Two by-elections in Dublin soon afterward gave Cosgrave large majorities, and he at once dissolved the fifth *dail.* The two main parties gained heavily from their previous allies, and Cosgrave won 61 seats as against 57 won by the Republicans.

The sixth *dail* assembled in Oct. 1927, and Cosgrave again formed a ministry, with support from the Farmers' party and independents. De Valera was now leading the opposition in the *dail,* supported generally by the Labour party and the National league, and an alternative to the Cosgrave ministry could easily be formed. The government had exercised almost unchallenged authority and had introduced a great number of drastic changes, many of them unpopular. The young ministers had tended to disregard criticism while they pursued their program of reconstruction, and they increased resentment by their undisguised satisfaction at their success. But economic conditions favoured them during the sixth *dail,* until the general trade depression of 1930 began to affect Ireland also. Cosgrave's ministry, while introducing protective tariffs and encouraging the foundation of new industries behind the customs barrier, had relied chiefly upon trade with England. Agriculture had benefited from that policy and from taking advantage of imperial preferences in which the Free State shared. But the economic crisis in England brought down prices for Irish produce, and unemployment was spreading. Discontent gave new life to the activities of the Irish Republican army, and Cosgrave introduced yet another amendment to the constitution to establish a military tribunal for political crime. De Valera opposed it, with increasing support, and in Feb. 1932 the general elections produced the seventh *dail,* in which De Valera had gained enough seats to form a ministry, with the Labour party's support.

De Valera in **Office.**—After ten years in office, Cosgrave had been prime minister longer than almost any other statesman in Europe. But De Valera had been the Republican leader since 1916, as the senior survivor of those who escaped execution after the rising. He had a definite program which appealed especially to the poorer classes, who felt that Cosgrave had chiefly encouraged the large farmers and the middle classes. With trade depression increasing, De Valera promised relief by wider social services, by reducing the high salaries of public officials and especially by his promise to withhold the land purchase annuities which were being paid to the British government. This promise was especially effective in the western counties, where the land annuities were the principal outgoings of the small farmers. At the same time he renewed his appeal to national sentiment by demanding the removal of the oath of allegiance and the abolition of the governor general as representative of the king. His personal prestige was strengthened by the accident that, soon after he assumed office, the international Eucharistic congress was held in Dublin. A million people, including great numbers of Irish pilgrims from overseas, attended the impressive ceremonies.

De Valera's refusal to continue payment of the land purchase annuities produced an economic conflict with Britain which enabled him to press at the same time for abolition of the oath of allegiance. The annuities had been cancelled by the Government of Ireland act of 1920, which never became operative, but Cosgrave's government had subsequently accepted liability for paying them as part of the financial agreement of 1926, which abolished all Irish liability for the imperial public debt in compensation for throwing over the promised adjustment of the Northern Ireland boundaries. De Valera claimed that this agreement was invalid because it was never submitted to the *dail.* The British government insisted that the moneys were due, and J. H. Thomas, as secretary of state for the colonies, retaliated by securing the imposition of tariffs on imported Irish cattle and farm produce. De Valera then imposed a similar punitive levy on Eng-

lish coal and other imports. The annuities were still collected, but for the Irish exchequer. An economic war developed with crippling results for the more prosperous Irish farmers, though the small farmers were less directly affected. Denmark and the dominions had new opportunities of capturing the English market from their Irish trade rivals; and at the Ottawa conference later in 1932, Ireland gained no benefit, whereas Cosgrave had always obtained sympathetic support at such conferences. Nevertheless the economic war had created favourable conditions for De Valera to pursue his deliberate policy of achieving full political and economic independence. A conflict with the governor general, James MacNeill, after the Eucharistic congress in June enabled him to demand MacNeill's retirement, and he then insisted successfully in asserting the right to nominate MacNeill's successor. The Viceregal lodge ceased to be the official residence, and D. Buckley, a veteran of the Gaelic revival who had taken part in the rising of 1916, became governor general, living in a modest house in south Dublin. By simple legislation De Valera abolished the oath of allegiance as prescribed by the treaty. While the economic war continued, protective tariffs were used with increased vigour to promote a general policy of achieving economic self-sufficiency. Austerity as the price which must be paid while full independence was being achieved became the subject of constant exhortation. Salaries of ministers were reduced, while the greatly reduced expenditure on the governor general's establishment was cited as an example that more modest standards must be adopted. An offer by the British government to invoke arbitration on the disputed land annuities, by a commission which would include no members of the commonwealth, was rejected by De Valera, and the conflict became more intense. In Jan. 1933 he appealed directly to the country, and in the eighth *dail* he had 77 seats instead of 70. He had now a bare majority of one, and the Labour party continued to support him.

Internal troubles increased with the growth of unemployment and the depressing effects of the economic war. Evidences of Communist influence began to appear, especially among the I.R.A. The Army Comrades association formed a new organization of national guards, led by Gen. Eoin O'Duffy, whom De Valera had dismissed from command of the civil guard. Demands from the I.R.A. for his dismissal had made De Valera's action appear as a weakening of his authority, and O'Duffy soon became prominent as leader of the Blue Shirts, which came into collision with the government as an apparently Fascist movement. De Valera had attempted on first taking office to repeal the Public Safety act which had been passed by Cosgrave's government after the murder of O'Higgins, but had failed to secure a majority in the *dail.* He now invoked the act against O'Duffy's Blue Shirts and declared the national guard an illegal organization. O'Duffy lacked the sagacity necessary for leading the opposition in such conditions, and his movement soon lost much of its earlier support. The Civil War which broke out in Spain in 1936 had encouraged his Fascist sympathies, and he enrolled an Irish brigade to serve under Gen. Francisco Franco, which, however, found little scope in Spain and received small sympathy in Ireland. Recruitment of Irish volunteers for Spain was made illegal by the *dail.* While the economic war continued, De Valera exploited his oppartunities for reducing any formal dependence upon the British connection. Cosgrave's government had already achieved notable advances toward full autonomy by gaining the support of other dominions at the Imperial conferences. Ireland had been actively represented in the League of Nations since 1923, and in Sept. 1932, shortly after assuming office, De Valera had been elected president of the League's council and had made a notable presidential address at Geneva. During the Spanish Civil War he had supported the British attitude of nonintervention. But he had abolished the oath of allegiance and forbidden appeals to the judicial committee of the privy council. He had reduced the governor general's status to a minimum, and he announced his intention of framing a new constitution. The senate, which still represented chiefly the conservative elements, with a large proportion of former Unionists, was to be replaced by a more widely representative body. With continued support from the Labour party, De Valera had been pursuing his policy of self-sufficiency and extending the social services. Tension in the economic mar was partly relaxed in 1935 when a coal-cattle agreement was negotiated, after much skilful diplomacy, by Dulanty as high commissioner in London. Within stipulated limits, it was agreed that Irish cattle should be allowed into England in return for similar exports of English coal to Ireland. These agreements were renewed in 1936 and again in 1937.

Constitution of 1937.—De Valera proceeded to introduce his proposals for the new Irish constitution, "as if there were no relationship with the states of the British Commonwealth." His proposals were introduced when the British government was unexpectedly confronted with the constitutional crisis that resulted in the abdication of King Edward VIII. Under the Statute of Westminster each dominion was expected to ask the imperial parliament to enact a statute of abdication; but De Valera declined to make any such request. The *dail,* however, passed an act accepting the abdication, and it authorized King George VI to act as a symbol of Ireland's co-operation in the commonwealth on such matters as the Irish executive council might refer to him for advice. De Valera had thus gained a direct opportunity for establishing his own conception of Ireland's special position as a state in "external association" with the British Commonwealth.

The new constitution gave effect to this general idea. It did not proclaim a separate and independent republic, but it abolished the title of the Irish Free State and substituted the word "Eire" (Ireland). The British government accepted these proposals, in spite of protests from the Northern Ireland government. De Valera held another election to secure approval of his proposals, and the new constitution was formally ratified by a plebiscite which was held concurrently with the elections. It became operative on Dec. 29, 1937. One symbolic change was that the former governor general was now replaced by a president, elected by the whole people, who was to be the nominal head of the state. The leader of the largest party in the *dail* was to be prime minister. The first president, elected by the consent of all parties, was Douglas Hyde, a famous Celtic scholar who had been the chief organizer of the Irish language revival and president of the Gaelic league. As a Protestant, the son of a clergyman and a graduate of Trinity college, Dublin, his unanimous choice was regarded as evidence of good will toward the Anglo-Irish minority. That point was especially important, because even the new constitution was only a further stage toward attaining the national independence of a united Ireland, which could not be completed without the inclusion of the six counties of Northern Ireland. Full achievement of what the first *dail eireann* had proclaimed was not yet within reach, and the continued conflict with the British government had hardened the opposition of the Ulster Unionists.

The Naval Bases.—Events in Europe were creating a new situation, which concerned De Valera directly in his dual capacity as prime minister and minister for external affairs. As president of the League of Nations council at Geneva in 1932 he had spoken gravely of the risks of war. During the Civil War in Spain, as already noted, he had supported the British policy, and during the invasion of Ethiopia he had given full support from Ireland for sanctions against Italy. The growing fears of a European war, however, had a direct concern for Ireland, because the Anglo-Irish treaty had left certain naval bases in Ireland under British occupation. Cork harbour and Berehaven in the southwest, besides Lough Swilly in the north, were still occupied by the British fleet. In the event of war in Europe, this would involve Ireland inevitably as a participant. The Republican program, to which De Valera was irrevocably committed, demanded absolute independence and sovereignty for the whole island, which implied an unfettered freedom of decision. De Valera had insisted repeatedly, in all negotiations with London, that in the event of war Ireland would never give active support to England while partition continued. Now that war was apparently imminent, Neville Chamberlain had to face the probability of renewed difficulties in Ireland if the British naval bases there became isolated. The new Irish constitution, evolved after several years of economic conflict, showed-that De Valera was uncompromising in his claims to sov-

ereignty but anxious to restore friendly relations. Chamberlain's government accepted the new situation in Dec. 1937 by announcing that the British and dominion governments "are prepared to treat the new constitution as not effecting a fundamental alteration in the position of the Irish Free State."

Anglo-Irish Agreement of 1938.—Chamberlain then invited De Valera to hold new discussions in London covering the whole position. Conversations were accordingly opened in Jan. 1938 and resulted in three agreements on April 25. The preamble announced that they had been made with the object of promoting friendly relations between the two countries, of facilitating trade between them and of reaching a final settlement of all financial claims. The agreements went far beyond the immediate dispute concerning the land annuities and the resulting economic war. They made a dramatic change by relinquishing British occupation of the Irish naval bases outside Northern Ireland. The treaty of 1921 had provided that until arrangements were made between the two governments for the Irish Free State to defend its own coasts, "the defence by sea of Great Britain and Ireland should be undertaken by the imperial forces." In view of later developments, Eire was now entitled to declare itself neutral in case of war, but the naval bases at Cork harbour, Berehaven and Lough Swilly were still under British occupation. De Valera now claimed that Eire was prepared to undertake its own coastal defense, while Chamberlain recognized the obvious difficulties in maintaining isolated naval bases in case of war. Chamberlain decided to rely upon Irish good will in withdrawing the British naval forces. It was agreed that before Dec. 31, 1938, the United Kingdom would transfer to Eire the property and rights of the admiralty at Berehaven and also the harbour defenses there and at Cork harbour and Lough Swilly. This part of the new agreement was vehemently opposed by Winston Churchill, who was not then in office, on the ground that British naval defense would be greatly hampered by the surrender of the Irish bases.

Besides terminating the British naval occupation, the agreements provided for a settlement of the land annuities dispute and a cessation of the trade war. The original treaty had contained vague provisions for adjustment of financial claims on both sides, but these had been generally settled by the agreement of 1925 which abolished the Ulster boundary commission and cancelled almost every outstanding financial liability except the land annuities. It was now agreed that, apart from a separate payment for damages to British property which had been agreed upon in 1925, Eire should pay £10,000,000 to the British government before Dec. 1938. This was to be a final settlement of all outstanding claims between the two governments. At the same time the British government was to abolish the special duties which had been imposed to collect the amount claimed for the land annuities. Almost all exports of Irish animals and agricultural produce had been subject to these duties, ranging from 20% to 40%. Quota restrictions on Irish imports had also been imposed, and imperial preference had been withdrawn from Irish produce. There had been some concessions under the coal-cattle pacts of 1935, 1936 and 1937, but many severe tariff restrictions had been introduced on both sides. De Valera had utilized the abnormal situation to develop new Irish industries behind protective tariffs, and the money collected for land annuities had been spent on subsidizing exports. The new agreements brought an end to such penal tariffs on both sides; but Irish trade was already beginning to follow a new pattern, and exports to Britain had been prejudiced by the loss of preferential treatment.

Irish Neutrality.— The new Anglo-Irish agreements, much wider in scope than had been expected, enabled De Valera to appeal for a new verdict of popular approval. The *dail* approved the new pact on April 29 with only one dissentient, and the general election on June 17 returned De Valera to power with a clear majority, having 77 votes against 45 for Cosgrave's Fine Gael, 9 Labour and 7 independents. On July 11 the last British troops were withdrawn from Cork harbour. Events in Europe were shaping rapidly, but Chamberlain had been fully aware that the Irish government might proclaim its neutrality in case of war. He had told the house of commons plainly, in explaining the agreements on May 5, that De Valera had attached primary importance to the question of partition, which the British government had considered itself unable to discuss. In a statement published on Oct. 18, shortly after Chamberlain's return from his visit to Hitler in Munich, De Valera declared that "quite obviously the existing partition would be a grave danger to England in the event of that country becoming involved in a European war." He asserted that "we have definitely committed ourselves to the proposition that this island shall not be used as a base for enemy attacks on Great Britain," and that quite possibly "a united free Ireland" would be willing to co-operate with Britain to resist a common attack. But until there was a "united, free, independent Ireland," Irish support could not be expected. In the same interview De Valera expounded his own views on the possible settlement of partition. He agreed, though reluctantly, that Northern Ireland might keep its "local Parliament with its local powers," but that "the powers at present reserved to the English parliament shall be transferred to the all Ireland Parliament."

A series of bomb outrages committed by the I.R.A. in Belfast and in English cities during the folloning winter and spring aroused anger in England and compelled the Irish government to tighten its control by new legislation against subversive activities. But on April 16, 1939, De Valera announced that in the event of war he would try to maintain and preserve Irish neutrality. The extension of conscription in England raised the question of compulsory military service in Northern Ireland, and on May 2, 1939, De Valera protested against its application there. Two days later Chamberlain announced that Northern Ireland would continue to be exempted from conscription. When war came, De Valera at once announced that Ireland would continue its policy of neutrality. On Sept. 27 Sir John Maffey was appointed to the new position of United Kingdom representative in Eire.

World War II.—During the first phase of relative quiet, the Irish government was concerned chiefly with economic measures to meet the war situation and with the suppression of seditious activities by the I.R.A. In Jan. 1940 power was taken to intern persons suspected of activities against the state. But by May the need for serious national defense became apparent, and weekly conferences were arranged between the government and leaders of Fine Gael and Labour. All parties united in a recruiting rally in Dublin on June 16, and on June 29 Lord Craigavon, in response to urgent messages from Churchill and Franklin D. Roosevelt, promised co-operation with Eire for national defense. But the basis of co-operation was disputed, and De Valera announced on July 5 that Ireland must be both united and neutral. Craigavon then reported to the Northern Ireland parliament that De Valera had refused his offerof joint defense. On Nov. 7 De Valera again asserted that there could be no question of handing over ports in Eire as bases for Britain. His chief preoccupation, since the German occupation of France, had been the possibility of a German air-borne landing in Ireland, and Irish neutrality was jealously preserved to prevent any pretext for such attack. But in Jan. 1941 German bombs and magnetic mines were dropped near Dublin, and De Valera had to protest formally to Berlin. That same month it was made known that nine Irish ships had been sunk since the war began.

On April 13, in a broadcast, De Valera asserted that Eire would defend its neutrality by armed force. But in May the intention to apply conscription in Northern Ireland made him protest again, and on May 27 Churchill announced that it would not be applied. Four days later German bombers did serious damage in Dublin, but regrets and a promise of compensation were forthcoming from Berlin. A new situation arose after the United States entered the war in Dec. 1941; and while De Valera no longer feared invasion by either German or British forces, there was nem pressure from the United States against his neutral policy. On Jan. 27, 1942, he protested strongly against the landing of U.S. troops in Korthern Ireland. declaring that the Irish government had not been consulted; President Roosevelt replied by expressing amazement at the protest. On Feb. 3 De Valera appealed for the enrolment of an Irish army of 250,000 men "to maintain Eire's liberty." But the U.S. forces in Northern Ireland had been rapidly increasing,

and on July 1 it was revealed that the United States had built a powerful naval base, costing several million pounds, at Derry.

Lord Craigavon had died in Nov. 1940 and been succeeded as prime minister of Northern Ireland by J. M. Andrews. Andrews resigned in May 1943, and Sir Basil Brooke replaced him. In June De Valera decided to appeal for a new mandate, and in the general election he lost his former clear majority, returning with only 67 seats. Cosgrave's Fine Gael also lost seats, and Labour came back with 17, while the Farmers and independents together had 22. But De Valera was re-elected prime minister in July, and in November he was still insisting that Eire should remain neutral. In fan. 1944 Cosgrave retired from leadership of the chief opposition party and was replaced by Gen. Richard Mulcahy.

Pressure from the United States increased while preparations for the landings in Normandy were progressing. In March 1944, De Valera rejected a formal request by the United States for the removal of axis consular and diplomatic representatives from Eire "because their presence constituted danger to the lives of American soldiers and the success of Allied military operations." The British government then immediately suspended, for military reasons of paramount importance, all travel between Britain and Eire or Northern Ireland. But De Valera's neutral policy and his firmness in resisting pressures still commanded general support in Eire. A defeat in the *dail* on the Transport bill gave him a pretext for holding another election, and he was returned with 76 seats and a majority of 14 over all other parties. On June 9 he was re-elected prime minister by 81 votes to 37.

His government was thus securely in office during the closing phase of the war. On May 13, 1945, Churchill in his victory broadcast made reference to the difficulties which had resulted from surrender of the Irish ports, and asserted that if necessity had arisen they would have been seized by the British navy. De Valera replied on May 16 with remarkable restraint, declaring that Churchill had, by resisting that temptation, advanced the cause of international morality. With the restoration of peace, Eire quickly attracted an immense number of visitors from England, and relations were entirely friendly. A new president was needed when Douglas Hyde's term expired in June, and Sean T. O'Kelly, one of De Valera's principal ministers, was elected by 565,000 votes to 453,000 for the Fine Gael candidate. In July De Valera declared in the dail that Eire had been in effect a republic since the new constitution became operative in Dec. 1937.

Postwar Prosperity. — In supplying food and other exports to Britain during the war years, Eire had accumulated large sterling assets. The postwar influx of English visitors, who came eager to enjoy the abundant supplies of food, clothing and other rationed goods, added to these favourable balances, and they were further increased by the large number of English people who bought houses and settled for a time in Eire. The country's new prosperity was reflected in the budget of May 1946, which reduced income tax by 1*s*. in the pound. There was a wave of inflation with prices rising fast, while trade required abnormally large purchases to replace stocks and to buy goods which had been unobtainable for years. Tourist development soon became one of the principal sources of income to meet the cost of such necessary imports. In 1947 tourism was estimated to have earned nearly £30,000,000, and forecasts by the travel organizations predicted that Ireland would soon rank next after France and England in tourist earnings. But this sudden influx of visitors, combined with heavy expenditure on capital and consumption goods, was producing serious problems. In Sept. 1947 De Valera went to London for talks on trade and finance with C. R. Attlee and Sir Stafford Cripps. A restless spirit was growing in Ireland, after De Valera had been continuously in office for 1 j years. A new party, Clann na Poblachta, formed by Sean MacBride, appealed specially to the new generation and to those who were tired of the old party rivalries. At two by-elections at the end of 1947 it presented its first candidates and won both seats. De Valera had threatened to appeal to the country if he were defeated, and in Feb. 1948 a new general election resulted in his resignation. His party was still by far the largest in the *dail,* but the other groups combined unexpectedly under a new leader.

Interparty Government. — In the 13th *dail* the number of members had been increased, by a redistribution of seats, from 138 to 147. De Valera refused to enter into any coalition with other parties, though his Fianna Fail had won 68 seats and Mulcahy's Fine Gael had only 31. Labour's forces were split, with 14 seats held for the Labour party led by W. Norton and 5 for National Labour. There were now 13 independents, among whom the ablest figure was James Dillon, who had been the only active advocate of Ireland's participation in the war. MacBride's new party, Clann na Poblachta, had put forward many candidates but won only nine seats. The Farmers' party held seven more. It was obvious that De Valera could easily form a coalition with a few of the smaller groups, but he refused all such approaches. Since Cosgrave's retirement, there had been no Fine Gael leader who commanded general support, and Mulcahy soon agreed to make way for any new leader who did not arouse hostile memories.

Urgent consultations with the independents and with MacBride's party resulted in agreement to combine under a new leader, John A. Costello. He had been attorney general and had close experience of imperial and international conferences, but with a large legal practice he had taken little part in political controversy. The desire for a change of government was especially strong among younger persons, who felt themselves excluded from all opportunity so long as De Valera kept his older colleagues in office. It was agreed quickly that an interparty government should be formed under Costello, without any formal coalition and with each party free to press for its own program. On that basis Costello secured 75 votes, after De Valera's nomination as prime minister had been outvoted, and the interparty ministry took office, with promises of reducing extravagant expenditure.

During the general election there had been little difference between the rival programs except that Costello's Fine Gael had openly declared its support for close relations with the British Commonwealth. MacBride's new party was regarded as the most adventurous, with its demand for a separate Irish currency and for an active policy to end partition. But its conditions for supporting Costello had been simply that MacBride himself should become minister for external affairs and his young colleague Noel Browne should be minister for public health. McGilligan, the ablest survivor of Cosgrave's former team, became finance minister. Dillon, as the most important independent, took charge of agriculture. Norton, the Labour leader, became deputy prime minister. But Costello's inexperience of leadership, which he had never desired, was soon reflected in nervousness about De Valera's intentions for the future. After 1 j years in office he undertook a world tour, and his speeches in the United States, India and Australia suggested that he would revive the fuller demand for national independence and for ending partition. His prestige outside Ireland was so evident that Costello found it advisable to undertake a similar mission overseas, and he accepted an invitation to visit Cahada in August. Until his departure there had been no rumour of any impending constitutional change. But in Montreal on Sept. 1 Costello made his first declaration of his new policy. After reviewing the constitutional developments in Ireland since the treaty of 1921 and the progressive stages of national independence, he claimed that Ireland's sovereignty was no longer in doubt but that the question now arose whether the existing constitution was in a form "compatible with our national sentiment and historical tradition." It was plain that the new government proposed to forestall any intention by De Valera of demanding full independence as a republic.

On Nov. 17 Costello introduced in the dail the Republic of Ireland bill, which proclaimed secession of the 26 Irish counties from the commonwealth and empowered the Irish president to exercise all functions concerning external affairs previously exercised by the British crown. The state was to be the Republic of Ireland, but the name "Eire" or "Ireland" would continue to be used. While the bill was in preparation urgent talks were held on Nov. 15 between Irish ministers and British and commonwealth leaders. MacBride then announced that as from Jan. 1949 there would be in Britain three categories of citizens: British, commnnwealth and Irish. Attlee conferred with Sir Basil Brooke, the Ulster premier,

and insisted that no change affecting the constitutional position of Northern Ireland be made without the consent of its people. Costello in introducing the bill proclaimed that it was "conceived in no spirit of hostility to the British people or the institution of the British Crown." He believed it would produce greater friendship between Great Britain and Ireland. The bill was not opposed at any stage and became law on Dec. 21. De Valera expressed his cordial support, regretting only that effective jurisdiction for the republic over the whole of Ireland could not yet be claimed.

The British government had shown its desire to assist in overcoming difficulties by declaring that Irish nationals would not be regarded as foreigners. But consequential legislation was necessary, and the Northern Ireland ministers pressed for new assurances in London. Brooke held a general election in Northern Ireland on Feb. 10, 1949, which produced an emphatic verdict for retaining the British connection. Labour lost 3 seats, and the Unionists now held 37 out of 52. But MacBride on Feb. 26 asserted again that Eire would not consider joining the North Atlantic treaty unless partition were first abolished. On April 17 the Irish republic was formally proclaimed in the Irish cities, and messages of good will were sent from King George VI and from Pres. Harry S. Truman. But in May Prime Minister Clement Attlee introduced the Ireland bill to provide for consequential changes. It expressly "recognised and declared that the part of Ireland heretofore known as Eire ceased to be part of His Majesty's Dominions" as from April 18, but clause (b) declared "that Northern Ireland remains part of His Majesty's Dominions and of the United Kingdom" and affirmed that "in no event will Northern Ireland or any part thereof cease to be part of His Majesty's Dominions and of the United Kingdom without the consent of the Parliament of Northern Ireland." This clause provoked great indignation in Ireland, as being a claim that the six counties should be permanently excluded from jurisdiction of the Irish parliament; whereas the Government of Ireland act of 1920, as well as the treaty of 1921, had contained provisions for united control. Large public meetings of protest were held in Ireland, and on May 10 the *dail* unanimously voted a resolution by Costello protesting against the Ireland act.

Within its first year Costello's government had thus unexpectedly severed relations with the commonwealth and apparently left less ground than ever for difference among the principal Irish parties. Partition was now the chief outstanding problem, but the cleavage with the Ulster parliament had been deeaened by secession. With no clearly defined program, the interparty government was soon weakened bv the competing claims of its component groups. Public expenditure rose rapidly to meet such demands, and heavy purchases to replace exhausted stocks were depleting the large sterling assets that had been accumulated during World War II. Ireland had obtained inclusion in the benefits of the European Recovery program to assist agricultural production. Dillon's ambitious scheme for land reclamation with U.S. aid promised big results over a long period; but his first success in increasing Irish exports of eggs and butter to England was not maintained when export prices fell, and the cost of imported fertilizers and maize was increased by the sudden devaluation of sterling. Internal discords in the ministry reached a crisis over Noel Browne's plan for free public health services under state control, which was strongly opposed by the Catholic bishops. Costello then repudiated Browne's proposals, and his narrow majority in the *dail* was at once shaken.

The Elections of 1951 and of 1954.—In May 1951 a general election was held, to clear the air. The new *dail* that resulted scarcely differed in composition from the previous one, the interparty groups retaining 78 seats and Fianna Fail gaining one. which brought its total to 69. MacBride's new party, however. had been split by a bitter feud with Browne, and some of the independents withdrew their support from Costello. De Valera then. though still refusing to enter any grouping. won promises of support outside his own party and was elected prime minister by 74 votes against 69. Taking office in June, he declared that the republic would continue to stand aloof from the British Commonwealth and pursue a policy of neutrality. His ministry consisted almost entirely of his former colleagues, with hardly any attempt to enrol younger members; and in April 1954, by which time his party had been defeated in four out of five by-elections since 1952, he decided to dissolve the *dail*. In the ensuing general election (May 1954), only 65 seats went to Fianna Fail. On June 2, therefore, though Fine Gael now had only 50 seats, Costello was elected prime minister by the interparty grouping, which gave him 79 votes against 66.

Raids by the I.R.X. on British military barracks at Armagh and Omagh—in the following year, 1jj. a raid was even made on a barracks in England itself and arms and ammunition were stolen from it—made it necessary for Costello to reaffirm that the final authority of the Irish nation resided in the *dail*.

The new minister of health. while postponing the coming into operation of certain measures of the much-debated Health act passed by the previous government, was able to state that the mortality rate from tuberculosis in 1953 had fallen to 40 per 100.000 of the population, the lowest yet recorded in Ireland and half the 1950 rate.

(D. G.)

POPULATION

In 1961 the population of the Republic of Ireland was 2,814,-703, slightly less than the figure for 1946, which was 2,955,-107. In the intercensal period 1946–51 the number of marriages registered was 79,231, or about j.5 per 1,000 of the population; the number of births was 322,33j, or about 22.2 per 1,000; and the number of deaths was 197,281, or about 13.6 per 1,000. The natural increase in the population was 12 5,054. Net emigration was 119,568, leaving an increase in population of 5,486, the first increase recorded between two census dates since 1841. Between 1900 and 1946 the population had declined by about 8%. A high proportion of the migrants were women; the number of females per 1,000 males of the population was 965 in 1951—one of the lowest ratios in the world.

Until 1930 Irish emigration was directed mainly toward the United States. After that time the flow was mainly to Great Britain. Of those emigrating to Great Britain a considerable number returned home for permanent residence after an absence of a few years. In 1950, 73,000 emigrated to Great Britain, but about 36,000 persons returned home.

The official languages of the republic are Irish (see IRISH LANGUAGE) and English. About one-fifth of the population speaks Irish. the revival of which official policy encourages. The teaching of Irish is an important feature of the educational system. and a knowledge of the language has gradually been made compulsory for most examinations. Despite the efforts made to foster it, however. enthusiasm for the Irish language abated after the achievement of independence from Great Britain.

Religion.—Under article 44 of the constitution. the special position of the Roman Catholic Church was recognized "as the guardian of the Faith professed by the great majority of the citizens"; recognition was also given to the Church of Ireland, the Presbyterian Church, the Methodist Church, the Religious Society of Friends, the Jewish congregations and "the other religious denominations existing in Ireland at the date of coming into operation of the Constitution." "Freedom of conscience and the free profession and practice of religion are, subject to public order and morality, guaranteed to every citizen." The state guaranteed not to endow any religion and not to impose any disabilities or make any discrimination on the ground of religious profession, belief or status. According to the 1946 census the number of persons of each religion in the republic was: Roman Catholics. 2,786,-033; Protestant Episcopalians, 124.829; Presbyterians, 23,870; Methodists, 8,355; Jews. 3,907; Baptists. 462; others. 7,651.

Education. — Elementary education, which is given in national schools, is free. Since 1922 the Irish language has been an essential feature of the curriculum in state-aided schools, and there is insistence on the desirability of teaching classes, so far as is practicable, through the medium of Irish. Attendance at some school is compulsory for children between the ages of 6 and 14 years, and more than 40% of children between 14 and 16 years attend voluntarily. either in elementary or in other schools. The total number of national schools in 1955 was 4,874, as compared with 5,648 in 1925–26. The average number of pupils on the rolls fell from 518,000 in 1925–26 to 490,157 in 1955. The total number of teachers — two-thirds women — varied only slightly after 1925. State expenditure on primary education increased from £3,500,000 in 1925–26 to £8,262,490 in 1954–55.

Secondary education is given in private schools which, in many cases, are conducted by Catholic religious orders. Where state grants are paid, as is the general rule, the schools are open to inspection. In contrast with falling numbers of pupils in elementary schools, the number of pupils attending recognized secondary schools rose from 25,500 in 1925–26 to 56,411 in 1955. There were 458 recognized secondary schools in 1955, in about half of which instruction was either entirely or partly in Irish. State expenditure on secondary education was £1,689,870 in 1954–55.

Vocational schools in cities, towns and some rural areas provide continuation and technical education. They are maintained partly from the rates and partly from state grants. The total expenditure from public funds was £1,016,230 in 1954–55. There were 90,000 students, nearly three-quarters of whom were over 16. Agricultural and veterinary education is provided in institutions managed either by the department of agriculture or by religious orders. Short courses in agricultural instruction are also organized locally by statutory county committees which receive grants from public funds. Higher agricultural education is given by the universities.

The oldest university in Ireland, the University of Dublin (Trinity college), was founded in 1591. The National University of Ireland, founded in 1909, has constituent colleges in Dublin, Cork and Galway and treats St. Patrick's college, Maynooth, as a recognized college. University education is financed partly from state grants.

CONSTITUTION AND GOVERNMENT

Constitution. — The constitution shows three main influences: Irish nationalism; English and Free State parliamentary traditions; and Catholic philosophy.

The preamble of the constitution invokes the Holy Trinity and, acknowledging the dependence of the people of Eire, declares that the purpose of the constitution is the promotion of "the common good, with due observance of prudence, justice and charity, so that the dignity and freedom of the individual may be assured, true social order attained, the unity of our country restored, and concord established with other nations."

The constitution declares Eire to be a democratic state, sovereign and independent. The head of the state is the president (*Uachtaran na hEireann*), who is elected for seven years by the direct vote of all citizens. Nominations are made by members of the *oireachtas* (parliament) or of the county councils. The president appoints the prime minister on the nomination of the *dail,* and on the nomination of the prime minister and with the previous approval of the *dail* he appoints the other members of the government. He signs and promulgates laws. He can refer certain bills to the supreme court to test their constitutionality. He also has power to refer certain bills to a popular referendum upon petition of a prescribed percentage of the *dail* membership. He is supreme commander of the armed forces. The president is advised by a council of state consisting of former presidents, former and incumbent prime ministers and chief justices, as well as of others, some of whom he may name.

The *oireachtas* consists of the president and two houses. The house of representatives *(dail eireann)* consists of 147 members elected by adult suffrage under a system of proportional representation. The government, which consists of from 7 to 15 members, is responsible to the *dail.* The maximum term of the *dail* is seven years. The *dail* alone can initiate money bills, and the *seanad eireann* may only make recommendations on them. *Seanad eireann,* an unsuccessful attempt to create a vocational chamber, is composed of 11 members nominated by the prime minister and 49 members who are elected by the *dail* and the county councils from panels representative of the universities, culture and education, agriculture, labour, industry and public administration and social services. The system of proportional representation is used in the election of a *seanad,* which has to take place within 90 days after a dissolution of the *dail.* The *seanad* cannot veto legislative proposals and has but 90 days for the consideration or amendment of bills passed by the *dail.*

The constitution recognizes the family as the unit of society with rights superior to all positive law. Divorce is practically forbidden. Private property is recognized as a natural right of man, but this and other personal rights may be limited by law out of consideration for the common good. No religious endowment is permitted.

An interesting feature of the constitution is the enumeration of directive principles of social policy. The courts may not take cognizance of them in determining the application of laws. The principles, intended for the guidance of the *oireachtas,* include the right of every citizen to a decent livelihood, the establishment of families in economic security on the land, and the regulation of credit and of the distribution of property in the interests of the common good.

For the first three years after its establishment the constitution was amendable by ordinary legislation. Thereafter a popular referendum was necessary.

External Relations. — An important change affecting the relations of the Free State with the Commonwealth of Nations occurred when Edward VIII abdicated on Dec. 11, 1936. An act was passed to remove from the constitution all reference to the king and to abolish the office of governor general. The Executive Authority (External Relations) act of Dec. 11, 1936, accepted the abdication of Edward VIII. It also provided that executive authority. which it vested in the Free State executive council, could, in certain circumstances, be exercised for the appointment of diplomatic representatives and conclusion of international agreements by the king. The king had ceased to be head of the state, but, by virtue of his recognition as the hereditary symbol of commonwealth co-operation, he might, on the advice of the Free State executive council, exercise certain powers concerning external relations. The new constitution enacted in 1937 did not alter the operation of these provisions. Diplomatic representatives continued to be appointed by the king when advised by the Irish government, and the credentials of foreign diplomatists accredited to Ireland were addressed to the king.

The Executive Authority (External Relations) act, 1936, was repealed by the Costello government in 1948 when the Republic of Ireland act was passed. Under this act the exercise of executive powers concerning external relations was transferred to the president acting on the advice of the government. The description of the state was declared to be the Republic of Ireland, but in accordance with the constitution, which was not affected by the act, the name of the state remained Ireland. The aim of the act was to clarify the constitutional position and to terminate association with the commonwealth. This aim was accepted by the commonwealth countries. The Ireland act, 1949, which was enacted by the British parliament, declared that from April 18, 1949, the state had ceased to be a British dominion; it did not, however, become a foreign country so far as British statutes were concerned, and its citizens did not become aliens in Great Britain. Australia: New Zealand, South Africa, Canada and Southern Rhodesia adopted legislation declaring Irish citizens to have the same rights and obligations as their own citizens.

Judiciary. — Judges are appointed by the president on the advice of the government; they retire on pension at the age of 70. They are independent of the executive in the exercise of their judicial functions and are subject only to the constitution and the law.

There are four courts: the district court has civil jurisdiction

up to £25 and minor criminal jurisdiction; the circuit court has civil jurisdiction up to £300 and extended criminal jurisdiction, and acts as a court of appeal for the district court; the high court has unlimited juriidiction in civil and criminal cases and acts as a court of appeal for the circuit court; the supreme court acts as a court of appeal for the high court.

Defense. — The supreme command of the defense forces is vested in the president. The minister of defense is assisted by a council of defense consisting of the minister, his parliamentary secretary, the chief of staff, the adjutant general, the quartermaster general and the permanent secretary of the department of defense. The establishment provides for a permanent force of just under 13,000 officers and men, including the air corps and naval services. The number in the reserve (first and second line) in 1955 was 23,714. The first-line reserve is composed of officers and men who have already been trained during service in the permanent force. There is no compulsory military service. Minimum service is two years' permanent enlistment and six years in the reserve. Expenditure on defense was estimated at £7,114,230 for 1955–56.

Social Services. — The comprehensive organization of social services began with the Irish Poor Relief act of *1838,* which divided the country into poor law unions and created the workhouse system of relief. In 1923 home assistance was substituted for workhouse relief. In *1851* free medical attendance became available for the sick poor in their homes or in dispensaries. Health services are organized and directed by county medical officers. Public hospitals provide treatment free or at a charge graduated according to means. and proposals were introduced in 1952 for the improvement and extension of state-sponsored health services generally. For tuberculosis and some other diseases examination and treatment are free, and cash allowances are paid, in certain circumstances, to patients who are prevented by their illness from providing for their own maintenance and that of their dependents.

Income-maintenance social services, administered by a department of social welfare, include unemployment insurance and assistance, national health insurance, contributory and noncontributory pensions for widows and orphans, children's allowances and noncontributory old-age and blind pensions. Unemployment and national health insurance is compulsory for specified insurable occupational groups, and contributions are payable by workers, employers and the state. Manual workers in the building trade may be insured against loss of employment resulting from bad weather.

Grants are paid by the state to local authorities. public utilities and private persons for building and reconstructing houses. In 1954, 10,490 houses were built and reconstructed under state-aided schemes, and for 1955–56 the estimate for state grants was £2,250,-*000.*

ECONOMICS

Agriculture. — The total acreage under crops in 1954 was 3,686,456; this included *1,872,266* ac. under hay, 1,187,296 ac. under cereal crops and *607.169* ac. under root and green crops. The acreage under fruit was *11,*698.

The total acreage of plowed land rose from 1,492,000 in 1939 to 2,567,000 in 1944, during a period nhen wartime regulations for compulsory tillage were in force. From 1944 to 1954 there was a decline of more than 30% in the area of plowed land, but it still remained somewhat greater than it had been in 1939. The wartime increase in tillage was the result mainly of a temporary expansion of the acreage under wheat and oats.

After 1932, when the acreage of wheat was only 21,000 government policy encouraged the growing of wheat. Acreage began to expand after 1933 when legislation was enacted to permit the payment of bounties on home-grown wheat and the imposition of restrictions on imported wheat and on certain feeding stuffs. By 1939 the acreage had increased to 255,000; it reached a peak of 662,000 in 1945 but fell to 358,006 in 1955.

Tillage has in general played a comparatively unimportant part in the Irish agricultural economy. As a result mainly of increasing foreign competition in grain in the last decades of the 19th century, the farming system gradually changed to stock raising. Between *1861* and 1955 the number of cattle increased from *2,802,715* to 4,455,600. The Irish system of animal husbandry is based on grass; the decline in cereal and other tilled areas was accompanied therefore by an increase in hay and pasture areas. In 1953 almost 58% of the total land area was used for pasture and hay; crops, flax and fruit accounted for more than 10% of the total area.

There were 379,317 agricultural holdings in the republic in 1953. Of those, 64,041 were less than 1 ac.; *171,444* were more than *1* ac. and less than 30 ac.; *136,669* were more than *30* ac. and less than *200* ac. Holdings varied greatly in size, but the average nas about 30 ac. Holdings of betneen 15 ac. and 100 ac. constituted the mainstay of the country, and (leaving out of account those of less than 5 ac.) 207,850 holdings or nearly 55% of the total were under 50 ac. in 1953. There were *52.036* holdings between 50 ac. and 100 ac., and only *7,163* over 200 ac. of which not more than about *1,*500 were over 500 ac.

The principal crops grown in the republic are oats, wheat, potatoes, turnips and barley. Sugar beet was the only new crop introduced after the establishment of the state in 1922 and the Beet Sugar (Subsidy) act, 1925, marked the beginning of an important state-sponsored industry. The first sugar factory was opened in Carlow in *1926;* three additional factories were erected in 1934 at Mallow, Thurles and Tuam. The Irish Sugar company operating these factories became outstandingly successful, producing sugar at less than world prices and fostering agriculture by extending credit to farmers for seeds, fertilizers and machinery.

Following recommendations of the agricultural commission of 1923, legislation was enacted for the improvement of livestock breeding, the establishment of high standards in the production and marketing of creamery butter and for the testing, grading and marketing of eggs. As part of a general rationalizatiori of the dairy industry the majority of privately owned creameries were purchased by the state and transferred to co-operative societies. In 1930, when as a result of the world agricultural depression the prices of dairy produce fell sharply, a duty of fourpence per pound was imposed on imported butter. Previously, it had been the custom to export the surplus of Irish dairy produce of the summer months and to import butter to meet home requirements in late winter and spring. After 1930 the export of Irish butter declined; by 1950 home-produced butter was held in cold storage to meet winter requirements; in 1954 a surplus of butter was available for export.

The compulsory licensing of bulls, and other government schemes for providing premium bulls and boars and for subsidizing the purchase of pedigree rams, substantially raised the quality of the country's livestock. The cattle-export trade consists of fat cattle and of store cattle exported on sale and fattened abroad.

The government established an agricultural credit corporation to provide long-term loans for farmers and to co-ordinate the activities of local co-operative credit societies. Despite the existence of these credit facilities, agricultural capitalization in the republic remained extremely low, with considerable scope for further agricultural investment. In 1937, out of approximately *202,000* agricultural holdings in Denmark (a country often contrasted with the Republic of Ireland), only about 7,400 holdings were free from debt; on the average, a debt of more than £25 *10s.* had been incurred per each cultivated Danish acre. Debt per cultivated Irish acre in 1937 was slightly more than £3 *10s.,* indicating the low level of agricultural capitalization in the republic rather than freedom from the necessity to borrow.

In 1949 a land rehabilitation project was introduced which had as its aim the investment of £40,000,000 in agriculture over a period of ten years. This was the most ambitious scheme yet undertaken for the improvement of agriculture, and there was a reasonable hope that it might make a permanent contribution to the reconstruction of an industry which for more than a century had not made the progress which the natural resources of the country would seem to warrant. In the 19th century the capital of the country was drained away and utilized elsewhere, while the Irish farmer was offered little incentive to improve his holding.

After 1850 efforts were made to improve the arterial drainage of Ireland, but financial, legislative and social restrictions prevented the work from being effectively done until the enactment in

1945 of the Arterial Drainage act, which enabled operations to be undertaken on a broad basis. This measure made possible a great advance toward using the full productive capacity of the land.

Land Purchase.—Between 1870 and 1919 a series of ameliorative land acts was adopted by the British parliament as part of a program of agrarian reform for Ireland. The acts of 1870 and 1881, while mainly concerned with remedying defects in the relation between landlord and tenant, were also designed to achieve an alternative solution to the land problem by enabling occupiers to acquire by agreement the superior interests in their holdings with the aid of funds lent by the state. Subsequent acts extended these facilities of purchase. The Wyndham act of 1903 was of particular importance because it was aimed at the purchase of estates rather than of individual holdings, and it greatly cheapened and facilitated legal procedure. The total amount of the purchase money for which advances were made under the land purchase acts of 1870–1919 in respect of lands in the republic was just £100,000,000; 316,395 holdings amounting to a total area of 11,304,668 ac. were affected by these transactions.

The comprehensive Land act of 1923, one of the first important economic measures adopted by the native legislature on the attainment of self-government, aimed at completing land purchase and relieving congestion. It provided that holdings in any part of the state in which a dual interest of landlord and tenant still existed should be transferred to the Irish Land commission and then become the property of the tenants, subject to the payment of specified annuities toward the compensation of the former landlords. A system of standard prices was prescribed; in addition, the state provided the vendor of the land with a contribution equal to 10% of the standard price as well as an amount in respect of legal costs. The price, including the state contribution, was payable in 43% land bonds guaranteed by the state and by the British government. Advances made to purchasers were to be repaid by an annuity at the rate of 4¾% of the amount advanced. The price to be paid was equal to about 15 years' purchase of the value of the holding. Wide powers were given the Land commission to acquire untenanted land for the creation of holdings in relief of congestion, and to consolidate and exchange holdings for the same purpose. The purchase price for untenanted land was payable as in the case of tenanted land in guaranteed 4½% land bonds, but no state contribution was given. Untenanted land, unlike tenanted land, is, for the most part, land on which only one interest subsists, that of its landlord or proprietor.

Later land acts were directed mainly at increasing the powers of the Land commission for the acquisition of land, for the relief of congestion and for the division of that land among unemployed agricultural workers, former evicted tenants and other suitable persons. The act of 1933 reduced, by at least half, the amount of the land purchase annuities payable by farmers. It also gave substantial concessions in regard to arrears of annuities.

The annuities arising under the land acts before 1923 formed an important element in the financial relations between the republic and Great Britain. Until 1931 the Irish government made payment in respect of these land annuities to the British government. The principal item consisted of annuities amounting to about £3,000,000 a year, payable by Irish tenant purchasers in respect of advances made by the British government under the land acts of 1891–1919. Until 1932 the Irish government had accepted responsibility for the collection of these annuities from the tenant purchasers and for their transmission to the British government. In 1932 Eamon de Valera's government disclaimed liability for all but a small part of these payments; thenceforward they became payable as revenue to the Irish exchequer; they were later halved under the act of 1933. Other payments which had previously been made to the British government were also discontinued in 1932; the total of all the intergovernmental payments terminated at that time amounted to about £5,000,000 a year. The withholding of the payments marked the beginning of an economic dispute between the two countries which continued for six years. In an effort to recoup the amounts involved, the British government imposed tariffs on agricultural products imported from Ireland and also restricted by means of quotas imports of Irish cattle. The dispute, which caused widespread economic and social distress in Ireland, was ended in 1938 when the two governments negotiated a comprehensive trade agreement, all outstanding Irish financial liabilities being settled by a capital payment of £10,000,000. The question of long-term prices for Irish agricultural exports as well as other matters relating to postwar trade between the two countries was dealt with in the Anglo-Irish trade agreement of July 1948.

In the 1950s the division and resettlement work of the Land commission was still continuing, but the growing need for mechanization of farm operations as a means of increasing output seemed to set definite limits to further extensive division of land. There is no doubt, however, that the program of agrarian reform introduced in 1870 had brought very great benefits to Ireland.

Occupiers of the land had become full owners of their holdings on the payment of terminable annuities representing much less than the rents which their forbears were willing to pay when the principle of a fair rent was first recognized in the second half of the 19th century. Between 1923 and 1953 the Irish government advanced about £40,000,000 for land purchase and for the division of untenanted land.

***TABLE** I.—Land **Use**, 1930 and 1955*

(In acres)

Item	1930	1955
Crops		
Wheat	26,740	357,300
Oats	643,910	548,700
Barley	116,195	210,200

Industry.—The lack of satisfactory deposits of coal or other minerals precluded the growth of heavy manufacturing industries in the Republic of Ireland, but an extensive system of light industries assumed considerable importance. The separation of the six partitioned northern counties from the republic further accentuated the predominance of agriculture in the south of what had always been an overwhelmingly agricultural country. Nevertheless, certain long-established and world-renowned manufacturing industries existed in 1922. These consisted mainly of brewing, distilling, biscuit making, poplin weaving and bacon curing; all had roots deep in the economy, and most of them commanded a valuable export trade.

The widespread poverty of the country in the 19th century prevented Ireland from availing itself of the great technical advances which had taken place in Great Britain. Moreover, the Act of Union of 1801 denied Irish industries the benefits of protection after 1825, and many enterprises foundered as a result of foreign competition. The revival of native manufacturing industries became a foremost part of the policies of the Irish nationalist movement, and successive native governments after 1922 sponsored policies for the extension of industrialization with a view to effecting a better economic balance between agricultural and manufacturing enterprise. The doctrine that protection was necessary to encourage the revival and expansion of industry was widely propounded and fairly generally accepted. It was, however, more critically applied by W. T. Cosgrave's government than by subsequent governments. In the budget of 1924 protective duties were imposed experimentally on five classes of goods, and in 1925 three additional categories of duties were introduced. The government indicated that it had adopted no doctrinaire attitude on the merits of either free trade or protection; the matter was regarded as one of expediency which might be variously decided in different circumstances. The Tariff Commission act of 1926 inaugurated a cautious regime of "selective protection." Each proposal for a protective tariff was examined solely on its economic merits. Of 15 applications considered between 1926 and 1933, recommenda-

tions in favour of protective duties were made in 12 cases. In 1934 the Tariff Commission act was repealed De Valera's government, which had been elected to office in 1932, was pledged to a policy of protection for relieving unemployment and developing the resources of the country. A more extensive form of protection was therefore adopted; any interests prepared to establish a new industry or to extend an existing one could apply for the imposition of the duties necessary to afford protection. As a result foreign competition was in many cases either eliminated or modified. Legislation was introduced in 1934 to permit the quantitative regulation of imports by means of quotas, and a substantial range of imported industrial goods was affected. The importation of wheat, uheaten flour, maize, maize products and a wide range of other feeding stuffs was prohibited.

There had been two phases, therefore, in industrial policy up to 1939. Until 1932 policy had been determined mainly by the consideration that industrial protection even when desirable tended to increase the costs and so to impair the profitableness of the country's principal industry — agriculture. After 1932 the advancement of industrialization for social as well as purely economic reasons became the most significant determinant of policy. Each phase, however. made notable contributions to the development of the country. Despite the world depression of the 1930s and the six-year economic dispute uith Great Britain, industrial development continued at an increasing pace until the outbreak of World War II.

From 1922 until 1939 most progress was made in industries producing consumer goods, which previously had had to be imported. boots, shoes, paper, hosiery, linen and cotton goods and clothing. The important primary industries for beet sugar and cement production were also established.

Industrial progress was sharply arrested by the mar, particularly in enterprises nhich relied on imports for raw materials and fuel. Recovery was effected with remarkable rapidity, however, when the war ended. Between 1946 and 1950 the volume of industrial production increased by well over half, and the number of persons employed in all industries (except agriculture) increased from 167,000 to 220.000. These developments were marked by increasing awareness of the need for greater industrial efficiency and by groning interest in the use of opportunities for securing higher standards of industrial management. It was becoming recognized that the growth of industrial activity depended on the development of a substantial export trade to competitive markets and that there were limits to the toleration by domestic consumers of the protective measures which had fostered industries during their infancy. This new attitude toward the future of mdnufacturing industry found expression in the founding in Dec. 1952 of a management institute supported by industrialists generally and by the universities and encouraged by the minister for industry and commerce.

Specialist institutions were set up by the state to assist the promotion of manufacturing industry by private enterprise. The capital for this purpose is, as a rule, provided by private and institutional investors, but powerful assistance to industrial development has been given by the Industrial Credit Company. Ltd., created by the government in 1933 as a channel for directing domestic saving into Irish industrial enterprise. The company. acting as a general industrial finance house, was emponered to sponsor public issues, including governmental and corporation issues. A certain amount of the capital required for industry has come from foreign sources, but the Control of Manufactures acts precluded the external investment in a new project for a manufacturing industry of more than 49% of the share capital or of more than one-third of the amount involved in any class of share which directly or contingently carried voting rights. Certain kinds of enterprise exempt from this control were covered by separate legislation.

An institute of industrial research and standards makes scientific information available, and an industrial development authority advises the minister for industry and commerce on the establishment of industries of a kind not already in existence. Another state-sponsored body, Coras Trachtala Teoranta, fosters the development of industrial exports, mainly to hard-currency areas. undertakes market research abroad and investigates industrial export potential generally.

TABLE II.—*Industrial Employment and Production*
(1938=100)

Year	Average number of persons employed	Index of industrial production
1938	166,000	100
1948	198,000	128.6
1954	228,000	18j.j

Of the working population of the republic slightly more than 20% is engaged in industries other than agriculture. Despite the fact that agriculture is the predominant industry, this percentage is low; the republic in the 1950s was not even moderdtely industrialized by contemporary European standards. There nas. nevertheless, a very much greater diversity of economic activity than there was in 1922.

The trend of industrial employment and production in all industries (except agriculture) and services is indicated in Table II.

Trade and the Balance **of** Payments. — International trade has always been of great importance to the republic because of its size and 'geographical position and because of the nature of its economy. In 1950, for example, exports and imports totalled £232,000,000, or about £77 per head of population. as compared with about £80 for Great Britain, one of the greatest trading nations in the world. Traditionally the republic's imports of goods exceed its exports, the deficit being financed by substantial earnings on invisible account, mainly tourist income. emigrants' remittances and income from foreign investment. After 1947 these deficits

†After reckoning "invisible" payments and earnings.

were also financed by capital imports. the proceeds of aid under the European Recovery program and drawings on external assets accumulated mainly during World Wars I and II nhen the volume of imports was reduced and the volume of exports maintained.

Power and Fuel. — A notable stimulus to industrial advance was provided by a scheme of hydroelectric development begun in 1925 with the harnessing of the river Shannon. Later the Liffey and the Erne rivers were also harnessed. Two peat-burning generators, one at Portarlington and one at Allenwood, were built, and there are two stations in Dublin. one coal-burning and the other oil-burning. The total installed capacity of generating plant by 1952 was 308,000 kw., and additional generators then under construction were expected to raise this total capacity to 609 500 k ~ $ In 1952 the capacities of hydro and steam plant were about equal. but it nas expected that when the construction program was completed the capacity of hydro plant would represent only 35% of the total.

Under the Electricity Supply act of 1927 a public corporation, the Electricity Supply board, was established and by 1953 it controlled practically the complete generation, transmission. distribution and sale of electricity in the republic. The capital requirements of the corporation are provided by the state. Existing legislation in 1952 provided for a total investment of about £73,000,000. These advances are repaid to the state over a period of 50 years; interest is also paid on advances and normal provision is made for depreciation. in 1926–27 electrical output was about 50,000,000 units (kw.hr.); in 1951–52 output had risen to 1,033,000,000 units (kw.hr.), a twentyfold increase in a quarter of a century. In 1951–52 production per head of population nas 34j units (kw hr.). nhich was low compared with other small agricultural countries in Europe; the corresponding figures for Denmark and the Netherlands, respectively, were 590 units and 735 units.

Industrial consumption accounted for about one-third of total Irish output.

In 1934 a state company was set up to develop the country's peat bogs by modern mechanical methods. Peat which is cut and harvested mechanically is a clean and efficient fuel. It is produced either in the form of "sods," containing about 30% moisture, or in the form of briquettes, which consist of milled peat taken off the surface of the bog at 55% moisture and artificially dried before being briquetted with 12% moisture. As already indicated peat is also used for generating electricity in stations built on the bogs. Every county in the republic has its bogs, but the principal areas extend across the middle of the country from the borders of Dublin westward to the Atlantic. In addition to mechanically produced peat, a great quantity of the fuel is harvested by hand, mainly by farmers on their own turbaries for their own use; in 1950 about 2,400,000 tons were produced.

Communications. — Under the Railways act of 1924, 26 separate and distinct railway companies were amalgamated, and in Jan. 1925 the Great Southern Railway company came into being. The peak of Irish railway prosperity had been reached during World War I. After 1918 the beginning of competition from road transport introduced the railway system to financial and economic problems which rapidly grew in magnitude. In 1927 the Railways (Road Motor Services) act authorized the railways to operate road services either directly or through their agents. The position of the Great Southern Railway company continued to deteriorate, however, and further financial reconstructions led eventually to nationalization. In 1944 legislation was enacted to secure the amalgamation of the company's services with those of the Dublin United Transport company, which had been successfully operating the city's omnibus and tramway services. Despite this move the financial problems of the public transport system persisted, and on June 1, 1950, the undertakings which had been created under the act of 1944 were merged with those of the former Grand Canal company in a newly constituted board of Coras Iompair Eireann. Extensive modernization of the railways followed, but continued and growing competition from private road vehicles left the public transport service generally in a precarious condition, and the future structure of the system remained uncertain. In 1953 there were 108.805 private motorcars and 33,196 commercial goods vehicles licensed in the republic; the corresponding figures for 1930 had been 32,632 and 7,695, respectively.

To help to maintain essential supplies during World War II a statutory company, Irish Shipping, Ltd., was set up on the initiative of the government, and its ships sail under the Irish flag to Baltic, North American and other ports.

In 1936 the state sponsored the formation of a commercial air transport service by the establishment of Aer Lingus Teoranta. That company developed air transport extensively and maintained high standards of safety, efficiency and reliability. It operates direct air services to London, Paris, Amsterdam, Jersey, Glasgow, Manchester, Liverpool, Lourdes, Biarritz and Barcelona from Dublin airport. The airport at Rineanna, County Clare—Shannon airport—is regarded as one of the safest in the world; it provides excellent facilities for the Atlantic air routes and those to Great Britain and the continent and achieved a foremost position in international air navigation. There is a daily service to and from Dublin. Seven private aerodromes are also licensed.

National Income. — The estimated national income was £147,000,000 in 1926, £151,900,000 in 1938, £302,100,000 in 1947, £347,000,000 in 1950 and £448,000,000 in 1954. These figures, representing current prices, take no account of changes in the value of money, but if related to the price index for personal expenditure on goods and services, they indicate the following approximate variations in real national income: (1) an increase of about 14% between 1926 and 1938; and (2) an increase of about 25% between 1938 and 1954, most of which took place between 1945 and 1954. In 1938 agriculture contributed 23½% of the national income; in 1954 its contribution was 30.6%.

The nonagricultural sector of the economy contributed 69% of national income in 1938 and 63% in 1954; a considerable part of the increase in this sector was the result of state capital expenditure, particularly on housing construction.

Banking and Finance. — The republic has its own paper and metallic currency. The currency unit is the Irish pound, with the same value as the pound sterling. The principal circulating medium is the legal tender note convertible into British legal tender at the Bank of England. The total monetary circulation in March 1955 was £77,990,797; in March 1939 it had been 617,605,098 and in March 1952, £62,789,224.

Under the Central Bank act, 1942, eight associated commercial banks operate in the republic. The total of their current and deposit accounts in March 1951 was £260,200,000 and £298,200,000 in March 1955. The net surplus of the foreign assets of the associated banks over their foreign liabilities was £120,500,000 in March 1955.

The total revenue received into the exchequer increased from £39,782,000 in 1942–43 to £83,905,310 in 1951–52. In 1954–55 current revenue amounted to £106,700,000 and net borrowings, etc., to £32,700,000. Total current expenditure out of the exchequer in 1954–55 amounted to £105,400,000 in respect to supply services, but £14,700,000 of this amount represented expenditure on capital services.

Net exchequer borrowings were £21,800,000 in 1950–51, £38,800,000 in 1951–52 and £32,100,000 in 1954–5j. These borrowings were derived partly from current savings of the public, partly from the sale of foreign securities held by state funds and, particularly in 1950 and 1951, from the Irish currency counterpart of European Recovery program funds. The national debt of the republic increased steadily after World War II; most of it is held internally, and the main external liability is a loan of $128,200,000, obtained under the European Recovery program. Between March 1948 and March 1952 total state debt increased from £100,000,000 to £192,000,000. The budget of 1952 raised the standard rate of income tax by 1*s.* to 7*s.*6*d.* in the pound, subsidies on butter, tea and sugar were withdrawn, the flour subsidy was reduced and additional indirect taxation was imposed on tobacco, beer, spirits and oils. These measures were designed to achieve a balance between revenue and current outgoings and to provide for some additional expenditure on current social, health, educational and defense services.

The principal aim of the budget of 1952 was to "restore order in the public finances." It had been hoped to achieve a balance in the exchequer accounts, but the actual out-turn showed a deficit of more than £2,000,000. The budget was more successful economically than financially: domestic consumption was reduced; the demand for imports was abated; and the deficit in the balance of payments fell from £61,000,000 in 1951 to £9,000,000 in 1953. Current revenue amounted to £95,900,000 (an increase of £12,000,000 over that of the previous year). Current expenditure amounted to £98,000,000 (an increase of £7,400,000). Capital issues, financed from borrowing, amounted to £32,900,000; the ultimate sources of these borrowings were: national loan, £20,000,000; small savings and investment income of departmental funds, £5,900,000; sales of foreign investments, £4,500,000; and bank advances £2,500,000 (net).

The 1955 budget provided for certain tax reliefs and increased social services but the standard rate of income tax remained at 7*s.*6*d.* in the pound. The budget provided for capital outlay estimated at £34,000,000 to be financed from borrowing. Housing expenditure constituted more than a quarter of the total; £4,670,000 was provided for agricultural development, £4,000,000 for electrical projects and £3,120,000 for transport.

In March 1955 the gross liabilities of the state amounted to £331,000,000. Assets held against these liabilities amounted to £181,000,000. The charge for debt service (interest and sinking fund) was £15,000,000.

IRENAEUS (b. *c.* 130), bishop of Lyons at the end of the 2nd century, was one of the most distinguished theologians of the ante-Nicene Church. Very little is known of his early history. His childhood was spent in Asia Minor, probably at or near Smyrna; for he says (*Adv. haer.* iii. 3, 4, and Euseb. *Hist. Eccl.* v. 20) that as a child he heard the preaching of Polycarp, the aged bishop of Smyrna (d. 156). He can hardly have been born very long after 130, for later on he frequently mentions having met certain Christian presbyters who had actually seen John, the disciple of our Lord. At the time of the persecution of the Gallic Church under Marcus Aurelius (177) he was a presbyter of the church at Lyons. In 177 or 178 he went to Rome on a mission from this church, to make representations to Bishop Eleutherius in favour of a more lenient treatment of the Montanists. (*See* MONTANISM; Eus. v. 4. 2.)

On his return to Lyons Irenaeus was called upon to replace Bishop Pothinus, who had perished in the persecution (Eus. v. 5. 8). As bishop he carried on a great and fruitful work. Though the statement of Gregory of Tours (*Hist. Franc.* i. 29), that within a short time he succeeded in converting all Lyons to Christianity, is probably exaggerated, from him at any rate dates the wide spread of Christianity in Lyons and its neighbourhood. He sought to reconcile the numerous sects which menaced the existence of the church. In the dispute on the question of Easter, he endeavoured to effect a compromise, and in particular to exercise a moderating influence on Victor, the bishop of Rome, and his unyielding attitude towards the dissentient churches of Africa, thus justifying his name of "peace-maker" (Eirenaios) (Eus. H.E. v. 24. 28). The date of his death is unknown. His martyrdom under Septimius Severus is related by Gregory of Tours, but by no earlier writer.

The chief work of Irenaeus, written about 180, is his "Refutation and Overthrow of Gnosis, falsely so called" (usually indicated by the name *Against the Heresies).* Of the Greek original of this work only fragments survive; it only exists in full in an old Latin translation. The treatise is divided into five books: of these the first two contain a description and criticism of the tenets of various heretical sects, especially the Valentinians; the other three set forth the true doctrines of Christianity. His work is the first systematic exposition of Catholic belief. The foundation upon which Irenaeus bases his system consists in the episcopate, the canon of the Old and New Testaments, and the rule of faith. With their assistance he sets forth and upholds, in opposition to the gnostic dualism, *i.e.,* the severing of the natural and the supernatural, the Catholic monism, *i.e.,* the unity of the life of faith as willed by God. The "grace of truth" (the *charisma),* which the apostles had called down upon their first disciples by prayer and laying-on of hands, and which was to be imparted anew by way of succession (διαδοχή, *successio*) to the bishops from generation to generation without a break, makes those who receive it living witnesses of the salvation offered to the faithful by written and spoken tradition. The Scriptures of the Old and New Testaments, rightly expounded by the church alone, give us an insight into God's plan of salvation for mankind, and explain to us the covenant which He made on various occasions (Moses and Christ; or Noah, Abraham, Moses and Christ). Finally, the "rule of faith" (*regula fidei*), received at baptism, contains in itself all the riches of Christian truth.

This exposition by Irenaeus of the divine economy and the incarnation was taken as a criterion by later theologians, especially in the Greek Church. (*Cf.* Athanasius, Gregory of Nyssa, Cyril of Alexandria, John of Damascus.) He himself was especially influenced by St. John and St. Paul. Before him the Fourth Gospel did not seem to exist for the Church; Irenaeus made it a living force. His conception of the Logos is not that of the philosophers and apologists; he looks upon the Logos not as the "reason" of God, but as the "voice" with which the Father speaks in the revelation to mankind, as did the writer of the Fourth Gospel. And the Pauline epistles are adopted almost bodily by Irenaeus, according to the ideas contained in them; his expositions often present the appearance of a patchwork of St. Paul's ideas. Certainly, it is only one side of Paul's thought that he displays to us. The great conceptions of justification and atonement are hardly ever touched by Irenaeus.

Till recent times whatever other writings and letters of Irenaeus are mentioned by Eusebius appeared to be lost, with the exception of a fragment here or there. Two Armenian scholars, Karapet Ter-Mĕkĕrttschian and Erwand Ter-Minassianz, published from an Armenian translation a German edition (Leipzig, 1907; minor edition 1908) of the work "in proof of the apostolic teaching" mentioned by Eusebius (*H.E.* v. 26). This work, which is in the form of a dialogue with one Marcianus, otherwise unknown to us, contains a statement of the fundamental truths of Christianity. It is the oldest catechism extant, and an excellent example of how Bishop Irenaeus was able not only to defend Christianity as a theologian and expound it theoretically, but also to preach it to laymen.

BIBLIOGRAPHY.—The edition of the Benedictine R. Massuet (Paris, 1710 and 1734, reprinted in Migne, *Cursus patrologiae,* Series Graeca, vol. v., Paris, 1857) long continued to be the standard one, till it was superseded by the editions of Adolph Stieren (2 vols., Leipzig, 1848–53) and of W. Wigan Harvey (2 vols, Cambridge, 1857), the latter being the only edition which contains the Syriac fragments. For an English translation *see* the *Ante-Nicene Library.* Of modern monographs consult H. Ziegler, *Irenaeus, der Bischof von Lyon* (1871); Friedrich Loofs, *Irenäus-Handschriften* (Leipzig, 1888); Johannes Werner, *Der Paulinismus des Irenaeus* (Leipzig, 1889); Johannes Kunze, *Die Gotteslehre des Irenaeus* (Leipzig, 1891); Ernst Klebba, *Die Anthropologie des heiligen Irenaeus* (Münster, 1894); Albert Dufourcq, *Saint Irénée* (Paris, 1904); Franz Stoll, *Die Lehre des heil. IRENE, the name of several Byzantine empresses.

1. IRENE (752–803), the wife of Leo IV., East Roman emperor. Originally a poor but beautiful Athenian orphan, she speedily gained the love and confidence of her feeble husband, and at his death in 780 was left by him sole guardian of the empire and of their ten-year-old son Constantine VI. Seizing the supreme power in the name of the latter, Irene ruled the empire at her own discretion for ten years, displaying great firmness and sagacity in her government. Her most notable act was the restoration of the orthodox image-worship, a policy which she always had secretly favoured, though compelled to abjure it in her husband's lifetime. Having elected Tarasius, one of her partisans, to the patriarchate (784), she summoned two church councils. The first, held in 786 at Constantinople, was frustrated by the opposition of the soldiers. The second, convened at Kicaea in 787, revived the adoration of images and reunited the Eastern church with that of Rome.

As Constantine approached maturity he began to grow restive under her autocratic sway. An attempt to free himself by force was met and crushed by the empress, who demanded that the oath of fidelity should thenceforward be taken in her name alone. The discontent which this occasioned swelled in 790 into open resistance, and the soldiers, headed by the Armenian guard, formally proclaimed Constantine VI. as the sole ruler. A hollow semblance of friendship was maintained between Constantine and Irene, whose title of empress was confirmed in 792; but the rival factions remained, and Irene, by skilful intrigues with the bishops and courtiers, organized a powerful conspiracy on her own behalf. Constantine could only flee for aid to the provinces, but even there he was surrounded by participants in the plot. Seized by his

attendants on the Asiatic shore of the Bosporus, the emperor was carried back to the palace at Constantinople; and there, by the orders of his mother, his eyes were stabbed out.

Irene reigned in prosperity and splendour for five years. She is said to have endeavoured to negotiate a marriage between herself and Charlemagne; but according to Theophanes, who alone mentions it, the scheme was frustrated by Aetius, one of her favourites. A projected alliance between Constantine and Charlemagne's daughter, Rothrude, was in turn broken off by Irene. In 802 the patricians, upon whom she had lavished every honour and favour, conspired against her, and placed on the throne Nicephorus, the minister of finance. The haughty and unscrupulous princess, "who never lost sight of political power in the height of her religious zeal," was exiled to Lesbos and forced to support herself by spinning. She died the following year. Her zeal in restoring images and monasteries has given her a place among the saints of the Greek church.

2. IRENE [DUCAS] (c. 1066–*c.* 1120), the wife of Alexius I. The best-known fact of her life is the unsuccessful intrigue by which she endeavoured to divert the succession from her son John to Nicephorus Bryennius, the husband of her daughter Anna. Having failed to persuade Alexius, or, upon his death, to carry out a *coup d'état* with the help of the palace guards, she retired to a nunnery and ended her life in obscurity.

3. IRENE (d. 1161), the first wife of Manuel Comnenus. She was the daughter of the count of Sulzbach, and sister-in-law of the Roman emperor Conrad III., who arranged her betrothal. The marriage was celebrated at Constantinople in 1146. The new empress, who had exchanged her earlier name of Bertha for one more familiar to the Greeks, became a devoted wife, and by the simplicity of her manner contrasted favourably with most Byzantine queens of the age.

H. v. Kap-Herr, *Die abendlandische Politik des Kaisers Manuel* (Strasbourg, 1881).

IRETON, HENRY (1611–1651), English parliamentary general, eldest son of German Ireton of Attenborough, Nottinghamshire, was baptized on Nov. 3, 1611, became a gentleman commoner of Trinity college. Oxford, in 1626. graduated and entered the Middle Temple in 1629. On the outbreak of the Civil War he joined the parliamentary army, fought at Edgehill (1642) and at Gainsborough (1643), was made by Oliver Cromwell deputy governor of the Isle of Ely, and next year served under the earl of Manchester, afterward supporting Cromwell in his accusations of incompetency against the general. On the night before the battle of Naseby, in June 1645, he surprised the royalist army and captured many prisoners, and next day was made commissary general and appointed to the command of the left wing, Cromwell himself commanding the right. The wing under Ireton was partly broken by the charge of Rupert, and Ireton was wounded and taken prisoner, but after Cromwell's rout of the enemy he escaped.

Ireton took an active part in the campaign of 1645–46 which resulted in the overthrow of the royal cause. On Oct. 30. 1645, Ireton entered parliament as member for Appleby, and while occupied with the siege of Oxford he was, on June 15, 1646, married to Bridget, Cromwell's daughter. He was opposed to the destructive schemes of the extreme party. disliked especially the abstract and unpractical theories of the Republicans and the Levellers, and desired. while modifying their mutual powers, to retain the constitution of king, lords and commons. He urged these views in the negotiations of the army with the parliament, and in the conferences with the king, being chiefly entrusted with the drawing up of the army proposals. He endeavoured to prevent the breach between the army and the parliament. but nhen the division became inevitable he took the army side. He aroused great suspicion by supporting the negotiations with the king. But becoming at length convinced of the hopelessness of dealing with Charles, after the king's flight to the Isle of Wight he urged the parliament to establish an administration without him.

Ireton served under Sir Thomas Fairfax in the Second Civil War in the campaigns in Kent and Essex, and was responsible for the executions of Sir Charles Lucas and Sir George Lisle at Colchester. After the rejection by the king of the last offers of the army, he showed special zeal in bringing about his trial, was one of the chief promoters of "Pride's Purge," attended the court regularly, and signed the death warrant.

Ireton accompanied Cromwell in his Irish campaign as second in command; on the recall of his chief to take the command in Scotland, he remained as lord deputy to complete Cromwell's work of reduction and replantation. He was rapidly bringing his task to a close, when he died of fever on Nov. 26, 1651, after the capture of Limerick. His loss "struck a great sadness into Cromwell," for as well as possessing high abilities as a soldier, and great political insight, he resembled in stern unflinchingness of purpose the protector himself. Ireton left one son and three daughters.

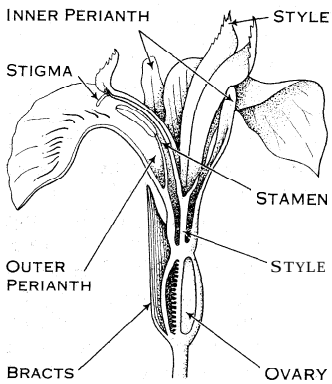
See R. W. Ramsey, *Henry Ireton* (London, 1949; New York, 1950).

IRIARTE (or YRIARTE), **TOMÁS** DE (1750–1791), Spanish poet, was born in the island of Teneriffe. His *Fábulas literarias* (1781), composed in a great variety of metres, show considerable ingenuity in their humorous attacks on literary men and methods; but their merits have been greatly exaggerated.

During his later years, partly in consequence of the *Fábulas,* Iriarte aas absorbed in personal controversies with Forner and others.

See E. Cotarelo y Mori, *Iriarte y su época* (1897).

IRIDACEAE (the iris family), a family of flowering plants belonging to the order Liliiflorae of the class Monocotyledons, containing about 900 species in 60 genera, and widely distributed in temperate and tropical regions. The members of this family are generally perennial herbs growing from a corm as crocus and gladiolus, or a rhizome as iris; more rarely. as the Spanish iris, from a bulb. A few South African representatives have a shrubby habit. The floners are hermaphrodite and regular as in iris and crocus, or with a symmetry in the median plane as in gladiolus. The arrangement of the flower parts resembles that in the nearly allied order Amaryllidaceae (narcissus, snowdrop), but differs in the absence of the inner whorl of stamens.



IRIS (IRIS PSEUDACORUS). LONGITUDINAL SECTION THROUGH FLOWER
FROM GROOM, "ELEMENTARY BOTANY" (G. BELL)

The most important genera are *Crocus* (*q.v.*), with about 75 species, *Iris* (*q.v.*), with about 200 and *Gladiolus* (*q.v.*), with 200. *Ixia, Freesia* (*q.v.*) and *Tritonia* (including *Montbretiu),* all natives of South Africa, are well known in cultivation. *Sisyrinchium,* blue-eyed grass, is a new world genus of 75 species extending from arctic America to Patagonia and the Falkland Islands. One species, S. *angustifolium,* an arctic and temperate North American species. is also native in Galway and Rerry in Ireland. Other British representatives of the familv are: *Iris pseudacorus* (yellow iris), common by river banks and ditches. *I. foetidissima* (stinking iris); *Gladiolus illyricus,* a rare plant found in the New Forest and the Isle of Wight; and *Romulea columnae,* a small plant with narrow recurved leaves a few inches long and a short scape bearing one or more small regular funnel-shaped flowers, which occurs at Dawlish in Devonshire.

In the eastern United States there are 10 species of *Iris* and 13 species of *Sisyrinchium,* but in the Rocky mountain region these genera are represented by only 2 or 3 species. Many new species of *Iris* have been described from the southern United States.

IRIDIUM, a chemical element, is a precious heavy white metal, one of the six platinum metals (*q.v.*). Its specific gravity, 22.56 is equaled by osmium; these metals are the densest terrestrial substances. With a melting point of 2,4j0° C., iridium is difficult to fuse. Its boiling point is estimated at above 4,800° C. The metal is hard and brittle; however, it becomes ductile and can be worked at a white heat, from 1.200° C. to 1,500° C. The chemical symbol of iridium is Ir; atomic number is 77 and atomic weight is 192.2.

In the massive state the metal is practically insoluble in acids and is not even attacked by aqua regia, which dissolves gold and platinum. Iridium is oxidized by a mixture of fused potassium hydroxide and potassium nitrate. Iridium crucibles are superior to those of platinum because of their resistance to carbon and phosphorus at high temperatures. However, their gradual loss in weight by air oxidation above 1,000° C. is greater than that of platinum.

Because of difficulties in preparation and fabrication the pure metal has no important applications. The element's principal use is in the preparation of platinum alloys. Pure platinum is a soft metal and unsatisfactory for many uses. Alloyed with from 5% to 10% iridium, it forms a readily norked metal, much harder and stiffer and more resistant to chemical attack.

For ordinary purposes these iridium-platinum alloys are always used unless pure platinum is needed for special reasons. They are used for jewelry and surgical pins and pivots. With their superior resistance to the action of the high-temperature electric spark they are widely used for electrical contacts and sparking points.

The international prototype standard metre of length and kilogram of mass have been constructed from the alloy containing 90 parts platinum and 10 parts iridium.

Iridium has also been used as a major component of precious metal tips on gold fountain pens.

Iridium is generally obtained from the native alloy. osmiridium, but is always found in small amounts in platinum-bearing ores. Its discovery in the acid-insoluble residues of platinum ores was announced by Smithson Tennant in England in 1804. It was named by him in consequence of the various colours of its compounds. In metal preparation, osmiridium is heated with zinc to give an acid-soluble alloy. After separation of osmium as OsO_4 the platinum is removed by repeated fractional precipitations of the compound $(NH_4)_2PtCl_6$. The ammonium hexachloroiridate (IV), $(NH_4)_2IrCl_6$, then crystallized, is decomposed to give sponge metal.

Iridium forms the oxides Ir_2O_3 and IrO_2 and important series of compounds with oxidation states $+3$ and $+4$. In many of these compounds it exists in complexes in which chloride, ammonia, water and other groups are bonded covalently to a central iridium atom. These complexes are of the inert type, in that the groups are replaced slowly.

Iridium compounds decompose readily upon ignition. and the element in analysis is determined gravimetrically as metal. Strong oxidizing agents or electrolysis will give oxidation states higher than $+4$ of transient stability in water. (D. S. Mx.)

IRIS, in Greek mythology. daughter of Thaumas and the ocean nymph Electra (according to Hesiod), the personification of the rainbow and messenger of the gods; as a messenger of the gods. she is mentioned frequently in the *Iliad,* but never in the *Odyssey,* where Hermes takes her place.

In Homer. she is the messenger of both Zeus and Hera, but later the servant of Kera. By command of Zeus she carries in a ewer water from the Styx, with which she puts to sleep all gods who perjure themselves. Her attributes are the *caduceus* (herald's staff) and a vase.

IRIS, a large genus of popular herbs of the family Iridaceae much grown for ornament. They have a petaloid six-parted perianth. an inferior ovary and only three stamens (the outer series). being thus distinguished from the Amaryllidaceae, which have six stamens. They are handsome showy-flowered plants, the Greek name *Iris* ("rainbow") having been applied on account of the hues of the flowers. The genus contains over 1j0 species widely distributed throughout the north temperate zone.

In North America there are about 30 native species, found chiefly in the eastern United States; among the best known are the blue flag (*I. versicolor*), which grows in wet places from Newfoundland to Manitoba and southward to Florida and Arkansas. and the western blue flag (*I. missouriensis*), native to met soils from Korth Dakota and New Mexico westward to California and British Columbia.

The Eurasian **I,** *pseudacorus,* the yellow flag or iris, is common in Britain on riverbanks and in marshes and ditches. It was called the "water-flag" or "bastard floure-de-luce" by John Gerard in his *Herball* (1 597); its flowers appear in June and July, and are of a bright golden yellow colour. *I. foetidissima,* the fetid iris, stinking gladwin or roast-beef plant. is a native of England south of Durham and also of Ireland, southern Europe and Korth Africa. Its foliage, when bruised, has an offensive odour.

J. HORACE MCFARLAND

BLUE FLAG IRIS (IRIS VERSICOLOR)

Iris florentina, with white or pale blue flowers. a native of the south of Europe, is the chief source of the violet-scented orris-root used in perfumery. *Iris pallida* and its relatives appear to be the origin of the large common blue iris of gardens, the bearded iris or *fleur-de-lis* and probably the Illyrian iris of the ancients. *I. pallida* and *I. variegntn* have also been assumed to be the parents of the so-called German iris, better knonn as tall bearded iris: but these plants. long known as *Iris gernznnica,* are of very doubtful origin, never having been found as native plants

The garden plants knonn as Spanish iris and English iris are both of Spanish origin and have very shony flowers. Along with some other species such as *I reticulata* and *I. persica,* both of nhich are fragrant. they are great favourites nith florists. All these just mentioned differ from those formerly named in the nature of the underground stem. which forms a bulb and not a strict creeping rhizome as in *I. pseudacorus, pallida, florentina,* etc.

For many centuries. probably long antedating the culture of any of the above species. Japanese horticulturists mere hybridizing what are today knonn as Japanese iris Hundreds of named forms of these. in a variety of colours. are perhaps the showiest of all garden irises. They appear to be derived from *I kaempferi* or its allies, a plant with a creeping rootstock, long leaves and, in the cultivated forms. very large flowers (six inches across in some varieties). The original species nhich is wild in eastern Asia, was in ancient times developed by Japanese families or guilds, some of nhom produced identical varieties but applied their onn names to them. The hundreds of named forms are hence in much confusion but the folloning appear to be reasonably accurate: Gold Bound and Morning Mists (white); Blue Belle and Blue Bird (blue), Pink Progress (pink) and Mahogany and Purple and Gold (reddish purple). Most Japanese vernacular names are hopelessly confused.

The iris floner is of interest because of the flower shape, which appears to prevent self-pollination and ensure cross-pollination by insect visitors. The floner parts are so ingeniously arranged that an insect bearing pollen from one floner will, in entering a second, deposit the pollen on the stigma: the pollen which it bears in emerging will not be rubbed off on the stigma of the same flower.

The rootstocks of irises may be planted shallonly in spring (in colder climates) or autumn in an open, sunny exposure and well-drained garden soil. Propagation is commonly by division of rootstocks just after the flonering period. Irises do not breed true from seed; honever, seeds may be planted upon ripening and may germinate the folloning spring Although irises thrive under a variety of conditions, mulching is desirable in cold climates.

There are large collections of iris at Washington, D.C., and at Cornell university, Ithaca, N.Y. The American Iris society has published a catalogue comprising thousands of varietal names, and the Royal Horticultural society has issued a schematic key for the whole genus as well as a key for the tall bearded sorts. The keys are tables by which the plants can be identified on the basis of their relationships.

(N. Tr.; X.)

IRISH LANGUAGE. Irish is the only representative of the Goidelic or Gaelic branch of the Celtic languages (*q.v.*). Its history may be divided into four periods: (1) that of the Ogham inscriptions, probably A.D. 300–500; (2) Old Irish, 600–900; (3) Middle Irish, 900–1200; (4) Modern Irish, 1200 to the present day. This division is, of course, arbitrary, and archaizing tendencies confuse the situation, especially during the period 1100–1600, after which the literary language ceases to dominate and the modern dialects, among which may be reckoned Scottish Gaelic and Manx, appear.

Although there are more than 300 Ogham inscriptions, none is of more than a few words and the great majority are names in the genitive case, so that their evidence is almost entirely phonological. Original final syllables are generally preserved and the language is remarkably like that of the Gaulish and British inscriptions; the *q*, which corresponds to Brythonic *p*, is distinguished from *c*. There is no sign of intervocalic consonant weakening; when this happened is not known, but it is firmly established in Old Irish, where it has affected word clusters as well as individual words, so that words originally ending in a vowel weaken a following consonant as though it were in intervocalic position, although nearly all original final syllables have been lost by the Old Irish period. This mutation continues to be very important functionally in all dialects; *e.g., a bó,* "her cow," but *a bhó,* "his cow," where *b* is weakened to a spirant *v* (written *bh*). Nasalization, arising from a lost final nasal, continues in all the dialects of Ireland but has been given up in Scottish Gaelic and Manx, except for a few fossilized forms; *e.g.,* Ir. *a mbó,* "their cow," where *mb=m;* Sc. G. *am bò.*

Old Irish had developed a very strong stress accent on the first syllable of the word, with resulting loss of weak syllables. The vowels of lost weak and final syllables often have a reflection, however, in consonant quality. Every consonant can have three qualities: palatal (Ir. *caol,* "slender") if originally followed by *i* or *e;* neutral (Ir. *leathan,* "broad") before *a* and *o;* and *u*-coloured before *u*. The last category fell, together with the second, in the Old Irish period, but the other two have continued to exist in all the dialects, though the distinction is almost obliterated in the last stages of Manx. As the final syllables were lost, these distinctions of quality became of great morphological significance; *e.g., cat,* "cat," *cait,* "cats"; the *i* is purely graphic and the difference of pronunciation is nearly that between Russian *brat* and *brat'*. The stress on the first syllable continues to be typical of all dialects, often, as in Scottish and northern Irish, with reduction of unstressed syllables, but southern Irish in the early modern period transferred the stress to syllables containing a long vowel; Manx shows both tendencies and the lines of distribution have not yet been fully worked out. Old Irish was recognizably an Indo-European language, while possessing a very individual treatment of such features as compound verbs and infixed pronouns. The verbal system, however, shows a rapid development from the beginning of the Middle Irish period, especially characterized by the spread of the periphrastic construction with the verb "to be" and the verbal noun—a development common to all the languages of the British Isles. In Scottish Gaelic and Manx, as in spoken Welsh, this continuous present has almost superseded the old present forms, which have taken on a future meaning, with the consequent loss of the old future tense. Meanwhile the loss of the infixed pronoun brought about the rise of the independent pronoun, first as object and then as subject, when it takes the third singular form of the verb. This tendency, which can be traced to the beginning of the Modern Irish period, has again developed farthest in Scottish Gaelic and Manx, where, as in modern Danish, there is only one verbal form for each tense; southern Irish is considerably more conservative.

In vocabulary, again, while the archaic texts show many words with Indo-European etymologies, the rapid dilution of these in later texts points to a very large substratum (which, it has been suggested, may contain Brythonic elements). Later contributions are Latin, in two strata, one very early, the other later and showing signs of a British pronunciation; Scandinavian (especially in Scottish Gaelic and Manx); Norman French; and, finally, English, which plays a very large part in the modern dialects.

There are no examples of writing in Irish before the 8th century; the system evolved then was based on the British pronunciation of Latin and has never been satisfactory, still less so since many of the weakened consonants disappeared altogether in the early modern period while continuing to be written. Scottish Gaelic as such first appears in the 18th century. At first greatly influenced by Irish spelling, it has gradually evolved into a less clumsy system and has abandoned the traditional variety of the western half-uncial alphabet which is still used to a large extent in Ireland. Manx had the misfortune to be first written down in the 17th century in an orthography based on that of English, which often makes it hard to say what sounds were intended, especially since hardly any genuine speakers survive. In Ireland and Scotland, where there are still considerable Gaelic-speaking areas, dialect surveys are being undertaken, with a view to the construction of linguistic atlases.

IRISH LITERATURE. Ireland is unusual in that it has two literatures, one in the native language and another in the language of the English conquerors. This division excludes numerous writings in Latin, mostly theological and antiquarian, from Johannes Scotus Erigena to Sir James Ware, as well as some works in French, from the early poems of the Norman conquerors to the

Mémoires du comte de *Gramont* of Anthony Hamilton (1713). This article deals first with Gaelic literature and then with Irish writing in English, commonly called Anglo-Irish literature.

(X.)

GAELIC LITERATURE

The Celtic language spoken in Ireland from the earliest historic period, often described as Gaelic (or Goidelic, from Old Irish *Goidel,* a Brythonic loan word of which the modern equivalent is Welsh Gwyddel, "Irishman"), has no close connections on the continent of Europe, where evidence shows instead a connection with Celtic, of which the surviving Brythonic languages are representatives (see GAELIC LANGUAGE). Nor is it certain when Goidelic was brought to Ireland, but research suggests a date not long before the beginning of the Christian era.

The earliest evidence consists of sepulchral inscriptions in the Ogham alphabet. These are found mainly in the southwest of Ireland, but there are examples from the rest of the country and from Wales, where small Goidelic colonies existed. These inscriptions, usually ascribed to the 4th and 5th centuries, show an archaic state of the language, phonologically very close to the early Brythonic of British and Gaulish inscriptions; its relation to the Irish found in the earliest literary sources may be compared with that between Latin and Old French. The alphabet in which these sources were written was the Roman one, introduced by the Christian missionaries in the 5th century. The precise date at which it began to be used for writing Irish is uncertain, for we have no examples before the 8th century, and even then only incidentally, in scribal notes and glosses. The language of the 8th- and 9th-century manuscripts, conventionally called Old Irish, provides an indispensable criterion for dating other material, and it is the discovery in later manuscripts of linguistic forms considerably more archaic than those of the classical Old Irish period that allows us to ascribe the compositions in which they occur to the 7th century or perhaps even the 6th. None of these later manuscripts, on which we depend for our knowledge of early Irish literature, is earlier than the 12th century, when the vernacular was already nearer to Modern Irish than to Old Irish. We owe the preservation of the older literature to the piety and conservatism of monastic scribes. All attempts to divide a literature chronologically are of necessity unsatisfactory; but the existence for more than 1,000 years of a literary class in Ireland allows certain landmarks to be established. Four periods may be recognized: (1) the early period, when the literature was composed by the order called filid and by churchmen and was preserved in the monasteries; this stretched from the earliest times to the 12th century and linguistically covered the whole field from archaic Old Irish to late Middle Irish; (2) the middle period, when the custody of the tradition passed to the lay and hereditary bardic order; this dated from the middle of the 12th century to the middle of the 17th and is linguistically late Middle Irish and classical Modern Irish; (3) the late period, when both literati and patrons had disappeared and the literature became purely popular and peasant; this continued from the middle of the 17th century until the end of the 19th, and during it the language, at first close to classical Irish, evolved finally into the dialects as they are known today; (4) the revival period, from the end of the 19th century to the present day.

EARLY PERIOD

Irish literature was from the earliest times an aristocratic one, kept in the hands of a professional class, the *filid* (singular *fili,* etymologically "seer"); it has been suggested, with considerable probability, that *fili,* bard (originally apparently a lower grade of poet than the fili), *brithem* (judge), senchaid (historian) and drui (druid) all belonged originally to the same privileged caste. The drui was ousted by the Christian clergy, though he is still a prominent figure in the sagas; the other professional orders are ranked by the early laws together with the landowning aristocracy. The status and rewards of the jlid are also set out—no doubt a necessary provision, for the extravagance of their demands is a recurrent theme and caused them to be severely censured as early as the assembly of Druim Ceta in 575. Their duties were to know the sagas and genealogies and to compose encomiastic poems; that is, to serve the past and present glory of the ruling class. This function did not, however, prevent a considerable pride, even arrogance, in their calling, and they could enforce their demands by the threat of the lampoon (der), which could not only take away a man's reputation but also damage him physically and even kill him. The laws set out penalties for the abuse of the der, and the belief in its powers continued up to modern times.

Verse.—The earliest verse has not been well preserved, no doubt because of its considerable obscurity. For the official work of the *filid* it is necessary to rely on the fragments in the annals and genealogies and, above all, in the later treatises on metrics, where they often appear in very corrupt form. There are, however, two fairly long pieces in what must be regarded as a poetical style. The first and perhaps the older is the Fdeth Fiada (Cry of the Deer), a rhythmical incantation traditionally ascribed to St. Patrick; whether of the saint's composition or not, it is undoubtedly very archaic in language. There is less doubt about the *Amra* (Eulogy) on St. Columba (521–597); this, couched in rhetorical style, in short sentences linked by alliteration, is ascribed to Dallan Forgaill, who was chief poet (rigollam) of Ireland. This device of alliterative rhythmical prose is used again in the sagas, and the technical term for it is a Latin loan word, retoric. Probably the oldest metre in the strict sense of the word is that in which two half-lines are linked by alliteration—a system strikingly reminiscent of early Germanic verse. Another pattern which can be discerned is that of a heptasyllabic line with trisyllabic ending; this is found both in legal tracts and in the sagas. Rhyme is found from the 7th century onward. Although it is often a full rhyme, the requirement is only that there should be identity of vowel and syllabic length and that the consonants should belong to the same phonetic class—a system found also in early Welsh. At the same time the quatrain, with seven or eight syllables to the line and rhyme between the second and fourth lines, was derived from Latin hymn metres. Still later are found the first examples of a metre later to become the most popular of all—debide (literally "cut in two"), where the quatrains consist of two couplets, and the rhyme between the two lines of each couplet is usually that of a stressed syllable with an unstressed one.

The official poetry consists, as must be expected, mainly of panegyric, elegy and similar products of the *fili's* relation to his patron. The incident in Tromddm Guaire (*Guaire's* Oppressive Guests), a late satire, where a king is made to say, after hearing a poem, "that is a good poem, for him who could understand it," may contain more than a grain of truth, for the poets often affected a deliberately obscure style, like the Provençal trobar *clus.* Naturally enough, it is their official rather than occasional work which tends to be preserved, but some fragments showing a genuine lyric note have survived to be collected and published in Irish and German by K. Meyer in *Bruchstücke der älteren* Lyrik *Irlands* (Berlin, 1919).

It must be assumed that the remarkable freedom from dialect variations found in Irish right up to the modern period was a result of the influence of the filid, and later the baird, but there is no evidence that their language was handed down otherwise than orally until the time when the filid are found in the monasteries. The whole written tradition is monastic, and the name of the Christian learning, *légend* (Lat. legendum), suggests a contrast in techniques. But from the beginning the church in Ireland not only tolerated but cultivated the vernacular in religious writing, and after the first few centuries it had completely superseded Latin in every field except the purely liturgical.

Religious Verse.—The official verse of the church is hardly more lively than that of the *filid;* for example, the *Félire* or Calendar of Oengus, composed about 800 and containing a quatrain for each day of the year. More interesting is the 10th-century *Saltair* na Rann (Psalter), a biblical history in 150 debzde poems, which contains a great deal of strange learning. But it is not these ponderous works which constitute the real glory of Irish religious verse, but rather the personal note heard in the voice of the monk who asks forgiveness for his lapses in meditation, or the nun who asks God

to grant her the nursing of the infant Jesus. The anonymous poets who composed such poems as these, as well as the famous address to Pangur, the white cat. were not filid, and they avoided the more complicated metres but had the immense advantage of using a language which had been cultivated for many centuries, to which they brought a freshness of insight denied to the filid.

Nature Poetry.—The happiest wedding of the literary tradition and religious feeling was in the nature poetry, hardly to be paralleled elsewhere in Europe. The native poetry had already shown, both in the lyrics in the sagas and in the seasonal songs, a remarkable sensitivity to natural beauty; perhaps because some of these were ascribed to Find Fili, later confused with the hero, this type of verse became associated with the Fenian tradition. That the filid could adapt their technique to new circumstances is shown by an 11th-century poem on the sea, where the preface, choice of theme and free use of kennings all suggest Scandinavian influence. The monastic movement in the Irish church provided a far stronger impetus to nature poetry. Exile from men, whether beyond the seas or to lonely places in Ireland itself, was held to be, a bloodless but meritorious martyrdom, and the bare cells of the hermits brought them very close to earth and sky and their creatures. This almost Franciscan poetry mould naturally have an especial appeal to monastic scribes, so that a considerable amount of it has been preserved.

Historical Verse.—Remembrance of the past was an important part of the work of the *fili;* indeed, some of the earliest poems are more metrical genealogy than anything else. As time went on and many texts became obscure and different traditions conflicted, the necessity for compendiums of information grew, and these were often couched in metrical form. They are especially numerous toward the end of the early period. In a long poem, Fianna bdtar i *nEmain (The Warriors Who Were* in *Emain),* Cinied ua Artaciin (d. 975) summed up the saga material, while Fland Mainistrech (d. 1056) collected the work of the generations of filid who had laboured to synchronize the traditional history of Ireland with that of the outside world as it was then known. Equally important is the great collection, existing both in prose and verse forms, called the *Dindshenchus,* which, as R. Flower has well said, formed "a kind of Dictionary of National Topography, which fitted the famous sites of Ireland each with its appropriate legend." And, indeed, the development of a loose debide form, making rhyming easy, produced mnemonic verse on all sorts of subjects—hagiology. grammar, lexicography, metrics and law.

Prose.—The Saga.—The early Irish epic is a prose narrative, which usually. though not always, contains non-narrative passages in a heightened style, whether retoric or verse; these passages often take a dialogue form. E. Windisch first pointed out the resemblance between this and the type of epic found in early Sanskrit sources and suggested that the tradition went back to early Indo-European times. It seems at least to be common Celtic; whatever the date and origin of the poems which 'make up the Welsh Gododdin, they do not constitute an epic, and Sir Ifor Williams has seen in the scattered *englynion* of the early manuscripts the lyrics from an early saga cycle the prose of which has been lost. There are parallels for this in Irish; in the love tale Liadain and Cuirithir the prose consists of a few scattered and cryptic sentences and the famous poem of the Old *Woman* of *Beare,* the Irish *Vieille Heaulmiere* may also be a fragment of an old story. This does not imply a common Celtic literature, but that the traditions of early storytelling in both languages were similar to what is found best preserved in early Irish. In saying this, the difficulties of interpretation arising from the conditions already mentioned must be remembered. The oldest stories found in Ireland show linguistic forms which suggest that they had reached settled patterns in the Old Irish period; we possess no manuscript evidence earlier than the time when late Middle Irish was passing into Modern Irish. The historical background to this is obvious; the Scandinavian invasions of the 9th and 10th centuries disrupted the entire Irish polity and seriously affected literary studies, as they did everything else. Not until the 11th century did life become sufficiently settled for the works of the past to be collected in the monasteries, and this antiquarian revival was both eclectic and uneven. The great codex Lebor *na* Huidre (The Book of ***the Dun*** Cow), written early in the 12th century, shows, both in the main text and in the later interpolations, older treatments of the saga material than those found in the Book of *Leinster,* written a few score years later. Only the shortest stories are preserved in forms approximating to the original; the rest abound in doublets, repetitions and conflations due to uncritical editorial handling of earlier material. The rhythmic prose used in the heightened passages of the older stories rapidly became unintelligible and was replaced in later recensions by longer poems in the syllabic metres.

It was the duty of the fili to know these stories (*scél*), both primary and secondary. Although in this function he may be described as a *scélaige,* he was really fulfilling the same office as the *senchaid;* that is, the preservation of the glories of the past. Occasionally the authenticity of the *scél* is guaranteed by bringing one of the old heroes into contact with later generations, whether it be the supernatural appearance of Cu Chulainn to St. Patrick, Senchin's evocation of Fergus mac Róig, or Oisín's miraculous survival. Although these stories tend to group themselves in cycles, they range over a period from the earliest fables to the 11th century, and in the catalogues—containing the titles of many stories now lost—they are arranged by type rather than by period, so that the headings are stormings, cattle raids, courtships, battles, voyages and so on. There are nearly 100 *scél* in the primary class and half as many in the secondary.

Whatever the attitude of the storytellers and their hearers to these stories may have been, they must be regarded as almost completely unhistorical, so far as personages are concerned; even those which relate to the 7th century usually fail to agree with the more reliable evidence of the annals. It is possible, however, that some of them may contain traditional material capable of historical interpretation. The oldest of them preserve for us a picture of a primitive and pre-Christian state of society—fighting from war chariots, the taking of heads as trophies, the privileged position of the druids, the force of taboo (*geis*) as a supernatural sanction—for which there is little or no evidence from historical sources. They are best paralleled by the classical descriptions of the continental Celts, and the preservation of a memory of them is a result of that conservatism of the Irish literary classes which made a 16th-century bard ignore the bow and the gun alike and send his patron into battle armed only with sword and spear. It is hard to arrive at any convenient division of these stories. The mythological cycle, so called because of the frequent references in some of the stories to immortal beings, cannot easily be separated from the cycle of the kings; all were of equal historicity from the storytellers' point of view and all are equally unhistorical from ours. The most important cycle is that of the Ulaid, the people who gave their name to the modern province of Ulster. As so often happens, their days of power and influence were long over when the sagas took the form in which they are known today, and the problem of why their tradition especially should have been so much cultivated by the *filid,* and why it should have been so much neglected when the period of the filid came to an end, is still unsolved. But certainly the figures of Conchobar, king of the Ulaid; Cu Chulainn, the boy warrior; Medb, queen of Connaught; and Noisi and Déirdre (*q.v.*), the doomed lovers, are outstanding both in early Irish literature and, even more, in that of the Anglo-Irish revival, and it is on elements from the sagas of the Ulaid that the nearest approach to an Irish epic was built—Tdzn *Bó Cúailgne* (*The* Cattle *Raid* of Cooley).

It is probable that even when first put together, in the 7th or 8th century, the Tdzn was not a very coherent work of art; it must be remembered that the oldest type of *scél* does not exceed a few thousand words and is striking chiefly for the laconic vividness of its narrative and the wit of its dialogue. There is little attempt at construction; the longer stories are no more than a chain of loosely connected incidents. *Táin* Bd *Cúailgne,* which would appear to be a conscious attempt to provide Ireland with an epic comparable to the Aeneid, shows this tendency carried ad *absurdum.* There are dramatic episodes, such as Medb's dialogue with the soothsayer and Cú Chulainn's dealings with the Connaught scouts, but the long series of single combats becomes wearisome and the story

tails off badly. Undoubtedly the finest section is that where Fergus, an exile from Ulster, recalls for Medb and Ailill the deeds of Cú Chulainn's youth. This story of the boyhood of a hero abounds in convincing touches and is obviously the work of an accomplished artist, and it has been transmitted to us, by some fortunate chance, in a reasonably correct form. But the Tdin generally is of less literary interest; its value for the literary historian lies in the fact that, as it was being continually worked over, it provides a kind of stratified record of the degeneration of Irish style. Just as the bare prose of the early period is replaced by bombastic alliterative passages, and the retoric, emotive in its obscurity, by longer and longer poems in clumsy debide, so the ruthless humour with which Cu Chulainn's early killings are described is replaced by the sentimentality of the fight between him and his boyhood friend Fer Diad.

The Tdin collected around itself a number of ancillary stories, not the least important of which is that of its revelation to the *filid* in the 7th century by the ghost of Fergus. This may point to the date at which a number of tales of the Ulaid were first combined into an epic. Better known is the tragedy of Noísi and Déirdre, linked through their enemy Conchobar to the Ulster stories. In a modern form it became known as one of the Three Sorrows of Storytelling, being linked incongruously with a "mythological" story about the children of Tuireann and a late romance called Oidheadh *Cloinne* Lir (The Children of Lir). It is, of course, known to the world through the work of the Anglo-Irish school, notably J. M. Synge and W. B. Yeats. Equally full of drama, but not so easily adapted to modern taste, is *Scél Mucce* Mic Da Thd (The Story of Mac Da Thd's Pig), which includes such primitive elements as the award of the best portion of meat to the leading champion, the boasting competition which ensues, and the resolution of the contest by the production of a head just taken in single combat.

Although the early sagas exaggerate to the point of grotesqueness, there is little trace in them of the supernatural. This can hardly be explained by the monastic origin of the manuscripts; the few attempts to introduce Christian elements are easily detected interpolations, and it is more probable that pagan deities, as such, played comparatively little part in the stories, even in their oldest form. Immortals are found, certainly, especially in the stories ascribed to a period deep in antiquity; the Dagda, Lug, Manannán, Midir and Oengus are all beings of more than human stature, and some of them may, in name at least, be linked with Gaulish and Welsh gods and heroes. But they interfere little in mortal affairs and cannot be said to constitute any kind of pantheon; they live in dwellings (sid), which may be mounds or islands but in either case hide them from mortal eyes. In general, mortals may visit the sid only at the wish of its occupants, usually because a woman of the sid has fallen in love with a mortal man. Life there is eternal, but no mortal can return to the world without taking on the burden of the pears he spent in the *síd*. If the pre-Christian Irish had a belief in the immortality of the soul, no intimation of it reaches us from the sagas.

One of the most delightful of these stories is *Imram* Brain (The Voyage of Bran), edited by K. Meyer and A. Nutt (London, 1895), which describes a voyage to Tir inna mBan (the Land of Women). The same plan is followed in other *imrama* (which were to have their ecclesiastical counterpart in the Navigatio *Brendani*), but the later tales tend to stress the marvellous rather than the supernatural. A recently edited story of the *síd* is Tochmarc Étaine (*The* Courtship of *Étain*), which describes how Étaín, once a royal immortal, was reincarnated as a woman and married to Eochaid Airem. Her original husband, Midir, finds her again, wins her from her earthly husband at the gaming board and carries her back to the sid, where he holds her in spite of all attempts to rescue her. Nowhere are the unchanging delights of the other world better described than in the songs in which Midir reminds his lost wife of her former home.

Other Early *Stories*.—In this period stories with an origin outside the recognized tradition began to appear. An obviously exotic element is represented by Togazl Troi (The Taking of Troy) and The Story of Alexander, which appear in the oldest saga lists, but the classical learning had comparatively small effect until the next period. The same is true of the stories of Finn; although Meyer demonstrated in Fianaigecht (Dublin, 1910) that the traditions go back to an early period, their real development was at the time when the *filid* were no longer in control. Later research would indicate that the "wild man of the woods" cycle associated with the name of Suibne Geilt had its origins in Strathclyde, where Irish and Brythonic literature must have been in contact at an early date; this mixture of hagiographical, saga and nature material is one of the most attractive stories of the later period. For a discus. sion of the Suibne story, cf. J. G. O'Keeffe, *Buile* Shuibhne (London, 1913); J. Carney, Eigse, vi, 83 ff. (Dublin, 1950).

Religious Prose.—Although Irish was used for didactic purposes from the earliest period (one of the most archaic pieces of prose is the fragment known as the *Cambrai* Homily), the material is mostly derived from Latin, and that belonging to the earliest period consists mainly of monastic rules, *exempla* to illustrate a moral and anecdotes about saints. The two latter types often show a style and humour worthy of the professional *scélaige*. At a later stage a number of homilies such as In Tengae *Bithnue* (The *Evernew* Tongue) appear; they are interesting, both linguistically and because their sources are often obscure, but of small literary value. The lives of the saints have little interest, either from the literary or the biographical point of view. Intended, no doubt, to be edifying, they are works of fantasy, incorporating with the passage of time more and more elements from folklore on one side and from the saga material on the other. The emphasis is always on the miraculous; it is the fact that they incidentally contain a great deal of information about everyday life in early Ireland that makes them so valuable today as social documents. Naturally enough, Latin and Irish traditions are mingled in this field, in which the standard works are those of C. Plummer, Vitae Sanctorum Hiberniae (Oxford, 1910), and Bethada *naem nÉrenn* (Oxford, 1922). Another important type of religious work is the vision, the best known example of which is Fis *Adamnáin* (The Vision of Adamndn), whose soul is represented as leaving his body for a time to visit heaven and hell under the guidance of an angel. To what extent this type of Irish religious work, found also in Latin, may have influenced Dante is still a subject for speculation. Both the saints' lives and the visions tended to degenerate into extravagance and buffoonery—so much so that parodies on both were composed. The outstanding example is *Aislinge* Meic Con Glinne (The Vision of Mac *Con* Glinne), which describes how a king possessed by a demon of gluttony is cured by the recital of the vision of a land of Cockaigne.

Speculative and Technical Writing.—Theory has always been at least as important as practice in Irish cultural life, and the filid built up for themselves a considerable body of academic speculation. Very little has survived, but we have obscure fragments on the nature of inspiration and the origin of language, combined with more practical instructions on matters of metrics and style. At an early stage this learning became interpenetrated with that of Latin, as the collection of texts gathered together under the title of *Auraicept na nÉces* (The Scholars' Primer) shows; and a full technical vocabulary was built up to deal with Latin, as well as Irish, grammar. In several very ancient texts the discussion of the art of the poet is mixed with questions relating to his legal status. As early as the 10th century the changes in the language had necessitated glossing and interpretation of the older texts; Cormac mac Cuilennáin, the bishop-king of Cashel (d. 903), compiled a glossary of archaic words with illustrations, etymologies (of the school of Isidore) and illustrative passages.

Just as important to the *fili* as the study of the language and literature was that of history and genealogy. J. MacNeill was the first to point to the immense amount of work that was done in adapting the Latin historical synchronisms to the legends and genealogies of Ireland. A synthetic history of the pre-Christian period was thus built up, and the genealogy of the leading families carried back to Adam. The sequence of events depicted in a compilation such as the Leablzar *Gabhála* (Book of Conquests), with its Milesians, Fomorians, Tuatha DC Danann and whatnot, has been a fruitful source of speculation to modern archaeologists

and historians. Far more reliable are the annals kept in the monasteries from early times; these are generally agreed to be reliable from the 6th century onward.

Law and medicine were both important professions in ancient Ireland. By a curious chance, we owe most of our early knowledge of medicine to legal men, for the only surviving material, apart from a few charms, is from legal tracts of the Old Irish period, which deal with the status and responsibility of doctors. No doubt medical knowledge was conveyed orally from master to pupil. The same may have been true of legal studies themselves at first, but there exist texts the language of which clearly shows that they were composed in the earliest period known to us. Remarkably archaic in content as well as in language, they no doubt represent several traditions. but chief place was held by the *Senchas Már (Great Old Law Book)*. a codification given its authority by ascription to a commission sitting under St. Patrick. This must be regarded as an appeal to history of the same type as was used in the literature, and the real date of systematization must be placed several centuries later. Nevertheless, the oldest strata of the laws are now recognized as providing the best evidence not only of archaic Old Irish but also of social life in early Christian Ireland. The system, however, is merely a description of the legal relationships of a small landowning aristocracy. As life became more complicated, it appears to have broken down altogether, and the judges seem to have given their decisions as simple arbitrators, supporting their judgments with imperfectly understood tags.

MIDDLE PERIOD

The 12th century is a period of contradictions. On the one hand, the oldest surviving codices were being written in the monasteries, preserving the literature of many centuries earlier with remarkable fidelity; on the other hand was the gradual rise of a new literary order which, while elaborating the verse forms to a far greater extent than before, at the same time recognized the changes in language which had taken place and codified for poetic use a language which must have been very near the vernacular of the day. After the 12th century the hereditary bardic families became the custodians of Irish literature and continued in that function until the collapse of the Gaelic polity. R. Flower suggested that the bardic movement may have received its impetus during the reign of the centralizing Brian Bóroimhe (Boru) (926–1014), and this may well be true. The conditions mere favourable, for the upholders of the older tradition had become almost completely identified with a church which was now doubly threatened by the Norman invasion and by the introduction of new orders of monks from abroad. Also, the language had evolved so far during the unsettled period of the viking raids that the older tradition must have become almost unintelligible; the Book of Leinster *Táin,* for example, swarms with fantastic and, one is tempted to say, unreal linguistic forms. The new bardic families were at first completely divorced from ecclesiastical influence, though we soon find them sending their sons into the recently introduced orders, above all the Franciscans, who mere to become by the end of this period the greatest custodians of the tradition.

Bardic Verse.—The bardic reform of verse was sweeping. The language was brought into conformity with the speech of the time, the large number of metres used by the *filid* was greatly reduced and, in compensation, a greater strictness in rhyme and lavishness in ornament—internal rhyme and alliteration—was insisted on. The scope of the verse became considerably less; the vast bulk which has come down is praise poetry, addressed either to the poet's temporary or permanent patron or to God. This arose naturally from the status of the new order of poets; being no longer associated with monastic foundations, they were dependent entirely upon patronage for the high standard of living which they claimed as their own right, for the bards were no less arrogant than the *filid* whom they replaced. After a course of training which lasted six or seven years, these journeymen poets were free to seek a temporary or permanent patron. It is no accident that they praise generosity as highly as bravery in their poems, which many of the chiefs had copied into family verse books (*duanaire*). There is a considerable monotony in these poems, for, though a chief must be described as victorious, it was considered prudent to avoid mentioning the details, lest the poet should wish to sell a poem to the defeated enemy at some future time. Nevertheless, there is often real poetic feeling in the earlier poems; but by the end of the period many poets were content to string together the clichés evolved through the centuries, with little regard for meaning so long as the metre was correct.

Modern taste finds little of interest in even the best of the official bardic poetry; it is the handful of occasional verse which survives that shows real worth. One of the earliest poets of the great bardic family of Ó Dálaigh, Muireadhach Albanach (c. 1214–40), has left, as well as a stirring defense of his action in killing a tax collector, an elegy on the death of his wife which is unsurpassed in Irish literature. Such gems are rare.

A new note was brought into Irish literature by the Gaelicized Norman invaders, that of the *amour courtois,* and the combination of this exotic element with the wit and felicity of the bardic style has left a number of enchanting poems. No doubt there were once many, many more than those collected by T. F. O'Rahilly in *Ddnta Grddha* (Cork, 1926), but it was only by a fortunate chance that precious vellum was devoted to the preservation of such frivolities. A different kind of departure from praise poetry is the *crosánacht,* a poem in which the verse is frequently interspersed with humorous or satirical prose passages.

The Fenian Cycle.—The vast bulk of native prose of this period is concerned with the hero Finn and his war band (*fian;* hence "Fenian"). In spite of their comparative neglect in the 12th-century manuscripts, the stories about Finn, Oisin, Caoilte and the rest must have existed among the people for many centuries. MacNeill may be right in seeing in them the traditions of a subject race, for the proportion of folklore elements in them is far higher than in the aristocratic Ulster cycle. The outstanding work is *Agallamh na Seanórach (The Interrogation of the Old Men),* in which Oisin and Caoilte are represented as surviving the battle of Gabhra and living on until the time of Patrick, whom Caoilte accompanies through Ireland, explaining to him the origin of the names of the places which they visit—a technique no doubt borrowed from the older *Dindshenchus,* as is also the form of prose with verse passages. But whereas in the Ulster cycle the introduction of the hero of former times is merely a way of authenticating the story, in the Fenian stories it is used to introduce a note of nostalgia for past glory, so that in modern speech "Oisin after the Fianna" is the type of the survivor of a heroic period. No doubt this contrast reflects that between an old hierarchical society and one facing a rapidly changing and hostile world. The Fenian stories never received such careful literary treatment as did those of the older tradition, and the old form was soon abandoned for prose tales and ballads—the latter something of an innovation in Irish literature, though there are examples of metrical versions of prose sagas even in the Ulster cycle. The prose tends to degenerate into a bombastic and alliterative style, seen at its worst in *Cath Fionntrágha (The Battle of Ventry).* There are echoes of this style in the "runs" of the modern folk tale, where the Fenian tradition is supreme. The ballads are easier reading and may be regarded as the beginnings of popular, as opposed to professional, literature in Irish. The metres represent such a drastic simplification of the bardic technique that versification became even easier than in the English ballad, and a distinct change in theme can be seen as this literature passed into the hands of the people. St. Patrick still makes his appearance, but he is now a malevolent and hostile figure, starving and bullying the aged heroes who represent the pagan and warlike tradition. These ballads had an immense popularity among the common people; the collection made by James Macgregor, dean of Lismore, early in the 16th century, shows that the tradition of ballads about Oisin and Finn, on which James Macpherson was later to base his forgeries about Ossian and Fingal, was already flourishing.

Other Prose.—Retelling of the stories popular with the *filid* of course continue to be found, but these steadily dropped out of favour. Sometimes they were combined with folk-tale elements, as was the case with the very old saga of Fergus mac Léti, which was rewritten, perhaps in the 14th century, to include a story of

a people of tiny stature — the leprechauns of folklore. It has been suggested that Jonathan Swift may have heard some version of this and incorporated it in his *Gulliver's Travels*. A curious example of a saga technique being applied to a great historical personage is the *Cogadh Gaedheal re Gallaibh (The War of the Irish With the Foreigners)*, which deals with the wars of Brian Bóroimhe; the style is bombastic and inflated, and it was to find many imitators, of which probably the worst is Lughaidh Ó Cléirigh's *Life of Aodh Ruadh Ó Ddmhnaill*. Most important of all, a flood of translations from both Latin and English began. The stories of Marco Polo, Sir John Mandeville, Prester John and Guy of Warwick, as well as classical and Arthurian stories in their mediaeval adaptations, become well known in Ireland. The new religious orders were responsible for the translation of many spiritual and devotional works. There was also a considerable amount of technical writing. On the native side, the most important was the grammatical and metrical teaching which was set out in many elaborate tracts, giving examples of correct and incorrect usage. Legal science appears to have been moribund. From abroad came translations of medical tracts in large numbers. Continental teaching seems completely to have superseded the native tradition during this period. The churchmen made the experiment, remarkable for the time, of handling philosophical material in the vernacular; unfortunately very few of these tracts are extant and almost nothing has been published.

By the 15th century the printing press was beginning to make literature available to larger numbers in most European countries. In Ireland, however, in spite of the fact that Irish was the language of most of the country and that the literature was flourishing at that period, there was one fatal obstacle; the Irish did not control the towns, and so had no access to printing. Irish literature perforce remained an aristocratic one, the preserve of those who could afford to maintain the literati and supply them with the costly vellum, which was not replaced by paper until the end of this period. It is easy to understand that this literature had little effect on the masses of the people.

LATE PERIOD

It was during the reign of Elizabeth I that English policy first succeeded in breaking the power of the Irish and Anglo-Irish nobility, and the process was completed by the middle of the 17th century. The emigration or dispossession of this nobility entailed also the disappearance of the bards who were at once its dependents and propagandists — a fact well known to the English power, which persecuted the "rhymers" bitterly. Their eyes fixed on the past, they had shown no sign of interest in the renaissance of learning going on elsewhere; with their elimination the old tradition itself was doomed, and there were no learned men to found a new one. Indeed, from this time onward the Irish language itself began to slip from its position as the common speech of the country.

Verse. — The poets did not give up without a struggle. In the early part of the 17th century they were engaged in a long and heated poetic debate on early Irish history, and the tradition was to survive in Scotland, together with the native aristocracy, until after the 1745 rebellion. But bardic language and diction, unchanged for more than 400 years, were too difficult for poets who had not undergone the strict discipline of the schools. Without patrons the schools soon died, and hardly any correct bardic verse was written in Ireland after 1650. But just as the bards had taken over from the *filid* 500 years before, so a new school of poets took over from the bards. And just as the bardic measures had been in preparation for centuries before they established themselves as canonical, so the song metres which replaced them had existed for centuries among the people, though rigorously excluded from the vellums. The new poets abandoned the syllable counting by lines with a fixed number of stresses; the stressed vowels rhymed in patterns which might be very simple or, later, bewilderingly intricate, but simple vocalic assonance took the place of the earlier rhyme. The language of poetry moved consistently toward the language of the people, and this, combined with the freedom of the new metres, allowed the poets to speak with a new vigour. While they had little patronage, there was at least an increasing supply of paper, so that their works, still barred from the printing press, were able to be circulated freely among the literate. Naturally enough, the tone of verse throughout the 17th century was one of passionate defiance of the new regime. In it is found the first coherent expression of patriotism conceived as devotion to an abstract ideal rather than as loyalty to an individual — a concept of considerable importance in the later history of the country. But it must be admitted that much of the verse of this period represents a mere nostalgia for the past, the vain regrets of men who had been forced to exchange the pen for the spade.

By far the greatest of the poets of the song metres was Dáibhidh Ó Bruadair, who died at the end of the 17th century (works edited with translation by J. MacErlean, London, 1910–17). Ó Bruadair and Ó Raithile, of slightly later date, still had some patrons. After them the poetic tradition, while remaining, in Munster at least, extraordinarily subtle in craftmanship, was preserved only among the common people and ceased to have any contact with reality, as the *aisling* (vision) poetry, singing a Jacobite restoration, sufficiently demonstrates. But it had real vigour in such themes as satire and *pastourelle*, and these peasant poets maintained the literary tradition until the end of the 18th century. The last magnificent flowering of the Munster tradition was *Cúirt an Mheánoíche (The Midnight Court)*, written by Brian Merriman, a Clare schoolmaster (translated by Frank O'Connor, London and Dublin, 1945). Perhaps the best-sustained poem in Irish, it is an exercise on traditional themes, such as that of the *mal mariée*, in a metre which is an ingenious and successful adaptation of the heroic couplet to the Irish style. After it, Irish poetry became a matter of folk songs, and even these were produced less and less after the crushing blow to the language inflicted by the great famine (1846–47).

Prose. — During the 17th century the tradition continued to produce a good deal of prose, mainly antiquarian and of inestimable value today, for the writers were able to draw on many sources now lost. By far the most important is *Annála Rioghachta Eireann (The Annals of the Four Masters)*, a compilation of all the available material on the history of Ireland to 1616, made under the direction of the Franciscan lay brother Micheál Ó Cléirigh (Michael O'Clery; *q.v.*). Less readable, but also of great historical importance, are the genealogies compiled by Dubháltach Mac Fir Bhisigh. Geoffrey Keating (c. 1570–1646), who wrote a dignified yet simple prose based on the bardic language, produced the first historical (as opposed to annalistic) work in Irish in his *Foras Feasa ar Eirinn* (edited with translation by D. Comyn and P. Dinneen, London, 1901–08), as well as some fine verse in both the old and the new metres, and two spiritual treatises. A number of religious works, printed by the Irish Franciscans in Louvain, were smuggled into the country; it is significant that manuscript transcripts are more numerous today than printed copies. The earliest book to be printed was the Protestant translation of the New Testament (in 1603), but for obvious reasons this has exerted little influence.

An interesting development in prose style was the satire called *Páirliment Chloinne Tomáis (Parliament of Clan Thomas)*, in two parts, probably of different authorship, one written before, one after, the Cromwellian wars. It appears to have been written by a representative of the bardic order, for it attacks with equal savagery the new ruling class and the native peasantry, using a style very close to that of the earlier *crosánacht*, but with the prose now predominating over the verse. It found several imitators, but the old tradition was by this time too attenuated for so aristocratic an attitude to be maintained.

The imaginative prose of the paper manuscripts was in general of a much more popular kind; it consisted mainly of developrnents of the Fenian themes or of romances in which themes drawn from Irish and foreign mediaeval literature were freely mingled with folklore and *fabliau* elements. As in the case of the song metres, there is reason for believing that these romances had a considerable tradition behind them before they appeared in writing. They were the form in which the people assimilated the literature circulating among the aristocracy. The circumstances of their trans-

mission have caused a considerable divergence in the forms in which they are found; it may be for this reason that comparatively few of them have been published, let alone studied. With a public growing steadily more apathetic and less able to read Irish, there could be little hope for prose production. During the 18th and early 19th centuries the only books printed in Irish were a few catechisms and devotional tracts. The manuscript tradition was carried on by a few devoted scribes into the first half of the 19th century, when it all but died out. By the middle of the century there was no literary activity in Ireland and all but a handful of the speakers of the language were illiterate in it.

REVIVAL PERIOD

An antiquarian interest in the Irish language and its literature had begun early in the 19th century, and the publications of J. Hardiman, J. O'Donovan and E. O'Curry, especially the last-named's *Lectures* on the Manners *and Customs* of the Ancient *Irish* (London, 1873), had caught the imagination of many of the educated classes, whose language of culture had for centuries been English. The Young Irelander Thomas Osborne Davis was probably the first to see how the restoration of the Irish language could be made a political force in a national movement, but the increasing interest remained for a time academic and did not turn to discussion of measures for the preservation or extension of the speaking of Irish until the establishment of the Gaelic league in 1893. This movement had its counterparts in every European country from Catalonia to Finland, but there were difficulties in Ireland unparalleled elsewhere. The speakers of Irish had sunk to the status of a minority and, worse still, since the language of Irish nationalism had been English for more than 200 years, neither they themselves nor their English-speaking fellow countrymen looked on Irish as a prerequisite of separate nationhood. The curious result was that the revival in Irish, came from the enthusiasm of antiquarians and nationalists, few of them Irish-speaking in origin, rather than from the Irish-speaking peasants themselves—a situation which still exists to some extent. The culmination of the revival movement was the situation in the Republic of Ireland, where Irish and English enjoy equality before the law and all schoolchildren must reach a given standard in both languages. We need concern ourselves only with the results for Irish literature.

The revivalists were faced with a grave difficulty when they came to face the problem of writing a language which had lost its old standard and had split up into dialects. The classical bardic language was too archaic to be restored, and no Ivar Aasen or V. S. Karajich came forward to form a new language on the base of the dialects. The inevitable result was that native speakers and learners alike wrote the language of their native or adopted parish, a situation which continued, although by the middle of the 20th century a standard evolved by government departments was being increasingly accepted. This might have happened naturally had there been more speakers in the province of Munster, where the literary tradition was best preserved. It was a Munster priest, Father Peter O'Leary, who gave impetus to the revival with a stream of novels, essays and translations of all sorts, and it was a Munster fisherman, Tomás O Criomhthain, who produced the finest book of the revival in his An *tOileánach* (The *Islandman*) (translated by R. Flower, Dublin, 1934). In the Ulster dialect there was some good writing by Séamus Ó Grianna ("Máire") and his brother Seosamh Mac Grianna. Connaught produced three good short-story writers in Padraic Ó Conaire, Máirtín O Cadhain and Liam O'Flaherty (who also wrote in Englishj. In general the short story is the most successful as well as the most popular form. The novels demonstrate the national inability to handle *l'œuvre* de *longue haleine*. The drama, still lacking theatres, consists mostly of translations, and no poet of force has yet appeared. While a 20th-century literature is thus being built up in Irish, the older tradition has not been forgotten, and the Irish Folklore commission collected vast numbers of folk tales and songs and undertook the classification and publication of the material.

BIBLIOGRAPHY.—*General* works: The older period is covered by R. I. Best, *Bibliography* of Irish Philology and *of* Irish Printed *Literature*. vol. i (Dublin, 1913), vol. ii (Dublin, 1942); the literature of the revival period is dealt with by R. de Hae and B. Ni Dhonnchadha, *Clár Litridheacht na Nua-Ghaedhilge, 1850–1936,* 3 vol. (Dublin, 1938–40). There is no adequate history, A. S. de Blácam's Gaelic Literature *Surveyed* (Dublin and Cork, 1929) being merely a popular account. For the first two periods R. Flower, The *Irish* Tradition (Oxford, 1947), and M. Dillon, *Early Irish* Literature (1948), are authoritative studies. The most important periodicals are Zeitschrift *für* celtische Philologie (later *keltische*) (Halle, 1896–); Revue celtique (Paris, 1870–1934), continued as *Etudes celtiques* (Paris, 1936–); School of Irish Learning, Eriu (Dublin, 1904–); National University of Ireland, *Éigse* (Dublin, 1939–); *Celtica* (Dublin, 1950–); Folklore of Ireland Society, *Béaloideas* (Dublin, 1927–).

Early period: J. Vendryes, "L'Ecriture opamique et ses origines," Etudes *celtiques,* vol. iv (Paris); K. Meyer, Selections From Ancient Irish Poetry (London, 1913), Learning in Ireland in the Fifth Century (Dublin, 1913); R. Thurneyson, Die *irische Helden- und Königsage* (Halle, 1921); M. Dillon, Cycles of the Kings (London, New York, 1946); *Early Irish Society* (Dublin, 1954); K. jackson, *Studies in Early Celtic Nature* Poetry (Cambridge, 1933); T. F. O'Rahilly, Early Irish History and *Mythology* (Dublin, 1946); D. A. Binchy, "The Linguistic and Historical Value of the Irish Law Tracts," Proc. Brit. *Acad.,* vol. xxix (London, 1943), Studies *in Early Irish Law* (Dublin, 1936); G. Murphy, *Saga* and Myth in Ancient Ireland (Dublin, 1955).

Middle period: E. Knott, *Tadhg Dall O Huiginn* (Dublin, 1922–26), is the best study of bardic system and technique. See also E. C. Quiggin, "Prolegomena to the Study of the Later Irish Bards," Proc. *Brit.* Acad., vol. v (London, 1913); P. Walsh, Irish Men of Learning (Dublin, 1947).

Late period: D. Corkery, *The Hidden Ireland,* 2nd ed. (Dublin, 1925); G. Murphy, "Notes on Aisling Poetry," *Éigse,* vol. i (Dublin, 1939); J. H. Delargy, "The Irish Storyteller," Proc. Brit. Acad., vol. xxxi (London).

Revival period: The best appreciation is M. L. Sjoestedt-Jonval, "La Littérature qui se fait en Irlande," *Etudes celtiques,* vol. ii (Paris).

(D. GE.)

ANGLO-IRISH LITERATURE

It is impossible to dogmatize, as some have tried, about the limits of Anglo-Irish literature. It is enough to exclude on the one hand writers of Irish descent who have no direct connection with the country, such as the Bronte sisters, Edward FitzGerald, Edgar Allan Poe, Eugene O'Neill and T. E. Lawrence; and on the other, English writers domiciled in the country for a considerable time and showing decided traces of this in their work, such as Edmund Spenser and Anthony Trollope. We cannot draw hard and fast boundaries between a distinctive Irish literature in English and the contribution of Irish writers to English literature. The difference may be a real one, but it is too vague and uncertain to be taken into account here. The one type of writing merges into the other. All must count as Anglo-Irish literature, in whatever country and for whatever public it was originally produced. As to what constitutes an Irishman, one can only fall back on birth, early training and habitual residence.

The Beginnings.—Irish people take readily to writing in any language, perhaps more readily than they do to reading. Ireland's total output of literature must be enormous. It is therefore perhaps surprising that the first products of Anglo-Irish literature were so inconsiderable. It must, however, be remembered that until the 17th century the language of Ireland was Irish. The so-called Anglo-Irish were a small colony, a garrison holding a perilous outpost, constantly yielding linguistic as well as physical ground to the resurgent Gael; and even among the colonists English had to struggle for supremacy with Latin and French. A few manuscripts have survived, showing the existence of a vernacular poetry of no great originality or distinctiveness. The most striking example is the 13th-century satire *The* Lund of Cockaigne; but it is hard to say if any work lacking local allusions was originally composed in the country.

The first notable Irish writer in English was Richard Stanyhurst (1547–1618j, who contributed sections dealing with Ireland to Holinshed's Chronicle's, and attempted to write English quantitative verse on Latin models, with extraordinary results. From this time on, as the colony grew in numbers and importance and the conquest of the whole country was seriously attempted, the stream of Anglo-Irish writing began to swell, and gradually Gaelic as well as English names began to appear. In the next century may be found Sir John Denham (1615–69), author of the much admired Cooper's **Hill** and one of the pioneers of a smoother and

more regular versification, Lord Roscommon (c. 1630–85), Nahum Tate (1652–1715) and Nicholas Brady (1659–1726) among minor poets; Lord Orrery (1621–79) among minor dramatists; and Sir John Temple (1600–77), father of the more famous Sir William, may be mentioned among minor historians. But there was as yet no major name.

The 18th Century. — Writers of the first rank did not appear until the establishment of English as the predominant language, after the overthrow of the Gaelic culture and the arrival of hordes of new immigrants who were not so easily absorbed as their predecessors had been. But from then on, Irish writers of English were among the great. The first of these was Jonathan Swift (1667–1745). Irish-born of English parents and educated wholly in Ireland, he became a dominant literary figure in England. He returned to Ireland unwillingly as dean of St. Patrick's cathedral, Dublin, to become the idol of Ireland for his championship of a people he hated and loved, as he hated and loved all humanity, and to end as one of the great names in the literature of the world. Swift to the world at large means Gulliver's Travels. Ireland has rather remembered his tracts on its own wrongs, such as the *Drapier* Letters, among the first of a long series of such writings by Irishmen, which raised pamphleteering to the status of literature.

Nor does the dean stand alone at the beginning of the century. If Swift made politics literature, his friend George Berkeley (1685–1753) (*q.v.*), bishop of Cloyne, wrote philosophy which, apart from its importance in the history of human thought, is almost as admirable from the purely literary point of view as that of Plato. And it must not be overlooked that Bishop Berkeley was a convinced and admitted Irishman and a lover of his country, about whose welfare he expressed strong views in his *Querist*.

The Theatre. — Perhaps the greatest contribution of Ireland to the literature of the English language has been neither in philosophy nor in politics but in drama, especially comedy. Where would the English theatre be without William Congreve, George Farquhar, Oliver Goldsmith, Richard Brinsley Sheridan, Oscar Wilde, George Bernard Shaw? The first permanent theatre in Dublin was established in 1662. The swarms of Irish dramatic authors, both of native and of English stock, as well as of actors and managers, from the Restoration to the 20th century defies enumeration. Here we are concerned only with the authors. William Congreve (1670–1729) (*q.v.*), probably English-born but entirely Irish in rearing and education, is the greatest name in English Restoration comedy. George Farquhar (1678–1707) (*q.v.*), coming from the north though of Gaelic origin, has a gaiety and humanity all his own. Passing over Sir Richard Steele (1672–1729), a sentimental dramatist but primarily an essayist, and Thomas Southerne (1660–1746), a tragedian, we come to Oliver Goldsmith (1728–74), who touched nothing which he did not adorn, or was, if one prefers it, jack of all literary trades and perhaps entirely master of none, and who was the author of one supreme comedy, She Stoops to Conquer, said to be based on his own early experiences in County Longford.

Richard Brinsley Sheridan (1751–1816) was born in Dublin of a decidedly literary family of native origin. He was exiled at a very early age through the misfortunes of his father and never returned to Ireland; but he maintained the witty tradition of Anglo-Irish comedy, raising it to unprecedented heights in his immortal comedies The Rivals and The School for Scandal. There were many successful minor Irish dramatists, including Arthur Murphy (1727–1805) and Hugh Kelly (1739–77), but the plays were the common repertory of the English-speaking theatre of the time. The few plays written especially for Irish consumption were of no particular merit.

Poetry and Prose. — Turning to poetry mention must be made again of Swift and Goldsmith, and Thomas Parnell (1679–1718) (*q.v.*), a melancholy though not unpleasing poet, chiefly remembered for his *Nightpiece* on Death, must not be forgotten. There were some minor poets, but on the whole Anglo-Irish poetry did not flourish till the romantic movement late in the century. As for prose, the novel was only just coming into existence. Once again Goldsmith produced a major work, The Vicar of *Wakefield*. Laurence Sterne (1713–68) was born in Ireland, though he did not live or work there. Political eloquence in those days grew into literature. Edmund Burke (1729–97) (*q.v.*) was a political philosopher and an orator whose speeches read better than they sounded. Sheridan was as great a parliamentary speaker as he was a dramatist. No less notable was the eloquence of John Philpot Curran (1750–1817), and some of the speeches on Irish themes by Henry Grattan (1746–1820) are among the greatest of their kind.

The 19th Century. — With the 19th century came a change. The old, conquered Ireland, prostrate for so long, was beginning to rise to its feet. The Anglo-Irish colony, too, was gaining self-confidence and feeling itself a distinct entity. Nationalism, liberalism and revolution were in the political air, while romanticism was beginning to affect the arts. Moreover, antiquarianism had begun to uncover the Gaelic past. This had never been wholly forgotten; even Dean Swift had translated a poem from the Irish. But Charlotte Brooke (1740–93), the daughter of Henry Brooke, a dramatist and novelist himself, was the first to make verse translations on a more extensive scale, and soon there were others. Native and settler alike began to feel a new interest in their country. Irish nationality, as it is known today, was born. Until this time we have had for the most part merely to consider books by Irish authors; thenceforth books about Ireland predominated. Of such books an enormous number was produced. The romantic movement and the discovery of Ireland's ancient tradition provided an incentive. Irish literature in English became more plentiful and more distinctive than ever before.

Poetry. — For the first time poetry came to the forefront. Anglo-Irish verse was definitely established by Thomas Moore (1779–1852). Moore was a most versatile poet and a singer of his own songs. In his Irish *Melodies* he attempted to solve the problem of setting English words to Irish airs, which was not so easy as it sounds. The result may not please the purist in folk song, but it was very singable as well as good poetry; as the matter of the songs was Irish, often vehemently so, the wrongs of Ireland were warbled in English drawing rooms, with great ultimate advantage to the Irish cause. Nor did Moore's own people fail to appreciate him; he was a national hero as no other Irish poet has been. Quite apart from his songs, his oriental epic Lalla Rookh brought him wealth and fame. At one time there was a tendency to deprecate Moore, both as poet and as Irishman. Fortunately, this attitude seems to have largely passed away.

Moore wrote in English. In order to be Irish, he did not think it necessary to write in dialect or to attempt the style of folk poetry, as did some of his contemporaries, such as J. J. Callanan (1795–1829), who wrote very free adaptations from the Irish. Another contemporary, however, George Darley (1795–1846), wrote in a most exquisite and scholarly style, and his work was mistaken for that of an Elizabethan or 17th-century poet. It is a pity that most of his work is now inaccessible. A slightly earlier writer was the Spenserian poet Mary Tighe (1772–1810), much admired in her own day, and with good reason, for her Psyche.

In 1842 the patriotic organization known as Young Ireland, led by Thomas Osborne Davis (1814–45), an eloquent and sincere writer in prose and verse, founded a new paper, the *Nation*. A large number of poets and prose writers attached themselves to it. Besides Davis himself, who died young and regretted in 1845, poets of merit were Thomas D'Arcy McGee (1825–68), Richard Dalton Williams (1822–62) and Lady Wilde (1826–96). Another notable journal of the time was the Dublin University Magazine, which lasted for about 40 years and was probably the finest magazine ever produced in Ireland. Its politics were the direct opposite of those of the Nation, but it was mainly literary, and most of the best Irish writers contributed to it. Of its poetical contributors the most notable was James Clarence Mangan (1803–49) (*q.v.*), an enormously prolific and most uneven writer of every kind of verse, including numerous translations from languages which he probably did not know of poems which did not exist. At his best, when inspired by his love of Ireland or by his own miseries, due largely to alcohol, he was one of the very greatest poets of Ireland. He was much influenced by the German romantics and in turn

influenced Edgar Allan Poe. Another notable poet was Sir Samuel Ferguson (1810–86), who wrote on Irish themes in a strikingly original way, inspired to some extent by Gaelic examples. Among other poets of a very poetical time were Denis Florence MacCarthy (1817–82) and Aubrey de Vere (1814–1902), who were more typical of their period. William Allingham (1824–89) wrote poems in ballad style and a long and interesting narrative in verse, *Laurence Bloomfield in Ireland.* He later settled in England and became an associate of Dante Gabriel Rossetti. He adopted the Pre-Raphaelite manner, which links him with W. B. Yeats and the next period of Irish writing.

Prose.—Among the novelists are found Charles Maturin (1782–1824), whose *Melmoth the Wanderer* had a wide influence in Europe. Even better known was Maria Edgeworth (1767–1849) (*q.v.*). In the course of a long and busy life she produced many novels, always with some edifying tendency but none the worse for that. She knew the Ireland of her day well and depicted it with insight and humour in *Castle Rackrent* and *The Absentee.* A landlord's daughter, she believed firmly that the solution of Ireland's troubles lay in the improvement of the outlook of its landlords. Novelists who wrote of country life mainly from the point of view of the tenant were William Carleton (1794–1869), a powerful storyteller though a poor stylist, whose masterpiece is *Fardorougha the Miser;* and the immensely popular Charles Joseph Kickham (1826–82), poet, Fenian and political convict, whose *Knocknagow* was for long Ireland's favourite reading. Other novelists of rural life were Gerald Griffin (1803–40) and the brothers Banim. Lady Morgan (1783–1859) wrote *The Wild Irish Girl* and other novels.

William Hamilton Maxwell (1792–1850) wrote lively stories dealing largely with sport. He inspired the better-known Charles Lever (1806–72). Lever, at one time editor of the *Dublin University Magazine,* wrote a long series of novels, lively and interesting, though often careless. He knew Ireland well and could write seriously enough of Irish matters; but as some of his best-known work is broadly humorous, he has been unjustly accused of ridiculing the nation. Another humorous writer, often mentioned with Lever though not his equal, was the versatile Samuel Lover (1797–1868).

Joseph Sheridan Le Fanu (1814–73) was a successful writer of a different kind. Owner and editor of the *Dublin University Magazine* in the 1860s, he wrote many novels and short stories, chiefly dealing with mystery, crime and the supernatural. He was perhaps the greatest Irish master of the ghost story. *In a Glass Darkly* contains the best of his work of this kind. *Uncle Silas* is his finest novel. He was also a poet, and there is a poetic quality about all his work which raises it far above the commercial thriller.

John Mitchel (1818–75), author of the *Jail Journal,* W. E. H. Lecky, the historian (1838–1903), and Edward Dowden, the critic (1843–1913), were all outstanding 19th-century writers in their several ways. Only the drama produced no outstanding name.

The Literary Renaissance.—Toward the end of the 19th century a new movement in Irish literature became apparent. In fact, such changes came over literature everywhere. In the 1890s two great Irish dramatists appeared, the first for a century: Oscar Wilde (1854–1900), son of Sir William Wilde, a fine writer on Irish antiquities, and Lady Wilde of the *Nation;* and George Bernard Shaw (1856–1950). Neither wrote of or for Ireland, but they were outstanding Irish dramatists in the old Anglo-Irish tradition. Perhaps they were the last of their kind; for a definitely Irish theatre was now arising, as part of a new, consciously Irish literary movement, known as the Irish literary renaissance.

The movement, which was closely allied with a new and strong political nationalism and with a revival of the Irish language, centred from the first around the greatest Irish poet, William Butler Yeats (1865–1939) (*q.v.*), Pre-Raphaelite, theosophist, modernist, but always a thorough Irishman. Though he contributed to the foundation of the first Irish theatre, the Abbey, his dramas were few. He wrote some beautiful plays, but they were not easily produced. His chief colleague at the Abbey was Lady Gregory (1852–1932), who not only took a leading place in the management but also contributed many plays, mostly peasant comedies. The greatest dramatic name of the movement was that of John Millington Synge (1871–1909). He wrote in a peasant dialect, largely of his own invention, and his plays have great beauty and power. His early death was an irreparable loss to Irish drama. Later, the theatre, founded for poetry and noble speech, became absorbed in realism, mostly rural realism. Lennox Robinson (1886–1958) and T. C. Murray (1873–1959) are the most important of the realists, and Sean O'Casey (1884–) replied to peasant realism with his brilliant and moving dramas of the Dublin slums. Subsequently he left Ireland and attempted a kind of symbolical drama with less obvious success. Later dramatists continued to supply plays to the Abbey and its younger rival, the Dublin Gate theatre, and most modern Irish writers occasionally attempted drama. St. John Ervine (1883–) wrote successfully for both the Irish and English theatres.

In poetry, besides Yeats, was George Russell, known as Æ (1867–1935), mystic, patriot and agricultural reformer, who left a large quantity of beautiful if rather vague verse. Also notable were Padraic Colum (1881–), Austin Clarke (1896–), Seumas O'Sullivan (1879–1958), F. R. Higgins (1896–1941) and Oliver St John Gogarty (1878–1957). The Republican movement which led to Irish independence had its poets, P. H. Pearse (1879–1916), Thomas Mac Donagh (1878–1916) and Joseph Mary Plunkett (1887–1916), all executed after the rising of 1916; and a strong sympathizer in Francis Ledwidge (1891–1917), a rural lyricist, though he was killed fighting for England in World War I. More recent poets are numerous, but too many are either a pale reflection of the earlier writers of the literary renaissance, or a still paler reflection of English literary fashions. A very individual writer who went his own delightful way was Lord Dunsany (1878–). He was not only a poet but a prolific and successful writer of novels, plays and short stories.

In the realm of the novel were the historical tales of Emily Lawless (1845–1913) and Standish James O'Grady (1846–1928), while Canon P. A. Sheehan (1852–1913) presented aspects of Irish life through the eyes of an Irish priest. By way of contrast there was George Moore (1852–1933), an imitator of French naturalism, who suddenly attached himself for a time to the Irish cultural movement; his delightfully impudent account of its leading figures in *Hail and Farewell* is on the whole more readable than his over-carefully written novels.

So we come to the amazing productions of James Joyce (*q.v.;* 1882–1941), who made himself and Dublin famous throughout the world. Whatever else may be said of his work, it was redolent of Dublin from end to end. James Stephens (*q.v.;* 1882–1950) wrote fanciful stories as well as verse of some charm. The excellent novels of E. Œ. Somerville (1861–1941) and Martin Ross (1865–1915), some humorous, some tragic, must also be mentioned.

The Moderns.—Of later writers, Liam O'Flaherty (1897–) produced a new and more violent type of fiction, stripping away many of the illusions which enveloped Irish writing, but probably creating a few of his own. When he was not writing sensationally for sensation's sake, his novels and stories were full of power. Brinsley MacNamara (1890–), also a dramatist, wrote tales of the quiet midlands which were original and interesting. Frank O'Connor (1903–) began as a poet, earned distinction as a novelist, but later wrote mainly short stories and articles. Sean O'Faolain (1900–) was equally versatile. His biographical works are outstanding. Elizabeth Bowen (1899–) and Kate O'Brien (1898–) were popular women novelists. Stephen Gwynn (1864–1950) excelled in biography, history and many kinds of writing. His son Denis Gwynn (1893–) followed worthily in his footsteps. (*See* also ENGLISH LITERATURE; POETRY.)

IRISH MOSS or CARRAGEEN (Irish *carraigeen,* "moss of the rock") a seaweed (*Chondrus crispus*) which grows abundantly along the rocky parts of the Atlantic coast of Europe and North America. In its fresh condition the plant is soft and cartilaginous, varying in colour from a greenish yellow to a dark purple or purplish brown; but when sun-dried and bleached it has a yellowish, translucent, hornlike aspect and consistency. The principal constituent of Irish moss is a gelatinous substance carrageenin. Carrageenin for commercial use is extracted by boiling Irish moss that has been dried to a hornlike aspect and consistency, In Europe, Irish moss used for the extraction of carrageenin is obtained from plants cast ashore. In the United States it is collected from shallow water and dredged with special rakes. Commercial uses of carrageenin include its use as a thickener in calico printing. for clarifying beer and as a suspension medium. One use as a suspension medium is in the preparation of chocolate milk by dairies. (G. M. S.)

IRKUTSK, a city in the East Siberia region, administrative centre of an *oblast* of the same name. in the Russian Soviet Federated Socialist Republic, in latitude 52° 36' N., longitude 104° 10′ E., altitude 1,490 ft. It is situated on the right bank of the Angara river, a tributary of the Yenisei river, 45 mi. below its outflow from Lake Baikal; its suburb Glazkovskoe lies on the left bank, and a pontoon bridge spans the river, which is 630 yd. wide. The railway and station are on the left bank. The Irkut river, from which the town of Irkutsk takes its name. enters the Angara river on its left bank, but is not navigable, and the small Ushakovka river flows through the town and enters the Angara on the right bank. The town grew out of the winter quarters established by Ivan Pokhabov in 1652 for the collection of the fur tax from the Buriats. Its position for trade with China, the Amur region, the Lena gold fields and the fur regions of Siberia made it an important city; its estimated population in 1948 was 300,000. A post road runs north to the Lena and Yakutsk and southeast to Listvenichnoe on Lake Baikal, and other roads link it with the east. The Angara is navigable for steamers to Lake Baikal, though the current is against them. The river is frozen from January to April. The average January temperature is —5.4° F., July 65.1° F.; the average rainfall per annum is 14.5 in. The town is well built with wide streets and has a drainage system and an electric power station. In 1879 fire destroyed many of the public buildings, including the library and museum of the Russian Geographical society which has there the headquarters of its Siberian section, with valuable books, maps and exhibits. The town has long been a cultural centre for the district. It contains schools, a training college for teachers and a Workers' Scientific institute. St. Innocent's monastery, five miles outside the town, influenced much of eastern Siberia. Its industries include brewing. timber milling. flour milling, leather works, the making of fur and sheepskin coats and various small articles especially for the posting routes. It was a storm centre from 1918 to 1921, and much damage was then done to the town and railway. The state gold treasure, which had been removed from Leningrad under the charge of employees of the tsarist regime. was handed over by them to the Bolshevists in Irkutsk in 1920; and Admiral Kolchak was executed there in the same year. The town was in tsarist times the centre of the Irkutsk province, an area occupying 287,061 sq.mi., but is now only the centre of one of the 20 counties of the Siberian area (*q.v.*).

IRMIN or IRMINUS, in Teutonic mythology, a deified eponymic hero of the Herminones. The chief seat of his worship was Irminsal, or Ermensul. in Westphalia. Wooden pillars raised to his honour were regarded as sacred by the Saxons.

IRON ranks second in abundance among the metals and fourth in abundance among the elements. The earth's core is largely metallic iron. but in the crust the element has had an opportunity to react with other substances and the free metal is rarely found except in meteorites or disseminated as minute speculae in basaltic rocks. Iron is a constituent of hundreds of mineral species; small amounts are found also in water, plants and blood.

Meteors are composed chiefly of iron, and tools and weapons were made from this by primitive man. The Aztecs had implements made of meteoric iron before the coming of the white man, and prized this metal above gold. In general use, however, bronze tools and weapons came long before iron ones, the smelting of copper being an easier process than that of iron. The metallurgy of iron is believed to have been developed in western Asia in the 2nd millennium B.C., spreading in waves that reached other regions at intervals centuries apart.

The Assyrians and Egyptians made considerable use of iron. In Gen. iv. 22, Tubal-cain is mentioned as an instructor of workers in iron and copper; and iron was utilized to make tools and weapons in the time of David. The Dorian invaders. who were the forerunners of the classic Greeks, were equipped with iron tools and weapons, Homer speaks of a ball of iron as the prize awarded to Achilles for athletic prowess. The Greeks obtained ores from the south coast of the Black sea, and the Romans from Spain and Elba; evidently there were earlier sources in India.

Igneous rocks contain an average of 5.01% of iron. The important ores are the oxides and carbonates from which the metal is obtained by smelting with carbon.

This is done commercially by blowing heated air through a mixture of ore, coke and limestone in a blast furnace under conditions where a maximum temperature of about 1,300° C. is reached. The crude metal obtained is called cast iron or pig iron and contains various impurities; carbon, silicon. sulfur, manganese and phosphorus are most important. Steel and wrought iron are made by oxidizing the impurities in pig iron with air or ferric oxide at high temperatures and collecting them in a suitable flux to obtain the required degree of purification. Commercial production and industrial uses of these materials are treated under IRON AND STEEL, this article being limited to a general description of the properties of the element and its important compounds.

Iron, as commonly available, nearly always contains small amounts of carbon, which modify its properties. It may be prepared by passing hydrogen over purified iron compounds (the oxides for example) at high temperature or by electrodeposition from solutions of iron salts.

PHYSICAL PROPERTIES

Iron is tetramorphous. The delta form exists above 1,400° C., at which temperature there is a transition to gamma iron. The latter has a face-centred cubic lattice, is weakly paramagnetic and forms solid solutions with iron carbide (Fe_3C); this property is of importance in the preparation of steel. At 89j° C. there is a transition to beta iron. This form is body-centred cubic, weakly paramagnetic and stable down to 766° C., where alpha iron is obtained. The body-centred cubic lattice is retained in this transition but alpha iron is strongly paramagnetic, indicating a definite change in electronic structure in going from beta iron to alpha iron. In the alpha form, iron is a soft, ductile. gray-white metal of high tensile strength.

Values for some of the physical properties of the pure metal are given in the accompanying table.

Physical Properties of Iron

Coef. expansion; cubic 0° to 100° C. ..... 0.04355/° C.	Tensile strength annealed wire ..... 50–60 × 10^3 lb./sq. in.
Electrode potential $Fe=Fe^{++}+2e$ 25° C. .... +0.440 v.	Boiling point ..... 2,73j° C.
Ionization potential of gas atom ..... 7.83 v.	Density 20° C. ..... 7.86 g./ml.
Resistivity 20° C. ..... 0.04100 ohm-cm.	Melting point ..... 1,530° C.
	Radius of Fe^{++} ..... 0.7j A
	Specific heat (average 0° to 100° C.) .. 0.11 cal./° C.

CHEMICAL PROPERTIES

Iron, the metallic chemical element of atomic number 26, symbol Fe, has an atomic weight of 55.85, which represents a mixture of the isotopes 56, 54, 57 and 58 in that order of abundance. Radioactive isotopes with mass numbers j3, 55 and 59 have been prepared.

Iron is a member of the first transition series, in which the electrons in the third level increase from 8 to 18, and has the following outer electron arrangement: $3d^6$, $4s^2$.

The properties of iron are similar to those of the other transition elements, particularly cobalt and nickel. Iron is also related to ruthenium and osmium, the corresponding elements in the second and third transition series. In common with the other transition elements in this series?it readily loses its 4s electrons to form the +2 oxidation state shown in ferrous iron. The properties of ferrous ion are similar to those of the other +2 ions in the series and it resembles manganous ion, particularly, in the solubilities of its compounds. Ferric iron, the +3 oxidation state, is readily obtained and the ion resembles the chromic ion in the solubilities of many of its salts. The +4 state is realized in perferrite, FeO_3^{--}, and the +6 state in ferrate, FeO_4^{--}, both being obtained by the action of strong oxidizing agents in alkaline media. Only a limited number of ferrites and ferrates are known and the most important oxidation states of iron are the +2 and +3.

The Metal.--In accordance with the potential given in the table, metallic iron acts as a strong reducing agent. Solutions containing the ions of gold, platinum, silver, mercury, bismuth and copper are reduced by iron to yield the metal in each case. In contact with nonoxidizing acids, iron dissolves by reducing hydrogen ion to hydrogen gas, forming ferrous ion. Since the metal reduces ferric to ferrous ion, moderately strong oxidizing agents produce ferrous ion if the metal is in excess and ferric if the oxidizing agent is in excess. Iron combines directly with most of the nonmetals at moderate temperatures and may be made to "burn" in many of these cases because of the large amounts of heat evolved in the reactions. Upon immersion in concentrated nitric acid, which does not dissolve it, iron is made "passive" and will not dissolve in dilute acids nor in the metal ion solutions listed above. This phenomenon is shown by other transition metals such as chromium, molybdenum, cobalt and nickel in this series and by many other metals. In general, passivity is produced by the action of strong oxidizing agents, including anodic polarization, and may be destroyed by the action of reducing agents, by scratching the surface. or by specific agents in particular cases. It is apparently caused by the formation of surface oxide films and is useful in controlling corrosion.

Under the usual atmospheric conditions iron rusts to form hydrated ferric oxides. This process occurs in two steps: first, iron dissolves in the acid solution provided by the moisture and the carbon dioxide of the air to form ferrous ion and liberate hydrogen; second, oxygen from the air oxidizes the ferrous ion to form hydrated ferric oxides. The first step is slow with pure iron but is catalyzed by many impurities which facilitate the liberation of hydrogen from the metal surface. (See CORROSION AND OXIDATION OF METALS.) Iron reacts with steam to produce hydrogen and ferroferric oxide, or ferrous oxide if the temperature is above about 570° C. Ammonia acts on iron at high temperatures to form hydrogen and the nitride Fe_2N. Carbon dioxide is reduced by the metal at elevated temperatures to carbon monoxide with the formation of ferrous oxide.

Properties of Ferrous and Ferric Ions.—Ferrous ion is pale green in solution and in most of its hydrated salts. Solutions of ferrous ion are only slightly hydrolyzed since ferrous hydroxide is a fairly strong base. The electrode potential of the ferrous, ferric couple is −0.77 v. at 25° C., and solutions of ferrous ion are unstable with respect to air oxidation. Common reagents used to oxidize it to ferric are permanganate, dichromate, peroxide. bromine and nitric acid. Ferrous ion may be precipitated from approximately neutral solution as the sulfide, hydroxide, phosphate, arsenate, carbonate and oxalate; the ferricyanide may be precipitated from acid solution. In strongly acid solution ferric ion is yellow; as the acidity is decreased, hydrolysis occurs to an increasing degree, forming basic ions and colloidally dispersed hydrated ferric oxide, which colour the solution brownish yellow. There is little tendency to form acid ions even in strongly basic media although many compounds contain the +3 state as ferrite, FeO_2^-. Ferric ion is commonly reduced to ferrous by sulfide, sulfite, stannous chloride, zinc amalgam, hydroxylamine and iodide. It may be precipitated from weakly acid solution as the hydroxide, ferrocyanide, phosphate, arsenate, and by the formation of salts with many organic compounds.

In addition to forming simple salts, where the valence and the oxidation number are equal, ferrous and ferric iron form many complex compounds and ions in which the co-ordination number is six; that is, where there are six atoms or groups attached to the metal ion. Simple examples of such complex formation are ferrocyanide $Fe(CN)_6^{-4}$ and ferricyanide $Fe(CN)_6^{-3}$ ions.

The formation of complexes is common to almost all of the ions that have more than eight electrons in their outer shell and is associated with the existence of partially occupied orbitals of closely related energies that can be used to accept electron pairs from various atoms or groups. In the case of ferric and ferrous iron six pairs of electrons can be so shared by using the vacant 3d (two), 4s (one) and 4p (three) orbitals, giving the co-ordination number of six, independent of the oxidation state of the iron. Complexes are formed with iron in which the type of binding of the complexing groups is ionic as well as covalent. Ferric iron forms complex ions with such inorganic groups as water. ammonia, cyanide, fluoride, chloride and thiocyanate and with such organic ions as oxalate, citrate, tartrate, tannate and gallate, to mention only a few. In addition there are an extremely large number of chelate compounds formed with organic molecules in which each of the organic molecules is bound to the iron through two of its atoms, making use of both valence and co-ordination bonds. Most of these compounds are very stable and are soluble in organic solvents but not soluble in water. Many of the organic reagents such as cupferron, orthophenathroline, 8-hydroxyquinoline and dipyridil, used in analysis for iron, form such chelate compounds; ferric and ferrous hemoglobin, so important in blood, are of this type.

See CO-ORDINATION COMPOUNDS.

COMPOUNDS OF IRON

Oxides, Hydroxides and Acids.—Iron forms three oxides: ferrous oxide, FeO; ferric oxide, Fe_2O_3; and ferroferric oxide, Fe_3O_4. It also forms ferrites, perferrites and ferrates which may be regarded as salts of the potential acids, ferrous, $HFeO_2$; perferrous, H_2FeO_3; and ferric, H_2FeO_4.

Ferrous oxide is a black pyrophoric powder readily soluble in acids. It may be obtained by reducing ferric oxide in hydrogen or by the action of steam, carbon dioxide or oxygen on iron at high temperatures.

Ferrous hydroxide is precipitated from neutral or basic, air-free solutions as a white flocculent material that is rapidly oxidized by air to become green and finally reddish brown as ferric oxide is formed. It readily absorbs carbon dioxide to form ferrous carbonate and is easily dissolved in acids.

Ferric oxide or iron sesquioxide exists in several anhydrous and hydrated forms including the important ores hematite and specular iron; the minerals limonite and goethite; and iron rust. It is obtained as a steel-gray powder by igniting almost any ferric compound in air; when finely powdered, the ignited material appears brownish red. After ignition it dissolves extremely slowly in acids, hydrochloric acid in combination with a reducing agent being the best solvent. The finely divided oxide is used as an abrasive called "iron rouge" and as pigment, venetian red.

Ferric hydroxide is not simply characterized since hydrated ferric oxides of various structures and compositions are included by the name. It precipitates as a red-brown gelatinous material that is difficult to filter and tends to form stable colloidal dispersions that are usually positively charged. Among structures that have been characterized by X-ray patterns are alpha Fe_2O_3 hydrate, precipitated as a brown gel by the addition of alkalies to ferric solutions; beta Fe_2O_3 hydrate, formed by the hydrolysis of ferric chloride solutions; and gamma Fe_2O_3 hydrate, obtained under certain conditions when ferrous is oxidized to form ferric hydroxide. The freshly precipitated forms are readily soluble in acids but become more difficult to dissolve if they are partially dehydrated There is only a slight solubility in strong bases with the formation of ferrite ion, FeO_2^-. Purified colloidal ferric hydroxide is used in medicine as "dialyzed iron."

Ferrites may be prepared by fusing ferric oxide with basic oxides to form such compounds as sodium ferrite, $NaFeO_2$. Magnesium ferrite occurs as the mineral magnoferrite, and zinc ferrite occurs as franklinite; iron commonly occurs as ferrite in many complex minerals. The important mineral magnetite is ferrous ferrite. $Fe(FeO_2)_2$.

Ferroferric oxide, mentioned above as ferrous ferrite and magnetite, is always attracted by a magnet and is frequently magnetic; specimens in the latter case are loadstones. The compound is most simply obtained by passing steam over red-hot iron and is commonly observed as mill scale in the fabrication of iron and steel. It dissolves in acids forming ferric and ferrous ions in the ratio of 2 to 1 and a brown hydrated form may be precipitated from such a solution by the addition of alkali.

Perferrites of barium ($BaFeO_3$) and strontium ($SrFeO_3$) have been prepared by heating a mixture of barium hydroxide or strontium hydroxide and ferric oxide in a stream of oxygen. Water decomposes these compounds with the liberation of oxygen.

Ferrates are formed by strong oxidizing agents acting on iron ions in fused alkali or in concentrated alkaline solutions. Thus chlorine acts on a suspension of ferric hydroxide in concentrated potassium hydroxide to form an amethyst or purple-red solution of potassium ferrate. The addition of barium ion to this solution precipitates barium ferrate. $BaFeO_4.H_2O$, as a dark red powder. Barium ferrate is fairly stable. It dissolves in acetic acid to form a red solution, is not attacked by cold sulfuric acid but evolves chlorine and oxygen from cold hydrochloric acid.

Arsenides, **Arsenites, etc.**—Several iron arsenides occur as minerals; mispickel or arsenical pyrites, Fe_2AsS_2, is an important commercial source of arsenic. A basic ferric arsenite, $4Fe_2O_3.As_2O_3.5H_2O$, is obtained as a flocculent brown precipitate by adding an arsenite to ferric acetate or by shaking freshly prepared ferric hydrate with a solution of arsenious oxide. The last reaction is the basis of the application of ferric hydrate as an antidote in arsenical poisoning. Korma! ferric arsenate, $FeAsO_4.2H_2O$, constitutes the mineral scorodite.

Carbides, Carbonates, Carbonyls, Cyanides.—The importance of the carbide Fe_3C, cementite, in the manufacture of steel is treated under IRON AND STEEL. (See also CARBIDES.)

Ferrous carbonate, $FeCO_3$ occurs as the mineral siderite or spathic iron ore. It is precipitated from ferrous solutions, by the addition of a soluble carbonate, as a white flocculent material that rapidly oxidizes in air to become green and finally brown as ferric salts form. It is readily soluble in acids. Ferric carbonate cannot be precipitated from solution because of hydrolysis which leads to the formation of ferric hydroxide and basic carbonates.

Carbonyls of iron form an interesting group of compounds. Finely divided iron slowly reacts with carbon monoxide to form ferropentacarbonyl, $Fe(CO)_5$, which distills off at 120° C. It is a pale yellow liquid which freezes at −21° C., boils at 102° C., decomposes above 200° C. and is decomposed by air and moisture. When ferropentacarbonyl is dissolved in a base, the carbonate and the ion $Fe(CO)_4^{--}$ form, the latter being the anion of the acid carbonyl hydride, $Fe(CO)_4H_2$. Carbonyl hydride is formed when the solution is acidified in the cold. Upon oxidation with hydrogen peroxide, carbonyl hydride yields $Fe_3(CO)_{12}$. In sunlight the pentacarbonyl loses carbon monoxide to form the nonacarbonyl, $Fe_2(CO)_9$, and upon heating the tetracarbonyl, $Fe_3(CO)_{12}$, is obtained. The nitrosocarbonyl, $Fe(CO)_2(NO)_2$, is also known.

For the relation of these compounds to the other carbonyls see CARBONYLS, METAL.

Cyanides.—The very stable complexes ferrocyanide, $Fe(CN)_6^{-4}$, and ferricyanide. $Fe(CN)_6^{-3}$, are formed in excess cyanide and are not decomposed even in strong acid solutions. The ferrocyanide, ferricyanide potential is about −0.4 v., so that the oxidation and reduction of these ions is easily accomplished by many of the common oxidizing and reducing agents. Sodium and potassium ferrocyanides are obtained as by-products in the distillation of coal, after absorbing the evolved hydrogen cyanide in iron oxide "purifiers" Potassium ferrocyanide is commonly called yellow prussiate of potash and the ferricyanide, red prussiate of potash.

Addition of ferric ion to a solution of ferrocyanide first yields soluble prussian blue, $KFeFe(CN)_6$, and then $Fe_4[Fe(CN)_6]_3$, which is the insoluble pigment prussian blue. Many metal ions such as zinc, uranyl and copper form insoluble ferrocyanides of analytical use. Ferrous ion forms a white precipitate ferrous ferrocyanide. With ferricyanide, ferric ion forms a brown soluble ion and ferrous ion forms Turnbull's blue, $Fe_3[Fe(CN)_6]_2$, which is insoluble. In both ferrocyanide and ferricyanide, one of the cyanide groups can be replaced by other groups such as nitrite oxide, carbon monoxide. sulfite, nitrite or ammonia to form complex pentacyanides. The compound $Na_2FeNO(CN)_5$, sodium ferrinitrosopentacyanide (often called sodium nitroprusside), is used as a test for sulfide in basic solution where an intense blue colour is produced.

Blueprint paper is made by treating paper with ammonium ferricyanide and ferric citrate. Upon exposure to light the ferric ion is reduced by citrate to ferrous which then reacts with the ferricyanide to form insoluble prussian blue. The paper may then be developed by washing out the unchanged ferricyanide and ferric salts with water. (See also PRUSSIC ACID.)

Halides of ferrous ion have the general formulas FeX_2, where X represents any of the halogens. They can be prepared by passing the halogen acid, HX, over metallic iron or by reaction of excess metal with the halogen. X_2, under controlled conditions. The anhydrous salts are very hygroscopic, form a series of hydrates and, with the exception of the fluoride, $FeF_2.8H_2O$, are very soluble in water. The hydrated salts may be prepared by dissolving the metal in aqueous halogen acid solution from which the salts can then be crystallized. The anhydrous salts absorb ammonia to form ammoniates corresponding to their absorption of water to form hydrates.

Ferric iodide does not exist. The other ferric halides, FeX_3, can be made by the action of the halogens on the metal, and the hydrated salts can be crystallized from solutions made by dissolving freshly precipitated ferric hydroxide in aqueous halogen acids. The anhydrous salts are hygroscopic and are quite soluble in water. Ferric ion forms complex ions with the halides and many of the corresponding complex salts are known such as K_3FeF_6, $(NH_4)_3FeCl_6$, etc.

Pharmacopoeia1 forms of the halides include *syrupus ferri* iodide, a dilute solution of ferrous iodide, and liquor ferri chloridi, a strong solution of ferric chloride.

Hydrides of iron do not form as definite compounds but the metal does dissolve hydrogen and some of the other gases to form solutions. The solubility of hydrogen in iron increases from roughly 0.03 vol. of hydrogen per volume of iron at 400° C. to one volume per volume at the melting point. Iron is permeable to hydrogen at high temperatures. Electrolytic iron contains dissolved hydrogen which can be removed in a vacuum. See also HYDRIDES.

Nitrides, Nitrates, **etc.**—Several nitrides are known. A. N. Guntz obtained ferrous nitride, Fe_3N_2, and ferric nitride, FeN, as black powders by heating lithium nitride with ferrous potassium chloride and ferric potassium chloride, respectively. G. J. Fowler obtained a nitride, Fe_2N, by treatment of anhydrous ferrous chloride or bromide with ammonia at 460° C.; reaction of ammonia with finely divided reduced iron; or by the reaction of iron amalgam with ammonia at 420° C.; and also, in a compact form, by the action of ammonia on red-hot iron wire. It oxidizes on heating in air and ignites in chlorine; on solution in mineral acids it yields ferrous and ammonium salts, hydrogen being liberated. (See NITRIDES.) Ferrous nitrate, $Fe(NO_3)_2.6H_2O$, is a very unstable salt and is obtained by mixing solutions of ferrous sulfate and barium nitrate, filtering and crystallizing in a vacuum over sulfuric acid. Ferric nitrate, $Fe(NO_3)_3$, is obtained by dissolving iron in nitric acid (the cold dilute acid leads to the formation of ferrous and ammonium nitrates) and crystallizing, when cubes of $Fe(NO_3)_3.6H_2O$ or monoclinic $Fe(NO_3)_3.9H_2O$ crystals are obtained. It is used as a mordant.

Ferrous solutions absorb nitric oxide, forming dark green to black solutions which contain the ferronitroso ion, $FeNO^{++}$. The reaction is utilized in the brown ring test for nitrates. Red-

dish-brown amorphous powders of the formulas $2FeCl_3.NO$ and $4FeCl_3.NO$ are obtained by passing the gas over anhydrous ferric chloride. By passing the gas into an ethereal solution of the salt, nitrosyl chloride is produced, and on evaporating over sulfuric acid, black needles of $FeCl_2.NO.2H_2O$ are obtained, which at 60° C. form the yellow $FeCl_2.NO$. Complicated compounds discovered by O. Pavel are obtained by the interaction of ferrous sulfate and alkaline nitrates and sulfides. Two classes may be distinguished: (1) the ferrodinitroso salts, *e.g.*, $K[Fe(NO)_2S]$, potassium ferrodinitrososulfide; and (2) the ferroheptanitroso salts, *e.g.*, $K[Fe_4(NO)_7S_3]$, potassium ferroheptanitrososulfide. These salts yield the corresponding acids with sulfuric acid.

Phosphides, Phosphates. — H. le Chatelier and S. Wologdine obtained Fe_3P, Fe_2P, FeP and Fe_2P_3, but failed to prepare five other phosphides previously described. Fe_3P occurs as crystals in the product of fusing iron with phosphorus; it dissolves in strong hydrochloric acid. Fe_2P forms crystalline needles insoluble in acids except aqua regia; it is obtained by fusing copper phosphide with iron. FeP is obtained by passing phosphorus vapour over Fe_2P at a red heat. Fe_2P_3 is prepared by the action of phosphorus iodide vapour on reduced iron. Ferrous phosphate occurs in nature as the mineral vivianite, $Fe_3(PO_4)_2.8H_2O$. It may be obtained artificially as a white precipitate, which rapidly turns blue or green on exposure, by mixing solutions of ferrous sulfate and sodium phosphate. It is employed in medicine. Normal ferric phosphate, $FePO_4.2H_2O$, occurs as the mineral strengite, and is obtained as a yellow-white precipitate by mixing solutions of ferric chloride and sodium phosphate. It is insoluble in dilute acetic acid but dissolves in mineral acids. The acid salts $Fe(H_2PO_4)_3$ and $2FeH_3(PO_4)_2.5H_2O$ have been described. Basic salts have been prepared and several occur in the mineral kingdom; dufrenite is $Fe_2(OH)_3PH_4$. See PHOSPHORIC ACIDS AND PHOSPHATES.

Sulfur Compounds. — Ferrous sulfide, FeS, results from the direct union of its elements. It is best prepared by stirring molten sulfur with a white-hot iron rod; the sulfide drops to the bottom of the crucible. It then forms a yellowish crystalline mass, which readily dissolves in acids with the liberation of hydrogen sulfide "gas." Heated in air it at first partially oxidizes to ferrous sulfate, and at higher temperatures it yields sulfur dioxide and ferric oxide. It is unaltered by ignition in hydrogen. A black finely divided form results when ferrous salts are precipitated by ammonium sulfide.

Ferric sulfide, Fe_2S_3, is obtained by gently heating a mixture of its constituent elements. or by the action of hydrogen sulfide gas on ferric oxide at temperatures below 100° C. It is also prepared by precipitating a ferric salt with ammonium sulfide; unless the alkali be in excess a mixture of ferrous sulfide and sulfur is obtained. Magnetic pyrites or pyrrhotite has a composition varying between $5FeS.Fe_2S_3$ and $6FeS.Fe_2S_3$. It has a somewhat brassy colour, and occurs massive or as hexagonal plates; it is attracted by a magnet and is sometimes itself magnetic. The mineral is abundant in Canada, where the presence of about 5% of nickel makes it a valuable ore of this metal. Iron disulfide, FeS_2, is found as the mineral pyrite, which is important as a source of sulfuric acid, and also as the mineral marcasite (*q.v.*); the formula of copper pyrites is $(Cu,Fe)S_2$ Pyrite may be prepared artificially by gently heating ferrous sulfide with sulfur, or as brassy octahedra and cubes by slowly heating an intimate mixture of ferric oxide, sulfur and salammoniac. It is insoluble in dilute acids, but dissolves in nitric acid with separation of sulfur.

Ferrous sulfate, green vitriol or copperas, $FeSO_4.7H_2O$, was known to and used by the alchemists; it is mentioned in the writings of Agricola, and its preparation from iron and sulfuric acid occurs in the Tractatus *chymico-philosophicus* ascribed to Basil Valentine. It occurs in nature as the mineral melanterite, either crystalline or fibrous but usually massive; it appears to have been formed by the oxidation of pyrite or marcasite. It is manufactured by piling pyrites in heaps and exposing them to atmospheric oxidation. the ferrous sulfate thus formed being dissolved in water and the solution run into tanks where any sulfuric acid which may be formed is decomposed by adding scrap iron. By evaporation the green vitriol is obtained as large crystals. Ferrous sulfate forms large green crystals belonging to the monoclinic system; rhombic crystals, isomorphous with zinc sulfate, are obtained by inoculating a solution with a crystal of zinc sulfate, and triclinic crystals of the formula $FeSO_4.5H_2O$ by inoculating with copper sulfate. By evaporating a solution containing free sulfuric acid in a vacuum, the heptahydrated salt first separates, then the penta-, and then a tetrahydrate, $FeSO_4.4H_2O$, isomorphous with manganese sulfate. By gently heating in a vacuum to 140° C., the heptahydrate loses six molecules of water and yields a white powder, which on heating in the absence of air gives the anhydrous salt. The monohydrate also results as a uhite precipitate when concentrated sulfuric acid is added to a saturated solution of ferrous sulfate. Ferrous sulfate forms double salts with the alkaline sulfates. The most important is ferrous ammonium sulfate, $FeSO_4.(NH_4)_2SO_4.6H_2O$, obtained by dissolving equivalent amounts of the two salts in water and crystallizing. It is very stable and is used in volumetric analysis. It is often called Mohr's salt.

Ferric sulfate, $Fe_2(SO_4)_3$, is obtained by adding nitric acid to a hot solution of ferrous sulfate containing sulfuric acid, colourless crystals being deposited on evaporating the solution. The anhydrous salt is obtained by heating these or by adding strong sulfuric acid to a solution. It is sparingly soluble in water, and on heating it yields ferric oxide and sulfur dioxide. Many basic ferric sulfates are known, some of which occur as minerals. The iron alums are obtained by crystallizing solutions of equivalent quantities of ferric and an alkaline sulfate Ferric potassium sulfate, common iron alum, $K_2SO_4.Fe_2(SO_4)_3.24H_2O$, forms bright violet octahedra.

Analytical. — The common qualitative tests for iron are: the formation of Turnbull's blue when a soluble ferricyanide is added to ferrous ion; the formation of prussian blue when ferric ion is precipitated by the addition of a soluble ferrocyanide; the formation of an intense red colour when a soluble thiocyanate is added to ferric ion. In the usual systematic scheme of qualitative analysis iron is precipitated as ferrous sulfide as a member of the ammonium sulfide group of elements.

Quantitative methods for the gravimetric determination of iron include precipitation as ferric hydroxide with ammonia and ignition to ferric oxide, precipitation by cupferron and ignition of the cupferride to ferric oxide. These methods require that the iron be previously separated from a larger number of other metals which would also be precipitated under the conditions required. Accurate volumetric methods for iron involve a reduction to the ferrous state by the use of stannous chloride or zinc amalgam and a titration of the ferrous iron using such oxidizing agents as permanganate, dichromate or ceric ion. A titration of ferric ion with standard titanous solution is sometimes made. Small amounts of iron are determined colorimetrically, and a large number of organic reagents are known which yield intensely coloured compounds; orthopenanthroline, which forms a coloured compound with ferrous iron, is commonly used in the colorimetric determination of small amounts of the element.

The thiocyanate reaction is also of use in estimating iron colorimetrically.

Therapeutics. — Although elementary iron comprises only an estimated 0.004% of the average adult body weight, it is an essential element in the body. An intake of 10–20 mg. of iron per day appears to meet the normal metabolic requirements of the average adult. Red meats, egg yolk, carrots, fruits, whole wheat and green vegetables contribute most of the iron in the usual diet. The largest portion (about 55%) of total body iron is found in the red blood cells as an essential constituent of hemoglobin. About 20% of the total is stored in such organs as the liver and spleen, and in bone marrow, to be readily available for conversion to hemoglobin as needed. Except for a small fraction in blood plasma and some iron that is unassociated with hemoglobin in erythrocytes, the remainder is found as muscle hemoglobin, in striated muscle, and as "parenchyma iron" in striated muscle and in almost all other tissue.

Both ferrous and ferric iron form metalloporphyrins in which

the iron atom is bound to the four nitrogen atoms in the centre of the flat porphyrin ring. The particular metalloporphyrin obtained from protoporphyrin and ferrous ion is heme, $C_{34}H_{33}N_4O_4FeOH$. Heme combines with various proteins, presumably by the interaction of the iron atom in the heme with protein nitrogen atoms to establish the maximum co-ordination number of six for the iron. If the protein is globin the resultant molecule is hemoglobin, while other specific proteins give rise to such important enzymes as catalase, cytochrome, peroxidase and Warburg's respiratory enzyme. Hemoglobin, represented as Hb, reacts with oxygen to form oxyhemoglobin, HbO_2, in an amount that is proportional to the pressure of oxygen, until a maximum of about 1.36 c.c. of O_2 gram of Hb has reacted. This is an entirely reversible process and the oxygen taken up to form the equilibrium amount of HbO_2 at some particular Pressure of oxygen will be given up by the HbO_2 if the oxygen pressure is reduced to its original value. It is by the use of this property that hemoglobin functions as an oxygen carrier in the body. The most important therapeutic use of iron is in the treatment of hypochromic anemias, which are commonly the result of an iron deficiency that impairs the formation of hemoglobin and may impair other functions of the red blood cells. Iron is of little value in the treatment of normochromic and hyperchromic anemias which are not caused by iron deficiency. Any of a large number of iron compounds may be used to supply the element in therapy, and inorganic salts are as effective as organic compounds for the purpose. Among the commonly used preparations are: reduced iron, U.S.P.; iron and ammonium citrates, U.S.P.; ferrous sulfate, U.S.P.; ferrous carbonate as Blaud's pills, U.S.P.; or as mass of ferrous carbonate, U.S.P.; ferric pyrophosphate, N.F.; ferrous glutinate and ferrous gluconate.

Soluble ferric salts find a very limited use in the treatment of skin disorders. They are protein precipitants and can produce astringent and irritant effects on the skin and mucous membranes.

IRON AGE: *see* ARCHAEOLOGY.

IRON AND STEEL. Iron is the most useful metal of material civilization; it means plants, tools, machinery. It is principally used nhen alloyed with other elements, notably carbon; a moderate amount produces steel, an excess produces cast iron. Many special steels for particular uses have been devised in recent years; these steels contain a proportion of other metals, such as manganese or chromium (resulting in manganese steel, or chromium steel in these two cases, for instance). About 164,000,000 net tons of pig iron and 232,000,000 net tons of steel were made in 1952—a fairly active year.

Outline of Manufacturing Process.—The source of commercial iron and steel is the oxide ores of iron, occurring in great abundance in all continents. Ore is charged into the top of a shaft-like blast furnace together with coke and some limestone. Hot air is blown into this furnace near the bottom, burning the coke and furnishing the gases and heat necessary to reduce the iron oxide to molten iron metal; trickling down over the nhite hot coke it absorbs an excess of carbon; drained from the bottom is the impure high-carbon alloy pig iron, which is merely remelted and cast into moulds to form the familiar iron castings of commerce. Limestone is charged into the furnace to convert earthy minerals mixed with the iron ore (gangue) and the coke ash into a fusible slag; this is also drained periodically from the furnace hearth. The blast furnace therefore operates continuously; solids are charged at the top, liquid iron and slag are drawn from the bottom.

To change pig iron into steel two methods are used extensively, the Bessemer converter and the Siemens-Martin open-hearth furnace. The converter is a brick-lined vessel, with perforations in the bottom through which air is blown. Into this vessel some molten pig iron is charged, and the air blowing through the metal burns out the carbon and some of the other impurities; at these high temperatures there is a pronounced selective action so that relatively little of the iron is burned. Combustion of these impurities furnishes the necessary heat to maintain operations. At the end of the blow, a matter of ten to 15 min., the purified metal is dumped into a ladle, and an alloy of manganese and iron known as spiegel is added to degasify the melt, whereupon the finished steel is poured into ingot moulds. Refining pig iron in an open-hearth furnace is a much more deliberate process, requiring about 10 hours. The furnace is a flat shallow basin with a low roof. At either end are ports through which fuel and hot air enter; the flame sweeps through. out the ports at the other end, and thence into chambers filled with checker brick to absorb some of the waste heat. At intervals the flow of gases is reversed by suitable valves thus returning the recovered heat to the furnace hearth. Scrap and pig iron are placed in the furnace through side doors, and melted down. Iron ore and limestone are also added, and a series of chemical reactions takes place between the iron oxide and the impurities in the metal; the latter either vanish as gases or accumulate in a scum of thin slag. When the reactions are complete the bath is tapped into a ladle from which the slag overflows, and the finished steel is then cast into ingots. Ingots are squat prisms of steel and are given marketable shape in the rolling mills. By successively passing between rolls with steadily diminishing apertures, bulky ingots are converted into long rods, bars, plates, rails or various structural shapes. Rather thicker bars are known as billets and are used in forge shops for hammering out more intricate pieces of nonuniform cross section. Specially shaped rolls and auxiliary machinery also convert bars into sheet steel, plate into pipe, and rods into wire products.

EARLY HISTORY

Antiquity of Iron.—Few implements of iron or steel survive for many years before they rust away, consequently there is little direct evidence to prove the point; nevertheless the antiquity of iron smelting is great. It doubtless has been discovered and rediscovered many times; explorers reaching primitive peoples in many parts of the world find the native blacksmith using methods very similar to those known to other tribes at far distant times and places. An iron blade, probably 5,000 years old, has been found in one of the Egyptian pyramids. Even without this discovery one could plausibly maintain that the ancient Egyptians *must* have had skilled steel workers in order to have built the great pyramids and other monumental architecture, to say nothing of the statuary and hieroglyphics cut into the hardest rocks. Steel working and hardening, an advanced stage in the art which doubtless required centuries to reach, was common 3,000 years ago in Greece, and is mentioned in Homer. It is more probable that iron was first found in the ashes of a big fire built near some red paint rock than that the first tools were made from meteorites. When paint rock and fire came to be associated with iron as cause and effect, the next step was to produce it intentionally in fires built against a bank exposed to prevailing winds, or in pits or rude rock furnaces where the fires were fanned by bellows, one of the earliest mechanical devices.

These are the primitive methods which survive today in the Catalan forge (see FURNACE, METALLURGICAL): a mixture of charcoal and iron ore, selected for its purity, is heated intensely for several hours, with fuel additions made from time to time, and a vigorous blast of air fanning the fire. The iron ore becomes an incandescent sponge of metal; the clay or other minerals mixed with the iron oxide together with the charcoal ash sinter into a slag, permeating the sponge and protecting the reduced iron from further action. After a given time, the furnace is broken into. the glowing ball of iron pulled out, and, while white hot, hammered vigorously to expel as much of the slag as possible and to weld the particles of metal into a coherent mass.

Steel from Indirect Processes.—With various changes in the furnace details, and in methods of producing the air blast, these methods produced all the iron available from the beginning up to the 14th century. It was truly a *wrought* iron, the best product containing no more than 0.1% of total impurities alloyed with the

metal, but shot through with microscopic slag particles, aggregating 3% or more of the total ueight. Steel was made sometimes as an accidental product in the old forges; by design the wrought iron bars would be packed nith charcoal in clay boxes or jars and heated for days, nhereupon the iron absorbed enough carbon to become steel and thus acquired the superior hardness and strength necessary for keener tools.

As the demand for iron grew, the furnaces became bigger, and a stronger blast of air was required to drive the products of combustion from the bottom up through the mixed charge. It resulted that the iron ore nas reduced to spongy metal in the upper part of the furnace, and it then proceeded to absorb more carbon as the charge settled down, thereby converting itself to pig iron, a much more readily fusible alloy. The bigger, taller furnaces introduced in the early 14th century therefore produced liquid pig iron, a complex alloy of iron, carbon and other elements. Subsequent developments have been along three main lines: (1) increasing the size of the furnace and developing mechanical auxiliaries to produce pig iron more economically and in greater amounts; (2) invention of various processes for changing this impure pig iron into the more useful wrought iron; (3) production of steel either by way of wrought iron or from pig iron direct. Sir Henry Bessemer's process, announced in 1856, for making steel from pig iron in a pneumatic converter, began the steel epoch. Cheap and ample supplies of steels in a wealth of sizes, shapes and surface finishes, grades of hardness or types of alloy are now available to meet the special demands of metal workers, machinery builders or tool users.

