A notable feature of this linguistic situation was the preponderance of languages on the Pacific side of the continent. Of Powell's original list of 53 stocks, 37 were in territory draining into the Pacific and 22 were actually on that coast, while only 7 were found on the Atlantic coast. In terms of population, more than 70% of the population north of Mexico was comprised in eight language stocks. These stocks, with respective populations (after Mooney) were: Algonkin 192,400; Eskimo-Aleut 89,700; Siouan 88,500; Iroquian 71,700; Muskogian 66,500; Uto-Aztekan 63,100; Athabaskan 60,500; and Salish 57,900. Eighteen other language stocks had an average population of about 12,000, while 29 were spoken by from 5,000 to 500 people, with an average of 2,000. (See also AMERICAN ABORIGINAL LANGUAGES.)

CULTURE PROVINCES

Distributions. — Reconstruction of American prehistory had not yet succeeded at mid-20th century in filling in the details of dispersal and development that must have taken place during the long interval between the earliest occupation levels and the first evidences of sedentary cultures. Moreover, as new discoveries tended to push the first human horizons further back into antiquity, the more precise dating made possible by tree-ring chronology and by radiocarbon disintegration tended to lessen the age of later occurrences and thus the gap between the two known limits grew further apart and the difficulty increased. The year 1000 B.C. has been postulated as marking the beginning of civilization in the western hemisphere, this being the approximate time when agriculture was substituted for hunting in the middle regions of the new world and when the series of cultural advances which culminated in Maya architecture and the Maya calendar began. The beginnings of agriculture may actually belong to a more remote period, as will be discussed below, but in any case an interval of from 10,000 to 15,000 years must somehow be explained. In the opinion of some authorities, a time span of 25,000 years might be required to account for ecological adjustment to the numerous climatic belts represented in the two continents. As suggested by R. H. Lowie, man in the long interval was pushing forward the innumerable qualitative social and individual choices which finally brought him to a stage characterized by agriculture and pottery making. In the process, not one but a score of hunting and gathering societies may have evolved. Agriculture, which in the new world is assumed to start with maize culture, may actually have been the outgrowth of experimental plantings carried out independently in different areas of the new world and with different plants, such as manioc in the tropical lowlands and the potato in the Andes. Adjustments, strivings and solutions in a world of limited theory and scant technology necessarily consumed great time lapses.

There are indications of a solution to the problem by means other than speculation. The Cochise culture of southern Arizona, mentioned above, may be the interval which, for the southwestern area at least, spans the period under scrutiny. Three stages have been distinguished for the Cochise development, the oldest of which, the Sulphur Springs stage, was tentatively dated at 10.000 or more years ago. The climate was then wetter and colder and the bones of extinct animals — mammoth, camel, dire nolf, bison and horse — were directly associated with man-made implements. These were not the implements of a hunting people, however; they were grinding tools consisting of flat milling stones and small handstones, and implements for cutting. chopping and scraping — no blades or projectile points. A second stage, occurring between 8,000 and 3.000 B.c., is designated Chiricahua. The grinding tools and chipped implements suggest an evolutionary development out of the earlier types, though found in younger strata in the same general area. The culture as a whole was first thought to have disappeared in the third, San Pedro, stage about 500 B.C. Pottery and presumably agriculture entered the southwest at about that time, but the original Cochise sites yielded no evidence of either. Ventana cave, on the Papago Indian reservation, seemed to suggest that the people responsible for this culture did not disappear. Three levels of occupation occurred in Ventana cave, the oldest of which contained flaked implements having possible relationship to the Folsom culture, together with the bones of both modern and extinct animals. The next upward layer, in addition to animal remains, had a great number of grinding stones and flaked implements. The grinding stones resemble those identified with the Chiricahua stage, while the flaked instruments have some resemblance to types established for the early cultures of the Pinto and Mohave basins in California. The upper part of this second stratum contained a number of projectile points of the type ascribed to the San Pedro stage. The third and top layer contained pottery of the modern Papago Indians as well as of the antedating Hohokam culture (see below). Types of grinding tools present in the Cochise culture persisted there, but in addition a type of mano (handstone) associated with maize grinding and flour making appeared. The inference is that pottery and agriculture arrived in the area during the last stage of occupation at Ventana cave and were taken over by a living people who continued into modern times. The southmest, with its arid climate extending back over several thousand years and with numerous caves and rock shelters, offers the greatest likelihood of preserving the full story. Actually. many aspects of the story are already known.

The Southwest. — The southwest, including the southern portion of Colorado, most of Utah, Arizona and New Mexico and northwestern Mexico, consists of several culture provinces, sharing a certain contemporaneity and the same general geographical region. At least two, and possibly three, agricultural peoples are included, and these in turn are surrounded in a great arc by various peoples of a marginal agricultural and hunting economy. The area divides into three climatic zones: (1) high, moist (22–40 in. annual rainfall) and cool; (2) high, dry and cool; and (3) low, dry and hot.

Best known of the southwestern groups are the Pueblo Indians, whose ancestors built the great cliff villages now seen in ruins and the equally remarkable multiple apartment houses of adobe and stone masonry. Some of the latter are still occupied, while the Pueblo Indian inhabitants speak languages and observe ceremonies, the origins of which are at least pre-Spanish. The Pueblo culture was preceded in the same general area by a people to whom the term Basket Maker has been applied; and, because the history of occupation continues without interruption in a kind of evolutionary process. it has become customary to refer to the two as the Anasazi culture. The word is derived from a Navaho language term meaning "the ancient ones." The central focus of this Anasazi culture was in the northeastern part of Arizona and northwestern New Mexico, with those portions of Colorado and Utah immediately contiguous. In time, however, Anasazi traits ranged as far as the Idaho line, westward into Nevada and considerably southward and eastward from the points of beginning.

The origin of the Basket Maker Indians is not precisely known. When first settled in the northern portion of that province, they were already excellent weavers of baskets. though not potters, and they were already supplementing hunting with agriculture, growing maize and pumpkins. They were predominantly longheaded, though some a ere roundheaded and some were apparently crossed between the two head types. They sometimes sheltered in caves, and when they built shelters in the open, the houses were partly below ground and were roofed over with poles and mud. Storage pits for food. often lined with stone slabs set on edge, were characteristic. The basic pattern continued into a following period, designated Modified Basket Maker, when agriculture occupied major interest, though hunting and nild seed gathering were not abandoned. Beans had been introduced as an additional food crop.

SOME FEATURES OF 19TH-CENTURY INDIAN LIFE

1. Arikara Indians of North Dakota at a grass dance, about **1850**
2. Incident in the life of Jaw, a Teton Sioux of Standing Rock **reservation** in the Dakotas. He made the drawing himself, on white muslin, to recount the story of a successful war expedition
3. Paiute Indian woman weaving a basket before her brush shelter which consisted of a framework of poles covered with boughs, about **1873**
4. Umatilla Indian child of Oregon, about **1900.** The flat cradle was made on a basketry or wickerwork base, covered with buckskin and cloth. The floral designs on the headboard were probably not aboriginal in style
5. Hair dressing among Hopi Indian women in the village of Walpi, Ariz., **1879.** The pueblo tribes used a stiff brush of spear grass for combing and dressing the hair
6. "Lone Dog's Winter Count," dating from **1800,** painted on buffalo hide by a Yanktonai Indian of Montana. A winter count is an **extended** calendar history. Each sign depicted some outstanding event or circumstance **used** to distinguish each year as **it** passed
7. Navaho woman at her loom before an earth lodge, or hogan, on the Navaho reservation, Arizona, **1880**

19TH-CENTURY INDIAN DWELLINGS

1. Canvas tepees in a village on the Umatilla reservation, Oregon
2. First (or east) mesa in a Hooi village at Walpi, Ariz., about 1872; typical multistoried pueblo apartment dwellings made of stone and adobe
3. Indian brush lodge, 1894
4. Cold Creek Indians in bivouac on Severe river, Utah, 1873. The Indians were probably on a hunting trip when they set up the improvised shelter
5. House of the Hopi captain of Shongopovi in Arizona, about 1870. The three-story terraced dwelling was built of stone with adobe or mud mortar to hold the stones in place, and also plastered with mud on the outside. Roofs at the various levels were flat and were used as dooryards for the upper-story rooms

8. Stock: Algonkin. Tribe: Sauk and Fox

Houses were joined together in straight lines or in crescents, and a new type of building began to appear. This was a circular room, built partly underground. It was an enlargement of the old storage pit, but now was evidently used for ceremonial purposes, and was probably the precursor of the "kiva" found in modern pueblos. The word kiva is derived from the Hopi language and means "old house." The most notable change from the previous period is the introduction of pottery, sun dried at first, and sometimes made in basket moulds. Soon, however, true pottery was being made.

The beginnings of Pueblo culture, as in the case of the early Basket Maker, are obscure. Some movement westward and northward occurred, and some new traits began to appear. The number of roundheaded people increased noticeably. In addition, the practice of flattening the back of the head became general, achieved evidently in infancy by fastening the child to a hard cradleboard. The same type of above-ground, straight-line or crescent-shaped multiple house was built, two rooms wide. However, stone masonry began to replace the pole-and-mud and adobe construction of the earlier period. Agriculture, including several varieties of corn, may have been augmented at that time by the cultivation of a native long-staple cotton. Pottery was not much improved, but it included a greater variety of shapes and decoration. Basketry was much less common. The early phases of Pueblo culture are termed Developmental Pueblo, and in that period are included the emerging features which in an earlier classification were designated Pueblo I and Pueblo II. Throughout that early period, the area of occupation continued to expand. The kiva became larger and eventually was built entirely underground. Entrance was gained through an opening in the ground-level roof. Domiciliary houses became larger but the basic character remained about the same. Pottery varied according to shapes, finishes and methods of decoration.

The great Pueblo period (Pueblo III) followed (A.D. 1050–1300), sometimes called Classic Pueblo, a period which most people probably associate with the term Pueblo. It was the time of the great cliff houses, such as Mesa Verde (Cliff palace and Spruce Tree house), and the large apartmentlike structures in Chaco canyon (Pueblo Bonita) and elsewhere. An actual shrinking in area took place as people from the outer fringes of the occupied region moved in to build the large dwelling units. Also, since a number of the outstanding structures were built in quite inaccessible canyons and mesa walls, there is the possibility that hostile strangers had reached the outlying districts. The physical type remained the same, except for increased predominance of roundheadedness. Artificial head flattening continued to be practised. The most notable advance over previous periods was in architecture and pottery. The arch was not discovered; but masonry walls were greatly thickened, dressed stones being used in many localities, to bear the greater weight of massive structures. Houses varied from 20 to as many as 1,000 rooms, and from one to four stories in height. Each of the larger houses mas in effect a single village. Windows and doors were quite small, and usually no openings were made in the lowest level of rooms, which were entered by means of a ladder through the roof. Floors were terraced or set back, and these terraces were much used as outdoor living space. Roofs were constructed to carry great weights by laying a series of heavy beams, covering these with a mat of smaller poles and brush, then laying on a coat of adobe six to eight inches thick. Kivas were greatly enlarged in some areas, ranging from 50 to as much as 80 ft. in diameter. Craftsmanship in pottery reached a high level of excellence. Specialization became so pronounced in the different centres, as in Chaco canyon, Mesa Verde, Kayenta and a number of others. that the style of each can be recognized easily, once the basic patterns of construction and design are learned. The earlier black-on-white and red-on-white designs were still used, but polychromes of three or more colours were produced and decoration was applied more lavishly. Cotton cloth, blankets and bags were woven, and yucca fibre also entered into various articles of clothing and utility objects such as mats. Feather-cloth robes were worn in cold weather.

Abandonment of the cliff houses and large community buildings marked the close of the great Pueblo period. No single reason is adequate to explain this abandonment and the subsequent moving away of the builders. Probably several forces were at work, among them incursion into the northern part of the territory by nomadic Athabascans (Navaho and Apache [*q.v.*]) and a prolonged drought, which examination of tree rings in the area shows to have existed from A.D. 1276 to 1299. It is also possible that lack of central leadership, such as characterizes the modern Hopi (*q.v.*) Indians, led to internal dissensions and splitting up of the families brought into close association in the large community centres.

Pueblo IV period (A.D. 1300–1700), also called Regressive Pueblo, was characterized by a general movement southward and eastward and new villages, some as large as or larger than those of Pueblo III, were built on the Little Colorado. Puerco. Verde. San Francisco. Rio Grande, Pecos, Upper Gila and Salt rivers. The great pueblo of Pecos dates from that period, as does Tyuonyi in Bandelier National monument. Pottery showed new developments, both as to technical construction and decoration. Geometric patterns were largely replaced by naturalistic representations of birds, animals, insects and the human figure Glazing was frequently used. The modern period, Pueblo V, is usually dated from the beginning of permanent Spanish settlement at the close of the 17th century. During the interval from 1540, when the Spaniards first entered the Pueblo country, and the recapture of the country by Diego de Vargas in 1692–94, the number of Pueblo settlements declined from about 80 to 25 or 30. Much of the culture and many of the skills in agriculture and crafts continued down to modern times.

Beginnings of Agriculture.— The beginnings of this Anasazi culture are not too clearly established. As mentioned above, the Basket Maker people were already practising agriculture when they first appeared. It is usually assumed that a prior, or nonagricultural, stage preceded, but no physical evidence of such a stage had been discovered by mid-20th century. Believing that agriculture was introduced in the southwest at about the beginning of the Christian era, writers have generally placed the beginnings of the Basket Maker culture at a time just prior to A.D. 1. New evidence discovered at Bat cave, N.M., in 1948 seemed to promise considerable revision of these dates. At that site, located on the shores of prehistoric Lake San Augustin, six levels of human occupation were identified. The top, or most recent, layer contained pottery fragments ranging in date between A.D. 500 and 1000. Geological evidence for the beginning period of occupation is 2500 B.C. Maize, including shelled cobs, separate kernels and other parts of the plant, was found at all levels, beginning at the bottom. Analyzed botanically, the maize found at Bat cave contained specimens of the most primitive form of corn yet discovered, and incidentally provided data in support of the Mangelsdorf-Reeves theory of maize origins The age estimates were partly confirmed by the radiocarbon disintegration test. A report published in 1951 indicated an age of 3,000 to 3,500 years for the oldest material.

Tree-ring chronology, developed in the southwest, proved invaluable in establishing guideposts in time. The method was an indirect outgrowth of research carried out by A. E. Douglass, of the University of Arizona, Tucson, to discover what effect sunspots have on climatic conditions. This led to a study of annular growth rings of trees seen in cross section, and eventually Douglass and his associates developed a chart of growth patterns against which he could compare specimens of logs from any area in the southwest. The earliest date on this time chart is A D. 11.

Hohokam.—The term Hohokam is derived from the Pima language (meaning "those who have gone") and is applied, like Anasazi, to a cultural development the origins of which are obscure and which covered a long period of time The area in general is south of that occupied by the Basket Maker-Pueblo people, extending into northern Mexico. It is primarily a desert area of high temperatures, sparse rainfall and xerophytic vegetation. The Hohokam were already practising agriculturists when their remains are first encountered. In later stages, irrigation canals were built and river water was brought to the fields. The absence of such canals in the first (Pioneer) Hohokam period leaves the assumption that planting was confined to river bottoms and that flood irrigation was relied upon. Pottery was also made in that first period. Dwelling houses were partly excavated, but separate walls of poles and brush matting were erected within the pit, and similar material formed the roof. The Hohokam never built large community houses such as characterized the Anasazi people; their villages instead consisted of separate individual houses. The physical type cannot be ascertained, since the Hohokam practised cremation. The beginning date for this culture has generally been given as 300 B.C., based on tree-ring chronology, as far as such evidence goes, supplemented by stratigraphic analysis of pottery remains.

In the succeeding Colonial period, a general expansion of the culture occurred until it occupied most of the southern half of Arizona. The first irrigation canal, diverting water out of the Gila river near modern Sacaton, Ariz., was dug during that period (c. A.D. 500–900). Also at that period occurred for the first time large excavated areas (maximum size 180 x 61 ft.) thought to be ball courts similar to those found frequently among the Mayas of Central America. The Mayan ball game, described fully by early Spanish colonists, was played with a solid rubber ball; and a similar ball was found in a Hohokam site.

Such a relatively specialized trait helped confirm the impression that agriculture, perhaps pottery, and other material culture features of the southwest derived from Middle America and even from South America. The Hohokam people on the Gila river and their relatives in the modern Mexican state of Sonora were on an ancient trade route which followed the coastal strip along the Gulf of Lower California until it reached the Rio Grande de Santiago, ascended that stream to modern Guadalajara and thence passed into the Valley of Mexico.

Hohokam pottery, even at the lowest level, reveals great technical skill The finishing process was the so-called paddle-and-anvil, by which the walls are brought to the desired thickness by pounding or pressing. A round stone anvil is held inside the vessel to support the clay wall while a scraping tool works on the outside. Among the Anasazi, the prevailing technique was the coil method, in which the fingers press the walls to the approximate thickness while the clay is still wet, and afterward a sharp stone is used to scrape off excess thickness when the clay has become leathery. Also, the Hohokam as early as the Colonial period began to use freehand drawing of birds, human beings, insects, snakes and other animals in pottery decoration, while the Anasazi did not depart from geometric designs until Pueblo IV, some centuries later.

The Sedentary period (*c.* A.D. goo–1100) added clay human figurines to the list of Hohokam traits. A more startling development, however, was that of copper bells cast in wax moulds. The copper appears to have been mined in the general area, but the derivation of the casting technique is obscure, and no other copper objects were found among the Hohokam. Casting of metals was practised in Central America and again in the Andean region of South America, but nowhere in North America outside the Hohokam area.

The Classic, or final, period of Hohokam culture (A.D. 1100–1400) is notable ior the peaceful intrusion of the Salado Indians, a branch of the Anasazi culture. The shifting of the Pueblo people southward from the great cliff dwellings and community houses in the north, because of drought or the pressure of other people coming in from the north, had the evident effect of displacing populations throughout the southwest. The Salado people came from the upper reaches of the Salt river, occupying an area within the modern Fort Apache Indian reservation until about the year A.D. 1200. They were in the Hohokam territory from about that time, lived there for several decades then withdrew and disappeared from sight. There is no evidence of hostility and every evidence of amicable relations between the two peoples. The principal effect of the presence of this Pueblo people in the Hohokdm country is revealed in architecture. Single-type houses clustered in villages continued to be built until the advent of the Salado people Presently great community houses with massive walls of adobe (building stone was not available in the area) began to be built. The Casa Grande National monument near Coolidge, Ariz., is a survival of that period.

After the Salado Indians disappeared, the Hohokam culture seemingly declined immediately. Deeper invasions into the southern area by nomadic Athabaskans may have precipitated the change. In historic times the Pima Indians occupying the Hohokam area were much harassed by marauding Apache bands. Possibly the concentrations of people, with dependence on nearby lands, proved too vulnerable to raiding parties. By scattering over a wider area, the safety factor would be increased for the group as a whole. The Pima Indians and their kinsmen, the Papagoes, who are presumed to be the direct descendants of the Hohokam, were living in just such scattered small villages when the Spaniards first encountered them.

Mogollon.—This third southwestern area was formerly considered a local variation of the Anasazi culture. Investigation, however, demonstrated that it is distinct from both the Basket Maker-Pueblo and the Hohokam areal developments The view is now held that Mogollon represents one line of descent from the San Pedro stage of the Cochise culture (see above), the other line being the Hohokam. In other words, Mogollon and Hohokam share a common origin in the old seed-gathering complex of southwestern New Mexico and southeastern Arizona. The Mogollon occupied the eastern half of that old region, which is in part at least a mountainous country, lying east of the San Pedro river in Arizona.

The relationship to the San Pedro material is reflected particularly in stone implements found in the earliest Mogollon sites. Subsistence was obtained principally from wild seeds, roots and nuts, although some evidence of beginning agriculture exists. Hunting was probably not important since arrow and spear points are rare and even animal bones are not often found. Pottery was already being made in the earliest Mogollon period, designated Pine Lawn (C. A.D. 400–500), and it differs in type from either Anasazi or Hohokam. The people lived in small villages of separate circular houses, the floors of which were from 1 to 3 it, below ground level. The houses lacked fireplaces and the entrance was through a kind of tunnel. In these features the houses were peculiar to the area. Other periods for which diagnostic material was catalogued include the Georgetown, San Francisco River, Three Circle and Mimbres, each estimated to have a span of about zoo years in ascending order. Masonry walls began to appear in the houses of the Three Circle period, although the floors of these continued to be below the outside ground level. In the succeeding, Mimbres, period the pit house disappeared and all-masonry houses were built aboveground. The villages were greatly expanded. Mimbres pottery, among the finest found in the south est, is especially notable for the excellence of the freehand drawing of the human, animal and insect forms used as decorative elements. The presumption is that Anasazi people entered the area during the Mimbres period (C. A.D. 1050–1200). Thereafter, for reasons not yet understood at mid-20th century, the dwellings on the Mimbres river were deserted and the people apparently drifted southward into northern Mexico. In Chihuahua state, Mimbres-type pottery was produced. Eventually community houses oi several stories, built with massive adobe walls, echo the late development in the Hohokam country. It seems possible, therefore, that the Mogollon and Anasazi (Salado) people moved together into Chihuahua and contributed their skills to the local culture.

Southwest Periphery.— The Anasazi, Hohokam and Mogollon peoples were surrounded on three sides, and at different times, by tribes practising a marginal agriculture or no agriculture at all. On the fourth side, the south, were sedentary cultures not unlike their own. Whether the Athabascan Navaho and Apache people entered the area as a disruptive force or as peaceful neighbours is not definitely known. It is possible that hostility characterized the early relations, but in time the Pueblos and their Navaho-Apache neighbours accommodated to each other. The Navahos evidently joined the Pueblos in driving the Spanish out of New Mexico in 1680, and following that event some Rio Grande Pueblo families joined the Navahos and were incorporated into the tribe. It is believed that these Athabascans came down from the north, possibly from as far north as Canada, where the bulk of the linguistic stock is located today. They were already in the southwest when Francisco de Coronado entered the region in 1540, and the assumption is that the original immigration occurred at the close of the 13th century, coincidental with the abandonment of the great Pueblo communities in the San Juan river area. When they reached the southwest, the Navahos were nomadic hunters and food gatherers, but in course oi time they adopted agriculture from the Pueblos and made some pottery. By the beginning of the 18th century, agriculture was the basic economy and livestock raising (sheep and goats) had become established. Weaving of woollen blankets had also begun by that time. The Apache bands, with the exception of the Jicarilla, seem to have borrowed less from the sedentary peoples of the southwest and more from the Plains tribes.

On the Colorado river, a group of tribes belonging to the Yuman language family combined agriculture with wild seed gathering and hunting. Three oi these tribes were in the vicinity of the Grand canyon: Yavapai, Havasupai and Walapai. Of these the Havasupai derived at least half its subsistence from agriculture, and the others a lesser amount. The tribes at the lower end of the Colorado river, Cocopa, Yuma, Mohave and Maricopa (the latter tribe joined the Pima Indians on the Gila river before 1700), were primarily agriculturists, utilizing flood irrigation in the river bottom. Their excellent pottery was derived from Hohokam types.

Intermountain.— The Great Basin and adjoining portions of plateau country north and south were more fertile and hospitable in glacial and postglacial times than in modern times and probably served as one of the corridors for the later migrating people seeking the interior of the continent. Archaeological exploration brought to light a number of locations where occupation occurred at very early times. Gypsum cave in extreme southern Nevada, Lake Mohave and Silver lake in southern California are among the most ancient. Other caves in the Bonneville basin (which includes modern Great Salt lake) and Lake Lahontan basin (western Nevada) are considered to be quite old, ranging in age between 3,000 and 15,000 years. Projectile puints found in the Great Basin resemble rather closely the Folsom points found east of the Rocky mountains, and this suggests that a related culture may have occupied the intermountain area at about the same time. Classification oi the culture found in the Great Basin area proved rather difficult. Earlier writers were inclined to deny the existence of a separate culture for that area and to explain what was found there in historic times as the result of borrowing from neighbouring regions; *e.g.,* California, the Plains, the southwest and the northwest. The later view was that a basic generalized culture obtained in the area in ancient times, and afterward spread and specialized in outlying areas like California. The problem of properly characterizing the basic culture for the area was intensified by the scarcity of materials. The many scattered remains, as those from the early sites mentioned, did not provide a sufficient range of associated types to allow qualitative judgment. Where stratigraphy occurs, the earliest material is Anasazi (Basket Maker period), suggesting that, as to certain characteristics at least (basketry, maize), the origins of intermontane culture derive from the southwest. Other characteristics, however, such as hunting with traps, nets and snares, the atlatl and possibly the bow, may have reached the region from the north! and then diffused to the Basket Maker people. Pueblo culture traits spread over the area somewhat later, reaching the southern boundary of Idaho, westward into eastern Nevada and even crossing the Colorado river into southern California. This diffusion of Anasazi culture into the Great Basin began probably as early as A.D. 500 and persisted until some time after AD. 1200.

Toward the end of that period, a non-Puebloid hunting people designated Promontory (from Promontory point in Great Salt lake) appeared in the Salt lake basin. Various traits, such as moccasins, iur mittens, beaver teeth dice and the sinew-backed bow were suggestive of

a northern origin. They were a nonagricultural people, although they produced pottery of a type iound among some northern Plains tribes. Other traits were subsequently borrowed irom the Puebloid people occupying the area Both peoples soon vanished and were succeeded by Shoshonean tribes, the modern occupants of the Great Basin and contiguous areas These tribes, it is thought, expanded from locations previously occupied in western and southwestern Nevada. They continued to expand their territory somewhat, crossing the Continental Divide into Montana and Wyoming. After 1700 the Comanche split off from the Wyoming branch and presently were harassing other tribes in the southern plains. The Shoshoneans, following their appearance in the historic territory, began to borrow traits from neighbouring areas, such as salmon fishing irom the north, twined basketry, pottery, Plains-type skin garments and, eventually, the horse. This reconstruction is somewhat more complex than earlier descriptions, but it offers a reasonable accommodation of the known facts.

California. — The California area was marked by a great complexity of individual languages (about 20 in Powell's classification) and separate tribal groups. In some instances, groups oi not more than 500 people, speaking a distinct language, lived in the immediate proximity of another group of no greater size, speaking a quite different language, and neither seemed to impinge upon the other. If a multiplicity of separate languages is symptomatic of the condition that prevailed in very early times, then Caliiornia settlement should reflect great antiquity. The earliest migrating Asiatics, it might be assumed, found themselves brushed aside by later and larger aggregates speaking a common tongue, and found in Caliiornia a haven apart irom the main stream of traffic. There is practically no archaeological evidence in support of such a hypothesis, however. Mention has previously been made of the sites explored at Lake Mohave and Pinto basin in southern California. Unfortunately in these cases, while the geological features involved can be dated with reasonable assurance at 10,000 to 15,000 years ago, there is reason to doubt in each case whether the human remains are contemporaneous. On the coast of southern California, campsites of a people designated San Dieguito have been found. These were tentatively dated at 2000 B.C. In central Caliiornia (valleys of the Sacramento and San Joaquin rivers), the earliest sites are: Borax lake, probably antedating 1000 B.C.; early Buena Vista, on the lake of that name, and Oak Grove, in the Santa Barbara area, both dating from about 1000 B.C. At mid-20th century, northern Caliiornia had not yet yielded archaeological material of value. In spite of the great complexity of linguistic and demographic factors, the Caliiornia culture area presents no striking deviations. Agriculture was not practised except along the Colorado river, since throughout the vast central portion of the area and southward along the coast an ingenious method of leaching acorn pulp and converting it into flour supplied abundant and constant food. Along the coast, fisheries, including the hunting of sea mammals in the Santa Barbara region, supplied the basic diet. Pottery making was restricted to the desert area east of the Coast range in southern California until rather late in the prehistoric period, when it appears on the southern coast and in the upper San Joaquin valley. Basketry, however, was widely distributed and attained distinctive skills and designs. Those produced by the Pomo Indians in the central region are especially notable.

Northwest Coast. — In the absence oi any archaeological evidence of antiquity, the *Northwest Coast culture* must be regarded as of recent iormation. It was, in iact, a culture still expanding and diversifying when Europeans first came into contact with it. Another general observation is the apparent lack oi influence oi culture traits derived irom Middle America and Mexico. On the other hand, influences from Asia are noticeable; *e.g.,* armour made of closely articulated wooden rods, and hats. The area falls into three subdivisions, the defining of which depends on identiiying the sources of certain characteristic traits rather than on any strong differences in the traits themselves. The major trends and patterns were shared in common. The over-all region extends irom northwestern Caliiornia to the head oi the inland waterway along the coast of southeastern Alaska, and within the general area the following aspects or geographical divisions occur: *Northern,* including territories occupied by Tlingit, Haida and Tsimshian Indians; *Central,* the Milbanke-Queen Charlotte sound region, occupied by the Kwakiutl and perhaps Bella Coola; and *Southern,* the Straits of Georgia and Puget sound, occupied by the coast Salish. The Columbia-Fraser river and adjacent interior regions are somewhat apart from this classification since they are, indeed, partly transitional between the northwest coast and the plateau, or intermontane, areas. Economic dependence was almost entirely upon fisheries, particularly salmon, though every kind of fish, sea mammal, shellfish, seaweed and birds feeding upon the sea were used. To a lesser extent, food resources of the land were used. So intensively was this natural iood habitat utilized that the density of population, as calculated by Kroeber, was greater in the northwest coast area than in any other part of prehistoric America north of Mexico. Great use was made oi cedar and other woods in building plank houses, great dugout canoes, food vessels, boxes for storage and cooking, and in carving masks and various ceremonial paraphernalia. Clothing and other fabrics were made of the inner bark oi spruce and cypress. By combining mountain goat wool with this bark fibre, yarn was produced ior weaving into blankets and robes. Organization was on a village rather than a tribal basis. Each village had a permanent winter site but moved seasonally as the people went from salmon stream to halibut grounds, to hunt sea mammals or to follow other pursuits in the course of the year. The potlatch ceremony, with its emphasis on giving away wealth to acquire public standing, was perhaps the most distinctive trait in the entire culture.

Arctic Coast. — The Eskimo people quite likely represent the latest ethnic stock to migrate into the new world, probably about the beginning of the Christian era. In physical type, the Eskimo resembled the earliest immigrants in that he was noticeably longheaded. Since roundheaded men are known to have iollowed the earlier longheads, the Eskimos coming at a still later time should have had a broad cephalic index. The fact that they contradict this expectation is acknowledged but not explained. The origins of the culture are not clearly defined, though exploration carried out aiter about 1940 suggested certain lines of development. The earliest remains are found in the Bering strait and immediately adjoining Arctic ocean areas. The designation Old *Bering Sea* is used in describing these earliest remains, which are those of an already highly specialized Eskimo culture. A partly contemporaneous, and possibly partly older, culture identified as *Ipiutak* centred at Point Hope on the arctic coast. and shared a number of traits with the Old Bering Sea phase of Eskimo, but also included some features which point to other comparisons. In stone work, particularly, including types of projectile points and cutting and thrusting implements equipped with stone blades inserted in bone and ivory heads, the Ipiutak material finds close parallels with related types of implements belonging to the Neolithic horizons across all of northern Eurasia. The possibility of establishing relationships between the Bering sea artiiacts and lines of diffusion spreading from Lake Baikal in Siberia at a time prior to the Christian era is thus suggested. It must also be concluded, however, that this Siberian Neolithic is not the prototype oi new world lithic industries, or at any rate that the Eskimos could not have been the carriers oi the oldest stages of that culture. Bering strait and vicinity appear as the beginning point, and from there Eskimo traits spread through successive stages identified as *Punuk, Birnirk, Post-Punuk, Dorset* and *Thule,* eastward across the northern shelf of the American continent and on to Greenland.

Eskimo culture is notable for the versatility it has shown in adapting to a changing environment. In some areas seals are the main staple, and a variety of hunting methods was devised. In caribou country, Eskimos came to depend entirely on upland hunting and never went near the sea. Elsewhere they became expert whale and walrus hunters and devised tools and equipment accordingly. They built housing out of materials at hand — driftwood, whalebone, sod or snow blocks. The latter structures were limited to the eastern areas (Coronation gulf, Baffinland) and to occasions of seals being hunted on ice at great distances irom shore. Among the most typical Eskimo inventions should be listed two types of skin boats, the umiak, a heavy boat used in whaling, and the lighter kayak; the harpoon with detachable head and bladder or inflated skin float; snow goggles; stone oil lamp; tailored clothing; dog traction. The adaptation to environment is still further emphasized by the Eskimos of southwestern Alaska, the Alaska peninsula, Kodiak Island and Cook inlet, and by the *Aleuts.* The latter speak an Eskimoid language which is not intelligible to a Bering sea Eskimo, for example, but otherwise they are the same people. The beginnings of the Cook inlet and Aleutian settlements are approximately contemporaneous with the Bering sea Eskimos. The region is one of heavy rainfall. Hence, transportation is entirely by boat, and the economy is limited to hunting of sea mammals, fishing and taking oi birds.

Subarctic.—Below the arctic basin occupied by the Eskimo people, an area of tundra, giving way at last to extensive coniferous forests and great inland waterways, was utilized by tribes of hunters. Their specializations were not so striking as those worked out by the Eskimos, but they served their purpose. The climate being subarctic and wholly unadapted to agriculture, the population was severely limited by the animal carrying capacity oi the area. Subsistence was obtained principally irom the caribou herds, though moose and deer and fish taken in rivers and lakes were also in the diet. Because of the rigorous environment, the people were not able to adopt or absorb cultural developments which might reach them either from the Eskimo north or irom the agriculturist-hunter tribes speaking similar languages in the south. Because snow in the interior was deeper and drier, the toboggan was substituted for the Eskimo's runner sledge, and snowshoes were distinctive traits. Extensive birch forests provided bark ior canoes, cooking and eating vessels, and covering ior the conical houses and shelters. The area divides roughly into two linguistic groups: (1) the Algonkin-speaking Cree (*q.v.*) (various divisions), Naskapi, Ojibwa' (*q.v.*), Ottawa and Algonkin, occupying the region north of the Great Lakes and east of the Nelson and Churchill rivers; and (2) the Athabascan-speaking Hare, Yellowknife, Dogrib, Slavey and Chipewyan on the Mackenzie river; the Loucheux, Sekani, Carrier and Babine in the western mountain area; several tribes along the Yukon river; and the Beaver and other tribes in British Columbia.

Eastern North America. — The agricultural practices of the aboriginal population of the eastern part oi the continent (approximately east of the 100th meridian) diiier so markedly irom those of the southwestern tribes as to suggest a diiierent source of origin. The western practice was to grind corn on a stone metate by means of a mano, a cylindrical or rectangular stone rubbed against the metate. The re-

sulting meal was then fashioned into flat tortillas or wafers and baked on hot stone. In the eastern area, corn was pounded in a mortar made of wood or stone, or made into hominy, and the product was boiled rather than baked. In the west, moreover, agriculture tended to absorb the full attention of the people, and ceremonial life more or less revolved around the incidents of planting and assuring a good crop. In the eastern zone, something less than 1% of potential crop land was actually cultivated, and the impression is obtained that agriculture was regarded as a supplementary means of livelihood rather than the mainstay. Surplus agricultural foods, moreover, seem to have encouraged warfare rather than the peaceful arts. The contrast in dietary practices suggests that the southwest derived its tradition and technology from the central valley of Mexico, since metate grinding is continuous between the two regions. No immediate answer is advanced to the question of origin in the case of eastern practices. Three possible routes are: (1) eastward from the Pueblo area; (2) northeastward out of Middle America, following the Gulf of Mexico into Texas; or (3) across the sea from the Antilles. There are strong objections to all three explanations. Possibly agriculture came late into the area as part of a complex which included the considerable social organization that must have gone into the great mound structures. Withdrawal or termination of that original stimulus, and consequent decline of mound-builder societies, would have removed the incentive for a strong agricultural development.

While a definite time period cannot be given for the earliest occupation of the eastern area, remains discovered up to mid-20th century were suggestive of the Folsom-Yuma artiiacts of the Rocky mountain region. The first skeletal remains are those of a longheaded race. Settlement doubtless occurred, as in the west, in early postglacial times, and the earliest settlers were probably hunters accustomed to a nomadic type of existence. By about A.D. 500, according to tangible evidence, agriculture and pottery making had been introduced, and the building of burial mounds was spreading over the country. The earliest examples of eastern pottery were found in Florida, Georgia and Alabama, and in certain northeastern sites. Pottery from the two regions differs in style and technical construction and apparently had different origins. Immediately preceding the introduction of agriculture into the eastern area, dependence for livelihood was centred on fishing, and the densest population was along the ocean shores, the rivers and fresh-water lakes. This would account for the great shell mounds underlying the sites occupied later by farming groups.

The most spectacular culture oi the eastern area is the *Hopewell,* which flourished approximately A.D. goo–1300. The name is derived from the Hopewell farm in Hamilton county, Ohio, where the first site was explored. It was to this culture that the term mound builders was at one time widely applied. The term is considered a misnomer, however, for later investigations revealed that the practice of constructing earth mounds was widespread in area and in time, and the purposes served by the mounds differed greatly.