Modern metallurgical developments have consequently been away from the simple and direct production of wrought iron to the complex indirect manufacture of steel. The change from the small, intermittent operations controlled by a highly skilled artisan to the large continuous furnaces, machine driven, has been associated with enormous expansion in total output and as great a saving in labour, and a notable conservation of raw materials.

Steel from Direct Processes.—Some metallurgists, however, believe that the excessively high temperatures attained in the modern blast furnace cause the pig iron to alloy nith undesirable compounds, notably of nitrogen, which cannot be eliminated later, and which, they say, cause the present day metal to be inferior to that produced by the old direct processes operating at a low temperature. Hence many methods of making iron and steel direct from the ore have been proposed since 1910, and extended experimentation on a semicommercial scale has produced some marketable metal by these processes. Most of them rely upon the fact that iron ore is reduced by gas in the upper cooler part of the blast furnace. That is, the reaction

$$Fe_2O_3 + 3CO \rightarrow 2Fe + 3CO_2$$

is substantially completed at 800° C., low red heat, too low to break up other minerals in the ore. Consequently hot iron ore is passed through a revolving kiln containing producer gas, and the iron sponge formed therein is either passed direct to an electric melting furnace, or quenched rapidly to prevent reoxidation, separated from unreduced ore and gangue, and the metallic portion briquetted or melted. That these so-called direct steel-making processes are destined to supplant the present indirect system of smelting ore to an impure product, and refining the latter, is very unlikely. In view of the great investment in the present plants for making steel which is reasonably satisfactory to the user, any innovation would have to show a considerable saving in costs, or have material collateral advantages or improved quality, before it could be widely adopted. Such savings and advantages have not been demonstrated.

IRON ORE

Iron is smelted from several oxidized minerals occurring in abundance in the earth's crust. In order of commercial importance these minerals are hematite (Fe_2O_3), magnetite (Fe_3O_4), limonite (hydrated iron oxide) and the carbonate siderite ($FeCO_3$). Great deposits of these minerals in relatively pure state, close enough to the surface to be mined easily, are in many regions. They are so common that an iron and steel industry will be developed whenever and wherever a population of machinery-using humanity accumulates. Iron deposits located in sparsely settled countries are potential ores of the future; for present uses an ore must be so situated and of such a nature that it can be mined, smelted by methods now known and transported to market at a profit. Proximity to cheap fuel will enhance the value of ore—in Great Britain inland furnaces smelt local ores containing as low as 23% iron. The enormous ore deposits near Lake Superior in North America are 1,000 mi. from coking coal and an iron-consuming population, but intensive production and cheap water transport on the Great Lakes enable these deposits to dominate the American market. On the other hand Brazil has huge untouched reserves of iron too far inland to export and with no home demand. The European continent depends upon the minette ores of Lorraine—ores which until the beginning of this century were valueless for steel making because no way was known to eliminate a high percentage of harmful phosphorus.

American Deposits.—The most productive iron ore region in the world is in very old (pre-Cambrian) strata surrounding Lake Superior, on the border between United States and Canada. Several long narrow areas called ranges contain the workable ores, which are hematites. Data on these ranges follow (shipments in long tons of 2,240 lb.):

Name	Location	Opened	Shipments in 1937	Total shipments including 1937	Greatest yearly shipments
Old Ranges					
				Million	
Marquette	Michigan	1854	5,747,812	194	5,747,812
Menominee	Michigan	1872	2,649,062	183	6,569,000
Gogebic	Michigan & Wisconsin	1884	5,661,270	207	8,763,000
Vermilion	Minnesota	1884	1,453,080	65	2,084,000
New Ranges					
hlesabi	Minnesota	1892	45,823,571	1,031	45,823,571
Cuyuna	Minnesota	1911	1,775,445	38	2,479,000

The deposits in the Mesabi range are flat, thick and close to the surface and are, therefore, mined in open cuts by steam shovels. Underground mining is the rule in the others, the veins being fairly steep and worked to 3,000 ft. depth. The wealth of these ranges is such that ores of various analyses and textures are available. One-fourth of the output is Bessemer ore, suitable for acid steel, containing on the average 55% iron and 0.04% phosphorus. The Cuyuna ore contains notable amounts of manganese. Basic or non-Bessemer ores from the ranges are higher in phosphorus and averaged 51.5% iron in 1937, with silica forming the principal impurity.

In view of the tremendous annual production of the Mesabi range, it may be questioned how long it will be before the region is uorked out. The average iron content of all lake ores dropped from 55½% in 1902 to 51¾% in 1910, and has been maintained since then only by mining increasing amounts of high-grade ore and washing, screening or drying one-third of the remainder. Minnesota is estimated by the state geologist to have demonstrated reserves of 1,250,000,000 tons of recoverable ore. Cnless these resenes are increased by new discoveries the Mesabi range will be worked out by 1975 or 2000, depending on whether the predepression or the postdepression rate is figured. But any prediction about the age of a mining district must prophesy also the state of the future art of ore concentration—lean rock today may be workable ore tomorrow. In fact, this region contains an unlimited tonnage of magnetite-bearing ore called taconite, which contains about 25 to 30% iron.

While seven-eighths of American ore comes from the Lake ranges, the balance of about 8.000.000 tons is taken from many ore occurrences in the Clinton formation in the Appalachian mountains, an uplift which parallels the Atlantic coast from north

to south. In the northern region the ores are predominantly magnetites; at the southern end in the State of Alabama, deposits of a low-grade red hematite with an easily fusible gangue are found near extensive coal measures. All these deposits are mined by underground methods; among them are mines which have produced continuously since the earliest iron smelting in America

Lorraine Deposits.--Ore beds second in importance only to those in the Lake Superior region occur in strata of Mesozoic age near the Franco-German border, extending northward into Luxembourg and Belgium. They are of recent commercial development. While only 830,000 tons were produced in 1897, they are now the chief ores for the French, Belgian, German and Luxembourg blast furnaces which together in 1937 produced 30% of the world's pig iron. Mining is done in three principal basins, Longwy near the Belgian border, Briey, and Nancy at the south. Previous to the World War much of this area was German territory, and practically all of the rest was promptly overrun and occupied by the invading army. Possession of this all but essential region was thereafter one of the aims of the contending Powers. Great damage was done during the occupation and the retreat, and not until 1926 did the area approach the productivity of 1913. While the output of the region exclusive of Belgium and Luxembourg was about 40 million tons in 1913, equally divided between France and Germany, the French department of Meurthe-et-Moselle was able to hoist only 5 million tons in 1920. Recovery of the reunited provinces proved to be so rapid. however, that the ore output reached 37 million tons in 1926. The ore beds occur in flat strata 60 to 120 ft. thick, from 300 to 750 ft. below the surface. The iron is contained in tiny nodules of hematite, cemented with a calcareous or a siliceous gangue. It is only necessary to combine these two to procure a self-fluxing, easy smelting mixture, very desirable commercially even though its iron content is quite low. Representative analyses, after driving off 8 to 12% moisture, are as follows:

	siliceous ore	Calcareous ore
	%	%
Iron	35 to 37	38 to 42
Silica	12 to 18	4 to 8
Alumina	3 to 7	3 to 7
Lime	3 to 7	9 to 13

Phosphorus is strikingly uniform, being 1·7 to 1·9% of the iron contained, and the Lorraine pig iron must therefore be used in basic steel making, as later to be explained.

Ores in Great Britain.— Since the rich blackband, clay iron stone and brown hematites of the Carboniferous strata have been almost exhausted, 80% of the iron ore mined in Great Britain is now taken from leaner strata, averaging only 27½%, which are a continuation of the Lorraine beds. Workable deposits extend in a broad strip from the coast of Yorkshire south-west to that of Dorset and are estimated to contain 3,400 million tons of workable ores. The beds are nearly horizontal, and consequently have broad outcrops in gently rolling ground, thus permitting them to be mined by quarrying operations. As a rule the individual deposits are small, and do not warrant the powerful excavating machinery installed in the great Mesabi pits. A maximum working face is 30 ft. Such "marlstones" (or simply "stone") contain the iron in tiny ooliths like the Lorraine ore, but near the surface the iron has been oxidized and hydrated to limonite, and at depth is a carbonate. Gangue materials are either calcareous or siliceous. These deposits have been longest mined at Cleveland, and here a limited area has produced 5½ million tons a year since 1875. All mining is underground in carbonate ores sometimes as deep as 600 ft.; 9 to 12 ft. beds are reckoned excellent. A governmental survey made in 1918 found only 200 million tons of recoverable ore here in reserve. An average analysis follows:

Oxide (FeO)	28%*
Silica (SiO_2)	12%
Alumina (Al_2O_3)	10%
Lime (CaO)	5%
Sulphur	0·26%
Phosphorus	0·47%
Water	6·8%

*(24·6 to 33·3%)

Cleveland ores therefore are suitable for basic steel making, wrought iron manufacture or general iron foundry work. Except for the several post-war years of acute industrial depression, Great Britain's ore demands have been about stationary since the turn of the century. Each year Cleveland hoists 5½ million tons, other regions dig 9 million tons and 6 million tons are imported, principally low-phosphorus ore from Spain and Sweden.

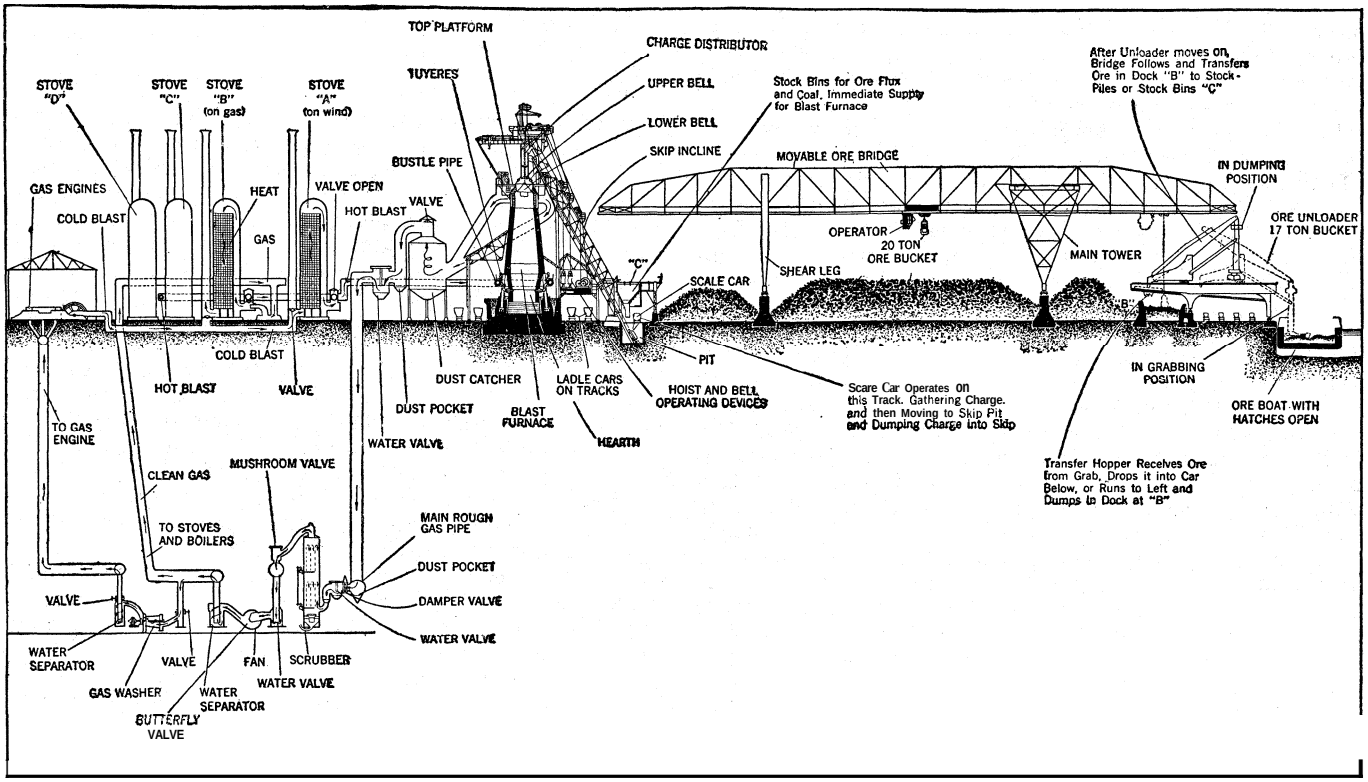
Future Stores of Iron.— Whether there is any likelihood of exhausting the available iron ore is a question which has occupied some minds. From the above remarks, it may appear that certain regions, such as the Mesabi range and the Cleveland beds, may be exhausted in the near future. However there is little to fear but that other deposits, only slightly less favoured, will supply the gap. Conservative estimates by economic geologists indicate that there are now about 30 billion tons of ore in reserve, which at the present annual consumption of 100 to 125 million tons, should last 200 years. Of this huge tonnage, two-thirds is located in the Western hemisphere; Brazil and United States possess most of this, but Newfoundland and Cuba both have notable deposits; France has half the balance, and the rest is scattered about in readily accessible locations. All such computations assume a certain state of metallurgical art in order to define ore. But metallurgical art is constantly advancing. Since so large a proportion of the earth is iron, it is safe to say that in the future, as in the past since before history began, the mind of man will always find means to win from mother earth this most useful metal, in supply ample for his current needs.

PREPARATION OF ORE FOR SMELTING

Transport.— In England and on the Continent much of the iron ore is smelted in furnaces erected nearby—even at the mine mouth. Freight is a minor matter. That which is transported from overseas is handled for the most part in ordinary cargo vessels. In America, however, the long haul down the Lakes from the ranges to the furnaces has caused the development of very specialized handling equipment. At the mines, hopper-bottom railroad cars of 50 to 60 tons capacity are loaded by steam shovels in the pit, or from storage bins at the mine, and hauled to the nearest port. Here long lines of ore bins are built out into the water; whole trainloads of ore are dumped in a few minutes by pneumatic devices. When these bins are full an ore boat docks alongside, opens her hatches, and a load of 10,000 tons of ore is spouted into her in less than a half hour. Ore boats that are used for service on the relatively calm Great Lakes are of special construction and are essentially long, self-propelling barges with a movable deck. Arrived at its destination, the hatches are again opened, and enormous grab-buckets reach through into the hold, scooping out the ore and dropping it inshore, either in railroad cars, or on a stock pile. If the furnace plant is inland, trainloads of ore are hauled to the site, and dumped in bins or placed in stock piles. Hopper-bottomed cars are used almost exclusively for this purpose, although for stockpiling it is generally found better to install a car-dumper, which turns the car upside down, and then to move the ore to the pile by a grab-bucket and overhead bridge. One cannot comprehend the magnitude and power of this unloading machinery, unless it has been seen in operation. Large stock piles, which are almost unknown elsewhere, are the general rule in America, where water transportation is entirely suspended by ice during the winter months. Limestone and coke are also stocked in sufficient quantity to provide against irregular deliveries from a distance.

Dressing.— Up to the beginning of the 20th century iron ore was seldom treated in any way prior to its utilization High grade materials, however, are becoming increasingly scarce, and the future will see a rapid extension of ore dressing methods

Screening is the simplest method Some 17 million tons of Lake ore were improved by this method in 1927. In England as well the miner frequently digs marlstone without removing the



BY COURTESY OF THE WELLM N-SEAVER-MORGAN COMPANY, CLEVELAND, OHIO

FIG. 1.—DIAGRAMMATIC ELEVATION OF BLAST FURNACE WITH AUXILIARIES AND STOCK PILES

loamy overburden; the quarried material is then crushed, and the fine particles screened out and discarded. In this way the average iron content of the ore is increased, and the suitability for smelting improved, for too many fices in the charge slow down blast furnace operations.

Washing is also common in America. This is an application of the water concentration methods so highly developed in ore dressing (*q.v.*) used at copper, lead and zinc mines. Some five million tons of Mesabi ore were treated in log washers in 1927. The washer is an inclined trough; from end to end is a stout shaft or log, with plow blades so set on its circumference that when the shaft revolves the plows clear the trough bottom and move any solid material gradually along. The fine screenings enter at one end, and travel against a copious current of water, which washes out the finer, clay bearing particles, lean in iron.

Calcining is common in England, particularly on the Cleveland carbonate ores. A Gjers kiln is ordinarily used, a short cylindrical steel shell set vertically, and lined with fire urick. A mixture of ore, with about 5% slack coal, is charged through the top as the burned ore is withdrawn at the base. Such a kiln will drive moisture and carbon dioxide from about 1,000 tons of ore in a week; Cleveland ores lose 27 to 30% in weight, but the resulting ore has had its iron percentage increased thereby to about 31%; still a very lean ore, viewed by American standards. Lorraine ores contain much moisture, but cannot be calcined, btcause this preliminary heating causes them to fall to powder.

Sintering is a method of converting fine ores or flue dusts into a porous clinker which can easily be smelted. American and Swedish magnetite ores, low in grade, are frequently concentrated by fine grinding, and drawing the iron bearing minerals out of waste rock with strong magnets. This fine magnetite is then moistened and mixed with fine coal and a little flux or with blast furnace flue dust, and spread over a travelling grate, the coal ignited and burned in a strong down-draft. The resulting clinker smelts so much more easily than the dense magnetic ores that the latter, even of high grade, are frequently sintered at the American plants.

BLAST FURNACES

Having followed thus far the mining, transport and preparation of ore, attention should next be given to the process of smelting it into metal. In the present state of the art, this is done in a blast furnace, and the metallic product is a high carbon alloy of iron called pig iron and containing more or less silicon and manganese. Since an article is devoted to the construction and operation of the blast furnace (*q.v.*) these matters will be summarized only briefly here; more attention however will be given to that entire assemblage of auxiliary, equipment (*see* fig. 1) which together goes to form the blast furnace department of a modern steel making plant. A blast furnace and its top works often rise 200 ft. above the ground level. It is round in cross section, bound with steel plates, and lined with a thick wall of special fire brick. Piercing the very top of the shell are two side openings leading into brick lined pipes—downcomers—for venting the furnace gases. The top is closed by a double bell, which in effect is an air-lock for introducing charges of ore, coke and limestone, while permitting no gas to escape. Charging is continued at such a rate that the furnace shaft is always full. About 8 ft. above the furnace base is a series of 10 or 12 water-cooled nozzles called tuyères, equally spaced around the circumference, through which hot air is blown into the interior. The coke in the mixed charge bums in this air, producing a region of intense heat sufficient to melt the metallic iron descending to that level from above, and superheat it so much that when it trickles to the hearth it collects at the bottom of the shaft in a pool which remains molten for hours. Five or six times a day this iron is drawn off or cast by opening a tap-hole at the very bottom.

Reduction of Iron Ore.—Much study has been given to the chemical reactions which reduce the ore to iron. They can only be presented here in highly simplified form. At the tuyères the heat is so intense that coke burns to carbon monoxide, thus:

$$2C + O_2 = 2CO$$

It is this gas which reduces the ore, and at a fairly low temperature, *i.e.* near the top, by a series of reactions which may be simplified as

$$Fe_2O_3 + 3CO = 2Fe + 3CO_2$$

The secret of rapid furnace driving to produce big tonnages is to use such ore, or prepared sinter, that the gases may permeate it readily and completely. Pure iron is relatively infusible—melting point 1,539° C.; when alloyed uith 4.3% carbon its melting point

is about 1,130° C. The freshly reduced iron in the blast furnace picks up this necessary carbon to convert it into the more fusible pig iron, either by physical contact with the hot carbon, or by the gas reaction

$$2CO = [C]_{Fe} + CO_2,$$

a reaction which is the basis of the case-hardening phenomena. By no means all the CO is oxidized to CO_2 by the furnace reactions. A typical analysis of the gases from the furnace top is

Carbon monoxide (CO)	24·5%	by volume
Carbon dioxide (CO_2)	12·0	
Hydrogen (H_2)	1·25	(from moisture in the air blast)
Methane (CH_4)	0·25	
Nitrogen (N_2)	62·0	

rich enough in the combustible gases CO, H_2 and CH_4 to be valuable as a fuel. Leakage must be carefully avoided, for the monoxide content makes it highly lethal.

Slag Formation. — Impurities in the ore and the coke ash must also be disposed of. They consist of earthy substances like clay. If they contain a preponderance of a single oxide like silica (SiO_2) they cannot even be melted unless sufficient limestone is present to flux them — that is to say, convert them into an easily fusible glass or lava-like substance called slag (*q.v.*) or cinder. The formation temperature of slag depends upon the relative proportion of basic oxides (lime CaO, or magnesia MgO) and acid oxides (silica SiO_2, or alumina Al_2O_3) which are present in the furnace charge. The operator therefore chooses his ores and fluxes with the aim of producing a slag which works well at some temperature, which he does not measure, but which he knows will produce the kind of pig iron which is demanded by his customers. Like the iron, slag melts in the hot region above the tuybres and trickles down, forming a pool floating on the iron. It is tapped or flushed through a cinder notch located between the tuybre line and the furnace bottom; usually just before the iron is tapped.

Ore Handling. — A medium-size furnace making 600 tons of pig iron a day will consume 1,160 tons of ore, 580 tons of coke, 290 tons of limestone, and 2,370 tons of air blast. It produces in addition to the iron, 330 tons of slag, 70 tons of dust and 3,400 tons of gas. It requires 17,000 tons of water to keep the furnace parts cool and to wash the dust from the gas. Therefore equipment must be provided to handle expeditiously no less than 26,000 tons of material each 24 hours. Such auxiliaries are so large and so numerous that the furnace itself is frequently inconspicuous, despite its huge bulk (fig. 1). In America, much space is ordinarily given to stock piles. Ore that comes from such storage, or direct from the mine, is dumped into bins alongside the furnace. Other compartments hold coke and flux. On a track underneath operates a scale car, which stops under appropriate gates and the attendant draws off a specified amount. When the proper quantities have been assembled, the car proceeds to the skip pit, and drops its load into a car which in turn is hoisted up the inclined bridge and dumped into a hopper at the very top of the furnace.

Furnaces a century ago were usually built on sloping ground, and the ore and charcoal wheeled off the hill top and dumped into the furnace. Later, when the value of the gases was discovered, a single bell was used to close the furnace top, and as the tonnage requirements increased, ore, coke and flux were shovelled from stock piles into carts, which were then pushed to the furnace, hoisted on platform elevators, and dumped by hand. Material handling by machinery is essential for furnaces making more than a hundred tons of iron a day.

Disposal of Iron and Slag. — In view of the congested surroundings, the pig iron and slag tapped from a big furnace are led by clay-lined troughs or runners to the edge of the foundation where they flow into ladle-cars standing below, and are hauled away while still liquid. If the furnace is serving a steel-making plant, the iron may be taken direct to a steel-making furnace. More usually it is poured into a mixer that is in effect a storage reservoir, sometimes of 1,500 tons' capacity. A mixer is usually shaped like a huge barrel, made of strong steel plate and lined with fire brick; it may be rolled on its foundation by suitable trunnions so the opening may at one time receive metal from a ladle-car above, or later discharge it into another for transfer to the steel furnace. The bad effect on steel-making processes of sudden variations in composition of the pig iron, so-called off casts, is minimized by dilution in a pool of reserve metal. Furthermore, some of the harmful sulphur may be eliminated from high manganese pig iron in the mixer, if the temperature is properly controlled. Iron which cannot be converted promptly must be cast into pigs. Much of this work is done by machinery. A pig casting machine is an endless chain to which is attached a series of moulds. A ladle-car of iron pours slowly as this conveyor moves underneath. After the iron is chilled, the conveyor passes through a long water tank for more rapid cooling. When the chain moves over the tail pulley the moulds turn upside down and the now solid pig iron drops into a railroad car. Some furnaces specializing on foundry iron, and of rather limited tonnages, run their iron direct from the tap hole into pig moulds formed in the sandy floor of the furnace house (see PIG IRON). Slag may be hauled to a nearby bank, dumped and wasted. In some localities, the slag may be marketed for railway ballast, filling material, or concrete aggregate. It would then be run molten into a water sump, the stream being broken up by a strong jet of water. Granulated in this manner, it can be reclaimed by grab-bucket and crane and shipped. Since the slag is essentially a calcium aluminium silicate, large tonnages are utilized as raw material in the manufacture of Portland cement.

Utility of Blast Furnace Gas. — As noted above, gases from the furnace top are good fuels, but they bear too much dust to be used without cleaning. Even when burned under boilers it is found that dust will fuse to the water tubes, reducing the efficiency of heat transfer and increasing the cost of maintenance to a prohibitive figure. For use in internal combustion engines, the cleaning must be even more complete. Much of the coarser ore and coke particles swept out of the furnace with the gas remains in the dust catchers, one or two cylindrical tanks placed in series just alongside the furnace proper. Essentially they are enlargements of the downcomer pipes; the velocity of the gas and its carrying power are reduced in passing through them. A change in direction of travel also aids in catching solids, which as they accumulate are drawn off from the hopper-like bottom. Usually the reclaimed dust is mixed with fine ore, sintered, and resmelted. Mixed blast furnace and coke oven gas is a good fuel for heating cold steel. Formerly it was usual to send hot gas from the dust catchers direct to the stoves, but lately furnace managers have been convinced that this rough gas contains entirely too much dust for this purpose, and the efficiency of the heat transfer suffers therefrom. Consequently further cleaning, either by scrubbing towers, by electrostatic precipitation, or by filtering through bags is now commonly undertaken. Electrostatic precipitation has the advantage that it handles gas without cooling it and may recover valuable amounts of potash for fertilizer. In this process the slightly humidified gas is passed through vertical pipes; in the centre of each is a wire charged at high voltage. In the electrical field so formed solid particles drift toward the grounded pipe walls, adhering there until dislodged by hammering.

Fig. 1 shows a scrubber, of which two would be required, each about 80 ft. high by 12 ft. diameter. By means of spray nozzles and screens the ascending gas is mixed in these towers with fine particles of water. The dust content, which on entering is about 3.5 grains per cu ft., is washed out except for about 0.2 grain. A powerful fan is necessary to draw the gas through the scrubber and give the necessary delivery pressure; water jets are introduced through the shell at several places so the fan acts as a further cleaner, delivering gas to stoves or boilers with about 0.05 grain of dust per cu.ft. Frequently all the gas is burned in this way, utilizing the steam so generated to drive blowing engines or electric generators. When it is desired to use the heat more efficiently, internal combustion prime movers may be installed (see INTERNAL COMBUSTION ENGINES) whereupon an even cleaner gas is required. Dust may be reduced to less than 0.01 grain per cu ft. by a rotary masher, which is a combination turbo blower and cleaner. Water used for these cleaning purposes may be used again after passing through a cooling tower and settling basin.

BLAST FURNACE PLANT

Blowing Engines.—Fig. 1 indicates the essential steps whereby the energy contained in the furnace gases is utilized to generate hot blast and auxiliary power for pumping, hoisting and lighting. Cleaned gas is used to drive gas engines direct connected with compressor cylinders. Compressed air goes to the furnace by way of a stove. therein acquiring a temperature of some 700° C., and on through a brick lined hot blast main to a bustle pipe circling the furnace. From the bustle pipe gooseneck connections deliver blast to the furnace through the tuyère openings. The required amount of air is fixed by the size of the furnace and the pressure, which varies from 12 to 20 lb. per sq. in. uith operating conditions, and must be delivered without fail. About 50,000 cu. ft. of air per min. is necessary for a furnace making 600 tons of pig iron per day *(see* BLOWING ENGINES).

Dry Blast.—One auxiliary (not shoun in fig. 1) more commonly installed in Great Britain, although proposed by the American James Gayley, reduces the humidity of the blast. Gayley showed that water vapour entering the tuyères, amounting in summer to about 250 gals. per hour, is dissociated into its elements by the white hot coke, this action absorbing heat not usefully regained within the furnace. Variations in moisture content are especially undesirable, for these produce variations in the temperature at the focus, and consequently change the chemical composition of the pig iron. To produce a low and uniform humidity in the air blast, the compressors may suck air through an adequate refrigeration system, (*See* AIR CONDITIONING.) Silica gel has been proposed as a more proper medium to dry the air blast.

Stoves.—Four stoves are usually installed to heat the blast. These are steel cylinders up to 100 ft. high and 22 ft. diameter. Each has a vertical combustion chamber, either at side or centre; the burned gases then return to the bottom through a multitude of narrow flues made of fire brick *(see* COWPER STOVE). In the passage they give much of their heat to the brick work, and flow off through a chimney. In operation (fig. 1), stoves B, C, and D may at any hour be filled with burning gas, thus acquiring heat; the cold blast passes through one of them, stove A; when this one cools off, valves are changed in a certain order, to prevent accumulation of explosive gas-air mixtures; stove **A** mill then be on gas, *i.e.*, heating; stove *B* will be on wind, *i.e.*, giving up its heat to the air passing through it enroute from engines to furnace. Usually valves are changed every hour. In a four-stove installation, therefore, each stove is heating for three hours, and cooling for one. Many designs have been proposed for the method of building the stove interior. A tno-pass stove is simplest, and most favoured in America, where the trend is to use cleaner gas, injected with a regulated amount of air for combustion, through carefully designed burners. Cleaner gas permits much smaller chequer-uork, higher heat capacity, longer life before the openings are plugged with fused dust, frequently enabling satisfactory furnace operation with only three stoves. A three-pass stove, nhere the gas is introduced at the bottom, goes up, down, up again and out a short stack built on top the stove, is favoured by some designers. *(See* HOT BLAST.)

Valves for handling these furnace gases are of special construction. On the cleaning system a water valve is favoured. As shown in the diagram of the blast furnace department, it is nothing much but a large pot with a diaphragm extending from top toward the bottom. To close this valve it is only necessary to fill the pot with water until the bottom of the diaphragm is submerged several inches; draining the pot opens the valve. Valves for handling hot blast are more difficult to construct and to maintain in good condition. Also, since the valve seat is exposed to the corrosive action of hot gases, it requires occasional replacement. This can be done by loosening all the turnbuckle clamps, nedging the flue sections apart, and sliding the old seat out sideways. The valve disc is also a hollow copper casting with spherical bottom; cooling water enters the hollow stem as shown. To open the valve it is only necessary to lift the disc up until it strikes the bricked dome. All blast furnace stoves have four valves. Two are shown on stove A (fig. 1); stove A is on wind, the chimney valve and the gas burner opening being closed. Stove B is on gas; the chimney valve is open, the gas burner in place, and the valves into the cold and hot blast mains are closed.

Blast Furnace Operation.—From the foregoing description it may be surmised that the blast furnace superintendent's task is primarily to harmonize operations of various large mechanical elements. But the furnace itself is his greatest care, even though the principal reactions within it are in mobile equilibrium. Slight variations from normal are self-adjusting—that is to say, if for some reason a surplus of heat is generated, the action within the furnace changes in the direction which will absorb that extra quantity of heat. Nevertheless the skilled operator is quick to observe clues which indicate deviations from the normal, and he immediately makes such adjustments in the operating conditions as experience tells him will avoid any serious irregularity. A hundred years ago his problem was simpler. His furnace plant consisted only of stack and blower; his ore was pure and rich, carefully selected by hand; his fuel was charcoal, ideal in character; the driving rate was slow; under such circumstances his pig iron was relatively free from impurities. Even to-day some of this charcoal pig iron is made in small furnaces with either cold blast or hot blast, and is favoured by foundrymen for castings which require a dense, tough and strong body, or by manufacturers of high grade tool steels. Rich ores and forests were very soon exhausted, however, and the progress of metallurgy has been associated with the ability to recognize the specific effects of each disturbing element and to devise ways and means to utilize the impure ores and coke fuel remaining, for many of the minerals entering the furnace top with the iron ore are broken up and the elements therefrom alloy with the pig iron, often to its detriment.

Control of *Sulphur*.—Sulphur, largely from iron pyrite contained in coke ash, is the worst offender; if left in the iron sulphur causes it to he very brittle at red heat ired short) High sulphur castings often crack in the moulds after cooling, and high sulphur steels may break when being worked in rolls or forging. Since no sulphur is removed in the converter or open-hearth steel making processes, it is essential that this element be eliminated from the pig iron. This is done in the blast furnace by charging limestone so the slag shall be distinctly basic, and thus have a higher solubility for sulphur compounds. Such a slag requires more coke, and German works now smelt uith minimum heat and desulphurize the pig iron with sodium carbonate. Once in the iron, its harmful effects may be mitigated in castings if two or three times as much manganese is present; an innocuous manganese sulphide results. In steel, zirconium has been found to have the same effect. Sulphur may be eliminated in electric furnace steel by refining at a high temperature under a "carbide" slag very high in lime on nhich floats some coke. Pig iron for grey iron castings must therefore have less than 0.10% sulphur; structural steel must contain less than 0 06%; many alloy steels are specified to contain less than 0.04% sulphur.

Effect of *Silicon* on **Pig** Iron.—A blast furnace working very hot tends to reduce silicon and manganese from any minerals containing them present in the charge. Manganese is now considered beneficial in all subsequent processes, but silicon must be sharply limited to pass some specifications. Silicon in pig iron causes much of the carbon present to separate and collect into tiny flakes of graphite, permeating the entire metallic structure; this graphite is responsible for the characteristic grey fracture of castings for machinery; its presence also makes for easy machineability. The carbon nould otherwise exist in the alloy as a compound of iron, a carbide, Fe_3C, called cementite, and form a much harder, stronger alloy. Consequently in such things as car wheels or in nhite iron castings, nhich are later to be converted into malleable iron by annealing, the silicon must be strictly limited. Silicon in pig for steel making must also be under close control, as we shall presently see. T'nerefore for those irons where both sulphur and silicon are limited, the ore and fuel must be specially selected for a low content of sulphur.

Grey and *White* Iron.--Carbon is another element in pig iron which will vary somewhat. It may be from 3.0 to 4 25%, depending upon furnace conditions. Generally if either silicon or phosphorus runs unduly high, the carbon will be low. Manganiferous

irons, on the other hand, are usually high in carbon. The colour of a freshly broken piece of pig iron is due to the way the carbon is held, rather than its total quantity; in white iron, nearly all the carbon is combined with iron in the carbide cementite; in grey iron, seven-eighths of it is in the form of graphite; intermediate proportions are called mottled irons.

Phosphoric Ores and Iron.—Phosphorus, until about the turn of the century, was the most undesirable element entering the blast furnace. Whereas much sulphur can be slagged off. between 90 and 100% of the phosphorus entering with the ore and the fuel ash comes out with the iron, and an excess makes both iron castings and steel brittle. For some types of thin castings requiring fluid iron *e.g.*, stove plates, from about 1.0 to 1.5% of phosphorus may be permitted, but in steel it is kept as low as sulphur, namely from 0.02 to 0.07%; in general, the lower the better the steel. Consequently the phosphoric iron ores of Lorraine were of small value—in fact of no value for steel-making until the Thomas-Gilchrist basic process was suggested (1878). Subsequent developments have converted the phosphorus in the ore to a pronounced economic asset. In view of all these facts, the furnace operator selects and mixes the ores and fuels which are available to him, and then adjusts his flux and controls his hearth temperature, by varying the amount of coke charged and the temperature of the blast, so the desired kind of iron will issue from the tap hole (see CAST IRON). Further notes on the varieties required for the various conversion processes will be given later.

WROUGHT IRON

Wrought iron, as compared to the total tonnage of steel, is an unimportant commodity. It amounts to less than 3% of the total production of steel. But it is important for its unique combination of physical properties, enabling it to survive since the time 75 years ago when it was the principal metal of engineering construction.

Puddling Process.—If about 600 lb. of pig iron and considerable iron ore are placed on the hearth of a small reverberatory furnace and melted, various reactions occur between the iron oxide from the ore and the impurities in the droplets of pig iron. The first reactions to occur may be simplified as follows:

$$2\,FeO + Si = SiO_2 + 2Fe$$
$$FeO + Mn = MnO + Fe$$

The iron thus reduced from the ore enters the pool of metal, and the silicon and manganese oxides join with the surplus ore to form a highly basic slag. This slag has the ability to absorb any phosphorus oxides which result from reactions between the phosphorus alloyed in the metal and the surplus iron oxide in the slag. The workmen stir the slag and iron together, an operation which is known as puddling; after the silicon and manganese have been substantially eliminated from the metal the carbon content begins to go down. The reaction may be written as follows:

$$[C]_{Fe} + O = CO.$$

Carbon monoxide gas bubbling upward causes the bath to boil. Removal of all these alloying elements leaves practically pure iron, of a much higher melting point. Toward the end of the process, therefore, the bath is converted into a metallic sponge of white hot, pasty iron, filled with liquid slag. This is cut into zoo lb. balls by the furnaceman, surplus slag squeezed from the dripping mass, and the resulting balls rolled into flat muck-bars. The metal is hot enough to weld together satisfactorily, and the process is accompanied by a great spray of slag sparks, squeezed out by the rolls. Muck-bars are cut to short lengths, arranged and wired together in piles, heated to a welding heat and re-rolled into marketable shapes.

Nature of Ferrite.—From a knowledge of the manufacturing process it may be understood that commercial wrought iron is essentially pure iron containing a greater or lesser number of slag particles.

The chemical changes which occur in the process of refining are thus indicated:

	Forge pig iron	Metallic portion of wrought iron
	%	%
Carbon	3·5 to 4·25	0·02
Manganese	0·25 to 1·0	0·005
Phosphorus	0·5 to 1·0	0·07
Sulphur	0·03 to 0·10	0·02
Silicon	1·0 to 2·0	0·03
Iron	95 to 92	99·855

About 3% of the best wrought iron by weight is slag.

A view of a polished section through a microscope shows the structure of wrought iron. The mirrorlike metal appears white in a photograph; the stony lustre of the slag particles appears grey. The slag itself is not a simple glass; it is a high iron silicate containing more or less manganese and phosphorus and frequently develops well-crystallized minerals. Slight etching of the polished surface under examination develops characteristic markings; the metallic portion seems to consist of a number of closely fitted or interlocking grains. If one of these grains were picked out, it would have an irregular surface; nevertheless it is undoubtedly true that its inner structure is that of a true crystal—that is to say, the atoms are arranged in regular rows, in geometric order. Such tiny crystals have a body-centred, cubic crystal structure and are called ferrite.

Properties of Wrought Iron.—Wrought iron has superior properties for forge welding, because at high heats the slag particles melt and spread into a film protecting the metal from atmospheric oxygen. The purity of the iron is responsible for its toughness, resistance to shock and bending. It also resists atmospheric and aqueous corrosion, either by virtue of purity of the metal or by virtue of the slag inclusions, or for some other reason. These special properties cause it to be in demand for pipe, chain cable, boiler stays, sheet iron and blacksmith's bar iron. For some of these purposes a variety known as charcoal iron (see IRON) is preferred. Wrought iron is moderately strong in tension, developing from 45,000 to 55,000 lb. per sq.in. ultimate strength. Furthermore it is a soft metal—Brine11 hardness measuring 75 to 80. Likewise the production of big masses of it is tedious, and puddling requires a large amount of exhausting labour from skilled workmen. These facts all combiaed to hamper competition with the harder and stronger steel—the Bessemer's process showing how to make the latter in great quantity, rapidly and almost automatically. In 1883 70% of all the pig iron made in England was made into puddled bar; in 1897 only 5%.

Aston's Process.—Mechanical puddling furnaces have been proposed and used to some extent, but the manufacture of metal in small batches is not in keeping with modem mass production. A more promising development consists of the process established in 1927 in America through James Aston. Knowing the essential characteristics of the ferrite and slag constituting wrought iron, he produced pure iron in a Bessemer converter, following the regular steel-making practice, and poured this iron into a pool of synthetic slag, which had been melted in a large cupola. Strong evolution of dissolved gas caused the metal to granulate into very fine particles; the resulting spongy mass of iron and slag was withdrawn, squeezed and rolled in the conventional manner.

BESSEMER STEEL

Early Steel-making Processes.—Prior to 1870 the principal metallic materials of construction were cast iron and wrought iron. The former could be made quite hard, but then was brittle; the latter resisted shock excellently, but was comparatively soft. There was a great and growing demand for metal which was both strong, wear resisting and tough, but there was no method of producing it cheaply enough to make, for example, railroad rails. Consequently, the discovery of the Bessemer process for making cheap steel was a godsend—an eager market was waiting; and in turn the satisfied market created other demands. Steel had been known for centuries. While accurate statistics are lacking one may reasonably guess that 250,000 tons a year of blister steel and crucible steel were being made in Europe in 1865. Blister steel

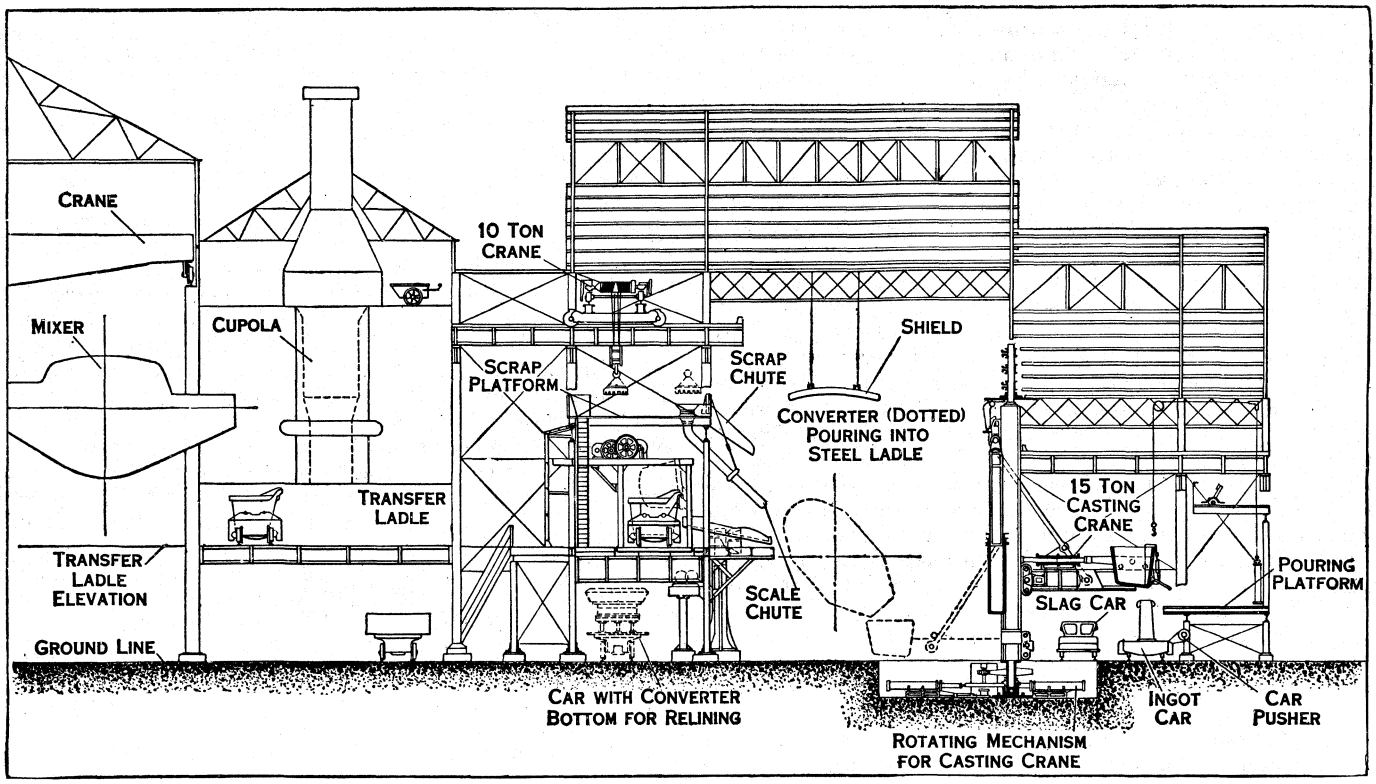


FIG. 2.— GENERAL CROSS SECTION OF CONVERTER HOUSE

was, and still is, made by packing wrought iron bars in a long stone box full of charcoal, and heating the container for several days at a full red. Carbon gradually is absorbed by the iron under these conditions, and it becomes steel. In order to improve the quality by equalizing the carbon content in this steel, and also eliminating the slag contained in the original wrought iron, blister steel is cut in short lengths and melted in a clay crucible (see CRUCIBLE STEEL).

For the manufacture of fine tools and cutlery such processes survive even yet, principally in the Sheffield region where the industry formerly thrived. But obviously this very indirect method of getting steel, bit by bit, was totally incapable of supplying the needs of the coming mechanical age.

Bessemer's Invention.— As has been pointed out, the alloyed impurities in pig iron can be eliminated by oxidizing them. In all the old refining processes, iron oxide in the form of ore, mill scale, or iron silicate slag (basic cinder) is the means nhereby the necessary oxygen is carried into the pig iron under purification. While experimenting on some methods for improving metal for cannon in 1856, it occurred to the English inventor Henry Bessemer that this oxygen for refining could be taken directly from the air if a blast were blown on or through the melted pig iron. On trial it not only purified the iron, but instead of blowing cold and freezing, the metal became hot enough to remain molten even when all the carbon was gone and hitherto infusible pure iron remained. The whole reaction required only a few minutes; at the end an ingot of mild steel could be cast, ready for the forge or rolling mill.

It took years of experimentation before the new process became a commercial success. The conservatism of engineers and constructors retarded the adoption of cheap steel and the useful mechanical auxiliaries, largely perfected by the American, Alexander L. Holley, which enables a modern plant with two converters to send forth a continuous procession of ingots, without halt, day and night (see BESSEMER, SIR HENRY; CONVERTER STEEL).

Converter House.—(See fig. 2.) Molten pig iron comes from the blast furnaces in ladle cars, and an overhead crane lifts the ladles and pours the contents into the mixer. By joining a reservoir of several hundred tons of metal, wide variations in chemical composition in a single cast are lost by dilution. A reservoir of uniform and promptly available raw material is thus established. Uniformity and continuity are foundations of rapid production of Bessemer steel; neither of these results when converting metal direct from the blast furnace or remelted pig iron from the cupola —although the latter sources may be used in emergency. At the proper time a ladle of iron, 10 to 25 tons depending upon the size of the converter, is poured from the mixer; it tilts by rolling on a circular track under positive control of a screw mechanism or hydraulic ram. A small locomotive pushes this full ladle car to the converter house, and by means of a launder the contents are run into the hot converter, with mouth tilted over to receive the charge. The blast is turned on, the converter tilted up to vertical position, and the blow is on.

Conversion Process.—The converter itself is a cylindrical steel pot perhaps 10 ft. in diameter by 20 ft. high, mounted on elevated trunnions and geared into a rack and pinion so it can be turned completely over. It is lined a foot thick nith a refractory mixture. The bottom bricks are perforated by many small openings, tuyères, through which air is sprayed into the metal at high enough pressure to keep it from trickling down into the wind box attached to the bottom of the converter shell, yet not so high as to throw too many splashings out the open mouth. Oxygen in the air blast burns the pig iron it first strikes. This product of reaction may be represented by FeO, and it is swiftly distributed throughout the churning mass. At the temperature of operation silicon and manganese atoms have a greater affinity for oxygen than iron has, so these two reactions occur:

$$Si + {}_2FeO = {}_2Fe + SiO_2$$
$$Mn + FeO = Fe + MnO$$

These oxides are insoluble in metal and accumulate into droplets of slag—a mixture of iron oxide, manganese oxide and silica. When the metals silicon, manganese and iron combine mith oxygen, or burn, much heat is released—enough to heat the incoming air and escaping nitrogen, to provide for radiation losses. and to increase the temperature of the remaining metal and slag so it is always quite liquid. During this early stage of the blow the red hot nitrogen coming from the mouth glows faintly. Gradually the carbon begins to burn, thus:

$$FeO+[C]_{Fe}=Fe+CO.$$

A roaring boil then takes place in the vessel; the carbon monoxide burns in a big, yellow, luminous flame at the converter mouth, and countless flying sparks of metal and slag add to the spectacle.

In only a few minutes the carbon is gone; the flame flickers, and suddenly contracts. This is the signal for turning the vessel over on its side, and stopping the blast. Inside the hot converter is now a seething mass of fluid iron, practically free of silicon, manganese and carbon, covered with a thin layer of slag. The metal, however, contains much gas in solution and if cast immediately would solidify in a spongy mass. Consequently some cupola-melted spiegel—a pure pig iron containing 20% manganese —is run into the converter. A rapid reaction ensues, wherein the steel is freed of oxygen by combination with the excess of manganese and carbon in the spiegel. The converter then tilts further over, discharging its contents into a waiting ladle. The blow has taken perhaps 12 min.; no greater time is necessary to add the spiegel, pour out the steel, turn the converter upside down to discharge any loose slag chunks, and back up to receive another ladle of liquid pig iron. A second converter alongside will be blowing while the first is dumping. In fact the whole equipment of the converter department is co-ordinated for a complete cycle every 12 to 15 min., and is built of the most rugged proportions, so delays from breakdowns will seldom occur.

Converter **Lining.**—The violent reactions at high temperatures cause considerable scour on the lining of the vessel; especially the tuyère brick at the bottom must be replaced after 20 to 25 blows. Holley is responsible for the plan of sectionalizing the converter shell; when a new bottom is required a car carrying a stout jack is placed under the upright converter, a series of bolts unloosed, and the jack lowered away, carrying with it the entire bottom part of the shell. This car is immediately replaced by another carrying a newly made bottom, already warm, ready for lifting and bolting into place. It is therefore unnecessary to leave a shell in the stand while it cools and the lining is repaired, dried and reheated—a matter of several days—but these sectional lining operations are done in a separate department and replacement of bottom or mouth portion requires less than 30 min. In American practice the lining material is a highly siliceous rock, ground with a little fire clay, moistened and tamped in place with pneumatic rammers. Such a lining is known as an acid lining, and steel made therein is called acid Bessemer steel.

Pig Iron Used.—Since the reactions described above leave untouched any sulphur or phosphorus, it is necessary that the pig iron entering the converter be quite low in these two elements. Furthermore silicon is limited by the rate of driving. It is the chief heat-producing element; if silicon in the pig is high the converter shell and its contents get superheated during continuous blowings and must be cooled either by dropping a quantity of cold scrap into the shell, by blowing steam in with the blast (which dissociates and absorbs heat), or by delays for radiation. On the other hand if the converter with a new bottom is a little cold, it is tilted partly over so some blast does not penetrate the iron, but burns the CO to CO_2 thus liberating more heat within the vessel. Maximum production may be had by blowing a pig iron with higher silicon and lower carbon; reducing the blowing time by charging mill scale or ore at the beginning of the blow; and charging scrap to absorb the excess heat generated. But in general the pig iron used for acid Bessemer practice, and the product therefrom will be about as follows:

	Carbon	Silicon	Sulphur	Phosphorus	Manganese
Pig iron . .	3½ to 4	1 to 1¼	0·05	0·09	½ to 1¾
Full blown .	0·03	0·01	0·05	0·10	0·03
With spiegel .	0·1 to 0·4	0·10	0·06	0·10	0·90

Growth of Uses.--Obviously such material as represented by the last analysis is immeasurably superior to wrought iron for railroad rails. The carbon content is responsible for hardness, wear resistance and strength which wrought iron could never acquire. Furthermore, the amount of carbon, and the corresponding degree of improvement in properties, is under control, for it is only necessary to place some charcoal in the steel ladle to make a higher carbon steel, or to use a spiegel or a ferro-manganese containing higher manganese and lower carbon when a milder or softer steel is desired. It is not surprising, then, that when the process was finally established on a producing basis in Bessemer's own plant in Sheffield, the product was rapidly absorbed for rails and tires. In 1868 there were 110,000 tons produced; in 1888 Bessemer steel reached its peak of production in Great Britain of 1,700,000 tons. Puddling had meanwhile declined; 70% of British pig iron went into wrought iron in 1883; only 5% in 1887. A similar story may be told of America. In 1867 460,000 tons of iron rails were made and sold for $83 per ton; that same year 2,550 tons of Bessemer steel rails were produced and some purchasers paid $170 a ton for them. By 1884, however, the last iron rails were made, steel had replaced them to an annual production of 1,500,000 tons a year, and the selling price was $32 per ton. In 1938 rails declined to a minor commodity in America and those were made of open-hearth steel, for reasons to be given later. Much Bessemer steel is still made into skelp for welded pipe, into wire and free machining steel (low in carbon, but high in sulphur and phosphorus).

THOMAS-GILCHRIST DISCOVERY

Control of Phosphorus.—This so-called acid process demands low-phosphorus ores and pig, and such material in Europe is relatively scarce and costly. Early efforts to remove phosphorus in the converter failed. Arguing from an analogy in the puddling furnace, where a slag rich in iron oxide will carry off phosphorus oxides, it was thought that if the converter blast was carried on after the carbon was gone, much iron oxide would go to the slag, and it would then be in a condition to absorb the phosphorus. When this was tried, however, the iron wasted away, ate into and ruined the lining, but unfortunately had no effect on the phosphorus. Not until 1876 did the Englishmen, Sidney G. Thomas and Percy **C.** Gilchrist discover that if the converter were lined with a basic material like burned limestone, dolomite or magnesite, and if burned lime were charged with the pig iron, then a basic slag would form and be maintained in such condition that it would absorb and hold phosphorous oxides produced during the blow. This is the basic Bessemer process now so widely used on the Continent for the production of so-called Thomas steel.

Basic Bessemer Process.—A modern basic plant is arranged much like its counterpart using the acid process. Converter shells are lined with different materials. Dolomite is freshly calcined in a cupola, ground with hot dehydrated tar, and the sticky mass tamped between the shell and a centre form. The perforated bottoms are lined two ft. thick, yet must be replaced daily.

In its modern development a heat of Thomas steel is made thus: Into a 10-ton converter 1½ tons of freshly burned lime are charged and then 10 tons of pig iron. The blast is turned on, the converter tipped up, and the blow proceeds exactly like an acid heat already described, but it continues after the carbon flame drops. In this last stage the following reaction occurs:

$$5FeO+2P=5Fe+P_2O_5$$

and the phosphorus joins with excess lime in the slag to form a calcium phosphate. There is no flame to indicate occurrences in the converter during this period. The duration of the after blow is judged from a knowledge of the phosphorus contained in the original pig iron. When the process is thought to be complete, the converter is tipped to its side, the blast turned off, and a spoonful of metal cast into an iron mould. This test ingot is chilled, hammered into a bar, and nicked, bent and broken. If the metal is brittle and coarsely crystalline, the air blast is resumed for a few seconds, and another test taken, and repeated until the metal is tough and fine grained. This finishes the blow. Next the slag must be skimmed off as quickly as possible, because phosphorus has a trick of returning to the metal on slight pretext; then the spiegel or other recarburizer and degasifier is added, and the steel poured into the ladle. About the only additional equipment in the converter house needed beyond that found in

an acid Bessemer plant is some handy means of caring for the large volume of slag produced. This slag, by the way, is ground and sold as fertilizer; it contains up to 20% of soluble phosphoric acid.

Thomas Steel.—In this Thomas-Gilchrist process, the pig iron must have relatively low silicon to limit the amount of slag formed. Phosphorus is the principal heat producing element, and it may be as high as 3%. It is doubly essential that a mixer be used to store pig iron, in order that phosphorus may never show wide fluctuations in analysis, heat to heat. Percentages in average analyses are as follows:

	Carbon	Silicon	Sulphur	Phosphorus	Manganese
Basic pig.	3½ to 4	0·5 to 1	0·05	2 to 2½	1 to 1½
Thomas steel	0·10 to 0·60	0·20	0·05	0·03 to 0·10	0·30 to 0·50

The process was introduced in Germany in 1879, and at the present time is used to refine the bulk of the pig iron produced from the Lorraine deposits in France, Germany, Luxembourg and Belgium.

Thomas steel provides satisfactory material for all classes of tonnage steels used on the continent, such as bars, boiler plate, pipe, structural steel and rails. But despite the fact that the Thomas-Gilchrist process was proposed to solve the problem of high phosphorus British ores, Thomas steel is not popular among English engineers, and hardly any of it is now made in England. This is probably due to the fact that the home ores do not smelt into a low-silicon high-phosphorus pig iron necessary for the economical operation of a basic converter, and further that the basic open-hearth furnace has meanwhile been developed to refine such phosphoric pig irons as are made.

OPEN-HEARTH PROCESS

As soon as the Bessemer process attained a production stage it was found that the mild steels intermediate in carbon content, strength and ductility between carbon-free wrought iron on the one hand and high carbon crucible steel on the other, were most useful materials for machinery and engineering structures. These mild steels were really new materials, never before procurable in quantity, and inventors attempted to make them in ways which would not infringe the Bessemer patents. An insuperable difficulty was the inability of any furnace, even when burning high volatile coal under forced draft, to melt them. As in the puddling process, when the refining reached a certain stage, the metal became a pasty sponge. This obstacle was met by Sir William Siemens, who resurrected a forgotten proposal to regenerate some of the waste heat (see FURNACE, METALLURGICAL). He passed the smoke through brick chequerwork; after the passages had thus been highly heated, air for combustion of the coal was drawn through the chamber. This pre-heated air had the effect of increasing the flame temperature materially. Using a furnace with such a device Emile and Pierre Martin made steel at Sireuil, France in 1864, by melting a good grade of pig iron, then adding some selected wrought iron scrap which alloyed with the pig iron, continuing these additions until the carbon content was reduced to the desired percentage mainly by dilution (the Martin pig and scrap process). William Siemens (*q.v.*) and his brother Friedrich found it necessary to erect an experimental furnace plant in Birmingham to develop the application of their ideas in the steel industry. By 1868 the principal features of the modern open-hearth process were there developed; namely, gaseous fuel, regenerative chequerwork for pre-heating both air and gas, a thin furnace roof of silica brick and the method of refining pig iron by ore or iron oxide (the Siemens pig and ore process). These entire furnaces, hearth, sidewalls and roof mere made of highly siliceous refractories; the only slags which would not corrode these contain an excess of silica—so-called acid slags. Not until Thomas had shown how to remove phosphorus by a basic, high lime slag in the basic lined converter did it occur to anyone to make on open-hearth furnace with hearth and side walls of sintered dolomite—lime and magnesia oxide—and to refine the steel under a high lime slag. J. H. Darby built the first of these basic open-hearth furnaces at Brymbo, Wales in 1884. The most available ores in both England and America smelt into pig iron well suited for such basic open-hearth refining; furthermore the product is distinctly superior in quality to Bessemer steel. Consequently at the present time the latter is used in America for the production of low-carbon steels for nonengineering purposes. Basic open-hearth steel, however, makes boiler and ship plate, structural steel, rails and all the higher carbon machine steels (and even alloy steels), such as shafting and forging billets. Production by processes is shown in the following table—it will be observed that the basic open hearth is competing with the basic converter even on the continent.

Steel Production in 1937

	United States	Great Britain	France	Germany
Acid Bessemer	3,449,927	233,000	46,000	none
Basic Bessemer	none		5,258,000	7,958,000
Acid open hearth	499,793	2,260,000	2,279,000	164,000
Basic open hearth	45,772,510	9,677,000		10,494,000
Electric	845,537	452,000	308,000	535,000
Crucible	934	no estimate	12,000	

Furnace Auxiliaries.— The essential furnace is often dwarfed by the auxiliaries found necessary for rapid and economical production. (See fig. 3; also FURNACE, METALLURGICAL.)

In the first place adequate fuel must be provided; consequently alongside is another building containing gas producers (see GAS INDUSTRY) of the continuous type. A series of such producers in operation discharge gas into one main pipe from which it is drawn to the furnaces as needed. The producer house must have adequate coal handling machinery; a plant with 10 60-ton furnaces would use 400 tons of coal a day, with means for hauling or sluicing the ashes anay, and boilers for raising steam to blow into the producers. Gas producers are usually found as standby equipment, even where other fuels are used, such as mixtures of blast furnace gas, by-product coke oven gas, natural gas, tar, and oil. Next a stock of adequate raw material is necessary. If open-hearth and blast furnaces are within the same fence, melted pig iron (hot metal) will be used. That requires a mixer for intermediate storage. Otherwise an ample stock of iron in pigs is required. Furthermore a big tonnage of steel scrap of various kinds is used—the proportions of pig iron and scrap charged into steelmaking furnaces now depends solely upon the relative availability and cost of these two materials. Scrap must be segregated as to nature and approximate analysis; big shears and drop balls (skull crackers) are necessary for cutting and breaking unwieldy pieces; travelling cranes and lifting magnets are installed for economical handling of this material. Bins and stockpiles must be provided for the various special metals used for alloying or degasifying the hot steel, for the limestone, fluorspar and other fluxes, for the silica, chrome, magnesite and other fire brick to repair the furnace, for the dolomite or silica rock used for making the bottoms. In basic open-hearth plants an auxiliary building is necessary for grinding, calcining and storing the dolomite continually needed for repairing the furnace bottom and side walls (banks). Spiegeleisen, if used for a deoxidizer, must be melted in a cupola or electric furnace.

Means must be provided for introducing the fuel into the furnace, and reversing the flow of flame at frequent intervals. This requires proper valves in the flues, with an appropriate series of interlocking operating devices. Latter-day trends in furnace design call for much shorter and more direct flues than shown in the cross sectional view, and the use of water cooled gate valves offering no obstruction to gas flow when open. Waste heat boilers are also quite frequently placed between regenerators and chimney, together with fans to pull the hot gases through them. A most interesting device is installed to charge solid material through the doors into the furnace itself. By this means long delays between heats to refill the furnace are avoided, together

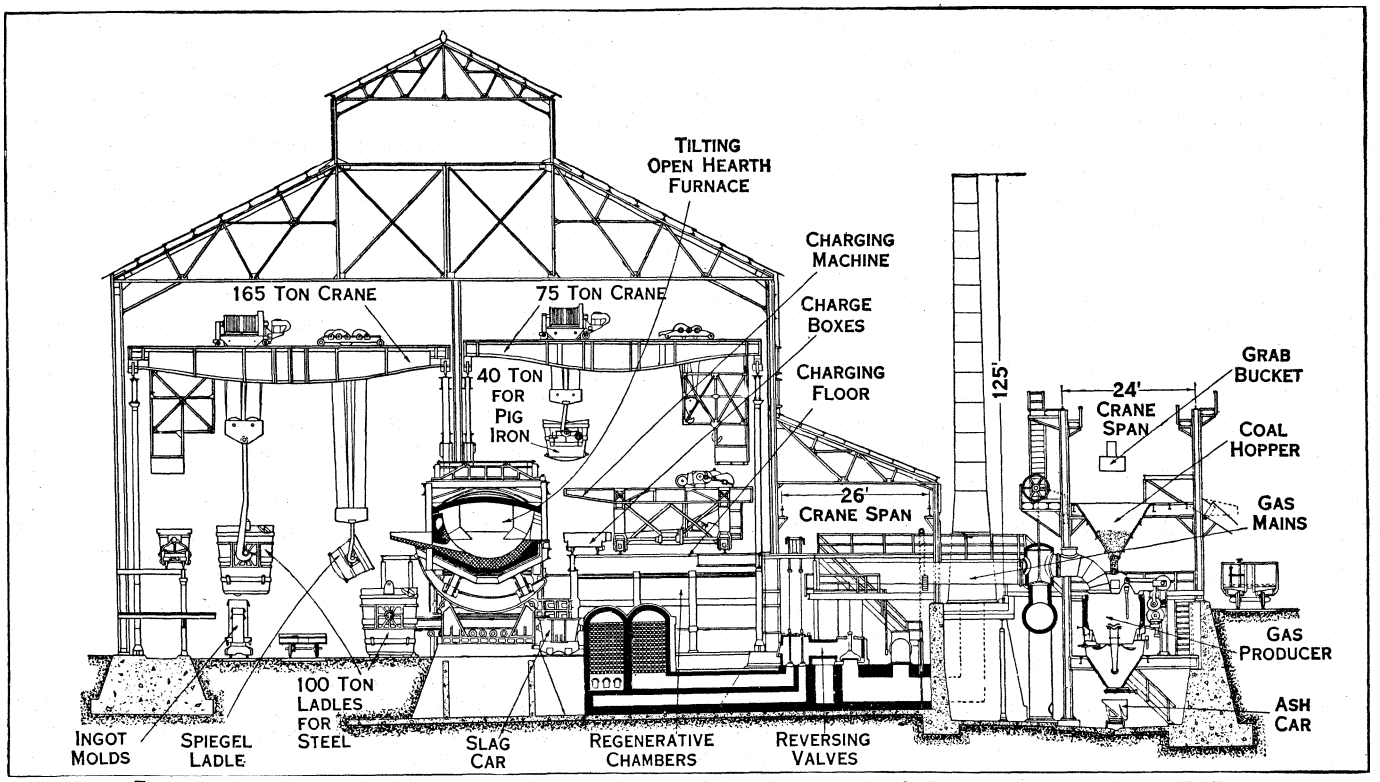

FIG. 3.—GENERAL DIAGRAM OF AN OPEN-HEARTH PLANT SHOWING GAS PRODUCERS AND CRANES FOR HANDLING METAL

with much exhausting labour. All solid materials are now loaded into charging boxes, cast steel trays about 24 in. wide and deep and about 4 ft. long, thus holding at least a ton of the bulkiest steel scrap. A complete charge for a furnace is assembled into 40 or 50 such boxes, placed on a train of small flat cars, and moved to a track running close to the furnace doors. On a wide gauge track alongside. the charging machine operates. Its ram engages an end socket on the box and is locked in. The ram then lifts the loaded box off the car, moves it forward through the open door into the furnace, slews it to either side and tips it upside down, discharging its contents in the correct place. These motions are then repeated in the reverse order. When the empty box is on the car, the charging machine moves sidewise, taking with it the entire train of loaded cars until the next full box is spotted directly in front of the proper door. This is then picked up, thrust into the furnace, and dumped. In this manner a 60-ton furnace can be loaded in less than an hour. Equipment must also be installed to pour the finished steel into ingot moulds, but this is an operation which, both in the principles involved, and in practice, is similar to casting a Bessemer heat, and will be described later.

Open-hearth Steel from Cold Metal.—The basic open-hearth process (1956) makes by far the most steel. Many steel-making furnaces are distant from blast furnaces, so they operate entirely on cold stock, and as noted, any proportion of pig and scrap may be charged, as economics require. This process as commonly practiced in a stationary furnace and its elementary chemistry are here briefly explained. After a furnace has been tapped and the bottom and banks repaired charging is begun. Plate scrap, if available, is spread out to protect the bottom, followed by several tons of limestone, depending upon the impurities to be removed from the pig and scrap. The furnace is then filled as full as possible, with scrap, pig iron and some iron ore; the doors are then closed, the flame given an excess of air and melting begins; as the mass melts and settles, the balance of the cold metal is added. Melting pig iron will trickle down over the white hot steel, still solid. Silicon and manganese in the pig iron droplets oxidize by the excess oxygen in the furnace atmosphere, and join with the iron oxide forming on the white hot steel and some of the lime on the bottom or furnace wall forming a slag. In four to five hours the moiten metal is virtually free from silicon, and much manganese has also gone into the slag. Vigorous stirring is necessary as chemical reactions only occur at the surfaces where metal and slag are in mutual contact. This is effected principally by gases rising from the limestone, and some two hours after the metal is fluid it continues to break up, thus

$$CaCO_3 = CaO + CO_2$$

The gas coming to the surface in big bubbles causes a characteristic boil. The lime also floats up, joining the slag as a base, not only releasing some of the iron oxide contained therein for refining reactions, such as

$$2P + 5FeO = P_2O_5 + 5Fe$$

but also maintaining the basic slag necessary to dissolve and hold this phosphorus oxide. When the lime is all up further boiling in the bath is due to the chemical reaction between iron oxide and carbon (which has been going on continually but its mechanical effect somewhat overshadowed by the lime boil).

$$FeO + [C]_{Fe} = Fe + CO.$$

The iron oxide is dissolved by the metal from the slag. Bubbles of carbon monoxide gas evolved continue to keep the metal and slag in motion. The active refining reagent in the open-hearth furnace is the same as in the Bessemer and the earlier refining processes, namely iron oxide, but its origin is different. In the open-hearth process iron oxide is formed by oxidation of the steel during melting, picked up from the rusty scrap, and added as desired to the slag in the form of ore. During the late refining period, the furnaceman frequently takes a spoonful of metal from the bath, pours test ingots and breaks them, judging from the fracture the content in phosphorus and carbon. It is necessary to regulate the proceedirigs so that phosphorus in the metal shall be down to the desired minimum some time before the carbon is down. This relative elimination can be controlled by adjusting the temperature (reversing the flow of gases more frequently increases the heat), changing the slag by adding either lime or ore, increasing its fluidity by adding fluorspar (CaF_2) or increasing the carbon by adding some low-phosphorus pig iron. In about three hours the carbon boil should subside, the bath should be low in phosphorus,

and the slag essentially a high lime silicate — to hold the phosphorus; the furnace is then driven hard to increase the metal's temperature sufficiently for casting. The slag and the metal have been slowly losing iron oxide and carbon respectively by mutual interaction, and the metal gives up considerable gas held in solution. Since 1930 much attention has been given to the relationship between composition and viscosity of the slag existing in the refining stages and the quality of the finished steel. Slag composition is rapidly estimated on the furnace floor by pouring a small "pancake" of slag in a standardized manner and examining its surface, colour and fracture. Its viscosity is measured by the distance the slag flows down a pipe-stem mould. Likewise carbon in the steel may be closely estimated by rapid magnetic tests; the rate of carbon drop is also an indicator of the state of oxidation in the heat. High grade steels are deoxidized by the controlled slag in the furnace, after which further ,deoxidizing substances like ferro-manganese or ferro-silicon may be added to the metal bath,. followed by various alloying elements like chromium if an alloy steel is to be made. When the word is given, the furnace crew thrusts a long heavy bar through an opening in the centre door, across the furnace into the bath; several battering-ram thrusts break through the plugged tap hole, and white-hot metal rushes down the spout into a ladle set beneath. This ladle is just large enough to hold the steel; slag which follows after overflows into a pit or slag ladle alongside.

VARIATIONS IN PROCESS

Use of Molten Pig. — Various methods deviate from the above routine and have been devised to adapt the open-hearth process to the economic conditions to be met by the steel-maker, especially as to the relative amount of scrap steel and molten pig iron available. These range from processes for handling a preponderance of scrap and a minor amount of molten pig iron (as is usual in America) to the Talbot process described below for handling up to 80% hot metal (as is practiced in England, 1939).

In American stationary furnaces of, say, 100 tons capacity the limestone and scrap are charged as indicated above and heated strongly until well melted. During this time the slag forms from oxidized iron and calcined lime. Within two hours all but the heaviest scrap has melted and molten pig iron is poured in. A rapid reaction starts between the iron oxide in slag and melted scrap and the carbon, phosphorus, and silicon in the molten pig iron. Carbon oxides boiling up through the slag cause it to froth and swell and much of this "flush slag" flows off through a hole in the back of the furnace well above the normal shore line. This slag carries a little sulphur, and much of the silicon, phosphorus and manganese in the pig iron, and the amount of finishing slag is correspondingly reduced.

Continuous Steel Making. — Benjamin Talbot first built furnaces for continuous production of steel at Pencoyd, Pa., in 1899, although the Talbot process is more popular in England (1939). Furnaces are of large capacity — 200 to 300 tons of metal — and are mounted like a mixer on trunnions; they can be tilted forward and slag skimmed or metal poured through a spout, normally far above the liquid bath. Most of the finishing slag and about 10 tons of steel from the previous heat are retained in the furnace and on this is charged enough burnt lime and ore so the first slag can be removed when the metal is 0.30% carbon above that desired. After heating the slag and furnace for 2 hours scrap as available is charged, heated another 2 hours, and about three-quarters of the required molten pig iron is poured in. Reaction is vigorous for about 4 hours, and then the remainder of the hot metal is added. The bath quickly comes to a good boil and the slag is carefully skimmed off 1 hour later. This slag carries most of the phosphorus; it may analyze 17% P_2O_5 and is a valuable by-product. The finishing slag is then made up of lime and scale (iron oxide) and the bath worked until carbon, sulphur, and phosphorus in the metal are reduced to the required point, taking about 3 hours, whereupon ferro-manganese is added and the steel is poured into waiting ladles. The analysis can be "caught on the run," and held for adjustments, alloying, or making up a second refining slag. The process, therefore, in addition to consuming large proportions of hot metal, is able to produce quality steels of varying specifications at will, thus being a prototype of the electric furnace, to be described later.

Duplex Processes.--Other means of speeding the rather deliberate open-hearth reactions are used extensively, perhaps the most important being a combination of acid Bessemer and basic open hearth. This enables the steel-makers to start with a high sulphur ore, smelting it to a high silicon, low sulphur pig iron, blowing the silicon and carbon out in a converter, and transferring the molten steel to a large tilting furnace where the phosphorus, oxide and gases are eliminated. In American practice 250-ton tilting furnaces are used; 50 tons of molten steel are reserved in the hearth, a highly basic combination of ore and lime is charged, melted. and about 150 tons of blown metal poured in. When the temperature and slag are correctly adjusted, a ladle of basic pig iron from a mixer is charged. A strong carbon boil ensues immediately, and the slag foams up and overflows, carrying much of the phosphorus and some sulphur. When the first reaction quiets down, a second ladle of pig iron causes it to resume, and drives out the rest of the phosphorus. The slag is then skimmed off, enough pig iron is added to bring the carbon to the desired percentage, and the metal finished and superheated for pouring. From such a furnace, 200 tons of steel can be taken every 3 or 4 hours.

Duplex processes of the sort described but using two open-hearth furnaces originated in Germany and are used for irons somewhat too low in phosphorus for the basic converter. In the first furnace, run at a rather low temperature, the phosphorus and silicon are eliminated into a lime slag rich enough for use as a fertilizer. The furnace is tapped, the slag separated, and the metal introduced into another and hotter furnace, wherein awaits a proper slag for rapid carbon elimination. This is called the Bertrand-Thiel process; the Hoesch modification recharges the partly purified metal back into the furnace from which it has just been drained. Super-refining molten basic steel in an electric furnace is another variety of duplexing which has been practised in America; by eliminating sulphur and oxidizing particles, good steel is made, but the difficulty of co-ordinating operations to avoid idle stand-by of costly furnaces has prevented the wider adoption of duplex processes.

Acid Steel. — Furnaces made with siliceous bottoms and banks, the descendants of the original open-hearth furnaces, still exist in considerable number. They make steel under slags which are essentially mixtures of iron, manganese and silicon oxides, having well over 50% of the latter, and are so quite acid in nature. Such acid steel has an enviable reputation for quality, but since the furnace reactions remove neither sulphur nor phosphorus, the raw materials and fuel must be selected with much more care.

Pig and scrap, as available, are charged cold into the furnace, which has a higher roof to withstand the higher refining temperature; during melting, nine-tenths of the manganese and silicon are oxidized, and join with the rust and burned iron to form a slag. Carbon is eliminated slowly by reaction with the iron oxide in the slag; a little ore is added some two hours after the charge is well melted to keep this reaction going until the residual carbon in the metal equals that required in the steel being made. Temperature is driven higher and higher. Toward the end of this refining period — which may require seven hours — some manganese and silicon re-enters the metal, reduced from the slag by reversible chemical reactions, and are very effective in removing oxygen and other dissolved gases At the end the metal is slowly losing carbon but gaining manganese and silicon. However, manganese is still too low for most steel specifications, so an appropriate amount of ferro-manganese is added some 20 min. before tapping A complete cycle of operations may require up to 16 hours when making steels for ordnance. The superiority of acid open-hearth steel is due to the better grade of raw material used, the small amount of slag formed (perhaps 7% of the metal), the more deliberate working of the heat enabling the furnaceman to bring his metal to the right analysis without making large additions of alloys, and the ability to eliminate gases and non-metallic impurities from a super-heated fluid metal while it is still in the furnace.

ELECTRIC STEEL

Electric furnaces (*q.v.*) are usually round in plan, with low side walls, flat domed roofs and invert bottoms, built inside a stout bowl of steel plates, which in turn is attached to some tilting device. Side walls are pierced by one or more doors and a pouring spout. The side wall and bottom linings may be either acid—silica brick and fused siliceous material—or basic magnesite. (The acid furnace is confined generally to small installations in foundries, and is merely a melting and super-heating device, since the unique carbide slags to be described later cannot be formed inside a siliceous lining.) Roofs are of silica brick, and are pierced for carbon or graphite electrodes, one for each phase of current, of proper size to carry the electricity without undue resistance. Furnace capacities range from ¼ ton for small foundries, to 50 tons for super-refining liquid steel. Size is limited by the size of electrodes available; of the latter, a carbon 40 in. in diameter is the maximum; a 7-ton furnace would be about 12 ft. in outer diameter, with 13 in. side walls, and hearth 5½ ft. inside height. In operation, the electrodes are automatically adjusted so the lower ends are constantly a correct distance above the slag. Electric currents of large amperage arc cross this gap, flow through the slag to the metal and there neutralize equal currents of opposite phase led in through the other electrodes. Heat is generated principally by the resistance offered by the air gap and the slag layer to the flow of this current. The electrodes are consumed gradually, combining with oxygen of the air within the furnace, producing a carbon monoxide atmosphere, desirable for steel refining.

Advantages of Electric **Heat.**—No virtue is given to electric steel by the electricity. It is merely a convenient source of heat, under close control. The advantages of electric furnaces for steel making are: (a) ability to generate a high temperature and thus cause certain desirable reactions to occur; (b) virtual absence of products of fuel combustion and their unwanted compounds of carbon, hydrogen, sulphur and oxygen; (c) the ability to remove a slag and make up new ones, thus controlling refining reactions; (d) the metal is hotter than the refractory, a prime advantage in cost over crucible melting; (e) less slagging of alloying elements, thus making for economy and control of chemical composition within narrow limits. Such advantages are illustrated in the process of super-refining molten metal from the open-hearth furnace; in such operations the basic electric furnace is a unit of a duplex or even a triplex process—the pig iron may be desiliconized in an acid converter, de-phosphorized in a basic open hearth, and de-oxidized and de-sulphurized in a basic electric furnace.

Super-refining Molten Steel.--Open-hearth steel is taken from the furnace when the carbon has dropped to the required figure, and a little ferro-silicon or aluminium added to the ladle to prevent further decarbonization during the transfer. In such condition the phosphorus and silicon are both very low—0·010% or less—while the sulphur depends upon the purity of the metal at the beginning, none being lost in the process so far; in fact the metal picks up a little from the furnace gases. If a nickel steel is to be made, the correct amount of shot nickel is added when this liquid metal is poured into the electric furnace. After the current has played long enough to remelt any crust of metal which may have chilled, a highly basic white slag is made up and melted, consisting mostly of burned lime with only enough silica sand and fluorspar to give it the proper fluidity. In quantity this would amount to about 3% of the metal. An excess of ground carbon is then shovelled in, the furnace closed, left under current for from 1½ to 5 hours, depending upon the quality of steel required, and the doors opened only for sampling or adjusting the slag. Under these conditions of a reducing atmosphere, a high lime slag, and intense heat, calcium carbide is formed by reaction between the lime and crushed carbon

$$CaO + 3C = CaC_2 + CO$$

Slag samples quenched in water give off much acetylene (*q.v.*) easily distinguished by its characteristic odour. Such a carbide slag not only reduces oxygen in the steel but is capable of abstracting the sulphur. The reaction for the latter may be something like this:

$$3MnS + 2CaO + CaC_2 = 3Mn + 3CaS + 2CO$$

By this means ordinary open-hearth charges which usually melt to 0·05% sulphur are reduced to one-half that amount in a four-hour cycle, while selected charges melting to 0·015% sulphur can be driven to less than 0·010% in a heat taking 8 hours. It will be observed from this reaction that some manganese is necessary. This will be residual in the open-hearth metal, for it has been found that if say 2% manganese is in the original pig iron, the resulting steel, containing 0·30 to 0.50 manganese will be of much better quality, sounder and cleaner, than from a low-manganese charge.

When the soapy slag stops its slight foaming, it is a sign that desulphurizing and deoxidizing are about completed, and the various alloys necessary to make the required analysis are added at intervals in order of their oxidizing power, namely, ferro-silicon first, then ferro-manganese, ferro-chromium, and finally ferro-vanadium. Carbon is picked up from the carbide slag and from these alloys. After all these alloys are melted and diffused the current is shut off and the metal lies quiet for 30 min. or more, to allow entrapped particles of slag to arise and the superheated metal to cool and liberate dissolved carbon monoxide gas. Slag is then most carefully skimmed, and the steel poured into a ladle which may contain a little carbon, ferro-silicon and ferro-zirconium. After 30 min. further cooling the metal is teemed into warm, scrupulously clean moulds with hot tops. A sectioned ingot will show no cavities as large as a pin head.

Quality of Deoxidized Steel.—Quality of such deoxidized and desulphurized steels rests in a number of characteristics, some not capable of evaluation, such as better response to heat treatment, less non-metallic inclusions, as shown under the microscope and after deep pickling in strong acid. A better gauge is the transverse properties. If a well made heat of basic open hearth steel is forged into a big gun, tension test pieces cut out of this forging will show high ductility if the piece is cut in a directon parallel to the axis of the gun. On the other hand if these test pieces-are cut tangentially to the bore, the ultimate strength is satisfactory but the ductility is not much more than half the longitudinal piece. Unfortunately this transverse weakness is in the very direction which must bear the heaviest stress when the gun is fired. An accepted explanation of this phenomenon is that the work of forging ranges the non-metallic impurities into layers parallel to the faces of compression, and interrupts the metallic continuity. Obviously, the cleaner the steel the less would be the transverse weakness. For that reason important forgings, such as hollow tubes to resist internal pressure, are commonly made of acid open-hearth steel. Super-refined basic electric steel is even better, as shown by the following typical tests from big gun forgings of nickel steel:

	Longitudina!	Tangential
Ultimate strength, lb. per sq. in.	110,000	110,000
Elastic limit, lb. per sq. in.	58,000	58,000
Elongation in 2 in., %	24	21
Contraction in area, %	56	42

Melting Cold Scrap.—By far the larger number of electric furnaces are of small capacity for melting cold scrap. While it is possible to refine impure pig iron in either the acid or basic electric furnace, it has been generally foucd more economical to start with clean, relatively heavy, high manganese scrap and melt without additions of iron ore. In a basic furnace considerable lime would be charged into the empty furnace; melting is done under the heaviest power input practicable. The slag formed on the steel is always black from the rust and oxide formed during melting. This slag is removed as soon as the charge is melted, and some ground carbon electrode butts are shovelled into the furnace and flapped under the metal. As the carbon dissolves, it first tends to deoxidize the steel

$$[O]_{Fe} + C = CO$$

and the carbon monoxide gas comes up in bubbles. Some surplus carbon helps bring the carbon to the required analysis. Then a

white or carbide slag is made up, and the refining and alloying is done with current of lower voltage and as described above.

Induction Furnaces.— The 1939 substitute for the crucible melting hole is the high frequency induction furnace. The furnace case is a small cubical box which can be tilted about one upper edge. It contains a cylindrical spiral coil of water cooled copper tubing which carries alternating current at about 2,500 cycles per second. The coil is electrically and thermally insulated, and inside it is rammed a magnesite refractory to form a crucible, into which is charged selected steel and ferro-alloys for simple melting and mixing without refining. The intense alternating magnetic field set up inside the coil induces eddy or Foucault (*q.v.*) currents in this metal to heat and melt it. Electrodynamic movement of the bath keeps the metal well stirred, which is of advantage in making high alloys of heavy metals, such as high speed tool steel (*q.v.*), but tends to stir in particles of incidental oxide slag. As a simple melting furnace of rapid action the induction furnace has no equal.

Statistics show that electric steel has practically supplanted crucible steel in America, but has not been so successful in Great Britain. Italy being rich in water power. but very poor in fuel, has at least 200 electric furnaces with annual capacity of one million tons, but nearly all of them produce tonnage steels. Much controversy exists as to the relative quality produced by the two processes. It is probably true that there is little difference when selected raw material is charged, an expert furnaceman is employed, and equally careful pouring, forging and annealing practice is adhered to—in other words, when equal care is given to the respective heats. But steel from either process can be disappointing when conditions get out of control The crucible is more convenient for smaller casts of plain high-carbon steels; the electric is more convenient for heavy ingots of lower carbon, higher alloy steels.

INGOTS

Gases in Liquid Metal.— Early attempts to make steel in England by Bessemer's process were failures because the metal when poured into ingot moulds boiled over and the remaining portion when solid would be full of blow-holes, like a Swiss cheese Robert Mushet noted that the only apparent difference between sound ingots and the spongy ones was that the former were made of high-manganese pig iron and a little manganese remained in the steel; consequently he proposed adding some of the metal after the blow. Thus originated the practice already mentioned of adding spiegel or ferro-manganese to heats of steel made by any of the Bessemer or open-hearth modifications. Superheated liquid steel absorbs gases from the atmosphere or oxygen from the slag. This gas is only slowly evolved as the steel cools off, but it boils out vigorously just at the freezing point. In the crucible and acid open-hearth process much of this oxygen is eliminated by holding the melted metal quietly in the furnace until reactions between the siliceous linings and the metal allow the latter to absorb some silicon which in turn is very effective in removing dissolved or combined oxygen existing in the steel, and causing it to solidify quietly without effervescing, which imparts superior physical properties. This time-consuming reaction is avoided when producing cheaper steels in great tonnages by adding the degasifyers to the steel in the ladle, or even as it is poured into the ingot. Melted spiegel-eisen is used for medium carbon Bessemer steels. Since spiegel ordinarily contains 20% manganese and 5% carbon, it will be observed that sufficient manganese to quiet the steel will also introduce considerable carbon. Should this be too much for the desired grade of steel, ferro-manganese is used instead. Since a relatively small amount of this is required small pieces are placed in the ladle. and melted by the inrushing steel; if the metal on casting still seems too effervescent, a few aluminium shot are thrown into each ingot. The principal effect of each of these metals is to rob harmful iron oxide existing in the steel of its oxygen, thereby transferring it to MnO, SiO_2 or Al_2O_3 as the case may be. These oxides are highly insoluble in metal, and tend to accumulate into slag particles and float; but there is little opportunity for elimination when the reactions occur in the ladle or ingot mould. Entrapment of submicroscopic inclusions is not an unmitigated evil; under proper control the effect is to restrict crystallization of the steel during solidification and in later heat treatment, and such fine grained steel has superior toughness and most other physical properties (except depth of hardening).

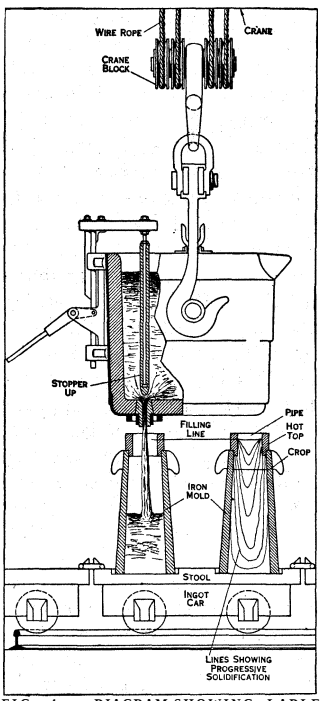

FIG. 4.— DIAGRAM SHOWING LADLE AND METHOD OF POURING INGOTS; AND LINES SHOWING PROGRESSIVE SOLIDIFICATION OF INGOTS

Teeming Practice.— It is usual practice to transfer steel from converter or open-hearth to ladle somewhat too hot to pour; also to use a ladle of correct size so most of the slag overflows. Ladles, therefore, contain from j to 200 tons of steel, depending on the furnace served (*see* fig. 4). They are strong steel pots lined with fire brick, and equipped with trunnions and shackles for crane transport. The hot metal is kept in the ladle sometimes as much as half an hour, to enable all trapped slag particles to float. Then the ladle is carried to the ingot moulds, and the metal teemed through a hole in the bottom. When one mould is filled, the metal stream is interrupted by lowering the stopper until the ladle may be moved to an empty mould. Splashing against the sides of the moulds must be avoided, for such splashings are the most general cause of surface defects on the finished articles.

Steel castings are ordinarily teemed in the same way; furnaces in steel foundries are usually very small as compared with furnaces serving rolling mills. 97% of all the steel made is cast into ingots.

Cavities in Ingots.— Well-killed steel contracts in volume when it changes from liquid to solid; consequently a mould poured level full will have a top cavity, or pipe, when solid. Good practice so proportions the chilling effect of the mould? the temperature of the steel and the rate of pouring that the ingot solidifies from the bottom up. A hot-top in the form of a firebrick collar, set on top of the mould, as shown, is a most useful device for keeping the top portion of the metal fluid until the last, and in condition to feed and fill the shrinkage cavity below (*see* fig. 4). A certain segregation or concentration of alloying elements also occurs toward the pipe; consequently all the defective top must be cropped as indicated and remelted as scrap. Segregation and piping is also minimized by casting ingots big-end-up and by slow pouring of rather cool metal. The latter is well accomplished by having several ingot-moulds on one stool, teeming into the central one, and allowing metal to rise in the others through connecting passages in the common base. Enough gas is left in most low carbon tonnage steels so a slight effervescence occurs in the mould, just enough to counteract the piping tendency. When properly made and cast, such ingots will have a flat top, a smooth solid surface, but a number of deepseated small blow holes. During subsequent rolling these are squeezed shut and the metal welds together more or less effectively. Metal of this sort is called "rimming" steel; the dense surface of the metallic ingot is an ideal start for thin sheet, which is almost all surface.

Stripping and Soaking.— Size of ingots depends upon the use to which the metal is to be put. Ingots of alloy steel and high grade tool steel sometimes weigh no more than 100 lb. Forging ingots are from two to five times the thickness of the biggest part of the resulting forging; those for rails, plates and structural shapes are adjusted to the size and capacity of rolling mill, and

the cross section of the desired product; for rolling mills they are generally square in cross section, with rounded corners, and about three times as high as thick. A common size is 2x2x6 ft. weighing about 6 tons. Forging ingots are frequently fluted hexagons or octagons in cross section. The moulds are heavy-walled iron castings, made of low-phosphorus low-sulphur pig iron, such as is suitable for the acid Bessemer process, sprayed with lime wash or other coating. When the metal in the ingot has well solidified, the train of moulds is moved to a stripper, an overhead crane with a vertical plunger which can be forced down by suitable gearing on top of the ingot, holding it down against the stool. A pair of stirrups then loop over the ears on either side of the mould, and lift; if the inner surface of the mould is in good condition and smooth, no difficulty is had in thus removing the mould, and it is then placed on an empty car alongside. At this time the surface of the ingot is at a full red heat, yet the interior may still be white hot To equalize this heat the ingot is placed in a soaking pit, a square fire brick chamber large enough to contain two to six ingots standing on end; an arched cover rolls aside for entrance. Auxiliary heat is supplied as necessary by a gas-air flame, operating through regenerative chequer-work, ports and auxiliary control as described for open-hearth furnaces. Pit capacity for at least 100 ingots is required to maintain a steady supply of properly heated metal to a modern rolling mill.

ROLLING MILLS

Hot Working. — A spongy lump of wrought iron, hot from the furnace, requires forging in order to squeeze out much of the trapped slag, and to consolidate the metal. Even the best ingot of steel is improved by hot work, such as forging or pressing; its fracture is changed from a coarse crystalline cleavage like sugar to a mossy or fibrous appearance associated with greatly increased toughness; it also becomes more amenable to heat treatment. Formerly all this was done on the blacksmith's anvil. Massive gun tubes and armour-plates are forged slowly in hydraulic presses; heavy engine parts, axles and cranks are beaten out by steam-hammers; repetition tools, levers and machine parts are forged under drop-hammers. In every instance the aim is to convert a steel casting (ingot) into a special shape and with improved physical properties.

Modern machines and structures--even foods and personal conveniences — require large quantities of steel parts of uniform cross section, such as plates, bars, beams, rails, pipes, sheets, etc. These are made in rolling-mills where the work is performed by passing the red hot metal through one pair of heavy rollers after another, so grooved and spaced that each succeeding pass is smaller and more nearly the required final shape. While the products of a rolling mill vary widely in weight and shape, a common characteristic is that each piece is of uniform cross section from end to end, and is of a length limited only by the size of the original ingot, or by the size of the runout floor.

The word mill may mean the entire steel making plant, just one department, or one stand of rolls in the department. Complete departments have various names, such as rail mills, structural mills, plate mills, merchant bar mills, depending upon the product they most efficiently produce. Each such mill contains a number of roll-stands of decreasing size and power, from the blooming or cogging mills which do the heaviest work, down through the intermediate stands to the last pass, finishing mill or finishing stand, which impresses the exact final cross section.

There still exist many rolling-mills, some producing the highest type of tool steel, which start with a small piece of metal (a 150 lb. ingot or a chunky rolled bar called a billet) and produce rods, bars, hoops or flats a fraction of an inch thick. Metal is passed back and forth by tongs in the hands of skilled labourers. Such roll stands are usually arranged side by side and the hot bars are looped from stand to stand, entering from alternate sides, until the final shape is produced. Sometimes curved guides are installed to do the work of alternate workmen; as the size of the bars increases hand labour cannot cope with the situation. Most rolled shapes start from white hot ingots, perhaps six tons in weight, which are taken from soaking pits by a travelling crane, placed on the first of a series of "tables" — power driven roller conveyors — which transport the metal wherever a distant electric switch operator directs.

Blooming mills are usually arranged so the ingot is passed back and forth several times through the same roll stand. This requires a screw-down device and indicating dial on top of the housing for lowering and reversing the rolls progressively as the piece becomes smaller. The spindles connecting the rolls to the driving engine or motor are of most rugged construction, for upwards of 20,000 h.p. is transmitted at times.

Heating Furnaces. — In a modern rail-mill the ingot, having been reduced to a long bloom perhaps 8 in. square in cross section, has its ends sheared off to sound, unpiped metal by massive guillotine shears operated by hydraulic power, and is cut into such lengths that each billet will make one or two rails of required length and cross section; these are then reheated before further rolling; other mills which reheat cold billets require special furnaces, now usually gas or oil fired, frequently having waste heat boilers or recuperators (see also FURNACE, METALLURGICAL; FURNACE, ELECTRIC). Furnaces have a long rectangular hearth, slightly inclined, as wide as the billet is long, and a low roof. Water-cooled skids carry the weight of the steel and prevent scraping on the brick furnace-bottom. At the cool end billets are pushed in sideuays by a plunger. one by one, moving all ahead closer to the hot end. Every time a cold piece enters the furnace, a hot one is pushed out the other end on a roller table leading to a roll stand; other continuous furnaces have water-cooled rollers or other devices built into the bottoms for moving lighter pieces such as wire coils through them at a slow steady rate.

Rail Manufacture. — A reheated bloom in a rail-mill may then be given four more passes in another reversing mill, called the first roughing stand, passing then to the first finishing stand. This is three-high, *i.e.*, there are three rolls in a stand. The forward pass is through a groove cut in the lower and the middle roll; the receiving table is then elevated bodily and a backward pass is made between a groove cut in the middle and upper roll. Four such passes and a final one through a finishing stand completes the rail; a total of 15 passes and one reheating will convert an ingot into a rail weighing 100 lb. per yard. Structural shapes such as angles, channels and I-beams, are rolled in a similar routine. Frequently rail mills, by simple change in rolls, are made to produce structural steel when there is no market for rails. Special and extra heavy equipment is necessary to roll the massive H-beams with deep flanges so popular for building columns.

Plate manufacturing departments are less complicated than a rail mill, although the machinery may be more rugged. First the ingot — 6 to 10 tons or even heavier — is rolled to a flat slab in a blooming mill, sheared into pieces, and the slabs reheated. Further work is done by cylindrical (ungrooved) rolls. Sometimes a single reversing a-high roll stand does all the work; at other times two three-high mills with elevating tables may be observed. On account of the enormous bending stresses carried by the rolls when rolling wide plates, many two-high reversing stands have been built as four-high mills, having two rather small working rolls, each backed up with a larger one for stiffness. Plates of more uniform thickness, edge to centre, may be made in this way. It should be observed that the action of a rolling-mill does not widen the piece very much — most of the change in volume results in increasing its length. Consequently a heavy slab is cut to a length which equals the width of the required plate, and it enters the plate rolls sideways. Cross rolling in this way results in a better plate; metal worked in only one direction acquires transverse weakness. This means that the tensile strength of test bars cut with their axes parallel with the direction of extension during rolling will be higher than when cut from the plate with axis in any other direction. Other interesting mechanical devices are included in a plate mill which cannot be described here in detail. Among them are plate straighteners, cooling beds, cross cut and edge shears, turnover devices, castor beds and magnetic grips. Side shearing on narrow plates may be avoided by using a universal mill, which is a roll stand to which is added a pair of stout

vertical rolls. The latter are adjustable, up to perhaps 48 in. apart, and are set a proper distance to keep the hot plastic plate the exact width during its formation.

MILLS FOR SEMI-FINISHED MATERIALS

Continuous **Mills.**—Four classes of semi-finished materials are manufactured in such tonnage that special mills are set up to produce them, namely: sheet bars, skelp, strip, and wire rods. These products are the raw material for special manufacturing plants often located at a distance from the steel furnaces. Sheet bars are worked into tinplate, galvanized, and uncoated sheet; pipe is made from skelp; strip is narrow sheet for hoops and bands; and rods are drawn into wire, from which all kinds of fencing, screening, cable, nails, and springs are made. Sheet bars and skelp are made in bar mills, frequently located immediately beyond a blooming mill, which take a 6 in. square bloom hot from the shear, and roll into the thin narrow plate without reheating. Such a plan requires the most rapid handling to complete the rolling before too much heat is radiated. This is done by placing a succession of two-high roll stands in tandem, within a few feet of each other, and guiding the bar automatically from one roll to the next. Since each pass elongates the piece, the speed of each roll is higher than the preceding, and the relation between speed and reduction must be nicely adjusted so the hot bar will neither buckle nor be stretched at any stage. A succession of eight or ten such rolls, with perhaps three pairs of vertical rolls to control the width—interspersed in the train—can produce standard width 8 in. sheet bars or skelp from 6 to 20 in. wide (suitable for forming into pipe up to 6 in. diameter), and from $\frac{1}{8}$ to $\frac{3}{8}$ in. thick, at the rate of 4,000 to 20,000 tons per week depending upon the sectional area of the bars manufactured. Since a mill of this sort can easily produce material far too long to ship, flying shears are set beyond the finishing roll to cut the bars to length. Many designs have been made, capable of square cutting a rapidly moving bar. Sheet bars are sometimes quenched by travelling down a long table under a series of water spray nozzles. Interesting piling devices are used.

Sheet Mills.—Sheets are $\frac{1}{8}$ in. thick or less, whereas plates have sufficient mass to retain heat until rolled to proper gauge, and a surface cbvered with mill scale is quite good enough for most purposes. Sheets, on account of their thinness and the excellent surface demanded by such finishing operations as galvanizing or lacquering, must be rolled in an entirely different manner. Many sheet mills are still operated by hand after the methods originated in Wales two centuries ago and have larger and more rugged equipment, generally producing material 18 to 30 gauge thick, whereas tin plate is smaller in area and thinner—28 to 38 gauge. The 1930s saw a replacement of many hand mills by a few continuous sheet mills, especially in the American industry.

Sheet bars are cut with length slightly greater than the width of the required sheet, heated to a dull red 850° C, and rolled sideways through a two-high mill with massive cylindrical rolls, 32 in. diameter. One workman catches the bars as they come through and passes them back to another over the top roll; a third screws down the top roll gradually to continue the reduction. The crew passes two bars back and forth very dextrously; when these bars have been flattened to about $\frac{3}{32}$ in. one is placed on top of the other, the top roll raised, and the pair rolled down until each is about twice as thick as the desired sheet. In the best practice, one pass is then given in the mill to be used for finishing, in order to "shape" the pack to this mill.

By this time, reheating is necessary; the pair is opened, that is the two sheets are separated, and placed in a furnace until the temperature is up to about 800° C. Low temperatures and a smoky flame are necessary to prevent surface oxidation in the furnace. A pair of these sheets are then further rolled to the required thickness in a finishing mill, more accurate in construction and requiring more skill to operate. For thin gauges, sheets are folded double and rolled in packs of four or even eight. Frequent opening and reheating is necessary in the latter stages of the process. They are then straightened and sheared to size.

Many surface finishes are required by customers who manufacture a multitude of objects of sheet metai. The sheets may be annealed either by being passed slowly through a long furnace with hot central zone—blue annealing—or by being piled in a tight box containing a prepared atmosphere to protect the steel from tarnish and heated for hours at a considerably lower temperature—box annealing; or the cold sheets may be given several passes through accurate rolls for a smooth surface and a somewhat stiffer temper. Interspersed with these cperations, the oxide or mill scale may be removed by pickling in weak sulphuric acid. Finally the cleaned cold-rolled sheets may be dipped in white metal for a protective coat, wiped, cooled, polished and boxed. Coating with zinc is called galvanizing; tin or tin sheet is thin steel dipped in pure tin; terne sheet is dipped in a lead-tin alloy.

Strip and Continuous Sheets.—Desire to eliminate the large amount of labour required for sheet working by the above described process has led to the recent production of sheets in continuous mills. Since 1900 it had been common to roll strip up to 3 in. wide and 16 gauge or less in thickness, in very long coils in a series of roll stands placed close together; mills have been built for wider and wider strip-sheet, until sheet 8 ft. wide was produced commercially in America in 1939, but no thinner than 16 gauge. In a narrow strip, hoop or cotton-tie mill, a continuous heating furnace feeds flat bars about the width of the finished piece, endwise into the first of a series of six tongue and groove rolls, perhaps 10 in. diameter. One edger may be installed after the third roll, and the remainder then be flat rolls. Then the bar passes through a series of three very accurate finishing rolls, sometimes being bent sharply, scraped, and air blasted before entering the last roll to remove the scale. These finishing rolls are cylindrical, and the guides are shifted sidewise at frequent intervals, to prevent the chilled strip from wearing the roll-surface irregularly; speeds are watched closely; the first roughing roll is very slow, the last very fast; in fact the trziling end of the billet may still be in the furnace when the front end is being reeled, zoo ft. away, at the speed of 1,000 ft. per minute. One great advantage of such close-set continuous mills is that the time of passage from furnace to finishing roll is the same for all parts of the billet; consequently the temperature at the last pass is uniform, and the thickness after cooling is also quite uniform. Finished strip is automatically turned on edge, looped back and forth on a broad slow moving conveyor belt passing through a muffle; emerging it is cool enough for reeling, cutting to length and bundling. About 40 men are required to operate such a strip mill producing from 10 to 20 tons of strip per hour, depending upon its width and gauge. Such strip has a surface covered with mill scale, or if this is scraped off, a blued colour formed during slow cooling. For higher finishes and stiffer tempers, the strip may be pickled and cold rolled rather slowly tJ accurate gauge and smooth surface.

In the new continuous sheet mills, slabs weighing up to a ton and a half, the product of a blooming mill, are reheated to the proper temperature and delivered to the first roll stand, where jets of high pressure, superheated steam strike the hot slab just as it enters the rolls, thus breaking loose most of the scale. This roll stand is set somewhat further from its successors than the space between later stands. Some of this table is utilized for a turning mechanism, so that the slab can be turned sidewise, since its original length should represent the width of the strip. Heavy machinery also holds the slab down while its edges are squeezed to the correct distance apart. The slab is also held here a little time to radiate down to the necessary temperature; the latter is fixed by the speed of the remaining stands and the desired delivery temperature. Once started on its way, the slab passes through three or four heavy, four-high roll stands comprising what is known as the roughing train. separated far enough so the slab is entirely free in its passage along the roller table from stand to stand. This roughing train will reduce the thickness of the $4\frac{1}{2}$ to 5-in. slab to somewhere around 1 in., and correspondingly increase its length. It is usual for these stands also to have vertical edging rolls set at their entering side to keep the width of the hot metal correct. The work rolls in all these four-high mills are relatively small in diameter and have very heavy, massive hacking-up rolls. Next in train comes a series of six four-high stands set fairly close together, each one rotating

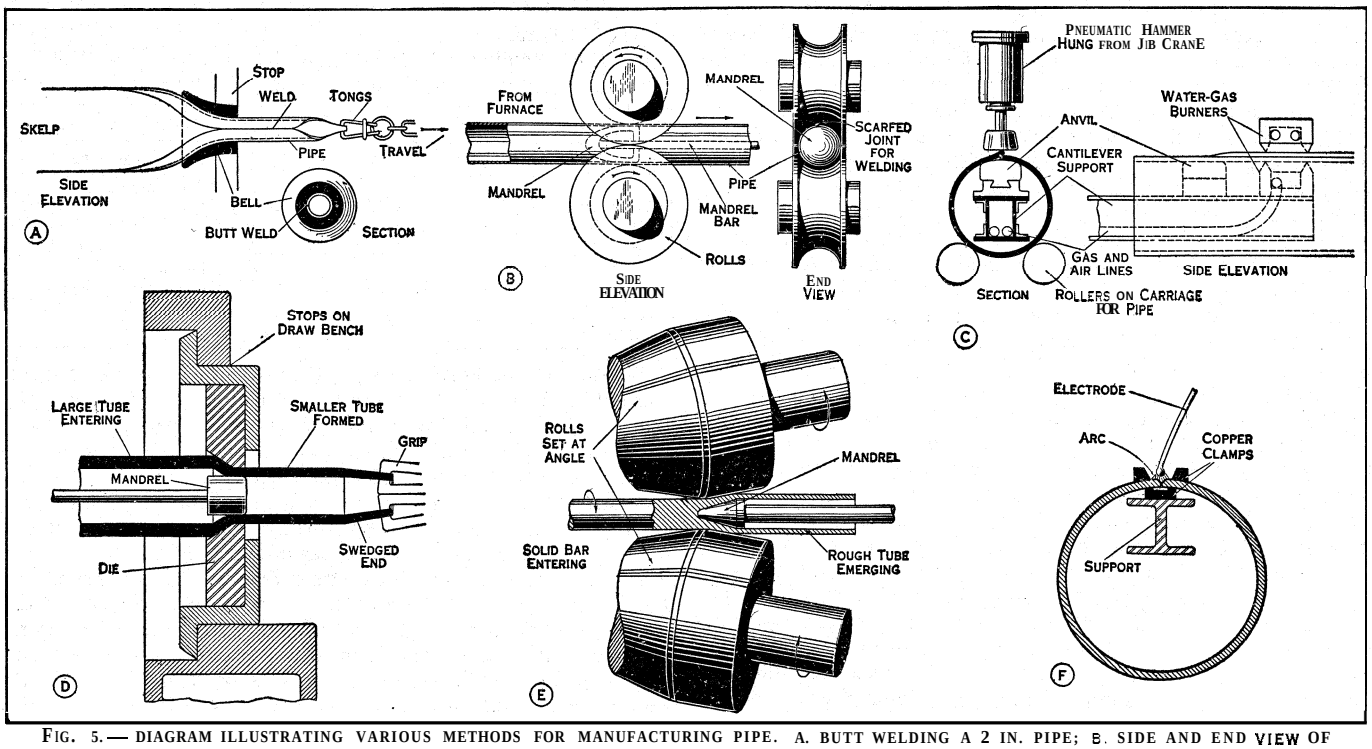

FIG. 5.— DIAGRAM ILLUSTRATING VARIOUS METHODS FOR MANUFACTURING PIPE. A. BUTT WELDING A 2 IN. PIPE; B. SIDE AND END VIEW OF LAP WELDING; C. HAMMER WELDING OF 30 IN. PIPE: D. DRAWING SEAMLESS PIPE; E. MANNESMAN METHOD; F. ARC WELDING OF 30 IN. PIPE

at a faster speed than its predecessor, the last one delivering sheet of required thickness from, say, $\frac{1}{4}$ in. down to $\frac{1}{16}$ in., at a speed of 30 miles an hour. The metal emerges from the last stand before the trailing end is clear of the first, so safe passage without breaking requires finger-tip control of the speed of the mills, as well as accurate and ready adjustment of the clearance between rolls—that is, the relative amount of reduction, stand to stand. All of these controls are electrical in nature and are centred in a pulpit where the operators are in full view of the entire operation. Temperature of delivery of the sheet is important for many applications. Instantaneous and automatic optical pyrometers, indicating and recording temperatures not only of the slab at the beginning, but of the finished sheet at the end, are essential items of equipment. Sometimes the hot-finished sheet is rapidly cooled by water sprays; at other times the sheet is delivered as hot as possible to the coiling devices and the tightly wound coil is cooled quite slowly.

This sheet-mill product may be cut or slit into such sizes as make it available for other operations, such as thin plate or thick sheet for tankage or barrels, or it may be slit into narrow strips suitable for making into pipe. However, if it is to be further rolled into thinner sheet, the mill scale is pickled off, and then the material is rolled through four-high cold rolling mills, usually set three in tandem. Reduced finally to the proper thickness and hardness, the coil is uncoiled through a leveller and automatic shear which cuts and piles the sheets, after which they are sent to the annealing department for proper annealing. This is now done in controlled atmosphere so that there is no scaling and even iittle discoloration. After a final pass through a four-high stand ("skin rolling and levelling"), the sheets are resquared, inspected, oiled, and shipped.

Pipe.—Skelp, the flat bars from which small sized pipe is made, is rolled in a continuous mill specially designed to produce bars true in thickness, width, and properly bevelled on the edges. Frequently the finishing stand is adjustable, and a skilled workman varies the roll spacing slightly in accordance with his estimate of the temperature of the metal issuing, thus compensating for the different amounts of contraction during cooling. Skelp is cut 20 ft. long, one end pointed, and then charged into a flat hearth, properly designed to produce a uniform white heat throughout; when reaching the welding temperature the metal appears to be covered with a shiny grease, which is molten iron oxide. The operator then catches the pointed end in tongs, and by means of a draw bench (see WIRE) draws the white hot bar through a welding bell (fig. 5-A) forming the flat bar into a tube and pressing the butted ends together into a true weld all in one operation. Further operations reduce the pipe, but only slightly, to the correct size, straighten it, remove the scale, shape and thread the ends, proof test it, and finally cover it with a protective coating.

Butt welding is done on pipe from $\frac{1}{8}$ to 3 in. nominal inside diameter. Common pipe from 2 to 18 in. is more usually made of flat plate by lap welding (see fig. 5-B). Plates are piled into a furnace, heated to a dull red, and run one by one through scarfing rolls, which form the necessary bevel on the edges for an overlapping seam. The hot steel is then drawn through a forming bell which curls it up into a tube (fig. 5-A). After reheating to the welding temperature this tube is caught between a pair of rolls and rolled over a manganese steel mandrel (fig. 5-B), and the joint welded by the high heat and great pressure at the point of contact. When the length has been rolled, the bar which has been holding the mandrel in posidon is withdrawn from the far end of the pipe, and the latter rolled away for the finishing operations already enumerated. It requires only a few seconds to weld a standard length pipe by either of these processes. Welded pipe over 30 in. in diameter is made by hammer welding or more recently by automatic arc-welding. In the former. the wide plate is curled on plate bending rolls and the overlapping joint heated and forged shut in sections During the heating cycle two water-gas burners play a flame on a portion of the joint from both inside and outside; when the correct temperature is reached the lower burner is replaced by an anvil and the upper by a pneumatic hammer. and the hot spot welded and hammered down flat (fig. 5-C). The next section is similarly treated. After welding the length is re-rolled for shape and annealed, the ends sized and shaped, and the pieces tested and dipped in anti-corrosive liquid.

For arc-welding, the edges of the plate are planed to a bevelled V opening (fig. 5-F), the pipe bent to shape in rolls, clamped between long copper bars, and the bevel filled with metal from a slowly travelling wire, from which an electric arc is struck to the steel plate below. Details of this and other welding methods are given in the article on **WELDING**.

Seamless **Tubing.**—In America, seamless tubing is preferred for all purposes where the internal pressure is high and service severe, and a rapidly increasing amount of such pipe is being made in diameters up to 12 in. First, a round billet at full red heat is pierced by inclined rolls and mandrel. As sketched in fig. j-E, two 36 in. rolls of special shape are set side by side, with axes crossing and about 10° askew. The shape is such that the rolls grip the end of the ingot and spin it forward slowly, forcing it over a mandrel set between them. The operation is such that the mandrel seeks and maintains a truly axial position. After piercing the inner and outer surfaces are smoothed and the tube brought to exact size by several rollings over a mandrel, as in lap welding. Further operations from straightening to shipping are performed with considerable care. Not only is such pipe more reliable for the lack of any welded seam, but the piercing operation is so strenuous that nothing but metal of good quality can endure it. Therefore the tubing can safely withstand a considerably higher pressure than the best of welded pipe. Seamless tubes after cold drawing to thin walls are much used for structural members on bicycles, automobiles and aircraft, and for shaping into metal furniture and machine parts. Cold drawing is done as sketched (fig. 5-D). A tube somewhat too large and thick in wall has the end swaged down slightly. All oxide is then pickled off, the tube washed, dried and dipped in tallow or other lubricant. The pointed end is thrust through a round die, and gripped by draw-bench tongs. Next, a mandrel is thrust through the tube from the far end until it has a position directly within the die, and then the tube drawn forcibly through the annular opening thus formed. In this way the outer and inner diameter may both be controlled. Each draw hardens the metal and makes it more brittle; after a few such passes, if the required size is not yet reached, the pipe is given a low temperature anneal to relieve the cold-working strains, and the process continued.

Rods and Wire.—As indicated above, wire rods are frequently rolled from 2 in. billets, 30 ft. long, on continuous mills, and the sixteenth or finishing pass delivers a 0.2 in. round to reels at a speed of 45 m. an hour. Such a mill will produce 1j tons per hour, with a complete labour force of 4j men. Other arrangements utilize a continuous mill for breaking down a 4 in. billet, and about a dozen loops fed by hand in a cross-country mill to finish. Rod reels are dumped automatically, and the rod cold-drawn through dies, with frequent annealings and other intermediate operations, into wire of various diameters, finishes and tempers. The operations are described more fully under WIRE. Most of this wire is stranded into cable or wire rope, woven into screens, netting, or fencing or made into nails. All such is done by automatic machinery so economically that the increase in cost of nails, for instance, over wire is 15 cents per 100 lb., which not only includes manufacture, but the cost of the keg as well.

CLASSIFICATION AND USES OF PLAIN CARBON STEELS

Production and Consumption.—Any classification which accounts for the destination of steel made by any combination of the above described processes must evidently be impossible on account of its complexity. As to process, it may be said that any of them can be made to produce steel which easily passes present commercial specifications, even for so severe a duty as railroad rails. The following figures show the distribution of American production of steel, 1938, according to *The Iron Age:*

Sheet, strip and tinplate	41%
Bars	15%
Pipe	11%
Wire	9%
Plate	8%
Structural shapes	8%
Track material	5%
Miscellaneous	3%

In England the quantity of plates and track material is relatively larger, because of a more active ship-building industry and large exports respectively. The feature of the American industry is the large increase in sheet production, and the rapid decline of track material.

A similar classification of the chief lanes of consumption in the United States is given in the table which follows. It should be noted in this connection that in England and the Continent the proportion of exports is very much larger, and the relative position of automobiles and other machinery would probably be reversed. Figures are average for' 1933–38 inclusive.

Industry	Proportion	Chief Purchases
Automotive	21%	Sheets, strip and bars
Building and construction	12%	Plates, structural shapes and reinforcing
Containers	10%	Sheet
Railroads	9%	Track material and plates
Exports	5%	..
Oil, gas, water	5%	Pipe
Machinery	4%	Bars and sheets
Furnishings for buildings	4%	Black plate and sheets
Agriculture	3%	Wire and galvanized sheet
Jobbers and distributors	15%	Wire, pipe, sheets, bars
Unclassified	12%	..

Grades **of** Carbon Steel.—Carbon is the principal alloying element used for hardening and strengthening iron- Consequently the utility of various iron-carbon alloys—the plain carbon steels which comprise such a large majority of the entire production—depends upon the amount of carbon present, and has led to the separation of the entire possible range into approximate grades: Ingot iron, made in a basic open-hearth furnace, has the lowest possible content of carbon and other alloying elements. It is used largely for sheets on account of its corrosion resistant properties. Extra soft or dead soft steel contains from 0.08 to 0.18% carbon, used where ductility, toughness, weldability or ease in cold working is desirable, and strength or stiffness a minor consideration, *i.e.,* for pipe, rivets, sheet, wire, and case hardened parts. Structural grade or mild steel contains from 0.15 to 0.25% carbon, used where a combination of strength and easy machineability is desired, for forging or flanging operations, *i.e.*, for buildings, bridges and railroad rolling stock, for boilers, drop forgings, and bolts. Medium grade contains 0.25 to 0.35% carbon and is even harder and stronger than mild steel, yet it may be hot-forged without difficulty, used for ship building, shafting, and forged machine parts. Medium hard steel contains from 0.35 to 0.65% carbon, and enters into the range where the final condition and reliability is much dependent upon the past mechanical and heat treatment; it is used for large forgings for locomotives and other prime movers, car axles, and in the higher carbons for railroad rails. Hard steel ranges from 0.65 to 0.85% carbon, and is used only after it is heat treated to a correct combination of strength and ductility, used for wrought steel wheels, locomotive tires, wood cutting tools, and sledges. Spring grades range from 0.85 to 1.05%, used in a heat treated condition, wherein a great range of hardness, resiliency and brittleness is possible, *i.e.,* automobile springs, cold chisels, rock drills and shear blades are made of these steels. High carbon tool steels range from 1.05 to 1.20%, used only after heat treatment for railroad springs, metal cutting and forming tools. A characteristic of these carbon steels is that each 0.01% of carbon increases the ultimate strength in the annealed condition by approximately 1,000 lbs. per sq.in., but at the expense of the ductility or toughness. Hardness also is increased.

	Ultimate strength	Reduction in area	Brinell hardness
	Lbs. per sq. in.		
Rivets	50,000	30% in 8 in.	95
Medium hard forging	75,000	20%	134
Spring steel	125,000	10%	200
Same after quenching	200,000	0	600

Combinations of even higher strengths with considerable ductility and impact resistance may be had only in alloy steels, of which a number have been developed with special properties.

Use of alloy steels, which prior to 1910 was confined mostly to big guns, armour and projectiles, has spread rapidly into all metal working industries, among which the automotive leads. Production statistics are either lacking or uncertain because there is no agreement as to what constitutes an alloy steel. The trend (1939) is toward lower and lower contents of alloy made by basic open-hearth furnaces, operating under very special control for deoxidation and grain size. As pointed out in the article on STEELS, ALLOY, they are special steels, not merely a carbon steel to which

STEPS IN STEEL MAKING

1. View of the upper part of a blast furnace, showing a skip car (lower left) on the inclined track carrying raw materials to the top for charging. These materials — iron ore, coke and limestone — are reduced to molten iron, the first step in the manufacture of steel. The iron is then tapped into waiting ladle cars which carry it to open-hearth furnaces, electric furnaces or Bessemer converters, where it is made into steel
2. A Bessemer converter in full blow. By forcing air through the molten iron, the carbon, manganese, silicon, other elements and impurities are oxidized and eliminated to form steel in about 15 minutes
3. The open-hearth process. The raw materials are charged into a large, shallow furnace hearth. About five hours are required for melting. For about six hours more the heat is allowed to "work" while the refining action takes place, forcing many of the impurities into the slag which forms on top of the molten metal. The picture shows the tapping of a finished heat of steel from the open hearth into a ladle (left). The slag floating on top runs off into the slag pot at the right
4. Pouring (teeming) molten steel from a ladle into ingot moulds
5. The moulds are stripped from the formed ingots, which are then sent to the soaking pits pictured. These furnaces heat the ingots thoroughly and uniformly. The ingots are then ready for the first rolling in the blooming mill
6. First rolling operations of the steel in the blooming mill, where the ingots are reduced and elongated as they pass back and forth through a set of rolls. Up to this point, the steps in making steel are similar, although hundreds of chemical formulae are used to vary its composition, and some variations in procedure are made during various steps according to the destined use of the steel

PROCESSES IN FINISHING STEEL

1. In the manufacture of welded pipe, blooms and billets are first rolled in the blooming mill, then rolled into skelp in the skelp mill. Buttweld pipe is made by drawing the heated skelp through a welding bell, as pictured
2. The Mannesmann process of making seamless pipe. The blooms are heated, then rolled into rounds at the round mill. The rounds are cut to desired length, centred for piercing and heated again to the proper temperature for piercing. Finally the pipe goes to the sizing mill, where it is brought to true diameter by a series of grooved rolls. In the picture, semifinished pipe is emerging from a seamless-tube mill
3. Ingots rolled in the blooming mill are cooled, conditioned and reheated to proper rolling temperature for operations known as descaling, roughing and finishing. In the picture the slab at the right has passed through the last roughing stand and is proceeding to the finishing train. The slab in the left foreground is entering the last roughing stand
4. Examining tin-plated steel. This type of steel is rolled from slabs on the continuous strip mill, wound into coils, placed in a continuous pickler, cold rolled and rewound before it is sent to the tin mill
5. Polishing machine which produces various degrees of brightness on sheets of stainless steel

some alloys have been added. Production of such material is at least 3% of the total steel made (1939).

Nickel and *Chromium.*—Although there are infinite possibilities in alloying, by far the most important steels are those containing nickel and chromium, used for crank shafts, axles, gears and other automotive and machine parts. Relatively few analyses are in use, the present tendency being to minimize the number of alloy steels in process so as to avoid mixtures of the stock. The popular nickel steels contain up to 3.5% nickel and 0.10 to 0.50 carbon. Chromium steels range from 0.60 to 1.50 chromium with the carbon in direct ratio from 0.15 to 1.10.

Kickel-chromium steels are more numerous. For machine parts, one series has nickel about 1·25%, chromium 0·6% and carbon 0·10 to 0·50; another has about 1·75% nickel, 1·0% chromium; a third has 3·5% nickel, chromium 1·5%. Nickel and chromium when added to steel increase its strength and hardness without an increase in brittleness. Nickel steels—not heat treated—are used for structural steel in long span bridges, and high strength boiler-plates; heat treated for gun tubes, engine forgings and castings, and shafting. Chromium steels are used for projectiles, for grinding rolls and for roller bearings, and with nickel or vanadium for armour plate and heat treated machine parts, axles, and gears. Rustless irons and steels contain 12 to 18% chromium and up to 8% nickel. (See also STAINLESS STEEL.)

Manganese is present in all steel, but when it adds up to between 1·0 and 2·0%, and carbon 0·30 to 0·50, the steel acquires special properties. These analyses are favoured in America for high strength castings, heat treated forgings, rifle barrels and for case hardening. So-called silicon structural steel used in long span bridges and for boiler plate, is really one of the lower manganese steels of this classification. The tough Hadfield manganese steel, used in castings for shock and wear resistance, contains 11 or 12% manganese and 1·0 to 1·2% carbon.

Vanadium is an element which has a powerful deoxidizing and scavenging effect; thus a vanadium-treatment on steel which shows very little of the element in the analysis makes for soundness, fine grain structure and reliability in forgings. From 0.5 to 2.0% is added along with other alloys to make high speed steels and tools for hot work.

Molybdenum is added to chromium, nickel, and chromium-nickel steels in from 0.2 to 0.3% to widen the range of heat treatment for given values, and to improve the forging and machining properties, and their resistance to creep when working at high temperature. Carbon-molybdenum steels of controlled grain size and hardenability are favoured by some American metallurgists.

High-speed Steel.—Carbon tool steels for cutting metals are heat treated by quenching from a high temperature, which gives them hardness, and then by reheating or tempering to a moderate degree to restore toughness. In use they must be operated at such low speeds that the friction between chip and tool-nose will not reheat the cutting edge above the drawing temperature, else the hardness and usefulness of the tool is destroyed. Better speeds could be made by using self-hardening tool steels, those which are hard after a slow cooling from a high temperature, such as the patented tungsten-manganese alloy invented by Robert Mushet in England sometime between 1860 and 1870, or the chromium-tungsten substitutes adapted by some American steel makers. During a 26-year research into the art of cutting metals, Frederick W. Taylor and Maunsel White discovered, 1898 to 1900, that if these steels were quenched from an austenitizing temperature, so high that it would utterly ruin a carbon steel, the hardness would be retained even when the cutting speed was so high that the nose of the tool and the chip leaving it were red hut. Modern high-speed steels possessing this property of red hardness fall into four general classes:

	High tungsten	Low tungsten	Molyb-denum	Cobalt
Carbon	0·65	0·65	0·85	0·75
Tungsten	18·0	14·0	2·0	18·0
Chromium	4·0	4·0	4·25	4·0
Vanadium	1·0	2·0	1·0	2·0
Molybdenum	..	..	8·0	1·0
Cobalt	..	..	..	8·0

These are crucible or electric steels carefully forged to break up the crystals of complex carbides forming during the solidification of the ingot and distribute them evenly throughout the bar. A well annealed bar is not very hard (Brinell 240) and can be machined into a complex tool like a milling cutter, and then heat treated; pre-heat to 850° C, heat rapidly to 1,300° C, cool in oil or an air blast, giving a Brinell hardness of at least 600. Reheating 30 min. at 600° C is then necessary to give the quality of red hardness; the Brinell hardness is even higher and the toughness materially better. As an indication of the revolution which these steels have effected in machine shop practice, a plain carbon tool steel will cut 16 ft. per min. on a medium steel forging, an air hardening steel 26 ft. per min., the same after being given the high quench 60 ft. per min. and a modern high speed steel 100 ft. per min. or more, all cuts being of same depth and feed, and on the same material Cobalt high speeds are for cutting extra hard or gritty substances.

Tungsten Steels.—Other alloys whose properties are due principally to tungsten, in addition to the air hardening tool steels and the high speed steels, are tool steels to which from 1 to 5% tungsten is added to improve the quality of the wood working or other tools which would be made of the plain carbon steels They are also good for making finishing cuts on metal after the most of it has been removed by deep cuts with high speed steel. Magnets are also made of steels with 6% tungsten and 0·7% carbon, quenched but not tempered.

SOME FERRO-ALLOYS

Ferro-alloys are highly important and include those metallic substances used for finishing carbon steel and manufacturing alloy steel. Most of them are electric furnace alloys of iron and carbon plus the third distinguishing metal, manganese, silicon, chromium or some other, although for some purposes the carbon content must be as low as possible. For such specifications the alloys are made using either metallic aluminium or silicon for the reducing agent.

It was early discovered that manganese must be added to make sound steel by Bessemer's process. As already noted, the usual ferro-alloy for this purpose is spiegel-eisen, a blast furnace product made from iron ore sufficiently high in manganese to smelt into a pig iron containing 10 to 30% of that element, with carbon about 5%. Spiegel cannot be used for low carbon steels because the required amount of manganese carries with it too much carbon. For such purposes, *ferro-manganese* is used, containing nominally 80% manganese and $6\frac{3}{4}$% carbon. This is also a product of the blast furnace when smelting an ore containing 40 to 50% manganese, low in iron. Since manganese and iron are so alike chemically, the actions in the furnace are very similar to those previously described. The output in ferro-manganese from 50% ore is only about one third as much as though common pig iron were produced; the blast is 250° F hotter and the coke consumption twice as much; about $\frac{1}{5}$ of the manganese is lost in the slag. While ferro-manganese can be made in an electric furnace of the pit type (see ferro-silicon) it cannot compete with the blast furnace product except under special economic conditions, as in Norway, or where carbon below 0·25% is required, as for high manganese alloy steels.

Ferro-silicon is the next most important alloy. A 12% silicon pig iron may be made in the blast furnace, but alloys higher in silicon are now used to deoxidize nearly all steel for castings, to quiet most tonnage steel from basic open-hearth furnaces, and to make several silicon alloy steels. Ferro-silicons are exclusively an electric furnace product and are made in several grades—50, 75, 80, and 95%. Carbon is about 0·5%, phosphorus and sulphur less than 0.10%—the former particularly must be kept to the minimum to prevent the alloy from absorbing moisture from the air and generating poisonous phosphine gas (PH_3). A pit-type electric furnace is employed, rectangular in cross section, with bottom built of carbon blocks. Into this shaft are suspended three carbon electrodes, one for each phase of current; a granular mixture of pure quartzite, clean iron turnings and coke is shovelled into the open top, filling the entire furnace. Passage of current

from electrodes to furnace bottom gives the necessary heat for the coke to reduce silicon metal from the rock. Carbon monoxide produced by the reaction rises and burns at the top of the charge column, and a molten alloy of iron and silicon collects on the hearth, from which it is tapped periodically.

Ferro-chromium.—This is one of the earliest ferro-alloys produced in an electric furnace. At present the commercial alloys contain about 67% chromium. The so-called high carbon alloys range from 4 to 8% carbon by units, whereas the low carbon alloys necessary to make stainless irons range from 0·20 to 2·0% carbon by steps. Chromium metal up to 98% pure is also commercial. Ferro-chromiums are ordinarily made in closed furnaces of the Heroult type, with bottoms laid in carbon blocks. A charge of chromium ore, iron or iron ore, anthracite coal for reducing, and flux for slagging impurities, is mixed and shovelled in, the doors closed and electric current turned on. Carbon reduces the metallic oxides in the intense localized heat; at the finish the molten charge is poured into slabs, broken, analyzed and graded for shipment. To reduce high carbon, these varieties are remelted with concentrated chromium oxide, under a lime-fluorspar slag. Nickel is added to molten steel as shot metal, or a nickel-steel scrap may be used to make alloy steel—nickel having no tendency to enter the furnace slag.

Ferro-vanadium is one of the most difficult alloys to make, on account of the activity of the element. The pure metal is not commercial. B. D. Saklatwalla developed various means of commercial alloy production, using a mixture of vanadium oxide, iron oxide and powdered aluminium, either in crucibles by means of the thermit reaction, or in shaft furnaces with the assistance of the electric arc. At present the ore is smelted in a reverberatory furnace, and the vanadium concentrated in the slag. This slag is ground, mixed with carbon, iron scale and fluxes (glass cullet, lime and fluorspar) and fed in a fine stream into a covered furnace, directly through the arc between graphite electrodes, thus effecting the reduction almost instantly in the intense heat. Reduced alloy and slag collect in the hearth and are tapped three or four times a day. A common analysis contains 35% vanadium.

Ferro-tungsten.—Tungsten ore is widely distributed, and the concentrate comes to the refiner in such complex mixtures of minerals that the first step is frequently the production of the oxide WO_3 by chemical means (see TUNGSTEN). This oxide is easily reduced to metallic powder without melting by mixing with fine carbon, sealing in a crucible and heating to 1,300° C for several hours. Ferro-tungsten, which has become more popular for making high speed steel, may contain from 60 to 85% tungsten, and is made in single-phase electric shaft furnaces. The bottom is one terminal; the electrode set above is surrounded by a shaft of loose brickwork, and a mixture of oxide ore, iron and carbon is filled in. As the reduced alloy builds up on the hearth it chills into a thicker and thicker button, because it has an unusually high melting point; when this solid metallic mass has grown to a point where its electrical resistance interferes with operations, the temporary furnace is torn down and the sow crushed, analyzed and classified.

METALLOGRAPHY AND HEAT TREATMENT

General Structure of Steel.—Much may be discovered about the general structure of the metal by a close scrutiny with the naked eye, or with a little magnifying glass. Such studies (macroscopy) include examination of the finished surfaces, of freshly broken fractures, and of rough polished sections etched in various ways. Information gained from a freshly broken fracture has not yet been systematized and correlated with microscopic appearance except as to grain size of the steel after heat treatment. To be of value it requires a keen eye to note small differences, and much practice and everyday familiarity with the fracture of satisfactory metal. In the hands of a skilled inspector it is the first step in securing uniformity in raw materials.

General Structure may best be exhibited on a roughly polished surface by etching in freshly prepared ammonium persulphate solution (10% $(NH_4)_2S_2O_8$). It shows immediately differences in grain size caused by differences in heat treatment or other cause.

Deep etching is much favoured in America for acceptance tests on high grade steel. It shows any non-uniformity in chemical composition or general bad quality. The smooth sample is held in hot hydrochloric acid (diluted 50%) for about 30 min. Impure spots, blowholes or cracks are eaten more deeply than elsewhere, and the result is an irregularly pitted surface.

During solidification of a steel ingot, excess of sulphur compounds will collect toward the centre and top part, where they are trapped and remain during further rolling and manufacture. The distribution of sulphur compounds in a smooth section may be shoun by pressing it firmly for about a minute against a sheet of photographic paper moistened with 2% sulphuric acid, then washing and fixing. The dark areas indicate the location of higher sulphur in the steel. Phosphorus also accumulates around the borders of the large metallic crystals which form in the ingot. and during rolling or forging are pressed out into stringers or sheets in ruling directions.

Ordinary plate or forging steel will always be found thus marked. In forging, these *flow* lines are arranged more or less parallel to the finished surface, and the dies are so constructed that the flow lines take an easy curve around corners. Any crinkling is associated with a weak brittle region. To show phosphorus segregations a polished surface is washed in alcohol, and immersed in 10% copper-ammonium chloride. A thin copper plate will coat out on those portions low in phosphorus, leaving high-phosphorus regions bright.

The fact that the hardness, toughness and general desirability of a piece of steel could be profoundly modified by a simple heating and cooling has been known since time immemorial—in fact what we now know as steel was perhaps not recognized as having great merit until the fortunate discovery of heat treatment was made. This is a quite mysterious happening, this heat treatment, and it is not surprising that down through the long centuries when the art was guarded as a closed secret, many superstitions arose regarding the efficacy of certain heating fires and quenching fluids, and much quackery had free scope to practice its hocus-pocus. Within the past century the chemist and physicist have done much to clear up the mystery by analyzing the various operations; we now know the essential differences between the various steels, irons, fuels, atmospheres, and quenching fluids. Only since the beginning of the century, however, have intensive studies with the microscope, pyrometer, hardness and tension testing machines, brought forth a knowledge of the changes which go forward in steel or iron during a heating and cooling cycle, and working hypotheses of the causes of hardening (see METALLOGRAPHY). Logically, an ingot in a soaking pit prior to rolling, or a billet in a heating furnace prior to forging, may be said to be undergoing heat treatment, but from a workshop viewpoint the term is restricted to a heating and cooling to restore original ductility and workability in a partly finished piece, or a heating and cooling—sometimes repeated—to induce special properties in the finished article.

Furnaces (*q.v.*), in regard to size, depend upon the pieces to be treated and the temperature required. A well designed furnace is one which easily attains the necessary temperature, and maintains that heat uniformly in all parts, with an atmosphere which does not deteriorate the furnace,-and yet has the desired effect or no effect, upon the metal being treated. Fuels may be coke or coal, gas, oil or electricity. No source of heat, pure heat, disassociated from the products of combustion, has any virtue over another source—it is merely a matter of which is the most convenient and economical. Gas and electricity are now favoured because of their ease of manipulation to give uniform temperature—choice depends upon the relative cost per thermal unit, and the atmosphere required. For instance, it is handiest to use electric resistors for heating elements in a furnace for annealing transformer sheets in a hydrogen atmosphere. Gas or oil fuel would probably be chosen for treatments on products such as roller bearings running into tons per day. Recuperators or regenerators are frequently installed to save heat. Mechanical devices for putting the metal in and taking it out, such as charging machines, furnace bottoms built on wheels or moved on rollers, revolving heating muffles and conveyors, are installed to save

labour wherever the weight of material receiving uniform treatment is very great. Temperature control is most important. Well conducted shops issue definite instructions on all important work giving the rate of increase in heat, duration at heat and speed of cooling. Continuous furnaces are devised to maintain this cycle automatically. Batch furnaces are controlled by hand, or by automatic control of the fuel burners through pyrometers (*q.v.*), which are installed in all furnaces, sometimes several in a single furnace, and indicate or make a permanent record of the temperature at all times. An important method of localized heating is by high frequency currents; pieces such as crankshafts are rapidly heated one at a time at only those bearing surfaces which are to be hardened.

Atmosphere within the fumace is important. In an open flame furnace scaling (or the production of oxide on the metal's surface) may be minimized by feeding rather less air than the gas or oil requires for complete combustion. This deficiency of oxygen means that little or none will be available to react with the hot metal. In long heating of thin sheet, or long annealing of tool steel, where the surface must be preserved, the work is protected from the furnace atmosphere by closed boxes or tubes. Protective atmospheres have been highly developed in the 1930–40 decade. Steel and gas are heated together in a muffle, or heated without a muffle by electric resistors or by flames contained in alloy tubes. Atmospheres for bright annealing are relatively easy to prepare of flue gas, partially burned fuel gas, or even gas engine exhaust; due to the comparatively low annealing temperature — 650" C — any mixture of an excess of carbon monoxide over carbon dioxide will protect the steel. It must be fairly dry to prevent tarnishing by steam on the cooling cycle. Protection during higher heating — goo° C. — for quenching is far more difficult because the reactions are much more rapid and the steel must neither oxidize nor must it gain or lose carbon. Such atmospheres are bone-dry and oxygen-free mixtures of hydrogen, nitrogen, and carbon monoxide; they may be prepared from burned natural gas (methane, CH_4) by removing excess oxygen by hot copper, washing out CO_2 with caustic, and absorbing moisture in activated alumina. On the other hand, certain reactions may be induced during heat treatment — for this purpose the material is packed in boxes with substances forming the necessary gaseous atmosphere, or the fumace is a closed muffle through which a stream of the proper gas slowly travels. Case hardening (*q.v.*), for instance, is done by packing the metal pieces in carbonaceous compounds and heating, or by piping in a gas which is principally carbon monoxide.

Quenching, to cool heated metal, may be done in various liquids, depending upon the speed required. All kinds of solutions of outlandish materials have been used, but there is no virtue in a quenching fluid except the ability to abstract heat quickly. In practice, the most drastic quench is given by a properly disposed nest of nozzles, spraying cold water at high pressure on the hot steel, Next comes a bath of iced brine; then cold water, then high flash point oil, then boiling water, then molten lead, then air blast, then quiet air, and even slower cooling may be done in 8 hours by burial in lime; a dying furnace may require from 24 hours up to seven days. Quenching baths require methods for circulating the medium, maintaining its correct temperature either by heating or refrigerating coils, and dashing it against the metal so no air or steam bubbles remain attached to the hot metal, else soft spots will occur on an otherwise hardened surface. Conveyors or other mechanical methods of getting the hot metal rapidly into the quench and removing it when cold, are installed to save labour. In order to understand what goes on during these heating and cooling cycles, an introduction to the science of metallography and the so-called iron-carbon equilibrium diagram is necessary.

Metallography (*q.v.*) is the study of the inner structure of metals and how this varies with the chemical composition of the alloy and its past heat treatment or the work that has been done on it. It also includes the study of the relationship between the inner structure of metal and the physical properties, such as strength, toughness, and hardness. In this study the use of a microscope is a long step in advance of the ancient practice of breaking the metal and looking at the fracture. It enables the student to magnify the apparent size of the grains a thousandfold. **A** sample of the piece under study is given a high polish, etched slightly in a suitable acid, and placed on a microscope stage with a special illuminating device for opaque objects (see MICROSCOPE). The resulting structure may by appropriate means be photographed for permanent record, and for study in connection with information on its past history, and its physical strength, hardness or electrical characteristics. Important physical properties affected by heat treatments include strength, toughness, hardness, electrical and magnetic characteristics, corrosion resistance. Of these, the first three are most relied upon. Machines and methods for making tension tests and determining the ultimate strength, elastic limit and ductility are described under MATERIALS. **STRENGTH** OF. Hardness is measured by the size of impression left by a steel ball or a diamond cone weighted down by a given load. Toughness or impact strength is measured by the amount of energy absorbed from a swinging hammer by the instantaneous fracture of a standardized test piece.

Evidence That Metal Is Crystalline. — Viewed through a microscope. an etched metal surface presents a mosaic patchwork of interlocking and nice-fitting grains.

Much evidence is at hand to support the idea that these granules, despite their irregular boundaries, are crystalline; *i.e.,* the ultimate atoms are in an orderly geometric arrangement of rows and ranks. The fact was finally proven by X-rays in a manner easiest explained by this analogy: If a street lamp is viewed through a window screen the brilliant centre appears to have a series of bright rays extending outward, caused by reflections of light from every wire so placed as to throw light back into the eye. The geometric pattern of rays is caused by the geometric arrangement of the wires; arguing by analogy, if the atoms of metal are arranged in definite geometric patterns, then an X-ray beam penetrating the crystal would be reflected in definite ways and emerge in a geometric pattern, in fact, a mathematician can predict the atomic spacing and arrangement from the diffraction pattern so produced. Thus it is found that wrought iron at room temperature is in the body centred cubic arrangement. That means that if the space occupied is subdivided by imaginary planes into a space-lattice of tiny cubes regularly placed on top and to both sides of each other, the iron atoms are located at the corner of each of these imaginary cubes, and each cube will have one atom in its centre.

INFORMATION FROM TEMPERATURE CHANGES

Allotropic Changes in Pure Iron. — Much information about metal can be gained by studying the rate at which its temperature changes during uniform cooling. As long as the temperature falls uniformly, the loss by radiation is accounted for by loss in sensible heat. But suppose the surroundings are unchanged yet the rate of cooling is arrested, or even reverses — evidently some chemical or physical change is taking place inside the metal which generates a portion of the heat which is being constantly radiated. Such spontaneous heat evolutions or absorptions, arrests in the time-temperature curves, in purest iron occur at 768°, 910°, 1,390° and 1,539° C. Pure iron or ferrite at room temperature consists of an aggregate of tiny crystals of so-called alpha iron, crystallized in body centred arrangement. On heating. this ferrite gradually loses its magnetism, becoming practically non-magnetic at 768° C., but without changing its atomic arrangements. This non-magnetic alpha iron has been called beta iron, and was erroneously thought to be the cause of the hardening phenomenon — it being given a fictitious hardness. At 910° C. alpha iron recrystallizes on heating with absorption of considerable heat and a contraction of 1½% in volume. The elementary cubes in the space lattice now have atoms at each corner and at the centre of each face, a face-centred cubic form known as gamma iron. At 1,390° the reverse change takes place: so-called delta iron existing between 1,390° and the melting point appears to be a form of non-magnetic alpha iron, stable at high temperature. At 1,539° the metal melts, with large absorption of heat and profound change in all physical

properties. Precisely the reverse changes occur on slow cooling, as noted in the thermometric chart. A, and A, lag somewhat on reversing the direction; *i.e.,* occur at slightly lower temperature on cooling than the reverse change during heating.

Temperature	Arrest	State
		Molten (amorphous)
1,539° C.	...	Melting and freezing point
		Delta iron (body-centred cubic)
1,390° C.	A4	Recrystallization
		Gamma iron (face-centred cubic)
910° C.	A3	Recrystallization
		Alpha iron (nonmagnetic alpha iron; body-centred cubic)
768° C.	A2	Magnetic point, no crystalline change
		Alpha iron (magnetic) (body-centred cubic)

Solidification of Steel.—It has been found that iron containing a little carbon starts to solidify on cooling at a lower temperature than 1,539° C. (the melting point of pure iron) and furthermore that this depression in the freezing point is greater and greater the more and more carbon is in the melt. This is plotted graphically in line ***AC*** in fig. 6. Line ***AC*** is called the liquidus; at all temperatures and compositions above and to the right of ***AC*** the alloy is molten. Hot solid iron at 1,130° C. will dissolve 2% carbon, and rather less as the temperature increases. This relationship is also plotted by the lines AH and *JE,* called the solidus. At all temperatures and compositions below and to the left of *JEC* the alloy is solid. The region between the liquidus and the solidus denotes that at those temperatures and compositions the alloy is in a two-phase solid plus liquid condition.

The way 2 1% carbon steel solidifies is worthy of study. Its condition at any temperature may be investigated by drawing a vertical ordinate at the composition representing 1% carbon. The diagram shows immediately that the first solid material appears on cooling to 1,450° C. However, this solid is not pure iron but a solid solution of carbon in iron whose chemical composition is found on the solidus (the point about 0.4%). This solid is much richer in iron than the melt, so its appearance leaves the melt richer in carbon, and it must be cooled further before more solid appears. Thus, by continuous solidification of iron poor in carbon and decreasing temperature, the sample reaches, let us say, 1,400° C. At 1,400° C. the melted portion has acquired a composition represented by about 1.6% carbon, and the solid appearing from it is a solid solution containing 0.7% carbon. And so it goes: At 1,350° C. the mother liquor has 2.2% carbon but the quantity of liquid is negligible. The solidified material has 1% carbon.

The first-formed solid material will act as a nucleus for the later which solidifies as the melt chills down. This causes the early-formed solid, low in carbon, to be in contact with later-formed solids higher in carbon. Yet at this lower temperature the material in the cores of the crystals has a greater capacity for carbon than it had before, since the solubility of carbon increases with decreasing temperature down to 1,130° C., and there is a tendency for carbon to pass from the high carbon melt, inward through the outer crystalline layers, until the carbon content of the solid solution becomes more nearly uniform. It requires a slow cooling or a long annealing to cause entire equalization of carbon; the "solid solution alloys" cast and cooled at normal rates usually show a cored structure under the microscope, caused by systematic variations in chemical composition between the material first solidified and the last-freezing mother liquid. Assuming that the cooling has been very slow, and equalization of carbon in the solid portions perfect, the last of the mother liquor in the 1% steel disappears at 1,350° C.; the metal is entirely solid.

AUSTENITE

Solid Solution.—Since the word solution ordinarily connotes a liquid, the term solid solution appears to be a contradiction of terms. The solid solution of iron and carbon is so important that it has been given a special name, austenite, in honour of the English metallurgist Sir William Roberts-Austen. If any steel is homogenized by long heating at 1,130° C., the temperature of maximum solubility of carbon in gamma iron, and can be examined by a light microscope at any temperature within the austenite or gamma phase field, it will look like a pure metal; *i.e.,* a series of abutting crystalline grains of uniform appearance—saving the slight coring which may remain after insufficient anneal, or some surplus material insoluble under any conditions. Thus the solid solution has some of the essential characteristics of a liquid solution—it is a uniform dispersion of atoms of one element among atoms of another, and the proportions may be anything within the limits of solubility. Austenite in fact is an aggregate of crystals of gamma iron; iron atoms are arranged in the face-centred cubic system, within which are tucked away the carbon atoms in the interstices of the space lattice.

Decomposition of **Austenite.**—Another similarity between the solid solution austenite and such liquid solutions as salt in water is that the mutual solubility of carbon in iron, or iron in carbon, whichever appears to be the excess element, changes with lowering temperature, and the then insoluble substance crystallizes out. Such changes can occur in the atomic arrangement in entirely solid metal. The latter is not a fixed and entirely rigid structure, except perhaps at absolute zero. The atoms, while they do not wander about at random, as in a liquid, are in a state of thermal agitation and are moving in small orbits or oscillating back and forth with more and more vigour as the temperature goes up.

Under such circumstances considerable rearrangement may take place by interchange of position, or by stranger atoms' slipping through the open spaces in the crystalline lattice. Such crystalline rearrangements generally occur in a reasonably small temperature interval, involve an evolution or absorption of heat, and are recorded on time-temperature or cooling curves.

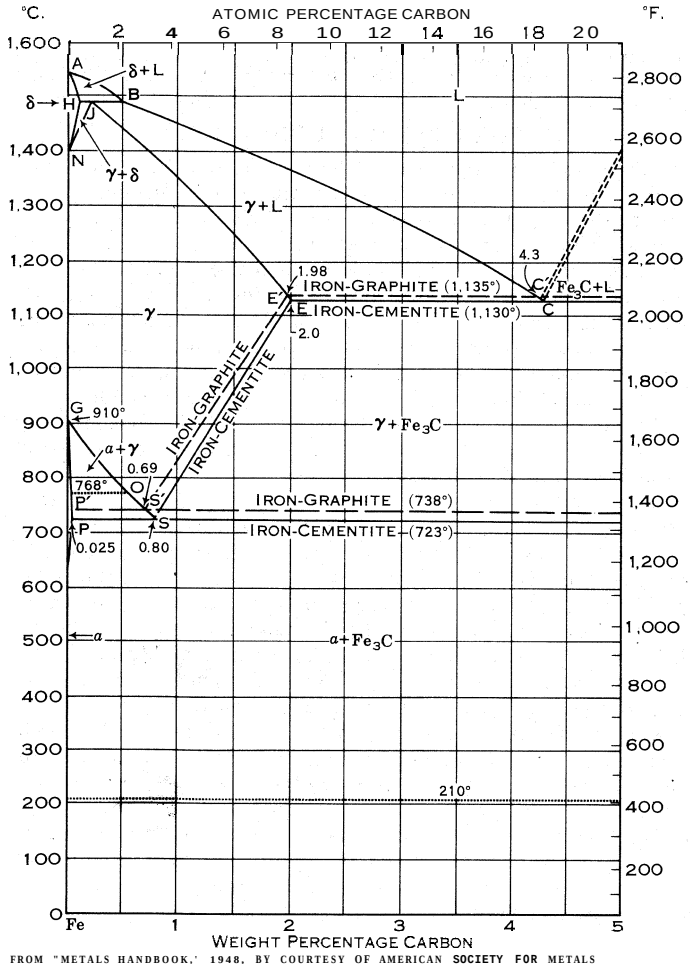
Cooling curves on a low carbon steel show that the change occurring in pure iron at 910° C. from gamma to alpha form is lowered progressively with the increasing carbon content. Furthermore a new and important evolution of heat occurs in all steels at about 723° C., increasing in intensity as the carbon goes up. These two temperature arrests, called A, and A,, coincide at 0.8% carbon. At higher carbons two diverging temperature effects are again noted. These facts are noted on fig. 6, the steel end of the iron-carbon equilibrium diagram, by the lines GSE and *PS.* This is an underlined V, a shape familiar to the physical chemist as noting the break-up of a solution into two mutually insoluble constituents.

In steel, the solution is austenite; the excess constituent first precipitated out in low carbon steels is iron, or ferrite, while that first appearing in the highest carbon steels is not carbon but an iron carbide, Fe_3C, cementite. An 0.8% carbon steel corresponds to the eutectoid. Since it appears in a solid solution it is termed a eutectoid. If examined under the microscope, a slowly cooled 0.8% carbon steel is made up of tiny flakelike lamellae of iron and iron carbide, arranged in rough parallelism and having a pearly lustre. Hence its name, pearlite. A cooling eutectoid steel reaching 723° C. is simultaneously saturated in both constituents—they separate out simultaneously, side by side, in closely intermixed platelets or lamellae.

Structure of Low Carbon Steels.—The mechanism may be illustrated by studying a cooling steel containing 0.25% carbon. Ferrite starts to be precipitated when the temperature reaches 840° C., and more and more pure ferrite precipitates out as the temperature falls, leaving a mother substance richer and richer in carbon. This action continues until at 723° C. the remaining solid solution has reached saturation (point *S,* 0.8% carbon, the eutectoid), and that portion then rearranges itself into pearlite. Medium carbon and hard steels have relatively less and less free ferrite and more and more pearlite. An 0.8% carbon steel is all pearlite. Slow-cooled higher carbon steels (so-called "hypereutectoid" steels) have excess cementite in white veinlets surrounding pearlite masses.

Reverse changes to those described above take place on heating; that is, the phases in a slowly cooled steel dissolve and the structure again reverts to a uniform solid solution when heated above the line GSE.

Structures in Quenched Steel.—The above described changes take place in a slowly cooled steel. If cooling is more rapid, time



FROM "METALS HANDBOOK," 1948, BY COURTESY OF AMERICAN SOCIETY FOR METALS

FIG. 6.— THE QUASI-EQUILIBRIUM OF Fe WITH Fe_3C (SOLID LINES) AND THE TRUE EQUILIBRIUM OF Fe AND C (DOTTED LINES)

is not given for the atomic rearrangements necessary for such complete recrystallization, and certain intermediate microstructures may be observed. The most rapid quenching of austenite may be able to preserve this structure unchanged in the cold metal. In fact this can be done, especially in steels with considerable alloying elements such as manganese or nickel. X-ray investigation of such a specimen of austenite proves that the metallic atoms build up a face-centred crystalline lattice characteristic of gamma iron. The carbon atoms are more or less uniformly distributed but not combined in any definite compound. Such quenched manganese steels are exceedingly tough; while they are not so hard as other steels under the Brinell test, it is impossible to cut them with a chisel; they resist wear, scour and impact well. High manganese steels are therefore suitable for such things as steam-shovel teeth and rail crossings.

High carbon steels, without alloys, can seldom be quenched rapidly enough to preserve much pure austenite. Under the microscope a polished and etched surface appears to be crisscrossed with sharp needles. This structure is called martensite; it is the hardest and most brittle condition of steel. X-ray studies show that the iron has completely transformed into a body-centred tetragonal crystalline lattice similar to a lattice of alpha iron strained by trapped atoms of carbon; it also indicates that the new crystals are exceedingly small, far below the ability of the microscope to see. The needlelike markings are relics of the larger austenite grains rather than actual structures of martensite.

At the interior of a quenched high carbon steel specimen, where the cooling rate is slightly slower than on the surface, the martensite needles may be mixed with rounded areas which etch much more rapidly, appearing black in fact. This structure is called fine pearlite; it also appears in a lower carbon steel rapidly quenched. In older literature fine pearlite was called primary troostite; none of the individual lamellae have grown to a point where they can be seen even at 5.000 magnifications; however, X-ray analysis and the electron microscope prove it to be an aggregate of excessively small lamellae.

Troostite, with hardness of 41 to 44 units on Rockwell "C" scale, is much softer than martensite (C-63 to C-65), but is noticeably less brittle.

Scientific studies since 1935 have shown that, while the temperature of transformation of the austenite solid solution into pearlite is lowered somewhat from 723" C. as the rate of cooling is increased, and the result is finer and finer pearlite (primary troostite), this change in carbon and alloy steels always occurs at high temperatures — above 500° C. Time is required for the process. however, and if enough time is not given at those high temperatures during a rapid quench, then the austenite is retained unchanged to a low temperature. and transforms almost instantly into martensite (a solid solution of carbon in tetragonal ferrite) at 150° to 100° C. If carbon steels are quenched into a molten salt bath at some intermediate temperature, say 400° C., and held there long enough, the austenite leisurely transforms into another acicular microstructure whose exact nature is as yet unknown. The name bainite has been given to this structure. In carbon steels bainite has medium hardness and superior toughness. In some alloy steels the intermediate structure appears during normal oil quenching, and its properties are not always so desirable.

If a quenched steel is moderately reheated (tempered or drawn) it loses a little of its hardness, but the added toughness is necessary for practical use. That is, tools are quenched and tempered. The microstructure is apparently unchanged, except that the acicular martensite etches much more rapidly. On reheating to higher and higher temperatures the atomic carbon first collects into submicroscopic crystals and the appearance under the microscope is uniformly structureless; later, as the carbide crystals grow, a cloudy microstructure, still unresolvable, appears and is called tempered martensite. If time and higher temperature below the transformation range (A_1) is sufficient, tiny globules of carbide appear throughout the entire mass, a structure known as spheroidized cementite. This is the most easily machineable condition for high carbon steels.

THEORY OF HARDENING AND TEMPERING

"Slip Interference." — These various actions which go on within solid steel at moderate temperatures are of the greatest commercial importance, for they control the important operations of hardening and tempering steels. In the simplest example these consist of slowly heating the steel to a temperature somewhat above line GSE, holding it there long enough for it to become a uniform solid solution, then quenching it rapidly, thus retarding the reverse reactions as much as possible, and finally reheating the quenched bar moderately to produce tempered martensite, still hard but much less brittle than the freshly quenched structures. The classically accepted explanation of the hardening phenomenon is known as the slip interference theory, definitely formulated and systematized by the U.S. metallurgists Zay Jeffries and R. S. Archer. It starts with the knowledge that metals are crystalline, and that metallic crystals when they are stressed beyond the elastic limit, do not tear apart irregularly, but one portion slides past another portion along definite crystalline planes without appearing to let go. Such motion is speedily jammed and stops because it tends to disarrange all the neighbouring crystals. The slip plane also heals immediately. Much of the hardness of quenched steel is believed to be due to the submicroscopic size of the constituent crystals; the boundaries of each one interfere with slip under stress in all the neighbours; since slip cannot occur, the metal resists deformation, and is therefore hard. In steel another hardening factor supplements this slip interference at the grain boundaries, namely, the presence of a great number of carbon atoms, cementite molecules or even tiniest cementite crystals uniformly dispersed through the ferrite grains. Such particles harden the entire metal from two causes: first, they prevent the start of any slip between crystalline layers as would billions of tiny

staples in the leaves of a book; and second, the slips once started despite this hindrance must drag against a multitude of anchors.

Hardening by Cold Work.—Since a ductile metal like iron deforms plastically under cold work or stress beyond the elastic limit by internal slip along crystalline planes: it would appear that this slip has the effect of breaking up the original crystals into numbers of small ones. For that reason cold work hardens the metal; finer grained metals are harder. Under the microscope the slip planes are seen only in special circumstances, but the original grains appear to be flattened out and assume a shape more or less parallel to the extension. In extreme cases: as in wire for suspension bridge cables, a high carbon steel with original tensile strength of about 80,000 lb. per sq.in. can be cold worked into a condition where it will carry 220,000 lb. per sq.in. before rupture. Microstructure of such a wire parallel to the direction of drawing shows the original crystalline boundaries flattened out until the structure seems to be fibrous.

Increase in hardness is accompanied by an increase in brittleness, so excessive cold work is liable to break the article, either during manufacture, or in its after history—season cracking. To avoid this danger, and to restore ductility, the piece may be annealed (*q.v.*) or reheated moderately to a point which does not affect the microscopic appearance yet the added atomic mobility at higher temperature permits such rearrangements as necessary to relieve internal stresses associated with work hardening.

Recrystallization.—A little higher heat on a cold worked piece of metal will cause the previous grain structure to be entirely replaced by a new arrangement. This is known as recrystallization. The recrystallization temperature varies with the amount of cold work previously done on the metal. Long stay at temperatures above this will cause the growth of large crystals. Such is to be avoided because it makes for a condition known as Stead's brittleness.

Slip planes started across a large crystal find less supporting material at the grain boundaries, and the self-healing action ordinarily occurring during plastic deformation is absent; the crystal splits transgranularly along the cleavage plane.

Refining the Grain.—Recrystallization by moderate heat after cold work is to be distinguished from recrystallization on a higher heating to above the line *GSE*. The alpha iron then transforms into crystals of gamma iron. Apparently the new crystalline arrangement is almost entirely independent of the old; if the temperature is maintained for some time the new set of austenite crystals grow in average size as the temperature or time increases. On slow cooling through the transformation range these new austenite grains eject the excess constituent to the borders, and the kernels are the locus of the pearlite regions.

Thus by a heating and cooling through the transformation range, the grain size of steel can be changed, refined or enlarged, as desired. After the desired austenite grain size is obtained, a common cooling operation is normalizing—cooling the steel in still air.

Burning.—Excessive heating of steel ruins it by burning. A burnt steel is brittle and the brittleness cannot be removed by heat treatment. Microscopic examination shows that the grain size is unusually large, due to the high temperature experienced, and the grain boundaries contain considerable oxide.

Burnt steel in fact has been heated beyond the solidus (line *JE*) and the high carbon regions in the austenite have actually melted. The melted metal absorbs furnace gases very quickly, which are responsible for the incurable damage done in the molten portions of the steel.

BIBLIOGRAPHY.—The fullest account of American practice is contained in J. M. Camp and C. B. Francis, *The Making, Shaping and Treating of Steel* (1939); for British and Continental see F. W. Harbord and J. W. Hall, *The Metallurgy of Steel* (1923); H. P. Tiemann, *Iron and Steel* (1933), a pocket dictionary of terms and a brief encyclopaedia of the whole subject; American Society for Metals, *Metals Handbook* (1948). Some fine text books cover only portions of the subject, such as Robert Forsythe, *The Blast Furnace and the Manufacture of Pig Iron* (1922); Walter Lister, *Practical Steelmaking* (1929); A. W. and Harry Brearley, *Ingots and Ingot Moulds* (1919); D. K. Bullens, *Steel and its Heat Treatment* (1939); Z. Jeffries and R. S. Archer, *The Science of Metals* (1939). Professional societies which devote much attention to the manufacture of iron and steel, and whose journals contain accounts and symposiums on the current state of the art are: (British) Iron and Steel Institute, American Iron and Steel Institute, and American Society for Metals. Leading journals of the trade are *The Iron Age, New York; Steel, Cleveland, Ohio; Iron and Coal Trades Review, London;* and *Stahl und Eisen*, Dusseldorf. (E. E. T.; R. E. GE.)

STATISTICS OF PRODUCTION

In tracing the development of the world's iron and steel output it is often customary to commence with Great Britain, for although the output of pig iron in Great Britain at mid-20th century was less than 10% of the world's total, and about the same in steel, nevertheless Great Britain was the birthplace of the modern iron and steel industry, and many of the developments connected with the industry originated there. Until 1871 the output of pig iron in Great Britain exceeded that of all other countries put together; in 1890 Great Britain was for the first time surpassed by the United States: in 1904 for the first time by Germany, and in 1921—because of a coal stoppage—for the first time by France. In 1931 the output of the U.S.S.R. exceeded Great Britain for the first time.

According to Robert F. Mushet the output of pig iron in Great Britain in 1720 was 17,350 tons, but T. S. Ashton, in his *Iron and Steel in the Industrial Revolution*, gives reasons for thinking this too low, preferring the estimate of William Rea, an ironmaster of Monmouth, who put the output of pig iron at this period at about 25,000 tons per annum; he also points out that Scrivener's *History* (p. 57) wrongly gives 1740 as the date of Mushet's estimate, an error which has been followed by many later writers. The 25,000 tons produced in 1720 had risen to 68,300 tons by 1788; but, whereas the majority of the furnaces in 1720 had been charcoal, 55 in 1788 were coke furnaces. It is not possible to describe the reactions of improvements in blast furnaces upon the demand for iron, nor of the demand for iron (created by engineering inventions) upon blast-furnace improvements; suffice it to say that by 1840 production of pig iron had risen to 1,396,000 tons; by 1860 to 3,890,000 tons; and by 1880 to 7,750,000 tons. Having nearly trebled in the 20 years between 1840 and 1860 and doubled between 1860 and 1880 the increase between 1880 and 1900 was no more than 16%. In the next several decades production lagged, but in the late 1940s it recovered close to the volume of the best years of the early part of the 20th century.

It was not until the development of the pneumatic converter in 1856, a discovery claimed by both Sir Henry Bessemer, an Englishman, and William Kelly, an American, that the production of steel at relatively low prices was made possible. This was followed by the discovery of the open-hearth process by Siemens Bros. in 1864–67. Between 1877 and 1883 another obstacle to low-cost production of high-grade steel was removed through the perfection by Sydney Gilchrist Thomas and his cousin of a technique for removing phosphorus from steel during the processing period. The influence of these improvements on steel production is indicated by the rapid expansion of output in Great Britain. From 220,000 tons in 1870, it had grown to 4,900,000 tons by 1900. By 1920 it had almost doubled again, and shortly after World War II steel production was around 15,000,000 tons a year, or three times larger than at the beginning of the 20th century.

It is impossible to trace, even in this broad outline, the progress of development in the other iron and steel producing countries. In all cases, except where the industry is of comparatively late growth, iron was first smelted with charcoal, and coke but slowly won its way; e.g., mineral fuel was first used in France in 1782, but by 1819 only two furnaces were using coke out of a total of 350 (*Memoirs of the Geological Survey of Great Britain*, vol. i. pt. 1, 1856, quoted by Ashton): but in all countries the great bulk of the steel output is made by the Siemens process, which, after its discovery, rapidly supplanted the pneumatic converter process because of its economy and regularity of operation.

In 1880 open-hearth production in Great Britain accounted for about 20% of the total output, but by mid-20th century it was almost 100%.

Pig Iron: World Output.—It will be seen from Table I that in the 100 years ended 1910, the average increase in world

production of pig iron in any decade was 60%, while because of the dislocation caused by World War I, a loss of 3% was experienced in the 10 years ended 1920. However, in the decade ended 1930, the upward trend was resumed with increases of 26% and 29% each in the next two decades. A contributory cause of the slow growth after 1910 was that following World War I a greater proportion of steel scrap was used in steelmaking. The rate of progress of steel output was rapid until 1929, but after that year irregular because of unsettled world conditions. The rate of increase was greater than in the case of pig iron output.

Outputs of Pig Iron and Steel by Chief Countries.—Although output of pig iron in Great Britain reached a record of more than 10,260,000 tons in 1913 and never recovered completely from its subsequent decline, output of steel surpassed the production of that frequently and by wide margins. Output of steel in 1948 was nearly twice as large as in 1913. This high postwar level made Great Britain the first country among major world producers to exceed its highest annual output of the war period. Production in the United States, after a severe slump in the decade prior to World War II, climbed swiftly to new heights during the war, exceeding 80,000,000 tons in 1944. Near the end of the war and immediately following, with output greatly reduced in most of Europe, the United States was called on to produce more than half the world's annual output of steel.

*Prior to 1920, Lorraine is included with Germany, but after that date with France. Austria is included with Germany, 1937–44.
†Includes Poland through 1919.

At the end of the war, world production of both pig iron and steel slumped from the record levels that had been attained. By 1947, however, steel output had recovered to the level of 1937, highest year prior to the war, and pig iron production also had recovered substantially.

Iron and Steel Exports.—Table IV, which gives the exports of iron and steel (as far as possible according to the board of trade's classification) from chief producing countries, shows that exports from Great Britain in 1948 had not yet reached the record figure of 1913, when they amounted to nearly 5,000,000 tons. The best British years after the latter date were 1923, when exports from European countries were curtailed because of the Ruhr occupation, and 1927, when arrears accumulated during the coal stoppage of 1926 were being worked off. The decline in the British export trade took place in spite of great reduction in prices, for, as shown by the board of trade's price index number, prices of iron and steel products had fallen from 1920 to about 1928, after which time prices about doubled.

Annual exports of iron and steel from Great Britain and Belgium-Luxembourg shortly after World War II showed little

change from the exports immediately preceding the war. Exports from the United States were several times larger than prior to the war.

After World War II, during which the great bulk of iron and steel produced nas immediately consumed, it was clear that the potential demand for iron and steel was considerable. but in the early postwar years most countries were too impoverished to make that demand effective, while most belligerent countries who before the war supplied capital for development were no longer able to do so on the same scale.

After World War I, France acquired Alsace and Lorraine from Germany. French production of iron and steel was greatly increased, leading to stronger competition in Europe. The German iron and steel industry underwent violent changes in the two wars but from second place among world producers between the two wars, that country's output was reduced at mid-century to a small, uncertain position. The industry in France. Belgium and Germany had always depended heavily on exports in proportion to domestic business.

The increase in production in the U.S.S R. of both pig iron and steel after 192j had probably never been equalled. In 1925 output of pig iron was 1,300,000 tons, while in 1939 it was 1j,-000,000 tons. an increase of more than 1,100%. Steel production in 1925 amounted to 1,840,000 tons, but by 1939 it had expanded to nearly 23,000,000 tons. a gain of more than 1,200% Thus. in 14 years the U S.S.R. rose from sixth in importance among world producers to a position of nearly a tie for second place behind the Cnited States.

U.S. Production. — The output of pig iron in the United States, the world's largest producer since 1897, was 30,966,000 tons in 1913 and of steel ingots 31,301,000 tons. The enormous contracts for munitions, machine tools, etc., placed by the Allies during World War I, as well as the demands for equipping its own army, necessitated the extension of existing iron and steel plants and the erection of new ones. After the war, the great increase in capacity was absorbed by the growing internal demand and by 1937 output of pig iron was 37,130,000 tons and of steel 50,570,-000 tons. These tonnages, somewhat less than in 1929. but the highest in the 1930s, were far surpassed during World War II and the postwar years.

Continued expansion after that war placed steel capacity in the United States four times larger than at the beginning of the century.

With the development of alloy steels, which greatly widened the field of steel consumption, together with such refinements in production as the continuous sheet and strip mill which acted to lower greatly the cost of steel: the saturation point of steel consumption seemed as far away at mid-20th century as it was when the pneumatic converter was invented. However, plastics. and new processes for producing and fabricating such nonferrous metals as aluminum, magnesium, copper and zinc alloy die castings, constituted a challenge to the steel industry's position. Yet, on the other hand. steel had supplanted wood on a large scale for such applications as small home building, interior constructions, etc.. which might counterbalance the effects of the greater use of plastics. etc. It might be reasonably, assumed. however. that the low cost of steel would for a long time support its position as the basic material of the modern world. This position apparently was more assured with huge new iron mining developments following World War II. (W. A. PH.; W. S. To.)

IRONBARK, the name applied to species of *Eucalyptus* (*q.v.*) in Australia. from the hardness of the bark.

IRON GATE (Eisern Tor). a shallow. rocky stretch of the Danube, about one and one-half miles in length, beginning just below the Island of Ada Kalah. From the Iron Gate, where the river bed falls. to the Black sea. is the lower course of the river. By the term Iron Gate is often understood the narrowing banks of the Danube where the Carpathian arc joins the Balkan mountains. More accurately, the name belongs to the rocky bed of the river at this juncture which, until the close of the 19th century. kept these waters treacherous to navigators and closed to shipping for three months of the year. At high tide the craggy rocks (one of them known as the Grandmother's Tooth) are not visible to the eye. but the water continues to rush and seethe past them, forced on by the current as it hits the underwater line of jagged stone ridges. In the 1890s a clearance was blasted through along the right bank of the Danube, making way for the Sip canal, opened in 1898. Responsibility for the operation and maintenance of the canal and for improving the navigability of the Iron Gate was vested in an international commission for the Danube in 1921, by a statute of the Versailles treaty.

The first rift in this arrangement came in 1936 when Adolf Hitler denounced the statute and recalled the delegates to the commission from the two German riparian states. After World War II, the old commission was replaced by a new Danube river commission made up of a bloc of Soviet-dominated states.

IRON MASK (*masque* **de** *fer*). The identity of the man in the iron mask, one of Louis XIV's political prisoners who died in the Bastille, is a famous historical mystery. In 1698, Saint-Mars, the new governor of the Bastille, brought with him from Île Ste. Marguerite a prisoner whom he kept masked and whose real name was not known. This prisoner died on Nov. 19. 1703; and his name was entered in the register of Saint Paul as Marchioly, aged about 45. Even during his lifetime, legend grew up around this person, and Saint-Mars himself admitted circulating fairy tales about him. He was soon suspected of being connected with the royal family. Voltaire added immensely to the legend by describing the mask as of iron, and the man as a natural brother of Louis XIV—a theory which Dumas in the *Vicomte de Bragelonne* did much to popularize.

It mas even asserted that this prince had a son who founded the Bonaparte family in Corsica; while other speculations identified him with Monmouth, Beaufort, Fouquet and even Molière.

It is believed that the man in the mask was either Count Mattioli or Eustache Dauger. Mattioli was the Mantuan minister who attempted to sell to France the frontier fortress of Casale, but revealed the transaction at the last moment, and was eventually secured by Louis' agents. In spite of the tempting argument from the name under which the prisoner was buried it is difficult to accept a solution which seeks to identify the mysterious "mask" with a man whose identity was generally known.

The other candidate, much more likely, is Eustache Dauger; but the principal problem for the investigator remains: who was Dauger? Several theories have been put forward on very slight evidence. It seems clear that he was a Catholic and not an Englishman; but the fact that at a time of emergency he was allowed to act as valet to Fouquet has drawn a red herring across the trail. Monsignor Barnes identified him with Abbé Pregnani, involved in the religious affairs of Charles II, and for that reason possessing dangerous information. That the prisoner was sent to Pinerolo from Dunkirk favours the idea of some connection with England; and Monsignor Barnes at first went on to claim that the abbe' was a natural son of the English king. This hypothesis linked up the problem with a second—that of James de la Cloche—and soon proved untenable.

The problem is probably more difficult than important. There is, however, a fascination in the interesting evidence, and in the possible theories which may be constructed from it.

The period was one in which intrigue was at its height, and the affairs of individuals were so intertwined with those of states that every figure of importance appears as the centre of a labyrinth whose key may be anywhere. Romantic imagination has done the rest.

IRON MOUNTAIN, a city of Michigan, U.S., the seat of Dickinson county, adjoining the city of Kingsford, is just north of the Menominee river, which separates the upper peninsula of Michigan from Wisconsin. Iron Mountain; the commercial centre of the county. was settled as a mining community in 1879 and incorporated in 1887. It was so named because of its proximity to a bluff heavily stratified with iron ore. Mining continued to be important in the economy until the 1930s, when ore deposits were virtually exhausted. Kingsford was incorporated in 1925 as an outgrowth of Ford Motor company operations.

The Iron Mountain-Kingsford area is studded with small plants

which manufacture metal parts; electric controls: chemicals; furniture, paper and other wood products; and wearing apparel. The Pine mountain ski slide, on nhich the world's foremost skiers have jumped distances up to 313 ft. is but one of many tourist attractions Iron Mountain is also the home of a large veterans' administration hospital. For comparative population figures for both cities see table in MICHIGAN: *Population.* (R. F. O'D.)

IRONSTONE, referring in the past to certain iron carbonate deposits, notably the clay ironstone concretions, this term later came to mean an iron-bearing formation. Iron, the fourth most abundant element in the earth's crust. occurs in nearlv all rocks. the iron content varying from nil to several per cent. In some sedimentary strata it exceeds 15%; such rocks are called an iron-bearing formation, an iron formation or ironstone.

Ironstones are sedimentary deposits of varied composition. They may be iron sulfides (pyrite), iron carbonate (siderite), iron silicates (chamoisite, greenalite, etc.) and iron oxides (hematite, etc.). These materials are generally mixed nith silica (commonly chert), clay, etc., and form strata of ironstone.

Among the best-known ironstones are those of Pre-Cambrian age in the Lake Superior region. These average 25% iron but in places are enriched and constitute iron ores. Since their discovery they have yielded about 2,000,000,000 tons of ore (50% or more iron). Silurian ferric oxide ironstones occur in the Appalachian region and are mined in the Birmingham district of Alabama.

Ironstones were precipitated in marine waters, in lakes and in swamps ("bog ore"). Their mineralogy is dependent on the oxidizing potential of the environment.

See F. J. Pettijohn, *Sedimentary* Rocks, pp. 449–467 (1957). (F. J. P.)

IRONWOOD, a name applied to many hard and heavy woods or to the trees that produce them. Certain ironwoods (e.g., *Krugiodendron, Olneya*) sink in water. Many are very difficult to work, and so require the use of machine tools rather than hand labour. Among the ironwoods of the United States, the most widely distributed are *Ostrya virginiana,* also called hop hornbeam. and *Carpinus caroliniana,* also called hornbeam and blue beech (see HORNBEAM). These trees, members of the birch family, range over eastern United States and adjacent Canada. Their wood is used for fuel, levers, fence posts and tool handles. Ironwoods of more southerly distribution in North America include desert ironwood (*Olneya* tesota) of southwestern United States and adjacent Mexico. Its wood makes excellent fuel and is used for novelties. Black ironwood (Krugiodendron *ferreum*), one of the world's densest woods (specific gravity 1.34–1.42), is native to southeastern United States, southern Mexico, British Honduras and the West Indies. Ironwoods of somewhat similar distribution are those derived from *Cyrilla racemiflora,* also called leatherwood; from species of *Jacquinia,* also called joewood; and from Exothea *paniculata,* known in Florida as butterbough or inkwood. Catalina ironwood in the California coastal islands is *Lyonothamnus floribundus. Reynosia septentrionalis,* found in Florida and the Bahamas, is known as red ironwood. The durable wood of *Hypelate trifoliata,* white ironwood, is used in Florida for fence posts. Woods known as ironwood in Jamaica include *Sloanea jamaicensis* and *Turpinia paniculata,* neither of commercial importance. The useful timber of Dialium *guianense* is called ironwood in British Honduras. Asiatic ironwoods include Xylia *dolabriformis* and *Mesua* ferrea, valuable timber trees. Among Australian trees that may be known as ironwood are scrub ironwood (*Myrtus acmenoides*); lemon ironwood (*Backhousia* citriodora); giant ironwood (*Syncarpia subargentea*); species of *Geijera,* also called axe-breaker; and *Notelaea ligustrina,* also called silkwood. Uganda ironwood (*Cynometra alexandri*), of Uganda and the Belgian Congo. and black ironwood (Olea *laurifoliaj*, of South Africa: are used for heavy construction. One of the most durable timbers of west tropical Africa is ekki, red or west African ironwood (Lophira procera var. *alata*). (J. W. TT.)

IRONWORK, in this article. refers to iron used in the interior or exterior design of buildings of all kinds. The earliest uses of iron were practical; it has only relatively recently been used ornamentally. An Egyptian sickle found under the sphinx at Karnak is thought to be over 5,000 years old. Iron tools were made by the Chinese as early as 2300 B.C. Glaucus of Chios is generally credited as having invented the welding of iron about 600 B.C. At Delhi. India, a solid pillar of malleable iron (23 ft., 8 in. high, with a diameter of 16 in. at the base and 12 in. at the top) probably dates to about A.D. 400. Wrought iron was first produced in the U.S. in 1622. See also BRONZE AND BRASS ORNAMENTAL WORK. (G. K. G.).

I. HISTORY

A. ASIA

1. India and Southeast Asia.—The manufacture of iron and steel by primitive small-scale methods has survived in southern India and Ceylon to the present day. The iron is smelted directly from the ore. and true carbon steel of high quality is made by melting the iron with a small proportion of green wood in a clay crucible heated to a high temperature. The slag heaps of ancient furnaces are common and the processes have probably been in use for more than 2,000 years, but it is unknown whether they are of indigenous invention or acquired. In southern India iron immediately succeeded stone as a material for tools and weapons. and prehistoric iron weapons began to come into use about 500 B.C. Alexander received a gift of Indian steel from the Punjab chiefs; steel dating from the 2nd century B C. has been found at Besnagar and in Ceylon, and tempered steel is referred to in the *Ummagga* Jataka. Indian iron and steel weapons have been famous throughout the middle ages, and the steel was exported to Persia and further west, where it formed the material of the Damascus blades of the Saracens. Buddhist begging bowls are generally made of iron. The wrought-iron pillar of Delhi, set up about A D. 400 by Kumaragupta I. in honour of his father, is over 23 ft. in height and weighs more than 6 tons; it demonstrates the abilities of Indian metalnorkers in handling large masses of material, for not until the latter part of the 19th century could anything of the same kind have been made in Europe. There are other large iron pillars at Dhar and at Mt Abu.

The decoration of iron and steel takes various forms. The shapes of weapons are usually of great elegance. and decoration is never permitted to interfere with utility. The most remarkable carved steel weapons are those of southern India (Tanjore), the Deccan and Rajputana; but the art extended to Malaysia and Indonesia, as will be seen in any of the fine chiseled creese from Bali. Decoration by the application of the second metal is effected by damascening or incrusting.

In koftgari, or true damascening, grooves are cut in the surface of the iron or steel to be ornamented, and gold or silver wire is laid in them. The mire is hammered until completely united with the ground metal. which may then be smoothed and polished to shon the design. The design may consist of geometrical or floral ornament or an inscription. In incrusted work. the required form is first carved on the surface of the ground metal, the edges of the carved area being slightly undercut. A thin plate of gold or silver of the same size is beaten down onto the carved surface. The edges of the applied metal slip into the undercut groove and are held tightly as a result of the hammering. See also INDIAN ART; INDONESIAN ARCHAEOLOGY; INDONESIAN ART. (A K. C.)

2. China.—Iron began to take its place in the brilliant Bronze Age culture of China about 500 B C. By the end of the 2nd century A.D. bronze weapons had been almost completely supplanted, while iron had been generally substituted for bronze in common use in utensils and vessels of various kinds. tools, chariot fittings and ex en small pieces of sculpture. These were commonly cast in sand molds were patterned after bronze prototypes and were typical in style and decoration of the Han period.

From the 9th century iron increasingly took the place of bronze in China as a material for sculpture, especially in the north and under the Sung dynasty. The few extant examples from the 11th century and later show work done on a larger scale and in coarser technique than the bronzes, though the modeling is usually more naturalistic.

Several iron pagodas, ranging in size from miniature models to

towers 30 or more metres in height, and dating from the 10th to the 14th century, give further evidence of the dexterity of the Chinese iron caster. These imitate in detail both the structural and decorative effects of the more common tile-roofed brick pagodas. Iron for temple furniture has long been in use, and a large number of the braziers, censers, caldrons and bells found today in the temples are of iron.

In China in the 17th century the iron picture was developed, the craftsmen seeking to reproduce in permanent form through the medium of wrought iron the effects of the popular ink sketches of the master painters. When completed, these pictorial compositions were mounted in windows, in lanterns or in frames as pictures. When in the latter form a paper or silk background often bore the signature and seal of the maker, heightening the resemblance to a painting. The craft flourished in Anwhei province and is still practised, though with less patience and fineness than formerly.

3. Japan. — The Iron Age in Japan is supposed to have begun in the and century B.C., though the chief early remains are weapons from the dolmens of the 2nd to the 8th centuries A.D. The Japanese iron founder attained a considerable skill at an early date and acquired a social position which was never attained by the bronze caster, or by the ironworkers in China where the Bronze Age tradition was much stronger.

It is apparent that iron was used in China chiefly as a substitute or imitative medium, worked often with great skill but with little artistic invention. In Japan, however, the ironworker developed a distinctive and original means of expression and high artistic attainment in furniture for the sword. With the rise of feudalism and the establishment of the samurai class after the wars of the 12th century, the equipment of the warriors became an object for the efforts of the artist.

At first these efforts were devoted to the embellishment of defensive armour, but from the 15th century the sword became the centre of attention. The blade is not properly part of our subject, but in the mountings. especially the guards (tsuba), we find exquisite artistry expressed chiefly in iron. A remarkably soft and pure variety of the metal especially free from sulfur was employed. It was worked by casting, hammering and chiseling; and innumerable surface effects were obtained by tooling, inlaying, incrustation, combination with other metals and patination by various, usually secret, processes.

Simple conventional patterns, crests and pictorial designs were the bases for the decoration. As these were often furnished by painters or designers the criterion of connoisseurship in Japan is the unsurpassed technical quality of the handling of the iron itself. With the promulgation of the edict of 1876, prohibiting the wearing of swords, this art came to an end, but the skill of the Japanese ironworker may still be noted in numerous small decorative objects. (B. MAR.)

B. EUROPE

1. Belgium and Holland. — The ironwork of these two small countries has been of great influence, and of greater quantity than the number of extant early examples might seem to indicate. Authorities generally agree that wrought ironwork in these countries prior to the 15th century was equal, if not superior, to contemporary craftsmanship in other countries. Yet so few pieces remain that the significance of craftsmen of the Low Countries has often been underestimated. During the 15th century design and craftsmen from the Low Countries began to make their influence evident across the channel in England. The outstanding craftsmen were of the Massys family of Louvain. Representative examples of this period are in the great church at Breda; the treasury door of the cathedral and some presses in the church of St. James, both at Liége; and hinges of the church of Notre Dame, Hal. The beautiful spires of Bruges, Ghent and Antwerp should also be mentioned. It is believed that the ironwork of St. George's chapel, Windsor, was executed in Belgium; its main features of Perpendicular Gothic with flamboyant details, are not approached by any similar English work.

During the first half of the 16th century, before the Spanish occupation, there were diversified forms of ironwork, such as protective grilles for doors, windows and chapels, often in fleur-de-lis patterns; window gratings of vertical bars, frequently octagonal in section; and interlacing bars, producing rectangular or lozenge-shaped patterns. Only a few examples still exist; *e.g.,* some lunettes in the *hôtel de ville* of Brussels; a tabernacle grille from the chapel of the counts of Flanders and a window grille from St. Bavon, both from Ghent and now in the Victoria and Albert museum. London; and hinges at the *hôtels de ville* of Bruges and Ypres. Few Renaissance screens have survived.

During the second half of the 16th century the cruelty of the duke of Alba and his 20,000 troops, together with the threat of the Inquisition, drove hundreds of artisans to England. The effect was to change the nature of ironwork there, and to produce the mannerisms characteristic of the so-called Jacobean style. After the Spanish domination there was little indigenous design in Holland and Belgium, and such ironwork as was produced, fell under the spell of French importations.