Characteristics of the Hopewell culture, which centred in southern Ohio but reached also into Indiana, Illinois, Wisconsin, Michigan, Iowa, Kansas, Tennessee. Pennsylvania and New York, are those of a farming population still relying to a certain extent upon hunting and fishing and the gathering of wild nuts, fruits, seeds and roots. The amount of pottery and ornamental stone work and metalwork iound in association with Hopewell villages suggests that some division of labour may have taken place. In addition, the nature and size of the earthworks at many sites inevitably suggests that forms of public labour, whether voluntary or conscripted, may have been employed. The earthworks are sometimes of a type to suggest deiensive purposes, but more often they served as burial mounds or apparently formed the bases of temples or other structures. The best pottery was well made, with decoration applied by incised or stamped lines, often in naturalistic outlines. Even more notable are the effigy pipes, carved in stone and polished, representing birds, fish and various other animals. The metalwork has been called the finest in North America in pre-Columbian times. Copper in sheet forms was used extensively; some silver and meteoric iron, and occasionally gold, entered into various ornaments and utility pieces. Metal casting was not known, and the processing was limited to beating and annealing of raw ores. Sheets of mica were also employed and help to characterize the culture. Trade routes were evidently well developed, ior material irom as far away as the Rocky mountains and the Atlantic coast was iound in Hopewell sites, and articles identified as manuiactured by the Hopewell people were iound in localities as far distant.

The Hopewell culture represents the climax of a widely diffused pattern of agriculture, pottery and mound building to which the term *Mississippi* is attached. In its later manifestations, the culture is characterized by highly sedentary peoples living in fairly concentrated population centres. The influences which built up the culture seem to have arisen in the southeast and in the Lower Mississippi valley. Earlier levels of occupation in both regions contain traits which were later elaborated by the Hopewell and other groups. Throughout the area this Mississippi pattern was preceded by an earlier pattern of culture which lingered and absorbed traits irom the later culture. These earlier people were less sedentary in their habits, more loosely organized; they made a simple potter), depended on hunting but practised a limited agriculture. This ruder culture, to which the term *Woodland* is applied, appears to be of northern origin, and it has been suggested that Algonkin peoples were the carriers. The Muskhogean tribes, on the other hand, were probably responsible for the Mississippi culture. These historic tribes, whose territories reached from the Lower Mississippi river to Florida, are identified with important prehistoric sites.

As these eastern cultures flourished, they extended their influences northward and westward, and movements of people were partly responsible ior the diffusion. The Plains area in this manner absorbed and adapted to local conditions many traits irom the east.

Plains Area.— The underlying pattern in the Plains, as elsewhere in aboriginal America, was that of a hunting culture. In the high Plains, the basic material was identified as Folsom (Lindenmeier site). A somewhat later level of occupation (*c.* 3000 B.C.) occurred at Signal Butte in western Nebraska, but this too was a hunting, prepottery culture. By about A.D. 1000 a less nomadic, though still primarily hunting, economy appeared in the Nebraska region, along with rude, grit-tempered pottery. Agriculture may have been limited to squash and gourds, as neither beans nor maize was found. The tools and other remains are similar to the so-called Woodland traits of the eastern area. Evidences of this stage of culture are found in numerous sites in Nebraska, Iowa, Missouri, Kansas and (less certainly) Oklahoma. Scattered pottery remnants indicating Woodland influence have been found as far west as Colorado and the Yellowstone river, though the greatest concentration is east of the Missouri river.

At a later time, but still prior to Columbus' voyages, a second wave of people moved into the Plains, again probably irom the east. Traces of this second migration are widely dispersed, suggesting a fairly long interval of settlement. By this time horticulture, including the growing of maize and beans, had become the principal means of subsistence. Permanent buildings occur; the house type was a rectangular, semi-subterranean, earth-covered lodge. Pottery was abundant and better made than in the previous stage. Decoration was confined to incised lines around the neck or rim of the vessel. Regional variations have been found and identified by local place names. The first to be studied was the *Upper Republican* (river) *culture* in southern Nebraska and related sites on the Loup river in central Nebraska. Characteristic are small villages, built in the open along river terraces, housing 50 to roo inhabitants. Agricultural tools consisted of planting sticks and hoes made from the shoulder blade of a bison. Surplus corn was stored in underground storage pits. Complete absence of the metate, or grinding slab,. of the southwest suggests that maize was milled in a wooden mortar. Hunting was not abandoned since weapons and skin-working tools are still found. Various sites in Kansas closely parallel the Upper Republican material, traces of which are found as far away as the Texas panhandle, eastern Colorado and Wyoming, and perhaps the Dakotas. A further variant, found in the Missouri river bluffs of eastern Nebraska and northeastern Kansas, is designated the *Nebraska culture.* No basic differences occur, but the sites yield a richer array of pottery types, ornamentation and tools. Cannibalism may have been practised, though the evidence is not conclusive. The inference here is that Upper Republican and Nebraska were both regional specializations of a generalized culture which bad spread over a rather wide area. The complete absence of any traces of an earlier underlying culture in either area suggests, moreover, that the basic elements were brought in by a migrating people moving out of an older cultural environment.

One possible route of diffusion from the southeast into the Plains was through the Natchez (*q.v.*) people on the Lower Mississippi and the Caddo and affiliated tribes along the Red river in Texas. Near there also were the Pawnee and their affiliates, the Arikara, who eventually in historic times drifted northward and became associated with the Mandan in North Dakota. The Red river pattern was based on agriculture. The pottery was excellent in design and finish, with intricate patterns of broad and fine incised lines. Tempering to ensure evenness of firing was accomplished by adding grit, sand, crushed shells and other materials. Villages abounded, composed of domed circular houses made of thatch, such as Coronado reported seeing in Kansas. This basic house type eventually spread throughout the central and northern Plains, though brush and earth were substituted as a covering as people moved away from regions where palmetto, reeds or other thatching material grew. This inferred route finds some confirmation near the mouth of the Platte river in northwestern Missouri. There, in association with house types resembling those of the Nebraska culture, were iound quantities oi pottery sherds in which shell tempering was used, instead of grit or crushed rock such as was used by the people of the Nebraska and Upper Republican cultures

Entry into the Plains area by Europeans occurred in 1541, when Coronado marched from Pecos Pueblo (east of the Rio Grande) into the region near modern Wichita, Kan. The party reported meeting two types of natives: one nomadic (probably Apache), and the other dwelling in villages of round straw houses and raising maize, beans and melons. The latter were probably Wichita Indians, of the Caddoan linguistic stock. Following that initial contact, the Plains area remained relatively obscure, and Europeans were not aware of the profound changes and movements that took place. The acquisition of the domesticated horse in the decades following the establishment of a permanent Spanish outpost at Santa Fe, N.M., in 1605 was responsible for the major displacements, though intruders from outlying regions supplied the initial incentive to move and to consolidate. Large vil-

lages, occupying as many as 100 ac., had come into existence on the Loup and Platte rivers in east central Nebraska in prehorse times. These villages were situated on river bluffs for defensive purposes, and their inhabitants were probably ancestors of the modern Pawnee. Other concentrations took place in central Kansas and in the westward extensions of the Oneota *culture* (identified with Chiwere Sioux), which moved from the Wisconsin area into eastern Nebraska, Kansas and southwestern Missouri.

The horse inevitably speeded up the process and in many cases brought about complete abandonment of previous pursuits. Thus, the Comanche and Kiowa, erupting out of the northwest at the beginning of the 18th century as mounted horsemen, started dislocations of sedentary tribes and European settlers alike. The Cheyenne (*q.v.*) and Arapaho (*q.v.*), abandoning earth-covered lodges in Minnesota and North Dakota, gave up horticulture about 1700. Behind them, possibly crowding these two tribes into the northern Plains, were various bands of Dakota (Sioux), who had also been living a sedentary village existence. They in their turn had been dislodged from the Great Lakes region by Chippewa Indians, who had obtained European firearms from the French at an earlier date. Thus, most of the tribes which in the minds of later-coming white men were typical nomadic horse Indians, were newcomers to the area and in some cases had been farmers and village dwellers not many generations before their first contacts with Europeans. Still other tribes, starting from a tradition of agriculture, made a kind of unhappy compromise with the changed conditions. Among these were the Pawnee and their kinsmen the Arikara, and the Siouan-speaking Mandan, Santee, Omaha and Oto. The tribes which apparently took to the horse culture with the greatest alacrity were those which came into the Plains as northern hunters: the Blackfeet (see BLACKFOOT), Gros Ventres, Sarsi, Assiniboin, Comanche and Kiowa.

INDIANS IN CONTEMPORARY LIFE

The great diversity which marked Indian cultures persisted in modern times. Some tribes disappeared by amalgamation with other tribes or by wars and epidemics, and some languages perished. The process of acculturation worked at varying rates within the Indian societies, transforming and devitalizing segments of custom and practice. Notwithstanding these factors, Indian populations north of Mexico continued to manifest an unexpected viability. It is estimated that more than half the languages spoken in that area at the time of discovery were still in use in the 20th century (see Table II).

A discussion of contemporary Indian population is complicated by lack of a consistent definition of the term Indian, a condition that prevails throughout the western hemisphere. In the United States, a person is an Indian if he is an enrolled member of an Indian tribe or a descendant of such an enrolled member and recognized by the tribe, regardless of degree of Indian blood. The situation in Canada is basically similar. In both countries, many persons of varying degrees of Indian ancestry are not counted as Indians because they are not affiliated with a tribe. The United States government in 1950 recognized as Indians approximately 400,000 persons in the 48 states and an additional 35,000 Indians, Eskimos and Aleuts in Alaska. In Canada the 1950 estimate, including Eskimos, was about 140,000. The population of Greenland, about 22,000 in 1946, is predominantly Eskimo, with a European component of not more than 500 persons. On the basis of Mooney's figures for the dates indicated, it will be noted that the Indian population north of Mexico at mid-century was approximately one-half what it was at the time of the first white contacts. In the United States, at least, this population was increasing faster than the general population. The annual net increment of the Indian population in Canada was 1,500, or better than 1%. It is not possible, obviously, to state in quantitative terms the extent to which Indian attitudes, customs or values had continued to function. Neither is it possible to deny the existence of attitudes, customs and values identifiably Indian after the lapse of several centuries.

The modern position occupied by Indians in the United States and Canada is not readily understood without some explanation of prior events. In both countries Indians are considered wards of the nation, but the term does not elucidate itself as a reference to the usual relations of guardian and ward. In the United States, for instance, Indians are full citizens and may vote in every state of the union. In Canada individual Indians may be enfranchised by meeting certain legal requirements; and many took advantage of the opportunity.

The beginnings of the relationship are to be found in some of the earliest pronouncements of the Spanish crown. The discovery of the continents in the western hemisphere was an unforeseen event. Columbus, it will be recalled, was searching for a western, and shorter, route to the Indies, as Asia was then called. Europe was quite unprepared for the problem of admitting into world society, as it then existed, a human population not previously known. Questions were seriously raised as to whether these people, on rational as well as moral grounds, had the capacity to govern themselves or to own property.

Luckily for the new world inhabitants, the questions fell to the Spanish theologian Francisco de Vitoria to answer. His lectures, delivered at the University of Salamanca in 1539, voiced a humanistic view of conquest and the rights of subject peoples which in time became the prevailing view in international law. More immediately, his opinion was reflected in the promulgation of the Laws of the Indies in 1542, which decreed that Indians were free persons and were not to be taken as slaves; that disputes among Indians should be settled according to their own customs; and that property should not be taken from them except in fair trade. Vitoria denied that either the emperor of Spain or the pope was lord of the universe; even if the contrary were true, this would still not deny to Indians the right to hold property. Elsewhere he reasoned, if it be argued that Spain must administer in behalf of the Indians because of their lack of intelligence and experience, two limitations must still be imposed: the administration must be temporary, until Indians were capable of governing themselves; and the administrator must work, not for his own profit, but for the welfare of the Indians. This, in essence, could be the justification given by the modern administrator of Indian affairs.

It does not detract from the importance of Vitoria's utterances to remark that Spain in pursuing its colonial aims ignored him and the Laws of the Indies as well. Reformers such as Bartolome de las Casas made the world aware of the wrongs visited upon the Indians. In time, a large part of western Europe was enthralled by the concept of the "Noble Savage," a phrase evidently first used by John Dryden in his Conquest of Granada. The moral views of such men as Vitoria in the Spanish world and William Penn and others in the English sphere were the safeguards which in time brought public policy to erect barriers against racial injustice.

Colonial Policies.—The formulation of this public policy was a subject of concern to each of the major European colonizing powers. The Spanish tried assiduously to Christianize the natives by mass methods and to remake their living patterns. Orders were issued to congregate scattered Indian villages in orderly, well-placed centres, assuring the Indians at the same time that by moving to such centres they would not lose their outlying lands. This was the first attempt to create Indian reservations. The plan failed to protect the Indians in their land, according to Father Torquemada, who reported about 1599 that there was hardly "a palm of land" that the Spaniards did not possess. Many Indians who did not join the congregations for fear of losing what they owned, escaped into remote mountain places and lost their lands anyway.

The Russians never undertook seriously to colonize in the new world. When Peter the Great sent Adm. Vitus Bering into the northern sea which bears his name, the interest was in scientific discovery, not overseas territory. Later, when the problem of protecting and perhaps expanding Russian occupation was placed before Catherine, she declared (1769): "It is for traders to traffic where they please. I will furnish neither men, nor ships, nor money, and I renounce forever all lands and possessions in the East Indies and in America." In keeping with her thinking that it was "for traders to barter and for kings to govern," Catherine granted monopolistic trading privileges to the Russian American company, and the Russian government never thereafter seriously reconsidered its position.

The Swedish and Dutch attempts to colonization lasted so short a time that neither left a permanent imprint on new world practices. The Dutch government, however, was probably the first of the European powers to enter into a formal treaty with an Indian tribe, the Mohawks (see MOHAWK) (1643). Thus began a relationship, inherited by the British, which ultimately determined the ascendancy of the English over the French in North America.

France handicapped its colonial venture at the start by transporting to the new world a modified feudal system of land tenure which discouraged permanent settlement. The first royal commission, issued to the marquis de la Roche in 1598, recited: "We have given him power, to grant lands . . . to gentlemen and to those whom he shall consider persons of merit, in the form of fiefs, seigniories, chatellenies, countships . . . and other dignities." The first effort failed entirely, and while permanent establishment of the French in North America was effected by Samuel de Champlain in 1608, he is said to have issued only three seigniorial grants in the succeeding 20 years. Throughout the period of French occupation, the emphasis was on trade rather than on land acquisition and development. So general was the failure of the holders of large grants to encourage development that royal orders were issued in 1711 to provide that "at the expiration of a year, all seigniors who have shown conspicuous failure in developing and settling their seigniories should be deprived of their grants." Thus, France, by trying unsuccessfully to transplant a system of land tenure which at the very time was falling out of use in Europe, made no contribution to the formulation of an aboriginal land policy.

French administration did, however, establish practices in trade relations with the various tribes which can be traced through many subsequent events. The French instituted the custom of inviting the headmen of all the tribes with uhom they carried on trade to come once a year to Montreal, where the governor of Canada himself met the tribesmen in council, gave out presents and talked of friendship. The governor of Louisiana met the southern Indians at Mobile. The English, reluctantly, found themselves competing on the same basis of annual gifts. Still later, U.S. peace commissioners were to find it expedient to offer permanent annuities in exchange for tribal concessions of land or other interests.

The various English colonies established along the Atlantic seaboard were from the beginning a threat to continued Indian occupation of the area. Realization of this fact fired King Philip, the

Wampanoag leader, to his vain attempt to annihilate the northern colonists in 1675. The English were interested in land and permanent settlements. At the same time, the English, beginning quite early in their occupation, felt an obligation to bargain with the Indians and to conclude formal agreements, with compensation to Indian owners. The Plymouth settlers, coming without royal sanction, thought it incumbent upon them to make terms with the Massachusetts Indians. Lord Baltimore in 1635 and William Penn in 1682, while possessing royal grants, nevertheless took pains to purchase occupancy rights from the Indians. It became the practice of most of the colonies to prohibit indiscriminate and unauthorized appropriations of Indian land. The usual requirement was that purchases could be consummated only by agreement with the tribal headman, followed by approval of the governor or other official of the colony. At an early date also, specific areas were set aside for exclusive Indian use. Virginia in 1656 and commissioners for the United Colonies in 16 j8 agreed to the creation of such reserved areas. Plymouth Colony in 1685 designated separate tracts for individual Indians which could not be alienated without their consent.

Proclamation of 1763.—In spite of these efforts by the separate colonies and by the English ministers to protect Indian lands, unauthorized entry and use continued as a source of constant friction through the colonial period. Rivalry with the French, who lost no opportunity to point out to the Indians how their lands were being encroached upon by the English; the activity of land speculators, who succeeded in obtaining large grants beyond the settled frontiers; and finally the startling success of Pontiac in capturing English strongholds in the old northwest as a protest against this westward movement, together prompted the king's ministers to issue a proclamation which had been under discussion for some time. This royal proclamation of Oct. 7, 1763, formalized the concept of Indian land titles for the first time in the history oi European colonization in the new world. The document prohibited issuance of patents to any lands claimed by an Indian tribe unless the Indian title had first been extinguished by purchase or treaty cession. More particularly, in response to demands of Indians tbat their lands be respected, the proclamation reserved for the use of the tribes "all the Lands and Territories lying to the Westward of the sources of the Rivers which fall into the Sea from the West and Northwest." Land west of the Appalachians might not be purchased or entered upon by private persons, but purchases might be made in the narne of the king or one of the colonies, at a council meeting of the Indians.

This policy of quieting title continued in effect up to the termination of British rule in the American colonies and, in substance, was adopted by the United States as its official policy. The Appalachian barrier was soon passed—thousands of settlers crossed the mountains during the American Revolution—but both the Articles of Confederation and the federal constitution reserved either to the president or to congress sole authority in Indian affairs, including authority to extinguish Indian title by treaty. When French dominion in Canada capitulated in 1760, provision was made that "The Savages or Indian Allies of his most Christian Majesty, shall be maintained in the lands they inhabit, if they choose to remain there." Thereafter the proclamation of 1763 applied equally well in that country and was embodied in the practices of the dominion government. (The British North America act of 1867, which created modern Canada, provided that the parliament of Canada should have exclusive legislative authority with respect to "Indians, and lands reserved for the Indians." Thus, both countries made control over Indian matters a national concern.)

United States Policy.—The first full declaration of United States policy was embodied in the so-called Northwest Territory ordinance of July 13, 1787, which stated: "The utmost good faith shall always be observed towards the Indians, their lands and property shall never be taken from them without their consent; and in their property, rights, and liberty, they shall never be invaded or disturbed, unless in just and lawful wars authorized by Congress; but laws founded in justice and humanity shall from time to time be made, for preventing wrongs being done to them, and for preserving peace and friendship with them." This doctrine was embodied in the act of Aug. 7, 1789, as one of the first declarations of congress under the constitution.

The final shaping of these several statements of the legal and political rights of the Indian tribes is found in the opinions of Chief Justice John Marshall, notably in the decision written by him in the case of Worcester v. Georgia, where he held: "The Indian nations had always been considered as distinct, independent, political communities, retaining their original natural rights, as the undisputed possessors of the land, from time immemorial . . . The settled doctrine of the law of nations is, that a weaker power does not surrender its independence—its right to self-government—by associating with a stronger, and taking its protection. A weak state, in order to provide for its safety, may place itself under the protection of one more powerful, without stripping itscli of the right of government, and ceasing to be a state."

The first major departure from the oft-repeated policy of respecting Indian rights of property and political self-rule came with the Indian Removal act of May 28, 1830. For the first time coercion was resorted to by the United States, in the cases particularly of the Cherokee and Seminole tribes, as a means of securing compliance. The Removal act was not in itself a coercive measure, since it authorized the president only to negotiate with the Indian tribes east of the Mississippi on a basis of payment for their lands and improvements in the east and a grant of land west of the river, to which perpetual title would be attached. In carrying out the law, however, resistance was met with military force. In the decade following, almost the entire population of perhaps 100,000 Indians was moved westward. The episode moved the comte de Tocqueville to remark in 1831: "Whilst the savages were endeavouring to civilize themselves, the Europeans continued to surround them on every side, and to confine them within narrower limits . . . and the Indians have been ruined by a competition which they had not the means of sustaining. They were isolated in their own country, and their race only constituted a little colony of troublesome strangers in the midst of a numerous and dominant people."

The territory west of the Mississippi, it turned out, was not so remote as had been supposed. The discovery of gold in California at the midpoint of the 19th century started a new sequence of treaties, designed to extinguish Indian title to lands lying in the pathway of the various overland routes to the Pacific. The sudden surge of thousands of wagon trains through the last of the Indian country and the consequent slaughtering of the prairie and mountain game which provided subsistence for the Indians brought on the most serious Indian wars the country had experienced. For three decades, beginning in the 1850s, raiding parties and sporadic pitched fighting took place up and down the western plains, high lighted by such incidents as the Custer massacre by Sioux and Cheyenne Indians (1876), Chief Joseph's running battle in the same year against superior U.S. army forces and Geronimo's long duel with military and civil authorities in the southwest, resulting in his capture and imprisonment in 1887.

Toward the close of that period, the Ghost Dance religion, arising out of the dream revelations of a young Paiute Indian, Wovoka, promised the Indians a return to the old life and reunion with their departed kinsmen. The songs and ceremonies born of this revelation swept across the northern Plains. The movement came to an abrupt end Dec. 29, 1890, at Wounded Knee creek, South Dakota. Believing that the Ghost Dance was disturbing an uneasy peace, government agents moved to arrest ringleaders. Sitting Bull mas killed (Dec. 15) while being taken into custody, and two weeks later units of the 7th cavalry shot down more than 200 men, women and children who bad already agreed to return to their homes.

A further major shift of policy had occurred in 1871 after congressional discussions lasting several years. The president, with the advice and consent of the senate, had continued to make treaties with the Indian tribes and to commit the United States to the payment of sums of money. The lower house protested, since a number of congressmen had come to the view that treaties with Indian tribes were an absurdity (a view earlier held by Andrew Jackson). The senate yielded, and the act of March 3, 1871, declared that "hereafter no Indian nation or tribe" would be recognized "as an independent power with whom the United States may contract by treaty." Following this declaration, Indian affairs were brought under the legislative control of the congress to an extent that had not been attempted previously. Tribal authority with respect to criminal offenses committed by members within the tribe was reduced to the extent that murder and six other major crimes were placed under the jurisdiction of the federal courts. The list of crimes was later extended to ten.

The Allotment Act.—The most radical undertaking of the new legislative policy was the General Allotment act of Feb. 8, 1887. By that time the Indian tribes had been moved out of the main streams of traffic and were settled on lands which they had chosen out of the larger areas they had formerly occupied. Their choice in most cases had been confirmed by treaty, agreement, act of congress or executive order of the president. The tribes which had obtained subsistence from hunting over wide areas found reservation confinement a threat to their existence. Generally they had insisted on annuity payments or rations, or both, and the peace commissioners in behalf of the United States had been willing to offer such a price in return for important land cessions. In time, the view came to be held that reservation life fostered indolence and perpetuated Indian customs and attitudes which held Indians back from assimilation. The strategy offered by proponents of this theory was the Allotment act, which authorized the president to divide the reservations into individual parcels and to give every Indian, whether he wanted it or not, a particular piece of the tribally owned land. In order not to make the transition from Indian custom too abrupt, the land would be held in trust for a period of 25 years, after which a patent in fee simple would devolve upon the individual. With it would go all the rights and duties of citizenship. Reservation land remaining aiter all living members of the tribes had been provided with allotments, was declared surplus, and the president was authorized to open it for entry by non-Indian homesteaders, the Indians being paid the homestead price.

A total of 118 reservations was allotted in this manner. The result was not what had been anticipated. Through the alienation of surplus lands (making no allowance for children to be born) and through patenting bf individual holdings, the Indians of thrse reservations lost 86,000,000 ac. out of a total of 138,000,000 in Indian ownership prior to 1887. A generation oi landless Indians resulted, with no vocational training to relieve them of dependence upon land. The strategy iailed additionally in that ownership of land did not effect an automatic acculturation in those Indians who received individual parcels. Through

scattering of individuals and families, moreover, social cohesiveness tended to break down. The result was a weakening of native institutions and cultural practices with nothing offered in substitution. What was intended as transition proved to be a blind alley.

The trend in Indian population had been perceptibly downward through the decades after mid-19th century. The California Indians alone, according to Mooney's estimates, dropped from 100.000 in 1853 to not more than 30,000 in 1864 and 19,000 in 1906. Cholera in the central Plains in 1849 struck the Pawnee. As late as 1870–71 an epidemic of smallpox brought disaster to the Blackfeet, Assiniboin and Cree. Reports of declining population were widespread and gave currency to the concept of the Indian as "The Vanishing American." The decision of 1871 to discontinue treaty-making and the Allotment act of 1887 were both founded in the common belief that the Indians would not long survive and hence it did not much matter whether their views were sought in advance of legislation or whether lands mere provided for oncoming generations. When, therefore, it became obvious after about 1920 that the Indians, whose numbers had remained static for some years, were surely increasing, the United States found itself without a policy for advancing the interests of a living people.

A survey requested by Secretary of the Interior Hubert Work in 1926 and carried out by the Institute for Government Research, with Lewis Meriam in charge, brought into clear focus the failings of the previous 40 years. The investigators found most Indians "extremely poor," in bad health, without education and lacking adjustment to the dominant culture around them. Under the impetus of these findings and other pressures for reform, congress adopted the Indian Reorganization act of June 18, 1934, which contemplated an orderly decrease of federal control and a concomitant increase of self-government and responsibility in the Indians.

The essentials of the new law were as follows: (1) allotment of tribal lands was prohibited in the future, but tribes might assign use rights to individuals; (2) so-called surplus lands not pre-empted by homesteaders might be returned to the tribes; (3) tribes might adopt written constitutions and charters of incorporation embodying their continuing inherent powers to manage internal affairs; and (4) funds were authorized for the establishment of a revolving credit program, for land purchases, for educational assistance and for aiding the tribes in forming organizations. Moreover, the act could be rejected on any reservation by referendum of the eligible voters.

The response of the Indian population to the opportunities opened by the 1934 act was indicative of their ability to rise above adversity. About 160 tribes, bands and Alaska villages adopted written constitutions, some of which combined traditional practices with modern parliamentary methods. The revolving credit fund helped the Indians build up their herds and improve their economic position in many other ways. Beef cattle owned by Indians increased from about 170,000 head in 1932 to around 390,000 head in 1950, the number fluctuating with the market. On a number of reservations the carrying capacity of the land was reached, or passed, and no further increase was possible. It was estimated that about 12,000 Indian families were wholly or partly rehabilitated. The repayment record was especially outstanding. Borrowers from the fund were tribal corporations, credit associations and co-operative groups, which, in turn, loaned to individual Indians and to group enterprises. The total amount of money in the revolving credit pool, including sums which the tribes advanced from their trust fund accounts, amounted to about $20,000,000 by the 1950s. Of the amount falling due in 1942, 91.9% was repaid on schedule, 2.9% was extended and 5.2% was classed as delinquent. The record thereafter improved steadily. In 1949, for example, 96.7% was repaid on schedule, 2.26% was extended, 0.05% was cancelled and 0.99% was delinquent. In that year, of the $12,000,000 which had been loaned and on which payment was due, only $3,627 was cancelled as uncollectible.

Land purchase funds authorized by the 1934 act were used to buy 395,500 ac., and tribes used their own moneys to acquire an additional 390,000 ac. By other means, such as the restoration of unentered Indian lands and the transfer of parcels of public domain, Indian land holdings were increased by an additional 3,000,000 ac.

The gains were not limited to the economic area. In education and health, increased professionalization of staffs, improved methods, modernization of plants and larger operating funds resulted in services more nearly comparable with those available to the general population. In these fields especially, one of the outstanding developments was the extent to which other agencies began serving the Indian population. Thus, at mid-century, more than half of all Indian children in school were attending public schools, under contract arrangements by which the federal government compensated the school district (because of loss of revenue from tax-exempt Indian lands). Many contracts in the health field were made with private and public institutions, including medical and hospital care and public health work. The bureau of Indian affairs completed an arrangement with the United States public health service by which the latter agency supplied expert medical personnel and consultants.

Originally, the United States exercised no guardianship over the person of the Indian; when John Marshall first used the term, he was making an analogy that the relation of the United States to the Indian tribes was like that of guardian to ward. After 1871, when internal tribal matters became the subject of national legislation, the number and variety of regulatory measures multiplied rapidly. In the same year that the Indian Reorganization act was passed, congress significantly repealed 12 statutes which in an earlier day had made it possible to hold Indians as virtual prisoners on their reservations. Controls of that nature ceased to exist. Indians might come and go as freely as all other persons. The act of June 15, 1924, which extended citizenship to all Indians born within the United States, opened the door to full participation. Not many Indians took advantage of the law, and because of their lack of interest a number of states excluded Indians from the franchise. Organization of tribal governments following the Reorganization act seemed to auaken an interest in civic affairs beyond tribal boundaries, and as Indians asked for the franchise, state officials usually found that an order of the governor or an opinion of the attorney general was sufficient to reverse prior interpretations. In only two states, Arizona and New Mexico, was court action necessary, with decisions favouring the Indians in 1948.

The courts of the United States consistently upheld the sanctity of treaties made with Indian tribes, and with equal justice the courts also held that property may not be taken from Indians, whether or not a treaty exists, "except in fair trade," as Vitoria had maintained in 1539. The latter contention was offered by the Walapai Indians against the Sante Fe railroad. The company was required by the courts in 1944 to relinquish about 500,000 ac. which it thought had been granted to it by the United States. The lands had been occupied from time immemorial by the Indians, without benefit of treaty recognition, and the supreme court held that, if the occupancy could be proved, as it subsequently was, the Indians were entitled to have their lands restored. In 1950 the Ute Indians of Utah and Colorado were awarded a judgment against the United States of $31,750,000 for lands taken without adequate compensation where the land had previously been recognized and defined in a treaty.

Indian tribes were long precluded from bringing action against the United States unless congress approved in a special jurisdictional act. This procedure resulted in so burdening the Indian affairs committees of house and senate with requests for separate bills, some of which remained on legislative calendars year after year, that a special Indian claims commission was created by the act of Aug. 13, 1946. This legislation provided that all tribes must file their petitions within five years, and the commission must reach a finding on all cases filed with it in another five-year period.

The troubled history of Indian affairs administration in the United States had been anticipated by Henry Knox in a letter addressed to George Washington on July 7, 1789. As first secretary of war, Knox was the first federal official having general charge of Indian affairs. After remarking that certain individuals were of the opinion that it would prove impractical to civilize the red man (the argument was intended to rationalize a policy of forceful seizure of Indian lands), Knox wrote: "That the civilization of the Indians would be an operation of complicated difficulty, that it would require the highest knowledge of the human character, and a steady perseverance in a wise system for a series of years, cannot be doubted. While it is contended that the object is practicable, under a proper system, it is admitted in the fullest force, to be impracticable according to the ordinary course of things, and that it could not be effected in a short period."

INDIANA, one of the middle western states of the United States, is popularly known as the "Hoosier state," a term of uncertain origin. The second state to be carved out of the Northwest territory, Indiana entered the union as the 19th state on Dec. 11, 1816. The state capital is Indianapolis. Indiana is bounded on the north by Michigan, on the east by Ohio, on the south by Kentucky (from which it is separated by the Ohio river) and on the west by Illinois. In size it ranks 38th among the states, its total area being 36,291 sq.mi., of which about 106 sq.mi. is water. The tulip tree has been designated the state's official tree and the peony is the state flower. The state bird is the cardinal. The state flag is blue with a yellow border. In the flag's centre is a torch with six rays extending out from it. In a circle around this design are 13 stars; 5 other stars, representing the first 5 states to be admitted after the original 13, are grouped around

the base of the torch. A large star above the flaming torch represents Indiana.

PHYSICAL GEOGRAPHY

Physical Features and Soils.—Indiana is located principally within the east central lowland (approximately between latitude 37" 47' and 41° 46' north, and longitude 84° 49' and 88" 2' west). Although from the air its surface would appear quite level, the state is actually an undulating plain, which reaches its peak altitude of about 1,250 ft. above sea level in Randolph county, in the east-central area of the state, and its lowest altitude of slightly more than 300 ft. in Posey county where the Ohio and Wabash rivers merge. About 90% of the surface of the state is between 500 and 1,000 ft. above sea level. In general, the surface slopes toward the west, but also toward the south.

Most of Indiana's major rivers flow in a southwesterly direction. The longest river, the Wabash, with a total length of about 475 mi., flows from west-central Ohio northwest, then southwest and south across the state to its junction with the Ohio; it forms much of the boundary between Indiana and Illinois. The principal tributaries of the Wabash are the Salamonie, Mississinewa, Eel, Tippecanoe and White rivers. Of these the White river, with its east and west forks, is the most important. The Whitewater, in southeastern Indiana, is another important river. All of these rivers, as well as the Kankakee, which has its source near South Bend and flows southwest into Illinois and eventually into the Mississippi river, are within the Mississippi basin. Part of northern Indiana, however, is drained by the St. Lawrence-Great Lakes basin; the Maumee, for example, flows northeast from Fort Wayne into Lake Erie and the St. Joseph flows from north-central Indiana into Lake Michigan.

The northern third of the state, with the exception of the sand dunes along Lake Michigan, is a generally rolling area in which the soil is mainly an extremely fertile loam with much humus. The northern region has numerous moraines and lakes of glacial origin. Among the largest and better known lakes are Lake James, Lake Wawasee, Lake Winona, Lake Maxinkuckee, Bass lake, and Lake Shafer. Most of central Indiana is flat with glaciated soil which is principally a fertile loam. The southern third of the state, most of which was not leveled by the glaciers, has varied surface features. Except for the generally flat Wabash lowlands, next to the Illinois border, the soil is mainly clay which is much less fertile than the soil of central and northern Indiana. The central part of southern Indiana is scenic and hilly country. Southern Indiana has limestone formations which have resulted in sinkholes, lost streams and beautiful caves such as Marengo and Wyandotte, the latter among the most beautiful in the United States. There are also many mineral springs, the best known being those at French Lick and Martinsville.

Climate.—The climate of Indiana is invigorating; there is variety without harsh extremes. The mean annual temperature is about 53° F., varying from 50° in the north to 55° in the south. The coldest months are Dec. and Jan., during which period the mean monthly temperature is about 30°. July and August are the warmest months, at which time the mean monthly temperature is about 75°. The prevailing winds are from the west. The mean annual rainfall is about 40 in., varying from about 35 in. in the north to about 46 in. in the south. The growing season averages approximately 160 days in the north to approximately 180 days in the south.

Plants and Animals.—When the pioneers first arrived in Indiana the greater portion of the state was covered by forests. Oak, hickory, walnut, tulip, butternut, beech, elm, maple, mulberry, cherry, sassafras: sycamore and other trees were common. Important areas, notably in the northwest and around Vincennes, were prairies consisting largely of grasses and reeds. In places prairies and forest were intermingled.

Wild berries, fruits and flowers were abundant in the early days though they were unevenly distributed over the state. Strawberries, blackberries, raspberries, cranberries and huckleberries were gathered by the pioneers, as were grapes, persimmons, apples and plums. Wild flowers were numerous and widely scattered. Among the commonest were marigold, cowslip, sweet william, cyclamen, Indian paintbrush and buttercup.

There were many kinds of game and fur-bearing animals in the early days, beaver, fox, deer, otter, bear, raccoon, rabbit, squirrel and muskrat being among the most valuable. Among the birds there were pigeons, blue jays, whippoorwills, ducks, geese, turkeys, grouse, quail and other song and game birds.

Some of the native trees, berries, fruits, flowers, animals, fish and birds have disappeared, Most of them remain, however, though in smaller numbers than in the early days.

State Parks.—In 1919 the Indiana conservation department was established and the development of the state parks became one of its principal responsibilities. In addition to the parks, this department developed historical memorials, game preserves and sanctuaries, fish hatcheries, state forests and nurseries, and promoted conservation. The oldest state park, McCormick's Creek, was opened near Spencer in Owen county in 1916; later that year Turkey Run state park was opened in Parke county. During the 1920s the following state parks were established: Clifty Falls, overlooking the meandering Ohio river; the Dunes, along the southern shore of Lake Michigan; Pokagon, adjacent to Lake James in northeastern Indiana; Spring Mill in Lawrence county notable for its scenery and restored pioneer village; picturesque Brown County with its rustic surroundings; and Shakamak, which includes parts of Clay, Sullivan and Green counties. Additional parks were added in later years.

HISTORY

Earliest **Inhabitants.**—Successive groups of Indians had lived in Indiana before the arrival of Europeans in the 17th century. Some of them were mound builders, and study of their remaining mounds has resulted in an ever-increasing knowledge of the life led by these early inhabitants. They were followed by others before Europeans appeared in Indiana. In 1800 various tribes of Indians lived in the area, the three leading tribes being the Delaware. Potawatomi and Miami; others included the Piankashaw, Kickapoo and Wea. The Indians were dependent upon crops, especially corn and vegetables, as well as upon hunting and fishing for their food. In 1820 most of the Delaware left Indiana for new homes west of the Mississippi. Most of the Potawatomi left during the late 1830s and early 1840s, and most of the Miami during the 1840s. The lesser tribes meanwhile had left the state; individual Indians from various tribes, however, remained in Indiana. In fact, the descendants of some of them still reside there, notably in the upper Wabash valley and along the tributaries of the river.

Exploration and Settlement.—The earliest Europeans to reach Indiana probably were anonymous and unlicensed French fur traders. Their penetration of the area was a part of the larger movement of French fur traders up the St. Lawrence river and into the vast region, rich with furs, including and surrounding the Great Lakes. Doubtless, the fur traders visited northern Indiana in increasing numbers during the last half of the 17th century.