See Charles ffoulkes, *Belgian Ironwork* (1915). *(G. K. G.)*

2. England. — The initial use of wrought iron was purely protective because violent attacks were frequent, and doors had to be strengthened with massive ironwork inside and out. Window openings, especially those of the treasuries of mansions and cathedrals, were for similar reasons filled with strong interlacing bars of solid iron; a good example remains at Canterbury cathedral. When in course of time the need for protective barriers ended, there came greater freedom of work and a definite ornamentation. Throughout England, medieval church doors are found with massive iron hinges, the bands worked in rich ornamental designs of scrollwork, varying from the plain hinge band with crescent, to the most elaborate filling of the door. Examples exist at Skipwith and Stillingfleet in Yorkshire, many in the eastern counties, others in Gloucester, Somerset and the west Midlands. The next important application of ironwork came with the erection of the great cathedrals and churches, whose shrines and treasures demanded protection. Winchester cathedral possesses the remains of one screen with a symmetrical arrangement of scrollwork. The grille above the tomb of Queen Eleanor at Westminster abbey recalls Thomas de Leghtone, a master craftsman in iron who had succeeded another great smith, Henry of Lewes. Tombs were enclosed within railings of vertical bars with ornamental finials at intervals, such as that of the Black Prince at Canterbury. A new development appeared in the early years of the 14th century when the smith, working in cold iron, attempted to reproduce Gothic stone tracery in metal. This work was more like that of a woodworker, than of a smith, often consisting of small pieces of iron chiseled and riveted, and fixed on a background of sheet iron. Many small objects such as door knockers, handles and escutcheons are to be found executed in the same manner. A typical monumental example is in Henry V's chantry at Westminster abbey, but the most magnificent is the great grille at St. George's chapel, Windsor, made to protect the tomb of Edward IV. For many years it was assumed to be the work of the Fleming, Quentin Massys, but it is now known to have been executed by an Englishman, John Tresilian.

Smithing declined in England during the 16th century. The development of the art during the Renaissance period was very uneven in the various countries of Europe. In England the smith fell behind and seemed to have lost interest, producing no very great or important work. He continued to make iron railings, balconies and small objects for architectural application, such as hinges, latches, locks and weathercocks. But toward the end of the 17th century, there was a growing interest in beautifying houses and laying out gardens and squares with a commensurate demand for balconies, staircases and garden gates. The man to whom the credit is usually given for the revival of ironwork in England was Jean Tijou, a Frenchman who together with many of his Protestant fellow craftsmen, had been forced to leave his country owing to the revocation of the Edict of Nantes in 1685. After some years in the Netherlands he came to England in 1689 where he enjoyed the patronage and favour of William III and his queen. His most important works for his royal patrons are to be seen in the immense

mass of screens and gates with which he embellished Bampton Court palace. He also executed work at Burleigh house, Stamford. Probably by the queen's wish he was associated with Sir Christopher Wren then engaged on the rebuilding of St. Paul's cathedral. Wren apparently was not very keen on ironwork, and probably exercised some restraint on Tijou, with the result that his work at St. Paul's is more dignified and freer from appendages than that at Hampton Court.

A great amount of fine ironwork of the 18th century may be studied in London in the form of gates, railings: lamp holders, door brackets. balconies, staircases; in almost every suburb may be seen gates and brackets. The precincts of the colleges of Oxford and Cambridge, as well as almost every old town in England, furnish a variety of handsome work. Throughout the 18th century the smith was a busy man; the general tendency of his work, unaffected by the rococo movement on the continent, was toward a less ornate but more characteristically English style, Perpendicular, severe, lofty and commanding, as contrasted with Tijou's French love of richness and mass of details.

At the end of the 18th century the work of the architect brothers Adam shows a departure from true smithing; its slender delicate bars are enriched with rosettes, anthemion and other ornament in brass or lead. The effect is pleasing and harmonizes with the architecture with which it is incorporated.

BIBLIOGRAPHY.—J. Starkie Gardner, *English Ironwork of tha XVIIth and XVIIIth Centuries* (1911), no better source can be referred to for either historical matter or exhaustive illustrations for the period covered; Francis Rowland Yerbury, *Georgian Details of Domestic Architecture* (1926); Mervyn E. Macartney, *The Practical Exemplar of Architecture,* series i–iv (1908–13), the illustrations are mostly of English work, although some are of Italian gates, railings, etc.

3. France.—Medieval door hinge ornaments were not basically different from those in England. and beautiful work is found on church doors, especiaily in central and northern France. It reaches a height of greater elaboration and magnificence than in England, the culminating example being the west doors of Notre Dame, Paris, the ironwork of which is so wonderful that it was attributed to superhuman authorship, Grilles at Troyes and Rouen reveal a high standard of excellence. Working the iron cold, and employing methods associated with carpentry, was immensely popular; it was applied to small objects such as door handles, knockers, ambry doors, and above all to locks. These exhibit an amazing amount of detail and a delicacy of finish such as could only come from a French craftsman.

The Gothic tradition survived in France until well into the 16th century, and was marked by the production of work of the highest skill. largely in the form of locks. knockers and caskets of chiseled iron. The introduction of the Renaissance style did not radically alter the direction of the smith's art—a strange fact when it is remembered how Germany and Spain were fabricating works of enormous size and magnificence in wrought iron. France, like England at that time. was content to make door furniture, in the form of locks, keys. bolts, escutcheons and the like, but did little ironwork of any great size. A school of locksmiths came into being under Francis I and Henry II, working from designs by Androuet du Cerceau in the 16th century, and Mathurin Jousse and Antoine Jacquard in the 17th. The bows and wards of keys were of unusually intricate design, and the locks of corresponding richness. Representative pieces may be seen at the Victoria and Albert museum: London. Among them is the famous Strozzi key, said to have been made for the apartments of Henry III, the bow of which takes the favoured form of two grotesque figures back to hack. But as far as architectural ironwork was concerned, France remained almost at a standstill until the accession of Louis XIII in 1610. Under that monarch, a worker at the forge himself, came a great revival. It seemed to be uninfluenced from without, at first weak. as if feeling its way, but by the end of the 17th century it had attained a marvelous pitch of perfection. It proved to be the beginning of a new movement. the force of which made itself felt in the adjoining countries and inspired ironworkers with new energy. Unfortunately, however. this at times dwindled into mere imitativeness. From the accession of Louis XIV the French ironworkers must be acknowledged as the cleverest in Europe, combining as they did gcod and fitting design with masterly execution. Their designs were often very daring, exploiting all the latent and previously unexplored possibilities of iron. They recognized its great adaptability and took every advantage of it, at the same time being conscious of its limitations. Their forms of expression aere endless.

Screens and gates were needed for parks, gardens and avenues, staircases for mansions and palaces. screens for churches and cathedrals. Among celebrated designers were Jean Lepautre. Daniel Marot and Jean Bérain. Earlier work had been of a simple character, balconies for instance, being in the form of a succession of balusters, but as the smith became more versatile and imaginative, they took the form of panels of flowing curved scrolls, rendered with a freedom never attained before. while constructive strength was observed and symmetry maintained. Enrichments were usually attached in hammered sheet iron. These may be considered the distinguishing features of Louis XIV work such as that at St. Cloud, Chantilly, Fontainebleau and elsewhere. But under Louis XIV all previous efforts were surpassed in the work for his palace at Versailles.

The art of ironwork received a further impetus by the introduction of what is known as the rococo style. The movement initiated in 1723 was due principally to the imagination of two artists, Just Aurèle Meissonier, architect, and Gilles Oppenordt. There was a balanced asymmetry in the design, and fantastic curves with a luxury of applied ornamentation. To the French smith it furnished the opportunity for a yet greater display of his skill. He was clever enough to secure a feeling of stability in his work by counterbalancing swirling masses of ornament with straight constructional lines; he knew how to introduce an iron screen of rococo style into a Gothic church or cathedral without giving offense to the eye or arousing any uncomfortable feeling of incongruity. With astonishing manipulative power he worked as if the material under his hand were soft and pliable, rather than solid and unyielding iron.

Later in the 18th century ironwork took on a more classical appearance, owing to the general revival of interest in ancient art, and many Greek and Roman details were introduced into the ornamentation. The amount of work executed was prodigious, and its beauty and craftsmanship may be seen in most cities of France; e.g , in Nancy.

Nearly all the adjacent countries mere seized with the desire to imitate this French rococo style. England excepted.

Martinie, *La Ferronnerie, Exposition des Arts Decoratifs* (192j).

4. Germany.— In the Romanesque period in Germany bronze was preferred to iron; the earliest examples of ironwork are later than those of France and England. The first iron grilles were imitations of French nork, having C-scrolls filling spaces between vertical bars. Typical examples of door hinges prior to the 14th century were those at Kaisheim, St. Magnus church, Brunswick, and St Elizabeth's church. Marburg (the latter having a curious cross in the middle). Throughout the Gothic period in Germany, the imitation of natural foliage was the basis of design.

There were no new marked developments in ironwork during the 14th century Smiths confined their efforts mostly to hinges. Up to this period the vine had been the only motif for elaborate hinges, but flat, lozenge-shaped leaves were introduced, such as at Schloss Lahneck on the Rhine.

During the 15th century grilles became more popular. One of the best examples is the grille in the chapel of Bishop Ernst. Magdeburg cathedral ic. 1498), with elaborate Gothic tracery, nine columns and a cornice. In hinges the cinquefoil displaced the quatrefoil, as at Orb, Oppenheim and Magdeburg. The Erfurt cathedral nas enriched with notable hinges having the vine pattern interpolated with rosettes and escutcheons of arms. Hinges for houses usually were the plain strap type, but when ornamented

they consisted of superimposed layers of sheet iron. As in other parts of Europe at this time, pierced sheet iron was fashioned into tracery of a semiarchitectural nature: much like Gothic windows. Pierced ornament and twisted rods were often combined to form grilles, with their extremities beaten into complicated foliage forms. German smiths were noted for their armour from the 14th through the 16th centuries.

During the Renaissance, ironwork in Germany was in use everywhere and for every purpose: for screens in churches, window grilles, stove guards, gates, fountain railings, well heads, grave crosses, door knockers, handles, locks, iron signs and small objects for domestic use. Smiths were their own designers, and more often than not planned intricate devices merely to show their skill in executing them. They set no limits to their problems, and so far as manipulative excellence went, they were the foremost nation of Europe. But clever as their workmanship undoubtedly was, their designs frequently showed a lack of stability and a tendency to run riot. Thus many of their most imposing works consist largely of filling panels with elaborate, interlacing scrollwork, and the sense of constructional and protective strength is missing.

An abundance of smiths' work is to be found in the southern parts of Germany. Iron bars, circular in section, were most frequently used, and the most common features are: interlacing bars, terminations of flowers with petals and twisted centres, foliage or human heads. All of these characteristics occur with almost monotonous repetition, witnessing to skill, but also lack of imagination and sense of design. The style may be studied in many German and Austrian cities; *i.e.*, Augsburg, Niirnberg, Frankfurt, Salzburg and Munich; the work at Innsbruck is also well known.

The German smith gave much attention to door knockers and handles, enclosing them in pierced and embossed escutcheons. as well as locks with very involved mechanism. German influence made itself strongly felt in Switzerland, Austria and Czechoslovakia.

The baroque and rococo periods are distinguished by a perfection of detail which exceeded that of German medieval or Renaissance ironwork. Although it too often lacked restraint and taste in design, the execution was amazingly skillful. Smiths used wrought iron as though it were a plastic material, meant to be employed in extravagant forms wherever possible. Some examples are at Zwiefalten. Weingarten and Klosterneuburg.

BIBLIOGRAPHY.—Ferdinand Stuttman, *Deutsche Schniedeeisen-Kunst: I–Mittelalter, II–Renaissance und Frühbarock* (1927); Lüer & Creutz, *Geschichte der Metalkunst,* a general history in German, illustrated by examples of all periods; Martin Gerlach, *Ornamente alter Schmiedeeisen* (189j), consists of 50 plates of photographs ably taken and well reproduced.

5. Italy.— The few extant examples of ironwork in Italy prior to the 14th century indicate a wide appreciation of how the material could best be worked with only the tools of the smith. Some noteworthy examples are: chancel grille at left of nave, Orvieto cathedral (1337); grille at baptistry of Prato cathedral (1345); chancel screen in the sacristy chapel of Santa Croce, Florence (1371); and the grille to the Capella degli Spagnoli, Santa Maria Novella, Florence.

In the 15th century armour was of such excellence that at a great Spanish tournament in 1434, only Italian weapons and armour were permitted — and that at a time when monumental Spanish cathedral screens had no peers.

Until the 16th century Italian smiths respected the natural characteristics of wrought iron by relying almost entirely upon those forms which could be wrought with hammer and anvil. The grille was generally made by dividing it into regular panels with vertical and horizontal bars (sometimes triangular in section and enriched with dentils). Often the quatrefoil filled some or all of these panels; they were made in Tuscany from a pierced plate, and in Venice from separate scrolls collared together. A respected example is in the Palazzo della Signoria, Siena. crowned by a *repoussé* frieze, and surmounted by a cresting of flowers; spikes and some animal heads.

It might have been thought that in the fountainhead of the Renaissance, ironwork would have proceeded at the same pace and with the same brilliant success as architecture, sculpture, bronze casting and the other arts. Strangely enough, little use of it is found in connection with the fine buildings of the revival. Bronze was favoured, and uhat in other countries is found in iron, has its counterpart in Italy in bronze. As time went on the smiths grew less inclined for the more difficult processes of hammering and welding, and contented themselves ultimately with thin, ribbon iron, the various parts of which were fastened together by collars. Work of the later periods may be distinguished, apart from the design, by this feature, whereas the English and French smiths vigorously faced the hardest methods of work, and the German and Spanish smiths invented difficulties for the sheer pleasure of overcoming them.

Notable centres of artistic ironwork were Florence, Siena, Vicenza, Venice, Lucca and Rome, where important pieces may be found in the form of gates. balconies, screens, fanlights. well covers and a mass of objects for domestic use, such as bowl stands, brackets and candlesticks.

In screenwork the favourite motif was the quatrefoil, which is found with many variations ever since the 14th century. Early examples are strong and virile, later ones tend to weakness. The C-shaped scroll is used in many combinations. The churches and palaces of Venice contain many examples. Peculiar to Italy are the lanterns and banner holders such as may still be seen at Florence, Siena and elsewhere, and the rare gondola prows of Venice. Of the ironworkers of the early Renaissance the most famous was Niccolo Grosso of Florence, nicknamed "Il Caparra" because he gave no credit but insisted on money on account. He worked at the end of the 15th century. Vasari thus eulogizes him: "He was truly unique in his craft. and has never had and never will have an equal." From his hand is the well-known lantern on the Strozzi palace in Florence, repeated with variations elsewhere in the same city. Siena can show other lanterns and banner holders attached to the facades of its palaces. Cressets are still to be seen at Lucca and a few other towns. The Victoria and Albert museum, London, contains two gondola prows, in fine pierced iron.

The decadence of 17th- and 18th-century ironwork paralleled that of architecture. Designs were borrowed directly from France and Germany. The metal was too often worked cold, using thin members and the resulting construction was flimsy. Scrolls were often encased in thin, grasslike leaves. Conventional or naturalistic floners were tacked on as seeming afterthoughts. Instead of using rods and bars, ribbonlike bands were used, with cast ornaments pinned on. Intersecting tracery was copied from Germany. The best examples of this period are confined to Venice and northern Italy, such as the screen in the south aisle chapel of San Ambrogio, Milan; the chapel enclosure in San Pietro, Mantua; and the screen in the Palazzo Capodilista, Padua.

See Guido Marangoni (ed.), *Enciclopedia delle moderne arti decorative italiane, II–Il ferro nattuto* (1926); Giulio Ferrari, *Il ferro nell' arte italiana* (1923), an Italian text illustrated with many of the best examples of Italian craftsmanship.

6. Spain.— Prior to the 15th century Spanish ironwork was basically similar to that in France and England. The Spanish smith accepted the limitations imposed by anvil and ancillary tools, but he skillfully exploited to the limit all manner of variations; *e.g.,* twisting square rods, coiling flat bars into C-shaped scrolls of all sizes and devising imaginative crestings to surmount the top of church chapel screens or domestic window grilles. Many Moorish craftsmen of extraordinary ability were enticed to remain in Spain as the Moors were slowly pushed southward; the resultant blending of Gothic with Moorish resulted in the so-called Mudéjar style.

Ironwork of the Renaissance period from about 1450 to 152j, reached a height of grandeur and magnificence attained in no other country. Of all the Spanish craftsmen the smith and the armourer were the busiest, especially during the 16th century. The particular manifestation of work in iron. which for more than a century towered above all the others, may be seen in the screens of monumental size (*rejas*) to be found in all the great cathedrals of Spain.

These immense structures, rising to 25 or 30 ft.. show several

horizontal bands or tiers of balusters, sometimes divided vertically by columns of hammered work and horizontally by friezes of hammered arabesque ornament. Usually such screens are surmounted by a cresting which is sometimes of simple ornament. but more often is a very elaborate design into which are introduced a large number of human figures. Shields of arms are freely incorporated. and the use of bright colour and gilding adds to their impressive beauty. The great balusters were always forged from the solid, and their presence in hundreds demonstrates the extraordinary skill and power of the Spanish smith. The *reja* shut off the high altar of the church or cathedral from the nave, and a further opportunity came to the smith when the choir was moved from the transept, to west of the crossing. This necessitated a second screen to enclose the east end of the choir. and naturally this screen could be in no way inferior to that in front of the high altar. Thus in many cathedrals two of these monumental *rejas* are found facing one another. It was the smith's opportunity, and he availed himself to the full. Monumental *rejas* may be seen in all the large cathedrals of Spain—Barcelona. Saragossa, Toledo, Seville. Burgos. Granada. Cordova and many others.

Ironwork on a smaller scale is found in gates, balconies and window screens; wrought-iron pulpits also exist. The panels of hammered and pierced iron, heightened with colours and gilding, were used in connection with domestic architecture; many doors were ornamented with elaborate nailheads or embossed studs.

C. United States

1. Early History.— The characteristics of the earliest ironwork in the various colonies naturally reflected those of the parent countries. The English were more sparing in its use in the Sew England colonies. than were the Germans in Pennsylvania or the French in Louisiana. In the 17th and 18th centuries ironwork was used mostly for such practical purposes as weathervanes. foot scrapers. strap hinges, latches. locks and particularly for the necessities and conveniences for fireplaces (firedogs. cranes, skewers. toasters, kettle warmers and spits). It was not until the late 18th century. nhen the threat of Indian raids and food shortages had waned, and the established communities enjoyed a sense of tranquility and prosperity, that smiths fashioned wrought iron into railings, fences, grilles, gates and balconies. Square or flat iron bars were generally used to produce designs that were usually light, airy and graceful, and rather in contrast to the contemporary European preference for sturdier forms.

The revolt against English political rule was reflected in the decline of English ironwork traditions, and in the steadily increased acceptance of the work by French and German craftsmen throughout all the 13 colonies.

Gradually ironwork designs tended to develop characteristics of an American or composite nature, as a logical consequence of the diverse origins of colonists and smiths. An innovation, which appeared toward the end of the 18th century, was the combination of structural wrought-iron rods or bars. nith lead or cast-iron ornamental features. While the use of wrought iron declined during the 19th century, during its last quarter the use of cast-iron columns and panels for non-residential buildings increased. These designs. timid or bold, decorative or structural, engendered the prototypes of commercial buildings for the ensuing decades.

Unfortunately the longevity of structures in U.S. cities has been short. There are fen examples of 18th or early 19th century iron-aork extant in New York. not many more in Boston, some in Philadelphia, but more in and near Washington, D C.. such as the excellent balconies and railings at the Octagon (headquarters of the American Institute of Architects). Charleston, S.C., has a rich legacy in gates. notably those at numbers 12, 23 and 36 Legare street, 63 Meeting street, and the unusually beautiful pair at St. Michael's church. The latter is credited to Justi. who came to Charleston from Germany in 1820. Two other gifted German artisans who settled in Charleston. were Werner in 1828, and Julius Ortman in 1847,

New Orleans has more ironwork than other U.S. cities, thanks to a group of citizens dedicated to the preservation of the old French Quarter. Its earliest ironwork was forged by Spanish and French smiths. Unfortunately fires, rust and remodeling have so taken toll of the Spanish ironwork, that almost the only remaining example of importance is the gateway of the Cabildo (town hall). It has moldings beaten from solid bars, like mady of the old *rejas* in Spanish cathedrals. After the Louisiana purchase in 1803. the influx of ironworkers from northern states brought about a broadening of influences that are apparent in designs and techniques. Ironnork of New Orleans can be roughly divided into three periods: (1) forged wrought iron by French and Spanish artisans with strongly marked European characteristics; (2) a transitional period nith wrought-iron structural members embellished nith cast-iron ornaments in the Directoire and Empire styles of France. plus some U.S. innovations; and (3) entire grilles, screens and treillage made entirely of cast iron. No other city in the U.S. has two- and even three-story iron porches and balconies which can compare with those of New Orleans. Some

of these lacy structures were built above the sidewalks, such as those on St. Peter street. Balconies sometimes not only extended across an entire façade, but continued undaunted around a corner, as on the original building of the Little theatre.

2. Mid-19th Century Onward.— Distinctive national characteristics in the design of ironwork gradually tended to disappear in Europe, due to increased travel and communications between countries. The influence of French Renaissance architecture (modified or revived) continued to exert a viable effect where the acceptance of the *art nouveau* (last quarter of the 19th century) was flaccid or denied. However, in England 18th century designs continued with slight modifications. In the U.S. probably the most important force, prior to World War I, was exercised by architects trained in Paris, with the result that ironwork designs were very similar to French work of this period.

The increased mechanization of all forms of manufacture understandably affected the character and use of ironwork. As the cost of cast iron came down, its use increased. Because wrought iron is produced by hand by beating red-hot iron on an anvil. not much change was possible through increased mechanization. whereas the casting of molten iron lent itself to improved equipment and techniques. The lowered cost of duplicating ornamental cast-iron components, the introduction of structural steel parts, and the widespread acceptance of porches and shop fronts made of iron, expanded the usage of ironwork to the modest building. whereas it had been generally confined to public or monumental structures. Foundries in the U.S. established a flourishing business in pierced cast-iron panels. modeled after Louisiana porch treillage.

Compared with prior periods, the last half of the 19th century will scarcely be commemorated as introducing enduring or beautiful ironwork forms. It was not until the first quarter of the 20th century that a master craftsman-designer gave impetus to a new conception of design forms and textures. Edgar Brandt of Paris broadened the scope of decorative usage by the rich inventiveness of his compositions, and by an entirely original approach which resulted in a wrought-iron texture that is akin to beaten silver. Examples of his work at the Exposition des Arts Decoratifs Moderne at Paris in 1925 had an immediate effect upon ironwork designed and executed in the U.S. during the great building boom which lasted until about 1930. During this period both wrought and cast iron enjoyed an unprecedented period of popularity, not only in the form of bank screens. entrance doors and grilles in commercial or public buildings. but as decorative grilles and gates in expensive private homes. In many cases the craftsmanship equaled that of representative examples of the Gothic or Renaissance periods in Europe.

One of the most gifted and dedicated iron craftsmen in the U.S., Samuel Yellin of Philadelphia. raised the standards of wrought-iron craftsmanship to its apex during the 1920s. He not only trained an atelier of craftsmen for the first time in the U.S., but by his efforts, nrought iron was recognized as being capable of enriching even the most monumental building. Yellin's influence was brought to an untimely termination by the depression of the early 1930s. As building activity declined after 1930, so did the use of ironwork, but it did not increase with the revival of building after World War II.

11. *TECHNIQUE*

A. WROUGHT IRON

Wrought iron is the type of ironwork that is forged on an anvil. There are no fabrication similarities to cast iron. which is poured in a molten state into prepared sand molds. There are three kinds of iron, whose physical characteristics vary chiefly according to their carbon content: wrought iron has .04%; machine, open-hearth or Bessemer steel has .2% to .6%; cast iron has 2% to 6%.

1. Properties.—Wrought iron is fibrous in structure and light gray in colour. It can be hammered, twisted or stretched when hot or cold. The more it is hammered, the more brittle and hard it becomes. but it can be brought back to its original state by annealing (heating and then cooling slowly). It will not shatter u hen dropped

The grade of wrought iron least susceptible to rust, yet the most malleable and tough. is called Norway or Swedish iron. Among the chief sources of the ore are the bottoms of shallow Swedish lakes, where from 4 to 6 in. are deposited over a period of 15 to 30 years The usual forms of wrought iron available to the craftsman are rods or bars, and thin plates. It is from these that his final product must be fashioned on an anvil.

2. Fabrication.— From earliest times. the smith has had a forge to heat the iron, an adjacent water tank in which to cool it, an anvil on which to form it, plus a wide assortment of hammers and tools. One of the few changes has been the mechanization of the blower at the forge, in place of the hand- or foot-operated bellons. The smith knows from the colour of the heated iron when it is at the optimum temperature for a specific operation; dark red

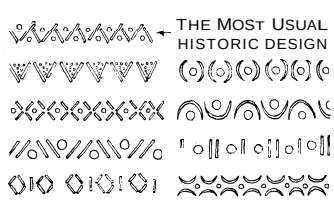
FIG. 3.— DRAWING SHOWING THE DECORATIVE POSSIBILITIES INHERENT IN TWISTED BARS

indicates suitability for surface finishing; bright or light red show that the iron is malleable but the surface will scale and it is therefore not suitable for finishing; light yello denotes a good forging temperature; and uhite designates the correct temperature for welding

The most important tool is the anvil. The English type, generally used for forging wrought iron, has a flat. top surface. which is used as a solid base for hammering the heated iron into shape, for welding, for splitting or for incising decorative chisel marks

in the hot iron. One end of the anvil is shaped like a pointed cone, and is used for forming curved surfaces. The other blunt end, or heel, has one or two square or rectangular holes on top, into which fit various tools which are used for holding one end of a bar, making twists or holding scroll forms.

3. Design.—The two most important factors in wrought-iron design, are: (1) the form of the material (bars, rods and thin sheets); and (2) the relatively short time period in which iron can be forged while hot. Although the Spanish craftsmen of the late 15th century proved they could work almost impossible shapes in their unsurpassed cathedral grilles, this type of ironwork is not considered a realistic exploitation of the material. Ideally wrought-iron design should use forged bars and rods in imaginative forms, practical, yet decorative. Ornamentation is most successful when it is an integral part of the design (twisted bars, scrolls, chisel mark incisions, etc.), rather than a realistic imitation of nature, riveted on afterward. From the anvil is derived the expression, "to strike while the iron is hot," and this implies spontaneity and rapid hammer blows. The wrought-iron craftsman should not be expected to repeat with meticulous exactitude one intricate component after another. In fact, wrought iron by a master craftsman is esteemed for the variations which naturally occur.



FROM WROUGHT IRON IN ARCHITECTURE BY GERALD K GEERLINGS COPYRIGHT 1929 CHARLES SCRIBNER S SONS RENEWAL COPYRIGHT 1957 GERALD K GEERLINGS RE PRODUCED BY PERMISSION OF THE PUBLISHER

FIG. 4.—CHISEL-MARK ORNAMENTATION

The individual components of a wrought-iron design are often plain or twisted rods, with or without chisel mark incisions. They are frequently composed as a series of straight, parallel members, or in combination with scrolls, or a repeat design of some geometric shape such as the quatrefoil. Where two curved members are tangent, they are characteristically secured together by bands or collars, rather than by welding. Where two straight bars intersect, it is accredited craftsmanship to make the vertical bar pierce or thread the horizontal member. Grilles consisting of two series of parallel small-diameter rods, one series at right angles to the other, were sometimes interlaced or woven in decadent periods.

The term *repousse'* refers to three-dimensional, ornamental wrought ironwork. Depending upon the depth of the relief; various fabrication techniques may be employed. Sheets $\frac{1}{16}$ in. or less in thickness, generally are used. The general configuration of the modeling is obtained by beating the back of the sheet; the final details are embossed on the front face, The finer the scale and detail, the more work which must be done when the iron is cold. *A repousse'* design may be pierced, but this term usually connotes a solid sheet forged into a mask, a shield or an entire embossed panel. The traditional means of setting off a cutout *repousse'* design was to superimpose it on a vermilion-coloured background panel. Modern approximations of *repousse'* work consist of mechanically stamped designs touched up with random hammer blows.

4. Care.—The texture of wrought iron is one of its principal assets, so painting it in order to prevent rust. is not nearly as desirable as preserving the highlights of the original finish with wax. Professional craftsmen recommend removing all traces of rust by rubbing with emery cloth, augmented by a few drops of turpentine if the rust is heavy. Then the entire surface should be rubbed with any good liquid floor wax, or beeswax dissolved or softened in turpentine. After about 15 minutes when the wax has set, the surface should be rubbed with a soft cloth. This treatment should be repeated about once every three months.

B. Cast Iron

1. Properties.—The carbon content of cast iron varies from 2% to 6%. Cast iron is melted in a furnace or cupola, stoked with alternate layers of coking iron, then poured into prepared sand molds. After the cast iron cools in the mold, the sand is cleaned off, and the work is virtually complete. Its shape is fixed, and while a casting can be slightly trued up by the judicious use of a hammer, it is in no sense as workable as wrought iron. Because it is brittle, it is almost certain to shatter if dropped.

2. Fabrication.—An iron casting is not the creation of a single craftsman, but the combined result of the skilled efforts of several groups of artisans. There must be an architect's or designer's drawings at full size, showing in detail all the features of the design. From these dranings full-size models or patterns must be made in wood, plaster or wax, depending upon the nature and the intricacy of the casting to be made. These patterns must be made slightly over-sized, according to a shrinkage scale; when the molten iron cools it will be slightly smaller than the patterns used in the molds.

The next step is to use the patterns to make sand molds, into which molten cast iron will be poured. For each casting there must be one sand mold for the back face of the casting (the cope), and another for the front or finished face (the drag). These two molds must be made so that when fitted and clamped together, there will be a space between. When this space is filled with molten metal and cooled, the result will be a casting with the desired size, shape, thickness and surface ornamentation of the pattern. If the casting is to be an ornamented panel, with a raised centre portion, a wood pattern might be used, with the ornamentation either carved in wood or applied. The drag mold (for the front face of the casting) is prepared by first placing on the foundry floor a plain-surfaced follow board. The pattern is placed on this, face up, supported by a bed board, in cases where the pattern has a raised centre portion. A parting powder is dusted on the face of the pattern (so that at a later stage the sand will not cling to the pattern when it is removed). Then the pattern is sprinkled or riddled with facing sand, which is firmly rammed as it is added. Finally heap sand is added until the rectangular, boxlike drag is filled to the top edge. A bottom board is then clamped on the top to hold the pattern and sand in place. Then the entire drag is turned upside down. The bed board, which had been on the floor and now is on the top, is removed. The pattern is then very carefully withdrawn from the sand, and its imprint inspected to be certain that it is a precise duplicate (reversed of course) of the pattern. Slight imperfections in the sand surface are filled if necessary. and loose sand is removed.

The next step is to repeat the same process for the cope, the sand mold for the back face of the casting. When completed, there thus will be two rectangular boxes, each rammed with sand, bearing the imprint of the pattern, and a space between them equal to the thickness of the metal. The drag remains on the foundry floor, but the cope is superimposed, being lifted in place with a crane if it is large. The sand of the (upper) cope mold has funnel-shaped openings provided (sprues), into which the mol-

FIG. 5.— MOLTEN METAL BEING POURED INTO A MOLD

ten metal will be poured. Horizontal grooves are then made in the sand of the cope called gates. which will provide tunnels for the metal to flow from the vertical sprues. In addition, there are risers (grooves in the sand located as far as possible from the sprues) to allow gases and displaced air to escape. The molten cast iron is ladled until the metal begins to fill the risers. When pouring a very large casting, a reservoir or pouring basin is provided above the cope, to contain sufficient molten metal to supply the entire mold simultaneously.

Technical metallurgical knowledge is required both in preparing the cast iron in the furnace or cupola, and in determining when the iron is right for pouring. Mechanical skill is necessary in ladling the molten metal from the cupola into the mobile mixing ladle, and from the latter to the prepared sprues of the cope. Foundries usually operate on a schedule so that the pouring of all molds is done toward the end of the working day. About two or three minutes after a mold is poured, the iron is said to be set. At this stage there are two foundry practices. In one, the clamps which hold the cope and drag together, are loosened, the cope is removed, and the molder in charge estimates where the casting should be entirely uncovered or "stripped" of sand, or, whether to uncover only those parts of the casting which have the thickest metal, and to retard those areas where it is thinnest by shoveling on more sand in order to equalize the shrinkage rate between thick and thin parts. Skilled manipulation at this point determines the difference between a casting that is true and satisfactory, and one that is warped. and will consequently require tedious labour to straighten out. On the other hand, some foundries allow the casting to cool as slowly as possible, without removing any sand, and perform any straightening later. A casting which has cooled slowly is more readily straightened than one which has done so quickly.

FIG. 6.— CAST-IRON FABRICATION: TOP, DRAG BEING PREPARED; CENTRE. DRAG IN POSITION. WITH COPE SUPERIMPOSED. BOTTOM. COPE FROM ABOVE WITH GATES AND RISERS SHOWN

Key: (A) Follow board; (B) Bed board; (C) Pattern; (D) Drag outer frame; (E) Bottom board; (F) Cope outer frame; (G) Sprues; (H) Gates; (J) Gaggers to reinforce the sand; (K) Risers

After the castings have cooled overnight, they are sandblasted to remove any sand that may adhere. Unwanted protuberances, such as those nhere gates and risers were located. are ground or cut off. Following this, the process is not unlike the operations in a woodworking shop; edges and surfaces that must conform to narrow tolerances are trimmed and planed. Ornamental features in cast iron cannot be chased and polished as in cast bronze If the ornamental cast-iron details are not replicas of the original pattern, the only recourse is to make a new casting. *See* also CAST IRON.

3. Design.—From the foregoing description of fabrication, it is obvious that certain forms are more suitable to cast iron than to wrought iron For example, if repetitive balusters or columns, or panels nith low-relief ornamentation are desired, cast iron is the most suitable material In the U S. excellent examples are to be found in the cast-iron railings and porches of Charleston, S C , and New Orleans. Some of the patterns used in the 19th-century, are still being used today. The same is also true of ornamental fire backs (for the rear of fireplaces). Some good examples of 20th-century cast ironwork are. the imposing entrance and window spandrels of the Fidelity Mutual Life Insurance building. Philadelphia (Zantzinger, Borie & Medary, architects); the window frames and panels of the Integrity Trust Company building. Philadelphia (Paul Cret. architect); the entrance and show window of the Packard Motor building, Philadelphia (Albert Kahn. Inc.. architect. and Philip S. Tyre, resident architect) ; the mullions and window spandrels of the Home Savings bank. Albany, N.Y. (Dennison & Hirons, architects) ; and the entrance to the Federal Trust building. Newark, N.J. (Dennison & Hirons, architects. George E. Jones, associate architect).

4. Care.—The material has a fairly uniform, cold, gray colour when the casting is cooled and cleaned. The usual finish procedure is to give the casting an initial coat of red lead. red oxide of iron paint. or a gray priming coat, followed by whatever final coat is desired. If there is delicate modeling which will be lost under successive coats of paint, it is recommended practice to burn off the old paint, and start off again with a priming coat, followed with a finish coat.

(G. K. G.)

IRONY, a form of speech in which the real meaning is concealed or contradicted by the words used (Gr. *eironia* from *eiron,* "one who says less than he means"). It is particularly employed for the purpose of mockery or contempt.

The Greek word was used for an understatement in the nature of dissimulation. It is especially exemplified in the assumed ignorance which Socrates adopted as a method of dialectic, the Socratic irony (see SOCRATES). In tragedy. what is called tragic irony is the device of making a character use words which mean one thing to him and another to those acquainted with the real issue.

IROQUOIS. During the colonial period the Iroquois were. north of Mexico, the native American people of greatest political importance. The name has been adopted for the entire linguistic family of which they were the most conspicuous representatives.

The Iroquoian family occupied three territories, a northern, southern and southeastern. In the northern area there lived, besides the Iroquois proper, the Conestoga or Susquehanna in Pennsylvania; the Erie and Neutrals south and north of Lake Erie; the Tionontati or Tobacco nation, and the Huron (*q.v.*) in Ontario; and a series of tribes on the St. Lawrence later merged with the Huron. The southern division consisted of the Cherokee (*q.v.*); the southeastern, of the Tuscarora (*q.v.*), Nottoway and Meherrin. These tribes were all semisedentary, practised maize agriculture, lived in villages palisaded in time of need. were divided into totemic, matrilineal clans, and manifested tendencies toward the formation of fairly cohesive confederacies. in which blood lineages integrated in clans, clans in tribes and tribes in leagues. Religion was relatively simple on the ritualistic side, and somewhat interwoven with political ceremonial. Warfare was frequent and ruthless, captives being either tortured, enslaved or adopted. In all these traits the Iroquoian tribes resembled the Muskogian (*q.v.*), and differed somewhat from the Algonkin (*q.v.*), who were patrilineal, on the whole less given to farming, less developed in political sense and cohesiveness. and less aggressive in warfare though perhaps equally brave. It is therefore likely that a culture of Algonkin type. probably carried by Algonkin peoples, once prevailed uniformly over northeastern United States and eastern Canada, and that into this there intruded cultures and peoples of southeastern origin, first the Mound Builders (*q.v.*) in the Ohio valley. and later the northern Iroquoians in the region of the lower Great Lakes; the aboriginal Algonkin, however, surviving as a fringe completely surrounding these north Iroquoians. In New York, where archaeological exploration has been unusually well co-ordinated, its results confirm this view. The most notable point of difference between the northern Iroquoians and the Cherokee and Muskogi of the southeast seems to be the somewhat higher status of woman among the former.

LEAGUE OF THE IROQUOIS

The Iroquois proper of history comprise the Mohawk, Oneida, Onondaga, Cayuga and Seneca, living in this order from east to n-est in central New Tork. According to tradition. Hiawatha, a Mohawk, and Dekanamida, reputed a Huron by birth, induced the five tribes to form a league which preserved the integrity of each, but united them in a common council, and common ceremonies, with a fixed number of chiefly delegates from each tribe. In a sense this was representative democracy; and each delegate was elected; but he was chosen by the members of a lineage as representative of that lineage, and therewith of a clan and tribe, so that a group-hereditary principle prevailed. Each such clan delegate had further to be approved by the tribal and league council. There was no head of the league; and deliberate action usually became effective only upon unanimity. Apparently this league differed from other native confederacies. which were common in the eastern United States and southeastern Canada, in being more precisely defined and organized. It allowed of the development of a tradition of political sagacity independent of the occasional superior individual, and this in turn permitted the fruits of wars to be conserved instead of dissipated, with success still further strengthening the established policy.

The league in its historic form is estimated to have been constituted only a generation before the coming of the whites among the Iroquois. about 1570. During this formative period the Iroquois drove from the St. Lawrence a series of tribes who joined the Huron. In the first half of the 17th century they harried and wore down the Conestoga, their kinsmen on the south, and the Algonkin tribes on their east. Their most striking successes came about the middle of the century, after they had acquired guns in friendly trade with the Dutch. In rapid succession they attacked and broke up four Iroquoian tribal aggregations to the west of them: Huron, 1648–50; Tionontati. 1649; Neutral, 1650–51; and Erie, 1653–56. Parts of some of these nations were transplanted among the Iroquois, where they gradually became absorbed; remnants fled. scattered. joined one another or alien tribes and became lost to history. The completeness of their destruction was perhaps partly due to their habit of concentration in large palisaded towns; the more scattered Algonkin generally withstood the Iroquois longer. The Illinois suffered badly at the hands of the Iroquois. the Delaware submitted in 1720 and all Virginia was harassed. Only the distant Ojibwa set a boundary to the Iroquois conquests in the west, and the Cherokee and Catawba of North Carolina to the south. though the latter were almost worn down in the struggle. The Tuscarora, an Iroquoian tribe of North Carolina who had voluntarily moved to New York. were formally admitted into the confederacy about 1715, this being henceforth the League of Six Nations. Other tribal remnants of various origin sought shelter with them, and these, with the absorption of captives, helped to make up the Iroquois losses in constant warfare. At that, the five tribes probably never numbered more than at present, 16,000.

From the first the Iroquois were consistent and bitter enemies of the French. who had shown amity to their traditional foes. They remained in friendship and trade with first the Dutch and then the English. who utilized them against their Indian enemies and the French, whereas the Iroquois profited in firearms. other trade articles, and the sanction if not protection of civilized powers. They undoubtedly greatly hampered French extension from Canada southward: but for the consistent Iroquois check, the English colonies would have been flanked behind by the French and the history of their development might have been very different. This is a remarkable achievement for a savage people that never put into the field an army greater than 2,000 men.

When the American Revolution broke out. the league as such took no part. but most of the tribes sided with the British: and were defeated by the Americans. The Mohawk and Cayuga mainly withdrew to Ontario, many of the Onondaga and Seneca remained on reservations in western New York and part of the Oneida after a time moved to Wisconsin. The present population is considerably diluted with white blood; two-thirds are on Canadian soil, including the descendants of seceding groups won over to the French inter-st at the end of the 17th century. The league is still perpetuated as a ceremonial form. (A. L. K.)

IRRATIONAL NUMBER: see NUMBER.

IRRAWADDY or IRAWADI, the principal river of Burma, traversing the centre of the country, and running throughout its entire course in British territory. It is formed by the confluence of the Mali and N'mai rivers (usually called Mali-kha and N'mai-kha, the khn being the Kachin word for river) in 25° 45′ N.

The N'mai is the eastern branch. The definite position of its source is still uncertain, and it seems to be made up of a number of considerable streams. all rising within a short distance of each other in about 28° 30′ N. It is shown on old maps as the Lu river of Tibet; but it is now quite certain that the Tibetan Lu river is the Salween. and that the N'mai has its source or sources near the southern boundary of Tibet, to the northeast or east of the source of the Mali. At the confluence the N'mai is larger than the Mali. The general width of its channel just above the confluence is 350 or 400 yd. In the rains this channel is filled up, but in the cold weather the average breadth of the river is from 150 to 200 yd. The N'mai is practically unnavigable. The Mali is the western branch. Like the main river, it is called Nam Kiu by the Shans. It rises in the hills to the north of the Hkamti country in about 27° 50′ N. Between Hkamti (*q.v.*) and the confluence it runs in a narrow channel through continuous hills. About 1 mi. above the confluence it is 150 yd. wide in January and 17 ft. deep, with a current of $3\frac{3}{4}$ mi. per hour.

Steam launches can only ascend from Myitkyina to the confluence in the height of the rains. Native boats ascend to Laikaw or Sawan 26° 2′ N., all the year around, but can get no farther at any season. From the confluence the river flows in a southerly direction as far as Bhamo. then turns west as far as the confluence of the Kaukkwe stream, a little above Katha. where it again turns in a southerly direction as far as the great bend near Mandalay, where it is joined by the Myit-nge. Thence it follows a westerly course and is joined by the Mu stream—an important source of water for irrigation in the Shwebo district—on the north bank. Beyond Myinmu it again assumes a southerly direction and is joined by its chief tributary, the Chindwin, described below. Between the confluence and Mandalay the river varies in width from 50 to 4.000 yards. It is narrowest in the three well-known defiles. The third or upper defile lies between Myitkyina and Bhamo and is entered 3 mi. below Sinbo by a channel only about 50 yd. wide and below this, throughout the defile, it averages about 100 yd. wide.

At the "Gates of the Irrawaddy" at Poshaw two prism-shaped rocks narrow the river to 50 yd.. and the water banks up in the middle with a whirlpool on each side of the raised pathway. All navigation ceases here in the floods. The defile ends at Hpatin, and below this the river widens out to a wet-season channel of 2 mi., and a breadth in the dry season of about 1 mi. At Sinkan, below Bhamo, the second defile begins. It is not so narrow nor is the current so strong as in the third defile. The narrowest place is more than 100 yd. wide. The hills are higher, but the defile is much shorter. At Shwegu the river leaves the hills and becomes a broad stream, flowing through a wide plain. The first defile is tame compared with the others. The river merely flows between low hills or high wooded banks. The banks are covered at this point with dense vegetation, and slope down to the water's edge. Here and there are places which are almost perpendicular, but are covered with forest growth. The course of the Irrawaddy after receiving the waters of the Myit-nge opposite Sagaing, as far as 17° N. lat., is exceedingly tortuous. Below the junction of the Chindwin and Irrauaddy, the tributary streams throughout the dry belt are but small, though some, especially those in the Minbu district, are important sources of water for irrigation, and others, like the Taw river, are used for floating teak logs to the main river. At Akauktaung, where a spur of the Arakan hills ends in a cliff 300 ft. high, the river enters the delta, the hills giving place to low alluvial plains, now protected on the west by embankments. From 17° N. lat. the Irrawaddy divides and subdivides, converting the lower portion of its valley into a network

of intercommunicating tidal creeks. It reaches the sea in about 16° N. lat. by nine principal mouths. Practically no water, however, now reaches the sea through the western and eastern mouths (the Bassein and Rangoon rivers respectively) though these are the ones used by sea-going ships to reach the ports of Bassein and Rangoon.

The largest tributary of the Irrawaddy is the Chindwin, its entire course being in Burmese territory. It is called Ningthi by the Manipuris. The Chindwin is formed by the junction of the Tanai, the Tawan and the Tarôn or Turông, but it is still uncertain which is the main stream. The Tanai previously was looked on as the chief source. It rises in about 25° 30' N. and 97° E.. on the Shwedaung-gyi peak of the Kumôn range, 12 mi. N. of Mogaung, and flows due north for the first part of its course until it reaches the Hukawng valley, when it turns to the west and flows through the middle of the plain to the end of the valley proper. There it curves round to the south, passes through the Tarôn or Turông valley, takes the name of the Chindwin. and maintains a general southerly course until it enters the Irrawaddy, after flowing through the entire length of the Upper and Lower Chindwin districts.

The Tarôn, Turông or Towang river seems to be the real main source of the Chindwin. It flows into the Hukawng valley from the north, and has a swift current with a succession of rapids. Its sources are in the hills to the south of Sadiya, rising from 10,000 to 11,000 ft. above sea level — mountains that are covered at least with winter snows. Below the Hukawng valley the Chindwin is interrupted at several places by falls or transverse reefs. **At** the village of Haksa there is a fall, which necessitates transshipment from large boats to canoes. Not far below this the Uyu river comes in on the left bank at Homalin, and from this point downward the steamers of the Irrawaddy Flotilla company ply for the greater part of the year. The Uyu flows through a fertile and well-cultivated valley, and during the rainy season it is navigable for a distance of 150 mi. from its mouth by steamers of light draught.

The area of the catchment basin of the Irrawaddy is 158,000 sq.mi.; the total length of the main river from its known source to the sea is about 1,250 mi. Throughout its course, except through the defiles, it is full of islands and sandbanks; its waters are extremely muddy, the mud being deposited partly in the delta, in part being carried far out to sea. The river commences to rise in March; about June it rises rapidly, and attains its maximum height about September. The total flood discharge is between 400,000,000 and 500,000,000 metric tons of 37 cu.ft. From Rangoon up to Bhamo the river is navigable a distance of nearly 900 mi. for large steamers all the year round; but small launches and steamers with weak engines are often unable to get up the second defile in the months of July, August and September, owing to the strong current. The Irrawaddy Flotilla company's steamers go up and down several times a week, but the mails are carried to Bhamo by a ferryboat from the railway terminus at Katha.

The river Irrawaddy itself supplies no main irrigation works; the great value of the river is as a highway. It is the only means of reaching such important centres as the oilfields of Yenangyaung and Singu. which are served as yet neither by road nor railway. The Irrawaddy is nowhere bridged. though crossed by two steam ferries (at Henzada and at Sagaing) to connect the railway system on either bank. (L. D. S.)

IRREDENTISTS, an Italian patriotic and political party which was prominent in the last quarter of the 19th century. The name was formed from the words Italia irredenta — unredeemed Italy — and the party had for its object the emancipation of all Italian lands still subject to foreign (*i.e.*, Austrian, French and British) rule. The lands which they claimed as Italian were south Tirol (Trentino), Gorz, Istria, Trieste, Tessino, Nice, Corsica and Malta. The agitation was, however, mainly superficial, and sank into insignificance when the French occupation of Tunis in 1881 offended the Italians deeply, and their government entered into those relations with Austria and Germany which led to the Triple Alliance. The name "Irredentists" is also used of any other nationalist group aiming at the emancipation of any of their countrymen subject to foreign control.

IRRIGATION is the artificial application of water to land. Modern irrigation and the associated practices of drainage, fertilization, mechanization and mass production for special markets under professional management are producing a revolutionary efficiency in agriculture that, along with an attractive and profitable way of life, best guarantees food and fibre for the fast-growing population of the world.

Normally vegetation grows on soil watered by rain. Where rain is so seasonal that it does not meet the requirements of a particular crop or is deficient or practically nonexistent, the drying of the soil to an ever increasing degree retards, until it eventually prevents, vegetable growth. Irrigation can give better results than nature itself produces by fitful rainfall, because water can be given regularly just when it is needed.

This article briefly sketches the historical background of irrigation and the development of ancient and modern mechanical aids, and deals with methods of securing irrigation water, storage of water, legal title to water, principal systems of irrigation, little-used systems, drainage in relation to irrigation, irrigation practices, supplemental irrigation and a brief survey of irrigation throughout the world in the second half of the 20th century. For another method of farming with a limited natural supply of water see DRY FARMING. For additional information on irrigation projects see DAMS. See also separate articles on individual states and countries, as EGYPT; IDAHO; etc., and on rivers, as COLORADO RIVER; NILE; etc. See also GROUND WATER; HYDROLOGY; SOIL.

I. HISTORICAL BACKGROUND

The use of irrigation as an aid to the growth of vegetation is an ancient art. (See AGRICULTURE, PRIMITIVE.) The probabilities seem to point to Egypt as its place of origin. The paintings and sculptures of ancient Egypt show that the peasantry bailed up water at least 4,000 years ago, and there is evidence of earlier irrigation there and in other parts of the ancient world which strengthens the belief that irrigation preceded, and made possible, the development of ancient civilization. Reliance was not placed entirely on direct labour; mechanical aids were invoked, and such machines as the shaduf, the sakia and Archimedes' screw were invented.

1. Ancient Mechanical Aids. — The simplest device for lifting water consists of a long tapering and nearly horizontal pole supported on a horizontal crossbeam some eight feet or ten feet above the ground. A skin or bucket is hung on a rope from the longer

and thinner end and a counterbalance placed on the shorter and thicker end. The worker pulls down on the rope to fill the bucket, after which the counterbalanced end drops and raises the bucket of water to his hand where it is emptied. Each of these devices can irrigate about two acres and two or more of them can be placed one above another for the higher lifts. In Egypt this is called a shaduf or shadoof, while in India the name is *denkli* or paecottah.

The Egyptian sakia (called a *harat* or Persian wheel in India) is operated by oxen. It is so arranged that a vertical wheel turns continuously. Two parallel endless ropes pass over the wheel and are attached to buckets spaced a short distance apart. While half the buckets are descending and filling, the other half are rising full of water. At the top they tilt automatically into a prepared channel leading to the field. Each machine can irrigate from 5 ac. to 12 ac., depending on the height of the lift.

The most ingenious of these old devices is the Archimedes' screw which was invented about 200 B.C. in Syracuse. A corkscrew-shaped tube is placed in or around a wooden cylinder some one or two feet in diameter. One end of this 10- to 15-ft. cylinder is under water and the other end rises about 3 ft. to the bank where water is discharged as the cylinder is rotated by hand. Knowledge of these mechanical aids probably spread to other ancient empires. All are still in constant use.

2. *Modern Mechanical* **Aids.**—Not until the era of steam, the internal-combustion engine and electricity, which brought with it the power to drive pumping plants of all kinds, was human and animal life relieved of almost all the duty of directly lifting water onto the soil. Irrigation makes use of such pumping plants in all sizes, ranging from one- or two-horsepower engines up to huge installations whose power is measured in thousands of horsepower and which are capable of dealing with great volumes of water.

Electric motors are now generally used for the larger pumping plants, diesel engines for those of moderate size and gasoline or liquid petroleum gas engines for smaller plants. Portable plants are available for areas up to several hundred acres. Usually the power and pump are directly connected in a single unit. Centrifugal pumps are preferred for lifting from open water while turbine pumps are used in wells of a few feet to hundreds of feet in depth. The axial-flow or propeller pump that was developed in New Orleans, La., for drainage of that city, is best for lifting large volumes of water through low heads or differences in elevation. Each power plant and pump is designed by hydraulic engineers especially for the work which it is to accomplish.

An important mechanical development after World War II was the use of 20- to 40-ft. lengths of lightweight portable aluminum pipe with special couplings which permit the pipe to be quickly assembled, dismantled and moved to a new location on the surface of the ground. This is especially useful in portable irrigation systems where the pipe is laid quickly over the ground, then dismantled and moved to another tract of land by one or two men, thus minimizing the investment necessary.

II. METHODS OF SECURING IRRIGATION WATER

Much irrigation water is pumped from ponds, reservoirs, lakes, streams, canals, pits and wells, occasionally as high as several hundred feet for valuable crops. The more abundant and cheaper water supplies are found in the larger streams and usually are obtained therefrom without pumping by diversion dams. Often these structures raise the level of the water in the river and sometimes provide storage. From them, canals and many other types of structures convey and distribute the water over the land.

1. Canals.—Man was not satisfied with his efforts to supply water to the fields and early saw that he could assist nature by taking nater from a river at a point higher upstream than the point immediately opposite his onn particular field, and thus take advantage of the difference of level betneen these two points, or the fall of the river. Take the case of the fall of a river being only 12 in. in one mile—as is not unusual. As some slope must be given to the water in a canal to make it flow, and if this is, say, six inches in one mile, the canal water will stand higher by six inches at the end of each mile of length than the river opposite to it. Obviously, therefore, if there is much difference between the level of the land that is to be irrigated and the water surface in the river at the point where the water is led into a canal, the latter, to be effective, must take off many miles upstream of the areas it is intended to serve.

2. *Diversion Dams.*— That the use of diversion dams (also called weirs or barrages) as an aid to heightening water level is old there is no doubt, yet only in modern times has the idea been used to any great extent. These structures are built across a river so that a higher level can be produced on the upstream side of the dam simply by closing sufficiently the sluices, or gates, placed in them. This enables the water floning at the higher level to irrigate the land much nearer the headuorks of the canals taking off from either bank. Thus these structures, like the canal already mentioned, are devices for doing, almost forever without any further labour than adjusting the sluices. what hitherto had to be done, laboriously and expensively, by the aid of manual or mechanical work.

When these structures are necessary in those parts of a river's course where there is no other foundation than sand or silt, water is seldom raised more than ten ft. Whatever heading up of the waters is necessary, it should avoid reducing the silt-carrying power of the river.

III. STORAGE OF WATER

1. Reservoirs.— At an early stage man must have realized the advantage of storing water against periods of shortage, as rivers and wells run low at times even if they do not run dry. At what date reservoirs first came into use as an additional aid to a regular supply is unknown; the remains of ancient reservoirs throughout the world, however, testify to the antiquity of the idea.

The earliest form was probably the earthen embanked reservoir, or tank, as it is called in India. The tank suffers from the disadvantage of retaining all the silt contained in the water stored in it. In time this leads to practical obliteration and a new tank has to be constructed elsewhere. Reservoirs with masonry dams were also built. These, too, became filled with silt, and not until modern times, and until the Periyar dam was built in India (1895) with sufficient sluiceway near its base to pass all the floodwaters and arrest only the later clean supply, was the problem tnet and a reservoir constructed which, in a silty river area, could be depended upon to keep itself clear of detritus. A magnificent example is the dam at Aswan, on the Nile in Egypt (1902–33), where the whole of the heavy flood passes through the structure without dropping any of its silt content and only clear water is stored. Thus a nearly perpetual life is guaranteed to the reservoir.

When dams are built in rivers where relatively little silt is carried, little provision for passing silt is made since it is anticipated that the reservoir will fill with silt only after a long time; then another storage dam will be built farther upstream. The original storage will be lost, but the difference in water level above and below the old dam will remain available for hydroelectric power.

In modern practice, storage reservoirs are often created by multipurpose dams that will make the water available for municipal supply, hydroelectric power, industry, irrigation and navigation while also giving protection against floods. Silt and polution control, fish and wildlife protection and recreation often are important by-products. A series of these dams on a stream and its tributaries often provides comprehensive, integrated, basin-wide development. In a few cases, water is stored in one drainage basin, or natershed, and conveyed for use into another. Seven of the world's eight greatest surface reservoirs are in the U.S. *See also* DAMS; RESERVOIRS.

2. *Natural Underground Storage.*— Throughout the ages man has availed himself of a small part of the enormous supplies (exceeding those of all reservoirs and lakes, including the Great Lakes) of underground water, often called ground water (q.v.). Most of this water has accumulated over long geological ages, but some is replaced by current rainfall as used Heavy pumping reduces the permanent supply and lowers the water table, or level of the water, in the ground, and both of these effects make pumping increasingly expensive, a condition already serious by the second half of the 20th century in the southaestern United States and

elsewhere.

Perhaps the largest and cheapest supplies of ground water for irrigation are found in humid deltas and coastal plains where the water is not too salty. There the heavy rainfall maintains a relatively inexhaustible underground supply and large river flows also are available. See also HYDROLOGY.

IV. LEGAL TITLE TO WATER

Population increases were accompanied by an alarming growth in the variety of industrial and other water uses in the second half of the 20th century. It appeared that availability of adequate water would largely determine where civilizations would develop.

The right to use specific supplies of water for irrigation and other purposes has caused militant and legal action throughout history. While these contests for water rights (*q.v.*) continued between nations, states, cities. industry, agriculture and individuals, in the 20th century resort to force was rare. The respective claims were customarily settled through the considerable body of applicable law and by negotiation.

Priority of appropriation and use may be advantageous. However, the trend of settlements is toward giving less weight to priority and to the English common-law principle of riparian rights, which entitled owners of land adjoining a defined natural watercourse to a reasonably undiminished and unpolluted flow but made little provision for irrigation; and toward giving predominant weight to the principle of beneficial use for the many.

Water is scarce in the western U.S. and serious difficulties have arisen regarding water rights. The arid states, however, enacted comprehensive statutes which enabled most disputes to be adjudicated satisfactorily. In the more humid eastern U.S. the growing use and scarcity of water increasingly drew attention to the urgent need for legislation defining rights to use both surface and underground waters. In the more acute situations, inventories of available water and of the community uses for it were made as a first step toward the complicated public relations, educational efforts and legislation that were needed. In any event, the prospective irrigator should consult competent local authorities and assure himself of a reasonably permanent right to the use of water before undertaking expensive irrigation.

V. PRINCIPAL SYSTEMS OF IRRIGATION

1. Basin System.—There are two main forms of irrigation. In the more primitive and inexpensive system the area to be served is surrounded by embankments, and is thus called a basin; into this a canal leads the waters from the river until a depth of three or four feet is attained. Many of these basins were of great size, the largest covering as much as 60,000 ac. The water is run off after a time and the exposed area is sown with crops which need no further watering to bring them to maturity. The system obviously originated in the fact that a river can be easily made to give a supply once a year during its flood period, whereas enormous expense would be required to make it do so at other times. It happens, also, that the production of food crops follows the flood season in many rivers; the system devised, therefore, was one which took advantage of a river's flood season.

Fig. 1, representing a basin system in upper Egypt, will serve to explain this system of irrigation, the firm lines representing canals, the broken lines embankments along the river and between basins. It will be seen, beginning on the east or right bank of the river (top of fig. 1), that a high-level canal flowing, like the river, to the north, from an upper system divides into two. The right branch waters all the desert slopes within its reach. The left branch passes, by a structure, under the main canal of the system, taken from the river close at hand (and therefore at a lower level: see Canals, above). This left branch irrigates the high strip of land bordering on the river. In years of very favourable flood, this high-level canal may not be wanted at all; irrigation could be done from the main canal with the great advantage that the main canal water would carry with it much more silt than would be carried from the tail end of the high-level canal which took off the river perhaps 25 mi. farther upstream. The main canal flows freely over the areas C and D and, if the flood is good, over B and a part of

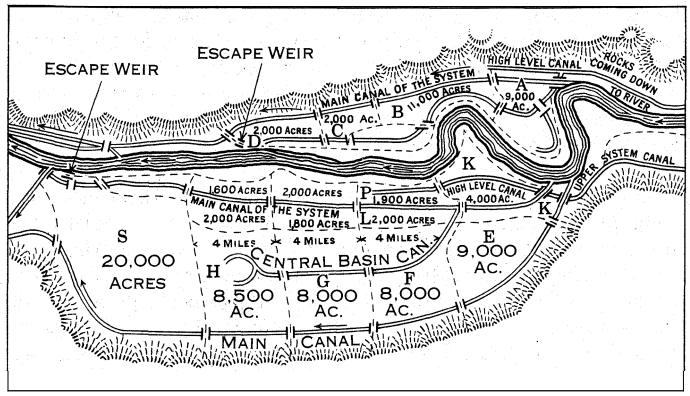

FIG. 1.—MAP OF A BASIN SYSTEM OF IRRIGATION

E, K, P, L, large basins irrigated by the high-level canal
F, G, H, S, basins irrigated by the central basin canal

A. It is carried around the next desert point, and to the north becomes the high-level canal. The masonry works required for this system are a structure to pass the high-level under the main canal near its head, bridges fitted with sluices where each canal passes through an embankment and an escape weir at the tail of the system to return the water to the river. The left (west) bank is similarly watered.

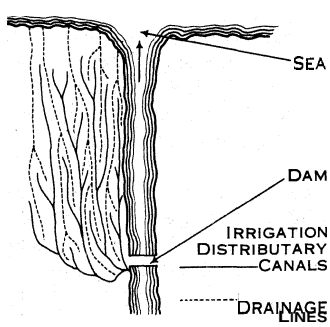
2. Perennial System.—The other modern and expensive system, where a perennial supply of water is made use of, is also fed by canals, but in this case the canal system is enormously developed compared with that of the basin system. In the latter, one canal only may be required to feed many basins by running through the higher-level basins and terminating at the middle of the last one of the series. In the perennial system, branch canals lead off from the main canal, lesser branches lead off from the main branches, and so on in ever decreasing size until as a last branch the smallest runlet is reached. The cost of this canalization is great, but the returns are correspondingly valuable. and usually about two crops can be grown each year instead of the single crop possible with basin irrigation.

Fig. 2 shows a perennial canal system. Only the main canals and principal branches are shown. The main canal may extend over any distance up to 200 mi. or even more. This plan also shows how efficient drainage is provided between the canals. A more detailed canalization from the branches is shown in fig. 3.

VI. OTHER SYSTEMS

1. Minor Systems.—Dating from Roman times, water meadows in England have been flooded in the wettest and coldest times of the year so that the warmer water might be used as a protection against frost. Warping is an old English practice of flooding land so that the suspended silt may be deposited to form a new topsoil on which crops will be grown under rainfall only.

2. Subirrigation.—In a few localities water is applied laterally and upward from ditches, drains or pipes located below the surface of the ground. It may result naturally or be installed artificially.



BY COURTESY OF THE U.S. BUREAU OF RECLAMATION

FIG. 2.—DIAGRAM SHOWING IRRIGATION PROPERLY COMBINED WITH DRAINAGE

3. Sewage Farming.—Many towns situated in inland districts, instead of passing their sewage into the nearest stream, deal with it by means of modern settling tank systems, from which the effluent is run off into small canals which irrigate suitable cultivable areas. The yield of crop produced is great, as such waters contain a very high percentage of nitrogenous matter. The drainage of Cairo, Egy., for instance, is said to be 30 times as valuable as the equivalent of Nile water, even in flood time when

the latter bears its fertilizing silt. Sewage irrigation is not commonly practised in the U.S.

VII. DRAINAGE

A necessary concomitant to irrigation is drainage of the soil. In few areas does nature provide it adequately without artificial aid. Poor drainage, resulting in excessive salts in the soils, popularly called alkali, has reduced yields in the arid western areas of the U.S. by some 20% and has occasionally caused abandonment of the land as was often true in ancient countries of the middle and far east. Heavy rainfall in parts of the eastern U.S. and elsewhere causes other difficulties.

For many years the supply of irrigation water was the only problem effectively considered by engineers; the disastrous results which followed in many, if not all, cases from a neglect of the provision of adequate drainage, however, awakened everyone to the necessity of supplying it if optimum moisture control was to be attained, and if fields were to continue fertile in order to raise maximum crops and to utilize longer grouing seasons.

Land may be smoothed with proper slopes and ditched so as to remove excess water before it enters the soil and thus prevent erosion, leaching of nutrients and standing pools of water on the surface, and to permit early spring planting. If carefully planned, this smoothing also can prepare the land for surface irrigation, thus serving two purposes by one earth-moving operation. After excess water enters the soil, its removal is an expensive and specialized undertaking that is not directly connected with irrigation, although it sometimes may be necessary for irrigated land. (See also LAND RECLAMATION.)

Much of the more promising surface irrigation occurs in humid or semihumid regions where it can be combined with drainage, usually in broad river valleys, alluvial deltas and coastal plains. Huge areas in these regions-await this type of development which, for example, has begun in the 20,000,000 ac. along the lower Mississippi river where the poorly distributed annual rainfall averages 50 in. Here combined ditching and leveling with heavy grading equipment is little more expensive than for irrigation alone, water supplies are cheap and relatively inexhaustible, expensive flood control and main drainage systems are already installed, the country is settled and large acreages are held under single ownerships that simplify organization, professional management and low-cost mass production under mechanization.

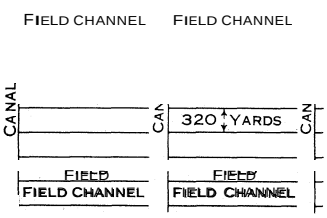


FIG. 3.—PLAN OF FIELD CHANNEL IRRIGATION

VIII. IRRIGATION PRACTICES

1. Distribution.— Where irrigation is carried on throughout much of the year, as in the perennial system, proper water distribution becomes a most important operation. It is often considered sufficient if during any one season two-thirds of the area commanded is actually supplied with water. This encourages that rotation of crops which seems to be a necessity of good farming, and also the lying fallow for a time of some part of the soil, which also appears to be a necessity in all countries during a portion of each year. Some crops, of course, require water much more often than others; much depends on the temperature at the time of irrigation; and seasons vary from year to year and from place to place. During the winter months in northern India magnificent wheat crops can be produced which have to be watered only two or three times. But to keep sugar cane, indigo or cotton alive in summer before the monsoon begins in India, or the Nile rises in Egypt, the fields should be watered at least once every 15 days, while rice requires an almost constant supply of water. Several irrigations per season are required over much of the U.S.

2. Quantity.— Even if the crops grown under irrigation were in each case identical, in different countries and at different seasons the conditions are so variable as to preclude a statement of volumes of water which would be applicable everywhere. The depth of water applied varies with its purpose, with the climate, season, soil, subsoil, drainage, crop and other factors. Usually, from 2 to 6 in. in depth of water may be given at every one of the several times of watering under the perennial system, whereas the one watering of the basin system may take 30 to 50 in.

Seasonal net requirements of delivered water in the U.S. average from 1 ft. in depth where the effective rainfall is more than 12 in. during the crop-growing season, to as high as 3 ft. where the annual precipitation is less than 10 in., the season long and temperature high.

3. Measurement.— Various devices have been perfected for accurately measuring the amount of water flowing past a particular point. The rate of flow is usually measured in cubic feet per second (second foot) and the volume in acre feet, that is, one acre foot being the volume equal to 43.560 cu.ft. required to cover one acre with water one foot deep. A flow of one cubic foot per second will furnish nearly two acre feet in 24 hours.

By measuring the water, analogously to measuring household water by a meter, it is possible to divide the water equitably among users, charge for the amount delivered and thus conserve scarce and valuable water. Measurement of the volume delivered also enables the irrigator to compute the depth of water that he is applying, a vital fact in attaining maximum production. Only by applying the right amount at the right time can optimum results be secured; otherwise irrigation may be ineffective or even harmful.

4. Applying the Water.— A proper control of irrigating water can save hard and expensive physical labour, assure uniform and satisfactory results and improve the yield as much as 100% over inefficient methods. Uncontrolled streams of water cause erosion, inefficiency, waste and uneven distribution and they may even create expensive damage claims. Makeshift devices and procedures may be worse than useless and expert advice is essential. Water is applied to land by flowing it over the surface or by sprinkling from pipes, either method being satisfactory if properly planned and used. The newer sprinkling method predominates in the eastern U.S. and the older surface method in the west.

Experience indicates that a plan for irrigating any field should be chosen so that it will be suitable for different crops, both because of the desirability of rotation and because other crops may become more profitable.

5. Surface Irrigation.— Where topography and soil are favourable, where skilled irrigators are obtainable, where pumping is unnecessary, where surface drainage would be helpful and where labour and farm equipment are more available than cash, or where many of these conditions exist, surface irrigation may be preferable. Small canals, ditches, flumes or pipes convey the water to the field

In order that water may flow uniformly and easily over the land, the surface must be reshaped to a suitable slope, only rarely made level. This leveling removes such humps and hollows as would interfere with the flow of water and improves the slope. The type and amount of leveling required is dependent upon the topography, depth and quality of soil, crops to be raised, method of irrigation to be employed, and flow of water available. A ground surface free of irregularities permits even distribution of water to the land and crop, a resultant saving in water and labour, and a uniform crop yield. Yields are increased, sometimes as much as 50% to 100%, as a result of leveling. Initial light leveling will nearly always pay in facilitating the distribution of the water in the fields, and usually initial heavy leveling will be advisable, especially for reducing costs on large acreages and where surface drainage is desirable. Efficient equipment is generally available for both light and heavy leveling.

Irrigation water is usually made to flow over the ground through furroms, small ditches or runlets sloping downward between rows of plants; corrugations, which are smaller and closer furrows through closely cultivated plants; flooding, where a shallow sheet of water is confined by small dikes or levees within sloping border strips, contour strips or level basins as it advances over the land; and, less satisfactorily, through wild flooding manually out of ditches without benefit of land preparation and water control as

just described. Other surface methods are used occasionally.

6. Sprinkler Irrigation. — For those not skilled in irrigation and where drainage is unnecessary, overhead sprinkling from pressure pipes. usually with revolving sprinklers and under engineering direction, offers the surest method of applying water. It may be used on most topography without leveling and without experienced irrigators and, where pumping would be necessary in any event, it may well be the best method. Sprinkling is widely and increasingly used under engineering direction.

7. When and How **Much** to Irrigate. — There are both practical and theoretical approaches to this question and, in addition, judgment must be developed through local experiment and experience. To get the full value and the best yields from irrigation. the moisture content in the soil must usually be kept well above the wilting point and slightly under the storage capacity of the soil in the root zone. When a crop wilts. irreparable damage usually has occurred. On the other hand: too much water can leach the plant nutrients from the soil, keep air out of the soil and cause erosion. In the latter 1950s studies, described later, were under way to determine the optimum soil-moisture content for specific crops at various stages of growth; they indicate that much better crop yields may become possible under carefully-controlled optimum moisture conditions.

8. Fertilization. — Of the many factors controlling plant growth. two limit growth more often than all of the others combined. namely, (1) a lack of adequate moisture control and (2) a lack of ample amounts of the so-called plant foods or plant nutrients. Through irrigation and drainage, farmers can deal satisfactorily with the moisture problem. By the addition of fertilizer (see FERTILIZERS ASD MANURES), often applied in the irrigation water, they can supply plant foods without which crop production would be limited. This combined use of irrigation, drainage and fertilizer opens up a new frontier for agriculture. Together they present one of the great advances of modern times for growing more and better crops without expanding acreage.

IX. SUPPLEMENTAL IRRIGATION

The older irrigation in the United States was generally developed before the middle of the 20th century by groups of farmers on large projects that by the late 1950s totaled about 28,000,000 ac. west of the 100° meridian which runs north and south through the centres of the Dakotas, Nebraska and Texas and through the western ends of Kansas and Oklahoma. There the annual rainfall of from ½ in. to 20 in. is very light during the growing season and heavy irrigation is essential.

On the other hand, supplemental irrigation has been practised mainly since mid-century by individual farmers on much smaller projects totaling by the late 1950s 3,000,000 ac. east of the 100° meridian. There the normal annual rainfall of between 20 in. and 50 in. is fairly adequate during the growing season and only light irrigation is required, although that small amount produces large returns. Seldom was water added artificially before 1950 except to a limited extent on lawns, golf courses, gardens. rice fields and horticultural crops. However, from 1950 to 1960 in the U.S. about as many acres were brought under eastern supplemental irrigation as were added to the larger and older western total irrigation; moreover, more irrigable land is available in the east than in the west.

As efficient and expensive agriculture developed and as disastrous droughts afflicted much of the humid and semihumid eastern U.S in the 1950s, this region turned to supplemental irrigation mainly as insurance against droughts. It soon became apparent that added water also increased crop yields in most years, not only during obvious droughts in very bad years, and that even abundant annual rainfall seldom provided enough moisture at all of the times that it was needed. Next it was realized that maximum yields resulted only when the highest type of crop culture was combined with adequate water in the root zone of the soil reservoir at the right time in the growth schedule. Doubling of yields or a return of 100% on the annual cost of supplemental irrigation was not uncommon and it appeared that even larger returns might be anticipated as practices improved. Since supplemental irrigation is expensive in both first cost and operating cost, and since it is quite different from ordinary farming, it must be undertaken and conducted under expert advice. Only when it is accompanied by every modern aid to better agriculture will the best yields be obtained.

1. **Optimum** Plant Growth. — Studies in the nearly forgotten science of phenology, the relation of climate to the growth of plants. were undertaken by C. W. Thornthwaite and others having as their first objective the scientific scheduling of supplemental irrigation and of the crops grown thereunder. Unless supplemental irrigation is applied at the right time and in the right amounts to maintain optimum soil-moisture conditions, it is not only wasted but it may actually be harmful, and crop scheduling is essential to efficient production. Scientific supplemental irrigation requires that both of these practices be utilized. With optimum moisture, scheduling and nutrients provided, actual crop growth can be measured daily and necessary remedial action taken immediately. before permanent injury has occurred. to keep that growth up to its climatic and economic potential, with resulting yields that have seldom been attained in the past.

Fig. 4 shows an actual case relating growth to its potential under an optimum level of soil moisture. a relationship possible only where irrigation is available whenever needed as. for example, under individual pumping. Where canal water is delivered by rotation many days apart and in sufficient quantity to fill a badly depleted soil reservoir. as is often the case in the arid west, it may not be possible to maintain the optimum level.

The solid upper curve shows the soil moisture deficiency in the root zone nhen irrigation is used, and the dotted upper curve shows the deficiency as it would be without irrigation. all plotted downward on the left-hand scale. In this locality the heavy rainfall of 50 in annually frequently filled the soil reservoir to 0 on the scale. Irrigation was used only four times as shown by the solid dots at the top.

The solid line running upward to the right shows potential growth in this locality, and the dashed lower curve plots the actual measured daily gronth of the cotton plants. all plotted upward on the right-hand scale. When actual growth as plotted on this dashed curve began to drop away from potential growth to-

ward the end of July, remedial action should have been taken by irrigating, fertilizing. weeding, pest control or whatever appeared to be necessary. The curves are plotted daily to show nhen remedial action is necessary, usually several weeks before it becomes apparent on the plants.

The upward potential growth curve and the downward parts of the soil moisture deficiency curve are computed and plotted from evapo-transpiration, which is the moisture being used by the plants and being evaporated into the atmosphere (see DROUGHT).

X. IRRIGATION THROUGHOUT THE WORLD

1. World Survey. — As the second half of the 20th century was well under way. the total irrigated acreage of the world had nearly tripled since 1900. The largest acreages were credited to China, India, the United States. the U.S.S.R and Pakistan. The total for all countries was about 320,000,000 ac., as compared with a total of about 110,000,000 ac in 1900.

A general idea of the nature and expansion of modern irrigation and associated water control throughout the world was indicated by a few of the plans and accomplishments in the late 1950s. The government of Communist China announced readiness to start construction on the first and largest of the 46 dams projected to control the floods of the Yellow river. produce electric power far in excess of the previous total and greatly increase the irrigated acreage. Taiwan (Formosa) and South Korea were modernizing and increasing their irrigated land area by several per cent annually. There. and throughout much of the far east, large rice acreages limited to one crop annually would be able to grow two crops annually when additions to their water supply were secured. India completed Hirakud dam on the Mahandi river in the state of Orissa (1957), creating a storage capacity of more than 6 000,000 acre feet and permitting the eventual irrigation of some 670,000 ac. The project, entirely an Indian engineering effort. was begun in 1948. In Pakistan, construction was well along on the Warsak dam. planned to generate 240.000 kw. of electricity and effect the irrigation of 120,000 ac. Spain's effort to restore productivity to the Guadiana river valley and provide electricity for Madrid had brought about the irrigation of some 33,000 ac. of an expected ultimate 300,000 ac. Work was also started to use the Ebro river for the early irrigation of about 250,000 ac. and eventual service to 2,500,000 ac. Australia opened the Eildon reservoir to create an irrigation storage capacity of 2,750,000 acre feet of water near the source of the Goulburn river in the province of Victoria. Venezuela completed the nine-mile long earth dam on the Guarico river, expected to bring about the irrigation of 272,000 ac. of pasture and forage land.

In Italy. the Flumendosa project was planned to effect the irrigation of 123,joo ac in the Campidano di Cagliari, a plain in southwestern Sardinia, by three dams on the Flumendosa river and its tributaries. with connecting tunnels and irrigation distributaries. The most important feature of a four-year program in Japan was the proposed irrigation of 42.000 ac already under paddy and 40.000 upland acres in the Aichi region on the island of Honshu. This was reported as the nation's first attempt to irrigate ridge lands. Among the several objectives of the Bhumiphol project in Thailand was the provision of additional water for the irrigation of more than 2,000,000 ac. in the area served by a large new system in the Chao Phraya river basin.

Both total and supplemental irrigation are being rapidly extended and improved by governments throughout the world in a scientific manner that will ensure greatly increased crop yields by modern procedures.

See also articles on various countries.

2. United States. — Perhaps the most efficient development of irrigation may be found and studied in the United States. In a single year of the late 1950s, the United States bureau of reclamation announced a construction program that, upon completion. would provide water for 150,000 ac. not previously irrigated and additional supplies for 94,000 ac. Contracts were let for the construction of main features of Glen canyon dam, major structure of the comprehensive upper Colorado river basin storage project, and for Trinity dam in the expanding Central valley project of California. That state started construction of Oroville dam. initial and key unit of the Feather river project, which was planned to serve extensive areas in central and southern California hundreds of miles distant. Beyond the foregoing western expansion, and in the same year, the United States soil conservation service helped to place a comparable acreage under supplemental irrigation in eastern U.S.

Relatively small areas in the southwestern portion of the country were irrigated in prehistoric times. The customs and methods used were improved by the Spanish conquerors and their descendants. Modern irrigation in the U.S. west began with the arrival of the Mormons in Utah in 1847 and increased to about 31,000,000 ac. early in the second half of the 20th century. Taking into consideration the available land and the availability of water supplies of reasonable cost, it was estimated that some 20,000,000 ac. more of western land could be developed by irrigation and perhaps another inadequately supplied 10,000,000 ac. could be furnished with additional water. In the humid eastern U.S. it was felt that an equally large acreage might be brought under supplemental irrigation, as described above.

Irrigation development in the United States followed a natural course concurrent and interwoven with the settlement and development of the west. The first works were simple ditches built by the settlers for diverting water from streams to easily reached farm lands in the valleys near by. These settlers mere not financially able to build costly works and common practice involved the use of mood and temporary structures.

In course of time, however, many land and water corporations were formed. with the aid of invested capital, for the purpose of exploiting the agricultural resources of the west. There followed legislative action by the states to enlarge the powers of farmers' organizations, enabling them to bond their land and raise funds for building, purchasing and reconstructing irrigation systems. In 1902 congress passed the Reclamation act by which the federal government became an active participant in irrigation work. These agencies employed experienced engineers and designed and constructed more extensive and permanent irrigation works. The work of building new systems and remodeling and reconstructing existing enterprises continued. and the makeshifts of earlier periods were generally replaced by substantial structures of concrete and steel.

A degree of efficiency and permanence was attained in irrigation systems comparing favourably with those of any other country. The original Reclamation act was revised and greatly enlarged in scope and under it the U.S. reclamation service and its successor, the bureau of reclamation (est. 1924), built many of the world's largest irrigation structures. It investigated and planned a comprehensive development of all the available water resources of the western states for their optimum utilization for irrigation and related purposes in large integrated basin-wide projects involving many large storage reservoirs, transmountain diversions, etc. In co-operation with the U S. army corps of engineers. it continued to investigate and report on the comprehensive use of water resources for the arid west and to aid in construction and operation. The U.S. soil conservation service promoted irrigation in the humid east.

The United States was believed to rank first in the number. dimensions and permanency of its dams for storage of irrigation water; in the efficiency of mechanical equipment used to pump and control nater for irrigation; in the efficiency of works to convey water to and distribute it on farms; and in scientific agricultural applications.

Chemical and agricultural science, mechanization, agricultural education and mass production for special markets under professional management combined to bring about a very efficient agriculture which was correspondingly expensive; while governmental aids tended to support prices at only modest levels, if at all. Under these conditions farmers seldom can afford to spend the larger production costs without having adequate, even if expensive, irrigation water to assure a good crop.

The necessity of these expensive aids ior profitable modern agriculture established a trend toward increased acreage under a

single management in order to secure low-cost agricultural mass production analogous to large-unit industrial mass production. Costly irrigation and drainage accentuated this trend and made it increasingly difficult for the traditional small family farm unit of the U.S. to furnish a satisfactory living for the family. There were, indeed, exceptions under special conditions, when a single-family farm unit might be very efficient. Various types of farm organization were being studied with a view to increasing the acreage irrigated under a single management. Historically, irrigation has always forced individuals to organize into larger groups with larger investments and better management. It continued to play this important role.

(H. RY.)

IRVINE, a royal and small. burgh and seaport of Ayrshire, Scot., standing on the Irvine, which with the Annick runs into the Garnock estuary; it is 8 mi. W. of Kilmarnock. Pop. (1951) 14,745. Area 2.8 sq.mi. Alexander II granted it a charter which was confirmed by Robert Bruce. About the end of the 17th century it was reckoned the third shipping port in Scotland, but its importance declined, partly because of the partial silting of the harbour, and partly because of the establishment of harbours at Ardrossan and Troon. Now mostly coastal shipping uses the harbour. The academy is a pre-Reformation foundation. While the town is essentially industrial, it lies in the centre of golfing country, there being two first class golf courses on the northern boundary—Bogside and Irvine municipal—and the well-known Gailes and Barassie golf courses on the southern boundary. Industries include ship repairing, the manufacture of cold-formed metal sections, iron founding, brass founding, pipe manufacture, hosiery works, sawmills, block works, chemical works, bottle works and horn products. The principal exports are bricks, tar, cement, fireclay goods, pipes, gravel and sand; imports include timber, limestone and cement.

IRVING, the name of a family of English actors.

SIR HENRY IRVING (1838–1905), the most famous English actor after David Garrick, was the son of Samuel and Mary Brodribb and was born at Keinton Mandeville, Somerset, on Feb. 6, 1838, being christened John Henry. As a youth he was employed as a clerk in the City of London, but in 1856 he decided to be an actor, taking the name of Henry Irving. His first appearance was at the Royal Lyceum theatre, Sunderland, as Gaston, duke of Orleans, in Bulwer-Lytton's *Richelieu.* For ten years he played in provincial stock companies, acting more than 500 parts. In 1866 he was engaged by Dion Boucicault to play in Manchester the leading part, Rawdon Scudamore, in *The Two Lives of Mary Leigh* which later, retitled *Hunted Down,* was transferred to the St. James's theatre, London. This led to Irving's engagement by Alfred Wigan at the newly opened Queen's theatre, and in 1870 he made his first conspicuous success as Digby Grant in James Albery's *The Two Roses* at the Vaudeville. His performance in this part and, on the night of his benefit, his dynamic recitation of Thomas Hood's *The Dream of Eugene Aram* inspired Hezekiah Bateman, the American impresario, to engage him as leading man at the Lyceum theatre. Bateman's enterprise was a failure until he allowed Irving to produce and to play the leading part of Mathias in *The Bells,* a version of Erckmann-Chatrian's *Le Juif Polonais* by Leopold Lewis. Irving's success as Mathias was immediate and sustained; the play ran for 150 nights and remained a feature of his repertory until his death in 1905. Irving, after playing the title role in W. G. Wills's *Charles I* and *Eugene Aram,* and in *Richelieu,* made in 1874 a bid for supremacy as an actor by appearing as Hamlet. The humanity and distinction of his performance won him public acknowledgment as the leader of his profession, and the play had an unprecedented run of 200 nights. When Bateman died in 1875 Irving. under the management of Mrs. Bateman, continued to play in partnership with her daughter Isabel until 1877, appearing successively in Shakespearean tragedy and contemporary plays.

In 1878 Irving became lessee and manager of the Lyceum. With Ellen Terry (*q.v.*) as Ophelia and Portia, he revived *Hamlet* and produced *The Merchant of Venice* (1879). His Shylock was as controversial as his Hamlet, the dignity with which he invested the Jew pleasing some as much as it offended others. The play became a mainstay of his repertory; he declared toward the end of his career "in all humility . . . mine is the only great Shylock." After the production of Tennyson's *The Cup* he invited Edwin Booth (*q.v.*) to play with him at the Lyceum, the English and American actors alternating in the parts of Othello and Iago. Irving's brilliantly conceived Iago was highly praised; his Othello, which lacked physical force, comparatively failed. In 1882–83 Irving and Ellen Terry had their greatest Shakespearean success in *Much Ado About Nothing.* Later in the year, Irving paid the first of several visits to the United States with the whole Lyceum company and with the scenic and lighting effects for which his theatre was famous. He continued in management of the Lyceum until 1899, producing *Twelfth Night* (1884), *Olivia* (a dramatization by Wills of Goldsmith's *Vicar of Wakefield;* 1885), *Faust* (1886), *Macbeth* (1888), *The Dead Heart* (1889) and *Ravenswood* (1890). In 1892 Irving's performance of Wolsey in *Henry VIII* was acclaimed, and in 1893 he produced Tennyson's *Becket,* in which, as the archbishop, he made a deep impression upon his audiences. Further productions, such as *King Arthur* and *Don Quixote* (1895), *Cymbeline* and *Richard III,* one of his most striking interpretations (1896), and *Peter the Great* (1898), did not meet increasing costs. In 1899 ill health and misfortunes, which included the destruction by fire of almost all his stocks of scenery, induced him to surrender his control of the Lyceum to a limited liability company. In 1902 the company went into liquidation and Irving's reign at the Lyceum ended. His farewell season at Drury Lane in 1905, however, showed that his powers as an actor and his popularity with the public were undimmed. On Oct. 13 of that year he died, shortly after playing Becket at the Theatre Royal in Bradford. He was buried in Westminster abbey.

Both on and off the stage Irving maintained a high ideal of his profession. In 1895 he received the honour of knighthood, the first ever accorded an actor. His acting, apart from his genius as a stage director, divided criticism, opinions differing as to whether his mannerisms of voice and deportment hindered or helped the expression of his ideas. He excelled in the portrayal of fear, horror, scorn or malignity. A commanding personality such as his was bound to colour whatever part he assumed, but the richness and originality of this colouring were as admirable as the intellect and imagination with which his interpretations were conceived.

In 1869 Irving married Florence O'Callaghan, but after the birth of their two sons, Henry Brodribb and Laurence Sidney Brodribb, Irving and his wife were legally separated.

HENRY BRODRIBB IRVING (1870–1919), elder son of Sir Henry Irving, was born in London on Aug. 5, 1870. He was educated at Marlborough and at New college, Oxford, where he joined the Oxford University Dramatic society. He was called to the bar in 1894, but soon abandoned a legal career for the stage. His first appearance in London was made in Sept. 1891 with John Hare at the Garrick theatre in T. W. Robertson's *School.* In 1894 he joined Ben Greet's company, where he met Dorothea Baird, whom he married in 1896. His first notable success was in Barrie's *The Admirable Crichton* (1902–03). In 1905 he appeared as Hamlet at the Adelphi theatre, where his scholarly and vital performance established him as a creative actor of distinction. Forming his own company, he produced a successful version of Robert Louis Stevenson's *Dr. Jekyll and Mr. Hyde* and Stephen Phillips' *The Sin of David.* He was lessee and manager of the Savoy theatre from 1913 until his death in London on Oct. 17,

1919. Irving was a keen student of criminology and published *The Life of Judge Jeffreys* (1898), *French Criminals of the Nineteenth Century* (1901), *A Book of Remarkable Criminals* (1918) and *Last Studies in Criminology* (1921).

LAURENCE SIDNEY BRODRIBB IRVING (1871–1914), younger brother of Henry Brodribb Irving, was born in London on Dec. 21, 1871. He was educated at Marlborough and, to enter the diplomatic service, studied for three years in St. Petersburg, but financial stringency prevented him from fulfilling this intention. Returning to England in 1893, he began his career as an actor in Frank Benson's Shakespearean company. In 1894 he made his first important appearance in London in Barrie's *Walker, London.* He married the actress Mabel Hackney and with her presented foreign plays of distinction to English audiences, notably *The Three Daughters of M. Dupont,* his own dramatization of Dostoevski's *Crime and Punishment* and M. Lengyel's *Typhoon.* In the last play (1912) he revealed himself as an actor of genius, which his brief appearances as Iago and as the Earl Skule in *The Pretenders* by Ibsen later in that year confirmed. In 1914 he took his company to Canada and was returning thence when he and his wife lost their lives in the sinking of the "Empress of Ireland" on May 28. 1914.

Laurence Irving wrote several plays, including *Peter the Great, Bonnie Dundee* and *Richard Lovelace.* His scholarship, allied to his unusual sensitivity, enabled him as an actor to portray with remarkable integrity the manners and characteristics of foreign peoples.

IRVING, EDWARD (1792–1834), Scottish church divine, whose followers founded the Catholic Apostolic Church (*q.v.*), was born at Annan, Dumfriesshire, on Aug. 4, 1792. At the age of 13 he entered the University of Edinburgh. In 1809 he graduated M.A., and in 1810, on the recommendation of Sir John Leslie, he was chosen master of an academy newly established at Haddington, where he became the tutor of Jane Welsh, afterward Mrs. Thomas Carlyle. He became engaged in 1812 to Isabella Martin, whom he married in 1823, but meanwhile he gradually fell in love with Jane Welsh, and she with him. He tried to get out of his engagement with Miss Martin, but was prevented by her family. Irving introduced Carlyle to Jane Welsh in 1821. He left Haddington for Kirkcaldy in 1812. Completing his divinity studies by a series of partial sessions, he was licensed to preach in June 1815, but continued to teach for three years. In the summer of 1818 he resigned his mastership and went to Edinburgh. He was meditating a missionary tour in Persia when, in 1819, he was appointed assistant to Thomas Chalmers in St. John's parish, Glasgow. Irving's preaching awakened little interest among the congregation of Chalmers, Chalmers himself, with no partiality for its bravuras and flourishes, comparing it to "Italian music, appreciated only by connoisseurs"; but as a missionary among the poorer classes he wielded an influence that was altogether unique. In 1822 he was ordained minister of the Caledonian church, Hatton garden. London. There his sermons at once attracted a crowd of fashionable people.

For years the subject of prophecy had occupied much of his thoughts, and his belief in the near approach of the second advent had received corroboration in the work of a Jesuit priest. writing under the assumed Jewish name of Juan Josafat Ben-Ezra. In 1827 he published a translation of it, accompanied with an eloquent preface. Probably the religious opinions of Irving had gained breadth and comprehensiveness from his intercourse with Samuel Taylor Coleridge, but gradually his chief interest in Coleridge's philosophy centred around that which was mystical and obscure, and it probably accounts for his adoption of the doctrine of millenarianism. The first stage of his later development, which foreshadowed the establishment of the Irvingite or Holy Catholic Apostolic Church, was associated with conferences at his friend Henry Drummond's seat at Albury concerning unfulfilled prophecy, followed by study of the prophetical books and especially of the Apocalypse, and by several series of sermons on prophecy both in London and the provinces. Crowds filled the largest churches of Edinburgh in the early summer mornings to hear his apocalyptic lectures in 1828. In 1830 his hopes were aroused by the seeming actual revival in a remote corner of Scotland of those apostolic gifts of prophecy and healing which he believed to be kept in abeyance by the absence of faith.

Irving welcomed the new power with a conviction which was unshaken by the remonstrances or desertion of his dearest friends, the recantation of some of the principal agents of the gifts, his own declension into a subordinate position, the meagre and barren results of the manifestations and their general rejection both by the church and the world. His excommunication by the presbytery of London, in 1830, for publishing his doctrines regarding the humanity of Jesus Christ, and the condemnation of these opinions by the general assembly of the Church of Scotland in the following year, were secondary episodes. The irregularities connected with the manifestation of the gifts gradually estranged his own congregation, and on the complaint of the trustees to the presbytery of London, whose authority they had formerly rejected, he was declared unfit to remain the minister of the National Scotch Church of Regent square. After he and those who adhered to him (describing themselves as of the Holy Catholic Apostolic Church) had in 1832 moved to a new building in Newman street, he was in March 1833 deposed from the ministry of the Church of Scotland by the presbytery of Annan on the original charge of heresy. With the sanction of the power he was now after some delay reordained "chief pastor of the church assembled in Newman street." He died on Dec. 7, 1834.

The writings of Edward Irving published during his lifetime were *For the Oracles* of *God, Four Orations* (1823); *For Judgment to come* (1823); *Babylon and Infidelity foredoomed* (1826); *Sermons,* etc. (3 vol., 1828); *Exposition of the Book of Revelation* (1831); an introduction to a translation of Ben-Ezra; and an introduction to Horne's *Commentary on the Psalms.* His collected works were published in 5 volumes, edited by Gavin Carlyle. *See* also the article CATHOLIC APOSTOLIC CHURCH.

The *Life of Edward Irving, by* Mrs. Oliphant, appeared in 1862 in 2 vol. Among a large number of biographies published previously, that by Washington Wilks (1854) has some merit. *See* also Hazlitt's *Spirit of the Age;* Coleridge's *Notes on English Divines;* Carlyle's *Miscellanies* and Carlyle's *Reminiscences,* vol. i. (1881).

IRVING, WASHINGTON (known by a number of pseudonyms including GEOFFREY CRAYON and DIEDRICH KNICKERBOCKER) (1783–1859), is variously called "first American man of letters," "dean" or "father of American literature," and "inventor of the short story." He was born in New York city on April 3, 1783, the year of the peace that ended the American Revolution. Much of the praise bestowed on him was deserved; some of it was owing primarily to his having been "first." Intellectually, Irving was a lesser man than many of his predecessors. He lacked the religious intensity of Mather, the philosophical acumen of Edwards, the versatility of Franklin, the statesmanship of Jefferson or the dedication of Paine. Yet he outlives them all in the history of American letters. His greatest literary success was won with *The Sketch Book* in 1819—precisely at the moment when British-American animosity had reached a new high—as if in answer to Sidney Smith's contemptuous query, "In all the four quarters of the globe, who reads an American book?" It was a book which all the world, especially many Englishmen, read with delight. While it gave little evidence that Irving was a man of great ideas, emotional depth or imaginative power, it established him as a talented writer, possessed of a temperament and a style, which he combined and varied deftly from sentiment and romance to wit and urbanity in ways to leave no doubt that here at last was an American whose elegant good taste was instinctive. Far from a bumptious provincial, he was a cosmopolite, speaking a language universally recognized in cultivated circles.

In the attainment of the graces of living, Irving was conditioned by his rearing. The favourite and last of 11 children of an austere

Presbyterian father and a more genially-minded Anglican mother, young Irving grew up in an atmosphere of indulgence. A disposition toward frailty and sensitivity got for him the best that family competence and brotherly favouritism could supply. He escaped the regularity of a collegiate education which his father required of his older sons, but because it was still customary for a gentleman to have a profession, even though he might not practice it, he read intermittently at the law, notably in the office of Josiah Ogden Hoffman, with whose pretty daughter Matilda he early fell in love. His "inveterate enemies, the fathers of the law," did not prevent his participation, as a gay-young-man-about-town, in the social whirl of the city or his association with young men bent, like himself, on enjoying life in terms of feminine society, theatrical entertainment and literary amusement. Associations of this kind led to his writing a series of whimsically satirical essays over the signature of "Jonathan Oldstyle. Gent.," published in Peter Irving's paper, the *Morning Chronicle*, during 1802–03. This youthful playing with the pen was interrupted by several trips up the Hudson, another into Canada in the interest of his health, and during 1804–06, an extended tour of Europe, during which his health improved markedly. his manners were given a brush and several notebooks were filled with experiences picked up in a constant round of sight-seeing, flirtatious pleasantries and frivolous entertainment.

On his return, he passed the bar examination late in 1806 "by the grace of God and Josiah Hoffman," his tutor and chief examiner; and soon thereafter he set up as a lawyer by moving into his brother John's office at No. 3 Wall street. But he argued no more cases than Oliver Wendell Holmes later healed broken bodies. During 1807–08 his chief occupation was to collaborate with his brother William and James K. Paulding in the writing of a series of 20 periodical essays entitled *Salmagundi*. To secure variety, they followed the Addisonian scheme of having the several subjects treated by several quaint gentlemen. each reminiscent of members of the Spectator club. They posed as "critics, amateurs, dilettanti, and cognoscenti" and proceeded, in true *Spectator* fashion, "to instruct the young, reform the old, correct the town, and castigate the age." They went on merrily, moralizing seldom, content to take "the world as it goes," yet gently satirizing the ways of the fashionable world, ridiculing the pretentions of political upstarts and social climbers, inserting squibs on the theatre, waging war against boorishness and mediocrity. "folly and stupidity," while teaching "parents how to govern their children, girls how to get husbands, and old maids how to do without them." Occasionally they mixed in a little pointed satire of Jefferson, his "rabble republican" followers and the "logocratic" democracy they sought to institute. *Salmagundi* made an impression. and became a mild terror in certain quarters of the town. While concerned primarily with passing phases of contemporary society, the essays retain significance as an index to the social milieu in which the Federalistically indoctrinated young men moved so easily.

His next book, *Diedrich Knickerbocker's History of New York* (1809), was planned merely as a parody of Samuel Mitchell's pretentious guidebook to New York city, but was eventually expanded into a comic history of the Dutch regime in New York, prefaced by a mock-pedantic account of the world from creation onward. Like *Salmagundi*, it embodies a great deal of contemporary social and political satire: born of youthful exuberance and effrontery.

The composition of this "first great book of comic literature written by an American" was interrupted in April 1809 by the sudden death of Matilda Hoffman. Grief incapacitated him for a while; but in the end the hard work necessary to complete *Knickerbocker*, the'success of the book and his transfer in 1811 to the newer and wider scene of Washington as a lobbyist in the interests of the Irving brothers' hardware-importing firm helped transmute his grief into the realm of memory. His life. however, seemed to him more or less aimless for some years more, during which he turned to a variety of pursuits. He prepared an American edition of Thomas Campbell's poems, edited the *Analectic Magazine* and acquired a staff colonelcy during the War of 1812. In 181 j. when his brothers' business (in which he had been a non-participating but profit-sharing member) declined, he sailed for Europe to look after the firm's interests in Liverpool, only to find that his efforts were not enough to stave off bankruptcy. What turned out more profitable in the end were the literary associations that he formed in London, and more especially a visit to Sir Walter Scott, who encouraged and stimulated him to renewed effort. The result was *The Sketch Book of GeoffreyCrayon, Gent.* (1819–20).

A true sketch book, miscellaneous and uneven, a composite of sentiment and romance, satire and whimsicality, fact and fiction. old and new world—its thirty-odd pieces include the first three so-called modern short stories ("The Legend of Sleepy Hollow," "Rip Van Winkle" and "The Spectre Bridegroom") and an essay, "English Writers on America," in which Irving spoke sane, abiding and forthright words on the nonsensical controversy which kept the British and the Americans in a bad humour with each other. The tremendous success of the book assured Irving, now reliant on his own resources, that he could live by his pen. and two years later he produced *Bracebridge Hall*, a sequel as it were to *The Sketch Book*. When critics pointed out literary borrowings and refurbishings of old tales in these two books, Irving set upon a studied search for novelty. Aware that his mind was not truly creative but rather receptive—that it needed some outside stimulation, such as travel, new associations. or old tales and anecdotes might provide—he resolved. "I shall occasionally shift my residence and write whatever is suggested by objects before me." Hence he traveled in Germany, Austria, France, Spain. the British Isles and later in his own country; his pictures are the transcriptions of an antiquary rather than the conceptions of a creator.

Seeking better health and expecting to exploit the wealth of German folklore, Irving went to Germany, where during the winter of 1822–23 (spent mainly in Dresden) he gathered the materials for a "German sketch book," *Tales of a Traveller* (1824). This proved to be little more than a hodgepodge of travel reminiscences and badly-assimilated ragtags of legendary lore, which the critics attacked savagely. Next he turned to Paris, where he collaborated in various dramatic and operatic productions, notably with John Howard Payne; and early in 1826 he accepted the invitation of Alexander H. Everett, then chargé d'affaires in Madrid, to attach himself to the American legation in Spain and there to translate M. F. de Navarrete's recent book on Columbus. Instead, he chose to produce his own *Columbus* (1828). followed by *The Companions of Columbus* (1831). Although both have long been superseded by later researches. they still supply readers with the essentials of Columbus' romantic life and exploits. Meanwhile Irving had become absorbed in the legends of Granada and of the Moorish past, and residence in the old Alhambra provided a fit setting for the composition of his *Conquest of Granada* (1829) and *The Alhambra* (1832), the latter the Spanish counterpart of *The Sketch Book*.

After 17 years' absence. Irving returned to New York in 1832. where he was warmly received. Impressed by the opening of the western frontier, he made an adventuresome journey west and produced in rapid succession *A Tour of the Prairies* (1835), *Astoria* (1836) and *The Adventures of Captain Bonneville* (1837) Except for four years (1842–1846) of distinguished service as minister to Spain, Irving spent the remainder of his life at his home "Sunnyside" on the Hudson, surrounded and revered by friends and relatives, and devoted to literary pursuits, chiefly biographical: *Oliver Goldsmith* (1849), *Mahomet and His Successors* (1850) and a 5-volume life of his namesake, *George Washington* (1855–1859). He died on Nov. 28, 1859.

Pochmann (1934). The definitive biography is Stanley T. Williams, *Life of Washington Irving*, 2 vol. (1935). The best bibliographical information is in T. H. Johnson, *Literary History of the United States*, III, 578–583 (1948). (H. A. P.)

IRVING, a city of central Dallas county, Tex.. U.S., a residential community west of Dallas (*q.v.*) and within its metropolitan area. The tomnsites Kit and Gorbett preceded Irving, but when the Rock Island railroad shifted its proposed route the present location of Irving was determined in 1902 by Otis Brown and J. O. Schulze. Irving's population increased rapidly after

1950; for comparative population figures *see* table in TEXAS: *Population* (E. C. BE.)

IRVINGTON, a city in Essex and Union counties, N.J., U.S., bordering Newark and 10 mi. W. of New York city in the New York-Northeastern New Jersey metropolitan area. Pop. (1960) 59,379; for comparative population figures *see* table in NEW JERSEY: *Population.* It is highly industrialized; products manufactured there include foods, machinery, jewelry, toy electric trains, paints, electronics, plastics, tools and castings. The city has several parks and playgrounds, a large library, a hospital and many national club organizations.

The area was settled in the 1690s and was a part of Newark. By 1812 it became an independent township, called Camptown; this name was changed in 1852 to Irvington in honour of the writer Washington Irving. The city was incorporated in 1898. In its early history it was noted for its shipbuilding, its horse racing and its position. after 1802, as a relay station for the New York-Philadelphia stagecoach run. (W. L. CA.)

ISAAC, the only son of Abraham and Sarah and father of Jacob and Esau. He thus occupies a middle position between the two major figures in the ancestry of Israel. Apart from the incidents described in Gen. xxii (the rescue of Isaac from the sacrificial altar), Gen. xxiv (the wooing of Rebecca by proxy) and Gen. xxvii (the rivalry between his sons), the only incidents of his life are those included in Gen. xxvi, which describes mainly his dealings with Abimelech, king of Gerar. It is to be noted that these events can be closely paralleled from the Abraham narratives. Isaac is, in fact, the least distinguished and most vague of the three great patriarchal characters, and the most significant points in the passages which deal with him are (1) the mention of Beersheba as his home (*e.g.*, Gen. xxvi, 23, 33) and (2) the fact of his sowing corn, thus passing from the stage of pure nomadism to that of seminomadism (Gen. xxvi, 12). *See* GENESIS.

ISAAC I (COMNENUS), emperor of the east (1057–1059), was the son of an officer of Basil II named Manuel Comnenus. In 1057 he joined with the nobles of the capital in a conspiracy against Micnael VI, and after the latter's deposition was invested with the crown, thus founding the Comneni dynasty.

The first care of the new emperor was to reward his noble partisans with appointments that removed them from Constantinople, and his next was to repair the beggared finances of the empire. He revoked numerous pensions and grants conferred by his predecessors upon idle courtiers, and, meeting the reproach of sacrilege made by the patriarch of Constantinople by a decree of exile, resumed a proportion of the revenues of the monasteries.

Isaac's only military expedition was against the Hungarians and Petchenegs, who began to ravage the northern frontiers in 1059. Shortly after this successful campaign he was seized with an illness, and, believing it mortal, appointed as his successor Constantine Ducas, to the exclusion of his own brother John. Although he recovered, Isaac did not resume the purple, but retired to the monastery of Studion and spent the remaining two years of his life as a monk. alternating menial offices with literary studies. His *Scholia* to the *Iliad* and other works on the Homeric poems are still extant in manuscript. He died in 1061.

ISAAC II (ANGELUS), emperor of the east 1185–95 and again 1203–04, was the successor of Andronicus I. He inaugurated his reign by a decisive victory over the Normans in Sicily, but elsewhere his policy was less successful. He failed in an attempt to recover Cyprus from a rebellious noble, and by the oppressiveness of his taxes drove the Bulgarians and Vlachs to revolt (1186).

In 1187 Alexis Branas, the general sent against the rebels, treacherously turned against his master and attempted to seize Constantinople, but he was defeated and slain. The emperor's attention was next demanded in the east, where several claimants to the throne successively rose and fell.

In 1189 Frederick Barbarossa of Germany sought and obtained leave to lead his troops on the third crusade through the Byzantine territory; but he had no sooner crossed the border than Isaac, who had meanwhile sought an alliance with Saladin, threw every impediment in his way, and was compelled only by force of arms to fulfill his engagements. The next five years were disturbed by fresh rebellions of the Vlachs.

During one of these, in 1195. Alexius, the emperor's brother, taking advantage of the latter's absence from camp on a hunting expedition, proclaimed himself emperor, and was readily recognized by the soldiers. Isaac was blinded and imprisoned in Constantinople. After eight years he was raised for six months to his throne once more. *(See* CRUSADES.) Isaac died in 1204.

ISAAC OF ANTIOCH (called the Great) is the name used to distinguish Isaac of Amida, a 5th-century Syriac writer, from two Edessene Isaacs, one a late 5th-century monophysite priest who settled at Antioch and the other a monophysite at the time of Bishop Paul (512) but who became orthodox under Bishop Asclepius (522). Jacob of Edessa distinguishes the three Isaacs; Gennadius knows of two. According to Zacharias Rhetor, Isaac visited Rome, and Dionysius Telmaharensis mentions his poems on the secular games of 404 and the capture of Rome (410) by Alaric. The Jacobite patriarch bar Shushan (d. 1073) calls him the disciple of Ephraem's pupil, Zenobius. If Isaac is the author of the poem on the destruction of Antioch by earthquake in 459, the date of his death must be later than this, but some, *e.g.,* Duval, ascribe the poem to the earlier Edessene Isaac. Bar Shushan collected Isaac's writings but included many which have to be allotted to his namesakes and some even to Isaac of Kineveh, while some ascribed to Ephraem may be Isaac's, so great is the copyists' confusion, which modern scholars have not yet fully resolved.

See editions by G. Bickell (1873) and P. Bedjan (1903). See also A. Baumstark, *Geschichte der syrischen Literatur,* pp. 63–66 (1922). (W. D. McH.)

ISAAC, HEINRICH (born *c.* 1450), Belgian composer. The exact date and place of his birth are unknown, but about 1477 he apparently went to Florence, and for many years was organist at the Medici chapel. After Lorenzo di Medici's death he found his way to Vienna and obtained an appointment as composer at Maximilian's court at Innsbruck. In 1515 he returned to Florence.

His church music, of which much has been preserved, is masterly in form and Shows great skill and ingenuity in the leading of the parts. But side by side with monumental masses he wrote, while in Florence, light secular compositions of a kind suited to the atmosphere of the Medici court. He also helped Lorenzo with his *canti carnascialeschi* for May-day celebrations. Later, at Innsbruck, he wrote the very simple and beautiful German songs on which his fame rests. Many of his melodies were treasured among the people and revived again and again to suit new words. Thus, *Innsbruck ich muss dich lassen,* written it is said to words by the emperor Maximilian, served for the hymn *O Welt, ich muss dich lassen,* for Paul Fleming's *In allen meinen Taten,* and for two chorales in Bach's *Matthew Passion* (nos. 16, 44).

Of Isaac's ten published masses, five are included in *Misse Heinrici Izac* (1906); two in the Wittenberg edition (1541), *Carminum* and *Une musque de Biscay;* one in the *Liber quindecim missarum* (1539), the famous *O praeclara,* written on one four-note subject throughout; and two in Ott's collection, *Missae 13 vocum* (1539).

ISAACS, JORGE (1837–1895), Colombian poet and novelist, whose best work, *María,* is the most famous Latin-American novel.

Isaacs was born at Cali, in the province of Cauca. Colombia, in April 1837, the son of a prosperous English Jew. He received an excellent education, first at Bogotá and later in England. During the War of the Cauca (1860–63) he was reduced to poverty by the destruction of his patrimony in the Cauca valley.

Settling in Bogotá in 1864 he published a slight volume of *Poesías,* which attracted considerable attention, and in 1867 the novel, *María,* which won immediate recognition and remains his chief title to fame. Seizing the opportunity thus opened to him for a political career, he entered public life, and in 1871–72 was appointed consul general in Chile.

On his return he served in the provincial legislatures of Cauca, Cundinamarca and Antioquia, and filled numerous political, educational and editorial positions. He died in Abagüé on April 17, 1895.

Although he continued to write until his death, and was a generous contributor to periodical literature, none of his later efforts fulfilled the promise of his first two volumes. An idyllic picture,

very likely autobiographical, of life among the Cordilleras of his native Cauca valley, *María* was called by one eminent critic "the poem of America," and was translated into several foreign languages.

Among his poems, notable are "Río Moro" ("River Moro"), "La Noche Callada" ("The Silent Night") and "La Tumba del Soldado" ("The Soldier's Tomb"); *Saulo* is part of an uncompleted drama; *La* Revolucidn *radical en Antioquia* is his most important prose work outside fiction.

ISABELA, Philippine province in northeastern Luzon (*q.v.*). Area 4,069 sq.mi.; pop. (1948) 264,495, (1958) 317,960. The eastern section comprises the rugged, sparsely populated Sierra Madre which extends to the Philippine sea. Central and western Isabela lie in the fertile Cagayan valley, an important pioneer area since the early 1930s. Rice is the main crop with surpluses shipped to Manila; corn is the leading local food crop. The production of Virginia tobacco is significant. The provincial capital and agricultural centre is Ilagan. (R. E. HE.)

ISABELLA (1451–1504), LA CATÓLICA, queen of Castile, daughter of John II of Castile by his second wife, Isabella, granddaughter of John I of Portugal, was born at Madrigal on April 22, 1451. On the accession of her brother, Henry IV (1454), she was withdrawn by her mother to Arevals. Removed by Henry to the court, her hand was sought in application by many suitors, among whom were Alphonso of Portugal, Pedro Giron and Ferdinand of Aragon, whom she ultimately married on Oct. 19, 1469. An offer of the crown of Castile was made to her by the revolutionary leaders in the civil war; she declined it and in 1468 was recognized by her brother as lawful heir. On his death, she was proclaimed queen of Castile and Leon (Dec. 13, 1474). Spain undoubtedly owed to Isabella's clear intellect, resolute energy and unselfish patriotism much of that greatness which it acquired under "the Catholic sovereigns." The moral influence of the queen's personal character over the Castilian court was incalculably great; from the debasement and degradation of the preceding reign she raised it to being "the nursery of virtue and of generous ambition." She did much for letters in Spain by founding the palace school and by her protection of Peter Martyr d'Anghiera. The very sincerity of her piety and strength of her religious convictions led her at times into great errors of state policy; her efforts for the introduction of the Inquisition into Castile and for the proscription of the Jews are cases in point. It was a happy intuition that led her to give credence to the scheme of Columbus and to finance his undertaking, offering in a generous impulse to pawn her personal jewels if the treasury funds proved inadequate. She died at Medina del Campo on Nov. 24, 1504.

ISABELLA II (1830–1904), queen of Spain, was born in Madrid on Oct. 10,1830, the daughter of Ferdinand VII and Maria Christina. In virtue of the so-called Salic law of 1713, which however had been set aside in 1830, her uncle Don Carlos (*q.v.*) disputed her title on Ferdinand's death (Sept. 29, 1833). During the Carlist War (1833–40), when Maria Christina was regent, the government began suppressing the monasteries and selling their estates to raise money and to secure the purchasers' loyalty. The queen regent abdicated in 1840; Baldomero Espartero (*q.v.*), declared regent in 1841, was deposed after a pronunciamiento by R. M. Narváez in 1843; and Isabella was then declared of age (Nov. 8, 1843). Her marriage to her debilitated cousin, Don Francisco de Asís de Borbón, in 1846, simultaneous with that of her sister to the duc de Montpensier, embittered Anglo-French relations. Her reign was a succession of governmental changes, palace intrigues and pronunciamientos: Narváez, leader of the Moderados, was prime minister five times in all; the Progresistas under Espartero were in office from 1854 to 1856; and Leopoldo O'Donnell's second ministry (Unión Liberal, 1858–63) was the longest continuous one. Her private life gave rise to scandal and her capriciousness alienated her most patient servants. In Sept. 1868, Juan Prim and J. B. Topete (*qq.v.*) pronounced against her, Francisco Serrano (*q.v.*) defeated her army at Alcolea and she went into exile. In Paris on June 25, 1870, she abdicated in favour of her son Alphonso XII. She died in Paris on April 9, 1904.

ISABELLA OF BAVARIA (1370–1435), otherwise called ISABEAU, queen of France, was the daughter of Stephen II, duke of Bavaria. She was born in 1370 and was married to Charles VI of France on July 17, 1385, and crowned at Paris on Aug. 22, 1389. She fell under the influence of the dissolute court in which she lived and, the king having become insane (Aug. 1392), consorted chiefly with Louis of Orléans. After the assassination of the duke of Orléans (Nov. 23, 1407) she supported the Armagnacs until, having quarreled with them and with her surviving son, the young dauphin (afterward Charles VII), she went over to the side of the Burgundians (1418). By the treaty of Troyes (May 21, 1420), she gave her daughter Catherine in marriage to the king of England, Henry V, whom she recognized as the heir to the king of France. She died in Sept. 1435 and was interred without funeral honours in the abbey of St. Denis.

ISABELLA OF HAINAUT (1170–1190), queen of France, was the daughter of Baldwin V, court of Hainaut, and Margaret, sister of Philip of Alsace, and was born in 1170 at Lille. She was married in 1180 to Philip II Augustus and brought to him as her dowry the province of Artois. This marriage brought about the revolt of the house of Champagne; so that Isabella's coronation could not take place at Reims, and she was crowned at St. Denis instead on May 29, 1180.

In 1184, Philip, waging war against Flanders, was angered at seeing Baldwin support his enemies and called a council at Senlis for the purpose of repudiating his wife. But Isabella succeeded in dissuading him from this purpose. She died in 1190. Her son became Louis VIII of France.

ISABEY, JEAN BAPTISTE (1767–1855), French painter of miniatures, was born at Nancy on April 11, 1767. He went to Paris in 1785 and later became a pupil of J. L. David. Employed at Versailles on portraits of the dukes of Angoulême and Berry, he was given a commission by Marie Antoinette, the first of many which he received up to his death (in Paris, April 18, 1855) from the successive rulers of France. Patronized by Josephine and Napoleon, he arranged the ceremonies of their coronation and prepared drawings for the publication intended as its official commemoration, a work for which he was paid by Louis XVIII, whose portrait he executed in 1814. Although Isabey did homage to Napoleon on his return from Elba, he continued to enjoy the favour of the Restoration, and took part in arrangements for the coronation of Charles X.

The monarchy of July conferred on him an important post in connection with the royal collections, and Napoleon III granted him a pension and the cross of commander of the Legion of Honour. "Review of Troops by the First Consul" was one of his most important compositions, and "Isabey's Boat," a drawing of himself and family, had an immense success at the Salon of 1820. His portrait of "Napoleon at Malmaison" is held to be the best likeness of the ruler ever executed. His son and pupil Louis Gabriel Eugbne Isabey (1804–86) was a genre and marine painter and water colourist.

See Marion W. Osmond, Jean Baptiste Isabey, the Fortunate Painter (1947).

ISAEUS (c. 420 B.C.–*c.* 350 B.C.), a professional speech writer at Athens specializing in testamentary law, whose lucidity and logical method were a landmark in the development of forensic oratory. Accounts of his life are scanty and contradictory. His father is said to have been called Diagoras, which is not an Athenian name. According to one ancient source Isaeus was a Chalcidian, according to another an Athenian. To account for this discrepancy it has been suggested that his family belonged to a settlement of Athenian citizens at Chalcis. At any rate he spent his professional life in Athens, either as a citizen or as a resident alien. He appears to have taken no part in public life, but this is in itself no evidence that he was an alien: he may merely have had no desire to speak in public.

His profession was to write speeches for clients. He appears to have confined himself entirely to forensic speeches and almost entirely to those concerned with private suits. He had a minute knowledge of the laws of inheritance and expert skill in exploiting this knowledge to win a case. Too much weight should not be attached to ancient reports that he was a pupil of Isocrates and

Lysias. Of Isocrates' influence his work shows little trace. The influence of Lysias is indeed unmistakable, but probably, as Dionysius of Halicarnassus says in his work on the Attic orators, Isaeus merely imitated him. Ancient stories of his personal relations with Demosthenes can largely be discounted, but there is no doubt that Demosthenes' writing owed much to him.

The author of the pseudo-Plutarchean life of Isaeus says that 64 speeches were ascribed to him of which he believed 50 to be genuine. Eleven are extant and a considerable part of a 12th has been preserved in Dionysius' essay on Isaeus. In most cases dating can only be tentative, but all belong to the first half of the 4th century B.C. Every one of the 11 speeches deals, directly or indirectly, with a will. Six relate to disputed claims to an inheritance and three to prosecutions for false witness in testamentary suits. The fifth speech concerns an action brought to compel a man to discharge his obligations as surety in connection with a will, and the 11th the indictment of a guardian for ill-treatment of his ward. The incomplete 12th speech is not connected with a will case; it refers to an appeal to a law court by a certain Euphiletus against the decision of his demesmen to strike him off the register. Many fragments and titles of other speeches have also survived.

The professional speech writer was faced with a difficult problem. It was essential to present a case in a convincing and persuasive form, but if the writer's skill were too transparent, the jurors would be on their guard and the client's case might suffer., It is clear that Antiphon's self-conscious artistry had been found unsuitable for practical oratory. Lysias had allayed suspicions by writing in a simple style and by skillfully adapting the language and manner of a speech to the character of each particular client. Such characterization is not to be found in the work of Isaeus, but he resembles Lysias in the simplicity and clarity of his language and in avoiding pretentious embellishments. He makes sparing use of such linguistic adornments as antithesis, parison and anaphora. On the other hand he indulges freely in the so-called "figures of thought"; *e.g.,* rhetorical questions and the imaginary objections of an opponent.

Scholars have pointed out some divergences from strict Attic idiom in his writing; it is possible that these may be due to manuscript corruption. In general his style is lucid and businesslike, and the very fact that it lacked literary charm probably added to its effectiveness.

In the arrangement of his matter Isaeus shows himself remarkably independent of the rules for subdivision prescribed by rhetoricians. He follows no single plan but varies the structure according to the needs of each particular speech. He shows particular skill in interweaving narrative and proof, thereby avoiding a long, unbroken relation of facts, which in testamentary cases might be complicated and difficult to follow.

Perhaps Isaeus' most significant contribution to forensic oratory lay in his method of argument; he appears to have been the first orator to build up his case point by point with logic and reason. At the same time he took pains to make his arguments intelligible, partly by frequent repetition and recapitulation at the end of a speech.

BIBLIOGRAPHY.—The text of Isaeus' extant speeches was edited by T. Thaiheim, Teubner series (1903); with commentary but excluding fragments, by W. Wyse (1904); with translation by P. Roussel, Budé series (1922) and by E. S. Forster, Loeb series (1927). *See* also F. Blass, *Die attische Beredsamkeit,* vol. ii, 2nd ed. (1892); R. C. Jebb, *The Attic Orators From Antiphon to Isaeus,* vol. ii, 2nd ed. (1893). For the technicalities of Attic law *see* J. H. Lipsius, *Das attische Recht und Rechtsverjahren* (1905–1915). (*H. ISAIAH. It is important to realize that practically all we know of the life and career of the Prophet Isaiah of Jerusalem is contained in the book of Isaiah. But the book itself, as it lies before us in our Bibles contains much more material than that which is directly concerned with the life and work of the prophet. In its present form, as a book, it is a comparatively late production, compiled out of a series of prophetic collections made by a succession of redactors and editors. "These collections embody a nucleus of Isaianic material—the actual prophecies of Isaiah himself—which was added to and enlarged as time went on. But even in the earliest form of compilation which critical analysis can detect this Isaianic material has been combined with non-Isaianic matter." As we shall see, at least one, if not two other writers contributed largely to the book as we have it. As the late G. Buchanan Gray well remarks in his commentary on Isaiah (p. xii.), "No full justice can be done to a book which is a great monument to Jewish religion after the exile if all our attention is devoted to determining whether this or that passage is genuine and dismissing it as not 'genuine' if it is not the work of Isaiah. In reference to works such as the Book of Isaiah the term 'genuine' is indeed misleading. None of the nameless writers may have possessed the religious genius of Isaiah, but together they represent the play of the earlier prophetic teaching on the Jewish Church. In religion as elsewhere, great personalities count first, and it is the privilege of a student of the Book of Isaiah to come face to face with one, if not two, such personalities; but the religious community is the necessary outcome, or field of action, of the great religious personality and his teaching, and the student of the Book of Isaiah has but half entered into his inheritance if he communes with Isaiah and the great exilic prophet, but fails to feel the life of that post-exilic community, which not only preserved for themselves and for us the words of the earlier prophets, but preserved them in books which were also made to breathe the hopes and aspirations that sustained the Jews through centuries of isolation, oppression and temptation."

The book falls into two main divisions: (a) Chapters i.–xxxix.; (b) Chapters xl.–lxvi. The whole of the material contained in (b) is post-exilic in date; that contained in (a) is partly post-exilic and partly earlier. The material directly or indirectly connected with the prophet Isaiah of Jerusalem is all contained in (a).

Analysis of the Book.—One of the great triumphs of Old Testament Criticism is revealed by the criticai anaiysis of the Book of Isaiah. It is no part of our present task to trace the history of the development of this criticism. Suffice it to say that it reached its high watermark in the works of Duhm (Jesaia) 2nd ed. 1902 and Marti (Jesaia) 1900. Invaluable work had been done in this country by T. K. Cheyne in a succession of works, the most important of which for our present purpose is the *Introduction to the Book of Isaiah,* 1898. Since the publication of these treatises a certain amount of reaction has taken place in Isaianic criticism. It will be convenient for our purpose to follow Duhm and Marti as guides and to notice as we proceed the more important modifications that have come to the front since.

Chapter 1 forms a general preface to the whole Isaianic collection. The chapter is itself composite and was probably put together in its present shape by editors. The themes it deals with may be summarized as follows: (1) An address on Israel's faithlessness c. 701 B.C. (vv. 2–17), (2) the sin of Judah and the choice given (vv. 18–20) c. 701 B.C., (3) a dirge over Jerusalem's declension, passing over into a threat (vv. 21–26) before 701 B.C.; (4) a post-exilic addition dealing with the deliverance of a remnant and the annihilation of Apostates (vv. 27–28); (5) a fragment against nature-worship (vv. 29–31) *c.* 722 B.C. All these passages may be regarded as Isaianic except vv. 27–28. Note the heading v.1 which was added bv an editor to the whole book of collected prophecies. The rest of chapters i.–xxxix. can broadly be divided into four books, viz., Bk. 1 first collection of Isaiah's prophecies, Chapters ii.–xii.; Bk. 2 an intermediate collection of oracles mainly concerning foreign nations, Chapters xiii.–xxiii.; Bk. 3 a third collection of Isaianic prophecies dealing mainly with the deliverance of Jerusalem with an eschatological preface and appendix, chapters xxiv.–xxxv.; Bk. 4 a historical appendix to the collected form of Isaianic prophecies, chapters xxxvi.–xxxix.

1. The first collection of Isaiah's prophecies, Chapters ii.–xii. This is itself composed of minor collections (notice ii.1–iv.6 and vi.1–ix.7). We come to the earliest minor collection contained in chapter ii.1–iv.6. These chapters are carefully arranged being provided with an eschatological preface ii.2–4–, and a Messianic appendix iv. 2–6. Both these apocalyptic passages may be regarded as dependent upon Old Tradition (so Gressmann) and are probably older than Isaiah himself. Thus in the striking section ii. 2–4, which recurs in Micah iv. 1–4 both prophets are probably citing from a common source containing early features, *e.g.,*

that Mount Zion is made higher than all the mountains and here assumes the position of the Mountain of the Gods of old myth. Isaiah takes this old story as a sort of text with its idealistic description of the future and sets against it a picture in striking contrast with the evils of the present. The section that follows ii. 6–21 has for its main theme Israel's Sin and the Day of Doom, and gives the prophet's conception of the Day of Yahweh (note especially chapter ii. 11–17 and the passage against idolatry v.18 sqq.). A section follows on Judah's impending ruin, completed by c. 735 B.C., contained in iii. 1–15 and this again by a powerful passage directed against the ladies of Jerusalem, iii. 16–iv.1. The whole section is completed by iv. 2–6, apocalyptic in character. Here vv. 5–6 may form a later addition. The general theme of the passage is the felicity of the redeemed community after it has been purged by judgment.

Chapter v. forms a section by itself and may be dated c. 735 B.C. The theme of the chapter is the parable of the vineyard and its application. The parable is contained in vv. 1–7 (cf. Matt. xxi. 32 sqq.); vv. 8–24 contain a denunciation in the form of six woes directed against the upper classes (vv. 25–30 should follow chapter x. 4). The whole composition is a very powerful piece of writing.

The second minor collection (Chapters vi.1 to ix.8) contains important material. Chapter vi. gives an account of Isaiah's inaugural vision, date about 738, and may have been composed to form an introduction to the group that follows which consists of (a) chapter vii. (prophecies of the period of the Syro-Ephraimitish war); (for the sign of Emmanuel, vii. 14–16, see article EMMANUEL); (b) viii. 1–4, *c.* 734 B.C., and vv. 5–10 and 11–15 all of the same period. An epilogue of uncertain date follows in vv. 16–18. This is an important section which seems to have been written down when the failure of the prophetic addresses contained in vii. 1–8, 15, had become evident. The Prophet now solemnly consigns "the testimony" to an inner circle of disciples.

The final section culminates in the description of the Messianic King (viii. 18–ix. 6). The text of the opening verses seems to have been much edited, in fact rewritten to form an introduction to what follows. The grand picture of the Messianic King given in ix. 1–6 is probably from Isaiah's hands, though some critics have denied this. The date of the Messianic passage is uncertain; perhaps it may be assigned to the youthful period of Isaiah's life, when he despaired of the Davidic House as represented by Ahaz (contrast xi. 1–9). The section that follows ix. 7–x. 4, to which should be attached v. 26–30 may be dated about 735 B.C. It is an artistically constructed poem with a refrain and may be entitled "Yahweh's Outstretched Hand." It is mainly directed against north Israel and is a splendid example of Isaiah's poetical genius. A collection of oracles against Assyria with a Messianic appendix follows in Chapter x. 5–xi. 16. The Messianic section forms an appropriate conclusion. The Isaianic material here is fragmentary in character and has been edited to a certain extent by later hands. The general date of the fragments appears to be between 711 and 701 B.C. The date of the Messianic appendices xl. 1–9 and 10–16 is uncertain, but vv. 1–9 may be Isaianic while 10–16 probably belong to a later age; xl. 1–9 form perhaps the grandest of all the Messianic passages of the O.T. Its wonderful picture of the Golden Age marked by universal peace and its serene outlook on a transformed world are worthy of Isaiah. These features reflect the serenity of old age. Isaiah probably composed the passage towards the end of his life: notice the prophet's revived hope in the Davidic dynasty. Chapter xii. (probably post-exilic) forms the lyrical epilogue to the first complete Isaianic collection embodied in chapters ii.–xii. Chapter xii. is largely composed of reminiscences of the Psalter.

Book 2 forms an intermediate collection of oracles mainly concerning foreign nations, chapters xiii.–xxiii. The bulk of this section consists of ten "oracles" (burdens); and interspersed among these are four passages without titles which undoubtedly come from Isaiah's hand, viz. (a) xiv. 24–27 (b) xvii. 12–14 (c) Chapter xviii. and (d) Chapter xx. Of the ten oracles Chapter xvii. 1–6, 9–11, and xxii. 1–8, 12–14, may be assigned with confidence to Isaiah, while chapter xv. to xvi. 12 may be an older prophecy adopted by Isaiah and re-affirmed in a special postscript (Chapter xvi. 13–14). The only "oracles" which bear no relation to Isaiah or his age are Chapter xiii. 2–xiv. 23 against Babylon, which was probably composed during the Exile; chapter xix. against Egypt, Chapter xxi. and Chapter xxiii. Not improbably this collection in its original form, consisting of ten oracles had an independent existence. The editor of the complete Isaianic collection took over this book which contained a genuine Isaianic element by inserting the four passages mentioned above and then incorporated the whole into the collected form of Isaiah's prophecies. It should be noted that it occupies in the complete book a similar position to corresponding groups of oracles in Ezekiel (Chapters xxv.–xxxii.) and Jeremiah (according to the LXX arrangement). Probably this editor is responsible for the heading, chapter xiii. 1, or at least for the words which *Isaiah* Ben *Amoz* saw. The poem on the Fall of Babylon consists of (a) a prophecy directed against Babylon xiii. 2–22 and (b) a triumphal ode on the downfall of the oppressive power, xiv. (4b)–21. This latter is certainly one of the finest compositions in the O.T. The date of composition probably belongs to the latter years of the Exile and therefore is more or less contemporary with Deutero-Isaiah. Note the contrast in tone between this oracle and that of Chapter xxi. Chapter xvii. 1–11, containing an oracle about Ephraim and Syria, may be dated about 735 B.C. and the second of the appended Isaianic fragments, Chapter xvii. 12–14, about 702 B.C. This is a very fine piece of writing. The third of the appended fragments, containing an address to the Ethiopian Ambassadors, may be dated about the same time (Chapter xviii.). Chapter xix., an oracle about the fall of Egypt, seems to be of composite origin, vv. 1–15 perhaps may be dated between 528 and 485 B.C., while the remarkable verses, 16–25, forming an appendix, seem to belong to a later date still. Note the broad universalistic spirit of the passage which can hardly belong to an earlier time than the Greek period. Sellin, however, takes a different view. He dates vv. 1–17 prior to 663 B.C., and even vv. 18–25 he thinks are pre-Exilic. Chapter xx. contains the fourth of the appended Isaianic pieces. It may perhaps be dated about 711 B.C. in the reign of Sargon. The words translated Egypt (Misraim) and Ethiopia (Cush) may however be referred to a different provenance, if Winckler can be followed in assuming the existence of a Muṣri and Cush in north Arabia: it is possible that these terms have been confused with Egypt and Ethiopia in this chapter and occasionally elsewhere in the O.T. Chapter xxi. 1–10 containing a vision of the fall of Babylon may be dated about the end of the Exile. It is followed by two fragmentary oracles on Edom, and Kedar, and has appended to it an Isaianic fragment xxi. 16–17 which may be dated about 711 B.C. Chapter xxii. 1–14, an oracle on the Valley of Vision, may be dated about 701 B.C. Appended to this oracle is an interesting political invective directed against Shebna with a later appendix (Chapter xxii. 15 sqq.). The final chapter of this Section Chapter xxiii. deals in its present form with the Fall of Tyre and perhaps with the siege which the prophecy has in view is the one conducted by Nebuchadnezzar 586–573 B.C. (vv. 13 and 15–18 may be post Exilic additions). Duhm has proposed a brilliant solution by slightly altering the text in 8 and substituting Sidon for Tyre (Sidon is mentioned in vv. 2,4 and 12). The reference will then be to the devastation of Sidon by Artaxerxes III. A later editor again altered it so as to make it refer to the siege of Tyre by Alexander the Great. Book iii. contains the third collection of Isaianic prophecies dealing mainly with the deliverance of Jerusalem, with an eschatological preface and appendix. The centre of this group of chapters is largely composed of material from Isaiah's hand dating apparently from the crisis of Sennacherib's invasion in 701 B.C. To the post-exilic editor who combined this collection with the two preceding books, the dominating interest was eschatological.

The invasion of Sennacherib was invested with an eschatological significance, and was "regarded as typical of the last great attempt to extinguish the people of Yahweh" at the end of the age. This editor will also have been responsible for prefixing the eschatological preface (chs. xxiv.–xxvii.) and affixing the eschatological appendix (chs. xxxiv.–xxxv.) to the central group.

The third collection thus falls into three main parts, viz., I. Eschatological Preface (Chs. xxiv.–xxvii.). II. Prophecies dealing mainly with the Deliverance of Jerusalem (Chs. xxviii.–xxxiii.). III. Eschatological Appendix (Chs. xxxiv.–xxxv.). Chapters xxiv.–xxvii. are characterized by certain remarkable features. When the lyrical passages or songs are taken away there emerges a uniform apocalypse. The songs in question are (a) xxv. 1–5 (commemorating the destruction of a strong city); (b) xxv. 9–11 (the taunt song on Moab); (c) xxvi. 1–19 (a poetical meditation); and (d) the song in xxvii. 2–5. The subject of the main apocalyptic section is a great catastrophe which convulses the entire world. A picture of world-wide desolation is drawn in vivid colours. This is followed by a description of the divine judgment on the evil powers (heavenly and earthly) and of Yahweh's enthronement on Mount Zion (Ch. xxiv.). Finally the "Coronation festival" — " a feast of fat things for all peoples"— is described (xxv. 6–8). The date of this section is hard to determine. The earliest assignable date is in the reign of Artaxerxes Ochus and probably the limits are 350–330 B.C. A number of distinguished scholars, however, date these compositions late in the Maccabean period, but on insecure grounds. The doctrinal importance of the chapters is considerable. Thus ch. xxvi. 19 contains perhaps the first clear allusion to the doctrine of the resurrection; cf. the oracles contained in chapters xxviii.–xxxiii. Doubts have been raised as to the Isaianic character of xxviii. 23–29, a little poem in the style of the Wisdom literature which may well be Isaiah's. Ch. xxix. 17–24 is almost certainly post-exilic (the humble and needy of *v.* 19 are the oppressed pious so often mentioned in the Psalms). Ch. xxx. 18–26 also post-exilic. Ch. xxx. 27–33 doubtfully Isaianic, perhaps post-exilic. Chapters xxxii.–xxxiii. contain a description of the renovated state in the Messianic age and form a contrast with preceding chapters especially as regards the upper classes. With the exception of vv. 6–8 Chapter xxxii. might have been written by Isaiah. If so, with chapter xxxiii., it must be a product of the prophet's old age. Though the subject of chapter xxxiii. is undoubtedly the deliverance of Jerusalem from Sennacherib it is highly improbable that the chapter is a composition by Isaiah. It seems rather to be a sort of liturgical meditation by a post-exilic poet on the deliverance of Jerusalem. It is in fact a composition parallel to xxvi. 1–19 (cf. xxxvii. 22–32, also post-exilic). Sellin, however, warmly defends the Isaianic character of the passage, as well as of the previous chapters xxxiv.–xxxv., probably written by the same hand to form the eschatological appendix to the preceding group. Edom figures prominently in xxxiv.; but the apocalyptic character of the passage is not modified by this fact — Edom in fact became a symbolical name for the oppressive world-power. The earliest possible date of composition would be about 400 B.C.

A further appendix to the Isaianic collection ending at Chapter xxxiii. is contained in Chapters xxxvi.–xxxix. These chapters which are mainly narrative in character have been excerpted from the Book of Kings. They correspond to 2 Kings xviii. 8–xx. 19. The only divergencies are (a) the omission in the Isaiah text of the section contained in 2 Kings xviii. 14–16 and (b) the insertion in the Isaiah text of Hezekiah's psalm of thanksgiving Is. xxxviii. 9–20, apparently a late post-exilic composition. See further HEZEKIAH.

The Deutero-Isaiah. — With Chapter xl. a new section of the book of Isaiah begins. Here the background is entirely different from that of the earlier chapters contained in part I. The oppressive world-power is no longer Assyria but Babylon. The Exile is not so much predicted as pre-supposed. The chapters are the work of a great lyrical poet who sees everything through a sort of golden haze. Chapters xl.–xlviii., apart from some small interpolations, are the work of this writer who apparently composed them c. 538 B.C., *i.e.*, after Cyrus had appeared on the scene, but before his capture of Babylon. Theologically the chapters are of great importance, insisting as they do on the unique character of Yahweh who is the sole God — there is but one God Yahweh and Israel is his prophet. The chapters were apparently written in Babylonia. Chapters xlix.–lv., which by a majority of critics are ascribed to "Deutero-Isaiah" (style and phraseology are practically the same), are distinguished from the preceding chapters by the disappearance from them of the themes so prominent in the earlier chapters. Cyrus is no longer referred to. The Exodus from Babylon is no longer insisted upon. The future glory of Zion-Jerusalem is prominently dwelt upon, and the gathering in of the exiles scattered throughout the world is described. Possibly these chapters were composed, as Cornill suggests, "under the immediate impression produced by the issue of the edict in which Cyrus gave permission to the exiles to return home."

It is important to note Sellin's reminder that the whole work of Deutero-Isaiah is eschatological. "With the victory of Cyrus there dawns for him those last times which for centuries had been the object of a burning hope. By this everything is to be explained— the miraculous march through the wilderness, the picture of the New Jerusalem, the conversion of the heathen and the overthrow of the world-power" (cf. also xlix. 26: li. 6 sqq.). It has been commonly assumed that the prophecies of Deutero-Isaiah were circulated by this author in written form; but recently the view that the discourses were spoken orally at different times (perhaps in some place where the exiles met) has gained ground.

Trito-Isaiah.—With Ch. lvi. an entirely new section of the Book begins. Here everything breathes a different atmosphere. Zion's felicity — the day of longed-for salvation — has not yet dawned. But the obstacle is no longer Babylon, but godless members of the Jerusalem community and heretics. There is here no question of a Return — a new Exodus. The Jews are settled in the Holy Land; Jerusalem is no longer in ruins, but has a settled population; the Temple has been re-built. But matters are not well with the restored community. There are grave symptoms of internal weakness. Social conditions are unsatisfactory; the rich oppress the poor. The old Israelitish population of the land (in Judaea and Samaria) is unwilling to submit to the "yoke of the Law" and threatens to build a rival Temple. The chapters form a distinct group by themselves, though the various items are strung rather loosely together. They were evidently written at a critical time, when it was all-important to strengthen the faith of the strict, religious party by kindling hope among them in the coming salvation. The godless are to be brought into judgment, and redress is to come for the pious followed by the glorification of the Holy City.

Apart from some inconsiderable additions the chapters are regarded by many modern scholars, including Duhm and Marti, as having emanated from one author, who is styled for the sake of convenience the "Trito-Isaiah." He wrote in the middle of the fifth century, apparently (c. 450 B.C.), a few years before the arrival of Nehemiah in Jerusalem.

There are certain difficulties about the hypothesis of Trito-Isaiah which have been well summarized by Sellin, who points out that the themes which are prominent in the time of Malachi and Nehemiah are absent from these chapters. Moreover, there are two, if not three, passages which imply that the Temple was not in existence at the time when the author wrote (cf. lxiii. 18; lxiv. 8 *sq.*; and lxvi. 1–5). Possibly the first two of these passages are late interpolations, while the third does not necessarily imply the non-existence of the Jerusalem Temple. If these chapters are not a literary unity the best alternative view as to their origin is perhaps the following: a post-Exilic editor taking a section of writing which belonged to Deutero-Isaiah, viz., Chapters lx.–lxii., combined this, "with the work of a Jerusalemite prophet of the period between 586 and 520" (Sellin) and enlarged it with additions of his own.

It is impossible here to do more than refer to the so-called "Servant Songs" about which a whole literature has grown up (xlii. 1–4; xlix, 1–6; l. 4–9; lii. 13–liii. 12). Is the servant here a collective term for the true Israel, or does it stand for an individual and if so for whom? The commonly accepted view has been some form or other of the first or collective interpretation (see J. Skinner, The Cambridge Bible ad loc.); but recently several scholars have adopted the individualistic interpretation; so especially Sellin who now identifies the servant with Moses, though he formerly thought of Jehoiachin. See further discussions by S. A. Cook, Camb. Ancient History, iii. 489 sqq., and H. Wheeler

Robinson, *The* Cross and *the Servant.*

The Origin of the Book of Isaiah.— It may be inferred from Ecclus. xlviii. 20–25 that the book as we have it was then already in existence *c.* 200–180 B.C.; further it seems probable that about 400 B.C. a Book of Isaiah was in existence which contained chapters i.–xxxv. of our present book, to which chapters xxxvi.–xxxix. were added later. Between 400 and 200 B.C. the work of Deutero- and Trito-Isaiah which at first circulated independently, were added to the Isaianic collection. Not improbably the juxtaposition may have been due to Deutero-Isaiah himself. for there are linguistic points of contact between the later chapters and the work of Isaiah of Jerusalem. The earlier history of the Isaianic collection is wrapped in obscurity. It is clear that the prophet himself was primarily a preacher and delivered his discourses orally; they were written down only at a later stage. (Cf. the analogous case of Jeremiah, Jer. xxxvi.) Fragments of the prophet's discourses were no doubt carefully treasured by his disciples (cf. Is. viii. 16; xxx. 8). The collections were formed and later still further collections, the whole being brought up to date by eschatological additions.

The Life and Activity of Isaiah.— The prophet Isaiah, the son of a certain Amoz, was the father of two sons who bore highly symbolical names, viz., Shear-Jashub ("a remnant shall return") and Mahar-shalal-hash-baz ("swift spoil, speedy prey"). The prophet's family probably belonged to the aristocracy of Jerusalem and may have had connections with the royal house. The prophet seems to have been able to enter the presence of the king at will (cf. Chapter vii.). His active career extended from about 738 B.C. (cf. Is. vi. 1) to at least 701 B.C. and probably later 690 B.C. (?). He may have been martyred under Manasseh as Jewish legend attests. The prophet lived through a succession of political crises connected with the intervention of Assyria in western Asia, viz.: the Syro-Ephraimitish War 734 B.C.; the fall of Samaria, 722 B.C.; the siege of Ashdod by Sargon, 711 B.C.; the death of Sargon, 705 B.C.; and the invasion of Sennacherib in 701 B.C. Isaiah has well been called "the prophet of Faith." He stands a sublime figure for faith in the supremacy of the spiritual over the earthly; for the potency of high ideas and ideals over brute force and power. To have combined such a lofty faith with practical statesmanship — for Isaiah was essentially a man of action — is an achievement worthy of the greatest men of any age.

ISAIAH, ASCENSION OF, an interesting apocryphal book of the Old Testament. Its various constituents — the Martyrdom of Isaiah, the Testament of Hezekiah and the Vision of Isaiah — circulated independently as early as the 1st century. The first of these was of Jewish origin, and is of less interest than the other two, which were the work of Christian writers. The Vision of Isaiah is important for the knowledge it affords of 1st-century beliefs in certain circles as to the doctrines of the Trinity, the Incarnation, the Resurrection, the Seven Heavens. etc. The long-lost Testament of Hezekiah, which is, in the opinion of Charles, to be identified with iii. 13b–iv, 18 of the present work, is unquestionably of great value because of the insight it gives into the history of the Christian church at the close of the 1st century. Its descriptions of the worldliness and lawlessness which prevailed among the elders and pastors, *i.e.*, the bishops and priests, of the widespread covetousness and vainglory as well as the growing heresies among Christians generally: agree with similar accounts in II Peter, II Timothy and Clement of Rome.

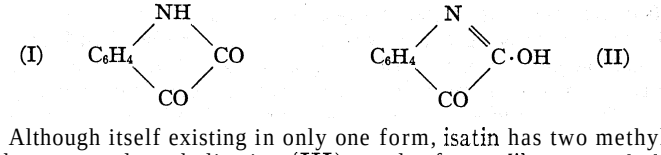
Of the three original sources, (1) the Martyrdom of Isaiah consists of i, 1, 2^a, 6^b–13^a, ii, 1–8, 10–iii, 12, v, 1^b–14, and is but an imperfect survival of the original work. (2) The Testament of Hezekiah is to be found in iii, 13^b–iv, 18, in a mutilated form, without beginning or end. (3) The Vision of Isaiah is vi–xi, 1–40. Its archetype existed independently in Greek, and differs in many respects from the form in mhich it was republished by the editor of the entire work. This editor had the three documents mentioned at his disposal; the first was of Jewish, the others of Christian origin; he reduced or enlarged them as it suited his purpose, and put them together as they stand in the present text. As regards the dates of the different elements, the Martyrdom belongs to the 1st century A.D., the Testament of Hezekiah to the period A.D. 88–100, the Vision of Isaiah to the close of the 1st century A.D., but the work as it now stands is probably not earlier than the latter half of the 2nd century.

See R H. Charles, *The Ascension of Isaiah* (1900), in *The Apocr. and Pseudepig. of the O.T.*, ii, 155–162 (1913), and in the S.P.C.K. "Translations of Early Documents" (1918). (W. O. E. O.)

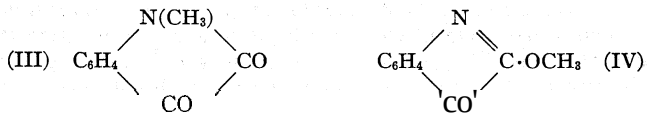
ISALLOBAR, a line entered on a meteorological chart connecting points having the same change in pressure in a given period of time preceding the time of observations represented on the chart. By international agreement, three-hour pressure changes or tendencies are transmitted by all stations and ships to the collecting-distributing centres with each observation. Isallobars may be drawn for these values or for those of 12-hour or 24-hour intervals obtained by comparison with pressure observations taken 12 or 24 hours previously. (H. R. B.)

ISAR (identical with *Isère*, in Celtic "the rapid"), a river of Germany. It rises in the Tirolese Alps. at an altitude of 5.840 ft. It winds in deep, narrow gorges through the Alps, and at Tölz (2,100 ft.), enters the Bavarian plain. which it traverses in a generally north and northeast direction, and enters the Danube immediately below Deggendorf. It is 163 mi. long with a drainage area of 3,461 sq.mi. Below Munich the stream is 140 to 350 yd. wide. and is studded with islands It is not navigable, except for rafts. The Isar is essentially the national stream of the Bavarians; it traverses the finest corn land in the kingdom On its banks lie the cities of Munich and Landshut, and the venerable episcopal see of Freising. See DANUBE.

ISATIN, in chemistry, an oxygenated derivative of indole (q.v.) prepared originally by oxidizing indigo nith nitric or chromic acid. It crystallizes in orange-red prisms melting at 200°-201° C. Isatin is of practical importance in the manufacture of vat colours For example. it yields Ciba red G (thioindigo scarlet G) by condensation with 2-hydroxythionaphthene and subsequent bromination of the condensation product Isatin is also of outstanding scientific interest because it was one of the first recognized examples of tautomerism (q.v.). It is a chemical individual nith two personalities Certain of its reactions suggest the lactam constitution (I) whereas others indicate the lactim configuration (II).



Although itself existing in only one form, isatin has two methyl ethers: pseudomethylisatin (III) made from dibromomethyloxindole, and methylisatin (IV) prepared by



the interaction of methyl iodide and silver isatin.

Isatin and its homologues are produced by condensing aniline and its homologues with hydroxylamine sulfate and chloral hydrate; an intermediate isatinimide is formed which on hydrolysis furnishes the corresponding isatin.

ISAURIA, a district in the interior of Asia Minor. The nucleus of it was that section of the Taurus which lies directly south of Iconium and Lystra. Lycaonia had all the Iconian plain; but Isauria began as soon as the foothills mere reached. When the Romans first encountered the Isaurians (early in the 1st century B.C.), they regarded Cilicia Trachea as part of Isauria, mhich thus extended to the sea; the whole basin of the Calycadnus was reckoned Isaurian, and the cities in the valley of its southern branch formed what was known as the Isaurian Decapolis. Toward the end of the 3rd century A.D., however, all Cilicia was detached for administrative purposes from the northern slope oi Taurus; Pisidia mas also detached, and made to include Iconium. In compensation Isauria received the eastern part of Pamphylia. Restricted again in the 4th century, Isauria ended as the wild district about Isaura Palaea and the heads of the Calycadnus. During the war of the pirates against Rome, the Isaurians took so active a part that the proconsul P. Servilius followed them into

their fastnesses, and reduced the whole people to submission. The Isaurians were afterward placed under the rule of Amyntas, king of Galatia; but it is evident that they continued to retain their predatory habits and virtual independence. In the 4th century they are described by Ammianus Marcellinus as the scourge of the neighbouring provinces of Asia Minor; but they are said to have been effectually subdued in the reign of Justinian. Isauria passed into the hands of Turcomans and Yuruks with the Seljuk conquest.

This comparatively obscure people had the honour of producing two Byzantine emperors, Zeno, whose native name was Traskalisseus Rousoumbladeotes, and Leo III, who ascended the throne of Constantinople in A.D. 718, reigned until 741, and became the founder of a dynasty of three generations. The ruins of Isaura Palaea are mainly remarkable for their fine situation and their fortifications and tombs. Those of Isaura Nea have disappeared, but numerous inscriptions and many sculptured steles, built into the houses of Dorla, prove the site. It was the latter, and not the former town, that Servilius reduced by cutting off the water supply. The site was identified by W. M. Ramsay in 1901.

ISCHIA (Gr. Pithekoussa, "the apes' island," Lat. Aenaria, in poetry *Inarime*), an island off the coast of Campania, Italy, province of Napoli, 16 mi. S.W. of Naples and 7 mi. S.W. of the Capo Miseno, the nearest point of the mainland. Pop. (1951) 31,813. It is situated at the west extremity of the gulf of Naples, and is the largest island near Naples, measuring about 19 mi. in circumference and 18 sq.mi. in area. It belongs to the same volcanic system as the mainland near it, and the Monte Epomeo (anc. Epopeus, "viewpoint"), the highest point of the island (2,589 ft.), lies on the north edge of the principal crater, which is surrounded by 12 smaller cones. The island was occupied by Greek settlers but its Eretrian and Chalcidian inhabitants abandoned it about 500 B.C. owing to an eruption, and it is said to have been deserted almost at once by the greater part of the garrison which Hieron I of Syracuse had placed there about 470 B.C., owing to the same cause. Later on it came into the possession of Naples, but passed into Roman hands in 326, when Naples lost its independence.

Several eruptions are recorded in Roman times. The last of which we have any knowledge occurred in 1301, but the island was visited by earthquakes in 1881 and 1883, 1,700 lives being lost in the latter year, when the town of Casamicciola on the north side of the island was almost entirely destroyed The hot springs (147°), are alkaline and saline, and are much visited by bathers, especially in summer. They were known in Roman times, and many votive altars dedicated to Apollo and the nymphs have been found. The island is mountainous, beautiful and fertile. Wine, corn, oil and fruit are produced, especially the former, while the mountain slopes are clothed with woods. Tiles and pottery are made. Straw-plaiting is a considerable industry at Lacco; and a certain amount of fishing is also done. The potter's clay of Ischia served for the ancient potteries of Cumae and Puteoli. The chief towns are Ischia on the east coast, capital and seat of a bishop, pop. (1951) 7,064, with a 15th-century castle, to which Vittoria Colonna retired after the death of her husband in 1525; Casamicciola, population (1951) 3,297 on the north; and Forìo on the west coast, population (1951) 3,997 There is communication with Naples, both by steamer direct, and also by steamer to Torregaveta, and thence by rail

See G Algranati, *Ischia* (1930). (T. A.; X.)

ISCHL, spa and town in Upper Austria, Bundesland, annexed to Germany, 1938–45. Between the Ischl and Traun rivers on a peninsula at an altitude of 1,530 ft., it is one of the most fashionable watering places in Europe, famous for its mild climate, its saline and sulfur drinking springs, mud, sulfur and brine baths. Much of its popularity has been due to the fact that it was from 1822 the summer residence of the Austrian imperial family. Ischl is a centre of the Austrian salt industry which has been carried on since the 12th century. Pop. (1951) 13,422.

ISENTROPIC CHART. The isentropic chart is used in weather forecasting and in problems of meteorological research. It was first suggested by Sir Napier Shaw in Great Britain in 1933 and later. in 1936, by Carl-Gustav Rossby in the U.S., when the network of weather stations taking upper air observations (see UPPER AIR SOUNDINGS) became sufficient to make construction practical. An isentropic chart shows the moisture distribution and flow of air along a surface of constant entropy, which in meteorology is also a surface of constant potential temperature. (See METEOROLOGY.) The isentropic surface is not at a constant level but varies in height from place to place over the earth, the variation being indicated on the isentropic chart by lines (isobars) showing the pressure at which the isentropic surface is iound. The moisture distribution is shown by lines of constant mixing ratio expressing the number of grams of moisture per kilogram of air (dry). The flow of air at the isentropic surface is represented by winds recorded from pilot balloon (*q.v.*) observations and stream lines computed from the field of pressure and temperature.

Air particles tend to flow along isentropic surfaces rather than at constant levels. By virtue of this fact the life history of air currents can be conveniently followed from day to day by means of isentropic charts. In addition, they give a lucid picture of the physical processes which produce the weather.

See Jerome Namias, An Introduction to Air Mass and Isentropic Analysis, American Meteorological Society (1940). (J. Ns.)

ISEO, LAKE OF, a lake in Lombardy, north Italy (anc. Lacus Sebinus), at the southern foot of the Alps, between the provinces of Bergamo and Brescia. The Oglio enters the north end at Lovere and leaves the south end at Sarnico to join the Po. Area 25 sq.mi., length 16 mi., greatest width 3 mi., greatest depth 823 ft., height of surface above sea level 610 ft. It contains the island of Siviano, culminating in Monte Isola (1,834 ft.) crowned by a chapel, while to the south is the islet of San Paolo, occupied by the buildings of a small disused Franciscan convent and to the north the equally tiny island of Loreto, with a ruined chapel containing frescoes. At the southern end of the lake are the small towns of Iseo (15 mi. by rail from Brescia) and of Sarnico. Toward the head of the lake, the deep wide valley of the Oglio is seen, dominated by the glittering snows of the Adamello (11,660 ft.). Along the east shore there is a fine carriage road.

ISÈRE, a de'partement of France, formed in 1790 out of the northern part of the old province of Dauphin&. Pop. (1954) 626,116. It is bounded north by the de'partement of the Ain, east by Savoie, south by the Hautes Alpes and the Drôme and west by the Loire and the Rhône de'partement. Area, 3,180 sq.mi. The de'partement consists of most of the upper course of the Isère river (*q.v.*) and of the Drac, among the French Alps, and of the lower land towards the great bend of the RhBne at Lyons (Bas Dauphin&). At Vienne the average annual temperature is 5.3° above that of Paris, but winters are cold amongst the mountains, and rainfall increases there to nearly 80 in. The de'partement is divided into three separate arrondissements (Grenoble, la Tour-du-Pin and Vienne). 45 cantons and 566 communes. It is in the region of the 14th army corps (Lyons). Its capital is Grenoble which is the seat of a court of appeal, of an académie (educational division), and of a bishop now in the province of Lyons, but before the Revolution in that of Vienne: other important towns are Vienne, St. Marcellin and la Tour du Pin. It contains coal and iron mines, slate and stone quarries, and several mineral springs. The forests cover much ground. Flourishing industries are those of cement, glove making, silk weaving and paper making, metal work of various kinds, etc. Wheat, oats, vines, mulberries, chestnuts, tobacco, etc. are grown. The pastures feed horses, mules and cattle, while sheep from Provence migrate into the department in summer. Crémieu is a hill town with ancient fortifications and market. La Grande Chartreuse is in the de'partement.

ISÈRE (anc. ISARA), tributary of the RhBne, southeast France, 180 mi. long, with a descent of 7,550 ft. and a drainage area of 4,275 sq.mi. It flows through the *départements* of Savoie, Isère and Drôme. It rises as a torrent in the Galise glaciers of the French Graian alps, and has successive sections of its course orientated southeast, northwest and northeast-southwest, crossing the geological outcrops for the most part obliquely, and receiving the Arly and Arc, among other streams. After traversing the northern part of the axis of the Belledonne chain, it enters the wider Graisivaudan valley, floored by Jurassic strata, which is parallel to the Belledonne and flows southwestward to its union with its southern feeder, the Drac, just below Grenoble; it becomes navigable at Montmélian.

ISERLOHN, a town in North Rhine-Westphalia, Germany, on the Baar, 17 mi. W. of Arnsberg, and 30 mi. E.N.E. from Barmen by rail. Pop. (1910) 46.221. Iserlohn is a very old town, its guild of armourers being referred to as ancient in 1443. Both in the town and neighbourhood there are numerous foundries and works for iron, brass, steel and bronze goods, while other manufactures include wire, needles and pins, fishhooks, machinery, umbrella frames. thimbles, bits and furniture.

ISFAHAN (the *Aspadana* of Ptolemy and *Spahan* of the Pahlevi texts), an Iranian Ostar or province and city. The province is bounded by the provinces of Kashan on the north, Khuzistan on the west, Yezd on the east and Fars on the south. Grain

cultivation in some districts is very large and much is exported to other parts of Iran; but the cultivation of the poppy, cotton and tobacco constitutes the chief wealth of Isfahan province. The general elevation lies between 5,000 ft. in the east and 9,000 ft. in the west. Population 1,516,443, (1956).

The city of Isfahan, formerly the capital of Iran, is now only the administrative headquarters of the province. Choosing Isfahan for his capital, Shah Abbas I made of it a large and imposing city. Its magnificence gave rise to the saying *Isfahán nisf-i-jahán* (Isfahan is half the world). The city lies in 32° 39' N. and 51° 40' E., at an elevation of 5,330 ft. along the north bank of the Zayinda Rud, which is crossed by three fine masonry bridges. The Allah Verdi Khan bridge consists of 33 arches, is 388 yd. in length with a paved roadway of 12 yd. breadth, and has galleried arcades on each side for foot passengers. Farther down the river is the even more beautiful bridge, the *Pul-Khajoo,* with its storied recesses and galleries and arcades that provide the population with a favourite place of rest and recreation. It was built by Shah Abbas II, in the middle of the 17th century. A little farther is a much earlier bridge and, well down the stream, the Sharistan bridge, the foundation piers of which date from Sassanian times. The water supply of the city is principally from open canals led off from the river and from several streams and canals which come down from the hills in the northwest. Pop. (1956) was 254,708. There are a few Zoroastrians and Bahais. Viewed from the air, the city presents an immense expanse of mingled buildings and gardens, 30 mi. in circuit; but, with the exception of the bazaars and other scattered agglomerations of houses, there is no continuous inhabited area, except in the centre. The city lies in a level tract of country which extends for miles to the east and north. Bare rugged mountains all but enclose the city on the south, west and northwest. A feature of the landscape is the large number of handsome towers which dot the plain, providing shelter for pigeons whose fertilizing manure forms a lucrative source of revenue.

The Modern City.—Although present-day Isfahan is in part a city of vanished glory, it is still a city of remarkable beauty. Many of its finest buildings having suffered from neglect during the 19th century, an official was sent from Tehran in 1902 to inspect the crown buildings and to report on their condition. Pursuant to his report it was decided to repair and renovate some, while others were demolished and their timber, bricks and stone sold to local builders. Many of the gardens for which in the early days it was famous, became wildernesses. But of the many fine buildings constructed by the Safavis the most important still remain, as do scores of lesser structures.

The heart of the city and central point of interest at the present time is the Maidan-i-Shah, an immense and still imposing rectangular space, 560 yd. from north to south by 174 yd., bordered by brick buildings of two stories of recessed arches or arcades. On the south side of the *maidan* is an arched portal leading to the famous Masjid-i-Shah, or royal mosque, completely covered with enamelled tile of great brilliancy, which was built by Shah Abbas I (1611) and is certainly one of the most beautiful buildings in the world. It has recently been put in perfect repair. On the eastern side stands the low-domed Masjid-i Sheik Lutf Ullah (1621), dedicated to the saintly uncle of Shah Abbas and his own private place of worship. The interior is of dazzling perfection, entirely covered with a combination of faience mosaic and painted tile. Opposite, on the west side, is the Ali Kapu (highest gate or sublime porte), a lofty building in the form of an archway crowned in the fore part by an immense open balcony (which formerly served as an audience hall and a vantage point from which the court could view the games and processions below). This gateway leads into the gardens of the former royal palace, which covers a considerable area with its courts and pavilions, one of which, the Chihil Situn (hall of 40 pillars), was famous as the verandah and throneroom of Shah Abbas. On the north side of the *maidan* is the gateway, covered with brick of faience, leading to the Royal (Kaisarieh) bazaar. Well to the N.E. of the centre of the town still stands the great Masjid-i-Jami or Cathedral mosque, historically and architecturally the most important building in Isfahan. It is a huge ensemble of more than a score of different constructions, some dating probably from the 10th century. Here are scores of superbly constructed rib vaults and two magnificent Seljuq dome chambers. The smaller one, which architects regard as the most perfect building in Isfahan and some are ready to say the most beautiful dome chamber extant, is dated 1088. It has remained in perfect condition.

From the precincts of the palace mentioned above runs the grand avenue or Chahar Bagh (four gardens), an avenue laid out by Shah Abbas I, nearly ¾ mi, in length and 200 ft. broad, leading to the bridge of Allah Verdi Khan and the high road to Shiraz. It was originally laid out with watercourses and fountains, and poplar and sycamore trees. On the east side of the avenue is the Masjid and the Madrassa Mader-i-Shah Sultan Husain, built in 1710, designed as a college for the training of mullahs and dervishes, and described by Curzon in 1892 as "one of the stateliest ruins that he saw in Persia." Never much damaged, it was restored to perfect condition recently. The bazaars of Isfahan lie behind the northern and eastern sides of the *maidan,* and in them it is possible to walk for three mi. or more under covered shade. They have all the characteristic features of other Asiatic marts and the trade carried on preserves for Isfahan some at least of the prestige which once belonged to the city. Brocaded cloths, printed cottons, felt goods, saddles, native weapons, lacquered ware, pottery, articles of silver filigree-work and of metal are among the characteristic merchandise.

Julfa, across the Zayinda Rud, is the Armenian suburb of Isfahan. Here Shah Abbas, about 1603, transplanted several thousand families of Christian Armenians from Julfa on the Araxes and settled them on the outskirts of his capital. They are strictly orthodox and have a cathedral and several handsome churches, decorated with the finest Iranian polychrome tile (haft *rangi*) and in the cathedral are Italian mural paintings done by journeymen artists in the 17th century. The population of the suburb has tended to decline in recent years.

In Isfahan itself the Church Missionary society has a church, medical mission, industrial home and schools and hostels both for boys and girls. Among these the Stuart Memorial college is the leading educational institution in this part of Iran.

From Isfahan there are several roads, to Tehran (240 mi.), to Shiraz (290 mi.) and to Kerman (400 mi.) via Yezd.

The temperature varies from a maximum of 97.8" F. in July to 23.8° in Jan. The relative humidity is 63 as compared with 54 at Tehaan and 67 at Bushire. The average rainfall over a period of 17 years was 4.74 in.

History — The natural advantages of Isfahan must always have made it a place of importance. In the most ancient cuneiform documents, referring to a period between 3000 and 2000 B.C., the province of Anshan, which certainly included Isfahan, was the limit of the geographical knowledge of the Babylonians, typifying the extreme east, as Syria (or Martu-ki) typified the west. The two provinces of Anshan and Subarta, by which we must understand the country from Isfahan to Shuster, were ruled in those remote ages by the same king, who undoubtedly belonged

to the great Turanian family; and from this first notice of Anshan down to the 7th century B.C. the region seems to have remained more or less dependent on the paramount power of Susa. The western Iranians, after separating from their eastern brethren on the Oxus as early perhaps as 3000 B.C., are believed to have bifurcated into two branches, westward into Media and southward towards Persia. The first substantial settlement of the southern branch would seem to have been at Isfahan, where *Jem*, the eponym of the Persian race, is said to have founded a famous castle, the remains of which were visible as late as the 10th century A.D. At the commencement of the 7th century B.C., Persia and Anshan are still found in the annals of Sennacherib amongst the tributaries of Elymais, confederated against Assyria; but shortly afterwards the great Susian monarchy, which had lasted for full 2,000 years, crumbled away under continued pressure from the west, and the Aryans of Anshan recovered their independence, founding for the first time a national dynasty, and establishing their seat of government at Gabae on the site of the modern city of Isfahan. The royal city of Gabae was known as a foundation of the Achaemenidae as late as the time of Strabo, and the inscriptions show that Achaemenes and his successors did actually rule at Anshan until the great Cyrus set out on his career of western victory. The provincial name of Anshan or Assan seems after the age of Cyrus to have given place to Gabene or Gabiane, which alone appears in the Greek accounts of the wars of Alexander and his successors, and in the geographical descriptions of Strabo. Gabae or Gavi became gradually corrupted to *Jai* during the Sassanian period, and it was thus by the latter name that the old city of Isfahan was generally known at the time of the Arab invasion. Subsequently the title of Jai became replaced by *Sheheristin* or *Medineh*, "the city" *par excellence*, while a suburb which took the name. of *Yahudieh*, or the "Jews' town," gradually rose into notice and superseded the old capital.

Sheheristān and *Yahudieh* in the early ages of Islam are described as independent cities, each surrounded by a separate wall; but about the middle of the 10th century the famous Buyid king, known as the *Rukn-addaula (al-Dowleh)*, united the two and many of the adjoining villages in one general enclosure which was about 10 mi. in circumference. The city, which had now resumed its old name of Isfahan, continued to flourish till the time of Timur (A.D. 1387), who is said to have erected a *Kelleh Minār* or "skull tower" of 70,000 heads at the gate of the city, as a warning to deter other communities from resisting his arms. Isfahan, however, recovered and when the Safavid dynasty, who succeeded to power in the 16th century, transferred their place of residence to it from Kazvin, it rose rapidly in population and wealth. It was under Shah Abbas I, the most illustrious sovereign of this house, that Isfahan attained its greatest prosperity. This monarch adopted every possible expedient, by stimulating commerce, and encouraging arts and manufactures, to attract visitors to his favourite capital. He built several magnificent palaces, decorated in the richest style, planted gardens and avenues, and distributed among them the waters of the Zendeh-rud in an endless series of reservoirs, fountains and cascades. The baths, mosques, colleges, bazaars and caravanserais of the city received an equal share of his attention, and European artificers and merchants were encouraged to settle in his capital. Ambassadors visited his court from many of the first states of Europe, and factories were permanently established for the merchants of England, France, Holland, the Hanseatic' towns, Spain, Portugal and Moscow. The celebrated traveller Chardin, who passed a great portion of his life at Isfahan in the latter half of the 17th century, has left a detailed and most interesting account of the statistics of the city at that period. He estimated the population at 600,000. There were 1,500 flourishing villages in the immediate neighbourhood; the enceinte of the city and suburbs was reckoned at 24 mi. while the old walls surrounding the city itself measured 20,000 paces. In the interior were counted 162 mosques, 48 public colleges, 1,802 caravanserais, 273 baths ,and 12 cemeteries. The adjoining suburb of Julfa was also a most flourishing place. The first blow to the prosperity of modern Isfahan was given by the Afghan invasion at the beginning of the 18th century, since which date, although continuing till the end of the century to be the nominal head of the empire, the city has gradually dwindled in political importance.

ISHII, KIKUJIRO, VISCOUNT (1866–1945), Japanese diplomatist, was born at Chiba, Japan. He intended to become a lawyer, but his studies in international law gave him a deep interest in foreign affairs. His early days were full of incident: the Meiji reconstructions took place before his eyes, and the constant stream of foreign influences aroused in him a desire to see and understand other countries. Leaving the law faculty of the Imperial university in Tokyo in 1890, he was made attaché to the Japanese legation in Paris. During his stay in Paris he applied himself to the study of European languages and became proficient in French and English. He was made third secretary in 1893, and about this time he devoted much attention to economics and international trade. He was distressed to observe that Japan did not hold such a position in the world's mart as in the opinion of most Japanese she deserved, and he set himself to find out the causes of the trouble. He endeavoured to form a Franco-Japanese mutual trade association, and although his efforts did not at first meet with the full success he desired, a certain stimulus was at once felt.

Some fruits of Ishii's labours were seen in the commercial mission which was sent from France to Japan in 1925.

In 1896 he was appointed consul to Chemulpho (Jinsen) in Korea. After this he was made second secretary and later first secretary at the Japanese legation in Peking. He was, therefore, in Peking in an official capacity during the Boxer rising. In 1900 he was appointed secretary of the head office and chief of the telegraph section of the home office department, which post he held until he became director of the commerce bureau in 1904. In 1907 he was sent to San Francisco and Vancouver in connection with the anti-Japanese riots there. His success in this matter was the direct cause of his appointment in the following year as vice-minister for foreign affairs. His love of France and understanding of French problems made him an easy favourite for the ambassadorship to Paris in 1912, and on his return he took over the portfolio for foreign affairs in the new government. He was chief of the foreign office for the period 1915–16, and in the latter year he was created viscount, having been made baron in 1912. He played a great part in American-Japanese relations and was a special envoy to the United States in 1917. He was nominated a member of the house of peers in 1916. In 1920 Viscount Ishii was for the third time officially delegated to Paris. In 1927 he became one of the Japanese delegates to the naval disarmament conference at Geneva.

He returned to Japan in the autumn of 1927, and retired from diplomatic service.

Perhaps Ishii's greatest claim on his country's gratitude was his work in connection with the so-called "gentlemen's agreement" made between Washington and Tokyo in 1917. Lansing was the United States representative in the negotiations, for which reason the arrangement is sometimes called the "Lansing-Ishii pact." The western coast of the United States made representations to congress deploring the increasing immigration of Asiatics, notably Chinese and Japanese. It was claimed that owing to the Asiatic standard of living being lower than that of Americans, there was a serious possibility of California becoming a Japanese colony, and the aid of legislation was invoked. The Lansing-Ishii pourparlers resulted in the postponement of suggested legislative measures, and a yearly maximum (tentatively fixed at 150) was proposed. Japan, through Ishii, agreed not to issue passports for more than this number annually to enter the United States as residents, and it was through Japan's alleged breach of faith in connection with this agreement that the Immigration Restriction act was passed by congress in 1924. In substance, this act was one of the proposals originally shelved by the labours of Lansing and Ishii. In Dec. 1920 he became Japanese delegate to the 11th session of the council of the League of Nations. In Aug. 1923 he became president of the council of the League and in the following month a vice-president of the assembly. In Sept. 1925 he was again a vice-president of the assembly.

In March 1926 he was president of the council at its 39th session, and acted temporarily as president of the assembly. He was killed in an air raid on Tokyo in 1945. (A. N. J. W.)

ISHIM, a town of the Uralsk region, Tyumen oblast, Russian Soviet Federated Socialist Republic U.S.S.R. in 56° 10′ N. and 69° 18′ E., on the Ishim river, a left bank tributary of the Irtish. Average January temperature, −3.8° F.; average July, 66.0° F.; rainfall 17.5 in. per annum. half of which falls between June and August. Pop. (1935) 18,153. A railway from Sverdlovsk (Ekaterinburg) to Omsk passes through the town. It is an agricultural centre, with fairs in December and May to which tallow, butter, skins, hides, cattle, horses, bristles, groceries and the products of local *kustar* (peasant) industries are sent.

ISHMAEL was the son of Abraham and his Egyptian concubine, Hagar. Through the jealousy of Sarah, mother and son were driven from the tribe, and saved from death by thirst through the miraculous discovery of a well (Gen. xxi, 8–20). Ishmael grows up an archer (Gen. xxi, 20) and a "wild ass of a man" (Gen. xvi, 12), living to the south and east of Palestine. He is the ancestor of 12 tribes of desert rangers (Gen. xxv, 12–18), of whom the most important seem to be Nebaioth (Assyrian Nabaitu and Pliny's Nabataei) and Kedar (Assyrian Kidru and Pliny's Cedrei).

A third tribe, Dumah, may be the Domata of Pliny, and Jetur seems to be the eponymous ancestor of the Itureans.

Ishmael, therefore, is used in a wide sense of the wilder, roving peoples encircling Canaan from the northeast to the south, related to but on a lower rank than the sons of Isaac. It is practically identical with the term Arabia as used by the Assyrians. Nothing certain is known of the history of these mixed populations. They are represented as warlike nomads and with a certain reputation for wisdom (Baruch iii, 23). Not improbably they spoke a dialect (or dialects) akin to Arabic or Aramaic. According to the Mohammedans, Ishmael, who is recognized as their ancestor, lies buried with his mother in the Kaaba in Mecca.

See T. Noldeke, Ency. Bib., *s.v.,* and the articles EDOM, MIDIAN.

ISHTAR or ISTAR, the name of the chief goddess of Babylonia and Assyria, the counterpart of the Phoenician Astarte (*q.v.*). The earliest written form of the name is Ash-dar, an Accadian rendering of the older Sumerian Innini, "Lady of Heaven." Ishtar was the Semitic deity identified with the Sumerian virgin mother-goddess, who was always associated with the planet Venus. For this reason Ashdar, Ishtar, is undoubtedly the same deity as the south Arabian Athtar, god of the planet Venus. At all events it is now generally recognized that the name is Semitic in its origin. Where the name originated is likewise uncertain, but the indications point to Erech, where we find the worship of a great Sumerian mother-goddess having no association with a male counterpart flourishing in the oldest period of Babylonian history. She appears under various names, among which are Nana, Innanna, Nina and Anunit.

As early as the days of Khammurabi we find these various names which represented originally different goddesses, though all manifest as the chief trait the life-giving power united in Ishtar. Even when the older names are employed it is always the great mother-goddess who is meant.

Ishtar is the one goddess in the pantheon who retains her independent position despite and throughout all changes that the Babylonian-Assyrian religion undergoes.

ISIDORE OF ALEXANDRIA (*fl.* c. A.D. 500), Neoplatonic philosopher, succeeded Marinus (the successor of Proclus) in the headship of the school of Plato at Athens. His main claim to distinction is that he was the teacher of Damascius, the last and one of the greatest of the Neoplatonic successors of Plato, who wrote Isidore's life in the customary enthusiastic manner of Neoplatonic biography.

Another Isidore, of Gaza, was one of the philosophers who accompanied Damascius to Persia after the closing of the schools of Athens in 529.

ISIDORE OF SEVILLE, in Latin called ISIDORUS HISPALENSIS (*c.* 560–636), Spanish encyclopaedist, theologian and historian, probably belonging to a family from Cartagena, succeeded his brother Leander as archbishop of Seville in A.D. 600 and headed the Spanish synod of Toledo in *633.* His summary of all knowledge accessible to him, Etymologiae or Origines, remained for many centuries one of the most important reference books: almost 1,000 medieval manuscripts of it are still in existence. In its 20 sections, Isidore handed down to posterity much that he had extracted from works of previous encyclopaedists (*e.g.,* Cassiodorus), specialists and Latin writers of all kinds, on the seven liberal arts. medicine, law, history, church matters, theology, anthropology, zoology, cosmology, psychology, architecture, agriculture, etc.

Other special treatises by him were devoted to linguistic matters (*Differentiarum* libri and, perhaps, *Synonymorum libri*), to natural science and cosmology (De *natura rerum* and De *ordine* creaturarum) and to history (a continuation of Jerome's and Gennadius' De *viris illustribus;* a re-elaboration and continuation of Jerome's history, under the title Chronica maiora; and a *Historia* Gothorum, *Vandalorum* et *Sueborum*). As a theologian, he wrote *Quaestiones* in *Vetus* Testamentum; biographies of 86 persons of the Bible (De ortu et *obitu patrum*); a handbook of morals and theology in the form of a collection of Sententiae, mainly based on Gregory the Great's *Moralia;* a treatise De *fide* catholica *contra* Judaeos (8th-century Old German trans. ed. by K. Weinhold, Paderborn, 1874); De haeresibus; a liturgical work De *ecclesiasticis officiis;* and a Regula *monachorum.* The Collectio *canonum Isidoriana* (ed. by P. Hinsch, Leipzig, 1863) is considered apocryphal by most scholars, but seems to have been compiled in Spain in the times of Isidore himself: it became one of the main sources of the great canonic compilations of the 12th century such as the *Decretum* Gratiani.

ISIN (modem Ishan Bahriyat). The ancient city of Isin has been identified with this site, which lies 14 mi. due south of Afaj, Iraq, in 31° 51′ N. and 45° 17′ E. The city of Isin was of late foundation and does not appear in inscriptions until the last years of the Ur-Engur dynasty of Ur.

After the final overthrow of the Sumerians of that city state the two dominant principalities in Babylonia were Larsa and Isin, which were of Semitic origin. From 2357 B.C. these two states had each a synchronous dynasty. In spite of various changes and the growth of the first dynasty of Babylon Isin managed to maintain itself, until in 2126 B.C. when it was conquered by the Elamites who had previously made themselves masters of Larsa.

Finally both cities were united to the Babylonian empire under Hammurabi.

The site consists of a low mound of about 200 ac., extending from northeast to northwest. A large building was built on the summit. Excavations by S. Langdon showed that the site was occupied in Neo-Babylonian times. A further mound was discovered there.

ISINGLASS, a pure form of commercial gelatin obtained from the swimming bladder or sound of several species of fish. The sturgeon is the most valuable, various species of which, especially *Acipenser* stellatus (the seuruga), A. *ruthenus* (the sterlet) and A. *güldenstädtii* (the ossétr), flourish in the Volga and other Russian rivers, in the Caspian and Black seas, and in the Arctic ocean, and yield the "Russian isinglass"; a large fish, *Silurus parkerii,* and probably some other fish, yield the "Brazilian isinglass"; other less definitely characterized fish yield the "Penang" product; while the common cod, the hake and other Gadidae also yield a variety of isinglass. The sounds, having been removed from the fish and cleansed, undergo no other preparation than desiccation or drying, an operation needing much care; but in this process they are subjected to several different treatments. If the sound be unopened the product appears in commerce as "pipe," "purse" or "lump isinglass"; if opened and unfolded, as "leaf"

or "honeycomb"; if folded and dried, as "book," and if rolled out, as "ribbon isinglass."

The finest isinglass is prepared by steeping the sounds in hot water in order to remove mucus, etc.; they are then cut open and the inner membrane exposed to the air; after drying, the outer membrane is removed by rubbing and beating. To increase its availability, the raw material is sorted, soaked in water till it becomes flexible, and then trimmed. The trimmed sheets are sometimes passed between steel rollers. which reduce them to the thickness of paper; it then appears as a semitransparent ribbon. This is dried and, if necessary, cut into strips.

The principal use of isinglass is for clarifying wines, beers and other liquids. Of secondary importance is its use for culinary and confectionery purposes; *e.g.*, in making jellies and stiffening jams. Mixed with gum, it is employed to give a lustre to ribbons and silk. It also has valuable agglutinating properties; on being dissolved in two parts of pure alcohol. it forms a diamond cement. cooling to a white. opaque. hard solid; it also dissolves in strong acetic acid to form a powerful cement, which is especially useful for repairing glass, pottery and like substances.

ISIS, the most famous of the Egyptian goddesses. She was of human form, in early times distinguished only by the hieroglyph of her name upon her head. Later she commonly wore the horns of a cow, and the cow was sacred to her; it is doubtful, however. whether she had any animal representation in early times, nor had she possession of any considerable locality until a late period, when Philae, Behbet and other large temples were dedicated to her worship. Yet she was of great importance in mythology, religion and magic, appearing constantly in the very ancient Pyramid texts as the devoted sister-wife of Osiris and mother of Horus. In the divine genealogies she is daughter of Keb and Nut (earth and sky). She was supreme in magical power, cunning and knowledge.

Isis was identified with Demeter by Herodotus, and described as the goddess who was held to be the greatest by the Egyptians: he states that she and Osiris, unlike other deities, were worshiped throughout the land. The importance of Isis had increased greatly since the end of the New Kingdom. The great temple of Philae was begun under the 30th dynasty; that of Behbet seems to have been built by Ptolemy II. The cult of Isis spread into Greece with that of Serapis (*q.v.*), early in the 3rd century B.C. In Egypt itself Isea, or shrines of Isis, swarmed. At Coptos Isis became a leading divinity on a par with the early god Min. About 80 B.C. Sulla founded an Isiac college in Rome, but their altars within the city were overthrown by the consuls no less than four times in the decade from 58 to 48 B.C., and the worship of Isis at Rome continued to be limited or suppressed by a succession of enactments which were enforced until the reign of Caligula. The Isiac mysteries were a representation of the chief events in the myth of Isis and Osiris—the murder of Osiris. the lamentations of Isis and her wanderings. followed by the triumph of Horus over Seth and the resurrection of the slain god—accompanied by music and an exposition of the inner meaning of the spectacle. These were traditional in ancient Egypt, and in their later development were no doubt affected by the Eleusinian mysteries of Demeter. They appealed powerfully to the imagination and the religious sense. The initiated went through rites of purification. and practised a degree of asceticism: but for many the festival was believed to be an occasion for dark orgies.

Isis nursing the child Horus (Harpokhrates) was a very common figure in the Deltaic period, and in these later days was still a favourite representation. The Isis temples discovered at Pompeii and in Rome showed that ancient monuments as well as objects of small size were brought from Egypt to Italy for dedication to her worship, but the goddess absorbed the attributes of all female divinities; she was goddess of the earth and its fruits, the Nile, the sea, the underworld. love, healing and magic. The worship of Isis survived in Italy into the 5th century.

At Philae the temple of Isis was frequented until the middle of the 6th century when the last remaining shrine of Isis was finally closed.

See G. Lafaye, art. "Isis" in Daremberg et Saglio, *Dictionnaire des antiquités* (1900); *id. Hist. du culte des divinités d'Alexandrie hors de l'Égypte* (1883); Meyer and Drexler, art. "Isis" in Roscher's *Lexicon der griech. und röm. Mythologie* (1891–92) (very elaborate); E. A. W. Budge, *Gods of the Egyptians*, vol. ii, ch. xiii; A. Rusch, *De Serapide et Zside in Graecia cultis* (dissertation) (1906). (The author especially collects the evidence from Greek inscriptions earlier than the Roman conquest; he contends that the mysteries of Isis were not equated with the Eleusinian mysteries.)

ISKENDERUN (formerly ALEXANDRETTA), a port, administrative centre of an *ilce* (district) and the largest town in Hatay *il* (province), Turkey, is situated on the eastern shore of the Gulf of Iskenderun. 27 mi. N. of Antioch (Antakya) and about 60 mi. S.E. of Adana. Pop. (1960) 63.736. Lying on an alluvial plain below the Amanus mountains (Nur Daglari), the town is modern with fine buildings and avenues decorated with subtropical plants. It is also a winter resort and has a military base. Iskenderun preserves the name but probably not the exact site of the city, Alexandria ad Issum, founded to commemorate Alexander the Great's victory over the Persians at Issus (333 B.C.). The name "Little Alexandria" may date from the 4th century A.D. The port was the main outlet for overland trade from Iran and India until the construction of the Suez canal. Its rapid growth after it was returned by France to Turkey in 1939 (*see* HATAY) was due to improved port facilities. It serves as a gateway to eastern and southeastern Anatolia and is connected by rail and road with other parts of Turkey. A main road to the south, crossing the Amanus range through the historic Belen pass, leads to Antioch, northern Syria (Aleppo) and thence Iraq. (N. Tu.; S. Er.; E. Tu.)

ISLA, JOSÉ FRANCISCO DE (1703–1781), Spanish satirist, was born at Villavidanes (León) on March 24, 1703. He joined the Jesuits in 1719, was banished from Spain with his order in 1767, and settled at Bologna, It., where he died on Nov. 2, 1781. His earliest publication was a *Carta de un residente en Roma* (1725), a panegyric of trifling interest, and he wrote *La Juventud triunfante* (1727) in collaboration with Luis de Lovada.

He first showed his gifts in the *Triunfo del amor y de la lealtad: Dia Grande de Navarra,* a satirical description of the ceremonies at Pamplona in honour of Ferdinand VI's accession; its sly humour so far escaped the victims that they thanked the writer for his appreciation of their local efforts, but the true significance of the work was discovered shortly afterward, and the protests were so violent that Isla was transferred by his superiors to another district.

Isla gained a great reputation as an effective preacher, and his posthumous *Sermones morales* (1792–93) justify his fame in this respect. His position in the history of Spanish literature is due to his *Historia del famoso predicador fray Gerundio de Campazas, alias Zotes* (1758), a novel which wittily caricatures the bombastic eloquence of pulpit orators in Spain.

See R. Gaudeau, *Les Prêcheurs burlesques en Espagne au XVIIIe siècle* (1891); V. Cian, *L'Immigrazione dei Gesuiti spagnuoli letterati in Italia* (Turin, 1895).

ISLAM (Arabic, "submission" to the will of God) is the name which all Moslems give to their religion; it claims to be a divine revelation communicated to the world through Mohammed, who was the last of a succession of inspired prophets, beginning with Adam. Its doctrine and practice are based upon (1) the Word of God, the Koran (*q.v.*), (2) the traditions (Hadith), or rather the sayings and manner of life (Sunna) of Mohammed, as contained in the traditions.

Doctrine.—The Moslem creed is "There is no god but God (Allah): Mohammed is the apostle of God." The acceptance of this fhith is held to imply belief in (1) God, (2) the angels, (3) the inspired books, (4) the prophets, (5) the day of judgment and (6) God's predestination of good and evil. In the Koran the unity of God is emphasized as against the mistaken conception of the Christian Trinity, and the divine nature is expounded through an enumeration of his various qualities under the three categories of power, unity and goodness. Around the throne of God are the angels, pure, sexless beings, some of whom bear the throne, while others praise him continually; they are also his messengers and are sent to help the faithful in their fight with unbelievers. Some

are the guardian angels of men, others are the watchmen of hell.

God created the world in six days, and set Adam in the garden of paradise, but, tempted by Satan, Adam fell. Intermediate between men and angels are the Jinn, male and female, created from fire; some are believers, others are infidels. The devil is sometimes described as one of the angels, sometimes as one of the Jinn; he was expelled from heaven because he refused to prostrate himself before Adam at his Lord's command.

God has revealed himself to man through prophets, to some of whom he has given a book; *e.g.*, to Moses the Law (*taurat*), to Jesus the Gospel (injil), to Mohammed the Koran. A prophet has been sent by God to each people, but Mohammed is "the seal of the prophets" (*i.e.*, the last of the series). His mission at first was to warn men of imminent judgment, and in the earlier chapters of the Koran descriptions of the resurrection, the last judgment and paradise and hell frequently occur.

Practice. — The religious practices obligatory on the believer are (1) recital of the creed, (2) performance of divine worship five times a day, (3) fasting in the month of Ramadan, (4) payment of the legal alms and (5) the pilgrimage to Mecca.

The creed must be recited at least once in a lifetime aloud, correctly, with full understanding of its meaning and with heartfelt belief in its truth.

Every man who professes Islam is required in ordinary life to worship God five times in each day. In the Koran only four times are mentioned. "Wherefore glorify God, when the evening overtaketh you, and when ye rise in the morning, and unto him be praise in heaven and earth; and in the evening and when ye rest at noon" (xxx, 16–17), but commentators say the "evening" includes the sunset and after sunset. The five times therefore are: dawn or just before sunrise, just after noon, before sunset, just after sunset and just after the day has closed. Tradition decides within what limits the ritual may be delayed without impairing its validity.

The service (salat — incorrectly translated "prayer" — for which the word du'a is used) is preceded by the lesser ablution (*wudu*) consisting in the washing of face, hands (to the elbows) and feet in prescribed manner. Complete washing of the body (*ghusl*) is required only after legal pollution. The worshipper faces the kiblah (direction of prayer), which was at first Jerusalem, but was changed by the prophet to Mecca. In a mosque the *kiblah* is indicated by a niche (*mihrab*) in one of the walls. The service consists of prescribed ejaculations, and the recital of parts of the Koran, always including the first sura, accompanied by prostrations of the body. (*See* Mohammed Ali, *The Holy Koran,* preface xviii–xxv.) Detailed physical positions are prescribed for each part of the worship; these vary slightly in the four Sunnite schools. On a journey, in time of war or in other special circumstances, the set form of worship may be modified in accordance with appointed rules. In place of the prayer just after noon, there is the prayer of the assembly, which is observed on a Friday (yaum *al-jum'a,* "the day of assembly") in a mosque, and is usually accompanied by a bidding prayer or declamation (khutba) delivered from a step of the pulpit (mimbar). Special services are also prescribed for certain occasions, as on the eclipse of the sun or the moon, etc. Among the Sufis special attention is given to informal prayer consisting chiefly in the continual repetition of the name of God (*dhikr*). (See SUFIISM.) This is still a characteristic of some of the dervish (*q.v.*) communities.

The command to fast begins with the words, "O ye who believe! There is prescribed for you the fast, as it was prescribed for those before you." The expression "those before you" has been taken to refer to the Jews, who fasted on the day of atonement, but more probably refers to the long fast of 36 days observed by the eastern Christians. In the passage of the Koran referred to (ii, 179–181) Moslems are required to fast during the month of Ramadan, "wherein the Koran was revealed," but if one is on a journey or sick, he may fast "another number of days," and if he is able to fast and does not, "he may redeem it by feeding a poor man," but "if ye fast, it is better for you." This fast was probably instituted in the second year at Medina. At that time the corrected lunar year was in use, and Ramadan, the ninth month, was always in the winter. A few years later Mohammed decreed the use of the uncorrected lunar year, which remains the standard of time for the Moslem world, so that the month of fasting now occurs at all seasons of the year in turn. The fast is severe and means entire abstinence from food and drink from sunrise to sunset each day of the month. The fast is associated with the statement that in this month God sent down the Koran from the seventh heaven to Gabriel in the lowest that it might be revealed to the prophet.

Alms are of two kinds: (1) the legal and determined (zakat), and (2) voluntary (sadakat). The former were given in cattle, grain, fruit, merchandise and money once a year after a year's possession. For cattle a somewhat elaborate scale is adopted. Of grain and fruit $\frac{1}{10}$ is given if watered by rain, $\frac{1}{20}$ if the result of irrigation. Of the value of merchandise and of money $\frac{1}{40}$ is prescribed. In the early days of Islam the alms were collected by officialsand used for the building of mosques and similar religious purposes. At the present time the carrying out of these prescriptions is left to the conscience of the believers, who pay the alms to any needy fellow-Moslem.

The fifth religious duty of the Moslem is the pilgrimage (hadj) to Mecca, which should be performed once by every Moslem "if he is able," that is, if he can provide or obtain the means to support himself on pilgrimage and his family during his absence, and if he is physically capable. The pilgrimage is made at one time of the Moslem year, namely, from the 7th to the 10th of the month Dhu'l-Hijja. For the arrangements for the journey from various countries to Mecca, *see* CARAVAN. When the pilgrim arrives within 5 or 6 mi. of the holy city, he puts off his ordinary dress after ablution and prayer, and puts on the two seamless wrappers which form the dress of the pilgrim (the *ihram*), who goes without head-covering or boots or shoes. He must not shave at all or trim the nails or anoint the head during the ceremonial period. The chief parts of the ceremonial are the visit to the sacred mosque (masjid *al-haram*); the kissing of the black stone; the compassing of the Kaaba (the *tawaf*) seven times, three times running, four times slowly; the visit to the Makam Ibrahim; the ascent of Mount Safa and running from it to Mount Marwa seven times; the visit to Mount 'Arafat; hearing a sermon; and going to Muzdalifa, where he stays the night; the throwing of stones at the three pillars in Mina on the great feast day; and the offering of sacrifice there. (For the localities *see* MECCA.) After the accomplishment of these ceremonies the ordinary dress is resumed, the pilgrimage is finished, but the pilgrim usually remains another three days in Mecca, then visits Medina to pay his respects to the tomb of Mohammed. Beside the *hadj* (great pilgrimage) Islam also recognizes the merit of the *'umra* (or lesser pilgrimage); *i.e.*, a religious visit to Mecca at any time accompanied by most of the ceremonies of the *hadj*.

THE DEVELOPMENT OF ISLAM

The battle of Siffin (657) between 'Ali and Mu'awiya was the occasion of the first breach in the unity of Islam, and the results remain to this day. The occasion was in the first case political in connection with the disputed succession to the caliphate (*q.v.*). After the battle 'Ali was compelled to submit his claims to arbitration, whereupon a number of his supporters (the Khawarij) broke away from him, declaring arbitration inadmissible where a clear mandate was to be found in the Book of God.

The most important sectarian divisions in Islam — Sunnites, Shiites and Khawarij — have their origin in divergent theories on the office of the caliph (khalifa), the head of the Moslem community as successor of the prophet.

Sunnites.—The Sunnites (Sunnis) form by far the larger number: by 1953 about 300,000,000 out of a total of nearly 350,000,000. They hold that the caliphate is an elective office and must be occupied by a member of the Meccan tribe of the Quraysh. They derive their name from the Sunna, or "path," *i.e.*, the traditional practice of Mohammed, as set forth in the Hadith (or Traditions); of these traditions six collections are regarded as authoritative by the Sunnites, viz., (1) the Kitab al-jami' as-Sahih of Bukhari (*q.v.*) (810–870), the most respected throughout the Moslem world and most carefully compiled; (2) the Sahih of Moslem

(817–875) with an introduction on the science of tradition; (3) the Kitab *as-Sunan* of Abu Da'ud (817–888); (4) the *Jami' as-Sahih* of Tirmidhi (*q.v.*); (5) the Kitab *as-Sunan* of Nasa'i (830–915); and (6) the *Kitab as-Sunan* of Ibn Maja (824–866). To the Koran and the Hadith, as authoritative sources of religious doctrine and practice, the Sunnites add *ijma'*, the universal consent which is held to justify practices or beliefs, although they are not warranted by the Koran or tradition and may be inconsistent with the apparent teaching of one or both of these. These beliefs and practices, which had often come from the pre-Islamic customs of those who had become believers, seemed to have escaped notice until the Abbasid period. They were too deeply rooted in the lives of men to be abolished. It became necessary either to find a tradition to abrogate the earlier forbidding one, or to acknowledge that ijma' is higher than the tradition. The former expedient mas resorted to by some later theologians (*e.g.*, Nawawi) by a fiction that such a tradition existed though it was not found now in writing. But in earlier times some (as Ibn Kutayba) had adopted the latter alternative. saying that the truth can be derived much earlier from the ijma' than from the tradition. because it is not open to the same chances of corruption in its transmission as the latter. Tradition itself was found to confirm this view, for the prophet is related to have said, "My people does not agree to an error."

But ijma' itself has been used in different senses: (1) the ijma' of Nedina was used to indicate the authority coming from the practices of the people of Medina (see below). (2) The ijma' of the whole community of Moslems is that most commonly recognized. It was used to support fealty to the Abbasid dynasty. By it the six books of tradition mentioned above are recognized as authoritative. and it is the justification of the conception of Mohammed as superhuman. (3) Some of the more thoughtful theologians recognized only the ijma' of the doctors or the teachers of Islam (the *mujtahidun*), these being restricted by the orthodox to the first few generations after Mohammed, while the Shiites allow the existence of such up to the present time.

The fourth basis of Islam. according to the Sunnites, is *kiyas* (*i.e.*, analogy). It is that process by which a belief or practice is justified on the ground of something similar but not identical in the Koran, the tradition or ijma'. Originally it seems to have been instituted as a check upon the use of private opinion (*ra'y*) in the teaching of doctrine. The extent to which it may be used is a subject of much discussion among theologians. Some would apply it only to a "material similarity," others to similarity of motive or cause as well.

By the 9th century there were established in the Sunnite world the four schools of law, which exist to the present day—Hanafi, Maliki, Shafiite and Hanbalite (for these and the wide extension of the concept of law in Islam, see ISLAMIC LAW). They assiduously cultivated the various branches of Moslem theology and law, and the students they trained became the *ulema* or *ulama* (learned), who filled such an important place in the history of Sunnite countries. In former times the colleges of Damascus, Baghdad, Nishapur, Bukhara. Cairo. Kairouan (Qairwan), Seville. Cbrdova were thronged by thousands of students; and the Xzhar university in Cairo still preserves some of the characteristics of these earlier seats of learning. From their ranks were chosen the *cadis* (judges), the *muftis* (the authoritative exponents of the sacred law), and in countries like Turkey, in which they enjoyed the confidence of the government, they occupied numerous other official positions. and acquired wealth and power. The *ulema* have constituted the only equivalent in the Moslem world to the priesthood in Christendom and have been active in the defense of orthodoxy and in resisting foreign influences. The Turkish republic has deprived them of most of their power, and in many other countries their influence has greatly declined. Among the Sunnites the various order of dervishes (*q.v.*) achieved a vast expansion.

The foundations of Sunnite theology for succeeding generations were laid in the 10th century by Abu'l-Hasan al-Xsh'ari (see ASH'ARI, AL-); he was for 40 years a Mu'tazilite, then became orthodox, and at once applied rational methods for the support and interpretation of the orthodox faith. Before him, reason had not been allowed any scope in orthodox theology. He was not the first to use it; some teachers (*e.g.*, al-Junayd) had employed it in teaching, but only in secret and for the few. The methods of scholastic philosophy were now introduced into Moslem theology. The chief characteristic of his religious teaching was the adoption of the via media between materialistic grossness and the ideas of pure speculative philosophy. Thus he taught, as to the attributes of God, that they exist, but are not to be compared with human attributes; as to God's visibility, that he can be seen but without the limitations of human sight. As to the great question of free will, Ash'ari denied man's power but asserted man's responsibility. So he passed in review the doctrines of God, faith. the Koran, sin, intercession, etc.. and for the first time in the history of Islam produced a systematic theology. The teaching of Ash'ari seems to have spread slowly in Iraq and parts of Iran, and was developed and perfected by Abu Bakr al-Bakilani. the Cadi. (*d.* 1012) but up to the middle of the 5th century of Islam (*c.* A.D. 1058) was suspected elsewhere and confounded with Mu'tazilism. The Ash'arite al-Juwayni (known as Imam al-Haramayn) was persecuted under Toghrul Beg (*c.* 1053) and exiled but was restored under Alp Arslan by the vizier Nizam al-Mulk, who founded an Ash'arite college (the Nizamiyya). In the west, Ibn Hazm (*q.v.*) fiercely opposed the system, but Ghazali established its orthodoxy in the east, and it spread from Persia to Syria and Egypt under the Aypubids and Mamelukes and thence to the Almohades in Africa under Ibn Tumart (1130). It remains the predominating influence to the present day, its only serious rival being the theological system of al-Maturidi, a Hanafi (d. 945), whose creed as represented in that of an-Nasafi is still used largely by the Turks. Since the 12th century no great theological movement has been made in Islam. The quiet of religious life has thrice been broken by Wahhabism (*q.v.*) in Arabia, by Babism (*q.v.*) in Persia and by the Ahmadiyyah (see below) in India.

Shiites.—Historically the next most important group, but by the 1950s shrunk in numbers to about 30,000,000, is that of the Shiites (Shi'ah, *i.e.*, "the party of Ali"). They regard Ali and his descendants as the only rightful caliphs. For them the caliphate was a God-given office and not one to be given by human appointment. Belief in this was an ordinance of God. an article of the faith. He who did not accept it as such was an unbeliever. This party originated among the mixed population of Iraq, partly Arab and Aramaean, partly Persian. These, on their conversion to Islam, brought with them many of their older beliefs, including Gnostic elements derived from the old religions of Babylonia, and the monarchical tradition of Persia. The idea of an absolute personal and hereditary monarchy was thus developed among the subjects of Ali. But in Islam there is no separation between politics and theology. The theological position of the Shiites was that the superhuman power of Mohammed descended to the members of his house (Ali and his children), so that they could interpret the will of God and tell future events.

The Shiites quite early broke up into a number of sects, several of which no longer exist. The most important modern one is that of the Twelvers (the Ithna'ashariyya), so called because they accept as imams twelve of the descendants of Ali. It is said that the 12th imam, Mohammed, disappeared about 874 but that he is still living and will return in the last days to establish the Shiite faith in the world. This has been the official creed of Persia since the beginning of the 16th century, and that of most of the Shiites of India, as well as those of Iraq and southern Lebanon. The Isma'ilis or Seveners are the followers of Isma'il. whom they regard as the 7th imam, rather than his younger brother, Musa (797), who is accepted by the Twelvers. To the Isma'ilis belong the Karmatians (*q.v.*), the Fatimites (*q.v.*), the Assassins (*q.v.*) and the Druzes (*q.v.*). The Zaydites are the followers of Zayd, a grandson of Husain, and are the most moderate of the Shiites, for though holding that the imamate belongs only to the descendants of Ali by Fatima, and that any of these might be imam (even though two or three should be in existence at the same time), they allow that circumstances might justify the appointment of another caliph for the time. Thus they acknowledge the imamates of Abu Bakr and Omar, though Ali was more entitled to the office. One

branch of the Zaydites, arising in the Yemen about 893, has remained there until the present day.

The Shiites differ from the Sunnites not only in their political theory of the caliphate, but in matters of law and ceremonial. They reject all the Sunnite books of Hadith or tradition, but have collections of traditions of their own and claim to follow the Sunna, or way, of the prophet, even as the Sunnites do. An allegorical and mystical interpretation reconciles the words of the Koran with the inordinate respect paid to Ali; the Sunnite doctrine of the uncreated Koran is denied. To the creed "There is no god but God; Mohammed is the apostle of God," they add, "and Ali is the vice-regent of God" (wnli, properly "confidant"). There are some modifications in detail as to the four main religious duties of Islam—the prescriptions of ritual purity. in particular, being made the main duty of the faithful. The prayers are almost exactly the same. but to take part in public worship is not obligatory, as there is at present no legitimate imam whose authority can direct the prayer of the congregation. . Pilgrimage to Mecca may be performed by a hired substitute, or its place can be taken by a visit to the tombs of Shiite saints; *e.g.*, that of Ali at Najaf, of Husain at Karbala. of Riza at Meshhed, or of the "unstained Fatima" (daughter of Musa, the 7th imam) at Kum. The Shiites are much the most zealous of Moslems in the worship of saints (real or supposed descendants of Ali) and in pilgrimages to their graves. and they have a characteristic eagerness to be buried in those holy places. They celebrate many religious feasts. Of these the great sacrificial feast (id al-azha; Turkish kurban *bairam*) is also Sunnite; the first ten days of the month Muharram are dedicated to the mourning for the death of Husain at Karbala which is celebrated by passion plays (ta'ziya), while the universal joy of the Nawruz, or the new year of the old Persian calendar, receives a Moslem sanction by the tradition that on this day the prophet conferred the caliphate on Ali. Shiite law permits temporary marriages (*mut'a*), provided that a dower is specified. and that a period—a year, a month or a day—is fixed. Another special doctrine is that it is lawful for a man in case of danger or persecution to deny his faith (taqiyya, "caution") and pass himself off as a Sunnite.

Khawarij.—The third sect (originating like the other two in disputes over the caliphate) added to their political doctrine that this office was open to any believer whom the faithful might consider fitted for it, even though he be a black slave; certain theological doctrines on the subject of sin (*e.g.*, they regarded anyone who had committed one of the greater sins as no longer a believer); and rejection of the doctrine of justification by faith without works. Under the Umayyads they were a source of trouble to the government through their constant risings, but under the Abbasids they became restricted to eastern Arabia, and only a few of them now survive there and in north Africa.

Apart from these three important groups which had their origin in primitive times and exist to the present day, there has been in Islam an immense activity in theological speculation. resulting in the formation of many sects, the majority of which have ceased to exist. The first impulse to these speculations appears to have come from contact with Christian theologians in Damascus during the Umayyad caliphate. Two sects arose under these influences—that of the Murjiites and that of the Kadarites. The Murjiites ("postponers") were so called because they postponed the judgment of human actions until the day of judgment. In politics they accepted the Umayyads as de *facto* rulers, since they were Moslems, and left the judgment of their actions to God. As theologians they taught that religion consists in belief (imam) in the unity of God and in his apostle, and in that alone; consequently no one who held this faith would perish eternally, though he had been a sinner. This was opposed to the Kharijite doctrine that the unrepentant sinner would perish eternally, even though he had professed Islam.

The Kadarites were concerned with the doctrine of predestination and free will. So long as Moslems were fighting the battles of Islam they naturally paid most attention to those revelations which laid stress on the absolute determination of a man's destiny by God. They fought with great bravery because they believed that God had foreordained their death or life, and they could not escape his will. In the quieter realm of town and court life and in their disputations with Christians they were called upon to reconcile this belief with the appeals made in the Koran to man's own self-determination to good, to courage, etc. The Kadarites declared that man had power over his own actions. But the teaching of predestination had gained too great a hold on Moslems to be thus displaced. The teaching of the Kadarites was held to be heresy, and one of its first professors. Ma'bad al-Juhani, was put to death in 699.

Many of the Kadarites were also Mu'tazilites, whose founder was Wasil ibn Ata, who separated himself (whence his followers were called Mu'tazilites. "separatists") from his teacher Hasan al-Basri and founded a school which became numerous and influential. The Mu'tazilites objected to the attributes of God being considered in any way as entities beside God; they explained away the anthropomorphisms used in speaking of the deity: they regarded the Koran as created and emphasized human responsibility in matters of religion. Briefly, they asserted the supremacy of reason ('aql) as distinct from faith received by tradition (naql). They also called themselves "the people of justice and unity" (*ahl al-'adl wat-tauhid*). Such a faith as this naturally found favour rather with the thinking classes than with the uneducated multitude, and so went through many vicissitudes. At the time of its appearance and until the reign of Ma'mun its adherents were few and uninfluential. After discussions among the theologians Ma'mun took the decided step of proclaiming that the Koran was created, and that a belief in this dogma was necessary. Mu'tazilites were appointed to official posts, and an inquisition (*mihna*) was appointed to enforce belief in their doctrine This movement was strongly opposed by the orthodox and especially by Ahmad ibn Hanbal. By him the founding of theology on reason was rejected, and he sufferedpersecution for his faith. Mu'tazilism retained its sway until 849, when the caliph Mutawakkil again declared the Koran uncreate and restored orthodoxy.

According to an early tradition Mohammed said that Islam would be divided into 73 sects. of which 72 would perish and one would be saved. The Arabic writers on the heretical sects of Islam feel compelled therefore to restrict their number of 72, but as they adopt diverse classifications the number of sects they describe amounts to several hundred.

LATER MOVEMENTS

In modern times the most important sectarian developments have been those of the Wahhabis (*q.v.*), the Babis (see BABISM) and the Ahmadiyya. The last of these movements was started by Mirza Ghulam Ahmad, who, in 1879, began to preach in the village of Kadian in the province of the Punjab, India. He claimed to be not only the promised Mahdi but also the promised Messiah—personages generally held to be distinct in ordinary Moslem theology. Another modification he introduced into Islamic doctrine had reference to the death of Jesus; the commonly accepted belief maintains that Jesus was taken by God alive into heaven. while a phantom was crucified in his place; in opposition to this he declared that Jesus was actually crucified but was taken down from the cross while still alive by his disciples, was healed of his wounds and afterward made his way into Kashmir, where he finally died, his tomb being still in existence in the city of Srinagar. Having thus removed the ground for any expectation of the second coming of Jesus from heaven to earth, he explained that he himself was the Messiah, not as being an incarnation of Jesus (for he rejected the doctrine of transmigration), but as having come in the likeness of Jesus—being Jesus for this generation just as John the Baptist was Elijah, because he came in the spirit and power of Elijah.

In proof that he had come in the spirit and power of Jesus, Mirza Ghulam Ahmad adduced the likeness of his own character and personality to that of Jesus, his gentleness of spirit. the peaceful character of his teaching. his miracles and the appropriateness of his teaching to the need of the age. In harmony with this pacific claim, he expounded the doctrine of jihad (usually interpreted as meaning war against unbelievers) as a striving after righteousness.

Mirza Ghulam Ahmad died in 1908, and a few years after his death his followers split into two parties, one having its headquarters in Kadian and the other in Lahore. Both these sections of the community succeeded in enlisting the services of devoted, self-sacrificing men, who are unceasingly active as propagandists, controversialists and pamphleteers. They set up an extensive missionary activity, not only in India, west Africa, Mauritius and Java (where their efforts are mainly directed toward persuading their coreligionists to join the Ahmadiyya sect), but also in Berlin, Chicago and London. Their missionaries devoted special efforts to winning European converts and have achieved a considerable measure of success. In their literature they give such a presentation of Islam as they consider calculated to attract persons who have received an education on modern lines, and thus not only attract non-Moslems, and rebut the attacks made on Islam by Christian controversialists, but win back to the faith Moslems who have come under agnostic or rationalist influences.

Apart from these organized movements, there was considerable theological activity in the Moslem world in the first half of the 20th century. This expressed itself especially in apologetic literature, which endeavours to present Islam in a form acceptable to the contemporary generation and to discard those special features which had exposed it to hostile criticism; thus polygamy, slavery and intolerance are declared to receive no sanction from the Koran, as rightly interpreted; in Islam the reconciliation of religion and science is effected. and the demands of the modern spirit of enlightenment are satisfied. Of such modernist literature there has been a considerable output, especially in Egypt and India; it naturally appeals most to those readers who have come under European influences and excites considerable opposition among more conservative orthodox circles, who remain loyal to the traditional schools of thought and resent the rejection of traditional mediaeval theology by the modem thinkers. The older sects continued to flourish, and the new thought did not attempt to organize itself on sectarian lines and thus remained largely a matter of individual opinion.

This lack of sectarian development is possibly in great measure due to the absorbing attraction that political problems exercised upon the Moslem world. Anxiety as to the fate of Turkey after World War I, the withdrawal of the holy cities from the control of the caliph and the occupation of Jerusalem by unbelievers, the separation of the sultanate from the caliphate in 1922 and the abolition of the caliphate altogether in 1924 were circumstances that profoundly stirred the minds of pious Moslems all the world over and did not create an atmosphere favourable to the calm consideration of purely dogmatic problems. Moreover, in many Moslem countries some form of nationalism obscured the larger vision of a united Islamic world; in Turkey it took at one time the extreme form of Pan-Turanism, or Pan-Turkism, which aimed at the union of all sections of the Turkish people in one vast confederacy and sought to purge the national life from all foreign admixture, in language, literature and political institutions; in India nationalist feeling prompted first a Hindu-Moslem entente, but subsequently led to the separation of Pakistan as an independent Moslem state in 1947; among the Moslem populations of Russia the formation of Soviet Socialist republics evoked nationalistic movements which temporarily thrust purely religious interests into the background; in Java and Sumatra the Moslems took the lead in establishing the new state of Indonesia (1949).

But Islam is so closely bound up with every aspect of the life of a Moslem people that even a purely nationalist political movement may react strongly on the religious life. This was notably the case in Turkey, where the government, besides abolishing the caliphate, confiscated the religious endowments and suppressed the religious orders; polygamy was practically made illegal; the date of Ramadan was fixed in accordance with astronomical science instead of being made dependent on reports that the moon had been seen (as had been the immemorial custom in the Islamic world); and the discontinuance of the wearing of the veil by women and the adoption of hats by men were typical of a changed attitude toward the established usages of Moslem society.

The breach with the past was nowhere so violent as in Turkey, but throughout the whole Islamic world there were indications of a changed attitude toward religious questions.

The old orthodoxy still held the allegiance of the masses, as well as many of the educated, but others, especially those whose education had brought them under European influences, sought a restatement of their religion, more in harmony with their general outlook upon life.

To those seeking a solution in the realization of some nationalist ideal, there remained little save a sentimental attachment to Islam, while they deprived it of any control over law and social organization; the reformers, on the other hand, claim for the precepts of Islam control over all the relations of human life, but seek to restore it to its primitive simplicity, believing that thus it can be brought into harmony with modern thought and modem conditions.

ISLAMIC ARCHITECTURE. Islamic architecture may be defined as the architecture of the peoples who have embraced the Islamic faith. The term Arab should never be used in this connection for it is completely misleading. The conquering Arabs, when they did begin to have architectural ambitions, employed the local people and drew upon their technical skill and architectural traditions.

THE FIRST THREE CENTURIES

In the time of Mohammed the Arabs had nothing worthy of the name of architecture. Only a small part of the population was settled and these lived in dwellings which were scarcely more than hovels.

When the hostility of the people of Mecca had caused Mohammed to migrate to Medina in A.D. 622, he built a house for himself consisting of a mud-brick enclosure about 50 yd. square. Against the outer side of the east wall were hujra ("small huts") for his wives. There is a description of them by an eyewitness who saw them just before they were demolished by order of al-Walid in 707: "There were four houses of mud brick, with rooms partitioned by palm branches, and five made of palm branches plastered with mud and not subdivided. Over the doors were curtains of black haircloth. One could reach the roof with the hand." (Ibn Sa'd, Tabaqat, I, 2, p. 180.) The courtyard, which afterward served as a place of prayer, was at first quite open, but, as the companions complained of being exposed to the burning heat of the sun, a shelter was erected, consisting of palm trunks used as columns supporting a roof of palm leaves and mud. Such was the house of the leader of the community at Medina. Nor did Mohammed wish to alter these conditions; he was entirely without architectural ambitions, and Ibn Sa'd quotes the following saying of his: "The most unprofitable thing that eateth up the wealth of a Believer is building." (Tabaqat, I, 2, p. 181; VIII, p. 120.)

The men who formed the armies of the conquest were mainly Bedouin, but even those who came from permanent settlements, such as Mecca and Medina, knew nothing of art and architecture.

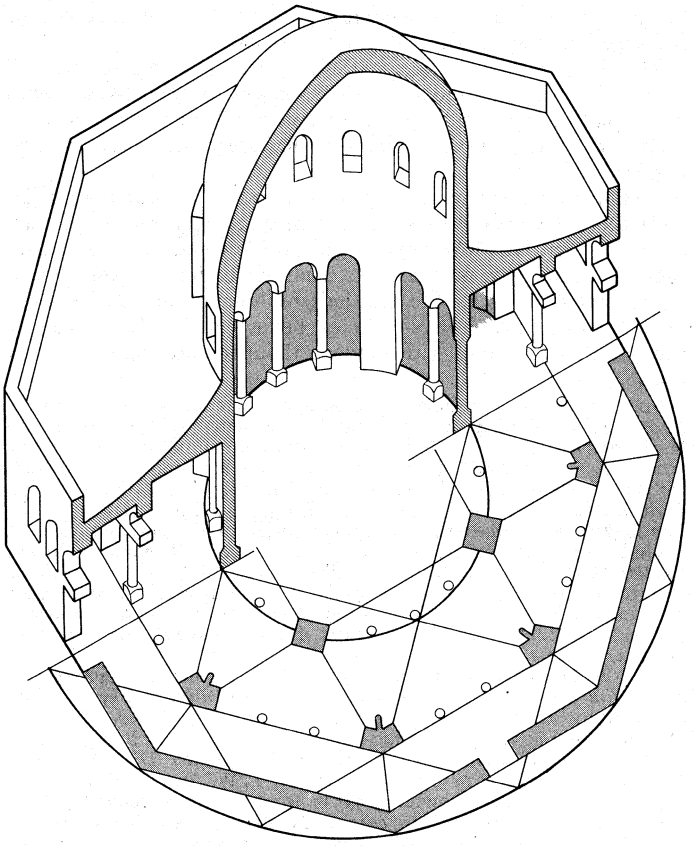

FIG. I.— THE DOME OF THE ROCK, JERUSALEM

Their advance was fanwise: those who advanced northward entered territory which had been under Hellenistic influence for 1,000 years, and those who advanced northeast entered territory which had been under Persian influence for even longer. And not only the cultural but also the material conditions were different. Syria was a country of excellent building materials. Syrian limestone was the best of its kind and cedar wood was plentiful, for the Lebanon had not yet been deforested. So those who invaded Syria found themselves in a country of splendid buildings—churches of cut stone, with arcades on marble columns and gable roofs of cedar, and with large surfaces covered with coloured glass mosaic on a glistening gold background. On the other hand, those who invaded Mesopotamia and Persia met with buildings of brick, sometimes of mud brick, sometimes vaulted but more often with flat roofs of palm trunks, palm leaves and mud. Hence the duality observed in early Moslem architecture.

In these early days the invaders, when they conquered a town in Syria, usually took one of the churches and converted it, a very simple matter, for the qibla (direction of Mecca) being due south and the churches being turned toward the east, it was only necessary to close the western entrances, make fresh ones in the north side and pray across the aisles. That this is exactly what happened can be verified in the Great mosque of Hama, where the west front of the Kanisat al-Uzma ("Great church"), which was converted into a mosque in 637, forms the west side of the sanctuary.

But the situation was different in Iraq, for there the Arabs founded new towns, so pre-existing buildings could not be employed. At Basra, founded *c.* 635, the first mosque was simply a rectangle marked out on the ground. According to another account it was enclosed by a fence of reeds. At Al Kufah, founded in 638, an area about 100 yd. square was enclosed not by walls but by a ditch only, the sole architectural feature being a shelter on columns (taken from the ruins of Hira) which ran along the southwest side of the mosque.

The first mosque in Egypt. the mosque of 'Amr built in 641–642, was equally primitive. It measured 50 X 30 cubits (about 80 × 50 ft.) and had six doors and a low roof, probably of palm trunks resting on palm-trunk columns.

The first mosques worthy of the name of architecture were the second Great mosques at Basra (665) and Al Kufah (670). The latter was built by a man "who had been one of the builders of Khusrau," and he designed the mosque with five rous of columns on the qibla side and two rows only on the other three sides. The columns, which were very tall. were not surmounted by arches, and it is obvious that the sanctuary must have looked like an apadana, or hall of columns, of the ancient Persian kings.

The oldest existing Moslem monument is the Dome of the Rock at Jerusalem, built by the caliph Abd al-Malik and finished in 691. It is a concentric annular structure consisting of a wooden dome 20.44 m. in diameter, set on a high drum and pierced with 16 windows. The dome rests on 4 piers and 12 columns which are placed in a circle and so arranged that 3 columns alternate with each pier. This circle of supports is placed in the centre of a large octagon averaging 20.60 m. a side, formed by eight walls 9½ m. high (excluding the parapet which adds 2.60 m.), each pierced in their upper half by five windows. Between the outer octagon and the inner circle is an intermediate octagonal arcade, the arches being borne by 8 piers and 16 columns. It is not a mosque but a *mash*had (shrine), built over the rock from which Mohammed was believed to have made his ascent to heaven on the horse Borak. The decoration is of the most splendid kind. The exterior was originally covered to half its height by marble paneling, and from there upward with glass mosaic on a glistening gold background. Internally all the arcades were likewise decorated with mosaic and the malls with quartered marble paneling; *i.e.,* each slab was cut in half and opened like a book, the result being that the veining ran toward the joint. The process is then repeated so that four slabs make a unit. Although this is the most beautiful way of using marble for paneling, it does not appear to have been employed after 750.

About 20 years after the completion of the Dome of the Rock, al-Walid (A.D. 705–715) built the Aqsa mosque at Jerusalem and the Great mosque at Damascus. In the former (nhich is not a conversion of a church built under Justinian, as is often erroneously stated, for Justinian's church stood elsewhere and lasted until after A.D. 800), the arcades ran at right angles to the qibla wall, in the latter parallel to it. The arcades in both cases were built in two tiers in order to obtain a great height of ceiling with comparatively short columns taken from other buildings, a system adopted later at Cordoba. At Damascus the mosque was built in what had been the temenos. or sacred enclosure, of a pagan temple, measuring about 136 m. from east to west and 100 m. from north to south. Three arcades, cut through their centre by a transept, were built parallel to the south wall and a single arcade round the other three sides. Of the four axial entrances of the temenos, three were preserved in the mosque, the fourth being blocked up by the mihrab (prayer niche indicating the direction of Mecca). Here again the same splendid decoration in marble and mosaic was employed as in the Dome of the Rock at Jerusalem. At the four corners of the ancient temenos were four square towers; these became the first minarets in Islam. (At Medina, where there was no minaret until al-Walid's time, the call to prayer was made from the roof of a neighbouring house.) Ibn al-Faqih (903) says: "The minarets which are in the Damascus mosque were originally watch-towers in the Greek days . . ." And Masudi says: "Then came Christianity and it (the temenos) became a church; then came Islam and it became a mosque and the four *sawami* (*i.e.,* the four corner towers) were not changed; they serve for the call to prayer at the present day."

The Omayyad caliphs were great builders of palaces, many of which have a fortified appearance externally. This is to be explained by the route taken by the armies of the conquest. They passed a long line of Roman frontier forts which ran from the Gulf of 'Aqaba to Damascus and beyond. Some of these were lived in by Omayyad princes; *e.g.,* Qastal and Azraq. Having been in the habit of occupying forts. they apparently came to look upon a rectangular enclosure flanked by towers as a necessary feature of a princely residence. Their palaces were richly decorated with

marble paneling and mosaics; *e.g.*, al-Walid's palace at Minya on the Sea of Tiberias (mod. Sea of Galilee), Hisham's palace at Mefjir (4 mi. north of Jericho). Some, like the one at Qusayr Amra, were even decorated with fresco paintings of human figures, for the prohibition against painting did not become formal until *c.* 800. Others even had a hunting enclosure several miles long attached to them; *e.g.*, Mefjir and Qasr al-Hair ash-Sharqi, hence the latter's name for Miskawaihi, under the year 315 H. (925–926) says, "This year there was a rising of the disbanded cavalry, who went out to the Oratory, plundered the Palace of the Pleiades (at Baghdad) and slaughtered the game in the Hair."

The fall of the Omayyad dynasty in 750 and the transfer of the capital of the caliphate from Damascus to Baghdad by the Abbasid caliph al-Mansur, was as far-reaching in its effect as the transfer of the capital of the Roman empire from Rome to Constantinople. Hitherto its capital had been in territory which, since the time of Alexander, had been in the sphere of Hellenistic culture. This was replaced by the cultural influences of Sasanian Persia, to which sphere Iraq belonged. This made itself felt in the design of the new capital, Baghdad, which was given a circular form like the Parthian capital Ctesiphon, Darabjird and Firozabad. A mosque 100 m. square with wooden columns supporting a flat roof was built in the centre of the city, and the caliph's palace, 200 m. square, was built in contact with its *qibla* side, so that the caliph could go directly from his palace into the *maqsura* of the mosque, a screened-off area which included the mihrab and the pulpit. This was the scheme first adopted at Damascus and then at Basra, Kufah, Wasit, Merv and other places. About this time was built the earliest example of a building entirely constructed with free-standing, pointed-arched arcades of 38 arches supporting tunnel vaults: the Cistern of Er Ramle, the only Abbasid monument in Palestine, dated 172 H. (789) by an inscription of Harun ar-Rashid.

In 827 Abdallah ibn Tahir, the Abbasid governor of Egypt, doubled the size of the mosque of 'Amr by the addition to the west of its exact area in the same shape. It follows that no part of the present structure lying to the right of a line drawn through its centre can possibly be older than 827. It then measured about 109 × 120 m., as does the present building. It is known (from excavations) that there were seven arcades on the southeast and northwest sides and four on the southwest side. On the northeast the arcades ran perpendicular to the court. The only decoration that has survived is that carved on the wooden friezes and the tie beams of a few windows. It consists of late acanthus ornament, derived from the Hellenistic art of Syria, and shows that the Abbasid art of Iraq, which is found 50 years later in the mosque of Ibn Tulun, had not yet reached Egypt.

Like the mosque of 'Amr, the Great mosque of Kairouan was founded in the early days of Islam, but no part of the present structure (except the minaret) is earlier than the 9th century, for the whole mosque was rebuilt by the Aghlabid Ziyadat Allah in 836. The sanctuary consists of 16 arcades of 7 arches, each running at right angles to the *qibla* wall but without reaching it, for a transverse arcade runs at a distance of 6 m. from it, and it is against this arcade that the 16 arcades stop. The side aisles are about 3.30 m. in width as against 5.40 m. for the central aisle, which must have measured 6.60 m. before its width was reduced by two arcades built in contact with it, without any bond or liaison of any sort. This modification was the work of Ibrahim II in 862–863, who also built the dome in front of the mihrab and lined the latter with beautifully carved marble panels, expressly imported from Iraq.

The most famous work of the Abbasid caliphs was the foundation of Samarra on the river Tigris, about 70 mi. north of Baghdad, in 836. The palace stands on the edge of the plateau which is about 17 m. above the alluvial valley. It is built partly of kiln-baked, partly of sun-baked, bricks and the decoration consisted of dadoes, generally of molded stucco, except in the throne-room group where they are of marble slabs. The scale of the whole layout is immense.

This palace was followed by the two great mosques of Samarra and Abu Dulaf. The former, as rebuilt in 852, is the largest mosque in Islam, for its outer walls, 2.65 m. thick of kiln-baked bricks with half-round buttresses at intervals of 15–16 m., form an immense rectangle 240 m. deep and 156 m. wide, in the favourite Abbasid proportion of 3:2. The area is nearly 38,000 sq.m. The flat roof rested directly on octagonal piers of brick with marble colonettes at the four corners, making a support roughly 2 m. square. There were no arches. The mosque proper was surrounded by an outer enclosure or *Ziyada*, measuring 376 × 444 m., and in this enclosure on the northeast side rose the minaret, the famous Malwiya, a tower with a spiral ramp about 2.30 m. wide which rises 6.10 m. for each complete turn. The total height to the top platform is 50 m. Between 860 and 861 another immense mosque was built at Abu Dulaf to the north of Samarra. It is 135 m, wide and 213 m. deep. Here the outer walls are of mud brick 1.65 m. thick, with half-round buttresses, but the flat roof rested on arcades of burnt brick at right angles to the *qibla* wall. The minaret is a miniature of the Malwiya.

In Egypt Ahmed ibn Tulun, a Turk born at Samarra, who had been appointed governor in 864, shortly after declared himself independent and decided to build a mosque in Egypt, of which the scheme of the outer walls and windows is Egyptian, being based on the exterior of the mosque of 'Amr of 827. The decoration, however, is directly derived from Samarra. The mosque proper forms a great rectangle 122 m. wide and 140 m. deep; it is surrounded on three sides by open courts or *Ziyadas* about 19 m. wide, the whole forming a rectangle 162 m, square (or 300 Nilometric cubits, the unit of measurement used for setting out the mosque). The *sahn* (central court) is roughly 92 m. square, with five rows of pointed-arched arcades on the *qibla* side and two rows on the other three sides. The door soffits are of wood decorated with Samarra ornament, and the borders and soffits of the arches are decorated with stucco ornament. There are 128 windows filled with stucco grilles of geometrical design of which, unfortunately, only about four are original.

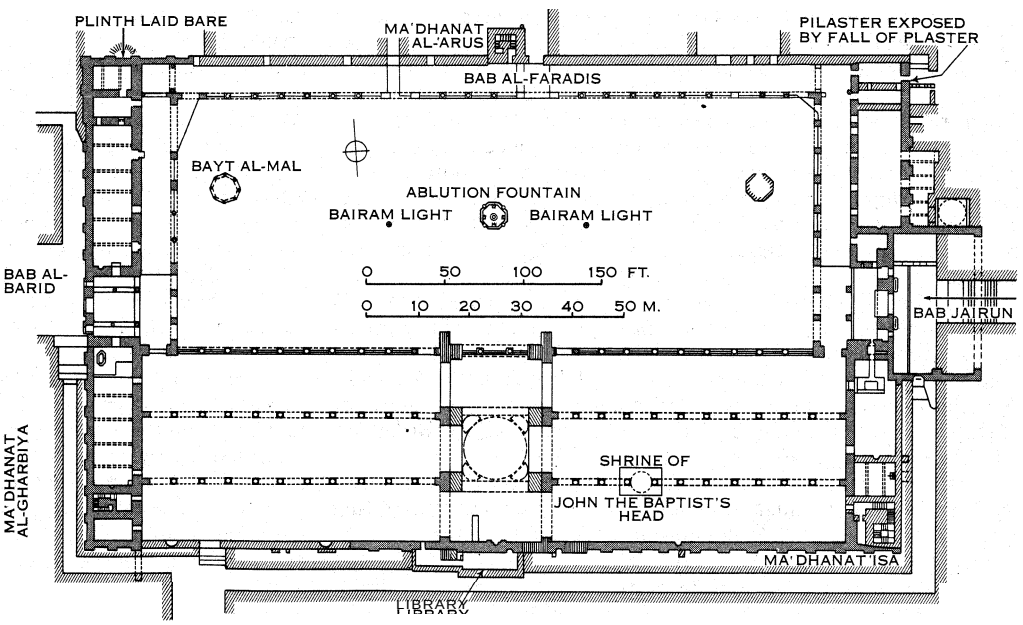

FIG. 2.—PLAN OF THE GREAT MOSQUE. DAMASCUS

PERSIA

Only two mosques dating before the middle of the 11th century have survived—the little Tarik Khana at Damghan and the mosque at Nayin. The former consists of vaulted arcades on round piers running toward the *qibla* wall, the latter of arcades parallel to it, with stucco ornament derived from that of Samarra. But under the Seljuks in the last years of the 11th century, a new feature appears at Isfahan, a large dome 15 m. in diameter in front of the mihrab, covering nine bays of the sanctuary (3 × 3) and consequently opening into it on three of its sides by three arches. An inscription states that it is the work of Malik Shah (1072–92). This type is also found later at Gulpaigan, Ardistan

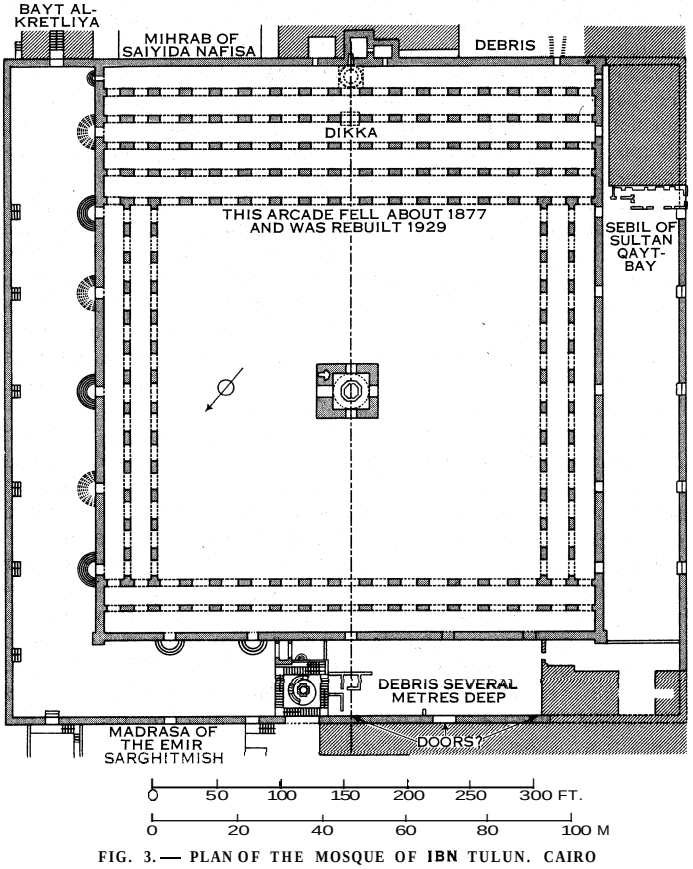

FIG. 3.— PLAN OF THE MOSQUE OF IBN TULUN. CAIRO

(1158) and elsewhere. In the latter, part of an arcade on round piers with 4th-century stucco ornament has survived, proving that this great domed bay was an insertion into an earlier mosque.

The 12th and 13th centuries witnessed the development of fai'ence decoration. Dadoes were composed of star tiles in golden-brown lustre on a white background, and splendid calligraphic borders framed the mihrabs; *e.g.,* the famous mihrab of 1226 from the Maydan mosque at Kashan, once in the Preece collection but later moved to Berlin. But the 13th century also witnessed the greatest disaster that has ever befallen Persia—the Mongol inroads.

This Mongol terror caused an enormous migration of architects and craftsmen, not only to Asia Minor (where the inscriptions on the monuments of Konia and Divigri bear witness to it), but also to Cairo, which became the refuge of Islam from the Mongols. Maqrizi says that "numbers of Orientals came to Egypt and built themselves homes on the banks of the Khalig and the Birkat al-Fil." (Khitat, I, p. 364–365.)

Persian mosques generally have a monumental entrance, consisting of a deep rectangular recess covered by a semidome resting on stalactites; *e.g.,* the Great mosque at Veramin (1324) and the Masjid-i-Jum'a of Shah Abbas at Isfahan. It seems probable that such portals are a development of the side bays of the caliph's palace (Bab al-'Amma) at Samarra, where this feature is seen in its simplest form—a rectangular entrance bay covered by a semi-dome on two squinches. During the Timurid period fai'ence tiles and fai'ence mosaic came more and more into use, and even greater surfaces were covered than had ever been before; *e.g.,* the mosque of Gawhar Shad at Meshed in Khurasan, one of the finest examples of polychrome fai'ence mosaic ever executed, and similarly the remains of the Musalla at Herat.

The Safavid period (1502–1736), of which one of the greatest rulers was Shah Abbas (1587–1628), was marked by his remarkable town planning at Isfahan; nothing of the sort had been attempted since the foundation of Baghdad and Samarra. The scheme included the Great Maidan, or square, surrounded by vaulted bazaars, with the portal of his mosque opening in the centre of the south side, the Ala-Qapu palace on the western side and the avenue over two miles long, known as the Chahar Bagh, with its plane trees and its famous bridge.

Many gilt domes date from this period; *e.g.,* the dome over the shrine of Imam Riza at Meshed. Sir John Chardin, who was in Isfahan in 1673 after an earthquake, saw the copper plates being made for the new dome: they measured 16 × 10 in. and he says that there were ten crowns worth of gold on each and that 3,000 had been ordered. Other examples exist at An Najaf and Kerbela (both due to Nadir Shah), Kazimain (due to Agha Mohammed Khan Kajar), Qum and Samarra (Fath Ali Shah).

Many truly monumental caravansaries were built during this period. Fine work was still being executed at the beginning of the 18th century, for example, the Madrasa of Shah Sultan Husayn at Isfahan (1700–10), but the disaster of the Afghan invasion hastened the decadence which was .complete by the end of the century.

Persian minarets vary slightly in form—a tall, slightly tapering cylindrical shaft, of which the earliest example is the Minar-i Ali at Isfahan, built by Malik Shah (1072–92), with a little covered balcony near the top for the *muadhdhin,* or the man who makes the call to prayer.

Persia was certainly one of the great creative centres of architectural development. For the science and skill shown in the construction of vaults, domes and pendentives, Persian architects must ever command respect and admiration, and in the field of polychrome decoration on the grand scale their achievements remain unrivaled.

TURKEY

Turkish architecture began when a branch of the Seljuk ruling family of Persia established itself in Asia Minor at the end of the 11th century. It therefore naturally bore a strong Persian imprint which was mixed in the 13th and 14th centuries with Syrian influences—in fact the mosque of Ala ad-Din at Konia (1220) was actually built by a Syrian architect, Mohammed ibn Khaulan. In material the country had the advantage over Persia, for splendid limestone was available, hence the superb masonry and rich carved ornament of the monuments of Sivas, Divrigi, Konia, Kayseri, Amasya, Mardin, Nigde, etc.; *e.g.,* the Tschifte Minare (1271) and the Gok Madrasa (1271) at Sivas.

To this period also belong two magnificent caravansaries, Sultan Khan (1229) and the Ak Khan (13th century). One of the outstanding features of Turkish architecture is the monumental portal with a stalactite hood, but it is composed in a different manner from the Egyptian type. In addition there is nearly always a semicircular recess below to right and left, a feature never found in Egypt except in the madrasa-mausoleum of Sultan Hasan. The minarets were derived from those of Persia, together with the practice of having a pair flanking the entrance. In addition to Syrian influence, Armenian masons undoubtedly played an important part, and there can be little doubt that the many circular and octagonal mausoleums, domed internally but covered by a cone externally, were influenced by the *kempet* (domes) of Armenian churches. The most pronounced example of Syrian influence is the Great mosque (1375) of Aya Suluk near Ephesus, which is obviously based on the Great mosque at Damascus.

With the conquest of Constantinople in 1453, an important change takes place in Turkish architecture. The supreme architectural qualities of Hagia Sophia had not led the Greeks to build

other churches like it; it represented a line of development which had been, so to speak, frozen at birth. But after the capture of the city, the brilliant architectural instincts of the Turkish architects realized its supremacy over all other Byzantine monuments, and almost every important mosque built by them in their new capital is a variation of its theme. Apparently they wished to obtain a perfectly symmetrical building with one great dome, four semidomes and four small domes between them, and this was achieved in the mosque of Ahmed in 1609. But it is generally agreed that the most successful mosques built by them are those of Suleiman the Magnificent in 1556–66 and of Selim at Adrianople, both designed by the famous architect Sinan (d. 1587). But whereas Hagia Sophia does not create a very good impression externally, below the springing of its piled-up dome and semidomes, the Turkish architects aimed at a good external effect also. The mosques of this period usually have four minarets, or even as many as six (*e.g.*, that of Sultan Ahmed), and the minarets usually have two and sometimes three galleries.

The most unfortunate event for Turkish architecture was the introduction of French and Italian architects and craftsmen by the French ambassador, the Comte de Choiseul Gouffier, in the middle of the 18th century, the result of which can be seen in the Nur-i Osmanie mosque of 1748–5j and later buildings.

EGYPT

In A.D. 969 the Fatimid conquest of Egypt took place, and the foundation of Cairo on unoccupied ground about 2 mi, north of al-Fustât. The mosque of al-Azhar was begun the following year, and although it has been much altered, it is easy to see that the original sanctuary was five aisles deep and the side aisles three; the north side was without a portico. A transept runs from the court to the mihrab, the five arcades stopping short on either side of it. The material used was brick, with stucco for the decoration.

Another great mosque was begun 20 years later and finished by the Fatimid caliph al-Hakim in 1003. It had a monumental entrance in the centre of the northwest side; there were also two important lateral entrances flanked by several lesser ones. The sanctuary had five arcades resting on brick piers cut through the centre by a transept, at the end of which was a dome on squinches and there was a similar dome at each of the back corners of the sanctuary. The outer walls were of stone and the arcades of brick. There was a minaret forming a salient at the two ends of the main facade, as in the Great mosque of Mahdia, the capital of the Fatimids.

Cairo was refortified by Badr al-Gamali in 1087–92, the town having outgrown its original enclosure, and three splendid gates of fine masonry, the Bab an-Nasr, Bab al-Futuh and Bab Zuwayla, and about 400 yd. of the Fatimid wall still exist. Crusading influence is excluded, for they were built ten years before the first crusade left Europe.

One of the glories of Fatimid architecture was its ornamentation, both its decorative Kufic inscriptions and fine arabesque. It witnessed the beginning of Syrian influence, which increased under the Ayyubids and Mamelukes.

The Ayyubid period (1171–1250) was marked by the military architecture of Saladin, who built the mighty citadel and part of the city walls, in which the most noteworthy feature is the bent-entrance (three in the citadel and two in the walls), the object of this device being to break the rush of a storming party. Other features of this period are the introduction of the madrasa, or theological college, the increasing use of hewn stone, the introduction of marble paneling for mihrabs, the development of stucco ornament in the direction of almost excessive fineness, the first use of glass in window grilles and the first steps in the evolution of the so-called stalactite pendentive.

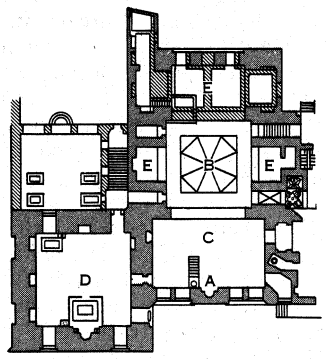

FIG. 4—PLAN OF THE MAUSOLEUM OF QAYT-BAY. CAIRO, SHOWING (A) MIHRAB, (B) COURT, (C) SANCTUARY, (D) TOMB AND (E) HALLS

The Ayyubid dynasty was followed by that of the Bahrite Mamelukes (1250–1382). This period witnessed an important development in the mosque plan, in the mosque of Baybars, where the small dome in front of the mihrab is replaced by a large dome covering nine bays (3 × 3) of the sanctuary. This feature was first introduced at Isfahan by Malik Shah (1072–92) and appeared later on at Ardistan (1158). It first appeared, outside Persia, at Mayyafariqin in 1158, a region which was in close relations with the Egyptian court. This feature occurs again in the mosque of al-Nasir Mohammed in the citadel (1335) and in that of his cupbearer al-Maridani (1340). The Syrian number and arrangement of the doors (3 axial ones) was also adopted. The stalactite portal was also introduced from Syria at this time. .

A Persian architect was employed under al-Nasir Mohammed for the mosque of Qusun, finished in 1330; this must be the explanation of the faience mosaic which now appeared for the first time in Egypt, in the mosques of al-Nasir Mohammed (1335) and Aslam al-Baha'i (1345), and in the mausoleum of Princess Toghai (d. 1349), and then suddenly died out. The period of the Bahrite Mamelukes was also marked by the final development and gradual extinction of stucco ornament, and by the introduction of splendid dadoes of polychrome marble.

The architecture of the Circassian Mamelukes (1382–1517) followed without any break in development. The rich stucco decoration, which had become extinct toward the end of the previous period, was not immediately replaced; at first the stone surfaces were left smooth and marble paneling was the chief enrichment, but when plastic skill in the new material was once acquired elaborate carved surface decoration once more became a regular feature. The stalactite pendentive underwent a change, the niches being set out Syrian fashion on a triangular frame but, unlike Syrian pendentives, each tier is curved in plan instead of cutting across the corner in a straight line and there is a great increase in the number of tiers, seven, eight or nine being quite common. The domes of this period, always of stone, are without rivals for lightness, beauty of outline and richness of decoration; *e.g.*, in the mausoleum of Sultans Barquq, Qayt-Bay, Qani Bay, etc. Fai'ence decoration was employed again at the end of this period, but only in the form of tiles instead of the much more effective fai'ence mosaic of the previous century.

It has been the custom to belittle the Turkish period (1517–1798), but it is probable that the enormous reduction in the amount of money hitherto spent by the rich Mameluke court was a more serious factor than an actual falling off in the quality of the work, and the mosques of Sidi Sariya in the citadel, Malika Safiya and Sinan Pasha at Bulaq justify this opinion.

The houses of Cairo rarely had more than two stories: on the ground floor was the *salamlik*, or men's apartments, and on the first floor the harem, or women's apartments. The chief feature of the façade, above the ground-floor level, was the attractive *mashrabiya* balconies. The following rules are generally observed: (1) the principal rooms face north (the direction of the prevailing wind) and look into the court around which the house is built; (2) the passage leading from the street to the court is built with a right-angled turn to prevent passers-by from seeing into the court; and (3) the entrance to the harem is placed on the far side of the court or in a second court.

The first half of the 19th century witnessed the introduction of the Stambuli style under the dynasty of Mohammed Ali.

WESTERN ISLAM

The Moslem architecture of Spain began with the arrival of Abd er-Rahman, the only member of the Omayyad family to escape the hatred of the Abbasids. He landed in Spain in 755 and by 787 had firmly established his rule and had built a mosque of cut stone at Córdoba. On the south side of the courtyard, which was not surrounded by porticoes until much later, was a sanctuary consisting of 11 aisles formed by 10 arcades of 12 arches each, at

right angles to the qibla wall (there was no transverse arcade at the back as at Kairouan). The central aisle was wider than the rest. The supports were marble columns with many kinds of Corinthian and composite capitals, taken from other buildings. As these supports, with their capitals and bases, only measure about 3.80 m. an upper arcade was added, as in the Aqsa mosque, to obtain the height necessary to support a flat ceiling about 9.30 m. from the floor. The execution of this idea, however, was carried out in a fashion somewhat different from that adopted in Syria, but it resembles the Aqsa mosque in that the aisles are roofed by parallel gable roofs with deep gutters between, which discharge by spouts placed above the piers of the facade on the court. The arches are built with stone voussoirs, alternating with composite voussoirs of four layers of red tiles ground down to a slightly tapering form. This alternation of colours is called *ablaq*. The existing Great mosque of Cbrdoba consists of this original part of 787 to which have been added three enlargements, two to the south toward the river and a third consisting of eight more aisles which, space to the south being lacking, has been added to the whole length of the east side. The second enlargement, due to al-Hakam in 961, is of extraordinary richness, especially the part in front of the new mihrab, where a screen is formed of interlacing arches, supporting three elaborately decorated domes, each set on the square in a different way. The mihrab is decorated with carved marble panels and gold and glass mosaic, said to have been executed by craftsmen sent by the Byzantine emperor.

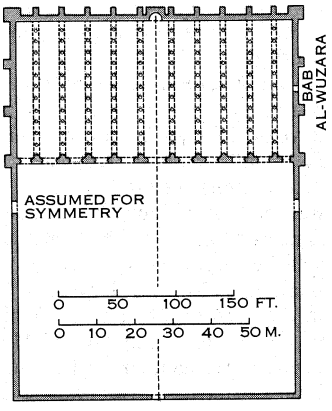

FIG. 5.—PLAN OF THE GREAT MOSQUE, CÓRDOBA, SPAIN

The Reconquista, or recovery of Spain by the Christian kings, began with the battle of Las Navas de Tolosa in 1212. This was a disaster for the Moslems, but the Nasrite kingdom of Granada survived until the end of Moslem Spain in 1492, and produced that famous masterpiece, the beautiful Alhambra (*q.v.*), the work of two kings. To Yusuf I (1334–54) is due the Patio de Comarès, to Mohammed V (1354–92) the Court of Lions and the halls belonging to it.

In North Africa the 12th century is marked by the decoration of the Great mosque of Tlemcen (1135–36), which is of extraordinary richness and beauty, especially the dome setting and the mihrab. A century and a half later came the superb decoration of the Great mosque of Taza.

INDIA

Although India was invaded by Mohammed ibn Qasim in A.D. 712 and again by Mahmud of Ghazni at the beginning of the 11th century, there is not a single example of Islamic architecture until the very end of the 12th century, when Mohammed of Ghor left Qutb-al-Din Aibak behind in India as the first sultan of Delhi. It is to him that the oldest part of the Quwwat al-Islam mosque is due, begun in 1193. This consists of a courtyard, measuring 105 × 142 ft., surrounded by pillared cloisters, short pillars from Hindu temples being superimposed to get the required height, the whole measuring 149 × 214 ft. externally. On the west (qibla) side the close setting of the columns is broken by five octagonal bays, presumably once covered by domes. All this was finished in 1196.

Then two years later a beautiful pointed-arched façade was built in front of the sanctuary, the central arch being wider and higher than the two to right and left. It was set in a rectangular frame which rose above the rest of the façade (a Persian concept known as a pishtaq, or frontispiece) and which consisted of bands of Hindu ornament and Kashki inscriptions. But these five arches are constructed with horizontal courses, for the Hindu masons employed by the conquerors were not acquainted with arcuate construction, and they employed the same technique for the arches when Iltutmish enlarged the mosque in 1229.

It was in the mausoleum of Balban (c. 1280), however, that true arcuated construction made its first appearance. The mosque had three axial entrances and was accompanied by the first minaret in India, the famous Qutb Minar, closely related to those at Ghazni, Afg., and the minaret discovered at Jam (1163–74) in the 20th century.

This mosque, with its three axial entrances, cloistered courtyard and sanctuary with large central arch more or less set the standard type for India (*e.g.*, those at Delhi, Agra, etc.), except that this central arch is sometimes flanked by the massive bases of a pair of minarets (*e.g.*, at Ahmadabad, Dholka, Champanir, etc.). Indian minarets are generally tall, circular or octagonal towers, with several galleries and a domed pavilion at the summit.

Mausoleums form another outstanding feature of Islamic architecture in India. There are three main groups: a domed square; a domed central chamber surrounded by four smaller domes (*e.g.*, mausoleums of Khan Khanan, of Humayun and the Taj Mahal, *q.v.*); and concentric octagons (*e.g.*, mausoleum of Sher Shah), the latter type being almost unknown outside India except for the Qubbat as-Sulaibiya at Samarra.

Unlike the Islamic architecture of Persia and Iraq, the Moslem monuments of India are characterized by their well-finished masonry and finely carved ornament, while the buff or red sandstone so frequently employed adds an attractive touch of colour.

ISLAMIC ART, the art of the followers of Mohammed, combined the influences of many regional cultures, extending from western Europe through the far east from the 7th century onward, into a unique style that attained its fullest development during the period between the 10th and 16th centuries. Islamic art is essentially an art of ornament.

Islamic History.—At the death of the prophet Mohammed in 632, his conquering Bedouin hosts already stood on the frontiers of the highly civilized empires of Byzantium and Persia. During the previous four centuries these empires had passed through great vicissitudes and only feeble remnants survived of the tradition of ancient Hellas. In Byzantium, Christianity prevailed; court, civil service and army, however, were intermixed with descendants of the barbarian tribes which had come during the migration of the nations, and in the Semitic provinces the Monophysite spirit rose up against the idolatry of the Greeks. In Persia, on the other hand, there ruled the Sassanids, whose power rested upon their hosts of cavalry from the interior of Persia, and who cultivated, side by side with the Zoroastrian religion of their fathers, ancient oriental traditions only faintly touched by Hellenistic influences.

When, on the death of the fourth elected caliph 'Ali in 661, the early communism of Islam came to an end, the whole of Tripoli, Egypt, Syria, Mesopotamia, Armenia, Georgia and Persia were already under the sway of Islam, which was soon extended to the rest of North Africa and Spain, Turkestan and the lower Indus valley. Until the middle of the 10th century all these lands were

ruled by the Arabs; but even under the first dynasty of the Omayyads (661–750) the Christian Syrians and Copts began to gain a considerable influence in intellectual life, followed by the Persians under the Abbasid dynasty (750–945), and the Ostrogoths under the Omayyad caliphs of Spain (independent after 755). The Arabs themselves owned few traditions of culture equal to the needs of a universal empire. With the decay of their empire, the Abbasid caliphs were forced to maintain their power with the help of mercenaries from the nomadic Turkish tribes of the north. From the middle of the 9th century onward these Turkish mercenaries began to create lieutenancies enjoying an even greater degree of independence, with the result that after 945 the caliphs found themselves reduced to a position resembling that of the popes.

In the middle of the 11th century western Asia was overrun by new hordes of Turkish nomads, who founded the Seljuk empire, which, however, soon disintegrated into a number of small states. In the first quarter of the 13th century the Mongols and their kindred peoples of horsemen from central Asia pushed as far as Syria, Asia Minor and Hungary. Other Turkish tribes followed, notably the hosts of the great conqueror Timur (Tamerlane, *c.* 1400) in Turkistan. In 1300 the Ottomans founded the Ottoman empire, and in 1502 the Kizilbash, of the Persian Shi'ah sect, founded the Persian empire under rulers of the Safawid house; these two empires survived until the 20th century.

In 1526, in India, which had previously lain under the domination of a series of Afghan and Turkish dynasties, descendants of Tamerlane founded the Mogul empire, which was ultimately destroyed by England in 1803. In Africa, on the other hand, the leadership soon fell to the nomadic Berber tribes, which formed, in addition to a number of small states, the orthodox kingdom of the Almoravides (1061–1147) and that of the Almohades (1147–1269) in the far west, and, after the loss of Spain in 1492, the kingdoms of the Marinids, Sadites and sherifs of Sijilmasa. Egypt was ruled from 969 to 1171 by the Shi'ite anticaliphs of the Fatimid dynasty — Berbers likewise — and before and after that period by mercenaries (mostly of Turkish race), including the Ayyubids (1174–1250), who were Kurds, and the Mamelukes (1250–1517), who were overthrown by the Ottoman Sultan Selim I. *See* also CALIPHATE.

Origins and Nature **of** Islamic Art. — In a world enclosed between desert and steppe and ruled by nomadic races, Islamic art inevitably followed an entirely different path from that of the west. Western classical art developed among settled tillers of the soil and in towns; it is intellectual. Characteristic of it is the clear structural consistency of architecture, which is carried on into architectural ornament. Naturalistic sculpture and relief, the portrayed figure, are preferred. The art of the nomads, on the other hand, proceeds from the tent and the loom, and for that reason the tectonics of Islamic architecture are limited to the primary forms, though they are frequently resolved into delightful shapes. Wall surfaces are adorned with purely geometrical decoration resembling rugs over the framework of a Kirghiz tent.

Islamic decorative art is based on pure ornament, script, arabesque and intertwined bands. As in early Irish, Scandinavian and Romanesque art, representations of human beings and animals are combined with fillet and arabesque ornament, and in plastic art they appear only in low relief. Only in painting do they acquire an independent life under antique Sassanian and eastern Asiatic influences, but even so they are partly in the nature of calligraphy, against the background of an equally conventional, tapestrylike landscape.

Except in the most recent period, naturalism never existed. Added to this, the Arabian world had a dislike of figural art. already perceptible in eastern Christianity. Figural representations were absolutely prohibited in the early period of Islam and under the Berber dynasties of Africa and the Mamelukes of Egypt and Syria, though under the Omayyads and Abbasids and most of the Shi'ite and Turkish dynasties it was only excluded from public buildings. *See* also BYZANTINE ART; ROMANESQUE ART.

Plastic Art. — Plastic art on the larger scale therefore seldom fell under outside influences. Thus the Seljuks brought with them from eastern Turkestan a plastic tradition akin to the Buddhist art of central Asia; this tradition is represented by the few extant statues and reliefs of lions, double eagles, dragons, angels, etc., from the city walls of Konia and Baghdad, and by a few stucco plaques depicting scenes of court life. Apart from these, human and animal figures in low relief are found scattered here and there among the decorative carving on rafters and beams dating throughout the period from the 11th to the 14th century. Under the Mogul emperors in the 16th and 17th centuries Indian influence appeared in the elephant statues of Fatehpur-Sikri and Delhi. Sassanian influence appeared in the 19th century in the rock reliefs of Fath 'Ali Shah of Persia. Other plastic art, however, was entirely restricted to small-scale works, chiefly figures of lions, elephants and birds in glazed stoneware or bronze, strongly conventionalized as the nature of the material required, and used as water vessels or smoking appliances. A madonna with Mongolian dress and appearance, made of fai'ence, is an exception.

Painting. — Figure painting was much more important. It is true that it was excluded from public, political and religious edifices.

In the private apartments. however — bathrooms and harems especially — painting was tolerated by the clergy, and found its expression in frescoes, illustrated erotic and edifying books, and household vessels, goblets, bottles, etc., adorned with figures. Even the caliphs decorated the private apartments in their palaces in this way. Thus between 712 and 715 the Omayyad al-Walid had the bathrooms in his desert castle of Qusair 'Amra painted throughout with frescoes in the later antique style, depicting birth and death, the three ages of life, hunters and hunting animals, musicians and dancing girls, women bathing, the caliph on the throne, the emperors overthrown by Islam and so on. The latter group betrays the influence of Sassanian art, which dominated the harem frescoes reconstructed out of scanty remnants in the Abbasid residence at Samarra (836–876). There are found dancing girls in every possible pose, naked and in flowing robes, with diadems and long braided hair, with floating veils, bowls and wine jars; huntresses and horsewomen, priests and warriors, and animals of every kind, in a heraldic style on medallions composed of intertwining tendrils and bands in endless repetition, symmetrical and hieratic.

In the Alhambra (*q.v.*) at Granada (13th–14th cent.) the last Moors of Spain were represented as noble knights and troubadours in roof paintings of an almost Gothic style. In the frescaes and faïence tiling of the castles of Isfahan and Ashraf, displaying exquisite calligraphy, and betraying strong eastern Asiatic influence, the amorous and oenophilous sentiment of the courtly youth of the Safawid era were represented. In India, the Mogul rulers of the 16th and 17th centuries had their harem apartments painted throughout with frescoes, though these mere discarded about 1700 by the orthodox emperor Aurangzeb; but wall paintings, some with Buddhist subjects, have been preserved in the bedroom of Akbar's soon abandoned residence at Fatehpur-Sikri, and from a few contemporary miniatures are known the semi-European paintings that Jahangir caused to be executed at Agra. *See* also PERSIAN ART, PAINTING AND CALLIGRAPHY.

Ornament. — Ornament is the centre of Islamic art. It supplanted all the other possibilities offered by different individual technics. Utilizing them all, dependent on none, it is a self-contained world of form, which embraces indifferently the walls of mosques and castles, the backgrounds of figure paintings, the details of sculpture, glasses, pots and vases, furniture and bronze implements, arms and jewelry, bookbindings and calligraphy, a vast storehouse of forms, turning every technique, every material to its own uses in the most perfect taste.

The motifs from which this ornament grew came from the later antique, the ancient east and the barbarian migrations. In the earliest monuments, particularly the great frieze in relief at Mshatta, the prevailing feature, as in Byzantine and Romanesque art, was the spiral tendril springing from the vine, its spaces filled in with vine leaves and branches of grapes, and diversified with all

kinds of animals and large rosettes. In the frescoes and in the third style of the stucco wall facings in the Abbasid residence at Samarra the same motif is found, though already again greatly conventionalized.

Beside it, however, is encountered a new type of ornament undoubtedly traceable to the wood carving of the nomad tribes of the north. consisting of very denatured palm leaves, whose contours soon became an independent style, a complex of free curves. Under the Turks and the Arab dynasties that took their artistic notions from them (10th to 16th century), this developed into a purely abstract art of decoration, carried to the furthest possible extent; its leading motifs are the fillet, the arabesque and the palm leaf.

The fillet is the most important and is derived from the northern nomadic art. Plain or twisted, with herringbone or circular patterns, it divides every area into border and central field, angle and centre medallions, friezes, etc. It curves into circles and wavy lines, imitates the shapes of architectural vaults, piles up tendrilwise in vaulted arcades and forms complicated trellis patterns. This developed into the twined pattern of stars and rosettes favoured during the Mameluke period, which presents designs that, immensely numerous though they are, are always mathematically accurate. The intervening spaces are filled with polygons of every shape, stars, garlands, rosettes, often plain or in simple patterns that secure their whole effect through colour contrast, and frequently are decorated with rich arabesques diversified with palm-leaf motifs.

The early twining vine leaf, the palm leaf. the tree of life of the ancient east, are combined in an inextricable dramatic unity, enriched since the Mongol period with completed palm leaves and even with distortions of these into diabolical masks, houses, etc., and Chinese cloud strata and shreds. Thus western Asia, especially Persia. was dominated by the arabesque, in delicate spirals, often of the shape of snail shells, with little rolled-up and not uncommonly pinnate leaves, and rosettes, and palm leaves radiating outward. It served also as a background for decorative figures of phoenixes and Chinese dragons, hunting animals and birds, musicians and dancing girls, but most of all for ornamental inscriptions.

The clumsy early Arabic script, the Kufic, with its numerous vertical and oblique strokes, produced an extraordinarily monumental effect, and for that reason, it continued to be employed as a decorative writing, and developed into a new form, used with special frequency in Persia — the floral Kufic, in which the top of the characters blossom into floral tendrils. This was also combined with the trellis ornament, a notable example being the stuccowork in the Alhambra at Granada.

The later cursive naskhi, with its wealth of curves and twists, also proved a highly decorative script, the final letters of words being generally crossed with the long strokes of the initial letters like an ornament. They were also frequently used to provide a delicate background to the heavier characters of the Kufic. The shikasta, and the animal figures which were artfully formed from the characters of some sentences (generally from the first sura of the Koran) were confined, however, to the Persian book-designer's art.

After the 16th century Islamic ornament began to decay. As early as the 13th century niches framed by arches and pillars, vases with bouquets of flowers, hanging lamps, cypresses, etc., had appeared sporadically; these now came into favour as decorative motifs, and their seminaturalism drove out the wealth of abstract ornament.

Architectural Ornament. — Since tectonic arrangement in architecture was confined to the broad lines, a wide field was presented for ornament. In the Omayyad period preference was given to the glittering glass mosaic and deep-shadowed pierced stone filigree work, both common in Byzantium. With the victory of the sun-dried brick under the Abbasids, these were superseded by stucco facing sometimes molded in the flat, sometimes likewise cut in high relief, as in the third style of Samarra and in wonderful inscriptions in floral Kufic from Persia, all originally richly painted.

Later, in the Turkish and Mongolian periods, stucco gave way to the cheaper substitute for the more costly mosaic, in freestone or brick, but most often in fai'ence tiling. The less important parts of the rough core of the wall, often quite carelessly put together, were overlaid with a particoloured mosaic of glazed bricks of varied shapes, making all kinds of twined patterns and formalized Kufic words endlessly repeated; while the major portions were covered with mosaics of tiles cut skillfully to the exact shapes of the prevalent patterns, in harmonious colour schemes, particularly blue, or in combinations of fai'ence ornament on a stucco ground (in relief) or friezes of inscriptions in incised stucco in the intervals of fai'ence mosaic. Admirable also are the script friezes of glazed tiles with dark blue characters on a ground of golden-brown arabesques.

With the decay of ornament after the 16th century, this type of mosaic was generally supplanted by square faience tiles with the decoration simply painted on them. Apart from one or two magnificent portions of buildings, Syria, Egypt and the west were content with coloured stuccowork and mosaics of particoloured stone plaques, generally white and red or white and black. For plan and tectonics *see* ISLAMIC ARCHITECTURE. *See* also ORNAMENT, ARCHITECTURAL.

Furniture. — Another reason for this rich wall decoration lies in the almost complete absence of furniture, in our sense of the term, in Islamic places of worship and dwelling houses. This, like the custom of sitting on the floor, was due to the nomadic habit. Household crockery was kept in stuccoed recesses in the walls, or on wooden shelves and in cupboards built into the walls; of the latter there is at Berlin a fine example from Aleppo, with biblical paintings in the Persian style.

Furniture, in our sense, was represented in private houses by small, low, round or oblong tables, and in India also by beds (charpoy). Persons of consequence used the takht, but sat on it in the same posture as on the floor; chairs came into use in the 17th century only in the highest circles. In the mosques the Koran was placed on a desk (kursi) like a campstool, and was often kept in a small circular cabinet; the pulpit (minbar) was a domed box at the top of a staircase, reached through a doorway that could be closed.

A feature of most of these objects is the way in which they are decorated with tasteful tarsia work of small boards, richly carved and inlaid with mother-of-pearl, ivory, etc. This was necessary owing to the wood available and the danger of warping. The harem doors were worked in like fashion, often with rich bronze ornamentation, and the balcony railings (musharabiya), made of small curved wooden pales. (*See* also WOOD CARVING.)

The remaining objects in the house comprised rugs and cushions, jewel cases and boxes, table utensils, lamps, smoking equipment, open charcoal pans (as stoves) and warming pans, candlesticks, etc., in bronze, fai'ence, glass, ivory and other materials. For rugs and woven fabrics, *see* EMBROIDERY; TEXTILES.

Ceramics. — The Islamic ceramic art built upon ancient oriental traditions, enriched them for its own religious purposes with a new and highly effective technique, and pursued its development under growing influences from eastern Asia.

The use of the coloured glazed brick was inherited from Babylon, as was the unglazed earthenware in the barbotin style (in which the pattern is made by applying bands of clay) with the tree of life and naked goddess (Astarte) motifs, enriched with Hellenistic and Sassanian elements, laurel and acanthus leaves, stubs of palm leaves, and later wreathed medallions centred with animal figures, griffins, eagles and the like. Examples are to be seen in the pottery of Samarra, though this is almost entirely in tiny shards. Echoes of this barbotin technique appear in the ware of Mosul down to the 14th century, and in the Gabri ware of Persia, in the sgraffito manner, often with lively painting, until *c.* 1200.

Contemporaneously, in Samarra, appeared the first lustreware. Early Islam was puritanical enough to proscribe gold — like silk — as a worldly luxury, and for that reason, in later times, fai'ence painted with a gold lustre changing to green, brown and violet was used as a substitute; in the earliest examples the forms of the magnificent golden and silver vessels of the Sassanian epoch

can still be plainly traced. This style rose high in favour, particularly in the Seljuk and Mongol periods, but disappeared at the beginning of the 17th century.

The Abbasid caliphs also imported porcelain, from China (Sung dynasty), and had its white, yellow and green overflow glazing and its stippled, fish and other designs imitated in earthenware. With the Seljuks came a new wave of far eastern influence, the chief centre of the industry under their rule being Rhagae, the forerunner of Teheran.

Minai ware consisted of bowls, beakers, tankards and bottles with spirited painting and gilding on a white ground, often with rich figure compositions in bands. There are also vessels of similar types as well as some akin to the bronzes, in animal and human form; their design is left white, generally on a ground of violet lustre, and shows the classical arabesque and palm-leaf motifs, sphinxes and birds with crowned women's heads, peacocks, elephants, scenes of court life and war, and, above all, horsemen with their characteristic pigtails and their garments adorned with arabesques. After the destruction of Rhagae by the Mongols, Sultanabad and Veramin became the centres of the ceramic industry in the 13th and 14th centuries. Favourite types were not only *minai* and lustreware, but also faïence in green and dark blue tones, in many cases with molded ornamentation, and tiles richly decorated in lustre. From the 16th century onward, Chinese white porcelain with blue and gray designs was imported in large quantities and became a regular type. Its decoration was copied and freely developed, but porcelain itself could not be successfully manufactured, and a kind of semifaïence, closely resembling it, was made instead.

Persian pottery formed the basis of that of Syria, Egypt, Spain and Asia Minor. In the Arab civilization, figure motifs disappeared early, and bands of script or arabesque, arranged radially or in rings, became the prevalent form. In Spain, under Christian rule, this art developed still further, and absorbed Gothic motifs; the 14th and 15th century wares of Malaga (whence the name majolica) and of Paterna and Manises, two suburbs of Valencia, exercised a very strong influence on the majolica ware of the early Italian renaissance.

On the other hand, in the Ottoman pottery of Kutaiah and Isnik (Damascus and Rhodos ware), which flourished from the 15th century onward, relatively naturalistic tulips, carnations, roses, lilies, cypresses, etc., and also figure subjects, were preferred for purposes of decoration, cobalt blue. turquoise, green and manganese violet being used as colours, generally on a white ground. *See* also POTTERY AND PORCELAIN.

Glassware and Crystalware. — Unlike pottery, glassmaking was inherited from Hellenic antiquity, and was centred in Syria and Egypt.

The Fatimid period produced narrow-necked bottles, tankards and beakers, and scent bottles ornamented with externally applied bosses, threads and bands, or with spiral tendrils and animal figures molded into the glass. In addition, imitations were made (Hedwig glasses) of rock crystal vessels with ornament consisting of figures and circular tendrils, of Sassanian origin. Many of these came early into the possession of religious or noble houses in Europe, and have thus been preserved. The most marvelous work, however, was produced at Aleppo in Syria, under the Ayyubid and Mameluke dominations. Bottles, beakers, goblets and above all hanging lamps for mosques, were covered with bands of arabesque and script and with medallions in enamel colours (white, red, blue and yellow) and gold; the subjects included figures of horsemen and others, and the coats of arms of the court offices. The celebrated "Luck of Edenhall" was a goblet of this type. Modern Persian glass originated in the industry promoted by Shah 'Abbas the Great (c. 1600). See GLASS.

Metalwork. — Here again oriental traditions, particularly those of the Sassanian empire and the far east, predominated. Most of the work was in bronze, iron being still used almost only for weapons. The use of gold and silver also was limited, because it was forbidden by the Koran; and although the prohibition was often ignored, the great value of such objects led to their early destruction and melting down. Islamic jewelry of the early period is therefore of extreme rarity, being represented only by a few buckles, bracelets, etc., of the Fatimid and Mongol periods, and such pieces as the Gerona silver chest (akin to the similar ivory coffers) in Spain and the Berlin silver tankard of the 13th century, with its embossed reliefs of Sassanian animal friezes. *See* JEWELLERY.

Bronzes. — Such animals in the Sassanian style, lions, dragons, sphinxes, peacocks, doves, cocks and the like, were also cast in bronze in three dimensions, and served, like their ceramic counterparts, as basins, braziers, etc. They were particularly sought after in the later Abbasid, Fatimid and Seljuk periods, and from Egypt they became the prototypes of similar European forms. It was the Seljuks, apparently, who introduced the round bronze mirror, the reverse of which shows in low relief either two sphinxes face to face — in the manner of the *minai* pottery — surrounded by a twined pattern, or two friezes with the astrological symbols of the 7 chief heavenly bodies (sun, moon and the 5 nearest planets) and the 12 signs of the zodiac, surrounded by a band of script; this goes back ultimately to Chinese origins.

Early mugs, etc., were ornamented with animals in low relief, but engraving quickly supplanted this. Under the later Seljuks (particularly the Ortoqid Atabegs of Mosul) and the Mamelukes, engraving became almost the only form of decoration, but only to serve as a basis for the yet richer technique of inlaying: small silver plates and wires, themselves delicately engraved, were hammered into the ribs and surfaces, which were hollowed out and undercut at the edges.

In place of this an Ortoqid bowl in the provincial museum at Innsbruck has the spaces filled in with cellular enamel. This was a method of evading the prohibition of precious metals, just as gold lustre was in pottery. The ornament consisted of friezes and medallions in lattice and arabesque work, the interstices being filled with figures of warriors, hunters, musicians, animals and astrological symbols. These were superseded later by Mameluke coats of arms and inscriptions. In the 15th century the technique was imported from Syria to Venice, where productions of the same kind, *alla damaschina* or *all' azzimina* were made right into the 16th century by Islamic masters, and were in great demand. In the east the process is still common, but both technically and artistically it has decayed.

In the 15th century, however, there was a renascence of pure metal engraving, but the design — inscriptions and arabesques in the Timurid and Safawid styles — was not cut into the material, but left free in the manner of a relief, the background being etched in black.

Decoration was applied to bowls, basins, mugs, vases, mortars, braziers, warming pans, candlesticks, smoking utensils, inkstands, jewel cases, Koran holders, mosque lamps and *kursis*. These are generally in the simplest possible forms — spherical, cylindrical, prismatic — and are developed by cutting off corners, adding projections, narrowing and channeling the walls, and by reduplication; the subjects include motifs of vegetation and animal life — the former mainly in the necks and feet of vessels, the latter for handles and ears, feet and sometimes small spouts. See also METALWORK, DECORATIVE.

Weapons. — Ancient Islamic weapons of any artistic value are comparatively rare: most of the extant pieces date from the 17th or 18th or even early 19th century, while the period from the 14th to the 16th is represented by a fair number of fine examples. Islamic swords were famous even in antiquity for their wonderful blades of Damascus and Toledo steel. This high standard was attained partly by a laborious process of repeatedly welding together pieces of iron of different qualities, but ultimately it was due to the peculiar process used for smelting the Indian raw material — a method whose results have been surpassed only by those of the modern Besserner process. The earlier blades are all straight; curved sabres and daggers did not become common until after 1500.

The blades were ornamented with inlaid work of gold and silver threads, arabesques, blessings and — on the celebrated Mongol blades — also phoenixes and dragons in the Chinese manner; at a later period the inlay was confined to the part near the hilt, the

remainder being adorned with engraved reliefs. For the handle and guards, gold and cellular enamel were used, as on the magnificent Boabdil swords named after the last Moorish king in Spain (15th century), with their hooked guards, and many Ottoman and Persian daggers and sabres of the 17th and 18th centuries. Nephrite, ivory and silver plating with jeweled ornament were also used, especially for daggers.

Scabbards had ornaments to match the hilts, and were covered with riielloed silver plating, leather, snakeskin or rayskin. Battle-axes and maces are also found, though these were often mere symbols of command and high position. The former display not only inlay, but also in many cases engraved relief and even filigree work. The heads of the maces were often made of rock crystal, but more frequently were cast solid, in a smooth pear shape, with grooves or bosses, richly inlaid. Shields were round with a boss in the centre: in Egypt under the Mamelukes they were of inlaid iron, elsewhere generally of leather, with painted lacquer surface.

The armour, of Sassanian origin, consisted of a mail shirt, arm-pieces and greaves, a round breastplate, and a pointed helmet consisting of several spangles riveted together. Not until a late period did a coat of four plates (char-aina), and even a cuirass in the Spanish manner, become common. From the 15th century onward the helmet was made in one piece, though there were in addition a number of movable parts such as nosepieces, cheek-pieces, neckpieces, etc. The decoration, however — grooves or medallions between radiating ribs on a broad frontlet — betrays the original construction. The earlier pieces (15th century) were broad and protuberant, and came so low down over the forehead that eye notches were necessary, the reason for this shape being that the turban was worn under the helmet; the later examples fitted closely, and were pointed or hemispherical with spikes attached, nosepieces and crests.

The usual ornamentation in the early helmets, most of which are ascribed to western Turkistan, consists of silver-wire inlay; later, in Persia, it is generally iron engraving, sometimes combined with inlaid work; and in the grooved Ottoman storm helmets, black etching. An offshoot of the last named is the Zischagge, often richly worked, which was used in the 17th century in Hungary, Poland and even Germany.

Bookbinding and Lacquering. — Koran manuscripts, and also rich miniature books were all bound in leather, the edges being protected by a flap. A very old binding from Egypt shows inlaid work, but apart from this the usual decoration up to the 15th century consisted of stamping with beaded edges, medallions in the centre and in the corners triangular ornaments of unobtrusive script, plait and palm-leaf patterns. From the 16th century onward, however, this decoration was transferred to the inner side of the cover, in finely-detailed filigree work against a brightly-coloured background.

On the outside it was replaced by opulent stamped gilding which had indeed a similar composition but was formed of arabesques and bands of clouds, and even of decorative figure groups; sometimes also the outside was covered in the Chinese manner with lacquerwork, which in the early period showed occasional dragons and phoenixes, and later flowers and romantic and genre scenes. From the end of the 18th century this technique was in high favour, and was applied not only to bookbindings, but also to writing cases, jewel cases, toilet accessories, and even shields and bows. See also BOOKBINDING; LACQUER.

Development and Influence. — When the great civilizations of Egypt and Babylon ceased to exist, the culture of Hellas had conquered the orient with Alexander's victorious progress. Islam was only one factor in the recovery of the east brought about by the Aramaic, Coptic, Persian and Arab stocks, parallel to which proceeded the migration of the nomads of central Asia and eastern Europe and the Germanic nations whom they pushed before them. This migration took its rise from the frontiers of China, and in the later thrusts of the Turks and Mongols it also overran the area of the Arabian civilization; and beside and behind it came the peaceful influence of the far east. Thus in its early period Islamic art continued the assimilation of Hellenistic and ancient oriental motifs begun by the later Persians, and from the Abbasid era it fell almost wholly under the tradition of the Sassanian empire.

With the rise of the Turkish dynasties the nomad character became increasingly marked, and from the Seljuk period onward the influence of eastern Asia grew in strength, particularly from the Mongol to the Safawid period. Meanwhile Islam fused all these influences into a completely individual abstract style, which reached its zenith, artistically and technically, between the 10th and 16th centuries.

Thereafter decadence began, veiled in the 17th century by extravagance of external splendour, but betrayed by a tendency toward some degree of naturalism and an increase of European influence, and leading to complete decay by the middle of the 19th century. During its greatest period, however. the influence of the Islamic culture extended through India as far as Java, to China, to the Sudan and to the whole of Russia.

The European culture of the middle ages and the Renaissance was very largely derived from it. Islamic brocades and carpets, ivories (coffers and olifant horns), 'glasses and aguamaniles, etc., found their way from Spain, Sicily and Fatimid Egypt into the ecclesiastical and princely treasure houses of Europe; in the period from the Crusades to the conquest of Granada the borrowings consisted mainly of Mameluke weapons and glass, *azzimina* bronzes, Toledo blades and majolica ware from Spain, albarellos, etc., and bookbindings.

In the east the Tatars brought their culture and art, especially weapons and clothes, to the Russians. Further, through the Turkish wars various Islamic utensils and objets #art — stuffs, costumes, rugs (Polish rugs), sabres, helmets, etc.—became naturalized in Hungary and Poland, and even in Austria, Saxony, Bavaria and Prussia.

ISLAMIC INSTITUTIONS. Of all the institutions of Islam the caliphate is the oldest, the most fundamental and in essence the most enduring. For its history see CALIPHATE; the present subject is its origin and nature. Muhammad ruled over his people as a divinely inspired and guided prophet. He led the public prayers; he acted as judge; he controlled the army. On his death a leader was put in his place of similar authority, though without the divine prophetic guidance. He was called the "successor" (khalifah, caliph) of the Prophet, later also the *amīr-al-mu'minīn,* commander of the faithful, and was elected by the Muslims, just as the Arab tribes had always elected their chiefs. He was thus an absolute ruler but was democratically elected. For the Sunnites it has been a matter of agreement (see ISLAMIC LAW) from the earliest times that the Muslim community must appoint such a leader (see IMAM). The Shi'ites, on the other hand, hold that the appointment lies with God, and that God always has appointed, though his appointment may not always have been known and accepted. Their position may be called a legitimist one.

Some few heretical sects have held that the necessity of a leader was based on reason, not on the agreement of the community. But, for all, the rule of the leader thus appointed is absolute, and all authority is delegated from him and, in theory, can be resumed by him at any time.

But Abū Bakr, the first caliph, nominated his successor, 'Umar, and that nomination was accepted and confirmed by the people. So a second precedent was fixed, which was again carried a step farther, when Mu'āwiyah I, the first Umayyad caliph, nominated his son, Yazid I, as his successor and caused an oath of allegiance

to be taken to him. The hereditary principle was thus introduced, though some relics of the form of election persisted. The Ottoman claim was based on an asserted nomination by the last 'Abbāsid, who died in exile in Egypt in 1538, of the Ottoman sultan, Salim I., as his successor. Such a nomination in itself was a perfectly legal act, but in this case had a fatal flaw. It was an absolute condition, laid down in tradition, that the caliph must be of the tribe of Quraish, that of the Prophet.

The duties of the caliph were to enforce legal decisions and maintain the divinely revealed ordinances; guard the frontiers and equip armies; receive the alms; put down highwaymen; maintain the Friday services and the festivals; decide disputes and receive evidence bearing on legal claims; marry minors, male and female, who have no guardians; divide booty. He had to be a free, male, adult Muslim; have administrative ability; be an effective governor and do justice to the wronged. So long as he fulfilled these conditions he was to be absolutely obeyed. The caliph, therefore, was the highest executive officer of a system assumed to be definite and fixed. To depose him a *fatwā* (see MUFTI) would be required—in Turkey from the Shaykh-ul-Islām—that he had violated some essential of the Muslim faith, and no longer fulfilled the conditions of a caliph.

The Diwans.—But it was impossible for the caliph personally to administer the affairs of the empire, and by degrees government bureaus (*dīwāns;* see DIWAN) were created to regulate and administer the system of taxation and the revenues of the state. The sources of revenue were (i.) the poor-rate (zakcit), a tithe paid by every Muslim; (ii.) the fifth of all booty; (iii.) the poll-tax (*jizya*) on non-Muslims; and (iv.) the land-tax (*kharāj*) also on non-Muslims. The non-Muslims must retain their lands, cultivate them and pay the land-tax and the poll-tax and give contributions in kind to support the local Muslim garrisons which were massed in great camp-cities at strategic points. The first patriarchal period of conquest, unearned wealth and the simple life passed rapidly into the genuinely Arab empire of the Umayyads, with whom came an immediate development of organization in the state. The seclusion of the caliph in Umayyad times increased still further when the administration of the state passed by delegation into other hands, and the caliph himself became a sacrosanct figurehead, as in the case of the later 'Abbāsids; when theories of semi-divine nature and of theocratic rule appeared, as in the case of the Fatimites; and finally when all the elaborate court ritual of Byzantium was inherited by the Ottoman sultans.

Under the 'Abbāsids the semi-independent provinces became fully independent, or at most acknowledged the caliph as a spiritual head and paid a nominal tribute. His name might stand on the coinage and prayers be offered for him in the Friday service, the two signs of sovereignty to this day in Islam. With this crumbling of the empire went a more elaborate organization; bureaus took the place of principles and of the energy of individual rulers.

The Vizierate.—Abu 'l-Abbās, the first 'Abbāsid caliph, was the first to appoint a vizier (wazir, "helper," so Aaron is *wazir* to Moses in the Qur'ān), a confidential minister to advise him and come between him and the people. The vizier sometimes became as important as the caliph, for with a weak ruler his vizier became absolute, with a strong ruler his vizier remained subordinate. Until the time of Rāḍī (934–940) the vizierate thus fluctuated in importance. In that caliphate the vizier lost all authority, and in his place came the *amir* al-umarci—equivalent to the major *domus* of the Franks—the head of the Turkish bodyguard, in terror of whom the caliph now stood. When in 945 the Būyids captured Baghdad and the caliph became a purely spiritual sovereign, they took the title "vizier" for their own chief minister, and the caliphs retained only a secretary. Under the Seljuks, however, they regained their viziers and some real authority.

Under the early 'Abbāsids the four most important ministers were the chief cadi, the chief of police or head of the life guards, the minister of finance and the postmaster, who was the head of the system of information and espionage which covered the empire. But at different times the different bureaux varied greatly. Under Mutawakkil we find the bureau of taxes and finance; bureau of the crown estates; bureau of state book-keeping; bureau of war, *i.e.* of hired troops; bureau which kept reckoning and control of the pensions of the clients and slaves of the ruling family; bureau of the post system; bureau of expenditures.

As the chief of police, mentioned above, was rather the head of the caliph's bodyguard, there was also a police system after our ideas, but more thoroughgoing. The *muhtasib* had charge in the broadest sense of public order and morals in the streets, and had oversight as to weights, measures and adulterations; but had no right to interfere privately or enter houses save in the clearest and most necessary cases. He had a summary jurisdiction in all minor cases where no trial was necessary; but where witnesses and oafhs entered the case must go to the cadi. Slaves and beasts of burden were under his guardianship; he prevented public scandals, such as the sale of wine; he regulated the public conduct of Jews and Christians. In the interest of public morals he had to find suitable husbands for widows and see that they did not marry before the legal time; questions of paternity also he had to investigate.

It is impossible in Islam to separate logically from the mass of institutions those which we should call religious, as Islam on all sides is for the Muslim equally religious. But perhaps the following may practically be separated under that rubric. Islam, runs a tradition, is built on five things: testimony that there is no god save Allah, and that Muhammad is the apostle of Allah; prayer; the poor-rate; pilgrimage; fasting. For these see ISLAM.

The law and usage of religious foundations in perpetuity (*waqf*, mortmain) became as important in Islam as monastic endowments in mediaeval Europe, and such foundations tended similarly to absorb the greater part of the national wealth. A pious foundation could he erected in such a way that either so much from its funds would be paid yearly in perpetuity to the descendants of the erector, or those descendants would be employed as officials of the foundation.

The Imam.—When it became impossible for the caliph to lead the people personally in prayer in the mosque, he delegated that part of his duties to another, hence called imām (*q.v.*). Naturally, then, the appointment of the imām would lie with the supreme ruler. This holds of the daily prayers in the principal mosque (al-masjid *al-jāmi'*) supported by the ruler where the Friday service is held, but in the separate smaller mosques built by each community the community chooses its own imām. The imām appoints the muadhdhin, the announcer of the hour of prayer from the minaret, and both have a claim on the state treasury.

Another office exercised when possible by the caliph, but very frequently delegated to some high dignitary, such as the heir to the caliphate or a prince, was the leadership of the pilgrimage caravan to Mecca and back. Sometimes this official, called *amīr-al-ḥajj*, was appointed imām as well. He then led all the pilgrimage ceremonies at Mecca.

The Cadi.—Islamic law (*q.v.*) is treated separately. Here, again, as judging is a duty of the caliph, a cadi is the delegate, or, when appointed by a vizier or governor, a delegate of his delegate. He examines into disputes brought before him and enforces his judgments, he names administrators of the estates of minors, the insane, etc.; he supervises the waqf property of mosques and schools in his district and inspects highways and public buildings; he watches over the execution of wills; he inflicts the due legal penalties for apostasy, neglect of religious duties, refusal to pay taxes, theft, adultery, outrages, murder; he can inflict the penalties of imprisonment, fine, corporal punishment, death; if there is no imām, he can perform his duty, as in fact can anyone who has the requisite knowledge.

The Army.—For the existence of an army in Islam, there are two grounds, the holy war (*jihdd, q.v.*) against unbelievers without the state and the suppression of rebellion within. Under Umar, every able-bodied male Muslim was theoretically a fighting man, part of the national militia. This army was divided into corps situated in the conquered lands, as armies of occupation, where they eventually came to form military colonies in great camp-cities. The occupied countries had to support them, and they were bound to render military service at any time. But as the ideal of Umar broke down before facts the use of mercenary

and slave troops finally increased; although there has always continued in Muslim armies acting against unbelievers a proportion of volunteers not paid a fixed wage but subsidized by the state from the poor-rate and alms funds. The generals were appointed by the caliph, and had either unlimited authority to act as his representatives, concluding peace, acting as cadi and imām, distributing booty; or were restricted within limits, *e.g.* to simple leading of the troops and carrying on military operations. As war by a Muslim power is essentially sacred war, the regulations of *jihād* must be considered here. Unbelievers must first be invited to embrace Islam and, if they follow a sacred book and are not idol-worshippers, are given a choice between (a) becoming Muslims; or (b) submitting to the Muslims and entering on a treaty with them of protection and tribute; or *(c)* fighting. If they accept Islam, their lives, families and property are secure, and they form henceforth part of the Muslim community. If they submit and enter on treaty relations, they pay a poll-tax, for which their personal safety is assured, and assume a definitely inferior status, having no technical citizenship in the state, only the condition of protected clients (dhimmis). If they elect to fight, the door of repentance is open, even when the armies are face to face. But after defeat their lives are forfeit, their families are liable to slavery, and all their goods to seizure. Apostates must be put to death. Four-fifths of the booty after a battle goes to the conquering army.

Education.— The glory of Muslim education was its university system, which fed the higher learning and did not serve every-day needs. Its primary system was very poor, almost non-existent; and technical education has never been recognized in Islam. Primary teachers were despised as ignorant and foolish. Their pupils were the young only; they taught the rudiments of reading, Qur'ān, catechism, prayer, writing and arithmetic, but very little of the latter. Technical education was given by the gilds through their apprentice system, teaching mechanical arts and crafts. All Muslim university education, like all Muslim science, revolved round theology. There were, apparently, only two outstanding exceptions to this rule, the academy of Ma'mūn (813–833) at Baghdad, and the hall of wisdom of the Fatimites at Cairo (1004–1171); both of these are explained by their environment. From the earliest times, independent scholars instructed classes in mosques —the common places of meeting for the community—and gave their pupils personal certificates. Their subjects were the reading and interpretation of the Qur'ān; the body of traditions from the Prophet; the thence deduced system of theology; the canon law. But the interpretation of the Qur'ān involved grammatical and lexicographical studies of early Arabic, and hence of the early Arabic literature. Theology came to involve metaphysical and logical studies. Canon law required arithmetic and mensuration, practical astronomy, etc. But these last were strictly ancillary; the object of the instruction was primarily to give knowledge of value for the life of the next world, and, secondarily, to turn out theologians and lawyers. Medicine was in Jewish and Christian hands; engineering, architecture, etc., with their mathematical bases, were crafts. Gradually, educational institutions came to be equipped with scholarships of money or in kind for the students. The first instance of this is generally ascribed to Nishapur (Naisābūr) in 1066; but it soon became general in the system and afforded a means of control and centralization. A final, and most important, characteristic was the wide journeying of the students "in search of knowledge." Scholars thus kept in touch with one another all over the Muslim world, and intellectual unity was maintained.

The Sayyids.—To the democratic equality of Islam, in which the slave of to-day may be the prime minister of to-morrow, there is one outstanding exception. The descendants of the Prophet and of his relatives (the family of Hāshim) formed and form a special class. held in social reverence, and guarded from contamination and injury. These are the sayyids (lords), and genealogical registers of them are carefully preserved. They are of all degrees of wealth and poverty, but are guarded legally from *mésalliances* with persons of ignoble origin or equivocal occupation. Their influence is very great, and in some parts of the Muslim world they enjoy the standing and reverence of saints.

ISLAMIC LAW. Law (Shari'ah) in Islam has a wider application than any western secular law, since it claims to regulate all the aspects of life—duty to God, to one's neighbour, to one's self. It is really a system of duties, ethical, legal, religious, and governs not only the private life of the pious Muslim, but also fixes the laws of marriage, divorce and inheritance, as well as the criminal law. Its historical development began with Muhammad sitting as judge in Medina; his decisions followed, at one time, the usages of the Arab and Jewish tribes of Medina; at another, his own personal judgment. At his death he left behind the legislative enactments embodied in the Qur'Bn, and the memory of his legal decisions. These were collected among the traditions (hadith), which recorded his sayings and doings, manners and customs, and his answers to questions on religious life and faith, and his decisions in legal disputes.

The first collecting of traditions was for private purposes, and the first publication dealing with them was legal, viz. the *Muwaṭṭa'* of Malik ibn Anas (d. 795), a corpus *juris* based partly on traditions. Thereafter came collections of two different rypes, the earlier, arranged according to the companions of Muhammad, on whose authority the traditions were transmitted, *e.g.,* the Musnad of Ahmad ibn Hanbal; the other, called *Muṣannaf* (classified), containing traditions arranged in chapters according to their subject matter. That of Bukhārī is the most famous, and is arranged to give a traditional basis for a complete system of canon law; another is that of Muslim ibn al-Ḥajjāj, who paid less attention to legal aspects and more to minute accuracy.

Another element which came into the development was Roman law, which the Muslim jurist found at work in the conquered Roman provinces and in law courts. Many principles of Muslim law can be traced to the Roman codes, and it was plainly influenced by the liberty involved in the *Responsa prudentium* of Roman lawyers, and by the broad conception of the law of nature in the Edict of the Praetor.

During the Umayyad dynasty, the public life of the state was no longer so religious as it had been while Medina was still the capital, and though law was still needed, it had to be opportunist. Its development went on, but became speculative. The study of tradition was now private, and its students were more and more the personally pious, no longer living in contact with reality; they regarded any system of government which did not simply reproduce the patriarchal form of Medina, as a thing with which no religious man could have aught to do.

The rise of the 'Abbāsids brought a change, in that they had promised a return to the old religious attitudes. But in substance they were much as the Umayyads, and though the state was outwardly on a pious footing, and the religious sentiment of the people was respected, the old, absolute religious law was not restored. It was made possible for more theologians and lawyers to work with the state, but an irreconcilable party still remained, and the situation was fixed as it is to this day.

Yet the 'Abbāsids did, in their way, encourage legal studies, and under them processes and results, long pursued in private, became public. Almost within the first century of their dynasty the four legal schools, or rites, were formed and the principles established which survive to this day.

ISLAMIC LAW SCHOOLS

The first school to take definite form was the Hanifite, founded by Abii Hanifa (d. 767), who left behind him a definite system. He used few traditions, and preferred to go back to the Qur'ān, and extract from it by reasoning the rulings which fitted his ideas. The 'Abbāsids adopted his school, and the Ottoman Turks also later, and it may be said to hold now a leadership among the four legal rites.

Malik ibn Anas, the founder of the Mālikite school, used traditions much more generally than did Abii Hanifa, but two of his principles marked a distinct advance and showed that he was no mere traditionalist. For one, he laid down the conception of public advantage (*istiṣlāḥ*); when a rule founded on even a valid analogy would work a general injury, it was to be set aside; justice must not be overcome by logic. And, for the other, he laid stress on the conception of the agreement (ijma'), an idea which was to have indefinite importance in the future. When the surviving companions of the Prophet, after his death, agreed upon any point as belonging to their store of tradition and experience, their agreement was accepted as final.

The third school was founded by ash-Shāfi'ī (d. 820), who laid great stress on tradition, but gave to the principle of agreement *(ijma')* its full rights. The agreement of the Muslim peoples was to be the voice of God. "My people," said a tradition from Muhammad, "will never agree in an error." So, over traditions and over the Qur'ān itself, the agreement tacitly or explicitly ruled and rules. It stamps as authoritative that which the other principles lay down. He also emphasized the principle of analogy.

The four bases thus laid down by ash-Shāfi'ī—Qur'ān; traditions; analogy; agreement—have come to be accepted by all existing schools. This applies to all spheres of life, ethical, social, theological, legal, and it should never be forgotten that the Qur'ān is only one of the sources for Muslim faith and conduct.

The fourth, the Hanbalite school, was founded by the scholars of Aḥmad ibn Hanbal after his death in 885. It minimizes agreement and analogy and is literal in its interpretations.

All these schools of law administer a scheme of duties, law which for centuries has had only a partial connection with the real legal systems of the Muslim peoples. Among the Wahhābis and Ibāḍites alone is it the whole of law. Else here, since the Umayyad period, its courts have been in great part pushed aside by others, and its scheme has come to be regarded as an expression of impossible theory.

For as Islam spread, it came to regions, climates, customs, where the Arabian usages no longer held. Not only were the prescripts of Medina ill adapted to the new conditions; the new people had legal usages of their own to which they clung and which nothing could make them abandon. So, as in religion the faiths of the conquered peoples were thinly veneered with Muslim phrases, in law there grew up a customary code (*'ādāt*) for each country, differing from every other, which often completely obscured and annulled the prescriptions of the shari'ah. The one was an ideal system, studied and praised by the pious learned; the other was the actual working of law in the courts.

There also arose a new and specific statute law. emanating from the sovereign, and sometimes codified as in the Turkish statute law (*qawānīn*) derived from various European codes. Thus there has grown up in almost every Muslim country at least two systems of courts, the one administering the shari'ah, and taking cognisance of private and family affairs, such as marriage, divorce. inheritance, its officials also giving rulings on purely personal religious questions, such as details of the ritual law, the law of oaths and vows, etc.; the other, the true law courts of the land, administering codes based on local custom and decrees.

A rift almost as important entered the legal life of the Muslim lands on another side. Non-Muslim communities, settled in Muslim territory, have been uniformly permitted to administer and judge themselves according to their own customs and laws. Accordingly, to various ecclesiastical organizations, Christian and Jewish, was given over the administration of these non-Muslim sections of the community, their bishops and rabbis becoming their responsible heads and the links of contact with the Muslim rulers.

In accordance with the same principle, the European merchant, living and trading in the East, was put first by usage and finally by treaty under the jurisdiction and control of his own consul. Thus there grew up the extraterritorial law of the capitulations and conventions, by which the sanctity of the person and household of an ambassador is extended to every European.

There may be said, then, in short, to be three elements in the legal life of a Muslim state: the shari'ah, the sacred and fixed law of Islam; the civil law, based on the usages of the different peoples, Muslim and non-Muslim, and on statutes going back to the will of rulers; the international law of the capitulations, with a contractual sanction of its own.

In modern times, frequent demands have been made by liberal Muslim thinkers that the principle of agreement (*ijmā'*) should be so extended as to render possible changes in the shari'ah, so as to bring it into harmony with modern conditions; but the orthodox legists have steadily resisted any such change. In 1926 Turkey adopted the Swiss civil code and the Italian penal code, thereby abolishing the sacred law of Islam altogether.

ISLAMISM: see PAN-ISLAMISM.

ISLAND, any area of land smaller than a continent and entirely surrounded by water. Islands may occur in oceans, seas, lakes or rivers. A group of islands is called an archipelago.

Islands may be classified as either continental or oceanic. Oceanic islands are those which rise to the surface from the floors of the ocean basins. Continental islands are simply unsubmerged parts of the continental shelf (*q.v.*) that are entirely surrounded by water. Many of the larger islands of the world are of the continental type. Greenland (840,000 sq.mi.), the largest island,' is composed of the same materials as the adjacent North American continent, from which it is separated by a shallow and narrow sea. Likewise the world's second largest island, New Guinea (319,000 sq.mi.), is part of the Australian continental platform and is separated from it only by the very shallow and narrow Torres strait. A slight warping of the sea bottom in the vicinity of Torres strait would be sufficient to join New Guinea to Australia; conversely, a slight rise in sea level may submerge a hilly coast and leave the hilltops remaining as small islands just off shore (examples being those off the coast near Boston, Mass., and the islands off the Maine coast).

The islands which rise from the floors of the ocean basins are volcanic. Lava accumulates to enormous thickness until it finally protrudes above the ocean surface. The piles of lava which form Hawaii rise to as high as 32,000 ft. above the ocean floor.

Many of the world's archipelagoes are arranged in island arcs, and they constitute some of the most active volcanic and earthquake areas of the world. Examples are the Leeward and Windward Islands at the eastern end of the Caribbean; the Aleutians; the Japanese archipelago; and the Philippines. Physical geographers believe that these are the areas of continental growth.

Island life exhibits features of special interest. The sea is a barrier to some forms of life but acts as a carrier of others, which, once established in their new home, frequently develop new features in their isolated surroundings. A long-established sea barrier results in marked differences between the animal life and vegetation even of adjacent islands, and from these differences may be deduced the origin of an island. Further, any detailed map of the biological regions of the globe illustrates the importance of islands in the determination of the boundaries of animal-life and vegetational types. For example, to the west of a line (Wallace's line) running between Bali and Lombok and between Borneo and Celebes the islands are biologically Asian, but to the east of the line, notwithstanding the narrowness of the Lombok strait, the vegetation and animal life are Australian. Oceanic islands are usually colonized by only a few animal forms, chiefly sea birds and insects. They are often clothed with abundant vegetation, the seeds of which have been carried by air and water currents, birds, etc., but the variety of plants is by no means so great as that on the mainland. (W. C. C.)

ISLAY is the southernmost island of the Inner Hebrides, Argyll, Scot., 16 mi. W. of Kintyre and ¾ mi. S.W. of Jura, from which it is separated by the Sound of Islay. Pop. (1951) 4,267. Its maximum breadth is 15 mi. and the maximum length 25 mi. The sea lochs Gruinart and Indaal cut into it so deeply as almost to convert the western portion into a separate island. It is rich and productive and has been called the "Queen of the Hebrides." The surface generally is regular, the highest summit being Beinn Bheigeir (1,609 ft.), but the shore is rugged. There are fresh-water lochs and rivers, which provide good trout and salmon fishing. Islay was the ancient seat of the "lord of the

Isles," the first to adopt that title being John Macdonald of Isle of Islay (d. *c.* 1386); but the Macdonalds were ultimately ousted by their rivals, the Campbells, about 1616. Islay house, ancient seat of the Campbells of Islay, is at the head of Loch Indaal. Much business is done in stock raising, dairy farming and cheese-making; oats, potatoes and various green crops are raised. The chief difficulty in the way of reclamation is the great area of peat (60 sq.mi.). The island has several distilleries, producing large quantities of whisky. Local limestone is used extensively as fertilizer, but deposits of lead, iron, slate and marble are no longer worked. Bowmore is the chief town and administrative centre, and Port Ellen, the principal port, is a holiday and golfing resort. The U.S. troops and seamen who were lost in the "Tuscania" and "Otranto" in 1918 are buried on the island, and there is a memorial tower on the Mull of Oa, 8 mi. from Port Ellen. Port Askaig is the ferry station for Feolin on Jura. There are five lighthouses on the island. In addition to a daily steamer service there is also a daily plane service connecting Glenegedale airport, Islay, with Renfrew (Glasgow airport).

ISLES OF THE BLEST or **FORTUNATE ISLANDS** (Gr. αἱ τῶν μακάρων νῆσοι; Lat., Fortunatae *insulae*), placed in Greek mythology in the Western ocean, and peopled, not by the dead, but by mortals upon whom the gods had conferred immortality. Like the Phaeacian land in Homer (Od. viii.) or the Celtic Avalon and St. Brendan's island, the Isles of the Blest have perpetual summer and abundance. No reference is made to them by Homer, who speaks instead of the Elysian Plain (Od. iv. and ix.), but they are mentioned by Hesiod (Works and Days, 168) and Pindar (*Ol.* ii.). By mediaeval map-makers, Madeira and the Canaries are sometimes named *Fortunatae insulae*. (See ATLANTIS.)

ISLINGTON (*Gislandun*=Gisla's dun, or hill), a northern metropolitan borough of London, Eng., bounded east by Stoke Newington and Hackney, south by Shoreditch and Finsbury, and west by St. Pancras, and extending north to the boundary of the county of London. Pop. (1951) 235,632. Area 4.8 sq.mi. The borough includes Holloway, Highbury, Barnsbury and Canonbury, whose names preserve those of ancient manors, and in Canonbury, which belonged in the 13th century to the priory of St. Bartholomew, Smithfield, parts of the old manor house, including Canonbury tower, remain. The fields and places of entertainment in "merrie Islington" were places of resort for Londoners in the 17th century and later. At Copenhagen Fields a great meeting of labourers was held in 1834 and to this site the Metropolitan Cattle market (covering about 33 ac.) was moved from Smithfield in 1855. The market square (about 15 ac.) became the site of the Caledonian market, a big general market with more than 2,000 stall holders which was held every Tuesday and Friday until the outbreak of World War II; in 1951 this market moved to Bermondsey. The Royal Agricultural hall, Archway hospital, Pentonville and Holloway prisons and the Arsenal football stadium are in the borough. New River Head is the termination of the artificial channel by which Sir Hugh Myddelton (1561–1631) brought water to London from the upper Lea valley. Islington's population includes metal, textile and transport workers and printers. The borough returns three members to parliament.

ISLY, the name of a small river on the Moroccan-Algerian frontier, a sub-tributary of the Tafna, famous as the scene of the greatest victory of the French army in the Algerian wars. The intervention of Morocco on the side of Abd-el-Kader led at once to the bombardment of Tangier by the French fleet under the prince de Joinville, and the advance of the French army of Gen. Bugeaud (1844). The enemy, 45,000 strong, was found to be encamped on the Isly river near Kudiat-el-Khodra, Bugeaud had a force of 6,500 infantry and 1,500 cavalry, with a few pieces of artillery. In his own words, the formation adopted was "a boar's head." On Aug. 14 the "boar's head" crossed the river about 9 mi. to the northwest of Kudiat and advanced upon the Moorish camp; it was immediately attacked on all sides by great masses of cavalry, but the volleys of the steady French infantry broke the force of every charge, and at an apt moment the French cavalry in two bodies, each of the strength of a brigade, broke out and charged. One brigade stormed the Moorish camp (near Kudiat) in the face of artillery fire, the other sustained a desperate conflict on the right wing with a large body of Moorish horse which had not charged, and only the arrival of infantry put an end to the resistance in this quarter. A general rally of the Moorish forces was followed by another action in which they endeavoured to retake the camp. Bugeaud's forces, which had originally faced south when crossing the river, had now changed direction until they faced almost west. Near Kudiat-el-Khodra the Moors had rallied in considerable force, and prepared to retake their camp. The French, however, continued to attack in perfect combination, and the Moors were defeated; peace proposals quickly followed.

ISMAIL I (1487–1524), shah of Iran from 1501 to 1524 and founder of the Safawid dynasty, was born on July 17, 1487, probably at Ardabil. Through his father, Sheikh Haidar, he was descended from the greatly revered Sheikh Safi al-Din of Ardabil, who had founded an order of Sufis there in the early 14th century. Sheikh Haidar, who was a fanatical Shi'ite, fell in battle against the Sunnis of Shirvan when Ismail was only one year old. After many hazardous adventures, in the course of which his two elder brothers perished, Ismail succeeded, with the support of seven Turkmen Shi'ite tribes, in establishing his authority in northwestern Iran and was crowned in Tabriz in July 1501. In a series of battles he gained control over the greater part of Iran in the next few years. He thereupon attacked the Sunni Uzbeks who had occupied part of northeastern Iran and defeated them near Merv in 1510. Although many of his subjects had at the outset been Sunnis, he converted the majority to Shi'ism, which became the state religion and served to bind the nation together.

When the Ottoman Turkish sultan Selim I savagely suppressed a revolt of his Shi'ite subjects in Anatolia and persecuted the survivors, Ismail marched to their assistance but his forces, which consisted only of tribal levies, were severely defeated in a hard-fought battle at Chaldiran in northwestern Iran (1514). Against Selim's well-trained janizaries and artillery Ismail had neither regular troops nor cannon. Selim marched on and occupied Tabriz, but a mutiny of his troops compelled him to withdraw to Turkey. Ismail recovered from this reverse sufficiently to prevent any further inroads by either Turks or Uzbeks, and when he died, at Ardabil in 1524, he left Iran a united nation strong enough to protect itself. His dynasty endured till 1736.

The Venetian traveler Giovanni Angiolello, who was in Persia in 1510, described Shah Ismail as "fair, handsome and very pleasing; not very tall, but of a light and well-framed figure. . . . He is as brave as a gamecock, and stronger than any of his lords."

See Ghulam Sarwar, ***History of Shah Ismail Safawi (1939).***

(L. Lo.)

ISMAIL (IZMAIL), a port and fishing centre of Bessarabia, Ukrainian Soviet Socialist Republic, U.S.S.R., on the left bank of the Kiliya (Chilia) branch of the Danube. Pop. (1956 est.) 43,000, including Rumanians, Russians, Ukrainians, Bulgars, Turks, Jews and gypsies. There are flour mills and trade in cereals, woods and hides. As a Turkish fort and capital of a sanjak, Ismail long enjoyed peace and prosperity. It was occupied by Russia in 1770, 1790 and 1812 and transferred to Rumania in 1856, to Russia in 1878 and to Rumania in 1918. Rumania ceded it to the U.S.S.R. in 1940 but recaptured it in 1941 and held it until 1944 when it was retaken by the Soviet Union.

ISMAIL HADJI MAULVI-MOHAMMED (1781–1831), Indian Moslem reformer, was born at Pholah near Delhi. In co-operation with Syed Ahmed he attempted to free Indian Mohammedanism from the influence of the native early Indian faiths. The two men traveled extensively for many years and visited Mecca. In the Wahhabite movement they found much that was akin to their own views and on returning to India preached the new doctrine of a pure Islam. The official Moslem leaders objected, and the dispute led to the reformers' being interdicted by the British government in 1827. The party then moved to Punjab where they made Peshawar the capital of the theocratic community which they wished to establish (1829). Ismail Hadji fell in battle against the Sikhs amid the Pakhli mountains (1831). Some of his adherents are still found in the mountains of the northwest frontier.

Ismail's book Taqouaiyat el Iman was published in Hindustani

and translated in the *Journal* of *the Royal Asiatic Society,* xiii, 1852.

ISMAILIA (AL ISMA'ILIYAH), a town in the Canal governorate of Egypt, located at the Isthmus of Suez where the Sweetwater canal from the Nile meets the Suez canal at Lake Timsah. It lies on the northwestern shore of the lake, a salt lagoon through which the Suez canal passes, and is 93 mi. N.E. of Cairo by rail, 48 mi. from Port Said and 52 mi. from Port Tewfik. Pop (1957) 94.572. The town was established in 1863 by the former Suez Canal company and named after the khedive Ismail. It shows French influence, being laid out on a gridiron plan, with squares, gardens and tree-lined boulevards. The company built for its employees houses. schools and a 200-bed hospital and provided recreational facilities. The central position of the town favoured the establishment there of the Central Movement office, which regulates the daily movement of shipping in the canal. Ismailia was the scene of the first scientific attack upon malaria, which later practically disappeared The town became a headquarters for the Allied forces during 1916 and has retained its military connections. On the other side of the lake are the so-called quarries of Hyenas, from which building material for the town was obtained. (A. B M.)

ISMAIL PASHA (1830–1895), hereditary viceroy of Egypt under Turkish suzerainty, was the second son of the vali Ibrahim Pasha (q *v.*). Born in Cairo on Dec. 31, 1830, he was educated in Paris and on reaching manhood undertook various diplomatic missions in Europe for the viceroy Mohammed Said Pasha, whom he succeeded in 1863. Ambitious to increase his prestige he obtained from the Ottoman sultan in 1867 the hereditary title of khedive. an honorific borne by his successors until 1914.

Beyond his frontiers Ismail pursued an expansionist policy. In 1865 he negotiated with the sultan the cession to Egypt of the ports of Sawakin (Sudan) and Massawa (Eritrea). He modernized the Egyptian army with Remington rifles and Krupp artillery and enlisted a corps of American officers who established a general staff, explored the Sudan and in 1877 prepared a notable map of Africa. In 1870–75 he extended Egyptian authority down the Red sea coast, planting garrisons at Harar and Berbera. but his attempt to occupy Kismayu in 1875 was prevented by Britain. In 1869 he commissioned Sir Samuel Baker to annex parts of Uganda: in 1874 Darfur was added to the Egyptian dominions. Ismail's territorial ambitions were thwarted in Equatoria where Baker's successor, Col. (later Gen.) C. G. Gordon, withdrew the Egyptian outposts from most of Uganda in 1876 and in Ethiopia where two Egyptian armies were disastrously defeated in 1875–76.

Ismail's westernizing domestic policy greatly benefited Egypt. Primary education was expanded in the provinces. The legal disabilities suffered by Egyptians under the capitulations were lessened by the institution in 1876 of mixed courts. An astute landlord of his vast estates and an enthusiastic town planner, he created the modern Cairo and in 1869 granted Alexandria a municipality. The summoning of a legislative assembly in 1867 marked the first approach toward constitutional government. His most spectacular achievements lay in the development of communications. He extended the railways. nationalized the postal service in 1865 and in the Sudan introduced telegraphs in 1866 and a short railway in 1875. In 1869 he presided over the opening of the Suez canal with lavish ceremonies.

His projects were often brilliantly conceived but they were compromised by his financial prodigality. By 1876 the Egyptian public debt exceeded £100,000,000. Pressed by Ismail's creditors the powers intervened and set up a dual control with a commission of the public debt. Ismail's resistance to the resulting encroachments upon his independence, culminating in his dismissal of the European commissioners. led to his deposition by the sultan at the instance of the powers on June 26. 1879.

Ismail died in exile at Istanbul on March 21, 1895. *See* also EGYPT: *History.*

See P. Crabitès, *Ismail, the Maligned Khedive* (1933); *G* Douin, *Histoire du règne du Khtdive Ismaïl,* 3 vol. (1933–41; unfinished) (R. L. HL.)

ISMAY, HASTINGS LIONEL ISMAY, 1ST BARON (1887–), British soldier who served in World War II as chief of staff to the minister of defense, was born at Naini Tal, India, on June 21, 1887, the younger son of Sir Stanley Ismay. Educated at Charterhouse and at Sandhurst, he was commissioned in 1905 and joined the 21st cavalry (Frontier force), Indian army, in 1907. Service on the North-West Frontier of India (1908) and in Somaliland (1914–20) was followed by appointments as assistant secretary (1926–30) and secretary (1938–40) of the Committee of Imperial Defense, and as chief of staff to the minister of defense (1940–46). He was promoted general in 1944 and created 1st baron in 1947.

In 1947 he returned to India as chief of staff to the last viceroy, Earl Mountbatten, and four years later became secretary of state for commonwealth relations (1951–52). Lord Ismay became secretary-general of the North Atlantic Treaty organization in 1952 and on vacating that appointment in 1957 retired from public life. His *Memoivs* were published in 1960. (C. N. B.)

ISMAY, THOMAS HENRY (1837–1899), English shipowner and founder of the Oceanic Steam Navigation company, which became famous as the White Star line, was born at Maryport. Cumberland, on Jan. 7, 1837. In 1867 he took over the White Star line of Australian clippers and in 1869 established, with William Imrie, the Oceanic Steam Navigation company. The firm having determined to enter the Atlantic trade, the first "Oceanic" (3,707 tons) was ordered from Harland and Wolff, of Belfast, Ire. The launching in 1870 marked a turning point in the development of the North Atlantic passenger liner; among the innovations introduced was the siting of passenger accommodations amidships. In 1892 Ismay retired from partnership in the firm of Ismay, Imrie and company, though he retained the chairmanship of the White Star line. He died near Birkenhead, Cheshire, on Nov. 23, 1899.

The White Star line continued until 1934, when it merged with the Cunard line to form Cunard White Star, Ltd. The assets of Cunard White Star were taken over by the Cunard Steam-Ship Co., Ltd. in 1950.

ISMET INÖNÜ (1884–), Turkish statesman, was born in Smyrna of a Turkish family of Malatya. Educated in the military schools, he became in 1903 an artillery lieutenant and in 1906 a captain on the general staff. After the Young Turks revolution of 1908, he was sent several times on military expeditions to Yemen. During World War I he served on the Syrian front and was in command of an army corps when peace was declared. At the time of the occupation of Constantinople by the Allies he escaped to Angora, disguised as a common soldier, and was appointed by the great national assembly to be chief of staff during the military operations of the nationalists against the caliphate army and Armenia. Later, as commander in chief of the Turkish western front, he insisted on the formation of a regular army in place of the irregular nationalist forces. In the meantime the irregular forces were unwilling to submit, and the Greek army had taken the offensive. At Inonii he defeated the Greeks, checked their offensive, subdued the irregular forces and succeeded in completing the organization of a regular army. He remained in command of the western front until after the battle of the Sakaria and the fall of Smyrna, in which events he was the right-hand man of Mustafa Kemal. In 1922 he signed the armistice concluded at Mudania with the Allies and secured the evacuation of Eastern Thrace. In 1923, as minister of foreign affairs, he signed the treaty of Lausanne; and during the autumn, at the time of the declaration of the republic, he became prime minister. After a rest because of failing health, he became prime minister a second time, toward the end of 1924. The abolition of the caliphate and the closing of religious schools and monasteries were brought about during Ismet's almost uninterrupted tenure of office. After Dec. 1934, when. in accordance with the new Turkish law, he adopted a surname, he became known as Ismet Inonii. Upon the death of Mustafa Kemal Atatiirk he was unanimously elected president of Turkey (Nov. 11, 1938). On March 8, 1943, he was unanimously re-elected by parliament for a second four-year term. From Dec. 4 to 6 of the same year he conferred with F. D. Roosevelt and Winston Churchill in Cairo on the improvement of the relations between Turkey and the United Nations.

In 1946 he was criticized by the opposition parties which won 69 electoral seats; and at the general election of 1950 the Republican People's party—of which, as president, he held (somewhat unwillingly) the leadership—was overwhelmingly defeated. Celâl Bayar, the opposition leader, was elected president.

As a statesman Ismet Inönü was cool and cautious. During his presidency he led his country successfully through a period of unprecedented difficulty and danger. He knew that the Turkish people wished him to keep them out of the war; and in spite of Turkey's treaty obligations he succeeded in doing so without forfeiting the support of her allies in the postwar world. After the war, realizing that Turkey's novitiate as a democratic state was over, he set aside the one-party system which had existed since 1923 and established full representative government with free elections.

ISMID (IZMIT, ISNIKMID, KOCAELI; anc. NICOMEDIA), a town of Turkey, near the head of the Gulf of Ismid, Sea of Marmara. Pop. (1960) 73,705. Ancient Nicomedia was built in 264 B.C. by Nicomedes I of Bithynia and became one of the chief towns in that part of Asia Minor. Diocletian made it the chief city of the east. It is in an agricultural district, producing cocoons and tobacco, and there are large forests of oak, beech and fir. The town is connected by railway with Haidar-Pasha, the western terminus, and with Ankara, Konya and Izmir. It contains a fine 16th-century mosque built by the architect Sinān. As the seat of a Greek metropolitan and an Armenian archbishop, Ismid retains some of its ancient dignity. The head of the gulf is silting up, and the port Darinje is almost 4 mi. from Ismid. The *il* of Kocaeli had a population of 254,263 in 1955.

ISNA (ESNA), a town of upper Egypt in Qina province, lies on the west bank of the Nile, 36 mi. S. of Luxor. Pop. (1957) 22,128 (mun.), mostly Copts. The town manufactures pottery and cottons and has large grain and livestock markets. Some trade is carried on with Kharga oasis, 110 mi. W.

Just below the town is the Isna barrage (1908), built to improve the irrigation of upper Egypt. The barrage, of granite and sandstone with 150 sluices, was reconstructed in 1948 and raises the upstream water level by 15 ft. (A. B. M.)

Esna takes its name from the ancient Egyptian Ta-Senet, but in Ptolemaic times it was called Latopolis, because*the fish *Lates niloticus* was worshiped there. The ruins lie buried beneath the modern town, and only the pronaos of the temple has been cleared. Dedicated to Khnum, the ram-headed creator god, the temple took from about 180 B.C. to A.D. 250 to build. It is in Ptolemaic style, though the decoration is largely Roman. Always a Coptic centre, there is a Christian church in the desert, within ½ mi. of the modern town. The Coptic population suffered severely under Diocletian's persecution of A.D. 303. (M. V. S. W.)

ISNEG (APAYAO), a Malayan-type people living in the mountains of northwest Luzon, Philippines. Isneg is the usual anthropological name, while Apayao is the district name, and also that of the subprovince of Mountain province within which nearly all of them live. The Isneg number today approximately 11,500, and are short in stature and rather darkly pigmented, probably through minor mixture with Negrito groups adjacent to them. They have a distinctive language, with several dialect areas. The main body of Isneg lives on the Abulug or Apayao river system which drains most of their territory; but a group called the southern Isneg lives on the Matalag river system in the south of the subprovince. The Isneg economy is based on natural rainfall ("dry") cultivation of rice, maize and tropical roots in shifting gardens, supplemented by hunting, fishing, keeping livestock, and trading tobacco and other products to the lowlands. Settlements are of hamlet size, scattered along the streams which drain the dense rain forests of the region. Each group of adjacent hamlets is crisscrossed by marriage and kinship ties. The region was noted for its headhunting, with warrior bravery and head trophies the principal basis by which males (if they survived) gained status, so that apart from a hamlet's immediate circle of friendly kinsmen all others tended to be enemies. The Isneg built substantial wood houses with high pitched roofs, but also had huts in their rotating fields: they also had distinctive dress and customs generally. Spanish missionaries worked up the rivers in the 17th and 18th centuries. but their converts were generally transferred to the lowlands; pacification was achieved by U.S.-Filipino constabulary forces in 1908–13.

See M. Vanoverbergh, The *Isneg*, Publications of the Catholic Anthropological Conference, vol. 3 (1932); F. M. and M. Keesing, *Taming* Philippine Headhunters (1934). (F. M. KG)

ISOBAR, a line on a map or thermodynamic chart, connecting points having the same pressure. Isobars for intervals of two to five millibars of pressure are important features of weather maps because of the relationship between pressure distribution, winds and weather. See METEOROLOGY. (H. R. B.)

ISOCRATES (436–338 B.C.), a famous writer and educationalist at Athens, who by the artistic form of his prose set a model which influenced many later writers. His father, Theodorus, was an Athenian citizen of the deme (township) Erchia; he owned a flute factory and was rich enough to perform expensive services to the state and to give his sons a good education. Isocrates' teachers are said to have included well-known sophists, but the details are uncertain. He must have been familiar with Socrates, although he does not appear to have been a member of the Socratic circle. Both sophistic and Socratic influences can be seen in his works. The family property was lost during the Peloponnesian War and, after the restoration of democracy in 403 B.C., Isocrates found it necessary to follow a profession. Physical infirmities prevented him from speaking in public and taking an active part in political life. For about ten years he wrote legal speeches for clients. It was an activity he despised and one to which he makes no allusion in his later works. About 392 B.C. he founded his famous school. It was highly successful and for over 50 years attracted pupils from all parts of the Greek world. He died soon after the defeat of Athens by Philip II of Macedonia at the battle of Chaeronea in 338 B.C.

Speeches.—Isocrates' extant works consist of 21 speeches (logoi) and nine letters. "Speech" is a convenient rendering of logos, but it is misleading. Only the six early forensic works are real speeches. It has been suggested that even these were rhetorical exercises, but most scholars believe that they were written by Isocrates, before he started his career as a teacher, for clients to deliver in the law courts. The rest are purely literary. Many by an artistic fiction are given the form of real speeches, but little attempt is made to keep up the illusion consistently. Some take the form of a hortatory address, others of a prose encomium. These literary speeches were presumably circulated as pamphlets among the Greek-speaking public. Isocrates seems also to have intended them to be recited by others to audiences. What are clearly instructions to reciters are to be found in the introductory part of the Antidosis. The literary speeches, the dating of which can in most cases only be approximate, may be roughly divided into two groups according to their subject matter:

Political Speeches.—Panegyricus (c. 380 B.C.) and Philippus (346 B.C.) deal with Greek unity and war against Persia. On the Peace (c. 356 B.C.) and Areopagiticus (c. 355 B.C.) give advice on Athenian foreign and home policy, respectively. In *Plataicus* (c. 373 B.C.) a Plataean citizen urges the Athenians to restore Plataea after its destruction by Thebes. Archidamus (c. 366 B.C.) is supposedly delivered by Archidamus III of Sparta, who comments on conditions of peace offered by Thebes.

Speeches on Education, Ethics and Literary Criticism.—Isocrates' views on education are given mainly in Against the Sophists (c. 390 B.C.) and Antidosis (354–353 B.C.). To *Demonicus* (c. 370 B.C.?), regarded by some as spurious, contains moral precepts. To Nicocles and Nicocles (both c. 370 B.C.) outline the duties of a monarch and his subjects, respectively. *Busiris* (c. 390 B.C.), Helen (date uncertain, perhaps 390–380 B.C.) and Evagoras (c. 365 B.C.) are ostensibly encomia, a genre of rhetorical literature then in vogue, but their main purpose is to advertise Isocrates' literary views. Panathenaicus (c. 339 B.C.), a long, rambling work of Isocrates' extreme old age, is partly an encomium of Athens, partly an exposition of his theories on writing and teaching.

Letters.—The letters, which are addressed to kings and rulers, serve the same purpose as the speeches: they advertise Isocrates'

views on current affairs. They may have been actually sent to the individuals in question, but most of them at any rate were intended for a wider public. There seems to be little essential difference between the letters and the speeches except that the former are shorter and less elaborately composed. All were written in Isocrates' old age. Their authenticity has often been questioned, but most of them at least are now considered genuine.

Political Views.—The dominant theme in Isocrates' political writings is the policy of unifying Greece against Asia. A war against Persia, he claimed, would give the Greeks a common cause and put an end to their disastrous internal dissensions. In his most famous work, the *Panegyricus,* published about 380 B.C., he urged Athens and Sparta to forget their quarrels and jointly lead Greece against the common enemy. His pleading was ineffectual, and in his subsequent efforts to find a champion of the Greek cause he turned first to Dionysius I of Syracuse, then to Archidamus III of Sparta and finally to Philip II of Macedonia. From his third letter written shortly before his death it appears that even after the battle of Chaeronea he continued to hope that Philip would lead a united Greece against Persia. There seems no reason to doubt the authenticity of this letter. Two works concern Athenian politics. In the speech *On the Peace (c.* 356 B.C.) Isocrates urged Athens to abandon its imperialistic ambitions and to recognize the right of Greek states to independence. In the *Areopagiticus (c.* 355 B.C.) he deplored the degenerate Athenian democracy of his own day and advocated a return to the restricted democracy of Solon and Cleisthenes. His political writing had little influence on the conduct of affairs; he himself complains bitterly that the Athenians preferred to listen to the platform oratory of the active politicians.

Educational System.—Isocrates' educational writings are interesting and revealing. *Against the Sophists* was written at the beginning of his teaching career. Only the first part, in which he disparages other intellectual and educational systems by comparing them with his own, is extant. His own views are more fully expressed in the *Antidosis,* written, according to his own statement, when he was 82 years old. He dissociated himself from contemporary rhetoricians whose methods, he claimed, had no educational value. Their purpose was a purely practical one; they concentrated on legal oratory, which Isocrates despised, and treated rhetoric as a technique consisting of rules and precepts which could be imparted by a competent teacher to any diligent student. His own system, which he preferred to call "philosophy," was far broader and more humane. He held that speech composition should be regarded as a creative process allowing full scope for individual talent.

On the details of his educational methods there is little information, but an essential part must have been the composition of speeches modeled on his own. He insisted that students must avoid narrow, petty or specialized themes and choose those of universal interest and importance. These must be expressed in a pleasing form which had attractions analogous to those of poetry. For mathematics and the speculative sciences he had little regard and he derided the conflicting results produced by the researches of the scientists and philosophers. Scientific knowledge *(episteme)* he contended was beyond the powers of human knowledge; the most man could do was to learn by practical experience. He preached a high standard of morality, but morality he conceived in terms of an enlightened self-interest *(pleonexia)*; those gained the true advantage who were righteous toward gods and men, in public and private life.

His pupils included sons of illustrious Greek families, men who became prominent in public life as orators and statesmen, and well-known historians, such as Ephorus and Theopompus. His success was remarkable, but he had many critics. Plato's Academy was founded shortly after Isocrates' school, and rivalry between the two establishments was inevitable. Covert attacks on Plato are found in Isocrates' works, particularly in the introductory part of the *Helen.* Plato's commentary on Isocrates comes mainly in the *Phaedrus,* but the allusions are veiled and scholars differ in interpreting them. Their general tenor, however, seems clear. Plato was willing to allow that artistically and morally Isocrates' humanism was on a higher level than the mere technique of other rhetoricians, but he considered his system unworthy of serious consideration because it was not founded on scientific method.

Conclusion.—Isocrates was not an original thinker. Nearly all his views, whether on politics or education, are adaptations of those already expressed by others. His greatest achievement was the artistic form he gave to his writings. The speeches written before his powers declined show infinite care both in structure and style. His method was to prepare a skeleton outline and build up the speech section by section, taking pains to avoid an abrupt transition from one subject to another. His style is an elaborate instrument of expression. Avoidance of hiatus and harsh collocatians of syllables produces a smooth, harmonious flow of language. This is enhanced by a subtle use of rhythm which defies analysis. It suggests a fondness for certain clausulae but never so obtrusively as to reveal a fixed metrical scheme. He avoided the more extravagant ornaments which gave Gorgias' prose a meretricious appeal, *e.g.,* unusual words, startling metaphors, jingling assonance, but in building up his periods he indulged freely in balanced clauses and antithesis. With much reading the balanced periods become monotonous. He himself seems to have been aware of this. In his advice to reciters of his works he warns them to read only so much as will not weary listeners. His influence on subsequent prose writers, notably Cicero, was considerable.

(H. L. H.-W.)

ISOGAMY, term applied in biology to conditions in which the sexual cells (gametes, *q.v.*) are alike, in contradistinction to heterogamy (*q.v.*) or anisogamy, where the gametes are differentiated into male elements (spermatozoa or spermatozoids) and female elements (ova). Isogamy occurs in some of the lower Algae and certain Protozoa, but it would seem that in most cases, if not in all, the gametes do not behave alike, so that they are functionally anisogamous. *See* ALGAE; FERTILIZATION; PROTOZOA; REPRODUCTION.

ISOLA DEL LIRI, a town of Lazio, Frosinone province, Italy. situated between two arms of the Liri river. waterfalls of the Liri and Fibreno furnish power for paper and textile mills. Pop. (1957 est.) 12,948 (commune). The 12th-century church of S. Domenico, about 1 mi. N., probably marks the site of the villa of Cicero.

ISOMERISM. In the period when chemical analysis was first introduced, the belief was generally held that the properties of each pure substance depended solely upon its chemical composition. Two samples of matter, which had the same properties, and so were composed either of the same substance or else of mixtures of the same substances in the same proportions, were therefore supposed to be identical in composition. Conversely, any difference that could be detected in the properties of two substances under the same conditions was held to be due to some difference in composition.

The fundamental postulate that the properties of a pure substance are uniquely determined by its chemical composition was subsequently found, however, to be subject to certain well-defined types of exceptions. These may be classified under the three headings as: (1) polymorphism, where the difference of properties exists only in the solid state and is considered therefore to be caused by a different arrangement of identical molecules or ions in a crystal; (2) polymerism, where the molecules are of identical percentage composition but of different molecular weight; and (3) isomerism, where the molecules are of identical percentage composition and molecular weight but are considered to differ in their internal structure or configuration. (It should be noted

that modern usage has somewhat altered the historical definition of the word "polymerism," given here. See POLYMERIZATION. The slight change in meaning thus introduced is, however, of no importance to the present article.) Although these three types of exception were grouped together at one time under the general term "isomerism," the distinctions outlined above are now commonly made, and the word "isomerism" is now restricted to the type (3). The present article will deal only with isomerism in this restricted sense. (For discussions of polymorphism, see CHEMISTRY: Physical Chemistry; for one of polymerism, see POLYMERIZATION.)

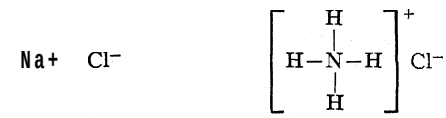
Structural Isomerism. — The field of isomerism is subdivided into two main divisions. structural isomerism and stereoisomerism. Two (or more) substances are said to be structural isomers of each other, or to be structurally isomeric, if they have the same chemical composition and molecular weight, but differ in structure; on the other hand, they are said to be stereoisomers of each other, or to be stereoisomeric, if they have the same composition, molecular weight, and structure, but differ in configuration. In order that the significance of this distinction may be made clear, the technical meanings assigned by chemists to the words "structure" and "configuration" must be discussed. The present section, however, will deal only with the concept of structure, since that of configuration is not required for an understanding of structural isomerism. (For the definition of configuration see the section below on Stereoisomerism and the more detailed article on STEREOCHEMISTRY.)

The structure of a substance (or, more precisely, of its molecules) is given by a detailed statement of the way in which each atom is linked by valence bonds to each of the other atoms of the molecule (see VALENCE). This statement may take any of several equivalent forms. One such form is based upon the use of purely verbal descriptions. Thus, the structure of the hydrogen molecule, H_2, may be expressed by the statement that the two univalent hydrogen atoms are joined to each other by a single covalent bond; the structure of the ethylene molecule, C_2H_4, may be expressed by the statement that each of the two quadrivalent carbon atoms is joined to the other by two covalent bonds, and also to two univalent hydrogen atoms by single covalent bonds; and so on. A verbal scheme of this sort. however, becomes too unwieldy for the description of the structure of a molecule of any complexity, and so a second, much more convenient, method of representation has been generally adopted. When this method is employed, any given structure is represented by a diagram, in which each atom is symbolized by the usual chemical symbol of the element in question, and in which each covalent bond is symbolized by a (usually straight) line drawn between the letters representing the appropriate atoms. Thus, the structures of the molecules of hydrogen and of ethylene, which were described verbally above, can be expressed by the diagrams I and II, re-

I II

spectively. Such symbols as these are usually referred to as the structures of the respective substances, although, in a strict sense, they are merely graphical representations of the structures of the corresponding molecules. (The more modern electronic structures, in which each line is replaced by a pair of dots, differ from the foregoing in no respect which is important to the present discussion. Such modes of description will therefore be ignored here. However, see VALENCE.)

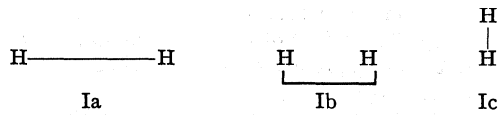
In the graphical scheme outlined above, no symbol for the representation of an ionic bond was mentioned. Actually, at the present time, the following convention seems to be generally adopted. If two or more parts of a molecule are not joined to each other in any way by covalent bonds, but instead are held together by only ionic linkages, then each of the parts (*i.e.*, ions) is represented separately by its corresponding symbol, and the various symbols are merely placed close together. The existence of the electrostatic attractive forces is shown by the presence of appropriate plus or minus signs, as superscripts, to indicate the charges on the ions. Thus, the structure III can be written for the molecule of sodium chloride, which exists in the gaseous but not in the solid state or in aqueous solution (see MOLECULE, CHEMICAL). If any ion contains more than a very few atoms, its



III IV

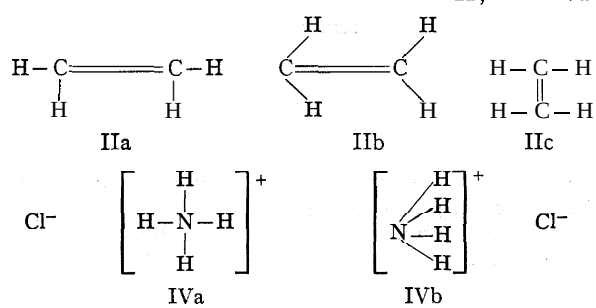
structure is often surrounded by square brackets for the sake of clarity. Thus. the structure of the molecule of ammonium chloride (if such a molecule be capable of existence at all, see MOLECULE, CHEMICAL) may be given as IV.

Significance of *Structural* Diagrams. — As has been explained, the function of a structure is to specify the pairs of atoms which are joined by valence bonds, and to state the number and type of the bonds which connect each of these pairs. Consequently, the exact geometrical properties of any diagram that may be written on paper are of no structural significance. In particular, the lengths of the lines which represent the covalent bonds, the angles between pairs of lines, and the relative positions on the page of the letters which represent the atoms must be ignored. The diagrams Ia, Ib and Ic, for example, represent exactly the



Ia Ib Ic

same structure that I does; in the same manner, IIa, IIb and IIc are to be considered identical with II; and IVa and



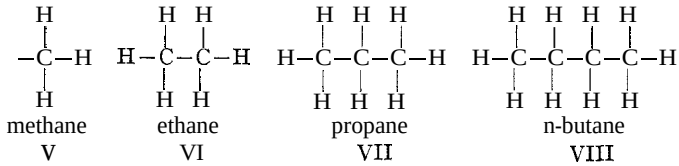
IIa IIb IIc

IVa IVb

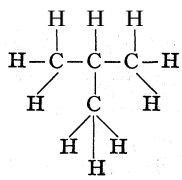
IVb are to be considered identical with IV. This fact is extremely important, since it greatly restricts the number of nonequivalent structures that can be written for a molecule containing a specified number of atoms of specified kinds. It must be constantly borne in mind, in fact, that diagrams which look entirely different superficially may actually represent the same structure. (The situation may be described in mathematical language by the statement that the chemical structures, as defined here, are topological diagrams and have no nontopological significance. See TOPOLOGY, GENERAL.)

The *Number* of Isomers. — A fundamental postulate of the structural theory of chemistry is that two molecules which differ in structure must correspond to different substances with different chemical and physical properties. A corollary of this fundamental postulate is that the number of theoretically possible structural isomers which have a given molecular formula (*i.e.*, which have a given chemical composition and molecular weight, see MOLECULE, CHEMICAL) must be equal to the number of nonequivalent structures permitted by the rules of valence. The general procedure of calculating isomer numbers can be illustrated with a few examples. For the molecular formula CH_3, only the single structure V can be drawn if carbon and hydrogen are, as usual, considered to be quadrivalent and univalent, respectively. Similarly, for the formulae C_2H_6 and C_3H_8, only the single structures VI and VII, respectively, are possible. In agreement with expectation, only a single substance exists for each of these formulae. On the other hand, for the formula C_4H_{10}, the two nonequivalent

structures VIII and IX can be drawn, and, accordingly, two isomeric substances exist; these are known as normal butane and isobutane, respectively. Moreover, for the molecular formula C_2H_4, only the single structure X is possible, but, for the formula C_3H_6, the two structures XI and XII, and, for the formula C_4H_8,

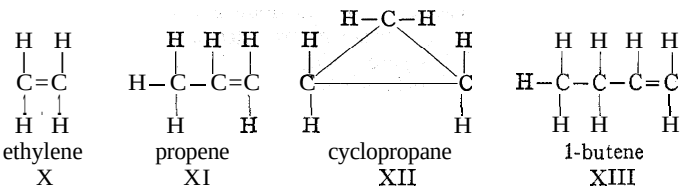


methane V; ethane VI; propane VII; n-butane VIII

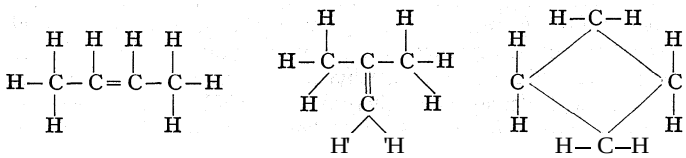


isobutane IX

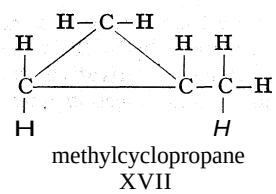
the five structures XIII–XVII, can be drawn. Again, the number of nonequivalent structures in each case is exactly equal to the number of existing structural isomers. This procedure, which can be extended in an obvious manner, and with uniformly satisfactory results, to all further types of molecular formula (however, see below), forms the basis of structural chemistry. Its success provides an important part of the experimental justification of the structural theory.



ethylene X; propene XI; cyclopropane XII; 1-butene XIII



2-butene XIV; isobutene XV; cyclobutane XVI

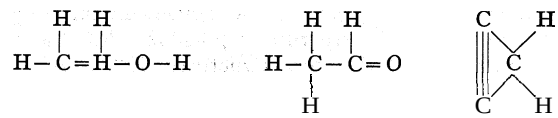


methylcyclopropane XVII

Anomalous Isomer Numbers.—The equality of the number of structures and of isomers corresponding to each molecular formula is subject to several different types of exceptions. The ideal situation would be that exactly one substance exist for each structure which can be drawn, and that, conversely, exactly one structure be associated with each substance which exists. Four types of exceptions to this ideal can be visualized, however, and examples of each type have been encountered: first, many structures which can be written correspond to no known substance at all; second, some structures must be associated with two or more different substances; third, some substances cannot be described by any structure of the usual type; and fourth, some apparently single substances behave as if they possess two or more distinct structures. If the prediction of the numbers of isomers is to be considered an essential function of the structural theory, these exceptions must be examined in order that their extent and significance may be evaluated.

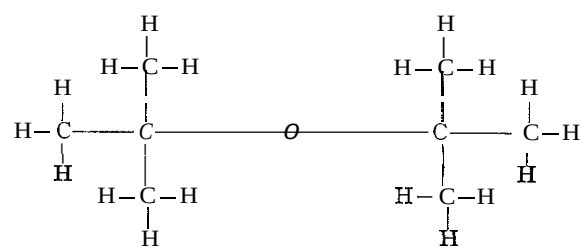
(1) The fact that many structures can be written for which no corresponding substances are known is often merely the result of the fact that no chemist has as yet been sufficiently interested, or had sufficient time, to prepare samples of all the theoretically possible isomers. Even relatively simple molecular formulae may permit enormous numbers of structures; for example, it has been calculated that the formula $C_{20}H_{42}$ permits 366,319 structures and the formula $C_{40}H_{82}$ permits 62,491,178,805,831 of them! (Of course, such large numbers as especially the second of these are experimentally meaningless, since, even if a sample of each of the substances were available, there would be no way of proving that no two of them were identical. Only about twenty different substances that have the formula $C_{20}H_{42}$ and about five with the formula $C_{40}H_{82}$ are known.) The most complicated molecular formula for which all possible structural isomers have been prepared seems to be C_9H_{20}, with altogether 35 nonequivalent structures. For other formulae, incomplete sets of more than 100 known isomers are not uncommon, however. The essential point to be brought out here is that, in those cases in which a serious attempt has been made to prepare all the possible isomers, and in which the factors discussed below do not make success impossible, the theoretical isomer numbers have usually been confirmed experimentally.

In some instances, however, attempts to prepare substances with certain structures have been unsuccessful in spite of repeated and varied attempts. For example, all attempts to prepare vinyl alcohol, XVIII, have led instead to the isomeric acetaldehyde XIX. Apparently, therefore, a substance with the structure



XVIII; XIX; XX

XVIII is incapable of existence or, at any rate, of isolation, because it undergoes a rapid and spontaneous transformation into a different, isomeric substance. This phenomenon is discussed in the article TAUTOMERISM. In other instances, certain structures which can be written on paper correspond to molecules which would be so highly strained that they could not be expected to exist. A simple example of this is represented by the structure XX (of the unknown cyclopropyne); further examples are discussed in the article on STEREOCHEMISTRY: Strain Theory. Finally, certain structures correspond to substances for which no methods of preparation are known at present. In such instances, however, the substances might be capable of existence if only suitable methods of preparation could be devised. Thus, for about 50 years all attempts to make tertiary-butyl ether XXI led instead to



XXI

entirely different (and nonisomeric) substances, as a result of the failure of the chemical reactions to follow the desired courses; nevertheless, this substance was finally prepared in 1941. There is no obvious reason why the situation may not be similar with many other, as yet unknown, substances.

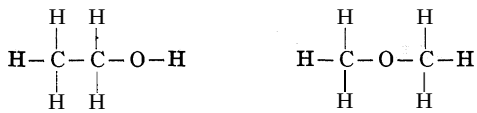
(2) The existence of structures which must be assigned to two or more different substances has made necessary a fundamental extension and broadening of the structural theory. The nature of the developments arising from this cause is discussed briefly in the section on Stereoisomerism below, and in greater detail in the article on STEREOCHEMISTRY.

(3) Some substances exist for which no structure of the usual type can be written. In nearly all instances, however, such substances have been brought successfully into the structural scheme

by suitable extensions of the theory. For example, it is now recognized that carbon. although it is quadrivalent in most of its compounds. is occasionally trivalent, and that many other elements also have greater or less tendencies to display variable valence. A large number of substances. to which structures could not be assigned if each element were considered always to have the same valence, can therefore be taken care of without difficulty. These variations in valence are fairly well understood, so that chemists usually know in advance when they are to be expected (see FREE RADICALS). New types of linkage which were not envisaged originally, such as the so-called hydrogen bond (see VALENCE), have been discovered; these frequently make possible the assignment of definite structures to otherwise anomalous substances. Finally, the theory of resonance (see RESONANCE. THEORY OF) has served to clear up most of the remaining difficulties by introducing a more generalized concept of structure. Although many substances still exist to which no structures have as yet been definitely assigned, there are now no longer many which seem to lie completely outside the structural scheme. (However, see the boron hydrides discussed in the article on BORON.)

(4) The existence of apparently single substances which act as if they have two or more structures has given rise to the concept of tautomerism (*q.v.*).

Assignment of Structures to Isomers.—The structural theory would be of relatively little practical value if it permitted only the calculation of the number of isomers and not the assignment of a definite structure to each of the isomers in those instances in which more than one structure is possible. For the formula C_2H_6O, for example, the two str'uctures XXII and XXIII



XXII XXIII

can be drawn, and the two substances, ethyl alcohol and methyl ether, are known. It is gratifying that the number of structures is equal to the number of isomers, but the chemist would still like to know which structure is to be associated with each isomer. The experimental methods for the determination of structure are varied, and only a few of the salient features of some of the most important methods can be mentioned here.

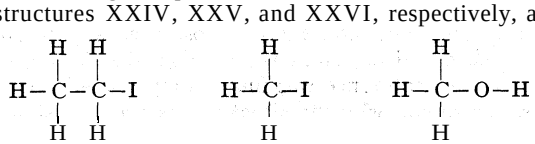
One of the most commonly applied methods for the determination of structure makes use of the chemical reactions of the substances in question. The assignment of structures to the isomeric ethyl alcohol and methyl ether, for example, can be made in the following way. The action of hydrogen iodide upon ethyl alcohol leads to ethyl iodide, C_2H_5I, and water, H_2O:

$$\underset{\text{ethyl alcohol}}{C_2H_6O} + HI \longrightarrow \underset{\text{ethyl iodide}}{C_2H_5I} + \underset{\text{water}}{Hz0}$$

whereas the action of the same reagent upon methyl ether leads to methyl iodide. CH_3I, and methyl alcohol, CH_4O:

$$\underset{\text{methyl ether}}{C_2H_6O} + HI \longrightarrow \underset{\text{methyl iodide}}{CH_3I} + \underset{\text{methyl alcohol}}{CH_4O}$$

For the three organic products of the two reactions, only the single structures XXIV, XXV, and XXVI, respectively, are pos-



ethyl iodide XXIV methyl iodide XXV methyl alcohol XXVI

sible. Comparison of these structures with XXII and XXIII shows that ethyl iodide XXIV is more closely related to XXII than to XXIII, and that methyl iodide XXV and methyl alcohol XXVI are more closely related to XXIII than to XXII. Consequently, the inference is drawn that ethyl alcohol has the structure XXII, since it leads to ethyl iodide, whereas methyl ether has the structure XXIII, since it leads to methyl iodide and methyl alcohol. In other words, the assumption is made that the courses of the chemical reactions are such that the least possible structural changes are produced. Although numerous exceptions to this rule of minimum structural change are now recognized (see MOLECULAR REARRANGEMENTS), it nevertheless forms at least part of the basis of most determinations of structure.

A second method for the determination of structure, which likewise involves the rule of minimum structural change, is based upon the study of the reactions by which the substances can be made. Thus, ethyl alcohol results from the action of dilute aqueous sodium hydroxide upon ethyl iodide:

$$\underset{\text{ethyl iodide}}{C_2H_5I} + \underset{\text{sodium hydroxide}}{NaOH} \longrightarrow \underset{\text{ethyl alcohol}}{C_2H_6O} + NaI$$

whereas methyl ether results from the action of concentrated sulfuric acid upon methyl alcohol:

$$\underset{\text{methyl alcohol}}{2CH_4O} + \underset{\text{sulfuric acid}}{H_2SO_4} \longrightarrow C_2H_6O + \underset{\text{methyl ether}}{H_2SO_4 \cdot H_2O}$$

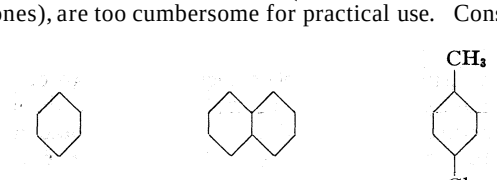
Since the structures of ethyl iodide and of methyl alcohol have been shown (see above) to be XXIV and XXVI. respectively, the principle of minimum structural change again leads to the conclusion that ethyl alcohol must have the structure XXII and methyl ether must have the structure XXIII.

A third method, which makes no explicit use of the principle of minimum structural change. is based upon a comparison of the reactions of substances of unknown structure with those of other substances of known structure. Thus, ethyl alcohol and methyl alcohol resemble each other closely in their chemical properties, whereas methyl ether behaves quite differently toward most reagents. In particular, the two alcohols react with metallic sodium to give alkoxides, and with acid chlorides to give esters (see ALCOHOL), whereas methyl ether is inert toward each of these reagents (see ETHER). Consequently, the structures of ethyl alcohol and of methyl alcohol may be presumed to be similar to each other. Since that of methyl alcohol is necessarily XXVI, that of ethyl alcohol must therefore be XXII. Moreover, the remaining structure, XXIII, must belong to the remaining substance, methyl ether. The assignment of structures is thus the same as by the preceding methods.

Still a further procedure for the assignment of structures to isomers is somewhat more fundamental, but much less commonly used, than the ones just described This method makes direct use of the numbers of isomeric derivatives that can be prepared from each of the isomeric substances in question It has found its greatest use in the determination of the orientation of substituents in benzene, and it is discussed elsewhere (see CHEMISTRY. Organic Chemistry).

Numerous further methods for the determination of structure are based upon the study of physical properties of various kinds. Mention may be made here of refractivities, molecular volumes, parachors, spectra, dipole moments. magnetic susceptibilities and nuclear magnetic resonance spectra. The diffraction of X rays by crystals and that of electrons by gaseous substances has also been used in a number of instances for the establishment of structure. For further discussion of these methods, the reader is referred to the individual articles dealing with them.

Abbreviated Forms of Structures.—The detailed structures such as XXIV, XXV and XXVI (as well as most of the preceding ones), are too cumbersome for practical use. Consequently,



XXVII XXVIII XXIX

abbreviated forms have been adopted for the purpose of convenience in writing and printing. Thus, XXIV becomes $CH_3–CH_2I$ or, more simply still, C_2H_5I; XXV becomes CH_3I; and XXVI

becomes CH_3OH. Even the rather complicated structure XXI can be expressed simply as $(CH_3)_3C–O–C(CH_3)_3$ or as $[(CH_3)_3C]_2O$. In the aromatic series, the structure of benzene (*q.v.*) is written as a simple hexagon, as in XXVII, that of naphthalene (*q.v.*) is written as in XXVIII, and so on; hydrogen atoms attached directly to the carbon atoms of the aromatic rings are usually not indicated explicitly, although other, heavier atoms and groups are always specified, as in the symbol XXIX for p-chlorotoluene. (The phenyl and naphthyl radicals, however, are frequently indicated by their formulae, C_6H_5 and $C_{10}H_7$, respectively.) Benzene is also frequently represented by the so-called Kebulé structure XXX or by the conventionalized diagram XXXI. Other aromatic hydrocarbons can be depicted similarly.

XXX

XXXI

Stereoisomerism. — When the structural theory was first developed, the natural assumption was made by most chemists that two substances with not only the same chemical composition and molecular weight but also the same structure would necessarily have to be identical. Nevertheless, examples were soon encountered in which this assumption appeared to be contrary to the facts. One of the first examples of this further type of isomerism to be carefully studied was that exhibited by tartaric and racemic acids. These substances must be assigned the same structure, $HO_2C–CHOH–CHOH–CO_2H$, and yet they differ in a number of their characteristic properties. In particular, they melt at different temperatures and have different densities, solubilities and crystalline forms. Moreover, tartaric acid is dextrorotatory (*i.e.*, its solutions rotate the plane of polarization of plane polarized light to the right, see STEREOCHEMISTRY), whereas racemic acid is optically inactive (*i.e.*, its solutions have no effect upon the plane of polarization). In a relatively short time, many further examples of the existence of a greater number of isomers than can be accounted for by the structural theory came to light. The extent to which these anomalous isomers differ in properties varies greatly from case to case. Sometimes, as with the dextro- and laevo-rotatory lactic acids (*q.v.*), $CH_3–CHOH–CO_2H$, they are identical in nearly all their properties except in their effects upon polarized light and their reactions with other optically active substances; on the other hand, as with the above tartaric and racemic acids, they may differ noticeably in nearly all their properties; and finally, as with maleic and fumaric acids (*q.v.*), $HO_2C–CH=CH–CO_2H$, they may both be optically inactive.

The detailed discussion of this further type of isomerism is given in the article on STEREOCHEMISTRY. Here, only a few of the most important features will be pointed out. The first fact that has to be established is, of course, that the substances under discussion are actually isomers of one another, in the restricted sense in which the word is used in the present article, and not either polymorphic or polymeric forms. Polymorphism is easily shown not to explain the observations, since the differences in chemical and physical properties and in optical activity are found to persist in solution and in the liquid and gaseous states. Polymerism also is shown to be not involved, since the substances have the same molecular weight. The conclusion can be drawn therefore that the substances are truly isomeric, and that, although they possess the same structure, their individual molecules are not identical. Such isomers are said to be stereoisomers, and their molecules are said to differ in configuration.

The only suggestion regarding the significance of configuration which has received serious attention is that it refers to the arrangement of the atoms in space. That the difference betaeen the dextro- and the laevo-rotatory lactic acids might be explained in some such manner was proposed in 1873 by J. Wislicenus; more complete theories, upon which all subsequent work in stereochemistry has been based, were brought forward the following year by two independent investigators, J. H. van't Hoff and J. A. Le Bel. For a description of their ideas and a further discussion of stereoisomerism, the reader is referred to the article on STEREOCHEMISTRY. (G. W. WD.)

ISOMORPHISM, in crystallography (*q.v.*) and mineralogy, the similarity of crystalline form in substances which are chemically related. Isomorphism is also used in mathematics as applied to groups to denote the correspondence between their operations. In biology, isomorphism refers to similarity between two groups of organisms of different ancestry due to convergent evolution, as exhibited, for example, in the body form of fishes and whales (*see* also MORPHOLOGY; EVOLUTION).

ISOPERIMETRY, a word originally used in geometry to refer to figures of equal perimeter; *e.g.*, a circle and an ellipse may have equal perimeters (circumferences) although not equal areas. One of the simplest of the problems arising in the study is to determine, from all plane figures having the same perimeter, the one that shall have the greatest area. This figure is the circle. Considered more generally, given any number of geometric figures, all defined in the same way, determine the form of the one possessing a maximum (or minimum) amount of a certain property; *e.g.*, of all the triangles having a given area (figures defined as plane, three-sided and of a given area), the one having the least perimeter is equilateral.

For the general definition and treatment consult works on the calculus of variations, where the theory is extended to include solid as well as plane figures.

ISOPRENE, a mobile volatile liquid, which is of interest chiefly because it can be made by the thermal decomposition of rubber and other terpenes and because it polymerizes readily to form rubberlike substances.

Isoprene has the chemical formula C_5H_8; the specific gravity is 0.69; and the boiling point is 34° C. See TERPENES and POLYMERIZATION.

ISOPTERA, an order of insects (*q.v.*), comprising the termites (*q.v.*) or so-called white ants of the tropics. See also SOCIAL INSECTS.

ISOPYCNIC, an adjective used in physics to mean constant density. In oceanography, isopycnic surfaces are considered in certain dynamic computations as the surfaces along which water particles actually move instead of along level surfaces, although the isopycnic surfaces are in most cases very nearly horizontal. The concept is similar to that of the movement of air on isentropic surfaces extensively used for computations and forecasting in meteorology. (H. R. B.)

ISOSTASY is a principle in earth science whereby one understands why continents stand nearly 3 mi. above the floor of the deep ocean, and why a major chain of mountains or an extensive plateau stands so high above the general continental surface. According to the principle, the solid rock underlying the deep ocean for a few tens of miles below sea level is heavier, volume for volume, than the average rock underlying a continent to the same depth, and still heavier than the average rock underlying a mountain chain or high plateau The continents may be said to float on the earth's body, the needed upward pressure being supplied by the downward pressure of the heavy rocks under the ocean, aided by the weight of the water, muds and oozes of the sea floor. Also the weight of each broad mountain chain and plateau is approximately balanced by the weight of the somewhat heavier rock of the continent from which such high land rises. Thus the greater reliefs are almost perfectly compensated by corresponding variations of average density of the materials extending for several tens of miles below the surface.

Investigation shows that the balancing pressure is transmitted below in a weak layer of considerable thickness. To emphasize this weakness (largely caused by high temperature) the layer has been given the technical name asthenosphere. Since the continents and mountain chains are not flattening under their own weights, considerable strength must be ascribed to their rocks above the asthenosphere. Because such volcanic islands as Hawaii and St. Helena, representing enormous loads piled on the ocean floor, now show no sign of sinking, it seems clear that the solid rock under the deep-sea oozes is also strong. In both continental and oceanic regions many relatively narrow downwarps and upwarps of the rocky surface are not compensated and yet appear to

be stable elements in the earth's topography. All around our planet, therefore, there is a strong surface layer of rock; this bears the technical name lithosphere.

The interface between asthenosphere and lithosphere is not level but is characterized by waviness. corresponding to the chemical composition and temperature (which control density) of the lithospheric rocks. To deduce the best reference spheroid for the figure of the earth, needed for accurate mapping, the geodesists have proved that the isostatic principle must be recognized; to allow for its influence they assume, for convenience in calculation, that the locus of compensation is a level passing through the lowest point at the bottom of the lithosphere. With that assumption these workers, using measured deflections of the plumb line and also measurements of the force of gravity at many stations on continents and islands and in submarines traversing the Atlantic, Pacific and Indian oceans, have greatly improved their conception of the earth's figure. (See GEODESY.)

By their own independent methods the seismologists have shown that the lithosphere under the oceans is decidedly denser than the average continental rock, and that the mountain chains are buoyed up by roots of rocky matter still lighter than the average rock of the continents.

In 1889 C. E. Dutton. a geologist, coined the name isostasy from the Greek *isostasios* ("in equipoise"; compare isos, "equal" and statikos, "stable"). He adopted the idea for two chief reasons: (1) the fact that the floor of each wide and thick mass of sedimentary rock laid on the lithosphere sinks by an amount not much smaller than the thickness of the mass; and (2) the fact that, when prolonged erosion removes a thick layer of rock from a broad mountain chain or plateau. the denuded area rises by a large fraction of the thickness of the vanished rock. From these facts he deduced the weakness of the asthenosphere and its ability to transmit the pressures caused by widespread loadings and unloadings of the lithosphere. The new name also meant for him that the major terrestrial reliefs are almost perfectly compensated by the horizontal variation of average density of the lithospheric rocks, allowance being made for the weight of the ocean water.

The isostatic principle is further illustrated by the basining of the lithosphere under the aeight of the extensive icecaps that covered northwestern Europe and northern North America during the Pleistocene epoch, and by the recoil of the downwarped lithosphere since the loads mere removed by melting.

The displacement of matter because of surface loading or unloading is called technically isostatic adjustment. The great viscosity of the earth's materials makes this a slow process. Recoil in the glaciated tract of Europe still continues, though the icecap began to melt away 40.000 years ago and 7,000 years ago had only about 1% of its original weight. Time lag in adjustment for any transfer of surface load and the strength of the lithosphere are two manifest causes for some imperfection of isostatic balancing. Some investigators believe that a small degree of strength characterizing the asthenosphere itself is a third cause.

(R. A. D.)

ISOSTERE, a line of constant specific volume, used particularly in charting the oceans for dynamic computations of currents. In oceanography the specific volume is usually expressed in cubic metres occupied by a metric ton (1,000 kg.) of water.

ISOTHERM, a line on a map or thermodynamic chart connecting points having the same temperature. See THERMODYNAMICS; METEOROLOGY; WEATHER FORECASTING.

ISOTOPE. An isotope is one of two or more species of the same chemical element that have different atomic weights. Most of the elements, in the form in which they are found in the earth's crust and atmosphere, are mixtures of several isotopes. These mixtures are in almost unvarying proportions. For example, natural tin has ten isotopes, ranging in atomic weight from 112 to 124, but all specimens that have been examined have the average atomic weight 118.70. In other words, ordinary tin is nature's standardized blend of ten varieties of tin atoms, no two of which have the same nuclear mass, although they are identical in all other respects.

The term isotopes was coined by F. Soddy in 1913 from the Greek *isos,* "equal," and *topos,* "place," to indicate substances occupying the same place in the periodic table of the elements; *i.e.*, having exactly the same chemical properties, but distinguishable from each other in some other way, such as mode of radioactive decay. With time the basic distinguishing feature of isotopes has been assigned to their respective atomic weights. Since chemical properties are determined by the positive charge on the nucleus (the atomic number) and by the consequent number of extranuclear electrons. this nuclear charge must be the same for isotopes. The differences in atomic masses of isotopes must therefore arise from differences in the masses of the nuclei involved. Present-day usage tends to restrict the word isotopes to atoms having nuclei with masses differing by approximately whole numbers on the atomic weight scale. The general term for an atom characterized by the constitution of its nucleus is nuclide, although isotope has often been used loosely in the past for this purpose. An example of the correct usage lies in the following sentences: "The element chlorine has two isotopes with masses 35 and 37. These two isotopes are examples of nuclides with a mass difference of two."

This article will concentrate on the properties of isotopes related to the stricter interpretation of the name. For further information on atomic and nuclear structure and related topics. see MASS SPECTROSCOPY; NUCLEUS; RADIOACTIVITY, ARTIFICIAL; and RADIOACTIVITY, NATURAL.

Discovery of Isotopes.—Previous to the first decade of the 20th century it was generally assumed that the mass of a standard number of atoms of a chemical element (the atomic weight) was a fundamental characteristic of the element. It was furthermore usually assumed that all the atoms of an element were the same and, in particular, had the same mass. The fundamental importance attached to the mass in characterizing an element is illustrated by the periodic classifications of the elements, such as that of D. I. Mendeleyev, which were made by ordering the elements, with a few minor exceptions, according to their atomic weights.

The first evidence that two substances having the same chemical properties did not have to be physically identical came from the study of the radioactivity of the heavy elements. B. B. Boltwood in 1906 and, considerably more conclusively, H. N. McCoy and W. H. Ross in 1907 showed that ionium (a radioactive product of the disintegration of uranium) and radiothorium (a disintegration product of thorium) once mixed with thorium could not be separated from it by any chemical means. The two substances had radioactive properties quite different from those of thorium and could be shown to have atomic weights differing by several units from that of thorium. It was to cover situations such as this that Soddy devised the name isotopes.

Soon after the acceptance of these ideas as applied to the heavy chemical elements, there came indications that isotopy might exist in the main group of naturally occurring stable elements. J. J. Thomson, during a 1913 investigation of the behaviour of positively charged ions in electric and magnetic fields, found that whereas many substances, when ionized, did behave as if they were made up of identical molecules, the rare gas neon appeared to have a species in about 10% abundance that was 10% heavier than the main constituent. His student F. W. Aston first attempted to confirm this result by trying to change the atomic weight of neon by repeated partial diffusion of the gas through clay pipes. His results, although positive (see below), were not definite enough to establish the idea of isotopy in light elements. Aston then went back to Thornson's methods and developed one of the first mass spectrographs (see MASS SPECTROSCOPY). With this he was able to show conclusively in 1919 that neon had two major constituents, one of mass close to 20 and the other with mass close to 22. The relative abundances were such as to explain the observed average atomic weight of 20.183.

The success with the element neon was followed by the discovery that chlorine had two isotopes (masses close to 35 and 37). Thereafter all the naturally occurring elements were examined and most of them were found to consist of more than one isotope.

Isotopes and Nuclear Structure.—With the discovery of isotopes. it became evident that all chemical elements that had atomic weights that were not close to integers consisted of mixtures of isotopes, each of which individually had a weight close to an integer. This finding has been confirmed and today it is well established that there are no isotopes with masses deviating from whole numbers by more than 0.1 atomic mass unit.

Modern ideas of nuclear structure picture the atomic nucleus as consisting of protons (*i.e.,* nuclei of normal hydrogen atoms) and neutrons. These two particles have nearly the same mass, close to unity on the atomic weight scale. This explains the integral masses observed for isotopes. The integer closest to the exact mass is known as the mass number (A) of the nucleus and is the sum of the number of protons (Z) and the number of neutrons (N) in the nucleus. The number of protons determines the positive charge and therefore the chemical properties of the atom.

Nuclei that have the same mass number are called isobars or isobaric nuclei; those that have the same number of protons, but varying numbers of neutrons, are isotopes; nuclei that have the same number of neutrons are known as isotones. The nuclear constitution of an atom is usually indicated by giving the chemical symbol (which determines the number of protons in the nucleus) with a superscript indicating the mass number and therefore, by difference, the neutron content of the nucleus. The superscript may be placed either before or after the chemical symbol. Thus Cl^{35} and Cl^{37} are the two stable isotopes of chlorine. The nuclei each have 17 protons. In the first isotope there are 18 neutrons. in the second 20 neuttons. The isotopes of hydrogen, H^1, $H^2 \equiv D^2$, $H^3 \equiv T^3$, have been given special names. protium, deuterium and tritium, respectively.

Finally we can define a class of nuclides which have the same number of neutrons and protons, and therefore the same mass number, but in which the nuclei are not in the same energetic state. Such nuclides are knoan as nuclear isomers (see below).

Isotopes of an element differ among themselves. (1) in any properties that depend on the mass; and (2) since the nuclear constitution is different, in all specifically nuclear properties. Thus they can be classified into stable isotopes and isotopes whose nuclei disintegrate spontaneously. The disintegration properties of radioactive isotopes, such as half life (time for half the isotope to disappear by decay) and modes of decay, are discussed under RADIOACTIVITY. ARTIFICIAL and RADIOACTIVITY, NATURAL. The stable isotopes are found as the constituents of the naturally occurring elements. They may also be produced by nuclear transformations. Although some radioactive isotopes exist in nature (see below), most have to be prepared by artificially induced nuclear transformations.

Just as the nuclear stability varies from one isotope to another, so do other nuclear properties such as the nuclear radius, spin, magnetic moment and electrical quadrupole moment. Likewise the nuclear reaction probability often is very different in one isotope than in another. Thus, U^{235} undergoes nuclear fission when bombarded with slow neutrons; U^{238} does not. Similarly. only one of the eight isotopes of cadmium. Cd^{113}, has an extremely large probability of absorbing slow neutrons; the other isotopes are relatively inert. The stability toward spontaneous disintegration of the nucleus and, to a certain extent, nuclear reaction probabilities of isotopes are related to their energetic stability. According to the Einstein relation between mass and energy, the energy content of a system is determined by the mass—the lower the mass, the more stable the system. Although the exact masses of isotopes are close to whole numbers, the deviations are real and significant. In all known cases the mass is lower than that of the same number of separate neutrons and hydrogen atoms. Thus all known atoms are stable with respect to complete decomposition into neutrons and hydrogen atoms.

The detailed variations in mass of nuclides are conventionally measured in terms of the packing fraction. $f_{A,Z}$, of a nuclide of atomic number Z and mass number A. The packing fraction is related to the exact mass, $M(A,Z)$, of the atom by the relation

$$M(A,Z) = A(1 + f_{A,Z})$$

Packing fractions of nuclides (except for hydrogen and deuterium) lie between $+10 \times 10^{-4}$ and -10×10^{-4}. In the case of the stable isotopes of a given element, the packing fractions of the even-mass-numbered isotopes usually form a smooth curve as a function of A, with a minimum (and therefore increased stability) for the isotope of close-to-average mass number. (See NUCLEUS for more data on energetic relations among nuclides and MASS SPECTROSCOPY for the methods of determining packing fractions.)

Variation in the Isotopic Composition of the Elements.—For most elements the relative amounts of the different isotopes in the natural mixture are very constant, irrespective of the source of the sample. In several cases the isotopic composition of elements in extraterrestrial sources such as meteorites has also been found to be the same as that of the same element on the earth's surface. However, elements that can be produced as a result of the fe nuclear transformations (spontaneous or induced) occurring continually on the earth have been found to have varying isotopic content. Thus, the isotopic composition of lead depends on how much thorium or uranium has been nearby during geological time, and for how long (see RADIOACTIVITY, NATURAL). Likewise, since all the helium present today on the earth is the result of nuclear transformations, the relative amounts of He^3 and He^4 are not the same in the atmosphere as they are in helium from gas wells.

Smaller differences in the isotopic composition of the lighter elements arise from the effect of mass on the rates and equilibriums of naturally occurring chemical and physical processes (see below). Thus the deuterium content of hydrogen from the water of the Dead sea is higher than that of hydrogen from most other sources. Even an element as heavy as sulfur has been shown to have an S^{34}–to–S^{32} ratio varying by up to 7%.

Isotopic Composition of Elements.—In spite of such small variations in the constitution of the light elements and the variation in the composition of some others from special sources, the isotopic composition of the great majority of the chemical elements is very constant. The table indicates the isotopic composition of the elements as they occur naturally, giving for each element the mass numbers of the isotopes and the percentage of the atoms of the normal element that consist of that particular isotope. Unless indicated, all the isotopes listed are stable.

It is seen by examination of the table that there. are stable representatives of all mass numbers between 1 and 209 inclusive, except for mass numbers 5 and 8. There are no stable isotopes of any element with these mass numbers. Elements of even atomic number have many more stable isotopes than those of odd atomic number. These latter never have more than two, almost always of odd mass number, whereas the even-atomic-numbered elements. except beryllium, have at least two isotopes and tin (Z = 50) has ten.

The 83 naturally occurring chemical elements are made up principally of 287 isotopes. 271 of which are stable. The other 16 are radioactive with half lives comparable to the age of the earth ($\sim 4.5 \times 10^9$ years) or longer. All the stable isotopes that are known occur in the chemical elements as we know them and in amounts that represent significant fractions (greater than 3×10^{-5}, except for He3) of their respective elements.

An important theoretical interest in the isotopic composition of the elements arises from this being one of the few quantitative evidences available of the process by which all nuclei were originally formed. The relative cosmical abundances of nuclides differing in proton content (Z) have obviously been badly distorted by chemical and physical processes occurring during geological time. Compared with this, the isotopic composition of the elements is very constant. Any theory of the formation of complex nuclei must consider regularities such as the preponderance of neutron-rich isotopes in the heavy elements, the frequent preponderance of light isotopes among the light elements and the generally low abundances of odd-mass-numbered isotopes of even-numbered elements.

Relationship of Chemical Atomic Weights to the Existence of Isotopes.—The chemical atomic weight of an element

is defined as the weight of a standard number of atoms of the element on a scale where the weight of the same number of oxygen atoms is 16.0000. (If this standard number of atoms is taken as Avogadro's number—$[6.0228 \pm .0011] \times 10^{23}$ atoms—the actual weight in grams is the gram atomic weight.) These weights are of great practical value in chemical analysis. As mentioned above. because of the existence of the phenomenon of isotopy, they have lost their fundamental interpretation as accurate measures of the masses of individual atoms. Thus there is no chlorine atom that has a mass on the atomic weight scale of 35.457 (the listed chemical atomic weight of chlorine); instead normal chlorine consists of atoms that have a mass of either 34 96905 or 36 96733.