Jesuit and other Roman Catholic missionaries soon followed the fur traders into the interior of North America. Father Claude Jean Allouez, who served the Miami Indians in the valley of the St. Joseph river in Michigan, possibly crossed into northern Indiana during the 1660s. Both trader Louis Jolliet and Father Jacques Marquette may have traversed the southern shore of Lake Michigan soon after their voyage of discovery down the Mississippi in 1673. In Dec. 1679 René Robert Cavalier, sieur de La Salle, and his party used the St. Joseph-Kankakee portage at South Bend in crossing from the Great Lakes to the Mississippi river. Some historians think that a decade earlier La Salle had proceeded from Lake Erie to the Ohio river and then descended this river at least to the falls at Louisville, but this possible early discovery of the southern boundary of Indiana remains doubtful.

The Maumee-Wabash route, with its short portage at Fort Wayne, proved more useful to the French than the St. Joseph-Kankakee route. Between 1700 and 1735 the French had established outposts at Miami (Fort Wayne), Ouiatenon (near Lafayette) and Vincennes. Vincennes became the leading French settlement in Indiana. Although some agriculture was engaged in

at these centres, they were mainly outposts in the widely diffused fur empire of France.

Geographical location made Indiana an important link between French interests in the St. Lawrence and Mississippi basins. The portages at South Bend and Fort Wayne were astride the continental divide between these basins. The three centres on the Wabash-Maumee were located on perhaps the most desirable water route between the French colonies of Quebec and Louisiana. The St. Lawrence and Mississippi outlets indeed have always been important to inhabitants of Indiana; the completion of the St. Lawrence seaway in 1959 strengthened the state's interest.

During most of the 17th century, distance and the Appalachian barrier deterred conflict between the French colonies and those of the English along the Atlantic seaboard. But during the French and Indian Wars (1689–1763) colonies and trade of both countries expanded as the conflict expanded in scope and intensity. By the treaty of Paris in 1763, most of Canada and all of continental United States east of the Mississippi were ceded to England, and France lost all its mainland possessions. Thus the Indiana area, along with the entire region that soon came to be known as the Old Northwest, passed from France to England.

Most of the Indians had either been neutral or else had sided with the French. Their resentment of the English occupation resulted in Pontiac's War in 1763 during which the English garrisons at Ouiatenon and Miami were taken by the Indians, although the uprising was soon quelled. In the proclamation of 1763 the English reserved the Old Northwest for the Indians and forbade further white settlement, though the French already there were not to be molested. In 1774 parliament passed the Quebec act which annexed the territory to Quebec. This act supported religious freedom and other privileges for the native French, nearly all of whom were Roman Catholic.

Many persons in the English seaboard colonies, especially in Virginia, regarded both the proclamation of 1763 and the Quebec act as contrary to their charter claims to the land as well as to their interests in the fur trade of the region. English occupation of the Old Northwest was nominal; troops were not sent even to Vincennes until 1777. During the American Revolution, forces led by George Rogers Clark of Virginia captured Vincennes in 1778. It was recaptured by the English a few months later, but retaken by Clark's forces in Feb. 1779 as a result of Clark's remarkable march from Kaskaskia.

Territorial Period. — By the treaty of Paris of 1783 title to the Old Northwest territory passed from Great Britain to the United States and the first authorized U.S. settlement was made at Clarksville, between the present cities of Jeffersonville and New Albany, at the falls of the Ohio (opposite Louisville), in 1784.

From 1783 until 1816 the Indiana area was a territory of the United States. At first both the United States and several states, especially Virginia, claimed all or part of the territory. The question of who owned the region was soon decided in favour of the United States, which had promised to dispose of it for the common good and eventually to carve from it equal states.

During the 1780s the United States established the following policies which were first tested in Ohio and Indiana: only the federal government was authorized to buy land from the Indians; such land must be surveyed by the federal government before it went on sale; land would be sold only by the federal government but it would be sold to individuals or to companies; and it was illegal to settle on land which belonged to the Indians or the federal government.

Following Clark's conquest of Kaskaskia and Vincennes, Virginia, the principal state claimant to the Old Northwest, organized the county of Illinois to include residents of these and other settlements. But there was little civil government in the region until the ordinance of 1787 became effective. This ordinance promised that 3 to 5 states would be carved out of the territory, and guaranteed new states equality with the original 13. The ordinance required that a territory pass through two successive territorial stages of government and have at least 60,000 residents before it would be eligible for statehood.

The Northwest territory was organized in 1787; the second, or representative, stage of territorial government was organized in 1799. The benefits of this second stage accrued mainly to the residents in the eastern area, which became Ohio. The residents of the remainder of the territory, who were largely French, preferred the return of the first, or nonrepresentative, stage of government. When the Northwest territory was divided in 1800 the larger western area became the Indiana territory and was thus returned to the first stage.

Indian opposition to American encroachments continued during the 1780s when various tribes unsuccessfully attempted to keep American settlers south of the Ohio river. As settlements north of the Ohio increased, Indian resistance stiffened and congress sent various expeditions to break it. Defeats were suffered by Gen. Josiah Harmar in what is now northwestern Ohio and northeastern Indiana (1790) and by Gen. Arthur St. Clair near Ft. Recovery, O. (1791). Stung by these defeats, the United States sent Gen. Anthony Wayne into the area. At Fallen Timbers in northwestern Ohio in 1794 Wayne defeated the Indians, and the next year, by the treaty of Greenville (O.), the greater portion of Ohio and a wedge-shaped slice known as the Gore, located along what was soon to be the Ohio-Indiana boundary, as well as scattered tracts of land were ceded to the United States.

Only about 2,500 whites lived in the present Indiana area in 1800, though about twice that number lived in the Indiana territory which then included nearly all of the present states of Indiana, Illinois and Wisconsin, a part of Minnesota and the western half of Michigan. When Ohio became a state in 1803 the eastern half of Michigan and the Gore were added to Indiana territory. In 1805 a separate Michigan territory was organized and in 1809 Illinois territory was also detached; Indiana's present boundaries were not established, however, until statehood was attained.

Between 1801 and 1809 William Henry Harrison (*q.v.*), as first territorial governor of Indiana, obtained the surrender of Indian claims to approximately the southern third of Indiana and to even more of Illinois. After 1809, under the leadership of the Shawnee Tecumseh (*q.v.*), Indian resistance again stiffened against the advancing Americans. In 1811, however, the Indians were defeated by Harrison at the battle of Tippecanoe, near Lafayette, and in 1814 another treaty of Greenville confirmed the cessions obtained prior to the War of 1812 with Great Britain. By 1815 the Indians had ceased to be a major obstacle to white settlement.

Statehood. — The first general assembly of Indiana territory had convened at Vincennes in 1805. Indiana's population continued to increase, even during the War of 1812, and in 1816 it became the 19th state. In 1813 Corydon had succeeded Vincennes as the territorial capital, and in 1825 Indianapolis became the permanent state capital.

Political democracy in Indiana had increased greatly during the years of territorial government. Membership in the council or upper house of the general assembly had been made elective, as was the office of territorial delegate to congress. Also, the property requirement for voting had been modified so that persons could vote either on the basis of property ownership or by paying a territorial tax.

Pioneer Life and Politics. — The half century from 1800 to 1850 was the pioneer period in Indiana. Settlement moved across the state mainly from south to north, but a large majority of settlers lived in the southern half of the state. The pioneer era was one of beginnings not only of homes, clearings, gardens and farms, but also of newspapers, churches, schools and libraries and of roads, bridges, streets, canals, steamboats, stages, railroads, the telegraph, household industries, trades and crafts, mills and shops. Equally important, the era witnessed the beginnings of town, township and county government, of political parties and party machinery and of state government. Indiana has had two state constitutions, both products of the pioneer era.

The pioneer period was characterized by extreme self-sufficiency and isolation. Not only were Hoosiers largely detached from older parts of the United States, but even neighbourhoods within the state were mainly self-sufficient and isolated from one another. Under these conditions the pioneers established the foundations from which Hoosier life and institutions developed, though they

built mainly upon Anglo-Saxon ideas and practices which, like the English language, were an accepted and valued part of their heritage.

One of the more interesting American experiments in communal living flourished at New Harmony (*q.v.*), on the Wabash river in Posey county, a village originally settled by the followers of George Rapp in 1815. Rapp, a German, was a religious ascetic who, with his followers, was interested in forming a community patterned after the primitive Christian church. Remaining in Indiana, however, only about ten years, Rapp sold his holdings to Robert Owen (*q.v.*) of New Lanark, Scot., who interested several well-known scientists in his settlement and with them went to New Harmony in 1826. Although the community had become a failure by 1827, its influence was great. Among the persons who lived at New Harmony were Owen's three sons; William Maclure, founder of the Academy of Natural Sciences in Philadelphia; and Thomas Say, the "father of descriptive entomology in America." Parts of the colony have been restored.

During the first quarter of the 19th century almost all Hoosiers were Jeffersonian Democrats (popularly known as Republicans up to about 1825). The state constitution of 1816 was a liberal Jeffersonian document. Between 1825 and 1850, however, political power in Indiana was disputed between the Democrats and the National Republicans (1825–34) and then the Democrats and the Whigs (1834–54). Although Indiana supported Democrat Andrew Jackson for the presidency in 1824, 1828 and 1832, the National Republican-Whig party was usually the majority party in state politics from 1825 to 1843. In the later year the Democrats elected their first governor and from that time until 1860 largely controlled the state.

During the 1820s and 1830s the problem of internal improvements became an absorbing issue in Ohio, Illinois and Indiana. This resulted in bipartisan support within Indiana for the internal improvements system of 1836. The subsequent failure of the system resulted in temporary bankruptcy for Indiana and contributed greatly to the Whig defeat in 1843. Previously the Whigs had chartered the second state bank (1834), which was successful until its closing in 1859. A new state constitution was adopted in 1851.

Later **19th** Century. — From the prosperous 1850s until World War I agriculture was the leading pursuit of Hoosiers, though factories and mills grew in size and rapidly increased their output. In these decades, and especially the early ones, agriculture had an importance in Indiana which it never had before or after.

In 1854 the new Republican party was organized, succeeding the Whig party, but Indiana was one of the last of the northern states in which it gained support. In 1860 the Republicans elected Henry S. Lane as their first governor. They also elected their state ticket, a majority in both houses of the general assembly and 7 of the 11 congressmen. Shortly after the election, Lane was sent to the U.S. senate, and Oliver P. Morton succeeded him as governor.

When the Civil War began in April 1861, Indiana offered many more volunteers than could be accepted by the Union. About 200,000 Indiana men, mostly volunteers, served in the Union military forces. Morton was one of the most loyal of the war governors of the north, but his partisan zeal and occasional use of arbitrary methods helped to widen the gap between Indiana Republicans and Democrats. Very few Hoosiers were disloyal to the Union, though numerous Democrats and even some Republicans honestly disagreed with Morton's methods. But narrow partisanship, obstructionism and failure to vote needed appropriations can be charged against the Democrats. Morton's efforts to pin the label of treason on the Democratic party, however, by the so-called "treason trials" in the midst of the 1864 campaign were inconsistent with the support which Democrats generally gave the war. Certainly southern Indiana, the Democratic stronghold, vigorously opposed Gen. John H. Morgan, the Confederate raider, during his 1863 invasion. Moreover, Democratic counties did their part in supplying the men who did the actual fighting.

During the last half of the 1860s and most of the 1870s issues concerning reconstruction, the status of the Negro (both in Indiana and in the south) and related problems dominated state politics. Indiana was one of the first of the northern states to return the Democrats to power following the Civil War. In 1872 Democrat Thomas **A.** Hendricks (*q.v.*) was elected governor, and from then until the campaign of 1896 the contest between Republicans and the Democrats was usually very close. From 1896 until 1908 Indiana gave the Republicans large majorities in both state and national elections. Though reforms were limited during the period 1865–1910, the Australian ballot was adopted in 1889 and state laws were enacted to improve working conditions, especially those governing the employment of women and children.

The influence of the Progressive party movement began to be felt about 1901. This bipartisan movement, especially championed in Indiana by Albert J. Beveridge, a Republican, permeated both major parties. Between 1901 and 1917 Indiana established a railroad commission and then expanded it into a utilities commission; adopted the direct primary for state and local nominations; supported the amendments to the federal constitution which resulted in the direct election of United States senators and federal taxes on personal as well as corporation income; expanded public education, especially vocational education; increased state regulation of banks, loan and insurance companies and the sale of stocks; created a legislative reference bureau and initiated the state board of accounts. An unsuccessful effort to revise the constitution of 1851 was also made.

Modern Times. — By the time of World War I the value added to goods by the manufacturing process exceeded the value of farm products, and thereafter the disparity rapidly increased in favour of manufacturing. With the increase in manufacturing, Indiana became more urban than rural. Central and northern Indiana, which had surpassed southern Indiana in population and wealth before World War I, widened their lead over the region which had led in population and manufacturing in pioneer days.

The Republicans, who won control in Indiana in 1916, maintained it through the 1920s. Though agriculture was economically depressed, business prospered and the prevailing mood of the people was conservative. Racial and religious prejudice engendered by the Ku Klux Klan reached a peak during the period, and one governor was sent to a federal penitentiary while another pleaded the statute of limitations to escape what might have been a similar fate.

The economic depression which began in 1929 was a decisive factor in returning the Democrats to power with a wide margin of victory in 1932. During the administration of Gov. Paul V. McNutt (1933–37) a gross income tax was enacted, welfare and pension legislation was adopted and state aid to schools was substantially increased.

From 1940 until 1958 Indiana was controlled mainly by the Republicans, though the personal popularity of Henry F. Schricker, a Democrat, resulted in his serving as governor during 1941–45 and 1949–53; he was the only chief executive ever elected to two terms under the constitution of 1851. In the 1940s the welfare and pension legislation of the 1930s was expanded. The victory of the Democrats in the state and congressional elections of 1958 suggested that Indiana was still a "doubtful state" politically.

GOVERNMENT

The constitution of 1851, though frequently amended, remains the basic document of Indiana government. Written under the influence of Jacksonian democracy, it restricted the power of the general assembly and provided for the popular election of many state and local officials. Because of Indiana's costly experience with state loans for internal improvements during the 1830s and 1840s, the constitution prohibited state borrowing except for certain emergencies. An amendment to the constitution may be proposed by either branch of the general assembly; if a majority of both houses vote in favour of an amendment and it is favourably voted upon by the general assembly chosen at the next general election, the amendment is submitted to the people; a majority of the popular vote is necessary for ratification.

Although suffrage for white males had been attained in territorial days, it was not until 1881 that the barriers against Negro voting were removed from the constitution of 1851. All Indiana voters must be properly registered, be at least 21 years of age,

be citizens of the United Staies and have been residents of Indiana for a minimum of six months and of their voting unit for no less than 60 days. General state elections are held on the first Tuesday after the first Monday in November in even-numbered years.

Executive. — The executive and administrative department of the state government is divided among elective officials and numerous boards and commissions. The governor, lieutenant governor and attorney general, as well as the clerk and reporter of the supreme and appellate courts, are popularly elected in presidential years for four-year terms. The secretary of state, treasurer, state auditor and superintendent of public instruction are elected for two-year terms. No governor may immediately succeed himself, and neither the secretary, treasurer nor auditor may serve for more than four in any period of six years. The governor has the veto power, but laws may be passed over his veto by majority vote of the assembly. Administrative agencies having important responsibilities include the state board of accounts, the public service commission, the alcoholic beverage commission, the state highway department, the state board of education and the state budget commission.

Legislative. — Indiana's general assembly has a senate of 50 members and a house of representatives of 100 members. Senators serve four-year and representatives two-year terms. The biennial sessions of the assembly begin on the first Thursday after the first Monday in January of odd-numbered years. Regular sessions are limited to 61 days and special sessions to 40. Two-thirds of the members must be present to make a quorum, and an actual majority of the members of each house is required to pass legislation. Although the state constitution requires reapportionment every six years, the districts from which senators and representatives are elected were last reapportioned in 1921.

Judiciary. — The state's judicial department embraces a supreme court of five judges elected by districts by the state at large; an appellate court with northern and southern divisions, which virtually results in two appellate courts; and a system of local circuit courts. Supreme and circuit judges are elected for six years and appellate judges for four. Special courts, such as probate and juvenile courts, exist in some localities, and justices of the peace are elected in the townships.

Finance. — In the second half of the 20th century, the state's general revenue from all sources amounted to more than $475,000,000 annually. Of this sum, about 12% was derived from the federal government and about 75% from state tax sources. Revenue was provided mostly by general property taxes, motor fuels taxes, gross income taxes and the sale of motor vehicle and operators' licences. The state's expenditures totaled more than $43'0,000,000; Indiana's constitution prohibits the accumulation of a state debt. Approximately 38% of the state's revenues were being spent on education, about 30% on highways, slightly over 9% on health and hospitals and nearly 5.5% on public welfare. The state's income was nearly 3.5 times greater than it had been at the beginning of World War II; Indiana's per capita income ranked it 16th among the states in 1950.

Local **Government.**—Counties, townships, cities and towns are important units of local government within the state. Counties are governed by elected commissioners, various elected officials and a number of boards and commissions. Townships are governed mainly by township trustees and local advisory boards. Cities are divided into five classes or categories. The mayor-council type of government prevailed after a 1921 law, that would have permitted cities to adopt a commission or commission-manager form of government, was declared unconstitutional in 1929. Small towns are governed mainly by local boards. Special school, health, drainage and various other districts also exist as local governmental units.

POPULATION

That part of Indiana territory which became the state of Indiana had a population of about 2,500 inhabitants in 1800 and 147,178 in 1820, four years after statehood was achieved. Its population ranked 18th among the 27 states and territories that then composed the union and was classified as 100% rural. When the pioneer period ended in 1850 there were 988,416 people, making Indiana the seventh most populous state. At the beginning of the 20th century, the state was eighth in rank of population with a total of 2,516,462 persons by the census of 1900. The slowest population growth occurred between 1930 and 1940; in 1940 the population was only 5.8% greater than it had been in 1930. The 1950 population showed a total of 3,934,224 persons living within the state, making Indiana 12th among the states. There were part or all of eight standard metropolitan areas (Anderson, Evansville, Fort Wayne, Indianapolis, Louisville, Muncie, South Bend, Terre Haute) in 1959 and, together with Lake and Porter counties (which in 1959 were separated from the Chicago standard metropolitan statistical area as the Gary-East Chicago-Hammond stand-

*Populations are reported as constituted at date of each census.
Note: Dash indicates place did not exist during reported census, or data not available.

ard metropolitan statistical area), they contained more than one-third of the total population. By 1960 these metropolitan areas housed nearly 50% of the total population. In 1960 Indiana had a population of 4,662,498, an increase of 728,274 or 18.5% over 1950.

No urban centres (that is, towns having at least 2,500 residents) were reported until the census of 1840, when New Albany, Madison and Indianapolis appeared. In 1850 these three towns were joined by Lafayette, Fort Wayne, Terre Haute, Evansville and Lawrenceburg as urban places, but each had fewer than 10,000 residents. In 1900 Indiana had 80 urban places, and in 1950 119. In 1850 between 4 and 5 of every 100 persons lived in urban centres; in 1900 the figure was about 34 and in 1950 60.

Indiana's urban population has always been widely diffused. No city except Indianapolis exceeded 100,000 residents until after 1900. Even Indianapolis, the largest city in the state, had not reached 500,000 inhabitants in 1960. At that time Gary, Fort Wayne, Evansville, South Bend and Hammond each had more than 100,000 inhabitants. Urbanization was especially rapid along the southern shore of Lake Michigan after 1900; Gary, second largest city in Indiana in 1960, was not founded until 1906. Much the greater portion of the population increase between 1850 and 1950 was in the urban element.

The population per square mile in 1950 was 108.7, as compared with 50.7 for the U.S. as a whole. The 1950 urban population was 59.9% of the total. In line with the rest of the U.S. the percentage of persons 65 years old or over was increasing (9.2% in 1950).

The pioneers of Indiana came principally from Virginia, Maryland, North and South Carolina, Kentucky, Tennessee, Ohio, Pennsylvania and New York, but more came from southern or slave states than from northern or free states. Only a limited number came from New England.

Immigration from other countries was not large during pioneer days (before 1850); of those who immigrated Germans and Irish were most numerous. After pioneer days these continued to be the leading immigrant groups, but beginning in the 1880s a considerable number also arrived from Italy, Poland, Belgium, Austria, Hungary and other parts of southern and east-central Europe. Immigration from other countries reached its peak in the generation immediately preceding World War I. There were 11,262 Negroes in Indiana in 1850, 57,505 in 1900, and 174,168 in 1950.

EDUCATION

Public Schools. — The constitution of 1816 made it "the duty of the General Assembly, as soon as circumstances will permit, to provide, by law, for a general system of education, ascending in a regular gradation, from township schools to a state university, wherein tuition shall be gratis and equally open to all." Although this mandate was much ahead of its time, Indiana had had public schools in pioneer days, but they existed on a local-option basis and generally had tuition charges. Most schools, at all levels, were under private or church sponsorship at that time.

The constitution of 1851 emphasized the importance of elementary or common schools, and the free school law of 1852 established the foundation for a state wide system of free elementary schools. Progress was slow, however, and school attendance was not made compulsory until 1897. In the 1850s elementary schools were often limited to annual terms of about 3 months; 100 years later, the minimum annual term was 8 months, though terms were often 9 to 9½ months, especially in the cities.

Dozens of academies and seminaries, generally short-lived, were founded in the pioneer era; except for county seminaries, these institutions were under private or church auspices. All of them received most of their support from tuition payments.

A few free public high schools were established in the 1850s, and they increased in number during the last half of the 19th century. Most of these at first offered only two or three pears of instruction, but they developed with the free elementary schools and were regarded as part of the common school system. In 1900 relatively few elementary school graduates also completed high school; by 1950 more than half did so.

The Indiana school system is administered by a state superintendent, elected biennially, various state commissions and committees; by local superintendents and boards in the cities; and principally by township trustees in the township schools. Under permissive legislation passed in the 1940s and 1950s some towns and rural areas formed consolidated school units administered by superintendents and boards as in the city school system. In the late 1950s Indiana was spending $291 annually per pupil or slightly less than the U.S. average. This was about three times the amount spent prior to World War II.

Higher Education. — Indiana University. — Indiana university, located at Bloomington in the southern part of the state, was chartered as a seminary in 1820 and its first instruction was given about 1524. By the second half of the 20th century the university's annual enrollment approached 25,000 and its teaching staff numbered more than 2,500, On the 1,850-ac. campus at Bloomington are located the college of arts and sciences, junior (freshman) division, school of education, school of business, graduate school, school of law, school of music, school of health, physical education and recreation, division of university extension and division of optometry. The schools of medicine, dentistry and nursing, divisions of medical technology, dental hygiene, medical record librarianship, graduate dietetics, X-ray technology and occupational and physical therapy are at Indianapolis. University centres are found at Indianapolis, Gary, East Chicago, South Bend-Mishawaka, Fort Wayne, Kokomo, Jeffersonville-New Albany, Richmond (with Earlham college), Vincennes (with Vincennes university) and Evansville (with Evansville college).

The university is goyerned by a board of trustees of eight members, five of whom are appointed by the governor on recommendation of the state board of education and three of whom are elected by alumni.

Other State Institutions. — Purdue university, the state university of agriculture and mechanical arts, organized in 1869, is located at West Lafayette (see LAFAYETTE). The state-supported institutions for the training of teachers are Indiana State Teachers college (organized in 1870 as the State Normal school) at Terre Haute and the Ball State Teachers college (1918) at Muncie.

Private Institutions. — Other educational institutions of Indiana include Anderson College and Theological seminary at Anderson (Church of God; 1917); Butler university, Indianapolis (Disciples of Christ; 1850); DePauw university, Greencastle (Methodist; 1837); Earlham college, Richmond (Society of Friends; 1847); Evansville college, Evansville (Methodist; 1854); Franklin College of Indiana, Franklin (Baptist; 1834); Goshen college, Goshen (Mennonite; 1894); Hanover college, Hanover (Presbyterian; 1827); Indiana Central college, Indianapolis (Evangelical United Brethren; 1902); Manchester college, North Manchester (Church of the Brethren; 1889); Marian college, Indianapolis (Roman Catholic; 1937); Rose Polytechnic institute, Terre Haute (nonsectarian; 1874); St. Francis college, Fort Wayne (Roman Catholic; 1890); St. Joseph's college, Rensselaer (Roman Catholic; 1889); St. Mary-of-the-Woods college, Terre Haute (Roman Catholic; 1840); St. Mary's college (1844) and the University of Notre Dame (1842), the latter one of the leading Roman Catholic universities in the United States (both Roman Catholic, near South Bend); Taylor university, Upland (nonsectarian; 1846); Valparaiso university, Valparaiso (Lutheran; 1859); and Wabash college, Crawfordsville (nonsectarian; 1832).

HEALTH AND WELFARE

Indiana was one of the first states to establish schools for the deaf and the blind. The state school for the deaf, the school for the blind and the first state hospital for the insane were all opened in Indianapolis during the 1840s. The last became the Central State hospital in 1883; other similar institutions are the Logansport State hospital, the Richmond State hospital, the Woodmere State hospital, Evansville, and the Madison State hospital (North Madison). Norman M. Beatty Memorial hospital at Westville and the Larue D. Carter Memorial hospital at Indianapolis were built in mid-20th century. Institutions for the feeble-minded include the Fort Wayne State school and the Muscatatuck colony

at Butlerville. Another hospital is the Village for Epileptics at New Castle. There is a state soldiers' home at Lafayette, a soldiers' and sailors' orphans' home at Knightstown, a state sanatorium at Rockville and the Indiana university hospitals at Indianapolis.

There are six correctional and penal institutions: the boys' school at Plainfield, the girls' school at Clermont, the prison for women at Indianapolis, the state reformatory at Pendleton, the state prison at Michigan City and the state farm at Putnamville. Indiana has a habitual-criminal law and a law providing for the sterilization of mental degenerates, confirmed criminals and rapists.

Relief for the poor is under township trustees. Welfare work is under county welfare boards and the state department of public welfare with its divisions of public assistance, services for crippled children, corrections and children's divisions.

THE ECONOMY

Agriculture. — Until about the time of World War I, agriculture remained the principal occupation in Indiana. The leading field crops in the early days were corn, wheat and oats, but especially corn. Minor crops included tobacco, rye, barley, buckwheat and flax, though most of the pioneers also raised various vegetables. The principal farm animals were hogs, horses, cattle and sheep, and most early farms also had chickens, ducks or geese. The combination of corn and hogs has always been the mainstay of Indiana agriculture.

The leading field crops of pioneer days have continued as the main crops. Corn retained its primacy, but beginning in the 1940s soybeans succeeded wheat as the second most valuable field crop. Until pushed into third place by soybeans, wheat ranked second in value, followed by oats, though oat production was often larger than that of wheat. Since the 1880s tomatoes have been a crop of considerable value. Minor field crops include tobacco, rye, barley, buckwheat, popcorn, melons, onions, Irish potatoes, strawberries and mint. Vegetables, berries and fruits have achieved commercial importance, as have clovers and grasses.

Hogs have always been the most valuable farm animal in Indiana, but cattle have increased in importance since pioneer days. Sheep decreased in importance during the 20th century, and horses have been displaced by machinery on most Indiana farms; in the 1950s the number of horses and mules was smaller than that of oxen in the 1850s. The value of poultry and poultry products exceeds the combined value of horses and sheep, including their products.

In the second half of the 20th century Indiana annually produced approximately 250,000,000 bu. of corn; 40,000,000 bu. of soybeans; 35,000,000 bu. of wheat; and 50,000,000 bu. of oats. On the farms there were about 4,480,000 hogs, 2,200,000 head of cattle and 547,000 sheep. The state had approximately 154,000 farms, about 94,000 of which were owned by their operators with an additional 31,000 partly so owned. Farm tenants totaled only 18.3% of the total. The average farm comprised 125.2 ac. The aggregate value of farm products surpassed $1,000,000,000 during most years. The value of crops greatly exceeded the value of products from livestock and poultry.

Manufacturing. — Pioneer manufacturing was limited in quantity, consisting almost exclusively of products of farms and forests such as clothing, food, utensils and furniture. Small factories began to increase in numbers during the 1850s, and by 1860 Indiana ranked tenth among the states in the value of its manufactured goods. In 1900 it had advanced to eighth place and had 18,000 plants producing goods aggregating $378,100,000 in value. In both intervals the four leading industries were meat processing, flour and grain milling, lumbering and liquor distilling. In 1900 the iron and steel industry ranked fifth in value of products, the manufacture of railroad cars sixth and foundry and machine products seventh.

In the second half of the 20th century Indiana remained high in place among the states in the value of manufactured products; it then had about 6,400 plants producing goods valued at $4,625,000,000. Indiana's leading manufacturing industries were primary metal products, transportation equipment, electrical machinery, machinery other than electrical, food and related products, chemicals and related products, fabricated metal products, stone, clay and glass products, petroleum and coal products and printing and publishing.

The steel industry, concentrated in the Calumet region along the shores of Lake Michigan in northern Indiana, is by far the state's leading industry, and the region is one of the most important centres of steel manufacturing in the world. The industry got its start in Indiana when a mill was established at East Chicago (*q.v.*) in 1893; in 1906 at Gary the industry began an expansion that had not ceased in the 1960s. Steel became the leading industry of the state about 1929. One of the world's largest oil refineries is located at Whiting, near Gary. East Chicago developed into a leading industrial centre and one of the greatest shipping points in the nation.

Other leading manufacturing cities are Indianapolis, South Bend, Fort Wayne, Evansville, Hammond, Anderson, Muncie, Michigan City, Mishawaka, Elkhart, Kokomo, Marion, La Porte and Terre Haute (*qq.v.*). Indianapolis is a centre of the slaughtering and meat-packing industry and the printing and publishing of newspapers and periodicals; it is also an important centre of the motor-vehicle, furniture and foundry industries. Elkhart is a manufacturing centre for musical instruments, La Porte for harvesting machinery and South Bend for automobiles. Fort Wayne produces gasoline dispensing pumps, tractors, trailers and electrical apparatus. Evansville manufactures automobile bodies, refrigerators and excavating machinery. Muncie is noted for its glass fruit-jar industry and Mishawaka for its rubber, woolen and leather goods.

Mining. — Much outranked by agriculture and manufacturing, mining contribution to the economy nevertheless has been significant and in some counties has exceeded agriculture and manufacturing in the value of its products. In the second half of the 20th century Indiana ranked about 20th among the states in the value of its minerals, coal, oil, stone and clay being the principal mineral products.

During the 1830s geological surveys indicated that the state had large quantities of stone and coal and a limited quantity of low-grade iron ore. Coal and stone production attained commercial importance during the last half of the 19th century. Indiana coal is of the bituminous type and of only fair quality, but Indiana limestone was widely used for public buildings because of the stone's beauty, workability and durability.

From about the time of the Civil War efforts to find oil resulted in occasional discoveries of natural gas, but the period 1886–1906 represented the height of the gas boom in Indiana. As the supply of gas waned that of oil gradually increased so that by 1950 oil ranked second to coal in importance.

Commercial manufacturing of pottery and other clay products early became significant. During the 20th century products such as crushed stone, sand, gravel, cement, peat, marl and gypsum gained in commercial importance.

Transportation. — During the early period the Ohio-Mississippi waterway was the principal route for exports and later, with the advent of steamboats, for imports. The internal improvements system of 1836 was an ambitious but unsuccessful effort to solve the transportation problem and end the isolation of east from west. The completion during the 1830s of the national road, which traversed the state, greatly aided internal improvement. Canals, which served an important purpose in their day, began to be replaced by railroads by 1850. About 2,000 mi. of railroads were built during the 1850s and mileage increased until the time of World War I when the state had approximately 7,400 mi. of track. After the war the railroads began to lose much of their traffic to trucks, buses, automobiles, pipelines and airplanes; revival of water transportation on the Ohio river and the continued increase of traffic on the Great Lakes also affected the railroads. By 1950 mileage had dropped to about 6,600 mi. and it continued to drop thereafter.

At mid-20th century Indiana had more than 11,000 mi. of improved state and federal highways and nearly 75,000 mi. of county

roads. Though the state refused federal grants-in-aid for certain welfare programs, it obtained substantial federal funds for highway construction under the national highway program initiated in 1956. There were more than 100 commercial and 75 public but privately owned airports. There were also several heliports and military air fields.

BIBLIOGRAPHY.—The newest and most comprehensive history of Indiana is that by John D. Barnhart and Donald F. Carmony, *Indiana, From Frontier to Industrial Commonwealth,* 2 vol. (1954), including a comprehensive bibliography. Other general histories include Logan Esarey, *A History of Indiana, 2* vol. *(1922 et seq.),* and Charles Roll, *Indiana, One Hundred and Fifty Years of American Development,* 2 vol. *(1931).* For an informative account of pioneer life in Indiana *see* Logan Esarey, *The Indiana Home (1943*; illustrated ed., *1953).* Much information about Indiana is available in the files of the *Indiana Magazine of History (1905 et seq.),* the Indiana Historical Society publications *(1897 et seq.),* and in the Indiana Historical collections *(1916 et seq.).*

Current statistics on production, employment, industry, etc., may he obtained from the pertinent state departments; the principal figures, together with the current history, are summarized annually in the *Britannica Book of the Year,* American edition. (D. F. CA.)

INDIANAPOLIS, the capital and largest city of Indiana. U.S., a port of entry and the seat of Marion county, is situated on the White river near the geographical centre of the state. One of the most populous cities in the world not located on navigable water, Indianapolis has exceptionally good facilities for other forms of transportation. It is the focal point of six federal and seven state highways, has an excellent municipal airport and several supplemental fields, and has long been a rail centre. Pop. (1960) city 476,258, standard metropolitan statistical area (Marion county) 697,567. (For comparative population figures *see* table in INDIANA: Population.)

The city is built on a level plain surrounded by low, gently sloping hills. It has wide, well-planned streets, winding streams, trees, lawns, gardens and shrubbery. In the exact centre of the original tract of four sections, surrounded by a circular walk, is Monument circle with the soldiers' and sailors' monument in the centre. It rises to a height of 284.5 ft. above the street level and is surmounted by a figure called Miss Indiana. An elevator runs to a balcony at the top, which commands a panoramic view of the city and many miles of surrounding country. At the base of the monument are fountains. From the downtown area four avenues radiate diagonally to the four corners of the city. The other streets run at right angles to one another. The main east-west street (Washington) is 120 ft. wide; most of the others are 90 ft. There are more than 30 public parks and about 50 playgrounds; boulevards include a 60-ft. driveway on the top of the concrete levee (40 ft. high), which was constructed (1914–16) along the west bank of the White river.

EWING GALLOWAY

SOLDIERS' AND SAILORS' MONUMENT, MONUMENT CIRCLE, INDIANAPOLIS. DESIGNED BY BRUNO SCHMITZ. IT WAS COMPLETED IN 1902. IN THE BACKGROUND IS THE STATE CAPITOL BUILDING

North of the circle is the World War I memorial plaza covering five blocks given by city, county and state and containing, among other public buildings, the national headquarters of the American Legion. The state house, constructed in 1881–88, in a square of eight acres, has a ground area of two acres and a central tower and dome 240 ft. high. Many of the public and business buildings are constructed of the famous Indiana limestone from the Bedford district in the southern part of the state. Northwest of the city is the motor speedway, where the 500 mi. race is held annually on Memorial day. A crowd of about 175,000 is attracted each year from all parts of the United States. The home of James Whitcomb Riley is a literary shrine.

Indianapolis was one of the first cities in America to adopt electric street lighting, in Nov. 1881. A city-plan commission (1919) and a zoning ordinance, adopted in 1922, outlined a scheme for residential, commercial and industrial districts.

The city has an excellent public library and is also headquarters of the state library. In the second half of the 20th century there were three daily newspapers: the *News* (1869) and the Star (1883) being jointly owned; and the *Times* (1888). Indianapolis also has an excellent symphony orchestra, a fine arts museum and a children's museum.

Indianapolis is the seat of the schools of medicine, dentistry and nursing of Indiana university and of a part of that institution's school of law, school of health, physical education and recreation, and division of adult education and public service. The city is also the home of Butler university (chartered 1850), related to the Disciples of Christ Church; Indiana Central college (1902) supervised by the Evangelical United Brethren church; the John Herron Art institute and school; and Marian college (1937), a Roman Catholic institution. Also located there are the Central State hospital for the insane, the state schools for the blind and deaf, the state prison for women (the first in the United States, opened in 1873), and (at Clermont, 10 mi. outside the city) the state reformatory school for girls, which was a department of the prison until 1899. Ten miles northeast of the centre of the city is Ft. Benjamin Harrison, a United States army post, named after President Harrison, whose home was in Indianapolis. The state fairgrounds and the state fish hatcheries are within the city limits.

Around the Indiana university school of medicine developed one of the important medical centres of the country. The school itself was formed in 1908 by the union of the Indiana Medical college of Purdue university and the earlier medical department of Indiana university, which together incorporated six institutions founded between 1869 and 1906 at several different points in the state. Its building is conveniently located on the spacious grounds of the Robert W. Long hospital (completed 1914) which is a part of the school's equipment. Nearby is the James Whitcomb Riley Memorial hospital for children, built by private subscription and conveyed to the university on the day it was dedicated (1924); and the William H. Coleman hospital for women (opened 1927), also under the university's management.