Because of the existence of three different isotopes of oxygen, the chemical and physical atomic weight scales differ slightly. The physical scale is based on a mass of 16.0000 for the isotope O^{16}; the chemical scale is based on a system in which the normal mixture of oxygen isotopes is assigned a mass 16.0000. Since the heavier isotopes of oxygen are rather rare, the two scales are not far different: one unit on the chemical scale is equivalent to 1.000275 ± 0.000005 units on the physical scale.

The same high precision of modern mass spectrographs that makes possible mass determinations of isotopes suitable for nuclear energy determinations also gives rise to the most accurate method of measuring the chemical atomic weight of a normal element. The chemical atomic weight is just the mass on the physical scale of the separate isotopes of the element averaged by weighting according to the abundance of the isotopes and then converted by the above factor relating the physical and chemical mass scales.

The existence of isotopes and the known or expected small fractionation of isotopes in chemical and physical processes (see below) set limits to the accuracy to which atomic weights have meaning. unless the exact isotopic composition is specified. It was pointed out by H. C. Urey and L. J. Greiff in 1935 that this limit had probably already been reached in the case of several light elements whose atomic weights were being quoted to a thousandth of an atomic weight unit. Even the standard element oxygen could be expected to show a variation in atomic weight in the fourth decimal place as a result of variations in isotopic composition.

Naturally Occurring Radioactive Isotopes.— Radioactivity occurring in nature arises from several sources. Thus there are the long-lived radioactive species (half lives greater than a few hundred million years) that have survived since the formation of the elements. The naturally occurring isotopes of thorium and uranium are of this type. Likewise potassium, rubidium and several other elements are slightly radioactive because of the presence of long-lived radioactive isotopes (see table). Next there are the shorter-lived radioactive isotopes that are present because their disappearance by decay is balanced by continual replenishment from some source. Thus some of the isotopes of thallium, lead, bismuth, thorium and uranium and all the isotopes of the other elements between bismuth and uranium aye radioactive and present in small amounts because they are being continually produced in the radioactive decay of very long-lived parents (isotopes of uranium and thorium). The most famous example of this type is an isotope of radium (Ra^{226}) which is present in uranium ores to the extent of 3.4×10^{-7} g. per gram of uranium.

Cosmic radiation incident on the earth's atmosphere is another such producer of slight amounts of radioactive isotopes. This, for example. is the source of the minute amounts of a radioactive isotope of carbon, C^{14}, that is present in all living tissue to the extent of about 12 disintegrations per minute per gram of carbon. The half life of this carbon isotope is 5,570 years. W. F. Libby developed the radiocarbon method of age determination of archaeological and geological specimens, useful in the range from 1,000 to 30,000 years, from the presence of this cosmic-ray-produced C^{14}.

These and other less important sources make most matter very slightly radioactive. In addition to these natural sources, the use of nuclear energy is producing, as by-products, radioactive isotopes which may become significant supplements to the natural radioactivity of the surface of the earth. Thus the explosion of megaton nuclear weapons had scattered sufficient radioactive debris all over the world that by 1957 all humans had absorbed detectable amounts of the radioactive nuclides Cs^{137} and Sr^{90}.

Radioactive Isotopes.— Radioactive as well as stable isotopes of all the elements have been prepared. By the late 1950s there was information on more than 1,100 radioactive nuclides, and the list was still expanding (see NUCLEUS for a chart of nuclear properties of the nuclides). Most of the radioactive nuclides are prepared by artificially induced nuclear transformations (see RADIOACTIVITY, ARTIFICIAL). The elements technetium ($Z=43$) and promethium ($Z=61$) and all the elements with atomic number greater than that of bismuth ($Z=83$) have only radioactive isotopes. In the case of xenon, besides the 9 stable isotopes, there are 20 known radioactive species with half lives ranging from about 1 second to about 35 days. Six of these are nuclear isomers. At the other extreme, hydrogen has only three known isotopes, two stable and one radioactive.

Effect of Isotopic Substitution on Physical Properties of Substances.— The rather belated discovery of isotopes as well as the difficulty of separation is of course a reflection of the smallness of the effectof mass on most physical and chemical properties. For example, the electronic energy states of atoms or molecules depend on the nuclear mass through the reduced mass, μ, of the electron-nucleus system; μ is defined by

$$\mu = \frac{m_e m_n}{m_e + m_n} \approx m_e\left(1 - \frac{1}{1837A}\right),$$

where m_e and m_n are the electronic and nuclear masses and A is the mass number of the nucleus', It is seen that such effects are of the order of 5×10^{-4} for hydrogen and correspondingly smaller for heavier atoms. In the case of hydrogen, however, the shift in electronic energy levels in going from protium to deuterium is easily detected spectroscopically, and was in fact the mode of discovery of deuterium by Urey, F. G. Brickwedde and G. M. Murphy in 1931.

The other consequence of the presence of isotopes on the optical spectra of atoms arises from the interaction of the magnetic field of the nucleus, if it has one, on the electrons of the atomic system. The result is a splitting of a spectral line into several components (called the hyperfine structure). The number of components and the separations depend upon the spin and magnetic moment of the nucleus and on the nature of the electronic state. Since this phenomenon depends on nuclear properties it varies from isotope to isotope It is most important for heavy elements, but even there it is difficult to measure. Analysis of hyperfine structure is an important method of determining nuclear spins and magnetic moments.

Molecular spectra are much more affected than are atomic spectra by the presence of isotopes, for these spectra reflect in part the vibrational and rotational energies of molecules. The quanta of vibrational and rotational energies are directly dependent upon the masses of the atoms involved and therefore upon the presence of isotopes. It was by examination of molecular spectra that several isotopes (for example, C^{13}, N^{15}, O^{17}, O^{18} and Si^{30}) were discovered.

The presence of isotopes affects physical properties other than spectroscopic. There is, of course, the direct effect of mass on the density of a substance. Because densities can often be measured extremely precisely, a density determination has been used in special cases to establish isotopic composition.

Another direct effect of mass on physical properties is the effect on the rate of diffusion of gaseous atoms and molecules. It has long been known that the rate of effusion of a gas through a hole of size smaller than the distance between the gas molecules varies inversely as the square root of the mass. It was by taking advantage of this property that F. W. Aston first achieved a partial separation of the neon isotopes, and basically similar processes are used today (see below).

In general, other physical properties of substances are significantly affected by the presence of isotopes only at low temperatures and in the case of molecules of low molecular weight.

Isotopic Composition of the Elements as They Occur Naturally

*Isotopic composition varies slightly with source.
†Isotopic composition varies considerably with source.
‡Isotope radioactive.
Source: This table has been taken almost entirely from D. Strominger, J. M. Hollander and G. T. Seaborg, "Table of Isotopes," *Rev. Mod. Phys.*, 30:585, no. 2, part ii of 2 parts (April 1958).

Accurate measurements, however, are continually detecting small differences in physical properties of substances related by isotopic substitution. For example, deuterium melts at 18.65° K. and boils at 23.6" K.; the corresponding temperatures for hydrogen are 13.95° K. and 20.38° K. Heavy water (D_2O) has a melting point 3.8" higher and a boiling point 1.4° higher than ordinary water.

Regarding the incompletely understood phenomenon of superconductivity at low temperatures. it is of interest that the temperature at which certain metals transform to the supertonducting state is affected by the isotopic composition of the metal.

Effect **of** Isotopic Substitution on Chemical Properties.— It has usually been assumed that isotopes and substances differing only in the presence of different isotopes have the same chemistry. However, accurate studies, particularly with deuterium, have indicated that the chemistry of isotopes is identical only in the limit of large masses and high temperatures. Whenever quantum mechanical effects are important, and in general they are most important for light masses and low temperatures, the masses of the atoms involved can be expected to affect the situation and, thus, the result to be sensitive to the isotope involved. This can be illustrated by the folloaing example: The forces between atoms are derived from the electric and electronic structures of the atoms. As indicated in the discussion on electronic states of atoms, these are essentially indistinguishable for different isotopes of the same element. The actual motion of the atoms produced by these forces, however, is affected by the atomic mass. In a given potential, the frequency of vibration and, therefore, the quantum of vibrational energy will vary inversely as the square root of the mass of the system. This affects not only the vibrational spectrum (see above) but also means that the zero point energy, the lowest energy state of the system, will be lower for heavier isotopes.

In this way it is quite easy to calculate quantitatively that the energy needed to dissociate the gaseous D_2 molecules into atoms at absolute zero will be 1.81 k. cal./mole ($\sim 2\%$) higher than that needed to dissociate the H_2 molecule. With elements heavier than hydrogen this effect becomes successively smaller. It remains always true, however, that, because of the lower zero point energy, more energy is required to break a chemical bond involving a heavier isotope than to break a bond involving a lighter one.

Using quantum mechanics to estimate the effects of mass, equilibrium constants can be calculated by statistical methods for so-called exchange reactions. These are chemical reactions in which the reactants and products differ only in the exchange of isotopes. For example, the reaction

$$CO_2^{16} + 2H_2O^{18} \rightleftarrows CO_2^{18} + 2H_2O^{16}$$

has an equilibrium constant given by

$$K = \frac{P_{(CO_2^{18})} \times P_{(H_2O^{16})}}{P_{(CO_2^{16})} \times P_{(H_2O^{18})}}$$

where $P_{(CO^{18})}$ designates the pressure exerted by CO_2^{18} at equilibrium, $P_{(H_2O^{16})}$ that of H_2O^{16}, etc.

The value of the equilibrium constant was calculated to be 1.128 at 0° C. and 1.110 at 25° C. by Urey and Greiff in 1935. It is seen that carbon dioxide in equilibrium with water will contain oxygen with slightly higher O^{18} content than does the water. It is also seen that at higher temperatures the oxygen in the carbon dioxide and in the water tend toward more equal isotopic compositions.

Predictions such as the above have been verified experimentally. Likewise it has been demonstrated that the rates of chemical reaction are affected measurably by isotopic substitutions. In general, the effects are greatest for the lightest elements and decrease with increasing temperature. Thus chemical reaction rates involving deuterium compounds may be up to several times slower than those involving the corresponding hydrogen compounds. This effect has been extensively used to investigate the mechanism of reactions that may involve transfer of hydrogen atoms. In view of the measurable effects of isotopes on both chemical equilibriums and the rates of chemical reactions, it is not surprising that the isotopic composition of the lighter elements in nature shows a definite variation from source to source.

Separation of Isotopes.— This term is generally taken to mean the production of an element with an isotopic composition significantly different from that of the natural element. In the extreme, such a process produces a relatively pure isotope. For most purposes, however, such as chemical or biological tagging experiments, complete separation is not necessary.

It has been mentioned that Aston first attempted to confirm Thomson's discovery of isotopes in neon by trying to separate them. He allowed part of a sample of normal neon to diffuse at low pressure through clay pipes, and repeated the process many times on the fractions obtained. He reported in 1913 that in this way he had been able to change the atomic weight of neon by almost 0.5%. Subsequent attempts by many persons using many different methods on different elements did not produce significantly greater separations. Finally, G. Hertz, in 1932, used the same basic methods as had Aston originally, but arranged the diffusing units in a cascade (see below). He produced neon with the heavier isotope, Ne^{22}, more than twice as abundant as the lighter one, Ne^{20}. In normal neon. Ne^{22} has an abundance of only 10%. Since these pioneer achievements, isotope separations by various methods have become increasingly common. Today small samples of almost any element with distorted isotopic abundances are available for research purposes. A few isotopes; *e.g.*, *D*. U^{235}, are separated on a large scale as a part of nuclear energy programs.

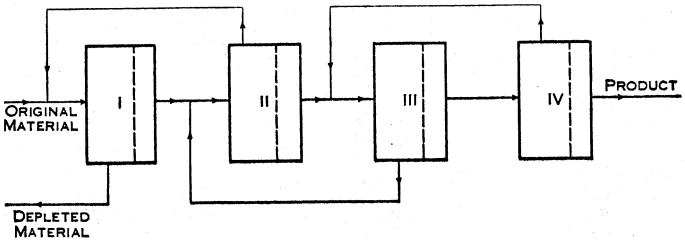
In almost all the methods used for separating isotopes there is involved the repetition of a basic step many times to achieve the desired extent of separation. A process is judged by two factors that have different relative importance in different situations. One is the separation factor per stage (f). This is defined as the ratio of the relative concentration of a given isotope after the basic step in the concentrated fraction to that in the stripped fraction. The latter is ordinarily indistinguishable from the original concentration entering the unit. Thus if the normal isotopic composition of an element is n_1 and n_2, and if, after one stage of the process, it becomes n_1' and n_2', then

$$f = \frac{(n_1'/n_2')}{(n_1/n_2)}$$

The second important factor is the amount of material processed per stage. In general, processes operating with good separation factors produce only small amounts of material and vice versa.

In order to achieve desired over-all separations with processes of low separation factors, many repetitions of the basic stage are necessary. For example, to get 90% U^{235} starting with normal uranium and a process with a separation factor of 1.0043 (a high one for a diffusion process), 1,660 stages are necessary.

Such large numbers of stages can be used only if they are arranged in a manner not to waste material. Such an arrangement is the cascade used by Hertz in 1932 and thereafter in most of the large-scale separation methods. A cascade arrangement of four stages is illustrated in the drawing. The boxes I, II, III and IV represent units. Into one of them (*e.g.*, III) goes a certain amount of feed material from the left. As a result of the operation of the unit, a small fraction of this feed material comes out of the unit toward the right, concentrated in the isotope in question. It forms the feed material for unit IV. The great majority of the feed material for unit III is slightly depleted in the isotope and is returned to become part of the feed material for the unit II. As a result of the operation of the cascade, the material coming out at the right from unit IV is concentrated in one isotope; the



CASCADE ARRANGEMENT OF FOUR STAGES FOR SEPARATING ISOTOPES

material being rejected by unit I is depleted in the isotope. The theory of such cascades is similar to that of multiplate-distillation columns and countercurrent solvent extractions.

Historically, of course, a unit in which a gas was diffused through small pores of a solid was the first type used in such a cascade (Hertz). Diffusion units are also used in the large-scale production of U^{235} in the United States. The gas employed is uranium hexafluoride. Diffusion processes, in spite of low separation factors, can be designed to handle large amounts of material and are susceptible to engineering for continuous automatic operation.

At the other extreme of separation factors is the electromagnetic separation process, which can produce small amounts of very enriched isotopes in one step. These units are simple mass spectrographs designed to collect the mass-analyzed beams instead of merely recording their presence. Large numbers of such units (called calutrons) were used in the United States in World War II together with the diffusion process to produce the U^{235} for nuclear bombs. In general, large-scale operations appear to be more economical with the diffusion process. On the other hand, the electromagnetic process is more versatile. In the 1950s it was used both in the United States and Europe to produce milligram quantities of almost any element with a distorted isotopic composition.

For the isotopes of hydrogen (deuterium and tritium) electrolysis of water solutions proved an effective way of separating isotopes. The liquid remaining after most of the water of, for example. an NaOH solution has been electrolyzed is concentrated in the heavier isotope. This water can be distilled away from the NaOH and made into a fresh NaOH solution and the process repeated. The separation factors in such a process depend upon the electrodes used and can be as high as seven. This, of course. is much higher than is ever encountered with other elements. The electrolytic process was used in Norway from the middle 1930s for the production of ton quantities of heavy water (D_2O). Libby used electrolytic concentration in his measurements of the tritium content of rains.

The chemical exchange method is another that often uses multistage cascades to increase the effect of a small separation factor per stage. Thus Urey made use of the exchange reaction

$$HC^{13}N(\text{gas}) + NaC^{12}N(\text{solution}) \rightleftarrows HC^{12}N(\text{gas}) + NaC^{13}N(\text{solution})$$

which has an equilibrium constant a little less than unity in a process that produces carbon with more than 20% C^{13} (instead of the normal 1.1%). Similar schemes were devised by Grey and co-workers to produce nitrogen and sulfur samples enriched in N^{15} and S^{34}. During World War II catalysts were found that would achieve equilibrium in the exchange reaction

$$H_2(\text{gas}) + D_2O(\text{gas}) \rightleftarrows D_2(\text{gas}) + H_2O(\text{gas}).$$

The reaction has an equilibrium constant of about three. This exchange reaction process as well as the straight separation of D_2O from H_2O by distillation are much more economical in most places than the electrolytic process. They have been used to produce the ton quantities of D_2O needed for nuclear reactors (see below).

In addition to the methods described, which have been used in relatively large-scale separations, isotope separations have been achieved using centrifugation and thermal diffusion (diffusion of gases in the presence of a thermal gradient).

Uses of Isotopes. — The uses of isotopes can be divided roughly into two categories. In one. application is made of some particular nuclear property of the isotope — either its radiations upon decomposition or some nuclear reaction probability. Since such uses do not depend upon the principle of isotopy, they will not be discussed in detail here.

The other class of application of isotopes depends on the fact that, to a very good approximation in most cases, all isotopes of an element have the same chemical properties. This makes it possible to label or tag an element by distorting its isotopic composition. The distortion is accomplished by the addition either of a radioactive isotope or of one of the stable isotopes of the element. The behaviour of this element can then be followed either by measurement of the radioactivity or by analysis with a mass spectrometer. The isotope added is often referred to as a tracer or indicator. The use of labeled atoms in this manner was introduced by G. von Hevesy and F. A. Paneth in 1913. They used a radioactive isotope of .lead (radium D or Pb^{210}) to study the solubility of lead salts. Since then, with the availability of radioactive or stable isotopes as tracers for almost all the elements, the use of labeled elements for many chemical, biological and industrial purposes has become widespread.

A type of investigation made possible by the availability of isotopes is that of exchange reactions (see above). In these there is no change in either the type or number of chemical species involved. Studies on the equilibriums and rates of such reactions are important not only for the separation of isotopes but also as a means of understanding chemical reactions in general and as a prelude to other applications of isotopes.

Isotopes have found extensive application in chemical analysis. An example is the isotope dilution method, used in many variations with both stable and radioactive isotopes. All the variations have in common the feature that the chemical separation procedures used do not have to be quantitative in order to provide quantitative answers. Thus to analyze for an element *A* in a mixture, a known amount of a tracer for *A* is added at the start. A chemical separation of A is carried out, yielding A in a chemically pure form. The fraction of the added tracer recovered measures the efficiency of the process. This, together with the absolute amount of *A* recovered, as measured either by weighing or by other conventional means, determines the total amount of *A* present in the original mixture.

A second analytical application, often called activation analysis, involves nuclear reactions and actually analyzes for particular isotopes. If these are present in a normal element the result is an analysis for the element. Thus the production of a radioactive isotope of an element upon exposure of a sample to slow neutrons measures the amount of isotope of one lower mass number present in the sample. The method can be calibrated by exposing a known amount of the element to the same neutrons and measuring the production of the radioactivity involved.

A third analytical application of isotopes and particularly of radioactive ones arises from the sensitivity of detection instruments used in isotopic analysis. An activity of 100 disintegrations per minute (easily measured) of an isotope with a one-day half life corresponds to about 200,000 atoms. Several of the transuranium elements have been discovered through their radioactive properties and the complete experiments involved less than 100 atoms. More generally, the behaviour of elements at very low concentrations can be studied using radioactive isotopes. Also, starting with larger amounts of radioactivity, the occurrence of very improbable reactions can be detected.

Specific applications of the above and other techniques of tracer application are too numerous to cover in detail here. It is true, however, that isotopes, both stable and radioactive, play an indispensable role in research on the problem of photosynthesis. Another area that might be singled out is the study of the animal metabolism of different types of food. It was established through the use of tracers that there is a continual exchange between almost all injected substances and those present in the animal body. Even portions of bones and teeth are accessible to exchange with injected calcium and fluorine.

In medicine the principal applications of isotopes involve the radioactive ones. The use of radium in the treatment of cancer has a long history. Later other radionuclides became available in sufficient quantity and were also used for the same purpose. Probably the outstanding example of the application in medicine of a radioactive isotope is the use of 8.0-day I^{131} in the diagnosis and treatment of thyroid ailments.

The industrial applications of isotopes were just beginning in the 1950s. An accomplished development was the use of gamma-emitting radioactive isotopes such as radium or Co^{60} instead of an X-ray machine for the radiography of metal castings. Such sources have the advantage of compactness and ruggedness which often make them preferable to electric machines. The convenience of

radioactive isotopes in furnishing high-energy radiations in a small space has found application in several other situations. Thus the ionization of air produced by these radiations is used to prevent the accumulation of undesirable static electric charges. Similarly the scattering of these radiations by thin films, being a sensitive function of the thickness of the film, is used widely in thickness gauges.

Isotopes of Importance in Nuclear Energy Programs.—The development of nuclear energy for both weapons and power has often depended upon the characteristics of individual isotopes rather: than that of the natural mixture occurring in elements. Thus U^{235} is the only isotope in natural uranium (in fact the only naturally occurring nuclide) that can support a chain reaction. In concentrated form (*i.e.*, separated from its diluent U^{238}) it can support a fast neutron chain reaction and therefore can be used for nuclear explosives. In its ordinary dilution it can be used to support a slow neutron (thermal) chain reaction. The extra neutrons in a chain-reacting pile can then be used either to make plutonium (Pu^{239}) from U^{238} or U^{233} from Th^{232}. Both Pu^{239} and U^{233} have fissionability characteristics comparable with that of U^{235} and so are usable either in weapons or as the basis for controlled release of nuclear energy.

In addition to these heavy nuclides, there are several isotopes of the light elements that are of importance in nuclear energy developments. They are useful either as moderators (to slow down neutrons) in uranium chain-reacting piles or as direct sources of nuclear energy. In the former category helium and carbon (in the form of graphite), and hydrogen, deuterium and oxygen (in the forms of light and heavy water) had already been used, and Be^9 and F^{19} were additional possible moderators in the 1950s. In the second category, the large-scale conversion of D^2 into He^4 was first accomplished by the U.S. in Nov. 1952 in a hydrogen bomb explosion on a Pacific atoll. In the late 1950s, the controlled release of such thermonuclear energy had not been achieved.

Nuclear Isomers.—Nuclear isomers are nuclei which have the same charge (Z) and mass number (A) but represent different energy states. Atoms differing because of the presence of nuclear isomers as their nuclei are isobaric isotopes. One of two nuclear isomers must be unstable with respect to de-excitation. Although the existence of any excited state is in a sense an example of nuclear isomerism, the term is ordinarily applied only to cases where the excited state has a measurable half life for decomposition (greater than about 10^{-10} seconds). Such nuclei are called metastable and are usually designated by an asterisk (*) or an ^{m} after the mass number. Thus Br^{80*} and Br^{80} represent a pair of nuclear isomers. Br^{80*} decays to Br^{80} with a 4.5-hour half life. See also NUCLEUS: Metastable Nuclei.

The first case of nuclear isomerism was discovered by O. Hahn in 1921. He found two nuclear species having distinctive radioactive properties that had to be assigned the nuclear constitution expressed by Pa^{234}. In the late 1950s there were more than 160 pairs of nuclear isomers known, as well as a few cases of triple isomerism. Since nuclear isomers have the same charge and differ in mass by less than a few thousandths of a mass unit (isotopes differ from each other by at least one mass unit), it is unlikely that atoms differing only in the presence of nuclear isomers as their nuclei will have detectable differences in chemical or physical properties.

ISRAEL, MANASSEH BEN (1604–1657), Jewish theologian and founder of the modern Jewish community in England, was born in Portugal, probably in Lisbon. His father, Joseph ben Israel, was a marrano (Jews or Moors on the Spanish peninsula who professed Christianity to avoid persecution). The family later moved to Amsterdam, where Manasseh studied for the rabbinate under Isaac Uziel. Two years after the death of his master, Manasseh was chosen to succeed him as rabbi and teacher though not yet 19 years of age. He acquired a reputation for his scholarship and theological argument, was one of the two principal teachers of Benedictus de Spinoza (*q.v.*) and numbered among his friends Isaac Vossius and Hugo Grotius. In 1627 he established the first Hebrew print shop in Amsterdam. He wrote prolifically and many of his works were widely read.

Manasseh was convinced of an imminent return of the Jews to the Holy Land, according to Messianic promise, but believed this depended first on a rescattering of the Jews into all countries. He was therefore interested in securing the readmission of Jews into England, where a ban on Jewish residence had existed since the edict of Edward I in 1290. Toward this end he wrote *Esperança de Israel* (1650; Eng. tr. *Hope of Israel*), which came to the notice of Oliver Cromwell and secured for Manasseh permission to visit England. There he pleaded his cause and eventually gained consent to end the debarment of Jews from living freely in England. In response to contemporary criticism, Manasseh wrote *Vindiciae Judaeorum* (Vindication of the Jews, 1656). After thus successfully concluding his mission in England, Manasseh returned to the Netherlands. He died in Middleburg, en route home, Nov. 20, 1657. A portrait etched by Rembrandt is extant.

ISRAEL, the name of the Jewish people as a religious community (I Chron. ii, 7); of the ancestor of the Hebrews, Jacob (Gen. xxxii, 28); of the northern tribes distinguished from Judah (II Sam. ii, 10); of the undivided kingdom (Gen. xlvii, 27); and of the Jewish people personified as God's servant (Is. xliv, 1, 21). The Hebrew term means "let El (God) persevere, persist." Found on the pillar of Merneptah, pharaoh of the Exodus. See HEBREW LANGUAGE; JACOB; JEWS; JUDAISM; PALESTINE.

ISRAEL, a country of Asia, situated on the eastern end of the Mediterranean sea. After nearly 2,000 years of statelessness and dispersion, and half a century after the first Zionist congress at Basel, Switz., the Jewish people on May 14, 1948, asserted their independence, fought for it and won it. It was the climax of perhaps the most tragic decade in the history of the Jewish people. In continental Europe, out of a Jewish population of 9,500,000, about 5,750,000 had been killed by the Germans; about 2,000,000 remained in the Soviet Union; world Jewry was reduced from 16,750,000 in 1939 to approximately 11,000,000 in 1946; about 5,000,000 of these were in the United States.

History.—On Nov. 13, 1945, it was announced that the British and U.S. governments had agreed to set up a joint committee of inquiry, charged with making recommendations on the future of Palestine, on the conditions of Jewish refugees in Europe and the possibilities of Jewish immigration into Palestine. On March 29, 1946, the Anglo-American committee recommended: (1) immediate immigration of 100,000 Jews; (2) repeal of Palestine legislation which restricted the transfer of land to Jews; (3) that Palestine should be neither a Jewish nor an Arab state but that the mandate should be transformed into a trusteeship of the United Nations with a progressive measure of autonomy for both peoples. As the U.S. government declined to share the resulting military and financial responsibilities, the British government did not implement the proposals; and—having failed to obtain agreement with the Jews and Arabs for its own plans for administration of the country, and faced with both Jewish and Arab revolt—referred the problem of Palestine to the United Nations.

A special assembly of the UN was held at Flushing Meadow, N.Y., and on May 15, 1947, a UN special committee on Palestine was set up to submit recommendations to the second regular assembly. The committee unanimously agreed that the British mandate should be terminated and that the independence of Palestine should be achieved without delay, but was divided in opinion about the future government. The majority recommended partition into a Jewish state and an Arab state, which should, however, be linked in an economic union; and Jerusalem and an area around it, including Bethlehem, should be an international enclave, under a trusteeship of the United Nations, and demilitarized. The minority recommended that Palestine be a single federal state, Jews and Arabs enjoying autonomy in their respective areas, and that Jerusalem be the capital. On Nov. 29, 1947, the assembly adopted the majority recommendations by 33 votes to 13 with 10 abstentions—the U.S. and U.S.S.R. being

among the states voting for the partition and Great Britain abstaining. The assembly also appointed a five-member commission to supervise the implementation of the plan and, in consultation with Jewish and Arab democratic parties, to elect provisional councils of government. The mandate was to come to an end in six months and the British forces were to leave the country by Aug. 1948.

The Arabs rejected the plan, and disorders immediately broke out in all parts of the country. Great Britain declared that it would not implement the decision by force. At the same time, it would be responsible for law and order until the administration left, and it was not willing to allow the United Nations commission to go to Palestine until immediately before the end of the mandate, which was fixed for May 15, 1948. For nearly six months there was utter confusion. Guerrilla warfare was waged between Arabs and Jews, and there were terrorist incidents by Arabs and Jews against the British forces. Arab bands from neighbouring countries, some from regular forces, infiltrated into the northern and eastern areas of Palestine, attacked Jewish villages and tried to blockade the road from Jaffa to Jerusalem and prevent supplies from being taken to the Jewish population. The Jews, though greatly outnumbered, had the better of the fierce fighting. They took Haifa on April 22 and Jaffa on May 13. The bulk of the Arabs in the areas allotted to the Jewish state took flight to the neighbouring Arab states.

Gen. Sir Alan Gordon Cunningham, the last high commissioner for Palestine, left on May 14, 1948, and on the same day the Jewish National council and the General Zionist council at Tel Aviv proclaimed establishment of a Jewish state, to be called Israel, of which it would be the provisional government. David Ben-Gurion was appointed prime minister, and on May 16 Chaim Weizmann was elected president of the provisional council. Straightway the U.S. government recognized the council as the de *facto* authority of the state, and de jure recognition by the U.S.S.R. followed on May 17. The five neighbouring Arab states —Egypt, Trans-Jordan (later renamed Hashemite Kingdom of Jordan), Iraq, Syria and Lebanon—announced that their armed forces would enter Palestine with the object of restoring order. The United Nations on May 20 appointed Count Folke Bernadotte as mediator, to bring about a settlement between Israel and the Arab states, while the consular commission in Jerusalem continued its efforts for a local truce. The Arab forces occupied the areas in the south and east, which were not yet controlled by the Jews, and tried to blockade Jewish Jerusalem. The Arab legion of Trans-Jordan, despite a desperate defense by the Jews, obtained the surrender of the small Jewish quarter of the old city. The Jews, however, had won control of the section of the main road to Jerusalem in the Judaean hills and beat off all Arab attacks on their scattered settlements.

Count Bernadotte obtained a cease-fire of four weeks from June 11 and put forward proposals for settlement, which were rejected by both sides. The Arabs refused a prolongation of the cease-fire, and hostilities broke out again in July. The Jews gained lightning successes in nearly all sectors; they occupied Ramleh and Lydda and the surrounding central plain, captured Nazareth and western Galilee (which had been allotted to the Arabs) and advanced their positions in the south. A second cease-fire was accepted on July 18. Count Bernadotte, assassinated in Jerusalem on Sept. 17 by Jewish terrorists, was succeeded as mediator by Ralph Bunche of the United Nations secretariat. Despite the orders of the United Nations, the truce was not observed faithfully by either side; and by the end of 1948 the Jews had occupied all the Negev up to the former Egyptian frontier, except a strip of coast between Gaza and Rafa, which remained in Egyptian possession.

The mediator secured separate armistice agreements between Israel and most of the Arab states (Egypt, Feb. 24, 1949; Lebanon, March 23; Trans-Jordan, April 3; Syria, July 20); and the Iraqi government withdrew its troops and transferred the areas occupied by them to Jordan. It was broadly agreed to fix a temporary frontier where the line had been at the beginning of the negotiations. Certain border areas were demilitarized; and the Jews secured adjustments in the western sector (so that the railway from Tel Aviv to Haifa was in their hands) and established a well-guarded corridor to Jerusalem. In Dec. 1948 the United Nations assembly had appointed a three-member conciliation commission to promote a final settlement and to arrange an international regime for Jerusalem; but all its efforts were frustrated. By the armistice agreements mixed commissions composed of Arabs and Jews, with a chairman from the United Nations staff, were established to deal with complaints of violation. Israel was admitted to the United Nations on May 11, 1949.

The provisional council of Israel, which had enacted an ordinance on the form of government, organized elections in Jan. 1949, for a constituent assembly (knesset) of 120 members, elected by proportional representation, with the whole country treated as one constituency. Of the 12 parties represented, the largest were two wings of Labour, divided on matters of foreign policy and the internal program: the Mapai (Israel Workers), which won 46 seats; and Mapam (United Workers), which won 19. The leader of Mapai, David Ben-Gurion, formed a coalition government with the United Religious front and smaller centre parties.

The draft constitution was not discussed It was decided to pass an interim organic law defining the legislative, executive and judicial powers and to let the rest of the constitution grow gradually. The knesset became a single-chamber parliament. The state was a republic. The president had the limited powers of a French president and appointed the prime minister after consultation with leaders of the parliamentary parties; the other members of the executive council (cabinet) were appointed on the prime minister's advice. The courts were independent of the executive, applying the law of mandated Palestine subject to new legislation. Besides the civil courts, religious tribunals for Jews. Moslems and Christians had jurisdiction in personal status. Arabs had equal political rights, and in 1956 eight Arabs were members of the knesset. Nazareth, a predominantly Arab town, had an Arab municipality and magistrate.

Chaim Weizmann, the first president (elected in Feb. 1949), died in Nov. 1952. The next president was Itzhak Ben-Zvi. a Mapai member of the knesset who had formerly been president of the Jewish National council in mandated Palestine. A second assembly had been elected in 1951, when the General Zionists, a bourgeois party. gained at the expense of the extreme parties both of the left (Mapam) and of the right (Herut). Ben-Gurion's second coalition government was at first composed of the same elements as his former one; but after a year the General Zionists were brought into it. In Dec. 1953 Ben-Gurion retired into private life in a collective settlement in the Negev—he returned as minister of defense in March 1955—but the coalition was maintained under Moshe Sharett, a member of Mapai, who had been foreign minister and combined that office with the prime minister's. The third general election was held in July 1955 and resulted in a swing back to the extremist parties, Herut and two divisions of the former Mapam, at the expense particularly of the General Zionists. Ben-Gurion formed a new coalition of the three labour groups with one of the religious parties and the Progressives. In 1956 Sharett was forced to retire as foreign minister and was replaced by Golda Myerson (Meyer), then minister of labour. The principal enactments of the assembly included the Law of Return, which gave every Jew the right of immigration in accordance with the policy of "gathering the exiles"; the Education law, which instituted free compulsory elementary education for all citizens, Arabs as well as Jews, between 5 and 13; the Law of National Service, which required Jewish men to give $2\frac{1}{2}$ years and women to give 2 years of service, partly in agricultural work, partly in military training; and the Law of Nationality, which conferred Israeli citizenship on the widest possible basis.

The question of Jerusalem remained unsettled. From 1948 the city was divided into two completely separated sections, Jewish and Arab. Israel moved the knesset and most of the government offices (previously in Tel Aviv) to Jerusalem in Dec. 1949. The government declared itself willing to have the holy places put under the protection of a UN commissioner but opposed international

administration of the city. The kingdom of Jordan was equally opposed to an international regime for Jerusalem.

In 1950 the United States, Great Britain and France issued a tripartite declaration that they would maintain a balance of arms between Israel and the Arab states and would check any aggression by either side attempting to change the frontiers fixed by the armistice agreements. From 1952 relations deteriorated, and frequent incidents on the Jordanian and Syrian borders disturbed the peace and were submitted by one side or the other to the Security council. Israel's plan for the use of the waters of the Jordan by a canal from Lake Hule (Huleh) to irrigate the Negev provoked violent Syrian resistance, and the Soviet veto at the council prevented action. An attempt of the U.S. president's emissary to get agreement on a comprehensive irrigation project for the benefit of Jordan, Syria and Israel was frustrated. Then in 1955 the supply by the Soviet Union of jet aircraft and heavy armament to Egypt increased the tension, and serious raids were multiplied. The secretary-general of the UN in April 1956 obtained an unconditional cease-fire between Israel and Egypt and the Arab states. Very soon, however, raids by Egyptian commandos *(fedayeen)* were resumed. and, following Col. Gamal Abdel Kasser's nationalization of the Suez canal, the parliamentary elections in Jordan (which reflected Egyptian influence) and Arab threats of invasion. Israel mobilized its forces and on Oct. 29 invaded Sinai. In five days its army had taken Gaza. Rafa and El Arish and occupied most of the peninsula east of the Suez canal.

The objects of the operation were to wipe out Egyptian raider bases, to open sea communication through the Gulf of Aqaba (Akaba) with Elath, and to put pressure on Egypt to negotiate peace. On Nov. 8 Ben-Gurion stated, under pressure of the UN, U.S. and the Soviet Union, that Israel would withdraw its forces from Egyptian territory when satisfactory arrangements were made with the UN international force. The withdrawal was completed by March 8, 1957.

In Map 1960 fugitive Nazi war criminal Karl Adolf Eichmann, once head of Hitler's extermination camps and reportedly responsible for the deaths of 6,000,000 Jews, was kidnapped in Argentina by Israeli agents and smuggled to Israel. There, after a lengthy trial, he was convicted of mass murder and sentenced to death. Hanged on May 31,1962, Eichmann became the first person ever executed by the state of Israel.

Territory and Population. — The area of Israel, as defined by the armistice agreement, was 7,993 sq.mi.—including all mandated Palestine west of the Jordan, except the plateaus of Judaea and Samaria (which were annexed by Jordan) and the Gaza strip (which was occupied by the Egyptians). The largely unpopulated Negev, with a narrow strip at its southeastern corner on the Guli of Aqaba, comprised more than half the territory. The population of Israel in 1961 was 2,173,923, including about 200,000 Arabs. There had been a Jewish immigration of about 850,000 in the years 1948–56, mainly from central and eastern Europe till 1950, and from the communities in oriental or Moslem countries, particularly Yemen, Iraq and North Africa, thereafter. (Oriental Jews constituted two-fifths of the population in 1955.) The government tackled the problem of settling the newcomers with material help from the Jewish Agency ior Palestine, representing Zionists of all countries. In the early period homes could be found ior them in evacuated Arab quarters of towns and villages (about 700,000 Arabs had fled during the fighting), and building became a principal industry. New towns were developed: the population of Beersheba, for instance, rose from 2,000 to 97,445, and by 1956 there were more than 400 new agricultural settlements, in addition to the 300 existing in 1948. The government's budget for settlement was provided partly by the Jewish agency, partly by international loans and partly by private investment. Tel Aviv-Jaffa (pop. 386,612) and Haifa (182,007) are the largest towns.

Economy and Finance. — A sustained effort was made to enable Israel to produce more of its requirements in food, and there was considerable industrial development. The mineral wealth oi the Negev was exploited, as also were the minerals in solution in the Dead sea. In the 1950s the principal industries were building, textiles, metals, diamond cutting and chemicals. Electric power for irrigation and industry was provided by the Palestine Electric corporation, the nationalization of which was carried out in 1954. The oil pipeline from Iraq to Haifa was put out of operation by the Arab stoppage of the oil flow, so that the oil refinery in Haifa had greatly to reduce its activity. Oil was struck in 1955 near Ascalon and by the end of 1956 provided about one-tenth of Israel's needs. An oil pipeline was laid from Elath to Beersheba in 1957 and the railway from Beersheba to Lydda was opened in 1956. Though exports steadily increased, the adverse balance of trade was still great. It was met by iour sources: reparations in kind paid by the German Federal Republic, to the value of more than $800,000,000 over a period of ten years from 1952; contributions from the free Jewish communities in all parts of the world; loans irom foreign countries, particularly the Independence loan floated by Israel in the United States; and the U.S. government's grant-in-aid. Jewish-owned sterling balances in the United Kingdom from Palestine were exhausted by 1952. The government, however, encouraged foreign investment by tax and customs concessions. There was, moreover, a steady development of the merchant marine and fishing; and, in addition to the ports of Haifa and Tel Aviv, the construction of a harbour at Elath on the Guli of Aqaba was undertaken. The government balanced its budget, including the heavy charge for defense. Revenue is derived principally from income tax, customs and excise, land and luxury taxes.

The unit oi currency is the Israel pound, divided into 1,000 prutas. Originally it was equivalent to the pound sterling, but the inevitable inflation brought a steep decline in the exchange rate, and in 1953 the government carried through a devaluation and fixed the rate at IL. 5 to the pound sterling, for most purposes, or IL. 1.80 to the U.S. dollar. The deflation policy successfully held the exchange rate. A new central bank was formed for the issue of notes.

The cost-of-living index, which mounted steeply during World War II, was by 1949 nearly four times what it had been in 1939; subsequently it again doubled itself. In 1949 the government introduced strict rationing and price control, but from 1952 controls were greatly reduced. Wages were maintained at a high rate by the General Labour federation, which comprised most of the workers. A great part of the agricultural settlement is organized through collective and co-operative villages *(kibbutzim* and *moshavim)*. Road transport services, building enterprise and cultural activities are in the form of co-operative societies. The federation conducts health and other social services, but the government passed a national insurance law for old-age and also widows' and maternity benefits.

Education and Culture. — Eight years after the establishment of the state, free elementary education was being given for more than 300,000 children. There were also many secondary schools maintained by municipalities and voluntary bodies, as well as teachers' training colleges and five institutes of higher education, namely, the Hebrew university of Jerusalem, the religious Bar-Ilan university near Tel Aviv, the Haifa Institute of Technology, the Tel Aviv University college and the Weizmann Institute of Science for Fundamental Research. All the institutes were rapidly expanding, and at the Hebrew university in the year 1956–57 the number of undergraduate and postgraduate students had risen from 1,000 in 1949 to 4,000. Faculties of medicine, law, agriculture and the social sciences had been added to those of the humanities and of science.

The army is an important educational instrument aimed at the integration of immigrants. In addition there is a large development of adult education by civil bodies, and resident colleges are established for intensive Hebrew education of the immigrant intellectuals. Hebrew is the language of the schools and of the-university, of the government offices and of the courts. There is a remarkable output of Hebrew literature and periodicals

Sre also JEWS; PALESTINE; ZIONISM.

ISRAELI, ISAAC BEN SOLOMON *(c.* 850–950), Jewish physician and philosopher, was born in Egypt and became court physician at Kairouan (Kairwan). His medical works were translated by Constantine the African (1087) and include a *Book on the Fevers* much esteemed in the middle ages. His extant philosophical writings are: a *Book of Definitions and Descriptions* (Hebrew trans by Nisim ben Solomon; Latin version by Gerard of Cremona, ed. by J. T Muckle in *Archives d'histoire doctrinale et littéraire du moyen âge,* vol. xii–xiii, Paris, 1938), mainly based on al-Kindi; a *Book on the Elements* (Hebrew trans. by Abraham ha-Levi bar Hisdai; Latin version by Gerard of Cremona); a *Treatise* on *Spirit and Soul,* probably part of an exegetical work in which Israeli sought to adduce scriptural support for his philosophical doctrines; the *Book of Substances;* and a treatise designated in Hebrew as *Chapter on the Elements.* The latter two works (ed. by S. M. Stern and by *A.* Altmann, *Journal* of *Jewish Studies,* vol. vii, no. 1–2, London, 1956) are based on a pseudo-Aristotelian source otherwise lost which offers an important variant of Neoplatonism. Israeli's doctrine had a pronounced influence on the 13th-century Jewish mystics in Gerona. Ibn Gabirol too seems to be indebted to it.

For medical and philosophical treatises extant in Latin see *Opera omnia Isaci* (Lyons, 1515). *See* also J Guttmann, *Die philosophischen Lehren drs Isaak ben Salomon Israeli* (Munster, 1911). (A. AN.)

ISRAELS, JOZEF (1824–1911), Dutch painter and etcher, leader of The Hague school of peasant genre painting which flourished in the Netherlands during 1870–90, was born at Groningen of Jewish parents on Jan. 27, 1824. He began his studies in Amsterdam, but admiration for Ary Scheffer led him to Paris (1845–47), where he worked under F. E. Picot. Horace Vernet and H. Delaroche. He first tried to establish himself as a painter of portraits and of conventional history pictures, but had achieved little success nhen in 185j ill-health compelled him to quit Amsterdam for the fishing village of Zandvoort, near Haarlem. The change of residence revolutionized Israels' art and henceforward he became the painter of Dutch fisherfolk and peasants. In 1871 he moved to The Hague. often working in nearby Scheveningen. He died at The Hague on Aug. 12. 1911. Israels' style was one of sentimental naturalism and he preferred pathetic themes like "The Shipwrecked Mariner" (1861, National gallery, London). (A. Bs.)

ISSACHAR, Jacob's ninth son. his fifth by Leah, is the eponymous ancestor of one of the northern tribes of Israel having affinities with the northern group of tribes rather than with the Joseph clans on their southern border. Issachar played but an insignificant part in Israelite history. The name hardly occurs in later times, and the references to the premonarchic period suggest an attitude of submissiveness to their Canaanite neighbours (cf. Gen. xlix, 14 et seq., and the fact that the Canaanite cities of the Plain of Esdraelon retained their independence comparatively late), though Issachar is mentioned in Jud. v, 15 as taking a part in the war against Sisera.

ISSERLES, MOSES BEN ISRAEL (c. 1525–1572), known as REMA, was born at Cracow and died there in 1572. He wrote commentaries as the *Zohar,* the "Bible of the Kabbalists," but is best known as the critic and expander of the Shulhan Aruch of Joseph Qaro (Caro) (*q.v.*). His chief halakhic (legal) works were Durke Moshe and *Mappah.* Qaro, a Sephardic (Spanish) Jew, in his code neglected Ashkenazic (German) customs. These deficiencies Isserles supplied. and the notes of Rema are now included in all editions of Qaro's code.

ISSUS, BATTLE OF (Oct. 333 B.C.). Topographically, the region in which the battle of Issus was fought is an interesting one. The field itself lies a few miles north of Myriandrus, at or near Alexandria (Alexandretta). It is surrounded by mountainous country and is approached by three passes: northwest of Issus, the Cilician Gates over the Taurus range; northeast, the Amanic Gates leading to the Euphrates; and south, the Syrian Gates leading into Syria and toward Sochi where Darius had assembled his army. Toward this last-mentioned pass Alexander marched, and either the Amanic Gates were unknown to him or, what is more probable, he never expected that Darius. whose main strength lay in cavalry, would desert the plains. The unexpected, however, happened, and Darius, rejecting the advice of his generals, marched on the Amanic Gates which lay to the rear of Alexander. If tactically this was a bad move, strategically it was a sound one, for by advancing through this pass Darius compelled Alexander to relinquish the initiative and fight a battle to regain command of his communications. On hearing what Darius had done, Alexander at once assembled his generals, pointing out to them the danger they were in, and then countermarched to meet the Persians.

As the Greeks debouched onto the coastal plain, Alexander deployed his army, the right wing resting on the foothills and the left on the seashore; the front of the army was about 1½ mi. from flank to flank. The Persians, who considerably outnumbered Alexander, were drawn up on both banks of the river Pinarus (Deli), their main force of cavalry being on their right. Alexander, noticing this, reinforced his left wing with the Thessalian cavalry and secured his right by a crochet of light infantry In front of his left wing he placed the Cretan archers and the Thracians; the Greek mercenaries he held in reserve.

The Battle. — The battle opened by a skirmish on the right flank, the Persians on the foothills being driven back. This done, Alexander first rested his men. then led them forward at a slow pace, and on nearing the Pinarus advanced his right wing at a run in order to close, and so lessen the time taken in crossing the arrow zone. Darius had established his headquarters in the centre of his line of battle. and toward him Alexander charged, throwing the Persians back in confusion. Then the unexpected happened. The phalanx, disordered while crossing the Pinarus, fell back, whereupon Alexander wheeled his right wing around to the left and charged in flank the Greek mercenaries who were driving back the phalanx Once he had extricated his centre, the pursuit of the defeated Persians was taken up. The traditional losses are 110,000 Persians killed and 450 Macedonians.

Tactics. — The main tactical interest in this battle is that though Alexander developed his attack from his normal order of battle he was in no way tied down by it but adapted it to the ground and the probable actions of the enemy. He did not advance to the attack until he had secured both his flanks, neither did he direct his decisive attack against the Persian cavalry, the most formidable troops confronting him, but against the enemy's command — that is. against Darius himself. Thus, he first decided on his objective; second, he secured his advance; and, third, only then did he launch his attack, which was carried out at top speed, and so simultaneously developed security and offensive power. The blow was an overwhelming one, yet in the elation of success Alexander did not lose his head, for directly he saw that his phalanx was in danger he wheeled his cavalry around to assist his infantry. By so doing he abandoned his goal in order to secure his base of action which was vital to him.

Lessons. — The main lessons of this battle are: correct distribution of troops to ground; concentration against the decisive point; and the maintenance of tactical direction. If the'phalanx had been destroyed while Alexander was pursuing Darius, the whole of the Macedonian army would in all probability have been overwhelmed by the Persian right wing. (See GRANICUS, BATTLE OF THE: Bibliography.) (J. F. C. F.)

ISSYK-KUL, also called Tuz-kul ("Salt lake") because of its brackish waters, and by the Kalmucks, Temurtu-nor ("Iron lake"); a lake in the Issyk-Kul *oblast,* Kirghizia Soviet Socialist Republic (*q.v.*), U.S.S.R., lying in a deep basin, apparently of tectonic origin, 5,400 ft. above sea level. It extends from 76° 10′ E to 78° 2′ E. and has a length of 113 mi. from west-southwest to east-northeast and a breadth of 36 mi.; its area is 2,394 sq.mi. The lake is at an altitude of 5,279 ft. and has a maximum depth of 2,303 ft. The name is Kirghiz for "warm lake" because of the fact that though ice may form occasionally, the surface of the lake is never completely frozen over. Issyk-kul lies between two westward running spurs of the Tien-shan, the Kunghei Ala-tau range to the north, which rises 15,653 ft., and the snow-clad Terskei Ala-tau range, which skirts the south of the lake at a distance of 5 to 13 mi. and rises to 17,323 ft. The passes over the Terskei lie at great altitudes, the Barskoun (12,316 ft.), the Dzhukuchak (10,190 ft.) and the Kerakyr (12,536 ft.). The Dzhukuchak, linking northward with Przhevalsk (Karakol), the eastern stage for steamer communication with the west of the lake, from which a comparatively easy route leads to the railhead at Tokmak, is most used, since it links south with the Ak-su oasis by the Bedel pass (14,055 ft.). Another route from Ak-su, involving a steep climb of 11,817 ft. over the Muzart pass in China, on the east of Khantengri, leads to the Tekes river.

The narrow plain which fringes the lake extends inland for 46 mi. to the east and then rises to the Santash pass, 1.922 ft. above the level of the lake (7,201 ft. above sea level), which forms a link between the Terskei Ala-tau and the Kunghei Ala-tau. A route from the east of the lake crosses this pass to Kulja in Sinkiang. There is an abundance of blossom, especially at the eastern end of the lake where beekeeping is profitable, more than 800 tons of honey being exported per annum. There are few trees, except in the valleys of the streams entering the lakes. Numerous small streams reach the lake from the mountain slopes, the two chief being the Tyup and Dzhirgalan from the east. The Chu river rises in several streams to the west of the lake and approaches the western extremity very closely in a curve which it takes before flowing northwest to lose itself in the desert; it is incorrectly shown on some maps as draining from Issyk-kul. **A**

marsh extends between the bend of the Chu and the lake, and a tiny stream drains from this marsh into Issyk-kul. Issyk-kul probably at one time drained through the Baum gorge at the northwest extremity of the lake, through which the route now goes to Tokmak and the Russian settlements on the fertile loess strip extending to Frunze. The present level of the lake is lower than in former times, and sandy marshes overgrown with reeds, the haunts of the wild boar and the tiger, have spread on the sites formerly occupied by the lake. Fish, especially carp, abound in the lake; its waters are too salty to provide drinking water. The soils on the shore of the lake are sandy, but in a few places there are fertile clayey patches. The nomad herdsmen pasture their flocks in the Issyk-kul valley in winter and on the high meadows in summer.

Along the narrow route by the southern shores of the lake passed the tribes driven westward by the Huns, notably the Indo-Scythian Yue-chi (*q.v.*) and the blue-eyed and fair-haired Uzuns, or Ussuns, from central Asia at the end of the 2nd century B.C. The former passed farther west, but' the latter settled in the valley and built the town of Chi-gu near the Tyup river, which still existed in the jth century. The rude stone images of the Uzuns are sometimes washed up from the lake and are of a type distinct from those of the Kalmucks or Kirghiz; a huge copper cauldron of the Czuns was washed ashore in 1842. The Uzuns disappear from history after the 5th century, but the fair-haired, blue-eyed, straight-nosed element sometimes met with among the Kirghiz of the Issyk-kul region indicates that they were probably absorbed by these tribes. The valley is at present occupied by the On (right or east) section of the Kara-Kirghiz, with Russian settlements at the eastern end of the lake. Hsuan Tsang (q v.), the Chinese Buddhist pilgrim. passed south of Issyk-kul in the 7th century and has left a description of the region. In the early 14th century Nestorian Christians founded a monastery on the northern shores of the lake, indicated on the Catalan map of 1374. The famous Russian explorer Nikolai Prjevalsky (*q.v.*) died at Karakol (now Przhevalsk) in 1888. The region was annexed to Russia in 1864.

ISTANBUL (formerly CONSTANTINOPLE), the largest city and seaport of the Turkish republic and the capital of Turkey until 1923.

The old walled city of Istanbul is situated on the western (European) shore of the Bosporus, a strait about 18.6 mi long linking the Black sea with the Sea of Marmara (Marmora). Guarding the Marmara end of the strait, it strategically occupies a triangular promontory, washed on the north by the Golden Horn (Halic), a narrow inlet, about 4.5 mi. deep, which forms an excellent harbour. A broad valley, through which there once flowed a small stream, the Lycus. divides the promontory from west to southeast into two masses of elevated ground: a long ridge overlooking the Golden Horn and an isolated hill in the southwest The ridge consists of six eminences, so that, all together, there are seven hills upon which Constantinople, like Rome, is said to be enthroned The first hill has the Seraglio palace. Hagia Sophia and the Hippodrome; the second the column of Constantine and the Nuruosmaniye mosque: the third the university and the mosque of Sultan Suleiman; the fourth the mosque of Mehmed II Fatih: the fifth the mosque of Sultan Selim; the sixth, which is the highest (250 ft.), the Edirne or Adrianople gate and Mihrimah mosque; the seventh, called in the middle ages Xerolophos ("dry hill"), is occupied by the quarter of Alti Mermer.

The Golden Horn, which is spanned by the Ataturk and the Karakoy-Eninonu bridges, divides old Istanbul, which contains the greater part of the city's archaeological heritage, from the quarters of Galata, once a separate walled city, and Beyoglu (formerly Pera). Facing Istanbul on the Asiatic side are Uskudar (ancient Chrysopolis) and Kadikoy (ancient Chalcedon). "Greater Istanbul." as it may be called, embraces not only these localities but an almost uninterrupted, though narrow, ribbon of settlements on both sides of the Bosporus and, for a considerable distance, on both the European and Asiatic shores of the Sea of Marmara. The inhabited areas stretch from old Istanbul to Kucukcekmece, about 18 mi. to the southwest and. on the opposite shore, from Uskudar to Pendik, a distance of about 16 mi. Close to the Asiatic shore of the Sea of Marmara, about 10 mi. from Istanbul, lie the Kizil Adalar or Princes Islands (*q.v.*), a cluster of four big and five small islands, used as a summer resort. Suburban developments have rapidly expanded, especially after World War II. The area enclosed by the municipal boundaries is 98 sq.mi., of which only approximately 9 sq.mi. are occupied by the old city.

Climate.—By virtue of its situation, Istanbul is influenced both by the climate of the Mediterranean and by that of the Black sea. The climate shows great variation depending on the prevailing wind: the north wind (*poyraz*) is the most frequent, resulting in a generally temperate climate. The south wind (*lodos*) is warm and damp, sometimes causing storms in the Sea of Marmara. In the winter a northwest wind (karayel) often blows from the mainland, bringing snow and short periods of intense cold. In general, fine weather lasts from May until October and often later. The most pleasant season is the autumn. The average annual temperature is 57° F., the average temperature of the coldest month (February) is 41° and of the warmest months (July and August) 73". Istanbul is subject to severe earthquakes which over the centuries have caused great damage to the monuments of the city.

HISTORY

Byzantium was the original name of the city before it was renamed Constantinople. The origin of Byzantium (allegedly so called after its mythical founder Byzas) is to be sought in the context of trading relations between Greece and the Black sea. Greek colonists, largely from the cities of Miletus and Megara, set up trading posts on the shores of the Propontis (Sea of Marmara) from the end of the 8th century B.C. onward. Byzantium nas a Megarian colony. According to tradition, it was founded about 657 B C. against strong resistance on the part of the native Thracian tribes. Byzantium fell under the sway of the Persian empire at about the time of the Scythian expedition of Darius I (512 B C.). Persian domination, temporarily interrupted during the Ionic revolt, continued until 478 B.C. when the city was captured by a Greek fleet Thereafter Byzantium became part of the Athenian confederacy; its growing prosperity is evidenced by the .Athenian tribute lists in which Byzantium figures as one of the most important contributors. In 411 B.C., however. with the decline of Athenian power during the Peloponnesian War (*q.v.*), Byzantium acknowledged Spartan supremacy. The city was recaptured after a siege by Alcibiades (*q.v.*), but after the total defeat of the Athenians, it fell once more under Spartan domination (405 B C.).

In 377 B.C. Byzantium joined the Second Athenian League. In 740 B C it was unsuccessfully besieged by Philip II (*q.v.*), king of Macedonia, whose failure ensured the independence of the city throughout the Hellenistic period. Even after the Roman conquest of the east, Byzantium remained free until its autonomy was taken away by Vespasian (AD. 70–79), although it was later restored. In 196 Byzantium, which had sided with the usurper Pescennius Niger, was captured after a long siege by Septimius Severus. Its walls were razed and its inhabitants massacred For a while it ceased to be a city and was annexed to Perinthus (Heraclea). But Severus soon changed his mind: Byzantium was not only restored but even enlarged, and renamed Antoninia after Severus' son M. Aurelius Antoninus (Caracalla).

The civil war between Constantine and Licinius was decided on the banks of the Bosporus. It was at Chrysopolis that Licinius suffered his final defeat (Sept. 18, 324). Immediately after this, Constantine, who must have been impressed by the strategic advantages of the straits, decided to make Byzantium his new capital. The foundation rites were celebrated on Nov. 8, 324; on May 11, 330, the imperial city, greatly enlarged, was officially inaugurated. It then bore the names of the New Rome and Constantinopolis (from the Greek Konstantinou polis, "Constantine's city").

Practically nothing remains of ancient Byzantium The city occupied the tip of the promontory and was protected by a line of walls (renowned in antiquity as being among the strongest of Greece) which described an arc starting approximately at modern

Sirkeci and ending on the Sea of Marmara east of the Hippodrome. The walls were rebuilt by Severus who carried them forward to the point later occupied by Constantine's forum (Cemberlitas). Severus also built a number of public monuments including the Hippodrome, which he left unfinished, the baths of Zeuxippus (next to the Hippodrome), a theatre and an arena for the exhibition of wild animals, and streets lined with porticoes. (See also BYZANTIUM.)

Constantinople.—The city, as rebuilt by Constantine, covered a much larger area. The walls extended from roughly the quarter of Fener on the Golden Horn to that of Samatya on the Sea of Marmara. Inside this enlarged circuit Constantine erected the buildings appropriate for an imperial capital. In the centre of an elliptical forum was placed a porphyry column (still standing) which supported the radiate statue of the emperor as Apollo Helios. Next to the forum rose the Senate house. The Hippodrome was completed and alongside it was built an imperial palace which remained the residence of the Byzantine emperors until the 12th century; this was known as the Great or Sacred palace. The palace opened onto a square called the Augustaion. Constantine also founded the church of Irene (Peace), which still stands although not in its original form, and the church of the Holy Apostles (now replaced by the Fatih mosque). The city was decorated with a multitude of statues that were removed from the principal towns of the eastern Mediterranean. New settlers were attracted by free distribution of bread and the granting of citizenship rights.

Constantinople experienced a period of rapid growth and building activity under Constantine's immediate successors. By the end of the 4th century Constantine's walls were already too narrow to contain the sprawling city. This factor, combined with the rising danger of barbarian invasion, dictated the erection of a new line of walls, which was done in the reign of Theodosius II by the praetorian prefect Anthemius (413). The walls along the shores of the city were constructed in the same reign by the praetorian prefect Cyrus (439). The area enclosed within the new walls was so large that no further need arose to extend them. The Theodosian walls are still standing.

The peak of medieval Constantinople was reached in the reign of Justinian I (527–565). The population of the city at the beginning of his reign may be estimated at about 500,000. In 532 a large part of the city was burned during the Nika insurrection, a bloody uprising of the Hippodrome factions. This gave Justinian an opportunity to indulge his passion for building. The basilica of Hagia Sophia (St. Sophia), probably built A.D. 360 by Constantius, son of Constantine, and dedicated not to a saint but to Divine Wisdom, was re-erected on a colossal scale (532–537). In addition, Justinian's building activity is represented today by the churches of St. Irene and SS. Sergius and Bacchus (Kucuk Ayasofya Camii) and by two great underground cisterns, that supposedly built by Philoxenus (Binbirdirek) and the Cisterna basilica (Yerebatan Sarayi). But these structures represent only a fraction of the buildings that Justinian put up in Constantinople, and which included upward of 20 churches, among them the famous basilica of the Holy Apostles (originally founded by Constantine), palaces, hospices, administrative buildings, colonnades and harbours.

The subsequent decline of Constantinople dates from the great plague which struck the city in 542 and is said to have killed 300,000 persons. As for the rest of the Byzantine empire so with Constantinople, the late 6th, 7th and 8th centuries were a period of extreme hardship and privation, followed by slow recovery in the 9th century. Building activity in Constantinople followed this curve; it was almost at a standstill during the period of decline, except for necessary works of fortification, then picked up again in the 9th century and continued until the end of the 12th, though on a smaller scale than in the period from Constantine to Justinian.

Throughout the middle ages Constantinople underwent a number of sieges, the mast serious being: by the Persians and Avars in 626, by the Arabs in 674–678 and 717–718, by the Bulgarians in 813 and 913, by the Russians in 860, 941 and 1043, by the Pechenegs in 1090–91. All of these were successfully resisted; it was not until 1204 that Constantinople fell to a foreign foe. For later sieges see below.

In 1082 the Venetians were given special trading privileges and quarters in Constantinople; they were followed by the Pisans, Amalfitans, Genoese and other Italians. Maritime trade. upon which the prosperity of Constantinople depended, was henceforth to be in the hands of westerners. Friction between the native and foreign elements culminated in a terrible massacre of the latter in 1182.

In 1203 the armies of the fourth crusade. deflected from their objective in the Holy Land, appeared before Constantinople ostensibly to restore the legitimate emperor, Isaac II. The city fell, but for a year remained under Byzantine government. On April 13. 1204, the crusaders once more captured the city and this time gave themselves to indiscriminate pillage and massacre. A western emperor, Baldwin of Flanders, was then chosen to rule in Constantinople, while the church fell under the control of the venetians who had been the prime instigators of the crusade. The Byzantines retrenched themselves in Nicaea and in the Epirus. while the remainder of their empire was partitioned by the westerners. The period of Latin rule (1204–61) was the most disastrous in the history of Constantinople: the city was systematically ransacked, all valuables and especially sacred relics were removed to the west, even the bronze statues were melted down for coin.

In 1261 Constantinople was retaken by Michael VIII Palaeologus, Greek emperor of Nicaea. For the next two centuries the shrunken Byzantine empire, threatened both from the west and by the rising power of the Ottoman Turks in Asia Minor, led a precarious existence. Some building was carried out at the end of the 13th and beginning of the 14th century, but thereafter the city was in a state of complete decay, full of ruins and tracts of deserted ground, contrasting with the prosperous condition of Galata across the Golden Horn. which had been granted to the Genoese by Michael VIII. When the Turks crossed into Europe in the mid-14th century the fate of Constantinople was sealed. The inevitable end was retarded by the defeat of the Turks at the hands of Timur (*q.v.;* Tamerlane) in 1402; but in 1422 Sultan Murad II laid siege to Constantinople. This attempt failed, only to be repeated 30 years later. In 1452 Sultan Mehmed (Mohammed) II proceeded to blockade the Bosporus by the erection of a strong fortress at its narrowest point; this fortress, called Rumeli Hisari, still forms one of the principal landmarks of the straits. The siege of the city began in April 1453. The Turks had not only overwhelming numerical superiority but also cannon which breached the ancient walls. The Golden Horn was protected by a chain. but the sultan succeeded in hauling his fleet by land from the Bosporus into the Golden Horn. The final assault was made on May 29 and, in spite of the desperate resistance of the inhabitants aided by the Genoese, the city fell. The last Byzantine emperor, Constantine XI, was killed in battle. For three days the city was abandoned to pillage and massacre, after which order was restored by the sultan.

As an ecclesiastical centre, Constantinople became the seat of a patriarch in 381 (see CONSTANTINOPLE. ECUMENICAL PATRIARCHATE OF). His rank was defined as being next only to that of the bishop of Rome. The patriarch of Constantinople is still the nominal head of the Orthodox Church. A patriarch of the Armenian Church also resides there. Constantinople was the seat of three ecumenical councils, the second (381), fifth (553) and sixth (680–681), as well as of many important local councils. The famous fourth ecumenical council was held in a suburb of Constantinople, at Chalcedon in 451 (see COUNCIL).

Istanbul.— At the time of its capture Constantinople was almost deserted. Mehmed II took measures to repeople it by transferring to it populations from other conquered areas such as the Peloponnese, Salonica and the Greek islands. By c. 1480 the population rose to between 60,000 and 70.000. Hagia Sophia and other Byzantine churches were transformed into mosques. The Greek patriarchate was retained, but moved to the church of St. Mary Pammacaristos (Fethiye Camii), later to find a perma-

nent home in the Fener. The sultan built the Old Seraglio (Eski Saray), now destroyed, on the site occupied at present by the university, and a little later the Seraglio (Topkapi Sarayi) which is still in existence; he also built the Eyup mosque at the head of the Golden Horn and the Fatih mosque on the site of the basilica of the Holy Apostles. The latter mosque was destroyed by the earthquake of 1766 and was subsequently rebuilt. The capital of the Ottoman empire was transferred to Constantinople from Adrianople (Edime) in 1457. The Turkish name Istanbul or Istanbol, attested before 1453, is a corruption of vulgar Greek *Stimboli* (eis tin *polin*); *i.e.*, "in the city."

After Mehmed II Istanbul enjoyed a long period of peaceful growth, interrupted only by earthquakes, fires and pestilences. The sultans and their ministers devoted themselves to the building of mosques, palaces, charitable foundations and fountains, so that the aspect of the city was soon completely transformed. The most brilliant period of Turkish construction coincides with the reign of Suleiman the Magnificent (1520–66).

The next major change in the history of Istanbul occurred at the very beginning of the 19th century with the approaching dismemberment of the Ottoman empire, the liberation movements in the Balkans and the era of internal reforms (tanzimat). The reforms were accompanied by serious disturbances, such as the massacre of the Janissaries in the Hippodrome (1826). With the triumph of the progressive Sultan Mahmud II over the conservative opposition. the westernization of Istanbul started apace. There was an ever-growing influx of European visitors who, since the 1830s. could reach Istanbul by steamship. The first bridge across the Golden Horn was built in 1838. In 1839 Sultan Abdul-Medjid I issued the charter of Gulhane guaranteeing to all his subjects, whatever their religion, the security of their lives and fortune. The process of westernization was further accelerated by the Crimean War (1853–56) and the quartering of British and French troops in Istanbul. The latter part of the 19th and beginning of the 20th century were marked by the introduction of various public services: the European railroad extending to Istanbul was built in 1871; the underground tunnel joining Galata to Pera in 1873; a regular water supply for Istanbul and the settlements on the European side of the Bosporus was brought from Lake Terkos on the Black sea coast (29 mi. distant from the city) by the French company. La Compagnie des Eaux, after 1885; electric lighting was introduced in 1912 and electric streetcars and telephones in 1913 and 1914. An adequate sewage system had to wait until 1925 and later.

In the first quarter of the 20th century Istanbul experienced various disasters marking the death of the Ottoman empire and the birth of modern Turkey. In 1908 the city was occupied by the army of the Young Turks who deposed the hated sultan Abdul-Hamid II. During the Balkan Wars (1912–13) Istanbul was nearly captured by the Bulgarians. Throughout World War I the city was under blockade. After the conclusion of the armistice (1918) it was placed under British, French and Italian occupation which lasted until 1923. The Greek-Turkish war in Asia Minor. as well as the Russian revolution, brought thousands of refugees to Istanbul. With the victory of the Nationalists under Mustafa Kemal Ataturk, the sultanate was abolished and the last sultan, Mehmed VI, fled from Istanbul (1922). After the signing of the Lausanne treaty, Istanbul was evacuated by the Allies (Oct. 2, 1923) and Ankara was chosen as the capital of Turkey (Oct. 13, 1923). On Oct. 29 the Turkish republic was proclaimed. Because of Turkey's neutrality during most of World War II, Istanbul suffered no damage, although a German invasion was feared after the Balkans had been conquered by the Axis. In 1955 Istanbul (as also Izmir) was the scene of severe anti-Greek riots, related to the differences between Greece and Turkey over Cyprus, in which Greek shops and property mere wrecked. The influx of automobiles brought acute traffic problems to Istanbul, especially after World War II. By the early 1960s large tracts of the city had been demolished or cleared to make way for modem highways.

MONUMENTS

Byzantine Monuments. — The most impressive vestige of secular Byzantine architecture in Istanbul is the city walls. The land walls, about 4.5 mi. long, consist of a double line of ramparts, the inner one erected in 413, the outer one in 447, and a moat. The inner wall is about 40 ft. high and 15 ft. thick, and is guarded by towers, about 60 ft. high at intervals of about 180 ft. The outer wall, which is lower, is also provided with towers. The walls were repaired at different periods and bear inscriptions to that effect. The seaward walls consist of a single line. Those along the Sea of Marmara are tolerably well preserved, while those along the Golden Horn have almost disappeared. Near the junction of the land walls with the Marmara walls stands the Golden gate, a triumphal arch flanked by square marble towers, erected *c.* 390.

The Byzantine palaces have almost completely perished. An excavation on the site of the Great palace, carried out by a Scottish expedition starting in 1935, has resulted in the discovery of a peristyle with a magnificent mosaic pavement probably dating from the late 6th century A.D. The only reasonably well-preserved example of Byzantine palace architecture in Istanbul is the so-called Tekfursarayi, attached to the land walls not far from the Golden Horn. It is the shell of a three-story rectangular building, and dates from c. 1300.

Of the famous Hippodrome only its curved end remains as well as three monuments on its longitudinal axis: the granite obelisk of Theodosius I, originally erected at Karnak in Egypt by Thutmosis III (c. 1504–1490 B.C.), the masonry obelisk of Constantine VII (A.D. 913–959). once covered with bronze plaques, and the mutilated Delphic serpent made after the battle of Plataea (479 B.C.). Of the many monumental columns which decorated Constantinople there remain only Constantine's porphyry column near the Nuruosmaniye mosque, the base of the column of Arcadius (395–408) in the Cerrahpasa quarter, the column of Marcian (450–57), known in Turkish as Kiztasi (column of the virgin), in the Fatih quarter, and a perfectly preserved Corinthian column in the grounds of the Seraglio presumably dating from the reign of Claudius II Gothicus (268–270).

Istanbul has a great number of underground Byzantine cisterns. These usually have vaulted roofs supported on columns. The most impressive of these are the Cisterna basilica near Hagia Sophia. which has 336 columns and still contains water, and the cistern of Philoxenus near the Hippodrome, which has 224 columns; the Philoxenus cistern is now dry. There are also four enormous open-air cisterns. one of which is outside the city.

Of the Byzantine churches the most important is Hagia Sophia, rebuilt 532–537, converted into a mosque in 1453 and into a museum in 1935. It is a rectangle 252 ft. long, 234 ft. wide, covered with an immense dome 110 ft. in diameter, rising to a height of 186 ft. The uncovering and cleaning of the mosaics of Hagia Sophia has been carried out by the Byzantine Institute of America, which began this work in 1931. There are about 25 other Byzantine churches in Istanbul, many of which are still used as mosques. The most interesting are: the ruined basilica of St. John of Studius (Imrahor Camii), founded in 463 by the patrician Studius, once the seat of a famous monastery; the octagonal church of SS. Sergius and Bacchus, built by Justinian between 527 and 536; the church of St. Irene, built in its present form by Justinian and used until about 1950 as a military museum; Church of the Saviour Pantocrator (Zeyrek kilise Camii) of the 12th century, with a magnificent inlaid pavement; the Virgin Pammacaristos (Fethiye Camii) of the 11th and 14th centuries, with interesting mosaics; and the Church of St. Saviour in Chora (Kahriye Camii), restored in the 11th century and extensively remodelled in the 14th. Kahriye Camii, now a museum. has a splendid mosaic decoration dating from c. 1320; this too has been cleaned and consolidated by the Byzantine Institute of America. (*See* also BYZANTINE ARCHITECTURE; BYZANTINE ART.)

Turkish Monuments. — The sultans' Seraglio (Topkapi Sarayi) is now a museum. With its gardens it occupies the entire tip of the promontory and is enclosed within a fortified wall. Begun by Mehmed II in 1462, it served as the residence of the sultans until the beginning of the 19th century. The Seraglio consists mostly of small buildings grouped around three courts. The most sig-

nificant buildings are the Faience kiosk (Cinili kosku) built in 1472, the Audience chamber (Arzodasi), the Hirkaiserif, a sanctuary containing relics of the prophet Mohammed, and the elegant Baghdad kiosk (Bagdat Kosku) commemorating the capture of Baghdad in 1638. The Seraglio houses the sultans' treasure and has important collections of manuscripts, china, armour, textiles, etc. After the abandonment of the old Seraglio, the sultans built for themselves palaces along the Bosporus, such as the Beylerbey palace (1865), the lavish Dolmabahce palace (1853). the Ceragan palace built in 1874 and burned in 1910 and the Yildiz palace which was the residence of Abdul Hamid II.

It is to its mosques that Istanbul owes its distinctive skyline. Architecturally. they may be separated into three groups. those built before *c.* 1500 reproducing the archaic formulas that had been applied by the Turks in the mosques of Nicaea (Iznik). Bursa and Adrianople (Edirne) ; the "classical" group which extends into the 17th century and is influenced by Byzantine architecture, especially by Hagia Sophia; later mosques marked by the introduction of western, first baroque and then neoclassical. elements The principal mosques of the first period are Mahmud Pasa Camii (1464), Murad Pasa Camii (1466), Atikalipasa Camii (1497) and. a little later, Sultan Selim Camii (1520). The "classical" period opens with Sultan Beyazid Camii (1501–05). and finds its highest expression in the work of the architect Sinan, viz. Sehzade Camii or Princes' mosque (1544–48), Suleymaniye Camii (1550–57), the masterpiece of Ottoman architecture in Istanbul. Mihrimah Camii and Rustempasa Camii (both middle of the 16th century) the latter famous for its Iznik faience tiles. Ahmed Pasa Camii (1555), Sokollu Mehmed Pasa Camii (1572). and Kilicalipasa Camii at Tophane (1580), a close replica of Hagia Sophia. The classical style is continued in Sultan Ahmed Camii (1616), popularly known as the Blue mosque and having six minarets, more than any other mosque of Istanbul: and Yeni Valide Camii or New mosque (1614–63), at the head of the Eminonu bridge. The most important specimens of the baroque period are Nuruosmaniye Camii (1755) near the Grand bazaar, Laleli Camii or the Tulip mosque (1763) and Fatih Camii (1767–71). Later mosques are of lesser interest.

Other curious examples of Turkish construction are the numerous fountains, the most elaborate being that of Sultan Ahmed III (1728) behind the apse of Hagia Sophia; the mausoleums of the sultans and their relatives, usually attached to mosques, especially those of Mehmed II by the Fatih mosque, Suleiman the Magnificent and his wife Roxelana by the Suleymaniye Camii. Murad III and Selim II by Hagia Sophia and Ahmed I on the Hippodrome; other appendages of mosques such as schools (*medrese*) and hostels for the poor (imaret) ; and bazaars, like the labyrinthine Grand bazaar (Buyuk Carsi) and the Egyptian market (Misir Carsi) at Eminonu. (*See* also ISLAMIC ARCHITECTURE : *Turkey.*)

Museums. — In addition to historical monuments which have been converted into museums. Istanbul possesses an important Archaeological museum containing Greek, Roman and Byzantine antiquities. Its most prized possession is the so-called Alexander sarcophagus of the 4th century B.C. as well as other sarcophagi found at Sidon. A special section of the museum is devoted to oriental antiquities; *e.g.,* Hittite, Assyrian. Babylonian and Egyptian.

POPULATION, ADMINISTRATION AND ECONOMY

Population. — Istanbul has always been a cosmopolitan city. Although census figures are not always reliable, it appears that the population of Istanbul was on the increase until World War I; thereafter it dropped. but has been increasing steadily since 1930. The count of 1876 showed 873,565 persons within the city limits; that of 1927 showed 690,857, of whom 447,851 were Muslim Turks and 243,066 non-Muslims (mostly Greeks, Jews and Armenians), including foreigners. The non-Muslim element has been dwindling; in 1945, out of a total population of 860,558, there were 663,278 Muslims, 147,568 Christians and 49,239 Jews. In 1960 the total population was 1,459,528.

Education. — Istanbul possesses a university founded in 1846 with faculties of letters, science, law, medicine and forestry; it is located in the buildings of the former Seraskerat (mar ministry). There are also a Technical university on the Galata side of the Horn, an Academy of Fine Arts, schools of technology, commerce and economics. Foreign educational institutions include the American Robert college for boys (founded 1863) and the American college for girls (founded 1871). both on the Bosporus; an English high school for boys and-one for girls; and the French-Turkish lycée of Galatasaray (founded 1867).

BY COURTESY OF TURKISH INFORNATION AND TOURIST DEPARTMENT

DOLMABAHCE MOSQUE, BUILT IN 1853, ON THE EUROPEAN SIDE OF THE BOSPORUS, WITH DOLMABAHCE PALACE IN BACKGROUND

Administration. — The municipal prefect of Istanbul is also the governor of the province (il) and is appointed by the president of the republic. The municipality (belediye) is divided into 12 circumscriptions (*kazas*), each governed by a kaymakam: Eminonu. Fatih (in the old city), Eyup. Bakirkoy, Beyoglu, Sisli, Besiktas. Sariyer (on the European side). Beykoz, Uskudar, Kadikoy, Adalar (on the Asiatic side).

Commerce and Communications. — Istanbul is the largest port of Turkey as well as being the industrial centre of the country. Maritime traffic, affected by the international situation, has remained somewhat sluggish owing to restricted intercourse with the Black sea countries. There are shipbuilding yards in the Golden Horn. Goods manufactured in the city include textiles, pottery, leather, cigarettes, liqueurs. flour. cement, glass and soap. Another growing source of revenue is tourism.

Istanbul is the terminus of the

international rail service (the former Orient Express) Paris-Milan-Belgrade-Sofia or Salonica-Istanbul, and the starting point (at Haydarpasa on the Asiatic side) of the Baghdad railway. The city is served by numerous maritime lines. From the airport of Yesilkoy, 17½ mi. W. of the city, there are services to most of the major cities of the world.

Internal communication of the city is served by buses which have now replaced streetcars, and an extensive network of ferries connecting the Galata bridge with the villages of the Bosporus. the Asiatic coast as far as Yalova, the Princes Islands and the Golden Horn.

Istanbul Province. — The *il* of Istanbul lies between longitude 28° and 30° and latitude 40° 45' and 41° 45', covering an area of about 2,080 sq.mi. It is bisected by the Bosporus and includes on the European side the towns of Silivri and Catalca, and on the Asiatic side Sile, Kartal and Yalova. The area has small deposits of metal and lignite. Agriculture is not developed apart from vegetable and fruit growing. The population of the province was 805,707 in 1927 and 1,542,941 in 1955.

ISTHMUS, a narrow strip of land connecting two larger land areas otherwise separated by the sea. Unquestionably the two most famous are the Isthmus of Panama, connecting North and South America, and the Isthmus of Suez, connecting Africa and Asia. Historically the Isthmus of Corinth was of major importance because it connected what otherwise would be the island of Peloponnese with the rest of the Greek peninsula. Isthmuses are of great importance in plant and animal geography because they offer a path for the migration of land plants and animals between the two great land masses that they connect.

(W. C. C.)

ISTRIA (ISTRA), after 1918 the Italian province of Pola, in the region of Venezia Giulia; area 1,435 sq.mi. In 1947 most of Istria passed to Yugpslavia, where it was divided along ethnic lines between Croatia and Slovenia. It comprises most of the Istrian peninsula (area 1,545 sq.mi.), stretching into the Adriatic between the Gulf of Trieste and the Gulf of Quarnero, and the islands of Cherso, Lussino and others. The coast line extends for 267 mi. and is indented on the west by the bays of Muggia, Capodistria, Pirano, Port Quieto and Pola, and on the east by those of Medolino, Arsa, Fianona and Volosca. A great portion belongs to the Carsic region and is occupied by the so-called Istrian plateau, flanked north and east by mountains (Monte Maggiore [Ucka], 4,580 ft.). It slopes south and west in undulating terraces toward the Adriatic. The Quieto in the west and the Arsa in the east, neither navigable, are the principal streams. The climate is warm and dry. The coasts are exposed to the sirocco from the south-southeast and the bora from the northeast. Wheat, maize, rye. oats, olives, figs and melons are grown. Viticulture is well developed. and the best sorts of wine are produced near Capodistria. Muggia, Isola, Parenzo and Dignano, while well-known red wines are made near Refosco and Terrano. The oil of Istria was already famous in Roman times. Cattle are bred. and lumbering gives beech and oak timber (good for shipbuilding), gallnuts, oak bark and cork. Fishing, recovery of salt from the sea water and shipbuilding are other occupations.

Istria was the ancient Istria or Histria, known to Rome as the, abode of fierce Illyrian pirates. It owed its name to an old belief that the Danube (Ister, in Greek) discharged some of its water by an arm entering the Adriatic in that region. The Istrians, protected by the difficult navigation of their rocky coasts, were subdued by Rome only in 177 B.C. after two wars. Under Augustus the greater part of the peninsula was added to Italy, and the later removal of the capital to Ravenna advantaged Istria. After the fall of the western empire it was pillaged by Longobardi and Goths; it was annexed to the Frankish kingdom by Pepin in 789; and about the middle of the 10th century it fell to the dukes of Carinthia, then successively to the dukes of Meran. the duke of Bavaria and the patriarch of Aquileia and the republic of Venice. Under this rule it remained until 1797, when Austria added it to the northeastern part which had fallen to its share as early as 1374. By the peace of Pressburg. Austria was in 1805 compelled to cede Istria to France. and the department of Istria was formed, but in 1813 Austria regained it and retained it until 1918.

ITACOLUMITE, a variety of porous yellow sandstone or quartzose schist occurring at Itacolumi, in the southern portion of Minas Gerais, Brazil The rock is of interest for two reasons. it is believed to be the source of the abundant diamonds of the district, and it is the best-known example of a flexible sandstone. If a piece 1 ft. in length and about ½ in. thick is supported at its ends, it will gradually bend under its own weight; if it then is turned over, it will bend in the opposite direction. The cause of the flexibility is ascribed to the porous character of the rock and the interlocking of the sand grains. (P. G. H. B.)

ITAGAKI, TAISUKE COUNT (1837–1919), Japanese statesman, was born in Tosa in 1837 He distinguished himself originally as one of the soldier politicians who contributed so much to the overthrow of feudalism and the restoration of the administrative power to the throne. After taking a prominent part in subduing the resistance offered by a section of the shogun's feudatories to those changes, he received cabinet rank in the newly organized system. But in 1873 he resigned his portfolio as a protest against the ministry's resolve to refrain from warlike action against Korea. Itagaki feared that the country was about to pass under the yoke of a bureaucratic government. He became thenceforth a warm advocate of constitutional systems, though at the outset he does not seem to have contemplated anything like a popular assembly in the English sense of the term, his ideas being limited to the enfranchisement of the samurai class. Failing to obtain currency for his radical propaganda, he retired to his native province, and there established a school (the Risshi-sha) for teaching the principles of government by the people, thus earning for himself the epithet of "the Rousseau of Japan." His example found imitators. Not only did pupils flock to Tosa from many quarters, attracted alike by the novelty of Itagaki's doctrines, by his eloquence and by his transparent sincerity, but similar schools sprang up among the former vassals of other fiefs, who saw themselves excluded from the government. In 1875 no fewer than seven of these schools sent deputies to hold a convention in Osaka, and an appeal to force seemed possible.

But the statesmen in power were not less favourable to constitutional institutions than the members of the Aikoku Ko-to (Public Party of Patriots), as Itagaki and his followers called themselves. A conference attended by Kido. Okubo, Inouye, Ito, Itagaki and others entered into an agreement by which they pledged themselves to the principle of a constitutional monarchy and a legislative assembly. Itagaki now accepted office once more. Finding, however, that his colleagues in the administration favoured a much more leisurely rate of progress than he himself advocated, he once more retired into private life (1876) and renewed his liberal propagandism. It is in the nature of such movements to develop violent phases, and the leaders of the Aikokusha (Patriotic association), as the agitators now called themselves, not infrequently showed disregard for the preservation of peace and order. Itagaki made the mistake of memorializing the government at the moment when its very existence was imperilled by the Satsuma rebellion (1877), and this evident disposition to

take advantage of a great public peril went far to alienate the sympathies of the cabinet. Recourse was had to legislation in restraint of free speech and public meeting. But repression served only to provoke opposition.

Throughout 1879 and 1880 Itagaki's followers evinced no little skill in employing the weapons of local association, public meetings and platform tours, and in Nov. 1881 the first genuine political party was formed in Japan under the name of *Jiyū-tō*, with Itagaki for declared leader. A year later the emperor announced that a parliamentary system should be inaugurated in 1891, and Itagaki's task might be said to have been accomplished. Thenceforth he devoted himself to consolidating his party. In the spring of 1882, he was stabbed by a fanatic during the reception given in the public park at Gifu. The words he addressed to his would-be assassin were: "Itagaki may perish, but liberty will survive." Once afterward (1898) he held office as minister of home affairs, and in 1900 he stepped down from the leadership of the *Jiyū-tō* in order that the latter might form the nucleus of the *Seiyū-kai* organized by Count Ito. Itagaki was raised to the nobility with the title of count in 1887. From the year 1900 he retired into private life, devoting himself to the solution of socialistic problems. His countrymen justly ascribe to him the fame of having been the first to organize and lead a political party in Japan. He died in 1919.

True to his liberal principles, he forbade his son to apply for the succession of his title and it lapsed.

ITALIAN FRONT, IN WORLD WAR I. On the outbreak of World War I the Austro-Italian frontier, as delimited after the war of 1866, was about 600 km. in length, four-fifths of it in the mountain zone and a considerable part in the high Alps. To some extent it corresponded with the crest of the mountains, but in several areas it was well to the S. or W. of it, and almost everywhere the summits and the most favourable positions were held by Austria. Commencing at the top of the Stelvio pass, it followed the Alpine ridge to the Tonale, deflected S. to the Adamello group and the lake of Idro, turned E. across the Lago di Garda, S. of Riva, ascended the M. Altissimo of the Baldo group, crossed the Adige S. of Borghetto, turned N.E. along the outer edge of the Asiago plateau, E. along the Cime Portule, Dodici, Undici, crossed the Brenta below Grigno, kept along the ridge of the Cadore mountains, crossed the Cordevole S. of Livinallongo, passed S. of Cortina d'Ampezzo, reaching the Carnia Alps at M. Popera, keeping due E. along the crest to the source of the Pontebba stream, turned S. along Morlasio, M. Canin, M. Maggiore and M. Kolovrat, W. of the Isonzo, followed the Judrio, crossed the Torre below its confluence with the Natisone, passed E. of Palmanova, and reached the sea between the lagoons of Murano and Grado. It formed two salients—that of the Trentino, driven like a wedge into the heart of the Venetian plain, with 12 military roads spreading fanlike from it in all directions, and that of the Friuli extending towards the Isonzo; the former was much more favourable to Austria than the latter was to Italy.

On the Italian side there was a main line of railway from Milan to the Austrian frontier at S. Giorgio di Nogaro, with a line pushing N. from Verona to the Austrian frontier at Borghetto, and another from Mestre N.E. to the frontier at Pontebba, a line parallel to the E. frontier from Udine to Palmanova, and a number of branch lines. On the Austrian side there were the main lines from the Brenner to the frontier, from Leoben to Pontebba and from Graz to Trieste and San Giorgio di Nogaro, an intermediate line along the Pusterthal, another from Klagenfurt to Gorizia and Monfalcone and various branch lines.

As soon as Italy intervened in the war the Italian troops effected a forward push and succeeded in some sectors in securing more favourable positions—the Tonale, M. Baldo, Col Santo, Pasubio, Vallarsa and Valsugana sectors of the Alpine front (see TRENTINO), and crossed the upper Isonzo at Caporetto, occupying the Monte Nero and Plezzo areas. On the middle and lower Isonzo the advance was held up by the defenses of the town of Gorizia (*q.v.*) and the Carso, although the river was eventually crossed at Pieris and other points and Monfalcone occupied. Subsequently, after heavy fighting, the enemy having been able to strengthen the naturally strong Carso positions, the Isonzo line was pushed forward until in Aug. 1916 Gorizia was captured, with a wide area on the Carso to the south of the town. Further progress on the Carso and at various points east of the Isonzo was effected in the autumn of 1916 and the first months of 1917, the Bainsizza plateau northeast of Gorizia being occupied after hard fighting in August.

On the Trentino front the Austrian offensive of May 1916 resulted in the loss by the Italians of several sectors on the Asiago plateau; but thk last mountainous diaphragm was held as well as the Pasubio, and an Italian counter-offensive recaptured most of the lost ground. On the other sectors there were few changes. When the Austrians broke through at Caporetto (*q.v.*) in October 1917 the II. and III. armies fell back on the Piave, the Carnia and Cadore sectors were evacuated and some important positions on the Asiago plateau were also lost. The new front was 200 km. shorter than the old. From the Stelvio to Asiago it was unchanged; in the latter sector it was well to the S. of the old line, and further E. it ran along M. Asolon, M. Grappa (*q.v.*), Col dell'Orso to the Piave S. of Valdobbiadene, and then followed the Piave (*q.v.*) to its mouth. Only slight changes were effected, except in the Grappa and Asiago areas where, after desperate fighting in November and December, the Italians fell back still further, until by the end of the year the new line was definitely stabilized. At the battle of the Piave some positions in the Asiago area were lost and the Austrians crossed the Piave at two points, but the Italians counter-attacked and regained all the lost ground.

There were no further changes until the Italian victory of Vittorio Veneto (*q.v.*), which ended the war on this front (Oct. 23–Nov. 3, 1918).

The strategic outline of the campaign on the Italian front is given *s.v.* WORLD WAR I; see also the references to separate articles above.

(L. V.)

ITALIAN LANGUAGE is the standard language used for official, formal and literary purposes throughout Italy, taught in schools to natives and foreigners. The common everyday speech is either a local Italian dialect different from the standard, or the standard influenced by local usage. The less formal the occasion and the less educated the speaker, the greater are the deviations from standard Italian; many persons cannot speak standard Italian at all. All speech forms called Italian belong to the Romance languages (*q.v.*).

The Dialects.—The number of dialects is very great, and the differences are so profound that many are mutually unintelligible. Thus the word "dialect" here connotes much more radical variations than it normally does in reference to English. The dialects may be divided into six major classes.

1. Gallo-Italian: (a) Piedmontese; (*b*) Ligurian; (*c*) Lombard; (d) Emilian.
2. Venetian: (*a*) Veneziano; (*b*) Trentine; (*c*) Istrian.
3. Tuscan: (*a*) Florentine; (*b*) Western Tuscan; (*c*) Southern Tuscan.
4. Corsican.
5. Central Italian: (a) Northern Latian; (b) Umbrian; (c) Marchigiano; (d) (Modern) Roman.
6. Southern Italian: (a) Southern Latian; (b) Abruzzese; (c) Campanian; (*d*) Calabrian; (*e*) Apulian; (*f*) Sicilian.

Different classifications are possible, as are further subdivisions.

Italian dialects are also spoken in the Swiss canton Ticino and on Corsica, and were spoken on the Adriatic island of Veglia (Krk) and in Dalmatia until the 19th and 15th centuries, respectively. (Some consider the last a separate Romance language.)

Italian in its various forms is spoken natively by about 49,000,000 persons. A considerable number of Italian immigrants to the United States and to Argentina continued to speak Italian, and used the language of their new homeland as a second language, but the succeeding generations became progressively monolingual speakers of English or Spanish. Since the loss of Italy's African colonies at the end of World War II, Italian, once the official language there, though not the mother tongue of the natives, has been on the wane.

The linguistic fragmentation of Italy and the tenacity of the dialects have historic causes. Although Italy was latinized by the conquering Romans, it is certain, though evidence is scanty, that the numerous pre-Latin languages of Italy persisted for some time after the Roman conquest and continued in certain local pronunciations of Latin. Furthermore, not all Italy was occupied by the Romans at the same time, hence it was not all exposed to the same kind of Latin, nor latinized with equal thoroughness. There was no policy of linguistic acculturation in annexed regions. Linguistic decentralization was intensified by the extreme and enduring political dismemberment of the peninsula after the fall of the Roman empire, and enhanced by the rugged geography of the country and the physical difficulties of communication.

The Standard Language. — Classical Latin, after the dissolution of the Roman state and the breakdown of secular education, became the property of a diminishing number of educated persons, largely of the clergy; it became unintelligible to the common man whose vernacular continued to change, as all language does. When it became urgent to employ, for state and private business, a language other than Latin which all could understand, and when literary men wished their works to appeal to a greater listening, if not reading, public, it became necessary to reduce previously unrecorded contemporary dialects to writing. This is a difficult task, even with the methods of modern linguistics, which is aggravated when the effort is deprecated as an attempt to replace a noble tongue by an allegedly vulgar patois.

In *De vulgari eloquentia* "About Popular Speech," written in Latin early in the 14th century, Dante, having skillfully surveyed the languages of Europe and Italy, proposed to establish for all Italians a literary language which should be constructed from all the dialects, preserving a core of common features and discarding extreme local peculiarities. But, contrary to his own theory, Dante himself wrote in his native dialect, Florentine. Thus almost single-handed he made Florentine the literary standard language of Italy, albeit without being fully aware of it. The elevation of a dialect to a literary language because of some prestige accrued to it is the usual phenomenon rather than the procedure Dante suggested. And Florentine acquired the necessary prestige mainly through Dante's own *Divina Commedia*, and later Boccaccio's *Decamerone*, and Petrarch's *Canzoniere*. But Florentine had to compete with other dialects in which meritorious works had been composed, such as the poetry of the Sicilian school, which flourished in Palermo at the court of the German emperor Frederick II (1194–1250) and ended with the Hohenstaufen dynasty. The dialect of the original poems is uncertain, most of the extant manuscripts being from Tuscany and liberally tuscanized. Florentine, however, was aided by the poetry in the *dolce stil nuovo* "sweet new style," produced by a Tuscan school; one of its leaders, Guido Guinizelli, a Bolognese, wrote in Florentine.

Graver obstacles were: the opposition of the learned men who did not wish to see Latin losing ground; the relatively slow spread of Dante's works due to extensive illiteracy and the cost of books before the invention of printing; the seeming needlessness of a national language in the absence of a nation; the cultural climate favouring a renascence of antiquity, which led one humanist of Florence to denounce the *Divina Commedia* as a vulgar piece written in a vulgar tongue, and Italian as a language unfit for poetry. (Petrarch himself was prouder of his Latin than of his Italian works.)

Thus developed the discussions of the *Questione della lingua* "Problem of the Language," which sought to decide whether Latin or Italian should become the national idiom, and, if the latter, which dialect and how "pure" (*i.e.*, free from archaisms, at issue especially from the Renaissance on, and gallicisms, which began to come into Italian and other European languages in the 18th century) it should be. In practice, however, Dante had already decided the quarrel in favour of Florentine. In 1525 the Venetian Pietro Bembo by publishing his *Prose della volgar lingua* fulfilled the two pressing requirements for a standard language (now one that was to be printed in relatively cheap books), an orthographic and a grammatical codification.

Even a standard language, which is by purpose conservative, must not be inhospitable to revision if it is to remain useful. Once adopted, standard Italian was prevented from evolving, and was nearly stifled by its grammarians. It became unwieldy, crammed with formulas and phrases thought beautiful or noble (*cf.* even the modern formal style in letters and officialese), and alienated from reality; it became inadequate over the centuries for the demands of a changing world and new literary trends. Some writers once more had recourse to the uninhibited, lively dialects, and a growing dialect literature in the 18th and 19th centuries threatened to reduce Italian, like classical Latin, to a dead language. It was resuscitated by the Milanese author Alessandro Manzoni (1785–1873), who wrote the second edition of his novel **I** *promessi sposi* "The Betrothed" in standard Italian. But he saw to it, in practice and also in numerous theoretical essays, that the language was reformed and revived, that it was allowed to fill its gaps, and that it would be nurtured by the stream of life it was to reflect and to serve. Manzoni's endeavours were succoured by the awakening nationalism.

Modern standard Italian is still basically the dialect of Florence (minus peculiar localisms like *la hasa* for *la casa, amaθo* for *amato*), but constantly enriched by borrowings from other dialects. Naturally, the dialect of Rome, the capital of the nation after 1870, is particularly influential. Some characterize current standard Italian as *lingua toscana in bocca romana* "Tuscan tongue in Roman mouth." Pronunciation is far from uniform in Italy, but in morphology and syntax all Italians can either speak or learn to speak the same language. Few people speak literary Italian natively, though the Tuscans, for obvious reasons, come nearest to the standard. With rapid improvements in education and communication, and the spread of newspapers, radio and television into remote areas, linguistic standardization of Italy, for better or for worse, should progress apace.

Linguistic History. — It is impossible to set a date for the end of Latin and the beginning of Italian; the development was uninterrupted and boundaries are arbitrary in spoken language. But in written texts a beginning of Italian may be discovered in the midst of Latin. Some writers realized that the spoken and the written idioms were not two kinds of Latin, the "good" written form (as nearly classical as authors could make it) and the "bad" spoken form, but were really different languages. Attempts were then made to write the spoken vernaculars also. The earliest evidence is a set of court records of the 10th century, in which the clerk put down the proceedings in customary subclassical Latin, but inserted the decisive deposition of witnesses verbatim in the language of the speakers, which was Italian (a southern dialect) rather than Latin. From then on, documents and monuments in the *lingua volgare* or *rustica* "vulgar or rustic language," were more frequent, without completely replacing Latin, however, for many centuries, especially in learned works. Galileo (1564–1642) was the first to use Italian for scientific works.

Toward the end and after the fall of the Roman empire, the incursions and occupations by speakers of foreign dialects and the growing number of foreigners in the civilian population and the army, were bound to modify native idioms, although the extent of the linguistic changes was small (much less than the transformation of English after the Norman conquest).

The most important invasions of Italy during the middle ages were those by the Visigoths (5th century, moving from the north to Calabria, but abandoning Italy after the death of their king Alaric), the Ostrogoths (later 5th and early 6th centuries, founding a kingdom with the capital in Ravenna, but after Theodoric's death in 526, overcome by Roman power revived by Justinian), and the Lombards (who remained longest, 568–774, founding a loosely integrated kingdom with the capital in Pavia, which was terminated by the Franks allied with the papacy); these Germanic invaders were followed in southern and central Italy by Arabic-speaking Moslems and by Norman *condottieri* whose sovereignty lasted until the 12th century. None of these significantly changed the Italian language; their only important traces are in lexical borrowings, of which the German, numbering about 1000, are the strongest contingent. This ineffectualness was due in part to the small number of invaders, but mainly to the cultural incompati-

bility of natives and invaders. The Germans were so awed by the superior Roman civilization that they did not even attempt to impose their ways.

Thus the dialects of Italy, including Dante's idiom, underwent little change through foreign influence. And since Italian has changed little since the 13th century, modern Italian diverges least of all the Romance languages from Latin.

Each dialect has its own linguistic history, although all are Romance. in particular Italian, dialects. All Italian dialects together with the other Romance idioms, partook of the common Romance changes *(see* ROMANCE LANGUAGES). Beyond these, the history of standard Italian is fairly simple, the complexities arising mainly from dialect mixture. For a more detailed historic description, Florentine is the obvious choice.

Phonology.— The accented *e* and *o* vowels of late spoken Latin, if open and in free position (*i.e.,* at the end of syllables) were diphthongized: *pĕdem* > *piede, bŏnum* > *buono;* in checked position they remained: *cĕrtum* > *certo, mŏrtem* > *morte;* if close, regardless of position, they remained: *pēsum* > *peso, vocem* > *voce, fīrmum* > *fermo, mūltum* > *molto.* The *a* remained, except in some northwestern dialects where, as in Northern French, *e* appeared in its place: infinitive *-are* > *are,* or *-e(re).* The *i* and *u* (resulting from earlier long **i** and **1,** the short *ĭ* and *ŭ* appearing as *ę* and o, respectively—except in some southern Italian areas) also remain. *filum* > *filo, murum* > *muro.* It is typical of Florentine, though not of other Tuscan dialects, that a following palatal or nasal element, produced *i* and *u* instead of the expected *e* and *o,* respectively: *lingua* > *lingua,* elsewhere *lengua; ungula* > *unghia,* elsewhere *onghia.* Southern dialects are noteworthy for metaphony, that is, the influence of an unstressed upon the preceding stressed vowel: *bonum* > *buono,* but *bonam* > *bona.* Piedmont and Lombardy have, again like French, the so-called umlauts *ü* and o (so transcribed after the German orthography).

The (unstressed) vowels tend to weaken, except for *a,* so that *e* and *i, o* and *u* often merge. Their development depends largely upon their position in the word: pretonic, posttonic, initial, final, intertonic. In southern dialects all final unstressed vowels may fuse into the schwa-sound a (pronounced like the second vowel in English "father").

The most striking phenomena among consonant changes are these: the palatalization and affricatization of stops before *e, i,* or yod, and of yod itself: *certum* [kertum] > *certo* [tšerto] (brackets enclose a phonetic transcription), *cibum* [kibum] > *cibo* [tšibo], *nationem* [natyonem] > *nazione* [natsione] , *gentem* > *gente* [dżente], *gyrum* > *giro* [dżiro], *iurare* > *giurare* [dżurare], *-arium* > *-aio, vinea* > *vigna* [vinya] ; the palatalization of consonant plus *l: plus* > *più, florem* > *fiore, clarum* > *chiaro* [kyaro] ; and the loss of most final consonants. In southern dialects *-nd-* and *-mb-* appear as *-nn-* and *-mm-: quando—quanno, gamba—gamma,* peculiarities often cited as attesting an Oscan substratum. In the north. single voiceless intervocalic consonants appear voiced, and long ones (spelled double; "long stops," a contradiction in terms, are really stops articulated with retarded explosion, *e.g.,* the two t's in English "put to" as opposed to "putting") are shortened. In the northeast *tš* and *dž* appear as *ts* and *dz.* In the south *-ll-* appears as a long cacuminal stop, generally spelled *-dd-* (transcribed *-ḍḍ-*) as in *Turiddu* for *Torello.*

Where standard Italian has forms divergent from the expected ones, dialect borrowings are often the cause. Sometimes doublets with different meanings are retained, such as *stazione* "station" and *stagione* "season." both from *stationem.*

Morphology and Syntax.— Beyond the common Romance developments listed in ROMANCE LANGUAGES, Italian has undergone few radical changes. It may be pointed out that the plural of nouns and adjectives is derived from the Latin nominative case, as in Rumanian but not in other Romance languages. The Latin *ille* "this (one)" and its paradigm become the Italian definite article. The use of subject pronoun is optional; it may convey emphasis.

Vocabulary is, as mentioned, overwhelmingly Latin. In the later middle ages and in the succeeding centuries, Italian borrowed (to the sorrow of the purists) from various European languages, especially French and Spanish during the periods of political and cultural ascendancy of these nations. The number of borrowed words is not great, but the frequency of occurrence rather high because among them are common words: *giardino* "garden," *mangiare* "to eat," *giallo* "yellow," *flotta* "fleet." Arabic words, often coming by way of Spanish, are recognizable by the prefix *al-,* Germanic words by *gu-* from Germanic w- *(cf.* the English doublet "guard" and "ward," the first being a Romance borrowing, the second the native German word) : Italian *guerra*— English "war."

Numerous learned words are later borrowings from Latin especially during the Renaissance (again often leading to doublets: *circulum* > *cerchio,* later borrowing *circolo*), and modern scientific terminology uses many Latin roots.

Modern Italian spelling employs the regular Latin alphabet. But Italian (quite unlike English) orthography is almost phonetic; once the regular equivalences of sound and spelling are mastered, Italian can be read and written correctly: there are no exceptions. Identical spellings for different sounds, as in English *rough, though, through, bough, cough, ought* do not occur in Italian, nor do different spellings for identical sounds as in English *through, zoo, shoe, flew, flue, do.* Placement of the stress may offer some difficulty: it is unpredictable (except where there is a grave accent on the final stressed vowel: *cittd, moltiplicità*). Certain etymological spellings, like *ph, th, y,* have been abolished in favour of *f, t, i (fotografia, teologia, sistema*). Italian grammars often stress the difference in the timbre of open versus close e and *o,* which is not apparent in the spelling; but this distinction is not significant and varies from region to region. The significant opposition of long versus short consonants, however, is regularly indicated *(sera* "evening": *serra* "he tightens"; *fato* "fate": *fatto* "done"; *casa* "house": *cassa* "box"; *capello* "hair": *cappello* "hat"), except where such lengthening occurs in transition from one word to another, as in *a casa* "at home," which is pronounced *accasa.* (In some compositions the double spelling has been standardized, so that *della* stands for *de la* "of the" and *dammi* for *da mi* "give me.") Italian spelling has no devices like the French cedilla or the Spanish tilde; such variations in sound are indicated by letter spellings. The grave accent is used regularly on the final stressed vowel, and occasionally to distinguish a verbal form *dd* "he gives" from a nonverbal *da* "from." The circumflex appears only in older writing as on *foglî,* now *foglii* or *fogli,* plural of *foglio* "sheet."

ITALIAN LITERATURE. One characteristic fact distinguishes Italy's intellectual life in the middle ages: the tenacity with which the Latin tradition remained alive *(see* LATIN LANGUAGE; LATIN LITERATURE). At the end of the 5th century the northern conquerors invaded Italy. The political structure of Rome crumbled to pieces; Goths, Greeks, Lombards and Franks were in turn pre-eminent in Italy. Theodoric the Great, however, who considered himself a lieutenant of the Byzantine emperor, was not averse to learning, and even the Lombard kings, who belonged to a truly barbaric stock, seem to have been compelled by the force of local habits to countenance the existence of lay and ecclesiastical schools. The persistence of lay schools throughout the middle ages is an Italian characteristic. Ecclesiastical schools were founded as a matter of routine; when the Benedictine institutions underwent a period of decadence, Irish monks settled in Italy and helped in reviving religious zeal and interest in learning.

If the original output of Italian scholars during the earlier middle ages was comparatively small, there were nevertheless men of outstanding merit practically in every century. Peter of Pisa was at Charlemagne's court together with Paul the Deacon who hailed from Monte Cassino; Gunzo of Novara migrated to the court of

the Saxon emperors; later Lanfranc of Pavia and Anselm of Aosta rose to important positions in France and in England. No doubt the persistence of the classical tradition among the native population was rendered possible by the relatively small number of barbaric settlers and helped by the sight of countless monuments of Roman greatness; this same persistence greatly hindered the re-elaboration of classical tradition and barbaric legends which gave rise in France to a new literature. Italians were late in the field and they preferred to import French works dealing with the Romans (*Faits* des *Romains*), Alexander the Great (Roman *d'Alixandre*) and Trojan legends (Roman de Troie). Likewise the Italians, whose vernacular dialects must have taken shape very early (there are records of passages in the vulgar tongue as early as the 9th century at Verona and in the south), were slow to realize that Latin, the language they were taught at school (*grammatica*), was no longer their real language; they were shy to break away from tradition: Gunzo of Novara (10th century) justified a grammatical slip he had made in a Latin speech by his habit of speaking the Italian vernacular which was similar to Latin, and yet until the 13th century no Italian dialect seems to have been used in writing, with the exception of some verses in a poem by the Provencal Raimon de Vaqueiras, an inscription at Ferrara and the song of a Tuscan jongleur (*Salva* lo vescovo senato).

The Fashion of French and **Provençal.**—By the end of the 12th and the beginning of the 13th centuries Latin had become unsuitable for the expression of everyday feelings; at the same time the courtly society of feudal castles, as well as the people loitering in the squares, wished for some kind of literary entertainment. In many a castle of northern and central Italy Provencal troubadours were welcome guests; their poems were transcribed in manuscripts which are still extant, and there were many Italians who wrote Provencal poems, such as the Marchese Alberto Malaspina (12th century), Maestro Ferrari of Ferrara, Cigala of Genoa, Zorzi of Venice, Sordello of Mantua, Buvalelli of Bologna, Nicoletto of Turin and others. The same courtly circles that appreciated Provençal lyrics greedily read Arthurian romances, at first in French and later in Italian translations. Carolingian poems, instead, found favour with the less educated people for whose benefit they were recited in the thoroughfares first by French jongleurs, who must have endeavoured to make themselves more easily understood by italianizing their pronunciation, later by Italian imitators. As a result there came into being several works written by Italians in imperfect French during the 13th century. Such were the "chansons de geste," Macaire, the *Entrée* en Espagne written by Nicola of Verona, the Prise de *Pampelune* and some others. Many such works have been lost, among them those which were later rendered into Tuscan *cantari* dealing with epic subjects, but a good number are still extant in prose as well as in verse, such as Le *Régime* du corps by Aldobrandino of Florence or Siena, a chronicle of Venice written in 1267 by Martino da Canale, a treatise on falconry translated by Daniele of Cremona (1251), the travels of Marco Polo written down, possibly from dictation, by Rustichello of Pisa (1298), who had previously lived at the court of Edward I of England and composed many Arthurian romances; the encyclopaedic work Lis Livres dou tresor of Brunetto Latini (just after 1260). Several authors—Canale, Ennachet, Latini (who wrote in France)—were at pains to state that they were using the French language because it was more pleasant than others and more widely understood. But so artificial an attempt must soon have proved a failure, for while it was in progress, there had begun an active effort at translating from Latin and French into the Italian vernaculars and also at writing original works in Tuscan and other Italian dialects.

It was in the course of the 13th century, and especially from 1250 onward, that the new literature largely unfolded and developed itself. This development was simultaneous in the whole peninsula, only there was a difference in the subject matter. In the north, the poems of Giacomino of Verona and Bonvesin of Riva were specially didactic and religious and were intended to be recited to the people. Uguccione of Lodi, Bonvesin, Giacomino, Girardo Patecchio and the others no doubt wrote in their local dialects, occasionally adopting words and forms from other dialects with the intention of thus attaining a higher literary standard, and their genuine forms may at times have been further modified by enterprising copyists who spoke different if neighbouring vernaculars. Some of these religious works may possibly have been connected with the heretical movements in Lombardy at the period.

The Sicilian School.—In the south of Italy French lyrics of the langue *d'oïl* and, even more, of the langue *d'oc* enjoyed favour in courtly circles. One of the most ancient poems of the Sicilian school, a name by which the poets of the court of Frederick II are indicated whether they hail from Sicily or not, is ascribed to John of Brienne, king of Jerusalem; and the emperor Frederick, perhaps himself a poet, certainly encouraged his friends to cultivate the vernacular muse. Modern critics have pointed out French influences in many of these lyrics, and it may be that the famous and much discussed *contrasto* of Cielo Dalcamo, a poet who had probably studied at Salerno, was an attempt at imitating local and French popular or pseudopopular poems. Despite some vigour, zest and coarseness the *contrasto* cannot rank with real popular poetry. The Provençals, however, had provided models which, being the product of social refinement in a feudal environment, must have proved more congenial to Frederick and his courtiers; and the lyrics of the Troubadours were often imitated by Pier della Vigna, Enzo (Frederick's son), Jacopo Mostacci, Jacopo da Lentino (probably the inventor of the sonnet) and the others; among them Giacomino Pugliese and Rinaldo of Aquino occasionally gave signs of genuine feeling. As has been noted, several of the poets of the Sicilian school were not Sicilians, but hailed from southern Italy, as Pier della Vigna and Rinaldo, from Tuscany, as Arrigo Testa, or from Genoa, as Percivalle Doria. Moreover Frederick and his courtiers were ever moving up and down Italy as the political situation required; and all of them endeavoured, when writing, to ennoble the language they used by discarding purely local forms and thus unconsciously worked toward a standard literary language. Later scribes may have emphasized such a tendency by altering Sicilian to Tuscan forms. Followers of the Provençals have been traced in Naples and Rome; and farther north, in central Italy, there were other forces at work besides the influence of the Troubadours.

Religious Poetry of the 13th Century.—The religious revival of the 13th century is connected in central Italy with St. Francis of Assisi (1182–1226). Around him a legend has grown up and from some parts of it we seem to be able to infer that its hero had a strong feeling for nature and a most warm and responsive heart. There is clear evidence of such gifts in his famous Cantico del sole, which despite rhythmical irregularities is considered the finest religious hymn of early Italian literature. The Franciscan movement inspired the composition of many religious lyrics; and when after the saint's death the order was split by dissensions, one of the upholders of strict adherence to the original rule, Jacopone da Todi (d. 1306), wrote poems of outstanding merit. He was a lawyer and had probably tried his hand at poetry before his conversion. A vehement passion must have stirred his heart and maintained a despotic hold over him, the passion of divine love. Under its influence he wished upon himself the severest sufferings and gave vent to his religious intoxication in his poems. There is no indication of deliberate artistic effort in his poems: there is only feeling, a feeling that absorbed him, fascinated him, penetrated him through and through. He was put in prison and chained, but his spirit lifted itself up to God, and that was enough for him. The same feeling that prompted him to pour out in song ecstasies of divine love and to despise himself moved him to reprove those who forsook the heavenly road, whether they were popes, prelates or monks.

To the religious movement in Umbria is also traceable the origin of religious drama. In 1258 an old hermit, Raniero Fasani, leaving the cavern in which he had lived for many years, suddenly appeared at Perugia. Those were difficult times in Italy. The breaking up of the feudal system, the incidence of economic forces connected with the rise of manufacturing industries, the struggles between popes and emperors kept the people in constant agitation and spread abroad paralyzing fears. Fasani represented him-

self as sent by God to disclose mysterious visions and to announce terrible visitations to the world. Under the influence of fear there were formed *compagnie di disciplinanti,* who, for a penance, scourged themselves till they drew blood, and sang *laudi* in dialogue in their confraternities. These *laudi,* closely connected with liturgy, were among the first examples in Italy of drama in the vulgar tongue. Their development, however, was rapid. As early as the end of the same (13th) century came the *Devozioni del Giovedi e Venerdi Santo,* which have some dramatic elements in them, though they are still connected with the liturgical office. There is also the representation *di un monaco che andò al servizio di Dio* ("of a monk who entered the service of God"), in which there is already an approach to the definite form which this kind of literary work assumed in the following centuries.

THE TUSCAN DIALECT

Tuscan Poetry. — In the 13th century Tuscany was peculiarly circumstanced both as regards its literary condition and its political life. The Tuscans spoke a dialect which most closely resembled the mother tongue, Latin — one which afterward became the language of literature almost to the exclusion of all others and which was already regarded at the end of the 13th century as surpassing the others: "Lingua Tusca magis apta est ad literam sive literaturam," writes Antonio da Tempo of Padua, born about 1275. Among the other cities Florence, thanks to geographical and economic causes, acquired a pre-eminent position. From 1266, when the Hohenstaufens were defeated at Benevento, the city was in a position to begin that movement of political reform which in 1282 resulted in the appointment of the *priori delle arti.* This was afterward copied by Siena, by Lucca, by Pistoia and by other Guelph cities in Tuscany. Economic prosperity found expression in the erection of churches and town halls and in their artistic decoration. It was no wonder that literature also rose to unlooked-for perfection. In Tuscany, too, there was some popular love poetry; there were imitators of the Troubadours and the Sicilians. such as Guittone del Viva of Arezzo and Dante of Majano; but literary originality took another line — that of humorous and satirical poetry. Folgore da San Gimignano is humorous when in his sonnets he tells a party of Sienese youths the occupations of every month in the year, or when he teaches a party of Florentine lads the pleasures of every day in the week; and likewise Cene della Chitarra when he parodies Folgore's sonnets. The sonnets of Rustico di Filippo are half fun and half satire; laughing and crying, joking and satire, are all to be found in Cecco Angiolieri of Siena. But another kind of poetry also began in Tuscany. Guittone d'Arezzo, besides imitating the love songs of the Provençals, attempted political poetry, and thus struck an original note. A more fruitful development occurred at Bologna, the seat of an already famous university. The poets of Provence had paid the same kind of homage to their ladies that the noblemen owed to their feudal overlords; at Bologna, where the new tendencies of the scholastic philosophy were much discussed, a poet was born, Guido Guinicelli di Magnano (1230?–75?), who followed at first the lead of Guittone but soon struck out on an original path, ascribing to his lady the power of calling into activity all the good qualities which a-ere dormant in him; as he was gifted with an extraordinary power of dramatic imagination and real feeling, he succeeded despite some philosophical subtleties in composing lyrics of striking beauty which brought about a revolution in Italian poetry and strongly influenced Cavalcanti and Dante.

But before Dante is discussed, certain other facts, not, however, unconnected with his formation, must be noticed. Didactic poetry, which was direct in northern Italy, adopted the device of allegory in Tuscany. Thus Brunetto Latini, whom Dante looked upon with filial affection, wrote the *Tesoretto,* in which the author professes to be lost in a wilderness and to meet with a lady, who is Nature, from whom he receives much instruction. Francesco da Barberino, a learned lawyer, wrote two little allegorical poems — the *Documenti d' amore* and *Del reggimento e costume di donna. A* fourth allegorical work was the *Intelligenza,* attributed to Dino Compagni.

Prose in the 13th Century. — While the production of Italian poetry in the 13th century was abundant and varied, that of prose was scanty, The oldest specimen dates from 1211 and consists of short notices of entries and expenses by Florentine bankers from Siena. In 1253 and 1260 there are some commercial letters. The original compositions in the *langue d'oil* were followed by translations or adaptations from the same. There are translations and adaptations from French originals: some moral narratives takes from religious legends; a romance of Julius Caesar; some short histories of ancient knights; the *Tavola rotortda;* translations of the *Milione* of Marco Polo and of the *Tesoro* of Latini. At the same time there appeared translations from Latin of moral and ascetic works, of histories and of treatises on rhetoric and oratory, several of which were the work of Bono Giamboni. Among the oldest prose writing is a scientific book — the *Composizione del mondo* by Ristoro d'Arezzo, who lived about the middle of the 13th century. This work is a copious treatise on astronomy and geography. Ristoro seems to have been a careful observer of natural phenomena, and consequently many of the things that he relates were the result of personal investigations. There is also another short treatise, *De regimine rectoris,* by Fra Paolino, a Minorite friar of Venice, who was probably bishop of Pozzuoli and who also wrote a Latin chronicle.

The 13th century was very rich in tales. There is a collection called the *Cento novelle antiche* (or *Novellino),* which contains stories drawn from oriental, Greek and Trojan traditions, from ancient and mediaeval history, from the legends of Brittany, Provence and Italy and from the Bible: from the local tradition of Italy as well as from bestiaries and ancient mythology. There were other prose tales inserted by Francesco da Barberino in his work *Del reggimento e costume di donna,* but they are of much less importance than the others. Some attention should be paid to the *Lettere* of Fra Guittone d'Arezzo, the subjects of which are moral, religious and political. During the later middle ages it had become the fashion to ornament Latin orations and letters with all sorts of rhetorical devices, among them rhythmic *clausulae* (*cursus);* and such a practice. which was enforced by a number of rhetorical treatises *(artes dictandi),* Guittone followed when writing Italian, with results that are often extravagant.

The **"Dolce Stil Nuovo."**—Lyric poetry rapidly reached a high standard of perfection in Tuscany at the end of the 13th century. It followed to some extent Guittone's and much more Guinicelli's models, but its achievements were principally due to Cavalcanti. Guido Orlandi, Lapo Gianni, Dino Frescobaldi, Dante. Cino da Pistoia and a few others must all be grouped around Cavalcanti. They were named by Dante "poets of the *dolce stil nuovo.*" The secret of their success was a fresh and sincere inspiration; as Dante expresses it—

> Quando
> Amore spira, noto, ed a quel modo
> Ch' ei detta dentro, vo significando—

that is to say, that these poets express their feelings as love inspires them, in an appropriate and graceful manner, fitting form to matter, and by art fusing one with the other. In Lapo Gianni the new style is not free from some admixture of the old associations of the Siculo-Provencal school. Sometimes, however, he draws freely from his own heart, and then the subtleties and obscurities disappear, and his verse becomes clear, flowing and elegant.

Guido Cavalcanti (*c.* 1250–1300) was a learned man with a high conception of his art. He felt the value of it and adapted his learning to it. His poems may be divided into two classes — those which portray the philosopher and those which are more directly the product of his poetic nature imbued with mysticism and metaphysics. To the first set belongs the famous poem *Donna mi prega,* which in fact is a treatise on the nature of love and was annotated later in a learned way by Marsilio Ficino and others. But there are many of his poems, the *ballate* particularly, in which the truth of the images and the elegance and simplicity of style are admirable and make us feel that we are in quite a new period of art.

Among the followers of the new school was also Cino da Pistoia (1270–1336) of the family of Sigisbuldi. His love poems are so

sweet, so mellow and so musical that they are only surpassed by Dante's. The pains of love are described by him with vigorous touches. It is easy to see that they are not feigned but real. The psychology of love and of sorrow nearly reaches perfection.

DANTE, PETRARCH AND BOCCACCIO

Dante (1265–1321).—As the author of the *Vita nuova,* the greatest of all Italian poets, Dante Alighieri, also belongs to the same lyric school and partly shares Guinicelli's and Cavalcanti's conception of love. In the lyrics of the *Vita nuova* there is a high idealization of love. untouched by anything earthly or human, and the poet seems to have had his eyes constantly fixed on heaven while singing of his lady. Several of the lyrics *(rime)* not included in the *Vita nuova* or the *Convivio* deal, too, with the theme of the "new life"; while other pieces are philosophical and bridge over to the *Convivio (c.* 1307), an unfinished philosophic treatise in which are to be read some of the finest passages of early Italian prose. Dante expressed original views about the literary language of Italy in another unfinished work in Latin *(De vulgari eloquentia, c.* 1305); just as later, probably in 1313, he expounded his political system in the Latin *Monarchia* and in some letters. Toward the end of his life he composed a short treatise *De aqua et terra* and two Latin eclogues of great interest. But the work which made him immortal is of course the *Divina Commedia,* probably written between 1307 and 1321. In 100 cantos Dante describes a vision, during which he visited Hell, Purgatory and Paradise under the guidance of Virgil (symbolizing human reason) and later of Beatrice (human reason illumined by revelation). Many incidents in this pilgrimage, as well as the pilgrimage itself, have an allegorical meaning, and Dante succeeded in expressing his opinion upon the political and social realities of his age and upon all the subjects that principally interested him in the course of an anticipated Last Judgment to which he dared to summon men of past ages and his own time. It was so clear to him that he had a mission to fulfill and a message to deliver that he felt inspired to greater effort by the very daring of his undertaking. And though as a pilgrim through the afterworld he described himself as having risen from human to celestial heights, as a poet he kept faith to the same moral and political ideals for which he had fought and suffered. Even those readers who may be unequal to the effort of making out the grand lines of his majestic structure cannot fail to see and to remember the ineffable charm of some particular passages tender or ghastly, stern or moving.

Dante is often said to have summed up the middle ages for the men who came after him; it should not be overlooked, however, that there is much in his work that seems to herald the age that was to follow. He claimed to have learned his literary style from the classics and from Virgil in particular; and if his was not yet a scholarly return to the classics, the angle from which he looked upon them was no longer completely mediaeval.

Petrarch (1304–1374).—The next step was to be taken by Petrarch (*q.v.*), and it will be easier to grasp its significance if one bears in mind that his principal aim was a rebellion against the philosophy of the schoolmen and against the deductive method in science and philosophy by which every truth could only be derived from what Aristotle and his commentators had said. This rebellion he fostered by holding up Plato, whose works and ideas were only indirectly known to him, in opposition to Aristotle and by summoning to his aid the results of his own introspection. The data of introspection he sought to compare with the records which great writers of antiquity had set down of their own experiences. It was necessary, then, to know exactly what the ancients had written and therefore to discover and to collate as many of the manuscripts of their works as were still traceable. Scholarship and antiquarianism were means to an end and not ends in themselves for Petrarch. He was the first humanist and at the same time the first lyric poet of the modern school. His career was long and eventful. He lived for many years at Avignon, cursing the corruption of the papal court; he travelled through nearly the whole of Europe; he corresponded with emperors and popes; he was considered the first man of letters of his time; he had honours and moderate riches; and he always experienced restlessness, melancholy and incapacity for satisfaction—three characteristics of the modern man. He loved Laura, whoever the lady was, and Laura may have for a time countenanced his courtship but ever remained out of his reach. His life was passed in pining for her, admiring her beauty, sorrowing for her coldness and sometimes rebelling against love; for love of woman and desire for worldly fame hindered, in his view, the spiritual freedom of man and his striving toward Christian perfection. These perpetual alternations of his moods he embroidered upon with faultless technique, whether or not he happened to be prompted by feeling, throughout the *Rime sparse,* as he seems to have called his Italian lyrics when, long after Laura's death (1348), he revised and collected them, including also a few political and occasional poems. A clearer but far less successful expression of his views is to be found in the vision that he called **I** *Trionfi,* clearly imitated from Dante's *Commedia;* but no one can hope to penetrate the world of Petrarch's thought who has not read his *Secretum,* a dialogue between St. Augustine and himself, the treatise *De vita solitaria,* the great body of his Latin epistles, and last but not least his epic poem in Latin, *Africa,* by which he sometimes expected to be remembered by posterity.

Boccaccio **(1313–1375).**—Giovanni Boccaccio had the same enthusiastic love of antiquity and the same worship for the new Italian literature as Petrarch. He supervised the work of Leonzio Pilato (Leon Pilatus), a Greek born in Calabria, who put together a Latin translation of the *Iliad* and the *Odyssey.* Boccaccio's vast classical learning was shown specially in the work *De genealogiis deorum,* in which he enumerates the gods according to genealogical trees constructed on the authority of the many who wrote about the pagan divinities. Boccaccio was also the first historian of women in his *De claris mulieribus* and the first to tell of the vicissitudes of famous men in his *De casibus virorum illustrium.* He continued and perfected former geographical investigations in his interesting book *De montibus, silvis, fontibus, lacubus, fluminibus, stagnis, et paludibus, et de nominibus maris,* for which he made use of Vibius Sequester, but which contained also many new and valuable observations. Of his Italian works his lyrics do not approach the perfection of Petrarch's. His narrative poetry is better. He was the first to use *ottava rima* in a work of some length and written with artistic skill, such as is his *Teseida,* the oldest Italian romantic poem. The *Filostrato* relates the loves of Troiolo and Griseida (Troilus and Cressida). The *Ninfale fiesolano* tells the love story of the nymph Mesola and the shepherd Affrico. The *Amorosa Visione,* a poem in *terza rima,* doubtless owed its origin to the *Divina Commedia.* The *Ameto* is a mixture of prose and poetry and is the first Italian pastoral romance.

The *Filocolo* takes the earliest place among prose romances. In it Boccaccio tells in a laborious style, and in the most prolix way, the loves of Florio and Biancofiore. The *Fiammetta* is another romance, taking its pattern from the loves of Boccaccio and Maria d'Aquino, a supposed natural daughter of King Robert, whom he always called by this name of Fiammetta.

The Italian work which principally made Boccaccio famous was the *Decameron,* a collection of 100 short stories, related by a party of men and women, who had retired to a villa near Florence to escape from the plague in 1348. The short story, so abundant in the preceding centuries, especially in France, now for the first time assumed an artistic shape. The crudeness of the old *fabliaux* gives place to the careful and conscientious work of a mind that has a feeling for what is beautiful, that has studied the classic authors and that strives to imitate them as much as possible. Over and above this, in the *Decameron* Boccaccio is a master in character-sketching and an observer of passions. In this lies his novelty. Much has been written about the sources of the short stories of the *Decameron.* Probably Boccaccio made use both of written and of oral sources.

Unlike Petrarch. Boccaccio felt for Dante something more than love—enthusiasm. He wrote a biography of Dante, of nhich the accuracy has been not altogether successfully challenged in the past, and he gave public lectures on his poem in the church of Santo Stefano di Badia at Florence.

Imitators.—Dante and Boccaccio were not without their imi-

tators. Fazio degli Uberti and Federigo Frezzi imitated the *Divina Commedia,* but only in its external form. The former wrote the *Dittamondo,* a long poem, in which the author supposes that, being taken by the geographer Solinus into different parts of the world, he was told the history of them by his guide. Frezzi, bishop of his native town, Foligno, wrote the *Quadriregio,* a poem of the four kingdoms — Love, Satan, the Vices and the Virtues. The poet has Pallas for a companion.

Ser Giovanni Fiorentino wrote, under the title of *Pecorone,* a collection of tales, which are supposed to have been related by a monk and a nun in the parlour of the monastery of Forli. He closely imitated Boccaccio and drew on Villani's chronicle for his historical tales. Franco Sacchetti also wrote short stories for the most part on subjects taken from Florentine history. His book gives a convincing picture of Florentine society at the end of the 14th century. A third writer of short stories was Giovanni Sercambi of Lucca, who after 1374 wrote a book, in imitation of Boccaccio, about a party of people who were supposed to fly from a plague an3 to go travelling about in different Italian cities, stopping here and there telling stories. A later, but important, name is that of Masuccio Salernitano (Tommaso Guardati), who wrote the *Novellino.*

OTHER 14TH-CENTURY WRITERS

Chroniclers and Ascetic Writers. — At the end of the 13th century we find a chronicle by Dino Compagni. A merchant, he was democratic in feeling and was a supporter of the new ordinances of Giano della Bella. As prior and gonfalonier of justice he always had the public welfare at heart. He belonged to the party of the Bianchi and opposed the claims which Boniface VIII made on Florence. In spite of its title, his *Cronica* is a monographical account of the political crisis in Florence (1300–01), together with its prelude and its aftermath (1280–1312). The narrative is constantly personal. It often rises to the finest dramatic style. It is one of the most important sources for that period of Florentine history, notwithstanding several factual mistakes which are to be found in it. On the contrary, Giovanni Villani, born *c.* 1276, was more of a chronicler than a historian. He relates the events up to 1347. The journeys that he made in Italy and France and the information thus acquired account for the fact that his chronicle, called by him *Istorie fiorentine,* comprises events that occurred all over Europe. What specially distinguishes the work of Villani is that he speaks at length, not only of events in politics and war, but also of the stipends of public officials, of the sums of money used for paying soldiers and for public festivals and of many other things of which the knowledge is very valuable. Matteo, the brother of Giovanni Villani, continued the chronicle up to 1363. It was again continued by Filippo Villani. Gino Capponi, author of the *Commentari dell' acquisto di Pisa* and of the narration of the *Tumulto dei Ciompi,* belonged to both the 14th and the 15th centuries.

Neither Petrarch nor Dante could be classified among the pure ascetics of their time. But many other writers come under this heading. St. Catherine of Siena's mysticism was political. She was a really extraordinary woman, who aspired to bring back the Church of Rome to evangelical virtue and who has left a collection of letters written in a high and lofty tone to all kinds of people, including popes. She joins hands on the one side with Jacopone of Todi, on the other with Savonarola. Hers is the strongest, clearest, most exalted religious utterance that made itself heard in Italy in the 14th century.

Another Sienese, Giovanni Colombini. founder of the order of the Gesuati, preached poverty by precept and example, going back to the religious idea of St. Francis of Assisi. His letters are among the most remarkable in the category of ascetic works in the 14th century. Jacopo Passavanti, in his *Specchio della vera penitenza,* combined instruction with narrative. Domenico Cavalca translated from Latin the *Vite dei santi padri.*

Poetry in the 14th Century. — In direct antithesis to this is a kind of literature which has a strong popular element. Humorous poetry, the poetry of laughter and jest, which as we saw was largely developed in the 13th century, was carried on in the 14th by Bindo Bonichi, Arrigo di Castruccio, Cecco Nuccoli, Andrea Orgagna, Filippo de' Bardi, Adriano de' Rossi, Antonio Pucci and other lesser writers. Antonio Pucci was superior to all of them for the variety of his production. He put into *terza rima* the chronicle of Giovanni Villani (*Centiloquio*) and wrote many historical poems called *serventesi,* many comic poems and not a few epico-popular compositions on various subjects. A little poem of his in seven cantos treats of the war between the Florentines and the Pisans from 1362 to 1365.

Many poets of the 14th century left political works. Fazio deqli Uberti, the author of *Dittamondo,* wrote also a *serventese* to the lords and people of Italy, a poem on Rome, a fierce invective against the emperor Charles IV; and Francesco di Vannozzo, Frate Stoppa and Matteo Frescobaldi deserve mention. From this period also dates that literary phenomenon known under the name of Petrarchism. Petrarchists were already singing of love in Petrarch's manner, but others treated the same subject with more originality, in a manner that might be called semipopular. Such were the *ballate* of Ser Giovanni Fiorentino, of Franco Sacchetti, of Niccolò Soldanieri, of Guido and Bindo Donati.

There cannot have been an entire absence of dramatic literature in Italy in the 14th century, but traces of it are scarce, although we find them again in great abundance in the 15th century. One drama of the 14th century mas, however, unique: the *Ecerinis* written by Albertino Mussato of Padua in 1315. Mussato, a political man and the historian of Henry VII, aimed at strengthening the antagonism against Cangrande della Scala by describing in a Senecan style the evils of the tyrannical government of Ezzelino da Romano.

The revival of learning which Petrarch had fostered as a means to a philosophical, moral and political revolution so fascinated many of his admirers that it became for them an end in itself. Petrarch had affected to look upon his works in Italian as trifles (he called them *nugellae vulgares*): the scholars who took over the literary leadership after him, Coluccio Salutati and partly Luigi Marsili, still admired Dante. Petrarch and Boccaccio's Italian works but always wrote in Latin themselves, and for many decades Latin triumphantly rivalled Italian.

THE RENAISSANCE

In the 15th century a great number of scholars industriously and indefatigably carried on the rediscovery of antiquity. Such were Niccolb Niccoli, Giannozzo Manetti, Palla Strozzi, Leonardo Bruni (Leonardo Aretino), Francesco Filelfo, Poggio Bracciolini, Lorenzo Valla. Manetti spent his time translating from Greek, studying Hebrew and commenting on Aristotle. Palla Strozzi sent into Greece at his own expense to search for ancient books and had the works of Plutarch and Plato bought for him. Poggio Bracciolini went to the Council of Constance and found Cicero's orations buried in a monastery. He copied Quintilian with his own hand, discovered Lucretius, Plautus, Pliny and many other Latin authors. Guarino da Verona went through the east in search of codices. Giovanni Aurispa returned to Venice with many hundreds of manuscripts. These Italians were but handing on the solemn tradition which, although partly latent, was the informing principle of Italian mediaeval history and now at length came out triumphant. This tradition was that same tenacious and sacred memory of Rome. that same worship of its language and institutions, which at one time had retarded the development of Italian literature and now grafted the old Latin branch of ancient classicism on the flourishing stock of Italian life. Men came to have a more just idea of nature: the world was no longer cursed or despised; man was born again; and human reason resumed its rights. Both the individual and society were changed under the influence of new facts.

Characteristics and Development. — First of all there was formed a human individuality, which was wanting in the middle ages. As J. Burckhardt remarked, man became an individual. He began to feel and assert his own personality, which was constantly attaining a fuller realization. As a consequence of this, the idea of fame and the desire for it arose. The mediaeval principle of conduct was turned upside down: men who had hitherto turned

their thoughts exclusively to heavenly things and believed exclusively in the divine right now began to think of beautifying their earthly existence. of making it happy and gay, and returned to a belief in their human rights. This was a great advance, but one which carried with it the seeds of many dangers. The conception of morality became gradually weaker. The *fay ce que vouldras* of Rabelais became the first principle of life. Religious feeling was blunted. Besides this, a great literary danger was hanging over Italy: humanism threatened to submerge the youthful national literature. There were authors who laboured hard to give Latin forms to Italian. Provincial dialects tried to reassert themselves in literature. The great authors of the 14th century were forgotten or despised by many people of the cultured class. In spite of its glorious beginnings, the light went out from Italian literature for almost a century after the death of Boccaccio.

It was Florence that saved literature by reconciling the classical models to modern feeling. At Florence celebrated humanists wrote also in the vulgar tongue and commented on Dante and Petrarch and defended them from their enemies. Leon Battista Alberti. the learned Greek and Latin scholar, wrote in the vernacular; Vespasiano da Bisticci, uhilst constantly absorbed in Greek and Latin manuscripts. produced the *Vite d' uomini illustri,* rivalling the best works of the 14th century in their candour and simplicity; and Andrea da Barberino wrote the beautiful prose of the *Reali di Francia.*

The **Academies.**—As a consequence of the intellectual movement toward the Renaissance, there arose in Italy in the 15th century three academies, those of Florence, of Naples and of Rome. The Florentine academy was iounded by Cosimo I de' Medici. Having heard the praises of Platonic philosophy sung by Gemistus Pletho, who in 1439 was at the council of Florence, he took such a liking for those opinions that he soon made a plan for a literary congress which was specially to discuss them. Marsilio Ficino described the occupations and the entertainments of these academicians: there, he said. the young men learned, by way of pastime, precepts of conduct and the practice of eloquence; there grown men studied the government of the republic and the family; there the aged consoled themselves with the belief in a future world. Such men as Pico della Mirandola, Politian *(see* below) and Alherti were among the members of the academy, besides the Medici. The Roman academy was founded by Giulio Pomponio Leto, with the object of promoting the discovery and the investigation of ancient monuments and books. It was a sort of religion of classicism, mixed with learning and philosophy. Platina (Bartolomeo Sacchi), the celebrated author of the lives of the first hundred popes, belonged to it. At Naples, the academy known as the Pontaniana was instituted. The founder of it was Antonio Beccadelli, surnamed Il Panormita, and after his death he was succeeded by Giovanni Pontano (Jovianus Pontanus) who gave his name to it and became its moving spirit.

Lorenzo de' Medici and **Politian.**—It was with Lorenzo de' Medici (1449–92) that the Florentine influence on the Renaissance gathered momentum. Lorenzo's mind was moulded by classical education: he attended the lectures of the Greek Argyropulos, befriended many Platonists, took pains to collect codices, sculptures, vases, pictures, gems and drawings to ornament the gardens of San Marco and to form the library later named after him. In the halls of his Florentine palace, in his villas at Careggi, Fiesole and Poggio a Caiano, stood wonderful works of art by Antonio Pollaiuolo. Sandro Botticelli. Filippino Lippi and Andrea del Verrocchio. And yet if we read Lorenzo's poems we only see the man of his time, the admirer of Dante and of the old Tuscan poets, who took inspiration from the popular muse and who endowed his poetry with the colours of the most pronounced realism as well as of the loftiest idealism. who passed from the Platonic sonnet to the impassioned triplets of the *Amori di Venere,* from the grandiosity of the *Selve* to *Nencia (see* below, *Pastoral Poetry)* and to *I Beoni,* from the *Canto carnascialesco* to the *Lauda.*

Next to Lorenzo comes Politian (Angelo Ambrogini, 1454–94), who also united, and with greater art. the ancient and the modern, the popular and classical styles. In his *Rispetti* and in his *Ballate* the freshness of imagery and the plasticity of form are inimitable. A great Greek scholar, a forerunner of scientific methods in textual criticism, he wrote Italian verses with polished simplicity and refinement; the purest elegance of the Greek sources pervaded his art in all its varieties, in the idyllic play of *Orfeo* as well as in the enchanting poem called *Stanze per la giostra.*

Savonarola's **Reaction.**—Lorenzo in his livelier mood favoured masquerades and festivals, for which he and his friends composed poems such as the *trionfi* and the *canti carnascialeschi.* It was the moral laxity and the heathen ideals expressed in such poems as these that the Dominican Girolamo Savonarola of Ferrara set himself to reform when he arrived in Florence (1489). He directed his attack against Lorenzo the promoter of classical studies, the patron of pagan literature. rather than against Lorenzo the political tyrant. Animated by mystic zeal, he took the line of a prophet, preaching against the reading of voluptuous works and against the tyranny of the Medici and calling for popular government. His attempt to put himself in opposition to his time, to arrest the course of events. to bring the people back to the faith of the past, the belief that all the social evils came from a Medici and a Borgia, his not seeing the historical reality as it was, his aspiring to found a republic with Jesus Christ for its king—all these things show that Savonarola was more of a fanatic than a thinker. Nor has he any great merit as a writer. He wrote Italian sermons, hymns *(laudi),* ascetic and political treatises, but they are roughly executed and important only because they throw light on the history of his ideas. The religious poems of Girolamo Benivieni are better than his and are drawn from the same inspiration. In these lyrics, sometimes sweet, always warm with religious feeling, Benivieni, and with him Feo Belcari, carry us back to the literature of the 14th century.

The Tridentine Reaction. — The fundamental characteristic of the later Renaissance is that it perfected itself in every kind of art, particularly in uniting the essentially Italian quality of its language with classicism of style. This period lasted from about 1494 to about 1560. In the middle of the 16th century, however, two events exercised a considerable influence upon Italian thought and consequently upon literature and art: the Council of Trent and the rediscovery of Aristotle's *Poetics.* The Council of Trent, having failed to find a compromise with the northern Reformers, set itself to restore discipline within the ranks of the Roman Church by a strict enforcement of authority. It was then realized that the assimilation of classical ideas, symbolized by such popes as Nicholas V, Pius II and Leo X, had imperilled the very existence of the church by its consequent laxity of morals. The Society of Jesus and the *Index librorum prohibitorum* mere the more conspicuous organs by which a deadening discipline was brought to bear on the men of the later Renaissance. At the same time the *Poetzcs* were rediscovered and commented on, and the principle of authority that prevailed in politics and religion was thus introduced in literature as well: only such literary forms were considered legitimate, as could be supposed to have Aristotle's support.

Heroic Poetry. — Italy never had any true epic poetry in its period of literary birth. Still less could it have any in the Renaissance. It had, however, many *cantari,* poems so called because they contained stories that were sung to the people dealing with the heroes of Charlemagne and King Arthur. But the first to introduce elegance and a new life into this style was Luigi Pulci (1432–84) who grew up in the house of the Medici and who wrote the *Morgante Maggiore* at the request of Lucrezia Tornabuoni, mother of Lorenzo the Magnificent. The material of the *Morgante* is almost completely taken from an obscure chivalrous poem of the 15th century (later rediscovered by Pio Rajna). On this foundation Pulci erected a structure of his own, often turning the subject into ridicule, burlesquing the characters, introducing many digressions, now capricious, now scientific, now theological. With a more serious intention Matteo Maria Boiardo (1434–94), count of Scandiano, wrote his *Orlando innamorato,* in which he seems to have aspired to embrace the whole range of Carolingian legends; but he did not complete his task. Here, too, we find a large vein of humour and burlesque. Yet Boiardo is drawn to the world of romance by a profound sympathy for chivalrous manners and feelings—that is to say, for love, courtesy, valour and

generosity. A third romantic poem of the 15th century was the *Mambriano* by a certain Francesco called Il Cieco da Ferrara. He showed the influence of Boiardo, especially in something of the fantastic which he introduced into his work.

It was Boiardo's success that encouraged Lodovico Ariosto (1474–1533) to write his *Orlando furioso*. The world of chivalry interested him mainly as a canvas on which to embroider his beautiful patterns. Under the influence of classicism he rendered the structure of his poem more compact and harmonious; and if his characters lack some of the vigour with which Boiardo had endowed them, they are given a perfection of poise and of artistic delineation such as only a master craftsman could create. He worked for many years with unflagging enthusiasm at the revision of his poem, being fully aware that no poet could ever treat the octave stanza with the same easy grace and dazzling perfection.

Meanwhile there was an attempt at the historical epic. Gian Giorgio Trissino of Vicenza composed a poem called *L'Italia liberata dai Goti*, in which he forced himself to observe all the rules of Aristotle; Trissino's work is poor in invention and without any poetical colouring. Luigi Alamanni's *Girone il Cortese* and *Avarchide*, and Bernardo Tasso's *Amadigi* belong to the same period and to the same school of poetry and are not much more successful. We may mention here Annibal Caro's translation of the *Aeneid*.

Torquato Tasso (1544–95), who was perpetually obsessed by religious scruples and critical uncertainties, well exemplifies the post-Tridentine period. He was only 18 years old when, in 1562, he tried to reconcile the Aristotelian rules with the variety of Ariosto in an epic poem, *Rinaldo*. He later wrote the *Aminta*, a pastoral drama of exquisite grace. But the work to which he had long turned his thoughts was a heroic poem, and that absorbed all his powers. He himself explained what his intkntion was in the three *Discorsi*. written while he was composing the *Gerusalemme:* he intended to choose a great and wonderful subject. not so ancient as to have lost all interest, nor so recent as to prevent the poet from embellishing it with invented circumstances; he meant to treat it rigorously according to the rules of the unity of action observed in Greek and Latin poems, but with a far greater variety and splendour of episodes, so that in this point it should not fall short of the romantic poem; and finally, he decided to write it in a lofty and ornate style. This is what Tasso did in the *Gerusalemme liberata*, the subject of which is the liberation of the sepulchre of Jesus Christ in the 11th century by Godfrey of Bouillon. Tasso possessed an unparalleled gift for melodious verse; he lacked power, and in order to bring in the element of surprise so persistently advocated by the commentators of the *Poetics*, he occasionally had recourse to tiresome antitheses and exaggerated metaphors.

Drama.—As the work of Matteo Boiardo originated from the popular *cantari*, the *sacra rappresentazione* developed from the mediaeval *mistero* ("mystery-play"). Although it belonged to popular poetry, some of its authors were celebrated men of letters. It is enough to notice Lorenzo de' Medici, who wrote *San Giovanni e Paolo*, and Feo Belcari. From the 15th century, some comic and profane elements found their may into the *sacra rappresentazione*. Politian emancipated himself from its biblical conventions in his *Orfeo*, which, although in its exterior form belonging to the sacred representations, yet substantially detaches itself from them in its contents and in the artistic element introduced.

The first to occupy the tragic stage during the 16th century was Giangiorgio Trissino with his *Sofonisba*, following the rules of the art most scrupulously. The *Oreste* and the *Rosmunda* by Giovanni Rucellai were no better, nor was Luigi Alamanni's *Antigone*. Sperone Speroni in his *Canace* and Giraldi Cintio in his *Orbecche* tried to ensure success by barren innovations of technique. Superior to these was the *Torrzsmondo* by Torquato Tasso.

The Italian comedy of the 16th century was almost entirely modelled on the Latin comedy. Only two writers stand out among the many who wrote comedies—Machiaveli *(see* below) and Ariosto. In his *Mandragola* Machiavelli, unlike all the others, composed a comedy of character, creating types which seem to be alive even now. Ariosto was far less original. The notorious Pietro Aretino might also be included in the list of the best writers of comedy.

Pastoral Poetry.—The eclogues of Virgil, Nemesianus and others had enjoyed great favour during the middle ages, particularly during the so-called Carolingian Renaissance. Dante imitated Virgil when composing his eclogues to Giovanni del Virgilio; Albertino Mussato followed in his steps, so did Petrarch and Boccaccio, who also wrote a pastoral novel, the *Ameto*. This artificial conception of a pastoral world. so far removed from rural and real life, pleased Italians no less than it had pleased other Romance peoples. Winsome and gentle shepherdesses appear in the poems of Guido Cavalcanti, Franco Sacchetti and many other poets in Tuscan and other dialects down to Lorenzo de' Medici. who also attempted a more definitely rural form with his *Nencin da Barberino* (if indeed he was the author of this poem). The *Nencia* was imitated by Luigi Pulci (*Beca da Dicomano)*. Boiardo composed eclogues in Italian. but it was left to Jacopo Sannazaro, the author of some piscatory eclogues in Latin, finally to fix the characteristics of pastoral poetry in his immensely popular *Arcadia* (1504). This partly allegorical story mingles prose with verse, forming. in all sections a mosaic of classical reminiscences and ever tinged with a melancholy charm. With Sannazaro the realm of shepherds and nymphs finally became something akin to the golden age, a dream world men would enjoy when seeking refuge from the realities of an age in which the collapse of political independence, wars and violence caused more suffering than men of letters cared to describe realistically.

For the later period Giovanni Battista Guarini (1538–1612) ought to be recorded as the author of a pastoral drama *(Pastor Fido*, 1590) which vied in fame with Tnrquato Tasso's *Aminta* (1573), both works having a lyrical rather than a dramatic character. Giovanni Andrea dell' Anguillara made a celebrated translation of Ovid's *Metamorphoses*.

Lyrical Poetry.—Originality was almost entirely wanting in lyrical poetry, since it seemed as if little better could be done than to copy Petrarch. Still, even in this style there were some vigorous poets. Giovanni della Casa (1503–56) and Pietro Bembo (1470–1547) nere technically refined. Even Michelangelo Buonarroti was at times a Petrarchist, but his poems at least bear the stamp of his original genius. And a good many ladies are to be mentioned with these poets, such as Vittoria Colonna, Veronica Gambara and Gaspara Stampa.

Humorous Poetry **and** Satire.—The 15th century had not been without humorous poetry; Antonio Cammelli, surnamed Pistoia. is specially deserving of notice. Francesco Berni (who also reshaped and tuscanized Boiardo's *Orlando innamorato*) carried this kind of literature to perfection in the 16th century. From him the style has been called "bernesque" poetry. It was art for art's sake that inspired and moved Berni to write, as well as Grazzini *(see* below) and other lesser writers. Bernesque poetry is the clearest reflection of that religious and moral scepticism which was one of the characteristics of Italian social life in the 16th century and which showed itself more or less in all the works of that period. The Berneschi, and especially Berni himself, sometimes assumed a satirical tone. But theirs could not be called true satire. Pure satirists, on the other hand, were Antonio Vinciguerra, a Venetian, and, in his *Satire*, Luigi Alamanni. Ariosto's *Satire* read as chapters of a humorous autobiography.

Historiography.—The Italian historians of the 15th century mostly wrote in Latin and were often readier to consider "eloquence" of style or the interests of their patrons than truthfulness; notable exceptions were Leonardo Bruni, who made good use of the documents to which he had access in his history of Florence, and Lorenzo Valla of Forlì. who gave evidence of his pugnacious temperament in some historical tracts, among which the one disproving the legend about the Donation of Constantine is the most famous. Pontano wrote the history of Naples in elegant Latin, Bernardino Corio that of Milan in far less admirable Italian.

Machiavelli and Guicciardini were the chief originators of the modern science of history. Niccolb Machiavelli (1469–1527) can also be described as the creator of the experimental science of

politics. His principal works are: *Il Principe;* the *Discorsi sulla prima deca di Tito Livio; Dell' arte della guerra;* and *Le Istorie fiorentine.* The *Prince* and the *Discourses* were written while Machiavelli was in an enforced retirement from active political work. They have in common the purpose of expounding the political theories that Machiavelli had been evolving in the course of his career and while reading ancient historians. In addition, the *Prince* has the immediate aim of inciting a "new prince" to found a strong state embracing the whole of Italy, whereas the *Discourses* devote more attention to the preservation of states and put the accent on the republican form of government. The *Art of War* is a technical treatise advocating the institution of a popular militia. Machiavelli was capable of cold reasoning, while at the same time an idealist; and the unquenchable longing for a strong and united Italy, able to resist foreign aggression, underlay his masterly theorizing. He would not allow his political thought to be influenced by ethical or other nonpolitical considerations. The vividness and directness of his style are fascinating.

Francesco Guicciardini (1483–1540), like Machiavelli a historian, a statesman and a student of politics, was less of an idealist and did not share Machiavelli's enthusiasms. His insight into the nature of man was exceptionally sharp, even if so pessimistic as to be depressing; he preferred to base his political conclusions on careful weighing of the particular circumstances of each situation rather than on general theories (*Ricordi politici e civili*). His *Storia d'Italia,* which extends from the death of Lorenzo de' Medici to 1534, is full of political wisdom and is written in an impressive style.

Throughout the 16th century historians were legion, following the tradition set up by Machiavelli and Guicciardini. The Florentine Jacopo Nardi, Benedetto Varchi and Giovanni Battista Adriani, the continuator of Guicciardini, deserve special mention, together with Bernardo Segni, Pierfrancesco Giambullari, Bernardo Davanzati, Paolo Giovio and Camillo Porzio. Pietro Bembo wrote the history of Venice (continued by Paolo Paruta), Angelo di Costanzo that of Naples. Giorgio Vasari (1511–74) rendered a signal service to art historians with his *Vite,* or biographies of artists, and Benvenuto Cellini (1500–71) wrote an autobiography fascinating for its liveliness and sincerity.

Didactic Works and Miscellaneous Prose.—Leonardo da Vinci wrote a treatise on painting, Leon Battista Alberti one on sculpture and architecture. But these two men are mainly important as embodiments of a characteristic of the age of the Renaissance—versatility of genius, power of application along many and varied lines and excellence in different fields.

In the 16th century there were not a few didactic works, including two in verse, *Le Api* by Giovanni Rucellai and *La Coltivazione* by Luigi Alamanni. A much more important book, however, is the *Cortegiano* of Baldesar Castiglione (1478–1529), in which the author imagines a discussion between knights and ladies in the palace of the dukes of Urbino as to what are the gifts required in a perfect courtier, giving a valuable illustration of the intellectual and moral state of the highest Italian society in the first half of the 16th century. Wide fame was also achieved by Giovanni della Casa's *Galateo,* a book giving rules of behaviour in polite society, and by Bembo's *Gli Asolani.* Marcello Adriani translated Plutarch's *Lives* and *Moralia.*

The most important of the writers of short stories of the 16th century were Anton Francesco Grazzini (called Il Lasca) and Matteo Bandello: the former, playful and bizarre; the latter, informative from the point of view of social history. Agnolo Firenzuola was another elegant and pleasing writer of short stories; he also translated the *Golden Ass* of Lucius Apuleius. Giovanni Battista Giraldi's tales had a didactic purpose; much more amusing are Giovanni Francesco Straparola's fairy tales. Annibal Caro translated the *Daphnis and Chloe* of Longus.

Finally, mention must be made of the philosopher Giordano Bruno (*q.v.;* 1548?–1600).

THE SECENTISMO

Spanish oppression and the tyranny of the Counter-Reformation seem to have exhausted Italian creative power which was already worn out by the great output of the Renaissance. From about 1559 began a period of decadence in Italian literature. The suspicious rulers fettered all freedom of thought and word; they tortured Campanella and burned Bruno. In this period the phenomenon known in the history of Italian literature as *secentismo* (comparable to similar phenomena in the English, French and Spanish literatures) manifested itself. Its writers, devoid of sentiment, resorted to exaggeration: the utter poverty of the matter tried to cloak itself under exuberance of form.

Marina.-The foremost of the *secentisti* was Giovanni Battista Marino (1569–1625), whose main work, *L'Adone,* consists of 45,000 lines. His aim was to excite wonder by novelty; hence the most extravagant metaphors, the most forced antitheses are to be found in his book; supreme technical skill, particularly in the sensual passages (Marino's art was decidedly sensuous), goes together with lifelessness. Marino's imitators were innumerable. In general, one may say that most 17th-century poets were infected with "marinism." Some, however, struck a more or less original note; in particular, Gabriello Chiabrera (1552–1638), who made successful experiments in imitating the metres of classical poetry (especially of Pindar) and excelled in his *canzonette* (graceful and musical lyrical poems) described as *"anacreontiche";* Fulvio Testi (1593–1646), whose choice style and patriotic sentiments are sometimes ennobled by inspiration; Francesco Redi (1626–98), whose dithyramb *Bacco in Toscana* is full of gaiety and vitality; Vincenzo da Filicaja (1642–1707), whose sonnets, full of rhetorical emphasis, are chiefly remembered for their patriotic feeling; and Alessandro Guidi (1650–1712).

The **"Arcadia".**—The Academy of Arcadia was set up in 1690 with the avowed purpose of "exterminating" bad taste; foremost among its founders were Giovan Mario Crescimbeni and Giovanni Vincenzo Gravina. The program of the Arcadia was in tune with a generally felt need of the age—that of reacting against the bombastic style of the 17th century. This reaction, however, consisted in imitating the simplicity of the shepherds supposed to have lived in Arcadia in the golden age. Thus a new artifice was obviously replacing the old one: effeminacy and affectation instead of bombast, over-refinement instead of turgidity. G. B. Zappi and Carlo Innocenzo Frugoni (1692–1768) were among the most typical products of this school of poetry; but Paolo Rolli (1687–1765) deserves higher praise for the freshness of his *canzonette,* and his name can be coupled with that of Metastasio in this respect.

Scientific Prose, History and Satire.—It would be wrong to suppose that the foregoing occupied the whole of the 17th-century literary scene. Galileo Galilei (1564–1642), who built the foundations of modern science and led the struggle against the Aristotelians and their narrow-mindedness, earned for himself a great place in literature because of his prose style, which is clear, goes straight to the point and possesses an unconscious artistry without rhetorical ornaments. Tommaso Campanella (1568–1639), the philosopher who sought to unite humanity under a utopistic theocracy based on natural religion, also wrote robust and sincere though rough-hewn poetry. Trajano Boccalini (1556–1613) was the standard-bearer of the fight against Spanish domination and for political independence; his best-known books (*Ragguagli di Parnaso,* 1612–1613; *La Pietra del paragone politico,* 1614) are satirical in character and full of an effective and caustic humour. Paolo Sarpi (1552–1623), the author of the *Storia del Concilio di Trento,* was the most powerful advocate of the liberty of the state against papal interference.

The popularity of satire, too, was a healthy sign of reaction against the prevailing political, social and literary conditions. Prominent in this genre were Benedetto Menzini and, even more, the painter Salvator Rosa (1615–73), who attacked in his seven *satires* the vices and shortcomings of his age; his writings (poems and letters) reveal at once an exuberant personality and a genius that anticipated the artistic outlook of a later age. Alessandro Tassoni (1565–1635) acquired great fame with a mock-heroic poem, *La Secchia rapita,* which is both an epic (partly based on historical fact, partly on imagination) and a personal satire. Other notable writers of heroicomic poems were Francesco Bracciolini

(Lo Scherno degli dei) and Lorenzo Lippi (*Il Malmantile racquistato*).

Every review of 17th-century literature should mention Giambattista Basile (1575?–1632), a prose-writer in Neapolitan dialect, whose collection of tales *(Lo Cunto de li cunti)* proved to be the forefather and often the source, of a large number of the fairy tales written since.

THE 18TH CENTURY

With the end of the Spanish domination, political conditions in Italy began to improve. Reforms were gradually introduced in most parts of the country.

Research.—Giovanni Battista Vico (1668–1744) was a token of the awakening of historical consciousness in Italy. In his *Scienza nuova* he applied himself to the investigation of the laws governing the progress of the human race and ruling over the course of events From the psychological study of man he endeavoured to infer the *comune natura delle nazioni*, that is, the universal laws of history, or the laws by which civilizations rise, flourish and fall.

From the same scientific spirit which animated the philosophical investigation of Vico, there was born a different kind of investigation, that of the sources of Italian civil and literary history. Lodovico Antonio Muratori (1672–1750), after collecting in one entire body *(Rerum italicarum scriptores)* the chronicles, biographies, letters and diaries of Italian history from 500 to 1500 and after discussing the most obscure historical questions in the *Antiquitates italicae medii aevi*, wrote the *Annali d' Italia*, minutely narrating facts drawn from authentic sources. Muratori's associates in his historical researches were Francesco Scipione Maffei of Verona (the tragic dramatist) and Apostolo Zeno of Venice. Girolamo Tiraboschi and Count Giovanni Maria Mazzuchelli of Brescia devoted themselves to literary history. Literary criticism also attracted great attention; Muratori, Vico, Gravina, Maffei and several others, while advocating the imitation of the classics as a cure for literary decadence, well realized that such imitation must needs be cautious, and thus anticipated critical standpoints that were later to come into favour during the age of romanticism.

The new spirit of the times also led men to inquire into the mechanism of economical and social laws. Ferdinando Galiani wrote on currency; Gaetano Filangieri wrote a *Scienza della legislazione*. Cesare Beccaria, in his famous little book *Dei delitti e delle pene*, made a contribution to the reform of the penal system and promoted the abolition of torture. Pietro Giannone defended the freedom and independence of secular states in his *Istoria civile del Regno di Napoli*.

Satire.—Giuseppe Parini (1729–99) seems to embody the literary revival of the 18th century. In his days the nobles and the rich spent their lives in empty pursuits or in shameless self-indulgence, wasting their time and fomenting corruption. It was against these social conditions that Parini's muse was directed. In the *Odi* the satirical note is already heard. But it came out more strongly in the poem *Il Giorno*, in which he pretends that he is teaching a young Milanese patrician all the habits and ways of gallant life; he shows up all its ridiculous frivolities, and with delicate irony unmasks the futilities of aristocratic habits. Dividing the day into four parts, (*Mattino, Mezzogiorno, Vespro, Notte*) he pursues his pupil's occupations and holds them up to ridicule. As a work of art, the *Giorno* is notable for the skill with which its delicate irony is constantly kept up and for the classical elegance of its blank verse. In the *Odi* Parini's moral conscience and high principles add value to the lyrical beauties of each poem.

Gaspare Gozzi's satire was less pungent, but directed toward the same end as Parini's. In his *Osservatore veneto*, something like Addison's *Spectator*, he hit the vices with a delicate touch and inculcated a practical moral with much good sense. Gozzi's prose is very graceful and lively. Another satirical writer was Giuseppe Baretti (1719–89). In a journal called the *Frusta letteraria* he took to lashing without mercy the works which were then being published in Italy. He learned much by travelling; and especially his long stay in England and the friendship of Samuel Johnson contributed to give independence to his criticism.

Melodrama and Comedy.—Drama, too, felt the influence of the times. Apostolo Zeno and Metastasio (the Arcadian name for Pietro Trapassi, 1698–1782) endeavoured to make "melodrama and reason compatible." The latter was particularly successful in depicting human passions in a mild and musical way. Comedy was reformed by Carlo Goldoni (1707–93), the author of about 250 plays, who created the comedy of character for Italy—helped no doubt by Molière's example. Goldoni's characters are acutely, even if optimistically. described: he studied nature but did not plunge into psychological depths. He portrayed the Venetian scene masterfully, writing many of his comedies—perhaps the best, in the Venetian dialect.

Pietro Chiari and Carlo Gozzi also stand out among 18th century playwrights. Two of the many adventurers of the time, G. B. Casti and Lorenzo da Ponte (Mozart's librettist) likewise wrote dramatic works; but the former is chiefly remembered for his long fable, *Gli Animali parlanti*, the latter (who ended his checkered career in the United States) for his *Memorie*.

Patriotism **and** Classicism: **Alfieri.**—The ideas that were making their way into French society in the 18th century and afterward brought about the Revolution of 1789 gave a special direction to Italian literature of the second half of the 18th century. Love of liberty, desire for equality and hatred of tyranny created in Italy a literature which aimed at national objects, seeking to improve the condition of the country by freeing it from the double yoke of political and religious despotism. But all this was associated with another tendency: the Italians who aspired to a political redemption believed that it was inseparable from an intellectual revival. These ideas and aspirations were effectively voiced in Pietro Verri's periodical *Il Caffè*.

Patriotism and classicism were the two principles that inspired the literature which began with Vittorio Alfieri (1749–1803). He worshipped the Greek and Roman idea of popular liberty in arms against the tyrant. He took the subjects of his tragedies mostly from the history of these nations, made continual apostrophes against the despots and made his ancient characters symbolize the ideal world of his mind; he did not trouble himself with the verisimilitude of the characters. But as the style of the "Arcadia" was still flourishing, it was necessary to arm the patriotic muse also against it: if the Arcadians, not excluding Metastasio, diluted their poetry with languishing tenderness, the new writers had to fight their trend, to be concise, strong, bitter, to aim at the sublime as opposed to the lowly and pastoral. The stern example set by Parini and Alfieri's grand manner exercised a potent influence.

Alfieri also wrote a remarkable autobiography which provides an invaluable commentary on his determination to put Italy on the level of other nations as far as tragedy was concerned. Among Alfieri's predecessors in the tragic theatre, Francesco Scipione Maffei (*q.v.*) is the most deserving of notice.

THE 19TH CENTURY

Foscolo **and Monti.**—Ugo Foscolo (1778–1827) was an eager patriot who carried into life the heat of the most unbridled passions and into his art a manner occasionally rhetorical but always inspired by classical models. The *Ultime Lettere di Jacopo Ortis* is the story, in the form of letters, of a young man who is led to suicide by frustrated love at once for a woman and for his fatherland. Many of its pages are moving or inspiring. and the book was extremely popular; but it is marred by lack of development in the plot, psychological incoherence and a somewhat strained style. In the lecture *Dell' origine e dell' ufficio della letteratura* Foscolo for the first time gave evidence of his profound critical insight and may be said to have pointed the way to modern Italian criticism. His poem **I** *Sepolcri* had a great and well deserved success. In less than 300 lines Foscolo succeeded in giving lyrical expression of supreme beauty to a fundamental trait of Italian history which he probably learned indirectly from G. B. Vico, for the Italians have ever sought inspiration in their past, and in this poem past glories are extolled as incentives to, and good omens of, a great future. Two odes, some matchless sonnets and the unfinished poem *Le Grazie* are also a testimony of Foscolo's outstanding poetic merit. He went as an exile to England and died

there. He wrote for English readers some *Essays* on Petrarch and on the texts of the *Decamerone* and of Dante, which are truly remarkable pieces of constructive criticism.

If in Foscolo patriotism and classicism together formed almost one passion, as much cannot be said of Vincenzo Monti (1754–1828), in whom the artist was absolutely predominant. He had no one deep feeling that ruled him: rather the mobility of his feelings was his characteristic. He saw danger to his country in the French Revolution and wrote the *Pellegrino apostolico,* the *Bassvilliana* and the *Feroniade;* Napoleon's victories caused him to write the *Prometeo* and the *Musogonia* in his praise; in his *Fanatismo* and his *Superstizione* he attacked the papacy; afterward he extolled the Austrians. Thus every great event made him change his mind, with a readiness which was due to his absorption in art and literature. It would be unjust to accuse Monti of baseness: nature in giving him only one faculty had made the poet rich and the man poor. Knowing little Greek. he succeeded in making a translation of the *Iliad* which is remarkable for its neoclassical beauty.

Foreign Influences.— A remarkable translation of the *Odyssey* was produced about this time by Ippolito Pindemonte, whose truly preromantic poetic output was deeply influenced by 18th-century English literature. Another of the many writers who drew inspiration from English models (particularly T. Gray and E. Young) was Alessandro Verri *(Le Notti romane).* Filippo Pananti was equally under the spell of English intellectual life, but its impact on his style and mood was far more superficial, although he spent some years in England. His *Poeta di teatro* is a poetic novel written in a jocose vein.

A wider and more lasting appeal was exercised by *Le Poesie* di *Ossian, a* verse translation by Melchior Cesarotti (1730–1808) of the so-called Ossianic poems. Preromantic taste was greatly affected and influenced by those lyrical and epical, mysterious and gloomy fantasies.

The **Purists.**—Cesarotti had also occupied a prominent position in the world of learning at the end of the 18th century; his *Saggio sulla filosofia delle lingue* (1785) was an important pronouncement in the course of the dispute on the Italian language then raging. It was not altogether surprising that precisely when so great a political agitation prevailed the question of the Italian language should be heatedly discussed, for it had raged during the 16th century already, when Bembo, Machiavelli and Castiglione, among others, had discussed it, and it was to occupy later on the minds of Alessandro Manzoni and his friends. For the time being the trend was toward a pedantic classicism in the choice of words and expressions as a reaction against the excessive Gallicism which had been favoured in theory and in practice by some of the 18th century innovators, such as Verri and Beccaria. *Purismo,* as this tendency was called, appeared to its supporters to be a manner of patriotism. Among them may be mentioned Antonio Cesari of Verona (1760–1828), who republished ancient authors and brought out a new edition, with additions, of the *Vocabolario della Crusca.* He wrote a dissertation *Sopra lo stato presente della lingua italiana* and endeavoured to establish the supremacy of Tuscan and of the three great writers Dante, Petrarch and Boccaccio. But patriotism in Italy has always had something municipal in it, and a Lombard school opposed this Tuscan supremacy. At the head of the Lombard school were Vincenzo Monti and his son-in-law Count Giulio Perticari. Monti accordingly issued a *Proposta di alcune correzioni ed aggiunte al vocabolario della Crusca,* in which he attacked the Tuscanism of the *Crusca.* The dispute about language was ranked with the literary and political disputes, and all Italy took part—Basilio Puoti at Naples, Paolo Costa in the Romagna, Marc' Antonio Parenti at Modena, Salvatore Betti at Rome. Giovanni Gherardini in Lombardy, Luigi Fornaciari at Lucca, Vincenzo Nannucci at Florence.

A patriot, a classicist and a purist at the same time was Pietro Giordani (1774–1848); he was almost a compendium of the literary movement of the time. His works were few and comparatively unimportant but his position among his contemporaries was such as to single him out as the last great exponent of *purismo.*

The Romantic Movement.— The French domination in Italy had a twofold effect: it caused people to realize that the ancient and often purely sentimental aspirations toward political unity and independence were within the range of possibilities, for all separate little states and their rulers had been swept away by Napoleon; and it convinced Italians that no reliance could be placed on foreign help if such an aim was to be attained, for the French themselves, who had entered Italy as liberators, had proved oppressive masters. An artificial form of classicism was associated with the Napoleonic pre-eminence so that when Napoleon fell, forces antagonistic to classicism were released. The 18th-century critics had long since denounced some of the exaggerations of the classicists; literary romanticism had won favour in France, and French romantics, if erroneously, considered their tendencies akin to those of the German romantics. Between 1816 and 1818 a battle was fought for romanticism particularly in Milan where a romantic periodical, *Il Conciliatore,* was published. G. Berchet (the patriotic poet and author of *La Lettera semiseria di Grisostomo,* the manifesto of romanticism), the dramatist Silvio Pellico, L. di Breme, Giovita Scalvini, E. Visconti were among its principal contributors; their polemical efforts were silenced when several of their group were arrested by the Austrian police (1820) because of their liberal opinions; among the accused was Silvio Pellico, who was later to write a famous account of his experiences, Le *Mie Prigioni* (1832). It appears from the articles in the *Conciliatore* and from other essays that the new school, though advocating the study of modern works in different languages) a certain independence from classical imitation and the discarding of classical conventions, was on the whole consistent with Italian tradition, a point that was made even clearer by the works of Manzoni, who was hailed as the chief exponent of this school.

Manzoni (1785–1873).—*I Promessi Sposi* (1825–26) is the work that made Alessandro Manzoni immortal. S o doubt he got the idea of writing a historical novel from Sir Walter Scott's successes; but he produced not merely a historical novel but an eminently realistic work of art. His characters are so true to life that they hold the reader's attention throughout the novel: from the greatest to the least they stand before us with the human qualities not of one time more than of another, but of all time. Manzoni's ideal was "a true subject, a moral purpose and a pleasing form as a means of attraction." The 17th-century background of Manzoni's novel is vividly and faithfully described, and the slender but skilfully contrived plot is all merged, so to speak, in its historical surroundings. At the same time the novel is meant to bear out its author's views on life, morality and religion. A keen though kindly sense of humour pervades the whole work, which is written in an admirably modern, fluent and elegant style. As a poet, Manzoni had gleams of genius, especially in the ode *Il Cinque maggio,* written on the death of Napoleon, and in those passages of the *Inni sacri* (five poems in celebration of as many ecclesiastical festivals), where he described human affections. His two tragedies, *Il Conte di Carmagnola* (1820) and *Adelchi* (1822) marked the victory of romanticism over the die-hard classicist school; they rely on strict historical truthfulness and rank high in Italian dramatic literature; but the moral purpose is less ably blended with the underlying artistic conception in these plays than in I *Promessi Sposi,* and this detracts from their dramatic merit. Their three choruses stand out as being particularly successful and moving. Great importance attaches to Manzoni's literary, linguistic, historical and philosophical writings.

Apart from Pellico, G. B. Niccolini (1782–1861) was the only other dramatist of note of the romantic period; but his output, which gradually evolved from a classical to a romantic pattern, was never based on historical research and never rose above the surface of events. Eloquence was his strong point, and this he directed toward the aim of stirring his compatriots to love of liberty.

Leopardi (1798–1837).—The great poet of the age was Giacomo Leopardi, born at Recanati, of a patrician family, bigoted and avaricious. He became so iamiliar with the writings of Greek authors that he afterward used to say that the Greek mode of thought was more clear and living to his mind than the Latin or even the Italian. Solitude, sickness and domestic tyranny, prepared him ior profound melancholy. From this he passed into

complete religious scepticism. His matchless poems (*I Canti*) attain to the highest degree of lyrical beauty and are one of the most agonizing cries in modern literature, uttered with a solemn quietness and conviction that at once elevates and terrifies. Form and content are so perfectly harmonized that. whatever one's opinions, one cannot help being carried away by Leopardi's *ennui* and universal sorrow. But besides being a great poet of nature and of sorrow, he was also an admirable prose writer. In his *Operette* morali — dialogues and discourses marked by a cold and bitter smile at human destinies which freezes the reader — the clearness of style, the simplicity of language and the depth of conception are such that he can be considered one of the most perfect prose writers of Italian literature.

Historiography. — The political preoccupations prevailing at the end of the 18th century were not without effect on historical studies: the purely documentary researches of the previous century gave way to the interpretation of past ages from a modern angle. One of the most interesting historians of the earlier part of the new century was the Neapolitan Carlo Troya. His *Storia d' Italia nel medio evo* (1839) was to express a new conception of life. The Piedmontese Carlo Botta was also prompted to write history by political considerations, but his work was notable for rhetorical eloquence of exposition, not, like Troya's, for penetration and originality. Botta wrote a history of Italy from 1789 to 1814; later on he continued Guicciardini's *Storia* to 1789 and wrote an account of the *Guerra d'indipendenea degli Stati Uniti d'America* (1809).

Close to Botta comes Pietro Colletta, a Seapolitan. He also in his *Storia del reame di Napoli dal 1734 al 1825* strove to defend the independence and liberty of Italy. He had a rapid, brief, nervous style, which made his book attractive reading.

While realism in art gained ground the positive method in criticism kept pace with it. From the manner of Botta and Colletta history returned to its spirit of learned research, as is shoun in the *Archivio storico italiano*, established at Florence by Giampietro Vieusseux. and in such works as Gino Capponi's *Storia della Repubblica Fiorentina,* Manzoni's own remarkable treatise *Sopra alcuni punti della storia longobardica in Italia* and Michele Amari's very fine history of the *Vespro siczliaizo.* (A. Ba.; C. F.; U. L.)

The Risorgimento.—After 1821 the literature of Italy was mainly concerned with political events. The names of romantics and classicists survived. but the representatives of either school were actuated by patriotism. Manzoni's novel created so deep an impression that several writers of little merit followed in his tracks. The novels of Carlo Varese, Giovanni Rosini, Defendente Sacchi. Cesare Cantù and many others are scarcely deserving of record; but other works were written that cannot so lightly be dismissed. Tommaso Grossi (1790–1853), Manzoni's friend, composed a historical novel, *Marco Visconti,* lacking in vigour of characterization and conventional in its description of the middle ages, which enjoyed, however, a large measure of popularity. Massimo Taparelli d'Azeglio (1798–1866), a painter and a statesman as well as an author, had a political object in view in writing his *Ettore Fieramosca,* on a heroic episode of the Renaissance, and his *Niccolò de' Lapi* on the private life of a Florentine family of the middle classes during the siege of 1530. Though it is overcronded with incidents, the first of these two novels is full of zest. Later D'Azeglio entered politics and was several times prime minister; during a period of leisure he composed an excellent book of memoirs, *I Miei Ricordi.* D'Azeglio was a Piedmontese and a monarchist. Yet another author of historical novels, Francesco D. Guerrazzi (1804–73), was born at Leghorn and was a republican and a follower of Mazzini. Writing was, to him, a means of fighting against oppression; he led the Tuscan revolution of 1848 and in the intervals of political activity he brought out several novels, of which the *Assedio di Firenze* is the most notable. His style is frankly rhetorical and his historical accuracy is open to criticism, nevertheless there was such vigour and conviction in his writing as to impress his readers. Garibaldi knew Foscolo's *Sepolcri* by heart and his followers called each other by the names of Guerrazzi's characters. It is among Garibaldians that one finds the last historical novelists. G. C. Xbba wrote *Sulle rive della Bormida,* based on an episode of the French domination in Piedmont, and *Da Quarto al Volturno,* a moving account of Garibaldi's campaign in 1860; and the Friulian Ippolito Nievo, who also was one of the Thousand, nrote *Le Memorie di un ottuagenario,* a cyclic novel that just falls short of being a masterpiece through lack of revision, Nievo having been drowned in 1861 in his 29th year. Giovanni Ruffini, an exile and a friend of Mazzini originally wrote in English his two novels, *Lorenzo Beizoni* and *Il Dottor Antonio.*

The pressure of political events caused many works to be written, most of nhich were of course of ephemeral value, though not a few are of notable importance. Giuseppe Mazzini (1805–72) wrote profusely on art, literature and music; at first he championed romanticism, later he opposed it as laying too great a stress on the individual. but at all periods his style was as vigorous as his convictions were sincere; among his political works may be mentioned *Fede ed avvenire* (1835), *Doveri degli uomini* (1844) and *Ai giovani d'Italia* (1860). Cesare Balbo, the historian, should also be recorded here as the author of the essay *Le Speranze d'Italia,* but more important was Vincenzo Gioberti (1801–52), a Piedmontese priest, a philosopher and a man of wide vision, who left his country and the clergy because of his love of liberty. In 1843 he published his *Primato morale e civile degli Italiani* in which he advocated the moral and historical right of the Italians to independence and the creation of an Italian confederation under the presidency of the pope. This book formed the basis of the political creed of the Italians, other than the followers of Mazzini, who took part in the events of 1848–49. The failure of the revolution caused him to revise his opinions and to advocate the institution of a monarchy under the house of Savoy in his *Rinnovamento civzle d'Italia* (1851).

Patriotic themes were common in the poetry of the period. Besides Manzoni, Leopardi and Niccolini, two exiles, Gabriele Rossetti (the father of Dante Gabriel and Christina) and Pietro Giannone, should be mentioned in this connection. The lyrics of Goffredo Mameli, who died fighting in Rome in 1849 at the age of 21, of Alessandro Poerio and of Luigi Mercantini are little better than impromptu verses, but Mameli's at least are vigorous enough to have survived the generation for which they were written. The work of Giuseppe Giusti (1809–50) had greater literary merit, and his satires, not unlike those of Pierre Béranger, were avidly read; but he seldom gave the full measure of his capacity as in the lyric *Sant' Ambrogio.* However. he was endowed with true Tuscan wit and fluency, and his pointed satire was ably directed against political oppressors and human weaknesses alike. Even livelier and wittier were the poems in Milanese dialect of Carlo Porta (1775–1821), and the sonnets in Roman dialect of G. G. Belli (1791–1863). Belli, however, was not a patriotic poet.

Francesco Dall 'Ongaro (1808–73), Aleardo Aleardi (1812–78) and Giovanni Prati (1814–84) were sentimental romantics and patriots. Prati was, indeed, the standard-bearer of the so-called "second romanticism," a movement that had its heyday between 1850 and 1870 and was characterized by its sentimentality and mannerism. Prati's *Edmengarda* (1841) was acclaimed as a novel and original work of art and Aleardi was held in high repute; but very soon they and the mediocre imitators of Manzoni brought romanticism into disrepute and prepared the way for Carducci's reaction. In other departments of literature there was no outstanding figure. P. Cossa was a successful playwright who composed tragedies on Roman subjects; P. Ferrari of Modena (1822–89) transformed the romantic comedy of Gherardi del Testa into modern drama either illustrating a historical period or stating a social problem.

Carducci and Pascoli.—The great figure of the age was Giosuè Carducci (1835–1907). He lived through the feverish period of 1859–60 and his patriotic enthusiasm was changed to disillusionment by the difficulties in which the new kingdom was involved and the manner in which they nere faced by the politicians. He looked to history for inspiration to the classics as models; and he believed his literary gifts to invest him with a political mission. As a poet-seer endoaed with a forceful personality, much learning and uncompromising sincerity he exercised a kind of literary dictatorship. His poems dating trom 1861 to 1900 and published under various titles are collected in his *Poesie.* A determined op-

ponent of romanticism, he attempted a revival of classical metres in his *Odi Barbare* (1877–89); in these and in the other poems of his maturity *(Rime Nuove,* 1861–87; *Rime e ritmi,* 1898) he expressed with admirable power his vigorous outlook on life and his sense of classical beauty and sang the past and contemporary glories of Italy. He was also a polished writer of prose and a scholarly historian of literature; his literary essays have a permanent value, although philosophical criticism such as that of De Sanctis was distasteful to him.

Francesco de Sanctis (1817–83), who was exiled by the Bourbons of Naples, considered literature the expression of social and moral conditions, and on the basis of a sound philosophical training on the works of Giovanni Vico and Georg Hegel he inaugurated aesthetic criticism. His *Saggi critici* and particularly his masterly *Storia della letteratura italiana* were not fully or generally appreciated in his day, but have since received recognition and formed the starting point of the philosophical revival of the later 19th century.

While Carducci was still alive, Giovanni Pascoli (1855–1912) acquired a great reputation and succeeded him in the chair at Bologna. His art was always impressionistic and fragmentary, his language occasionally childish and laborious; but his lyricism, at first timid and tender and altogether rustic and domestic *(Myricae,* 1891) rose gradually to fuller tones, and his concern for the underprivileged (peasants, orphans and even little birds) shifted to the loftier themes of antiquity, Roman heritage and greater Italy. His original vein still found a touching expression in the best among the *Canti di Castelvecchio* (1903); and the classicism of the *Poemi conviviali* (1904), much subtler and more temperate than literary or political neoclassicism usually is, was rather imbued with melancholy nostalgia than swollen with celebration. He tried his hand, however, in the epic genre with the *Canzoni di* Re *Enzio* and such other feeble imitations of Carducci and d'Annunzio; and in later years he produced—both in rich humanistic Latin and in self-consciously elaborate Italian—ample heroic hymns in honour of the sacred cities of Italy, eternal and modern, Rome and Turin.

(H. O.; C. F.; U. L.)

Beside men of such stature, lesser men, however deserving of notice, almost pale into insignificance: even poets as honest and highminded as the Piedmontese Giuseppe Giacosa (1847–1906), author of two greatly applauded plays *(Partita a scacchi,* 1871; *Come le foglie,* 1900), or as gifted as Arturo Graf, Giovanni Marradi and Guido Mazzoni. Giacomo Zanella (1820–88), a classicist, wrote poetry full of inspiration, though lacking in depth. Cesare Pascarella (1858–1940) wrote in the Roman dialect poems full of verve, wit and human feeling.

In the realm of prose, the forceful style and rugged personality of Alfredo Oriani (1852–1909), a novelist, essayist and historian *(Lo Lotta politica in Italia,* 1892) received less notice than was their due. S. Farina and G. Rovetta were minor if popular novelists.

The Realist **Novel.**—Giovanni Verga (1840–1922) stands out as by far the greatest Italian novelist of his time and as probably one of the greatest Italian novelists of all times; he was a realist, indeed, the master of Italian realism, and his two best novels *(I Malavoglia,* 1881; and *Mastro Don Gesualdo,* 1889), which describe the dismal conditions prevailing in Sicily during the first part of the 19th century, often soar to a poignant intensity of desperate fatality. Verga was also an exceptionally gifted writer of short stories *(Novelle rusticane,* etc.). Although his success was not immediate, it proved lasting and his influence on all further developments of Italian literature was paramount. A friend and a follower of his was Luigi Capuana (1839–1915); and the much younger Federico de Roberto (1866–1927), who wrote a masterly novel *(I Vicerk,* 1894), must also be considered as belonging to the same group.