The transportation facilities of Indianapolis and its position in the midst of the corn belt, near large coal fields, and with populous markets in every direction, have combined to make it an important commercial and industrial centre. It has a large trade in grain. In the early 1960s there were more than 1,100 industrial plants in the city, some of them the largest of their kind in the world, which produced approximately 1,200 different commodities. Chemicals and allied products, transportation equipment and elec-

trical machinery were major products. Among the other items produced on a large scale were airplane and truck engines; pharmaceuticals and biologicals; ferrous and nonferrous castings; phonograph records; radio and television sets; sound, electronic and electrical equipment; food products; canning and meat packing; power transmission devices; rubber products; road building and earth moving machinery; truck bodies; saws; wood products; heating and ventilating equipment; paper products; transportation equipment; and clothing.

History.—When Indiana was admitted to the union in 1816 congress gave it four sections of public land for its capital. The commissioners appointed to select the site placed it in 1820 almost exactly in the geographical centre of the state, at the cabin of John McCormick, on the White river, in the midst of dense forests and without any means of communication with the rest of the state. A town was laid out in 1821 (the "original mile square," bounded by North, East, South and West streets) and some activity in land speculation followed; but when the seat of government was moved there from Corydon in 1825, there was but a single street and 600 inhabitants. The legislature met in Indianapolis for the first time in 1825. It mas incorporated as a town in 1832, with a population of 1,000; the name is from Indiana and Gr. *polis,* "city." The first state capitol was completed in 1835.

Some impetus was given to the city's growth by the opening of the National road to that point in 1827, and later, beginning in 1847, by the coming of the railways, but development was slow until after the Civil War. The city was chartered in 1847, and in the same year a free public school system was inaugurated. In 1850 the population was only 8,091. By 1860 it had grown to 18,611, and in the following decade it increased to 48,244. In the next 20 years (1870–90), and again between 1890 and 1910, the increase was considerably more than 100%, and in the years 1910–30 it amounted to 56%. The increase from 1940 (386,972) to 1960 was 21.2%. The remarkably rapid expansion of the city after World War II led the Indiana general assembly in 1959 to authorize further growth by annexation across county lines.

In the years following World War I, Indianapolis, like many other midwestern communities, suffered from the influence of the Ku Klux Klan on political affairs. In the middle 1920s exposure of the Klan's methods (largely through the initiative of the Indianapolis *Times*) led to its collapse. While Indianapolis, like most industrial cities, was adversely affected by the depression of the 1930s, its recovery was facilitated by the diversification of its industry and its strategic location. The city's economy expanded greatly during World War II and this expansion continued steadily in the postwar era.

INDIAN ARCHITECTURE, in this article, refers to the Buddhist, Hindu and Jain architecture of the Asian subcontinent of India, Ceylon, Malaysia and Indonesia, from earliest times to the 20th century. The architecture of this area created under Islamic rule is discussed in ISLAMIC ARCHITECTURE; MOSQUE; and TAJ MAHAL. The art of this area is treated in INDIAN ART; INDONESIAN ARCHAEOLOGY and INDONESIAN ART. This article is organized as follows:

I. Introduction
  1. Origins
  2. Arches and Domes
  3. Special Forms
  4. Doors and Windows
  5. Columns
  6. Walls
  7. Influences of Indian Architecture
  8. Technical Literature

I INTRODUCTION

1. Origins.—Indian architecture, like Indian sculpture, is essentially of native origin, belonging to the Dravidian rather than the Aryan race. Although the Vedic ritual required neither images nor temples, the non-Vedic cults, such as those of the dragons (Nagas), the tree spirits (yakshas) and the goddesses, may have had permanent shrines with images and wooden temples. References to images and temples begin to appear in the literature from about the 4th century B.C., and numerous types are represented in the reliefs from the 1st century B.C. In Hindu worship (puja, the service of a personal deity with offerings of food, lights, incense, etc., as distinguished from Yajna, the Vedic sacrificial ritual) the first essential is an altar, with or without a symbol or image, serving to receive offerings of flowers. Such an altar beneath a sacred tree, for example, constitutes a yaksha chaitya. The term chaitya denotes a shrine of any kind. The next step is a god's house (devalaya, devagara, ayatana, etc.), a simple roofed enclosure containing the altar and symbol or image.

The fundamental elements of temple architecture are indigenous and of great antiquity. Early Indian architecture was almost entirely of wooden construction, and the forms thus established were later closely imitated in brick and stone. The various forms of domed and barrel-vaulted roofs, gabled windows and roof ends, pillars and cornices were developed from wooden prototypes; the Toda hut. for example, even in the 20th century presents a striking likeness to a barrel-vaulted, gable-ended temple.

A part of Indian architecture, especially at an early period when the use of impermanent building material was otherwise still general, may be described as monolithic; that is to say, the shrine was excavated in solid rock, either by hollowing out the necessary chambers (so that only an internal architecture was brought into being), or by cutting away the exterior rock so as to leave an entire temple of solid rock. Remarkable works of both kinds exist. The former, the cave temple type, is best illustrated by the early Buddhist chaitya halls (Karli. Nasik, Ajanta, Bagh, etc.), in which the interior of an apsidal temple of wooden construction was reproduced in stone in every detail, and by such great Hindu excavations as those of Elephanta, near Bombay. Examples of the latter are the famous Kailasanatha at Ellora, near Aurangabad, the Masrur temple in Kangra. the "Seven Pagodas" at Mamallapuram south of Madras and the Vettuvankoyil at Kalugamalai in the far south. (See TEMPLE ARCHITECTURE.)

2. Arches and Domes.—As both the arch and dome were known to the Sumerian builder in the 4th millennium B.C., there is nothing surprising in the fact that both appeared in India long before the Islamic period, and in fact from the Maurya period onward. One of the earliest temple types is that of a square or circular domed structure, with a roll cornice below the dome. (See ARCH AND VAULT; DOME.)

3. Special Forms.—Some special forms characteristic of Buddhist and Jain usage should be briefly described. The most familiar of these is the stupa (tope. dagoba), an elaboration of the old Indian funeral mound. later carried out in solid masonry, provided aith enclosing walls or railings and decorated uith sculp-

tures. The essential parts of the stupa are the dome (anda or garbha), solid but for a small relic chamber near the ground level in the centre. and inaccessible after completion; one or more platforms, supporting the dome. sometimes provided nith stairways for access and serving for circumambulation; a small pavilion (harmika) on the summit, and rising from this a mast (yashti) bearing one or more symbolic umbrellas (chattavalis); one or more railings (vedikas) surrounding the dome or the whole structure. The stupa is almost exclusively of Buddhist or Jain significance, and as a symbol represents the death or final release of the great teacher, the Buddha or Mahavira. In the earliest types of Buddhist stupa the dome was hemispherical; but a more aspiring type was gradually developed. until there evolved such tall pointed forms as that of the beautiful Burmese Shwe Dagon. In some Burmese forms the basement was extended to a great height. and was provided with chapels within its mass. for which an Indian prototype can be cited at Mirpur Khas in Sind. At Borobudur in Java the basement platforms are seven in number, forming a massive pyramid; this plan in a somewhat simpler form occurred earlier in the Punjab, Kashmir and Turkistan.

Another characteristic form is the aisled apsidal worship hall best known from the early Buddhist rock-cut chaitya halls, but also represented by structural examples in brick or stone of Gupta and later date (Ter, Chezarla, Aihole; and in Pallava and later Dravida architecture, where the number of stories is increased, as the crowning member of a tower).

Also peculiar to India is the hypaethral tree temple, usually a pillared hall, square or circular, with a gallery and vaulted roof, but open in the centre and surrounding a sacred tree; nearly a dozen examples are represented in Buddhist reliefs, where the tree is the bodhi tree, the symbol of the Buddha's Great Enlightenment, but there is every reason to suppose that the type was a very ancient one, developed in connection with the worship of yakshas or tree spirits.

4. Doors and **Windows.**—Doorways of early buildings were provided nith decorated tyrnpanums, reproducing m-ooden forms, and with a gable or ogee arch above. Entrances to sacred areas were provided with toranas (resembling Japanese *torii*, nhere there may be a genetic connection); these consist of upright pillars bearing one or more architraves. of which the elaborate examples at Sanchi afford the best instances, though many others are represented in reliefs. Applied to a wall surface, the same form was used in rock-cut or structural shrines (*e.g.*, Nasik, cave 111), the pillars becoming jambs, the lower architrave the lintel, brackets still being represented, though no longer functional. In later southern architecture the gateway of the enclosing walls became an immense structural tower, called a gopuram, often completely dwarfing the main shrine.

The gable or dormer windows (gavakshas, kudus) which are found to be most characteristic as constructional elements in the early architecture and as ornament in the later, have been commonly designated "horseshoe arches from the form and chaitya windows from the large and conspicuous examples that pierce the faqades of the early excavated churches. In many cases the two ends of the arch spring from a pair of makaras (crocodiles), situated immediately over the capitals of the supporting pilasters and constituting a makara torana. The summit of the arch may be pointed, making it an ogee arch. This dormer arch is not confined to India, but reappears in the earlier architecture of Cambodia and Java. Cusped forms were developed early and survive in Islamic usage.

5. Columns.—Indian columns are of two kinds according to use, either single pillars (stambhas or lats), each bearing a symbol appropriate to the deity of the temple beside which it was placed, or structural pillars (khambhas) of temples or secular buildings. Both occur in a great variety of forms, but as regards the shaft, chamfering and an octagonal section are highly characteristic. All types are monolithic. Capitals, too, are varied. The typical early form has three members: below, an inverted lotus bell; in the middle, four addorsed animals (generally bulls or lions); and above, a trapezoidal cushion with small corner volutes (Assyrian rather than Greek in character). Typical of later northern medieval types is a ribbed cushion capital like an amalaka. Another common form mould be rectangular, with the lower outer angle rounded and sometimes ribbed. A usual form in medieval art is that of the brimming vase or jar with overflowing foliage, often developed into arabesque. Brackets. often decorated with figures of yakshis, are characteristic at all times.

6. Walls.—A sacred structure was usually enclosed by a wall (pakara) or railing. Such a wall consisting of plain slabs mortised into pilasters has been found in connection with a Vaishnavite shrine of Sunga date at Besnagar; and others. similar but sculptured, and of the same period, are represented by fragments from Amaravati and Jagayyapeta. The railings of the early Buddhist and Jain monuments are remarkable; these consisted of plinth, upright pillars, crossbars and coping, evidently based on wooden forms; the best preserved are those of the topes at Sanchi and that at Buddh Gaya, both of about roo B.C.; the most elaborate was that of Amaravati represented by remains now mostly in the British and Madras museums.

7. Influences of Indian Architecture.—The architecture of Malaysia and Indonesia is largely of Indian origin, and this is particularly evident in the earlier phases (pre-Khmer, etc.); but the forms appear to have been developed from older Indian types, rather than directly imitated from those of the Gupta and Pallava styles. Indian architectural forms are recognizable also in Gandhara, central Asia, China and Japan.

8. Technical Literature.—Before proceeding to a description of the architecture of successive periods and styles, it should be mentioned that there exists in India a vast technical literature (known as silpa shastra) on the subject. Such technical works date back in part to the Gupta period, perhaps much earlier; the medieval compilations are still in use by Indian architects, the sthapatis of modern buildings using either the Sanskrit originals or vernacular versions. No more valuable contribution to the study of architecture as a practical art could be made than a detailed description of building methods still in use in India. It has been shown that the Indian silpa shastras must have been used by Indian architects in Java and Cambodia.

II. INDIA

A. Indus Valley Culture Through the Gupta Period (*c.* 2500 B.C.–A.D. 600)

1. Pre-Maurya.—The oldest architectural remains in India are the remains of cities at Mohenjo-Daro and Harappa, dating from the middle of the 3rd millennium B.C. There the buildings are of well-burned brick, laid in mud or gypsum mortar. They include temples; a sacred tank lined with bitumen and provided with a drain over six feet high, with a corbel-vaulted roof; and substantially built and well-drained dwelling houses and shops.

The only surviving monuments that have been attributed to the Vedic period and culture (1500–800 B.C.) are the burial mounds at Lauriya-Nandangarh and certain ancient rock-cut tombs in Malabar.

There is every reason to suppose that the forms which are represented so admirably in the reliefs of Bharhut, Sanchi and Amaravati were already current during many centuries before the Maurya period. The special forms, indeed, are nearer to those of western Asia of the 6th or 7th century B.C. than they are to those of contemporary Persia, and it can hardly be doubted that they represent the Indian development of a widespread early Asian tradition. The forms include storied buildings supported on pillars with volute capitals resting on addorsed animals (bulls or lions), often with pot-shaped bases, and having barrel-vaulted roofs with gabled or arched ends and windows; battlemented brick walls; circular shrines with double-domed roofs; pillared barred-vaulted apsidal temples; hypaethral tree temples; monasteries of cells arranged around a central court; burial or memorial mounds (stupas) on platforms; monolithic pillars; and walls and railings.

2. Maurya **(322–185 B.C.).**—The most ancient excavated cave shrines. those of the Barabar hills, which are finely polished, date from the time of the emperor Asoka (*q.v.*). The entrance faqade of the Lomas Rsi (Rishi) cave is the earliest example of a dec-

orated tympanum with ogee arch, finial, curved beams, and resting on sloping jambs, all in imitation of purely wooden forms.

The remains of Asoka's capital at Pataliputra (Patna) have a rather special character, and perhaps reflect contemporary Persian influences. There have been excavated parts of a massive wooden city wall; a timbered flooring extending for 350 ft.; a series of wooden platforms apparently intended to support a stupendous superstructure; evidences of a pillared hall with 80 polished stone columns; a magnificent stone capital. a stone voussoir from an arch, a stone griffin bracket and other fragments. It is thought that the plan of the palace was identical with that of the Achaemenid palaces at Persepolis. Arrian speaks of Asoka's palace as no less magnificent than those of Susa and Ecbatana.

3. Sunga, Kushan and Andhra (185 **B.C.–A.D. 320**).— Numerous reliefs from Bharhut. Mathura (mod. Muttra) and Amaravati, foundations of ruined buildings and excavated churches (chaitya halls) and monasteries (viharas) prove the existence of an architecture advanced in scale and magnificence. The most remarkable examples illustrated in reliefs are the Sudhamma Sabha and Vaijayanta palace from Bharhut, the exquisite early shrine from Jaggayyapeta, the tree temples from Bharhut, Sanchi, Mathura and Amaravati and a little structural domed shrine from Amaravati.

Noted caves are the chaitya hall and vihara at Bhaja, the great chaitya halls at Karli and Nasik and the Jain monasteries of Udayagiri and Khandagiri in Orissa. Of stupas, those of Bharhut, Sanchi and Amaravati are notable; while in Gandhara, both at Taxila and in Afghanistan (extending thence to Turkistan a little later). there are countless remains of stupas richly decorated with Greco-Buddhist sculpture, and many ruined monasteries. Connected with the stupas are their railings and gateways, of which those at Sanchi are perfectly preserved and those of Amaravati are well known from the British museum series. A seal discovered at Patna, with a Kharosthi inscription of not later than the 2nd century A.D.. represents a tall straight-edged sikhara (tower) shrine, doubtless of brick construction. A true arch above the entrance doorway is clearly shown. and the cella contains a seated image of Buddha. The representation closely resembles the well-known Buddhist temple at Buddh Gaya, and may be it.

A famous structure often referred to at a later date by the Chinese pilgrims was the stupa of Kanishka near Peshawar. According to the Chinese account the basement rose in five stages to a height of 150 ft.. the wooden superstructure to 400 more and the iron mast with 25 copper umbrellas *88* ft. more.

4. Gupta (*c.* A.D. **320–600**).—Of this period both Buddhist and Hindu buildings in stone or brick and excavated shrines are characteristic. The most distinctive temple type is that consisting of a square cella, with plain walls and flat roof, and either surrounded by a pillared hall, as at Bhumara, or preceded by a small and graceful pillared porch as at Sanchi, Tigowa, Pithaora and Nachna-Kuthhara. The little temple at Sanchi well illustrates the fine proportions and appropriate use of ornament characteristic of the early Gupta period. The most important related groups of excavated shrines are those of Udayagiri in Gwalior state (Hindu), Ellora (Visvakarma chaitya hall) and Bagh and Ajanta (caves XVI, XVII and XIX, especially the last with its well-known magnificent façade). Farther south, at Badami, Aihole and Pattadkal, three of the earliest Chalukyan buildings are of Gupta date or a little later. The Ladh Khan, *c.* A.D. 450, was constructed of slabs and pilasters in archaic style; the Durga temple, about 100 years later, is apsidal like a chaitya hall, combined with a northern Nagara sikhara. Very interesting apsidal brick temples survive at Ter in Sholapur district and Chezarla in Kistna district.

The northern sikhara shrines, usually brick towers with stone doorways, began to appear during this period. For the most part the earliest examples are straight edged, or nearly so, and with angle amalakas at every course or every second or third course. The example at Deogarh is entirely of stone; not less important is the brick tower at Bhitargaon, with a recessed frieze of carved brick and terra-cotta panels of Brahmanical subjects. A little later than the Gupta period, but suitably mentioned here, is the brick tower at Sirpur, probably the most exquisite example of a richly decorated brick structure to be found in all India. The monastic university of Nalanda was founded by Baladitya at the close of the 5th century. Hsuan Tsang saw there a great brick temple over 300 ft. in height. The great Hindu temple at Konch, near Buddh Gaya and similar in many details, though the spire is curvilinear, may well be of Gupta date.

B. Period of the Hindu Dynasties (7th–19th Century)

From the Gupta period onward it is convenient to describe the architecture in terms of the three great styles: Nagara (northern or Indo-Aryan); Vesara (later Chalukya, Hoysala and Solanki, of the Deccan. Mysore and Gujarat); and Dravida (southern Dravidian). Separate mention is made of Kashmir and the civil architecture of Rajputana.

1. Nagara.—Here the most conspicuous feature is the curved outline of the sikhara. which is composed, as in the south, of many stories representing reduplicated cornices and roofs. Because of the great compression of each story. the vertical lines of the whole form are far more conspicuous, at least in the later types, than are the horizontal lines of the successive cornices. The tower, usually square, rarely circular in plan, is corbeled inward until the sides nearly meet, the whole is crowned by a huge ribbed lenticular stone, the amalaka which supports the usual vase finial.

At successive stages along the edges of the tower will be found quarter or angle amalakas. one at each stage in early types, more widely separated later. These angle amalakas are clear evidence of the rooflike character of each stage; and indeed, nothing is more characteristic of Indian architecture or more valuable for the elucidation of its history than that the ornamentation consists essentially of reduced, simplified or archaic forms closely related to those of the whole building. The porch or mandapa is usually open and pillared, sometimes roofed with a dome, more often with a pyramidal roof composed of repeated cornices. In the Nagara style a barrel-vaulted roof is very rare, but examples are to be seen at Gwalior (Teli-ka-Mandir) and in Orissa (Vaital Deul at Puri).

The early capital with addorsed animals disappears after the Gupta period, to be replaced by square cushion capitals of various kinds or by a development of the pot-shaped capital into a brimming vase (purna kalasa) with lotus flowers and foliage falling from the mouth onto the four corners; in cave temples, *e.g.*, the great Saiva shrines at Elephanta, near Bombay, a globular amalaka capital is highly characteristic.

The most southerly extension of the style is found at Badami, where the apsidal Durga temple, perhaps of Gupta date, already has a northern sikhara. There, and in several other places, the two styles can be seen side by side. It is however in Orissa, Bundelkhand and Rajputana that the finest and most continuous series is to be found. In Orissa the series shows a continuous development from the 8th to the 13th century; the Parasuramesvara and Lingaraja temples at Bhuvaneshwar, the Sun temple at Konarak and the Jagannatha at Puri are most remarkable, and the beauty and grandeur of most of these would be difficult to exaggerate.

At Khajuraho in Bundelkhand there is another magnificent series, dating between 950 and 1050. The Kandarya Mahadeo temple is the finest; the effect of height, actually 116 ft. over-all, is increased by the great depth of the basement and by the vertical lines of the reduplications of the main form upon itself. There, as well as in Orissa and elsewhere, the temples are covered with figure sculpture.

From Bengal and Bundelkhand the style extends through Rajputana (where the Siddhesvara at Nemawar, Indore state, is of prime importance and one of the best preserved medieval monuments extant) to the Punjab (Amb and Kafir Kot), Rangra and Kulu (Baijnath, Masrur and Bajaura). Modern temples in the Nagara style include the Visvesvara at Benares, the funeral chapels at Gwalior. the Jugal Kisor and Madan Mohan at Brindaban and, among the many alms halls, ghats. wells and temples built by Queen Ahalya Bai (1765–95), the Grstanesvara temple at Ellora.

2. Vesara.—After the recovery of the old Chalukyan territory by a later branch of Chalukyas or Solankis in 973, a new style of architecture came into being in the Deccan and flourished during the 11th and 12th centuries. Another branch of the Solanki family held Gujarat from the 11th to the end of the 13th century. During the 12th and 13th centuries the Hoysala dynasty ruled Mysore.

The Vesara style of architecture is found throughout the area. Conspicuous features are low elevations (contrasting with those of the high Nagara and Dravida sikharas) and wide extension. the star-shaped plan of the cella, the grouping of three shrines about a central hall. low pyramidal towers, elaborated pierced windows, elevated basements with richly decorated courses and. in general, an excess of ornament. In the Dharwar district. the Dodda Vasavanna is perhaps the most elaborate building in western India. In Mysore the most celebrated shrines are those of Dodda Gadavalli, Somnathpur, Belur, Balagami and Halebid and the Jain bastis at Sravana Belgola.

In Gujarat the most famous temple was that of Somnath (Kathiawar), wrecked by Mahmud of Ghazni in 1024. At Anahilpattana the greatest royal builder was Siddha-raj (1093–1143). There as at Vadnagar and Mudhera are the ruins of important shrines. A special characteristic of the local style is the erection of kirttistambhas. or "towers of glory"; the finest of these, in the Chittoor fort, was built in 1440–48 to commemorate the erection of the Kumbhasvami temple.

More famous are the Jain temples at Mt. Abu in Rajputana, particularly those of Vimala Shah and Tejahpala, about A.D. 1032 and 1232 respectively. These are domed shrines with pillared halls, built entirely of white marble, carried with infinite labour up the mountain from the plains below. The most remarkable features are the domed ceilings, with deeply undercut. fretted marble which has been compared to "frozen lace," with a central pendant.

Deservedly famous too are the Jain temple cities of Girnar and Satrunjaya, with buildings ranging from the 13th to the 19th century. These cities of temples built on hilltops were exclusively places of pilgrimage, never otherwise inhabited. Of ordinary cities there are nell-preserved remains at Dabhoi and Jhinjuvad. At the later capital of Ahmedabad the architecture is almost entirely Moslem. but it was executed in the same style and by the local craftsmen, adapted only to Moslem necessities by omission of figure work from the niches.

3. Dravida.—In southern India, according to the Mandagapattu inscription of the great Pallava king Mahendra-varman I (600–625), temples had been built of brick or timber, reinforced by metal and mortar; only from the 7th century onward are excavated monolithic and structural temples found in stone. It is difficult to characterize the style in detail because of the continuous development. Markedly contrasting with the Nagara style of the north are the conspicuous horizontal lines of the towers or spires, produced by a repetition of heavy roll cornices, dividing one story from the next; each story is decorated with little pavilions (pancarams) or dormer windows The walls are often plain, with narrow pilasters, gradually elaborated as the style develops. The pillars are at first supported by lions, and polygonal in section, with a thin flat abacus and roll brackets. later a pendent lotus. The summit of the roof is always a square, circular or polygonal dome (stupika), or barrel vaulted and apsidal, in the latter case appropriately designated as gajaprstha ("elephant's back"). The temple is always enclosed by a high nall or nalls pierced by four gateways (gopuram); in some cases, as at Madura, the enclosure becomes a veritable sacred temple city wherein all the activities of life are carried on.

The early Dravidian style (Pallava and early Chalukya) is admirably illustrated in the Pallava temples of Mamallapuram (the "Seven Pagodas") and Kanchipuram in the east and early Chalukya shrines at Badami. Aihole and Pattadkal in the west. The earliest monuments are cave temples at Undavalla; then come the "Seven Pagodas ` and cave temples in the 7th century and, in the 8th. the structural temples of Kanchipuram and the Shore temple at Mamallapuram, after which the style passes gradually into that of the Chola period.

In the west. at Badami and Aihole, there are six cave temples, two Jain and four Brahmanical, one dated 578. The structural Malegitti Sivalaya, c. 625, magnificently situated on the summit of a hill is perhaps the purest and best example of the style; it is small and massive. but finely proportioned. Much larger and magnificent both in design and execution are the two great temples due to the queens of Vikramaditya II, dated about 740. Of these the Virupaksha, still very massive, was probably built by workmen brought from Kanchipuram, where the Rajasimhesvara (or Kailasanatha) temple had been built not long before the city fell to the Chalukyan invaders; it is known from an inscription that Vikramaditya nas so much impressed by that great shrine that he not only refrained from destruction, but himself made offerings and overlaid the images with gold. In A.D. 753 the Rashtrakutas invaded and occupied the Chalukya territory. No doubt as a result of this invasion workmen mere carried off, and this probably explains the form of the great Kailasanatha rock-cut shrine at Ellora which is evidently modeled closely on that of the Virupaksha at Badami. This wonderful temple, cut out of the side of a hill. is a complete model of a structural building and, together with the someuhat later and very similar Jain Indrasabha, also at Ellora, marks the farthest limit of the northward extension of the Dravida style. The Bhoganandesvara temple at Nandi, C. A.D. 800, affords another important example of a Rashtrakuta building in Dravida style.

In the Chola (c. 907–1053) period the tower of the central shrine is typically developed to a great height by a reduplication of the corniced stories, as in the great vimanas at Tanjore, the centre of Chola power, and at Gangaikondapuram, both of the early 11th century. The former is 190 ft in height. There are also good examples of the style at Polonnaruwa in Ceylon, built during the Chola domination. The Pandya period (1251–1310) is characterized by the development of the great gateways. with a lower story of stone and superstructure of brick, covered mith brick and stucco images plastered and painted. They have the aspect of veritable skyscrapers, and completely dwarf the main shrines.

These later phases of the southern style are characterized by the development of the great pillared halls (mandapam). The monolithic pillars are cut into groups of slender columns. or are provided with elaborate brackets, nearly the full size of the pillar itself and representing leogriffs (yalis) or horsemen on rearing horses attacking leopards or consisting of dancers, deities or effigies of founders.

Of the earlier series, the great shrines at Vijayanagar, Avadaiyar Koyil and Tadpatri are the most remarkable; of the later, the great buildings of the Kayaks of Madura, dating from the 17th century, are well known to all travelers in India. It is perhaps rather anfortunate that the Dravida style is best known by one of the latest examples. the Minakshi shrine at Madura; the whole complex is indeed impressive, but it gives little idea of the earlier purity of Dravida design.

4. **Kashmir.**—In Kashmir, which had been a dependency of the Kushan empire and later an independent kingdom, the prolific building period extended from the 8th to the 13th century. The style has local peculiarities: the double-pointed pyramidal roof, pediments enclosing a trefoil niche. lantern ceilings, fluted columns with Doric or Ionic capitals and large peristyles are very characteristic. The architecture here preserves a certain quasi-classical character derived from Gandhara and not seen in the rest of India, though often recognizable in central Asia. At Parihasapura a large Buddhist stupa with a double platform and stairways on each side is contemporary with the Javanese Borobudur; there are temples of extraordinarily massive construction, one flooring stone consisting of a single block 14×12×6 ft. The court of the Martand Sun temple is about 220×142 ft.; that of the Pandu-kund in Jammu about 191×121 ft. Related architectural forms are found at Malot in the Punjab and at, Gop and some other places in Kathiawar. The trefoil arch, derived from the section of a chaitya hall. while confined to Kashmir as an important architectural form, occurs also at Sarnath, Sirpur and elsewhere.

5. Rajput Civil Architecture.— Twenty or thirty royal resi-

dences, a number of cities and ghats, surviving from the 15th century, show a civil architecture of extraordinary grandeur and beauty. The Rajput style is less intricately ornamented but of more monumental dignity than the better known Moslem palaces of the 17th century.

The earliest well-preserved palaces are those of Chittoor and Gwalior, the latter magnificently situated on the edge of a great flat-topped hill, with several great gateways guarding the approach and a small palace, the Gujari Mahal, at the foot of the hill. Begun under Man Singh in the 15th century, it was completed during the Mughal (Mogul) occupation in the 17th century. Bir Singh Deva's 17th-century palaces at Datia and Orchha are almost equally splendid. The palace at Amber is more nearly like Mughal nork, and so too the lovely marble pavilions by the lake at Ajmer. The whole city, palaces and island palaces of Gdaipur (c. 1600–1740) are of romantic beauty. The Jodhpur palace, 17th century, is situated on the top of a rock dominating the city below and guarded by bastions of tremendous size. The modern city of Jaipur, the Benares ghats (with buildings mainly of the 18th century), the ghats at Maheshwar and Ujjain, the modern work at Bulandshahr, Mathura (mod. Muttra), etc., and the cenotaphs of Rajput princes in many capitals are all evidences of an architecture by no means lost, but still practised. The little modern railway station at Alwar shows how this tradition has been adapted to present-day requirements; the new city at Delhi is a monument to the neglect of indigenous resources. (*See* DELHI: New *Delhi.*)

III. CEYLON

Among the oldest surviving structures in Ceylon are the great stupas or dagobas of Anuradhapura, the capital of the island kingdom from the middle of the 3rd century B.C. to the end of the 10th century A.D. In Ceylon stupas are classified according to the shape of the dome, characterized as bubble shaped. bell shaped, lotus shaped, heap-of-paddy shaped, and are conspicuously simple in architectural form. The typical Sinhalese stupa is comprised of a threefold circular base, a dome and a superstructure of harmika and yashti. The strictest ritual governed the laying of the magical foundation stones and rigid systems of proportion fixed every dimension.

All of the ancient dagobas were built of brick and stone over a rubble core: and were covered with chunam plaster painted white. The main approach was always from the south, the direction associated with the sun at its zenith and with the supreme moment of the enlightenment of the mortal Buddha. The most important of the colossal stupas of the ancient capital is the Ruanveli dagoba whose dimensions are as great as all but the largest of the Egyptian pyramids. It was conceived as a giant replica of the universe and enshrined the largest collection of the relics of Buddha in the island.

A unique and typical element of Sinhalese stupa design is seen in the four sculptured platforms (vahalkada) fixed around the base of this monument at the four cardinal points.

The Thupnrama, built on a smaller scale, is surrounded by three consecutive rings of carved stone pillars which were once used to support a wood and metal dome, sustained by wooden rafters and completely enclosing the stupa. Structures of this type were designated as thupa-ghara and are related to ancient circular shrines in India proper, no longer extant. The temples associated with all of the great dagobas and known as vihares were characteristically rectangular in plan and usually had a single entrance on one long side. A single chamber was enclosed by walls of brick which, together with the pillars inside, supported a roof of wood and metal.

The Lohapasada or "Brazen palace," built by King Duttha Gamani as a royal monastery, was supported by 1,600 monolithic granite pillars standing in an area 250 ft. square. Originally a nine-storied pyramidal structure built of wood with fittings of precious jewels and ivory, it was destroyed by fire in the 4th century and rebuilt with five stories. It received its name from the roof. which was sheathed in copper.

In the 6th century the capital was temporarily moved to Sigiriya, a great natural rock fortress, where a parricide king installed himself as a demigod in a splendid complex of palaces. apartments, galleries and pleasure gardens with which he clothed the entire summit and face of the cliff.

Repeated raids by the Tamil armies of south India forced the final abandonment of Xnuradhapura late in the 10th century. After a brief period of Chola occupation, a new capital was established at Polonnaruna. The greatest periods of building at the new site coincide with the reigns of the greatest of the Polonnaruwa sovereigns, Vijayabahu I (1059–1114), Parakramabahu I (1164–97 or 11j3–86) and Nissamka Malla (1198–1207).

The most notable group of architectural monuments is that collection of shrines located in the Great Quadrangle, an area which at one time must have been the centre of the capital. There are found some of the most beautiful and perfectly realized buildings in all of the Indian norld. The Sat Mahal Pasada. a seven-storied brick pyramid, conforms in shape to the imagined structure of the norld mountain, Meru, and was thought of as a variant of the stupa. The Hata-da-ge, a rectangular structure built entirely of finely cut ashlar masonry, and the Wata-da-ge, a sublime circular shrine of stone and brick, face each other and share a common axis. The beauty of each derives from the subtlety of its proportions and from the sensitive contrasts of the plain and decorated surfaces. Nearby, a stone railing encompasses a unique cluster of granite columns carved in the shape of curling lotus stems with capitals formed like lotus buds.

The tiny pavilion, once canopied in wood, is called the Nissamka Lata Mandapaya, and was probably used as a shrine for the offering of flowers. Great rectangular Buddha halls, vaulted and decorated throughout with frescoes and stucco sculpture, and circular buildings of varying sizes are also among the dedications of the Polonnaruwa kings. A number of Hindu temples, built by the Tamils during the Chola occupation, display an exclusively south Indian character.

Later. the capital had to be moved again, finally, to Kandy, where an independent monarchy survived until 1815. No monument worthy of serious consideration, however, seems to have remained from the later periods. Some of the old architectural forms were continued in the wooden style of the Kandyan era and a certain feeling for complex ornamentation developed; yet few buildings of real artistic quality seem to have been produced after the final renascence under the Polonnaruwa kings.

IV. MALAYSIA

There can be traced in each area of Malaysia and Indonesia, first of all. an Indianesque period. when the local art is closely related to that of India and the forms of Indian art were reproduced; then a classical period (AD. 800–1200) in which local national formulas are evolved and crystallized; and finally a local national phase no longer in direct contact with India, and passing into a stage of folk art which has survived up to the present day. It is at all times an injustice to apply to the local schools the name of Indian colonial art, for although the structural and decorative elements are all originally of Indian origin, the originality and energy of the local forms derive from indigenous sources, and the expression of local ethnic character is everywhere apparent.

A. BURMA

Ruined buildings and sculptures of a Gupta type have been found at Tagaung, Prome, Thaton and elsewhere. Farther north, remains of the old city and a gateway dating from the 9th century can be seen at old Pagan. Among other structures dating from the 10th century at Pagan are the Nat Hlaung Gyaung Vishnuite temple (A.D. 931) and the cylindrical Ngakywe Nadaung, a stupa recalling the Dhamekh at Sarnath.

But it is only with the unification of Burma, accomplished by Ananrata (1040–77), that a great building era was initiated. Remains of no less than 5,000 "pagodas." mainly stupas but also Buddhist temples, can be traced in the Pagan area. Two types are especially characteristic. In one the basement terraces of the chapel or stupa are developed to a great height, giving a cubical effect, and provided with chapels and galleries in their mass, for

which an early Indian parallel is afforded by the stupa at Mirpur Khas in Sind; the Ananda, Thatbinnyu and Shwegugyi pagodas are examples. The other is that of a stupa supported by a high pyramidal terraced basement provided with four median stairways as a means of access, and often with smaller stupas at the angles, thus repeating a type already established at Borobudur, which in turn derives from the terraced stupas of the Punjab, Kashmir and Turkistan.

Other structures exhibit special peculiarities, for Anawarata and his successors were in touch with all parts of the Buddhist world of that time, and built in various manners. Connections with northern India, Bengal and Nepal were especially close. The Mahabodhi stupa is clearly a direct imitation of the ancient Indian shrine of the same type at Buddh Gaya, described above, which was itself in turn restored by pious Burmese Buddhists in the 12th century. Active construction at Pagan continued well into the 13th century. after which the unity of the country was for a time destroyed by Shan invasion.

The unfinished Mingun pagoda, begun in the 18th century, was to have been the largest in Burma, and what remains is still over 140 ft in height, though this represents only a third of the proposed elevation. It is highly characteristic that ancient stupas of small size were again and again enclosed within larger structures and thus lost to view, so that huge pagodas like those at Prome and Pegu, while really representing ancient foundations, are in their present aspect comparatively modern.

Mandalay was founded only in 1857, and occupied by Mindon, the last great royal patron of Buddhism in Burma. The palace. a wooden structure in which material from an older palace at Amarapura (the previous capital, near Pagan) was employed. like most wooden palaces consists of connected halls, pavilions and galleries within a walled enclosure. The main features of the style are the use of immense teak columns, lacquered and gilt multiple roofs and spires with flamboyant crockets, and an interior decoration in which glass mosaic plays an important part. Other fine examples of late Burmese wooden architecture are afforded by monasteries such as the Myadaung Kyaung and the Sangyaung at Mandalay, monuments to the piety of various queens. Still more modern is the famous Shwe Dagon pagoda (stupa) at Rangoon; its tapering form. the outline of the spire almost continuous with that of the body, contrasts conspicuously with the more monumental hemispherical and cylindrical types of early Indian art. There is a general tendency to the development of more refined and aspiring. less massive types in all the later stages of Indian architecture wherever it is found. *(See* BURMA.)