In order to secure a realistic reproduction of life, all these writers drew their subjects almost invariably from the life of their town or district, thus creating a tradition of "regionalist" novels. The same may be said of the Neapolitan Matilde Serao (1856–1927) and of the Tuscan Renato Fucini (1843–1921). To some extent it could be said of Antonio Fogazzaro (1842–1911), too, although his characters move in a wider circle. Fogazzaro was a deeply religious man and was much influenced by Manzoni and the German romantics. His later tales (*Il Santo,* 1906, well-known because of the criticism which it provoked from the ecclesiastical authorities; *Leila,* 1911) did not equal the mellowness and sentimental seductiveness of previous works *(Piccolo mondo antico,* 1895, generally acknowledged as his masterpiece; *Piccolo mondo moderno,* 1900). This was due partly to the growing disagreement between the writer's unchanging moods and the needs and tastes of a changing time, partly to the stiffening attitude of the Roman Catholic Church toward modernism. Rather vaguely if he is to be judged as a philosopher or theologian, but very intensely insofar as he described emotions. Fogazzaro had striven for an alliance of religion and science, of piety and progress. The condemnation of modernism as a heresy, which became final in the papal encyclical *Pascendi* (1907), laid waste the foundation on which he had built the optimistic world of his fiction, where pride of intelligence went together with the peacefulness of conformism and ascetic seekers after God did not disclaim the charms of earthly love.

Other 19th-Century Authors.—A lasting, though less resounding, fame was won by Emilio de Marchi (1851–1901), whose literary allegiance can be traced back directly to Manzoni; his novels (particularly *Demetrio Pianelli,* 1890) reveal the thoughtful and kind-hearted nature of their author and are not devoid of a sense of humour. An altogether different writer was Edmondo de Amicis (1846–1908), whose *Cuore* (1886) became a classic of children's literature and whose short stories and travel books are mainly remarkable, not indeed for vigour of thought, but because they are truly representative of the mood of the masses in his tirne.

Finally the writers of the "Scapigliatura Milanese" deserve mention. This movement, which had Milan as its centre, was strongly imbued with romanticism—not the "second romanticism" (against which it waged war) but the original article. It affected an attitude of rebellion and a dislike for bourgeois orderly life, taking its cue from French "Bohémiens." The novelist Giuseppe Rovani (1818–74; *I Cento Anni,* 1859–60), Emilio Praga (1839–7j) and the poet and musician Arrigo Boito (1842–1918; he mas Verdi's librettist) were the foremost among the "Scapigliati."

In literary criticism the historical method prevailed. Under the inspiration of such teachers as Alessandro Ancona, A. Bartoli, C. de Leva, Pasquale Villari, D. Comparetti and G. I. Ascoli a great amount of scholarly research was carried out and was expounded in learned monographs: facts were ascertained and obscure points were cleared up in political and literary history. (U. L.)

THE 20TH CENTURY

D'Annunzio (1863–1938).—The literature of the 20th century was marked at its inception by the rising influence of Gabriele D'Annunzio. Nietzsche's theory of the superman and a revived Roman patriotism, unmistakably aiming at imperial conquest, merged visibly in the mature phase of D'Annunzio's imagination and in the immature imitations of his followers. The master's literary quality, on the whole, deteriorated from his culmination, which was reached in the earliest years of the century, to his later efforts; and there is a steep descent in his stage production from the passionate glamour of *Francesca da Rimini* (1902) and the enchanting colour and melody of the tragic pastoral entitled *La Figlia di Iorio* (1904) to the weary overemphasis of such plays as *La Fiaccola sotto il moggio* (1905), *La Nave* (1908), *Fedra* (1909) and *Il Martirio di San Sebastiano* (1911), the latter published first in French and set to music by Claude Debussy. The same is noticeable, although less obviously, in his verse. from the sweeping autobiography of *Laus vitae* (1903) and the exultant nature represented in *Alcyone* (1904), to the nationalistic and militaristic program poetry of a collection like *Le Canzoni della Gesta d'Oltremare* (1912). Even in the narrative genre in which he had given his best during his youth, to mark thereafter his step, there appears to be a difference between the firmness of *Il Piacere* (1889), *Il Fuoco* (1900) and *Le Novelle della Pescara* (1902) on the one hand and the devious glibness of *Forse che sì forse che no* (1910) on the other.

But while the values of his literary work vere weakening, he

was injecting into his poetry the meaning and purpose of his will and applying the incitements of poetry to the decisions of life. This double transmutation of biography into poetry and poetry into biography happened with him far more strikingly than with Byron or any other forerunner. He struck the keynote to Italy's intervention in World War I; and his prominence as an inspirer in word and deed persisted all through the struggle. During the armistice, Sept. 1919, at the head of a small army of irregulars, he occupied Fiume, where he reigned like a prince of the Rensissance until the end of 1920. The seed that had been laid by him came to fruition shortly afterward in the Fascist march on Rome and in Mussolini's conquest of Italy. Oct. 1922.

Croce and Gentile.— More aloof from daily events and from the currents of popular or sectional emotion was Benedetto Croce (1866–1952). He had a high repute as a philosopher. but the main weight of his significance is apparent in the field of the history of letters.

Possibly his treatise of ethics (*Filosofia della pratica,* 1909) is the most consummate of his books, but neither this nor any other of them compares in effectiveness with the *Estetica.* Published first in 1902, it inaugurated the new century like a clarion call to youth. Many of its readers overstressed or perverted outright whatever indications in favour of boundless indicidualistic expressionism and of ultimate dissociation of the aesthetic from the moral values the book contained. In several literary circles the suggestions coming from Croce were interpreted as if agreeing with the teachings of D'Annunzio, and the same was to happen a few years later in the ethico-political field when Croce, keenly interested in the diffusion of Georges Sorel's message and especially of Sorel's *Réflexions sur la violence,* contributed indirectly to the moods of the forthcoming nationalist and Fascist upheavals. He himself, the philosopher, warned by the growing difficulties in applying his aesthetic doctrine to concrete subjects of literary criticism, by the objections of some of his pupils and opponents and, last but not least, by the innate moderation of his mind, tried repeatedly to correct his theory without discarding its primal tenets. Various stages of such alterations were consigned to books or collected essays like *Problemi di estetica* (1910), *Breviario di estetzca* (1913), *Nuovi saggi di estetica* (2nd ed., 1926), and *La Poesia* (1936). They made his aesthetic speculation more comprehensive, but also more vague.

In literary criticism, especially successful when exercised on Italian contemporary literature and on writers of the past most congenial to him *(La Letteratura della nuova Italia; Saggi sulla letteratura italzana del seicento)* as well as in historiography (excellent among other books are *Storia del Regno di Napoli, Storza d'Italia dal 1871 al 1915* and *Storia dEuropa nel secolo XIX),* Croce's inexhaustible vein and tireless diligence provided Italy with a monumental work. Pre-eminent among its features are common sense interspersed with humour, charming even when the final point is less convincing, and the neatness of an almost unlimited humanistic scholarship. Such traits are expressed in a prose as fluent as it is polished, as spontaneous as it is appropriate, never inhibited or stilted: a rare appearance in the pageant of Italian letters.

The closest friend of Croce's youth, Giovanni Gentile (1875–1944), whose remarkable contributions to literary criticism can be seen in such books as *Dante e Manzoni* (1923) and *Filosofia dell' arte* (1931), deduced rigorously from certain principles of neoidealistic philosophy which he had held in common with his elder associate, a theory of the absolute state leading him to fascism. Croce avoided this dead end and reaffirmed steadfastly his allegiance to the liberal faith, never satisfactorily defined in his work either from a philosophical or from a social and economic standpoint, but unquestionably alive with moral fervour. Direct participation or even expression in politics nas obviously forbidden to a nonconformist in the era of Mussolini; Croce's opposition, however, is testified—even if, as a rule by implication and innuendo—in the issues of his bimonthly review *La Critica* (founded 1903).

After World War II Croce played an important part in the definition and re-establishment of democracy in Italy.

Poetry from 1900 to 1920.—With the close of the great cycle of lyric poetry which ran from Parini to D'Annunzio, particular trends become more and more difficult to discern. Many poets still clung to traditional patterns, as did A. S. Novaro, Francesco Pastonchi, Angiolo Orvieto; and pure Grecian grace flowed to the poems of Salvatore di Giacomo (1862–1934; collected *Poesie,* 1907) from the secluded source of his Neapolitan inspiration. In Rome. Trilussa (Carlo Alberto Salustri; 1873–1951) carried on the old tradition of Belli and of Cesare Pascarella by pouring his sceptical wisdom and easy-going maliciousness, sometimes with a political sting, into innumerable fables and sonnets in Roman dialect. In Milan, Ada Negri (1870–1945) gave a touch of spontaneity and of feminine warmth of heart to her verses. Another Neapolitan, Francesco Gaeta (1879–1927), is less easy to define: in some ways he was akin to the "Crepuscolari," although he was endowed with a stronger and more courageous personality than most of them.

The "Crepuscolari" (poets, as it were, of a disenchanted twilight after the dazzling D'Annunzian day) heralded in their mild way the break with poetic tradition which became a more and more marked feature of 20th-century poetry. Although their predilection for choice words and a nonchalantly polished style reveal that they could not wholly escape D'Annunzio's dominant influence, they rebelled against his heroic outlook by striking notes of indolent melancholy and of self-complacent resignation: taking their cue from French and Belgian decadentism they groped for an ideal, failed to find it and were left with the boredom and emptiness of life as their main theme. Fausto Maria Martini (1886–1931), Marino Moretti (1885–), Sergio Corazzini (1887–1907) and Aldo Palazzeschi (1885–) were the most striking representatives of this mood. But Guido Gozzano (1883–1916) won more permanent laurels than any of the "Crepuscolari"; he skilfully blended an attitude of disenchanted naïveté *(La Via del rifugio,* 1907; *I Colloqui,* 1911) with a capacity for cynical introspection, using a style often described as poetically colloquial.

A more acute stage in the spiritual crisis of Italian culture was marked by Futurism, the pseudoliterary and pseudoartistic movement heralded in 1909 by Filippo Tommaso hlarinetti (1876–1944).

The Futurists noisily set out to proclaim the subversion of all aesthetic and intellectual standards, to abolish every intermediary between word and expression (by the use of *"parole* in *libertà"*) and to create an art appropriate to an era of scientific and industrial dynamism; in their view, the inspiration of poetry and the urge of physical violence should be one and the same. As a whole, Futurism (although it can now be seen as the starting point of a feeling of revulsion against the traditional language of Italian poetry) was hardly more than a farce, amusing in parts. Vet Marinetti was a close friend to the young hfussolini, and his joke contained some premonition of a time to come.

Journalism, Criticism and Historiography.— As the line of demarcation between literature and politics was fluid, so was it between the university and the periodical press, between high learning and popularization. Among the intermediaries between scholarship or philosophy and broader audiences, *La Critica* of Benedetto Croce preserved through the decades an undisputed primacy, but a long lineage of smart reviews stretched from the *Leonardo* (Florence, 1903) of Giovanni Papini (*q.v.;* 1881–1956) to the *Voce* (Florence, 1908 and ff.) of his friend Giuseppe Prezzolini (1882–), from the Roman neoclassicist *Ronda* of V. Cardarelli. A. Gargiulo and Riccardo Bacchelli to the *Convegno* in Milan and other more eclectic or more exclusive journals in the 1920s and 1930s. A list of those who achieced reputation mainly through agencies of this sort would make a long catalogue; Enrico Thovez (1869–1926), Ardengo Soffici (1879–), Renato Serra (1884–1913). Scipio Slatnper (1888–1913). Emilio Cecchi (1884–), Adriano Tilgher (1887–1941), Mario Vinciguerra and Francesco Flora can be singled out in so far as they exercised influence also through the medium of relevant books and through strong adherence to particular trends in literary criticism and aesthetics.

Historiography, in all its branches, flourished; whether it mas in care of specialized scholars like Ettore Pais (1856–1939), *Storia*

di Roma nei primi cinque secoli; Gaetano De Sanctis (1870–1957), *Storia dei Romani;* Luigi Salvatorelli, Ernesto Buonaiuti, Piero Martinetti (*Gesú Cristo e il Cristianesimo),* or in the vivid interpretations of Guglielmo Ferrero (*q.v.*; 1871–1942), *Grandezza e decadenza di Roma* (1902–07). In literary history the guidance of Francesco De Sanctis (1817–83) was acknowledged by nearly all. Of those who contributed best to its progress, P. Rajna, E. G. Parodi, A. Gargiulo, G. De Robertis. G. A. Cesareo. Guido Mazzoni, V. Rossi, M. Barbi, C. De Lollis, Arturo Farinelli, G. Bertoni, L. Russo, G. Toffanin, A. Galletti and especially Attilio Momigliano (1883–1952) won a following also among laymen.

In these exchanges between centre and provinces as well as between artists or scientists and the public of various regions and strata. the Italian language found at last the stability and unity, together with the vernacular liveliness, that had been desired for centuries.

At the same time, the standards of learning were high, witness not only the rich production in philosophy and all humanities, but also the many thousands of columns of the *Enciclopedia Italiana,* which was published in 1929 ff., but had been planned earlier.

(G. A. Bo.; U. L.)

The Fascist Era.—The Fascist regime (1922–43) on the whole affected literature unfavourably. Conditions under a dictatorship are such as to thwart uninhibited expression. In the theatre, the works of such well-established playwrights as Luigi Antonelli (1882–1942), Sem Benelli (1877–1949; *La Cena delle beffe,* 1909), Roberto Bracco (1862–1943), Luigi Chiarelli (1877–1949; *La Maschera e il volto,* 1916), *E. L.* Morselli (1882–1921; *Glauco,* 1919), Dario Niccodemi (1878–1934) and Rosso di San Secondo (1887–1956) continued to hold the eye of the public. The main interest, however, remained focused on Luigi Pirandello (1867–1936), who received a Nobel prize in 1934. Pirandello's dramas *(Cosi è se vi pare, 1918; Sei personaggi in cerca d'autore, 1921*; *Enrtco IV, 1922; Questa sera si recita a soggetto,* 1930; etc.) gained international success by the originality of the dry geometric method of their treatment and by the unconventionality of an often paradoxical technique. their characters move on the stage in puppetlike fashion, devoid of human flesh and blood and responsive to a weird string-pulling from behind the scene; yet at the same time they are torn by powerfully felt, though unresolved, conflicts —the conflicts among the different beings that cohabit in the same brain. Drama was the ultimate and most congenial form for the expression of Pirandello's disbelief in the rationality of life and in the coherence of human personality—a disbelief which assumes that we can make of life whatever our creative or destructive imagination wants it to be. But before turning to drama, he had tried his hand and perfected his style on fiction. Here his roots lay in the common terrain of the Sicilian realistic school, of which Giovanni Verga, Luigi Capuana and Federico de Roberto had been the major exponents; but his numerous short stories *(Novelle per un anno, 1922* ff.) were admirable for the uncompromising pessimism of the background from which their sketchy characters emerged rather than for such pity and hope as had inspired his predecessors. Already in his early novel, *Il* Fu *Mattia Pascal* (1904), the fundamental topic of his work—an implacable attack against the hypocrisy of social conventions—is quite amply developed.

In the narrative genre some of the old masters continued to hold their own. Grazia Deledda (1871–1936; her masterpiece. *Elias Portolu,* 1903; Nobel prize, *1926)* portrayed her native Sardinia in an uninterrupted flow of novels in which nobility and even outright beauty of style and sentiment were not obscured by monotony. Alfredo Panzini (1863–1939) wrote many novels and short stories in which an exquisite and altogether literary irony invariably seasoned whatever might taste bitter in a reality rather contemplated as puzzling than apprehended as dreadful. More familiar matter was provided for larger clientèles by Virgilio Brocchi (1876–) and by Salvator Gotta *(1887–*) who, together with Delfino Cinelli *(1889–*). Bruno Cicognani *(1879–*), Umberto Fracchia (1889–1930), Enrico Pea (1881–1958), Antonio Baldini *(1889–*), Emilio Cecchi *(1884–*). Bruno Barilli (1880–1952) and Corrado Alvaro (1895–1956), took the places that had belonged to Luciano Zuccoli (1879–1929) or to Matilde Serao in the previous generation. Similarly Ugo Ojetti (1871–1946), an elegant chronicler and supple portraitist *(Cose viste,* 1923 ff.), largely occupied the place that had been held for several decades by Ferdinando Martini (1841–1928). Massimo Bontempelli *(1884–*) exercised his talents in surrealistic compositions. Giuseppe Antonio Borgese (1882–1952) gained greater fame for his works of literary criticism and aesthetics than for his novel, *Rubè (1921).* a picture of the moral and intellectual disintegration out of which fascism was soon to grow. The output of Giovanni Papini (1881–1956) embraces the fields of philosophy and literary criticism, of autobiograpy *(Un Uomo finito, 1912)* and religion, and is as plentiful as it is uneven, though his earlier works stand out for polemical brilliance and zest; a "Crepuscolare" turned Futurist, he became later a mystic.

Next to these already well-known writers, there were some who made their mark during the Fascist era. Italo Svevo (pen name of Ettore Schmitz, 1861–1928), perhaps the most impressive of them, won literary fame late in life *(La Coscienza di Zeno,* 1923); though it is usual to link his name with those of Joyce and Proust or with German romanticism, his own brand of searching psychological analysis defies classification. Of the younger generation, Riccardo Bacchelli *(1891–*), a poet and later a playwright as well as a successful novelist, owes his renown to *Il Diavolo al Pontelungo* (1927) and, even more, to *Il Mulino del Po* (1938–40); both these powerful and well-contrived novels follow in the wake of the best Italian narrative tradition. It was the fate of Ignazio Silone (pen name of Secondo Tranquilli, 1900–) to acquire a wide international repute before his best novels *(Fontamara, 1933*; *Pane e vino,* 1937) were known to his compatriots; for Silone was a political exile, and his books handled convincingly the theme of the anti-Fascist struggle; when they appeared in Italy after World War II, however, the public was already out of tune with their style and mood.

The "Hermetic" Movement.—Poetry in the Fascist period underwent an interesting process of involution which extended the break from a centuries-old tradition, partly under the stress of political conditions in Italy, but even more under the influence of French symbolism. This process amounted to a new and indeed revolutionary use of words and to an attempt at isolating, so to speak, their "lyric potentiality" and at discarding all accessory or decorative elements. Obscurity inevitably resulted, so that the new manner came to be called *ermetismo,* because the meaning of the words was hermetically sealed and because the poet aimed at isolating himself, with uncompromising integrity, within the solitary sphere of his inner self. Fragmentariness, aridity and an attitude of utter indifference were the main features of this movement, which disregarded the appeal of popularity. Its herald was Arturo Onofri (1885–1928), and its best exponents were Giuseppe Ungaretti *(1888–*), in whose brief sketches each word is charged with an extraordinary significance and intensity of emotions, and Giuseppe Montale *(1896–* ; *Ossi di Seppia, 1925, Le Occasioni,* 1939), who took the visible aspects of the external world as "occasions" for a corrosive and cynical symbolizing of his sorrowful outlook on life. Dino Campana *(1885–1932),* Salvatore Quasimodo (1908–) and Leonardo Sinisgalli (1908–) may be mentioned among the rest of the "hermetic" poets. Umberto Saba *(1883–*) preserved a more immediate human appeal and a greater touch with everyday realities.

World War II and Its Aftermath.—Toward the middle of the 20th century. the outlines of the literary scene become too dim to be seen in detail, and the individual voices were too deeply submerged by the din of the crowd to be discerned and evaluated clearly.

"Hermetic" poetry lingered on during World War II. (Mario Luzi, 1914– ; Alfonso Gatto, 1909– ; and many others); but with the subsequent violent changes in the political climate it evolved so much in the direction of articulacy as to become unrecognizable, the first steps in this direction being taken by Ungaretti himself (*Il Dolore,* 1947).

Italian poetry after the war, while still in the throes of the spiritual crisis that characterized most of the first half of the cen-

tury, and still groping for new ways of expression, seemed likely to exchange the gloomy mood of the Fascist period for a brighter and more vigorous attitude.

In the field of narrative literature Italy displayed remarkable vitality and maturity during the 1940s. Having felt sooner and more intensely than other nations the crisis that led to the war, Italy was braced at the end of the conflict for the task of expressing artistically its painful experiences in the previous eventful years, its feeling of rebirth and its new mood of alertness and of undefined but marked expectation. Already in 1941 two novels, Cesare Pavese's *Paesi tuoi* and Elio Vittorini's *Conversazione in Sicilia,* were obviously promising a new stage in literary development.

From these two works and from certain aspects of American narrative literature (as exemplified by William Faulkner, Ernest Hemingway, or John Steinbeck) Italian postwar neorealism took its cue. This neorealism had its roots in the Italian realistic tradition of the late 19th century; but it differed from the latter inasmuch as the reality that was its theme was not a historical reality, but a lyrically interpreted one, evoked at once with lucidity and with the detachment of dreams and given an almost magic hue. The treatment moreover was strongly analytic, or rather psychoanalytic, and the style was colloquial and unpretentious, thus carrying on in the field of prose the reaction to a classical and rhetorical tradition already noticed in regard to poetry. While poetry, however, remained exclusive and pleased only the initiate, prose affected a simplicity of style which gave it a wider appeal. Trends parallel to literary neorealism were also apparent in painting and in the cinema.

Elio Vittorini (1908–), a restless artist forever experimenting in new techniques. was perhaps the most promising of the younger writers (*Uomini* e *no,* 1945); the premature death of Cesare Pavese (1908–50) robbed Italy of a novelist who had already proved his exceptional gifts in such novels as *Prima che il gallo canti* (1949) and *La Luna e i falò* (1950) where balance and control were coupled with a clear insight into the conscience of man. Next to these two masters of neorealism, Vasco Pratolini (1913–) proved himself to be in the forefront of postwar narrative literature; his *Cronache di poveri amanti* (1947) was a novel full of vitality and rich with the teeming life of the Florentine working classes. Many drew their materials from war experiences, as Giuseppe Berto (*Il Cielo è rosso,* 1947), or from a reelaboration of prewar experiences, as Carlo Levi (1902–) nhose *Cristo si è fermato a Eboli* (1945) not only shows a moving sincerity but also sketches a social, moral and, above all. poetical portrait of a people and of a district. Of the older generation, Aldo Palazzeschi, already mentioned as a "Crepuscolare" (he was later a Futurist before temperamentally pursuing his further vagaries from style to style). eclipsed the lustre of his earlier novel, *Le Sorelle Materassi* (1934), with an uneven but even more pleasing novel, I *Fratelli Cuccoli* (1948). Finally, Alberto Moravia (Alberto Pincherle, 1907–) achieved an international repute with his consummate art as a storyteller; his gifts, already apparent in his first novel *(Gli Indifferenti,* 1929), were refined by experience in his later production, throbbing with curiosity for the processes of the human mind. His cold and detached way of exciting indignation, while pretending to refrain from passing judgment, was such as to mask the occasional weaknesses of his plots. In *Agostzno* (1946), *La Romana* (1947), *La Disubbidienza* (1948) and *Amore Coniugale* (1949) his psychological analysis was convincing but limited to certain problems or situations; in *Il Conformista* (1951) he seemed to have deepened and widened his field of observation.

By the middle of the 20th century the very standard-bearers of neorealism seemed gradually to move away from it, Vittorini in his later and more lyrically inclined novels *(e.g., Le Donne di Messina,* 1947), Pavese in his last and posthumous works *(Saggi,* 1952; *Il Mestiere di vivere,* 1952).

There is no doubt. however, that neorealism was a lively movement, truly representative of the temper and of the spiritual needs of the nation in the postwar period.

BIBLIOGRAPHY.—Extremely valuable information, criticism and bibliography for all centuries of Italian literary history are to be iound in *Storia letteraria d'Italia,* 13 vol., 3rd rev. (Milan, 1936–47), the most comprehensive publication of its kind, and in *Storia dei generi letterari,* 20 vol. (Milan, 1904–47). More succinct, but useful, literary histories are. V. Rossi, 3 vol., 15th ed (Milan, 1946); F. Flora, 5 vol. (Milan, 1948); N. Sapegno, 3 vol. (Florence, 1947); A Momigliano, 3 vol. (Messina. 1934); and A D'Ancona and 0. Bacci, 6 vol. (Florence, 1926–29) U. Renda and P. Operti, *Dizionario storiro della letteratura italiana,* 3rd rev. (Milan, 1952) is a repertory of biographies and bibliographies The collection *La Letteratura italiana: storia e testi,* 83 vol. (Milan-Kaples, 1951–), was planned to comprise 75 volumes containing texts, the remainder dealing with literary history. For a bibliographical repertory of 20th-century publications *see* G. ITALIAN **WARS.** The war which broke out in 1848 had for its theatre the northern provinces of Italy and was due to the inhabitants' endeavouring to gain their national unity. To expel the Austrians who were in possession of Lombardy and Venetia was the principal aim of the inhabitants. For a discussion of the political events of this period *see* ITALY: *History.*

THE FIRST WAR

March 1848.—News of the outbreak of the revolution in Vienna in March 1848, together with the revolt of the Hungarians, was the signal for the Italian patriots to rise in Milan four days later (March 17) against the Austrians. Radetsky, the military governor, decided after severe street fighting to retire into the citadel. Seeing that his force was too small to cope with the rising, he evacuated the citadel. On the 23rd he was at Lodi. There he heard of the intended march of the Sardinians on Milan and of the fact that Venice had fallen. The Austrian position was grave, and the only available reinforcements, those in Tirol, were being hurried to Italy. King Charles Albert, who assumed command of the Sardinians, crossed the Ticino at Pavia and Buffalora, intending to pursue the enemy, thought to be in flight. By the first week in April he was at Cremona with 70,000 men. Charles Albert marched to Pastrengo, intending to bar Radetsky's retreat to Tirol. After the action at Goito, April 8. the king crossed the Mincio, while Radetsky retreated to a position west of Verona. The Sardinian attack failed on May 6 at St. Lucia, but Radetsky refrained from following the enemy till reinforcements arrived. Nugent, with part of the expected reinforcements moved from Gorizia to Verona. Evading battle with the papal forces under Durando and Ferrari, he joined Radetsky on May 23.

The Austrian leader assumed the offensive, threatening the Sardinian right and rear and intending to relieve Peschiera. He entered Mantua on May 28. Encountering strong resistance, after the fall of Peschiera, Radetsky attacked Durando with 30,000 men and forced him to surrender with 18,000 men on June 11. Restoring order in the Brenta valley, Radetsky, reinforced, returned to Verona with 60.000. Charles Albert, with 75,000 men, occupied the hilly country around Custozza and the Rivoli plateau. After foul' days fighting, the Sardinians were driven across the Mincio and in full retreat. Charles Albert tried in vain to obtain an armistice. Radetsky, moving by parallel roads, defeated the hostile right at Crema and Lodi and reoccupied Milan on August 4. The Sardinians having crossed the Ticino, an armistice was concluded on August 9.

The Second Campaign. — By the beginning of 1849 Charles Albert was again forced to take up arms in March, entrusting command to Chrzanowski a former Polish general. His forces amounted to seven divisions, three being thrown forward to the Ticino at Galiate, Tregate and Vigevano, with two others at Novara and Ollegio, while another stood under Ramorino, south of the Po opposite Pavia. Radetsky intended to concentrate at Pavia, interposing between the two Sardinian forces north and south of the Po, and then to march against the principal force. He evacuated Milan on March 17, feigning to retire toward Piacenza. Two days later he wheeled to his right and made for Pavia so as to cross the frontier as soon as the armistice expired. Firmly believing the Austrians were retreating, Chrzanowski gave

orders to cross the Ticino at Magenta on March 20.

Radetsky crossed the Ticino and destroyed the bridge at Mezzano Corte, whereby Ramorino was cut off from Chrzanowski's main army. Hearing of Radetsky's advance, Charles Albert decided to meet him at Vigevano. Radetsky sent three corps to Mortara, outflanking the enemy's right with one and with another guarding his own right flank at Vigevano, Mortara fell. the Sardinians retreating to Novara. Next day Radetsky advanced toward Yespolate, with an outflanking detachment on Robbio. The five Sardinian divisions were drawn up at Novara, ready to receive battle that day. Radetsky, believing he was faced by a rear guard, changed his plan of a massed advance on Kovara to a left wheel toward Vercelli, with but one corps going to Novara.

The following morning the Austrian 2nd corps encountered the whole hostile army at Novara and for hours was in the greatest danger. The 3rd corps, coming up, saved the situation in the afternoon and mas, in its turn, followed by the 4th, which threatened the enemy's right. The reserve corps arriving, Radetsky ordered a general advance. the Sardinians falling back in disorder on Novara. An armistice mas arranged that night, Charles Albert abdicating in favour of his son, Victor Emmanuel, and Radetsky giving up the advance on Turin.

THE SECOND WAR

Austria's Ultimatum. — War began on April 26, 1859. Sardinia had rejected the Austrian ultimatum to disarm, dispatched on the 19th, and Gyulai ordered the frontier to be crossed the following day. Having crossed the Ticino at Pavia and Bereguardo, Gyulai reached Valenza on May 3, when a report coming from Vienna, stating the French mere already in Turin in great strength, stopped his advance. He now decided to move on Turin and attack the French columns debouching from Suza. On May 8 the Austrians reached the Sesia at Vercelli. but reports announcing the advance of strong hostile forces on Piacenza forced Gyulai to retire to the Lomellino, with his headquarters at Mortara. A bridge was constructed at the confluence of the Po and Ticino to facilitate a retirement to the south if necessary. The French were already on Sardinian soil and were rapidly joining their allies. Some had come across the Alps by Mont Cenis and Mont Genevre, while the rest had arrived by sea, disembarking at Genoa. Napoleon, assuming command, continued undecided whether to advance to Piacenza, south of the Po, or to move via Magenta on Milan. The first encounter took place at Montebello on May 20, when Stadion was sent to ascertain the strength of the enemy at Voghera. After a brisk fight with Forey's division. the Austrians fell back but were not pursued. This confirmed Gyulai in the belief that the French would march on Piacenza, while Napoleon imagined the Austrians intended a big offensive south of the Po.

He now gave orders to move north by a long flank march on Magenta. as proposed by Jomini. The Sardinians started on May 25, reaching Vercelli on the 29th, while the French made for Casale-Valenza, their right being protected by a division at Voghera and Valenza. Gyulai soon heard of the Sardinian march but mistook it for a feint to divert his attention from the Po.

An action occurred on May 30 at Palestro, which the Sardinians were to hold, to facilitate the French crossing of the Sesia at Vercelli. Fighting was resumed the next day, when the French 3rd corps participated in repulsing the enemy. The French main army was approaching Kovara on June 1, while the Sardinians, with the remaining French forces, were around Palestro-Vercelli, the river Agogna being between them; the Austrians might have attacked them, knowing how widely they were spread out, but Gyulai decided to retreat across the Ticino, which he did next day. His idea was to retreat to the Mincio, but Kuhn, his chief of staff, protested against so hurried a retirement.

Meanwhile, the allies approached the Ticino, seizing the crossings at San Martino and Turbigo. The 2nd French corps. together with the 2nd guard division, crossed the river and occupied Robeccheto early on June 3. The allies now stood as follows: the 1st corps at Lumelogno and the 4th corps at Novara; guards with the 3rd corps at Novara; Sardinians at Galiate. A detachment guarded the extreme right flank at Mortara. The French general headquarters, being badly served by the cavalry, ascertained only early on June 4 that Gyulai had crossed the Ticino the previous evening.

Napoleon intended to attack the Austrian right flank with the 2nd corps and Sardinians, while advancing with the main body, consisting of the 3rd and 4th corps with the guards, against the bridges of San Martino, and to force his way across. Gyulai, on his part, wished to give battle on June 5, holding the enemy with his right, the jth and 6th corps, at Magenta, and to strike the enemy debouching from San Martino with his remaining five corps. Events turned out differently. MacMahon's detachment advanced in two columns early on June 4, but, on approaching Buffalora at midday, met with an obstinate resistance, which held up his advance. The Austrians had 12,000 men posted there, 8,000 at Magenta, 12,000 to defend the bridges and 27,000 at Abbiategrasso. A second move was made at about 4 P.M., when the Austrians were driven back to Magenta.

Meantime, Napoleon, having in hand but a small force at San Martino, awaited MacMahon's advance, which would open the road for his own troops. Hearing firing from the direction of MacMahon's force, Napoleon sent a division of the guards to storm the bridges and support MacMahon toward Buffalora. A desperate struggle ensued, Mellinet's guards encountering 18,000 Austrians, who were trying to wreck the bridges. Urgent messages were sent to the 3rd and 4th corps to forward reinforcements. The French across the Ticino were now able to hold their own for the time being, and it was fortunate for them that MacMahon shortly afterward renewed his effort to press forward, the Austrians gradually giving way before him. Hearing that Magenta had been captured by the enemy, Gyulai gave orders to retreat late that night in the direction of Cremona-Piacenza. The French feared an attack on June 5, and rightly so, as the Austrians could have collected 110.000 men for a renewed battle, but hearing of the retreat of the enemy, they entered Milan on June 7. Next day they drove back the Austrian rear guard at Milegnano, the enemy retreating to the Mincio, which was crossed on June 16. That day the emperor Francis Joseph took command of the army, having Baron Hess as his chief of staff.

Contact with the enemy was lost at the crossing of the Chiese June 1j, but little skill being shown by the allied cavalry, the Austrians assembling in full security behind the Mincio. By the 21st the allies were over the Chiese, with headquarters at Montechiaro, numbering 107,000 French, with 48,000 Sardinians. No fighting was expected west of the Mincio. isolated hostile horsemen alone being visible. A balloon detachment made an ascent at Castiglione June 23, but no enemy was to be seen.

The Austrians decided to take the offensive and crossed the Mincio on June 23 over 12 bridges. By the evening they stood on the line Pozzolengo-Solferino-Pvledole. The 2nd corps was left at Mantua against the hostile jth corps, which was known to be moving south of the Po. A division from the 2nd corps was sent to Marcaria. Neither opponent expected a battle on the 24th. The Austrians believed the enemy would be encountered in two or three days time. while the allies did not expect them this side of the Mincio, which they had to cross on the 24th. The Austrians had every chance of success, had they utilized the 2nd corps at Mantua against the French flank and rear. Lack of initiative and excessive centralization prevailed in their army. The battlefield can be divided into two parts: the hilly (northern) part around San Martino-Solferino; the (southern) plain between Guidizzolo-Medole. The allies stood as follows: the Sardinians on the left at Lonato; the centre: the 1st and 2nd corps and guards, Castiglione-h'lontechiaro; the right: the 3rd and 4th corps, Medole-Castelcoffredo. The Austrians advanced in close formation. The 8th corps. Pozzolengo; the jth, Solferino; the 1st, Cavriana; the 3rd, Guidizzolo; the 4th, Volta; the 9th, Robecco-Medole; the 11th, Cereta. Their plan was to hold the allies by incessant attacks, while making for Carpendolo from the south against the allied right. Their march forward was to begin at 9 A.M. on the 24th.

Firing between the outposts began at 5 A.M. east of Castiglione, and gradually the 1st and 2nd French corps were involved in fighting around Solferino. To the south the 4th corps was also

shortly engaged in a fierce encounter at Medole. The 3rd, delayed by crossing the Chiese, nas hurrying forward but, on approaching Castel Goffredo, heard rumours of a hostile movement from the south, which did not take place. The 2nd corps, being held up at Casa Morino, asked in vain for help from the 4th. and the latter, in turn, pressed the 3rd to assist it. In the north the Austrian 8th corps was hotly engaged from daybreak and held up the Sardinians after seizing San Martino by incessant attacks throughout the day. By 11 A.M. the Austrians were desperately defending Solferino, and, to ease the situation, the Austrian emperor ordered the and army to advance on Castiglione, instead of Carpendole. But all attempts were made in vain against the French 3rd and 4th corps which were attacking in their turn. At 2 P.M. Solferino was captured, thanks to the assistance of the guards. The 2nd army, receiving a second order from Francis Joseph, made a fresh effort, but at 3 P.M, the 1st army having begun to fall back, the battle was practically lost, and the Austrians began their retreat to the Mincio. On the extreme right the 8th corps repulsed every Sardinian attack, falling back only when informed of the 2nd army's retreat. There nas no pursuit. The Austrians fell back on Verona. An armistice was concluded at Villafranca on July 8, Austria ceding Lombardy, while Napoleon received Savoy and Nice from Sardinia.

Venetia.—Seven years had elapsed since the war of 1859, but the Italians still cherished hopes of annexing Venetia, which. nith the exception of Rome. was the remaining Italian state not incorporated in the kingdom. Foreseeing that the Schleswig-Holstein disputes between Austria and Prussia would certainly end in hostilities. Italy signed a treaty of alliance nith Prussia on April 8, 1866. It was stipulated that they were to demand Yenetia from Austria. support by force of arms the reforms for a German confederation and not sign peace separately.

Austria was forced by her political circumstances to assemble two armies. one on her northern frontiers, against Prussia, and a much smaller one against Italy. She relied, to make up for her numerical inferiority, on her small but highly trained forces and on her strong defensive position in the quadrilateral. By an agreement with Prussia: Italy was to invade Venetia. mobilizing her forces for that purpose, in the middle of April 1866 and concentrate them in two groups.

The Austrians under the Archduke Albert, with General John as chief of staff. disposed of but 75,000 well trained troops. He took up a central position between Montagnana and Lonino within reach of either Rovigo or Verona, as he learned the enemy would advance in two separate armies from two directions: one from the Mincio, the other from south of the Po. On June 20 orders were issued to advance to Verona, the archduke intending to attack the Italian king. Garibaldi, meanwhile, was advancing into Tirol. On the 23rd the archduke, having completed his concentration between Verona-Pastrengo, sent his troops into the hills, his plan being to take the offensive the next day, striking the Italians when they would be advancing toward the Adige. The Italians, not expecting serious resistance, advanced with little precaution.

When at Villafranca the Italians were checked by artillery and cavalry, and 20,000 remained inactive all day. Meanwhile, they fell in with the main hostile forces on the heights of Peschiera-Custozza. The Austrians, in their turn, began the attack along the whole line. Battle raged all day with varying success till about 5 P.M., when the Italians were forced to retire to the Mincio. A fortnight later the archduke and the bulk of the army were transported to defend Vienna against the Prussians, and when hostilities closed in Austria the archduke was sent with 1 j5,000 men to Isonzo. No further fighting took place, however, and peace was signed October 3, Austria losing Venetia, though the Italian navy sustained a crushing defeat at Lissa on July 20 when attacked by Tegetthof. Only in 1870. however, did Rome once again become the capital of Italy, the French being obliged to withdraw their garrison from the Eternal City after the French empire had fallen. (A. SMI.)

ITALIC DIALECTS comprise a well-defined subdivision of the Indo-European languages spoken in Italy in ancient times, of which only one. Latin, survived, as Italian: through postclassical and medieval times into modern. In addition to the non-Indo-European Etruscan, there were also spoken in ancient Italy other Indo-European languages, *e.g.,* Messapic, to which the term Italic is not applied; this distinction must be borne in mind. By Italic, then, is understood that subdivision of the western group of Indo-European languages spoken in ancient Italy, which, as tested by the accepted criteria of agreement and of regular, but not uniform, development in vocabulary, syntax, accidence, word formation, and treatment of a common stock of speech sounds, makes a coherent group of dialects. This group is distinguished, by the same criteria, from other western Indo-European subdivisions.

This Italic subdivision: however, falls into two smaller classes: Osco-Umbrian and Latin-Faliscan. The agreements between these two classes are so numerous and so striking that it is necessary to regard them as together forming a single group. The argument that they are separate Indo-European subdivisions need not be pressed further than to say that the speakers of the two classes entered Italy in successive waves. The argument that Osco-Umbrian is in some features closer to Greek than to Latin is unconvincing.

Italic as a whole shows remarkable agreements with Keltic and, in less degree, with Germanic. Perhaps the most striking features that separate Osco-Umbrian from Latin are the substitution of p for I. Eu. q^u where Latin has qu or c (before u or a consonant) and *u* (initial and intervocalic), and the substitution of b for I. Eu. g^u where Latin has *gu* (after *n*), g (before u or a consonant) (c by assimilation); *e.g.*, 0. *púd,* pod, U. *puŕ-e,* Latin quod, I. Eu. $*q^uod$; O. *kumbened, conuēnit,* U. *benust, uenerit,* L. *uenio,* Gothic *qiman* "come," Skt. *gácchati* "he goes," I. Eu. $*g^uem$; U. *umen* (older **omben*), L. *unguen,* I. Eu. $*oŋg^uen$.

Keltic also falls into two subdivisions, similarly distinguished by their treatment of q^u (see J. Whatmough, "Development of I. Eu. labiovelars," Melanges Pedersen [*Acta Jutlandica,* IX, i] 1937, especially pp. 47–48), thus Ir. cia "why," W. *pwy* "who" (cognate with O. pod, L. *quod* above). There are also other important points of agreement between Keltic and Italic.

Of all the ancient languages of Italy, only one, namely Latin, is fully documented and therefore fully known. It remains here only to say something about the geographical distribution of the dialects, the dates between which they are recorded, the nature of the documents in which they are preserved and the varieties of alphabet in which those documents are recorded. Apart from Latin, which also has epigraphic as well as literary evidence, the other dialects are known only in inscriptions, some from a certain number of glosses, *i.e.,* definitions of dialect words, preserved in ancient writers. The evidence of ancient names, local. divine and personal, is by comparison unimportant, but (like the glosses) usually confirms the other evidence (or is confirmed by it) and occasionally, especially in the more scantily recorded dialects, contributes a few items of information that would otherwise be totally unknown.

Latin was originally the language only of Rome and its immediate vicinity. Its neighbour and congener Faliscan was properly the dialect of Falerii in southern Etruria and of a tract of surrounding territory as far south as Capena. It is probable that these dialects mere introduced into Italy by an early wave (not later than the beginnings of the Early Iron Age) of Indo-European speaking tribes, nho, coming down from the north, crossed the eastern Alps and then the Apennines to reach the west coast of Italy, where they were subsequently isolated by the Etruscans. In fact, traces of kindred speech have been detected among Alpine dialects, of which Venetic shons some features curiously reminiscent of Latin, e g., medial b and d from Indo-European *bh,* dh; ks and kt preserved; genitive singular *i* or o stems; dative-ablative plural *-os* [*-bos*].

(*See* the Harvard dissertation of M. S. Beeler, "The Phonology of Venetic.")

A group of Raetic inscriptions discovered in 1936 and 1937 in the Val Camonica (north of the Lago d'Iseo) reveals striking similarities with Faliscan. *e.g., sanquuos,* genitive singular of a u stem; cf. Faliscan *zenatuo(s)*; *tito,* dative singular, as in Faliscan *titoi,*

tito.

(See J. Whatmough, *Classical Philology,* vol. xxxv, pp. 186–188, 1940.)

The Osco-Umbrian dialects are believed to have entered Italy at a later date. Umbrian is wedged between Etruscan and Picene, and the southernmost extension of Oscan to the toe of Italy and across the Straits of Messina dates from *c.* 300 B.C. The following may be distinguished: (1) southern Oscan, represented chiefly by the Tabula Bantina (Apulia), but also by fragmentary remains in Lucania and in the country of the Bruttii; (2) central Oscan in Campania and among the Samnite tribes (Hirpini, Samnium, Frentani), which is the main source of information about Oscan, especially as it appears in the numerous inscriptions of Campania, so that "Oscan" unqualified usually means the central Oscan of Campania, though the language of the Tabula Bantina is not essentially different and contributes much to knowledge of the dialects; (3) northern Oscan, represented by inscriptions of the Paeligni, Marrucini and Vestini, which, because of their peculiar features and limited sources, are usually spoken of specifically.

A pair of Volscian inscriptions (Velitrae, Antium) represent the dialect of the Volsci who lived in southern Latium. Records of a number of minor dialects (of the Marsi, Aequi, Hernici, Praenestini and Sabini) in central Italy are commonly grouped together as Latinian, though actuzlly they all belong (except Praenestine) with the Osco-Umbrian group. Volscian shows strong similarities of development to those of Umbrian. All the pre-Latin dialects of regions of Italy other than those here enumerated belong to other linguistic Indo-European groupings (Greek, Keltic, Illyrian and Ligurian), the non-Indo-European Etruscan of the west coast alone excepted.

Knowledge of a dialect cannot be claimed without primary records of that dialect; in the case of ancient dialects, this is tantamount to saying without written records of it. All varieties of writing in articulate documents of ancient Italy (a few Phoenician and late Semitic inscriptions excepted, and of course the non-native texts on exotic objects brought in by trade) stem from some variety of Greek alphabet. So far as the dialects described in this article are concerned, the alphabets in which they are preserved to us stem without exception (not even Latin) from a proto-Etruscan or Chalcid-Etruscan alphabet, which is a variety of western Greek alphabet (like the old Attic alphabet). This form of writing cannot have been introduced into Italy much before *c.* 800 B.C. The oldest dialect or Latin inscription (that of the Praenestine fibula) is dated *c.* 600 B.C. But neither dialect nor Latin inscriptions are numerous before the middle of the 3rd century B.C. There are no Oscan inscriptions of later date than the Pompeian graffiti which were written shortly before the eruption of Vesuvius overwhelmed Pompeii in A.D. 79. Since, however, Oscan has left some clear marks of its influence on southern Italian dialects, it probably was not extinct at so early a date. Official documents in Oscan cease at dates which vary with the advance of Roman control (at Capua in 211 B.C., for example; at Pompeii in go B.C., when Sulla captured the city; and indeed everywhere after the Social War of 90–89 B.C.).

With the help of such fixed points as these, the relative chronological order of inscriptions may be determined, within broad limits, on epigraphic grounds.

Both the Oscan and the Umbrian, like the Etruscan and the oldest Latin, alphabets have the letters facing to the left (ꟻ b) and also have a right-to-left direction of writing. The Latin alphabet is in use in the later inscriptions, and in some of the southern Oscan inscriptions the Tarentine-Ionic variety of Greek alphabet is used. For details *see* C. D. Buck, Grammar *of Oscan and* Umbrian, pp. 22–24.

ITALO-CELTIC: *see* ITALIC DIALECTS.

ITALO-TURKISH WAR. Following the diplomatic discussions which took place between Rome and Constantinople during the summer of 1911, an ultimatum from Italy was delivered to the Porte on Sept. 28, demanding Turkey's consent to a military occupation of Tripolitania and Cyrenaica. A period of 24 hours was set by the ultimatum, and as the Turkish reply did not meet the Italian demands a state of war was declared as from 2.30 P.M. on Sept. 29.

Italian Naval Activity.—Military action was slow to succeed the formal declaration of war, and it was not till Oct. 11 that the first transports reached Tripoli. Meanwhile the Italian navy had been busy. On Sept. 28 a squadron appeared off Tripoli, and notice was given that if the town were not surrendered it would be bombarded. The obsolete fortifications were bombarded for two hours on Oct. 3, after the Turkish authorities had declined to surrender the town. By next day, the Turkish garrison, acting upon order received from Constantinople, had retired into the sandy plains, and on Oct. 5, a force of 1,600 sailors was disembarked. Meanwhile hostilities had been begun elsewhere. On Sept. 29 and 30 Italian destroyers under the command of the duke of the Abruzzi sank the Turkish torpedo-boats off Prevesa in Epirus and on Oct. 1 Admiral Aubry left Augusta to go in search of the Turkish fleet, which the declaration of war had found at Beirut. But the orders given him were suddenly countermanded, and instead of steaming to the Aegean in order to intercept the Turks, he was sent to Tobruk, which was occupied by a detachment of sailors on Oct. 4. The renunciation of the attempt to cut off the Turkish fleet was inspired by political reasons.

Italian Expeditionary Force.—A week elapsed between the landing of the sailors at Tripoli and the arrival of the expeditionary force, and it was not till Oct. 20 that all the equipment had been put on shore. The force consisted of some 9,000 rifles with a few field and mountain batteries and two squadrons of cavalry. There was very little transport, for it had not been anticipated that the Turks would retreat towards the interior and receive support from the native tribesmen. That Neshat Bey, the Turkish commander in Tripoli, did receive this support was largely due to two men—Ferhat Bey, deputy for Tripoli, and Suleiman el Baruni, a Berber from Fessato, who was deputy for the Jebel region. Meanwhile Homs, Derna and Benghazi had been occupied. There was some resistance at each place, especially at Benghazi, but the first fighting of any importance was a sudden attack on Oct. 23 upon the Italian lines at Shara Shat in the Tripoli oasis, backed by a rising behind the lines. Two companies of Bersaglieri were cut to pieces, and the rest of the regiment were hard put to it to hold their own. Further attacks led to a withdrawal of the line, and to the clearing of the oasis behind the trenches. Large reinforcements were sent from Italy, and by the fourth week in November General Caneva, who was in command of the expedition, had about 25,000 rifles and 16 batteries. He took the offensive, and in two actions cleared the oasis and sent the Turks and their tribesmen allies packing. Turkish headquarters were established at Aziziya, some 30m. south of Tripoli.

Political Aspect.—At the beginning of November the Italian Government had considered the possibility of extending the theatre of war, on the sea at least, hoping to induce Turkey to give up the struggle. Austro-Hungary intervened, backed by Germany, invoking Article VII. of the Triple Alliance. Italy's action being limited in this way, it was necessary to solve the problem directly, but the task was more difficult than it need have been owing to the limitations laid upon General Caneva by the Italian Government. General Caneva's orders appear to have

been that he must not risk reverses or suffer heavy loss. In the circumstances, an expedition in pursuit of the Turks, and their mobile allies seemed hardly practical. In any event, months went by without any action of importance in Tripolitania. In Cyrenaica there was one fight near Benghazi, when a force of Arabs who had come near the town were attacked and severely punished. Derna was closely beset throughout the winter, and Enver Bey, who had succeeded in reaching Cyrenaica towards the end of the year, organized a formidable resistance, securing relative unity among the tribesmen, and a willingness to co-operate with the Turks, which had never before existed.

Italian Offensive Renewed. — In April, the long spell of inaction in the western province came to an end, and from that time onward the resistance of the Turks and Arabs was gradually broken by a series of operations at various points. In April Italian warships appeared off the entrance to the Dardanelles. They were fired on by the Turkish forts and their answer drew a fresh and very energetic protest from Vienna. The northern Aegean was left alone by the Italians henceforth, but in May the island of Rhodes and 12 small islands of the Sporades (subsequently famous as the Dodecanese) were occupied by Italy. During the summer there were a number of successful actions in Tripolitania, and peace negotiations were begun at Ouchy in August. Progress was very slow, and it was not until Oct. 15, when two important victories had been won by the Italians, at Derna and Sidi Bilal (near Zanzur) that the Treaty of Ouchy mas signed.

Conclusions. — The conduct of the Tripoli campaign was prejudiced, first, by the failure of the Italian Government to judge the situation correctly, and secondly, by the limitations which were laid upon the military command. It was not possible at once to launch a desert expedition, and the difficulties of an advance to the Jebel, through country largely waterless, may be said to justify the adoption of a less ambitious plan. What is difficult to understand is the practical veto upon action of any kind, which immobilized large forces from December till April and delayed the carrying out of the policy which eventually put an end to hostilities. the policy of extending the area of operations and striking a blow whenever the chance offered.

The operations of the summer changed the situation, but Italian prestige was not wholly restored by the later successes, or by the subsequent actions against the tribesmen who did not lay down their arms when the treaty was signed. The policy of the Government bore heavily upon the army, which came in for much unfair criticism and increased the difficulties of those who undertook the administration of the country after the peace. The troubles which were to come with the outbreak of World War I may be traced in part at least to the hesitations and uncertainties of the six months following the landing.

ITALY (ITALIA), the name applied both in ancient and in modern times to the great peninsula that projects from the mass of central Europe far to the south into the Mediterranean sea, where the island of Sicily may be considered as a continuation of the continental promontory. The portion of the Mediterranean commonly termed the Tyrrhenian sea forms its limit on the west and south, and the Adriatic on the east; while to the north, where it joins the main continent of Europe, it is separated from the adjacent regions by the mighty barrier of the Alps, which sweeps round in a vast semicircle from the head of the Adriatic to the shores of Nice and Monaco.

The land thus circumscribed extends between the parallels of 46° 40' and 36° 38′ N. lat. and between 6° 30' and 18° 30' E. long. Its greatest length in a straight line along the mainland is from northwest to southeast, in which direction it measures 708 mi. in a direct line from the frontier near Courmayeur to Cape Santa Maria di Leuca south of Otranto, but the great mountain peninsula of Calabria extends about 2° farther south to Cape Spartivento in lat. 37° 55′. Its breadth is, because of its configuration, very irregular. The northern part measured from the Alps at Monte Viso to the mouth of the Po is about 270 mi. wide, while the maximum breadth from the Mont Cenis to Duino is far greater. Peninsular Italy, which forms the largest portion of the country, nowhere exceeds 150 mi. in breadth and does not generally measure more than 100 mi. across.

Italy's southern extremity, Calabria, forms a peninsula, being united to the mass of Basilicata or Lucania by an isthmus only 35 mi. in width, while that between the gulfs of Sant'Eufemia and Squillace, which connects the two portions of the region, does not exceed 20 mi. The area of the republic of Italy is 116,294 sq.mi., or, excluding Sicily and Sardinia, 97,068 sq.mi.

Land Frontiers. — Italy's northern land frontier is formed by the Alps, which divide it from France, Switzerland and Austria. In the east the treaty of Paris (1947) fixed an ethnic boundary between Italy and Yugoslavia; the southern end of this boundary was along zones A and B of the former Free Territory of Trieste. Zone A was later incorporated into Italy.

The French Frontier. — The French frontier starts from the Ligurian coast at Ponte San Luigi about 3 mi. W. of Ventimiglia at the mouth of the Roya river; keeps to the west of the Roya for about 9 mi, then crosses it southeast of Breil and, since 1947, runs northeastnard to Monte Marguareis, thus taking the small communes of Briga and Tenda into France. From hiarguareis the frontier goes west along the watershed to Cima di Collalunga, where it joins the main Alpine watershed and follows it in a general northerly direction to the Mont Blanc mass and Mont Dolent at its eastern end. The most important alteration made in this frontier by the treaty of 1947 was that which included Briga and Tenda and several electric power stations, particularly that at San Dalmazzo, in France. Between Tenda and Collalunga France acquired a stretch of wild mountain country by the moving of the frontier on to the main watershed.

In the Mont Thabor-Chaberton area north of Briançon the treaty eliminated certain small Italian salients into French territory, which were said by the French to constitute a threat to Briançon. A little farther north an alteration on the Mont Cenis plateau gave France the hlont Cenis lake and with it the control of the water supply to the big Italian power station of Venaus. One small rectification on the col of the Little St. Bernard pass transferred the hospice to France in order to give the French better strategic control over the approach from the Valle d'Aosta. The important road and railway from Cuneo through the Tenda pass to Ventimiglia run partly through French territory; the main railway line from Turin into France enters France by the Mont Cenis tunnel under the Col Fréjus. All of this frontier lies among the mountains (many of them more than 10,000 ft. high). Though there are a number of high passes, there are only four, apart from the Tenda pass, crossed by roads; viz., the Little St. Bernard, the Mont Cenis to Lanslebourg, the pass by Claviere to Briançon and that between the Cottian and Maritime Alps by Argentera.

The Swiss Frontier. — The Swiss frontier runs from Mont Dolent to Piz Lat close to the Resia pass in an east-west direction. East of the Great St. Bernard the frontier follows the line of the crests including the hfatterhorn and Monte Rosa. From Pizzo d'Andolla the line runs northeastaard, leaving the whole of the Simplon pass in Switzerland. From Punta di Valrossa west of the St. Gotthard pass the frontier describes a great V southward. Switzerland thus includes the top end of Lago Maggiore and most of Lago di Lugano and comes within 3 mi. of the town of Como before the frontier runs northward again to Pizzo Tambo near the Splugen pass. From the Splbgen the frontier goes southward to the western end of the Bernina Alps along their crests, southward again to Tirano and then northward to Campo di Corno, leaving the whole Bernina pass in Switzerland. From there it runs mainly northward, crossing the Stelvio pass at right angles, to Piz Lat and the Resia pass. This frontier is crossed by the railway lines to the Simplon, St. Gotthard and Bernina passes and by many international roads.

The Austrian Frontier. — The Austrian frontier, fixed by the treaty of St. Germain (1919), runs along the high Alps to the east and west of the Brenner pass. Starting from the Resia pass

the frontier runs along the crest of the Venoste (Otztal) and Stubai Alps to the Brenner and then along the Aurine (Zillertal) Alps to the Vetta d'Italia, the most northern point of Italy; from the Vetta it runs south along the Pusteria Alps to the Carnic Alps, which it follows in an easterly direction to Monte Forno, its junction with the Italo-Yugoslav frontier, leaving Tarvisio and the Predil pass inside Italy.

The Yugoslav Frontier.—The frontier fixed by the treaty of Paris follows the northern part of the line proposed by the French as one which would conform to the ruling of the Council of Foreign Ministers of France, Great Britain. the Cnited States and the U.S.S.R. to fix a frontier which would be in the main an ethnic line leaving a minimum population under alien rule. But the calculations of the French were based on the inclusion of Trieste and its immediate surroundings in Italy; the creation of the Free Territory of Trieste destroyed the balance and left a large number of Italians in the coastal towns of Istria under Yugoslav rule and practically no Yugoslavs in Italy.

The northern part of the frontier lies west of the Isonzo river which it crosses at Salcano about 2 mi. N. of Gorizia; it then skirts Gorizia closely, leaving the town in Italy but the springs which provide its water supply in Yugoslavia. From Gorizia the line runs southward to a point about 1¼ mi. N.E. of the village of San Giovanni, where the frontiers of Italy, Yugoslavia and the Free Territory of Trieste meet. The Italo-Trieste frontier runs southward from this point into the Adriatic just west of Duino.

PHYSIOGRAPHY

While the Alps thus constitute the northern boundary the configuration and internal geography of Italy are determined almost entirely by the great chain of the Apennines, which branches off from the Maritime Alps between Nice and Genoa and, after stretching in an unbroken line from the Gulf of Genoa to the Adriatic, turns southward and continues throughout central and southern Italy, of which it forms, as it were, the backbone, until it ends in the southernmost extremity of Calabria at Cape Spartivento. The great spur or promontory projecting toward the east to Brindisi and Otranto has no direct connection with the central chain.

One result of the manner in which the Apennines traverse Italy from the Mediterranean to the Adriatic is the marked division between northern Italy, including the region north of the Apennines and extending thence to the foot of the Alps, and the central and southern parts of the peninsula.

Northern Italy.—By far the larger portion of northern Italy is occupied by the basin of the Po, which comprises the whole of the broad plain extending from the foot of the Apennines to that of the Alps, together with the valleys and slopes on both sides of it. From its source in Monte Viso to its mouth on the Adriatic—a distance of more than 280 mi. in a direct line—the Po receives all the waters that flow from the Apennines northward and all those that descend from the Alps toward the south, including the Mincio (the outlet of the Lago di Garda). The next river east of the Mincio is the Adige which, after pursuing a parallel course with the Po for a considerable distance, enters the Adriatic by a separate mouth. Farther to the north and northeast the various rivers of the Veneto flow directly into the Gulf of Venice.

The geography of northern Italy is best described by following the course of the Po. The river starts as a mountain torrent descending from the north flank of Monte Viso, from a point more than 6,000 ft. above the sea. After less than 20 mi. it enters the plain at Saluzzo, between which place and Turin (30 mi.) it receives three considerable tributaries—the Chisone on its left bank and the Varaita and Maira on the right or south. A few miles below Valenza it is joined by the Tanaro, which brings the waters of several minor rivers.

More Important are the rivers that descend from the main chain of the Graian and Pennine Alps and join the Po on its left bank. Of these the Dora Riparia, which flows into the Po just below Turin, rises in Mont Genèvre and flons past Susa at the foot of the Mont Cenis. Next comes the Stura, which rises in the glaciers of Roccamelone; the Orca, flowing through the Val di Locana; and the Dora Baltea, which has its source in the glaciers of Mont Blanc and thence descends through the Valle d'Aosta for about 70 mi. till it enters the plain at Ivrea and, after another 20 mi., joins the Po below Chivasso. (See SAINT BERNARD PASSES.) About 25 mi. farther on. the Po receives the Sesia, which rises at the southern foot of Monte Rosa and enters the Po 14 mi. below Vercelli. A little above this confluence, at Casale Monferrato, the navigable portion of the river begins (337 mi. to the mouth, minimum width 650 ft., minimum depth 6 ft. with many shallows and sandbanks). About 16 mi. E. of Vercelli it is joined by the Ticino, a large and rapid river, which flows out of Lago Maggiore (*q* v.). The next great tributary, the Adda, flows out of Lago di Como at Lecco, and thence traverses the plain for 70 mi. till it enters the Po between Piacenza and Cremona. It receives the waters of the Brembo, descending from the Val Brembana, and the Serio from the Val Seriana above Bergamo. The Oglio rises in Monte Tonale above Edolo and descends through the Val Camonica to Lovere, where it expands into the Lago d'Iseo (*q.v.*). From Iseo's southwestern end, the Oglio has a long and winding course through the plain, reaching the Po above Borgoforte. In this lower part it receives the smaller streams of the Mella, which flows by Brescia, and the Chiese. from the small Lago d'Idro, which lies between Lago d'Iseo and Lago di Garda.

The last great tributary of the Po is the Mincio, which flows from the Lago di Garda (*q.v.*) and has a course of about 40 mi. from Peschiera sul Garda. at Garda's southeastern angle, till it joins the Po. About 12 mi. above the confluence it passes under the walls of Mantua (*q.v.*) and expands into a broad lakelike reach so as to encircle that city entirely.

The Adige, joined by the Isarco below Bolzano, enters the great plain at Verona, following a course from north to south nearly parallel to the rivers last described. But below Legnago it turns eastward and runs parallel to the Po for about 40 mi., entering the Adriatic by an independent mouth about 8 mi. from the northern outlet of the greater stream. The two rivers have, however, been joined by artificial cuts and canals, thus permitting free circulation between them.

The Po itself, which is there a very large stream with an average width of 400 to 600 yd., divides into two arms, known as the Po della Maestra and Po di Goro, at Santa Maria di Ariano, and these arms are subdivided into several other branches, forming a delta more than 20 mi. in width from north to south. The point of bifurcation, at present about 25 mi, from the sea, was formerly much farther inland, more than 10 mi. W. of Ferrara, where a small arm of the river, still called the Po di Ferrara, branches from the main stream. Before 1154 this channel was the main stream, and the two small branches into which it subdivides, called the Po di Volano and Po di Primaro, were in early times the two main outlets of the rive:. The southernmost of these, the Po di Primaro, flows into the Reno and enters the Adriatic about 12 mi. N. of Ravenna, so that, if these two arms are included, the delta of the Po extends for about 36 mi. from south to north. The main exit of the river in 1950 was the Po della Pila. The whole course of the river, including its windings, is estimated at 420 mi.

In the first 21 mi. of its course, down to Revello (west of Saluzzo), the Po descends no less than 5,250 ft., a fall of 47.3:1,000. From the confluence of the Ticino its fall is about 0.3:1,000; from the beginning of the delta below Ferrara, 0.08:1,000. At Turin it has an average width of 400 to 415 ft., a mean depth of 3½ to 5½ ft. and a velocity of 1 to 3 ft. per second. The mean depth from the confluence of the Ticino (altitude 217 ft.) downward is 6 ft to 1 j ft.

The total length of the embankments exceeds 600 mi. Its confinement between these high banks and the great amount of sedimentary matter which the river brings down with it have gradually raised its bed so that in its lower course it is often above the level of the surrounding country. A result is the rapid growth of the delta (1300–1600, 127 ac.; 1823–93, 174 ac.). The Po della Maestra advances 282 ft. annually, the Po delle Tolle 262 ft., the Po della Gnocca 111½ ft., and the Po di Goro 259 ft. The low ground between the lower Po and the lower Adige and the sea is known as Polesine.

Besides the delta of the Po and the large marshy tracts which it forms, there exist on both sides of it extensive lagoons of salt water, generally separated from the Adriatic by narrow strips of sand or embankments, partly natural and partly artificial, but having openings which admit the inflow and outflow of the sea water and serve as ports for communication with the mainland. The best known and the most extensive of these lagoons is that in which Venice is situated, which extends from Lido di Iesolo in the north to Foce del Brenta in the south. a distance of more than 40 mi.; but they were formerly muck more extensive and afforded a continuous means of internal navigation by what were called the "Seven seas," from Ravenna to Altino, a few miles north of Torcello. That city, like Ravenna, originally stood in the midst of a lagoon; and the coast east of it to near Monfalcone, where it meets the mountains, is occupied by similar expanses of water, which are, however, gradually becoming converted into dry land.

The tract adjoining this long line of lagoons is, like the basin of the Po, a broad expanse of perfectly level alluvial plain, extending from the Adige eastward to the Carnic Alps where they approach close to the Adriatic between Aquileia and Trieste and northward to the foot of the main chain of the Alps which there sweeps round in a semicircle from the neighbourhood of Vicenza to that of Aquileia. The space thus included was known in ancient times as Venetia, a narne applied in the middle ages to the well-known city; the eastern portion of it became known in the middle ages as Frioul or Friuli, a district which is of special interest for the form of Romance language still spoken in it.

Returning to the south of the Po, the tributaries of that river on its right bank below the Tanaro which flow from the Ligurian Apennines generally dwindle in summer into insignificant streams. The principal are: (1) the Scrivia, a small but rapid stream flowing from the Apennines at the back of Genoa; (2) the Trebbia, a much larger river which rises near Torriglia within 20 mi. of Genoa, flows by Bobbio and joins the Po a few miles above Piacenza; (3) the Nure, a few miles east of the preceding; (4) the Taro, a more considerable stream; (5) the Parma, flowing by the city of the same name; (6) the Enza; (7) the Secchia, which flows by Modena; (8) the Panaro, a few miles to the east of that city; (9) the Reno, which flows by Bologna, but instead of holding its course till it discharges its waters into the Po, as it did in Roman times, is turned aside by an artificial channel into the Po di Primaro. The other small streams east of this have their outlet in like manner into the Po di Primaro, or by artificial mouths into the Adriatic between Ravenna and Rimini. The Marecchia river, which enters the sea immediately north of Rimini, may be considered as the natural limit of northern Italy. (See RUBICON.) The Savio is the only other stream of any importance that has always flowed directly into the Adriatic from that side of the Tuscan Apennines.

The narrow strip of coastland between the Maritime Alps, the Apennines and the sea (called in ancient times, as now, Liguria [*q.v.*]) is throughout its extent, from Nice to Genoa on the one side and from Genoa to Spezia on the other, almost wholly mountainous. The steep slopes facing south enjoy so fine a climate as to render them favourable to the growth of fruit trees, especially the olive, which is cultivated in terraces to a considerable height up the face of the mountains, while the openings of the valleys are generally occupied by towns or villages, some of which are favourite resorts.

Because of the proximity of the mountains to the sea the rivers in this part of Italy are generally mere torrents. The largest descend from the Maritime Alps between Nice and Albenga: the Roya, which rises in the Col di Tenda and descends to Ventimiglia; the Taggia, between San Remo and Oneglia; and the Centa, which enters the sea at Albenga. The Lavagna, which enters the sea at Chiavari, is the only stream of any importance between Genoa and the Gulf of Spezia. But immediately east of this bay (a remarkable instance of a deep landlocked gulf with no river flowing into it) is the Magra, a large stream that descends from Pontremoli down the valley known as the Lunigiana, and brings with it the waters of the Vara. The Magra (Macra), in ancient times the boundary between Liguria and Etruria, may be considered as constituting on that side the limit of northern Italy.

The Apennines (*q.v.*), as has already been mentioned, traverse the whole breadth of Italy there, cutting off the peninsula proper from the broader mass of northern Italy by a continuous barrier of considerable breadth, though far lower than the Alps. The Ligurian Apennines are a continuation of the Maritime Alps. From the neighbourhood of Savona to that of Genoa they do not rise to more than 3,000 to 4,000 ft. and are traversed by passes of less than 2,000 ft. As they extend toward the east they increase in height; Monte Bue rises to 5,915 ft., while Monte Cimone (7,096 ft.) is the highest point in the northern Apennines.

Between Tuscany and the Emilian provinces a continuous ridge runs from the mountains at the head of the Val di Mugello (due north of Florence) to the point where they are traversed by the Furlo pass or Cola di Furlo. through which runs the Candigliano, a tributary of the Metauro (Metaurus). The highest point in this part of the range is Monte Falterona, above the sources of the Arno, which attains 5,426 ft. Throughout this part of Italy the lower slopes of the Apennines are generally covered with extensive forests of chestnut, oak and beech, while the upper slopes afford good pasture.

Central Italy. — The geography of central Italy is almost wholly determined by the Apennines, which extend in a direction roughly north-northwest to south-southeast almost precisely parallel to that of the coast of the Adriatic from Rimini to Pescara. The line of the highest summits and of the watershed is about 30 mi. to 40 mi. from the Adriatic, while about double that distance separates it from the Tyrrhenian sea on the west. In this part of the range almost all the highest points of the Apennines are found. From the group called the Alpi della Luna (4,770 ft.) near the sources of the Tiber, they continue in Monte Nerone (5,007 ft.), Monte Catria (5,584 ft.) and Monte Maggio to Monte Pennino (5,151 ft.) near Nocera and thence to the Monti Sibillini (7,657 ft.) near the source of the Nera. Proceeding southward there are Monte Vettore (8,064 ft.), Pizzo di Sevo (7,946) and the two great mountain masses of Monte Corno, commonly called the Gran Sasso d'Italia, the most lofty of all the Apennines, attaining to a height of 9,583 ft., and Monte della Maiella, whose highest summit rises to 9,170 ft. Farther south no very lofty summits are found till the group of Monti del Matese (6,725 ft.) in Samnium, which according to the division adopted here belongs to southern Italy, is reached. Besides the central masses there are two other lofty peaks, outliers from the main range and separated from it by valleys of considerable extent. These are Monte Termini110 (7,278 ft.) near Leonessa and Monte Velino (8,192 ft.) near Lago Fucino, both of which are covered with snow from November to May. But the Apennines of central Italy, instead of presenting, as do the Alps and the northern Apennines, a definite central ridge with transverse valleys leading down from it on both sides, in reality constitute a mountain mass of considerable breadth, composed of a number of minor ranges and groups of mountains, which preserve a generally parallel direction and are separated by upland valleys, some of them of considerable extent and considerable elevation above the sea. Such is the now-drained basin of Lago Fucino (*q.v.*), while the upper valley of the Aterno, in which Aquila is situated, is 2,380 ft. above the sea. The valley of the Gizio (*see* SULMONA) connects with the upper valley of the Sangro by a plain called Piano delle Cinquemiglia at a height of 4,298 ft. Nor do the highest summits form a continuous ridge of great altitude for any considerable distance; they are rather a series of groups separated by much lower areas forming natural passes across the range and broken in some places (as is the case in almost all limestone countries) by the sudden turning at right angles of the naters from the upland valleys and their breaking through the mountain ranges which bound them. Thus the Gran Sasso and the Maiella are separated by the deep valley of the Aterno, while the Tronto breaks through the range between Monte Vettore and the Pizzo di Sevo.

This structure of the great mass of the central Apennines has in all ages exercised an important influence upon the character of this part of Italy, which may be considered as divided by nature

into two great regions, a cold and barren upland country, bordered on both sides by rich and fertile tracts enjoying a warm but temperate climate.

The district west of the Apennines coincides in general with Etruria and Latium. The northern part of Tuscany consists to a considerable extent of the lower slopes and of offshoots of the Apennines, which, apart from the slopes and spurs of the main range that constitutes Tuscany's northern frontier toward the plain of the Po, throw out several outlying ranges or groups. Of these the most remarkable is the group between the valleys of the Serchio and the Magra, commonly known as the mountains of Carrara. Two of the summits of this group, Pizzo d'Uccello and Pania della Croce, attain 5,843 ft. and 6.096 ft. Another lateral range, the Prato Magno, which branches off from the central chain at Monte Falterona and separates the upper valley of the Arno from its second basin. rises to 5,426 ft.

The rest of this area is for the most part a hilly, broken country, of moderate elevation, but Monte Amiata, south of Siena, an isolated mass of volcanic origin, attains a height of 5,689 ft.

South of this the country betneen the frontier of Tuscany and the Tiber is in great part of volcanic origin, forming hills with distinct crater basins, in several instances occupied by lakes (Lago di Bolsena, Lago di Vico and Lago di Bracciano). This volcanic tract extends across the Campagna of Rome till it rises again in the group of the Alban hills, the highest of which, Monte Faete and Monte Cavo, rise to more than 3,000 ft. There the Apennines are separated from the sea, about 30 mi. away, by the undulating volcanic plain of the Roman Campagna, from which the mountains rise in a wall-like barrier of which the highest point, Monte Gennaro, attains 4,170 ft. South of Palestrina again, the main mass of the Apennines throws out another lateral mass, known in Roman times as the Volscian mountains (now called the Monti Lepini), separated from the central ranges by the broad valley of the Sacco, a tributary of the Liri or Garigliano, and forming a large and rugged mountain mass, 4,521 ft. in height, which descends to the sea at Terracina, and between that point and the mouth of the Liri throws out several rugged mountain headlands which constitute the natural boundary between Latium and Campania; *i.e.*, between central and southern Italy. Besides these offshoots of the Apennines there are in this part of central Italy several detached limestone mountains, rising like islands, of which the two most remarkable are Monte Argentario on the coast of Tuscany near Orbetello (2,083 ft.) and Monte Circeo (1,775 ft.) on the edge of the Pontine marshes. The two valleys of the Arno (*q.v.*) and the Tiber (q v.) form the key to the geography of central Italy west of the Apennines.

On the Adriatic side the central range approaches much nearer to the sea, and consequently the rivers that flow from it are of little importance. From Rimini southward some of the largest are: (1) the Foglia; (2) the Metauro; (3) the Esino; (4) the Potenza; (5) the Chienti; (6) the Aso; (7) the Tronto; (8) the Vomano; (9) the Pescara; (10) the Sangro; (11) the Trigno, which last forms the boundary of the southernmost province of the Abruzzi and may therefore be taken as the limit of central Italy on the eastern side. This district is much broken up by these rivers and by smaller torrents, but is fertile. especially in fruit trees, olives and vines. It has always been populous, with many small towns but no great cities. Its chief disadvantage is the absence of ports, the coast preserving an almost unbroken straight line, with the single exception of Ancona, the only port worthy of the name on the eastern coast of central Italy.

Southern Italy. — The great central mass of the Apennines, which traverse central Italy from northwest to southeast, continues in the same direction for about 100 mi. farther, from the basin-shaped group of the Altipiano del Matese (which rises to 6,726 ft.) to the neighbourhood of Potenza, in the heart of the region of Basilicata. nhich corresponds roughly to Roman Lucania. The whole of the district knonn in Roman times as Samnium is occupied by an irregular mass of mountains, of much inferior height broken up into a number of groups, intersected by tortuous rivers. This mountainous area. which has an average breadth of from 50 mi. to 60 mi., is bounded on the west by the plain of Campania, called the Terra di Lavoro, and on the east by the broader and more extensive region of Apulia, composed partly of level plains but for the most part of undulating downs, contrasting strongly with the mountain ranges of the Apennines which rise abruptly above them. The central mass of mountains, however, throws out two outlying ranges, the one to the west, which separates the Bay of Naples from that of Salerno and culminates in Monte Sant'-Angelo above Castellammare di Stabia (4,720 ft.), while the detached volcanic cone of Vesuvius (over 4,000 ft.) is isolated from the neighbouring mountains by an intervening strip of plain; the other on the east forming Monte Gargano (3.461 ft.), a detached limestone mass which projects in a bold spurlike promontory into the Adriatic and makes the only break in the otherwise uniform coast line of Italy on that sea.

From the neighbourhood of Potenza the main ridge of the Apennines runs nearly due south to within a short distance of the Gulf of Policastro and thence to Monte Pollino, the last high summit. The range continues, however, through Calabria to the southern extremity or "toe" of Italy; but the broken limestone range, which is the true continuation of the chain as far as Nicastro and Catanzaro and keeps close to the west coast, is flanked on the east by a great mass of granitic mountains, rising to about 6,000 ft. and covered with considerable forests, from which it derives the name of La Sila.

A similar mass, separated from the preceding by a low neck of Tertiary hills, fills up the whole of the peninsular end of Italy from Squillace to Reggio di Calabria.

The long spurlike promontory which projects toward the east to Brindisi and Otranto is a continuation of the low tract of Apulia, with a dry calcareous soil of Tertiary origin. Monte Vulture, which rises in the neighbourhood of Melfi and Venosa to 4,357 ft., is of volcanic origin. East of Vulture the ranges of low bare hills called the Murge of Gravina and Altamura gradually sink into those which constitute the peninsula between Brindisi and Taranto ending in Cape Santa Maria di Leuca, the southeastern extremity of Italy. This projection, the "heel" of Italy, in conjunction with the great promontory of Calabria, forms the Gulf of Taranto, which is about 70 mi. wide.

Of the rivers of southern Italy, the Liri (*q.v.*), which has its source in the central Apennines above Sora, not far from Lago Fucino, and enters the Gulf of Gaeta about 10 mi. E. of the city of that name, brings down a considerable body of water. So too does the Volturno, which rises in the mountains between Castel di Sangro and Agnone, flows past Isernia, Venafro and Capua and enters the sea about 15 mi. from the mouth of the Garigliano. About 16 mi. above Capua the Volturno is joined by the Calore, which flows through Benevento.

The Silarus or Sele enters the Gulf of Salerno a few miles north of the ruins of Paestum. South of this the watershed of the Apennines is near to the sea on the west. Hence the rivers that flow into the Adriatic and the Gulf of Taranto have much longer courses than those of the nest coast, though all have the character of mountain torrents. Proceeding south from the Trigno there are: (1) the Biferno and (a) the Fortore, both rising in the mountains of Samnium and flowing into the Adriatic west of Monte Gargano; (3) the Cervaro, south of this great promontory; (4) the Ofanto, the Aufidus of Horace, which rises about 15 mi. W. of Conza and in its lower course flows near Canosa di Puglia and traverses the battlefield of Cannae; and (5) the Bradano, which rises near Venosa, almost at the foot of Monte Vulture, and flows toward the southeast into the Gulf of Taranto, as do the Basento, the Agri and the Sinni. The Crati, which flows from Cosenza northward and then turns abruptly eastward to enter the same gulf, is the only stream worth mentioning in Calabria; while the arid limestone hills projecting eastward to Capo di Leuca have no rivers at all.

Lakes and Islands. — The great lakes of Italy lie on or near the northern frontier, Orta, Maggiore, Como, Iseo and Garda. These are glacial lakes of great depth, long and narrow and surrounded by mountains. The lakes of central Italy are either alluvial, such as Trasimeno [the only large lake left since Fucino was drained between 1854 and 1876), or crater lakes. The latter

are found in the volcanic districts west of the Apennines and occupy deep cup-shaped hollows which have undoubtedly at one time formed the craters of extinct volcanoes. Such is the Lago di Bolsena, the smaller Lago di Vico (or Cimino) and the Lago di Bracciano, while to the south of Rome the lakes of Albano and Nemi have a similar origin.

The only lake in southern Italy is the small Lago di Matese in the heart of the mountain group of the same name. On the coast of the Adriatic north and south of the promontory of Gargano are brackish lagoons opening to the sea.

For the two great islands of Sicily and Sardinia, see the separate articles. Of the smaller islands that lie near the coasts of Italy, the most considerable is that of Elba (*q.v.*). North of this and about midway between Corsica and Tuscany is the small island of Capraia (*q.v.*). Gorgona, about 25 mi. farther north, is still smaller. South of Elba are the equally insignificant islets of Pianosa and Montecristo (*qq.v.*), while Giglio (*q.v.*) lies much nearer the mainland, immediately opposite the mountain promontory of Monte Argentario. The islands farther south in the Tyrrhenian sea are of an entirely different character. Of these Ischia and Procida, close to the northern headland of the Bay of Naples, are of volcanic origin, as is also the more distant group of the Ponza Islands (*q.v.*). The island of Capri, on the other hand, opposite the southern promontory of the Bay of Naples, is a precipitous limestone rock. The Aeolian or Lipari Islands (*q.v.*), a volcanic group, belong rather to Sicily than to Italy.

The Italian coast of the Adriatic presents a great contrast to that sea's opposite shores, for while the coast of Dalmatia is bordered by a succession of islands, great and small, the long and uniform coast line of Italy from Otranto to Rimini has not a single closely adjacent island; the small outlying group of the Tremiti Islands (north of Monte Gargano and about 15 mi. from the mainland) alone breaks the monotony of this part of the Adriatic.

Geology. — The geology of Italy is mainly dependent upon that of the Apennines (*q.v.*). On each side of that great chain are found extensive Tertiary deposits, sometimes, as in Tuscany, in the district of Monferrato, forming a broken, hilly country, at others spreading into broad plains or undulating downs such as the Tavoliere of Apulia and the area that forms the spur of Italy from Bari to Otranto.

Besides these areas, and if we leave out of account the islands, the Italian peninsula presents four distinct volcanic districts. In three of them the volcanoes are entirely extinct, in the fourth they are still active.

1. The Euganean hills form a small group extending for about 10 mi. from near Padua to Este, separated from the lower offshoots of the Alps by a portion of the wide plain of Padua. Monte Venda, their highest peak, is 1,960 ft. high.

2. The Roman district extends from the Alban hills of Latium (Colli Laziali; see ALBAN HILLS [to be distinguished from Monte Albano north of the Arno]) to the Ciminian hills and thence to the mountains of Radicofani and Monte Amiata. It is generally held that these volcanoes were at first submarine (which would account for the stratification found and for the excellent quality of the volcanic tufa so much used for building stone) and that the coast was gradually raised. (See LATIUM.)

3. The volcanic region of the Terra di Lavoro of Campania is separated by the Volscian mountains from the Roman district. The highest cone of Roccamonfina, at the north-northwestern end of the Campanian plain, is Monte Santa Croce, 3,291 ft. high. The Campi Flegrei cover all the country round Baiae and Pozzuoli and the adjoining islands. Monte Barbaro (Gaurus), northeast of the site of Cumae, Monte Epomeo (2,585 ft.) in Ischia and Camaldoli (1,488 ft.) west of Naples are the highest cones. The lakes Averno (Avernus), Lucrino (Lucrinus), Fusaro (Palus Acherusia) and Agnano (drained) are within this group, which has shown activity in historical times. A stream of lava issued in 1198 from the crater of Solfatara, which still continues to exhale steam and noxious gases; the Lava dell'Arso came out of the northeastern flank of Monte Epomeo in 1302; and Monte Nuovo, northwest of Pozzuoli (455 ft.), was thrown up in three days in Sept. 1538. Since the eruption in A.D. 79, Vesuvius (*q.v.*) has been constantly active.

4. The Apulian volcanic formation consists of the great mass of Monte Vulture.

The whole of the great plain of Lombardy is covered by Pleistocene and Recent deposits. It is a great depression — the continuation of the Adriatic sea — filled up by deposits brought down by the rivers from the mountains. The depression was probably formed during the later stages of the gro th of the Alps.

Climate. — The geographical position of Italy makes it one of the hottest countries in Europe. The effect of its southern latitude is, however, tempered by its peninsular character and by the great range of the Alps with its snows and glaciers to the north. There are thus irregular variations of climate, and great differences exist between northern and southern Italy. The climatic frontier between Italy and central Europe is formed rather by the Apennines than by the Alps.

The great plain of northern Italy is chilled by the cold winds from the Alps, while the damp warm winds from the Mediterranean are to a great extent intercepted by the Ligurian Apennines. Hence that part of the country has a cold winter climate, so that while the mean summer temperature of Milan is higher than that of Sassari, Sardinia, and equal to that of Naples, and the extremes reached at Milan and Bologna are a good deal higher than those of Naples, the mean winter temperature of Turin is actually lower than that of Copenhagen. The lowest recorded winter temperature at Turin was 5° F.

Central Italy also presents striking differences of climate and temperature according to the greater or less proximity of any given area to the mountains. Thus the greater part of Tuscany and the provinces between it and Rome enjoy a mild winter climate. The increasing height of the Apennines as they proceed south produces a corresponding effect upon the temperature. In the central range of the Apennines are the coldest districts of Italy. In all the upland valleys of the Abruzzi snow begins to fall early in November, and heavy storms occur often as late as May. Potenza has one of the coldest climates in the country and the lowest summer temperature. Southern Italy has in general a very different climate from the northern part and, though large areas are occupied by mountains sufficiently high to retain the snow for a considerable part of the year, the districts adjoining the sea enjoy a climate similar to that of Greece and the south of Spain.

Rainfall is heaviest in the Alps and lightest in the lowlands. The prevailing westerly winds bring rain to the west of the mountains, leaving the east comparatively dry. There is permanent snow only in the Alps.

Flora. — About 4,000 species of flowering plants have been identified in Italy, very few of which are endemic. Although there is a certain amount of overlapping, they belong to two distinct types of plant community: the central European species from the north; and the Mediterranean species from the south and east. Characteristic of the central European element are coniferous and deciduous forests and brushwoods, perennial herbs that die down before the winter frosts begin and alpine plants. These types are found in the Italian Alps and most of the northern plain and along the Apennines as far south as northern Sicily. Along the coastal strips (particularly by the Tyrrhenian sea) and around the shores of the Alpine lakes, the mildness of the climate enables Mediterranean and even subtropical plants to flourish. Coniferous forests containing Mediterranean species of pine and juniper, macchie (low scrub), hills clothed with olives, flowering annuals and plants with underground bulbs are characteristic of the Mediterranean element. They are mainly found in the peninsula and in the islands. The characteristic cypress, found in and around so many villages and cemeteries, the ilex growing on the hills and the stone pine. found chiefly near the coast, are also native trees. The high proportion of evergreens has a marked effect on the landscape in winter.

In the montane zones of the Alps and, to a lesser extent, of the Apennines, there are extensive coniferous forests consisting of various pines, larch. silver fir and spruce (only native in the Alps and northern Apennines but planted elsewhere). Of deciduous trees the beech is widespread in the Alps and along the Apennines

to northern Sicily uhere it grows up to 6,000 ft. or more on Mount Etna. The sneet chestnut covers vast areas in the montane zones, but in Sicily it grows mostly on the mountains of the northeast. It was planted to replace the native oaks because of its food value. Deciduous brushwoods in this zone consist of oaks (often coppiced), hazel and other shrubby plants. In the Alps, above the forest limit, come the brushwoods where the green alder is often the dominant plant with dwarf junipers, alpine roses, etc. This kind of brushwood is less well developed in the Apennines. In the Mediterranean regions, characteristic of the macchie are the strawberry tree *(Arbutus)*, mastic, *Pistacia terebinthus*, heaths and aromatic herbs.

Up in the mountains, above the brushwoods, alpine pastures occur between the rocks and the bogs. In addition to many grasses, sedges and rushes, brilliantly flowering plants such as gentians, saxifrages, *Primula* and many more flourish. Among the rocks and stones grow houseleeks. stonecrops, edelweiss and so on. On the screes and slopes alpine pinks, alpine anemones, gentians, dwarf rhododendrons and others find a footing.

It is remarkable that many of the more conspicuous plants of Italy are of comparatively late introduction. More than 350 which are now established were unknonn in ancient times. The orange and lemon are late importations from the east and they and the mulberry. which has been cultivated for centuries, are abundant in all areas free from frost. Vines. both wild and cultivated, grow everywhere. Prickly pears (*Opuntia*), agave and Indian corn, so common on the shores of southern Italy and along the Riviera di Ponente. are of Mexican origin and so could not have been introduced earlier than the 16th century. The sweet chestnut was introduced by the Romans, or possibly before. The eucalyptus is of quite modern introduction and has been extensively planted in malarial districts. Among trees the locust tree *(Robinia pseudoacacia)* and the bastard indigo (*Amorpha fruticosa)* from North America are naturalized and grow everywhere. Two North American aquatic plants have become important because of their high rate of increase, the Canadian pondweed *(Elodea canadensis)* and *Azolla caroliniana*.

Fauna. — The natural fauna of Italy shows relationships with the fauna of central Europe, the Balkans and Africa. The number of species of beasts and birds is much smaller than it should be because of the unchecked killing that continued for centuries. Some animals owe their preservation to the big landowners of the past and are now protected by the state. Bears are extinct except for a few in the upper Sangro valley in the Abruzzi; wolves are rare and are found chiefly in the Abruzzi, in the mountainous districts of the south and in Sicily. Roe deer are the commonest deer, but there are also red deer in certain places such as the Venetian Alps; the chamois still lives in the Alps but is uncommon; the ibex or wild goat *(stambecco)* is restricted to the Gran Paradiso national park. The most abundant of the larger mammals is the wild pig. The arctic hare, marmot and ermine occur in the high Alps; the wildcat haunts the coniferous forests of the Alps, Tuscanp and Sicily. The west slopes of the Calabrian mountains and Sicily are the chief homes of the hedgehog. porcupine and badger. Hares, foxes, martens, weasels, squirrels, dormice and moles (absent from Sicily) are found in all suitable places. The sea mammals include the common dolphin.

Shooting has made birds noticeably scarce so that there are very few smaller resident species. The most widespread of the larger birds is the partridge, but in the Alps there are still blackcock, capercaillie, ptarmigan and other game birds. There are many kinds of waterfowl, mostly migratory, in the marshes, and a small colony of green ibis near Vercelli. Birds of prey, such as eagles, falcons and vultures, being inedible, have escaped persecution and are common. In the spring and autumn migrating birds, especially the smaller ones such as quails, larks and thrushes, are snared in huge numbers for food.

There are not very many fresh-water fish. except eels; the most important are trout in thk mountain streams, pike and perch in the northern rivers and lakes, and tench and salmon. Of sea fish there are many varieties, the tunny, sardine and anchovy being commercially the most important. Small cuttlefish are commonly eaten. Lizards are found everywhere. Among poisonous animals are vipers in the mountains. especially in the Alps, a centipede (*Scolopendra*), the little scorpion, the tarantula, vault spiders and many mosquitoes. Migrating grasshoppers sometimes attack parts of the country. There is a great variety of seashore animals, especially along the southern shores.

ARCHAEOLOGY

Archaeology had its beginnings in Italy in the attempt, made even before the Renaissance, to satisfy the curiosity of pilgrims about the marvels of ancient Rome. A more unscientific guidebook than the *Mirabilia Urbis Romae*, probably composed *c.* 1140–43 (*see* R. Valentini and G. Zucchetti, *Codice Topografico della Città di Roma*, iii, p. 6, Rome. 1946) and first issued in manuscript, could hardly be found; but its very flaws betrayed the need for more adequate statements and revisions soon came. A more effective spur to accurate knowledge of antiquities was the desire of artists to collect and study ancient fragments as models for their own work. Niccola Pisano in the 13th century turned to antiquarian studies for this purpose; much of Andrea Mantegna's work shows him to have had an almost excessive enthusiasm for the antique; and Michelangelo began his modelling nith a study of the collection of antiques that the Medicis had made in Florence. Similarly painters sought for hints in the buried rooms that contained the wall decorations of Rome's imperial palaces.[1] In some rooms of Nero's Golden house, discovered and first entered in the 15th century, many artists left their names on the stuccoed walls while going through with torch and notebook, and designs from the same rooms were copied and used by Giovanni da Udine and Raphael in decorating the loggias of the Vatican. Even more diligent and exact was the study of Roman architectural remains by the Renaissance architects. Brunelleschi made an exhaustive study of the Roman monuments before he began the construction of the dome of Santa Maria del Fiore in Florence in 1417; Raphael, who for several years was commissioner of antiquities at Rome, drew up elaborate plans for the publication of ancient monuments; Bramante and Michelangelo, who had to prepare themselves for the task of designing the new St. Peter's, spent much time in appraising such structures as the Pantheon and Constantine's basilica. The voluminous notebooks of architects[2] (Giuliano da Sangallo. Baldassare Peruzzi, Pirro Ligorio, Andrea Palladio, Labacco and others) reveal a keener study and saner comprehension of the principles of Roman architecture than was possessed by the students of the 17th century. Since many structures seen by these men later disappeared their notebooks have proved to be of inestimable value to modern archaeologists. Finally, there mere men at the very dawn of the Renaissance who appreciated the value of the information contained in ancient inscriptions. Cola di Rienzi, for instance, in 1347 read to the people the bronze fragment of Vespasian's so-called *lex de Imperio*, exhibited by him on that occasion at the Lateran to prove that in antiquity the emperors of Rome derived their authority from the people.

THE RENAISSANCE

The First Museums. — The Renaissance had a far larger store of architectural remains to draw upon than did later students; of statuary. however, there was but little. Though a Constantinian description of the city, as transmitted through devious channels, appears to have mentioned the existence of 3,j8j bronze statues in Rome in the 4th century. Poggio. when travelling through the city in the 1jth century, could find only the "Capitoline Wolf" and the equestrian statue of Marcus Aurelius; and in the 20th century there were but few more bronze statues from Rome itself. Bronze, of course, had suffered most from the vandalism of the middle ages,

[1] T. Ashby, *Drawings of Ancient Paintings in English Collections* (Brit. School, 1914–16); F. Weege in *Jahrb. Arch. Inst.*, pp. 151–229 (1913).

[2] *E.g.*, A. Bartoli, *I Monumenti Antichi di Roma nei Disegni degli Uffizi di Firenze* (1914–22); Ashby, *Drawings Attributed to Andreas Coner* (Brit. School, 1904).

but antique marble statues were almost as scarce in Poggio's day. However, the great activity in building that set in at Rome in the 15th century led to quarrying in the old ruins for building materials; and in such delving many marble statues were found which, if noticed by artists, were saved from the contractors' limekilns. Pope Sixtus IV, who was guilty of destroying several old structures in his search for materials, is to be thanked for starting the good custom at Rome (the Medicis had anticipated him at Florence) of saving such statuary by founding the Capitoline museum in 1471. A generation later (1506) Julius II established the Belvedere court in the Vatican palace to serve as a museum, and the Laocoon group found that year was placed there, to join the famous "Apollo Belvedere" and soon to be joined in turn by the Apollonius torso. Shortly after. Michelangelo at public expense set up the equestrian statue of Marcus Aurelius on the Capitoline and arranged the fragments of the consular *fasti*, recently found, in a room in the palace of the Conservatori specially adapted for them.

Destruction of Ancient Remains.—Excavations were not yet conducted solely for the acquisition of knowledge of art or of the past. The digging was a more or less haphazard mining for objects to sell or to use in decorating villas, or it was conducted under papal concession with stipulations to produce so many cartloads of marble or travertine. In such cases the fragmentary statues that were found all too frequently went into the limekiln. For constructional and decorative work Roman marble had gone far and wide. There are precious marbles in the cathedral of Aachen that were brought from Rome by Charlemagne; a large part of the cathedral of Pisa was built in the 11th century at the expense of the ruins of Ostia. The baptistery of Florence and the cathedral of Orvieto are largely of Roman material, as are even some tombs in Westminster abbey. Practically all the palaces and churches of Renaissance Rome derived their marbles from the old ruins. Nearly half the outer ring of the Colosseum and large parts of the Basilica Julia. of the Circus Maximus and of many other buildings were allotted to contractors. Almost all the buildings of the Forum, now represented by bare cores of concrete and brick, had their marble facings stripped off by quarrymen long before the scientific excavator cleared away the debris in the 19th century. Fortunately the art-loving draughtsman was often at hand to sketch the architectural decorations before they were hauled off, and the scholar often had a chance to copy the inscriptions before they were destroyed. And though marble made a very fine lime and fragments of statuary therefore risked much in being discovered, there was a good demand for the statuary itself by the end of the 11th century. From that time most of the best objects brought to the surface doubtless survived.

In 1444–46 Flavio Biondo composed a *Roma Instaurata* which was much more than an improvement on the traditional guidebooks. It rejected mediaeval legends and described old Rome from a careful study of classical texts, also attempting (with no little success) to identify the ruins then existing. The book is modern in the spirit of its scholarship, and its publication proves that many were interested in what may legitimately be called archaeology. In 1453 Biondo's *Italia Illustrata* did the same work for a large part of Italy. To be sure the modern reader discovers many errors in these two books, but if they are approached from the *Mirabilia* rather than from the point of view attained after centuries of research. the merits of this courageous scholar can only be admired. It is not surprising that by 1478 Rome had an academy of antiquaries devoted to the study of topography and monuments as well as of texts.

After the disastrous looting of Rome by the imperial army in 1527. interest in ancient art waned for a time. The popes of the 16th century after Julius II did little for the museums and mere very free in giving grants to contractors to tear down and use the materials of old monuments. Thus the tomb of Caecilia Metella and the Janus Quadrifrons were saved only by the remonstrances of the populace after grants had been given to dispose of them. The famous Septizonium stood till 1588 when Sixtus V ordered Domenico Fontana to use its materials for the repairs of several churches and public buildings.

Inscriptions.—Meanwhile a scientific interest in inscriptions was growing. It has been shown how Rienzi made use of one to demonstrate a historical fact. Ciriaco of Ancona[1] (*c.* 1390–*c.* 1450), attracted to the subject by a collection of inscriptions made by Poggio, made careful copies during his extensive mercantile journeys, inspired by the conviction that these stones often attested facts of history more reliably than the texts. His collection, prepared before the invention of printing, did not survive as a unit, but his manuscripts were freely used by other scholars. After him others made similar collections, often intercepting the stone on the way to the limekiln and rescuing its readings. The large collection of Panvinius (Onofrio Panvinio, 1529–68) seems to have fallen into the hands of Smetius, a diligent Dutch epigrapher whose own cpllection (as published with additions by Justus Lipsius, 1588) in turn went into the first great corpus of inscriptions that purported to be complete, the famous collection of Jan Gruter (1603). Joseph Justus Scaliger (1540–1609) made this corpus available for antiquarian studies by classifying its vast store of facts in 24 indexes. Raphael Fabretti (1619–1700) was the next scholar who gathered and interpreted inscriptions with success, publishing his thorough work on the Roman aqueducts in 1680. The marchese Francesco di Maffei (1675–1755) did valuable service by submitting to keen criticism the large collection of Lodovico Muratori; Gaetano Marini (1742–1815) emended and explained the difficult inscriptions of the Fratres Arvales (1795), and finally Bartolommeo Borghesi (1781–1860), by his keen analysis of the accumulated material and his vast series of studies in history and administration which were based largely upon epigraphical sources, determined and illustrated the methods of epigraphy. Theodor Mommsen, inspired by the work of Borghesi, elaborated a plan for a new and more scientific collection of all Latin inscriptions and, producing a volume to serve as a model, persuaded the Berlin academy to undertake the publication of a complete corpus on this plan. From 1862 the volumes of this *Corpus Inscriptionum Latinarum* were issued in a consistent stream.

17TH AND 18TH CENTURIES

Private Collections.—To return to the subject of sculpture, it was chiefly in the 16th century that the great princely collections of Italy were formed—the older Borghese (later sold to Napoleon), the Barberini, the Pamphili treasures, the even more remarkable ones of the Ludovisi and the Giustiniani, not to mention a number of smaller ones. Parts of these were made up by purchase. but digging on the vast estates of the princes themselves yielded no small part of them. When some of these nobles were forced to sell portions of their collections, the courts of Madrid and Dresden began to buy antiquities extensively, and in the 17th and 18th centuries Englishmen made purchases for the decoration of their country places *(see* F. Poulsen. *Greek and Roman Portraits in English Country Houses,* Oxford, 1922). Thus English, French and German dilettanti became interested in Greek and Roman art and had no small share in encouraging a more careful study of the subject.

Herculaneum.—Meanwhile Herculaneum and Pompeii had become known. In 1709 Emmanuel Maurice, duc d'Elbeuf, sank a shaft through the lava where it was known that ancient remains lay, and these were speedily identified as belonging to Herculaneum. By good fortune the ancient theatre was soon found and many pieces of bronze and marble statuary recovered. In 1738 Charles VII of Naples (later Charles III of Spain) continued the work, which he placed largely under the direction of Spanish military engineers. Diaries of valuable objects found were now kept, though as yet no systematic records of the daily excavations. In 1750–55 the splendid Villa of the Papyri with its scores of statues was excavated. Two years later the Accademia Ercolanese was formed. Between 1757 and 1792 it published eight finely illustrated volumes of excavated objects and these, though deficient in aesthetic analyses, are still of value as a record. King Charles also made trial excavations at Pompeii. where the debris was more easily moved. His operations were begun by about 12 men burrowing here and there for chance finds. Not till 1763, when the advice of the Accademia Ercolanese was followed, was the debris

[1] *See* Sir J. E. Sandys, *Latin Epigraphy,* p. 22 (Cambridge, 1927).

permanently removed from the excavated areas. Notes of finds were still kept in desultory fashion. A careful record of daily work was not thought of, and no attempt made to preserve what was not immediately taken to the royal collections.

Winckelmann.—In 1755 Johann Winckelmann, inspired by the collection of antiquities which Dresden had acquired from Rome. went south to study. He spent years with the collections of Rome and Herculaneum and, as a fruit of this study, issued in 1764 his epoch-making *History of Ancient Art,* in which he attempted to outline the history of art from early Egyptian times (the Vatican had a few examples of Egyptian art discovered in the debris of Rome) to late Roman times. To be sure there were at Rome and Naples very few examples of genuine Greek art; consequently Winckelmann could not produce a well-proportioned history. Indeed the English dilettanti of the period had acquired in their travels in Greece a more accurate comprehension of the best in ancient art though they were at the time more concerned in describing and analyzing portions than in recording the story of the whole. The services of Winckelmann were of the kind that appeal particularly to the scholar. in that his book provided a model of careful description, aided the memory and gave points of view for the classification of new discoveries. The book mas very influential at the time and nhen, before the end of the century, the Pio-Clementino museum was opened in the Vatican, Giovanni Battista Visconti, and still more his son Ennio Quirino, wrote the catalogue of the splendid collection with a mastery of the technique that owed much to Winckelmann.

The Napoleonic period brought new funds and some enthusiasm for excavations. The work at Pompeii was pushed with more vigour and nith some system. The French architect Charles Mazois brought out a valuable publication of the finds, especially architectural. The eagerness to find works of art worthy of the museum was still dominant, but it was no longer the sole object. The savants in Napoleon's train cannot be denied an appreciation of the encyclopaedist's vienpoint. At Rome the most important archaeological work of this regime was the very costly excavation of the centre of Trajan's forum, a work not then finally completed. During this period however. Italian archaeology came near to receiving a severe blon in that Napoleon removed to Paris many of the best norks of the art of Rome (1797) and, with them, the able archaeologist Ennio Visconti. But with the fall of Napoleon the papal delegate to the peace conference successfully reclaimed most of the treasures that had belonged to the Vatican and Capitoline museums. Italy thus regained its position of first importance for students of classical archaeology.

THE 19TH CENTURY

Upon the re-establishment of the papal government the work of excavation continued. Carlo Fea *(see* below) has a strong claim to be considered the founder of scientific excavations, though the above-mentioned works by Fabretti and Marini rank high as publications. An epoch in archaeology was marked by the foundation of the Instituto di Corrispondenza Archeologica in 1829 by a group of about 70 scholars, about equally divided among Italian, German. French and English savants. Its purpose mas to get support from as wide a circle of scholars and dilettanti as possible for good reporting and publication of finds, to raise the standards of work, to discuss antiquities in frequent sessions and to gather an adequate library in Rome. The head of the institute was the duc de Blacas (Pierre Louis Jean Casimir, duc de Blacas d'Aulps), while the more active spirits were the German scholars Eduard Gerhard and Christian, baron von Bunsen, and the Italian Carlo Fea. The annual publications. called the *Annali* and the *Bollettino,* and the occasional *Monumenti Inediti* kept the members all over Europe well informed in careful reports of all important work progressing and did much to encourage excavators to do their work in the most approved fashion. After many vicissitudes the body finally (in 1871) emerged as the German Archaeological institute, which down to World War II carried out excellent work at Rome.

During the 19th century official and unofficial excavations were carried on all over Italy *(see* Adolf Michaelis, *A Century of Archaeological Discoveries,* Eng. trans., 1908). A brief survey of what was accomplished in the Roman Forum will best reveal the trend of archaeological work. After 1800 there n-as at least no more sheer vandalistic quarrying. Indeed the wholesale mining of the 15th and 16th centuries had not left many usable pieces of building material in the debris. Hence the excavators of the 19th century had little hope of finding much except bare foundations with which to reconstruct the ground plans of the old Forum. However, the spirit of historical criticism, revealed in the works of Giovanni Vico. Ednard Gibbon and Barthold Niebuhr, was non also the driving spirit of the archaeologists. Hence it is not surprising to find that Carlo Fea. placed in charge of excavations by Pope Pius VII in 1803. determined upon a thorough removal of all debris and an orderly recording of finds for the primary purpose of reconstructing the plans of the buildings of which he should find traces. He worked systematically near the arch of Septimius Severus and near that of Constantine. The French government continued nith no loss of zeal from 1810 to 1813, adding the Velia near the arch of Titus to the program. (A few years later, in 1821, Giuseppe Valadièr was commissioned by Pius VII to restore the arch.) With the return of Pius VII Carlo Fea again was placed in charge, now delving into the debris near the three columns of Castor. Some aid was now accepted from foreigners interested in the work, such as Elizabeth. duchess of Devonshire, and the duc de Blacas, nho was the French ambassador. From 1827 to 1835 much was accoinplished near the temple of Concord. and a portion of the Basilica Julia was uncovered under the direction of Antonio Nibby. Pius IS employed the somewhat too imaginative Luigi Canina who continued the work at the west end of the Forum. Fea, Nibby and Canina unfortunately were all somewhat misled by the fantastic plans of the Forum drawn by the 17th-century architects. Stefano Piale, in 1832, submitted these plans to sharp criticism but failed to carry conviction against the voluminous and picturesque publications of Canina. It was not till about the middle of the century that archaeologists reached some degree of consensus about the correct orientation of the Forum and the right designation of several of the foundations. After Canina's death excavations progressed very slowly until 1870, nhen the ne\\ royal government took up the nork with vigour. placing in charge Pietro Rosa, who had excavated on the Palatine for Napoleon III. Rosa cleared a large part of the Basilica Julia and of the central part of the Forum during the next six years. Unfortunately he sometimes left his finds in tantalizing confusion. In 1876 Giuseppe Fiorelli, nho had developed an excellent technique at Pompeii (1860–75), came to Rome to take charge. He knew the value of meticulous reporting and was influential in having the Reale Accademia Nazionale dei Lincei begin in 1876 the valuable official publication ot excavations in the *Notizie degli Scavi.* Fiorelli cleared most of the area along the Sacred Way from the temple of Divus Julius to the arch of Titus; and in 1882–84 Rodolfo Lanciani, to whom Roman topography owes much, demonstrated in the clearing of the Atrium Vestae that archaeologists needed not only to excavate and report but also to protect the ruins and dispose of the objects found in such a way that the student might correctly read the meaning of what was left.

The imperial street level had now been reached throughout the central part of the Forum, and after 1884 the state suspended work until more properties could be bought. However, several individuals, notably Christian Huelsen, W. L. Nichols and O. L. Richter, were permitted to make researches which proved fruitful. Meanwhile historical criticism was somewhat influencing archaeology in that it demanded data on the period of early Rome and insisted that the spade must penetrate beneath the imperial pavements. In 1898, when Guido Baccelli was minister of public instruction, the energetic and imaginative architect Giacomo Boni was placed in charge of excavations and permitted to dig to lower levels. The results mere impressive. In 1899 the "black stone" was found and beneath it the famous archaic inscription with many primitive objects about it. Then there came to light the old Vulcanal, foundations and decorative terra cottas of the early republic and finally, in 1901–03, the *sepulcretum* on the edge of the Forum, which at once confirmed many traditions regarding primitive Rome. The public was perhaps more ready to appreciate the new discov-

eries than the archaeologists to interpret them. but scholars of all nations especially Huelsen. Richter and T. Ashby, aided in the publication and in the discussion of the finds. The abovemementioned German institute had excellent scholars on its staff, and the French school had been established in 1873, the American School of Classical Studies in 1894 (later merged with the American Academy in Rome) and the British school in 1901. The Forum was to these a fruitful laboratory of observation. After 1904 Boni shifted his interests more and more to the Palatine but left to his successors the task of utilizing his notes on the excavations.

Meantime there were many sporadic finds of importance all through Italy, rome in systematic excavations, others in the course of private building operations. The Alexander mosaic. nhich indirectly contributed much to the history of painting, came to light at Pompeii in 1831, the "Lateran Sophocles" at Terracina in 1837, the "Augustus of Prima Porta" in 1863, the foundations of the Capitoline temple in 1865, the house of Livia in the French excavations of the Palatine in 1869, the house of the Farnesina gardens in 1878. the Apollonius bronze pugilist in 1884, the Ludovisi throne in 1887, the silver treasure of Boscoreale in 1895 and the last fragments of the "Ara Pacis" in 1903 and 1937.

ETRUSCAN AND PREHISTORIC

Etruria.—In Etruria occasional finds had been made ever since the Renaissance and gathered to public and private museums. These had created a local interest in Etruscan art but a general enthusiasm was hardly aroused until 1827 when scme tombs with remarkable wall paintings were opened at Corneto (the ancient Tarquinii). The very next year Lucien Bonaparte found that his estate in Etruria contained a large part of the vast cemetery of ancient Vulci, and the feverish excavations that followed brought to light hundreds of the finest Greek vases. When these were carefully published by Gerhard in the *Rapporto Volcente* of the Instituto di Corrispondenza Archeologica in 1831, which contained the first logical classification of such ware, the real study of Greek vase painting began.

When in 1836 Alessandro Regolini and T'incenzo Galassi found at Cerveteri the remarkable tomb nhich bears their name. and the objects nere placed by Pope Gregory XVI in the Vatican, the artistic outlook was at once widened by connecting Etruria nith the east. Xlphonse François, in 1844, found at Chiusi the splendid black-figure vase later placed in Florence, and this proved stimulating to archaeological study by filling a serious lacuna in the story of vase painting. When in 1848 George Dennis issued his remarkable work called *Cities and Cemeteries* of *Etruria,* most of the important sites cf Etruria had been discovered and to a large extent exploited.

Meanwhile the marchese Giovanni Campana had. in private excavations conducted largely for the sake of enlarging his own collection. found the tomb at Veii named after him (1842). It was not till 18jo that he disclosed the Grotta dei Rilievi at Cerveteri, with its painted stuccoes and its remarkable terra-cotta sarcophagus. He was exceedingly successful in the Etruscan field; but in his enthusiasm he neglected sadly to record his excavations, and when because of bankruptcy his magnificent collection nas sold, the larger parts to Paris and St. Petersburg, Italy had lost not only very precious relics of past art but also much of the evidence essential to the proper coinprehension of that art. Campana was. of course, working for himself in a divided Italy nhere uniform state supervision of excavations could not exist. During this period it nas largely as a result of the activities of the Instituto di Corrispondenza Xrcheologica at Rome that specialists were at times allowed to inspect diggings. to report them with some care and by their reports. to shame exploiters into some respect for scientific interests. But it was only after the unification of Italy, when such excavations were placed under the supervision of a government department, that they could be properly controlled and adequately published. It would be difficult to overstate the debt that art and archaeology one to the Italian go ernment for its enlightened interest, for its generous expenditure on excavations, museum buildings and publications and for its intelligent choice of genuine scholars to conduct the necessary work.

Prehistoric Archaeology.— Prehistoric archaeology ultimately became very important in Italy, but it was slow in arousing attention because of the nealth of classical works of art to be found and interpreted. The Terramara sites of the Po valley were locally known in the 18th century, but were pronounced to be Cimbric or Boian sites of little interest. As early as 1817 Alessandro T'isconti had had the breadth of view to give a valuable description *(Diss. Acad Rom.,* i, 2) of the Iron Age cemetery discovered by chance shortly before in the Alban hills, but the objects found were not properly cared for and their importance was not generally recognized. Real interest was awakened only after the first Hallstatt finds had attracted scholarly attention in 1846 and the pile dwellings of Zurich had been found in 1854. In 1853 the Villanovan cemetery near Bologna was discussed by Giovanni Gozzadini, who first proposed the theory that the Villanovans were proto-Etruscans. Louis Gabriel de Mortillet, excited by the discoveries at Zurich, set out to find similar settlements on the borders of the Italian lakes and succeeded in 1860. The next year Bartolomeo Gastaldi made a first attempt at explaining the construction of the Terramara sites; and Luigi Pigorini, with an enthusiasm and keen judgment which for more than 60 years proved so fruitful for Italian prehistory, turned to the problem in 1862 and 1564. After giving a good survey of this field of study at the anthropological congress at Stockholm, Sned., in 1874, he founded in 1875 the *Bollettino di Paletnologia Italiana,* which at once became a leading publication distinguished for thoroughness and sanity. He now built up a remarkable prehistoric museum in Rome and induced the government to grant funds for systematic excavations on prehistoric sites and to impose a careful supervision over private excavations. G. A. Colini. who later had charge of the museum in the Villa Giulia (devoted largely to Etruscology). also turned his talents to the investigation of prehistoric remains, issuing an important series of studies in this field. Antonio Taramelli also norked tirelessly on the island of Sardinia, and Paolo Orsi, while chiefly interested in the Greek civilization of Sicily and Magna Graecia. by no means neglected the prehistoric sites of his field. Oskar blontelius, nith his monumental work *La Civilisation primitive en Italie,* was useful in spreading a knonledge of this subject. That was followed in England by T. E. Peet's *The Stone and Bronze Ages in Italy* (1909) and by D. Randall-MacIver's *The Villanovans and Early Etruscans* (1924) and *The Iron Age in Italy* (1927). The remarkable corpus of prehistoric finds contained in Friedrich von Duhn and Franz Messerschmidt's *Italische Graberkunde* (1924, 1939) is a work of profound erudition; von Duhn had for 50 years been reporting all the important excavations nith a steady judgment and unsurpassed grasp of the subject.

Excavations in the 20th Century.— After about 1910 excavations were continued with renened vigour by the government and in the charge, usually, of the most competent scholars Of these undertakings only the most important can be mentioned In the north the researches at Este and in Picenum led to discoveries of great importance to anthropology, and abundant material nas found at Bologna, Vulci, Veii, Terni and in the Alban hills for the further study of the Villanovan period

For Etruscan studies. Caere yielded exceedingly fine Greek vases besides valuable funerary objects and inscriptions of importance in restoring the history of Etruscan culture from the earliest days till Roman times. Unfortunately. very fen of these tombs have been published *(see* Raniero Mengarelli in *Studi Etruschi,* p. 145, 1926; Pallottino, *La Necropoli di Cerveteri*). Veii proved unexpectedly fruitful. The foundations of a three-cella temple were found, and near it considerable fragments of the late 6th-century terra-cotta figures which once stood upon the ridgepole and later were placed in a special room in the Villa Giulia. The "Apollo Contending With Hercules" is a masterpiece (Pallottino, *La Scuola di Vulca,* 1941). On the acropolis of the city were found parts of the old fortifications, foundations of several Etruscan dwellings, tno public buildings and a large elliptical basement supposed to be the foundation for a straw-thatched town hall of very early date. Farther north nere discovered the stone walls of a 7th-century dwelling house of five rooms—the oldest

structure of its kind in Italy (*Not. d. Scavi*, p. 166, 1913; p. 380, 1922). The tombs proved that Veii was once a Villanovan city which fell into the hands of Etruscan rulers some time before Rome's foundation.

At Populonia, which prospered on the manufacture of the iron ore of Elba, many important finds were made. During World War I numerous shiploads of iron slag from the ancient Etruscan furnaces were removed for resmelting, and in the process an old cemetery was uncovered. These tombs and others near by were found to be well stored with urns, arms and ornaments, the first harvest of which A. Minto published in a volume entitled *Populonia*. A similar series of excavations at Marsiliana was also published by the same scholar. The systematic exploration of the site of the city of Tarquinii yielded far-reaching results, especially from the walls and the great temple with its terra-cotta adornment (*Not. d. Scavi*, p. 193, 1948). At Orvieto a 4th-century Etruscan temple with excellent pedimental terra cottas was found, important especially because of the tendencies of contemporary Greek art which they reflect. Good illustrations of these finds were published in *Dedalo* (vol. vi, p. 137, 1925–26). Vignanello yielded good Greek vases as well as much Etruscan ware. A grave at Todi was found to contain numerous red-figure vases and some Etruscan armour. Finally, at Rome, on Monte Mario behind the Vatican, casual building operations revealed a very interesting 7th-century Etruscan village built over the site of an early Bronze-Age settlement. A special journal for Etruscology called *Studi etruschi* was launched at Florence in 1926. The corpus of Etruscan inscriptions was also advanced by several fascicules with many new inscriptions, but by the 1950s no real advance had been made toward their interpretation.

LATER FINDS IN ROME

The city of Rome at mid-20th century was still yielding a constant stream of ancient works of art. The government secured possession of the Capitoline hill and ordered the excavation of the site of Rome's chief temple. The massive foundations of Tarquinius' structure were laid bare and found to agree with the dimensions recorded by ancient authorities (*Not. d. Scavi*, vol. xviii, p. 38, 1921). Unfortunately, little or nothing of the decorative terra cottas of the old temple came to light, but an interesting deposit of early votive objects was found not far from it. At the foot of the hill, the vicinity of the church of Sant' Omobono proved to be rich in early materials, chiefly terra cotta. On the Palatine the rear of the imperial palace was cleared in 1907, and excellent wall paintings and mosaics of the Claudian and Neronian periods were brought to light in abandoned rooms beneath. In other rooms found under the front of the palace were discovered wall decorations of great interest dating from the Sullan period (*see* ROME: *Palatine Hill*). The so-called Villa Mills was stripped of its modern decorations to facilitate the examination of the walls which proved to be ancient. The most valuable treasure yielded by the Palatine was the exquisite "Nike" or "Aura" (Brunn-Bruckmann, *Denkmaler*, nos. 766–767). In the 1950s, the administration of Forum and Palatine was in the midst of a thorough investigation of the deepest levels and the earliest periods of occupation of both sites.

The government excavated a large part of the Augustan Forum. The numerous architectural fragments found from the temple of Mars Ultor, the portico near by and the marble covering of the enclosing wall are of great beauty and precision, and several inscriptions of historical importance also came to light. This excavation was continued northwest into Trajan's Forum and southeast into Nerva's. Furthermore the theatre of Marcellus was freed from its clutter of ugly shops; the temple of Fortuna in the Forum Boarium, two unidentified temples near San Nicola dei Cesarini and a sacred area containing four temples not far from Pompey's theatre were liberated; and the mausoleum of Augustus was thoroughly studied.

Many rooms of Nero's Golden house near the Colosseum were cleared. The debris had been searched long ago for works of art, but the walls, protected by the superimposition of Trajan's buildings, were found to be decorated in a style resembling that of the Claudian rooms of the Palatine. The small and richly coloured panels set in embroidered stucco are excellently executed but overloaded in design, as are the Renaissance loggia arabesques which they inspired.

In many places on the walls were found the signatures of Renaissance artists who had crawled over the debris to study the ceiling decorations (*see* above). Among statues found elsewhere should be mentioned, besides the "Nike," an excellent portrait of Augustus (*Not. d. Scavi, p.* 223, 1910), an "Artemis" from Aricia (*Jahrb. Arch. Inst.*, p. 112, 1922) and a bronze of considerable quality representing a youth of the Julio-Claudian house, taken to New York city (*Am. Jour. Arch.*, p. 121, 1913). Furthermore, some forgotten fragments of great importance, which had long lain neglected and awaiting study in the basement of the Vatican, include three heads from the Parthenon and a good copy of the head of one of the "Tyrannicides."

During World War I there was discovered under the railway outside of Porta Maggiore a mysterious underground "basilica" in an almost perfect state of preservation, probably of the 1st century A.D. It had been built by sinking shafts in which the concrete walls and the piers of the nave were moulded. After a concrete vault had been cast over the walls, the enclosed earth had been removed and the walls and ceiling plastered and very richly stuccoed in low relief with mythological and genre scenes. It is, perhaps, the best preserved monumental structure of the Roman world, and the lavish stucco work, though not quite as delicate as that of the house found in the Farnesina gardens, shows an ease and freedom of execution which give it high rank. Scholars inclined to the belief that it was the meeting place of a group devoted to some mystical cult (J. Carcopino, *La Basilique pythagoricienne de la Porte Majeure*, 1927). The tomb of the Aurelii found on the Viale Manzoni (*Mon. Ant.*, vol. xxviii, p. 289, 1922) awakened much comment because of its excellent figures in fresco and the Christian symbolism that some of the paintings appear to contain. There is a seated figure before a flock that seems to symbolize Christ as judge. Eleven excellent standing figures were with less certainty identified with the Apostles. Later excavations of imperial Rome also disclosed the evidence of oriental cults: the shrine of Jupiter Dolichenus on the Aventine was fully excavated and its equipment installed in the Capitoline museum. The two largest Mithraea known also came to light in this period, one under San Clemente, the other under the baths of Caracalla (*Not. d. Scavi*, p. 317, 1912). The tomb of the Scipios was at last carefully examined and restored.

Meanwhile, outstanding developments were taking place in the early Christian field. In the early decades of the 20th century, beneath the church of San Sebastiano, were found a number of decorated columbaria of the 1st century made for pagan cremation, which in the 2nd century had been converted into Christian burial places; the area was then levelled off and a room for funeral banquets constructed. The walls of this room contained a great number of invocations to Peter and Paul rudely scratched. These finds promised to have an important place in early Christian history (*Not. d. Scavi*, p. 3, 1923).

Then, in the late 1940s, systematic explorations beneath St. Peter's proved extraordinarily rich in results for both pagan and Christian antiquities. Restorations of the churches of Santa Sabina, Santi Quattro Coronati and San Giorgio in Velabro also revealed earlier structures of value to church history. In the rapid expansion of Rome following World War I a very large number of tombs with sarcophaguses, hundreds of important inscriptions and three new series of catacombs were found. These were reported in the *Notizie degli Scavi*.

LATER FINDS ELSEWHERE IN ITALY

Outside Rome the havoc of war incidentally revealed further details of the ancient structures at Palestrina, Albano Laziale and Terracina; and the most important excavations in Latium disclosed Horace's villa on his Sabine farm (*Mon. Ant.*, p. 457, 1926), an important votive deposit at Tivoli, details of Domitian's palace at Albano and of Hadrian's villa near Tivoli, a splendid temple with its terra-cotta decoration of the republican

period at Lanuvio (Mon. Ant., vol. 27, p. 293, 1921), valuable fragments of a pre-Julian calendar at Anzio (Not. d. Scavi, p 73, 1921) and a very important part of the seaport town of Ostia. At Ostia the finds were so numerous that a mere enumeration would require pages. The walls and gates of the oldest settlement (4th century?), which Virgil seems to describe in *Aeneid* vii, were disclosed; the more extensive wall of the 1st century B.C. was traced throughout, and two of its excellently constructed gates cleared; the forum of the late republic was excavated and a temple of Rome and Augustus found at one end and, beneath the pavement of the forum, a series of barrack rooms and offices of the oldest town. Many new temples, the offices of the city guard, the offices of the foreign shippers, the large cistern of the city, numerous state granaries, the foundations of what seems to be the earliest temple of Jupiter, the municipal senate house, a very interesting safety storage house and much else could now be studied. Of particular interest in revealing the plan of city dwellings were the extensive ruins of the Casa di Diana which, rising to three or four stories, contained many suites of independent apartments which received their light through windows opening to the streets. This, rather than the Pompeian type of dwelling, was now assumed for the city of Rome. Subsequently, a vast program of excavation in the seaward quarters of the city disclosed still more temples, a late classical type of dwelling, and abundant sculptures and inscriptions (see G. Calza, Ostia, 1949).

The excavations at Pompeii yielded in 1925 a bronze ephebus in the classical Greek tradition (A. Maiuri, Ant. Denkmaler, p. 43, 1929), perhaps the most striking work of art that the buried city had disclosed; and in 1930 a complete silver table service, of the finest craftsmanship, marvellously preserved (Maiuri, La Casa *del Menandro* e il *suo* tesoro *di argenteria*, 1933). The work of clearing the western part of the city progressed without interruption and was even carried some distance east along the line of a principal street, leading to the discovery of a great palaestra near the amphitheatre. A large number of houses of moderate size with fair wall paintings have been found; among the paintings were several of religious import—a Cybele group, a Pompeian Venus, a group of the 12 gods and a series of interesting mythological scenes (Not. d. Scavi, 1911 *ff.*). Of particular interest are several houses with balconies and an office decorated with representations of armour, supposed by some to be the headquarters of the *juvenes*, the ancient "Boy Scouts." The newly found structures were carefully restored and the paintings well protected from weathering and decay. Systematic investigations beneath the ground level of the first century yielded valuable information as to the earlier phases of the city. V. Spinazzola's report on the excavations of 1911–23 appeared in 1913.

The systematic excavation of Herculaneum, after a long period of inactivity. was resumed in 1927, and there the application of perfected technical processes led to important results. Important excavations were conducted on the Greek sites of lower Italy and Sicily, beginning with Cumae. for centuries the Greek tutor of Italian barbarians. There, investigations at the citadel added to knowledge of the temple of Apollo and revealed the vast subterranean galleries which must have inspired the opening passages of the 6th book of the Aeneid (Maiuri, I *Campi* Flegrei, 1934). In southern Italy. Paolo Orsi excavated Locri (see Oldfather, in Pauly-Wissowa, *Realencyclopädie, s.v.*), Caulonia (*Mon. Ant.*, xxiii, p. 685, 1914–16), Medma (*Not.* d. Scavi, p. 37, 1917) and other sites, with striking finds of Greek vases, fine architectural decorations in terra cotta and large numbers of clay votive figurines of no mean artistic value. At Cirb in Calabria he found a head from an acrolithic Apollo of c. 460 B.C. (Orsi. *Templum Apollinis* Alaei ad *Crimisa Promontorium*, 1933); and at Velia the remains of three temples. (For subsequent developments at this important site, see *Am. Jour. Arch.*, vol. lv. p. 178, 1951). But the most important work of the kind was Orsi's extensive excavation in Syracuse. especially at the great temple of Athena. There was found a rich store of objects from pre-Greek huts, early Greek edifices and many exquisitely executed terra-cctta fragments from structures antedating the temple of the Deinomenids (*Not.* d, *Scavi,* p. 519, 1910, and *Mon. Ant.*, vol. xxv, pp. 353–762, 1919). The most striking developments in the south after Orsi's death were in the prehistoric field and especially in the Aeolian Islands, where early settlements came to light. Meanwhile, in 1934, the chance find of the "Warrior of Capestrano" (Giuseppe Moretti, *II Guerriero italico* di Capestrano, 1936) cast a ray of light on the early inhabitants of the central Italian uplands; and in 1951 the exploration of two of Rome's early military colonies. Alba Fucens and Cosa, gave promise of filling notable gaps in the knowledge of the republican period. Furthermore, the state began a detailed archaeological survey, For-ma *Italiae*. (See also ROME: The Ancient City.) (T. F.; A. W. V. B.)

HISTORY

From the fall of the Roman empire till modern times the Italians had no political unity, no independence, no organized existence as a nation. Their history is not the history of a united people, centralizing and absorbing its constituent elements by a process of continued evolution, but of a group of cognate populations, exemplifying various types of constitutional development.

The early history of Italy will be found under ROME and allied headings. The following article is therefore mainly concerned with events succeeding A.D. 476, when Romulus Augustulus was succeeded by Odoacer. Prefixed, however, are three sections dealing with ancient languages and peoples of Italy, with the unification of the country under Augustus and with the growth of the road system, etc.

Ancient Languages and Peoples.—The ethnography of ancient Italy is involved in obscurity. The country attracted, even in early ages, successive swarms of invaders from the north. Ancient writers are agreed as to the diversity of races that was found within the limits of the peninsula. The traditions transmitted to us are often conflicting, while the idioms that prevailed in Italy in and before the 5th century B.C. are preserved, if at all, only in a few scanty and fragmentary inscriptions. (See, *e.g.*, LATIN LANGUAGE; OSCAN; VOLSCI; UMBRIAN LANGUAGE; ETRUSCAN LANGUAGE; LIGURIA; and below.) These imperfect materials combined with notices derived from ancient writers and the evidence of archaeological excavations furnished results of reasonable certainty.

The name "Italians" was at one time confined to the Oenotrians. According to Antiochus of Syracuse (*apud* Dion. Hal., Ant. *Rom.*, ii. 1), the name of Italy was first applied only to the southern portion of the Bruttium peninsula (now known as Calabria). But in the time of that historian. as well as of Thucydides, the names of Oenotria and Italia, which were then regarded as synonymous, included the shore of the Tarentine gulf as far as Metapontum and thence across to the gulfs of Laus and Poseidonia on the Tyrrhenian sea. It thus comprised only the two provinces subsequently known as Lucania and Bruttium (see references s.~. "Italia" in R. S. Conway's Italic Dialects, p. 5). The name seems to be a graecized form of an Italic *Vitelia*, from the stem vitlo-, "calf," and perhaps meant "calf land." "grazing land."

The term Italy now comprises the whole peninsula with the northern region as far as the Alps. Only the Etruscans did not speak an Indo-European language. Apart from Etruscan and the dialects of the Greek colonies, like Cumae. Neapolis and Tarentum, from the south to the north, the different languages or dialects in separate existence between 600 and 200 B.C. were: (1) Sicel; (2) South Oscan and Oscan; (3) Messapian; (4) North Oscan; (5) Volscian; (6) East Italic or Sabellic; (7) Latinian; (8) Sabine; (9) Iguvine or Umbrian; (10) Gallic; (11) Ligurian; and (12) Venetic.

It is probable that Venetic, East Italic and Messapian were connected and, with the ancient dialects spoken in Illyria (*q.v.*), might be provisionally entitled the Adriatic group. The Sicel language was of Indo-European character. How far the language or languages spoken in Bruttium and at certain points of Lucania, such as Anxia, differed from Oscan is not clear (see BRUTTII). No inscriptions can be referred nith certainty to the language of the Ligures. Other evidence seems to link them with the *-CO-* peoples (*see* VOLSCI).

It is difficult to determine the dates of the earliest appearance of

Gallic tribes in the north of Italy. Archaeological stratification shows that the Gallic period supervened upon the Etruscan. The Celtic and Etruscan elements together occupied the greater part of the district between the Apennines and the Alps down to its romanization in the course of the 2nd century B.C. Their linguistic neighbours were Ligurian in the south and southwest, and Venetic on the east.

A large force of Gauls came as far south as Rome in the year 390 B.C. Some part of this horde settled in what was henceforward known as the Ager Gallicus, the easternmost strip of coast later known as Umbria, including the towns of Caesena, Ravenna and Ariminum. A bilingual inscription (Gallic and Latin) of the 2nd century B.C. was found as far south as Tuder, the modern Todi (Italic Dialects, ii, 528; Stokes, Bezzenberger's Beitrage, ii, p. 113).

For the languages of the Italic group in the narrower sense—(1) Oscan; (2) the dialect of Velitrae, commonly called Volscian; (3) Latinian (*i.e.*, Latin and its nearest congeners, like Faliscan); and (4) Umbrian (or, as it may be called, Iguvine)—two principles of classification offer themselves, the first purely linguistic, the second linguistic and topographical. There is a broad distinction between the dialects which preserved the Indo-European velars and the dialects which converted the velars wholly into labials. For example, Latinian quis contrasted with Oscan, Volscian and Umbrian *pis* (see further LATIN LANGUAGE).

The only Latinian dialects of which, besides Latin, inscriptions are known as Faliscan and Marsian (see FALISCI; MARSI). The place names of the Aequi (*q.v.*) suggest that they belong to the same group in this respect. Except, therefore, for a very small and apparently isolated area in the north of Latium and south of Etruria, all the tribes of Italy, though their idioms differed in certain particulars, are left undiscriminated. Tradition asserts very strongly (1) the identity of the Sabines and Samnites; (2) the conquest of an earlier population by this tribe; and (3) evidence of the identity of the Sabines with one element in the population of Rome itself.

The ethnical or tribal and oppidan names of communities belonging to the Sabine stock are marked by the use of the suffix -NO- as in Sabini. There is some linguistic evidence that this stratum of population overcame an earlier population, which used, generally, ethnica in *-CO-* or -TI- (as in *Morruci*, Ardeates, transformed later into Marrucini, Ardeatini).

From this it follows: (1) Latin will be counted the language of the earlier stratum of the population of Rome and Latium, probably once spread over a large area of the peninsula and akin in some degree to the language or languages spoken in north Italy before either the Etruscan or the Gallic invasions; (2) what is called Oscan represented the language of the invading Sabines (more correctly Safines); and (3) what is called Volscian, known only from the important inscription of the town of Velitrae, and what is called Umbrian, known from the famous Iguvine tables with a few other records, would be regarded as Safine dialects, spoken by Safine communities more or less isolated in the midst of the earlier and possibly partly etruscanized populations (as early as the 4th century B.C. their language had suffered corruptions which it escaped both in the Samnite mountains and in Rome).

The **Augustan** Settlement.— In the very earliest times the name of Italy was correctly applied only to the southern part of the peninsula; only gradually was it extended to the central regions, such as Latium and Campania, which were designated as Opicia by writers as late as Thucydides and Aristotle. Under Roman rule the term was confined to the regions of the central and southern districts, exclusive of Cisalpine Gaul, and this continued to be its official signification down to the end of the republic. But the name came to be generally employed as a geographical term much earlier. Polybius repeatedly applied it to the whole country as far as the foot of the Alps; and this was a familiar use of the term in the days of Cicero and Caesar. The official distinction was, however, still retained: Cisalpine Gaul still constituted a province, and it was not till Caesar crossed the Rubicon that he entered Italy.

Augustus gave a definite administrative organization to Italy as a whole, and his division into 11 regions continued in official use till the reign of Constantine.

The first region comprised Latium, including the Volsci, Hernici and Aurunci, together with Campania and the district of the Picentini, and thus extended from the mouth of the Tiber to that of the Silarus (see LATIUM).

The second region included Apulia and Calabria, together with the land of the Hirpini (*q.v.*).

The third region contained Lucania and Bruttium; it was bounded on the west coast by the Silarus, on the east by the Bradanus.

The fourth region comprised all the Samnites (except the Hirpini), together with the Sabini (*q.v.*) and the cognate tribes. It was separated from Apulia on the south by the Tifernus river, and from Picenum on the north by the Matrinus.

The fifth region was composed solely of Picenum, extending along the coast of the Adriatic from the mouth of the Matrinus to that of the Aesis, beyond Ancona.

The sixth region was formed by Umbria, in the more extended sense of the term, as including the Ager Gallicus, along the coast of the Adriatic from the Aesis to the Ariminus, and separated from Etruria on the west by the Tiber.

The seventh region consisted of Etruria, extending from the Tiber to the Tyrrhenian sea and separated from Liguria on the north by the Macra river.

The eighth region, termed Gallia Cispadana, comprised the southern portion of Cisalpine Gaul and was bounded on the north by the Padus or Po river, from above Placentia to its mouth; it was separated from Etruria and Umbria by the Apennines, and the Ariminus river was substituted for the Rubicon as its limit on the Adriatic.

The ninth region comprised Liguria, extending along the seacoast from the Varus to the Macra and inland as far as the Padus river, which constituted its northern boundary from its source in Mt. Vesulus to its confluence with the Trebia just above Placentia.

The tenth region included Venetia from the Padus and Adriatic to the Alps, with the neighbouring peninsula of Istria and, to the west, the territory of the Cenomani (*q.v.*).

The 11th region, known as Gallia Transpadana, included all the rest of Cisalpine Gaul from the Padus on the south and the Addua on the east to the foot of the Alps.

The Roman Roads.—The mainstay of the Roman military control of Italy was the splendid system of roads. As the supremacy of Rome extended itself over Italy, the Roman road system grew, each fresh conquest being marked by the pushing forward of roads through the newly won territory and the establishment of fortresses. It was in Italy that the military value of a network of roads was first appreciated by the Romans. Also, it was for military reasons that from mere cart tracks they were developed into permanent highways.

From Rome roads radiated in all directions. Communications with the southeast were mainly provided by the Via Appia and the Via Latina, which met close to Casilinum, 3 mi. N.W. of Capua, the centre of the road system of Campania. There the Via Appia turned eastward toward Beneventum, while the Via Popilia continued in a southeasterly direction through the Campanian plain and the mountains of Lucania and Bruttium as far as Rhegium. Other roads ran south from Capua to Cumae, Puteoli (the most important harbour of Campania) and Neapolis. From Beneventum, another important road centre, the Via Appia itself ran southeast through the mountains past Venusia to Tarentum on the southwestern coast of the "heel," and thence across Calabria to Brundusium; Trajan's alternative road ran northeast through the mountains and the lower ground of Apulia, reaching the coast at Barium. Both met at Brundusium, the principal port for the orient.

The only highroad of importance froni Rome eastward, the Via Valeria, was not completed as far as the Adriatic before the time of Claudius; but on the north and northwest started the main highways which communicated with central and northern Italy

and with all that part of the Roman empire which was accessible by land. The Via Salaria, a very ancient road, with its branch, the Via Caecilia, ran northeastward to the Adriatic coast as did the Via Flaminia, which reached the coast at Fanum Fortunae and thence followed it to Ariminum. The Via Flaminia was the earliest and most important road to the north; and it was soon extended (in 187 B.C.) by the Via Aemilia running through Bononia as far as Placentia, in a straight line between the plain of the Po and the foot of the Apennines.

In the same year a road was constructed over the Apennines from Bononia to Arretium. Along the west coast the Via Aurelia ran up to Pisa and was continued by another Via Aemilia to Genoa. Thence the Via Postumia led to Placentia and Cremona, while the Via Aemilia and Via Julia Augusta continued along the coast into Gallia Narbonensis. The road system of Cisalpine Gaul was mainly conditioned by the rivers which had to be crossed and the Alpine passes which had to be approached. Cremona, on the north bank of the Po, was an important meeting point of roads, and Hostilia another; so also were Patavium and Aquileia, farther east. (See also ROADS AND STREETS.)

As to the roads leading out of Italy, from Aquileia roads diverged northward into Raetia, eastward to Noricum and Pannonia and southward to the Istrian and Dalmatian coasts. Farther west came the roads over the higher Alpine passes—the Brenner from Verona, the Septimer and the Spliigen from Clavenna, the Great and the Little St. Bernard from Augusta Praetoria and the Mont Genèvre from Augusta Taurinorum. Westward two short but important roads led from Rome on each side of the Tiber to the great harbour at its mouth. (X.)

Goths and Lombard% — Thedeposition of the western Roman emperor Romulus Augustulus by Odoacer in 476 opened a new period in Italian history. The revolution had been caused by the refusal of the western government to settle its barbarian army on Italian soil. The soldiers, who wanted to follow the example of Germanic peoples in other provinces of the empire, elected Odoacer their king, and after the deposition of the puppet emperor they were settled in Italy, Roman landowners ceding one-third of their lands. This settlement of a barbarian army was a turning point: Italy now shared the fate of other imperial provinces. Theoretically, the government of the country passed in 476, or at least after the death in Dalmatia of the last legitimate emperor of the west, Julius Nepos (480), to the eastern emperor at Constantinople. In fact, Odoacer was the master of Italy. He wanted not to detach it from the empire but to govern the Roman population as viceroy, while ruling his barbarian soldiers as king; and the emperor Zeno acknowledged his authority by accepting him as patrician.

In 488 Zeno sent the Ostrogoths under their king Theodoric (Theoderic or Dietrich) to Italy to attack Odoacer, with whom relations had become increasingly strained. In 493 Odoacer, having surrendered Ravenna, was killed by Theodoric. The dual government of Italy was continued. King of the Goths, who were settled like Odoacer's people before them, Theodoric ruled over the Roman population as imperial viceroy; and the Roman administration was left intact, civil offices being usually filled with Romans, military ones with Goths.

Theodoric having died in 526, his daughter and successor Amalasuntha was in 535 imprisoned and killed by her cousin Theodahad; this was the signal for Byzantine intervention. Justinian had recently recovered North Africa from the Vandals; the conquest of Italy was the next step. Belisarius, the victor over the Vandals, was sent to Italy, and the fall of Ravenna in j40 seemed practically to conclude the campaign. But Gothic resistance revived, and it took the eastern emperor more than 12 years to break it. The decisive battle was won by his general Narses, commanding a new imperial army, near Tadinae in 552; the last Gothic stronghold fell in 555. Italy came under Byzantine government. The country had been devastated by the wars, and Byzantine taxation lay heavily on it. Although the frontier defenses were reorganized, internal conditions must have assisted the Lombards when they invaded Italy under Alboin in 568.

The Lombard conquest (see LOMBARDS) led to the permanent settlement of a Germanic people in Italy and thus showed the failure of Justinian's policy of imperial recovery. But the Lombards were unable to conquer the whole of the peninsula, and the division of Italy into a Iarge Lombard and a smaller Byzantine part was to have far-reaching effects. Alboin died in 572, having conquered nearly the whole of the Po valley and Piedmont. From 574 to 584 the monarchy was suspended. About 30 dukes ruled over the conquered territories. But the conquest continued after Alboin's death, and was extended to central and to southern Italy. After the restoration of the monarchy by Authari in 584, the duchies remained the basis of Lombard government but were subordinated, in varying degree, to the king; the great southern duchies of Spoleto and Benevento were virtually autonomous. The Lombards did not recognize Byzantine sovereignty, and the dual government of the Germanic and Roman population was abandoned. The methods of settlement were infinitely harsher than under Odoacer and Theodoric, for the Romans were treated as a conquered nation. Large numbers of the Roman nobility appear to have been killed, and their lands confiscated.

The Roman coloni had already lost most of their freedom; they now became assimilated to the Lombard half-free. But a free Roman population survived in the towns. From the end of the 7th century the condition of the Romans seems to have improved; the peace with the Byzantines *c.* 680 probably contributed to this. In the course of time the Lombards assimilated much of the relics of Roman civilization, thanks largely to the adoption of Catholicism by the formerly Arian Lombards (the monarchy was permanently Catholic from 653). The decline of the Lombard idiom and the increasing use of the language of the conquered by the conquerors was a striking symptom of it.

The Roman city territories survived as administrative districts in the duchies, the dukes usually residing in their chief towns. A number of towns were under royal officials (gastaldi). The towns thus retained some importance as administrative centres of the Lombard kingdom; they were moreover seats of bishops and served as market places for the surrounding countryside, urban trade and crafts fulfilling at least some local functions.

Byzantine Italy was mainly confined to stretches of the coast with their hinterland. By the middle of the 7th century, it included Istria; the islands of the Venetian lagoon which had been settled by refugees from the mainland; the territories of the exarchate of Ravenna proper and of the Pentapolis (roughly from Rimini to Ancona); Perugia; the "heel" and the "toe" of Italy, separated by the duchy of Benevento; and the small territory of Naples and the fairly extensive one of Rome. including part of southern Tuscany. (See RAVENNA, EXARCHATE OF.) Moreover, Sicily, Sardinia and Corsica remained under the empire. In the imperial territories of Italy, the framework of the earlier Roman administration survived. As in other Byzantine provinces, the combination of civil and military power became characteristic of Byzantine administration. The exarch at Ravenna was the governor of imperial Italy; under him, dukes commanded new military districts; below them were tribunes as governors of tomns. Byzantine officials and local landowners. often identical, came to form a new ruling class; and this development contributed to bring about decentralization, which was also fostered by the difficulties of central government over the widely dispersed territories. Thus in Naples the dukes had acquired a semi-independent position by the 8th century; in Rome, the pope increased his secular authority (already considerable during the pontificate of Gregory I, 590–604), upheld by vast estates in Italy and Sicily. To a minor extent, the position of bishops in other towns tended to develop on similar lines. The revolution that swept Byzantine Italy in 726, although primarily provoked by the emperor Leo the Isaurian's iconoclastic policy, revealed these separatist tendencies. The papacy, which had taken a leading part in the revolution, suffered a setback after its suppression; but by 754 it had become virtually supreme in the Roman duchy.

Under the Lombard king Liutprand (712–744), the peace between Greeks and Lombards came to an end. The revival of Lombard expansion reflected the internal strengthening of the monarchy from the end of the 7th century. Liutprand seized

territories around Ravenna; he threatened both Ravenna (captured for the first time in *c.* 732–733) and Rome. King Xistulf (749–756) pressed this new attack with vigour; c. 751 Ravenna was finally lost by the Byzantines. The next move was against Rome; and in 753 Pope Stephen II crossed the Alps to appeal for help to the Frankish ruler Pippin the Short. Pippin invaded Italy twice. in 754 and 756, and both campaigns led to Lombard defeats. Aistulf was forced to return the recently conquered territories; but Pippin, instead of restoring them to Byzantium, gave them to Pope Stephen, to whom the promise of an extensive donation had been made in 754. Thus he became one of the founders of the papal states. The next Frankish intervention, under Charlemagne (*q.v.*), was caused by Lombard attacks on Pope Adrian I and ended in the annexation of the Lombard kingdom by Charlemagne, who assumed the title of king of the Lombards (774). He confirmed, and perhaps increased, his father's promise of donation to the papacy; but the establishment of Frankish rule created a new situation in which the wider territorial aspirations of the popes were not fulfilled. The latter remained in the possession of the Roman duchy, the small duchy of Perugia, the exarchate of Ravenna and the Pentapolis; but Charlemagne could make his authority felt within the new papal states. He now began to use the title of Roman patrician conferred already on Pippin by Stephen II. The imperial coronation in 800 was not only a recognition of his European power; it also confirmed and strengthened the position of the Frankish ruler in Rome and the papal states.

Carolingian Italy. — Frankish Italy had become a province of the new western empire. Its special place was recognized by the conferment of the royal title on its governor; but the centre of the empire lay north of the Alps. Charlemagne took over the Lombard administration with few major changes, the dukes and *gastaldi* being, as a rule, replaced by tounts. But the counts were more strictly subordinated to the monarchy than the Lombard dukes had been; at the same time, collaboration of counts and bishops mas encouraged, as in the rest of the empire. Frankish noblemen were not only entrusted with leading offices but were also granted lands and privileges in Italy; the new immigration strengthened the Germanic element in Italian society, into which feudalism now began to penetrate.

The partitions of the Carolingian empire during the 9th century changed the status of the Italian kingdom several times. Louis I the Pious, when he divided the empire in 817, decided that it should go to his son and coemperor Lothair I; and the treaty of Verdun (843) extended Lothair's territory as far as the North sea. Within this new dominion, between the French and the German kingdoms, Italy came once more under a separate administration and was given by Lothair to his son Louis, who retained it after his father's death. He had previously been crowned emperor as Louis II; but his position remained that of a king of Italy. He was the only Carolingian ruler after Charlemagne who made real — although futile — efforts to improve the internal conditions of the kingdom, which had suffered from the weakening of public authority. He also helped, with considerable success, to defend Italy against the Arabs. The Arabs had begun the conquest of Sicily in 827 and had taken Palermo (831) and Messina (843), an invaluable base for incursions into southern Italy. Conflicts and rivalries in that region assisted their attempts. Thus in 839 a double election led to civil war in the duchy of Benevento. Seizing Bari and other plates, the Arabs began to settle on the mainland. Their attacks along the Tyrrhenian coast threatened the maritime towns as well as Rome, uhich was partly sacked in 846. Naples, Amalfi and Gaeta put up a determined resistance, and Louis succeeded, after several campaigns, in taking Bari from the Arabs. The years after his death (875) were the epilogue of Carolingian rule in Italy. In 887 Charles the Fat, who had reunited the whole empire for a short time, was deposed by the East Franks. A section of the Italian nobility followed suit by electing Berengar of Friuli king of Italy (888).

The **Italian** Kings. — The following decades were marked by intermittent struggles for the Italian crown, in nhich the main contestants were powerful Italian princes — margraves or dukes of Friuli, of Spoleto, of Ivrea — the kings of Provence and the kings of Burgundy. Even the most successful of the Italian kings never succeeded in controlling the whole kingdom; and the possession of the imperial crown was not more than the possession of an additional title implying the right to protect the pope. Nor were they able permanently to defend the country against the Hungarians, who periodically ravaged northern Italy from 898, thus adding new dangers to the Saracen incursions. The growth of feudal powers provided the background to the political struggles; already before 888 the margraves of Friuli, Tuscany and Spoleto had ruled over large dominions; they were followed by others, such as the margraves of Ivrea and the counts of Turin. But also at a lower level, feudalism spread during the 9th and 10th centuries. As elsewhere in Europe, this went hand in hand with the disintegration of royal authority.

The Italian kings, in their need for support and also in order to provide for the better defense of the towns against the incursions, granted public rights in the towns to bishops whose secular authority — which had undoubtedly grown during these times of trouble — was thus strengthened. In Rome the house of Theophylact rose from the beginning of the 10th century to princely power at the head of the nobility. The papacy came to depend on it; and after the death of Theophylact's grandson Alberic, Alberic's son was elected pope as John XII (955). By that time the secular authority of the papacy was practically limited to Rome and the territory around it; but there Alberic pursued, in the pope's stead, a vigorous administrative policy. In southern Italy the Byzantines much improved their position toward the end of the 9th century. In successful struggles against the Saracens, they recovered the territories that had been conquered by them on the mainland; they reorganized their administration in the two new "themes" of Calabria and Longobardia; and they temporarily wielded considerable influence among the principalities and towns of south Italy, to which they gave valuable protection against the Arabs.

The Saxon and Franconian Emperors. — The German king Otto I came to Italy in 951 and forced the king of Italy, Berengar of Ivrea, to do homage to him (952). But in 960 Pope John XII appealed for help against Berengar's and his son Adalbert's aggression. Otto crossed the Alps again and was crowned emperor in Rome in 962, while Berengar's power collapsed. **A** new chapter in the history of Italy began.

Otto I laid the foundations on which German rule in Italy was to rest until the 12th century. Determined to assert his sovereignty over the feudal magnates, he accepted and fostered them as long as they were loyal to him. As the Italian kings had done, he made or confirmed grants of jurisdiction to Lombard bishops in their towns. (Bishops probably did not become counts until the 11th century; and even then the privileges were with very few exceptions confined to the towns and land around them. In Tuscany, moreover, jurisdiction was granted only in few relatively late cases; and even in Lombardy not all bishops received such grants.) In Rome he tried to revive the authority of Charlemagne but met with the resistance of the Romans; and although he made and deposed popes at will, there was strong opposition against his nominees, culminating in risings. In southern Italy Byzantine recovery had been only temporary; and the princes there soon regained their full liberty of action. They did homage to Otto, who thus extended his influence to the south. Pandulph of Capua was made margrave of Spoleto and Camerino and became Otto's most powerful supporter in that region. Western imperial designs on southern Italy led to war with Constantinople; peace was concluded, and Otto II betrothed to the Byzantine princess Theophano in 972.

Once again Italy had become part of an empire whose centre was north of the Alps. This was a source of both strength and weakness. It had helped Otto to succeed where the Italian kings had failed; on the other hand, government from Germany and occasional expeditions were to prove doubtful substitutes for continuous presence. Of all Otto's successors before Frederick II, only his grandson Otto III may have contemplated a change in this policy by taking up his residence in Rome. Inspired by

the ideas of Roman renewal, he may have thought of making the city the imperial capital. But he was probably far less prepared to abandon earlier traditions of German rule than might appear.

Italian opposition to the emperors was not lacking. After Otto III's death, the margrave Arduin of Ivrea was elected king of Italy by his supporters (1002); but his brief reign remained confined to northern Italy and met with much resistance from the episcopate. There were risings against the emperor in Pavia in 1004 and in 1024 (on Henry II's death) and in Ravenna in 1026. At the same time social tensions between nobility and episcopate and between higher and lower nobility began to foreshadow later conflicts in the communes. Thus in 1036 the Milanese lower nobility of the *valvassori* rose against the powerful archbishop of Milan, Heribert; aiter their expulsion from Milan, the revolt spread over Lombardy. Conrad II's feudal law of 1037 aimed at satisfying their claims by making all fiefs hereditary and consequently granting equal rights to the *valvassori* and to the higher nobility of the *capitani*.

The feudal law was issued during the unsuccessful siege of Milan, Heribert having rebelled against the emperor. This showed that a powerful episcopate was not always an asset and that there were limitations to the loyalty of the Lombard bishops—even before the investiture contest. Heribert strikingly personified the power that the Italian bishops could wield. Although not count of Milan, he was the actual ruler of the tonn and of a considerable territory outside it, and lord over a large number of vassals. Soon after, however, the power of the archbishops of Milan was broken during the civil and religious strife which began in 1056 with the Milanese reform movement of the Patarenes.

Rome continued to be a major problem for the emperors. In 1046 Henry III intervened in a contested papal election. Gregory VI. Benedict IX and Silvester III were all deposed and a German bishop elected in their place as Clement II. Eager to foster ecclesiastical reform, Henry III helped decisively, by his interventions in the papal elections, to assure its victory at the curia; Clement II and his successors were not only Germans but also supporters of the reform movement. But the reformed papacy soon turned against the time-honoured relationship between church and state and thus threatened one of the pillars of imperial government in Lombardy; while the Lateran decree of 1059 practically eliminated the influence of both the Roman nobility and the emperors on papal elections.

The investiture contest between pope and emperor began in 1076. It weakened ecclesiastical loyalties and made Matilda of Tuscany, the most powerful of the Italian rulers, Henry IV's enemy. Yet, despite the Norman alliance (see below) and the help of Matilda, Gregory VII could not prevent Henry's capture of Rome (1083–84). Norman help, when it came, was a double-edged weapon. Although it forced Henry to withdraw, the devastation of Rome by the Norman army ruined Gregory's position there—he died at Salerno in 1085. The conflict continued under his successors. In 111j Matilda died without heirs, and the succession to her vast properties, which she had left first to the papacy but probably later to Henry V, became a new source of conflict between empire and papacy.

The Normans in the South. — Pope Nicholas II, meanwhile, had in Aug. 1059, at Melfi, invested the Norman adventurer Robert Guiscard (*q.v.*) with all conquests in Apulia and Calabria and with all future conquests in Sicily; on the same occasion he invested another Korman, Richard of Aversa, with the principality of Capua. This was a landmark in the momentous events that had been taking place in southern Italy from the time when Norman mercenaries arrived in 1017 and served in a revolt against the Byzantines. From that time the Normans had taken part, in increasing numbers, in the conflicts between the principalities of southern Italy. Their permanent settlement began c. 1029 when Rainulf was granted Xversa. In 1041 they began their conquest of Apulia; a few years later Robert Guiscard was entrusted with that of Calabria. He pressed successfully the conquest of Calabria and Apulia and, with his brother Roger, began that of Sicily in 1060. The fall of Bari (1071) marked the final collapse of Byzantine power in Italy. In Sicily, Palermo was captured in 1072; but it was not until 1091 that the whole island was won from the Arabs. At first Roger governed Sicily as a separate county; but his son, the second Roger, united it with the duchy of Apulia after the death of Duke William (1127). In 1130 this Roger became king of Sicily, having obtained the investiture from the antipope Anacletus II; and in 1139 this was confirmed by Innocent II. In his powerful state, which included all Norman conquests in southern Italy and Sicily, Greek, Arabic and Norman institutions were welded into a new and singularly efficient structure, in which the feudal nobility and the towns were strictly subordinated to the monarchy. (See SICILY.)

Age of the Communes. — By the 11th century, several Italian towns had reached considerable prosperity. They were mostly in Byzantine territory or had maintained contact with Constantinople and could thus take full advantage of the revival of eastern trade.

Foremost mere Venice and Amalfi, the latter reaching the height of its commercial power about the middle of the century: others included Bari, Otranto and Salerno. For a short time a serious rival of Venice, Amalfi declined after having submitted to the Normans in 1073. Then Venice received. with the privilege of 1082, exemption from all customs duties within the Byzantine empire. During the 11th century Pisa, the natural port of Tuscany, began to rise amid struggles with the Saracens. whom it defeated repeatedly; and Genoa. which was to be its rival for centuries, was following suit. Among the inland tom-ns—as yet less conspicuous — Pavia, which had owed much of its early prosperity to its role as capital of the Lombard kingdom. was rapidly outdistanced by Milan; Lucca, on the Via Francigena from Lombardy to Rome, and ior a long time the residence of the margraves of Tuscany, was the most important Tuscan inlacd town.

The importance of fortified centres during the Kungarian and Saracen incursions contributed to the development of towns. Town walls were rebuilt or repaired, providing security both to citizens and to people from the country; and the latter found further places of refuge in the many fortified *castelli* with which the countryside began to be covered.

Simultaneously, local self-government developed. The movement began first in the Byzantine territories; thus Venice elected its doges (dukes) from the early 8th century onward, Amalfi, annual magistrates from the 9th century. In the Italian kingdom, on the other hand, the authority exercised by bishops or counts gave scant scope for urban liberties. Assemblies in front of the church, known since Lombard times, as well as the introduction of the Carolingian jury, were humble beginnings. The citizens helped to defend their towns against Hungarians and Saracens; and the notables (boni homines) took some part in local administration by assisting the bishop or count.

The communal movement created a new situation in northern and central Italy from c. 1080, while the Norman conquest of southern Italy put an end to the progress of municipal autonomy in that region. Whether it took the form of a conflict with the established authorities or of peaceful transition, the ultimate result of the communal movement was full self-government. Originally the communes were, as a rule, associations of the leading sections of the town population; but they soon became identical with the new city-state. Their first opponents were often. but by no means always, the bishops; in Tuscany, where margravial authority was strong, Henry IV encouraged rebellion against Matilda by granting extensive privileges to Pisa and to Lucca in 1081; and Matilda's death in 1115 made it possible for Florence to achieve independence. The investiture contest, which was liable to undermine episcopal authority, often encouraged the citizens to assume a bolder attitude in urban politics. But even before the contest, the Patarenes in Milan showed, after 1056, how dangerous to episcopal authority religious conflict could become.

The first organs of the commune were the general assembly of all its members (parlamento, concio, *arengo*) and the magistracy of the consuls; the latter are first mentioned at Lucca *c.* 1080. At an early date a council began to replace the unwieldy assembly for ordinary political and legislative business; and with the growing complexity of the constitution, further councils emerged,

conditions varying considerably from town to town. Communal law constituted a blend, under the influence of the revived Roman law, of urban customs and the new communal legislation. During the 12th century, the consular office was usually monopolized by the class that had taken the initiative in the establishment of the commune. This class was usually composed of small feudal or nonfeudal landomners and the wealthier merchants. In Pisa and Genoa the commercial element was predominant, while in parts of Piedmont the commune derived from the associations of the local nobility. Thus the early commune was predominantly aristocratic. The fortified towers of the leading families, resembling the feudal castles of the countryside, were characteristic of these conditions. In Italy there had in fact never been the same separation between town and countryside as, for instance, in northern France and in Germany; feudal society had penetrated into the towns, while nonnoble citizens were often landomners outside their walls. This link between town and country was to become progressively stronger and more complex in the course of communal history.

From the beginning the conquest of the country (contado) became one of the main objectives of communal policy. The small fortified townships (*castelli*) and the lesser rural places, which had also been widely affected by the communal movement, were now absorbed by the city-states. The divisions and subdivisions of feudal property, partly the result of the Lombard law of inheritance, weakened many feudal houses and thus facilitated the conquest, while the bishops could not prevent the extension of communal control to their lands. The members of the country nobility were subjected one by one and often forced to become citizens; others did so voluntarily. Only a small number of more powerful families, such as the house of Este, the Malaspina, the Guidi and the Aldobrandeschi, succeeded in maintaining their independence, and that not without frequent losses and concessions. Soon, however, it became evident that the territorial conquests, as well as the growth of urban liberties, must lead to conflict with the empire.

The Hohenstaufen Emperors. — That conflict began soon after the accession of Frederick I Barbarossa, the second Hohenstaufen emperor (1152). The decrees of Roncaglia (1158), issued at the beginning of his second Italian expedition, with the assistance of members of the new Bolognese law school, placed imperial policy on a new basis. Frederick's predecessors Lothair II (or III) the Saxon and Conrad III had only rarely intervened in the affairs of northern and central Italy. Conrad III never came to Italy at all. By the time of Frederick Barbarossa's first expedition (1154) the communes had greatly increased their power, and no organized attempt had been made to check them. Frederick tried to strike at the core of the problem by claiming for the empire the royal rights (regalia) which had in so many cases been usurped by the communes. The victims of this usurpation, however, had been far less the emperor himself than the bishops and the nobility, who for a long time had been in possession of most of the regalia. The innumerable grants of royal rights had formed an integral part of the traditional system of imperial government. Frederick intended to replace it, to a wide extent, by one of direct control. Imperial officials were to administer town and countryside; and if the communes were to be left some of their liberties, they were to owe them entirely to the emperor. In fact the emperor began soon to differentiate between the communes; those which took his side were granted considerable concessions, such as free elections of the consuls. The violent resistance of Milan and other towns mas largely responsible for this turn of Frederick's policy. It was significant that Milan's enemies, such as Lodi and Cremona, vigorously assisted in the siege of that town and shared in its destruction in 1162. On the other hand the revival of the struggle between empire and papacy provided the anti-imperial towns with a powerful ally. The double papal election of 1159 led to a schism; and while Frederick recognized Victor IV, Alexander III was prepared to support any communal reaction against the emperor. After the fall of Milan, Venice, threatened by the extension of imperial power, had taken the initiative in founding the Veronese league (1164); and in 1167 a second league was formed, including other Lombard towns. In the same year the two leagues joined and entered into close contact with Alexander. In the meantime Frederick had taken Rome; but an epidemic had decimated his army (1167), and his return route to Germany was almost cut by the Lombard revolt (1168). As a result, imperial authority practically collapsed in Lombardy and was much weakened in Tuscany. After his return to Italy, Frederick was prepared to give up the execution of the Roncaglian decrees. as was shown in the negotiations of Montebello (1175); but these negotiations were ineffective, and in 1176 Frederick was defeated by Milan near Legnano. In 1177 Frederick concluded a separate peace with Alexander III; and an armistice with the Lombard league was culminated after six years by the peace of Constance (1183). The Lombard communes were left the regalia inside the towns and, on certain conditions, in the territory, and they retained nearly all their liberties; but the consuls were to be invested by the emperor (a right of which he seems to have hardly ever made use). The peace concerned, however, only Lombardy. In Tuscany, Spoleto and the Marches, the imperial position had been greatly strengthened during the previous years, and the administrative reorganization that had failed in Lombardy was carried out with considerable success in that region. Moreover, Frederick was preparing the extension of German rule to the kingdom of Sicily.

The emperors had made repeated attempts at conquering the Norman kingdom. In 1137 Lothair II had achieved a short-lived success in Apulia; in 1166–67 Frederick had planned an attack on the kingdom. In 1184 the Sicilian heiress Constance, King Roger's daughter, was betrothed to Frederick's son and successor I-Ienry, an event of far-reaching importance for Italy and the empire.

At Frederick's death in 1190, Henry VI had already begun to assert his and his wife's claims to Sicily, King Roger's grandson William II having died in 1189. But resistance led by Tancred, an illegitimate grandson of King Roger, was strong. The kingdom had to be conquered, and it was not until 1194 that Henry succeeded in doing so. He left the Norman regime unchanged; the highly centralized Sicilian state was an invaluable addition to the resources of the empire in Italy. Henry's unsuccessful plan to make the empire hereditary would have led to permanent union, since the Sicilian crown was hereditary. Placing imperial rule on a much stronger basis than it had ever possessed: it would have been fraught with dangers for the political independence of the papacy. Thus the papacy made a determined effort, after Henry's death in 1197, to destroy forever the union of Sicily and the empire. Henry's death was followed by a double imperial election; in Italy, imperial administration disintegrated rapidly, the communes recovering everywhere what they had lost. Innocent III (1198–1216) took full advantage of this reaction and substituted papal government for imperial administration in the duchy of Spoleto and in the march of Ancona, thus once more extending the papal states to the Adriatic sea. Constance of Sicily renounced the imperial crown on behalf of her son Frederick, the new king of Sicily, and appointed Innocent III to be his guardian after her death (1198). The next step in the separation of Sicily from the empire was the renunciation of the kingdom by the Welf Otto IV (1201), who had been recognized emperor by Innocent against the Hohenstaufen Philip of Swabia. But after his imperial coronation in 1209, Otto turned to its conquest, the continuity of imperial policy proving stronger than promises and a change in dynasty.

In Sicily, the preceding years had been marked by internal disorders which threatened to destroy the work of the Norman monarchy. In 1211 Innocent decided to play off the young king Frederick against Otto by supporting his new election as future emperor in Otto's stead. Crowned as German king at Mainz (1212), Frederick II grew rapidly more powerful; and the battle of Bouvines (1214) sealed Otto's fate. But the success of papal policy was only temporary, for Frederick too did not keep his promise to separate Sicily from the empire.

Between 1220 and 1230 Frederick continued with great vigour and much success the policy of his German and Norman ancestors in Italy and Sicily. The years after his imperial coronation in

1220 were mainly devoted to rebuilding and consolidating the structure of the Norman monarchy. Further reforms took place in later years, and the constitutions of Melfi of 1231 admirably reflected the spirit and working of the highly centralized and bureaucratic Sicilian state. In northern Italy, active intervention began in 1226 and immediately led to the revival of communal resistance; and when in 1227 the new pope Gregory IX excommunicated Frederick after his failure to keep the date appointed for the crusade, the pattern of the reign of Frederick I was reproduced, the papacy allying itself with the Lombard towns against the emperor. Peace with the papacy in 1230 was of short duration. Open war with the Lombards broke out again in 1236; the great defeat of the league at Cortenuova (1237) was not fully exploited by Frederick; and in 1239 Gregory once more excommunicated the emperor. The capture of Rome now became a major objective; Frederick may have been on the eve of attaining it at the time of Gregory's death (1241). Peace negotiations with Innocent IV and the league broke down in 1244; and Innocent deposed the emperor at the council of Lyons (1245). In the following years the struggle continued with unprecedented violence. Despite numerous setbacks, the imperial cause seemed to be in the ascendant when Frederick suddenly died in 1250.

After 1237 he had reorganized imperial administration in northern and central Italy, introducing and adapting Sicilian methods of government. Vicars-general with wide authority governed new provinces, while under them local officials .administered towns and countryside. The preponderance of natives of the Sicilian kingdom in the Italian administration significantly contrasted with the leading role played by Germans under Frederick I and Henry VI. Sicily had become the main pillar of imperial rule in Italy, and its great resources held out a substantial promise of success. At the same time Frederick tried to preserve the support of the German princes by far-reaching concessions (1232).

Frederick's death was a turning point in the history of Italy; it marked the end of the Hohenstaufen policy of placing the country under a centralized monarchical government. The conflicts betneen Frederick's successors and the papacy continued until 1268. In 1265 Pope Clement IV invested Charles of Anjou with the Sicilian kingdom, where King Manfred, Frederick's illegitimate son, had been consolidating his power. In 1266 Manfred was defeated and killed in the battle of Benevento. Two years later Frederick's young grandson Conradin made a supreme effort to save the fortunes of his house; after a triumphant entry into Rome he was beaten by Charles at Tagliacozzo (1268) and executed at Naples.

During the struggles between papacy and empire Italy had become divided into two parties, papalist and imperialist, which in the course of the 13th century assumed the names of Guelph and Ghibelline. This had not only affected relations between states but had also divided the population of the towns, thus giving fresh impetus to local factions. The names of Guelph and Ghibelline remained a tragic legacy of the Hohenstaufen period to the political life of Italy.

Monarchies and Communes in the 13th Century.—By the end of the 12th century, the communes had triumphed in Lombardy and Tuscany; but although the communal movement extended also to other parts of the country, it did not prevail everywhere. Large regions of Italy retained or developed monarchical institutions — foremost the Sicilian kingdom, but also the papal states, Piedmont and Sardinia. Feudalism formed an important element of monarchical Italy, nhich represented also in this respect a contrast to the antifeudal policy of the communes. R'ith other European countries, monarchical Italy had in common the development of assemblies of estates (*parlamenti*), in which the towns were represented. Originating primarily from the earlier feudal assemblies, the parliaments of the 13th and 14th centuries reflected the attempt to give the towns together with the feudal classes an influential place in the political structure of the monarchical states. They thus constituted also a new development in the position of the towns, which often enjoyed considerable local autonomy under monarchical control. Conditions varied considerably, however, both with regard to the functions of the parliaments and the rights of the towns. Thus the papal states, comprising many communes which had been only recently acquired, contrasted with the Sicilian kingdom where the towns had remained strictly subjected to the monarchy from the time of the Norman conquest, whatever the privileges that had been granted to them.

In communal Italy, the internal conflicts that began to disrupt the communes in the 12th century created new and far-reaching problems. Caused by rivalries and feuds within the ruling oligarchies and already, sometimes, by social conflicts, they led toward the end of the 12th century to the institution of a single executive magistrate (*podestà*). This innovation did not, however, put an end to internal strife. While the consular government disappeared at the beginning of the 13th century, it became the general rule for the *podestà* to be a citizen of another town, so that the executive could no longer be the object of family rivalry. The struggles between the municipal parties, led by powerful families from which they often took their names, became a permanent feature of communal politics, and strife was intensified by the custom of the blood feud (vendetta) and by the expulsions of the defeated party. The growth of Guelphism and Ghibellinism gave the local parties endless possibilities of outside support and added fresh violence to their struggles. But they were no longer alone in their desire for political control.

The increase of economic prosperity and the growth of the town populations led to a challenge of the virtual rule of the aristocracy in the communes. The prosperity was primarily the result of the expansion of Italian trade and the development of Italian banking and industry. The crusades provided Venice, Pisa and Genoa and, indirectly, other towns uith new trading centres on the fringe of Asia; the fourth crusade gave Venice an empire in the Levant, the economic value of which was immeasurably great. The restoration of the Byzantine empire in 1261 was not a serious blow to Venice's new dominion; but it gave Genoa vast commercial opportunities at Venice's expense. The Sicilian policy of the papacy after 12jo—the offers of the kingdom first to Edmund, son of Henry III of England, and then to Charles of Anjou — provided Italian bankers and merchants with new fields of action. Hand in hand with increasing prosperity went immigration into the towns, the new citizens being recruited from all classes. The rise of the merchant and craft guilds was closely related to these developments, another form of organization of the *popolo* being military companies. The popolo roughly corresponded to the middle classes, and the final stage of its political formation was reached when it was organized like a commune, with executive, councils and statutes of its own. Conflicts betneen the aristocracy and the *popolo* began early but generally did not reach full strength until the 13th century. A first attempt to settle them led in Milan and other Lombard towns to the government's being shared between the two classes. Later on in the 13th century the organized *popolo* sometimes succeeded in establishing control of the commune, as in Florence in 12 50 and 1282.

Instability and civic strife were general traits of the 13th-century communes; the fate of the vanquished was bitter, the political exile becoming a typical figure; and the victor's desire for permanent power was determined not only by ambition but also by the fear of the consequences of defeat. To grant special powers to the leader of one's party or of the *popolo* might appear the easiest method to achieve this end; but the breaking donn of constitutional limitations opened the road for the establishment of despotic government.

Interstate conflicts, which had existed even before the rise of the communes, were a constant feature of Italian politics from the 12th century onward. Caused by quarrels over boundaries, by commercial and political rivalry or by Guelph and Ghibelline loyalties, they present a bewildering picture, which nevertheless reveals some patterns. Thus the conflicts betneen Pisa and Genoa, the principal rivals on the Tyrrhenian coast both aiming at control of Sardinia, continued intermittently throughout the 12th and 13th centuries and culminated in Pisa's decisive naval defeat of Meloria in 1284. which sealed its decline as a great maritime power. In the meantime, the struggle between Genoa

and Venice over the eastern trade, beginning in the 12th century, had been intensified by the establishment of Venice's Levantine empire in 1204 and the restoration of the Byzantine empire under Michael VIII Palaeologus in 1261. Commercial rivalry must have been largely responsible for Milan's traditional enmity with Pavia and Cremona. In Tuscany the struggles between Pisa and Lucca began in the 11th century. Lucca, once the most powerful Tuscan town, had been overtaken by Pisa, the chief Tuscan port. Florentine expansion led to mortal enmity between Florence and Siena from the 12th century onward, while Florence's growing economic and political power brought about struggles with Pisa from the beginning of the 13th. One effect of these conflicts was that the emperors always succeeded in enlisting the services of communes against other communes. Another result of the conflicts and of the territorial policy of the communes in general could be the acquisition of city-states by more powerful neighbours. But in this respect too the rise of the *signoria* proved a new departure.

Rise of the **Signorie.**—Frederick II's administrative reforms, as well as the temporary establishment of autocratic rule over seyeral north Italian towns by the Ghibelline Ezzelino da Romano (d. 1259) and then by Frederick's former official, the margrave Hubert Pallavicini (d. 1269), were important elements in the rise of despotism in Italy; while Piedmontese feudalism helped the margrave William of Montferrat to extend his control over many communes of Piedmont between 1260 and 1290. But the broad stream of despotism sprang from internal developments in the communes, in particular from the struggle for political power, from the frequent internal crises and also from the desire for peace at any price. The offices of *podestà* and *capitano del popolo* served as starting points; the new rulers, usually influential citizens and sometimes feudal lords, were given special powers and longer terms of office, notwithstanding constitutional limitations. They had reached their goal when *parlamenti* and councils elected them *signori* (lords) for life with unlimited po ers and when hereditary succession was assured. The new regime preserved the framework but not the spirit of the communal constitutions; under the absolute rule of the *signore* magistracies, councils and elections were left in existence. The *signori* owed their power originally to a measure of consent; and even when they had consolidated it they had still reason to care for popular support. But republican resistance was not lacking, and family rivalries could also lead to sudden changes of fortune.

The new regimt began in Lombardy and the Romagna; it was not until the early 14th century that it seriously affected Tuscany. By that time, a number of leading northern *signorie* had reached a strong position: the Visconti in Milan, the Scaligeri (Della Scala) at Verona, the house of Este at Ferrara. The Carrara established their *signoria* at Padua first in 1318 and finally, after an interlude of Della Scala rule, in 1337; the Bonacolsi of Mantua were replaced by the Gonzaga in 1328.

Meanwhile Florence and Venice were carrying out constitutional reforms which were doubtless responsible to a large extent for their survival as republics. In Florence the reforms of 1282–93 based the government on the 21 guilds, with the predominance of the greater guilds; and the Ordinances of Justice (1293–95) consolidated the rule of the *popolo* by excluding the magnates, who were largely identical with the nobility, from nearly all important offices. Similar measures against the magnates had been taken shortly before in Bologna (1282) and were subsequently taken in other towns. In Venice, on the other hand, the aristocracy decisively consolidated the regime which it had been building up from the 11th century onward by closing the great council, thus making membership practically hereditary (1297–1323). After further reforms during the 14th century, the aristocratic constitution remained almost unchanged until Napoleon's capture of Venice in 1797.

The **First** Angevins in the South.—The Angevin conquest of the Sicilian kingdom opened a new chapter in the history of southern Italy. Charles I retained much of the existing administration as reorganized by Frederick II; but the conquest was followed by a strengthening of feudalism, largely a result of the immigration of French noblemen. Relations between natives of the kingdom and French were at first often hostile. In Sicily they deteriorated to such an extent that the tension culminated in 1282 in the great revolt of the Sicilian Vespers (*q.v.*) which led to a new separation of Sicily from the mainland. The Sicilians offered the crown to Peter III of Aragon, and the Angevins were unable to wrest Sicily from him or his successors. Although the war of the Vespers was ended by the treaty of Caltabellotta in 1302, hostilities began again soon after. For the Angevins at Naples the reconquest seemed essential not only for their prestige but also for their security.

Charles I of Naples had at first acquired control of nearly all Tuscany and part of Lombardy, but his influence in those regions depended on the papacy and the Guelphs and was therefore necessarily weakened when their need to seek his protection against the empire disappeared after 1268. His power outside the kingdom was thus only temporary; but his Italian policy was resumed by later Angevins. Relations between the Sicilian kingdom and the Tuscan merchants remained very close. Charles' conquest of the kingdom could hardly have succeeded without their loans; and the commercial advantages that they derived from his victory were correspondingly great.

Guelphs and Ghibellines in the 14th Century.—The virtual absence of imperial authority between 1268 and 1310 constituted a momentous change in the political situation. The papacy profited from it in several respects. While in the Guelph towns of Tuscany its influence became considerable, its territorial power was, at least potentially, strengthened by the emperor Rudolph's final renunciation of the Romagna in 1278. In Florence the Guelph party split into the Blacks and Whites at the end of the 13th century; and Boniface VIII (1294–1303) asserted his influence there by intervening, while nearer Rome he pursued with great success ambitious territorial plans for his family, the Gaetani, at the expense of the Colonna and Aldobrandeschi. The setting-up of the papal residence at Avignon in 1309 proved a setback for the Italian policy of the papacy from which it did not recover until the 15th century. Republics and *signorie* freely asserted their independence, conditions being particularly favourable to the growth of small *signorie*—*such* as those of the Ordelaffi at Forli, of the Manfredi at Faenza, of the Malatesta at Rimini, of the Da Polenta at Ravenna, of the Pepoli at Bologna and of the Montefeltro at Urbino. Rome was the stage of constant struggles between the baronial families, the Colonna, the Orsini, etc.; and the remarkable successes of Cola di Rienzo in 1347 illustrated the weakness of the papacy.

In 1310 the German king Henry VII arrived in Italy, the first claimant to the empire for many decades to undertake an Italian expedition; in 1312 he was crowned emperor. The expedition led to a revival of Ghibellinism and strengthened the position of the Lombard *signori* who sided with Henry. Matteo Visconti recovered the rule of Milan, and the title of imperial vicar granted to him and to the lords of Verona and Mantua tied them to the imperial cause by improving their legal status; the imperial vicariate, however empty a title it became after Henry's death, continued to be sought after by the *signori*. For the time being, the greatest obstacle to Henry was Guelph Florence. A siege (in the autumn of 1312) had to be raised. Henry died in 1313, on his way to attack King Robert of Naples, the other great Guelph power. The expedition remained an episode, but the Ghibelline revival retained its importance for some time to come. During the struggles with Pope John XXII it became connected with antipapalist heresies, and prosecutions for heresy played an important role in papal warfare against the Ghibelline *signori*. In Tuscany the rise of Uguccione della Faggiuola as lord of Pisa (1313) and Lucca (1314) and then that of Castruccio Castracani, who ousted Uguccione from Lucca in 1316, was a heavy blow for Guelphism. The Florentines suffered crushing defeats in 1315 and in 1325. After the latter they made Charles of Calabria (son of Robert of Naples) *signore* of Florence (d. 1328). Castruccio acquired Pistoia and Pisa (1325, 1328) and threatened Florence with encirclement; but he died in Sept. 1328, and his dominions broke up immediately. The Italian expedition (1327–30) of the

emperor Louis IV the Bavarian was a fresh stimulus for Ghibellinism; its final decline resulted primarily from the scant role of the empire in Italian politics after this time; the two expeditions of Charles IV (1354–55, 1368–69) were of little consequence and vividly illustrated the eclipse of imperial authority.

The papacy had once more fought the Ghibellines vigorously; at the same time, John XXII had made a determined bid to recover control of the papal states. The papal legate in Italy, Bertrand du Pouget (1319–34), achieved only temporary successes; but the house of Este came to terms with the pope and were created papal vicars of Ferrara—a title copied from the imperial vicariate and soon to be generally used by the papacy to assert at least a minimum of sovereignty over the despots of the papal states.

Expansion of the **Signorie.**—One of the outstanding developments of Italy in the 14th century was the territorial expansion of a number of city-states. Expansion beyond the boundaries of the *contado* had occurred before the rise of the *signorie;* but the *signorie* were in *a* singularly favourable condition to carry it forward, since one man could be elected *signore* of more than one town. Thus Matteo Visconti of Milan (d. 1322) and Cangrande I della Scala of Verona (d. 1329) laid the foundations of great territorial states in northern Italy. The brief intervention of King John of Bohemia in that region (1330–33) proved ultimately an advantage to the Lombard *signori,* who extended their territories when John's power collapsed. In the race for territorial acquisitions—that is to say, acquisitions of other city-states—the Visconti were momentarily outpaced by the Della Scala, whose power stretched in 1336 from the march of Treviso to Lucca. It was rumoured that Mastino II was aiming at the Lombard crown. The leagues of 1336–37 against them brought about their fall. After the peace of Venice in 1339, the Della Scala dominions were practically reduced to Verona and Vicenza (Parma and Lucca being lost in 1341).

These events were characteristic of the instability of the *signorie.* Towns were often as easily lost as gained, and at home also the position of the *signori* was not always secure. On the other hand, republicanism continued to suffer reverses. Thus in Padua communal government came to an end in 1328, and in Tuscany the *signoria* gained much ground after Henry's expedition, Florence itself being not immune from it.

The war against the Della Scala had an aftermath in the war over Lucca. Sold by Mastino della Scala to Florence, Lucca was attacked and then taken by Pisa (1341–42). The result of this setback and of internal discontent was the *signoria* of the duke of Athens, Walter II (Walter VI of Brienne), in Florence from 1342 to 1343. It was followed by antidespotic reaction and by a period of increased political influence of the lesser guilds. These were also years of economic crisis for Florence. The difficulties and final bankruptcy (1345) of the great houses of Bardi and Peruzzi ruined many other companies and shook the economic life of the town. The Black Death of 1348, which decimated the population, caused further disaster.

In 1343 Robert of Naples died; during his long reign Naples had once again played a leading role in Italian politics as protector and leader of the Guelphs. But several years before his death Robert had practically withdrawn from these wider fields of action, and under his granddaughter heiress, Joanna I, a period of internal troubles began for the kingdom.

A new Italian problem had meanwhile arisen in the shape of the companies of mercenaries. Nearly all under foreign commanders, they had spread over Italy from the early 14th century onward. The internal troubles of the kingdom of Naples after Robert's death provided them with fresh opportunities, while the peace of Brétigny and Calais (1360) released many soldiers for service in Italy. Their ravages and disloyalties caused infinite hardships. But the Italian powers themselves were largely to blame as they made constant use of the companies. It was not surprising that the frequent leagues against the latter had little success.

Italy From 1350 to **1454.**—Giovanni Visconti acquired Bologna, the gateway to Tuscany, in 1350 and Genoa in 1353. The former event led to war with Florence, the first in a long series of conflicts between Milan and Florence. Genoa was lost in 1356 and Bologna in 1360, but both remained prominent objectives of Visconti policy. At that time a new political factor of lasting importance was emerging in northwestern Italy. The count of Savoy, Amadeus VI, subdued the Piedmontese branch of his house (1360–68) and established a powerful dominion which combined French and Vaudois with Italian territories. It was not surprising that he clashed with the Visconti (1372–75), equally aiming at predominance in western Lombardy. While the Visconti state was temporarily divided after Giovanni's death in 1354 into three and then into two parts. Florence was recovering from the earlier crises and was once more extending its territory, being well on the way to complete hegemony in Tuscany. The Guelph party was virtually in control of the state from 1354; resistance against its dictatorial methods flared up in 1378 and developed into a revolt of the poorest section of the population, the *popolo minuto,* against the traditional preponderance of the rich *popolo grasso* (the revolt of the *ciompi*). But by 1382 the *popolo grasso* had not only recovered, but permanently strengthened its position.

In the papal states a fresh attempt was made from 1353 onward to restore papal authority. The great successes of the new legate, the cardinal Gil (Aegidius) Alvarez de Albornoz, led to a complete change in the political situation. He forced the Malatesta and the Ordelaffi to submit and reorganized papal administration (the Egidian constitutions of 1357 remained its basis until the early 19th century). These achievements paved the way for the return of the papacy to Rome. Urban V attempted it in 1367, Gregory XI in 1376 during the mar of 1375–78 with Florence—a state now apprehensive of the effects of the papal recovery. Gregory's death in 1378 was followed by the outbreak of the Great Schism.

The last two decades of the century form. in more than one respect, a landmark. The War of Chioggia between Genoa and Venice ended with the failure of Genoa's supreme bid to destroy the power of its rival (1381) and thus decided the long struggle between the two powers. The Great Schism ruined the work of Albornoz in the papal states; in Naples, it led to civil war. Joanna I having adhered to the antipope Clement VII, Urban VI called her second cousin Charles of Durazzo (Charles III of Naples) to Italy against her; Joanna made Louis I, duke of Anjou, her heir. It mas not until 1399 that Ladislaus, Charles III's son, finally prevailed against Louis II of Anjou, as his father had done against Louis I (d. 1384). In Lombardy and Tuscany, the last 15 years of the century were marked by the rise of Gian Galeazzo Visconti. Having in 1378 succeeded his father Galeazzo in his parts of the Visconti dominions, he deposed, in 1385, his uncle Bernabo and thus reunited the whole Visconti state, giving it a stronger and more centralized administration. He attacked the Della Scala of Verona in 1387 and the Carrara of Padua in 1388 and annexed all the territory of the former and most of that of the latter. Florence feared that expansion into Tuscany would follow; war between Florence and Gian Galeazzo broke out in 1390 and again in 1397. In the meantime, the lord of Milan was raised to ducal rank by the emperor Wenceslaus, the first *signore* to reach princely dignity (1395). He acquired Pisa, Siena and Perugia in 1399–1400 and Bologna in 1402. He seemed on the eve of attacking Florence when he suddenly died in 1402.