B. CAMBODIA

1. Pre-Khmer or Khmer Primitive (5th–8th Century A.D.).—The history of Indian architecture in southeastern Asia can be followed in Cambodia better than anywhere else; there, despite the disappearance of wooden architecture, once more abundant than that in stone, the sequence is relatively complete. In the Khmer primitive or pre-Khmer (as different authors interpret it) architecture of southern Cambodia. dating from the 6th and 7th centuries (when permanent materials such as brick, laterite and stone were just coming into use), are found a series of buildings which exhibit striking analogies with those of the early Chalukyas of the western Deccan, as well as with those of the Pallavas and even with the earlier style of the Andhras.

A slab-built cella at Hanchei recalls the small shrine on the roof of the Ladh Khan at Aihole; it was once perhaps surrounded by a pillared hall as at Bhumara. Another very elegant square cella at Prei Kuk has shallow pilasters and characteristic Indian cornices with dormer arches framing Gandharva heads, and is quite Pallava in appearance. There also, and at Bayang, there are high brick towers suggesting such Gupta types as Deogarh or Bhitargaon; at Maha Rosei there is a granite shrine of Pallava type.

2. Classic Period, Khmer (9th–15th Century).—From the 9th to the 12th century and even later. Cambodian architecture develops still in brick and laterite. but more characteristically in stone. Indian forms are abandoned or freely modified, and local features appear, so that a truly national architecture comes into being. Unlike anything in India are the half-vaulted arches with curved stone sloping roofs imitating tiles, and so too the huge faces or masks on the sides of the early towers of the Bayon and Angkor Thom gateways. On the other hand the later towers develop as in India by a reduplication of stories, vertically compressed, and many motifs. seemingly novel, for example the Garuda caryatids of the Prah Khan walls and the Angkor Thom terrace, have really older Indian prototypes.

The classic Khmer architecture is widely distributed in northern Cambodia, perhaps the original seat of the Khmers. The best-known monuments, out of hundreds still in existence, are the city of Angkor Thom and the neighbouring temple of Angkor Wat (Angkor is a corruption of Sanskrit *nagnra,* "city" or "capital"; *wat* or *vat,* a later Siamese term for any Buddhist monument).

The city, occupied about A.D. 900, is of great extent, and contained within a moat, crossed by four causeways with parapets consisting of gods and giants holding the body of a giant Naga; these causeways lead to triple gateways large enough for the passage of elephants, and from these proceed four roads to the heart of the city. Near the city are the previous capital of Prah Khan, and other shrines such as the Neak Pean, Phnom Bakeng and Angkor Wat, and many artificial lakes. The city is situated in the plains, among the rice fields and near the great lake, both necessary sources of food supply for a great population. Its most important structures are the temple of Phnom Bakheng, the Bayon, the Baphuon and the Phimeanakas. The Bayon, intended to be Buddhist, was adapted to Saiva usage before its completion, and ultimately contained the statues of Hindu and Buddhist deities, the Deva Raja (a linga representing the king's divinity) and statues of deified royal ancestors. Its most conspicuous feature consists of the towers with enormous masks (representing Lokesvara) on each face; but equally interesting are the reliefs in which almost every aspect of contemporary life is depicted. The Baphuon, *c.* A.D. 1000, is a typical terraced, pyramidal structure (prang), with median stairways leading to a stone gallery above.

Of the many other temples built in less accessible sites, the Prah Vihear may be mentioned; it is magnificently situated on a spur of the Dangrek range. overlooking a rolling panorama of uninhabited jungle. Angkor Wat is the later Siamese designation of the most famous and most beautiful of Cambodian shrines, of which the true name is unknown, though there is reason to think the dedication was to Vishnu. The date is the early 12th century.

The 14th-century temple of Isvarapura at Bantei Srei is proof that the capacities of the Khmers were not destroyed by the earlier Siamese invasions. But the country had certainly been devastated and Angkor Thom abandoned by the 15th century, and when later inscriptions appear they belong to the Siamese period. Hinayana Buddhism replaced the mixed Mahayana Buddhism and Hinduism which formed the state religion of the Khmers in the classical period.

C. THAILAND

Siamese architecture. in its earliest periods, was little more than a provincial reflection of the Indian style. It subsequently came under the influences of Khmer, Burmese and Sinhalese modes of building, and finally developed in the direction of a richness of detail and an ornamentalism of form that is distinctively Siamese. Wat Mahadatu at Lop Buri is a typical example of the Siamese temple of the Khmer period. In plan, it repeats the usual Indian formula of a sikhara with a closed mandapa, and in elevation it is strongly reminiscent of the 10th- and 11th-century buildings at Angkor.

Wat Kukut at Muang Lamphun, erected in the 12th century, takes the form of a terraced pyramid, with niches holding Buddha images, and thus recalls the Sat Mahal Pasada in Polonnaruwa. Wat Chet Yot, a dedication of the Thai period, is a copy of the Mahabodhi temple at Pagan and ultimately derives from the great temple at Buddh Gaya as it appeared in the Pala period. Among the ruins of Ayutthaya (Ayudhya), the capital from 1350 to 1767, are a number of examples of the typical Siamese stupa. Round, with multiringed bases and bell domes, they climax in tapering

onionlike finials of peculiarly pointed form. The last phase of Siamese architecture is typified by the many shrines and palaces set up in Bangkok after 1782. These structures are built almost entirely of wood and are elaborately decorated with a mixture of forms borrowed from ancient Siamese and modern Chinese sources. They are characterized by an ornateness which produces an artificial splendour seldom equaled.

D. Champa

Eastern Indochina, once the seat of great Cham (*q.v.*) kingdoms, must have been hinduized at an early date, for there are traces of Hindu kingdoms both in the north and south as early as the end of the 2nd century A.D. All the early and much of the later architecture was wooden. The remains are of two periods, one classic, from the 7th century to about 1100, the other that of the decadence.

The sacred city of Mi-son was founded about A.D. 400, but the great brick tower non surviving was built on the site of the original wooden shrine soon after 600. The plan is square, but the cella is twice as high as it is wide, and the effect of height is increased by the narrow decorated pilasters which emphasize the vertical lines; the pyramidal roof consists of three diminishing stories, repeating the form of the cella on a smaller scale. The decorative motifs include makara niches, geese with extended wings, both old Indian motifs, and acroteria silhouetted against the sky. The whole is reminiscent of Indian Gupta toners and the pre-Khmer towers of Cambodia. In addition to this main shrine there are six great halls for the accommodation of pilgrims, for Mi-son was a sacred city rather than a place of habitation. Later, about 800, a great temple and monastery, the only important Buddhist buildings in Champa, were erected at Dong-duong by Indravarman II; but the place was soon ravaged by the Annamites. who were continually pressing downward from the north and ultimately accomplished the ruin of Cham civilization. Sanctuaries were built again near the new capital of Binh Dinh at the beginning of the 11th century; the colossal towers of Duong-long, and those known as the Towers of Gold, Silver and Copper, are striking monuments. But it was no longer possible to build up great temple cities in honour of the gods.

V. INDONESIA

A. Sumatra

Sumatra, Suvarnabhumi, the "Land of Gold," Yavadvipa of early Indian literature. received Indian colonists probably before the Christian era; in the 5th century Mahayana Buddhism was officially adopted as a result of a royal mission from Kashmir. I Ching passed by Palembang about 690 and found there a great centre of Sanskritic Buddhist learning.

Before this time the great Malay kingdom of Srivijaya, held for many centuries by the Sailendra dynasty, had been established with the capital at Palembang, controling the Malay peninsula and probably Siam as far as Prapathom. This was the greatest maritime power in southeastern Asia (Madagascar had been colonized by hinduized Malays early in the Christian era).

An inscription at Vien Srah in the northern part of the Malay peninsula records the erection there of brick towers and stupas. That of Kota Kapur in Bangka speaks of a military expedition to Java and in fact from before the middle of the 8th century the whole of central Java was subject to the Sailendras. The buildings there erected, however, will be discussed under Java *(see* below); in Sumatra proper the architectural remains are little knonn and not well preserved. *(See* Sumatra.)

B. Java

The old Hindu kingdom of Taruma in western Java is known only by inscriptions of 4th- and 5th-century date. The earliest architectural remains are those of the Dieng plateau, where in the 7th or early 8th century stone was employed in Java as a building material for the first time. The plateau was not an inhabited city. but a place of pilgrimage. a temple city comparable with Girnar and Mi-son. Out of many more, eight temples survive; they are known by the names of the heroes of the *Ramayana,* but these appellations have nothing to do with their original dedication to Siva. The Indian character of the architecture is conspicuous, and in all probability Indian architects were at work there. The construction is generally cubic, with strongly emphasized vertical and horizontal lines; the temples are two-storied, the roof repeating the form of the cella. The plan is square, and the walls are divided by pilasters into niches or panels with sculpture; a grotesque makara face crowns the doorways. This description applies to the four temples of the Arjuna group; but Candi Bhima is a pyramidal tower in the northern Indian Nagara style with successive horizontal stages repeating the fundamental forms, cornices with dormer arches framing Gandharva heads and angle amalakas at the fourth and fifth stages. A single amalaka crowned the now ruined summit. East and south of the plateau and at Mt. Ungaran there are numerous other small temples of the same period and style, but rather more freely and exquisitely decorated.

Among the great monuments of the Sailendra period is a lovely but ruined temple of Tara, at Candi Kalasan. It was the first Buddhist temple on Javanese soil and its date is A.D 778. This is a building of the Dieng Arjuna type, but the lateral niches are developed into side chapels. the ornament is more elaborate and there are delicate strips of floral tracery between the plain pilasters. Nearby is the three-storied rectangular Candi Sari. Candi Mendut, which is near Borobudur, is similar in plan, but there are no side chapels; on the other hand there is an open sculptured vestibule, and the exterior walls of the cella are richly decorated with figure reliefs. *(See* Java.)

Borobudur ("the Vihara of the Secret Aspect") is wonderfully situated on an eminence commanding an extensive view of rice fields and more distant towering volcanoes; it is a hill that has been terraced and clothed with stone. It is in fact a low pyramid composed of successively receding platforms with re-entrant angles. The structure is thus exactly analogous with that of contemporary buildings in Kashmir, of earlier stupas in the Punjab and Afghanistan and of the Rawak stupa in Turkistan, which are similarly provided with extensive basements having median stairways on one or four sides, though none of the Indian examples has more than two terraces, so that Borobudur represents a more developed type. (For the sculptures see Java: Archaeology.) Borobudur cannot be exactly dated, but it was probably built at the close of the 8th century.

Candi Sewu Prambanan is a Buddhist temple which dates from the early 9th century. The large central shrine represents a further development of the Candi Kalasan design, with side chapels open to the exterior and niches containing images. Around it, within the large area enclosed by the pakara. are two double series of small independent chapels, about 250 in number. The order and formality of the design are conspicuous.

After the "restoration," *c.* A.D. 860, the Hindu kings of central Java erected other great buildings at Prambanan. The Candi Loro Jongrang group consists of three large terraced temples dedicated to Brahma, Siva and Vishnu and some smaller shrines within the same enclosure. The Siva temple is typical; the actual shrine occupies the summit of a steep truncated terraced pyramid with median stairways on three sides leading directly to the main shrine and side chapels above. The whole site may have been a royal mausoleum as well as a place of ordinary worship. Nearby is the Buddhist Candi Plaosan.

These temples were no sooner built than abandoned, for about A.D. 915 central Java was deserted. and the further development of Javanese architecture must be studied in the east and in Bali.

At Candi Lalatunda and at Belahan there are sculptured bathing places built by Udayana and by his great son Erlanga. The best-known monuments. however, belong to the 13th and 14th centuries, the time of the great capitals at Singasari and Majapahit. At Singasari. Candi Kidal is a Saiva, and Candi Jago a Buddhist temple. but there is a mixture of the tno cults amounting almost to fusion, as was also the case in Cambodia; a like condition prevailed in Bali. In far eastern Java the great Buddhist shrine of Candi Jabung dates from 1354; the circular tower, unique in Java, stands on the usual high rectangular terraced basement, the transi-

tion from base to tower being skillfully effected. At Panataran near Blitar there is a large Saiva temple complex. recently excavated and partly restored; the basement of the main temple is square and terraced, with the usual recessed corners. The associated gates and the sculpture are already in a style forecasting that of Bali.

C. Bali

Bali, where alone in Indonesia Hinduism and Buddhism survived as practised cults, most probably had early and direct relations with India; but the migration of Javanese exiles to Bali at the close of the 1 jth century, by nhich time practically the nhole of Java had received Islam, must also be taken into account. In Bali the only important early remains are the royal tombs at Tampaksiring, dating from the 11th or 12th century, and the Pura ye Ganga temple, more or less in Panataran style, dating from the 14th or 15th century. The more modern temples of Sangsit, Bangli, Batur, Kesiman, Den Pasar, etc., consist of groups of small independent shrines enclosed by walls having high roofed gateways; with rich sculpture in limestone, in fantastic forms and high relief.

INDIAN ART, in this article, refers to the Buddhist, Hindu and Jain sculpture, painting and decorative art of the Asian subcontinent of India and of Ceylon, from earliest times to the present. The art of this area created under Islamic rule is discussed in Islamic Art. For the art of adjacent areas see Indonesia~Art and Archaeology; Persiax Art; and Tibetan Art. This article is organized as follows:

I. Introduction
  1. Indian Art and Western Art

I. Introduction

1. Indian Art and Western Art.—It may be useful for western readers to begin the consideration of Indian art by examining a few likenesses and differences between Indian and western art. Some of the points will be dealt with at greater length below. Indian art may be described as theological or traditional, since, like the art of the middle ages in Europe, it was dedicated to revealing the divine nature of the gods and enhancing the dignity of the church. Its didactic purpose was to instruct men in the truths of religion. The function of art was the making of the objects of worship in a life given over to religion. The Indian artist was trained in canons of proportion and harmony calculated to produce images which, in their abstract perfection, would suggest the divine nature of the original. Indian images are abstractions of the human form. Unlike the Greek artist, who sought to suggest divinity by the idealized perfection of the physical anatomy, the Indian artist strove to create a supernatural ideal often presented in terms only abstractly related to an actual physical body or its proportions. The Indian artist composed his figure according to canons of proportion intended to endow his idol with more than mortal impressiveness and beauty. The nude is not used in Indian art for its own sake, as in the western tradition, but in order to suggest the sensuality of fertility spirits or the yogic control of the Jain ascetic by means appropriately specific and abstract. In every period of Indian art painters and sculptors suggested the warmth and fullness of the fleshly body and the presence of enlivening breath by abstracting the swelling planes of which the body is composed. Some Indian figures of the nude, such as those of Jain ascetics, have a certain superficial resemblance to such western types as the early Greek Apollo or Kouros in the very abstraction of the anatomical form. But it must be remembered that in the Indian image this abstraction is intended to represent the body as a symbol of spirit and an expression of withdrawal from material being, whereas in the Greek statues abstraction is employed to express youthful beauty throbbing with physical life. The real differences between Indian and western art are more apparent in the comparison of such characteristic types as the Aphrodite of Greek art and the yakshi or fertility goddess of India. In the classical statues the erotic charm and function of the goddess are suggested by the artist's literal imitation of a body in marble, while the Indian image achieves the same iconographic end by means that are essentially abstract and at the same time completely plastic and appropriate to the medium. It might be pointed out that in an exactly similar way, even in portraiture, there is a complete suppression of individuality. In Indian art, portraits, just as much as representations of gods, are symbols of general ideas, a point of view in which reference to the particular has no place. It could be said that the principal link between Indian and western art is the employment of the human figure to reveal the imagined shapes of the gods. The main difference between the Indian and western approach have already been mentioned. It might be added that, whereas the western artist in the Greco-Roman tradition sought to create an ideal with reference to the beauty of actual human models, the Indian artist worked in what might be described as a metaphorical mode; that is, a representation of parts of the body and features in shapes suggested by similar forms in the world of nature, such as the lotiform eyes of the deities—shapes regarded as more final and perfect than anything to be found in the merely transitory appearance of human models. It must be remembered that the Indian gods were always portrayed as supermen. Such attributes as the multiple heads and arms of Hindu divinities, which would seem monstrous according to the western classical tradition, were entirely necessary to display the manifold attributes of their power, and invariably these multiple arms are disposed in such a way as to enhance the, dynamic and rhythmic conception of the figure.

2. Significance and Character.—Indian religion and ritual exist in two forms. known to Indians as the Vedic and the Agamic traditions. but the Vedic is more often designated by western scholars as Aryan and Brahmanical, and the Agamic as Dravidian (southern) and popular. Vedic (Aryan) religion consisted in a

worship of the great powers of nature by means of hymns and sacrifices (Yajna). nithout any use of temples or images, or any devotional cult properly so described. On the other hand, the much older and quantitatively predominant element of the population worshiped local and tutelary deities, powers of nature conceived as personal beings; these deities included the yakshas (genii, tree spirits, sources of life and abundance), Nagas (dragons, spirits of springs and lakes) and innumerable goddesses of fecundity or dssease, the Shaktis of later Hinduism. To this Agamic tradition belonged an elaborate cosmology, many myths, the doctrines of reincarnation and acts (samsara and karma), the practice of asceticism (sannyasa) and ecstatic meditation (yoga), which appear only late in Vedic literature.

The indigenous divinities were worshiped with devotion (bhakti) as personal beings and with a ritual (puja, a non-Aryan word referring to the anointment of sacred objects) which included offerings of flowers, food. lights and incense; and for this ritual images and temples, though of impermanent materials. wood and clay, must have been in use from a very early period.

The Vedic culture was gradually penetrated by indigenous belief and closed with the reactionary teachings of the Upanishads and Buddhism. where Yajna is discounted, puja not considered; the goal is release, the means is knowledge. Meanwhile, there was developing a higher and inclusive devotional theism. in which the sndigenous deities were fused with those of the Vedas. and interpreted in the light of philosophic and psychological speculation. The great system (see HINDUISM) thus built up, sanctioned on the one hand by scripture and on the other by popular belief, became a truly national vehicle of thought; Hindu theology and myth, in verbal and visual expression, provided 'means of statement for all that was felt and thought about the soul of man and the nature of the universe. At the same time, new divinities came into being, among others the Buddha himself; for the prevailing tendency involved in iconolatry, cult and ritual even such systems as those of Buddhism and Jainism, which had originated as purely psychological and ascetic disciplines.

For several centuries before and after the beginning of the Christian era the dominant mode of creative thought was theological. All the arts were governed by a great enthusiasm like that of the cathedral builders of medieval Europe. and in all enduring aspects and in their greatest splendour, they were in the service of the churches, upon whose endowment and adornment enormous wealth was lavished.

Long after the first creative impulses had been crystallized in the medieval period, there were developments of thought and feeling and modifications and elaborations of the older iconography that can still be traced. India, despite the destruction wrought by Mohammedan invaders, is even today covered with magnificent temples and a wealth of sculpture in which the spiritual and material history of two millenniums is visibly recorded. Further, the same initial impulses, translated to other lands and molded by the imagination of other races, Pyu, Thai, Khmer. Malay and Polynesian. created other and scarcely less significant and varied cycles of art in southeast Asia and influenced profoundly the spiritual and artistic development of central Asia. China. Korea and Japan.

Thus, Indian art is essentially a hieratic art devoted to the exposition of the personality and acts of deities, and providing for their service. Authoritative texts declare that the making of images of deities leads to heaven, not the making of likenesses of men; that only that which accords with the canons is beautiful in the eyes of the discerning, not that which pleases individual fancy.

3. Hieratic Art.—But while Indian works evoke aesthetic experiences when beheld by alien eyes. Indian art and European art are not identical in kind; the intention is different. Nor is there identity of method. In its main development, sculpture and architecture, Indian art was not produced with a view to aesthetic experience, nor even regarded as "art." Images, in particular. were not regarded as works of art but as means (sadhana) of edification.

An image is a piece of apparatus (yantra) employed in personal devotions, the object of which is an identification in consciousness of worshiper and deity. In the words of a well-known text, the deity can be worshiped (in spirit and in truth) only insofar as the worshiper becomes the deity. For this spiritual exercise yantras of two kinds are employed, one purely geometrical and linear, the other three-dimensional and more or less anthropomorphic or theriomorphic. Both types are alike in kind;

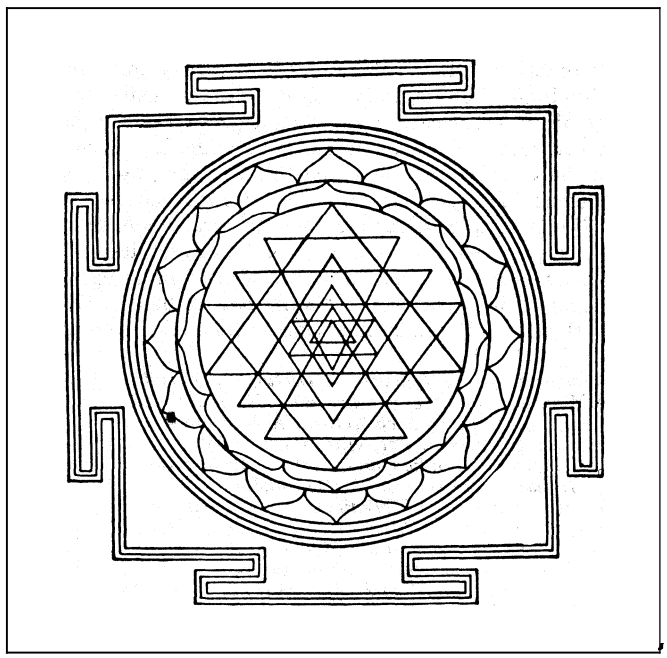

FIG. 1.— YANTRA. A DIAGRAM FOR WORSHIP

both are equally externalizations of mental visions evoked in dhyana (meditation) with a view to samadhi (superconsciousness).

The obtaining of this mental visualization (which is more essential than its material realization) is a process of yoga.

Such a visualization differs from those present in normal vision: it is more vivid; it fills the whole field of view; all parts are equally and simultaneously present; the relation of these parts is not organic. nor on the other hand accidental, but ideally determined; such an image can represent only a condition of being or. to use a more strictly Indian term, a type of activity.

Such an image is not a memory image. which is the foundation of all realistic art, inasmuch as time passes between the moment of vision and that of execution. What may at first sight look like the observation of nature at Amaravati or Ajanta is simply the most vital and the most felt part of Indian art; where the worshiper attains the most complete samadhi, the artist is most completely and literally identified with his subject. Critically examined, this art reveals no knowledge of anatomy, but rather a deep understanding of life, of emotion and of the language of gesture, long codified in the *Natya Shastra.* (*See* DANCE: *The* Orient: India *and* Pakistan.) Nor are its themes confined to those set forth in terms of human life; beside these are dogmatic and mythological forms unparalleled in nature.

4. Narrative and Decorative Art.—A part of Indian art is secular. There exist, beside the cult image, both narrative arts and an industrial art, or arts and crafts. The narrative art such as is used to illustrate Jatakas or the epics or the Krishna legend is not hieratic to the same degree as the cult image. hut is a dramatic presentation comparable to the stage. It is nevertheless governed by principles similar to those which determine the nature of the cult image: the use of formulas is general, and the part of the spectator quite distinct from that of mere perception. A typical peculiarity of Indian (and in general oriental) art is the kind of perspective known as vertical projection, whereby the landscape is presented as seen from a height, so that the horizon almost reaches the upper edge of the frame; the planes are differentiated in the sense that an object or figure behind another is represented as above it, while the atmosphere, apparently reduced

to the narrow space remaining above the horizon. is really brought forward to embrace the whole representation together with the spectator.

Although in Sanskrit literature much is heard of portraits of individuals recognized as likenesses, these are invariably drawn from memory, in the absence of the model, so far at least as the actual references inform us.

Further. Indian art reveals nothing like genre. The nude. for example, while sometimes represented with a frankness disconcerting to European eyes, is never studied or treated for its own sake, as in European art, and appears only as symbolism or narrative may require. In the same way landscape is never represented for its onn sake.

Thus, the narrative art of India is of the same kind as the purely hieratic art. All true pattern is of this kind; this is especially evident in its repetitive character and in a mathematical rather than organic relation of the parts. Accordingly. the industrial and "decorative ' arts in India cannot be sharply divided from the "higher" arts. In both, design and formula, rather than imitative shapes. are found; definite meanings are present in both. for oriental ornament is never originally without, and very rarely loses, a precise significance, and is never "merely" decorative.

5. A Theory **of** Beauty. — India developed. as a means of literary criticism, a theory of aesthetic experience of considerable importance in the history of aesthetic theory.

A nork of art is a statement informed by flavour (rasa); there are nine such flavours. the erotic, heroic, odious, furious, terrible, humorous. wondrous. pathetic and peaceful. The component elements of a work of art (physical stimulants of aesthetic experience) are determinants (vibhava, theme, etc.), consequents (anubhava. deliberate actions), moods (bhava. 33 transient [*e.g.*, joy, impatience] and 9 permanent [viz.. the 9 rasas listed above]) and involuntary emotional conditions (sattvabhava).

Aesthetic experience (rasasvadana) is the tasting of rasa. and depends mainly on the innate and acquired sensibility of the spectator (rasika).

6. The Artist. — A general term covering sculpture, reliefs and painting is citra; this word can also be used in a more restricted sense with reference to painting only. Silpa is the practical activity of the craftsman, rather than "art" in a modern sense. The artist or craftsman is designated as silpin. sthapati karmara, rupa-kara, citra-kara, etc. The higher craftsmen practise many arts: an architect. for example, will also be a sculptor, bronze founder and goldsmith. On the other hand workers in iron, weavers, potters and the like are restricted to a single craft. No artist is solely a designer, like a modern architect; the Indian architect is, during the greater part of his life, a manual worker.

II. INDIA

A. Prehistoric (Before *c.* 1500 B.C.)

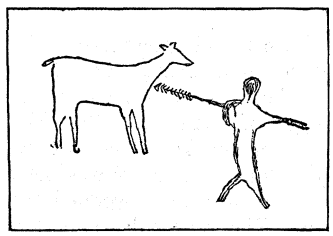
1. Paleolithic and Neolithic. — Rough chipped-stone implements have been found abundantly in southern India. But a great gap, ethnic and cultural, seems to separate them from those of the Neolithic period. Neolithic implements. both chipped and polished. some antedating and some coeval with the knowledge of copper have been found all over India. They exhibit a great variety of forms. including pygmy types. Most of the forms are identical nith those of western Asia and Europe; but a peculiar chisel-shaped, high-shouldered celt is found in Chota Nagpur, Assam and more abundantly in Burma. Indochina and the Malay peninsula. Indian culture must have had a continuous history from prehistoric times; this must be borne in mind in a discussion of the earlier history of Indian religion and art, especially in connection with the beginnings of sculpture and design.

2. Prehistoric Painting. — Primitive ruddle paintings have been found in natural caves in various parts of north central India. and have been regarded by some authors as of Neolithic or even Paleolithic date. Those from the Mirzapur district in the Vindhya hills include a representation of a rhinoceros hunt. This animal is non extinct in this area. The hunters are shown with barbed spears, suggesting certain of the ancient Indian copper

Cave paintings from the Hoshangabad district are said to include representations of a giraffe. Those from the Kaimur range (fig. 2) shon stag hunts. Those from Singanpur include an animal rather like a kangaroo and also some representations of a horse and of deer which present an extraordinary resemblance even in details to the Paleolithic paintings of Cogul in Spain.

The literature of the subject is cited by Herbert Kuhn. who discusses the Singanpur examples and their resemblance to Spanish drawings. Those from Hoshangabad are referred to in the Annual Report of the Archaeological Survey of India, part 1, p. 25 (1917–18).

3. Chalcolithic: Indus Valley Culture. — Excavations at Harappa in the Punjab and Mohenjo-Daro and Chanhu-Daro in Sind have revealed the existence of ancient city sites belonging to a Chalcolithic culture, known as the Indus Valley culture or. from its relation to the near east, the Indo-Sumerian period.



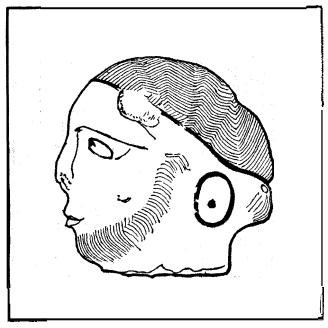
FROM JOURNAL OF THE ROYAL ASIATIC SOCIETY"

FIG. 2.—CAVE DRAWING, KAIMUR RANGE

The dating of the Indus civilization depends on compsrison with vestiges of similar architectural and sculptural remains in Mesopotamia and on the discovery of objects of Indian type in pre-Sargonid and Sargonid sites. Indic seals have been found at Ur, Kish and Tall al Asmar datable from about 2500 to 2350 B.C.. so that the beginnings of the Indus civilization have been fixed in the middle of the 3rd millennium B.C. This culture lasted until the 17th century B.C., when it was succeeded by an obscure and inferior culture known as the Jhukar which endured up to the time of the Aryan invasion of **1500** B.C.

The buildings at the Indus sites are of a well-burned brick. This method of construction and the existence of lofty citadels like the ziggurat platforms of Mesopotamia suggest a connection with the architecture of the ancient near east. Among the examples of sculpture, tno figures, one of a nude male from Harappa, the other a dancer, perhaps Siva, from Mohenjo-Daro, belong to a definitely Indian style of expression with their emphasis on the fullness and softness of the body suggested abstractly through the interlocking of the smooth convex planes of the surface.

Sculptures in marble include a bust of a man, possibly a shaman, and a bearded head wearing a skullcap (fig. 3). The masklike quality of these heads is distinctly Mesopotamian in character. In terra cotta. there are many figurines of a nude goddess with an elaborate headdress, girdle and the body ornament (channavira) characteristic of later Indian art; in terra cotta and in faïence, admirable figures of animals, including the bull, rhinoceros, dog and cock. All these are sculptures in the round. But the most abundant and not the least remarkable works of art are the square seals of faïence or ivory nhich bear in relief figures of animals, usually a bull, elephant or rhinoceros. with a cult object. apparently a wicker crib or manger, and pictographic signs. partly related to earlv Sumerian forms and even more similar to pre-Sumerian forms found at Kish but so far undecipherable. Some scholars believe that the later Indian Brahmi (Sanskrit') script was developed from this early pictographic type. One seal bears a seated cross-legged figure attended by snake-hooded Nagas, as in much later. Buddhist, art; another a sacred tree (the bo tree or pipal, *Ficus religiosa*, later a symbol of various deities. particularly the Buddha) with a horned dragon projecting from the trunk; another, a row of men bearing totem standards like



AFTER ARCHAEOLOGICAL SURVEY OF INDIA

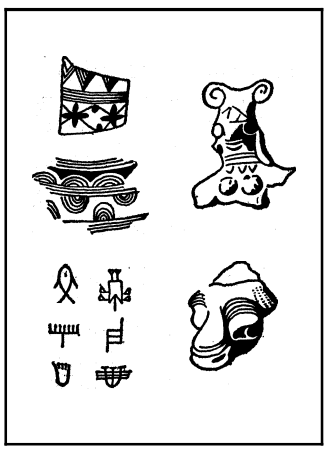
FIG. 3.— PREHISTORICSCULPTURE, INDUS VALLEY CULTURE

those of predynastic Egypt. One earlier seal from Harappa represents a tiger hunt.

Among personal ornaments are finely wrought gold, silver, and copper gilt jewelry, *chank* and carnelian beads, faience bangles. Other metals known included tin and lead, but not iron; some utensils and ornaments are made of bronze. India has no Bronze Age properly so-called but the alloy is found already at that early date and has remained in use to a limited extent ever since. though most of the so-called Indian bronzes are really of cast copper. A copper model of a hooded two-wheeled cart obtained from the lower strata at Harappa is evidence of the very early use of wheeled vehicles. Few weapons have been found.

The pottery is wheel made. and includes painted types; the shapes are varied, but types with handles are rare. The painted designs are usually in black on a dark red slip and consist of advanced geometrical patterns, foliar motifs and occasional figures of animals.

The dark red and black ware has been found abundantly at Nal in Baluchistan, associated with copper implements, also on the Waziristan frontier and in Seistan. The style bears some relation to that of Anau and of Susa II.



AFTER 'ARCHAEOLOGICAL SURVEY OF INDIA"

FIG. 4.—PREHISTORIC PAINTED TERRA COTTAS AND OF THE INDUS VALLEY CULTURE

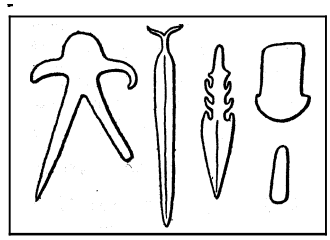
When the Indus culture was flourishing, the valley was better watered and more wooded than now. The same culture, perhaps in more provincial forms, 'may have extended to other parts of northern India, over an area reaching from Baluchistan to Kathiawar and through Rajputana to the Ganges valley, as indicated by the Gungeria hoard and other finds of copper and Neolithic implements.

The Indus Valley civilization and culture show close resemblances on the one hand with those of early Sumer and Babylonia (especially with the proto- or pre-Sumerian of Kish), and on the other with that of historic India. Apart from these archaeological evidences, there has gradually accumulated a mass of evidence tending to show that the early Indian and Mesopotamian cultures represent cognate developments. This applies especially to considerations derived from a study of the history of design (particularly in connection with the animal style and architecture), and to the analogies between Babylonian mythology and cult and those of the Dravidian (Agamic) tradition in India, such as the use of the same formulas in representing mountains, clouds and water; the motif of animals with long necks interlaced, and of heraldic and fabulous animals generally; the representation on Babylonian seals of dragons with serpentine bodies and human busts, like Indian Nagas; the cult of the waters connected with the symbol of the flowing vase in Babylonia and the brimming vessel or vase of plenty (purna kalasa) of India—the former significantly spoken of by Léon Heuzy as the marvelous symbol that was like the Holy Grail of the Chaldean epoch, and both of importance in connection with the origins of the Grail cult. To these may be added similarities of technical procedure, as in the process of decorating carnelian by calcining and in the similar composition of Indian and Assyrian glass.

AFTER ARCHAEOLOGICAL SURVEY OF INDIA

FIG 6 — TYPES OF PREHISTORIC PAINTED POTTERY FROM NAL. BALUCHISTAN

Neither the archaeological nor the mythological evidence suggests that the Mesopotamian and early Indian cultures were derived from each other, or that either borrowed extensively from the other at any one period, but rather that both developed in *situ,* though not without intercourse and contact, on the common basis of the early Chalcolithic culture which in the 5th and 4th millenniums B.C. extended from the Adriatic to Japan. It has been suggested that the numerous small cultures developed in Iran and Anatolia in the 5th millennium B.C. began to spread southward and southwestward into the plains of the great rivers. This movement produced Mesopotamian civilization in the late 4th millennium, and the Indus culture, not a Mesopotamian colony, was a later product of similar stimuli in the 3rd millennium. The original focus of this culture may have been Armenia, a country rich in metals and possibly the starting point for the many early race movements across the highlands of Iran—in one direction toward Elam and southern Mesopotamia, in the other toward central Asia and India. The Indus culture presumably ended with the Aryan invasions.



AFTER 'ARCHAEOLOGICAL SURVEY OF INDIA'

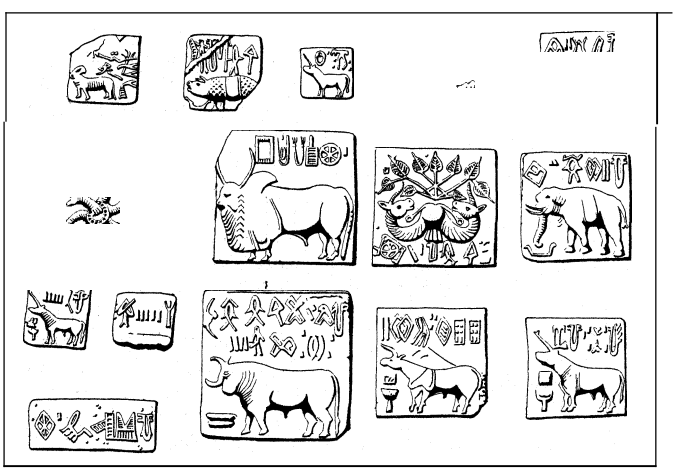
FIG. 7.— PREHISTORIC COPPER IMAGE (?) AND WEAPONS FROM GUNGERIA

B. VEDIC AND PRE-MAURYA

(C. 1500–322 B.C.)

It will be assumed that the Aryans entered India from the [illegible] about 1500 B.C. and occupying the Punjab, gradually passed on to the Ganges valley. They probably brought with them a knowledge of iron and a superior breed of horse, and it may have been these advantages that enabled them to subjugate the existing peoples uho already possessed cities and forts and a more developed material civilization. After the first period of conflict, the Aryans (as with the later invaders, Scythians, Huns and Mughals or Moguls) ceased to be foreigners and became Indians; long before 500 B.C. northern India had become the seat of a mixed culture in which—and especially in its art, both as regards motifs and technical achievement—the non-Aryan element predominated. The conguerors had been conquered by the conquered.

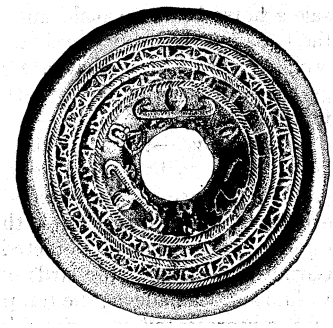
Vedic literature. mainly in the relatively later texts. reveals a knowledge of tin, lead, silver, gold and iron. of cotton, silk. linen and woolen garments, sometimes embroidered, vessels of gold and silver, iron needles. bedsteads, thrones, turbans, jewelry, earthenware, round and square huts and storied buildings and



AFTER ARCHAEOLOGICAL SURVEY OF INDIA

FIG. 8.— SIXTEENPREHISTORIC SEALS OF THE INDUS VALLEY CULTURE

wheeled vehicles. Some or all of these arts may have been known to the Aryans before they entered India, but probably the use of bricks, and certainly everything connected with maritime or purely Indian products (chank, ivory, cotton, pearls, indigenous dyestuffs. etc.), they must have found in India for the first time. The sulvasutras show a knowledge of principles now known as those of dynamic symmetry. Vedic culture shows little or no evidence of Babylonian or Semitic connections.



AFTER ARCHAEOLOGICAL SURVEY OF INDIA," BY PERMISSION OF THE HIGH COMMISSIONER OF INDIA

FIG. 8.— PRE-MAURYA STONE DISK FROM BHIR MOUND. TAXLLA

Some terra-cotta figurines. most of them of the mother-goddess type. from Mathura (mod. Muttra) and elsenhere have been dated in the pre-Maurya period. The greatest number of pre-Mauryan antiquities have been obtained at the Bhir mound, Taxila; most notable among these are the finely wrought polished sandstone disks, with bands of concentric ornament. in which are found cable, cross and bead and palmette motifs, the taurine symbol, elephants. fan palms and the nude goddess. It is also certain that the cutting and polishing of hard stones and the technique of glassmaking had attained. as early as the 4th and 5th centuries B.C., a perfection that was never afterward surpassed; and when in the Rlaurya period stone sculptures are first found, the surface of the hard stone is highly polished. One other important type of early art is represented by the punch-marked coin symbols; these coins were in use from about 600 B.C. to A.D. 100. The marks include several hundred types; among the commonest are the mountain (usually with three or more peaks—the so-called chaitya of older numismatists), river or tank with fish. sacred tree, elephant, horse. bull, sun, moon, caduceus and taurine; the lion, rhinoceros. makara (crocodile) and human figure are rarer. No linga (phallic symbol), thunderbolt, footmark or stupa is represented. These signs (rupa), forming an extensive symbolic repertory, appear to have been those of issuing and ratifying authorities. Many of the symbols are those of particular deities; for example, the three-peaked mountain with crescent moon is otherwise known to have been a symbol of Siva, and so also the bull. Few or none of the marks are exclusively Buddhist. Some are connected with particular cities, and in their day identified the issuing mints.

As regards design the same forms which are found in the reliefs of the Maurya, Sunga and Xndhra periods were already current during many centuries before the 4th B.C. These forms include meanders, palmettes, vases with flowers, sacred trees, diapers. spirals, frets. twists and the like. animals addorsed or affronted and fantastic animals of all kinds Many or all of these characteristic forms are clearly related to, but not identical nith, Mesopotamian types, Assyrian or older. They constitute a common ground of early Asian, and in India are cognates of the Mesopotamian forms, not late borrowings. The fact that they are found extant only in the stone sculpture when it first appears in the Maurya period is of course no proof of their late origin; some of the most ancient survive most characteristically in quite modern folk art, and may well have been current during three or four millenniums. Thus, the motif of animals with interlacing necks, knonn in Ceylon. where it is one of the commonest motifs of folk art, as puttuva. was already current in Sumerian art of the 4th millennium B.C., and many other instances of the same kind could be cited.

As regards sculpture, late Vedic literature, in nhich a large non-Aryan element had been absorbed, affords evidence for the making of images of popular deities in impermanent materials; and it is certain that the earliest known stone figures (after the Indus Valley types), viz., the yakshas of the Maurya and Sunga periods, despite their retention of primitive qualities (frontality, etc.), are not first efforts in any sense; they represent an already advanced stage in stylistic and technical development. There is also the evidence of pre-Maurya terra cottas representing the nude goddess and some other types. The latter are of very great importance for the history of art, for though they belong to a stylistic cycle older than that of the stone sculpture, and are still too little known, they provide connecting links in style. technique and costume between the oldest Indo-Sumerian art and that of the historical period. In their sense of the inseparability of beauty and fruitfulness, and in details of ornament (the body ornament later known as the channavira, and the broad auspicious girdle. the mekhala), as well as in some facial types, they are related to the earliest sculptures in stone.

C. Maurya, Sunga and Early Xndhra Periods (322 B.C.–*c.* A.D. 50)

1. Maurya (322–185 B.C.).—With the Maurya period, and especially the reign of Asoka (*q.v.*), from about 274 to 232 B.C., sculptural and architectural monuments in stone are found for the first time. These fall more or less definitely into two groups: (1) the court art of Asoka; and (2) the popular and perhaps more purely native art. The chief monuments of the court art are the remains of the great palace at Pataliputra (Patna) and the monolithic pillars on which Xsoka's well-known edicts are inscribed. The edict pillars, six in number, distributed over an area including Meerut, Allahabad. Benares and the Nepal Terai. have round polished monolithic shafts and are provided with elaborate capitals consisting of a lotus bell, an abacus decorated with geese, palmettes or Buddhist symbols and a crowning sculpture in the round consisting of one or more animals; they average from 40 to 50 ft. in height. The finest has been excavated at Sarnath, the old "Deer park" at Benares, where the "Turning of the Wheel of the Law" (the Buddha's first sermon) took place. There are four addorsed lions supporting a wheel (the Dharmacakra,

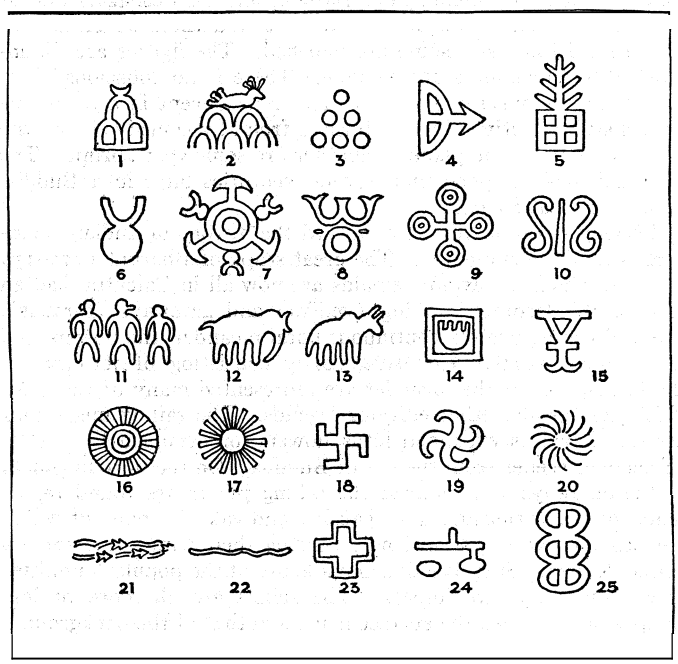


FIG 9 — SYMBOLS FROM PUNCH-MARKED COINS, 500 B C TO A D 100 (1, 2) Mountain; (5) railed tree; (6) taurine; (8) combined chakra and trisula; (9) Ujjain symbol; (10) Srivatsa; (16, 17, 20) solar; (21, 22) rivers; (24) steelyard; (25) tank

"Wheel of the Law and of Dominion"); the abacus is decorated with four smaller wheels and a bull, lion, elephant and horse. Other pillars bear a single lion, a bull or an elephant. The naturalistic treatment of these animals. the technical accomplishment of the work and the fact that this is evidently a stylistically late art all distinguish these sculptures from the contemporary religious sculptures to be referred to below. It has been argued that the court art of Asoka owes much to western sources. and even that it was produced by imported craftsmen. It is certain that close and friendly relations mere maintained between the Maurya and

Seleucid houses. The problem, however, is far from simple. All that is beyond doubt novel at that period is the use of stone to a limited extent for architectural purposes and probably the use of stone for large sculpture. Nor can the Maurya period. with its invaluable but very imperfect record, be considered alone; early Indian art as a whole and the folk art up to the present day bear an intimate relation to western Asian art. This relation is more obviously Babylonian-Assyrian than Persepolitan. Indian bell capitals, for example, are very different from those of Persia. Indian shafts are smooth or octagonal, and monolithic; Persian, fluted and segmented. The use of animal standards as symbols of deities is at once Indian, Chaldean and Assyrian, but not Achaemenid or Seleucid. The so-called Persepolitan capital with addorsed bulls (often horses, elephants or lions) again is so widely distributed and so much an integral part of the whole architectural style in the 2nd century that it could hardly have been introduced only a century earlier. So too with the civil architecture represented on the reliefs, showing walled cities with towers and battlements like those of Assyria, with the mythical monsters and with the elements of the decoration; in all, the relationship to western Asia is conspicuous, but the individual character is equally unmistakable. Nor is it possible to suppose that no art of any kind existed in India before Asoka, or that there existed some different sort of art just before Asoka, of which no trace can be found in the abundant reliefs just after him. Thus, Maurya and Sunga art directly continue the traditions of pre-Maurya art; Indian and early Persian art are both late phases of a tradition common to all western Asia.

2. Sunga (185–72 **B.C.**).—The early Indian stone sculpture in the round of Maurya and Sunga date is represented by a number of colossal figures in royal costume, apparently statues of independent or attendant yakshas and yakshis, two of these having been found at Parkham, near Baroda, and at Besnagar, one at Deoria near Allahabad, one in Mathura and three at Patna; all are in sandstone, and some are polished. The figures are distinguished by great mass and volume. There is no conscious effort toward grace, but a statement of an ideal concept in a technique that is still primitive; for the form is frontally conceived, and the transitions from one plane to another are somewhat abrupt. The style achieved its perfection several centuries later in a Buddha figure set up at Sarnath.

Bharhut.—From this time onward the history of Indian sculpture is richly documented. The great stupa of Bharhut (175–150 B.C.), of which the extant remains are now all in Calcutta. had an elaborately decorated railing (vedika) and gateways (toranas). The rail coping bears a continuous floral meander, the floaers and leaves being partly vegetative, partly consisting of jewelry; in the interspaces of the meander are represented many of the Buddhist Jatakas and other edifying legends. The railing medallions are developed as expanded lotus flowers, or occupied by Jataka subjects or scenes from the life of Buddha. On the upright pillars of the gateuays and some of the railing pillars are found representations of various devatas, yakshas and yakshis, many of which are provided with inscriptions recording their names, as, for example, Kubera; thus, Buddhism made use of the popular divinities as guardians and worshipers. The reliefs are all more or less compressed between the surface plane and that of the background, lacking equally the plastic volume of the Bhaja types and the technically more advanced relief of Sanchi; but the costumes. though modified, are closely related to those of Bhaja. The various decorative motifs, floral and geometrical, are indicative of a highly evolved art. Of the same date are some of the railing pillars of stupa II at Sanchi and the remains of early sculptured walls at Jaggayyapeta and Amaravati.

Bhaja.—To the same school of art belong the reliefs of the early vihara (monastery) at Bhaja—this is apparent in their volume and in details of the costume, particularly the enormous turbans and the pearl-fringed bracelets, which last are found also on some early Sunga terra cottas. One of the most remarkable of these reliefs seems to represent Indra, seated on his cloud-elephant Airavata. Sacred trees (chaityavrkshas), guarded by railings and adorned with garlands and umbrellas, are to be seen, and on one side a horse-headed yakshi and a man, perhaps with reference to the Padaku-salamanava Jataka. On the opposite side of the doorway, which divides what are evidently two parts of a single grandiose conception of earth and sky, is represented the sun in a four-horsed chariot.

Iconography.—Prior to the Sunga period the major Indian deities seem to have been represented mainly or exclusively by symbols. Since Asoka speaks of engraving edicts on already existing columns, it is possible that the Mauryan bull and elephant capitals were originally erected in honour of Siva and Indra. Garuda and makara standards of Sunga date at Besnagar refer to Vishnu and Kamadeva ; the fan-palm capitals. perhaps to Baladeva. Siva is represented on early coins by a bull or by a mountain of three peaks surmounted by a crescent; later. in the Kushan period, he appears in person together with the bull and other symbols; Indra and Agni appear on the coins of the Pancalas in the 2nd century B.C.; the abhiseka (lustration) of Sri-Lakshmi, on those of Azilises in the 1st (as well as on the earlier Bharhut reliefs and on terra cottas); other forms of Sri, on coins of Amoghabhuti. Indra and Brahma are freely represented in Buddhist art at Bharhut and Sanchi wherever the narrative requires; the former with his vajra (thunderbolt) and a vessel containing the "Water of Life" and usually with a cylindrical metal headdress (*q.v.*), the first appearance of any kind of crown in Indian art (the original royal headdress is a turban).

Patanjali, commenting on Panini, *c.* 200 B.C., refers to the public exhibition of images of Siva, Skanda and Visakha; and there is evidence enough in the later Brahmanas, lawbooks, epics and Buddhist and Jain literature to show that the use of images and temples (*q.v.*) had come into general prominence from about 400 B.C. onward. Probably the oldest surviving anthropomorphic representation of a deity, forming a cult image, is that of Siva on the Parasuramesvara linga, from Gudimallam in eastern India a little above Madras; there the deity stands on a dwarf yaksha vehicle, and in this respect and stylistically, though more developed, recalls the Kubera of Bharhut. This early figure of Siva is a great and powerful work, fortunately preserved from a period when a majority of Hindu images were still made of wood or clay. There is an interesting, though later, reference to such images in the Divyavadana, where Upagupta, worshiping an appearance of the Buddha created by Mara, explains that he is bowing, not to the object before him. but to the Master himself, "just as people venerating images of Gods do not revere the clay, but the immortal ones represented by them."

Orissa.—Datable in the 1st century A.D. are the excavated monasteries of Udayagiri and Khandagiri in Orissa. The best sculptures are reliefs forming a frieze in the upper story of the Rani Gumpha; the subject, which includes the hunting of a winged deer as a part, has not been identified. The monasteries there are, so far as can be determined, all Jain; but many of the motifs familiar to Buddhist art (*e.g.*, the lustration of Sri-Lakshmi and the sun drawn in a four-horsed chariot) are found. Above the arches of the cell doors are found three-headed serpents (Nagas), and below the frieze a series of small Garuda brackets, both features that were later on extensively developed in Khmer art.

3. Early Andhra (75 B.C.–A.D. 50).—*Sanchi*.—The most perfectly preserved Buddhist monument in India is the great stupa at Sanchi in Bhopal. Enclosed and hidden within it is an earlier brick stupa dating from the time of Asoka, but the stupa itseli, as enlarged and cased with masonry, dates from the 2nd century B.C., the plain railing from the same time and the gateways from the first half of the 1st century A.D. Stupa II at Sanchi is to be dated in the 2nd century B.C. and stupa III belongs to the 2nd century A.D.

The reliefs of the great gateways of the main stupa, occurring on the upright pillars and on the horizontal architraves, illustrate Buddhist legends, including Jatakas and scenes from the Buddha's ultimate incarnation. They are executed with a delicacy and wealth of detail suggestive of ivory carvings, and indeed a votive inscription records that some were carried out "by the ivory workers of Bhilsa." Apart from their original intention they afford a veritable encyclopaedia of manners, weapons, decoration

and symbolism. At the base of the upright pillars are beautiful figures of guardian yakshas; and the architrave brackets are yakshis represented as dryads clinging to their trees and leaning outward. On the tops of the uppermost architraves are Buddhist symbols guarded by cauri-bearing yakshas.

Just as at Bharhut, and in early Indian art generally, in the scenes from the Buddha's life: though they tell their story with perfect clarity. the Buddha himself is never represented in human fotm but only by symbols — footprints (padukas) and umbrella (chatta) or wheel (chakra) or tree. These symbols indicate the presence of the Buddha wherever required in the representation, and some refer to specific episodes in the life, including most of those which were afterward grouped together in panels illustrating the Four (or Eight) Great Events. Thus, the wheel designates the First Preaching of the Law; the sacred tree (Bodhi-druma) with its altar or railing. the Great Enlightenment. Where the tree is represented with guardian yakshas on either hand, the prototype of the later Buddha triads, where the Buddha is seated between a pair of attendant Bodhisattvas, can be recognized, for there is no doubt that the principal Bodhisattvas, especially Padmapani (Xvalokiteshvara) and Vajrapani, were originally guardian yakshas.

Further, the art of Sanchi, though Buddhist in theme, is scarcely Buddhistic in content: the legends illustrated are always edifying. but the manner of treating them and the feeling for the human form are far from ascetic or introspective. And this becomes especially evident in connection with the accessory figures, such as the dryads, filled as they are with the abundance and joy of life.

A very important school flourished at Mathura from the 2nd century B.C. to the 6th A.D. The early fragments are in a manner closely related to that of Bharhut. More important are those which cover the period of transition from the old aniconic to the later anthropomorphic representation of the Buddha figure: these are of Kushan and perhaps somewhat earlier (Indo-Parthian or Ksatrapa) date and will be discussed below.

D. Kushan (*c.* AD. 50–241)

Assuming a date of A.D. 50 for the invasion of the Kushans, it can safely be said that the first century and a half of the Christian era represents the most critical period in the history of art in India, the 2nd to the 4th century that of highest achievement. For the earlier period, and only to a somewhat lesser extent the later, the prolific school of Mathura is of primary importance, for types were evolved there that can be traced in all the later development. It must be remembered that at all times "Buddhist India" was equally and at the same time a Hindu India; the so-called Hindu renaissance of the Gupta period does not represent a reaction, but rather the flowering and culmination of a previous development. So far as cult and literature are concerned, this is self-evident; as regards the art. while Buddhist monuments are at first much more abundant and magnificent, this probably means that Hindu cults adhered longer to the use of impermanent materials such as wood and clay for buildings and images, as in southern India up to the beginning of the 7th century.

The period of florescence of Buddhist art at Mathura coincided with the period of the great Kushan dynasty. These Scythian invaders were established in northwestern India as early as the 1st century A.D. The dynasty came to an end in A.D. 241 with an invasion of Shapur I of Iran. The greatest ruler and patron of Buddhism was Kanishka, whose regnal dates are disputed: although some scholars believe his reign began as early as A.D. 78, others suggest a date as late as A.D. 144.

1. Buddha Types. — Within the first century and a half of the Christian era the Buddha figure for the first time replaced the old symbols, which nevertheless remained in use both in Gandhara and at Amaravati considerably later. Images of other deities had long existed. and the influence of current devotional tendencies acting on Buddhism and Jainism must have led to a similar development. The fixing of a date for the earliest images of Buddhas or jinas is more difficult. Paleographic evidence would seem to place those of jinas from the Kankali Tila, Mathura, as early as the middle of the 1st century. The only certain date for an early image of Buddha is that of the colossal image set up by Friar Bala at Sarnath in the third year of Kanishka's reign. It should be noted that this Buddha type is distinguished by certain peculiarities not found after the Kushan period (with one exception of 5th-century date), and rarely met even after the middle of the and century. The seated figure is always on a lion throne, never on a lotus. Many other images, both standing and seated, in the same vigorous style derived from that of the early yaksha types, have been found at Mathura or are of Mathura manufacture, exported and set up at sacred sites widely distributed in the Punjab and the Ganges valley.

The earliest Buddha (and jina) type shows the ends of the shorn hair forming a single conical spiral on the top of the head, bearing no resemblance to the ushnisha in the sense of a cranial protuberance such as characterizes the Buddha figure at Xmaravati, in the Gupta period, and subsequently both within and beyond the boundaries of India proper. When this cranial protuberance appears, it, together with the rest of the head, is covered with innumerable short and tight curls, curling to the right. According to the Buddha legend, the Bodhisattva, when first adopting the homeless life of an ascetic, cut off with one stroke of his sword both his long hair and the turban which covered it, and these were received by the gods and worshiped by them as the Great Crest relic (cuda maha); the remaining hair, two inches in length, curled tightly to the right, and so remained throughout the Buddha's life, never again needing to be shorn. This could have been understood to mean either a single curl or many curls; the ambiguity seems to be reflected in the two varieties of the Buddha type referred to above, the interpretation in the sense of many curls very soon supplanting the other. The question of the cranial protuberance is more involved. As in the case of other images of deities (the Buddha even in his own lifetime is more than man, he is recognized as "God of gods" when, at the Presentation, the tutelary yaksha of the Sakyas bows before him, and as the object of a cult he must be called a deity), the Buddha image represents a dogmatic conception; the essential element in this conception is that of the idea of the mahapurusha ("great male," also a designation of Vishnuj and chakravartin ("universal emperor" or, alternatively, "world teacher"). Buddhist texts take over from Brahmanical sources the lists of physical peculiarities which characterize such a being; for example, the soles of his feet and palms of his hands bear stigmata of the wheel, and there is a tuft of hair (urnaj between his eyebrows; all these peculiarities are commonly found in Buddha images. Most of the other marks are relatively inconspicuous or not externally visible. One is of particular importance for the present inquiry: the infant Bodhisattva is said to be unhisosiso, ushnisha headed. In interpreting this and other of the marks (in all 32 major lakshanas and 80 minor signs), it should be borne in mind that they must originally have been conceived as characterizing an adult. Now ushnisha in early Indian literature is the regular word used for the turban; which headdress is a mark of rank, worn by kings or by others on special occasions. Ushnisha headed can mean only: (1) having a head like a turban; or (2) having a turban on his head. Inasmuch as the 32 marks really characterize a chakravartin as an adult being, and as the turban is actually a mark of rank, the latter interpretation is to be preferred, in the sense "destined to wear the turban," as we have to do with a child. But as the Bodhisattva became not a universal emperor but a Buddha and abandoned his turban and long hair, he had to be, as always: represented (with the exception of certain crowned types which may be Dhyani Buddhas) as bareheaded. In the early Mathura figures the problem seems to be ignored. It would appear that after these had been in vogue for some time a necessity was felt to embody the unhisosiso idea in the canonical image, and this was done by making the ushnisha a cranial protuberance; this took place (in the 2nd century A.D.) at the same time that many curls were substituted for one.

The figure of Indra as Santi, of the Buddh Gaya railing (*c.* A.D. 100), has the hair represented in schematic curls, with the appearance of a cranial protuberance, and many representations of yakshas have curly hair; the existence of such prototypes may have contributed to the formation of the Buddha image as ulti-

mately accepted.

2. Hindu Types. — Next in abundance to the Buddhist remains are those of the Jains. The site of the Vodva stupa, founded in the 2nd century B.C., has yielded figures of jinas, similar to those of the Buddha except that in the case of Parsvanatha the jina's head is sheltered by the hoods of a Naga rising above it. Highly characteristic for Jain art are the ayagapatas, or votive slabs bearing reliefs representing stupas or elaborate designs, with a central seated jina, quadruple trisula symbol and the Eight Auspicious Symbols.

Figures of Hindu deities are found chiefly on the coins of Gondophares, Kadphises I and II, Kanishka, Huvishka and Vasudeva. The variety of types of Siva is especially noticeable. Many-armed and many-headed types appear for the first time in the 2nd century; Siva is then four armed and sometimes three headed (Mahesa), the latter type being evidently very popular since it spread quite early to Gandhara and central Asia, where it occurs in sculpture and painting. Many of the Yaudheya coins bear a six-headed Skanda. On coins of Kanishka a great variety of deities appears: Greek, Zoroastrian and Indian. The figure of the running nind-god is original and remarkable. The Buddha appears first on a coin from Ujjain, then in three types on coins of Kanishka. The Brahmanical temple site at Mat has yielded the famous inscribed statue of Kanishka and other royal effigies.

3. Gandhara (Greco-Buddhist) Sculpture. — The prolific Greco-Buddhist school of the former North-West Frontier (Afghanistan and part of the Punjab, including Peshawar and the site of Taxila) has always attracted the attention of archaeologists. Its subjects, as in Indian Buddhist art, are drawn from the Buddha legend, and there are countless images of Buddhas and Bodhisattvas and of other deities such as the Tutelary Pair, Kubera and Hariti. The influence of the school is widely extended in central Asia, affecting China. Korea and, to a lesser degree, Japan.

Very few Gandhara images bear dates, and no one of these dates is in a known era. According to some interpretations these dates indicate a beginning of the art in the 1st century B.C., but at Taxila, where excavations have been scientifically conducted, Greco-Buddhist art is entirely absent from the Scytho-Parthian and very early Kushan levels of the city of Sirkap, and appears only a little before the time of Kanishka. In any case the period of greatest production coincides with the reigns of Kanishka (A.D. 120) and Huvishka. in the 2nd century A.D. A. Grünwedel dates Kanishka A.D. 78 and makes the Gandhara school begin in the 2nd century, thus later than the establishment of the Mathura type. But the Buddha image may have come into use, as the result of a common religious necessity, simultaneously in both areas, though the priority for Gandhara, even if established, would not affect the fact that the Indian Buddha image of the Gupta period is derived directly from the early Mathura type, as this in turn is derived from that of the yaksha types of the earliest Indian school. It may be safely said that the influence of the Greco-Buddhist school in India has been much exaggerated.

The Gandharan type differs from Indian types in more than one way; iconographically by a different treatment of the hair, and in the seat, which in Gandhara is nearly always a lotus, in India at first always a lion throne, despite the fact that the lotus seat as a divine symbol had been long known. Stylistically. the differences are more profound. Gandharan is "late," and belongs to an age of aesthetic decadence in its own cycle; it is naturalistic by intention, although its appearance of realism is no longer based on any structural reality; its graces are deliberate and languid; the solid folds of the drapery are carefully represented. The Indian type still has all the energy and volume of primitive art; it makes no pretensions to grace. is without naturalistic intention, and the drapery is schematic and clinging. It would hardly be possible to juxtapose two contdmporary styles more distinct in kind.

The Gandharan art in its own environment is gradually indianized, and its productivity ends with the Hun invasions of the 5th century.

The finest, most "spiritual" examples of Gandharan sculpture are the stucco reliefs of the 3rd century and later.

E. Later Andhra (c. A.D. 50–320)

The reliefs of Amaravati, dating from the early and century A.D. and later, adorned a great stupa, with the largest and most richly decorated stone railing ever constructed, surrounding it. This stupa was one of numerous Buddhist monuments erected or enlarged by the later Andhra kings in the Kistna-Godavari delta, their seat of government. This later Andhra art is the most intimate and most enchanting of any in India. Just as in literature epic form was passing into "poetry" (kavya), so for the first time sculpture was becoming "art,"

The subject matter of the reliefs did not change, The principal compositions represent Jatakas and scenes from the life of Buddha (in accordance with traditions earlier than that of the Lalita Vistara). Vital monuments of the Buddha epic are more dramatically and emotionally conceived; the gestures, especially those of women, possess a peculiar poignancy, reminiscent of such contemporary Buddhist literature as the Bodhicaryavatara and the work of Santi Deva. This poignancy survives indeed at Ajanta, and Gupta art is very closely related to that of the Andhras in the 3rd century; but very soon, insofar as it belongs to life. it passes into the formalities of chivalry. and insofar as it belongs to art. into deliberate emphasis and even exaggeration. The same is true of the decorative motifs; a sense of organization already long perfected is applied there to traditional motifs, with an inimitable delicacy and firmness. The ornament, in fact, is of precisely the same quality, and has the same value as the reliefs with figures. An art which had been entirely corporeal now acquires a spiritual content, becoming Buddhist in a more than formal sense.

As regards the Buddha figure of Amaravati, and the similar early types found in Ceylon, the use of a cult image was still new, and the figure therefore retains more of the austerity and massive individuality of primitive art than do the reliefs and ornament.

F. Gupta (A.D. 320–*c.* 600)

In early Gupta art the spirit is still at the height of its vitality, but maturer. more intellectually conscious, more introspective; at the same time the expression is less reserved. Gupta art is characteristically logical, sophisticated, gracious and sensuous. Early Gupta art is important in the history of Indian art as representing a completely unified national style within the limits of India proper. and at the same time embodying the types of which the influence predominated in the southeastern and far eastern developments of Indian iconography and architecture. The Gupta style is unmistakably recognizable in the sculpture and architecture of jth- to 7th-century date in Burma. Siam and Cambodia.

The Buddha figure of the Gupta period is characterized by its definition and refinement; the diaphanous robe covering one or both shoulders clings closely to the body, almost without folds ("wet drapery"); the hair is invariably arranged in short curls, the ushnisha is indicated as a cranial protuberance; and there is a lotus or lion pedestal. usually with figures of donors. The finest examples have been found at Sarnath and Mathura and in relief at Ajanta. One colossal copper figure, neighing more than a ton, found at Sultanganj, is in the Birmingham Museum and Art gallery. Brahmanical sculpture is represented by mukha lingas (Siva) of admirable workmanship from Bhumara, Khoh and other sites in Bundelkhand; reliefs of Vishnu, Narasimha and Durga. and the magnificent Varaha Avatar at Udayagiri, Gwalior; Ramayana scenes from the basement of the late Gupta temple at Deogarh; sculptures of the Ramesvara cave, Ellora; and the stucco reliefs of the Maniyar Matha at Rajagriha.

The famous paintings of Ajanta and Bagh, all on the walls of excavated Buddhist temples and monasteries, the so-called caves. belong for the most part to the Gupta period, though none appear to be immediate products of Gupta patronage. Those of caves IX and X date about the beginning of the Christian era or even later; those of caves XVI and XVII, about A.D. 500; those of cave XIX, about the middle of the 6th century. Those of caves I and II date from the 7th century, and thus are early medieval. The subjects are all Buddhist, representing Jatakas and scenes from the life

FRESCO PAINTING OF THE BODHISATTVA, VAJRAPANI, A DIVINE-HUMAN ARMED WITH A THUNDERBOLT, FROM THE CAVES OF AJANTA

The Illustration was taken from Cave I. There are about 30 caves excavated in the south side of the bank of the ravine of the river Wagura, some three and a half miles from Ajanta, India, which were used as dwellings and meeting-halls by the Buddhist Order from 200 B.C. to the seventh century A.D. Many of the interior walls of these caves are covered with fresco paintings, which are very decorative. These have been preserved and form an important body of evidence of pre-Hindu art in India

SCULPTURES AND SCULPTURAL DETAIL

1. Vishnu. Stone. Height 8¾ in. Kashmir, 9th century
2. Avaiokitesvara, Bodhisattva. Copper, gilt and jewelled. Height, 12⅜ in. c. 11th century
3. Vishnu. Copper. Height 25½ in. Bengal
4. Bodhisattva. Brick and stucco. Northern temple, Polonnaruwa, Ceylon. 12th century
5. Devata, detail from the Rajrani temple, Orissa, c. 1150 A.D.
6. Deity on horse, detail from the Surya Deul, Konarak, Orissa, 13th century
7. The Eight Great Events (in the Life of Buddha); Slate. Pala, 10th century. Bihar or Bengal
8. "Rukmini." Sandstone. Height 5 ft. 4½ in. Nokhas, Etah District, c. 10th century
9. Mahavira (founder of Jainism). Soft schist. Later Caiuyka. c. 11th century. Aminbhavi, Mysore
10. Vishnu. Sandstone. Height 4 ft. Etah District, c. 1000 A.D.

Copper. **Venkatesvara temple, Tirumala**

of Buddha, with the popular mythology of yakshas and Nagas as incorporated in Buddhism.

G. Early Hindu Dynasties (c. 600–c. 850)

1. **Nalanda.**—Harsha (q.v.) in the first half of the 7th century revived the glories of the diminished Gupta empire. He may be regarded as responsible for the restoration of the great monastery at Nalanda, and for the transition from Gupta to medieval art in Magadha generally. He also took possession of the Valabhi kingdoms of Kathiawar and Gujarat, but was defeated by the Chalukyan king Pulakesin II. A more detailed account can be given of early medieval art in the Deccan and the far south.

2. **Pallavas.**—The Pallavas originated in the Kistna-Godavari area inheriting the artistic tradition of the eastern Xndhras. and were forced to move southward about 600. The sudden appearance of architecture and sculpture in stone is due to the accomplished Mahendra-varman I (600–625); it is known from one of his inscriptions that up to that time structural temples had been built of brick, timber, copper and mortar, and the implied absence of stone construction corresponds to and explains the appearance of Pallava art already fully evolved in the 7th century. All the sculpture at Mamallapuram, including that of the excavated and monolithic temples (the "Seven Pagodas"), and also the great rock-cut relief representing Bhagiratha's penance and the Descent of the Ganges. belong to the first half of the 7th century. The sculpture there. Pauranik in theme for the Pallavas were Hindu kings. is of a very high order. In the early 8th century the sculpture develops in more strictly architectural application. in connection with the great structural temples at the Pallava capital. Kancheepuram, passing in the 9th into that of the Chola period. Painting which has been assigned to the time of Mahendra-varman I has been found in a Jain excavation at Pudukkottai.

3. Early **Chalukyan.**—Some temples nith sculptures at Badami antedate Pulakesin I (550–566), founder of the dynasty. Later artistic history shons a mixture of northern and southern elements. but is mainly a development of Pallava forms. The Brahmanical caves at Badami and Aihole (especially cave III, A.D. 578) contain a series of large and important reliefs illustrating Pauranik mythology and legend Worthy of special mention also are the sculptured roofing slabs from Aihole, dating from the early 7th century, in the Prince of Wales museum. Bombay. The Virupaksha, most important of the structural temples at Pattadkal, was built about 740, probably by architects and masons brought from Kancheepuram, and shows a corresponding Pallava character in the sculptured reliefs. The Buddhist caves at Aurangabad. dating from the late 6th and early 7th centuries, contain many important figures. At Ellora, the Das Avatara. Ravana ka Khai, Dhumar Lena and Ramesvara caves appear to range from 650 to 750.

4. **Rashtrakuta.**—The Rashtrakutas succeeded the Chalukyas in the western Deccan in 753. Their most important monuments are at Ellora and Elephanta; the latter are easily accessible from Bombay. At Ellora the famous rock-cut Kailasanatha temple, a huge and complete monolithic shrine excavated in the side of the hill, is in a purely Dravidian style, immediately derived from that of the Virupaksha at Badami. Of the very numerous sculptures illustrating Saiva subjects, the finest represents Siva and Parvati seated on Mt. Kailasa. with Ravana imprisoned within the mountain below, endeavouring to cast it down and succeeding in causing a tremor. This, and the Varaha Avatar of Udayagiri, alluded to above, are the finest examples of reliefs which deal with nhat may be described as cosmic or geotectonic themes. Remains of painting on the ceiling of the porch of the upper story are of two periods. in part no doubt of the 8th century and nearly contemporary with the actual shrine. These are the oldest surviving Brahmanical frescoes, but literary references show that painting had been practised both as a religious and secular art from time immemorial.

At Elephanta the most famous and perfectly preserved sculpture is a colossal relief in the main excavation, a three-headed bust which has often, though incorrectly, been called a Trimurti. It is actually an icon of Siva in the form known as Mahesa, and many other examples exist, of which one of the best is a later relief in the University of Pennsylvania museum. Philadelphia.

5. **Kashmir.**—The old town of S'ijrabror has yielded early sculptures in which the influence of the Greco-Buddhist art of Gandhara is still apparent. The most interesting of these are representations of the goddess of fortune, Lakshmi, seated with a cornucopia. and these types can be folloned well into medieval times, gradually becoming completely indianized. The remains of a tiled cockpit of about the 5th century at Harvan are unique. The devices on the molded tiles represent men seated and in balconies, equestrian archers in chain armour, deer, fighting cocks, lotuses and a fleur-de-lis motif; in technique they recall the so-called Han grave tiles of China.

The Vantipor temple sites of early 9th-century date have yielded small and admirably executed stone figures of Vishnu in a style peculiar to Rashmir and the neighbouring Chamba and Kulu. and with these there appear also Siva types. including a three-headed Mahesa and an Ardhanarisvara. Similar Vishnuite images of brass inlaid with sil er and copper have been found in Kulu, together with a Buddha image in the same technique but of earlier (late Gupta) date. Buddhist 'bronzes" found in Kashmir, and ranging from the 6th to the 11th century, show that Buddhism survived to a late date, although it had already declined by the end of the 8th century, all the foundations of Avantivarman in the 9th being Brahmanical. The stone sculpture architecturally associated mith the great temples in Kashmir is unfortunately almost all in a ruined state.

H. Later Hindu Dynasties (From c. 850 Onward)

Later Hindu art again falls into three main divisions. corresponding to the geographical classification of the architecture, as Nagara (northern and eastern). Vesara (south central and western) and Dravida (southern). The character of Indian art had by this time definitely changed and hardened. The sculpture is no longer distinguished by plastic volume, but has acquired a linear character; that is, the form appears to be conceived from the standpoint of outline, and all the features are sharply defined. Its application is primarily architectural and one might say decorative, were it not for the fact that it retains a precise significance in all its details. Its forms are more complicated, partly because the theological development has brought in a greater variety of many-armed forms (these appeared first in the 2nd century, and were already common in early medieval work), and partly because of the tendency, innate in all late art, toward great intricacy and elaboration of detail and an overvaluation of merely technical skill, displayed as an end in itself.

1. Northern and Eastern. — The main schools are those of Bihar and Bengal (Pala dynasty); Orissa; and Bundelkhand and Rajputana. Under the Palas (750–1200) the main centre of production was at the important monastery and university of Nalanda in Bihar. The characteristic Buddhist images. together with Buddhist and Brahmanical examples from other sites in Bihar and Bengal. are executed with the utmost technical proficiency in a kind of black slate, and are represented in all large collections. Numerous and exquisitely made copper images have been excavated there or found elsenhere in Bengal (Rangpur and Chittagong). The themes were at first Buddhist. but the Buddhism was greatly mixed with Hindu elements and acquired as time passed a more and more tantric character. The names of two painters and sculptors, Dhiman and Bitpalo, are mentioned by the historian Taranatha as having been masters in the eastern school in the 9th century. The Bihar school exercised a powerful iconographic and stylistic influence on Sepal. Tibet. Burma and Java and Sumatra. Not only sculpture but also painting was practised; a number of Buddhist palm-leaf manuscripts from Bengal and Nepal. with painted wooden covers and illustrations in the text, have been preserved from the 11rth and 12th centuries. The style is most closely related on the one hand to the slightly later painting of the Gujarati school. and on the other to the contemporary frescoes of Burma (Pagan). The Pala school of painting in the 12th century was known even to the Chinese.