Gian Galeazzo had divided his state between his sons Giovanni Maria, who became duke. and Filippo Maria; but it rapidly broke up at the hands of his former captains, of local *signori* and of neighbouring states. The tide seemed indeed to have turned in favour of Venice and Florence. The Florentines conquered Pisa in 1406, thus gaining at last direct access to the sea. Venice seized most of Gian Galeazzo's conquests in eastern Lombardy. In 1405 it destroyed the Carrara, who had recovered Padua in 1390 and taken Verona after Gian Galeazzo's death.

These events were a landmark in the history of Venice, the beginnings of an active policy of territorial expansion on the Italian mainland where it had previously been primarily interested in commercial control. In 1416 war with the Turks began, the first of the wars during which Venice was to lose its Levantine empire.

In 1419–20 it finally conquered the Friuli; by 1420 it had recovered Dalmatia (lost in 1358). Complete control of the Adriatic sea, a fundamental objective of Venetian policy, appeared to be near realization at a time when Venice had become one of the great mainland powers.

At the beginning of the 15th century, Naples re-emerged under King Ladislaus for a short period of Italian power. Reviving the policy of earlier Angevins and taking advantage of the troubles of the papacy, Ladislaus occupied Rome and Latium and advanced into Tuscany in 1408–09; after a withdrawal, he again seized Rome and advanced north in 1413–14. He clashed with the Florentines, faced by another invasion of Tuscany. But at the height of his power Ladislaus died (1414). Under his sister Joanna II the kingdom was once more plunged into a mar of succession. In the meantime another and more lasting political revival had begun in northern Italy. Filippo Maria Visconti succeeded Giovanni Maria after his assassination in 1412; by 1421 he had reconstructed the Visconti state roughly within the boundaries of 1385, thus reawakening the fears not only of Florence but also of Venice, which owed so much to the break-up of the Visconti dominions. The submission of Genoa in 1421 and intervention in the Romagna (1422–23) recalled earlier Visconti objectives. War broke out with Florence in 1423 and with Venice in 1426; and mars continued intermittently until the middle of the century. Venice pushed its frontiers farther west by acquiring Brescia. Bergamo and Crema; it concluded final peace in 1454. Florence had already changed alliances earlier.

In 1447 Filippo Maria died, and the Milanese republic was restored — after nearly two centuries of despotic rule; but in 1450 his son-in-law, the former condottiere Francesco Sforza, took Milan and restored despotism under a new dynasty. A friend and ally of Cosimo de' Medici, he put an end by his victory to the long struggle between Florence and Milan.

The rebuilding of the territorial power of the papacy, which began after the accession of Martin V (1417), was a slow process; after promising beginnings under Martin, the situation deteriorated again under Eugenius IV (1431–47). But by the middle of the century the tide had turned; the council of Basle had been dissolved and Francesco Sforza had in 1447 lost the march of Ancona (which he had acquired in 1433). Nicholas V pursued a policy of pacification, and it was not until Sixtus IV that a fresh advance in territorial policy began.

In Naples the succession crisis lasted intermittently until 1442, when Alphonso V of Aragon, who was already king of Sicily, took Naples. Joanna II, who had at first adopted him as heir, had gone over in 1423 to Louis III of Anjou, Martin V's candidate. At her death in 1435 she left the kingdom to Louis's heir, René of Anjou; and now Alphonso made a fresh bid for the kingdom. After his victory he was invested with it by Eugenius IV (1443); but René of Anjou did not abandon his claim, which in 1494 was to form the legal basis for the French king Charles VIII's Italian expedition.

In Florence the government underwent a momentous change in 1434. From 1382 Florence was ruled by a group of leading families, headed from 1393 by hfaso degli Albizzi and, after his death in 1417, by his son Rinaldo. In a difficult position because of an unsuccessful war against Lucca (1429–33), Rinaldo struck against his chief rival, Cosimo de' Medici, whose family had been rising in political importance from the end of the 14th century. Cosimo was banished in 1433; but in 1434 Rinaldo fell from power and Cosimo was recalled while the Albizzi were exiled. A new epoch in Florentine history began. At first Cosimo followed largely the traditions of the oligarchical government and only cautiously extended his power beyond that enjoyed by the Albizzi. His position was greatly strengthened by the successes of his diplomacy. By making Francesco Sforza an ally of Florence, he established a new policy of friendship with Milan.

The peace of Lodi between Milan and Venice (1454) and the conclusion of an Italian league (1454–55) marked the end of a period of wars. The conflicts of the first half of the 15th century had helped to bring the new Italian art of war to maturity. Its founder had been, toward the end of the 14th century, Alberico da Barbiano; and mercenary warfare in Italy had subsequently passed into the hands of Italians. Muzio Attendolo Sforza and Braccio da Montone, who had both served under Alberico, gave rise to two difierent schools of warfare; at the beginning of the Neapolitan struggles under Joanna II they fought in opposite camps, adding military rivalry to the political issues. The rise of the Italian condottieri also led to new political developments. While minor signori, eager to increase their revenues, often served as condottieri, condottieri would sometimes become *signori*—an ambition more natural to Italian than to foreign captains. Shifting loyalties remained, however, a characteristic feature of the condottieri. The governments often suspected their generals and sometimes acted against them, the most spectacular example being the execution of Francesco da Carmagnola by Venice in 1432.

The new alignment of forces in Italy after 1450 was to determine much of the history of the following decades. The political map of the country had been simplified by the territorial expansion of Milan, Venice and Florence; five great powers now completely overshadowed the remaining smaller states, and the idea of a balance between them was beginning to take shape. After 1454, the Italian league and the triple alliances between Milan, Florence and Naples, although not permanent, pointed in this direction and held out at least some promise of peace. (N. R.)

The Italian League. — The second half of the 15th century witnessed a movement toward confederation among the Italian states. A common language and a common culture fostered the sense of nationality. This found expression in the league of 1455, the members of which were pledged to preserve peace among themselves and to resist foreign intervention. An alliance between Milan, Florence and Venice following the peace of Lodi had brought the league. into being. Nicholas V, eager to turn the forces of Italy against the Turk after the fall of Constantinople, ratified it in the name of the papacy and used his influence to bring Naples in. Almost all the lesser states were enrolled as adherents of one or the other of the five leading powers. The aim of the league was to maintain the balance of power by resisting acts of aggression on the part of any member state and to keep the foreigner out. It was instrumental in defeating René of Anjou's attempt to win the crown of Naples on the death of Alphonso V of Aragon (1458) and in securing the succession for the latter's illegitimate son Ferdinand I (Ferrante); in so doing it gained for Italy a respite from foreign intervention. When the pope and Venice made a combined attack on Ferrara in 1482 the intervention of Milan, Florence and Naples saved the city for the house of Este. Thus the league became a guarantee of the independence of the smaller states, enabling each to make its individual contribution to the civilization of the Renaissance. Freed from the burden of major wars, Italy enjoyed a period of prosperity in which all the arts flourished and the separate states were drawn closer together in pursuit of 'their common interests.

During these years political institutions tended everywhere toward despotism. The Medici became more indispensable to Florence and the Bentivoglio more autocratic in Bologna. Perugia submitted to the dictatorship of the Baglioni and Siena to that of the Petrucci. The head of each family was recognized as the leading citizen of his republic, being a despot in fact but not in law. Other rulers, who had been given the lordship of their city by popular decree, strengthened their title by obtaining investiture from pope or emperor. Thus the Gonzaga lords of Mantua became imperial margraves, the Este were invested with Modena by the emperor and with Ferrara by the pope. Imperial investiture as duke of Milan, for which Francesco Sforza had negotiated in vain, was granted to his son Ludovico. The interests of the popes approximated more and more to those of Italian secular rulers. Their aim was to establish their direct authority throughout the states of the church, and their means was the bestowal of lands and offices upon their relatives. Sixtus IV (1471–84) controlled the Sacred College through his Della Rovere and Riario nephews, and established another nephew, Girolamo Riario, as lord of Imola and Forli as a step toward the subjugation of Romagna. Thanks to the work of architects and painters brought thither by successive popes, Rome became a splendid

Renaissance capital. The despots made life fuller and gayer within their cities and added to their prestige abroad. Nevertheless their position was precarious. Citizens nurtured in the republican tradition acquiesced in despotic rule only so long as they felt its advantages. The murder of Galeazzo Maria Sforza in Milan (1476) and the attempt on the part of members of the Pazzi family against the Medici in Florence (1478) are typical of an age in which no ruler could rely upon the continued loyalty of his subjects. In Naples the Angevin baronage was ever ready to revolt against Ferdinand of Aragon. Even Venice, the most stable of Italian states, was unpopular with the nobles in its subject cities. conscious of insecurity at home and fearful of attack from neighbouring powers, each state thought more of securing some temporary advantage for itself than of the preservation of Italian unity. Lorenzo de' Medici (Cosimo's grandson, Lorenzo I il Magnifico) almost alone worked consistently for peace, using his tact and skill to minimize occasions for quarrelling. His death (1492) was the prelude to foreign invasion.

The French Invasions, 1494–1512.—X new age opened for Italy when Charles VIII of France turned his mind toward the pursuit of his claims to Naples, as the heir of René of Anjou. At this time a serious quarrel had broken out between Naples and Milan. Galeazzo Maria Sforza, Francesco's son, was succeeded as duke of Milan by his infant son Gian Galeazzo, the boy's uncle Ludovico (il Moro) acting as regent. When Gian Galeazzo grew up and married (1489) Isabella of Aragon, daughter of Alphonso, duke of Calabria (later Alphonso II of Sicily). Ludovico retained the government in his hands. He and his brilliant wife, Beatrice d'Este, usurped the place of the rightful duke and duchess, thereby arousing the indignation of the Neapolitans. Piero de' Medici, who succeeded to his father Lorenzo's supremacy in Florence, was incapable of healing the breach between his allies. while the election of Rodrigo Borgia to the papacy as Alexander VI increased the tension between the Italian powers. Ludovico, feeling himself isolated and expecting an attack from Naples, threw himself on the side of Charles VIII, who entered Italy as his ally (1494). Hardly had Charles passed through Lombardy on his unhindered march southward before Gian Galeazzo died. Ludovico, who incurred grave suspicion of having poisoned him, became duke of Milan. In Florence, Charles VIII's coming resulted in the expulsion of Piero de' Medici and the establishment of a republican government allied with France and drawing its inspiration from Fra Girolamo Savonarola. Savonarola's preaching brought about an astonishing religious revival in the city; but opinion turned against him as the first enthusiasm faded and as neither the new constitution nor the French alliance achieved the good results that he had foretold. In 1498 he was tried and executed on the charge of heresy. Meanwhile Charles VIII had won the throne of Naples and lost it again. In 1495 he was back in France, having narrowly escaped defeat at the hands of Italian forces at Fornovo as he crossed the Apennines; Spanish arms reinstated Ferdinand I's grandson in Naples as Ferdinand II. Charles had gained nothing, but his expedition paved the way for more formidable invaders. His cousin the duke of Orléans, who succeeded him as Louis XII in 1498, at once prepared to enforce his claims on Milan, inherited from his grandmother Valentina Visconti. Ludovico Sforza fled to the imperial court and on his return to Milan with an army in 1500 found the Castello in French hands. At the battle of Novara his Swiss mercenaries refused to fight against their compatriots in French service. Ludovico was captured and taken to France (he died at Loches in 1508). Louis XII, now duke of Milan, in 1500 concluded the treaty of Granada with Ferdinand the Catholic whereby France and Spain agreed to divide Naples between them. The conquest was easy and Frederick, the last representative of the illegitimate line of Aragon in Naples, retired to France. Ferdinand, however, soon picked a quarrel with his ally. The French were driven out by the end of 1503 and the two Sicilies were reunited under the Spanish crown. An important step toward Spanish domination of Italy had been taken.

Meanwhile the Italian powers made use of foreign invaders for their own ends. Louis XII had found it politic to ally himself with Alexander VI before coming to Italy; thus the pope's son Cesare Borgia embarked on his campaign of conquest in Romagna supported by French troops. Cesare seemed to be upon the point of creating a powerful Borgia state. embracing not only Romagna but Tuscany. when Alexander's death (1503) brought about his own fall. Most of his acquisitions in Romagna reverted to the Holy See. but Venice added to the cities that it already held there. The Venetian republic had gained ports in Apulia when helping to defeat Charles VIII and towns in Lombardy as the price of its alliance with Louis XII. Its territorial gains had been made at the expense of its neighbours, and these now included the pope and the kings of France and Spain. Thus Pope Julius II was able to bring a formidable array of enemies against the republic in the league of Cambrai (1508). Julius II's aim was to restore power and prestige to the church and, first of all, to bring all papal lands in Italy under his direct rule. He had already conquered Bologna and forced the Baglioni in Perugia to submit to his authority when he joined in the attack on Venice. The defeat of Venice at the battle of Agnadello (1509) mas followed by the dissolution of its mainland dominion. It was forced to accept the pope's terms, renouncing its claims to independence in ecclesiastical matters and ceding the cities which it held in Romagna. Julius was now undisputed master of the states of the church. with the sole exception of Ferrara, where the duke, Alphonso I d'Este, sheltering under the protection of France, refused obedience to his suzerain. Thereupon the pope proclaimed his intention to free Italy from the barbarians and formed the Holy league to drive out the French. In 1512 the battle of Ravenna was fought between Spanish: papal and Venetian forces on one side and French and Ferrarese on the other. Gaston de Foix, the brilliant French commander, bought victory dearly with his death. Before his leaderless forces had time to recover from the shock the Swiss, as members of the Holy league: invaded Lombardy, drove out the French and set up Maximilian Sforza as duke of Milan. In the same year the armies of the league restored the Medici to power in Florence. Only the death of Julius II in 1513 saved Ferrara for the house of Este.

Charles V.—The expulsion of the French brought Italy hope of freedom from foreign rule and moved Machiavelli to write his Prince. He dedicated it to Lorenzo II de' Medici who, because of the return of his family to Florence and the election of his uncle Giovanni to the papacy as Leo X, had. in Machiavelli's eyes. only to follow the advice laid down for him in order to become the saviour of Italy. Such hopes were illusory. The Italians had neither the will nor the power for united resistance to the foreigner, and France had been expelled at the cost of increasing the predominance of Spain. By the victory of Marignan (1515) Francis I of France broke the power of the Swiss and regained the duchy of Milan. The election of Charles V as emperor in 1519, following his succession to the Spanish kingdoms. was the prelude to the struggle between Habsburg and Valois which vexed Italy for the next 40 years. Charles began by driving Francis from Milan and investing Francesco Maria Sforza with the duchy. In 1525 Francis' attempt to regain it ended in his defeat and capture at the battle of Pavia. Alarmed at the growth of imperial power in Italy, Pope Clement VII (Giulio de' Medici) deserted Charles for Francis and engineered the league of Cognac (1526) to drive his former ally from Italy. Charles determined to make Clement see reason by force of arms, and in 1527 fresh troops from Germany joined the Spaniards in Italy. A mutinous and starving army led by the constable duke of Bourbon appeared before Rome. Bourbon was killed in the first attack, and the sack of Rome followed. The horrors of the outrage reverberated through Europe, and although Charles was not directly responsible his hold upon Italy was in jeopardy. Within three years; however, Habsburg domination of Italy was an accomplished fact. Andrea Doria brought Genoa and its fleet into Charles's service. Clement VII came to see that his interests both as Medici and as pope would be best served by alliance with Charles. When he was a prisoner in Castel Sant'Angelo the Medici had again been expelled from Florence, and the price of his forgiveness of Charles was the loan of imperial forces to overthrow the last Florentine republic. Flor-

ence fell after a heroic defense (1529–30) and Alessandro de' Medici (Lorenzo II's son) became duke of Florence. By the treaty of Cambrai (1529) Francis I renounced his claims on Milan and Naples, and when Charles was crowned emperor by Clement VII at Bologna (Feb. 1530) he had become the arbiter of Italy.

Charles V's settlement of Italy was based on the principle of favouring the interests of the native rulers in order to secure their support against France. He used his influence to reconcile Alphonso of Ferrara with the papacy. He restored Francesco Maria Sforza to Milan and married him to his niece Christina of Denmark, despite his treachery in having joined the league of Cognac. He raised Federico Gonzaga of Mantua to the rank of duke and in 1536 confirmed his succession to Montferrat. Cosimo, of the younger line of Medici, who in 1537 succeeded Alessandro as duke of Florence, was invested with Siena in recognition of his aid in suppressing the last Sienese republic. In 1569 he obtained from Pope Pius V the title of grand duke of Tuscany. The duchy of Parma and Piacenza, which the Farnese pope Paul III had created in 1545 for his son Pierluigi, was brought into the Habsburg orbit by the marriage of Duke Ottavio Farnese with Charles V's natural daughter Margaret. Thus throughout the Spanish supremacy Italian princes continued to preside over their courts, to cultivate the arts and to adorn their cities with sumptuous buildings. Nevertheless the great days of Italy were over. and the country as a whole suffered steady decline in wealth, prestige and freedom. In its later stages the war with France was fought for the most part outside Italy, but Francis I and Henry II in turn pressed their claims to Milan and Naples and never let slip an opportunity of fomenting Italian opposition to Habsburg rule. The death of Francesco Maria Sforza without heirs in 1535 was followed by fresh outbreaks of war and fruitless negotiations with France, until Charles settled the fate of Milan by investing his son Philip with the duchy (1540), at the same time transferring all imperial rights in Italy to Spain.

The Spanish Ascendancy. — In 1559, after Charles had ceased to rule, the treaty of Cateau-Cambrésis between Philip II of Spain and Henry II of France marked the final renunciation of Valois claims to Italian territory and added further to the Spanish dominions by assigning to Philip the Tuscan ports known as the Presidii. With Spanish viceroys in Milan and Naples, Italy had ceased to be independent. The power of the papacy had, however, increased rather than diminished during the Franco-Spanish wars. It had gained new life from the Counter Reformation, the work of Baroque architects added yearly to the splendours of Rome and the authority of the popes in the states of the church was undisputed. When, in 1597, Alphonso II d'Este died childless, Clement VIII refused to invest his cousin Cesare with Ferrara. The house of Este made Modena its new capital, where Cesare and his descendants reigned until 1859; and Ferrara was at long last incorporated in the papal states.

In 1631 Urbino, which had been renowned as a centre of the Renaissance under its Montefeltro rulers, also fell to the papacy. the last duke, Francesco Maria II della Rovere, having arranged for the devolution of his state to Urban VIII. Individual popes might pursue a policy of opposition to Spain, but papal government was as repressive in character as that of the Spaniards. In 1542 the Inquisition, already a recognized feature of Spanish rule, was established in Rome. Henceforth printing was controlled throughout Italy, heretics were sought out and burned, the least symptom of political unrest called forth punitive measures. Spain and the Counter Reformation destroyed the free spirit of an earlier age and sapped the energies of the people.

Among the Italian secular states Venice retained the greatest measure of independence. By 1517 it had recovered the bulk of its Lombard territories, which were to enjoy relative prosperity under its rule until the coming of Napoleon; and in spite of the submission forced from it by Julius II, the church in its dominions remained to a large extent under state control (Venice gave asylum to fugitives from the Inquisition for many years before it yielded to papal pressure and expelled heretics). This policy brought on Venice the enmity of both the papacy and Spain and led in 1606 to the contest with Paul V in which Paolo Sarpi acted as the champion of the republic. Venice was strong enough to ignore the interdict imposed and to secure its removal by a compromise that involved no surrender of principle. Nevertheless Venice had ceased to be a great power. The discovery of the Cape route to India robbed the city of its monopoly of the spice trade and thus struck a mortal blow at its commercial prosperity. Already in the 15th century its carrying trade had become less profitable through rivalry with the Turk. Now the trading system that it had built up declined in value because of the advantages of the sea route to western Europe enjoyed by the Portuguese. Meanwhile the city fought a losing battle for its dominion in the Levant. It shared in the triumphant victory over the Turk at Lepanto (1571), but in the peace that followed failed to recover Cyprus. In 1669 Crete was surrendered to the Turk after a 20-year struggle. By 1718 only Corfu remained of a once vast empire.

Italy as a whole declined in prosperity through the shifting of trade paths consequent on the discovery of the new world. The Florentine cloth trade had long passed its zenith, and the preeminence of Florence in banking passed to new centres of exchange such as Antwerp. In Genoa the noble families who had laid the foundations of Genoese maritime and colonial power were rich enough to build fine palaces, but their overseas empire was dwindling and the sale of Corsica to France in 1768 marked its end. Of the Spanish territories Lombardy in particular suffered from the presence of large military forces, taxation was everywhere excessive and government officials corrupt. An occasional rising took place, as for instance that of Masaniello in Naples (1647) and the rebellion of Messina (1676–78), which was first aided and then deserted by a French fleet. For the most part the people acquiesced apathetically in a regime which, while it cared little for their welfare, based itself on the principle of noninterference.

The most hopeful feature of the dreary years of Spanish domination was the emergence of Savoy as an Italian power. Charles III of Savoy had supported the emperor Charles V in his struggle with France until, in 1536, Francis I occupied his dominions. Thus Emmanuel Philibert, when he succeeded his father in 1553, was a duke without a duchy. He had distinguished himself in the service of Philip II of Spain, notably at the battle of St. Quentin (1557), and the treaty of Cateau-Cambrésis restored him to his possessions. When he had recovered Turin, which with certain other Piedmontese fortresses remained in French hands for a few years after his restoration, he transferred his capital to Turin from Chambéry. From that time Italian Piedmont took the place of French Savoy as the centre of interest for its dukes. In 1601 Charles Emmanuel I acquired Saluzzo, but had to cede Bresse, Bugey, Gex and Valromey to Henry IV of France. On the outbreak of the War of the Mantuan Succession in 1628 he hoped to secure the duchy of Montferrat. French aid, however, set up Carlo Gonzaga, duke of Nevers, in both Mantua and Montferrat, although the peace of Cherasco (1631), nine months after Charles Emmanuel's death, assigned considerable territories in the latter duchy to Savoy. The death of the last Habsburg king of Spain, Charles II, in 1700 provoked the War of the Spanish Succession, in which the conflict between Austrian Habsburg and Bourbon claimants necessarily involved Italy. Savoy held the key to the passes of the Alps between France and Lombardy, and Victor Amadeus II, with a good army and a united people, was courted by both sides. He was encouraged in resistance to France by his second cousin, Prince Eugène, a leading general in the Austrian army, who in 1706 relieved Turin and drove the French from Italy. The part played by Savoy in the war won for its duke a voice in the peace negotiations and a share in the spoils.

Austrian Ascendancy in the **18th** Century. — The terms of the peace of Utrecht (1713) recognized the duke of Anjou as Philip V of Spain but assigned Milan, Naples and Sardinia together with Mantua (from which the last Gonzaga duke had been ejected during the war) to his rival the archduke Charles. Thus Austria replaced Spain as the dominant power in Italy. Victor Amadeus, who aimed at securing Milan. had to be content with Montferrat and the island of Sicily with the title of king. Italy was sacrificed to the balance of power in Europe and its territories were assigned

to new rulers without regard to their history or traditions. The division of Sicily and Naples and their separation from Spain provoked great discontent, and this was exploited by Elizabeth Farnese, the Italian wife of Philip V of Spain, in the interests of her onn family. She was aided by the king's minister Giulio Alberoni, like herself a native of Parma, uho engineered abortive invasions of Sardinia and Sicily. Thereupon Austria took possession of the latter island, forcing Savoy to accept Sardinia in exchange (1720). From that time until they became kings of Italy. the dukes of Savoy bore the title of king of Sardinia. On the outbreak of fresh war between Habsburg and Bourbon over the Polish succession, Charles (eventually Charles III of Spain), the eldest son of Philip V's marriage with Elizabeth Farnese, led an expedition to Italy and won recognition as king of the Two Sicilies (Charles VII of Naples) in 1735. He failed however to gain the succession to Parma, where he had been proclaimed duke on the extinction of the Farnese line, or to Tuscany, where Medici rule ended with the death of grand duke Gian Gastone in 1737. Instead, Tuscany went to Francis of Lorraine, who had to yield his own duchy to France, and Parma was added to the Lombard dominions of Austria. Yet another European conflict, the War of the Austrian Succession, had its repercussions in Italy. When the emperor Charles VI died in 1740, the Bourbon kings of France, Spain and Sicily joined in the attempt to despoil his daughter Maria Theresa of her heritage. The failure of their efforts and the re-establishment of Austrian power in Italy was largely the result of the rivalry between Charles Emmanuel III of Savoy and Charles of the Two Sicilies.

During the War of the Polish Succession they had fought together against Austria, and Charles Emmanuel had occupied Milan for three years. Elizabeth Farnese, however, was anxious to secure Milan for one of her sons, and Charles Emmanuel, seeing that the prize that he coveted would not be won in alliance with the Bourbon powers. now went over to the Habsburg side. Under the treaty of Aix-la-Chapelle *(1748)* he failed to obtain either Milan or Genoa but received territories in Lombardy, which brought the eastern frontiers of his kingdom to the Ticino. The principal gain for the Bourbons was the establishment of Elizabeth's second son, Philip as duke of Parma, Piacenza and Guastalla. Italy settled down to a period of peace under an Austrian family system presided over by Maria Theresa and her husband, Francis of Lorraine-Tuscany (now emperor as Francis I). On her death in 1780 her eldest son. the emperor Joseph II, ruled in Lornbardy; her second son, Leopold, was grand duke of Tuscany; her daughters Maria Carolina and Maria Amalia were married to the Bourbon cousins Ferdinand of the Two Sicilies and Ferdinand of Parma; a third son, Ferdinand, ruled in Modena as husband of the heiress, Maria Beatrice d'Este. Genoa retained independence under French protection. Venice had entered upon the last stage of political decay and was famous chiefly for its theatre. pageants and gay luxurious life. The republic of Lucca was in the hands of a close oligarchy. In the Apennines the little republic of San Marino preserved the constitutional forms of a mediaeval city-state.

The Enlightenment in Italy.— The years 1748–92 were marked by reforming movements on the part of the principal rulers of Italy. Among the evils which cried out for remedy were the prevalence of crimes of violence, the appalling poverty of all but a fraction of the population, the excessive nealth and numbers of the clergy and. more especially in the south, the abuses arising from feudal privilege. In Lombardy a fixed tax on land known as the *censimento,* together with the abolition of privileges, did much to distribute the financial burden more evenly and to develop agriculture through its encouragement of the small proprietor. Under the terms of a concordat extorted from the papacy, many ecclesiastical possessions mere subjected to taxation, about 100 monasteries were suppressed and their property diverted to charitable and educational purposes Cesare Beccaria's famous pamphlet *Dei delitti e delle pene* inspired judicial reforms by which torture nas abolished and the criminal law made more humane In Tuscany, where the despotism retained something of the paternal and popular character given to it by the Medici, the grand duke Leopold I (later Holy Roman emperor as Leopold II) earned for himself a place among the leading *illuminés* of the age. Free trade, equality of taxation, prison reform, reduction of the armed forces, limitation of the power and wealth of the church were among the many salutary changes introduced by himself and his ministers. Charles of the Two Sicilies and. after Charles's accession to the throne of Spain in 1759, his viceroy Bernardo di Tanucci, did their best to improve the lot of the peasants by abolishing a number of personal services, admitting the right of appeal from feudal to royal courts and allowing peasants to sell their produce in the open market. They also made it their policy to assert the rights of the crown against the church in matters of justice, finance and clerical appointments. The expulsion of the Jesuits from the Sicilian kingdom and the discontinuation of the yearly tribute of a white palfrey in recognition of papal suzerainty over Sicily were among the signs of that emancipation of secular rulers from papal control which distinguished the period. By 1773 opposition to the Jesuits and their political influence had grown so strong that Clement XIV suppressed the society. The Savoyard kings, Charles Emmanuel III and Victor Amadeus III who succeeded him in 1773, pursued a similar policy, striving to improve social conditions in semibarbarous Sardinia and to increase the authority of the crown at the expense of both church and feudatories. Everywhere, however, reforms were made in the interests of the despot, imposed on the people without consultation and, for the most part, carried out by alien rulers. Even members of the house of Savoy were foreigners in Sardinia, and although they enjoyed in full measure the loyalty and support of the people of Piedmont, their rule there was rigidly authoritarian. Nevertheless the greater prosperity and awakened interest in the problems of government which followed on the reforming movement encouraged Italians to think and act for themselves. Vittorio Alfieri's tragedies which denounced tyranny and exalted liberty; the popularity among the growing middle classes of the Masonic lodges as a means of association; and the works of historians, economists, philosophers and scientists, who found in periodicals such as the Milanese *Il Caffé* a platform for the discussion of their ideas—all these were among the signs of new activity in Italy on the eve of the revolutionary period. (C. M. Ay.)

The French Revolutionary Period.— In March 1796 Napoleon Bonaparte was appointed by the Directory in France to command the army of Italy *(see* FRANCE: *History).* He began the invasion of the peninsula almost at once. Most of the Italian states formed part of the anti-French system, but none was able to offer an effective resistance. The Sardinian monarchy had already been weakened severely by the loss of Savoy and Nice in the French campaign of 1792 (Victor Amadeus III having joined the coalition against France; *see* FRENCH REVOLUTIONARY WARS) and by internal revolutionary movements. An Austrian system existed, based on Austrian Lombardy and dependent on marriage and family alliances, but Tuscany, potentially its most useful component, was determinedly neutral. The kingdom of Naples. another important unit in the Habsburg connection, was crippled by a clerical reaction and a feudal social structure which impoverished the peasant masses and stood in the way of all centralization. Parma and Piacenza and Modena, also aithin the Austrian orbit, were themselves occupied in undoing the effects of previous reform. The republics of Venice and Genoa, decaying under a narrowly oligarchical rule, preserved their stability with difficulty; Austrian designs on the Venetian hinterland were evident, while the Genoese had proved their own inability to govern both in Corsica and Liguria. The smaller republics, Lucca and San Marino, stagnated in an obscurely municipal isolation. The papal states had an administration perhaps even less adequate.

Bonaparte's campaign opened brilliantly with the defeat of the Piedmontese forces and the resultant defection of Sardinia from the Austrian alliance (armistice of Cherasco, April 27, 1796). The French army then crossed the Po, overran Parma and Modena, and on May 15 entered Milan, the capital of Austrian Lombardy. The remnants of the Austrian army were blockaded in Mantua. By June Ferdinand IV of Naples asked for, and obtained, an armistice. A part of the French army then invaded the papal

territories of Bologna and Ferrara (the Legations) and forced Pius VI to seek terms. In Feb. 1797 the peace of Tolentino was signed by French and papal representatives. Meanwhile, Bonaparte met and defeated the Austrian counterattack in a campaign that carried him to within 50 mi. of Vienna by the end of March. The negotiation of the preliminaries of Leoben closed the fighting.

At the beginning of the invasion there already existed in Italy some revolutionary groups. These were enthusiastically pro-French. There had already been risings led by these groups against the authorities of Piedmont, Naples and the Legations. At this time the bulk of the population greeted the French invasion with indifference and rarely with hostility. But the character of the occupation, the systematic plundering and exaction that were necessary both to supply an army living on the country and to maintain a flow of money to the Directory soon changed the indifference of the Italians into a sullen discontent. There were violent outbreaks against the French at Pavia, Genoa and Verona during 1796 and 1797 and others of less importance elsewhere. At the same time the hopes of the Italian Jacobins were dashed by the Directory's distrust of nationalist elements (which might favour the growth of a strong Italian state) and by the opportunism of Bonaparte's own policy.

The prestige and power which Bonaparte commanded at this time were such that he was able to reorder the peninsula almost at will. His conception of Italian policy was wholly different from that of the directors, who silently acquiesced in his actions so long as the stream of money continued to flow from Milan to Paris. The central feature of Bonaparte's conception was the establishment of a strong north Italian state.

In Oct. 1796 Reggio nell' Emilia, Modena and Bologna were associated to form the first of the revolutionary states founded in Italy, the Cispadane republic. Its constitution was based on revolutionary principles. In July 1797 the Cisalpine republic came into existence at Milan (it bore for a short time the name of the Transpadane republic). Within a month the Cispadane was merged in the Cisalpine, and the latter was soon enlarged by the addition of territory from the Venetian hinterland and from the Swiss cantons of the Valtellina. Like the Batavian republic, the Cisalpine had a constitution modelled on that of France. It possessed a nominally complete independence, maintaining its own embassy at Paris, but the presence of French forces, the continuous strain of a monthly subsidy to the French republic and the suspicion with which it was regarded by the rest of Europe prevented it from ever playing an effectively independent role.

Bonaparte's reorganization of northern Italy was completed by the remodelling of Genoa, henceforth called the Ligurian republic, and by the conclusion with Austria of the treaty of Campo Formio (Oct. 17, 1797). The preliminaries had agreed that the Venetian republic should bear the strain of the territorial compensations to be given to Austria for its losses in Lombardy. In the treaty of Campo Formio these compensations were extended to include the city of Venice itself, and the republic of St. Mark passed out of existence.

As had been their practice in Genoa and Venice, the French openly encouraged the democrats of the remaining independent Italian states to provoke the incidents which provided the formal excuse for invasion. It was in this way that Charles Emmanuel IV was forced to relinquish his Piedmontese possessions in Dec. 1798. He made vain attempts to control a revolutionary situation Inflamed by "patriotic" insurgent expeditions from the supposedly friendly Cisalpine republic but inevitably failed. He retired to Sardinia, leaving Piedmont to be annexed to France.

Joseph Bonaparte, French ambassador in Rome, similarly encouraged the Roman Jacobin minority in spite of the peaceful protestations of his government toward the papal states. The disturbances which arose soon furnished the excuse for invasion. In Dec. 1797 the French general Léonard Duphot was killed by papal security forces in a riot provoked by the Jacobin clique. In spite of the offer of redress and apology at once made by the papacy, Joseph Bonaparte withdrew to Florence, protesting that his safety was endangered, and Pierre Alexandre Berthier (who had succeeded Bonaparte in command of the army of Italy) occupied Rome, deposed the papal government and installed a puppet administration under the name of the Roman republic (Feb. 15, 1798). The unpopularity oi this government increased daily as its inability to stop French plundering became manifest. Pius VI was exiled, ultimately to France, where he died in 1799.

The kingdom of Naples brought about its own occupation by the decision of Ferdinand IV (I of the Two Sicilies) to re-enter the war against France. He was encouraged by the presence of a powerful British squadron under Horatio Nelson in the Mediterranean and by its victory over the French fleet at Aboukir in Aug. 1798. At the same time it appeared that shortage of supplies, the absence of Bonaparte in Egypt and the activities of the Directory's political agents had greatly reduced the army of Italy's fighting capacity. Ferdinand's own designs on former papal territory were the deciding factor; and on Nov. 28 the Neapolitan army, newly rebuilt by Sir John Francis Edward Acton and led by the imperial general, the baron von Mack, occupied Rome. At the same time a sea-borne expedition landed at Leghorn. The French had abandoned Rome, but after Jean Étienne Championnet had shaken off the control of the political agents, he defeated Mack at Civita Castellana. The re-establishment of the Roman republic and the general retreat of the Neapolitan army follo ed. Championnet pursued closely, hampered by a guerrilla war which began to flare up on the flanks of his advance.

The evacuation of the Bourbon court to Palermo (Dec. 21) and the surrender of Mack gave the signal for a revolutionary outbreak at Naples against the pro-French democrats who wished to hand the city over to Championnet. Three days of the most bitter street fighting were necessary before the French restored order. On Jan. 23, 1799, the Parthenopaean republic was proclaimed. The hatred of the populace of Naples and of the Calabrian peasantry for the supposedly atheist French and their Neapolitan allies almost completely stultified the reforms of the new administration. The inexperience of the democrats proved disastrous after the replacement of Championnet by Alexandre Macdonald and the removal of the only restraint on the exploitation of the new state. With the coasts surveyed by British warships it was inevitable that the countryside should slip almost at once out of the control of the government at Naples.

The revolutionizing of the republic of Lucca at the same time as the creation of the Parthenopaean republic was the last extension of French power in Italy before the onslaught of the second coalition.

The reconquest of Italy by the Austro-Russian army was accomplished even more quickly than the French campaign of 1796. The Russian marshal Suvorov inflicted a severe defeat on the French army at Cassano (April 28), and J. V. M. Moreau ordered Macdonald's army to move north to prevent the division of the French into two isolated groups. After another defeat, the French under B. C. Joubert, who had assumed command, retired on Genoa, and only Masséna, in Switzerland, was left as a protection to the southern frontier of France. The occupation of Lombardy by the Austrians necessarily resulted in the collapse of the Cisalpine republic, and the Roman and the Parthenopaean survived scarcely longer. In the south, above all at Naples itself, a period of the most cruel reaction began.

Russia soon recognized the determination of the Austrians to exploit to the full the situation created by the successes of Suvorov. The defection of Russia from the coalition followed. Neither the Austrians nor any of the restored authorities paid any attention to Italian national aspirations, which were, for a brief period after the French collapse, at their strongest. It was the second disillusionment in five years for patriots of all parties.

On Oct. 9, 1799, Bonaparte landed in France. A month later, by the coup d'état of Brumaire, he became first consul.

The reconquest of Italy did not begin until Bonaparte was completely sure of his security in France. In May 1800 he led a new army across the St. Bernard and marched straight on Milan. The city was re-entered (June 2), and the Cisalpine republic restored. On June 14 Bonaparte defeated the main Austrian army at Marengo, near Alessandria. During the truce that followed, Italy was once more at the disposal of the French army.

Better discipline and greater consideration for local opinion were shown by the army of the second French occupation. At the same time Bonaparte preserved a moderate limit to his diplomatic demands. Pius VII was allowed to continue in possession of the papal states. Tuscany, Piedmont and Liguria were put under provisional governments. When the final peace settlement was made (treaty of Lunéville, Feb. 8, 1801), the Cisalpine and Ligurian republics retained their independent existence and the settlement of Campo Formio was in general restored. The treaties of Aranjuez with Spain (March 21) and of Florence with Naples (March 28) completed the pacification of Italy. By the former, Louis, son of Ferdinand, duke of Parma, was enthroned in Tuscany as king of Etruria; and by the second, Ferdinand IV of Naples agreed to the closing of all Neapolitan ports to British shipping and to the admission of some French garrisons. Lastly, on Sept. 21, 1802, Piedmont was incorporated into the French republic and given representation in the legislature.

This phase of territorial reorganization was completed by the consolidation of Bonaparte's control of the Cisalpine republic. A *consulta* was held at Lyons, at which Talleyrand and his assistants engineered the passing by the nominally independent Cisalpine delegates of various changes in the constitution and the election of Bonaparte as president. The state was now called the Italian republic and was ruled autocratically by Bonaparte through a local administration presided over by the Lombard patriot and moderate, Francesco Melzi d'Eril.

The Napoleonic Empire. — On May 18, 1804, the first French empire was proclaimed. Numerous Lombards hoped that the offer of the crown of Italy might persuade Napoleon to accord a more genuine degree of independence to the Italian republic; and his acceptance of the offer was followed by his coronation at Milan (May 26, 1805) with the old iron crown of the Lombard kings, the traditional formula *Dio me l'ha data, guai a chi la tocca* being invoked. In the reorganization which followed this ceremony, Eugkne de Beauharnais was appointed viceroy and Melzi d'Eril retired to take a less active part in the affairs of the north Italian state. The subordination of the interests of the new kingdom of Italy to those of France remained as marked as ever.

New territorial changes followed. Lucca was granted to Elisa Bonaparte as a principality, while Parma was annexed to the empire. In June 1805 the government of Genoa was forced to ask for incorporation in the empire, and the Ligurian republic came to an end. This disregard of the provisions of Lunéville, which had been intended to guarantee the independence of the new states, led to the formation of the third coalition, Great Britain, Austria and Russia, later joined by Naples. After a fresh series of defeats the Austrians quickly agreed to the treaty of Pressburg (Dec. 26, 1805), which imposed the recognition of the Napoleonic settlement in Italy, the surrender of Austrian Venetia to the kingdom of Italy and submission to the French occupation of Istria and Dalmatia.

On Feb. 15, 1806, Joseph Bonaparte entered Naples. The Bourbon court once more fled to Palermo under Anglo-Russian protection. A British landing and the prolonged resistance of Gaeta did something to inflame the peasant rebellion which almost immediately broke out against the French; but Calabria was brutally pacified by a policy of savage reprisal. Joseph was proclaimed king of Naples (March 30), and under his rule the beginnings of a long-needed campaign of reform did much to alter the feudal structure of society and the chaos of feudal law. Judicial and criminal procedure were reformed in accordance with the Code Napoléon. These reforms were continued by Joachim Murat, who succeeded Joseph as king in 1808. Their effects were important but limited by the economic imprisonment of the kingdom within the continental system and by the failure of the government to achieve any important redistribution of land.

The restrictions of the continental system were a subsidiary cause both of the occupation of Tuscany by Elisa in 1808 and of the deterioration of relations of the empire with the papacy. Napoleon had shown care to enlist the authority and advocacy of the church in his support whenever possible, and to this end the concordat of 1801 had been directed. In spite of this, a refusal to grant papal sanction for the divorce of Jerome Bonaparte and the need to perfect the continental blockade led to the occupation of Rome (Feb. 2, 1808) and the overthrow of the papal government. In April 1808 the papal Marches were annexed to the kingdom of Italy; and after the occupation of Vienna in 1809 Napoleon proclaimed from that capital the end of the temporal power. Pius VII, having prepared a bull of excommunication against those concerned in this transaction, was immediately arrested and exiled (July 5). In 1810 Rome was formally annexed to the empire and declared its second city. Reforms were initiated and the Code Napoléon introduced — to the great resentment of a population strongly influenced by a numerous and newly dispossessed clergy.

There was at this time no part of the Italian mainland not dominated by Napoleon. Only Sardinia and Sicily remained under governments which had existed before the French invasions. The effects of this subjection on the economic life of the peninsula were disastrous, save in those areas where the blockade could be flouted with impunity. Those provinces annexed to France were the most rigorously controlled, but the kingdom of Italy was equally mercilessly exploited in French interests. Besides the local burden of the support of a large French garrison, the contingents for the Italian forces were a strain on the manpower resources of the peninsula. The drain of bullion was almost complete, and the liquidation of landed wealth did not go fast or far enough to offset this acute shortage. The commerce of the ports, so dependent on British Mediterranean trade, was ruined by the blockade. The natural markets of north Italian industry, Germany and Piedmont, were arbitrarily closed by the workings of the imperial customs system. The restraints thus imposed on industry and the lack of a strong *bourgeoisie* able to play an important national role were not unconnected.

By introducing the French commercial and banking codes, Napoleon contributed something valuable to Italian commerce. At the same time the improvement in communication brought about by the program of public works of the Napoleonic administrations was to help later development. The most important Napoleonic contribution to the historical development of Italy, however, was probably not material but ideological. A diffused experience of a common system of administration, the beginnings of a system of public education, common obligations of military service for natives of all regions and the existence of a common legal code counted for much in the formation of the patriots of the early years of the Risorgimento. The unpopularity of the French itself strengthened the independence of those who, like Ugo Foscolo, having been disappointed in their early hopes of the French, had been driven to rely more on purely Italian resources. Ultimately the failure of the French seems the result rather of an inability to press reform far enough than of overzealous innovation. Above all, little or nothing was done to associate the masses with the new regime by reforming the distribution of landed property. Almost all the Italian Jacobin manifestoes of 1796 had asked for this, but only the slightest beginnings were made by the Napoleonic reforms.

After the battle of Leipzig (Oct. 1813), the Austrian invasion of Italy began. In the face of a superior enemy, Murat deserted Eugkne de Beauharnais, who had refused his suggestion that they should seek a separate peace. At the same time, patriotic groups hampered Eugène's defense, hoping that Italian independence would follow a French collapse. The armistice of Schiarino Rizzino (April 23, 1814) recognized the kingdom of Italy, but too late to prevent the patriots associated with Count Confalonieri from gaining control of Milan. Eugène retired to Bavaria, knowing a restoration of himself to be impossible, and the Austrians at once occupied Lombardy. There mas no chance that they would surrender power to the once more disillusioned patriots. Murat's belated attempt during the Hundred Days to re-establish a Napoleonic state in the peninsula and his subsequent execution removed the last obstacles to the process of restoration.

The Restoration. — The restoration in Italy could not be a complete return to the order of 1791. Austria retained possession of Venetia, and prudence dictated to the statesmen of the con-

gress of Vienna that continued Austrian predominance in Italy should guarantee the peninsula against French influence. The cotnbined territories of Venetia and Lombardy were to be ruled as a single province, by a not unduly harsh or unjust administration. But the remoteness of the imperial government at Vienna and an increasingly illiberal regime soon aroused discontent in the Austrian province. Marie Louise, the former empress of France, ruled Parma, Piacenza and Guastalla in the Austrian interest and preserved some of the Napoleonic administrative and legal structure in the duchy. In Modena a complete reaction began under the rule of Francis IV, son of the previous duke, Maria Theresa's son Ferdinand. But Tuscany under Ferdinand III, the emperor Leopold II's son, was an oasis for Italian liberals during the years of persecution. But as Austrian princes, the rulers of Tuscany were always susceptible to pressure from Metternich on any major issue. Liberal hatred of Austria all over the peninsula sprang from the knowledge that Austrian intervention was the ultimate guarantee against constitutional reform anywhere in Italy.

Among the non-Austrian rulers restored in 1815, the king of Sardinia received some increase of territory by the addition of Liguria to Piedmont. Within Piedmont, the reaction against French innovations was violent but tempered by a jealousy of Austrian domination of northern Italy, which made some identification of the cause of Sardinia with that of Italy appear inevitable. In the papal states the reaction was catastrophic, the attempted reforms of Ercole Cardinal Consalvi collapsing under the incompetence of the central administration and the revived influence of the Jesuits. Almost from the first days of the restoration the provinces which had formerly belonged to the kingdom of Italy were in a state of revolutionary unrest. In Naples Ferdinand IV was hampered in his effortsto restore the *ancien régime* by the intransigence of Sicily (which had enjoyed some degree of liberty under a constitution imposed upon Ferdinand by the British forces of occupation) and by his dependence on many of the administrators and officersof the Murat epoch. Of the smaller states, Lucca passed to the formerly Parmesan Bourbons (in the person of Marie Louise, widow of Louis king of Etruria) and suffered some degree of clerical reaction, while San Marino survived the process of restoration almost unchanged.

The Early Revolutionary Movements.—Some middle-class and patriotic groups soon began to regret the passing of the Napoleonic administration and its opportunities. Discontent first became vocal in the Italian secret societies. The period of the ascendancy of the Freemasons ended with their quasi-official patronage by the French; but a group of societies known as the Carbonari had replaced them. These societies had originally come into existence at Naples as an anti-Bourbon force under the French administration; after turning to opposition under the restoration they had acquired an almost regularized existence as the focus of discontent in the south. Always largely middle class, they soon lost all contact with the masses, who remained loyalist and clerical in their sympathies.

In 1814 and 1815 the Carbonari spread to the Romagna. A similar organization in Piedmont, the Federati, derived its inspiration directly from France and was patriotic and anti-Austrian in purpose. The revolutionary plots of 1820 and 1821 were the work of these and similar societies and seldom looked beyond the confines of single states.

A revolution at Naples in 1820 forced Ferdinand to grant a constitution (July 7), which was based on the Spanish charter of 1812 (see SPAIN: History). A ministry of former Napoleonic officers and administrators was set up but had to face almost immediately a second insurrection at Palermo. This was wholly separatist in aim, a movement of all classes that cut across the constitutional revolution of the mainland. A local quarrel between Palermo and Messina further complicated the situation. No Sicilian deputies were present at the parliament which opened at Naples on Oct. 1. At the same time. at the congress of Troppau, Metternich had made clear the determination of the Holy alliance to preserve the Vienna settlement in Italy. Ferdinand, in spite of his constitutional oaths! applied to the Holy alliance for help. An Austrian army overthrew the revolutionary government in March 1821 and reconquered Sicily for the crown soon after. It remained in occupation until 1827 and enforced a violent reaction under the king and his police chief, Antonio Capece Minutolo, prince of Canosa.

A similar movement, but localized to a greater degree in the officer corps and more specifically anti-Austrian, broke out in Piedmont. Charles Albert of Savoy-Carignano, the heir apparent to King Charles Felix of Sardinia, was cognizant of the plot and assumed the role of regent for a few days when the *pronunciamiento* took place in March 1821. His grant of a constitution was at once revoked by Charles Felix; he was arrested; and after a few weeks an Austrian army recaptured Turin for the king. The chief result of the plot was the disgrace of Charles Albert and a temporary weakening of the normally anti-Austrian trend in Piedmontese policy. Both the Neapolitan and Piedmontese movements suffered from being the plots of small groups rather than true revolutionary movements; the same was true of the Lombard liberals, who suffered imprisonment after a series of trials (1821–23) and were almost all drawn from the ranks of the educated and noble classes. The investigation of the Piedmontese plot led to their discovery, and their contribution to the Risorgimento could consist only in the example of their courage and the legend of their martyrdom. The work of one, Silvio Pellico, was a notable contribution to the literature of the national movement.

Central Italy, especially the Legations, also suffered from disturbances. After the July revolution at Paris and the spread of the illusion that France would not permit Austrian intervention, the movement took a serious aspect in the papal Marches. The revolutionaries believed they had the support of Francis of Modena, who had toyed with the idea of a central Italian kingdom, and risings took place at Parma and Bologna, while that at Modena itself was forestalled by the arrest of the chief conspirators. But with Tuscany and Lombardy quiet and their hopes of help from France disappointed, the revolutionary governments which were set up proved helpless.

Their own internal divisions left them to face the Austrian invasion singly, not in alliance. Louis Philippe ordered the occupation of Ancona by a French force as a counter to the extension of Austrian power which the new restorations brought with them, and this completed the disillusion of those who had looked to him for help (Feb. 1832). A five-power memorandum had been addressed to the papal government recommending internal reforms before the final occupations of Bologna and Ancona but was virtually ignored by the papal administration.

The failure of Carbonarism was one of the stimuli prompting Giuseppe Mazzini to seek a new outlet for Italian discontent. On the succession of Charles Albert to the throne of Sardinia (1831), Mazzini addressed to him an appeal to lead a nationalist movement. Alarmed by a recent incursion of Italian patriots into Savoy from France, the king did nothing, apparently as Mazzini had hoped. Mazzini therefore proposed to rely solely upon a national insurrectionary movement, aiming at unity in a free republic. He envisaged the creation of the new Italy in terms as much moral as political and looked to patriotism and example rather than to diplomacy and tactics as his methods. In 1831 he founded the revolutionary organization Giovine Italia, whose influence spread rapidly among Italian exiles and inside the peninsula. But though it was more broadly based and national in outlook than the Carbonari, its recruitment still drew on a relatively small class of young bourgeois and middle-class radicals and made no effectiveappeal to the masses. In addition, Mazzini's distrust of Piedmont and his rejection of foreign intervention stood in the way of any final success. But from 1833 to 1845 repeated raids and insurrections organized by Giovine Italia kept alive the unionist cause and the tradition of revolt. Only with the failure of the expedition of the Bandiera brothers to Calabria in 1844 was the bankruptcy of this method in the face of popular apathy at last fully realized.

Federalism and Reform **in the** *1840s.*—In reaction against the waste of life and ill-success of Mazzini's program, moderate opinion tended to crystallize about federal conceptions of the solution of the Italian problem. In 1843 Vincenzo Gioberti published

his *Del primato morale e civile degli italiani*, which advocated a federal union of the existing states which would look to the papacy for leadership. A Piedmontese group, including Cesare Balbo and Massimo d'Azeglio, advocated a similar federation, but claimed its leadership rather for Piedmont as necessarily the main defender of the peninsula. Charles Albert's attitude toward Austria had stiffened in the years before 1846, and an unavowed toleration was given to the Turin moderates who emphasized the anti-Austrian rather than the constitutional aspects of the Italian problem. The election of Pius IX (June 16, 1846) in succession to the staunchly conservative Gregory XVI was the beginning of the crisis of the early Risorgimento. Pius was a man of liberal and patriotic views, influenced by Gioberti's conception of the role of the papacy and not clear, at the beginning of his reign, how far these views were incompatible with the European status of the papacy and the existence of the temporal power. His influence over the other Italian sovereigns and over the country clergy and nobility, none of whom would have been likely to adhere to the national movement without his example, was immense in 1846 and 1847.

Pius at once instituted a number of overdue reforms. An amnesty was granted, plans for railway development were drawn up, Rome received a municipal government, the laity were admitted to the civil administration, a council of state was set up, a new press law granted some degree of freedom of publication and a civil guard was formed. The democratic party, encouraged by these concessions, became more uncontrollable and Pius more alarmed as this process gathered momentum.

Alarmed by the reforms, Metternich permitted Josef Radetzky, the Austrian commander, to occupy the papal town of Ferrara on July 17, 1847, as a precautionary move and Parma and Modena later in the year. At the same time he approached France with a view to joint Austro-French intervention to stifle the reform movement. These measures identified Pius more firmly than ever with the growing national and liberal cause. Negotiations began for a customs union of Tuscany, Piedmont and the papal states, but were fatally hampered by the disparity between the essentially negative papal conception of such a union and the Piedmontese conception of it as a positive anti-Austrian force. More important was the response in the other states to Pius' example of internal reform. Lord Minto's ambiguous advisory mission from the British cabinet contributed to the same end. Leopold II of Tuscany granted a press law (May 6, 1847) which was immediately followed by a burst of reformist propaganda. Lucca was granted a civil guard on Sept. 1, Tuscany two days later. The growing violence of the democrats, above all at Leghorn, was already making settled government difficult in Tuscany.

Charles Albert had hoped to avoid constitutional reform but was constrained by moderate opinion to accept a more liberal ministry and to concede a press law. The wave of reformist agitation that followed prompted further reform in police and administration. By the end of 1847, Piedmont was also affected by the spread of democratic faction, notably at Genoa, and Charles Albert, like Pius, was already feeling compromised by his association with reform.

The War of 1848–49.—The situation was suddenly and radically transformed by the Sicilian revolution of Jan. 12, 1848, the first revolution of the year of revolutions. As in 1821, the local separatist movement of the island was complicated by a constitutional revolution on the mainland that soon followed the Palermo revolt. The islanders demanded independence or the Spanish constitution of 1812; and to preserve his grip on the mainland Ferdinand II (V of Naples) granted a constitution which went far beyond any previous reforms in any of the Italian states. But Sicily proclaimed its independence of the Bourbon monarchy on April 13.

Encouraged and frightened by the events at Naples, other sovereigns granted constitutions. Tuscany received one on Feb. 11, and Pius granted one on March 14. The only constitution that was to survive the revolutionary war was that of Piedmont (March 4), which became the constitution of united Italy.

The European situation was a favourable one for the reform parties. The February revolution in Paris and the March revolution in Vienna made any active intervention unlikely. Lombardy had been disturbed by riots and outbreaks in the early months of 1848. Finally, when news of the Vienna revolution reached Milan, that city rebelled in its turn and after the famous "five days" of battle forced Radetzky to withdraw (March 18–23). Simultaneously, a revolt at Venice restored the ancient republic under the leadership of Daniele Manin (March 22). Charles Albert saw that the moment for effective action against the Austrian army had come and led his army across the Ticino to Milan (March 24).

The Piedmontese army was weakened by detachments to the French frontier and did not succeed in catching Radetzky before he took refuge in the fortress area of the Quadrilateral (Verona, Peschiera, Legnago and Mantua). Charles Albert pursued him, broke into the Quadrilateral (battle of Goito, April 18) and soon afterward won the battle of Pastrengo (April 30), which forced the Austrian army to depend upon Venetia for its communications but did not shake its tenure of the fortresses. Tuscany and Naples had by now declared war, and a papal force under Giovanni Durando crossed the Po with the aim of operating on the Austrian communications in Venetia.

The decay of this still favourable situation began with a papal allocution of April 29 in which Pius, obsessed by the danger of an Austrian and German schism, disavowed any intention of declaring war on any Christian nation. The internal divisions of the Italian movement at once assumed a much enhanced importance. The Lombard rebels were already bitterly divided into pro-Piedmontese and anti-Piedmontese factions. Charles Albert's motives were also deeply distrusted by the Tuscan democrats. He himself would not entertain the notion of seeking French support, fearing the accession of strength that the Piedmontese republicans would draw from it. In addition, the north Italian peasantry was almost everywhere indifferent or hostile to the Piedmontese army.

Charles Albert's failure to take Verona was the military turning point of the campaign. An army under Laval Nugent evaded interception and reinforced Radetzky on May 25. Ferdinand II of the Two Sicilies had by this time recalled the Neapolitan troops (which had been moving northward) in order to deal with the revolution at Naples, now wholly out of hand (May 17). The annexation of Parma, Piacenza and Modena to Piedmont by, plebiscite gave Charles Albert no military help, while the similar annexations of Lombardy and Venice (July 7) increased suspicion of his real motives.

At the end of July Radetzky turned on Charles Albert and defeated him in a succession of battles around Custozza (July 23–27). To save the Piedmontese army Charles Albert abandoned Milan, amid the hostility of the city which was enraged by his "treachery." On Aug. 9 he withdrew from further fighting by concluding an armistice at Vigevano.

In all the states the extremist democrats now tended to assume power, though they were in fact incapable of controlling their followers. A revolt in Bologna failed to force Pius into a declaration of war, but drove out the Austrian garrison. In Rome the moderates were wholly discredited, and Count Rossi, an able liberal, tried in vain to preserve order. His ministry was ended by his assassination (Nov. 15). Pius fled in disguise to Gaeta on Nov. 24 and refused to return. A constituent assembly voted the end of the temporal power and proclaimed a republic (Feb. 9, 1849), and Pius appealed for armed intervention to secure his restoration.

Similar deteriorations took place in Tuscany and in Naples. Leopold and Ferdinand both abandoned the attempt to control the extremists and went to Gaeta. The Tuscan republic was proclaimed on Feb. 8. A few days earlier, a Roman invitation to Piedmont to nominate delegates to a constituent assembly for all Italy was rejected summarily by Gioberti's government. This government was soon replaced by another, under Urbano Rattazzi, which hoped to reopen the war. To redeem past promises to the Lombard patriots and to avoid the necessity of accepting an Austrian peace the armistice was denounced at its expiry (March 12), and war began on March 20. On March 28 Charles Albert abdicated after the decisive defeat of Novara. His successor, Victor Em-

manuel II, hastened to make peace.

Italy was now at the disposal of the Austrian army. Lucca and Florence were occupied, and Leopold II returned to his capital under Austrian protection (July **28**); Ferdinand of the Two Sicilies had crushed the Sicilian rising on his return. Already in April, unwilling to allow Austria to act alone in the restoration of the papacy, the government of Louis Napoleon had sent a French force under Nicolas Charles Victor Oudinot to Civitavecchia. The French suffered an initial defeat at the hands of Giuseppe Garibaldi, and the Roman republic, under Mazzini, defended itself heroically for a month; but Oudinot broke into Rome on June **29**. The assembly was dissolved a few days later, and the keys of the city sent to Gaeta. Garibaldi, with some of the garrison, set out for Venice and reached San Marino before his small force fell completely to pieces. Venice itself, deprived of Piedmontese naval support, surrendered on Aug. **26**. A peace treaty between Austria and Piedmont, imposing a heavy indemnity on Piedmont and restoring the territorial settlement of 1815, completed the pacification of **1849**.

This pacification marked. in general terms, the end of the revolutionary phase of the Risorgimento and the beginning of the diplomatic phase. The revolutionaries failed because of their internal dissensions, because of the distrust of Piedmont by the smaller states. because of the Piedmontese distrust of France and because of the confusion over the role which the papacy should play in the making of Italy. Moreover the mass of the population was unmoved by the revolutionary appeal. Only at Venice, Milan and Rome did genuine popular movements of all classes have any effect. The military superiority of Radetzky both in the quality of his troops and in generalship was the final factor assuring the Austrian restoration of **1849**. (J. M. Rs.)

Piedmont in 1850.—The defeat of Piedmont, together with the failure of Mazzini's republic at Rome and Manin's at Venice, led to a second restoration of the old despotic regimes and to the virtual occupation of central Italy by Austrian troops. The war had shown how little feeling there was among Italians for unification. Thereafter Piedmont alone among Italian states retained any initiative or independence, and this was largely offset by defeatism and by a cleavage between moderates and revolutionaries which failure in battle had exacerbated. There was serious dissatisfaction with the government. A revolt in Genoa necessitated the blockade and bombardment of the city by royal troops. It was resented that the armistice had been arbitrarily signed by the king without the participation of his ministers; and because of a hostile left-wing majority in the chamber, the king had to appeal against parliament to the people in a personal proclamation from Moncalieri. Only after new elections was the treaty of Milan ratified, early in 1850.

Neither the armistice nor the proclamation of Moncalieri had shown much regard for constitutional proprieties. Unlike other Italian states, Piedmont preserved intact its new constitution of **1848**, but this statuto was a conservative document, the handiwork of men of the right like Cesare Balbo and Ottavio di Revel. There was always a danger that Victor Emmanuel II might follow the example of Ferdinand of Naples and repudiate his constitutional oath. His mother and his wife were both Austrians, and he must have appreciated that representative institutions as yet evoked little esteem in the country. Massimo d'Azeglio, who was prime minister from **1849** to 1852, though a sincere liberal, had been disillusioned by the events of recent years into thinking that perhaps the *statu* - had gone too far and that a long time would be needed before Italians were ready for freedom and national unity. Most people probably uould have agreed with him.

Gradually, however, and almost unintentionally there developed the habit of ministerial responsibility to parliament. The presence of exiles from other provinces helped to identify Piedmont as the nucleus of a future Italy and to mollify the provincialism and illiberalism of Turin. Administrative unification helped to fuse the royal dominions of Savoy, Piedmont, Sardinia and Liguria, and deputies self-consciously learned to speak Italian instead of French or dialect so as to make themselves understood. A railroad was built to link Turin with Genoa; the Siccardi law was passed to curtail ecclesiastical jurisdiction; and battle was joined to limit the aristocratic monopoly in the senate, the army and the bureaucracy.

Cavour.—In **1850** the ministry was strengthened by the inclusion of Count Camillo Cavour, a financial expert who had recently entered parliament. Cavour soon set about breaking the hold of the house of Rothschild upon Piedmontese finances and defied the experts by imposing heavy taxes and changing the country's economy to one of almost complete free trade. This helped to destroy the restrictions of economic paternalism and municipalism and also won the favour of Great Britain as a new market for its exports. Conquering his own initial unpopularity, Cavour showed himself to be by far the ablest man in the coalition. He skilfully made a tacit aliiance with Urbano Rattazzi of the centre left to supplant D'Azeglio and then resigned, early in 1852. D'Azeglio's cabinet soon foundered on the king's refusal to permit the passage of further anticlerical legislation. Cavour was the obvious successor, as he was more amenable on this point, and his *connubio* (union) with the left gave him effective control of the chamber. In November he duly became prime minister. During the next nine years he was to preside over the formation of a new kingdom of Italy.

The *connubio* of right centre and left centre prevented the emergence of a two-party system in Italy; but it also prevented the king's following Louis Napoleon's example of a coup d'état. Cavour yielded to the king by withdrawing the civil marriage bill in **1853**, but the radicals were strong enough in his cabinet to force through an attack on mortmain lands and ecclesiastical salaries. In **1855** Luigi Nazaridi Calabiana, bishop of Casale. led a clerical counterattack against Cavour, and the king tried to veto a bill to dissolve some of the monasteries; but when Cavour resigned Victor Emmanuel was forced to recognize that he was not strong enough to flout parliamentary wishes too openly and sensibly gave way.

By this time Cavour was becoming chiefly interested in foreign policy. He continued to deplore the activity of those who wanted to unify Italy. His government condemned Mazzini to death and expelled hundreds of the extreme radicals, hounding their journals out of existence, revising the jury system when necessary and introducing harsher press laws. Nevertheless, nationalism was no longer a mere literary aspiration among the intellectuals, and Cavour was gradually being converted to the view that many of the visionary ideals of Mazzini were neither so dangerous nor so utopian as he had thought. In preparation for the future he made a deliberate attempt to show other European states that Piedmont not only could govern itself wisely and liberally but also was a force to reckon with abroad and could speak for Italians elsewhere in the peninsula. The army was reorganized by Gen. Alfonso Ferrero La Marmora. Austria was publicly reproached for its harsh rule in Lombardy and for its confiscation of the property of those Lombards who had fled into exile at Turin.

Cavour realistically perceived that Charles Albert and Mazzini had both been in error to think that foreign alliances were superfluous. French support was indispensable if Austria was to be withstood. It was thus the more disastrous when in 1854–55 the outbreak of the Crimean War temporarily healed the rivalry of France and Austria, and Piedmont's old game of playing one off against the other no longer worked. So as not to be completely isolated, Cavour subsequently joined in the war. He was forced into this step by the king, who was eager to retrieve the reputation of his army and had arranged if necessary to supplant a recalcitrant Cavour with a more warlike cabinet of the right. Cavour forestalled this by accepting the mar, overruling the almost unanimous opposition of the other ministers and courageously committing his country without any guarantees or conditions to a war where no direct national interest was involved. So doing, he kept power at home and hung onto French sympathy until better times should allow him to exploit it. As a reward, Piedmont was later given a seat at the peace conference in Paris (1856), where a few hours were given to general discussions on the unfortunate state of Italy. This was not much, but it was more than Cavour had at one time expected. The Italian question was at last open. Austria was isolated again,

and its occupation of central Italy was becoming recognized as a breach of the Vienna settlement.

At once Cavour began to prepare for a third war of independence against Austria. Railways were built with military strategy in mind; a naval base was constructed at Spezia; fortifications were erected at Alessandria—by royal decree, in order to avoid a parliamentary debate. By these means a moral ascendancy was captured over the rival republican program of Mazzini. The two programs, opposite though they seemed, each stimulated the other and both proved to be necessary ingredients of the process of unification. But the failures of Francesco Bentivenga in Sicily (1856) and of Carlo Pisacane in Naples (1857) showed that the time for isolated republican conspiracies was over and that the need was rather for diplomatic action backed by a regular army and the organization of a state.

Another sign of the times was that, instead of dreading Piedmontese expansion, other Italians were beginning to welcome it. The Venetian Daniele Manin, the Tuscan Baron Bettino Ricasoli, the Sicilian Giuseppe La Farina and Luigi Carlo Farini from the papal states were all turning to collaborate with Turin. The exiled Manin, founder of the National society, promised in a famous challenge to renounce his republicanism if only the house of Savoy would accept the doctrine of unity. Meanwhile about 30,000 exiles from other provinces had taken refuge in Piedmont—whereas hitherto men like Gabriele Rossetti, Anthony Panizzi and Pellegrino Rossi had rather taken foreign citizenship. As these later exiles were people of education for the most part, they came to have great influence on the press and on politics in Turin and largely contributed to the education of the Piedmontese in *italianità*. Cavour himself, though he refused the proffered alliance of Mazzini, accepted that of the National society and began to think that unity might not after all be the "nonsense" that he had lately called it.

The elections of Nov. 1857 came as a reverse to Cavour. Savoy, Sardinia and Liguria returned an opposition majority, and had he not been so self-confident he would have resigned. He also came near to a breach with the king over the latter's disreputable private life; and it weakened him still further when Rattazzi left the ministry early in 1858. Luckily for him, French support was now so firm that even Felice Orsini's attempted assassination of the emperor in Jan. 1858 could not shake it. Cavour cleverly divined that the Second Empire, though conservative at home, was revolutionary abroad and needed a policy of prestige and military victory. Furthermore, Piedmont was a necessary buffer which France could not allow to be defeated by Austria. It was rather a French interest to chase Austria altogether from Italy, especially as France could name as its price the provinces of Savoy and Nice.

The *War* of 1859.—In July 1858, unknown even to his colleagues, Cavour had secret talks with Napoleon III at Plombières, where together they hatched a plan to create a kingdom of north Italy including Lombardy, Venice and the central duchies. It then became Cavour's task to provoke a war by the following spring in such a way as to make Austria seem the aggressor. This might not have been so easy had not Austria also regarded the war as inevitable. After an alliance had been signed between France and Piedmont in Jan. 1859, Austria declared war in April. The French won the battle of Magenta in June, and the allies entered Milan. This was shortly followed by a second indecisive victory at Solferino. Napoleon, however, was disillusioned with the lack of support from other parts of Italy and knew that Cavour was working behind his back to annex Tuscany and Umbria as well as the other territories already agreed. This acquisition of part of the papal states would not only have scandalized Napoleon's Catholic subjects but also have created a stronger kingdom in Italy than he desired to see. Accordingly in July he unexpectedly arranged an armistice at Villafranca. The peace of Ziirich in November eventually gave Lombardy to Piedmont, but not Venice, not the formidable Quadrilateral and not the duchies. Napoleon's plan was to leave Italy a relatively weak confederation of small states under the general presidency of the pope, and in this plan, for the moment, he almost seemed to have succeeded,

Cavour protested unavailingly against this desertion and reached the point of using most disrespectful language to the king at the latter's headquarters in Monzambano. Reluctantly, but realistically, the king accepted the accomplished fact, and Cavour resigned in July 1859. For six months he was out of office, while a stopgap Rattazzi-La Marmora ministry proved itself unequal to the situation.

During this time attention was first fixed on central Italy, where the outbreak of war against Austria had caused spontaneous risings against the old ruling houses and their Austrian garrisons. Napoleon was resolutely opposed to the annexation of the duchies by Piedmont; and though royal commissioners had been sent to Bologna, Florence, Modena and Parma, these were obliged to resign after the armistice of Villafranca. However, the local revolutionary governments refused to be dismayed. Elections were held to confirm the triumph of the nationalists; more or less open dictatorial powers were conferred on Farini and Baron Ricasoli respectively; and Gen. Manfredo Fanti was seconded from Piedmont to organize an army of central Italy, with Garibaldi as his second in command.

Cavour, although out of office, had continued to give advice and encouragement to these revolutionaries in their effort to annex themselves to Piedmont. In Jan. 1860 he saw how to recapture the political initiative; and after ousting La Marmora he proceeded to upset Napoleon's original plans by offering to exchange Savoy and Nice for permission to carry out this new annexation. A treaty was signed in March to ratify his scheme. Plebiscites were held in each several region to confirm the exchange (March–April), so successfully that their sanction in each case was almost unanimous. The parliament that met at Turin on April 2 thus included Lombards, Tuscans and Romagnols. In less than a year Piedmont had more than doubled its size, against the strong wishes of most of Europe. It now included about 11,000,000 people, or half the population of the peninsula. Only the sacrifice of Savoy and Nice marred the general satisfaction.

Garibaldi's Conquest of Southern Italy.—The next stage in unification was the annexation of Sicily and Naples, and for this Italy had to thank the much-maligned radicals of the extreme left. In May 1859 Ferdinand II of the Two Sicilies was succeeded by his son, Francis II, who continued the traditional policy of refusing a constitution or a friendly alliance with Piedmont. There was little evidence of much nationalist sentiment in the south, but the brutal persecution and crass unenlightenment of the Bourbons had generated a widespread desire for change. In Sicily this was supported by a bitter and age-old dislike of rule from Naples; and Francesco Crispi, with other friends of Mazzini, found it easy to prepare and begin an insurrection. Early in May 1860 Crispi persuaded Garibaldi to lead 1,000 men from Genoa to support this revolt. They reached the island just before order had been restored. Aided by a peasants' revolt against the landlords, which spread disorganization and terror, Garibaldi wrested Palermo from a strong garrison of troops; and by the beginning of June nearly all the island was cleared of Bourbon soldiery.

Cavour had given no help to the original expedition and indeed had done his best to persuade Garibaldi not to sail. Excited however by the amazing success of the revolution, he quickly made up for this and soon sent royal commissioners to arrange the annexation of Sicily. Garibaldi was nevertheless determined to hold onto his dictatorial powers. His intention was that the states of Europe might be confronted with the acquisition not only of Sicily, but of Naples and Rome as well; and he knew that, were Cavour in charge of the revolution, the French could use their influence on him to stop his further progress. Crossing to the continent, he occupied Naples in Sept. 1860. Francis II fled to Gaeta, but the Bourbon army at last held Garibaldi on the Liri (Garigliano) river.

Unification, 1861.—Cavour then decided on one of his boldest strokes and in September, on the flimsiest of excuses, invaded the papal states. Napoleon III would never have allowed this but for the plea that Garibaldi could otherwise have carried the revolution into the Holy City itself. Carefully leaving intact Rome and its surrounding countryside, the northern army captured Umbria and the Marches, defeating the papal troops at Castelfidardo and entering Neapolitan territory in the middle of September. This simul-

taneously put pressure on Garibaldi to yield his conquests, and plebiscites were held in October which purported to express the wish of the people of Sicily and Naples for annexation to Piedmont. Garibaldi reluctantly retired to his island home of Caprera; Farini was sent to organize an emergency government in the south; and Gen. Enrico Cialdini supervised the capture of the last Bourbon strongholds early in 1861. Umbria and the Marches were also annexed, and representatives of these provinces and of the south were present when in Feb. 1861 parliament met at Turin and declared Victor Emmanuel to be king of Italy—his title remained Victor Emmanuel II. to show that it was no new state but a continuation of the old kingdom of Sardinia.

His lifework thus accomplished, Cavour died in June 1861 worn out with responsibility and with the strain of carrying virtually the whole burden of the country's administration. His achievements were the result of no preconceived plan, but of enlightened opportunism over means and ends. He had been an ambitious man. second to no one in unscrupulousness and Machiavellianism; but he remained faithful to the broad tenets of liberalism. Along with a remarkable power of grasp and penetration, he had courage and firmness of decision, a sense of proportion and a tact and skill in manoeuvre which in combination amounted to genius. It was a great misfortune for his country that he died so early and before the initial problems of the newly unified kingdom had been properly tackled. In his last days he attracted the applause of parliament by his proclamation that the capital of Italy had to be Rome. But how to proceed thither, how to reconcile the pope and Catholic opinion to a unified Italy, he did not yet know. Furthermore, he left behind him neither a properly stable parliamentary majority nor responsible and able leaders who could take over where he had left off.

Ricasoli, Rattazzi, Farini and Minghetti.—From June 1861 to March 1863 the prime minister was Bettino Ricasoli. Problems calling for his immediate attention included the "Roman question" and the desultory negotiations which Cavour had conducted with the Vatican. There was also the problem of administrative unification, the harmonizing of many diverse provincial systems of law and of varying levels of taxation: and a way had to be found to inject regional pride uith a common national consciousness. The inadequate administrative staffs of the government departments in Turin had to be suddenly expanded and taught how to deal with an infinite variety of local difficulties. Armies which had lately been fighting each other had to be persuaded to fuse amicably, and promotion in both military and civil services had to be distributed regionally so as not to offend mounded susceptibilities. Much ill-feeling was caused among Garibaldi's volunteers by the preferential treatment accorded their defeated enemies in the former Bourbon army. Serious opposition was also encountered from the many people in each province who would have liked to see many more concessions to local autonomy. Federalists like the Lombard Carlo Cattaneo refused to take their seats in a central parliament. Former capital cities such as Naples and Florence had to reconcile themselves to demotion. The Garibaldians and the yet more extreme Mazzinians were highly indignant that the Turin government had halted the revolution without marching into Rome. Adherents of the old regimes sometimes refused to take the oath required in favour of the new order and often were only biding their time against the day of a counterrevolution and the restoration of the old Bourbon and Habsburg rulers.

Ricasoli was a man of iron will and high ideals, and more ready to tolerate Mazzini than Cavour had been. He was also, as a Tuscan, a bulwark against the Piedmontization of the kingdom which many people so disliked. But he lacked alike the ability and the desire to win popularity, and he treated the king with tactless condescension. Victor Emmanuel therefore began to intrigue with Rattazzi to replace him, and the Piedmontese lawyer thus returned to power from March to Dec. 1862.

Rattazzi's great failure was in his incompetent handling of another attempt by Garibaldi to march on Rome. In June 1862 the volunteers began to reassemble in Sicily; and when no obstacle was put in the way of their landing in Calabria, Garibaldi assumed that the government, as in May 1860, was standing aside to see what his chances of success would be. Rattazzi tardily realized that, since a French garrison was still established in Rome, the expedition must be stopped; and in August Garibaldi was wounded and captured by the regulars at Aspromonte.

The next ministry, that of Farini, was quickly terminated on account of the premier's ill-health, and Marco Minghetti took office from March 1863 to Sept. 1864. A convention was signed with France in Sept. 1864, under which French troops were to be evacuated from Rome on the understanding that Italy would guarantee the inviolability of the Holy City. As an earnest of good will, the Italian capital was to be moved from Turin to Florence, with the implication that former designs on Rome had been renounced. The news of this pact at once provoked an insurrection at Turin, whereat the king simply dismissed Minghetti and summoned another Piedmontese, General La Marmora, to succeed him. The September convention was duly honoured, and in 1865 the capital mas transferred to Florence.

La Marmora and the War for Venice.—One of the chief problems in these years after 1860 was the endemic plague of brigandage in southern Italy. This was now organized for political purposes by the Bourbons from their exile in Rome, with the active support of the Vatican; and it had soon attached to itself a program which embodied most of the political and economic grievances of Naples. Southerners resented that they had been conquered and were treated almost as & defeated colony. Claims for local autonomy were not met after 1860; conscription was introduced; far larger taxes imposed than southerners had known under the loose and ineffective rule of the Bourbons; and the abolition of the old protective system also left the industries of the south helpless before competition from the north. So widespread was the disaffection that D'Azeglio made a published statement to the effect that the Neapolitan plebiscite in favour of annexation must have given a false notion of popular wishes Sixty battalions of soldiers were scarcely enough to control the situation, and civil war continued off and on for four or five years, marked by great ferocity on both sides. More people were said to have died in this prolonged campaign than in all the other wars of the Risorgimento put together; and even when law and order were restored the fundamental social and political reasons for unrest continued. Only after 1900 was the southern question to be given adequate recognition by politicians and students of sociology. No completely satisfactory solution was ever to be found.

The new kingdom of Italy took its first steps in foreign policy by preparing a fourth great war of liberation against Austria for the acquisition of Venice. Cavour had begun intriguing in 1860–61 for an insurrection in Hungary, and Victor Emmanuel was so keen on war that he entered into a secret understanding with Mazzini, unknown even to his ministers. As a foreign alliance was indispensable and as France already thought Italy quite strong enough, negotiations were opened with Prussia, where Bismarck was scheming to upset the preponderance of Austria in Germany. Austria then took fright and sought to purchase Italian neutrality by offering the peaceful cession of Venice. This offer La Marmora almost surprisingly refused. A strong faction existed which desired a prestige victory and hoped to conquer the province of Trentino as well. War was assured from the moment when a treaty was signed with Prussia in April 1866. Hostilities began in June.

The Italian army and fleet. though a good deal larger than those opposed to them, were sadly lacking in generalship, provisions and morale. General La Marmora (resigning the premiership to Ricasoli) planned a direct attack on the Quadrilateral, ignoring the lessons of 1848 and 1859 and refusing to collaborate in the efficient Prussian plan which in a bare fortnight led to the crushing victory of Sadowa. Instead the Italians were beaten at Custozza. The king had insisted on helping to direct operations; and this, together with the divided command and all the jealousies and incompetence of the general staff, led to a quite unnecessary retreat and prevented exploitation of the simultaneous Prussian success. Garibaldi was deliberately kept as much as possible in the background, though once again his volunteers came off better than the regulars. Worse still, the feckless Adm. Carlo Persano had to be repeatedly ordered out of harbour by the government and then led

his superior fleet to defeat at Lissa (for which he was dismissed from the service).

Meanwhile Bismarck, who wanted Austria as a friend against France, made a separate armistice in July, and Italy was forced to follow suit. Peace was eventually concluded in October. Austria ceded Venetia to Napoleon as a mediator, and he allowed a plebiscite to be held to confirm its union with the rest of Italy. This was a considerable acquisition. But the hoped-for prestige victory had not been won, and the Trentino was to remain in Austrian hands until 1918. Italians had overestimated their strength and internal cohesion and were now disappointed and depressed.

Ricasoli and Rattazzi, Second Ministries.—Ricasoli's second ministry lasted from June 1866 to April 1867, hardly longer than the average length of life of a government in the unstable conditions of Italian parliamentarism. The Austrian war almost coincided with a rebellion in Sicily, which lost Ricasoli much support. Sicily had never been reconciled to conscription and had been indignant at the martial law and military occupation which Gen. Giuseppe Govone had been obliged to enforce for the preservation of order in 1863. In 1866 a provisional government was set up by insurgents at Palermo, and an expeditionary force had to be sent from northern Italy to subdue the island once more. In March 1867 Ricasoli dissolved the chamber to try and secure a larger majority; but the elections did not improve his position and he resigned in favour of Rattazzi.

One of the few good features of Rattazzi's governments of 1862 and 1867 was his appointment of Quintino Sella and Francesco Ferrara as finance ministers. These men were responsible for facing the very serious question of the annual budget deficit coming on top of the heavy expenditure incurred in the wars of the Risorgimento. In some years the deficit was 50% of the total revenue, and it made matters worse that the ruling classes in the state habitually refused to burden themselves with an efficient system of tax collection. The introduction of a forced paper currency in 1866 lowered the national credit still further. As a partial remedy, the large areas of land held in mortmain by the church were nationalized in 1867 and bought up (mostly by speculators on terms very favourable to themselves) to help stabilize the national finances. The tobacco monopoly was also farmed out by the exchequer to a private company, to the great gain of the latter. In Jan. 1869 the hated grist tax on the grinding of corn was reintroduced, and this provoked extensive rioting among the poor on whom it weighed heavily and disproportionately. These various measures, socially and even economically undesirable though they often were, partially bridged the gap between revenue and expenditure.

The Occupation of Rome.—The sale of ecclesiastical lands was only one among a number of anticlerical measures. The situation and status of Rome inevitably made the Risorgimento an anticlerical movement, and not until 1929 did the pope recognize the absorption of the centre and the south into a unified Italy. In the years immediately after 1860, former concordats were repudiated, prominent churchmen were prosecuted and refused permission to exercise their functions, a civil marriage ceremony was introduced and declared obligatory and many more monasteries were dissolved. From the other side, Pius IX in 1864 issued a Syllabus of errors wherein all the major principles of liberalism were condemned as inconsistent with the Catholic faith.

In 1867 Garibaldi led another march on Rome, hoping to prove that the Italian people themselves could carry out the work of unification without French or Prussian aid. Once again Rattazzi dithered, in the expectation perhaps that it would convince Napoleon that there would be no peace until Rome was Italian. Then he changed his mind and resigned in October, giving place to Gen. Luigi Menabrea. Meanwhile Garibaldi found to his dismay that the people of Rome were indifferent if not hostile to his invading army, and when Napoleon III sent another expedition to defend the city, the volunteers were easily defeated at Mentana in November. The Italian government had again to decide against Garibaldi and sent its army to help his discomfiture. The delivery of Rome still awaited the aid of a powerful foreign ally.

The chance came in 1870 when the Prussian victory of Sedan finally destroyed Napoleon III's empire, and the French garrison of Rome was again withdrawn. The way had been paved by the meeting of the Vatican council in 1869–70 and its proclamation in July 1870 of the infallibility of the pope. This symptom of the increasing centralization and clericalization of the church revived some of the old opposition to ultramontanism among Catholic states and made it easier for an Italian column to bombard the city of Rome with impunity. Victor Emmanuel, as a sincere Catholic if one of irregular life, was until the last moment reluctant to take this step. But the ministry under Giovanni Lanza and Quintino Sella, which took office in Dec. 1869, threatened him with a major constitutional crisis if he refused; and the Prussian victory left no obstacle except the paper undertakings of Minghetti's convention of Sept. 1864.

On Sept. 20, 1870, Gen. Raffaele Cadorna forced a breach in the Porta Pia; and after a token resistance Pius IX accepted what he had not the force to withstand. A plebiscite was held in October which—as usual—gave an overwhelming majority for union with Italy. At last the Risorgimento seemed to have achieved its purpose: apart from Trento, Trieste and other frontier rectifications (some Italians were soon to add the names of Dalmatia, Corsica, Malta and Tunis) unification appeared to be complete, and attention could be concentrated on constitutional and economic problems at home.

First in importance was now the problem of trying to reconcile the Vatican to the loss of temporal power and to the existence of a secular and even anticlerical government in the Holy City itself. Defying excommunication, the civil authorities requisitioned the Quirinal and other palaces. In 1871 they then passed what they hoped was the generous Law of Guarantees to regulate the position juridically, so far as possible implementing Cavour's doctrine of "a free church in a free state." The pope's position was to be sacred and his person inviolable. While free discussion was allowable on religious matters, insults and outrages against the Catholic faith were punishable. The pope was allowed ownership of the Vatican and Lateran palaces and promised an annuity of more than 3,000,000 lire. He was to have diplomatic immunity for foreign representatives attached to his court. The state gave up its old jurisdictionalist rights over the church, and bishops no longer had to swear fealty to the king.

This law was thought by the left to give far too much liberty to the church. But Pius IX naturally thought it gave away too little; and consequently he refused to accept it as valid, rejecting even the annuity. He and his successors remained voluntarily "imprisoned" in the Vatican, refusing even to recognize the existence of the kingdom of Italy, declaring in the "*non expedit*" that it was inexpedient for Catholics to vote in the national elections and that they could be "neither electors nor elected." For the most part this was a formal protest only. In practice, methods of co-operation were devised and legal fictions developed to allow religious organizations to hold property and to grow in number and authority. Nevertheless it had the unfortunate effect of helping to prevent the growth of a strong conservative party in parliament, and outbursts of clericalism and anticlericalism contributed to perpetuate a cleavage in society that was always unhealthy and often dangerous.

In 1871, parliament and the government offices were moved once again, this time from Florence to Rome, and an attempt was begun to turn Rome into a modern capital. In the next 30 years many of its old picturesque areas were to be pulled down to make way for new and not always tasteful construction.

Minghetti's Last Ministry.—The ministry of Giovanni Lanza lasted from 1869 to 1873. During this time Sella did much to bring national expenditure more into balance with the revenue, though this was purchased by keeping taxation high and inequitably assessed and by selling the capital asset of the ecclesiastical lands. When the next prime minister, Minghetti, was able to announce a budget surplus in 1876, at last the new Italian state seemed to be paying its way. Many thought the price had been too high, but no one could deny that it had been a considerable achievement.

By this time Cavour's carefully built-up parliamentary majority had undergone much change. Inside the so-called right there were

many varying opinions and personal rivalries. Sella, for instance, could never sit in the same cabinet with Minghetti. The Piedmontese formed a regional group of their own in parliament to protest against the removal of the capital from Turin. and the Tuscans did the same when it was later moved again from Florence. Above all the south remained turbulent and voted increasingly for the left.

Rattazzi had died in 1873. but Agostino Depretis and Francesco Crispi were building up a composite left-wing group which stood for the concession of more democratic reforms and soon included a number of deserters from the right. After the elections of 1874, the opposition parties were nearly equal in strength to those of the government. Mazzini had died in 1872, and his extreme republicans were no longer a force to be reckoned with. Garibaldi was lending his name to the prophetic but unrealistic program of an incipient Socialist party; and yet, after going to fight for the French in 1870, he made only rare appearances on the political stage. Radicals like Crispi and Felice Cavallotti dutifully accepted the oath of loyalty to the king; and so, apart from the clericals on the right, there was only a handful of extremists on the left who remained outside the prescribed limits of the constitution.

A skilful tactician like Cavour might have known how to make another *connubio* with Depretis. Instead, the ministry of Minghetti became even more repressive and arbitrarily arrested some of its political opponents. When its plan to nationalize the railways antagonized a group of Tuscan and Lombard mercantile interests, a chance vote in March 1876 brought to an end the period of rule by the right. Their honest, courageous and thrifty conduct of government had set the country well on its way to power and prosperity; but they had at last lost the confidence of the people, and the need now was for younger men, with new ideas and more of a social conscience.

Depretis and the Parliamentary Left.—The year 1876 began a long period of government by the left. The first cabinet of Agostino Depretis was almost entirely composed of men new to office, most of them former radicals, many of them former republicans, but all of them now liberal monarchists. Their program comprised extension of the franchise, the decentralization of government, the abolition of the grist tax and other impositions which bore heavily on the poor, and a pervasive anticlericalism; but in other respects they were content to follow the policy of their predecessors, and people were able to say that government by the right and by the left was in practice much the same, except that the latter was perhaps not so good.

The new minister of the interior, who was the former radical agitator Baron Giovanni Nicotera, immediately set about preparing for the elections with all the mixture of corrupt and legitimate influence which Italian practice allowed to the authorities in power. The results achieved in Nov. 1876 gave an overwhelming majority of 420 ministerialists against about 87 seats for the ('opposition": over the whole of the south only 4 opposition deputies were returned. This eclipse of the conservative right proved very bad for political education in Italy, and conflict was soon transferred to inside the government coalition itself, with the result that successive ministries proved even more unstable than before.

Nicotera's electoral machine brought with it an increase in political corruption; and yet the lack of party discipline and of fixed party principles meant that there mas an absence of clear conflict between alternative policies. The dissolution of parties dated back at least to Cavour's connubio, and the confusion of political principles had also been a feature of government by the right. By now they were regarded as deliberate methods of government, in the attempt to avoid extremes, to perpetuate a broad coalition of the centre and to provide no chance of a return of the old right to power. Successive prime ministers came to power just by a slight shift of emphasis inside the general framework of this coalition, usually for personal reasons and not because some great principle was at issue. It was a system of government that soon became known by the name of *trasformismo* or transformism and was to be claimed as a typical and even praiseworthy manifestation of Italian politics.

Depretis, who had severely censured the political morality of the connubio in 1852, thus effected a very similar parliamentary liaison when he was himself faced with the responsibility of office. Gradually he won over the more moderate members of the right, like Minghetti, for a policy of mild reforms. One example was Michele Coppino's Education act of 1877 intended to bring in compulsory elementary education. When Nicotera's authoritarian and unconstitutional actions endangered the continuance of the coalition, Depretis replaced him by Crispi (Dec. 1877); and Crispi, who had roundly condemned transformism when out of office, now welcomed it as the means of attaining power.

The succession of Humbert (Umberto) to the throne on the death of his father Victor Emmanuel II in Jan. 1878 confirmed the almost universal acceptance of the monarchy. A month later Pius IX died, and the election of Leo XIII as pope served as an occasion to restate the cleavage between church and state. More than once Leo mas to threaten that the papacy might remove itself from Italy if the claims of the church did not receive more respect.

Meanwhile one ministry followed another in quick succession. Depretis had to form a second cabinet in Dec. 1877; Benedetto Cairoli formed a ministry in March 1878; Depretis returned at the end of this year but fell in July 1879, after a vote in which Cairoli and Nicotera joined the conservative opposition; Cairoli succeeded once more but had to resign again in November and reconstruct his cabinet with the help of Depretis. The advent of the left in power was evidently not leading to a more stable and durable government despite such a huge majority; nor, it was noticed, was its rule notably much more liberal or enlightened than that of its predecessors.

Foreign Policy: Tunisia and *the* Triple Alliance.—Not until after 1880 did Italy meet any severe test in the field of foreign policy. France, Prussia and Great Britain all had good reasons for wanting a moderately strong kingdom in Italy as an essential element in the balance of power, and Cavour had thus been able to run risks in the confidence that he had everything to gain and not a great deal to lose. With the completion of unity, however, Italy was no longer content to acknowledge the patronage of foreign states and in return lost its status of a protected territory. In France. the republican Adolphe Thiers reversed Napoleon III's pro-Italian sympathies. The appearance of a distinct and active Italian foreign policy, backed by eager participation in the armaments race, made other nations more chary of their support. Gen. Cesare Ricotti-Magnani was reorganizing the Italian army on the Prussian model; naval supremacy over Austria was declared to be essential; and the armaments industry was receiving heavy subsidies. The stronger Italy became, the more difficult it was to back down with honour from a position that was maintained only with a dangerously high expenditure of money and resources. Lacking iron and coal. Italy was at an inherent disadvantage here; and though in naval construction for instance it temporarily led the world, each new invention or process causec! an increasingly disproportionate outlay of the national income. A vicious circle was soon set up. Italy's prestige became more and more involved; the state spent more and more money on interests that flourished on war scares and war production; and patriotism developed into nationalism and imperialism. The country became increasingly sensitive over real or imaginary affronts at the same time as it became ever more difficult to withdraw with dignity once any commitment had been made.

The same increase in strength helped to make Italy, in a moment of abandon, give up its valuable independence and enter the European system of alliances. Traditionally it had been able to play off Bourbon against Habsburg, France against Germany and vice versa, remaining free from commitments until it could intervene decisively. This had been the policy of the house of Savoy in the 17th and 18th centuries. But now, instead of limiting its ambitions to the preservation of the balance of power (in which it could act as an important makeweight), Italy was induced to side openly with Germany just when Germany had upset the balance by defeating France in 1870. The long-term result was to bring Crispi to a humiliating defeat.

There had been little sign of this in the period 1869–76 when Emilio Visconti-Venosta was foreign minister, although an ex-

change of visits between the rulers of Austria, Prussia and Italy in 1873–75 had marked the beginning of a reconciliation between the three conservative central monarchies. Then in 1877 Crispi paid a visit to Bismarck that convinced him Germany was the state of the future and that Italy should hurry up with its armaments and attach itself to this rising star. In his view it would have been unheroic just to try and restore the balance of power. As Victor Emmanuel II said, "Italy must not only be respected, she must make herself feared." This belligerent attitude was encouraged by Cairoli's failure to bargain successfully at the congress of Berlin in 1878 for a share in the disintegrating Turkish empire. The policy of "clean hands" provoked the indignant wrath of Crispi and his friends.

The final impetus to the German alliance came over the frustration of Italian colonial ambitions in Tunisia. For more than 40 years Italian explorers and missionaries had been penetrating into North Africa, sometimes with government encouragement. The Genoese chamber of commerce and, especially, the Genoese shipbuilder Raffaele Rubattino had spent much time and money in prospecting for colonies, and attempts had been made to purchase concessions as far away as the East and West Indies. The cutting of the Suez canal in the 1860s gave an additional incentive to colonization. In 1869 the government, working through Rubattino, made a settlement at Assab on the Red sea. Opponents pointed out the risk of war, the impossibility of maintaining a strong colonial movement without more resources and a larger army than Italy could afford and the lack of a financial or industrial surplus sufficient to exploit colonies once acquired. But although responsible statesmen expressed doubts about the course of events. appetite was now whetted, and prestige was thought to demand the extension of this settlement inland and the establishment of another colony in Tunisia.

There was indeed a substantial Italian population already living in Tunisia, and the acquisition of the country was considered necessary for the security of Sicily. But when Austria, Russia and Great Britain all suggested to Italy that it might compensate itself there for Austrian expansion into the Balkans, Visconti-Venosta and Cairoli agreed that Italy could afford only economic penetration. France also had claims to this region, and French hostility could not be lightly provoked. But Cairoli mismanaged the position and led on public opinion at home to look on Tunisia as a natural extension of the mother country at the same time as he knew that his government had neither the will nor the means to forestall the intervention of France. Then, in 1881, a French force entered the regency in pursuit of rebels from Algeria, and in May the bey signed the treaty of Bardo accepting French protection. In the following year Great Britain won a similar status in Egypt. Italy had to watch the last vacant stretches of North Africa being occupied by other countries and the balance of power in the Mediterranean turning against it. On grounds of security, and even more on those of prestige, this aroused the most bitter feelings.

It was partly in reaction to this setback that the government decided to make a formal alliance with Austria and Germany, and to sacrifice the advantage of not being bound to either of the big power groups of Europe. This was a breach with tradition. Austria had been the hereditary enemy for as long as people could remember, and its retention of Trento and Trieste, to say nothing of the presence of its fleet in the Adriatic and its ambitions along the Balkan coast, seemed to mark Austria out almost inevitably as Italy's opponent in any future war. From the Austrian point of view, moreover. Italy represented the principle of nationality which threatened the very existence of the Austro-Hungarian dual monarchy. Yet although the comparative weakness of Italy made it of little potential use as an ally, Austria wanted a guarantee for its southern frontier. Bismarck was likewise anxious to enlist Italian aid or benevolent neutrality against France should the latter contemplate a war of *revanche*.

Italy itself by now appreciated the case for ending its apparent isolation in Europe. in order to prevent further humiliation at the hands of France. The loss of Tunisia thus enticed the country away from its natural policy of "no commitments" and unadventurousness. An Austrian alliance would preclude the recapture of Venice in another war. It would also obtain formal acceptance by one of the leading Catholic powers of Italy's conquest of Rome, and this was important in that the pope was still hoping for foreign intervention to restore him his old authority. In domestic politics there was the further consideration that the treaty of Bardo had seriously shaken the parliamentary position of the left, and some success abroad was necessary to restore confidence.

For these reasons the foreign minister, Pasquale Mancini, opened negotiations for an Austrian alliance; and in May 1882 the triple alliance was signed. It was to last until May 1915. Germany, Austria and Italy undertook to support each other if ever attacked by other powers and to maintain a benevolent neutrality if one of the three states was forced to declare war. Austria and Italy in particular promised to maintain the status quo in the Balkans; but if ever this should become impossible, neither of the two powers was to occupy territories without previous agreement and adequate compensation. The Austrians tried to include in the treaty a clause which bound signatories to maintain a conservative policy at home, but Italy refused to accept this.

What Italy gained from this treaty was a comfortable feeling that it was no longer isolated. There was not much profit in a guarantee against the unlikely event of French invasion, and the offer of compensation in the Balkans was to prove illusory when the moment came for its application. In exchange for this, Italy had given up its freedom to negotiate with both sides. It had apparently reconciled itself to the Austrian possession of Trento and Trieste. Also, whether intentionally or not, it mas committing itself to fight in some future war in which it might have little apparent interest and, in the meantime, to increase expenditure on military provision.

By article five of the constitution, the king had the right to make treaties of alliance on his own responsibility. He need only inform parliament of the obligations that he had assumed for the country whenever he thought fit. The triple alliance was in fact kept secret, though the knowledge that the government had thrown in its lot with the former national enemy was not long in leaking out. It was noticed with some irritation that Humbert had even been seen in the uniform of an Austrian colonel at Vienna.

Meanwhile some of the nationalists were beginning to propagate the cult of irredentism, that is to say the extension of nationalist aspirations to Trieste, Trento and the other terre irredente or "unredeemed lands" still owned by Austria. In Sept. 1882 there was an incident when an "Italian" from Trieste. Guglielmo Oberdan, attempted to assassinate the Austrian emperor Francis Joseph; and his subsequent execution made of him a martyr in the eyes of many Italian patriots.

It was an early sign of the fact that the apparent completion of Italian unity in 1870, far from making Italy a satisfied power as the Risorgimento leaders prophesied, had created an appetite for yet further expansion. Moreover, the larger Italy became, the greater was its strength to effect such expansion. The simultaneous pressure of Austria down into the Balkans and the remarkable growth of national consciousness among the Slavs who surrounded Trieste were alarming signs that the passage of years might weaken instead of strengthen the Italian case. If expansion did not come soon, it might never come.

Irredentism was as yet only on the fringe of Italian politics. Depretis had not been very happy about the triple alliance but was a realist and was determined to make the most of it. It was fortunate for Italy that, when the alliance came up for renewal in 1887, a heightening of tension between Germany and France and between Russia and Austria made friendship more desirable than it had been in 1882. As a result, Italy received larger concessions and more particular regard for Italian interests in the Mediterranean. Crispi then tried, for a time with success, to divert nationalist sentiment away from the debatable northern frontier to colonial expansion, from irredentism to imperialism.

Domestic *Politics*.—It is difficult to describe the balance of forces in parliament during these years 1880–87, because there were no exact parties, and political allegiance was to persons rather than to principles. After the elections of 1880, the centre groups

of Depretis and Cairoli were confronted with an increase in representation for the extremists both right and left. The so-called "historic left" round Crispi and Nicotera could number more than 100 deputies whenever they could be induced to vote together. Minghetti and Sella on the right commanded even more. In this fluid position there was a new cabinet almost every year, and if it was usually led by Depretis, this was only because of his superior skill in avoiding the more controversial issues and in building up a personal majority by clever and not always scrupulous concessions to the local interests which dominated in each constituency.

In 1881–82 there was introduced a Franchise Reform bill which quadrupled the electorate to make a total of more than 2,000,000 voters. This had been part of the original "program of Stradella" with which Depretis had come to office in 1876. It had been generally recognized that the suffrage should be extended along with the gradual growth of education and economic prosperity. Even some of the conservatives agreed with this, in the hope that the middle and lower classes of society would prove a conservative influence (in which belief they were not far wrong). The age limit and the tax qualification being reduced, the vote was thenceforward possessed by all who had their education certificate or who paid at least 19 lire a year in taxes.

The same law also tried the experiment of abolishing the old single constituencies and introducing the *scrutin de liste* (single ballot) as a method of voting. It was intended thereby to secure a better representation for minorities; and enlargement of the electoral districts was expected to strike a blow at the local cliques which had simply managed to adapt the new techniques of democracy to perpetuate their control of municipal and village administration. The experiment failed, and the old methods were resumed in 1891. Another effect of the Franchise act in practice was to give more weight to the industrial north against the agricultural south and also to cities generally against the country districts. The results of this were not long in showing themselves during the severe agricultural crisis which set in after 1885.

The passage of this bill shows how Depretis was strictly adhering to the policy of moderate reform, defying the extremists on either side. His primary aim was to keep his amorphous centre majority intact and himself supported in power by a moderate consensus. Trimming his sails to the prevailing wind, he soon abandoned the radicals and made overtures to the centre right under Minghetti. By 1882–83 it became clear that a new government majority was in being and that *trasformismo* had effectively confused the old nomenclature of left and right.

Depretis thus remained in office more or less continuously until his death in 1887. The forced currency was abolished in 1883, when the treasury resumed payments in gold. Abolition of the grist tax came into effect in 1884, and a new cadastral survey was taken for a reform of the land tax. In 1885 a convention was made whereby the state railways were farmed out to three private companies for 20 years. Enlightened public health measures were passed, and a government commission of inquiry into the condition of agriculture at last brought to light some of the necessary facts upon which an agricultural policy waited.

This legislative program received the general support of parliament, for the various groups in opposition seemed to be incurably divided. On the right, Ruggero Bonghi and Silvio Spaventa tried to stop the disintegration of their party and to resist the dissolvent effects of transformism. On the extreme left there was likewise a small group of radicals, the *estrema*, round Agostino Bertani and Felice Cavallotti, which refused to be confounded in Depretis' policy of compromise and expediency. There was another right-wing group round Antonio di Rudini and Sidney Sonnino which, despite occasional protests, gave conditional support to the government. Then there was the left-wing "pentarchy" formed of Crispi, Nicotera, Cairoli, Giuseppe Zanardelli, Alfredo Baccarini and their several clients, who vociferously claimed that Depretis had unscrupulously abandoned his former party but who then showed that they had nothing to learn from him when it came to tactical alliances in the struggle for power. When Depretis formed his last cabinet in 1887, Crispi and Zanardelli were among its members, despite their recent vilification of the irresponsible financial policy of their new colleague Agostino Magliani. The "wizard of Stradella" had so confused every issue that almost everyone had come to accept transformism. It appeared to be the only method of government which could transcend the bitter personal animosities and the almost anarchical individualism which typified the Italian parliament.

Crispi, to 1891.—The death of Depretis in July 1887 brought to the premiership the far more energetic and bellicose Francesco Crispi, who typically combined headship of the government with the two most important departmental posts, those of home and foreign affairs. Despite his former criticism, Crispi tried to continue with the transformist technique. But his uncompromising dogmatism, his personal churlishness and his impetuousness in action created opposition right and left. Where Depretis had been wont to "open his umbrella" at the first sign of a political storm (this had been his own description of his attitude), Crispi plunged headlong into any controversy; and his ability and enormous self-assurance usually carried him through to victory. Of all the pre-Fascist politicians, this was the man whom Mussolini most admired. He was at once the Jacobin reformer, the autocrat who concentrated all power in himself and rode roughshod over other ministers and even over the constitution itself, and the imperialist who believed fervently in the expansion of Italy and in its mission in Africa. It was unlikely with such a man that domestic politics would continue for long on the same even keel as with his predecessor.

Crispi was soon trying to patch up a reconciliation with the church. He knew the prestige that would accrue from healing the breach between Quirinal and Vatican, and he would have welcomed the aid of the church in his campaign against the Socialists at home and the heretic Ethiopians abroad. Here he met a reverse, for Vatican circles were still frightened that conciliation would expose the pope to suspicion of being unduly subject to Italian political influence and were anxious to demonstrate that he was more Catholic than Italian. Crispi was personally something of a freethinker. After this rebuff he reverted to his former anti-clericalism, and proceeded to nationalize most of the numerous charitable institutions owned by the church.

Crispi's ministry of 1887–91 was marked by a number of liberal reforms, especially the adoption of Zanardelli's new penal code which abolished the death penalty and made it easier for individuals to secure redress against the administration. A Municipal Franchise act widened the suffrage for local elections and gave greater responsibility to elected councils in local government. Crispi also introduced reforms in prisons and public health. Gradually, however, he became corrupted by power and began to think that Italians both needed and would appreciate something more dictatorial—or at least a chancellorship on the Bismarckian pattern. Faced with the problem of making parliament work without the aid of well-disciplined parties, he improved upon Depretis' methods, and while choosing his ministers from both right and left, often pushed through his reforms by arbitrary means or else acted on his own initiative before asking parliament for a retrospective bill of indemnity. Any opposition to himself was regarded as simply factious and irresponsible.

Crispi was his own foreign minister and a bad one. Italy's only hope of asserting influence in Europe was for France to be restored into a better balance with the Central Powers. Yet Crispi took animosity against France to absurd lengths and ostentatiously paid several obsequious visits to Bismarck in Germany, seeking to profit from any future German victories and so inciting his ally on to war.

Instead of opposing Austria as the old school of nationalists had done, he went out of his way to earn its good opinion. He proclaimed the existence of Austria-Hungary to be a necessity for Italy and angrily dismissed his colleague Seismit Doda, the minister of finance, for having failed to protest against irredentist speeches delivered in his presence at Udine. Crispi had convinced himself that Italy was a powerful country which had nothing to fear from war and therefore did his best to pick a quarrel with France. Some of the wilder politicians had been advocating a "bath of

blood" as a test of national virility; before long Crispi was to satisfy their wishes to overflowing in Abyssinia.

It was typical of the parliamentary situation that although Crispi, using every means of pressure, obtained a large majority in the elections of 1890, he was unexpectedly defeated by a vote in Jan. 1891. The slightest point served to reshuffle the many splinter groups in and out of the government, and on this occasion a tactless outburst about the supine foreign policy of his predecessors sufficed to upset him.

A man of such positive opinions could not but have made many personal enemies. He had divined and exploited the general wish in the country for prestige and national greatness and the desire for a government that would be not lax but active and forceful. At the same time he had underestimated the sensible caution of the governing classes, their alarm at his expenditure on military provision, their distrust of the promise of economic gain from colonial expansion, their irritation at his ruthless and dictatorial methods. People saw that he was dividing the country in two and provoking a dangerous restlessness among the poor. And his tariff war with France was proving to have been as unnecessary as it was disastrous.

The Economic Crisis After 1887.—Italy's repudiation of the French commercial treaty and its sudden conversion from free trade to protection mere partly responsible for the severe economic depression of these years from 1887 to 1891—which in turn was to have serious political repercussions. The construction of railway routes through the Mont Cenis and Brenner passes and thence all over Italy had exposed Italian farmers and industrialists to increasing foreign competition and to the price fluctuation of a wider market. At the same time. the triumph of steam navigation was bringing much cheaper freight charges, and this favoured the large-scale import of grain from America and Russia where it could be grown cheaply.

As a result there was a collapse of prices in the 1880s in response to which both industrialists and agriculturalists were loud in their demand for government protection. In particular the steel industry, always rickety because of the absence of fuel and raw materials in Italy, pressed the government to annul the commercial agreement with France and to make the country more independent of foreign supplies. This argument naturally appealed to a man like Crispi who wanted a strong domestic armaments industry and had a *parti* pris against France.

The results of this policy were not long in showing themselves. Complete self-sufficiency was of course unattainable, but any approach to it necessitated an increase in uneconomic and often inefficient production. By the imposition of heavy tariffs on imported metal, domestic consumers were made to subsidize the profits of a parasite industry. Moreover, political corruption became unbridled as the industry bribed deputies and newspapers to maintain this high level of protection.

Worse still, the increase in production from the new factories at Terni and the old workshops along the Ligurian coast had reached a point by 1890 when it exceeded any demand except on the hypothesis of war; and Crispi's belligerent foreign policy received all the more encouragement. The inefficiency of government protection can be judged from its both delaying the switch over in shipbuilding to the use of metal hulls and steam and keeping a wholly disproportionate area sown with cereal crops for which the land was unsuited and in which it gave only a minimal yield. Some protection was no doubt necessary, but the excess to which it was taken was damaging.

The political implications were as unfortunate as they were unforeseen. Instead of being forced to accept Italian conditions in negotiating a new commercial agreement, France easily turned to Algeria for wine and to the far east for silk, and these two staple Italian industries never recovered the ground thus lost. France had been Italy's best customer, taking about 40% of its exports; but these now came to a temporary stop. Southern agriculture received a crippling blow in order to pay for benefits reaped by northern industry, and the consequent increase in food prices took a great number of people below the starvation level, with disastrous political results. Ten years earlier the occurrence of the vine disease Phylloxera in France had led to a great expansion of viticulture in southern Italy; but now, just when the new vines were beginning to come into cultivation, most of southern Italy was turned into one vast depressed area, and before long rebellion was to break out openly.

This economic breach with France began in 1888, and though Crispi was obliged to climb down a little after 1890, the severance of relations had by then led to a heavy withdrawal of French capital. This was in part responsible for the collapse of certain important banks. There had latterly been much overspeculation in building and industrial ventures. and the banks had allowed far more credit than the law allowed. When signs of a financial crack began to appear in 1889, Crispi at first did nothing to halt this inflation of credit but rather encouraged its continuance, fearing the unemployment which would result from a contraction and giving undue weight to the advice of some of the financiers implicated. **A** secret report was written for the cabinet by an investigating committee under Senator Giacomo Alvisi. Though it was not published. it was later known to have revealed serious irregularities. The six banks of issue had abused their rights and by "favour loans" to politicians had come to wield considerable political influence. Bernardo Tanlongo, the director of the Banca Komana, had not only maintained an illegal circulation but had even printed false banknotes to the value of 40,000,000 lire. But far several years more all this remained concealed.

Rudini, 1891.—When Crispi fell before a hostile vote in 1891, he was succeeded from Feb. 1891 to May 1892 by Antonio Starabba, marquis di Rudini, who had led one group of the right ever since Minghetti's death in 1886. This signified the return to a milder and more conservative government. even though the state of parliament forced Rudini into a transformist coalition with Nicotera's faction on the left. Crispi's megalomania now gave way to retrenchment both at home and abroad. Military expenditure was decreased and the finances were thus reduced into better order. The new cabinet was also less anticlerical and more ready to consult parliament than its predecessor. Parallel with negotiations to renew the triple alliance in 1892, there was a noteworthy resumption of friendship with France and Russia; and the campaign for economic self-sufficiency was mitigated by the signature of commercial treaties to open up foreign trade. Despite all this, the parliament was still that elected under Crispi, and after a hostile vote Rudini resigned. His immediate successor was Giovanni Giolitti, a former colleague of Crispi, whose first ministry lasted from May 1892 until Nov. 1893.

Giolitti, to 1893.—Giolitti was a Piedmontese who had come to power by way of the civil service. Like Depretis he was first of all an administrator. His primary object was wherever possible to remain neutral in political differences, letting events take their natural course and so preserving tranquillity in the state at a difficult moment, while allowing new ideas and new ways of thinking to have free play and to usher in a period of progressive reform. Eventually, in the period from 1903 to 1914, Giolitti was to be the dominating figure in politics, and his skilful management of the elections of Nov. 1892 already gave a foretaste of his quality; but this time he came to grief over the question of the banks.

The Bank Scandals.—The scandals indicated in Alvisi's report (see above) were suddenly exposed when a copy of this secret document came to light in Dec. 1892. Giolitti was forced to arrest Tanlongo, whom he had just nominated to the supreme dignity of the senate. Crispi and Giolitti still tried to prevent a public inquiry, for this might damage Italian credit abroad as well as their own reputations. Rut the collapse of one bank after another made it impossible to conceal matters any further. A parliamentary committee of seven under Antonio Mordini had eventually to inquire into the condition of the banks of issue. Its report, read to the chamber in Nov. 1893, established that the two preceding cabinets had been aware of serious irregularities committed by Tanlongo and others; that Tanlongo had heavily subsidized the press; that a number of deputies, including several former ministers, had received from him "loans" of a considerable size Crispi and Giolitti were both found to have had financial dealings with the bank and to have been guilty of grave errors of judgment if no

worse. The air was cleared, the situation was shown to be not quite so bad as some had feared, and suitable reforms were introduced forthwith to make a recurrence of such irregularities unlikely; but the revelations forced the resignation of Giolitti, and he felt compelled to leave the country for a time.

The Sicilian *"Fasci," 1893.*—Giolitti's first experiment in the management of parliament had broken down, for he had not yet learned Depretis' technique of how to keep many groups in common harness. The nationalists disliked his truckling to France when in Aug. 1893 some Italian workmen were killed in a riot at Aiguesmortes. The landowners resented his refusal to take arbitrary action against unrest in Sicily. The contraction of the French market for Sicilian produce, the devastation wrought in the vineyards by Phylloxera and a diminution in the sulphur trade had combined to produce in Sicily a discontent which led to the organization of the peasants into groups known as fasci. Giolitti had refused to dissolve these workers' unions. He had further annoyed the conservative landowners by his advocacy of higher taxation for the rich. They therefore chose to regard him as a dangerous revolutionary who was undermining their social position in collusion with the Socialists; and so they successfully worked for his supersession in office by Crispi, despite the latter's inculpation in the bank scandals.

The peasants who formed the vast majority of the Italian population had not yet become politically class conscious, although their social revolts had punctuated and sometimes contributed to the course of political development during and after the Risorgimento. Their poverty was extreme, and their condition of life became unendurable in years of bad harvest or trade depression. No politicians had bothered much about their lot. Mazzini and the old school of radicals had been more concerned with political than with social regeneration. The Socialist Carlo Pisacane (d. 1857) had been an isolated figure. Then, after the experience of Mikhail Bakunin's revolutionary anarchism, a workers' party had been formed in 1882, in which year Andrea Costa entered parliament as the first Socialist deputy. But the early Italian Socialists had been mostly intellectuals like Antonio Labriola and Filippo Turati. They had also thought of the peasants as a conservative rather than a revolutionary force and had concentrated their attention on the industrial artisans who were multiplying rapidly during the great industrial expansion of the 1880s.

Contrary to the belief of Crispi and his friends, the Sicilian outbreak of 1893 had had little connection with organized socialism. It was rather a hunger rebellion, a protest against the local octrois on food through which the poor paid more than their fair share of the expenses of local government. Once again, as so often in the course of the 19th and 20th centuries, the peasants marched to occupy the large estates or latifondi. The landlords were usually absentee and few of them had done much to improve these scantily cultivated lands; frequently they had usurped the communal lands and so deprived the peasants of the old rights of grazing which had been part of their livelihood. The clash between rebellious peasantry and the authorities in 1893 was in part the result of deliberate provocation by the landowners, who saw in agitation and agricultural strikes a threat to their own prosperity. Crispi recognized in the situation an ideal opportunity to accuse Giolitti of weakness and to rally conservative opinion by magnifying the danger into a major threat of Socialist revolution. This false scare incidentally was used to prevent a proper debate on Mordini's report about the bank scandals (to the great relief of many politicians) and allowed Crispi himself to appear in his favourite pose as the strong man who alone could restore order.

Crispi, 1893–96.—On Giolitti's resignation, the king had first asked Zanardelli to form a government; but, disliking Zanardelli's proposed cabinet, he then put this task into the eager hands of Crispi in Dec. 1893. The fasci were suppressed, and martial law and military tribunals were employed to restore order and send some of Crispi's opponents to the penal islands. Where parliament proved refractory, legislation was enacted by royal decree. The Socialist party was dissolved. An attempt to raise the question of Crispi's complicity in the bank scandals was then quashed by the sudden closure of parliament. Crispi ruled without parliament for almost half a year. After that, elections were held in May 1895 and suitably managed to give the administration a large majority. Crispi's policy of authoritarian government at home and imperial expansion abroad received a fillip which was shortly to prove disastrous both to Crispi and to Italy.

Defeat in *Abyssinia.*—In 1882 Depretis had declared Assab on the Red sea to be a crown colony; but he had then, against Crispi's advice, refused the offer of Great Britain to assist in the occupation of Egypt. The left-wing liberals agreed here with the irredentists and even some of the Milanese industrialists that colonies were an expensive luxury which Italy could not afford. Unfortunately, considerations of prestige and national dignity were thought by others to demand a forward colonial policy. Once the first settlement had been made, moreover, its defense required still further expansion into the interior, and chance conflicts with local tribesmen were soon followed by the dispatch of punitive expeditions. Pasquale Mancini hoped that "in the Red sea we shall find the key to the Mediterranean"; and in 1885 he occupied Massawa. As this was one of the trade outlets for Abyssinia, the move brought down on Italy the antagonism of the negus John and of Alula, ras of Tigre. Certain "frontier incidents" led to a clash in which Alula with greatly superior numbers overwhelmed a force of 500 Italians at Dogali (Jan. 1887). Crispi declared that this could not go unavenged, and preparations were accordingly made for a larger expedition.

From his original distrust of colonialism, Crispi had changed into an exaggerated imperialist. On the death of the negus John in 1889, he backed Menelek, king of Shoa, in a war of succession against John's son Mangasha. A treaty was signed with Menelek in May 1889 at Uccialli, the Italian text of which gave the Italians the illusion that they possessed an acknowledged protectorate over Abyssinia. It also agreed to an enlargement of the original Italian colony, which in Jan. 1890 was given by royal decree the new title of Eritrea. In 1891–93 the governments of Rudini and Giolitti had retreated a little from this aggressive attitude, but Crispi's resumption of office in 1893–96 witnessed a further penetration into Tigre. In July 1894, Gen. Oreste Baratieri captured Kassala from the dervishes. In Eritrea, the French Lazarist missionaries were expelled and replaced by Italian Franciscans. Aduwa was occupied in 1895.

Serious disagreements had existed in the cabinet and war office over this extended occupation. Financial stringency forced Crispi to stint supplies and to urge Baratieri to make the territories pay for their own conquest. Meanwhile the new negus was forced into a common opposition with the ras of Tigre and with the dervishes. In Dec. 1895 Menelek destroyed an Italian column at Amba-Alagi, and only then did the Rome government realize the incompetence of Baratieri and decide to replace him. Hearing of this, the unfortunate general precipitated a larger engagement to retrieve his reputation and, after gross tactical errors, was completely routed with 6,000 men at Aduwa in March 1896. To make matters worse, in a public communiqué he threw the blame for defeat upon his troops. His own subsequent court-martial rather showed up his personal responsibility and that of the government which had chosen him and directed the campaign.

The news of this defeat came as a cruel blow to a public opinion which had been indoctrinated by Crispi in an exaggerated view of national strength. This was the penalty for handing power over to a strong man who treated all criticism of himself as unpatriotic. It was also a commentary on the Italian parliamentary system for failing to produce a powerful party in opposition which could focus discontents and place an alternative policy before the country. The elections of 1895 might have been interpreted as showing that Italians were glad to have a strong man who knew his own mind and could cut through the interminable criticism of factious groups in parliament. If so, the electorate had its deserts. Crispi had taken too much on himself and had been able neither to stand back and see where his policy was leading nor to look after the executive details. He tried hard to put the blame on the military, so that the king would confirm him in office; but the king had more sense. Troops were withdrawn from Abyssinia, an indemnity was paid to the negus and Kassala ceded to Great Britain.

Rudinì, 1896–98.—A new cabinet was formed in March 1896 by Gen. Cesare Ricotti-Magnani, who, however, made over the premiership to Rudini. This leader of the moderate right introduced his own brand of transformism once more, by making an alliance with the radical left of Cavallotti. An amnesty was accorded to those involved in the Sicilian outbreak. The liberal Zanardelli was brought in to strengthen the cabinet. and Visconti-Venosta was once more persuaded to take over the foreign office after an interval of 20 years. A *rapprochement* with France was the natural corollary of this latter appointment, and the recognition of the French position in Tunisia put an end to 15 years of tension. In Eritrea Ferdinando Martini inaugurated a period of relative quietude and prosperity. Crispi's policy was everywhere reversed.

But social unrest, far from abating, had rather grown as a result of Crispi's rule of martial law. It needed only another rise in the price of bread, and disturbances began to spread. The elections of May 1897 significantly strengthened the Socialists and the radical and republican groups that with them made up the parliamentary *estrema.* The Italian Socialist party had met for its first conference in 1892 and had laid down a program which refused all idea of co-operation with a nonsocialist government. Rudini took alarm at this parallel growth of economic distress with political insubordination, especially after the outbreak of mob rioting during May 1898. Martial law was proclaimed in Milan, Florence, Leghorn and Naples, and one military officer ordered the use of cannon in the streets of Milan. There was much loss of life. Military tribunals then imposed severe sentences. Universities were closed; thousands of Catholic and Socialist papers and associations were suppressed on the supposition that they were guilty of inciting to revolution.

Pelloux.—Indignation over these panic provisions led to Rudini's defeat in parliament in June 1898, and the king summoned Gen. Luigi Pelloux to replace him. Measures were introduced to give the administration greater freedom to suspend the ordinary constitutional guarantees of popular liberties whenever it was thought necessary in the interests of order. As these met with opposition from the left, Pelloux proclaimed them to be law by simple royal decree. The Socialists met this by the method of parliamentary obstruction, the only possible rejoinder to which was a proposal to reform the standing orders of the chamber so as to make it permissible for the speaker to cut debate short. In June 1899 discussion on emendation of the standing orders was arbitrarily cut off and a vote called. When the Socialist deputies overturned the voting urns they were imprisoned, and parliament closed. The courts, however, declared Pelloux's decree law unconstitutional and void, and when parliament assembled again the opposition deputies walked out of the house in protest. Pelloux thought it better to appeal for a verdict to the country and when the elections turned against him in June 1900 he resigned.

This conflict had narrowly averted the danger of a modification of the constitution in an authoritarian sense. It had taught the various groups of the *estrema,* including the Socialists, to work together; and with them were now associated the so-called constitutional left of Zanardelli and Giolitti. Very rarely indeed in Italian history has it been possible for such a common alliance of groups to be formed at a critical moment with a common policy of opposition and to present the electorate with something like a clear choice. Yet the narrowness of the victory had exposed a dangerous weakness in the parliamentary system. The bank scandals had already weakened people's confidence in parliament; so had the practice of obstruction, the quick succession of insecure governments, the readiness of the house to abdicate before a parliamentary dictator who alone could "get things done," and the evident malpractices in the conduct of elections. Important doubts about the nature of parliament were being raised by responsible liberals like Ruggero Bonghi, Gaetano Mosca and Sidney Sonnino, and suggestions were made that the king's authority might be increased, so that the ministry in power should not be responsible to parliament. Pelloux's failure momentarily removed this possibility; but many people had had their faith shaken in liberal democracy, and when the opposition groups fell away again from their common front there was always the danger that another Crispi or Pelloux might find it all too easy to upset parliamentary government altogether.

Saracco.—Some of the responsibility for what had happened fell on King Humbert, who, although he had not played a very active part in the politics of this stormy decade, had not advanced his reputation as a constitutional monarch and had on occasion actively intervened on one side of the current political dispute. A few weeks after summoning the elderly senator Giuseppe Saracco to succeed Pelloux, the king was assassinated by an anarchist, Gaetano Bresci, at Monza in July 1900. The deed was stated to be in revenge for those who had lost their lives at the hands of the authorities at Milan in 1898. Humbert was succeeded by his only son, Victor Emmanuel III. The new king was less popular than his father; but he was not the sort of man to carry out Sonnino's plan to reinforce the royal prerogative and began his reign as a model constitutional monarch.

Giolitti, 1901–05.—Saracco had been chosen as premier, like many of his predecessors, without much regard for the balance of opinions in parliament or in the country. His defeat in Feb. 1901 gave Victor Emmanuel the chance to restore confidence and tranquility by bringing in the left-wing liberals under Zanardelli with a broad but essentially liberal cabinet. The strongest man in it was the minister of the interior, Giolitti, who in 1903 succeeded Zanardelli as premier.

The chief problem these men had to face was that of the growing labour unrest, which Crispi and Rudini had failed to subdue by repression and martial law. Giolitti and Zanardelli had strongly championed the rights of parliament against the "exceptional laws" which Pelloux had tried to pass. They also maintained that the conservative imperialists were far more a peril to social and political stability than were the insurgent poor or the Socialists. They believed that the country would only settle down if a new equilibrium was achieved which gave the working classes a greater stake in the nation and a greater share in its prosperity. The rich had so abused their power, said Giolitti, that "we have a large number of taxes paid predominantly by the poor, but not a single tax that is exclusively on wealth as such." He therefore asked for more social justice, being confident that in the long run this would add greatly to the wealth of the community and that it would turn would-be rebels into defenders of social order. Henceforth labour unions were to be encouraged instead of prosecuted, and the government was to remain neutral in strikes so that wages as well as profits might find their own level.

It was a symptom of the advance in industrialization that the years after 1901 saw such a wave of strikes. Agricultural unrest still continued, as the peasants attempted to obtain better contracts with landlords or to resume former rights over enclosed common land. The drift of workers to the towns or overseas had a gradual effect in putting more bargaining power in the hands of the better-placed agricultural workers and in getting for them wages nearer to those current in the new centres of industry. Among the town artisans, however, strikes were even more common, so that Giolitti's theory was soon put to a severe test.

Naturally the Socialists exploited these grievances to the full and tried to organize labour leagues wherever possible. But from the first the Socialists were divided into a number of factions and so never constituted such a danger as their numbers and doctrines might have suggested. A revolutionary wing was led by Enrico Ferri, advocating uncompromising class warfare, while the moderate Riformisti represented by Leonida Bissolati-Bergamaschi were ready to ally with the democratic liberals. It was the aim of Filippo Turati to keep both these wings from open breach, and at the Socialist congress of 1900 he secured a compromise whereby the objectives of each were approved as a maximum and a minimum program for the party. As the minimum program included such aims as the amelioration of wages and conditions of work, Giolitti saw enough common ground there to try and attract the Riformisti away from their friends and into the government coalition. His concessions to the Riformisti were thus not just a sign of weakness (as his enemies said) but part of a larger plan to divide the party and to weaken the syndicalist, anarchist and

revolutionary factions inside Italian socialism. The party congress of 1902 marked the temporary triumph of the Riformisti, and this gave him encouragement.

At the same time Giolitti remained firm with the extremists and he showed that he could break a strike wherever he thought it was irresponsible or merely political, or wherever it affected public servants. Early in 1902 the employees of the Mediterranean railway threatened to strike for the recognition of their union and for greater security in employment. As this might have paralyzed the whole economic life of the country, the government called out all the railwaymen who were army reservists. In 1903 the Socialists refused an invitation to join the cabinet, but the fact that Giolitti made them the offer was significant. In the same year Ferri became editor of the party paper Avanti and ousted the Riformisti from their position of leadership. Another alarming symptom was the appearance of the Syndicalists, who proclaimed themselves opposed to all legislative parliamentary action and who favoured only direct revolutionary propaganda. In Sept. 1904 a general strike was proclaimed which spread to nearly all the industrial centres.

Giolitti saw that it possessed a frankly revolutionary character and so would lack some of the popular support which the ordinary grievances of the working classes evoked. Accordingly he gave the strikers full play, putting them in the wrong by his moderation and showing how ineffective was the general strike as a method of revolution. The strike fizzled out, and the feeling of reaction thereby generated against socialism was such that Giolitti was able to force a general election in which the extreme left suffered a minor defeat.

This was a triumph of political skill, just as the elections themselves were a triumph of administrative ability. By now Giolitti had learned how to keep a broad coalition in being and how to keep controversial issues as far as possible below the surface. His cabinet included several men from the right: Tommaso Tittoni, the prefect of Naples, as foreign minister and Luigi Luzzatti at the treasury. No sooner had his offer of an alliance to the extreme left met with a rebuff than he turned perceptibly toward the other direction. Zanardelli's project for the introduction of divorce legislation was thrown over in a new effort to conciliate the Catholics; and as a result the elections of 1904 saw some of the latter at last participating openly in politics.

This alliance with the Catholics was in the end to be an important access of strength; but the delicate balance thus contrived was not immediately stable, and by March 1905 Giolitti felt the need of retrenchment while he cast about for some new formula of cohesion. The railway workers had been practising a system by which they could obstruct and delay traffic without leaving themselves open to prosecution, and Giolitti's handling of the situation had met with much criticism. In order to escape further unpopularity, he made way for one of his own friends, Alessandro Fortis, as the next prime minister.

Fortis and Sonnino, 1905–06.—Some of the old ministers continued in office under Fortis. It was a colourless administration. Its most important measure was a bill for the purchase of the railways by the state. Haphazard enterprise had built many lines that were proving uneconomic to run, and it was generally agreed that only the state could foot the bill and deal with the railway strikes which were becoming so familiar an event. Fortis met considerable opposition from southern agricultural interests over the commercial agreement with Spain, which allowed the import of Spanish wine on favourable terms. In Feb. 1906 he fell, and the succession devolved on Sidney Sonnino and the right centre.

Sonnino had been waiting for this a long time. By now he had given up his earlier proposal that Italy needed a less parliamentary type of government, and people looked to him for a restatement of liberal conservatism within the limits of the existing constitution. His ministers included Luzzatti and Antonio Salandra from the right and beside them—by an incongruity now familiarized by long usage—two militant radicals from the extreme left, Ettore Sacchi and Edoardo Pantano. As Giolitti had won over a number of leading politicians from the right, Sonnino was forced to look far afield in order to make up a majority different from Giolitti's, and so a typical transformist gesture landed him with this unholy compact of irreconcilables. Ferri also decided to vote for Sonnino when he had refused to support the more liberal Giolitti. With such a composite majority it was unlikely that the government would last long. After three months, when it became obvious that Sonnino was far less able than Giolitti to manage labour strikes, the latter returned to power with another cabinet (May 1906).

Giolitti, Sonnino and Luzzatti, 1906–11.—Giolitti's third ministry had the unusually long duration of three years (1906–09). As before, it was mainly built up from the left centre, but Tittoni returned to the foreign office. It began auspiciously with the conversion of the public debt to 3½%, on lines already prepared by Luzzatti. Subsequent changes in the personnel of the ministry brought Pietro Bertolini over from Sonnino's party as minister of public works, and this tore another hole in the opposition alliance. When Gen. Ettore Viganb was succeeded by the senator Severino Casana, this was the first time that a civilian had ever been war minister. (It had been customary for the king to retain a specially close control over the service ministries as over the department of foreign affairs and often to appoint "nonpolitical experts" to direct them. Army generals had taken a special oath of obedience to the throne, and therefore frequently acted as servants of the king inside the cabinet, continuing in office from one ministry to the next. Indeed, Casana was quickly succeeded by another senior officer.)

This was a period of prosperity for Italy. For almost the only time in modern history, the annual budgets showed a favourable balance between 1900 and 1910, until another African war started the deficit again. Foreign trade doubled in this decade, wages rose, the general standard of life improved. Recognition of the southern question at last allowed the passing of remedial social legislation for the betterment of backward areas. The surplus agricultural labour which had depressed standards in rural districts was now taking to emigration overseas at the rate of 500,000 a year. This helped to raise wages at home, and the flow of remittances sent home by prosperous emigrants became an important item in the balance of payments. Meanwhile the development of hydroelectric power opened up new possibilities for Italian transport and industry, which had hitherto been crippled by the high cost of imported fuel. The Fiat company was formed in 1899 as a pioneer in automobile construction. By the concluding years of World War I it had become a great complex of highly modernized factories.

Meanwhile the relations between church and state began to show signs of change. Pope Leo XIII (1878–1903), although intransigent in word, showed much more political aptitude than his predecessor. His successor, Pius X (1903–14), was distinctly less insistent in his claims to temporal power, and his own political conservatism made him anxious that clerical influence should be felt in parliament to offset the advance of socialism. At the same time many prominent Catholics were trying to reconcile the church to the ideals of liberal democracy and even to vie with socialism in advocating social reform. From either angle it was now apparent that the refusal to recognize the loss of Rome had damaged both church and state; and since outside Rome the relations between clergy and local authorities had remained quite cordial and co-operative, many people on both sides argued that greater formal reconciliation was possible than the ultras had hitherto believed.

In local elections Catholics had always been allowed to vote, and it seemed only a natural extension when in June 1905 an encyclical practically abolished the non *expedit* and allowed more active participation by Catholics in national politics. The simultaneous breach between the Vatican and the French republic also made it more desirable to find a new lay ally and not to place every Italian in the dilemma of being either a good Italian or a good Catholic when the majority wished to be both. A number of religious institutions in the near east, formerly under a protectorate of the French government, were now placed under Italian protection. Giolitti also tried to make a compromise on the subject of religious education in such a way as to offend neither the Catholics nor the Freemasons and other anticlericals. At the elections of March 1909 more than a score of clerical deputies were returned, who

seemed to have forgotten about the temporal power and were ready to accept the lately anathematized monarchy.

In Dec. 1909 Giolitti's administration was defeated over a point of procedure, and Sonnino returned to office for a few months. In March 1910 Luzzatti succeeded with yet another hotchpotch ministry, Each of these short governments tried to outdo the other in reforms, hoping thereby to gain support enough to form a coalition that mas durable and coherent. But neither had the strength to carry them through, and it soon became obvious that they were only holding office on sufferance until Giolitti saw fit to return.

It was a current belief that Giolitti had resigned merely in order to run away from temporary unpopularity and was biding his time to watch political developments and intending to resume office at the first opportune moment. Those who had criticized his apparently weak handling of the strikes now had occasion to see that such men of the right as Sonnino and Luzzatti were equally powerless and that Giolitti's tactics might actually be taking the sting out of the *estrema*. In March 1911 Giolitti was summoned to form his fourth cabinet, which he made up for the most part of men who had served under Luzzatti. Once again he offered posts to the Socialists if only they would give up their maximum program and their tactic of nonco-operation with all bourgeois government. But in 1911 the extremists were recovering the control of the Socialist party which they had lost in 1908, and Turati decided that acceptance of Giolitti's offer might split the party beyond hope of recovery.

Foreign Policy, 1896–1911.—In the field of foreign affairs, the post-Crispi generation began to appreciate that the triple alliance had given Italy a false illusion of strength (which indirectly had led to Aduma) with little compensating support and assistance. Between 1896 and 1901 Visconti-Venosta therefore moved the country back into a middle position where it was courted by both Germsny and France and where its influence was consequently the greater. The triple alliance was renewed in 1902; but public opinion was no longer so favourably disposed toward it, and it was partially neutralized by written undertakings toward France. Victor Emmanuel III in Oct. 1903 visited Paris, and in April 1904 Pres. Émile Loubet returned the compliment in Rome. Meanwhile, the final rupture between France and the Vatican was also welcomed in Italy. French rights in Morocco were officially recognized, in return for recognition of an Italian sphere of interest in Tripolitania. An Italian note sent in Nov. 1902 gave a guarantee that the triple alliance was no longer directed against France. Another sign that the alliance was wearing thin was the independent understanding reached with Great Britain about interests in the Mediterranean.

Giolitti favoured this policy of good-neighbourliness and noncommitment. The triple alliance was again renewed in 1907 and 1912 but it was no longer an exclusive pact and, whatever it said on paper, was in practice to bind Italy hardly at all. On the contrary. Austria's petty·persecutions of its Italian subjects in the *irredente* provinces. support of the anti-Italian Slav elements on the Adriatic littoral and active propaganda incompatible with Italian interests in the Balkans as well as the anti-Italian war talk of Austrian military circles imperilled the relations of the two allies. A typical clash occurred in Oct. 1902 when the German students at Innsbruck rioted against the Italians at the university. In reply to this there was a renewed campaign of irredentism. Italian schools and commercial agencies were encouraged from Rome to form outposts of Italian culture and influence in Trieste and the Alto Adige (as South Tirol now came to be called).

Such was the position of growing tension when the Austrian annexation of Bosnia in Oct. 1908 upset the balance of power in the Balkans. Tittoni failed, moreover, to obtain the compensation explicitly allowed under the provisions of the triple alliance, apart from a tacit understanding that Italy could retort by the "pacific penetration" of illontenegro. The episode was a warning to Italy of what to expect from its ally, and led to the granting of greater credits for the army and navy. In 1909 an agreement was made with Russia at Racconigi to keep a wary eye on Austrian expansion in eastern Europe. In 1910 a new Nationalist party held its inaugural meeting in Florence, and its leaders Enrico Corradini and Luigi Federzoni began to reassert the old doctrine of expansion, antidemocracy and totalitarianism. These men were to link the period of Crispi with that of Mussolini. They welcomed war as an end in itself, as a test of national power and an example of virility; in domestic politics they were to ally themselves with those who wanted more discipline and fewer concessions in labour disputes. There was no lack of money to aid such a combination of causes. and their dramatic appeal to public opinion evoked a surprising amount of enthusiasm.

Conquest of Libya.—The nationalist movement soon concentrated its forces in advocating the occupation of the Turkish dependency in Tripolitania. Since the disaster of Aduwa there had been little that was spectacular to show in the colonial field—only an abortive expedition to China in 1898 and steady commercial exploitation in Eritrea and Somaliland. It was now argued once more that national self-confidence could only be restored by a successful venture in North Africa. No regard was paid to the even greater need for spending any available capital in the impoverished provinces of southern Italy and Sicily. Sentiment and prestige were held to outweigh all other considerations. Some people even deluded themselves into thinking that Tripoli was an area that Italians could settle and fructify.

Before long, Turkey became alarmed at Italian intentions and hence unwilling to allow further commercial concessions in North Africa without a guarantee of good conduct, which Italy was not able to supply. When the French took Morocco in 1911 and when Germany, foiled at Agadir, began to look farther east, it became apparent that Italy would have to intervene politically or else run the risk of losing its claims by default. Even Giolitti, anxious as he was to avoid foreign complications and expensive new responsibilities, could not afford to disregard the feeling concentrated behind the proposal to invade Tripoli. His majority in the house was imperilled. So without thinking twice or stopping even to make the preliminary diplomatic and military preparations that caution might have counselled, he provoked the necessary incidents and declared war.

The extreme left (including the Socialist Benito Mussolini) disapproved of this imperial venture; but otherwise public opinion was favourable enough. The war began in Sept. 1911 *(see* ITALO-TURKISH WAR), and in November Italian sovereignty was declared to extend over Tripolitania and Cyrenaica. The course of hostilities proved more difficult than had been expected. The rest of Europe was unfriendly and, while Austria placed a veto on the extension of fighting to the Adriatic and the Balkans, a serious diplomatic incident arose with France over the right to search vessels suspected of carrying contraband.

Peace preliminaries were finally signed at Ouchy in Oct. 1912, the sultan retaining only spiritual authority over the inhabitants of the annexed territories while Italy was given possession in North Africa and occupation of the Dodecanese Islands. But although Turkey thus acknowledged defeat, the indigenous Berbers carried on the war vigorously. Before long the Senussi hsd limited effective Italian control to a narrow coastal strip. Libya was yet to cost Italy dear. The expense of the war had again unbalanced the budget. In return for this, there was little increase in trade with North Africa or in settlement there. At home it had marked a significant victory for the parties that believed in violence, imperialism and authoritarianism. War had been declared and annexation proclaimed without the sanction of parliament, and the whole episode represented a decline in the standards upon which Giolitti had built his system of liberal government.

Giolitti's Domestic Policy, 1911–14.—Giolitti's last great reforms had been carried through in this period 1911–12. Luzzatti had introduced a scheme for extending the franchise, but Giolitti had defeated him by unexpectedly announcing his conversion to a much wider plan which in the end raised the electorate from 3,000,000 to 8,000,000 voters. Even the bulk of Catholics and conservatives nelcomed this, because they hoped that enfranchisement of the illiterate southern peasants would aid them rather than the radical left. In practice it was to help the transference of power from the old liberal ruling classes to new mass parties, whether Socialist, Catholic or Fascist.

Other reforms at this time included the payment of deputies, the government monopoiy of life insurance and a new Education act. The Coppino law of 1877 had nominally introduced compulsory elementary education; but the simplicity of avoiding laws and regulations in Italy had rendered it a dead letter, and almost half the people of Italy were still given as illiterate in the census of 1911. Luigi Credaro's act of 1911 was to meet with the same opposition of inertia; and though loans were offered at easy rates to local authorities for educational improvements, the communes were too poor and too lethargic to take them up.

One of the results of the Libyan war was to divide the Riformisti on the issue of pacifism, and this opened the way for the revolutionary faction to capture the Socialist party in the 1912 congress. Bissolati and Ivanoe Bonomi were expelled from the party for their approval of the government's African policy and formed a new group prepared to collaborate with the other constitutional parties in parliament. Turati stayed behind in the Official Socialist party; but he was now in a minority, and Benito Mussolini became editor of ***Avanti*** with an antidemocratic, intransigent "maximalist" program.

This split among the Socialists, together with the growing strength of the Nationalists and the entry of the Catholics into politics, made Giolitti turn slightly more toward the right. In Oct. 1913 the first elections were held under the wider franchise, and for these Giolitti made a compact which included Sonnino and the clericals. Since the extreme left would not join his majority, he had to strengthen himself in the other direction. The pact arranged by Vincenzo Ottorino Gentiloni earned him the support of the church, especially valuable in the rural constituencies; and although both the Radicals and the Socialists increased the number of their deputies to more than 70 each, the government did not at first seem to be in any danger. But the anticlericals, whether on the right or the left, took fright at this betrayal of the liberal position; and many others were offended at the scandalous methods by which votes were purchased or forged by the election managers. The defection of the Radical ministers from the cabinet early in 1914 then convinced Giolitti that he had better retire once again and wait for a more favourable moment to resume office.

Without realizing the fact, however, he had come almost to the end of his political career, and he was never quite able to reconstitute his majority. For more than a decade he had appeared to be a virtual parliamentary dictator. During this time the country had advanced notably in wealth and renown. Although Giolitti was to go down in history as a great corrupter of politics, in all probability the damage was done before he came on the scene, and his methods were not significantly worse than those of his predecessors. What he contributed was a competence in administration and a realism that saw the trends of the time and fell in with them. Many people were to look back on this as a golden age and to forget the premonitory signs of breakdown already beginning to appear.

World War I.—The events leading up to World War I found Italy in 1914 still officially allied to Germany and Austria. When in 1912 the triple alliance came up again for renewal, Italy had not dared to renounce it lest the act be taken as a positive affront to its former allies. Giolitti's government knew of Austrian intentions against Serbia in the Balkans, but did little to prepare the country for war and was no doubt hoping to invoke the clause in the alliance that gave Italy the expectation of compensations for any Austrian advance. Under the right-wing government of Antonio Salandra after March 1914, the marchese di San Giuliano continued as foreign minister with the moderately germanophile policy that he had maintained under Giolitti.

In June 1914 riots broke out at Ancona against this conservative government; a general strike was called, the peasants rose against the landowners and the revolutionary Socialists Mussolini and Pietro Nenni tried to turn the rising into an organized revolution all over Romagna and Emilia. Many towns were captured and run by the revolutionaries as autonomous republics, and only with difficulty did the troops and police restore order. One political motive behind the revolt had been a protest against conscription and against the bellicose nationalism that threatened to involve Italy in a greater and more costly war than that in North Africa. Acceptance of the implications of the triple alliance was likely to cause grave division at home.

It brought general relief when the Austrian declaration of war against Serbia was met by an Italian declaration of neutrality. Italy claimed that it was not bound by the alliance to take part in an aggressive policy or to fight against England; moreover it had not been consulted over the actions that precipitated the outbreak of hostilities. There was no thought at first of intervening with Great Britain and France; it was simply intended that independence of action should be reserved, and care was taken not to denounce the triple alliance in case future policy should dictate a claim for compensation from Austria in the Balkans as the alliance itself prescribed. The decision for neutrality was accordingly not left to parliament but was taken by an executive act that allowed Italy greater freedom of movement.

On San Giuliano's death in October, Salandra appointed Sonnino to the foreign office. One of his first actions was the occupation of the town and harbour of Valona on the Dalmatian coast. Peaceful penetration by Italy had been continuing for some while in this area, and there was thought to be a danger that Austria and Greece between them might spoil everything if Italy did not quickly stake out a territorial foothold. Occupation was also a countermove against the advance of the Slavs, which had lately been causing considerable preoccupation in Italy; it was also a pledge to hold against the possibility of victory by Austria.

At the same time, negotiations proceeded with Vienna over the compensations in the *terre irredente* which Austria might be prepared to surrender in payment for Italian benevolent neutrality. The "triplicists" were fairly numerous in conservative and diplomatic circles and in the army. The Catholics were firmly in favour of neutrality, because they disliked "atheist" France and Orthodox Russia, and their natural sympathies lay with Catholic Austria. Many people in Vienna were quite certain that Italian finances would not stand a war and thus thought that they could play for time in these negotiations. For them, the cession of territory to Italy was feared as a possible signal for the breakup of the whole Austrian empire; and Trieste in particular was indispensable as a port in the Mediterranean. Only too late, in March 1915, was some move made to meet Italian wishes, so as to prevent Rome from intervening on the other side.

By this time, feeling in many quarters was hardening in favour of intervention on the side of the Allies. The irredentists and the Nationalists saw that this was perhaps the last chance for completing Italian unity and affirming Italy's position as a great power. The democrats, Freemasons, republicans and Reformist Socialists were in favour of intervention out of sympathy with France against militarist and authoritarian Germany. As for Mussolini and the revolutionary Socialists, they abruptly changed from pacificism to the other extreme of bellicosity when they perceived how war might generate a revolutionary situation from which they stood to profit. Accordingly, Mussolini broke off from the Official Socialist party, resigned the editorship of *Avanti* and founded a new paper, *Il Popolo d'Italia,* which supported intervention.

Sonnino and Salandra were determined not to let the war end without trying to acquire at least a part of the Italian districts in Austrian possession and to secure a rectification of the frontiers of 1866 (which left Italy open to invasion). They had first demanded from Austria the Trentino, the Isonzo valley and a free hand in Albania. At the same time as negotiations were proceeding on these lines, the entente was approached to know what price would be offered by the other side for Italian aid. There was a danger that if it did not choose its partner quickly, the war might end soon without Italy's obtaining any advantage. On April 26, 1915, the treaty of London was concluded between Italy, Great Britain, France and Russia. In return for intervention, Italy was to receive the Trentino and all the Tirol up to the Brenner pass, Triesta, Gorizia, Istria and Dalmatia down to Cape Planka. Fiume was, however, not included. A week later, the triple alliance was at last denounced. All this had been done without reference to parliament or to public opinion and probably even without debate in the cabinet. There is little doubt that the majority of

the deputies agreed with Giolitti in advocating the continuance of a neutral policy as that from which Italy had most to gain. Giolitti knew at first hand the weakness of the armed forces and also believed that something could be obtained in the end from Austria in return for a simple and easy promise of nonintervention. But he dared not be too open in advocating these opinions for fear of weakening the government in its negotiations with Vienna. It came as a complete surprise to him and everyone that the king had dissolved a 30-year-old alliance and committed the country to war on his own executive authority.

Salandra was thus faced with a potentially hostile parliamentary majority as soon as the news of his act leaked out. So he put off the summoning of parliament and allowed free rein to interventionist demonstrations, bringing back Gabriele d'Annunzio from his exile in France for the purpose. Austria made a last-minute effort to offer some of the *terre irredente*. But Giolitti had done nothing to organize the opposition deputies to make criticism effective and was not himself in Rome. The king was also committed, and the king's influence on parliamentary votes was considerable. Mobilization proceeded, and the king refused to accept Salandra's resignation. When it finally met on May 20, parliament had only to ratify a *fait accompli*. Giolitti called off the struggle in order to save the national honour. Three days later Italy declared war on its ally of yesterday, and Salandra justified his action by invoking what in a celebrated phrase he called *sacro egoismo*.

Once it had voted full powers to the government, parliament played very little part during the rest of the war. The military leaders upon whom responsibility fell for planning the successive campaigns were severely handicapped by the lack of munitions and industrial capacity. The army had not yet recovered from the Libyan war. When expectations of an early victory began to recede, it also became clear that there were serious weaknesses in generalship and organization. On the Isonzo front the Italians had a decisive superiority in numbers, but the difficulty of the terrain, coupled with the fact that no strategic plans were ready for such a war against a recent ally, made progress almost negligible for the first year. Then in May 1916 the Austrian victories in the Trentino and on the Asiago plateau shook the cabinet, and in June the almost 80-year-old Paolo Boselli became prime minister. The new ministry was notable for little except that it included representatives of the Catholics and the Reformist Socialists. In Aug. 1916 Gorizia was captured by the Italians. Italy also at last declared war on Germany and so removed a source of friction with its other allies. In April 1917 an agreement was concluded with the French and British at Saint-Jean-de-Maurienne whereby in any future partition of Turkish territory the Smyrna area was to be assigned to Italy.

The strain of protracted war, the collapse of Russia and the grave privations at home had accentuated the feeling of depression in Italy. Enemy and neutralist propaganda contributed to this. The Socialist Claudio Treves coined a widely publicized phrase, "Next winter not a man in the trenches": and this, together with Pope Benedict XV's allusion to "the useless carnage" of the war, began to affect public opinion and the war-weary troops. On top of everything, Gen. Luigi Cadorna and his subordinate officers made certain serious military errors, and an Austro-German penetration at Caporetto in Oct. 1917 thrust the Italians right back into the plain of Lombardy on the Piave river.

The front was at last stabilized, British and French troops being hurried in to help. Cadorna was replaced by Gen. Armando Diaz. Boselli resigned in favour of Vittorio Emanuele Orlando, under whom Sonnino still retained the foreign office; and the radical Francesco Nitti was brought into the treasury. In the effort to repair the defeat, a magnificent response came from all sides now that the country was so obviously in danger.

In Jan. 1918 Pres. Woodrow Wilson published his fourteen points, and the Italians began to see how war aims to give autonomy to the peoples of Austria-Hungary and to rectify the northern frontier "along clearly recognized lines of nationality" would affect them adversely. But for the moment no protest was made, and potential differences between Italians and Slavs were buried in the effort to win the war. A Congress of Oppressed Nationalities was held at Rome in April 1918, and it presented to Orlando the so-called pact of Rome, which bore the promise of hopeful collaboration between both peoples. But this pact never received official sanction; and although Slav units fought on the Italian front, Italian ambitions were still directed to domination of the Adriatic and so meant inevitable conflict sooner or later with the Dalmatian populations.

In June 1918 another Austrian offensive was successfully halted on the Piave, and a final counteroffensive begin. While one Italian contingent was helping the Allies in Macedonia, Diaz won the victory of Vittorio Veneto at the end of October, after which an armistice was signed with Austria at the Villa Giusti near Padua on Nov. 3. In the whole course of the war Italy had lost between 400,000 and 600,000 men killed. It had been invaded and had suffered enormous damage and privations. It was not a strong nation, either physically or psychologically, which had to stand up to the strains of the postwar period.

The Peace Settlement, 1919.—In Feb. 1919 the Italian government presented a memorandum to the peace conference embodying and justifying its territorial claims. These for the most part corresponded to those agreed upon in the treaty of London of 1915, except that Fiume was also included. This represented a victory for the Nationalists, whose spokesman was the foreign minister, Sonnino. On the other hand, the so-called *rinunciatori* or renouncers were ready to give up Dalmatia, part of Istria and the Trieste hinterland, because they wanted at all costs to conciliate the Yugoslavs; while they claimed Fiume as Italian. some of them were even prepared to renounce the Alto Adige because of its German-speaking population; and Bissolati had resigned from the cabinet in 1917 when Sonnino had unexpectedly and arbitrarily declared the existence of an Italian protectorate over Albania. This division was fundamental and irreconcilable among Italian politicians and was even present inside the peace delegation. Bissolati resigned once again, and he was followed by Nitti in Jan. 1919. Sonnino, however, stuck to the treaty of London and was unmoved by the implications of the fourteen points or by the Yugoslav counterclaims up to the old Italo-Austrian frontier.

In Feb. 1919 the Adriatic question came up before the Paris conference, and these differences were brought out into the open. As no progress was made, Wilson published in April his famous appeal to the Italian people over the head of their government, setting forth his reasons for opposing the Nationalist claims. This appeal aroused considerable indignation, and the Italian delegation withdrew in protest from Paris for a fortnight. In Rome Orlando received an overwhelming vote of confidence and found adherents even among the Socialists. But he then had to return to Paris for fear that his allies might conclude a separate peace. There he failed to make any advantage out of the fact that the other powers wanted Italy to sign the German treaty and accept the League covenant. Meanwhile he had allowed D'Annunzio and the Nationalists to stir up popular feeling for the acquisition of both Fiume and Dalmatia. He had hoped that this would act as a pressure on the Allies to make them yield; but in fact it only aroused in Italians a sense of frustration at his own inability to get results, and in June a defeat in the chamber forced him to resign in favour of Nitti.

The settlement finally achieved for Italy gave the nation a great deal, if not all, of what it had fought for. Wilson agreed to allow strategic considerations to outweigh "clearly recognized lines of nationality" in many places. Italy got the Brenner frontier, although this meant the inclusion of many German-speaking people in the two new provinces of Trentino and Alto Adige; also the great port of Trieste and a compromise settlement in Venezia Giulia and the Istrian peninsula which brought 250,000 Slavs under Italian rule. In Sept. 1919 the peace treaty with Austria was signed at Saint-Germain-en-Laye, leaving the question of Fiume and Dalmatia still open. This was both more and less than what the treaty of London had promised. The other Allies had been enabled to disregard this treaty on the grounds that the United States had not signed and did not recognize it, just as the agreement of St. Jean-de-Maurienne was given up on the plea that it had not

been officially ratified. Italy thus did not obtain a footing in Asia Minor: nor did it acquire any material compensation in Africa for the German colonies which passed to other nations as mandated territory. Italy's chief gain—and it was very considerable—was that its old hereditary enemy, Austria-Hungary, was no more and that the principal *terre irredente* had at last been redeemed.

There was, nevertheless, general dissatisfaction at these results, and the Nationalists were able to manufacture a legend that Italy had won the war but lost the peace. The fact was that once again, as before in 1870, the balance of power in Europe had been upset, so that Italy, which was still essentially a weak country, found it impossible to make its influence felt by holding the scales. The situation was rendered worse by the fact that Orlando and Sonnino proved unyielding and unrealistic in negotiation and refused to face the fact that Yugoslavia was also one of the victorious powers which had claims that could not be disregarded. The aim of security defeated its own ends when it made an enemy of such a neighbour.

Internal Politics, 1919.—The governments of Orlando and Nitti had many internal difficulties with which to contend. Demobilization brought with it the dismal prospect of unemployment. The financial situation was serious, and the budget statement presented in Nov. 1918 showed a deficit of 6,271,000,000 lire. The bread subsidy involved a huge expenditure and could not easily be abolished because of the steeply rising prices and their effect on the cost of living. Doles to the unemployed and subsidies to the farmers and to the industrialists added to this burden. The working classes were now well organized for political action, and politicians did not dare to risk their popularity by a deflationary policy. In Jan. 1919 the Partito Popolare Italiano was formed by some of the Catholics, with a more definite program and a more complete organization than the elder Catholic group. Its leader was Don Luigi Sturzo, a Sicilian priest, who advocated reforms of a Christian-Socialist character, including the expropriation of some of the larger landed estates for the benefit of the peasantry, with compensation to the landlords. His party also had a large trade-union following and went far toward winning the rural workers from the Socialist labour leagues. But the church itself, though trying at first to have nothing officially to do with this new party, could not avoid using indirect influence to make it more and more conservative; and especially when Pius XI succeeded Benedict in 1922 the Popolari found themselves progressively divided and undermined. Although they obtained 100 deputies in the elections of 1919, they never had the strength that their numbers warranted.

The Official Socialists, with 156 deputies after those elections, were the largest compact party in parliament, if not in the whole previous history of the Italian parliament. They also controlled the local government in more than one-third of the provinces. But they, like the Popolari, were frightened at formulating a definite program with which to confront the difficulties of the times, because any such program would threaten some vested interest and lose electoral support, and any precise wording of a policy threatened to split the party into two or more fragments. Playing for safety, they continually refused to take responsibility for positive action, preferring just to oppose every government in turn and rejecting every suggestion of a progressive alliance against the forces of conservative reaction. Yet they also continued to frighten middle-class opinion with threats of revolution, which apparently they had little intention of carrying out. The Socialist congress in 1919, against Turati's advice, voted for the expropriation of the capitalists, if necessary by violence, and for the institution of a soviet republic in imitation of Russia. As an earnest of their supposed intentions, a series of avowedly revolutionary strikes broke out in every trade and even in the public services. Small wonder that propertied men began to fear for their livelihood and looked about for someone to lead a counterrevolution. It was not appreciated that the Socialist movement was far too irresolute and divided to be dangerous. Ever since Mussolini and the Syndicalists had left the party before the war, it had adopted a pacifist and defeatist mentality.

The man who was eventually to be engaged by the counterrevolution was of course this same Mussolini. But in 1919, the year in which the Fascist party was inaugurated, he had not yet completed his *volte-face* from revolutionary, republican socialism to being the spokesman of conservatism and monarchy. His party program included such demagogic measures as the imposition of a capital levy, the confiscation of ecclesiastical property and an unusually large tax on war profits. In the elections of November, the Fascists obtained not a single seat. This failure helped convince Mussolini that there was little hope of power if he continued to follow the radicals in his party instead of the trimmers and the opportunists.

The strength of socialism and the existence of these two new parties, the Popolari and the Fascists. made the task of forming the customary government coalition exceptionally hard. There had been little previous history of highly organized, dogmatic parties in Italy; and in this new situation the necessary compromises inherent in Giolitti's system were difficult to achieve. The electoral law of Sept. 1919 had adopted the proportional system, whereby the voter voted not for a candidate but for a list. Sonnino and Giolitti had opposed this change, because the gainers would clearly be the Popolari and the Socialists, both of them being well organized and based on mass appeal. In the subsequent elections, Giolitti, Nitti and Salandra had gone on with their small, bickering groups instead of sinking their differences and rivalries in the interests of a liberal bloc with a common list in order to counter the unconstitutional objectives of the extreme left and right. This was to invite failure. Subsequently, in the new parliament, each of them in turn was to foil the others' attempts to form a government of the centre.

Fiume and the Treaty of **Rapallo.**—Meanwhile, fresh troubles had broken out at Fiume, which, as an Italian island in a Slav sea, was a natural danger spot, one moreover where D'Annunzio's propaganda had dangerously involved the national honour. Clashes between Italians and French troops induced an inter-Allied commission to recommend the importation of British police to the town, and this mas the signal for D'Annunzio to lead some mutinous soldiers in a piratical raid on the city. Public opinion had been led to believe that Fiume was naturally Italian, unreasonably snatched away from Italy by jealous allies at the peace conference. It was also feared that the trade of Trieste would languish if Fiume remained independent under some rival power, because they were rival ports for the commerce of central Europe. D'Annunzio captured the city in Sept. 1919 and ruled it for more than a year to the accompaniment of much posing and speechifying.

Nitti's government officially deplored this adventure; but with such an uncertain majority in parliament, Nitti did not dare use forceful measures to restore the authority of the state. Indirectly, if not also directly, he helped to keep the Reggenza del Carnaro in existence and used it as a bargaining counter to convince Europe that Italy had been badly treated and must be appeased if war was to be averted. Apart from antagonizing the Slavs, the result was to set an example of successful, unpunished illegality and to fan the flames of nationalist ardour still further. The men of Fiume and the techniques they had employed there were later to be of great assistance to Mussolini.

Nitti's policy was just to let the spirit of unrest wear itself out, regardless of the immediate danger to the country. Yet at the same time he annoyed the Nationalists by granting an amnesty to deserters and by advising army officers to go about in mufti and disarmed when off duty. When he created a force of royal guards to preserve order against a new outcrop of strikes and riots, this was strongly resented by the Fascists and Socialists, against whom it had been directed. Such was the combination of forces against him that in June 1920 he resigned.

This brought back Giolitti to power for his last and least effective term of office. His foreign minister, Count Carlo Sforza, had to meet certain troubles in Albania, where Salandra had established an Italian protectorate. The cost of this occupation had been considerable. and it had still not won over much enthusiasm in Albania itself. Armed conflicts were frequent, and the unpopularity of the whole venture now led to another mutiny among the Italian troops. Giolitti gave in to this, surrendered the protectorate and withdrew the Italian army. This infuriated the Nationalists. At

the Spa conference in July 1920 Italy succeeded in getting its share of the German indemnity raised to 10% and that of the Austrian, Hungarian and Bulgarian indemnities to 25%. An interim settlement was made with Turkey in the treaty of Sèvres, signed in August. Then in November the outstanding differences with Yugoslavia were settled in a conference at Rapallo. Italy at last waived its claims to Dalmatia, except for the town of Zara. A frontier was agreed which allowed Italy possession of the islands of Lagosta and Pelagosa. Both powers recognized the independence of Fiume. The Italian-speaking inhabitants of the territories assigned to Yugoslavia were entitled to opt for Italian citizenship; and full freedom of language, culture and religion was promised to Yugoslavs in Italian territory.

This settlement brought considerable gains to Italy, although the fact that any concessions at all were made to the other party rankled with D'Annunzio and his friends. By a secret clause, which soon became public property although Sforza denied its existence, Port Baros adjacent to Fiume was promised to Yugoslavia. D'Annunzio, the self-styled regent of Fiume, refused to recognize this treaty, and Giolitti was at last bold enough to send Gen. Enrico Caviglia to oust him. He surrendered at the first show of force. It was then agreed to withdraw Italian troops from Dalmatia and Fiume, although they remained in Fiume during 1921 since the town elections were considered to demand their presence. Not long afterward, Mussolini decided to upset this arrangement and recover Fiume for Italy.

Giolitti's Last Government. — The temporary settlement of Fiume and the agreement of Rapallo showed that Giolitti had a clearer idea than most others of the path that Italy should follow. In domestic affairs he aimed once more at a compromise policy in order to secure as broad an agreement as possible. But the war of class against class was by now too strong for him. Internal troubles were reaching their worst in the autumn of 1920, and there were industrial, agricultural and railway strikes in various parts of the country.

In September a serious agitation broke out in the metallurgical industries. The factory owners, most of whom had made large profits in the war, were alarmed at the signs of a slump and decided that they could not afford to yield to the demands of their employees. Strikes at the Romeo works in Milan were thus countered by a lockout. In reply to this, the Federation of Metallurgical Workers called on all the metalworkers in Milan to remain permanently at the factories without working. The Federation of Mechanical Industries then extended the lockout to the whole of Italy. The workmen responded by seizing a number of factories and trying to manage them on their own without the owners or managers.

This was the famous "occupation of the factories," which some held to be the supreme justification of the Fascist revolution. In fact it was a haphazard affair, not desired or planned by the Socialist party. Giolitti skilfully avoided using force, for this might have united the several factions of socialism and also would have played into the hands of those counterrevolutionaries who were stirring up social and industrial conflict in the hope of precipitating a showdown. By simply letting matters take their own course, he successfully showed at once the weakness of the extreme left and the hollowness of the alarm shown by interested reactionaries on the right. Unfortunately he went too far in his pacifism and did not always take action to repress actual hooliganism and the more and more frequent breaches of the peace. The Fascists and the red guards outdid one another in armed disorder; and private justice grew up to supplement the evident deficiencies of public justice. Mussolini publicly welcomed the occupation of the factories; but before long he saw that his best hopes of achieving power were to throw his lot in entirely with the reactionaries, instead of trying to curry favour simultaneously on all sides.

For the moment, in Sept. 1920, Giolitti intervened with an acceptable compromise by which the workers evacuated the factories in return for some concessions — their effort to manage the factories on their own had proved a hopeless failure. The centre of interest shifted to the country districts where the braccianti or landless labourers had always been on the verge of starvation and were now being driven by postwar conditions into a state where they had almost nothing to lose and apparently almost everything to gain by insurrection. Nitti had already been forced, in a decree sponsored by Achille Visocchi, minister of agriculture, to allow retrospective sanction to some of the forcible land occupation effected by the peasants in fulfilment of promises made during the war. Over large areas in Emilia and the Romagna the labour leagues had acquired great authority in local government and were sometimes beginning to dictate terms of employment to the landlords. The latter replied that, if these wage demands were conceded, they would not have enough income remaining to pay their taxes; and to show their temper they set about organizing armed resistance. The Agrarian Association of Bologna was particularly effective in the organization of armed squads, and the Fascists soon emulated the technique.

Property owners everywhere began to rally in defense of their way of life. For them Giolitti came to be feared as a man who desired higher income tax and death duties and allowed strikes to continue with impunity and an eight-hour day to be enforced in industry. At the same time his fixed idea of letting social forces find their own level unimpeded played incidentally into their hands; for when they really set their minds to it they could muster far more massed power than the Reds, especially when aided by the organizing genius and ruthlessness of a Mussolini. It was perhaps natural for the middle classes after the Russian Revolution of 1917 to fear revolution only on the left and not from the right. Giolitti himself had little idea that fascism was to be feared and rather hoped to make use of it as he had made use of Catholicism or socialism to suit his own purposes — in this instance to bring socialist ambition within bounds.

His policy of domestic nonintervention was soon bearing fruit. At Bologna the Red leaders had to fly for their lives where lately their word had been law. The town council was forcibly dissolved and the Fascists wrecked or burned down various buildings owned by the Socialists. Throughout the Po valley the Fascists proceeded to break the domination of the "Red baronies"; the revolutionary leagues which had controlled labour in that area were dispersed; and one Socialist town council after another resigned in fear or was dissolved.

Parallel with this there was a disintegration at Socialist party headquarters. A demand arrived from Russia that the Italian party should carry out its old "maximum" policy and expel all those tainted with the Reformist heresy. The reason given was that only by violent revolution and absolute submission to the orders of Moscow could socialism succeed. At the general congress of the party at Leghorn in Jan. 1920 a compromise resolution was adopted. Turati, Treves and the main trade-union body grouped in the Confederazione Generale del Lavoro (C.G.L.) showed that they were still prepared to collaborate in the parliamentary system and still wanted at all costs to keep the comprehensiveness of the party intact. The Communists (represented by 18 deputies) thereupon broke away, formed a party of their own and tried to assert themselves in what amounted to almost open civil war against fascism. The vicious circle of assassination and reprisal thereby received a new stimulus.

In this atmosphere Giolitti's policy of social neutrality did not work. The need to repair the great financial deficit was already forcing him to commit himself on many points where it might have suited him to keep silent. At the end of 1920 he had brought in legislation about the registration of bearer bonds, which was designed to diminish some of the general tax-avoidance then so prevalent; and this had seriously shaken the adherence to his majority of share-capital owners. It was furthermore the final cause of alienating the church and the Popolari, for bearer bonds had been a common method of evading the law against ownership of property by the church. Another much-criticized move was the abolition of the bread subsidy in Feb. 1921, for this made enemies of many Radicals and Reformist Socialists. Financially such a measure was inescapable; but socially it seemed inequitable, and the consequent rise in food prices added fuel to the growing class war.

Because of the insecurity of his parliamentary position, Giolitti

dissolved the chamber in April 1921 and held elections in May. Altogether misreading the situation, he made an electoral alliance with the Fascists and Nationalists, hoping that this would give him a majority, but such a one as would leave him master of his allies instead of their slave. Out of 535 seats, the Popolari increased their representation to about 108; there were about 123 Official Socialists, 34 Reformists and 15 Communists; there were 64 Radicals, 10 Nationalists and 35 Fascists; and the remainder was made up of nondescript liberals. The fact that there mere now 35 Fascists in parliament where the 1919 elections had returned none must be in part attributed to Giolitti's error. Incidentally, he had permitted the use not only of the usual government influence on elections by corruption and intimidation but also of violence and even a reign of terror in many areas where police were told to maintain the fiction of "nonintervention." To crown all. Mussolini and the Nationalist Federzoni at once passed over to the opposition in parliament. They attacked Giolitti for his support of the League of Nations, for the occasional radicalism of his domestic policy and for his continued belief in the methods of parliamentary democracy. As he had not obtained the requisite majority, in June Giolitti resigned.

Bonomi and Faeta.—From June 1921 to Feb. 1922 the prime minister was Ivanoe Bonomi, with a cabinet in which the Popolari were at first the preponderating influence. Bonomi, although a Reformist Socialist in origin, had never altogether exculpated himself from the accusation that as war minister under Giolitti he had connived at military stores' passing into possession of the Fascists. Under his government fascism continued its gradual process of building up a nation-wide party organization, comprising a mixture of every extreme, idealists and undesirables, republicans and monarchists, agrarians and former syndicalists, reactionaries and Sorellian or Blanquist revolutionaries. There was nothing new in such a mixture for Italy, except that it included few but extremists of one shape or another. What was new and bewildering was the competitive armed violence of Fascist and Socialist squads—in which the Fascists nearly always proved to have better resources, more arms, much more money and greater cruelty and ruthlessness.

In many areas the Socialists soon dared not show themselves and had to allow their houses, printing presses and party headquarters to be pillaged at will, being forced in the end to advocate nonresistance and invoke government aid for the preservation of law and order. Local Socialist administrations were expelled in one place after another, the popular vote being simply set aside as irrelevant. The trade-union organization was crushed piecemeal, and rival Fascist syndicates erected in the unions' place. Still the government stood aside, perhaps secretly glad that the largest opposition group was thus neutralized and expecting that fascism with its small group of deputies could be easily tamed when its work of destruction was complete.

Meanwhile Mussolini was playing his own game of transformism. Although he held some powerful cards, his position in parliament was still very weak. The Fascist party was by no means united on policy, and he was only one leader among many. It was necessary to trim his sails to each favourable wind and to manoeuvre both with other parties and inside his own party. Thus in Aug. 1921 he signed a pact with the Socialists (which later on he preferred to forget). It was intended as a test of strength, to see if his other colleagues would follow him, and perhaps in the hope that the two avowed revolutionary parties might make up their differences and overthrow the parliamentary form of government which both affected to despise. But the local leaders—Dino Grandi, Roberto Farinacci, Italo Balbo *et al.*—dug in their toes at this sudden and illogical change of front; and when the agrarian backers of fascism brought Mussolini to book he changed back again and tried to cover up his tactical error. The threatened split in fascism was healed before the liberals and Socialists could think of joining forces against him.

Attacked on all sides, the Bonomi cabinet resigned in Feb. 1922. A ministerial crisis lasted for almost a month, during which each parliamentary leader in turn declined to form a cabinet, believing that he could achieve nothing with parliament so divided and factious and would only lose his reputation in a useless cause. At last a nonentity was found—as in so many similar moments in the past—who was sufficiently colourless and pusillanimous to avoid any definite commitment and who thus obtained a bare majority. This was Luigi Facta, the last prime minister before Mussolini. In the next few months some achievement was registered in the reconquest of Tripolitania from the Senussi and in the international economic conference which opened at Genoa in April; but at home there was a continuance of industrial troubles, and another unpredictable shift among the parliamentary groups in July put Facta in a minority.

Once again, the country had no government at all for several weeks and the Fascist squads pursued their old course unmolested and unpunished. Nitti, Filippo Meda, Giolitti, Bonomi, Sturzo, Turati, Orlando, none of these was prepared to sink mutual differences and personal dislikes to give the country a strong government which was also liberal and constitutional. Each was waiting for a "more favourable moment" in which to resume office; each faction. moreover, was beginning to suspect that no cabinet would succeed in which Mussolini was not a partner—such was the impressiveness of Mussolini's character, the force of his propaganda and the evident weakness of the state authorities. Accordingly, a number. of groups entered into unofficial relations with him, to prepare the way for receiving office in a future coalition. Meanwhile Facta returned to his position as premier, because, although defeated, there was manifestly no other combination which would yet work at all.

On July 31 a general strike was called throughout all Italy by an unofficial committee of certain labour unions, proclaimed to be a "legalist" strike by Turati because its professed object was to affirm the authority of the state against the Fascists. This was thought to be the last weapon yet remaining to the left, and it was a futile one. It upset the general public and its ridiculous failure proved to be the ultimate confession of Socialist bankruptcy. Not even at this moment were the Socialists anything like united over aim or tactics. Mussolini, on the other hand, saw in this strike his great chance to show himself the defender of law and order, the only element of authority and power when the state itself was apparently powerless.

The Fascists and Nationalists therefore ordered a general mobilization and issued a manifesto calling on public servants and the workers "to shake off the yoke of the politicians by whom they were led" and giving the government 48 hours in which to prove its power and break the strike—"after which fascism will assume full freedom to supplant the state." This was an admirable opportunity for the Fascists to seize control of the administration of such major towns as Milan, Genoa, Leghorn and Ancona, where the Socialists were still entrenched, and so to open the road for the final march on Rome.

The Socialists had for years dominated the town council of Milan, which was the industrial capital of the country and its wealthiest and most populous city. The commercial classes there were naturally pleased when Fascists took the place of the strikers and restored the train services on which they were so dependent. Much pleasure was also given in the same quarters when on Aug. 3 a veritable invasion of the town ended in the burning down of the building where the Socialist paper ***Avanti*** was printed and when finally the town hall was occupied and the Socialist administration forcibly ejected. At Genoa the Fascists led a similar and equally successful operation against the port consortium which was largely under the influence of the Red dockers' union.

Instead of arousing violent indignation, these illegal actions almost seemed to put the state authorities in the wrong and the Fascists in the right, for public opinion was probably against the strike. They also discredited the Socialist movement and its leaders and caused further divisions and loss of morale inside the party. Above all they discredited the government, which had shown itself unable to deal either with the strike or with the criminal actions of the strikebreakers. The continuance of the widespread anarchy was a primary aim of Mussolini's, because the economy of Italy was beginning to recover after the immediate postwar years. Strikes were diminishing, the cost of living was evening out and trade was reviving. But it was imperative for

Mussolini to keep up the appearance that economic breakdown was round the corner. All this had been achieved for him by Socialist incompetence and intransigence.

The new coalition which Facta formed in Aug. 1922 contained some well-intentioned liberals but also some people who, if not actual traitors, were at least disloyal. Once again the weakness of the Italian system of government was revealed. In the first place it had no room for an organized opposition ready to focus discontent and ready to take office with a clearly expounded opposition policy for the country's choice. In the second place it represented a series of imprecise coalitions, all of which lacked a common denominator, none of which dared risk discussion or action on the most burning questions of the day. The problem of whether or not to crush fascism while there was still time would have split this particular cabinet and so mas never squarely faced. Yet the liberal ministers did not resign from it, for the principle of collective responsibility had never been precisely established.

The strength of fascism at this moment is difficult to assess. The full support of the government election agents had not enabled the Fascists to win more than 35 seats in parliament; and although they were becoming strongly entrenched in local administration, this was usually by intimidation and terror. In southern Italy there was said to be very little fascism until after Mussolini's forcible conquest of power. It had some influence at court through the queen mother Margherita and in virtue of the threat that the popular Emanuele Filiberto, duke of Aosta, would be put up as a Fascist pretender to the throne if the king proved unyielding. The agrarians and industrialists were naturally in sympathy with a movement which came to stand for strikebreaking, lower wages and substantial economic protection; demobilized pfficers and the educated unemployed were especially open to Fascist propaganda; many among the Nationalists and the Catholics fell for its more specious attractions; and disorderly elements at every level of society welcomed the violence, the plunder and the chance to work private grudges off with impunity.

Whether or not all this amounted to a strong numerical body of opinion, it affected many among the so-called governing classes. The fact remains that many of the self-styled liberal newspapers were coming to approve the punitive raids of the Fascist squads and gave moral support to the Fascist demand for political power. Salandra, Giolitti, Nitti, Bonomi, Benedetto Croce and Luigi Albertini (editor of the *Corriere della Sera)* either actively or passively assisted the momentary alignment of public opinion which made possible the final coup d'état—although they all later regretted the fact.

Rather than positive strength, it was the weakness of its enemies that made this coup possible. At the Socialist congress held early in Oct. 1922 the party split into two further groups: the Unitari or collaborationists round Turati, Treves and Giacomo Matteotti; and the uncompromising Massimalisti who remained to dominate the official body. The Bonomi Reformists. the Syndicalists and the Communists round Antonio Gramsci had already formed separate groups. As a result of this split, the C.G.L. broke off its alliance with the Socialist party and declared itself a nonpolitical body. Likewise the Partito Popolare was divided by conflicting tendencies, and the Catholic party was seriously weakened when Pope Pius XI enjoined the bishops and clergy to abstain from partisan political activity.

Not the least part of Mussolini's skill lay in the way in which he managed to retain the more or less grudging support of so many liberals at the same time as he openly advocated revolution and the supersession of parliament. At a gathering at Udine on Sept. 29, 1922, he made an important declaration in favour of the monarchy, thereby winning the favour of many nonfascists. The ostentatious abandonment of his earlier anticlericalism and republicanism was typical of the man; but instead of being read as evidence of his fundamental opportunism, it was taken as a conversion to orthodoxy which rendered him "safe." Paolino Taddei, the minister of the interior, advocated the taking of firm steps to stop illegalism in the provinces, but he was again and again overruled by his colleagues. Most of the ministers were now convinced that the ministry would soon fall and were eager not to offend Mussolini, so that they might be included with him in the coalition that would follow.

The "March on Rome," 1922.--On Oct. *24* another Fascist congress was opened at Naples, when the statements of Mussolini and his friends left no doubt that, if not allowed peaceably into the government, they would resort to force. A Fascist quadrumvirate was formed of Michele Bianchi, the former syndicalist who was secretary of the party, Italo Balbo, the commander of the armed *squadre,* Gen. Emilio de Bono and Cesare de Vecchi, while Mussolini retired to await events near the Swiss frontier. As mobilization of the *squadre* continued, all depended on whether Taddei would have his way and whether there would be any clash between the *squadre* and the troops. Gen. Pietro Badoglio, as well as Gen. Emanuele Pugliese who commanded the army units in Rome, guaranteed that at a word from the government they could restore order and crush the threatened insurrection. But Facta, probably from cowardice and incompetence more than from premeditated malice, refused to give precise orders and chose to make Fascist victory almost certain by proffering the cabinet's resignation.

The king did not immediately accept this resignation, and the ministry continued in office several days longer. The various liberal leaders were only just beginning to see from Mussolini's remarks at Naples that he would now be content with nothing less than the lion's share in any new coalition. Early on Oct. 28 Bianchi sent the government a virtual ultimatum, calling for its effective resignation, and this at last provoked Facta to resist. Proclaiming a state of siege, he ordered the military to use force wherever necessary. As the king had only the night before promised to support this policy if ever Facta thought it advisable, the proclamation was published soon after daybreak, and some observers thought that all would now be plain sailing. But the king had taken counsel during the night with Nationalist and Fascist sympathizers, and the suspicion had been implanted in his mind that the army might refuse to obey orders and that the duke of Aosta would be able to force him to abdicate. Accordingly, in a moment of aberration, he refused to sign the decree.

For the constitutional impropriety of this act there can be no excuse. The king was making a political decision in defiance of his ministers. He had decided to appoint a new government based upon a coalition of the extreme right, although this was composed of less than one-fifth of the elected chamber — there was Salandra who led a group of about 30 conservative deputies. and there were also the 3 j Fascists and 10 Nationalists under Federzoni. A great number of precedents existed for choosing a premier from a minority group. But in handing power over to people who gloried in murder and openly proclaimed their contempt of parliamentary institutions, the king was making a gigantic political error which cost his country dear.

For a time the king did not understand the implications of his action, and he asked Salandra to form a ministry. But Mussolini now knew that the king was an accomplice who had committed himself so far that he would not dare to gainsay fascism in anything. As a result, Mussolini, who had long since won Salandra's collaboration by secret hopes of support, now put his veto on a Salandra ministry, knowing that he himself was the only alternative. On Oct. 30 a sleeping-car brought Mussolini to Rome from Milan at the king's invitation, and the so-called "march on Rome" was over. The next day some of the Black Shirts were brought in from surrounding villages to give the illusion of an armed occupation of the city. It did not suit the future dictator to let people think that he had risen to power by almost normal constitutional methods.

First Years of Fascist Government. — With a sure revolutionary instinct the new cabinet was chosen to give the appearance of one of the old familiar coalitions. Apart from Fascists, it included two mar "heroes," General Diaz and Xdm. Paolo Thaon di Revel; a Giolittian, Teofilo Rossi; a Social Democrat, G. A. Colonna di Cesarb; two liberals, Giovanni Gentile and Giuseppe de Capitani; two Popolari, Vincenzo Tangorra and Stefano Cavazzoni. At long last stringent orders were given for the cessation of all acts of violence. Yet the Duce chose to remind the deputies how he might

have simply abolished parliament: he was determined to make it quite clear that it existed on sufferance and could not expect his government to feel responsible to it.

From what one can see, contemporary newspapers reflected a general consensus in their expressions of relief that the long reign of anarchy was over. Indubitably parliament had shown itself incompetent to produce efficient and liberal government. Even the deputies themselves were relieved to sense that there was to be an end to their bickerings, and only about 100 voted against the new government — probably these were just the Socialists. When Mussolini demanded full powers for a year to carry out what reforms he thought necessary, they approved by a vote of three to one what they had always refused to Giolitti and others. So doing, parliament assumed some share of responsibility for all the tragedy of errors which lay in the future.

For several years there was no overt establishment of dictatorship. Numerous precedents existed for government by decree and for the executive's replacing elected councils by nominated government officials in the towns. Only gradually were old methods and institutions changed, at the same time as each of the opposition parties was weakened and divided still further. It was a primary object that there should be no move which could provoke a combination to join in opposition and nothing which should alarm people unduly or make them think that a revolution had taken place or was taking place.

This incidentally gave time for consideration of the *raison d'être* of fascism. Until now it had been to achieve power as an end in itself; but once in office it was time for it to choose between the many tendencies which had entered into the movement, to decide whether it was primarily revolutionary or conservative. Hitherto it had been a movement, not a doctrine, and evidently the objects of its struggle were not apparent even to its own members. An economic policy of economy and retrenchment was therefore borrowed from the old liberal school of economists. The right to strike was curtailed, and a longer working week mas restored. Nitti's royal guards were disbanded because they had dared to take action against Fascist illegality. To replace them, the Fascist squads were institutionalized into a security militia in Jan. 1923, ostensibly to assist in the maintenance of order. Gentile's educational theories were harnessed to make an Education act in 1923. From D'Annunzio was taken much of the choreography and verbal claptrap which had become familiar at Fiume. A form of guild socialism was lifted from the early Syndicalists. Meanwhile the wealthy were courted by repeal of Giolitti's new taxes, by abrogation of the law on the registration of bonds, by winding up the commission considering wartime profits and by the reduction of the sum spent on social welfare. For the moment the finance minister, Alberto de Stefani, pursued a policy of abolishing controls. Only after 1925 was increasing government intervention to become typical of fascism.

Almost at once a fusion was effected with the Nationalist party, and it was the ideas of Federzoni and Corradini which provided the substance of Fascist foreign policy. Mussolini in his earlier years had gone to prison for his pacifist views and had once fled to Switzerland to avoid doing military service. But he now easily renounced his former anti-imperialism and became a bellicose nationalist. In Aug. 1923, when an Italian was killed by bandits in the Balkans, Mussolini presented an immediate ultimatum to Greece and asked for an indemnity of 50,000,000 lire, following this up by the bombardment and temporary occupation of Corfu.

He then turned his attention to making a settlement with Yugoslavia which could compare favourably with that concluded at Rapallo by Giolitti. In Jan. 1924 the pact of Rome finally gave Fiume to Italy in return for recognition of Yugoslav claims to Susak and Port Baros. This began his attempt to revise the treaties of 1919 and was yet another blow aimed at the prestige of the League of Nations. To help the further progress of revision he also made his peace with Germany and Russia, the two chief "have-not" powers of Europe.