Sculpture in Orissa is typically Brahmanical, and occurs in connection with the series of great temples at Bhuvaneshwar, Konarak, Puri, etc., ranging in date from the 8th to the 13th century. The monumental horses and elephants and the erotic architectural sculptures of the Sun temple at Konarak are especially noteworthy.

2. Bundelkhand and **Rajputana.**—The magnificent temples of Khajuraho are literally covered with Brahmanical sculpture in a hard creamy sandstone, and isolated fine examples have been found at Mahoba, another Chandel capital. Jain sculptures too occur in abundance, but Buddhist works are relatively rare. To enumerate the sculpture in Rajputana would be impossible; there is much of quality.

3. South Central and Western. — An enormous revival of building and sculpture took place in the Deccan under the later Chalukyas after 973, under the Hoysalas of Mysore in the 12th and 13th centuries and in Gujarat under the related Solanki dynasty (10th to 15th century). The sculpture of the Deccan and Mysore is executed in a fine-grained dark chloritic schist, which is comparatively soft when first quarried, and lends itself to an unlimited elaboration of detail more appropriate to metalwork than stone. Almost all the work is of architectural application, and unbelievably rich in quantity and detail. Especially characteristic are the elevated temple basements, with tier upon tier of sculptured friezes, and the huge turned cylindrical pillars of the porches, with luxuriously developed bracket figures of dancers. In Mysore, Belur, Halebid, Dodda Gadavalli, Somnathpur and Sravana Belgola are among the most famous sites. At the latter place there is a remarkable monolithic image of Gommatesvara (son of the first of the 24 jinas of the Jain mythology), one of the largest freestanding figures in the world, 57 ft. in height. This was carved *in situ* for Camunda Raja in A.D. 981. Another figure at Ilivala is more than 20 ft. in height.

In Gujarat, Kathiawar and parts of Rajputana there existed another extensive development in a related style. In Gujarat proper, most of the temples are in ruins. At Girnar, Palitana and Taranga, Jain temple cities and places of pilgrimage, there is much sculpture still in *situ.* The most remarkable examples of the style, however, are to be seen at Mt. Abu (Dilwara, in southern Rajputana), in the temples of Vimala Shah (c. 1032) and Tejahpala (c. 1232); these are domed shrines with pillared halls.

4. Gujarati (**Jain**) Painting. — A Gujarati school of manuscript illustration flourished from the 13th to the 17th century, after which it was more or less modified by Mughal and Rajput influences. One manuscript dated 1237 is on palm leaf, all others are on paper; the earliest date is 1427. The majority of the manuscripts are Jain scriptures, but there is one secular example, a Vasanta Vilasa, dated 1451. Although the colouring is brilliant, the style is really one of pure draftsmanship; the outline establishes all the facts and this outline, though very facile and almost careless. is extremely accomplished.

5. Rajput Painting. — The tradition of mural painting, exterior and interior, even at the present day survives sporadically all over India: a good deal may still be seen in Rajputana, for example in the old palace at Bikaner. Paintings on canvas and illustrated manuscripts are very rare, but as paper gradually came into use, the older methods of painting on walls and panels or cotton cloth were employed on the new material. The technique of Hindu painting on paper is in fact identical with that of the older mural art as seen at Ajanta and described in the technical treatises. The themes of Rajput painting are religious (dealing especially with the Krishna cycle, but also with Saiva and Vishnuite mythology in general), epic (*Mahabharata* and *Ramayana*), lyrical and rhetoric (Rag-malas) and, less typically, secular (portraiture). The Krishna cycle and themes illustrating treatises on rhetoric (classification of heroines and emotional analysis), given a contemporary environment in court and village life, permit an exquisite delineation of every phase of love. The epic subjects, especially in early Jammu works, are treated on a large and almost mural scale. Especially characteristic are the sets of illustrations of the Rag-malas, vernacular poems describing the situations which are appropriate to each of the Ragas, or musical modes; these are usually 36 in number, and each has its particular hour and specific sentiment (see INDIAN MUSIC). Stylistically, Rajput paintings can be classified both geographically and in historical sequence. Very few examples show any approximation to the Gujarati style. The early ones from Rajputana and/or Bundelkhand are most distinctive; they show a robust analytical method of drawing, an indication rather than a representation of forms and an intensely brilliant colouring, like that of enamel or stained glass, by which the planes are established. A modified tonality gradually appeared, partly the result of Mughal influences; but the work of Jaipur artists, even from the 18th century when the outline had become more meticulous, can be recognized by its brilliancy and by its marvelous decorative treatment, especially of flowers and trees. The earlier Jammu productions too are strongly coloured, while the drawing is more provincial throughout. In some respects the most exquisite. and certainly the most refined if not the most powerful, phase of Rajput painting is that of the Kangra school, developed in the latter half of the 18th century under Raja Samsara Cand. Connected with this school are its offshoot in Tehri Garhwal and its early 19th-century secular development in Sikh portraiture. The Kangra school declined during the 19th century and became to all intents and purposes extinct. Related schools existed in Bengal and Orissa. By far the finest collection in the world is in Boston, Mass.; other examples are in the Lahore and British museums. and in private collections.

6. Miniature Painting. — It is highly likely that miniature painting in India is as old as the tradition of monumental painting. The earliest examples of Indian miniatures belong to the Pala period (8th–13th century). The technique and composition of these Buddhist illuminations reveal a perpetuation of classical prototypes such as Ajanta wall paintings. The Jain manuscripts of Gujarat, of the 13th century, have charm in wiry drawing and gay colouring, but are generally stereotyped in execution.

Rajput miniature painting is the work of artists attached to the courts of the Rajput princes from the 16th to the 19th century. Geographically it may be divided into a number of local schools in Rajputana, the Deccan. the Punjab, the Himalayas and Garhwal. The themes painted by the artists include Raginis or the personifications of musical modes connected with phases of love, illustrations of Indian epics and the romantic legends of the gods Vishnu and Krishna. Rajput painting is a combination of folk art and hieratic classic traditions and, more often than not, a reduction of the themes and techniques of mural painting to an intimate scale. Whereas the early miniatures of Rajasthan are primitive in conceptual presentation and decorative pattern, some of the later painting, like the 18th-century illuminations of the Kangra school in the Punjab, display a sophisticated combination of realism and lyric grace. Invariably, as in monumental painting, sacred legend is presented as contemporary experience.

The styles of illumination that flourished under the patronage of the Mughal emperors, from the 16th to the 19th century, differ from Rajput work in the complete absence of mystical and religious elements and in their emphasis on the picturesque and the natural. Although early Mughal painting was an outgro th of the Persian miniature style, in the great period under the emperors Jahangir and Shah Jahan the artists produced illuminations of an extraordinarily realistic character — perhaps under European influence — blended uith elements of Persian and Indian origin. In Mughal painting it is possible to differentiate between the work of local schools at Delhi, Lucknow, Jaipur, etc. The themes of the Mughal artists mere events from the life of the court, portraits and occasional subjects drawn from the world of the Hindu epics. Among the great masterpieces of the school are the paintings of birds and beasts executed by Jahangir's painter, Mansur.

7. Later **Developments.**—During the 19th century little of note in sculpture was produced in northern India. In southern India the indigenous tradition was preserved in greater purity; copper images, sometimes of large size and little inferior in quality to those of the 17th and 18th centuries, continued to be made, and hereditary craftsmen continued to work in stone.

In the 20th century a reaction against western mannerisms took place. especially in Calcutta where a considerable (Bengal) school of painters arose, and a very large number of pictures, mostly

water colours, were produced. The pictures are delicate and often very charming, but hardly powerful; the movement is comparable in some respects to that of the Pre-Raphaelites in Europe. Among the chief artists of this school may be mentioned Gogonendronath Tagore, mainly a worker in monochrome, who flirted with Cubism; Nanda Lal Bose; Asit Kumar Haldar; Samarandranath Gupta; and many younger men and some women.

III. CEYLON

1. Sculpture. — The artistic culture of Ceylon is at all times very closely related to that of southern India, but can be more conveniently treated as a consecutive development. One of the oldest documents is a carnelian seal representing a seated king, probably of the and century B.C., from the Yatthala dagoba in the south, now in Manchester. It is difficult to say whether any or how much of the sculpture surviving at Anuradhapura dates before the beginning of the Christian era; the greater part in any case belongs to the period ranging from the 1st to the 9th century. Among the finest sculptures in Ceylon, previous to their restoration and virtual destruction by pious Buddhists, were the Buddha figures, and one traditionally known as Duttha Gamani (reigned 1st century B.C.), at the Ruanveli dagoba site; the Euddha figures show a close relation with those of Amaravati and must date from about A.D. 200. Relief sculpture may date back to the 1st century A.D. or but little later; this applies especially to the Naga reliefs and formal trees rising from lucky vases, represented on stelae at the Eastern (so-called Abhayagiriya) and Ruanveli dagobas, for these are still in flattened relief and distinctly related in style to the Sanchi and early Sarnath reliefs of the 1st century A.D. The "moonstones," or stone doorsteps of monasteries or palaces, are of various dates, and consist of half-lotus medallions with friezes of animals (horses, lions, elephants and bulls, or geese carrying floral sprays). The steps above them are flanked by solid balusters (alamba bahu, hasti-hasta) consisting of heads and trunks of elephants, or makara heads spouting vegetation. while at each side stand reliefs representing Nagas holding lucky vases and cornucopias. The rock-cut reliefs of elephants at the Isurumuniya Vihara and the elephant reliefs by the Tissawewa lake are in Pallava style and evidently of 7th-century date.

At Polonnaruwa, the rock-cut statue traditionally regarded as a representation of Parakrama Bahu I (1153–86 or 1164–97) is magnificent. Not so fine, though impressive in scale and design, are the seated and reclining Buddha figures of the Gal Vihara, where there is also a colossal standing figure of the Buddha in prayer. Some of the brick and stucco figures of the Northern temple are extremely elegant. There exist colossal Buddha figures, also of the Polonnaruwa period, at Seseruwa, Awkana and Kon Wewa.

A limited number of small bronzes, or, more accurately, copper images, of very high quality have been found in Ceylon. One of the largest is a fine seated Buddha from Badulla, of about 6th-century date, but the finest of all are a well-known seated Avalokiteshvara and figures of Vajrapani and Jambhala. of 8th- and 9th-century dates, in Boston. There is a fair collection of similar figures in the British museum. Brahmanical bronzes apparently of Chola date have been excavated at Polonnaruna.

2. Painting. — Remains of painting have been preserved at a number of sites. There are a few traces of decoration at Anuradhapura, including some figures of dwarf yakshas. More remarkable are the Apsarases of the painted rock pockets at Sigiriya, dating from the 5th century and still in excellent preservation; these are voluptuous female figures, cut off by clouds at the waist in accordance with a characteristic convention, and casting down a rain of flowers upon the mortal world below them. At Hindagala near Kandy there is a fragment of fresco regarded by some as of rather early date. but probably medieval. By far the most extensive remains, though almost destroyed by neglect since their first discovery, are those of the inner walls of the Northern temple at Polonnaruwa; these illustrate Jatakas. but can be only inadequately studied in the bad copies exhibited in the Colombo museum. The Sinhalese chronicles (Mahavamsa) contain innumerable references to painting, but nothing more survived until the 18th century, when Kirti Sri Raja Simha, one of the last Kandyan kings, restored many shrines in the Kandyan provinces. Mention must also be made of the admirable decorated ceilings of Kelaniya, Kandy and some other places; these are often masterpieces of design. *See* also INDIAN ARCHITECTURE.

INDIAN BARRIER STATE, the name given to the proposals made in the United States in the 18th century to establish a neutral territory in the Mississippi valley that would be open to traders but closed to white settlers from any nation. It was to be a buffer zone between antagonistic countries

Often considered in negotiations concerning sovereignty in the west this proposal was made in 1755, when France and Britain were attempting to settle their conflicting claims in the Ohio valley. Again considered in 1761–62, the buffer zone was not needed after the Louisiana territory east of the Mississippi was ceded to England

In 1782 Spain, having had the Louisiana territory west of the Mississippi ceded to it. wanted to establish such a barrier state between the Mississippi river and the mountains, south of the Ohio. But the United States signed a separate treaty aith England in 1783 and established the western boundary of the United States at the Mississippi Spain's demands concerning the Indian state were not recognized Although the treaty of 1783 set the Great Lakes as the northern boundary of the new nation, many British traders retained their influence with the Indians. and a number of northwest military posts were not surrendered A confederation of Indians opposed the new government; and in order to mediate betneen the U.S. and the Indians, the British minister suggested that a barrier state be recognized in the Great Lakes area After the treaty of 1794, the military posts were surrendered. The Indians were defeated and the barrier state proposals were no longer considered. A British proposal to establish an Indian state west of the Great Lakes was also rejected by U.S. negotiators after the War of 1812.

INDIAN DESERT or THAR DESERT. Between the ancient Aravalli mountains and the wall-like front of the recently folded ranges nest of the Indus. and from the shores of the Arabian sea to within an average distance of 80 mi. from the Himalayas, extends a lowland region more than 200.000 sq.mi in area with an annual rainfall of less than 15 in. At one extremity it touches the northern tropic; at the other it passes beyond lat 32° N. Though known to geographers as the Indian desert, it now includes parts of both the republic of India and Pakistan In Pakistan it includes most of Punjab province and (west of the Indus) Dera Ismail Khan. the southernmost district of the North-\Test Frontier Province; the Kachhi district of Kalat (Baluchistan States union); the whole of Sind province together with Khairpur state which breaks across it from the Indian frontier to the Indus; and (southeast of the Sutlej-Indus line) Bahawalpur state.

In India it includes the western hem of southeastern Punjab state, the districts of Bikaner, Jaisalmer and Jodhpur in west Rajasthan, and Cutch.

A range of 10° of latitude implies considerable climatic diversity, and the area embraced leaves room for topographical variety. Yet it remains a major natural entity, the character of which is conveyed in the term "arid lowland." The tract has a general slope from the Himalayas to the Arabian sea; *i e*, northeast to southwest Along its inner margin, in Punjab state, India, the land between the rivers (doabs) rises to about 700 ft.; but the western portions of the doabs and the land south of the Sutlej. almost all Bahawalpur, lie below the joo-ft. contour line. The 250-ft. contour line cuts the Indus river as it enters Sind. the heart of nhich is well below this; the rest. with the conspicuous exception of the Kohistan or highlands. in the southwest of the province, not much above it.

To the southeast toward the Aravallis, the lowland attains a general level of more than 1,000 ft whence it grades down northwestward; *i.e.,* traversing the prevailing slope at right angles. Except for a fringe of Jaisalmer, and the basin of the Luni river draining southeast to the Runn of Cutch, all Rajasthan stands much higher than joo ft. and betrays its physical "betweenness." Its deep mantle of aeolian deposits allies Rajasthan superficially with the alluvial expanse upon which it encroaches. But it is not completely destitute of solid rocks, and these, rising as low heights above the sandy surface, indicate a deep-seated unity with peninsular India as a coastal margin shelving from the Aravallis toward the seas, persisting to the north until late geological time.

Climate. — Climatically the tract is one of extreme temperature range, daily and seasonal. This is tempered somewhat along the coast but increasingly marked northnard. November to February is warm. with a mean daily temperature of 55°–70° F. The minimum falls in January. The designation "cold season," which is applied to this period (particularly the latter half), serves to emphasize the contrast with conditions prevailing during the rest of the year; namely, the low night temperatures with liability to frequent frost in the Pakistani province of Punjab (Khushab mean minimum in January 41.5° F.; lowest recorded 25.0° F.) and in north Sind, though elsewhere such occurrences are very rare; the limitation imposed upon agriculture by the exclusion of essentially tropical plants at this season; and, lastly, the relief which its duration affords to Europeans. Pressure is high in relation to the neighbouring seas, and only light winds blow from northwest and west. Except during the passage of shallow cyclones from across the northwest frontier, toward the southeast, bringing a little rain to the Punjab fringe (rarely elsewhere), clouds are absent. March to October is hot. From May to July the mean daily temperature exceeds 90° F., with the maximum in June. Afternoon readings of 110° to 120° F. are registered Jacobabad, 127°, June 1919; highest ever recorded in this area). The rising temperature initiates a reversal in pressure and amid the changing conditions dust storms are generated.

Winds from the west and southwest are well established by April and persist until October, blowing with increasing strength as the depression deepens over the land until they reach their final expression in the southwest monsoon proper. But the air currents entering the lowland on that side emanate from the dry land belt about the head of the Arabian sea. Hence, they are not saturated like those which, originating over a broad ocean, impinge on the Bombay coast; but only "stray" just north of the Aravallis. They confer but scant benefit to the immediate coast fringe; beyond, they desiccate. Since also the Bay of Bengal branch of the advancing monsoon, which enters the lowland from the east on a downhill journey to its barometric goal, has already served the whole Gangetic plain, its remaining moisture is soon exhausted. Thus, of the 213,110 sq.mi. actually under review 47,590 receives less than 5 in per annum; 95,560, 5 to 10 in.; 69,960, 10 to 15 in. The following illustrates briefly the salient features of distribution, and how precipitation lessens from the northern and eastern rims of the desert to the western in the Upper Sind Frontier and Kachhi districts:

Station		Var.	Oct.-Feb.	Var.	March-May	Total (in.)
Shahpur	9.6	33	2.5	44	2.2	14.3
Sirsa	11.4	37	1.6	72	1.3	14.3
Pachbhadra	11.3	33	.7	81	.8	12.8
Bikaner	9.2	67	1.0	75	1.1	11.3
Jaisalmer	5.9	53	.5	80	.4	6.8
Multan	4.9	51	1.1	58	1.1	7.1
Karachi	6.1	80	1.3	71	.3	7.7
Jacobabad	2.7	75	.9	71	.5	4.1

Var. (variability) indicates departure from average seasonal rainfall as registered in half the years during 1890–1923, expressed as a percentage. In general, March to May returns are insignificant.

Water. — It is a truism that natural boundaries are zonal, not linear; and generalizations concerning the biological effectiveness of rainfall are dangerous. Space forbids qualifications; yet it may be accepted that over the lowland precipitation is such that it precludes the transformation of the surface by permanent cultivation,

and that over those parts which lie beyond the sphere of running water a desert landscape prevails. At once, therefore, it claims a continuous area of a little more than 100.000 sq.mi. cut off from effective water circulation. This involves Bikaner, with Jaisalmer and nearly all Jodhpur; Bahawalpur practically as far as the North Western railway, which runs parallel to the Sutlej; the Runn of Cutch, and north of it as much of Thar-Parkar district (Sind), Khairpur state and Sukkar district (Sind) as lie east of the Nara river (properly canal!. The desert's alternative name "Thar" refers to the sand hills accumulated by the prevailing winds, which transport thither the saline dust picked up over the Indus delta and the Runn. Two types of sand hills are recognized. (1) Longitudinal sand hills (Sindhi bhits) are parallel ridges aligned northeast southwest; *i.e.*, parallel to the prevailing winds. The *bhits* are restricted to the west (*i.e.*, Thar and Parkar south of Umarkst, eastward to the Luni basin). They reflect greater wind force than (2) the transverse type, to which they give way. through intermediate forms. northeast of Umarkst. These lie at right angles to the wind but are less regularly aligned than (1). The marginal dunes rise to about 200 ft. above the general sandy surface and are relatively permanent. Farther inland they are lower, in constant motion. and the landscape tends toward a low plateau of deep, loose sand, reminiscent of a billowy sea.

Deserted by a "westering" parent, the feeble monsoon streams which struggle across southeast Punjab, between the Sutlej and Jamna rivers, succumb in the face of the sand before the Rajasthan border is reached. The Luni river is the only significant watercourse within the area. It receives several Aravalli streams from the southeast and is at least a support to the subsoil water within its bend; but it loses itself in sand at the head of the Runn.

Salt. — The salinity of the soil, characteristic of the whole lowland and there very marked, is sufficiently accounted for throughout Thar by the action of the wind, bringing material from the seaboard. The evaporation of subsoil brine is common over Rajasthan (particularly in the Pachbhadra neighbourhood) and also beyond, southwest of Delhi, and in the Multan and Muzaffargarh districts of Punjab (Pakistan). The Rajasthan salt lakes, representing the fixation of salt washed into basins of internal drainage, are marginal to the desert. Of these: Sambhar, on the Jodhpur-Jaipur boundary, is the largest. It lies in a closed depression in the Aravalli schists (1,184 ft.). Its maximum spread is 90 sq.mi. and during a normal monsoon it averages 4 ft. deep in the middle: but is dry the greater part of the year. The upper 12 ft. alone of saliferous silt forming its bed represents a salt reserve of about 54,000,000 tons. The lake is worked on lease by the government of India, and the salt extracted is railed to Sambhar at the eastern end of the lake, whence it is distributed.

Gypsum, also occurring on the margins of some of the lakes, may prove more important in the future. In Sind and Khairpur, where the floor of alluvial clay remains uncovered or only thinly mantled with sand, shallow though often large expanses of water known as dhands are common in the hollows (tnlis) between the sand hills. They are fed by rain water percolating through the sand and emerging as a spring (sim) above the clay. Prior to the controlling of the Nara river many *dhands* were replenished by its flood spills, but these have now mostly dried up. *Sim* water is often sweet, and gives rise to fresh pools close to where it emerges and lying a few feet above the *dhand* proper, which is either alkaline or saline, rarely fresh, its particular nature being recognizable from its fringe of vegetation. The mineral *trona,* from the alkaline *dhands,* supports the soda (chaniho) industry of Khairpur state and Nawabshah district (Sind). Saline dhands yield salt and gypsum.

Vegetation. — A varied, open, shrubby and coarse herbaceous vegetation is characteristically present, salt lovers being conspicuous. On sweet, damp bottoms. and after rain, good grass abounds. Thus, fodder exists for large numbers of cattle, sheep, goats and camels; villages are scattered everywhere.

.When rain is propitious, millets (principally bajra) are raised and husbanded to eke out a milk diet supplemented otherwise only by such imported grain as is made available by the profits of the pastoral industry and associated crafts, such as the making of blankets. felts, *lohis* (coarse shawls), ropes, bags, brushes and leather goods, render possible. Typical desert talukns of Sind have shown a population density per square mile of less than 20 (cf. Diplo, 12; Chhachhro. 18); Jaisalmer, the "core" of the desert, has an over-all density of 5 per square mile; Bikaner gives 55 (Bikaner city, 117,113); Jodhpur, 70 (Jodhpur city, 180,717), but a heavy allowance must be made for that part of the district outside the essential desert. Roughly, the Thar desert has carried about 2.500,000 people, largely marginal.

The Runn of **Cutch** (Rann of Kachh or Kutch), embracing about 8.000 sq.mi., while a part of the desert, possesses a distinctive character. It is a low-lying. salt-impregnated alluvial tract. Seemingly uniformly level, it has a general imperceptible slope seaward. while minor irregularities give shallow surface depressions. When the surface is dry, it is hard and polished; "even a horse's hoof hardly dents it in passing." During the southwest monsoon. however. it is flooded by the waters of the Luni. Puran, West Banas and other rivers assisted by rain remaining on the hard surface, but the view that at this season the sea invades it (the sea level is raised 4 to 5 ft) has been disproved and abandoned. During flood the water varies in places from a few inches to some feet; but after it subsides. evaporation proceeds until only salt remains. Lying in a belt liable to pronounced seismic disturbance, the Runn suffered severe displacement in 1819; depression increased the "rann" proper, but aeolian deposits have diminished it since. It is a range for wild asses. The impoverishment of the Runn and much of what is now Thar reflects the "westering" of the Indus and associated Punjab rivers. A map shows that the streams making for Rajasthan across the low Sutlej-Jumna watershed converge toward a large dry watercourse (the Ghaggar), which runs parallel to the Sutlej and is traceable beyond through Sind to the Runn, roughly via the east Nara and Puran. This is the Hakra, or "Lost river." fed formerly by the Sutlej (possibly at one time by other Punjab rivers), and in its lower course (as the Mihran of Sind) by the Indus. Such was the known condition in the 8th century A.D. Subsequent probably to phenomenal flooding in north Punjab, thought to have taken place in the 14th century, a rearrangement of drainage initiated the decline of the Hakra. First a "westering" Indus ceased to feed its lower reach; eventually the Sutlej completely deserted it and passed to the Indus via the Beas. By 1790 the Hakra was dead. The tapping by bunds of the waters latterly feeding the Puran from an Indus distributary assisted to complete the dereliction of the abandoned delta (the Runn).

Irrigation. — Outside Thar, the immediate valleys of the rivers sustained by the snows of the Himalayas, tree-lined and recuperated by inundations, break the arid continuity, while as a result of irrigation the desert survives only in fragments. Consequent upon the melting snows, the Indus and rivers of the Punjab begin to rise in March. and normally spill over the land in mid-June. Floods culminate in August, and the rivers fall fairly rapidly to a minimum in about February. From antiquity channels have been dug to utilize the rising naters. Such inundation canals are necessarily restricted to the lower marginal lands; *i.e*, mainly newer alluvium (Khadnr), which in Punjab lies 10 to 50 ft. below the older alluvium (*Bhangar*) comprising the doabs, and varies from 4 to 10 mi. in width. Hence. they occur mainly where the "Five rivers" converge to form the single artery continued in the line of the Indus, and attain their maximum development in Sind, where the widening *Khadar* merges into truly deltaic land. Many of these canals existed prior to British rule; they were improved and others were added.

Agriculture.—It is, however, to the expansion of great perennial systems over the broad backs of the Punjab doabs, and the development of model agricultural colonies thereon, that the elimination of the desert between the Jhelum-Chenab on the one hand and the Sutlej on the other is due. Details of what this meant must be omitted, but the following Punjab census (1921) return is notenorthy: "In 1891 the population density contour line, 100 per square mile, which enclosed the oasis of Multan was no less than 160 mi. distant from the general 100 per square mile density line. Since 1891, however, due to the development of the Lower

Jhelum, Lower Chenab and Lower Bari doab canals the line has advanced at an average rate of about 10 mi. per annum, and in 1911 Multan had been turned. from the point of view of population, from an island into a narrow-necked peninsula." Agriculturally it meant the establishment of about 1,000,000 ac. of acclimatized American upland cotton with a staple of about 1 in., and a great wheat expansion. The Sutlej valley project was undertaken to convert certain inundation canals dependent on that river into perennial, and assure the flood supply of the rest, while extending irrigation into the Bahawalpur and Bikaner fringes of Thar.

Projects.— At mid-20th century the Punjab state government was anxious to complete the big task of building a dam on the Sutlej river, near the village of Bhakra, about 50 mi. upstream from Rupar Town. Plans called for the construction of a reservoir for irrigation canals and a hydroelectric power plant. About 8 mi. downstream from the Bhakra dam site, Nangal dam was completed in 1954. Nangal dam was designed to provide storage of the irregular flows caused by variations in load requirements at the Bhakra power plant and would provide a balanced supply of water for the Sirhind canal. Water could also be diverted to the Nangal Hydel canal. As a result of this project, irrigation would be extended to Hissar. Rohtak and other adjacent areas in arid southeast Punjab. The total cost of the Bhakra-Nangal project was estimated at Rs. 156 crores. The Indian prime minister opened the Bhakra canal system on July 8, 1954. Pakistan protested that this diverted waters essential to its life.

The recession of the western mountain wall enables the Indus, after receiving the united volume of the Punjab rivers, to enter Sind as a southwest flowing river. Near Schwan it turns south in the presence of the Laki range but manifests its "westering" tendency again in its final struggle seaward. The bifurcation of the Ochito and Haidari is regarded as the head of the delta; but, of course. throughout Sind the river is really deltaic, flowing on a ridge above the land on either side, restrained in parts by embankments, but requiring more to curb its devastating moods. while the lower part of the province is riddled with its dead channels. Only in the gorge between Sukkur and Rohri, where it traverses a gap at the north extremity of low hills running for 40 mi. S. from its left bank, and in the Kotri neighbourhood is its channel. constant.

In order to afford an assured supply of water to cultivators at all times, the Sukkur barrage project, after long years of discussion, was begun in July 1923. Excavation of 7,500,000 cu.ft. of earth was necessary to extend the total length of watercourses served to 54,300 mi. The project cost almost Rs. 24 crores.

The waters of the Indus river are headed up by 66 spans, which are 60 ft. wide and have 50-ton steel gates to regulate the flow. The barrage, about 1 mi. long. regulates the distribution of the water through seven canals and canal-head regulators—spans 25 ft. wide with three electric gates. There are four canals on the left bank—Rohri, the Eastern Nara, the Khairpur Feeder East and the Khairpur Feeder West—and three on the right bank—the North Western canal, the Rice canal and the Dadu canal.

Approximately 45,763 cusecs, or 285,100 gal. per second, is the total discharge of water into the seven canals. Named the Lloyd barrage in honour of Lord Lloyd, a governor of Bombay who zealously supported the project, it was completed in Jan. 1932. After the opening of the barrage and canal system, the acreage devoted to wheat and cotton increased markedly. At mid-20th century, 7,500,000 ac. were irrigated.

In Feb. 1950 the governor general of Pakistan laid the foundation stone for another Indus river barrage to be constructed above Kotri in Lower Sind. Expected to provide water for 28 lakh ac., the project would. it was estimated, make it possible to increase crop output fourfold. The cost was estimated to be Rs. 20.5 crores.

Westward beyond the sphere of the Indus, the desert landscape is at once established, and the irrigated patches of *daman* (clayey soil) created and sustained by flood torrents searing the mountain wall only throw the naked hideousness of the limestone rampart into bolder relief.

INDIAN HEMP (*Apocynum cannabinum*), a North American plant of the dogbane family (Apocynaceae), native to fields and thickets from Quebec to British Columbia and southward to Florida and Lower California. It is an erect, often much-branched perennial, 1 to 4 ft. high, with smooth, oblong, opposite leaves and small: clustered, greenish-white flowers, from each of which develops two very narrow fruit pods (follicles), about 4 in. long, containing numerous downy-tufted seeds. The tough bast fibres of the inner bark were utilized by the Indians for cordage. The variety of hemp yielding hashish is also called Indian hemp.

INDIAN INK, or INDIA INK: see INK.

INDIAN LANGUAGES. The main languages of peninsular India are largely those mentioned in the 8th schedule (articles 344[1] and 351), as modified to Sept. 1, 1951, in the constitution of India. They are: Hindi (coupled with Urdu! Hindustani, Punjabi [including those using "Gurmukhi" character] and Pahari, 149,944,311[1]); Telugu (32,999,916); Marathi (27,049,522); Tamil (26,546,764); Bengali (25,121,674[2]); Gujarati (16,310,771); Kannada (Kanarese) (14,471,764); Malayalam (13,380,109); Oriya (13,153,909); Assamese (4,988,226); Kashmiri (1,438,021[3]); and Sanskrit. Subsequently, English was publicly declared one of the languages of India. To these languages there must be added, for Pakistan. Lahnda (8,566,051[3]), or Western Punjabi, and Sindhi (4,006,147[3]). Pushtu (Pashto) and Balochi are Iranian languages. For 15 years English was to remain the official language of India, and in the meantime Hindi in Devanagari script was to be progressively established to take its place as the all-Indian language. Urdu, the official language of West Pakistan, was established in the Punjab under British rule after the conquest. 1848–49.

An Indian commission on the possibility of setting up new states on a linguistic basis for Andhra (Telugu), Karnataka (Kannada), Kerala (Malayalam) and Maharashtra (Marathi) reported in 1948, and Andhra state was later established. The report, however, concluded that "the formation of provinces on exclusively or mainly linguistic considerations is not in the larger interests of the Indian nation and should not be taken in hand." Pakistan recognizes two main languages, Urdu in the west and Bengali in the east.

The languages so far mentioned fall into two great families, Indo-European and Dravidian. The following languages belong to the Indo-Aryan group of the Indo-Iranian branch of the Indo-European linguistic family, and are sometimes described as Sanskritic since their affinities can to some extent be measured with reference to Sanskrit. the great classical source for most of present-day India, including loans in the Dravidian languages: (1) northwestern group: Lahnda and Sindhi; (2) southern group: Marathi and related dialects; (3) eastern group: Bengali, Oriya, Assamese, Bihari (including Bhojpuri, Maithili and Magahi, 37,000,000); (4) east-central group: Eastern Hindi and dialects; (5) central group: Hindi (and literary Urdu), Eastern Punjabi, Gujarati, Rajasthani (13,897,896[3]), Bhili dialects (2,110,410[3]); (6) northern or Pahari group: Eastern Pahari, Gorkhali (about 6,000,000[3]), Garhwali and Kumaoni (1,055,662), Western Pahari; (7) extra-Indian groups: Sinhalese (4,000,000[3]) and gypsy dialects of western Asia and Europe. The Dardic languages of the far northwest

[1]Except where stated, population figures are from the census of India, 1951, and exclude Pakistan.
[2]Excluding East Pakistan.
[3]1931 census.

are also Indo-European of Indian type and include Kashmiri and Shina (68,199[1]). The close relationship of Sanskrit with Greek and Latin was boldly stated by Sir William Jones in 1786. S. K. Chatterji calls this "great Aryan speech of India, our great spiritual and cultural link with the West."

Besides the four great literary Dravidian languages of south India — Tamil. Telugu, Kannada and Malayalam — there are a number of nonliterary Dravidian languages in the south such as Tulu

PROFESSOR J R FIRTH

GEOGRAPHIC DISTRIBUTION OF PRINCIPAL INDIAN LANGUAGES

(787,624), Kodagu (40,000[1]), Gondi (1,232,886) and, in far away Baluchistan, Brahui (225 000[1]).

Most of the other languages of India are allotted to two language families of lesser significance in India today. the Munda (sometimes called Austro-Asiatic or Austric) and the Sino-Tibetan. The Munda languages are thought by some to be related to the Mon-Khmer subgroup of southeast Asia. The largest population group in India speaking what some would call an aboriginal language is the group speaking Santali (2,811,578). Other related languages are Mundari (650,000[1]), Savara or Sora (256,259) and Khasi (292,923).

Manipuri (Assam) and Newari (Nepal) have been described as belonging to the Sino-Tibetan family, along with a number of other languages such as Lushai and Garo of the Bodo group.

Sanskrit, the sacred and classical language for 250,000,000 Hindus, is written in the Nagari or Devanagari script, accepted all over India. Hindi and Marathi are written in it, Gujarati, Bengali, Assamese in modified forms of it, and even the Dravidian languages of the south are written in closely related forms of it. Urdu employs the Persi-Arabic script and its classical sources are Persian and Arabic. It has been said that Urdu and High Hindi are based on one form of speech (Hindustani) split by two different classical traditions and two totally different scripts. Hindustani (if this name may still be used) "acts as the most natural inter-provincial link among speakers of the Aryan languages of the north. This is a sort of *lingua Indica*." (S. K. Chatterji, *Languages and* The *Linguistic Problem,* Oxford Pamphlets on Indian Affairs, No. 11, Oxford University Press. 1943.) *(See* also individual languages; *e.g.,* ASSAMESE; BALOCHI; BIHARI; etc.) (J. R. FH.)

INDIAN LAW. The law generally in force in the Indian subcontinent was varied and modified by the succession of governments in power there. Mohammedan law, for example, came with the Moslems and remained applicable to Moslems in personal matters when the English East India company had superseded the Moguls. The influence of English law pervaded the religious and sectarian legal administrations during the British imperial rule, and British enactments and decisions in the high courts left their mark on the system of the Republic of India. The republic, however, with its Hindu majority predominant in the population, inherited the law developed after the first Aryan invasions of India, and it is with the peculiar features of this Hindu law that the present article is concerned.

The article SANSKRIT LANGUAGE AND LITERATURE mentions the written sources of Hindu law. The more ancient of these are regarded as sacred. and, since it is sacred. Hindu law is theoretically unalterable. But. in fact, it has changed by admitting wholesale into Hinduism peoples who brought their customs with them. by slow local and family changes and by adaptations to historical, political, economic and social changes. As to custom, indeed, Manu's code says "immemorial custom is transcendant law." In actual practice and apart from modifications by custom, Hindu law as administered in the courts is substantially derived from the commentaries of the great commentators. For most purposes the chief among these are the *Daya Bhaga* of Jimuta Vahana in Bengal proper only, the *Mitakshara* of Vijaneswara all over India and the *Vayavahara Mayukha* of Nilakanta in western India.

The *Daya Bhaga* in Bengal and the *Mayukha* in Bombay overrule the *Mitakshara* where they differ from it, and in the case of the *Daya Bhaga* the differences are so far-reaching in the matter of family property and in the theory of inheritance that it is rightly held that there are tuo main schools of Hindu law, the *Mitakshara* school and the *Daya Bhaga* school. The former is divided into the Benares school (upper India generally). which prefers the *Mitakshara* to all other commentaries at all points, the *Mithila* school (northern part of the states of Bihar and Orissa), the *Maharashtra* school (western India) and the *Dravida* school (southern India).