In the summer of 1923 a bill was prepared to alter the representative system, so that the electoral list which obtained the largest number of votes should be entitled to two-thirds of the seats in the chamber, while the remaining third was divided among the other lists on a proportional basis. It should be remembered that the last elections had returned only 35 Fascist deputies; and yet both houses gave large majorities to this measure which threatened to make impossible any future alternation of parties in government. The deputies were simply agreeing to give a permanent majority to an avowedly antiparliamentary group. After this success, Mussolini could afford to renounce the full powers accorded him and proceed to the election of a new house that could be guaranteed to give him a yet easier passage to dictatorial power.

The one hope for the constitutional parties was to club together and oppose a single list to that of the Fascists. But in fact, when the elections were held in April, there were six opposition lists; and as the Fascists had all the aid of prefects and police and their terrorist militia, they obtained 65% of the recorded votes, so that they had two-thirds of the seats quite independently of the new law. There were to be more than 400 ministerial deputies in the new house. All the other parties together polled nearly 3,000,000 votes out of 7,500,000. There were 39 Popolari deputies, 25 Reformist Socialists, 22 Maximalists and 19 Communists. Salandra, Orlando and Enrico de Nicola had been included inside the Fascist list, and Giolitti's group had fought in alliance with the Fascists.

The *Murder* of *Matteotti*.—Despite this overwhelming victory, the Fascists — or certain more ruffianly elements among them — brutally assassinated Giacomo Matteotti, a Socialist deputy who had dared to impugn the regime before parliament. Mussolini was forced to disown the murderers and to arrest four leading Fascists as accomplices. The country was scandalized and the government shaken; but although criticism came more into the open and fascism was deserted by many who had joined it only when it had appeared invincible, the opposition did not press home their attack but withdrew from the chamber in passive protest.

This "Aventine secession" was intended to render parliamentary procedure impossible; but it was a futile measure against a man who already claimed to hold power by right of force and not in virtue of responsibility to parliament. Thus the Socialists, the Popolari and some of the radical liberals under Giovanni Amendola cut themselves off from the one place where Mussolini might have been publicly accused. When the king was confronted with evidence of Fascist criminality he was able to reply with the spurious but specious excuse that lack of opposition in parliament gave him no chance to intervene.

Even after Matteotti's murder the liberals in the senate gave Mussolini a convincing vote of confidence, and the Liberal party itself agreed to continue its general support of the government. Several liberals remained in the cabinet until the end of 1924. But in the second half of this year there were some notable defections from the government majority among those who had once welcomed fascism as an auxiliary but now feared it as a master. Orlando and Giolitti ranged themselves against the regime, without withdrawing from the chamber. The philosopher Croce had excused the unconstitutional methods of fascism and its bludgeoning tactics during the elections but now began to see the implications of what had happened for the liberalism which he had preached all his life. In December even Salandra changed his mind. The ex-servicemen's association also assumed an attitude of hostility to the government, at which Mussolini dissolved its directorate and replaced it with his own nominees.

This was a sign that the Duce had tested the weakness of his opponents and their reluctance either to combine against him or even to make direct accusations which he would have to answer. He now felt able to take another step in the establishment of a personal dictatorship. without fear that he m s going too far or too fast. The Matteotti affair had shaken him and caused a serious setback to his popularity; but it was soon almost forgotten. In the chamber he had to contend with only a dozen or so independent liberals and as many Communists. When newspapers like Sturzo's Popolo, the Socialist *Avanti* and Amendola's *Mondo* belatedly tried to impeach him, he replied with a new press law in July 1924 and gave the prefects the right to confiscate issues of "seditious" journals almost at will.

The ***Fascist* Dictatorship.**—Mussolini's final move was pre-

cipitated by the incriminating revelations of a former leading Fascist, Cesare Rossi, which left most politicians expecting that the king would have to force Mussolini to resign. It was, however, too late, and on Jan. 3, 1925, Mussolini dared to take full responsibility for the illegal actions of subordinates which hitherto he had repudiated. He formally announced that he would assume dictatorial powers and challenged his opponents to arraign him before the courts. At last the liberal ministers resigned. Leading members of the opposition were arrested—if they were lucky enough not to be attacked and mortally wounded, as was Giovanni Amendola. The most important national newspapers were forcibly acquired by pro-Fascist interests: the Corriere *della* Sera at Milan, the Giornale *d'Italia* at Rome, La *Stampa* at Turin and the *Mattino* of Naples. Mussolini declared his intention to *fascistizzare* the state. In March Roberto Farinacci, the former labour boss of Cremona, was made general secretary of the Fascist party and proceeded to reorganize it on much more intransigent lines. Other parties were dissolved. Henceforward there was no further room for anything that was not Fascist. This was a pattern which before long was to become familiar in Europe, and Italy had doubtful pride of place as the exemplar of a new order.

The last echoes of the Matteotti case during the Fascist regime were heard in 192j, when Amerigo Dumini and one other were found guilty by the court of appeal "of nonpremeditated unintentional homicide extenuated by the subnormal physical resistance of Matteotti and by other circumstances." Their sentence was shortly remitted so that they had to serve only two months in prison. The members of the administration accused of complicity were naturally exonerated and set free at once.

When a bill for reorganizing the army met opposition in military circles, Mussolini himself took over the war ministry, with Gen. Cgo Cavallero as undersecretary. Gen. Badoglio was appointed chief of staff and entrusted with co-ordination of the army, navy and air force. Adm. Thaon di Revel resigned in 1925, and Mussolini took over the ministry of marine and the newly created air ministry as well.

Mussolini's amazing self-confidence had been a great contributory factor in the rise of his party to power but was in the end to prove disastrous to himself and to Italy, for he centralized more and more in his own hands and became increasingly intolerant of criticism or even the delegation of power. Before long his henchmen saw that their only hope of keeping his good will was not to criticize, but instead to give him the illusion that he was always right. Becoming corrupted by power, he thus concealed from himself his own clumsiness in administration and in the formation of policy.

By trade he had been a journalist, and this he always remained, writing frequent anonymous articles in the press and treating every matter as something essentially simple which he could tackle by a mere surface acquaintance with the facts. At various times he held eight different portfolios himself, and the other ministers were seldom allowed a policy of their own. In return for permission to grow rich and corrupt, the Fascist gerarchi cheerfully left responsibility for decisions to Mussolini. As a result, decisions were not taken, the inefficiency and graft of subordinates was not checked, and in the end Italy was to declare war without anyone's knowing or daring to say that it was shockingly unprepared. Yet Mussolini's self-confidence never allowed him to perceive that all was not well, and he developed a pathetic trust in his own powers of intuition, even reaching the point of provoking the war for which he was so unready.

Economic Reforms.—After 1925 the relatively liberal economic policy of De Stefani was gradually abandoned. and politics played increasing havoc with finance. Expensive projects were undertaken for reasons of prestige or morale, despite the protest of some of the less doctrinaire and more honest and courageous ministers.

In the spring of 1925 financial difficulties had arisen resulting in a serious depreciation of the lira, which fell from about 100 to the pound sterling to close on 150. The government tried to put the blame for this on certain members of the opposition: it was said that they had hoped to break fascism through a financial disaster and had caused a panic by spreading the rumour that the government intended to emulate Germany and wipe out its debts by destroying the currency. So, as De Stefani had by now succeeded in reorganizing the fiscal system and balancing the budget, he was replaced by Count Giuseppe Volpi with a policy of revaluation. In the years 1925–26, Volpi successfully negotiated in Washington and London to reduce the heavy war debts which had been weighing on Italian finance.

Like many other previous governments, fascism made some effort to bring southern Italy up to the standard of the more progressive north, and a series of measures was enacted for co-ordinating land reclamation, drainage and the building of roads and railways. But once again it was to be proved how little necessary relation there was in Italy between legislation and its results. Like so many other Fascist measures, these had their most obvious effect in increasing the bureaucracy as a half-concealed way of meeting the unemployment problem; and the result was to eat up much-needed capital unprofitably, while the growth of bureaucratic regulations led to inefficiency and corruption on a yet larger scale.

Active state intervention in economic life thus became a principal characteristic of the regime, coupled with the aim to achieve self-sufficiency. The heavy industries certainly gained from this policy, for Ansaldo and some of the other big concerns had collapsed when World War I put an end to their artificial prosperity. Some of the landowners also profited from the "battle for wheat," in which heavy subsidies were used to raise output from 5,500,000 to 8,800,000 short tons a year. But both these types of production were uneconomical in Italy and could only be fostered by artificially inflated prices far above world levels: this was hard on the consumer and resulted in a sharp rise in the cost of living. In the struggle for autarky, consumption declined, vines and olive trees which had taken years to grow were cut down to make way for cereals, and the big, "uneconomical" industrial cartels were given much indirect protection for political reasons.

Constitutional Reforms.—A sample of other Fascist measures in these early years will give an idea of how the regime appeared when theory was translated into practice. Because of the "unsatisfactory results of the system of municipal elections," the government placed local administrations under the authority of a podestà appointed by royal decree. A law of Oct. 1925 provided for the appointment of a governor of Rome, and in 1926 the idea was extended to other towns and communes. The authority of the prefects was also strengthened in order to secure better co-ordination of the various provincial services and to take away responsibility from elected councils for the advantage of a nominated government official. Another law (Dec. 1925) was aimed against Freemasonry and its political influence. All associations were obliged to communicate their statutes and membership lists to the authorities, and civil servants were forbidden to belong to secret societies. A law of Nov. 1925 gave power to the government to dismiss any officials who attempted to prevent the enforcement of new legislation or to frustrate government policy.

In April 1926 the Fascist labour syndicates were given legal recognition as exclusively representative of the various categories of workers; 13 corporations were said to exist, representing landlords, peasants, professional men, employers, artisans and so forth. all controlled by the state; strikes and lockouts were declared illegal, and all disputes were to be submitted to compulsory arbitration. The idea, like most else in the Fascist system, was borrowed (this time from D'Annunzio and the Nationalists); but it mas said to be something essentially Fascist. The truth was that Mussolini, once in power, had some difficulty at first in finding any positive significance for fascism and snatched at any straw he could lay hold of. A National Council of Corporations was set up (on paper at least) as a political body, and thus another army of bureaucrats was brought into being, paid out of union subscriptions.

In Dec. 1925 a law was passed conferring greater power of parliamentary initiative on the prime minister and otherwise extending his authority. The king could no longer exercise his constitutional prerogative to dismiss ministers unless it was by the premier's advice; nor could any motion be debated in parliament without the premier's consent. Special penalties mere provided for any offenses committed against him. He was also allowed to issue de-

crees with the force of statute law. Since the Aventinians continued to remain absent from the chamber, the only opposition was concentrated in the tiny groups round Salandra, Giolitti, Orlando and the Communists.

Political life was becoming unreal and artificial. Debates were staged to impress outside observers, but there was no force in them. Decisions were made elsewhere; the reasons for public policy were often kept concealed and the arguments made in public were usually designed just to make good headlines in the press. As formal legislation was henceforth unnecessary, the really important matters were customarily kept away from public scrutiny. Moreover the actual connection between laws enacted and results achieved was frequently negligible.

It would therefore be otiose to describe at length the machinery of the Fascist state or the institutional reforms which had a momentary existence on paper before being superseded by others. One fundamental fact was that the Fascist party became identified with the state. Fascist officials, law courts, soldiers and laws grew up alongside their state counterparts, often with a conflicting authority and a duplicating function. By degrees party officials and institutions were recognized to have a defined function in, the constitution of the kingdom, and the Grand Council of Fascism became a far more important organ of government than was the cabinet of ministers.

In Nov. 1927 the Grand council drafted a new scheme for political representation, which became law in May 1928. In the next parliament the deputies were to number 400 instead of 535. Each of the 13 corporations and certain other recognized bodies of national importance had the right to be represented in a fixed proportion and to submit a list of candidates for election. The Grand council then chose the deputies from these lists, but it could modify them at will and exclude or add any names that it wished. Finally the electorate was called upon to ratify the list of names chosen by the Grand council. Only if the agreed list of candidates was rejected was any provision made for another election between rival lists. The result was to create a mere travesty of parliamentary government. There was no longer any representative system, only a means whereby citizens could express their general approval or disapproval of the policy of the government. A plebiscitary dictatorship had been established in law as well as in fact.

At a meeting of the Grand council in Sept. 1928 the powers and composition of that body were definitely laid down. The prime minister was its chairman, and its members included all the ministers, the quadrumviri of the "march on Rome!" the commander of the national militia, the secretary of the Fascist party and certain other Fascist leaders, the president of the special tribunal and the presidents of the confederation of workers' syndicates, of the agricultural confederation and of the industrial confederation and those of various other semiofficial bodies. The prime minister was to have complete freedom to summon anyone else that he wanted and could say what should or should not be debated in its sessions.

The functions of this Grand council were to ratify the lists of candidates for parliament before presentation to the electors, to decide the policy of the Fascist party and to be consulted on all matters affecting the constitution including the prerogatives of the crown, the succession to the throne, the composition and functions of the senate and of the chamber, international treaties and relations between church and state. It had also to draft and keep up to date a list of persons to be submitted to the crown for succession to the premiership in case of a vacancy. This provision incidentally ensured the continuity of the Fascist regime and welded state and party into what was hoped would be an indissoluble unit.

Persecution of opponents was rigorous but unsystematic and less inhuman than in Germany later. In the early years the squadristi had freely used rubber truncheons and castor oil; but the more or less complete success of Mussolini by 1925 made further opposition seem almost useless except for the most selfless and high-principled of men. In 1925 Croce published an "antifascist manifesto" which received a number of signatures among the intellectuals. Further over to the left, men like Piero Gobetti, Riccardo Bauer, Ernesto Rossi and Carlo and Nello Rosselli in their various heroic ways helped to keep some liberty of thought and action alive. Most of the old leaders went into exile, including Sturzo, Nitti, Turati, Sforza, Nenni and the Communist Palmiro Togliatti, most of them to return when the Fascist interregnum was over.

It was at the end of 1926 that the law was passed dissolving the "antinational" parties; *i.e.*, the Socialists, Republicans and Communists. Special penalties were prescribed for any attempt on the life of the premier and for a new class of offenses now deemed to be treasonable. The punishment of *confino*, or relegation to a fixed place of residence in some insalubrious province, was instituted for persons accused of minor seditious activities. A special tribunal was created for political crimes, which sat in camera and proceeded by methods of summary jurisdiction, after which there was no appeal. The paraphernalia of totalitarian dictatorship was almost complete. In November the surviving Aventinian deputies were declared by the chamber to have forfeited their seats. In order to give greater unity to the conduct of the country's policy, Mussolini himself then took over the ministry of the interior from Federzoni. In December the *fascio* littorio was declared an official emblem, thereby still further identifying fascism with the state.

A scheme for a new criminal code was drafted by Alfredo Rocco, a former Nationalist, and published in Aug. 1927. This embodied earlier provisions for the "protection of the state." Penalties were generally made more severe, and new punishments were allocated to certain offenses against morals, the practice and propaganda of birth control, etc. The death penalty was brought back under fascism, and trial by jury was abolished. A special police body was also created, which like the special tribunal was an arm of the Fascist party rather than of the state. The regime was soon spending ten times as much as its predecessors on security — a commentary on the restiveness of public opinion.

Popular Reactions. — There is, however, little doubt that fascism came nearer than any other government of modern Italy to the repression of ordinary crime. Thus the Mafia in Sicily had for generations maintained its secret organization and its system of private justice, intimidating everyone and always preventing the accumulation of evidence against it; but by 1928 the prefect of Palermo, Cesare Mori, was claiming that he had finally destroyed the society. Only 20 years later did it become apparent that this sort of organized illegalism had never wholly disappeared. The Mafia and the Camorra, like the endemic brigandage of the Napoletano, represented the protest of voluntary or involuntary outlaws against a hostile society. Fascism, like so many previous governments, proved surprisingly ineffective when matched against the natural anarchism of Italians and their basic lack of confidence in the workings of government and the administration of justice.

Mussolini failed similarly in his attempt to "italianize" the 200,000 German-speaking inhabitants of the Alto Adige and the 500,000 Slavs of Venezia Giulia which the settlement of 1919–20 had given to Italy. Italy was not bound by this settlement to respect minority rights and indeed claimed that it possessed no minorities. Already in 1925–26 a vigorous campaign was undertaken to introduce Italians into the local government in these areas and to forbid the use of German or Slav languages. Protests from abroad were laughed at. The Bavarian premier accused the Italian authorities of terrorizing the population and advocated a boycott of Italian goods. But a far more formidable obstacle was the simple nonco-operation of ordinary individuals where so much of their way of life was at stake. When it was ordered that religious instruction should be given in Italian only, many devout Catholics preferred to keep their children home, and even the appointment of keen Fascists as bishops in these frontier areas did not prevent passive resistance on a large scale.

The reaction of the country as a whole to Mussolini's dictatorship can only be surmised. The elections of 1929 and 1934 showed only a few thousand votes registered against the national list, but the figures are of course wholly unreliable. There seems to have been a good deal of grumbling and humorous laughter about the regime, but this is only what one would expect. Not until the late 1930s were there signs that a substantial number of people were aware that dictatorship meant inefficient government at home and suicidal aggressiveness abroad. Until that moment fascism

seemed to be wonderfully successful and was the admiration of many distinguished men even in democratic Europe. It had restored Italian self-confidence, stabilized social order at home and put an end to the postwar orgy of strikes. A nice combination of the carrot and the stick seemed to have rallied almost all Italy behind the regime.

Ecclesiastical Affairs.—One fact which earned for Mussolini much gratitude and admiration was his reconciliation of the Italian state with the Roman Catholic Church. Ever since 1870 there had been a breach between the two, and the pope had refused to recognize the lay occupation of Rome. Mussolini and Pius XI were each realists in their way, and both understood the benefits to be reaped from conciliation. There had been a strong secularist or anticlerical faction in fascism, and perhaps the predominant tendency in the movement was the sceptical nonconformism of Mussolini himself; yet by a skilful adaptation, the Duce turned himself into a favourite son of the church. The treaty and concordat of 1929 have been considered Mussolini's greatest diplomatic achievement. They allowed the existence of the tiny independent Vatican City State, over which the pope exercised temporal rule. A financial convention arranged for Italy to pay nearly 2,000,000,000 lire either in cash or consolidated stock as compensation for church properties seized in 1870. The concordat also regulated the status of the church and of religion in Italy.

Mussolini argued that in this settlement he had surrendered the form and retained the substance. Certainly, he had won a great moral victory in persuading the church to yield what it had not accorded to any of his liberal predecessors, and he proceeded to show that, having once gained this point, he was not going to allow the church such independence as would conflict with his totalitarian concept of the state. In the educational system, Catholic instruction was to be allowed only where it did not run counter to the precepts of fascism. The Catholic Boy Scouts could not continue except within the framework of the Fascist Balilla organization. Catholic Action was compelled to change its functions and limit its scope. In the encyclical Non abbiamo bisogno of 1931 the pope was even forced into some tentative censure of certain more obviously pagan aspects of fascism; but on the whole churchmen continued to give enthusiastic support to the regime, and church and state worked together in relative harmony. Neither side dared to provoke the other beyond a certain point.

Foreign Policy, to *1933*.—Mussolini had begun by saying that he would keep ideology out of foreign politics. But he soon changed this view to one in which every aspect of state policy had to reflect some peculiarly Fascist quality. Fascism was thus identified with national and imperial expansion, with revision of the postwar treaties so that Italy should receive a material reward more consonant with its worth and dignity. In 1925 negotiations with Egypt led to the cession of the Bay of Sollum in return for acquisition of the important oasis of Jarabub, headquarters of the Senussi sect. A treaty of conciliation and arbitration was concluded with Germany in Dec. 1926. In China, Italian troops were landed to assist in the protection of Shanghai. Although the Locarno treaty had been signed in 1925, a year or two later found Mussolini speaking publicly of the great European war which in ten years' time would give Italy its due. When Yugoslavia began to show signs of independence in its foreign policy and concluded a treaty of friendship with France in 1927, Italy reacted by making an alliance with Albania and attempting to renew its former protectorate over that country. By 1932 Mussolini was publicly saying that: "the 20th century will be the century of fascism, of Italian power, during which Italy will return for the third time to be the directing force in human civilization. In ten years' time Europe will be fascist."

Economics and fhe *Corporative* State.—Italy suffered like other countries from the world economic crisis after 1929. Mussolini's financial policy had already been directed to a revaluation of the lira in 1926–27, from 125 to the pound to 90, which many people thought had gone too far and too fast for equity and prosperity. Among other results it had reduced the profits of the export trade and brought a consequent increase of unemployment. Annual budget deficits began to reappear; the balance of international payments persistently showed a loss; exports greatly decreased; and the level of wages fell. The eight-hour day was given up, and before long unemployment soared to hitherto unprecedented levels, The picture was so bad that the government ceased publishing its statistics on wages and unemployment. Matters began to improve by 1933 but then worsened again when Mussolini began his policy of imperial expansion in Abyssinia.

In order to show that a mere matter of shortage of funds was not interfering with the original revolutionary urge of fascism, big schemes of public works were undertaken: showy public buildings in the new "Fascist style," the autostrade for tourist traffic, the electrification of railways, the reclamation of the Pontine marshes. Achievements were, however, only partial, and schemes usually had a political rather than an economic motive behind them. They had to be spectacular rather than efficacious. On the whole, Surprisingly little was spent on works of social welfare by the Fascist state.

One of the more important facts about Italian economic life after 1921 was the drying-up of the great stream of emigration. Before the war, emigrants had numbered more than 500,000 a year, mostly to North and South America; and this had done much to relieve the pressure of population at home, with a distinctly beneficial effect on wages and living standards. Then the United States and other countries of immigration began to impose restrictions on the rate of entry, until after 1924 there were often more Italians returning to their country of origin than there were going out from it.

This was in part deliberate policy, for Mussolini took pride in the high birth rate and evident "capacity for expansion" of his people and found in "overpopulation" a good argument to persuade other countries of his need for colonies. Large families were given economic encouragement, and a substantial bachelors' tax was introduced. But although Mussolini had the fantastic aim of increasing the population from little more than 40,000,000 to 60,000,000 by 1960, he was chagrined to discover that mere legislation was ineffective in stopping Italy from sharing in the general decline of the European birth rate. Meanwhile the great decrease in emigration removed one outlet for economic distress; and the very heavy drop in remittances from overseas settlers to their families at home was to constitute a serious loss in the balance of international payments.

Mussolini affected to believe that the creation of the "corporative state" was the greatest achievement of fascism. It was his object to develop an alternative to both communism and capitalism as a comprehensive method of tackling economic problems: The government had to exercise strict supervision over productive processes, maintaining private enterprise in theory, but reserving the right to intervene when it appeared inadequate. The banking system was remodelled, and government-controlled institutions were created for aiding vital industries in momentary difficulties and for liquidating those that were "unfit to survive." In fact, Mussolini's alternative was to retain the disadvantages of both capitalism and communism, without much in the way of compensation. The syndicates of employers and workmen were later reduced from 13 to 9, then expanded again to 22, and the government set up special labour courts to hear any disputes between them. A National Council of Corporations, composed of about 170 members, was erected as the general staff of the productive forces of the nation; and the councils of the 22 corporations, composed of approximately 800 members, acted similarly for each individual branch of production. The operation of the whole system was in theory to be supervised by the minister of corporations. This mas Mussolini himself, who was also president of each corporation. The machinery mas completely top-heavy, its functions nebulous, its cost enormous. Yet Mussolini was very fond of it and looked to the day when it would supersede the parliamentary system altogether, when the National council would act in place of the chamber. The first step was to let each corporation issue regulations which had the force of law for the branches of production under its control.

Preparation for War.—Tension with France arose in 1933 out of failure to solve the problem of naval parity at the London naval

conference; but the appointment of Sen. Henri de Jouvenel as French ambassador in Rome gave promise of a *rapprochement*. Hitler's rise to power in the same year was welcomed somewhat dubiously. Germany and Italy had much in common: both were revisionist powers abroad and totalitarian states at home. Nevertheless, it was by no means an Italian interest for Germany to extend its boundaries into Austria, and in 1933 Mussolini met the Austrian chancellor Engelbert Dollfuss and promised him Italy's friendship. In March 1934 protocols were signed in Rome by Mussolini, Dollfuss and the Hungarian Gen. Gyula Gombos, which provided for a closer economic union between their states and bound them to consult each other on all political questions of mutual interest. In June 1934 Hitler visited Mussolini at Venice and undertook not to intervene in Austria. But Italy's confidence in Germany was shaken by the purge of the Nazi party at the end of June and by the assassination of Dollfuss in July by the Austrian Nazis with German connivance. Italian troops were sent to the northern frontier ready to defend Austrian independence, and Mussolini extended his patronage to the prince von Starhemberg and Kurt von Schuschnigg.

These events brought about a temporary change in Italian foreign policy. The failure of the disarmament conference and of the London economic conference had caused dissatisfaction with the League of Nations, and at the end of 1933 the Grand council had announced that Italy's membership in the League was dependent on a radical reform of that institution. But in 1934 Italy's break with Germany was followed by a resumption of friendship with the League powers, and negotiations were at once opened with France. The French foreign minister, Louis Barthou, was about to leave for Italy to sign an agreement when he was assassinated at Marseilles in October. His successor, Pierre Laval, resumed discussions and brought them to a satisfactory conclusion in Jan. 1935. In May 1934 supplementary estimates for thousands of millions of lire were issued to cover expenditure on the air force and navy, and it was decided to lay down two new 35,000-ton battleships. Later in the year measures were passed to tighten up the obligation on all males to do military service. From the age of six. boys were to begin military instruction in the Balilla organization.

Italy was at this time just beginning to emerge from the economic slump, but the new war preparations were before long to cause a yet further decline in the standard of living of the people. In April 1934, for the second time, the salaries of civil servants were slashed by 12%. The situation of the treasury was temporarily relieved by conversion of the huge consolidated loan from 5% to 3.5%; but in the following year it had to be reconverted back to 5% under the stress of the Abyssinian campaign.

The Abyssinian War.—Ever since 1932 Mussolini had been preparing the great war against Abyssinia that was to wipe out the humiliating memory of Aduwa. By this time the permanent officials in the foreign office uho had restrained the wildest antics of Fascist policy had retired or been swamped by party placemen. Instead of concentrating the diplomatic and military efforts of the country to keep German influence out of the buffer state beyond the Brenner, ideological arguments were used to divert attention to colonial expansion, and this started the chain of cause and effect which led to the Axis pact and Italy's loss of all its colonies in World War II.

Mussolini at first had stood patron to Abyssinia, signing a pact of friendship and introducing it into the League. It had then been his claim that he had no territorial ambitions and was no "collector of deserts." But for ten years since then he had been preaching the glories of war and the necessity of expansion; he could hardly remain inactive for much longer without trying to apply his theories. A minor clash over the Abyssinian frontier at Wal Wal in Dec. 1934 had not attracted much notice at the time. Then, in Jan. 1935, came the agreement with Laval which seemed to presage a formal military alliance. General De Bono, the minister of colonies, was appointed high commissioner of Italian East Africa, and two divisions were mobilized for dispatch to Eritrea. In March 1935 Gen. Rodolfo Graziani, the most experienced of Italy's colonial commanders, was appointed governor of Italian Somaliland. Next month Italy, Great Britain and France affirmed at Stresa their desire to collaborate in maintaining European peace. This was a part of Mussolini's smoke screen and an attempt to cover his flank against a German move while he was busy in Africa.

Early in 1935 Abyssinia had appealed to the League of Nations under the terms of the covenant; but no action was taken, since it was hoped that the two parties would reach an understanding by direct negotiation. The British minister without portfolio for League affairs, Anthony Eden, then went to Rome with a proposal that Abyssinia should yield some territory to Italy and receive compensation in an adjoining part of the British empire. This Italy refused, for it would have given Abyssinia independent access to the sea and also have foiled the plan to obtain a striking military victory for purposes of prestige. Again in September a five-power committee of the League made compromise proposals; but while Abyssinia accepted them. Italy refused.

In Oct. 1935 open hostilities began, by which time Italy had 250,000 men under arms in east Africa. The Fascist party nominee, De Bono, had to be replaced almost at once by Badoglio, but there was little serious fighting possible for the Abyssinians against Italian strength backed by all the resources of modern military science (including poison gas).

The League had at once declared Italy to be the aggressor and in November brought economic sanctions into force. The absurdity of this action can be judged from the fact that oil was specifically exempted from the embargo. Sanctions just allowed Mussolini to justify his action at home and to point out to Italians how they nere being victimized by the "have" poxers who resented its intrusion among them. Sanctions also split the League countries and in the end forced Italy into alliance with Germany, which was one of the few states not to apply them. Laval and Sir Samuel Hoare, the British foreign secretary, prepared another compromise in December, but there was an outcry by British public opinion at what seemed like concession to an aggressor. Sir Samuel had to resign and was succeeded as foreign secretary by Eden, who already had the reputation of being an enemy of Italy. The whole sanctions policy was attributed to Great Britain by Italian public opinion, and the resultant tension was one more wedge driven into the Stresa front.

Addis Ababa fell in May 1936, and Victor Emmanuel (without being consulted) was given the grandiose title of emperor to mark the establishment of Italian sovereignty over Abyssinia. Badoglio and then Graziani were made viceroys of the new colony. The victory had not reflected any great glory on the Italians, though the organization of the campaign had been workmanlike. Their boasting about the poison gases sprayed on Abyssinian villages was not received well in the rest of Europe. But victory seemed to have done something to reconcile doubters at home to the regime. Fascism was being justified by success, and some even among the "opposition" approved of the war. The Catholics, in particular, seem to have been far more sympathetic to it than to that of 1915–18.

Several more years passed before Abyssinia was effectively occupied and subdued, and during this time the corruption now typical of fascism was much in evidence in the government of the colony. Despite the "economic necessity to expand" that had been argued as a principal cause of the war, the colonies continued to eat up more and more of the limited resources of the fatherland (which many of the sceptics thought might have been more profitably employed in backward areas at home) and gave a disproportionately small return in terms of wealth. Another deleterious effect of the war was its harmful impact upon the domestic economy. The law on the gold reserves of the Bank of Italy had to be repealed, and a tendency toward inflation was not long in showing itself. The budget indicated that the national accounts were wildly out of balance, and even the compulsory loans and other expedients now adopted proved quite ineffective to restore an equilibrium.

Mussolini later confessed that his power and prestige had been at their highest in 1937. After that, matters got out of hand. The fact that Italy, singlehanded, had with apparent success defied 52 nations of the League gave him the false impression that the coun-

try was powerful and could afford to throw its weight about and that the democracies were decadent and could be safely pushed along the path of appeasement. This was to prove a fatal illusion. Unfortunately fascism had outlawed anything in the way of an opposition; and not even the other Fascist leaders dared criticize the infallible Duce. Mussolini was always right: Mussolini ha *sempre* ragione was one of the slogans of the regime. There was thus no one to point out the implications of his aggressive policy, no one to suggest that industrially and militarily the country could not risk provoking a general mar.

From this moment, one may say, Italy was doomed; for Mussolini was not observant or intelligent enough to supply the criticism that was lacking elsewhere. He governed by intuition. oscillating violently from one extreme to another, from antisocialist to socialist, from conservative to revolutionary, from pro-German to anti-German; and though the people believed that there was some logic in this concealed from them, it was rather a morbid psychological trait.

Mussolini and Galeazzo Ciano, his new foreign minister, were ill-informed and thought that they could conduct the diplomacy of a major power with very little preparation or initial study. Italian policy thus remained unpredictable until the last. It was usually based on the shallowest of arguments, and never remained constant for long. Most of Mussolini's subordinates showed themselves to be trivial, irresponsible and incompetent, for he did not like strong men about him, or men with ideas.

The *Spanish Civil War.*—Ciano rose to power through undisguised nepotism, being Mussolini's son-in-law. A few weeks after his appointment as foreign minister, in July 1936, the Spanish Civil War broke out, and it was discovered that ideological reasons compelled Italian intervention against the democratic republic and in favour of the insurgents. Italy stood to gain little save prestige from this war. As things turned out, it gained little even of this and lost considerably in the way of men and military matériel. Mussolini associated himself with the agreement by which outside powers were not to intervene; but his soldiers still remained in Spain, and semiofficial estimates gave them as at least 50.000 in number. Too late Mussolini discovered that, while victory would not bring any material reward, defeat would be ruinous. What he had expected to be a short and glorious war in fact continued for three years, and Black Shirt troops suffered some notable reverses at the hands of an army in which anti-Fascist refugees from Italy were represented.

Germany meanwhile rejoiced to see the rift widening between France and Italy. To save itself from isolation Italy had to pay Germany's price and sacrifice its protection of Austrian independence. In Oct. 1937, moreover, the lira had to be revalued, and a new tax of 10% was imposed on the capital of limited liability companies. Before long the cost of prestige was to seem almost excessive.

Ascendancy of Germany.—Ideological arguments were behind the establishment of the Axis pact with Germany. Naziism and fascism agreed in their totalitarianism, in their opposition to liberalism and democracy and in their violent, revolutionary methods. As Hitler in the early years had learned a great deal from Mussolini, so after 1937 it was Italy that learned increasingly from the more efficient and more successful regime in Germany. The imposition of sanctions had indicated how little Mussolini could expect from the western democracies. So he followed Crispi's example in giving up a position of independence between the power groups of Europe and set his hopes on reaping some incidental gain from Germany's determination to upset the treaty of Versailles. As Italy's interests were mainly concentrated in the Mediterranean, it was against France and Great Britain that its claims were primarily directed.

In Sept. 1937 Mussolini visited Hitler in Germany, where he received a great welcome which flattered his vanity and persuaded him that Germany was bound to win the next war. Italy joined the German-Japanese anti-Comintern pact in November and withdrew from the League in December. This policy coincided with an increased armaments program, and in Jan. 1938 it was decided to lay down two more 35,000-ton battleships and a fleet of submarines. In the interests of further appeasement, however, care was taken not to antagonize Great Britain irretrievably while these preparations were being built up. March 1938 brought the German occupation of Austria, to which Italy had perforce to assent; and so, with the reappearance of a strong state upon its northern frontier, Italy threw away its chief gain from the settlement of 1919. Again in Sept. 1938 at Munich, although Mussolini intervened to prevent a premature war to conquer Czechoslovakia, Hitler was allowed to occupy the Sudetenland. The Munich conference confirmed Mussolini's underestimation of France and Great Britain and forced him all the more into the position of poor relation of Germany.

In Oct. 1938 the Grand council advocated certain measures limiting the professional activities of the Jews and excluding them from the fighting forces and the civil service. This was another sop to Hitler. Until this moment Mussolini had prided himself on his racial tolerance; he had in fact feared that the Germans despised Italians as non-Aryan. This difficulty was now tacitly overlooked, and scholars were turned on to show that the Italians were essentially Nordic. Some leading Italians were dismissed from their posts, to the damage of science and industry.

There is evidence that these new racial laws aroused considerable popular indignation and that they were sometimes disregarded. As fascism continued to become more and more totalitarian, it became more unwieldy, more inefficient, more corruptible and more disliked. The increasing interference in private life was resented by many who had once approved the exaggeration of the state whicn fascism had originally stood for; and the natural anarchism of Italians made much even of Fascist legislation a dead letter. Peasants refused to co-operate with the government in its policy of requisitions, fixed prices and compulsory acquisition of crops by the state. Scholars refused to take the oath of allegiance when it was extended to cover the regime as well as the king and the state. Enrico Fermi, the greatest of Italian scientists, escaped to America. Croce, in his magazine La *Critica*, kept up a continual fire of veiled criticism which must have had considerable influence among the intellectuals.

This is not to say that opposition was widespread or even very important. But as Mussolini's whimsical intuition became ever more decisive in the formation of policy, more and more people became alarmed. About the year 1938 Mussolini seems to have started reverting to the socialism which had dominated his early life and which had always infected one wing of his party. He began to attack everything that was "bourgeois," whether it was golf or first-class compartments on the railway or the pacifist mentality of those who put prosperity before national glory and power. After 1934 the budget was nowhere near balanced, but Mussolini ridiculed the forebodings of his finance minister, Felice Guarneri, who warned him that the country could not stand the pace. From this moment can be dated the growth of a defeatism among many of the financiers and industrialists whose support had once helped fascism into power. The Duce even announced a measure for splitting up the large estates of Sicily.

By the turn of the year 1938–39 matters were getting out of hand. The deputies in parliament were instructed to clamour vociferously for conquest of Nice, Corsica, Tunisia, Jibuti, Malta and Suez. Then parliament was told to vote itself out of existence and to give way to the chamber of fasces and corporations which was to take its place. It could not be allowed that fascism had played itself out. The country had to be in a continual state of revolution. Mussolini denounced the Italo-French agreement of Jan. 1935; but at the same time his jealousy of Hitler made him anxious not to appear to play second fiddle to Germany, and he was soon trying to assert his independence in a separate policy of his own. On a sudden impulse he converted the Rome-Berlin Axis into a formal alliance in May 1939; but there was little real friendship there, and this "pact of steel" gave Italy many of the disadvantages of a formal tie without some of its compensations.

Italy had exercised a predominant influence in Albania for many years; but in April 1939, after Hitler had invaded what was left of Czechoslovakia, Mussolini decided to assert himself by converting the protectorate of Albania into an actual colony. At the

very last minute it was decided to land an expedition there. Victor Emmanuel became king in Zog's place, and a personal union of crowns was thus established. But the other Balkan states were thereby antagonized, and the manner of the occupation was not such as to inspire much confidence in Italy's capacity to carry out a major war. Mussolini secretly told Hitler that the country would evidently not be ready for such a war within three years, and Italy began to plan on this supposition.

In his less sane moments. however, the Duce was carried away by his own rhetorical statements about mobilizing "8,000,000 bayonets"; and the evident willingness of the British prime minister Neville Chamberlain to suffer almost anything in the cause of peace confirmed his false illusion of strength. He was content just to assume that fascism had succeeded in militarizing the nation and in mobilizing indu try to produce a sufficient war potential. Occasionally he pierced the bluff of the service ministries which had multiplied on paper the strength of their units to earn his good opinion. But he chose to ignore the evidence at crucial moments when the issue was that of peace or war.

World War 11.—When he made his pact with Germany evidently Mussolini had not known that Germany, far from intending to wait three years until Italy was ready, was already preparing an invasion of Poland. Hitler also kept his ally quite uninformed about his intention to make a pact with the U.S.S.R. in Aug. 1939. Surprised by German bad faith, Italy became anxious lest it should be drawn into war, and Ciano was dispatched to Berchtesgaden in August. Hitler was, of course, unmoved by Mussolini's attempt to preserve peace and was content to allow that the *casus foederis* had not arisen so that Italian help would not be invoked.

The Italian army leaders were strongly in favour of neutrality, knowing how weak the armed services were. They had always resented the attempt to *fascistizzare* the army. The naval commanders knew how risky it was for a country so dependent on supplies from overseas to challenge the British and French navies. Balbo, De Bono and Federzoni were also reputedly neutralist, and when Germany began hostilities in September, Ciano obtained the succession of the less bellicose Ettore Muti to Achille Starace as secretary of the Fascist party.

This turn of events put Italy back into an arbitral position in Europe, where—as in 1914–15—it could barter its support between either side and profit from the exhaustion of both belligerents. But Mussolini felt this situation to be ignominious. War to him was something glorious and good in its own right; and as he greatly exaggerated Italian power, he could hardly continue for long without following one of his intuitive urges toward joining Germany. Little was done in the meantime to put Italian industry and armed forces on a war footing. Yet Mussolini was overcome with humiliation at having to stand idle while others made history without him. Badoglio and the king reminded him how completely unready the country was for the test of a major war; but when the news arrived of German victories in France and Scandinavia, he became frightened that further delay might make his intervention too late; and without consulting his ministers or the military experts he declared war against Great Britain and France on June 10, 1940.

The record of Italian armed forces during the second half of 1940 was far from brilliant. Despite the fact that France was already reeling from the German onslaught, Italian*troops were able to penetrate only a few miles beyond the French border before their two-weeks' war was concluded on the basis of the *status* quo at the time of the armistice. Mussolini had hoped to receive Nice, Savoy and the ports of Tunisia, but Hitler was more anxious to purchase the confidence of the new regime in France than to satisfy the ambitions of his fellow dictator.

To compensate for this there were victories in Africa against Great Britain. British Somaliland mas taken in August. There were infiltrations into the eastern Sudan and northern Kenya. Then, meeting very slight resistance, the Italians began to invade Egypt. But this was not enough, and soon Mussolini had to reconcile himself to the unpalatable fact that the war was not going to be the short and glorious campaign that he had anticipated. In Dec. 1940 the British counterattacked and drove the Italians out of Egypt into Libya as far as Tobruk. The British navy managed to reassert itself in the Mediterranean, and as a result of an attack on the Taranto naval base in November the Italian fleet for the time being was partially crippled.

These disasters were slight compared with the ignominious defeat of Italian armies in Albania and northern Greece. On Oct. 28, 1940, Mussolini sent his army into Greece with the object of staking out his claims in the Balkan peninsula before Hitler could do likewise. He did not inform Hitler in advance. The views of the Italian general staff were not considered, their objections being overruled as sheer defeatism. Then, to Mussolini's great surprise, the Italians were soon driven back from Greece in retreat through their own colony of Albania. This unprovoked attack provided the Allies with bases in the Balkans and also damaged the Axis in that the Italian defeat persuaded the Spaniards to remain neutral. Furthermore, it compelled Italy to beg German aid. Gradually the Germans took over the Italian war effort, and before long they were exploiting Italy almost as a defeated enemy.

In the spring of 1941 Italian East Africa fell to the British, together mith a large army under Amedeo, duke of Aosta (son and successor of Emanuele Filiberto). Abyssinia regained its independence. The Italian troops in North Africa had lost two-thirds of their strength in casualties and prisoners, and the history of Italy as an African power seemed near its end. In March the battle of Matapan off the southern tip of Greece resulted in the loss or serious damage of one Italian battleship and three heavy cruisers.

At this point the Germans came to the aid of their ally. Gen. Erwin Rommel took over responsibility for the Libyan campaign. Nazi troops in the Balkans forced the British to transfer the bulk of their army from Africa to Athens and Salonika. The German and Italian forces by-passed Tobruk and, in April, crossed once again into Egypt. In the same month Yugoslavia was invaded from the north, and the Greeks were speedily compelled to surrender. Mussolini hardly dared announce the fact to his people. Although the Italian contribution to the conquest of the Balkans had been slight, the Germans rewarded their allies with a small segment of Yugoslavia and certain Adriatic islands. Aimone, duke of Spoleto, the second son of Emanuele Filiberto, was allowed to call himself king of Croatia. Mussolini made the most of this; but he became increasingly impatient of infiltration by the Germans and began to talk of fortifying the northern frontier of Italy for the not-so-distant day when he would be fighting them.

The war extended eastward when the Germans opened hostilities against the Soviet Union—once again without warning their ally. Mussolini, in the folly of desperation, insisted against German advice that Italian units should fight on the new Russian front, as if they had not already more than enough to do elsewhere. At the end of 1941 Japan brought the United States into the battle. and Italy cheerfully declared war on this new enemy. A British offensive in the Egyptian Western desert in Nov. 1941 was followed by a second German counterattack in the spring of 1942, which took the front as far into Egypt as El Alamein.

But the longer the war continued, the more Italy was outdistanced in the field of provision and munitions. British convoys found it as easy to reach Malta as did Italian convoys to cross the narrow straits of Sicily. In the autumn of 1942, at the same time as the Russians won the defensive battle of Stalingrad, the Anglo-American landings in Algeria and Morocco, together mith Gen. Sir Bernard (later Viscount) Montgomery's sweep from El Alamein, loosened the Axis.' hold on North Africa, all of which was to be in Allied hands by the middle of May of the next year.

Civilian morale in Italy now sank disastrously. The king, some of the army leaders, some of the surviving liberals like Orlando, Bonomi and Croce, the Socialist underground and even *frondeurs* inside the Fascist party all began to cast about for some way of extricating the country from the war without too much physical damage or loss of face. It was the dissident Fascists who first had the courage to move, seeing that the uncontrollable Mussolini was losing everything for which they had struggled. The Allied invasion of Sicily on July 10, 1943, followed by the bombing of Rome which had hitherto been inviolable, at last brought home to

Italians some of the realities of war. On the night of July 24–25 the Fascist Grand council supported by 19 votes against 7 a motion of no confidence in the government. Among those who voted against Mussolini were De Bono, De Vecchi, Ciano, Grandi, Federzoni and Giuseppe Bottai.

Badoglio.—The king now took advantage of this division inside fascism and, instead of allowing the rebels to take over the government, arrested Mussolini when he came to report. Nor was there much protest when Marshal Badoglio was charged to form a new ministry. Fascism in fact had fallen, even though the war continued. Badoglio took some time to evade German vigilance and make the first secret overtures for peace. Only toward the end of August did his envoy meet the British and the Americans in Lisbon, and by that time the Germans had been strongly reinforced. The Italian armistice was signed early in September. At the same time the Allies landed in Calabria. But all Italy north of Naples passed at once into German hands; and though the Italian fleet sailed to Malta, the Italian army was for the most part easily disarmed by its former allies. In September a German parachute band carried out a brilliant escapade to recapture illussolini, and a Republican-Fascist government mas set up in northern Italy at Salò. Meanwhile Badoglio reconstituted the king's government at Brindisi and, in October, declared war on Germany.

Debates soon began on the nature of Italy's future government, especially on whether the king had become too far compromised with fascism to stay. But for the moment the six anti-Fascist parties of the liberation movement agreed on suspending this issue and joining a coalition. Palmiro Togliatti. returned from Russia, realistically joined the Liberals and Christian Democrats round Benedetto Croce and Alcide de Gasperi. The Maximalist Socialists reformed themselves under Pietro Nenni. and the milder Reformists under Giuseppe Saragat. A coalition government thus took shape under Badoglio in April 1944.

Bonomi, 1944–45.—When in June 1944 Rome fell to the Allies, Bonomi took over from Badoglio with another broad coalition. The country was allowed the status of a cobelligerent but not of an ally in the war against Germany. Italians played a considerable part in the liberation. and the Allies gradually relaxed their control of civil administration as the front line moved farther north. Great physical destruction, as well as inflation and the bitterness of civil war. left the country in a terrible state.

In April 1945 the Allies opened a general offensive in northern Italy. Italian partisans often seized power in advance of this offensive. and hence the extreme left emerged in control of much local administration. A partisan force intercepted illussolini and his mistress Clara Petacci near the Lago di Como and executed both near Dongo after a summary trial. Ciano and De Bono had already been executed by Mussolini. Grandi and Bottai survived, but most of the other gerarchi were dead. Germany capitulated in May.

Post-World War 11.—In June 1945 Bonomi gave way in the premiership to Ferruccio Parri, a former partisan and a member of the radical Partito d'Azione. Just after his accession to power the dispute with Marshal Tito over Trieste was temporarily settled by a compromise agreement under which Allied and Yugoslav troops partitioned Venezia Giulia. At home, famine conditions were widespread, inflation reached new heights and banditry received a new impetus from deserters, who could arm themselves mith the weapons that littered the countryside. The Allied occupation, however, was accompanied by substantial food shipments and other forms of ,economic aid from the United States. The introduction of DDT against the malarial mosquitoes by itself effected a major revolution for the good.

De Gasperi, *1945–53.*—Unable to solve domestic problems, Parri was succeeded by De Gasperi in Dec. 1945 with another coalition, including Communists and Socialists as well as Christian Democrats. De Gasperi was to prove himself the ablest Italian politician since Cavour. In a period of exceptional difficulty he managed to preserve a working majority through eight successive administrations until 1953. usually with the aid of the Liberals, the Republicans and the Reformist Socialists.

In May 1946 Victor Emmanuel III tried to save the monarchy by abdicating just before a referendum was held on the issue of republicanism. But the vote was 12.71 7,923 against the monarchy as opposed to 10,719,284 for it, and Humbert II went into exile after a month's reign. The voting confirmed, however, that southern Italy was stoutly monarchical, and this constituted one more dangerous division between north and south. A Neapolitan. Enrico de Nicola, was chosen as provisional head of the state by the constituent assembly now elected. This assembly comprised 207 Christian Democrats, 11 j Socialists, 104 Communists. 23 Republicans and only 19 Liberals. But the Socialist party divided itself once again in Jan. 1947, when Saragat formed a separate group and Nenni made common front with the Communists. The Communists left the government coalition in May 1947. The task of the constituent assembly was to devise a constitution to replace that granted by Charles Albert in 1848. In Jan. 1948 this new constitution came into force. It provided for an elected senate? for some regional autonomy in Sicily. Sardinia! Trentino and Aosta, and for the institution of a president of the republic. De Nicola became the first president and was succeeded by Luigi Einaudi in May 1948. Elections for the first parliament. held on April 18–19, gave 307 seats to the Christian Democrats and 182 to the Popular Front of Communists and Nenni Socialists combined. This was a majority such as Italy had never previously known in democratic elections, yet De Gasperi wisely persevered with a broad coalition program and even began to give land to the southern peasants by expropriating the larger estates. There was. however, a growing conflict between left and right wings of the Democristiani (Luigi Gedda. leader of Catholic Action. on the right. Giuseppe Dossetti and Giulio Pastore of the Catholic unions on the left). which weakened the government and held up social reform.

The treaty of peace was ratified in 1947. Yugoslavia received Fiume. Zara. Pola and Istria, while the future of Trieste was left still doubtful. France also obtained small portions of former Italian territory along the frontier. The Dodecanese Islands went to Greece. and the Italian colonies remained at the disposition of the United Nations. Italy's inclusion among the United Nations was vetoed by the U.S.S.R.. but the western nations soon needed Italy's support and so made substantial revisions of the treaty in its favour. In internal politics De Gasperi's coalition was weakened in 19jo–ji by the defection of the Saragat Socialists and the Liberals on its two extreme wings, but both groups continued to give general support to the government. Reconstruction proceeded well. and Giuseppe Pella's deflationary policy brought some good results. The discovery of oil in several areas and of very large supplies of methane gas opened prospects of an industrial revolution.

An unfavourable trade balance was also partially covered by a remarkable increase in tourism.

Pella, Scelba and *Segni.*—In the general elections of June 7–8, 1953, the Christian Democrats won 10,859,554 votes (40.1%) as compared with 12,741,292 (48.4%) in 1948; the number of their seats was reduced to 262. Their associates, Social Democrats (*i.e.,* Saragat Socialists). Republicans and Liberals, also suffered, their seats being reduced from 33 to 19, from 10 to 5 and from 19 to 14, respectively. Communists and Nenni Socialists this time went to the polls separately and won together 9.562,860 votes (35.3%) as compared with 8,151,529 (31.0%); they obtained 218 seats (143 Communists and 75 Nennists). The right-ning parties also increased their votes: the Monarchists had 40 seats instead of 14 and the neo-Fascist Movimento Sociale Italiano had 29 instead of 5. A period of relative government stability was over, as the two extremes gained at the expense of the centre, and the centre itself became less cohesive. The 2,500,000 Communists were contained only by stringent police measures enforced by a vigorous minister from Sicily. Mario Scelba. De Gasperi's ill-advised attempt to rig the electoral law had turned many moderates against him in this election. He resigned, and Pella took over for six months of caretaker government mith a coalition of Monarchists and Liberals. But this move to the right disturbed those who believed in agrarian reform. Amintore Fanfani tried in Jan. 1954 to find an alternative coalition more to the left, but could win neither the *saragatiani* nor the Monarchist party of Achille Lauro. It was Scelba who, in

February, restored De Gasperi's precarious equilibrium with Liberals and Socialists in the cabinet. De Gasperi died in August, and the secretaryship of the Christian Democrats went to Fanfani, thus posing once again the difficult problem of party unity. In April 1955, when Luigi Einaudi's term of office as president came to an end, the official Christian Democrat candidate stood down and Giovanni Gronchi, a left-wing Christian Democrat. mas elected at the fourth ballot. In June, dissensions within his own party forced Scelba to resign. On July 6 a moderate coalition government took office under Antonio Segni, former minister of agriculture and a strong advocate of land reform.

In foreign affairs, Italy supported the European Defense Community, and, after its collapse in Aug. 1954. Western European union.

In Oct. 1954 an agreement was made with Yugoslavia to divide the territory of Trieste. The Allied troops withdrew, and thus one great stumbling block for world peace was at least temporarily removed. (D. M. SH.)

POPULATION AND SOCIAL CONDITIONS

In the 75 years from 1861 to 1936, when the last census before World War II was held. the population of Italy rose from 25,000,000 to 42,127,123 (de *jure*). The *de jure* population at the 19jr census, within the new boundaries laid down by the treaty of Paris (1947) and including zone A of Trieste, was 47,515,537. The preliminary 1961 de *jure* population figure was 50,463,762, The birth rate declined between 1861 and 1951, but so did the death rate. particularly the infant mortality rate; and between 1946 and 1951 the natural increase in population averaged considerably more than 400,000 annually. as it did in the 1930s. The density figure for the whole country rose from 139 per square kilometre (359 per square mile) in 1936 to 159 per square kilometre (408 per square mile) in 1951. A density of 159 per square kilometre does not appear high when compared with 196 in the German Federal Republic, 207 in Great Britain and 284 in Belgium (all figures for 1951), but two factors must be taken into account: the hilly and mountainous nature of a great part of the country: and the fact that about 41% of the people are engaged in agriculture and the density of the farming population on agricultural land is high in Italy, about 170 per square kilometre for the country as a whole, rising to over 300 in Liguria, Lombardy and Campania (440 per square mile rising to over 777).

Table I gives population figures for the different regions (*regioni*). In 1951 nearly 21,000,000 persons lived in the eight northern regions, which include the great industrial areas of Turin, Genoa. Milan and the other big towns of the Po valley; nearly 8,700,000 in the four central regions, Tuscany (Toscana), Umbria, the Marches (le Marche) and Latium (Lazio); more than 11,900,000 in the five southern regions; more than 4,490,000 in Sicily; and about 1,280,000 in Sardinia. Within these main divisions of Italy the density per square mile varied in the north from 75 in the Valle d'Aosta and 139 in Trentino-Alto Adige to 751 in Liguria, in the centre from 246 in Umbria to 504 in Latium and in the south from 163 in Basilicata to 828 in Campania and was 452 in Sicily and only 137 in Sardinia.

Italian statistics take account of a marked characteristic of the distribution of the Italian population, the distinction between the scattered and the concentrated population, the latter being the population residing in the town or village that forms the centre of a commune. According to the census of 1936. the scattered population, nhich is mainly the rural population, amounted to 26% of the total for the country generally. No figures were available in the decade following World War II, but there had been little change in the general situation, although a movement auay from the centres had begun in the south. In Lombardy and Liguria the scattered population only amounted to 18.7% and 17.5% respectively. because of the concentration of the population in the great industrial toans. but still lower figures were found in the mainly rural areas of the south and islands—13.1% in Basilicata, 6 7% in Apulia, 10% in Sicily, 8% in Sardinia. In these regions conditions of climate, security and land distribution have caused the agricultural population to live in towns of varying sizes whence they go to work in fields often lying a considerable distance away.

The great industrial towns are mainly in the northern plain, particularly in Lombardy; in central Italy the towns are smaller but often historically important; in the south, with the exception of the ports and notably Naples, the majority of the towns are

*Cities or communes, with more than 145,000 inhabitants in 1954. †Census. ‡Estimate.

The consequence of the great and continuing increase of population and the high density, particularly in the poor agricultural districts of the south and islands, is a condition of grave overpopulation. which presents every Italian government with the difficult problem of how to absorb this annual increase of about 400,000 in a country with practically no mineral resources and with a great deal of hilly or even mountainous land. Before 191j the solution was found in emigration, but after 1945 Italy's governments realized that emigration could provide at best only a partial solution and that relief must be found in increased industrialization and in improved methods of farming.

There are great differences of character, dialect and customs in the different parts of Italy. In northern and in most of central Italy industrialization and comparative prosperity have resulted in an assimilation of habits and culture close to those of other western European countries. In the south, however, extreme poverty and widespread malarial conditions and centuries of misgovernment produced a low standard of living. which in some places approximates more closely to that of North Africa than to that of northern Italy. Lack of communications. except between the larger centres, has meant the retention of primitive ways of life as well as methods of agriculture, and in parts of southern Italy and Sicily habits formed during the Moorish and Spanish occupations still persist. This is well marked in regard to the position of women. In northern Italy, for instance, the women members of the farm household share in the work on the land, whereas in Sicily and parts of the south the woman scarcely ever leaves the house. Many south Italians were still in the latter 1950s physically unable to do a hard day's work; although malaria, a cause of incapacity in the past, had greatly declined, they were still often living close to starvation level. In many parts of the south, moreover, it is impossible for an agricultural labourer to find employment for more than from 100 to 150 days a year and. when he has mork, a man often has to walk from j to 10 mi. from his home to the fields before starting work. Although Italy was politically united from 1870, the differences betneen north and south continued to exist; even politically the enforcement of a system of centralized government. which had worked reasonably well in the small kingdom of Piedmont but was not suited to the different conditions of Sicily and the south, accentuated the diiferences. In view of this, a system of regional government, with an emphasis on some degree of local self-government, was planned by the constitution of 1948 but had not been brought into force by 1955 except in the four regions of Sicily, Sardinia, Valle d'Aosta and Trentino-Alto Adige. Economically, the north continued to tend to regard the south as a millstone around its neck. while the south maintained that it was taxed for the benefit of the north and that the north suppressed any movement to establish industry in the south. After 1945 Italian statesmen endeavoured to make their countrymen realize that Italy could only prosper if all its parts were to share in economic development. But the south, though it had produced some of Italy's most eminent thinkers, was still regarded by many northerners as barbarous.

Births, Deaths, Marriages.— The birth rate fell from 36.8 per 1,000 of the population in 1872–75 to 23.7 in 1938 and to 17.5 per 1,000 in 19jj. but the death rate also fell from 30.j in 1872–7 j to 14.0 in 1938 and to 9.1 per 1.000 in 19jj. The rate of natural increase, therefore, went up from 6.3 per 1,000 of the population in 1872–75 to 9.7 in 1938 and was 8.4 in 1955, the absolute increase being more than 400,000 a year both before and after World War II.

The birth rate varied greatly in different parts of the country. In 1954 it varied from 10.3 per 1.000 in Liguria, 11.2 in Piedmont and 12.8 in Tuscany to 24.4 in Apulia, aj.8 in Calabria and 25.5 in Basilicata. In some of the large northern towns the natural increase was small in spite of a low infant mortality. In 1953 the communes of Genoa, Florence and Bologna showed an excess of deaths over births. as did the regions of Piedmont and Liguria. Thus the rate of growth was greatest in the districts which were the poorest, the most overpopulated and the most exclusively dependent on agriculture. The number of male births remained about 6% above that of female. but there was a greater male mortality. In 1936 women constituted 51.5% of the population; in 1951 the numbers were 24,092,316 (or 51.0%) women and 23,126.218 men. The number of illegitimate births decreased from jo per 1,000 births in 1925 to 41 in 1938 and 34 in 1953.

Although the birth rate fell, Italy maintained a net reproduction rate above unity. In 1935–37 it was 1.131 for the whole country, but as with the birth rate there were startling contrasts between north and south. In five of the seven northern regions the net reproduction rate was below unity nhereas in the south and in the islands it was well above, rising from 1.434 in the Abruzzi to 1.635 in Basilicata. There was a steady decline in the death rate after 1946, when it was 12.1 per 1.000 of the population as compared with 14.1 in 1938; it fell to 11.5 in 1947, to 10.6 in 1948, to 10.5 in 1949 and to 9.2 in 1954, the last figure being comparable with the lowest norld rates. This decline was undoubtedly the result of progress in health measures, the effect of which was particularly marked in the great fall in infant mortality.

The greatest fall in infant mortality took place during the first 50 years of Italian unity, when the rate dropped from 219 per 1,000 live births in 1872–7j to 128 in 1922. After that it continued to drop—to 106 in 1938, to 74 in 1949 and to 58.5 in 1953, though this was still high compared with rates (1952) in Great Britain (28.6), the Netherlands (22.5) and Sweden (20.1). The figure for the whole country, moreover, concealed great variations within Italy. In 1953 the rate was as low as 39.6 in Tuscany but was still 100.8 in Basilicata (but even this last figure was a great improvement on that of 1938, when it was 157).

Table III shows the changes in the rates of deaths caused by diseases in 1949 and 1950 compared with 1937–39.

TABLE III.—Deaths per 1,000,000 Inhabitants

Cause of death	1937–39	1949	1950
Infectious and parasitic diseases	1,606	948	693
Tuberculosis	808	496	42j
Malignant tumours	862	1,030	1,071
Diseases of the nervous and digestive system	1,676	1,473	1,491
Pneumonia	2,055	978	746
Diseases of the circulation	2,036	2,107	2,02j
Diseases of early iniancy	585	447	246*
Childbirth	24*	16*	15*

*Deaths per 10,000 births.

The decrease in deaths from all forms of tuberculosis fell steadily from an annual average of 1,362 per 1,000,000 inhabitants in 1924–30 to 808 in 1937–39. It rose to 983 during the war years 1943–45, but by 1953 it was 232 or less than one-third of the rate for 1937–39.

Among parasitic diseases the great improvement was the decline of deaths from malaria. the scourge of the south and of the islands. From 1931 to 1936 the average annual number of deaths from malaria was 2,242; by 1937–39 it had fallen to 799; and, as a result largely of the determined onslaught on the *Anopheles* mosquito with DDT the number of deaths fell to 102 in 1949 and to 53 in 1950. All the regions where malaria was rampant profited (*e.g.*, in the Veneto 23 people died in 1938 and only 3 in 1950), but the chief improvement was in the south and in the islands. The number of

deaths in Latium fell from 25 in 1938 to 1 in 1950, in Campania from 3j to 9. in Apulia from 105 to 3, in Basilicata from 44 to 4, in Calabria from 13j to j and in Sicily from 170 to 11. In Sardinia, where a joint Italo-American attack on the mosquito took place in 1947–48, instead of 159 deaths as in 1938 there were none in 1950.

The marriage rate averaged about 7.5 per 1,000 of the population before 1939. It rose to 9.2 in 1946 but was back at 7.6 by 1949 and fell to 7.3 in 195j. Divorce is forbidden by the Roman Catholic Church, but the number of judicial separations was considerably larger after World War II than before it: 2,002 judicial separations were obtained out of 5,287 suits brought in 1939; 6,302 out of 10,275 in 1948; 5,506 out of 8,702 in 1949; and 4,695 out of 8,134 in 1953.

Table IV gives vital statistics.

Emigration. — Before World War I and again between 1919 and 192j the problem of Italian overpopulation was kept in abeyance, though not solved, by mass emigration from the worst overpopulated districts. There were two main streams of emigration: one overseas which tended to be permanent (though many Italians went even to the United States and Argentina expecting to return); the other to European countries which was mainly temporary and often seasonal (although there were considerable permanent settlements of Italians in France).

Before 1914 the Italian government encouraged emigration and held the view that it was of great value to the country. The emigrants raised both their own standard of living and, by means of remittances, the standard of their families at home; and the remittances also helped to balance Italy's foreign trade. Between 1900 and 1914, 9~000,000emigrants left Italy, of whom about 5,400,000 returned; the peak year was 1913, uhen 873,000 persons (1 in every 50 inhabitants) emigrated. These were the years of mass emigration of unskilled agricultural labour from central and southern Italy; and 64% of the emigration in 1913 was overseas. From 1902 to 1915 the natural increase in population averaged 388,180 annually. net annual emigration overseas (*i.e.*, emigrants less those who returned to Italy) averaged 159,990 or 41% of the increase in population. After World War I emigration soared again, rising to more than 600,000 in 1920. of which total 409,200 went overseas. The value of the remittances for that year was estimated at between 3,000,000 and 4 250,000 gold lire.

The United States was overwhelmingly important as a country of Italian immigration. Between 1901 and 1914 tno-thirds of the Italian immigrants to the new world went to the United States, and the average annual immigration into the United States from 1906 to 1910 was 266,000 while in 1920 it was considerably more than 300,000. The effect on the Italian economy of the United States Immigration acts of 1921 and 1924, the latter of which gave Italy a quota of only 3.845 immigrants a year, is easy to understand. The other most important immigration country overseas was Argentina. In 1913 and 1923 more than 100,000 Italians went there. The size of the emigration to the United States tended to overshadoa emigration to Europe. There are no figures for the return of emigrant Italians from Europe before 1921, but gross emigration from 1906 to 1910 averaged 1,288,000 yearly as compared aith 1,968,000 overseas. After 1918 emigration to Europe recovered rapidly; average gross emigration for 1921–25 was 172,-000, net emigration 93,000 annually.

After 1924 emigration dropped steadily, partly because of alterations in the attitudes of the countries of immigration, notably the United States, but also because of a change in the policy of the Italian Fascist government, which restricted emigration as causing an injurious political and military loss of subjects, however great the economic gain from their remittances. This attitude may have been unreasonable but it is understandable in view of the fact that in 1927 there were about 9,000,000 Italians resident abroad, 7,500,000 in North and South America and 1,250,000 in Europe, of whom 75% were in France.

The overriding economic problem of Italy after World War II was overpopulation, particularly in the south. The number of unemployed varied between 1,500,000 and 2,000,000 in spite of reconstruction work and European aid. The government sought to promote emigration, which would provide at least a partial solution of the problem for some time to come, since agrarian reform and increased industrialization could only take effect slowly. From early in 1946 various agreements mere made with European and South American countries for the reception of emigrants, the most important being those with France and Argentina. But progress was inevitably slow for several important reasons. In the days of mass emigration to Europe it had proved difficult for immigrant countries to satisfy their own people that Italians or other immigrants would not lower the standard of living. This difficulty arose again after 1945 in France; nor were the Italians satisfied with the arrangements for transfer of wages and family allowances in spite of agreements made between the two governments. Mass emigration to Latin America in the early years of the century had often produced unsatisfactory conditions for Italian labour, and the Italian government was consequently chary of encouraging emigration to Latin America without securing specific pledges from the immigrant countries. Also. though governments felt responsible for establishing their citizens in reasonable conditions, this admirable intention was not always practicable on any large scale for a poor country like Italy.

Another obstacle to Italian emigration was the fact that while the main demand of the immigrant countries was for skilled labour, Italy did not have enough skilled workers to meet the demands of increased Italian industrialization required to counteract agrarian overpopulation. Most of the skilled workers emerging from the training schools set up by the government were likely to be needed by the country itself. On the other hand, Latin America needed agricultural labour to develop large new areas, but conditions of life in these remote regions did not appeal to Italian emigrants.

Table V shows the overseas emigration figures for 1947–50 and for 1953.

Employment **and** Unemployment. — The distribution of the employed population, according to figures for 1936 and to those of the official sample survey of 1952, is shown in Table VI.

One of Italy's most valuable assets is its labour force. Only centuries of skilled labour could have made such a barren and mountainous country produce

*Including 20,534 to Venezuela and 12,250 to Australia.

as much as it did. while the work of Italy's skilled artisans has long been prized. But this plentiful supply of labour was painfully obvious after 1945. The devastation of roads. bridges and railways caused by the war meant that as soon as the war ended there was work temporarily for a great many labourers, and in fact this work of reconstruction mas carried out with speed and efficiency. But raw materials for Italy's skilled and semiskilled workers in engineering and textiles were in short supply for a long time, and unemployment was a heavy burden on the Italian economy after 1945.

The lack of any exact figures for unemployment, much of it partial and some of it seasonal, led to the appointment of a parliamentary commission of inquiry, which in 1952 produced a remarkable report on social conditions generally as a basis for its conclusions on employment and unemployment. The commissioners reported that in Sept. 1952 there were about 1.500,000 unemployed, 67% men and 33% women. This figure covered only persons formerly employed and young people in search of their first job; it took no account of housewives and pensioners hoping to find work to supplement their own or the family income, or of people trying to get better jobs. The number of young people in search of their first job varied from 500,000 to 670,000 according to various estimates, but even at the lower figure the country's failure to absorb its young people caused great concern to the commissioners. The worst features suspected before and confirmed by the inquiry were the large ertent of underemployment, particularly in agriculture, and the lack of any special qualifications by the vast majority of the unemployed. Only about 5% had had any kind of professional training, a lack acknonledged to be one of the chief obstacles to employment inside or outside the country.

TABLE VI.—*Employment*

figures for 1950 and 1953 were 48.5 and 56.54 respectively (1938 = 1). The main improvement in wages after World War II was, as elsewhere in western Europe, in the wages of the lowest paid workers.

Table VIII, which is based on calculations by Confindustria (the Confederation of Industrialists). demonstrates the change in the wage structure between 1938 and 1949. The rising cost of social contributions was often cited by employers as a stumbling block in the way of industrial development, with its consequent increase in the numbers employed.

For a comparison of wages and prices *see* below, *Finance*, Table XXV.

TABLE VIII.—*Average Daily Cost of an Industrial Labourer*
(In lire)

Year	A	Additional payments	Social contributions	Total
1938	18.40	1.01	2.03	21.44
	85.8%	4.7%	9.5%	100%

1949	982	182.65	397.12	1,561.77
	62.9%	11.7%	25.4%	100%

Social Insurance and Welfare Services.—Social insurances fall roughly into four groups: family allowances, much the most important; insurance for periods of difficulty (unemployment, accidents at work, illness in general and tuberculosis in particular); insurance for special occasions involving extra expenditure (marriages and births); insurance for the time when work is no longer possible (old age. disability and dependents after a worker's death). The legislation involved was begun early in the 20th century; enactments comprised workers' compensation (accidents), 1904; maternity benefits, 1910; unemployment, disability. old age. 1919; tuberculosis, 1927; family allowances, 1934; and sickness, 1939 and 1943. All these insurances were made applicable to workers and employees in industry, commerce and banking; all but unemployment insurance applied to agricultural workers. All were put on a contributory basis, plus treasury grants, but after June 1946 contributions were paid only by employers.

There is a great tradition of charity in Italy and there are a large number of charitable foundations. They include such institutions as day nurseries, orphanages, homes for beggars and homes for old people. Since 1862 all these foundations have been incorporated as juridical persons by the state, which has the right to inspect them, to audit accounts and to reorganize the foundations. There is a lack of co-ordination among the charitable institutions and between them and the more modern welfare services supplied by social insurance. Administration is in the hands of various independent agencies, some of them nation-aide (*enti* parastatali—semiofficial bodies), others provincial or local.

The Ente Comunale di Assistenza (the Commune's Institution for Relief) is the body which provides general assistance throughout Italy. Its general function is legally defined as that of giving direct and temporary assistance, including aid in money or in kind or in services. Specifically, it provides legal assistance, shelter and food for the homeless poor, help for minors and for the aged in institutions and emergency cash relief to people in temporary need.

Child welfare throughout the country is in the hands of the Opera Nazionale per la Protezione della Maternità e dell'Infanzia (National Association for the Protection of Mothers and Babies), founded in 1925. Its main work lies with expectant and nursing mothers and with babies under 6 years of age, and its methods are up-to-date and progressive. In 1952–53 it employed 7,320 consultant doctors and had under its control 317 nursery homes, 1.020 feeding centres for mothers and 35; homes for mothers and babies. Help was given to 351,000 women and to 1,548,000 babies and children.

Housing and Water Supply.—Many houses were damaged or destroyed by bombing and by the passage of the armies during World War II, and in the first years after the war practically nothing was done for working-class housing. In the large towns a certain number of luxury flats were built, but it was not until 1948 that a start with working people's houses was made on a small scale with the Fanfani plan, so called after Amintore Fanfani. the minister who introduced it. Many more homes were built thereafter by the government and by private enterprise, but a grave shortage still existed in the latter 1950s. Rural housing remained one of the urgent problems of southern Italy, where any scheme of agrarian reform involved the building of new houses for the

peasants settled on new holdings. The provisional housing figures given by the general census of 1951 showed a general figure for the whole country of 1.4 persons per room and 3.2 persons per house. The highest figure for regional capitals was found in the southern cities with their high birth rate and low standard of living; the number of persons per room was 2.2 in Naples and Bari, 2.5 in Matera and 2.; in Foggia.

Some of the most remarkable engineering feats by Italians, beginning in Roman times, are connected with water supplies. The remains of the aqueducts in the Roman Campagna are among the finest Roman monuments that survive. Northern Italy is in general reasonably well supplied from the rivers and from springs and deep wells, but great labour has been expended for centuries on a complicated system of irrigation. Rome is supplied by various aqueducts; the main one, the Marcia, is the successor of various older aqueducts and brings most of the city's drinking water from springs in the Aniene valley. It is in the southern regions of Apulia. Basilicata and Calabria and in Sicily and Sardinia that supply constitutes a grave problem. The rainfall in Apulia is meagre, and the limestone structure of the region lets most of the water percolate deep underground. where it cannot be reached. In Calabria, where the rocks of the high ground are impervious and the rain water runs off rapidly, there is severe summer drought and consequent water shortage. In Basilicata conditions are not quite so difficult, since there are fair springs; but there too the summer drought is severe. There are various important aqueducts in Basilicata, of which the chief is the Agri. In Apulia the problem has been largely overcome by the construction of the Apulian aqueduct, the largest in Europe; it nas begun in 1906, but the main duct was not completed until 1926 and the construction of branches and extensions nas still in progress in 1953. Water is brought from springs at Caposele, the source of the Sele river, on the Tyrrhenian side of the Apennines, and is carried by tunnels through to the Adriatic side. The main aqueduct is about 150 mi. long and is designed to supply about 2,000,000 people with 33 gal. of water a head per day.

In Sicily the water shortage is severe, and the problem of its supply is one of the first to be faced by land reformers. There are springs near the more permeable rocks, and tonns and villages grew up near them. But many villages are dependent on shallow wells worked by primitive methods, and in some districts drinking water has to be carried miles. Plans to increase the number of aqueducts could not be implemented without heavy expenditure.

Sardinia is even worse supplied. There is no spring rainfall, very little rain at all, and severe summer droughts when even the few considerable rivers nearly dry up. There are no large lakes except coastal lagoons and only three large reservoirs, one on each of the main rivers. (M. M. C.)

RELIGION

No inquiry about religious belief was made in the census of Nov. 4, 1951. In that of 1931, however, 41,014,096 Italians, or 99.6% of the population, described themselves as Roman Catholics. This must be assumed to be the total of those baptized into the Roman Catholic Church. Only about one-third of them attend Mass with any regularity, however. and only about one-tenth receive the sacraments at Easter; about 33% were still ready to vote at election time for Communist or Communist-supported candidates after they had been warned by the Holy Office, on June 30. 1949, that to do so was to incur excommunication *ipso* facto. Pet the almost universal admission of religious belief on the census forms of 1931 remained the best testimony to the profound attachment of the Italian people to the Catholic faith.

Legal Position of the Catholic Church. — The Lateran treaty of Feb. 11, 1929, which was confirmed by article 7 of the constitution of the Italian republic (see below), recognizes the Vatican City State as an independent and sovereign state and provides for its relations nith the Italian state, establishing an Italian embassy at the Holy See and a nunciature at the Quirinal. But the position of Catholics in Italy, as distinct from the position of the church,-still rests on Charles Albert's laws of 1848, as does the position of members of other religious communions. Article 1 of the Statute of the Kingdom of Sardinia, dated March 4, 1848, is reaffirmed in article 1 of the Lateran treaty, "by which the Catholic Apostolic and Roman religion is the sole religion of the State." By the same statute other cults were given the freedom which they still enjoy. The particular position of the Waldenses dates from the Edict of Toleration of Feb. 17, 1848, and that of the Jews from March 29 of that year. The position of the Catholic Church is regulated by the concordat which accompanied the Lateran treaty in 1929, of which article 1 gives the city of Rome a special character as the "centre of the Catholic world and place of pilgrimage," where the Italian government is obliged to prevent "whatsoever may be in opposition with its said character." Save in Rome and the suburbicarian dioceses (article 23), the names of those chosen by the Holy See for appointment as archbishops or bishops in Italy must by article 19 of the concordat be submitted in advance to the Italian government, in strict confidence, "so as to be assured by the same that it has no reason of a political character to offer against the nomination." Similar notice is given of parochial appointments, when the government has 30 days in which to lodge objection (article 21). All bishops take an oath of loyalty to the state (article 20) and must be Italian subjects speaking the Italian language.

The concordat restored to ecclesiastical institutions — that is, to all churches open for public worship and to all religious orders and congregations approved by the Holy See — the power of acquiring legal personality and made it possible again for them to be the owners of immovable property. By article 29 the state pledged itself to impose no special tax or levy on church property, and article 30 provided for the subsidy of clerical stipends by the state, to supplement deficiencies in ecclesiastical endowments.

Articles 3 and 4 give all priests and religious under vows exemption from military service (except that those not doing parish work may be required to act as chaplains in time of general mobilizationj and exemption also from jury service. Article 7 secures the seal of the confessional, article 11 gives state recognition to the major feasts of the church, and article 12 provides that there shall be prayers for the state in the churches on those days. Article 8 governs the position of priests offending against the civil law, articles 9 and 10 prevent the requisitioning or demolition of churches by the state and articles 13, 14 and 15 provide for the appointment of peacetime military chaplains.

By article 34 of the concordat the state recognizes the validity of Catholic marriage and its subjection to the provisions of canon law; nullity cases arc therefore reserved to the ecclesiastical courts, and there can be no divorce; but on the other hand marriages may also be celebrated before a registrar or by the recognized minister of some other religion, in which case they are not subject to canon lam.

"Considering the teaching of Christian doctrine according to the form received by Catholic tradition as the foundation and the crown of public instruction," the state agrees by article 36 of the concordat to permit religious instruction in the public primary and secondary schools and concedes to the bishops the right to appoint or dismiss those who impart such instruction and to approve the textbooks which they use. By article 5, no priest may be employed by the state, whether as a teacher or in any other capacity, without the permission of his bishop: and apostate priests and those subject to ecclesiastical censure cannot be so appointed or continued in their appointments; this official stigmatizing of former priests, who sometimes announce their adherence to another religion, is the legal background to incidents sometimes construed as acts of intolerance toward Protestants, whether on the part of the church, as in Milan in 1952, or on the part of the state. as in Naples in 1953.

Article 8 of the Lateran treaty provides not only that physical attempts against the person of the pope or provocation to such attempts but also "offenses and public injuries committed on Italian territory against the person of the Supreme Pontiff by discourses, acts and writings" shall be punished as they would be if directed against the head of the Italian state.

Administration of the Catholic Church in Italy. — As well

as being the head on earth of the Roman Catholic Church throughout the world, the pope is primate of the church in Italy and metropolitan archbishop of the Roman province. By recent custom, but not hy invariable rule, the archbishops of Bologna, Florence. Genoa, Milan, Naples. Palermo. Turin and Venice are members of the College of Cardinals; the last-named has had the title of patriarch since 1451. The dioceses were reduced in number in 1818, during the period of reform which followed the recovery of the papal states at the congress of Vienna, but they remain much more numerous than in any other country of the world. They were grouped into 18 *regioni conciliari* by a decree of the Consistorial congregation dated Feb. 15 and March 22, 1919, confirmed on Sept. 23. 1933.

Catholic Action. — Catholic Action, in Italy as elsewhere, dates from the pontificate of Pius XI (1922–39). Through it Catholics are increasingly encouraged to seek to influence public affairs, whereas before World War I the ruling advice for Italians was *non expedit (see* above, *History)*. The Italian state, by article 43 of the concordat, "recognizes the organizations dependent from Catholic Action, in so far as the Holy See has disposed that they carry out their activity outside any political party and under the immediate dependence of the Hierarchy of the Church, for the diffusion and exercise of Catholic principles." All Catholic priests are excluded by this article from "belonging to and fighting for any political party whatsoever."

Catholic Action, nevertheless, soon came into conflict with the Fascist regime, as described by Pius XI in the encyclical *Non abbiamo bisogno* of June 29, 1931; but a settlement was reached in the following September. After World War II the position was radically changed, with the emergence on the one hand of the Communists and on the other hand of the Christian Democratic party; and Catholic Action, while still formally nonpolitical, in fact played, under the leadership of Luigi Gedda, an increasing part in supporting the Christian Democrats. Its *contitati civici* were especially active in the months before the elections of May 1948. Before the elections of 1953 it broadened its approach somewhat, promoting the interests of certain other political groups as well as of the Christian Democrats.

Religious Minorities. — In parts of Calabria and Sicily there are local Catholic populations following the Greek or Byzantine rite, while remaining in communion with the see of Rome. They are the descendants partly of Albanian refugees of the 15th and 16th centuries (whence they are known as the Italo-Xlbanesi) and partly of Greek colonists of much earlier date. They have bishops of their own rite at Lungro in Calabria and at Piana dei Greci in Sicily. The title of *archimandritato del Santissimo Salvatore,* still held by the Latin archbishop of Messina, commemorates the greater importance which these groups had in the past. The Greek-rite monastery of Grottaferrata, in the Alban hills outside Rome, dates from the latter part of the 10th century and is the only monastery of the Eastern Church which has been continuously in communion with Rome through all the centuries of schism. In 1931, according to the census, there were 6,801 Greek Orthodox ("dissidents") in Italy and 83.618 Protestants; more than one-third of the total of Protestants were foreigners domiciled in Italy. The Waldenses (less correctly written as "Waldensians") are the most considerable element among the indigenous Protestants! although even they are French in origin and conducted their services in French until the latter part of the 19th century. Their church is Calvinist in character and counts about 30,000 adherents: mostly living in certain valleys of Piedmont to the west of Turin. At Torre Pellice, their headquarters, they maintain a college; they have a theological school and two churches in Rome. The Baptists number about 17,500, and the Methodists of the Chiesa Evangelica Metodista d'Italia (formed after World War II by the union of communities of British and American missionary origin) about 7,000. There is a small Lutheran community in Lombardy, largely of Swiss origin, and the Seventh Day Adventists and the Salvation Army are present on a small scale. It was estimated that there were about 30,000 Jews in Italy at the close of 1952; in 1931 there were 47,82j. About one-third of the Jewish community lived in Rome, and the remainder were concentrated in the industrial cities of the north.

The constitution of the Italian republic gave comprehensive juridical assurances to these religious minorities Religious confession does not affect the equality of all citizens before the law (article 3), and liberty of association (articles 2 and 18) and of assembly (17) covers religious purposes. The following provisions in particular are relevant. "All religious denominations are equally free before the law. Religious denominations other than the Catholic are entitled to organize themselves according to their own statutes, in so far as these do not conflict with the Italian legal order. Their relations with the State are governed by law on the basis of agreements with the respective representatives" (article 8); "Everyone has the right to make free profession of his own religious convictions in any form whatsoever, personally or as a member of an association, to advocate the doctrines thereof, and to practise its worship in private or in public, provided they are not rites which offend public morality" (19); and "The ecclesiastical character and the religious or ritual aims of an association or institution may not be the grounds for special legislative restrictions or special fiscal burdens imposed by reason of its constitution or legal capacity or any form of its activities" (20). Some members of Protestant bodies maintained that these guarantees were not always effectively implemented: but the fact that. for example, the Protestants were given broadcasting time on the state radio on Sunday mornings, even though they constituted a small minority, mas cited as evidence of an intention on the part of the state to treat them fairly. (M. DK.)

EDUCATION

The Italian educational system has always been highly centralized under the control of the minister of education. The state provides schools of every grade, and most of the universities are state universities with rectors appointed by the minister. Elementary schools are administered by the commune. which maintains them sometimes with help from the state; but for educational purposes even the elementary schools come under the district representative of the ministry, the *provveditore agli studi.* Secondary schools are directly under the ministry.

During the period of Fascist government from 1922 to 1943 two important education acts were put in force: the Gentile reform of 1923–24, so called after the chairman of the commission on education, the philosopher Giovanni Gentile; and the Bottai act or *Carta dellu scuola* (school charter), introduced in 1939 by the minister of education. Giuseppe Bottai. The Gentile reform laid donn the general lines of education; the Bottai act was largely concerned with the organization of different types of school and with the inculcation of Fascist ideas, particularly through the use of compulsory "readers." After 1945 much of this last act was swept away, but the general framework of schools, not unlike that of Great Britain, was retained.

Education from 6 to 14 years of age is compulsory; elementary education is free. But, though school attendance is legally compulsory, in some cases it is very irregular. The children are officially enrolled but sometimes only go to school for three or four months in the year, particularly in the country districts. This is true even in northern Italy in the mountainous areas, but it is much more marked in the south. nhere the teachers are badly paid and, above all, the housing problem often presents extreme difficulties. In the more remote villages of Calabria, where one small room with no windows may represent the school, the teacher may be unable to find lodging of any kind in the village and so may have to spend two hours travelling each way by the one bus in the day, nhich only allows the teacher to spend a short time with the pupils.

Elementary and Secondary Schools. — Elementary education proper begins at 6 years of age, but for younger children there are preparatory schools variously known as *asili infantili* (nursery schools). *scuole materne,* etc. These schools are not compulsory and are run by various private bodies and by the communes. The elementary schools consist of five classes and include some of the most interesting and progressive schools in Italy. Secondary education begins at 11 years of age and is not free though cheap,

but school books are expensive. Although schooling is legally compulsory until 14, the great majority of children (67% in 1952) leave school at 11 to start work. Those who continue go either into the *scuola media unica* where for three years they get a general education on academic lines. or into the *scuole di avviamento professionale,* schools with a professional bias, industrial, commercial, agricultural or nautical. From these professional schools the pupils can only go on to technical institutes. From the *scuola media* the pupils pass on to higher secondary schools. where the education lasts for five years (from 14 to 19 years of age). There are four main types of higher school: the *liceo classico* for classical and humanistic subjects; the *liceo scientifico* for mainly scientific study; the *istituto magistrale* for training teachers; and the *istituto tecnico-commerciale* for training students for technical and commercial posts. There are various other institutes which give special professional training; *e.g.,* agrarian and marine schools.

In addition to the state schools there are a large number of private schools, mostly Catholic schools run by the Jesuits, Benedictines, Salesians and other orders, to which most well-to-do children go. Private elementary schools can. by agreement with the *provveditore agli studi* of their area. obtain a form of state recognition and a subsidy from the education authorities, if they follow the state program of education. Private secondary schools can obtain state recognition known as *parificazione* (equalization) if they teach the subjects prescribed for the corresponding state schools. *(See* Table IX.)

TABLE IX.—*Elementary and Secondary Education, 1954–55*

Type	Schools	Pupils	Teachers
Nursery schools	14,875	1,052,050	27,828
Operated by the communes	4,018	313,659	8,122
Operated by religious bodies	4,658	350,133	9,337
Operated by private bodies	6,199	388,258	10,369
Elementary schools	41,943	4,655,992	178,591
State	35,764	4,299,561	164,593
Non-state (recognized, private, subsidized).	6,179	356,431	13,998
Secondaryschools	2,361	468,988	40,273
State	1,127	351,974	28,319
Non-state	1,234	117,014	11,954
Vocationalschools	2,460	490,553	41,339
State	2,038	449,632	36,384
Non-state	422	40,921	4,955
Higher classical, scientific and teacher's training schools	1,514	289,973	26,702
State	673	214,367	18,132
Eon-state	841	75,606	8,570
Technical institutes and institutes for girls	570	193,288	15,474
State	346	161,649	11,744
Non-state	224	31,639	3,730

Scuole **Popolari.**—Illiteracy has long been a sore point with progressive Italians. Although it had decreased steadily between 1871 and the illiteracy census of 1931, it was then still high in the southern regions and even in some of the central ones. Illiterates constituted 26% of the population in Umbria and the Marches, 39% in Apulia, 46% in Basilicata, 48% in Calabria and 40% in Sicily, with a total of about 7,500,000 (or 34% of the population), including 6,700,000 over school age. There was a serious increase in illiteracy as a result of World War II, but the desire to get rid of it was strong, not only among educationalists and politicians but among the people themselves. The so-called *scuole popolari* (schools for the people) set up in Dec. 1947, consisting of day and evening classes, were at first largely attended, particularly in southern Italy where the need for them was greatest. Unfortunately in the south suitable teachers were seldom forthcoming and for this and other reasons classes were not as well attended as had been hoped.

The Universities.— There are 21 state (excluding Trieste) and 5 "free" universities in Italy, besides the state university for foreigners (at Perugia) and a number of higher institutes which are reckoned to be of university standard. The state universities are those of Bari, Bologna. Cagliari, Catania. Florence, Genoa, Macerata, Messina, Milan, Modena, Naples. Padua, Palermo. Parma, Pavia, Perugia, Pisa, Rome, Sassari, Siena and Turin; the free are those of Camerino, Ferrara and Crbino. the Roman Catholic University of the Sacred Heart in Milan and the Commercial university of Milan. The number of university students was always large, and an enormous increase took place between 1930 and 1940. The number increased again after 1945. In the academic year 1947–48 there were nearly 180,000 students. But by 1954–55 the number was down to about 136,000 *(sc.* 136,458 in all, of whom 1.552 were at Trieste). Students enter the universities from the *licei* or *istituti tecnici-commerciali;* from the *istituti magistrali* they pass into the faculty of *magistero* (education) of the universities. In 1954–55 the students were divided among the various faculties and subjects as, follows: law, 28,863; economics and politics, 22,029; letters. including education, 23,203; medicine and surgery. 20,468; engineering and architecture, 15,731; science and mathematics, 20,861; pharmacy, 8,930; veterinary studies, 1,969; agriculture and forestry, 2.366; industrial chemistry, 2,075; various. 1,968.

The university course lasts from four to six years, and the student has to undergo a large number of examinations. Even when he has obtained his degree, he has to take the *esame di stato* (state examination) before entering any profession.

The universities are under rectors. There are four grades of teachers in the Italian as in other continental European universities. The lowest grade is that of the *assistenti* (assistants) appointed year by year by national competition or by the professors. The next grade, the *liberi docenti,* lecture and receive practically no pay. *Professori incaricati (i.e.,* entrusted with teaching) are appointed for one year by the universities with a low rate of pay. Full professors, *professori titulari,* are appointed by state competition on production of published work.

Academies. — The 15th, 16th and 17th centuries saw the foundation of many academies. where groups of students and patrons of the sciences discussed the new art and learning. The most famous, the Accademia dei Lincei, was founded in 1603 by Federico Cesi of Rome and tno other young men, Francesco Stelluti of Fabriano and Anastasio de Filiis of Terni, for the study of the mathematical physical and natural sciences. It included among its members most of the great scientists of the time, both Italian and foreign, prominent among them Galileo. Cesi's death in 1630 put an end to the academy's activities; various attempts were made to revive it, but none were successful until 1847, when Pope Pius IX restored it as the Pontificia Accademia delle Scienze — Nuovi Lincei. In 1870 a separate branch was established under the patronage of the crown, the Reale Accademia Nazionale dei Lincei. In 1875 the Reale Accademia established a second class of membership for the study of the moral sciences, history and philology. In 1929 the Fascist government set up a new academy, the Reale Accademia d'Italia, with magnificent premises in the Palazzo Farnesina The aim of the new academy was to supplant the old academies. especially the Lincei. which had shown signs of independence. In 1939 the Lincei were fused with the Reale Accademia d'Italia. On Sept. 28, 1944, the Reale Accademia d'Italia was suppressed by Bonomi's government and on the same date the Accademia Nazionale dei Lincei was re-established. It established two classes of members as before (72 Italian members, 72 corresponding members. with 72 foreign members). and possessed a valuable library; its headquarters at mid-century were in the Palazzo Corsini in Rome.

Libraries and Museums. — These are numerous in Italy, those even of small cities being often rich in manuscripts and valuable works. Statistics collected in 1893–94 and 1896 revealed the existence of 1,831 libraries. either private (but open to the public) or completely public. The public libraries were enormously increased after 1870 by the incorporation of the treasures of suppressed monastic institutions, but suffered seriously from lack of funds during and immediately after World War I The richest in manuscripts is that of the Vatican, especially since the purchase of the Barberini library in 1902; it contained about 53.000 manuscripts at mid-20th century. The Vatican archives are also of great importance. Most large towns contain important state or communal archives; the various societies for local history in the various regions of Italy (Società di Storia Patriaj do good work and issue valuable publications. The treasures of the archives were by no means exhausted in the early 1950s. The private archives of the great families often contain documents of the highest interest. Li-

braries and public archives were placed under the superintendence of the ministry of public instruction. A separate department of this ministry under a director-general was given charge of antiquities and fine arts, making archaeological excavations and supervising those undertaken by private persons (permission to foreigners, even to foreign schools. to excavate in Italy was rarely granted) and maintaining the numerous state museums and picture galleries. The exportation of works of art and antiquities from Italy without leave of the ministry was forbidden. An inventory of those objects, the exportation of which could in no case be permitted. was prepared. The ministry had at its disposal a fund for the purchase of important works of art of all kinds. (See also LIBRARIES.)

GOVERNMENT, LAW AND DEFENSE

On June 2. 1936, the Italians voted by 12,718,641 against 10,-718.502 in favour of replacing the monarchy by a republic. and on June 28 Enrico de Nicola became the provisional president of the Italian republic. A constituent assembly drew up a new constitution to replace the old constitutional statute of 1848 which had been amended almost out of recognition but never abolished by Mussolini, and on Dec. 22 adopted the new constitution by 452 to 62 votes. It was promulgated on Dec. 27, 1947, and came into force on Jan. 1. 1948.

Constitution. — The Italian constitution is a rigid one which can only be revised by a lengthy procedure. The drafting commission was determined to secure a system of parliamentary democracy and to prevent unconstitutional developments of the Fascist type. Also, like many modern constitutions. the Italian constitution includes provisions which cannot strictly be considered as constitutional, particularly those covering social and labour legislation. The revulsion against interference with individual liberty resulted in the large number of articles which lay donn fundamental principles regarding the rights of man, equality of all men before the law, the inviolability of personal liberty and of the home and freedom of speech, of assembly, of religion and of the press. Two of the general provisions are of special interest when viened in the light of the history of Italy. Article 6 states that the republic will protect linguistic minorities and Italian constitutional jurists maintain that the term republic covers not only the state or central authority but also the regions, provinces and communes This is an important undertaking in a country where the German and Yugoslav minorities mere badly treated between 1919 and 1939. Articles 7 and 8 define relations betueen church and state. Article 7 says: "The State and the Catholic Church are each, in its own order, independent and sovereign. Their relations are regulated by the Lateran Pacts [of 1929]. Modifications of the Pacts which are accepted by both parties do not require the procedure of constitutional amendment" So other modern constitution contains any similar provision, which involves a revision of the constitution if church or state desires to repudiate the concordat. Article 8 states that all religious confessions are equally free before the law and that confessions other than the Catholic have the right to be organized according to their own statutes insofar as they do not conflict with the Italian legal order. By the early 1950s the Protestant churches of Italy had already complained that their rights under this clause were being ignored.

The constitution can be revised but only by a constitutional law adopted by each chamber of parliament in two successive meetings at intervals of not less than three months. An absolute majority is required in each chamber on the second vote. Revision can be subject to a referendum like other laws. But one thing is not subject to constitutional amendment — the republican form of government.

Article 1 of the constitution affirms the principle of popular sovereignty: "Italy is a democratic republic based on work. Sovereignty belongs to the people. who will exercise it in the forms and within the limits prescribed by the Constitution." The sovereignty of the people is secured by the establishment of universal, adult suffrage, exercised both in elections to parliament and in the referendum, this last being one of the new features of the constitution. The centre of the constitution is parliament, which consists of tn-o chambers with equal powers: the chamber of deputies and the senate. These meet in joint session in certain cases provided for by the constitution: for the election or impeachment of the president of the republic; for the impeachment of ministers; and for the election of one-third of the members of the supreme council of the judiciary.

Legislative power belongs to the two houses collectively; legislation can be initiated by the government. by members of either house and by bodies on which it is conferred by constitutional law (this provision was regarded by the drafting commission as applying to the national economic council and to the regional councils which were to be set up). The people may also promote legislation by presenting a draft bill supported by at least 50,000 electors. Bills can be initiated in either chamber and must be approved by both before being promulgated by the president of the republic. who has the right to request a fresh deliberation by the chambers but must promulgate the law if it is approved a second time. A referendum for the abrogation of a law (other than laws dealing with taxation! the budget, amnesties or the ratification of international treaties) must be held if it is asked for by 500,000 electors or by five regional councils. Special attention is paid by the constitution to the subject of decree laws. It was largely by the use of decree laws that the Fascists imposed a totalitarian system on Italy within the framework of the constitution of 1848. Under the constitution of 1948 the government map not issue decree laws without the previous consent of parliament; if in case of extraordinary necessity the government adopts measures having the force of lam, it must on the same day present them for conversion into law by the chambers. which must be specially convened for the purpose if they have been dissolved. Parliament authorizes the ratification of international treaties and approves the national budget.

The position and powers of the president of the republic are carefully defined. The makers of the constitution were conscious of the danger of conferring executive power on the president, but at the same time they felt the need for a stabilizing and unifying influence and did not wish to make the president a mere figurehead. The president is elected for seven years by secret ballot at a joint session of both chambers and must obtain a two-thirds majority of the votes. He is head of the state and commander of its armed forces; he announces the holding of new elections and can dissolve one or both chambers; and he promulgates laws, declares war, has the right of pardon and presides over the supreme council of the judiciary. Rut the president does not govern. No act of his is valid unless confirmed by the ministers proposing it, who assume responsibility for it, and he cannot be held responsible for any act taken as president — except in a case of high treason or attack on the constitution. in which case he must be impeached before a joint session of parliament.

Executive power lies with the government which consists of the president of the council and of the ministers, who together constitute that council. The president of the republic nominates the president of the council and, on his advice. the ministers. The government must have the confidence of both chambers, and comment by Italian constitutional lawyers on this provision indicates that they regarded this requirement as establishing the responsibility of ministers to parliament. One of the weaknesses of the constitution of 1848 was its failure to establish responsibility to parliament. It merely said that ministers were responsible, not to whom they were responsible.

The president of the council decides on the general line of policy and is responsible for it; the ministers are collectively responsible for the acts of the council and individually for those of their own ministries.

Provision is made for what are called auxiliary organs: the national council for economic affairs and labour; the council of state for questions of law and administration; and the court of finance. All of these are advisory bodies, though the first has also the power to initiate legislation.

One important new organ of government set up in 1948 was the constitutional court, empowered to give decisions on the constitu-

tional character of laws and of acts having the force of law emanating from the state and the regions. The court decides in cases of conflict between the powers of state and region and between region and region and also in cases of impeachment of the president of the republic or of a minister. It consists of 1j judges. one-third nominated by the president of the republic, one-third by parliament sitting jointly and one-third by the supreme judicial bodies. The judges are to be nominated for 12 years, being chosen from the magistrates of the higher courts, professors of law and lawyers who have practised for 20 years.

Electoral Law.—According to the constitution both houses, the chamber of deputies and the senate, are elected by universal, direct suffrage. The chamber of deputies has one deputy for every 80,000 inhabitants, the senate (elected on a regional basis) one senator for every 200.000. Men and women of 21 and more years of age may vote for the chamber, those over 2j for the senate; deputies must be 25 years of age, senators 40; the chamber is elected for five years, the senate for six. Former presidents of the republic become senators for life, as do five senators nominated by the president of the republic for their outstanding contributions to the social. scientific, artistic and literary life of Italy.

The decree of Feb. 5, 1948. adopted for election to the chamber a system of proportional representation with voting for a party list. There were 32 multiseat constituencies, and every voter could indicate his preferences regarding individual candidates within that list; 530 deputies were to be elected in constituencies and 22 seats would be divided among the parties under a national pooling system (*collegio* unzco *nazionale*).

The decree of Feb. 6, 1948, concerned with election for the senate, combined proportional representation with uninominal constituencies. Besides the 237 elected senators the first senate of the republic was to include, exceptionally. 107 senators by right (senatori di dtritto), their qualifications being that they were former prime ministers. former presidents of the chamber or former deputies who suffered more than five years' imprisonment for their opinions under the Fascist regime.

The electoral law promulgated on March 31, 1953, revised the decree of Feb. 6. 1948, by stipulating that a party or a group of allied parties receiving an absolute majority of 50.1% of the poll would be allotted 65% of the seats in the chamber. The electoral system for the senate remained unchanged, but the senators by right disappeared after the election of June 7, 1953.

Local Government.— The republic is divided into regions, provinces and communes. The most important innovation introduced in 1948 into the structure of the state was the establishment of self-governing regions. "autonomous bodies (*enti*) nith powers and functions of their own in accordance with the principles laid down by the Constitution." In 1861, when Camillo Cavour died, his successors were absorbed by the difficulty of securing the recently non unity of Italy and were afraid to venture to introduce any measure of local autonomy. The French system of rigid central control of local government through the prefects of the provinces, which had not worked too badly in the small kingdom of Piedmont-Sardinia, was ill-adapted to the varying needs of the different districts of united Italy. Mussolini, however, found this centralized system admirably adapted for securing a stranglehold over the country. In consequence the opponents of fascism were determined to secure a large measure of decentralization and of local self-government.

The Region.—The name region (regione) is not new: certain statistical and other information had always been given under the headings of the various regions—Piedmont, Tuscany, Sicily, etc. It had been, however, merely a convenient name for a group of provinces carrying no implication of administrative or legislative functions. Under the constitution of 1948, 19 regions were established—Piedmont, Valle d'Aosta, Lombardy, Trentino-Alto Adige, Veneto, Friuli-Venezia Giulia, Liguria, Emilia-Romagna, Tuscany, Umbria, the Marches, Latium, Abruzzi e Molise, Campania, Apulia, Basilicata, Calabria, Sicily and Sardinia Five of these regions, Sicily. Sardinia, Trentino-Alto Adige, Valle d'Aosta and Friuli-Venezia Giulia, belong to a different category from the rest. Each of the other 14 regions was intended to have a statute of its own containing regulations to bring into force a system of government on the general lines laid down in the constitution; and these statutes were to be approved by an ordinary law of the republic. The statutes of the five special regions are less restricted and had therefore to be adopted by the passing of a constitutional law; they can only be amended by the procedure laid down in the constitution for constitutional revision. The first four special regions obtained their statutes on Feb 26. 1948; but since the future of Friuli-Venezia Giulia was felt to depend on that of Trieste. this region was treated as an ordinary region in the years following 1948.

The constitution gave the regions power to promulgate statutory legislation on definite subjects of local interest; *e.g.*, the organization of local police, the provision of public assistance and medical services, town planning and local communications. Their power to administer this legislation was limited, for there was no desire to have local administration centralized in the region any more than in the state. In cases of exclusively local interest national legislation could confer administrative power on the provinces. communes or other local bodies; and in all cases the region was normally intended to function administratively through the provinces and communes. It was also intended that the regions should have financial autonomy, and the constitution made special provision for the needs of the poor regions by laying down that the regions would not only have certain taxes assigned to them but would receive a quota of the general national taxation in proportion to their needs. In addition the constitution specifically provided for additional financial help in cases involving extraordinary expenditure, such as the development of the south and of the islands.

The official bodies of all regions were to be a regional council to exercise legislative and administrative powers; a giunta or executive committee; and a president to represent the region, promulgate its laws and direct administration. A commissioner of the government was to reside in each region and co-ordinate the administrative functions of the state with those of the region. By the end of 195j no elections to regional councils had been held, so that the regions as autonomous bodies with legislative and administrative functions still only existed on paper. Local government continued to be carried on by the smaller autonomous bodies, the provinces and the communes. which were described in the constitution as being also (*i.e.*, as well as the regions) "areas of national and regional decentralization."

The Commune.—According to the 1951 census there were 7,810 communes. Every square inch of Italy forms part of a commune, which may vary in size from a tiny village to a great city with more than 1,000,000 inhabitants. such as Rome or Milan. All, whatever their size, have the same administrative bodies and all are responsible for certain services: local police, public health, lighting, fire precautions and local public works. The funds of the commune come either from the possession of land and buildings or from various taxes, the chief of which is the *imposta di consumo* (commodity tax). All citizens 21 and more years of age living within the commune can vote in both communal and provincial elections. After Jan. 1946 elections were based on proportional representation in communes with a population of more than 30.000 and in provincial capitals even if their population was less than 30.000; in other communes election is by majority vote with certain special provisions intended to secure representation of minority groups. The organs of government are the mayor (sindaco), a council and an executive committee (giunta), all elected.

Tlze Province.—In 1951 there were go provinces, artificial creations of united Italy, which did not correspond to the old areas existing before 1861. The province has a dual character: it is an area of the state and, as such, the seat of various local administrative agencies of the central government; and it is also an autonomous local body with the duty of providing for local interests. Each province therefore has two sets of officials and administrative bodies. The prefect, the chief government official, is a high-ranking, salaried civil servant. appointed by a decree of the president of the republic on the recommendation of the min-

ister of the interior with the approval of the whole cabinet. He is charged with administering national legislation and the decrees of the ministries and, although primarily responsible to the minister of the interior, is also the local representative of all other ministries. He also has the task of supervising everything which concerns public security and enjoys the right to use the police and to call upon the help of the armed forces of the state. Justice, the armed forces and the railways are exempt from his direct control. All deliberations of the communal council and executive are submitted to the prefect, who can annul any decision of the commune or the province that he may judge to be contrary to the law. The prefect is assisted by a council *(consiglio di prefettura)* of three members, paid officials, presided over by himself or his deputy. They also preside over a committee (*giunta provinciale amministrativa)* consisting of two members of the council and four members elected by the provincial council *(see* below). All contracts entered into by the communes or provinces involving more than a small sum are supervised by the council, and the administration of their real property is watched over by the committee.

The local provincial organs of government are the provincial council (*consiglio provinciale*), an elected body varying in size according to the size of the province, and its executive committee (*deputazione provinciale).* The council has charge of public buildings and other property belonging to the province and must provide for poor relief and public health. for provincial roads and bridges and their upkeep and for certain public works. The funds of the province come partly from property in land and buildings, partly from taxation, partly from loans.

Justice.—Italian law is fundamentally based on Roman lam; but it also owes much to French law, and Italian lawyers have been greatly influenced by French juristic literature and by the decisions of the French court of cassation. The development of a unified system of justice was not easy in a country where the administration of justice had been so varied before 1870. but the influence of France, exerted through Piedmont, was a strong unifying element in the late 19th-century codes, on which the Italian system of justice was based. Immediately after World War I a group of distinguished Italian lawyers was appointed to draw up new codes, which were issued as the Codici Mussoliniani. New codes for criminal law and procedure came into force in June 1931; the new civil code. which included commercial law (formerly incorporated in a separate code), the code of court procedure and the navy code came into force only in April 1942. In theory the new codes were supposed to further "Fascist justice"; in fact they were the outcome of years of work by eminent Italians. Certain articles, such as those which had made strikes and lockouts illegal, were deleted after the destruction of the Fascist regime, and the Italian parliament continued to discuss various other reforms; but by the latter 1950s it seemed likely that, with some amendments, the codes would remain.

The main lines of the theory and practice of the administration of justice are laid down by the constitution of 1948. which devotes a whole chapter to the subject. Experiences under Fascist government showed how important it nas that the judiciary should be independent. The constitution accordingly states that "justice is administered in the name of the people; the judges are subject only to the law." The judiciary is an autonomous order independent of all others. and the judges cannot be removed. Judicial functions can only be exercised by ordinary magistrates. No extraordinary or special courts can be set up, as they were under Fascist rule.

Italian lawyers and politicians are divided on the question of the desirability of trial by jury. The constitution provides (article 102) for the creation of special sections of the ordinary courts to deal with particular subjects, in which sections ordinary citizens not belonging to the magistracy can take part; and for the definition by law of this direct share by the people in the administration of justice. Some lawyers hold that the provision makes it possible to introduce juries. but the minister of justice maintained in 1950 that the later article of the constitution (article 111), which states that the reasons for all jurisdictional decisions must be given *(motivati),* implies the rejection of the jury system with its plain decision of yes or no.

The Legal Profession.—There are two separate branches of the legal profession in Italy, and they are not interchangeable. The one branch is strictly legal and consists of *avvocati* (advocates) and *procuratori* (agents). Except in the lowest courts the *procuratore* is in charge only of the preliminary procedure and pleading is done by the *avvocato.* Both act as solicitors or barristers and a professional lawyer may be both a *procuratore* and an *avvocato.*

The other branch of the profession is the judicial. The magistracy is a part of the civil service, and advancement in the career is by competitive examination, although seniority is taken into account for some of the highest posts. The magistrates rise in rank from the *giudici conciliatori,* who correspond roughly to the British local justices of the peace, through the *pretori* and the judges of the *tribunali* and the *corti d'appello* to those of the supreme court, the *corte di cassazione;* the highest post is that of the first president of the *corte di cassazione.* Responsibility for the administration of justice belongs to the minister of justice, and for this purpose the country was divided into 17 judicial divisions and subdivisions, which differ from the ordinary areas of communal and provincial administration.

Courts.—The lowest civil courts are the local *uffici di conciliazione* (offices of conciliation), each presided over by a *giudice conciliatore* (local justice of the peace) who deals with minor cases involving sums of not more than 10,000 lire. Much stress is laid in Italy on the importance of conciliation. and normally 80% of disputes are settled in these courts or in those of the next grade, the *preture.* These courts are held in each large district or *mandamento* (there are more than goo) and are each presided over by a single *pretore* (corresponding to a British stipendiary magistrate), whose competence extends to cases involving sums not exceeding 100,000 lire. The next highest courts are the *tribunali,* each of them with a bench of three judges; and above them are the *corti d'appello* (courts of appeal), each nith a bench of five judges. These *corti* usually deal with appeals from the *tribunali,* but they may also sit as courts of first instance. There are *corti d'appello* in 22 large towns: Genoa, Turin. Milan, Brescia, Trento, Venice, Bologna, Florence, Ancona. Perugia, Rome. Aquila, Naples, Bari, Lecce, Potenza. Catanzaro, Messina, Catania, Caltanissetta, Palermo and Cagliari, and a subsidiary court in Reggio di Calabria.

The decisions of these *corti d'appello* are final on points of fact, but appeals on points of law may be taken from the *preture,* the *tribunali* and the *corti d'appello* to the supreme court, the *corte di cassazione* in Rome.

Minor criminal offenses involving imprisonment or restriction of the personal liberty of the offender for a period of less than three years are dealt with by the *pretore* sitting as a single judge in his court. The *tribunali* have a bench consisting of a president and two judges and consider appeals from the *preture;* the *corti d'appello* have a bench of four judges and have appellate jurisdiction to review sentences pronounced by the criminal divisions of the *tribunali.* In addition there are the *corti d'assise* which act as courts of first instance in cases of major crimes and felonies involving life sentences or long terms of imprisonment. They consist of a mixed bench of three professional and five lay judges, these last being chosen from a panel of men nho possess certain educational qualifications. Appeals from sentences delivered by the *tribunali* and the *corfi d'assise* can be taken to one of the two criminal divisions of the *corte di cassazione,* nhich, as in civil cases, acts as the supreme court in cases involving points of law but not of fact. Each division has a bench of seven judges, and they can combine to form a *sezione unita.*

Penalties and Crime.-The death penalty was abolished in 1877 but restored by the Fascists in 1926 for certain crimes against the safety of the state (in particular for attempts on the life of the king or of Mussolini). It was again abolished by article 27 of the constitution of 1948. In Jan. 1948, in consequence of this decision. death sentences mere altered to life sentences, and life sentences to imprisonment for 30 years. The practice of *confino,* or confinement to remote places on the mainland or to small is-

lands like the Lipari, which was used for political prisoners, was abolished in Dec. 1948.

There are various kinds of prisons as in other western countries. *Carceri* giudiziarie (judiciary prisons) are used for persons awaiting examination or under arrest and for prisoners undergoing short sentences. Persons serving sentences up to six months are usually in district prisons (*carceri* giudiziarie *mandamentali*), those serving sentences up to two years in central prisons. The other large class of prisons are knonn as *stabilmenti* di *pena* ordinari (ordinary places of punishment) and *stabilmenti* speciali The first include convict prisons (ergasfoli); the special prisons are those for habitual offenders and for prisoners sentenced to hard labour, as well as prisons for minors under 18. In addition there are the *stabilmenti* per *le misure amministrative* di *sicurezza detentive* (places for administrative security measures), nhich include agricultural colonies, institutions for criminal lunatics. etc.

Table X shows the prison population, from 1947 to 1953.

TABLE X.—*Prison Population*

Type of prison	1947	1949	1951	1953
Carceri giudiziarie	50,104	39,410	32,545	16,866
Stabilmenti di pena ordinari e speciali	13,287	16,178	14,527	11,394
Stabilmenti per. le misure amministrative di sicurezza detentive .	2,782	3,127	2,987	2,993
Total	66,173	58,715	50,059	31,253

Statistics show that the incidence of crime was considerably higher after World War II than in 1939. The biggest increase was in crimes of personal violence, which numbered 153,813 in 1948 and 167,002 in 1949 as compared with 119,037 in 1939. Cases of theft amounted to 369,891 in 1948 and to 312.481 in 1949, as compared with 230,890 in 1939. Murder figures for 1949 were double those of 1939. But crimes of violence had always been common and years of underground warfare encouraged the tendency.

Defense.—The Italian army grew out of the old Piedmontese army, which had played a major part in the unification of Italy. The law of 1875 introduced conscription for every able-bodied Italian but, chiefly for financial reasons, only a proportion of the available recruits were drafted; in 1906, for instance, of 475,737 liable for service, 122,557 were physically unfit and only 87.493 were conscripted. Under the law of July 17, 1910, the Italian army mas organized in 2j divisions, each consisting of four regiments of infantry; there were also three divisions of cavalry. The army comprised 96 three-battalion regiments of infantry, 12 of bersaglieri (riflemen) and 8 of *alpini;* 29 regiments of cavalry; and 51 regiments of artillery, including two of mountain and 10 of fortress artillery. At the beginning of 1914 the peace strength of the army was 15,123 officers and 289.910 other ranks. By the end of World War I, in which Italy participated from May 24, 1915, it mas estimated that 5,068,000 men had been mobilized. The navy, which in 1914 had a peacetime strength of 1,987 officers and 38,000 other ranks, had 114,000 men mobilized at the end of World War I.

Between World Wars I and II five new infantry and two new alpine regiments were formed and new three-regiment divisions created. The artillery was reorganized and expanded, and by 1938 there were 72 regiments including j of mountain and 5 of anti-aircraft artillery. In May 1940 the army comprised 20 divisions with about two-thirds of the necessary armament and training and another 20 divisions at half strength. The air force, created by the royal decree of Jan. 24, 1923, comprised about 1,200 aircraft in May 1940, one-sixth of them out of date. The navy at the beginning of World War II had 6 battleships. 22 cruisers, 61 destroyers, 71 torpedo boats and 105 submarines. The period of compulsory service was 18 months but, as before, there were frequent reductions of service and exemptions. The total of efiectives budgeted for in 1935, for instance. was: in the army. 17,500 officers and 234,300 other ranks in the home country and 2,500 officers and 65,600 other ranks in the colonies; in the air force, 25,800 officers and airmen; in the navy, 64,000 officers and sailors.

After World War II Italy's military position was strictly defined by the treaty of Paris in 1947. The treaty compelled Italy to destroy or remove all frontier fortifications within a distance of about 12 mi. of the French and Yugoslav frontiers; ordered the demilitarization of Pantelleria and the Pelagie Islands (Lampedusa. Lampione and Linosa) between Sicily and Tunisia and of Pianosa in the Adriatic; and strictly limited the maintenance of naval installations and fortifications in Sicily and Sardinia.

The strength of the armed forces was limited by the treaty to 300.000. as follows: army, 250,000, including frontier guards and 65,000 carabinieri (police); navy, 25,000; air force, 25,000, including combat, service and overhead personnel.

Strict limits were also imposed on Italy's possession or construction of war matériel. The number of heavy and medium tanks nas limited to 200, the air force was limited to 200 fighter and reconnaissance aircraft and to 1jo transport. air-sea rescue, training (school type) and liaison aircraft. Naval armaments were also limited. The total displacement of vessels held by Italy might not exceed 67,500 tons. and only the folloning units were allowed to be retained. 2 battleships (the "Andrea Doria" and the "Caio Duilio"), 4 cruisers, 4 destroyers, 16 torpedo boats, 20 corvettes. 35 mine sweepers, 8 vedettes and a number of small auxiliary vessels.

The radical postwar changes in the alignment of powers quickly transformed the former enemy into an ally of the western democracies. Italy became in 1949 a founder member of the North Atlantic Treaty organization. The military clauses of the Paris treaty nere not formally revised because the U.S.S.R. refused its consent; but they were actually alloned to lapse, and the only limit to Italian rearmament was determined by finance.

By 1955 Italy mas divided into 11 military regions (the so-called *Comiliter*) and had 10 infantry divisions, 5 *alpini* brigades and 3 armoured divisions. The air force territorial organization comprised four zones (Milan, Padua. Rome and Bari) with tno additional commands for Sardinia and Sicily. There were about 400 first-line aircraft; 15 squadrons were assigned to the 56th NATO tactical air force. The navy had 2 battleships (disarmed), 3 cruisers, j destroyers, 17 frigates and escort vessels, 23 corvettes, 59 mine sweepers. 52 motor torpedo boats. 6 gunboats, 2 submarines and 163 small auxiliary vessels. There were seven territorial navy commands. Military service was compulsory for a period of 18 months. Total effectives of the armed forces amounted in Jan. 1955 to 433,000; *i.e.,* 353,000 in the army (including 60,000 carabinieri or military police), 38,000 in the navy and 42,000 in the air force. Expenditure on defense increased from $482,000,000 in 1949 to $835,000 000 in 1953, but the proportion of the total budget expenditure remained about 24%.

ECONOMY

Italy's natural resources are scanty both for agricultural and for industrial purposes. Much of the country is rocky and mountainous or marshy, and soil fertility is mainly the result of the laborious work of centuries. Industrial resources are limited, and the absence of coal and iron in any quantity was particularly hampering in the early stages of industrialization.

Italy has only two important assets: an abundance of cheap labour and of skilled craftsmen and a reasonable amount of hydroelectric power. For employment and unemployment see under Population above.

AGRICULTURE AND FISHERIES

In spite of the growth of industrialization agriculture remains by far the most important Italian economic activity. According to the census of 1936 Italy had a rural population of about 18,500,000 out of a total population of 43,000,000, and 47% of the employed population were engaged in agriculture. (The sample inquiry made by the Italian Institute of Statistics in 1952 showed about 42.5% still engaged in agriculture.) These figures for the whole country show neither the high proportion of agricultural workers in the south (*e.g.,* 74.5% of the employed population in the Abruzzi and 75.4% in Basilicata) and even in central Italy (64.7% in Umbria and 66.7% in the Marches) nor the much loner proportion in Lombardy (only 28.6%) with its fertile land and high yields.

A great part of Italy is either arid and mountainous or marshy and hitherto malarial, but even so more than two-thirds of the land is under cultivation or pasture, and less than 8% is considered to be totally unproductive. In spite of a dearth of good land Italian farmers supply the greater part of the country's food requirements and contribute largely to its exports (approximately one-third before 1940 and one-quarter in 1953). Table XI shows agricultural land use between 1929 and 1954.

TABLE XI.—*Land Use*
(In hectares)

	1929	1948	1950	1954
Arable	12,752,977	12,954,100	13,050,000	13,186,905
permanent grassland	6,016,718	5,404,400	5,147,000	5,166,554
Specialized tree and bush	2,279,949	2,329,000	2,405,000	2,515,675

*Including sweet chestnut. †1931.

Land reclamation has gone on for centuries in Italy. where large areas of mountainous or hilly land have been made reasonably productive by the industry of the Italian farming population. Great parts of the Po valley were reclaimed in the 19th century, and the nork was still going on in the second half of the 20th. After World War I plans were made for co-ordinating public and private reclamation works. *Bonifica integrale* (integral reclamation) was the name given to land-reclamation plans under nhich owners were obliged to improve land reclaimed with state aid and a rural population was to be settled on it. By 1940 some progress had been made with reclamation in the Po delta. in Tuscany (in the coastal plain known as the Maremma) and in the Pontine marshes. Cnder the much-publicized scheme for the Pontine marshes an area of about 80.000 ha. (300 sq.mi.) was drained, roads. farms and villages mere built and about 3.000 peasant families brought from all over Italy and settled on farms of from 10 to 20 ha. (from 25 to 50 ac.).

Land Tenure and Farming Methods.—Italian farming displays great variety of method and tenure. It includes at one end the industrialized farming on a large scale of the Lombard plain and the Apulian tableland, which uses agricultural machinery and large numbers of paid employees, and at the other the primitive village economy of Sicily and the Abruzzi, where the hoe and sickle are the chief tools used, the traditional rotation of crops is still practised and the corn is threshed by animals. In the main, the chief characteristic of Italian farming is its intensive nature both on small holdings and on large commercial estates; but extensive farming still prevails in the Roman Campagna, in Basilicata, Calabria and Sicily.

About one-third of the 8,000,000 persons engaged in agriculture own their land, and more than 90% of the owners work the land themselves. Italy is therefore sometimes described as a land of peasant proprietors, but the description is misleading. About 8.000.000 holdings (or 83% of the total number of 9,700,000) are less than 2 ha. (5 ac.) and in all only occupy 13.7% of the agricultural land, while 53.7% are under ½ ha. and occupy only 3.2% of the land. These dwarf holdings are found all over the country but particularly in the mountainous districts, where their miserably poor owners eke out a wretched living by working as day labourers on the larger farms. At the other end of the scale farms of more than 50 ha. (125 ac.), which number only 0.6% of the total, occupy nearly half of the agricultural land of Italy. Altogether only about 3.4% or 333,000 farms are of more than 10 ha. (2 j ac.), but they cover about two-thirds of the farmland.

Large *Farms*.—Large farms of 100 ha. (250 ac.) and more are found chiefly in the Po valley, in Xpulia and in Sicily. In the Po valley farming is industrialized, machinery is used and large numbers of day labourers (*braccianti*) and labourers with yearly contracts (salariati) are employed. Irrigation, particularly in the lower valley of the Po, is of extreme importance. The chief products are maize, rice and dairy produce. The big industrialized farms of Apulia produce great quantities of wheat and olives grown as specialized crops. Farming there is precarious and requires a considerable amount of capital. Apulia is a limestone country with scarcity of water? and arable farming is something of a gamble. Specialized olive growing also needs capital. for the trees often produce nothing for several years at a time. besides taking about 30 years to mature. Many of the Apulian farms are owned by absentee landlords who employ a large number of day labourers; unemployment and temporary migration to other regions are common. The large properties of Sicily had not been industrialized by the middle of the 20th century. These are the famous *latifondi,* the subject of complaints since Roman times. They are mainly owned by absentee landlords who either let them out in tiny plots at high rents or have them worked by labourers. Extensive cultivation was long the rule all over the interior of Sicily, but after 1945 great schemes of agrarian reform were put forward for Sicily as for Italy as a whole.

The Mezzadria Tenancy.—There are cash-tenancy farms, especially in northern Italy, but the most common form of tenancy is the *mezzadria* (share tenancy), which is found almost everywhere but is prevalent in Emilia. Tuscany, Umbria and the Marches. Rather more than one-fifth of those engaged in agriculture are share tenants. The tenancy is based on a yearly contract; though in practice the same family has often farmed a particular piece of land for generations. The landlord provides the house, the seed and other things as fixed in the varying contracts and receives in return a share of the crop; this used to be a half, as the name mezzadria implies, but in 1946 the shares of landlord and tenant were fixed at 47% and 53% respectively. The tenant's position was made more secure by legislation after World War II. However, he is not a responsible tenant farmer, but cultivates his land in accordance with the orders of the landlord, who also decides when crops and livestock should be sold.

Agrarian *Reform*.—After World War II agrarian reform was one of the main concerns of the Italian government, particularly reform in southern Italy. where social and political conditions made prompt action as distinguished from planning essential. A large general measure of reform came under the consideration of the Italian parliament in 1948. and work was begun under a special law in the Sila (the high plateau in Calabria) and the adjoining lands on the Ionian sea coast and in certain of the most depressed agricultural areas of Italy where unemployment was severe (*e.g.,* in the Po delta, in the Maremma in Tuscany and in large parts of Apulia and Basilicata) under what is known as the *stralcio* (interim) law, whereby action could be taken while the slow process of discussing the general reform went on. Under the stralcio law about 500.000 ha. (1,235,000 ac.) were to be confiscated (compensation being paid to owners). reclamation was to be carried out where required and the land divided into peasant holdings. By 195j this measure of reform was well under way and was proving to be one of the most interesting social experiments ever undertaken. For the first time the peasants of the south saw practical measures to help them being started by the central government.

Cereals.—Cereals are Italy's chief crops, and wheat is the most important. Wheat is a staple crop, on every type of farm and in every kind of soil and climate, both in the hills and on the plains. It is the primary foodstuff of the people, being used for pasta (macaroni, etc.) as well as bread. Both financial and political reasons Icd Mussolini to encourage wheat production and so to reduce the burden of an import of nearly 2,500,000 metric tons a year; and by 1939, as a result of great effort, production had reached his goal of 8,000,000 metric tons. The area under wheat rose slightly, but the increase was attained largely by the use of more intensive methods of cultivation, particularly by deep plowing. seed selection and the use of fertilizers. Italian governments after World War II were especially anxious to encourage wheat growing in view of the heavy dollar cost of imported wheat, and one of the difficulties of putting into effect agrarian reforms was the unjustified fear of reducing production. The chief wheat-growing regions are Emilia. the Veneto, Lombardy, Apulia and Sicily. About one-seventh of the whole wheat area is in Sicily, but Sicily's annual production is about. 440,000 metric tons less than that of Emilia because of the low yield. The average wheat yield for the whole country—1.95 metric tons per hectare in 195j—is lower

than that of France or of Great Britain, but much of the wheat is grown in mountainous areas and in combination with vines or olives.

The other two important cereals grown are maize and rice. The two chief maize-growing regions are Lombardy and the Veneto, which together produce half the country's maize. Rice is grown in Piedmont and Lombardy, where the Po and its tributaries make it possible to flood the fields; before 1940 these regions produced more than three-quarters of Italy's total average of nearly 800,000 tons. which was more than two-thirds of all the rice grown in Europe. Rice production in 1953 had risen to more than 900,000 metric tons, and 242,000 were exported as compared with an average annual export for 1936–39 of about 150,000. See Table XII.

TABLE XII.—*Main Crops*

Crops	Area sown (000 hectares)			Production (000 metric tons)		
	1934–38	1948–52	1953–55	1934–38	1948–52	1953–55
Wheat	5,040	4,705	4,797	7,254	7,170	8,604
Maize	1,458	1,253	1,258	3,000	2,306	3,121
Rice	142	149	175	753	725	898
Oats	428	469	448	539	495	559
Barley	193	251	247	212	253	294
Rye	105	97	87	141	133	133
Potatoes	400	392	394	2,626	2,732	3,238
Sugar beets	115	168	224	2,879	4,590	7,159

Citrus Fruit, Olives and Vines.—More than 2,500,000 ha. (more than 6,000,000 ac.) are given over to tree and bush crops, which constitute an important element in Italy's domestic economy, both for domestic food supplies and as a valuable item in the export trade. Citrus fruits, particularly lemons, are a valuable source of foreign exchange and are mainly grown in the south and in Sicily. The average production of Sicily for 1953–55 was 362,500 metric tons of oranges and 286,400 metric tons of lemons. The other most valuable tree crop is the olive, since the oil largely takes the place of other fats in the Italian diet; little butter is eaten except in the north.

Olives grow everywhere, but particularly in Apulia, which produces more than twice as much olive oil as any other region. Italy, with an average of 274,280 metric tons for 1951–55, was second only to Spain as a producer of olive oil. Vines are also grown everywhere, sometimes alone but frequently in combination with other crops (particularly in Emilia, the Veneto and Tuscany, where wheat or other cereals are grown under the vines). In Italy wine is not a luxury but an essential item in the diet of the people. There are many varieties of wine, but the only ones exported in any quantity are Marsala (from Sicily), Chianti (from Tuscany) and vermouth. See Table XIII.

TABLE XIII.—*Miscellaneous Agricultural Production*

(In 000 metric tons)

Crops	1934–38	1948–50	1953	1954	1955

Hemp fibre	89.6	71.2	63.5	41.8	34.0

*000 hectolitres. †Average of three years. ‡1947–52 average. §Excluding limes.

Vegetables.—Potatoes are grown all over the country but especially in the Po valley, in Campania and in the Abruzzi (though the yield in the last two regions is much lower than that in the north). There is a considerable production of early potatoes. Other vegetables are also grown everyhere and thanks to the seasonal varieties of climate in different parts of Italy, can be produced profitably throughout the year. The leguminous vegetable crop for 1953 amounted to 363,300 metric tons from 100,000 ha. (250,000 ac.). Tomatoes are one of the most important vegetable crops and are grown particularly in Emilia, Campania and Sicily; 1,617,400 metric tons were produced from 97,000 ha. (241,000 ac.) in 1955. Attention, however, had to be given to the improvement of methods of production. packing and transport, since out-of-date methods kept costs high and stultified Italy's natural advantages as an exporter.

Industrial Crops.—Sugar beets are grown in northern and central Italy, particularly in the Veneto and in Emilia (see Table XII). Italy is self-sufficient but the per capita consumption is one of the lowest in Europe. Tobacco is cultivated in every region except Liguria and the Valle d'Aosta; production rose greatly after World War II (see Table XIII), leaving a large quantity for export. Hemp of a fine quality is grown mainly in Emilia and Campania and is exported in considerable quantities; after the G.S.S.R.. Italy is by far the biggest European producer. Before 1940 Italy was the largest producer of ram silk in Europe. Large numbers of mulberry trees, on which the silkworm feeds, are grown in the northern plain (about 76% of the raw silk came from Lombardy and the Veneto), along the Adriatic coast in Tuscany and in Calabria. Low wages, Japanese competition and, above all, the competition of artificial fibres led to a decline of 25% in the number of mulberry trees and of 30% in the output of silk between 1028 and 1938. Production of cocoons dropped from about 45,000,000 kg. in 1928 to an annual average of 38,000,000 for 1936–39 and remained at a still lower figure after 1945, amounting to only 9,639,000 kg. in 1955.

Livestock.—The mountainous districts all over Italy provide great stretches of rather poor pasture, suitable mainly for sheep and goats; *e.g.*, in Calabria, Apulia, Basilicata and particularly Sardinia, where 63% of the farmland is rough pasture. In Trentino-Alto Adige, the Veneto and Piedmont there are fine alpine pastures suitable for cattle, which are there bred mainly for milk and cheese. The country is desperately short of fodder. Practically all the good meadowland is in the north, and the only regions producing fodder in any quantity are Lombardy, the Veneto and Emilia.

The shortage of fodder accounts in part for the small number of cattle in Italy, and their distribution provides a good example of the great differences in the agriculture between region and region. In 1953 about 61% of the cattle were to be found in Piedmont, Lombardy, the Veneto and Emilia, and only in these four regions mas there a reasonably high density of cattle to agricultural land, averaging 70 cattle to 100 ha. (247 ac.). The average density for the whole country was 32 per 100 hectares (247 ac.), but the average for the southern regions was only 13, with a maximum of 19 in Campania and a minimum of 5 in Apulia. In the north there are large herds of dairy cows; in the south before the coming of the land reform cattle were bred primarily for work, not for milk or meats. One of the chief features of the reform is the introduction of milk cows.

There are sheep all over the south and in the islands; in Sardinia there are nearly 2,400,000, approximately one-quarter of the total for Italy. Sheer, are bred mainly for meat and also for milk, from which large quantities of cheese (Pecorino) are made. They are an important element in the rural economy, but in some cases their prevalence is an obstacle to agrarian reform. There are large numbers of goats in Sicily and Sardinia, but they were fewer in 1950, for example, than they had been 30 years before. Horses, mules and asses are bred chiefly in the south, though Lombardy has far more horses than any other region. Italian agronomists are well aware of the need to increase the country's livestock and supplies of fodder. Despite the serious depredation of livestock that Italy suffered in World War II, the numbers of livestock, except horses, asses and mules, were in 1953 well above those of

TABLE XIV.—*Livestock*

Livestock				1954
Cattle	9,875,000	10,141,700	10,002,000	9,746,400
	7,879,000	8,381,200	8,694,200	9,032,600
	3,303,000	3,512,200	4,215,100	3,744,800
	1,867,000	2,254,600	2,113,000	1,797,500
Asses		773,200	760,100	724,100
Horses		768,600	733,800	669,300
Mules		393,200	397,900	401,900

Livestock	1939	1951	1952	1954
Sheep	9,875,000	10,141,700	10,002,000	9,746,400
Cattle	7,879,000	8,381,200	8,694,200	9,032,600
Pigs	3,303,000	3,512,200	4,215,100	3,744,800
Goats	1,867,000	2,254,600	2,113,000	1,797,500
Asses	789,000	773,200	760,100	724,100
Horses	781,000	768,600	733,800	669,300
Mules	432,000	393,200	397,900	401,900

countries bordering the North Atlantic. In 1952, for instance, Italy's fisheries (including fresh-water fish) produced 192,000

metric tons. as compared with France's 468,000, Germany's 663,000 and the United Kingdom's 1,106,000. But among Mediterranean countries Italy has the largest fisheries. Landings in 1955 were 194.748 metric tons (*cf.*, 181.200 in 1938).

The proportion of the population dependent on fishing is. however, comparatively high. The 1937–39 industrial census gave 93.891 persons (including 6.389 in Venezia Giulia and Zara), or 0.47% of the occupied population. as engaged in the fishing industry, uhich comprised 53,194 establishments. The industry is on a small scale, equipment is somewhat primitive and the return for labour expended small. Fishing is mainly confined to a narrow coastal zone seldom more than ten miles wide, except in the northern Adriatic and off Sicily. Sardinia and Tuscany. The most important catches consist of small fish. particularly sardines and anchovies, caught chiefly off Istria and Sicily. except for the tuna or tunny fish, which is caught in considerable quantities, mostly off the coasts of Sicily and Sardinia, though also on the Tuscan and Campanian coasts. Some tuna is eaten fresh locally but the bulk is preserved in oil. The Italian fisheries do not supply all the needs of the home market; from 1950 to 1953 about 24,000 metric tons of fish were imported annually, mostly salt cod and stockfish.

The Italian fishing fleet in 1954 comprised 47,094 vessels. with a tonnage of 149,102, as follows: 2.800 steam and motor vessels (73,141 tons); 5,868 sail and auxiliary motor vessels (20,948 tons); and 38,426 sailing vessels (55,013 tons).

POWER AND MINERAL RESOURCES

Electricity. — Hydroelectric power, Italy's "white coal," is by far its most important natural industrial resource, and it was the development of hydroelectric technique that made the expansion of Italian industrialization possible. An unusually high proportion of the power used in industry is electrically applied, and 81% of the electric energy generated comes from water, about three-quarters of it from the Xlps.

The power system is based on an exchange of current between the different regions. In the north the water supply is most abundant during the summer months, nhen the snow melts in the Xlps; in central and southern Italy. where the rivers are smelled by the winter rains, the supply is greatest in the winter. These fluctuations are met partly by the use of reservoirs, partly by the widespread use of long-distance high-tension transmission.

Having acquired the province of Alto Adige (South Tirol) under the peace treaty of 1919, Italy invested a large amount of capital in the development of the hydroelectric capacity there. By 1940 nearly one-eighth of Italy's total production of hydroelectric poaer came from the region of Trentino-Alto Adige. the poner station at Cardano near Bolzano being the largest in the country (the importance of this power to the industry of the northern plain was one of the main arguments put forward in favour of the retention of the province of Bolzano by Italy during the Paris conference of 1946). A great increase in the number of power stations and in the production both of hydroelectric poner and thermoelectric power took place from 1948. See Table XV.

TABLE XV.—*Electricity: Installed Power and Production**

Item	1929	1938	1948	1950	1953	1954
Installed capacity						
Hydroelectric (000 kw.) .	3,350	4,900	6,307	7,168	8,874	9,330
Thermoelectric (000 kw.) .	738	980	1,201	1,395	2,398	2,465
Productinn (000,000 kw.hr.) .	10,380	15,544	22,694	24,681	32,619	35,574†

*Including that of industrial establishments. †38,124,000,000 kw.hr. in 1935.

As is the case with other industries, the south falls far behind the rest of the country. Geographical conditions, made worse by deforestation and by the failure to systematize the torrential rivers, have largely deprived it of hydroelectric power. The Italian government was, however, well aware of this deficiency, and a comparison of the 1948 and 1954 figures for the southern regions showed that considerable progress had been made. While 75% of all power stations and 75% of the installed power were still in the north (compared with 11% and 13% respectively in the south), the number of power stations in the south was nearly three times as great in 1954 as in 1948 and the amount of installed power had increased from 618,701 kw. in 1948 to 1,242,003 kw. in 1954.

The total amount of electricity consumed in 1952 was distributed as follows: to manufacturing, mining and building industries, 65.7%; to traction, 8.6%; to lighting, 9.3%; to agriculture, 1.3%; to domestic and public use other than lighting, 7.7%; other, including industrial heating, 7.4%.

The electric-power industry is mainly in private hands. Concessions for the development of water power, over which the state claims domain, were granted to companies for fixed terms of years; all power stations are subject to state regulation. The majority of stations are in the hands of large combines, such as the Società Edison and the Società Meridionale, and the monopoly thus created is one of those most bitterly attacked in Italy.

Minerals. — Italy's mineral resources are small; the only important deposits are those of bauxite, mercury. sulphur and iron pyrites. The contribution made by mercury and sulphur to Italy's economy is not of the highest importance since the quantities, values and amount of employment involved are small. Italy's chief lack is coal. A small amount of anthracite is mined in the Valle d'Aosta and about 1,000,000 tons of low-grade coal are produced annually in Sardinia. The Arsa coal field in Istria. which by 1940 was producing 2,000,000 tons of poor coal every year, was taken from Italy under the treaty of 1947. Lignite output, mostly from Tuscany, amounted to about 2~000,000tons a year by 1940. In 1953 the output of coal and lignite together came to about 1,900,000 tons. Italy imported about 12,000,000 tons of coal before World War II and about 9,000,000 in 1953.

The most important mineral is probably bauxite. Under the peace treaty of 1947 Italy lost the valuable bauxite and mercury mines in Istria, but there are large bauxite deposits at Gargano (Apulia) and in the Abruzzi, in Latium and in Campania; average output before 1940 amounted to about 370,000 tons annually (*i.e.*, about 9% of the world total), and, though in 1949 output was only about one-third of that quantity, it was increasing steadily and by 1953 had reached over 272,000 tons. The important mines in Monte Amiata, south of Siena, produced about 45% of the world's total output of mercury before 1940; and by 1953 production amounted to 1,769 tons, about three-quarters of that of 1938 and 36.5% of world output. Before 1940 the sulphur mines of Sicily and Emilia had a European monopoly of sulphur, when production amounted to about 13% of the total world output; later the cost of production and the need to modernize the mines limited output, which in 1953 was not much more than three-quarters of that of 1938.

Iron pyrites are mined in Tuscany, and before 1940 annual production amounted to nearly 1,000,000 tons. Besides supplying the Italian sulphuric acid and iron industries, pyrites before 1940 provided a valuable contribution to the export trade, chiefly to Germany and the Netherlands. By 1950 the home demand was greater than before World War II and although nearly 85,000 tons were exported 123,000 tons were imported. Production increased steadily after 1946 and reached 1,225,368 tons in 1953. The zinc and lead ores of Sardinia are of some importance. Most of the lead is smelted in Italy, but before 1940 more than half the zinc ore was exported, chiefly to Belgium. Small quantities of iron ore are mined in Elba and at Cogne in the Valle d'Aosta.

Before 1940 some authorities held that considerable quantities of mineral oil existed in Italy's subsoil, and after 1945 work went on in the Po valley; some oil was found, but by the latter 1950s output was still negligible, though experts were hopeful that the Sicilian deposits might prove valuable. Important developments, however, took place during and after World War II in Italy's output of methane gas; 17,000,000 cu.m. of gas were produced in 1938; the amount had risen to 117,000,000 cu.m. by 1948 and to 3,624,000,000 cu.m. by 1955. Almost all the gas was produced in the Po valley, uhere a network of methane ducts was constructed.

Italy is well supplied with stone for all building requirements; the quarries of white and coloured marble are famous, especially the Carrara quarries. But the demand for marble for export declined greatly after 1929 and remained low after World War II.

According to the industrial census of Nov. 1951, 96,439 persons, were employed in 6,196 mining and quarrying establishments.

TABLE XVI.—*Mineral Production*
(In metric tons)

Year	Coal and lignite	Iron ore	Pyrites	Zinc and lead	Bauxite	Mercury (mineral)	Sulphur
1938	2,358,514	990,043	930,312	268,341	360,837	195,523	380,345
1948	2,092,506	548,717	836,245	193,763	153,711	103,952	173,646
1951	2,054,923	552,851	898,186	277,922	174,014	174,662	200,549
1952	1,945,740	812,066	1,140,790	300,114	265,546	184,990	236,439
1953	1,905,898	933,375	1,225,368	275,442	272,228	197,498	227,757
1954	1,712,400	1,065,183	1,231,700	309,927	295,082	232,055	226,596
1955	1,551,600	1,348,579	1,289,187	323,326	325,962	232,013	201,661

Table XVI shows the output of Italy's mines before and after World War II.

MANUFACTURING INDUSTRIES

The census of 1936 showed that 5,375,152 persons, 29.3% of the employed population, were engaged in industry (including mining, building and certain occupations such as entertainment). The sample inquiry of 1952 showed nearly 6,000,000 or 30% of the employed population engaged in industry. The most important industrial area is the northern plain, where the supply of electric power is good. transport easy and capital readily available; moreover, communications with western Europe are less difficult than from other parts of the country and the people are skilful and open to new ideas. There are other important industrial centres in Tuscany, in Campania around Naples and in Apulia around Bari. The numbers employed in industry in the various regions differed greatly; e g, in Lombardy 47.5% of the employed population as compared with less than 20% in the Marches and Calabria. In 1936 the average for the eight northern regions was 35%, for the four central, 25%, for the five southern, 22%, and for the islands, 23%.

The industrial census of 1951 gave the number of industrial establishments (including mining, quarrying, building, electricity and the distribution of gas and water, and also fishing) as 711,554 (including 58j.657 artisan establishments) and the number of persons employed in them as 4,830,479 (92j.222 in artisan establishments). A large amount of industry was always carried on in small workshops and the census showed that in 1951 the proportion of firms employing less than 50 persons was 98% and that of those employing less than 10 persons 94%. The number of joint-stock companies rose from 6,850 in 1922 to 20,809 in 1938; nevertheless, they constituted only about one-thirtieth of Italian firms (employing about one-sixth of the total of workers in industry, commerce, transport and finance); by 1951 their number had increased to 26.731 employing 2,210,000 workers.

Table XVII gives details of the manufacturing industries according to the industrial census of 1937–39 and that of Nov. 1951.

TABLE XVII.—*Size of Manufacturing Industries*

Industries	Establishments		Persons employed (000s)		Installed power (in 000 h.p.)	
	1937–39	1951	1937–39	1951	1937–39	1951

Metallurgy and Metalworking.— The iron and steel industry is severely handicapped by lack of fuel and raw materials. About one-third of the steel output in 1938 came from Italian-produced pig iron and ferroalloys, the remainder from scrap, of which again only about one-third was home-produced and the rest imported either already broken or in the form of ships for breaking up. Recovery of the industry after 1945 was slow (see Table XVIII). The main steel-manufacturing centres are Genoa. Turin. Milan, Cogne (in the Valle d'Aosta, where local iron ores and anthracite are. used), Piombino (opposite Elba), Portoferraio (Elba), Terni (Umbria) and Naples. The chief producing firms are Ansaldo, Ilva, Terni and Fiat.

The aluminum industry, based on Italian bauxite, is the only considerable exporter among the metallurgical industries. By 1939 output amounted to 34,000 tons (about 5% of the world's total). By 1953 it was up to 55,500 tons, but the high cost kept both home consumption and export low. The chief smelting centres are at Porto Marghera (Venice), Bolzano and Mori (Lake Garda).

The chief branches of the metalworking industry before 1940 were concerned with motor vehicles, shipbuilding, armaments and electrical engineering. The general trend of the industry was toward amalgamation and high-quality production, and great parts of the industry mere under the control of two firms—Ansaldo of Genoa on the heavier side (for shipbuilding and armaments) and Fiat of Turin (for motor vehicles, agricultural machinery and aircraft). The motor industry was much the most important and showed great power of recovery after 1945; in 1953 production amounted to 709,418 vehicles, or nearly ten times the highest pre-war figure of 75,106 vehicles (1937). See Table XVIII.

In 1938 Italy had the fourth largest European merchant fleet —the sixth in the world (see under *Transport and Communications,* below)—and most of its ships had been built in its own yards, but much of the shipping was obsolete, as Italian shipbuilding never recovered after the economic crisis of 1931. The gross tonnage of merchant ships built in 1938 mas only 94,000 (after several years of still lower output); cf., 165,000 tons in 1931. Italy lost about three-quarters of its merchant shipping during World War II, and great damage was done to the shipyards, but by the end of 1949 much had been done to restore and modernize the shipyards and 87,043 tons of shipping had been launched during the year (see also Table XVIII). By that time, moreover: partly as a result of the receipt of Liberty ships from the U.S., the tonnage of mechanically propelled shipping mas only about 500,000 less than in 1941, and that of sailing vessels 20,000 less. By 19j3 the tonnage of mechanically propelled shipping had risen to 3,611,500, a 24% increase on that of 1945.

The production of electrical equipment was important before 1940 in view of the steady development of hydroelectric power. By 1949 the industry was again well under way and general prospects were good because, apart from the growing home market, there mas a considerable foreign demand; about 50% of the rotary machines and high-power transformers produced were exported.

The 1950s saw a rapid growth of light engineering. Index numbers of the output in 1948 of typewriters, sewing machines and calculating machines were 131,140 and 567 respectively (1938=100) and for 1951 they mere 254, 245 and 1,144. See also Table XVIII.

In general, however, the metalworking industry as a whole was still suffering in the 1950s from the disorganization caused by the cessation of arms production (particularly that of military aircraft) and from high-production costs.

The Chemical Industry.— The chemical industry has been largely influenced in its development by the abundance of hydroelectric power and by domestic supplies of salt and sulphur and is closely linked with the development of agriculture. Artificial fertilizers, which are among the industry's main products, have played an important part in the improvement of agriculture, and after 1945 efforts were made to step up their output; by 1953 they had reached 3,170,200 tons, an increase of 60% on 1938. Another important product is sulphuric acid, for which the main ram materials, pyrites, zinc blende and sulphur, are found in Italy. See Table XVIII. Most of the industry was under the control of the Montecatini combine.

Textiles.— The textile industry is, as it has been for centuries,

important, but there has been a change in the relative importance of the different textiles. The silk industry, which used to be the most important, suffered a rapid decline after World War I; the output of raw silk was nearly halved between 1920 and 1929. The dependence of silk production on cheap labour and the competition of Japan and, above all, of artificial fibres brought this about in spite of a government subsidy. The same tendency was visible after World War II. In 1949 only about 1,000,000 kg. of raw silk were produced; cf., more than 3,000,000 kg. in 1939. It is an industry of small firms and the chief centres are Milan and Como.

Cotton is quantitatively the most important of the Italian textile industries. Before 1940 the number of spindles—approximately 5,500,000—was only about one-seventh of that of Great Britain, but a higher proportion of the product was exported. Italian exports of cotton yarn and piece goods were equal to about one-third of those of Great Britain by weight, and Italy was the greatest producer and exporter of cotton goods in Europe after Great Britain. Most of the raw cotton is imported; a small amount is grown in Sicily. It is an industry mostly of small firms supervised by the Istituto Cotoniero Italiano. The main areas of manufacture are Piedmont, Lombardy and Naples, and in 1937–39 about 250,000 workers were einployed in the industry. By 1950 the industry had recovered from the effects of World War II, the output of yarns was higher and of piece goods not much lower than in 1938 and the export of both was higher; but it must be noted that in 1938 both production and export were much less than they had been in the period 1926–29.

The woollen industry is widely distributed over the country, but the big factories are at Biella in Piedmont and at Prato in Tuscany near Florence. About 70% of the raw material is imported, and most of the output is used in the home market. By 1950, though there was great need of modernization, the industry was rapidly recovering its prewar efficiency; the number of spindles had risen from 1,200,000 in 1938 to more than 1,500,000 and the number of power looms was much the same as in 1938, about 22,000. By specializing in fashion goods of imaginative design, a large quantity of which was exported by the latter 19jos (60%–70% of the output at Prato). the woollen industry adapted itself to changing needs better than the cotton and silk industries. Fine-quality cloth, comparable with the best Bradford worsteds though not competitive in price, was increasingly in demand both abroad and by the developing Italian fashion houses. The latter also relied largely on the techniques of hand weaving, the produce of small, specialized firms.

The artificial-fibre industry advanced rapidly during the 1930s, and by 1939 Italy's output of cellulose fibres was about 14% of world output. Italy was the third largest producer of staple fibre, coming next to Germany and Japan, and the fourth largest producer of continuous filament. About half the production was exported. The industry recovered rapidly after 1945, and in 1950 output of fibres amounted to about 103,000 tons (cf., 123,000 tons in 1938) and was equal to 6.3% of world output. The export of artificial fibres and textiles in 1949 was still only about two-thirds of that of 1938; but by 1950 it had surpassed it, and the contribution so made to the country's commercial balance was important. Ownership of the industry was concentrated in a few firms, the most important being that of Snia Viscosa.

TRANSPORT AND COMMUNICATIONS

Roads.—The road system of Italy is based on the system of roads built by the Romans in the latter part of the republican period and under the early principate. Many of the modern roads (*e.g.,* much of the Via Emilia and the Via Appia) are built on the line of the old roads, and many others follow the same general course. During the middle ages many of the Roman roads fell into disuse, and the development of the modern system took place, as in other countries, only with the coming of motor traffic, which increased so rapidly after 1920.

There are three categories of roads, state, provincial and communal, apart from the new motor highways, the autostrade, which were copied by the German *Autobahnen.* In 1954 the length of the state roads was 24.811 km., of the provincial 40.996 km., and of the communal 105,395 km., making a total of 171,202 km. This total gives an average of j69 km. to 1,000 sq.km. of land and 354 km. to 100,000 inhabitants. The provincial and communal roads are the responsibility of the provinces and communes respectively, though contributions may be made by the state for construction or upkeep. The cost of roads is largely met by taxes on road users. The *autostrade* were built, owned and operated by private companies, whose revenue mas derived from tolls and advertisements.

On the whole, main road communications are good. Many of the roads pass through difficult country; but even secondary roads are well engineered though the surface may be poor. The quality of the roads and the extent of the network deteriorates from north to south of the country. Whereas the length per 1,000 square kilometres in 1954 was 848 km. in Piedmont. 868 in Lombardy and 1,023 in the Veneto, it was only 364 in Apulia, 279 in Basilicata, 337 in Sicily and 196 in Sardinia. In the regions of the south and islands there was great need of more local roads in the early 1950s; the main roads were generally adequate but many of the smaller places were almost inaccessible. (In Basilicata, for instance, there were 1,213 km. of state roads, but only 417 of communal roads.)

After World War II road repairs were a heavy burden, particularly in the regions where actual fighting took place. The Italians showed great capacity and energy in facing the problem, so that 7,182 km. of damaged or destroyed state roads had been repaired and 2,968 bridges rebuilt or repaired by the end of 19j1.

Vehicles.—The number of motor vehicles registered, still small by British standards. nas nevertheless higher by 1954 than it had been before World War II. There were in circulation 744,299 motorcars, 2,271,136 motor bicycles. 9,175 buses and 329,588 trucks, besides tractors of various kinds. The bus services were greatly developed after 1945, both the ordinary country bus services and the so-called services of *gran turismo,* which by 1950 covered about 81.000 km., using comfortable long-distance buses.

Railways.— The labour of restoring the Italian railway system after World War II was immense. In 1938 the total length of track was 22,955 km.; by 1945 one-quarter of this length had been destroyed. Honever, 21.852 km. of line were in use by 1954, of which 16,570 belonged to the state railways and 5,282 to private companies. The most vital repairs needed were those to an enormous number of bridges and viaducts; the damage to iron bridges alone was estimated to cover about 3j km., including the total destruction of the great bridges over the Po at Piacenza. Pontelagoscuro. Borgoforte and Mezzanacorti. In addition about 59 km. of tunnels had been blocked and 90% of the electrified lines destroyed. By 1954, however, 7,723 km. or one-third of the nhole system had been electrified (cf , 6,640 km. in 1938), and more electrification was promised. The loss of engines. signal arms and signal-box levers was also great during the war: 56% of the steam locomotives, 67% of the electric locomotives and 85% of light self-

contained units such as electric rail cars. By 1953 prewar standards had been nearly reached, but there was not enough equipment for the needs of the 12,800,000 more passengers carried per kilometre than before 1940. In 1954, 59,010,000 tons of goods (excluding cattle) were transported by the railways (12,981,000 tons per kilometre) as compared with 63,100,000 tons (11,400,000 tons per kilometre) in 1939. Costs were kept low in comparison with the cost of living and with those of other European countries, and the old differential tariffs which gave reductions for long-distance travel were retained. These reductions were important for the economic development of southern Italy, with its few ports and indifferent roads.

Merchant Marine. — Shipping occupies an important position in the Italian economy partly because of the country's central position in the Mediterranean and partly because of the long coast line which encourages local trading by sea. By 1939 the Italian merchant marine, excluding its considerable tonnage of sailing vessels, ranked sixth among the world's merchant navies, being surpassed only by those of Great Britain, the United States, Japan, Norway and Germany. It consisted of 1,293 ships of more than 100 tons totalling 3,290,484 tons. This fleet had been reduced by the end of World War II to about 300,000 tons, mainly small vessels engaged in the coastal carrying trade. Reconstruction started nith the United States' offer of Liberty ships, 50 of which were made available in 1947; damaged ships were repaired, wrecks were salvaged new ships were built and by the end of 1950 the tonnage of mechanically propelled ships of more than 100 tons had risen to 3,600,640 (including those of Trieste) and the total merchant marine, including sailing ships. to 3,722.471 tons. Italy again held sixth place among the world's merchant navies with 3.7% of the shipping. There was a change in the composition of the fleet. liner tonnage amounted to 25% of the total before 1940, to 15.5% in 1950; and ordinary cargo boats, which accounted for 50% of the tonnage before 1940, accounted for 65% in 1950. By Jan. 1, 1956. the total tonnage of mechanically propelled vessels of 100 gross tons and over had risen to 4,040,476, and that of the total merchant marine, including sailing ships. to 4,108,809.

Great damage was done to the docks between 1943 and 1945. But nith the help of large government grants reconstruction went rapidly ahead, and 40,598 ships, totalling 85,059,000 tons, entered and cleared Italian ports in 1953; *cf.*, 38,755 ships (75,400,000 tons) in 1938. By 1955, 45,000,000,000 lire had been spent in this way. In 1953, moreover, 29,000,000 tons of goods entered Italian ports and 5,700,000 tons were cleared; cf., 17,200,000 and 1,600,000 tons in 1938. The goods traffic at the most important ports in 1938. 1953 and 1954 is shown in Table XIX.

Inland Navigation. — The navigable rivers and canals of Italy have a total length of about 1,350 mi., but inland navigation is of little importance. Apart from the lower reaches of the Arno and the Tiber, the navigable waterways are chiefly in the northern plain. Navigable canals are mainly north of the Po in Lombardy and at the head of the Adriatic in the Veneto. The freight transported on the waterways, including the lakes, amounted normally before 1940 to only 5,000,000 tons a year; in 1953 it was only 1,900,000 tons.

Air Transport. — In 1938 Italy had 51 air lines in commercial service. 10 of which served the interior of the country and 41 external territories (24 of them the Italian colonies of that time). In 1949 the total had risen to 57 lines, 28 working inside and 29 outside the country. One important postwar change was the development of the services south of Rome and to the islands. Before 1940 there were only three home services that went south of Rome or to the islands; in 1949 there were 19. There was a considerable increase in passenger traffic after 1946, but Italy still lagged behind other countries in goods traffic by air. Ciampino, the airfield outside Rome, became an important European airport thanks to its central position in the Mediterranean.

Posts, Telegraphs, Telephones and Radio. — Posts and telegraphs are government services. Telephones are partly controlled by the state, partly by five companies to which concessions were granted. The service nas improved greatly after World War II: 76% of the Italian communes had telephones in 1939; 87% in 1950. But for every 1.000 persons there were only, on an average, 24 telephone instruments, as against 182 in Switzerland, 132 in Norway, 102 in Great Britain and 69 in the Netherlands. In northern and central Italy, indeed. there mere more than 40 telephones for every 1,000 of the population; but in the south the figure was only 7.j. All radio services in Italy belong to the state, but the state directly controls only a few services, the rest being entrusted to concessionaires. The ministry of posts and telecommunications has direct control of wireless communication with merchant shipping at sea through its own coastal stations; it also controls wireless communication with the islands. Radio and television transmission is entrusted to the company known as Radio Audizioni Italia; international radiotelegrams and telephones are handled by Italcable and Radiostampa; the establishment and working of wireless transmission and receiving stations on board merchant vessels are controlled by two companies, the Società Italiana Radio Marittima and Telemar. Great damage was done during World War II to all Italian radio stations; those directly controlled by the government were nearly all destroyed. By 1945, moreover, short-wave transmission equipment scarcely existed; but radio transmissions to foreign countries were regarded in Italy as important, and the work of restoration was rapidly put in operation, with the result that 70 programs in 35 languages were being put out daily by 1952.

Television was entrusted to Radio Xudizioni Italia in 1948. and with the help of the European Recovery program the company imported a complete television plant from the United States.

(M. M. C.)

FINANCE

Italy's national income is derived in almost equal proportions from agriculture and from industry. Before World War II estimates of its magnitude were made from time to time by private students, but the varying methods of calculation used and the lack of sufficient data made them generally unreliable; we may nevertheless cite Jacopo Tivaroni's estimates of 6,000,000,000 current lire for 1860, of 13,000,000,000 current lire for the beginning of the 20th century and of 20~000,000,000current lire for 1914. After World War II, however, the official Istituto Centrale di Statistica evolved a method of calculating the national income, and it is to the Istituto's data that the following paragraphs refer. The term current lire signifies lire of the purchasing power that they had in the year cited in connection with them.

Table XX shows the Gross National Product (G.N.P.) and the economic balance sheet for 1938, 1953 and 1954. The figures therein given for the net value of private undertakings are analyzed in Table XXI, whence it appears that in 1954 agriculture, forestry and fisheries contributed about 27% and industry 45% to the net total, the remaining 28% being divided between trade, transport and communications and banking. In 1954 the largest contributions from the manufacturing industries were made by the engineering industry (20%), the food industry (19%), the textile industry (15%) and the chemical industry (14%).

Per capita income expressed in terms of lire of 1954 amounted to 193,000 lire in 1938 and to 246,000 lire (£141) in 1954 itself, account being taken of the changes in population that took place.

Trade and the Balance of Payments.—Foreign trade has always been extremely important to the Italian economy. Its structure is planned on the basis of the main characteristics of agricultural and industrial production. Imports consist mainly of raw materials, chiefly corn, oilseeds, coffee, cotton, wool, jute, wood, skins, iron and steel, copper, coal, mineral oils and rubber, to be worked with a view partly to producing finished goods for export, partly to supplying the primary needs of the population. Exports consist to a great extent of finished goods made from imported raw materials and of high-quality foodstuffs, the chief exports being cotton thread and woven goods. artificial fibres and woven goods, machines, garden produce, citrus fruits, rice and cheese.

TABLE XXII.—*Foreign* Trade
(Value in 000,000 lire)

Item	1934	1938	1946	1948	1950	1953	1954	1955
Imports*	7,675	11,273	91,484	844,266	900,303	1,512,686	1,524,439	1,691,164
Exports†	5,224	10,502	64,578	575,886	746,863	941,789	1,023,909	1,159,669

*1946–53: including foreign-aid shipments. †Including ships' stores.

The value of imports has almost always been considerably greater than that of exports: in the five years 1871–75 the average annual value of imports was 1,305,000,000 current lire, that of exports 1,197,000,000 current lire; in the years 1901–05 imports were valued at 1,903,000,000 lire, exports at 1.582,000,000 lire and in the years 1936–40 imports amounted to 11,294,000,000 lire and exports to 10,156,000,000 lire. It was only in 1941 and 1942, during World War II, when it was supplying Germany with large quantities of goods, that Italy had a favourable trade balance. See Table XXII.

In the years preceding World War II the deficit in the trade balance was always covered by the so-called invisible items: *i.e.*, by remittances from emigrants, by the proceeds of tourist traffic, by shipping freights, etc. It should, however, be remembered that between World Wars I and II, as more and more customs barriers were put up and as emigration was steadily made more difficult, both income from the export of finished goods and the value of remittances received were greatly reduced.

After World War II the natural deficiencies of the Italian economy. which had been much aggravated, were largely countered by free help from abroad. It was estimated that Italy received about $2, 500,000,000 from the European Recovery program and Mutual Security agency aid. Table XXIII, which shows Italy's balance of payments in 1938, 1953 and 1954, indicates the importance of the invisible exports. New difficulties in the balance of payments, meanwhile, were created when other countries imposed various currency regulations, which prevented the transfer of imports paid for by the sale of goods and services in certain monetary areas in order to acquire goods and services in other areas. As Italy was importing more than it was exporting in the dollar area and exporting more than it was importing in the sterling and European currency area, the relation between currencies became dislocated. This situation affected the reserve of currency, which could not be spent, held by the Foreign Exchange bureau; and the disequilibrium had to be financed by the issue of lire by the Bank of Italy.

The zonal distribution of the foreign trade of Italy was quite different in 1954 from the pre-World War II period. Before the war more than 50% of Italian foreign trade was concentrated in Europe. In 1954 68% of imports came from countries of the European Payments union (E.P.U.) (25% from the sterling area); 13% came from the United States and Canada. In 1954, too, 67% of exports went to countries of the E.P.C. (20% to countries of the sterling area); 9% of exports was directed to the United States and Canada.

The need to keep a steady currency balance with the countries belonging to the E.P.U. led Italy to adopt a free-trade policy for goods and services coming from that area. About 100% of the goods entered Italy free. Italy was a party to the General Agreement on Tariffs and Trade with comparatively low customs duties. In 1951, in order to help to stabilize the currency balance, Italy reduced customs dues by a further 10%.

Banking and Credit.— The banking system is regulated by a law of 1936, with various later additions of minor importance. This law controls banking activities in such a may as to safeguard the solvency and liquidity of the banks and to direct their business and investments. Special bodies keep an eye on the banks' observance of the regulations and prevent the adoption of policies harmful to the country's interests. The system is based on a few general rules, not on numerous minute regulations which would hamper action; and the central authority has power to lay down at its own discretion and within reasonably wide limits technical rules to which the banks must conform.

The Bank of Italy is the only bank of issue and holds the gold and currency reserves. It has financial relations with the state, not with private persons, being a bankers' bank. It rediscounts bills of exchange, advances loans against merchandise, issues bills of exchange, makes loans to the treasury, accepts deposits from the banks, etc.

In the period immediately after World War II the Bank of Italy was chiefly concerned with financing the deficit on the national budget; but later the financing of private business took pride of place, either by means of discounting and loans or by financing foreign trade through the Foreign Exchange bureau (Ufficio dei Cambij, which has the monopoly of buying and selling foreign exchange at the official rate. The Bank of Italy financed the excess of purchase of currency over sale that arose from Italy's favourable position in the balance of payments with regard to the sterling area and to other European and non-European currencies. The note circulation of the Bank of Italy amounted to 19,000,000,000 lire at the end of 1938 and to 1,538,000,000,000 lire at the end of 1954. The state's circulation in notes and metal money rose from 3,000,000,000 lire at the end of 1938

to 55,000,000,000 lire at the end of 1954.

The banking system draws a sharp distinction between short-term commercial credit and money credit whether medium or long term. Commercial credit is handled by five chartered public banks (*istituti* di diritto *pubblico*)—the Banco di Napoli, the Banco di Sicilia, the Banca Nazionale del Lavoro, the Istituto di San Paolo a Torino and the Monte dei Paschi di Siena—which carry on non-profitmaking banking business; by three national banks with branches throughout the country—the Banca Commerciale Italiana, the Credito Italiano and the Banco di Roma; by 146 large banking institutions organized on national lines; by 211 "people's co-operative" banks; by 57 private banks; and by two branches of foreign banks. In 1954 a committee of the various banks was set up to prescribe rules and to fix rates of interest and of discount governing the operation of credit and debit accounts.

The 80 savings banks and 17 pledge offices (*monti* di credito *su pegno*), while separately organized, are included among institutions which accept short-term deposits and make short-term investments; and the post-office savings banks carry out operations similar to those of the savings banks regarding acceptance of deposits. The post-office banks pay over their funds to the Bank for Deposits and Loans (Cassa Depositi e Prestiti) which, besides financing the treasury, makes long-term loans to local authorities and to bodies (consorzi) carrying out public works.

Altogether, including 697 rural and artisan banks. 1 j small banking institutions and 4 consorzi with a limited guarantee, there were in Italy 1,237 banking institutions with 7,910 branches in 1954; *cf.,* 1.849 institutions nith 7,384 branches in 1938.

Table XXIV gives figures for the amount of deposits in the 365 more important credit institutions and post-office savings banks. which handle 99% of the total number of deposits. Private credit,

both medium and long term, is handled by the chartered public banks and by private bodies controlled by special regulations. These include: the Istituto Mobiliare Italiano, which finances business and takes up shares in private businesses; the Consorzio per Sovvenzioni sui Valori Industriali, for granting subventions on the basis of industrial values; the Consorzio di Credito per le Opere Pubbliche, for financing public works; and the Istituto di Credito per le Imprese di Pubblica Utilita, for financing public utilities. There are in addition special branches of the Banca Nazionale del Lavoro, of the Banco di Napoli, of the Banco di Sicilia, of the Banco di Sardegna and of the Istituto di Credito Fondiario delle Venezie, which provide medium- and long-term credit to smaller industries, to hotels and tourist enterprises, to co-operatives and to mines. Other private credit organizations are the Mediobanca set up by three national banks; the Ente Finanziamenti Industriali, for the financing of industry (in which the main interest is that of the Banca Nazionale del Lavoro); the Centrobanca, the credit institute of the people's co-operative banks; and the Cassa per il Credito alle Imprese Artigiane, the credit institute for artisan undertakings. The state set up regional institutes for granting medium-term credit in 1950 and established the Mediocredito in 1951 to unite the available funds of all organizations authorized to give medium-term credit to undertakings employing labour in the localities where unemployment was most severe. For the economic development of the south the state set up Isveimer in south Italy and Irfis in Sicily.

The Istituto per la Ricostruzione Industriale, for industrial reconstruction, and the Fondo Industrie Meccaniche, or engineering industries fund. are controlled by special regulations and are responsible for management of the state-owned "key industries"; viz., iron and steel, engineering, shipping, electricity, banking, etc.

The Monetary Regime.—From the unification of Italy to World War I the Italian monetary regime was based on gold, though a nonconvertible paper currency was occasionally adopted in consequence of particular economic and political conditions. During and after World War I paper currency was adopted, with consequent deterioration in the exchange value of the lira in relation to the high-priced currencies, until in 1927 the value of the lira was fixed by law at 0.079191 gr. of fine gold. 19 lire being equal to $1 and 92.46 lire to £1 sterling. After the devaluation of the chief world currencies, the value of the lira was reduced to 0.04677 gr. of fine gold in 1936. its relation to the dollar and to the pound sterling being re-established as it was in 1927. The law of 1936 was still technically in force in 1954 although the changes of World War II and the following years had made its provisions inoperative.

Before World War II, legislation was introduced to put foreign exchange entirely under the control of the Ufficio dei Cambi (Foreign Exchange bureau), an organ of the Bank of Italy, which has a monopoly of control over dealings in means of payments abroad, over all trade in gold and over the management of foreign credits and bonds and of all other currency coming from tourists, emigrants, etc.

In 1943, as soon as the occupation of Italy started, the Allied military government fixed a rate of exchange of 100 lire to the dollar and 400 lire to the pound. In 1946 the official rates of exchange nere raised, bringing them to 225 lire to the dollar and 907 lire to the pound. In addition exporters were allowed to dispose of 50% of the currency that they obtained from sales abroad on the open market at a rate of exchange about double that of the official rate. In 1948 the official rate and the export rate of exchange became one for all practical purposes on a basis of 575 lire to the dollar and 2,317 lire to the pound. When the pound was devalued in 1949 the value of the Italian lira fell less in relation to the dollar than did the pound and other European currencies and went to about 62j lire to the dollar and about 1,750 lire to the pound.

Italy joined the International Monetary fund, but had not by 19jj announced its official parity with the fund. However, as a result of U.S. aid and of the home policy of defending the lira, the stability of the lira-dollar exchange after 1949 made it possible for Italy to respect the substance if not the letter of the main principles of the Bretton Woods agreements.

The Bank of Italy acquires gold on the basis of the official dollar exchange. At the end of 1954 the price of fine gold was 703 lire per gram. Besides the official market for currencies and gold, however. there is another one that the financial authorities tolerate but do not recognize. Currencies and gold dealt with on this market are used for buying a few types of goods that may be imported free of exchange control, for personal expenditure abroad and for movements of capital. At the end of 1954 the rates on this market stood at 635 lire to the dollar and 1,710 lire to the pound and at 72j lire per gram of fine gold.

Prices.—Prices on the Italian market have followed the changes in international prices with a slight time lag. The first notable disturbance took place during and after World War I. After readjustment they again folloned international prices, being affected accordingly by the great crisis of 1929–35 (the lowest level was reached in 1934; by 1938, wholesale prices were again approximately where they had been in 1929).

In the first years of World War II all kinds of measures were taken to stabilize prices and to control consumption in order to secure more and more of the national income for investments connected with war activities. As the war went on, this policy lost most of its effect, and the characteristics of inflation became more obvious after the armistice of 1943 when German and Allied troops occupied Italy.

In 1945, at the end of the war, prices were already up 25 times, with the national income halved in terms of real money and note circulation increased roughly tenfold. Open inflation had begun. Despite a rapid increase in production the inflationary process went

on, and in the course of a year prices doubled. In the spring and summer of 1947 the index numbers of wholesale prices reached a point 62 times greater than the prewar figure and the cost-of-living index numbers were up 53 times even though the cost of certain items in the domestic budget such as rent, gas and electricity had been restricted. Then, in the autumn, Luigi Einaudi, later president of the republic, was made minister for the budget. Measures were taken to control the banking system's reserves so as to achieve a due proportion between investments and what was really available in order to fill up the inflationary gap; and at the same time provision was made for reducing the deficit in the national budget. Prices reacted immediately; at first they stood still. then they fell—uholesale prices quickly, cost-of-living prices more slowly and less. Between 1948 and 1954 the wholesale prices were steady but the cost of living advanced slowly. The decrease in prices on the stock exchange was remarkable. Whereas by the summer of 1947 they had risen to be 3j times as great as they had been before the war, they now gradually fell to be only 17 times as great. Later shares quotations improved and at the end of 1954 were 36 times the prewar level. Because of the disinflationary policy it was possible to stabilize the purchasing poner of the lira and thus in the long run promote a more healthy development of economic activity as a whole.

TABLE XXV.—*Prices, Wages and Rates of Exchange*

Year	Index numbers				Lira-dollar rate	Lira-pound rate
	Wholesale prices	Cost of living	Industrial wages	Agricultural wages		
1938	1.00	1.00	1.00	1.00	19.00	88.76
1951	55.81	53.20	63.86	71.01	624.88	1,749.66

1954	52.93	58.06	77.77	86.84	624.83	1,749.53
1955	53.20	59.69	80.92	89.61	624.90*	1,759.93*

*As of Dec. 31, 1955.

Table XXV indicates the course followed by wholesale prices, the cost of living, wages and the changes in the exchange value of the lira in dollars and pounds sterling from 1938 to 1954. For further analysis of wages, *see* above, *Population and Social Conditions,* Tables VII and VIII.

The State Budget.—The state budget has only shown a favourable balance for brief periods. A deficit is the rule either because of the expense of necessary public works or because of periods of crisis. Between World Wars I and 11 there was a credit balance only for the years from 1923–24 to 1929–30. Residuary deficits from previous budgets were estimated at the end of the financial year 1955 to exceed the credits by 1,325,000,000,000 lire.

*Ending July 30. †Estimate.

Public Debt.—The deficits of the state budget and the need to maintain a modern standard in public works led to a steady increase in the public debt. World War I reduced the purchasing power of the lira to one-fifth of what it had been and so reduced also the real burden of the debt, nhich grew in terms of money from 16,000,000.000 lire in 1914 to 90,000,000,000 lire in 1919–20. Table XXVII shows the public debt in 1938–39 and after 1952.

Taxation.—During the 19th century taxes on real estate were more important in Italy than were those on personal property.

TABLE XXVIII.—*Taxation*
(In 000,000,000 current lire)

Type	1938–39	1952–53	1953–54	1954–55
Taxes on incomes and estates	7.5	383	440	451
Taxes on business	2.4	145	175	215
Taxes on movements and exchanges of goods and services	6.6	631	737	797
Taxes on luxury consumption goods	3.6	308	334	362
Taxes on essential consumption goods	2.9	145	154	177
Lotteries	0.5	30	32	32
Total	23.5	1,642	1,872	2,034

More recently taxes on income and indirect taxes on business acquired greater importance. Table XXVIII gives figures regarding the incidence of taxation in 1938–39 and after 1952.

Uniform legislation controls the imposition of taxes for local authorities (communes, provinces and regions). In 1938 the effective revenue of the communes amounted to 6,000,000,000 lire as against an expenditure of 6,300,000,000 lire; in 1954 their revenue had jumped to 414,000,000,000 lire but their expenditure had reached 557,000,000,000 lire. In 1938 the budgets of the provinces were balanced with revenue and expenditure each at 1,400,000,000 lire; but in 1954 they showed a deficit with revenue at 108,000,000,000 lire and expenditure at 126,000,000,000 lire. In 1954 the autonomous regions—Sicily, Sardinia. Trentino-Alto Adige and Valle d'Aosta—had a revenue of 57,000,000,000 lire and an expenditure of 56,000,000,000 lire.

Furthermore, it is necessary to take into account that in Italy the contingency and assistance charges fall almost wholly on the employers, meaning therefore a real taxation. In 1938 the taxation burden (state, provinces, municipalities, etc.) was 28,600,000,000 lire and the contingency charge 3,300,000,000 lire, an amount of 31,900,000,000 lire. In 1954 the taxation burden was 2,351,000,000 lire and the contingency charge 1,016,000,000 lire, an amount of 3,367,000,000 lire. The aggregate taxation pressure, estimated in terms of net national income, was 23.39% in 1938 and 31.23% in 1954.

Savings.—The Italian economy shows a low level of savings related to the low level of per capita income, and as a result Italy has always imported capital. The huge losses of World War II demanded an extra effort, ahich was made easier by U.S. aid more than by anything else, so that the relation between gross investments and national income stands at about 21%. Figures for money savings, whether deposited in the banks or in the post-office savings banks, have been given in Table XXIV. The self-financing of businesses by the employment of profits not distributed to shareholders and also by the issue of shares and bonds is, however, important. The value of issues of public and private shares and bonds amounted to 306,000,000,000 lire in 1952, to 365,000,000,000 lire in 1953 and to 309,000,000,000 lire in 1954 (cf., 2,100,000,000,000 lire in 1938).

Insurances provide another form of savings. There are various private insurance companies and the Istituto Xazionale di Assicurazioni, which is a public body. Whereas in 1938 premiums on life insurance amounted to 1,152,000,000 lire, by 1952 they had risen to 37,969,000,000 lire and by 1953 to 42,764,000,000 lire. Social and providential insurances are reasonably well developed *(see* above. *Population and Social Conditions).* In 1953 the Istituto Nazionale per la Previdenza Sociale banked 612,000,000,000 lire received in contributions and paid out 563,000,000,000 lire. Numerous other companies dealt in sickness insurance; their contributions amounted to 247,000,000,000 lire and payments to 203,000,000,000, lire in 1953. (L. L.)

ITAPÚA, the southeasternmost department of Paraguay, is separated from Argentine Misiones by the Paraná river which is the boundary for 173 mi. Area 6,380 sq.mi.; pop. (1950) 111,424. Like Argentine Misiones, it was settled by the Jesuits who established missions to convert the Indians. After their expulsion in 1767 the settlements were abandoned, but in the Trinidad district several churches and ruins survive as relics of the period. Encarnación (*q.v.;* pop. 13,321) is the departmental capital, providing the principal exit and entrance to the country. It is a saw-milling and processing centre for the forested and agricultural Paraná lowland. (G. J. B.)

ITASCA, LAKE, the main source of the Mississippi river, is located approximately 25 mi. S.W. of Bemidji, Minn., in Itasca State park, where the state maintains Douglas Lodge and other recreational facilities. It is a glacial lake that has an altitude of 1,475 ft., an approximate depth of 35 ft., and an irregular shoreline that encloses a surface of 1.75 sq.mi. From it, the Mississippi river flows southward 2,348 mi. to reach the Gulf of Mexico. Its shores are lined with virgin pine.

Although a fur trader employed by Astor's American Fur company, William Morrison (1785–1866), claimed to have visited the lake in 1803, Henry Rowe Schoolcraft, the United States superintendent of Indian affairs for Michigan in 1832, is considered by most authorities to be the man who proved that the lake is the main source of the Mississippi river. Many geologists, however, believe that a number of glacial lakes in the region supply the headwaters of the river. Schoolcraft is also credited as being the originator of the name "Itasca." By combining syllables of the Latin words *veritas* (truth) and *caput* (head or source), he formed the name Itasca.

Brower, *The Mississippi River and Its Source,* vol. vii, Minnesota Historical Collections (1893); Joseph N. Nicollet, *Report Intended to Illustrate a Map of the Hydvographical Basin of the Upper Mississippi River* (1843). (W. D. MR.)

ITCHING (PRURITUS) is a symptom of many skin conditions, particularly dermatitis and eczema, insect bites, hives, scabies and pediculosis (lice), prickly heat and some superficial fungous infections. It may be almost entirely psychic in origin (localized neurodermatitis), and in generalized form is sometimes a symptom of internal diseases such as jaundice, diabetes and leukemia. Itching is probably a modified form of pain (*q.v.*). Symptomatic treatment in the long run is unsatisfactory, though local applications or aspirin may be immediately helpful; relief of the underlying cause is essential. The application of complex chemicals to the skin in an effort to control itching may produce allergic reactions.

See also SKIN DISEASES. (D. M. P.; X.)

ITENEZ: see GUAPORÉ.

ITHACA (ITHAKI, THIAKI). next to Paxo the smallest of the seven Ionian islands, with an area of 33 sq.mi.; an eparchy of the nomos of Cephalonia in Greece whose population in 1951 was 5.830. It consists of two mountain masses, connected by a narrow isthmus of hills, west of a wide inlet, the Gulf of Molo. The northern culminates in Anoi (2,650 ft.), the southern in Hagios Stephanos (Merovigli) (2,100 ft.).

Vathy, the chief town and port of the island, lies at the northern foot of Mt. Stephanos, its whitewashed houses stretching for about a mile round the deep bay, to which it owes its name. As there is little arable land in Ithaca, the inhabitants are dependent on commerce for their grain supply; olive oil, wine and currants are the principal products. Goats are fed on the brushwood of the hills, and hares are exceptionally abundant.

The island is divided into four districts: Vathy, Aeto (or Eagle's Cliff), Anoge (Anoi) or Upland and Exoge (Exoi) or Outland.

The name has remained attached to the island from the earliest historical times with but little interruption of the tradition, though in Brompton's travels (12th century) and in the old Venetian maps it is called Fale or Val de Compar, and at a later date it not infrequently appears as Little Cephalonia. This last name indicates the general character of Ithacan history in modern and in ancient times; for the fame of the island is almost solely attributable to the Homeric story of Odysseus, its king in the heroic age. In the Odyssey the island is incidentally described with picturesque topographical detail. The Homeric localities for which counterparts have been sought are Mt. Neritos, Mt. Neion, the harbour of Phorcys, the town and palace of Odysseus, the fountain of Arethusa, the cave of the Naiads, the stalls of the swineherd Eumaeus, the orchard of Laertes, the Raven Cliff Korax and the island Asteris, where the suitors lay in ambush for Telemachus. There are two schools of identification, one placing the town at Polis on the west coast in the northern half of the island (Leake, Gladstone, etc.) and the other at Aeto on the isthmus. The latter site, advocated by Sir William Gell, was supported by H. Schliemann, who carried on excavations in 1873 and 1878. But no amount of ingenuity can fully reconcile the descriptions in the Odyssey with the actual topography.

Above all, the passage in the Odyssey in which the position of Ithaca is described offers great difficulties:

"Now Ithaca lies low, farthest up the sea line towards the darkness, but those others face the dawning and the sun" (Butcher and Lang).

Such a passage fits very ill an island lying, as Ithaca does, just to the east of Cephalonia. Accordingly, W. Dörpfeld suggested that the Homeric Ithaca is not the island that was called Ithaca by the later Greeks, but must be identified with Leucas (Santa Maura; *q.v.*). He succeeded in fitting the Homeric topography to this latter island, and suggested that the name may have been transferred in consequence of a migration of the inhabitants. There is no doubt that Leucas fits the Homeric descriptions much better than Ithaca; but, on the other hand, many scholars maintain that it is a mistake to treat the imaginary descriptions of a poet as if they were portions of a guidebook or to look, in the author of the Odyssey, for a close familiarity with the geography of the Ionian islands.

ITHACA, a city of New York, U.S., 56 mi. S.S.W. of Syracuse, at the southern end of Cayuga lake; the seat of Tompkins county. Ithaca is situated in rolling hill land of the Finger lakes country. Recreational opportunities are provided by neighbouring lakes and excellent state parks nhich are maintained in the area: Buttermilk falls, Fillmore glen. Robert H. Treman State park. Taughannock falls (215 ft, high) and Watkins glen.

Among the leading manufactures of Ithaca are adding machines, power-drive chains and shotguns. while nearby Groton is a significant manufacturer of typewriters. Surrounding agricultural lands are important chiefly for sales of dairy products, poultry and poultry products. Ithaca is the southern terminal of the New York Barge Canal system. (For comparative population figures see table in NEW YORK: Population.)

History.— The site of Ithaca. formerly in the Cayuga nation territory of the Iroquois confederation, was visited by a Continental raiding party during the Sullivan-Clinton campaign of 1779. In 1782 the area was included within the Military tract given to veterans of the American Revolution and the land was acquired by Simeon De Witt, surveyor general of New York, who in 1806 named the community Ithaca. Settlement commenced in 1789. Development of the community was fairly rapid, and was early based upon availability of water transportation and power, in addition to accessibility of lumber, salt. gypsum and products of fertile agricultural lands. Ithaca was incorporated as a village in 1821 and as a city in 1888. The city, with its vicinity, was once a location for silent motion pictures.

Education.— An outstanding educational centre, Ithaca is the home of Ithaca college and Cornell university. Ithaca college'is a private liberal arts college established in 1892; its students specialize mainly in physical education. music or drama.

Cornell university, situated on a hill commanding a wide view of Ithaca and Cayuga lake and occupying over 7,000 ac. of campus, farm, conservation and recreation land. is an unusual combination of endowed and public-supported institution. It was founded as a result of the Morrill act of 1862, under which New York received a substantial grant of public land for support of colleges teaching "agriculture and the mechanic arts.!' Ezra Cornell (*q.v.*) established the foundations and Andrew D. White determined the form of the new university; both were members of the New Tork legislature. Cornell, a citizen of Ithaca who had come into a fortune from his holdings in the Western Union Telegraph company. contributed an initial grant of $500.000 and 200 ac. on the condition that the college be located at Ithaca and that the state endow the institution with all its proceeds from the federal grant. Cornell himself took an active part in supervising the sale and allocation of these lands. and more than $3.000.000 was realized in profits. Cornell later gave the university an additional $400,000 of his own money.

A charter was granted April 27, 1365. White prepared the scheme of internal organization and the trustees elected him president in 1866. On Oct. 7, 1868. the university began operation. It was nonsectarian and coeducational and was to embrace any instruction and investigation deemed useful and proper by the trustees in addition to those branches of learning specified by the Morrill act. In the latter part of the 20th century the university comprised 15 colleges and schools, including the medical college (1898) and school of nursing (1942) in New York city and four university colleges supported by legislative appropriation, which have been part of the State University of New Tork since its creation in 1948. .