The Joint Family. — The striking feature of Hindu society and Hindu law is the joint family. It- is the form, no doubt. in which the Aryan patriarchal family *(see* INDIA: *Social Institutions)* has survived. The joint family is seen at its weakest in Bengal, the region where Brahmanical ecclesiasticism, on which the *Daya Bhaga* is based, has had its greatest effect.

Brahmanical influence on law probably increased at the post-Buddhist Hindu revival, but seems to have had little or no effect in the Punjab or among the Aryan, or Aryanized, peoples of the Himalayas. Among some of the Himalayan clans, which undoubtedly have Aryan blood in them, the joint family is more like the Roman family than it is among Hindus of the *Mitakshara* school in India generally. The joint family is so much taken for granted in the *Shastras* and the commentaries that it is scarcely described in them.

Since the question of whether a family's land could be validly alienated probably did not arise until comparatively modern times, the distinction between the right to manage. on the one hand, and ownership with the right to alienate, on the other, probably did not become an important point of law for many centuries. When it did arise, two conflicting theories emerged. One is that of the *Mitakshara,* that down to the great-grandson of a living ancestor a male Hindu acquires by birth a right of ownership as a coparcener in the ancestral family property. The other is that of the *Daya Bhaga,* that the living ancestor is the sole owner, with unfettered control and power to alienate, even for personal pur-

poses, and that on his death his descendants in the direct male line who have no ascendant living inherit the property in distinct and specified shares and may either divide it up or retain it as a jointly worked and managed property. Under the *Mitakshara* no coparcener's share is a definite thing, even if he has no ascendant living, until a partition is called for. Until that event occurs each coparcener's share can, in a manner, be said not to be ascertainable. And when a coparcener. even the common ancestor, dies, his rights pass by survivorship and not by inheritance.

Under the *Daya Bhaga*, then, when the common ancestor dies, the ownership passes in immediately ascertained shares to his heirs under *Daya Bhaga* law. But in such a case under the *Mitakshara* the ownership, that of the family. is unaltered, but in the family there is one coparcener the less. and the distribution on a partition made after his death will differ from that on one made before it. And. while the property remains joint, there is no passing of it by inheritance. The nature of the ownership of joint property is not discussed in either the *Mitakshara* or the *Daya Bhaga.*

If a family of brothers governed by the *Daya Bhaga* keep their property undivided, then, upon the death of one of them, his share goes to his heir or heirs, who. in default of agnate descendants, may be his widow, his daughters or the sons of his daughters, and in this last case his share will pass into another family, but it need not therefore be separated off by a partition. In a like case under the *Mitakshara,* if the deceased brother had any agnate male descendants they mere already coparceners in the family property. while his wife, his daughters and the sons of his daughters could not be coparceners. Upon his death there was one coparcener the less in the family, and the distribution on a partition would be somewhat altered. As long as two or more coparceners remain in a *Mitakshara* joint family, such property as it may own cannot pass out of it by inheritance.

There is a standing presumption that Hindus nearly related to one another by agnation form a joint family. When they are so far apart in blood as second cousins, that presumption is not very strong. And there is some presumption that anything in the possession of a member of a joint family belongs to the family. Honever, Hindu law now recognizes self-acquired property. though it took a long time to do so, even as the concept of *peculium* in Roman law was of slow growth. Gains of valour, science and learning made without help from family resources are the chief source of self-acquired property, apart from what is styled "obstructed inheritance."

But nhen self-acquired property passes by inheritance to agnate descendants it at once becomes ancestral, and under the *Mitakshara* the inheritors, unless they have already separated from one another, hold it as an ordinary joint family coparcenary. Under the *Daya Bhaga* the fact that each coparcener has a known and particular share of which he can dispose in his lifetime as he pleases by sale or gift or in any other way, without being answerable to anyone, greatly simplifies questions arising out of alienations. But under the *Mitakshara* the dealings by a coparcener with the share which would fall to him on a partition, and the rights of his personal creditors against that share, both while he is alive and after his death, have given rise to legal difficulties.

Noninheritors.—A joint family will usually have among it members who are not coparceners. Under the *Daya Bhaga* the wives of coparceners, the male agnate descendants of coparceners and the unmarried female descendants of coparceners or of their agnate descendants come into this category, as well as those who might in time be coparceners but that Hindu law debars them from inheriting; *e.g.*, those born deaf. dumb, blind or insane. Under the *Mitakshara* the dependent members will not include qualified sons, grandsons or great-grandsons of the senior generation of living coparceners, for these are coparceners themselves by right of birth, unless disqualified by any defects which debar from inheritance. But among the dependents there will be widows of deceased coparceners. Under the *Daya Bhaga* such a widow without sons or agnate descendants will herself be owner. at least for her life, of her deceased husband's share. Under both schools these dependents must be maintained: out of the shares of their respective branches of the family in the case of the *Daya Bhaga;* out of the general family fund in that of the *Mitakshara.* And, in theory. under the *Daya Blzaga* each actual coparcener, ahich here means the owner by inheritance, or possibly by purchase, of a share. can claim. at least approximately, that a corresponding share of the family income be allotted to him. In a *Mitakshara* joint family there is no such right. No one can claim more than that he is to be maintained. with his wife and other dependents. on a scale suited to the family's resources. Only if fraud or embezzlement or the like is alleged will current accounts be gone into. When a partition has to be made, a capital account is, of course, necessary.

Partition.— To the ancient Hindu lawgivers and commentators. partition and inheritance are different aspects of the same subject, and, in fact, in their view partition was the dominant aspect. This was because a Hindu ought to have at least one male agnate descendant. obtained in the last resort by adoption, and therefore ought to die a member of a joint family, if governed by the *Mitakshara.* Even under the *Daya Bhaga,* when two or more sons succeed their father. they do not get definitely marked out shares absolutely their own until they effect a partition. Partition is in theory simple enough under the *Daya Bhaga.* Each coparcener has a known share: all that has to be done is to lay out metes and bounds in the immovable property and to make a fair division of the movables. But when the *Mitakshara* applies, the first thing to be done is to determine the share of each coparcener. The division is made by branches. And when there is a division between a living ascendant and his descendants, the ascendant gets the same share as goes to each of his sons. Thus, a father and his four sons make a partition, and each gets one-fifth of the property. If any of the sons had predeceased the father, leaving sons or agnate grandsons, these latter between them take what would have been his share. If four brothers, whose father and other ancestors are dead, divide, each takes one-fourth.

Ancestral and Separate Property.— In case of dispute it is necessary under either school to decide what is and what is not family property. What is claimed and proved to be either self-acquired or separate property has to be excluded from the hotchpot, and there may have to be special provisions about the right to use wells, rights of way and other things which cannot be split into parts. It should be mentioned that under British administration in most provinces partitions of land assessed to land revenue came to be made by the revenue courts *(see* INDIA: *Finance*), and in those cases the joint owners often were not members of a joint family.

A father or other ascendant governed by the *Daya Bhaga* is sole owner as against his sons and other descendants; yet there are texts indicating that if he make a partition among his sons he must divide the property equally.

Honever, he undoubtedly can make a series of gifts to his sons or other descendants, and by them dispose of the estate in very unequal portions. At the back of this anomaly is the theory that a gift needs acceptance by the donee and actual transfer of possession to make it complete and cognizable in law, whereas a partition does not. If a member of a *Mitakshara* joint family obtains a partition of his share and has then no sons or other agnate descendants, the share is his sole and separate property. But it remains "ancestral," and as soon as he has a son born to him, or adopts one, that son becomes a coparcener in it with him and so with all his sons born subsequent to the partition and their sons and grandsons. Very often the question arises, "Has there been a partition or not?" The answer may affect the rights of a third party to whom a member of the family purports to have transferred property. The presumption as to jointness has already been mentioned. But whether there has been a partition or not is a question to be decided on the evidence. A fully united family is joint in house, food. worship and estate. But a family can easily be joint in house and worship and yet separated in food and estate, or it can be joint in estate and yet to some extent separated in house and in food. On effecting a partition, provision must be

made for the dependents; *e.g.,* unmarried daughters or sisters, mother uhose husband is dead. and incapables. When a dependent belongs plainly to one branch of the family. and that branch does not itself split up, the liability of course attaches to that branch; for instance, one of several brothers who separate remains responsible for his own daughters. But when brothers who have unmarried sisters or incapable brothers separate, either a special assignment must be made (for instance, to meet the expenses of a girl's marriage) or one member accepts responsibility and receives some sort of compensation. If it is a mother who has to be provided for, it is not uncommon under the *Mitakshara* for a part of the estate to be assigned to her. On her death it will be divided among her sons or their descendants.

As in a *Daya Bhaga* joint family, each coparcener has a definite share which descends by inheritance; when the estate of such a joint family is the subject of a partition. the matter to be ascertained is what portion thereof has devolved under the rules of inheritance to each present member since the death of the person who once held the whole of it. For under the *Daya Bhaga* all property goes by inheritance nhen its owner dies, whereas under the *Mitakshara* the rights of a coparcener, even if he be one of two only, go by survivorship on his death. So a Hindu governed by the *Mitakshara* risks losing all chance of inheritance to the rest of the family property when he separates by partition, for as long as two or more members remain joint even their nearest relations, once separated from them by partition, cannot inherit their joint property. since survivorship precedes inheritance,

Under the *Mitakshara,* only separate property and self-acquired property can pass by inheritance.

Impartible Estates.—Besides estates which under British provincial legislation were made subject to entail, there are some estates impartible by family custom or special tenure, mostly the residue of suppressed sovereignties or quasi-sovereignties. Junior members and branches of the family are entitled only to maintenance.

Cnder the *Mitakshara* the rule of succession may involve. first. discovering the nearest male agnates and then applying the rule of primogeniture among them, excluding more distant relations even in a senior branch.

Inheritance.—Here there is a divergence of principle between the two schools. The *Mitakshara* prefers all male agnates, however remote. to any cognate, however near, except the daughter's son. And, except under the *Maharashtra* subschool in western India, which does place some women in a more favoured position, the only women it brings in as near heirs are the widow, daughter, mother. grandmother and great-grandmother.

The basis of the scheme is preference by nearness of agnate relationship. The scheme of the *Daya Bhaga* is based upon efficacy of offerings made to the deceased; in fact, it holds that the heir gets the estate because he makes the offerings. So doubt the ancient rule, as J. D. Mayne surmises, was that the duty to make the offerings fell upon the person taking the estate. But, for the benefit of the priesthood, the later ecclesiastical theories of the Brahmans put all the stress upon the offerings and said that the estate followed them. This theory brings in some cognates in preference to more remote agnates.

There are three grades of offerings: (1) the full cake, or *pinda,* those making it being called *sapindas;* (2) the offerings of crumbs made by *sakulyas;* and (3) the offerings of water made by *samanodakas.* The cake offering is made for three generations, and the crumb offering for three more.

The leading rule is that a Hindu has to make the cake offering to his father, his father's father and his father's father's father and also to his mother's father, his mother's father's father and his mother's father's father's father. It is of importance that he does not make offerings to his father's mother's father, and so on.

A man is *sapinda* to his sons. to their sons and to their grandsons, as uell as to his three direct ancestors. And he is *sapinda* to the three generations in the direct male line from his *sapinda* ancestors, paternal and maternal. Except in the case of the daughter's son, the claims of all connected nith the deceased through a woman on the ground of being *sapinda* are rejected by the *Mitakshara* in favour of agnates however remote. But the *Daya Bhaga* admits these claims with the result. so far as the inner circle of heirs is concerned, of bringing into it sister's son, father's sister's son and grandfather's sister's son.

This inner circle includes those related to the deceased by being descended from a common great-grandfather, or nearer relation, by agnation; beyond it the differences between the two schools become much greater, in view of the *Daya Bhaga's* preference of all who offer the full cake over all who offer only crumbs and its doctrines about being mutually *sapinda* and about the effects of being *sapznda* to the same person.

Order of Inheritance.—The first heirs are sons, agnate grandsons and agnate great-grandsons. Grandsons and great-grandsons between uhom and the deceased a son or grandson survives do not take directly. but representation is allowed in the case of those between whom and the deceased the links are already dead. But for this case representation is nowhere allowed in Hindu law; *e.g.,* a brother excludes sons of deceased brothers. After the three generations of descendants come the widow, then the daughter and then the daughter's son. Daughters' sons take per capita, and a living daughter excludes all sons of deceased daughters. Next come the parents, of whom the *Mitakshara* places the mother, and the *Daya Bhaga* the father. first of the two. Then brothers, sons of brothers and agnate grandsons of brothers. Here the *Daya Bhaga* interpolates the sister's son.

Then come the grandparents and a like three generations from them. with the father's sister's son interpolated bv the *Dava Bhaga;* then the great-grandparents and the three generations from them. For the complications beyond this point. especially under the *Daya Bhaga,* thk reader should consult the works of Mayne and Sir Ernest Trevelyan cited in the bibliography below. The *Makarashtra* school brings in the sister between the two grandparents, and after each circle of heirs brings in widows of members of that circle before going on to males in the next larger circle.

Wills—There can be no doubt at all that in its beginnings Hindu law knew nothing of wills. There is no Hindu word for a will. A legacy can be regarded as a gift to take effect after death, and according to both Hindu and Mohammedan law a gift is of no effect until the donor has transferred possession to the donee. And, when dead. the donor is no longer there to do so. But undoubtedly Hindus were struggling toward a right to bequeath in the days before British rule, especially in Bengal. The doctrines of the *Daya Bhaga* had individualized property, and ecclesiasticism was bound to favour pious gifts and bequests. Slowly the supreme courts of British India recognized a Hindu's power to make a will. first in Calcutta after formally consulting the East India company's *sadr* court. It became settled law that a Hindu could dispose by will of all that he could unrestrictedly alienate in his lifetime; *i.e.,* in case of a male, of all his property under the *Daya Bhaga* and of all his separate and self-acquired property under the *Mitakshara,* and in the case of a female of certain classes of her property. The courts felt themselves compelled to deny to a testator the right to create anything approaching a perpetuity.

Debts.—Hindu law undoubtedly recognized that debts ought to be paid and had its methods of compelling payment. The religious view of debt in Hinduism is that he who dies in debt suffers torment or degradation in the next life, which can be ended only by payment of the debts, and Hindu law is a branch of Hindu religious teaching. Hence there is the principle that a son or grandson is under an especial obligation to pay the debts of his father or grandfather. As, in the ordinary way. he is the heir, this is fair and equitable. It was settled by legislation that no one, whether he take by inheritance or by survivorship, is bound to pay debts to a greater amount than the benefits he receives by the passing of the estate of the deceased. First, of course, it has to be ascertained what property the deceased left. So far as concerns the estate of a Hindu governed by the *Daya Bhaga* or the separate or self-acquired property of one governed by the *Mitakshara,* all debts which could have been recovered from him in his lifetime rank for payment. It is nhen the deceased died as a coparcener in a *Mitakshara* joint family that difficulties arise over

the "pious obligation" of sons and grandsons. A debt may have been incurred for joint family purposes. recognized as such by Hindu law. Then all the family property is liable for it. It may have been incurred for the debtor's personal purposes, and if the particular purpose of a debt was not illegal or immoral the doctrine of pious obligation will generally make liable for it all that share of the family property which on a partition would have gone to the debtor and his descendants. Or the debt may have been incurred for illegal or immoral purposes. If the creditor knew, or ought to have known, of such purposes, the family property is not liable for it at all. As the father can burden the sons by his indebtedness, if it be not the result of illegality or immorality, so too he can sell or mortgage their potential shares with his, especially to pay a debt already existing. And it was decided that the creditor can implead the sons and grandsons when suing the original debtor in the latter's lifetime. The effect of failure to implead them, or of failure to state distinctly that their shares are attached when execution of a decree is taken out. was the subject of numerous rulings of the high courts.

Alienation and Maintenance. — Originally, no doubt, a member of a *Mitakshara* joint family could not alienate his share of the property for personal purposes until he obtained a partition. According to rulings of the high courts at Madras and Bombay, not only could he do so, but his personal debts could be enforced against it, provided always that a decree is obtained and attachment of the share effected during the debtor's lifetime. On his death his rights vanish. acd. since they go by survivorship and not by inheritance, they could not be followed into the hands of the survivors unless the doctrine of "pious obligation" applies to the latter. The right of certain persons to be maintained out of family funds, or by their living agnate ancestors under the *Daya Bhaga,* has already been mentioned. But Hindu law also envisages other rights of maintenance. Quite independently of inheritance of ancestral or other property, wives, minor sons, unmarried daughters and infirm and penurious parents must be maintained by a Hindu who has means or can work. And widows and daughters of deceased members of a *Mitakshara* joint family and, under either school of law, widows of persons whose property is inherited by their sons, grandsons or great-grandsons have a definite right to maintenance. By decree of court that right can be charged upon the property, and under the *Daya Bhaga* a widow whose sons or other descendants divide up the property of their deceased father or ancestor can claim the allotment to herself for life of a share equal to that obtainea by each son; so. too. when brothers succeed to their father, and there is a widow of a predeceased brother to be maintained. In some circumstances family property can be followed into the hands of a subsequent purchaser to enforce a claim for maintenance.

A widow's right to maintenance ceases on remarriage, and any woman's ceases if she leads an immoral life.

Women's Property. — In some respects and as regards some kinds of property, the ownership by women under Hindu law differs from that by men. These differences depend on the source from which the property is derived. If a woman has inherited property from a male or has obtained it as a gift by her husband or as a share on partition, she does not own it in the same way as a man would do; she obtains only a kind of restricted ownership. She has the full enjoyment and management of it, but she cannot sell it or give it away or dispose of it by will; and at her death it goes not to her heirs but to the heirs of the person from whom she obtained it; her ownership simply comes to an end. If she obtained it by inheritance from a male it will go on her death to the heirs of that male; if as a share on partition, it will be divided among the other shares; if as a gift from her husband, it will go to the heirs of her husband.

In those parts of western India where the *Mayukha* prevails, by exception full rights of property are given to a woman who inherits from a male who belonged to the family in which she was born; *e.g.,* to a daughter inheriting from her father, or to a sister inheriting from her brother. On her death such property devolves as if she had been a man.

The estate of a woman who inherits only for her own life is one of the difficult problems of Hindu law. It is by no means the same as a "life estate" in English law. The woman represents the estate. She can absolutely dispose of it for a necessity or with the next reversioner's consent. She can surrender it to the next reversioner. And a purchaser or mortgagee dealing with a woman owner is especially put to inquire into the necessity or into the real consent of the reversioner, as the case may be. and is bound to act with the very utmost of good faith, because of the habitual seclusion of women of good social standing.

An alienation by a woman. not otherwise justified, is good for her lifetime, apart. of course, from fraud and the like, and a widow with power to adopt devests herself of the estate in favour of the adoptee. A woman owning an estate for life is absolute owner of savings that she effects out of income, and unless she deliberately adds them to the estate they go to her heirs.

There is also *stridhana,* the absolute property of women. The rules of schools and localities as to this vary. The chief sources of it are gifts from blood relations and gifts at marriage, besides the personal earnings of an unmarried woman. Generally *stridhana* is at its owner's complete disposal. The rules as to the inheritance of *stridhana* vary with the school, and even with the locality, and with the origin of the particular property. They favour women more than do the rules of inheritance to males.

Marriage. — The code of Manu enumerates eight kinds of marriage. some of which are barbaric or even savage. Four were "approved" and four "disapproved." Only two still survive — the *Brahma,* an approved form, nominally a gift of the bride by her father to the bridegroom, and, among the lower castes, the *Asura,* a disapproved form, nominally a purchase of the bride by the bridegroom. Marriages of children, which formerly were very common. were forbidden by legislation.

The essential part in a Hindu marriage is the seven steps taken together by bridegroom and bride round the sacred fire. Among the higher castes, the relationships within which marriage is forbidden are extensive. The parties should not belong to the same *gotra,* or large family, and must not be related within six generations on the father's side, or within, probably, five on the mother's. Marriage must be within the caste (*q.v.*) and sometimes, by custom. within the subcaste. Strictly speaking there is no divorce in Hindu law. But divorce is practised by many of the lower castes, and an unchaste wife forfeits all rights except that to "starving maintenance." A Hindu man may marry any number of wives and may have any number concurrently.

A Hindu woman can have only one husband. and strict Hindu law forbade the remarriage of widows, even of virgin widows. Many of the lower castes always allowed widows to remarry, some of them imposing conditions on such remarriage; and Act XV of 1856 made it lawful for any Hindu widow to remarry, although she forfeited on remarriage any property inherited by her from her first husband or from a predeceased son (unless she belonged to a caste which, before 1856, permitted remarriage accompanied by retention of such property) and all rights of maintenance as widow of her first husband. Under Act XXX of 1923 a Hindu man and a Hindu woman of different castes might marry.

Suttee. — The custom of suttee (*q.v.*) or *sati,* whereby a Hindu widow, especially in the higher castes, had herself burned alive on the funeral pyre of her husband, was prohibited and made an offense under Lord William Bentinck's administration in 1829. In consequence suttee fell into desuetude, and educated Hindus would revolt from it. But there were sporadic cases, even as late as 1954. Those who help the widow to immolate herself are guilty of culpable homicide not amounting to murder; if she is above the age of 18 years, the fact that she suffers death with her own consent then reduces the nature of the offense. If she is under 18 the offense is murder or abetment of murder, punishable even with death. The widow's own insistence on becoming *sati* became a feature of all modern cases.

Sonship. — In very ancient Hindu law the son mould seem to have been his father's property, much as he was in ancient Roman law (the common Indo-European ancestry of the Hindu and Roman peoples is reflected in their legendary traditions, some of which bear significantly on this very point of paternal authority).

In Manu eight kinds of sons are enumerated.

Most of them are "sons" because at the moment of birth the woman who bore them was owned by the "father." Some are bought or self-surrendered. Now only two kinds are recognized: legitimate sons born in marriage, and adopted sons (adoption of daughters is mostly unknown to Hindus). There are two extant forms of adoption. the *dattaka* and *kritima.* The former is used all over India. The connection between heirship and the duty of performing obsequies and ceremonials has already been noticed. To secure a Hindu's happiness hereafter, the ceremonials should be carried on by his descendants for at least three generations. A grandson or a great-grandson can, however, make up for the absence of a son or grandson or both. But it is a grave misfortune for a Hindu to have no such descendants at all; so a male Hindu who has no son, agnate grandson or agnate great-grandson may adopt a son. The adopter may be married. a bachelor or a widower.

Among the higher castes the boy must not have been invested with the sacred thread (possibly this would not apply when the child is a brother's son of the adopter or otherwise in the family', and must be the child of a woman whom the adopting father could have married had not someone else done so. So a brother's son and a wife's sister's son are obviously eligible. And the adoption must be within the caste. The child must be willingly given by his natural parents (a boy cannot be readopted); so an orphan cannot be adopted.

Because of the importance of having a Son, the widow of a deceased Hindu can sometimes adopt for him. Of course the condition of sonlessness must exist. Given this, in western India a widow can adopt unless her husband has forbidden her to while he was alive. In southern India she can adopt if in his lifetime her husband authorized it, or if after his death his near agnate relations approve of the adoption. In *Mithila* she cannot adopt at all, and elsewhere she can adopt if in his lifetime her husband authorized her to. These are the varying interpretations of the text "Nor let a woman adopt a son without the consent of her lord."

A married man who adopts does not need his wife's assent to the act, though she may become the adoptee's legal mother. Adoption removes the child entirely from his own family (except that he still cannot marry within its prohibited degrees) and makes him for all legal purposes, including inheritance from and by collaterals, the son of his adoptive father. Ceremonies are necessary, for an adoption is a religious act. Handing over by the natural parent or parents, with a sacred fire at the place, is the principal ceremony, and the absence of evidence of this would throw doubt upon the validity of an adoption, were this disputed. Among some of the lower castes, even a married man can be adopted, and the rule about the mother's being a possible wife of the adopting father does not hold.

A son adopted to a deceased Hindu by his widow becomes the former's heir at once. If there is membership of a *Mitnkshara* joint family, or if the adopting widow has succeeded to. and still possesses, her deceased husband's estate, things are simple enough. But adoptions by widows fail where their effect, if they were valid, would be to devest the estate of someone (other than the adopting widow) who holds it as heir of some deceased male, other than the person to whom it is sought to make the adoption.

This rule is not a mere piece of theory. for if a son adopted dies without male issue there may be authority to adopt one in his place, yet he may have married, in nhich case his widow. not his adoptive mother, will be his heir. An authority to adopt remains effective throughout the life of the widow to whom it is given, so long as she does not exhaust it.

Cases have been known where a widow made a valid adoption more than 50 years after her husband's death.

The conditions stated above, other than that of sonlessness, apply in the case of *dattaka* adoption only. The system of *kritima* adoption is much looser. It is followed now only in *Mithila,* where, as we have seen. a widow never can adopt to her deceased husband. In *krztima* adoption, a sonless man or woman can adopt a son to himself or herself. The adoptee must consent to the adoption and must be of full age. No ceremony is required, only mutual consent. The adopter and the adoptee succeed to each other, but neither succeeds to the other's collaterals. The adoptee is not taken out of his own family. The adoptee performs the obsequies of the adopter if the latter predeceases him. Any person within the caste, even for instance the adopter's brother or his sister's son, can be adopted, and the adoptee may be older than the adopter.

Under the interesting matriarchal system of the Nairs of Malabar, where the joint family is found in its strongest form, the only kind of adoption ever necessary is that of a daughter.

INDIAN LITERATURE. An account of the history of literature in the main Indian languages is to be found in the following articles: BENGALI LANGUAGE AND LITERATURE; BIHARI LANGUAGE: *Literature;* GUJARATI AND RAJASTHANI LANGUAGES: *Literature;* HINDI AND URDU LITERATURE; MARATHI: *Literature;* PALI LANGUAGE AND LITERATURE; PRAKRIT LANGUAGES: *Prakrit Literature;* SANSKRIT LANGUAGE AND LITERATURE. The present article is concerned chiefly with general considerations of literary activity in mid-20th century India.

In India literature is polyglot, and an adequate comparison with western letters can be made only by considering Europe as a whole. In Europe, despite a variety of languages, the approach is more or less uniform and the responses predictable; and a similarity of social conditions and outlook throughout the continent makes the same problems interesting everywhere. In India, however, an analysis must be made at various levels.

Nearly 5,000,000 out of a total population of more than 350,000,000 have a knowledge of English, and new English publications are quickly available. Moreover, there is no branch of English literary activity in which Indian writers have not claimed consideration. In every field of the humanities there have been Indians who have thought in English and expressed themselves with facility. This very large output of writings is, however, Indian only in authorship and frequently in subject, but rarely in spirit and manner. The conscious effort to master a foreign language sometimes results in a self-conscious elegance, an undue emphasis on semantic chastity and a tendency to overwrite; but otherwise there is little that is distinctively Indian about the approach and outlook.

Of the writings in Indian languages, much is a continuation of ancient modes and conceptions. But, thanks to the opening of windows which was a consequence of British rule, there are many translations or adaptations of works in European languages and a great mass of literature which is simply copied from European models. A later and the most flourishing stage is represented by that vernacular literature which, while it has absorbed European influences, has yet recovered an Indian outlook and temper. Born as the cultural counterpart of Indian nationalism, it gained strength after the attainment of independence.

There are 14 major Indian languages—Assamese. Bengali, Gujarati, Hindi, Kanarese (or Kannada), Kashmiri, Malayalam, Marathi, Oriya, Punjabi, Sanskrit, Tamil, Telugu and Urdu—each with a sturdy literature of its own. Sanskrit is not spoken, but is the chief classical language of India and new philosophical, philological

and religious works in this language are not infrequent. Occasionally new poems and dramas of considerable extent and literary merit also appear. Other classical languages used in India are: (1) Prakrit, normally the language of the Jains and used in books published in Bombay state or in the Hindi or Marwari-speaking area; (2) the Buddhist Pali, rare in India; (3) Tibetan, published at Calcutta and Darjeeling; (4) the Pahlavi of the Parsees, published in Pahlavi or Gujarati script in Bombay state; (5) Arabic, appearing chiefly in Delhi, Lucknow and Hyderabad (Deccan); (6) Persian, more occasional. Many of the vernacular languages, chiefly the Dravidian group, Tamil. Telugu, Kanarese and Malayalam, also have their old or classical periods; re-editions of their classical works are very frequent, and for the most part are published within the areas of the respective vernaculars.

Translations of Sanskrit works are innumerable in nearly all the vernaculars, the Hindu epic Bhagavadgita, for instance. being reproduced many times every year; and some of the same favour extends to several of the local classics. Among modem writers Rabindranath Tagore, Mohandas K. Gandhi and Jawaharlal Nehru have a vogue in several languages; and popular novels are frequently translated. India is indeed the paradise of translators. But the main way in which the Indian languages can draw on each other is still through the common medium of English. This was given striking recognition at the inauguration of a national academy of letters in Delhi in 1954. Its very name — Sahitya Akademi — legitimizes the hybrid culture of modern India, sahitya being Sanskrit for "letters" and akademi the Indianized version of the Greek word. All its proceedings are in English. The Akademi arranges for the translation of well-known vernacular works into all Indian languages. Attempts are being made to replace the English language by Hindi. The 1950 constitution of India laid down that Hindi should be the official language of the union and should replace English after 15 years. As Hindi is used by less than half the population. the government of India encourages its study in non-Hindi speaking areas, persuading state governments to make it a compulsory subject in schools and compiling, with the help of expert committees, Hindi dictionaries of technical terms. In the mid-1950s, however, it remained to be seen whether this effort to make Hindi the national language would succeed. A major obstacle is the script: some adopt the Roman and others the Devanagari; and most of the other leading languages have their own traditional scripts.

Popular Literature. — To begin with the lowest stratum, the existence in India must be noted of an extensive, really popular, literature in verse. In all parts of India, but especially in the Punjab, the Kanarese country and the Tamil area, there is a constant output of songs and ballads, provoked by any notable occasion, such as a prize fight, a flood or calamity, a crime, a tragedy, the rise or fall of a personality, a social event, an act of administration; these have a real though often brief life upon the lips of the people, who sing them over their work or at their social gatherings. In mid-20th century this form was largely used for political propaganda, innumerable small collections of national songs appearing in all the chief languages. The best and the most long-lived of these are the stirring lyrical compositions in Tamil of Bharathi. There are also many collections of songs for special occasions; *Garbhi* songs for women, marriage songs, songs for the Holi (spring) festival and other celebrations, boat songs for aquatic sports in Orissa and Bengal, and so forth. At certain times of the year the Moslems put forth vast quantities of "verses" in honour of Mohammed or dirges for Hasan and Husain, grandsons of the prophet. Religion has a large part in this poetic activity: songs in honour of Krishna throughout India, of the mystic Chaitanya in Bengal and of Maratha saints in the west; songs for pilgrims in the Telugu and Tamil areas; songs for temple rites; collections of Jain hymns; and the many publications of Christian sects. Not all such popular literature is, however, in verse, since there are occasions when sacred stories in prose are narrated in or near the temples.

An oral tradition also attaches to much of the various classical writings of India. This is the case not only with Sanskrit works such as the epics Mahubharata and *Ramayana,* some parts of the Puranas, and some stories, such as those of the god Savitri and King Harischandra (*q.v.*), but also with the classics of the several vernaculars. Not to mention the substance of stories and legends, the texts of such poets as Kabir and Tulsi Das (*q.v.*) in the Hindi area; Vidyapati Thakur, Govind Das and many others in Bengal; Narsinh Mehta, Mira Bai and Premanand in Gujarat: Namdev and Tukaram in the Marathi country; the woman philosophical poet Lalladevi in Kashmir and the Vaishnava and Saiva saints and moralists of the Tamil country are very familiar on the lips of ordinary people in their respective areas. Besides being used in education, they are frequently re-edited. In the Punjab some parts of the Sikh *Granth* (*q.v.*) are similarly used.

Between the oral and the literary streams stands the drama. In India it is indigenous in many forms, from the heroic to the morality, the miracle play, the farce and the shadow or puppet show. These popular forms of representation. which had more or less disappeared in all parts of India except the extreme south, are now being revived and encouraged. The ordinary play, produced chiefly in Calcutta. Bombay and Madras, is similar to the European form, and presents melodrama, social sketch, burlesque. problem play, love story, and so forth. The more literary drama, still sometimes in Sanskrit, takes its subjects chiefly from old Indian poetry and legend, and is often an adaptation of well-known Sanskrit works.

The pabulum of the ordinary reader in India is furnished by the magazine, containing essays, biographies and descriptions, short stories and serials, notes and illustrations. The total output is enormous; but the standards are very low. This literature presents a big problem to the bibliographer, and the Sahitya Akademi has taken up the task of cataloguing. Schools and colleges have their organs (usually bilingual), in English and the regional language). Trades and the business world, professions (teaching, medicine. law, astrology, etc.) and grades of the official service all contribute to the mass of English and vernacular matter. The cinema, music and the stage are represented by popular periodicals. Special interests. such as the cause of women, social service. co-operation, labour, economics, business, arts and sciences, travel and boy scouting, are similarly equipped. There are, however, few political periodicals of any standing. The chief vernaculars usually have at least one literary periodical of a fairly high standard. Some of these literary journals have flourished for a long time.

Modern Indian poetry, other than translations and adaptations of old Sanskrit works and themes, is usually in the form of short lyrics issued in small volumes. This form was made fashionable by Rabindranath Tagore (*q.v.*), whose poems, originally written in Bengali, were translated into all the major Indian languages after they attained fame in English. Larger productions are for the most part collected works of single authors. or anthologies. or the outcome of literary "eisteddfods" (mushairas). In the Hindi area the old style ballad is longer, as are Tamil kavyas on classical models. The poetry is generally ethical, philosophical or religious; but the satirical and controversial and. as we have seen, the political, claim a place. The verse forms not only manifest original power, but are greatly influenced by developments in the west; T. S. Eliot, for instance, has had considerable influence on Hindi and Bengali poetry.

Fiction on European lines is making rapid headway in India, and is supplanting the old romantic tales. at least so far as prose is concerned. The novel is popular both in the form of the short story and of more substantial books; and it reflects all the varieties of subjects which have a vogue in English, historical, social, romantic and adventurous (including the detective novel). But political and economic factors have been prominent in the. novels of the best writers, such as those in Bengali of Bankim Chandra Chatterji, and in Hindi of Premchand; and this tradition continued even after 1947.

Religious Literature. — Indian religious literature, in so far as it is not lyrical, philosophical, argumentative or philological, consists mainly of manuals of ritual for daily life (dinacarya) or for particular occasions (marriage, burial, times and seasons, pilgrimages and vows), and of the stories associated with them.

Since each section, from the Vedic Sakhas downward, must have its separate rituals, the number of such publications is naturally very great.

The reproduction of old canonical texts. with or without commentaries, not for purposes of ritual but for study and edification, accounts for a great mass of republication in the Punjab: there is, for instance, a steady stream of thick volumes of selections from the Adi-granth. Important religious groups usually have one or more periodicals. which. among other things. publish and comment upon their authoritative books. Philosophy is still more popular, in the real sense. in India than in any other part of the world. but the emphasis is more on theology, mysticism and comparative religion than on epistemology and logical positivism. The writings of Sarvepalli Radhakrishnan have helped to strengthen this trend.

Philology. — Philology of a more general character is no longer in India restricted to one or two classical languages. There are societies which devote themselves to the publication of old texts in the existing vernaculars. The Bangiya Sahitya Parishat, with its Pattrika (journal) and its series of separate old Bengali texts, has a very honourable record. The Tamil Sangam of Madura (which issues the *Sentamil*) is likewise distinguished. There are other Sahitya Parishats in West Bengal. and for Telugu there is the Andhra Sahitya Parishat.

For Hindi there is the Nagaripracharini Sabha; for the Punjab the Khalsa Tract society; in Gujarat the oldest is the Gujarat Vernacular society, while there is also a Sahitya Parishat, and a Sahitya-Vardhana society; in Marathi an important series of editions of old poetry was published under the title *Kavya*-samgraha.

Literary Research. — Philological activity, also found in association with the investigation of archaeology and pre-British history (and from which we may exclude the astounding output of educational works up to the level of university textbooks), is connected chiefly with organizations of some kind. The government of India itself maintains an archaeological survey which publishes annual reports in the several states and at headquarters, and special monographs as well as two periodicals relating to archaeology and epigraphy. Several state governments have published catalogues of Sanskrit manuscripts.

After the governments may be mentioned the universities. colleges and libraries. also active in the publication of texts and research results (especially the universities of Calcutta. Madras and Benares). Important journals are issued by societies (such as the Asiatic Society of Bengal. which has also published a *Bibliotheca Indica*, a vast collection of Sanskrit, Arabic. Persian and Tibetan texts: the Bombay branch of the Royal Asiatic society; the Bihar and Orissa Research society; the Hyderabad Archaeological society; the Bhandarkar Oriental institute) and some are occasionally started independently or by religious bodies. Private organizations have also undertaken the editing of encyclopaedias in the various languages. The books issued by authors, editors or individual publishers are. however. more numerous. Much is highly meritorious. some of it equal to the best productions of Europe. The monumental Linguistic *Survey of* India, edited by Sir George Grierson for the government of India, was completed in 1928.

History and Biography. — For educational purposes and general reading many short histories of India. of England and of other countries are produced both in English and in the vernaculars. Original research and independent judgment are to be found in the monographs and studies of particular regions, dynasties and viceroys: and the output of Indian historical scholarship is increasing. The Indian History congress has undertaken the publication in 24 volumes of a standard history of India. The government of India is sponsoring a history of the freedom movement in India. The National Archives of India edits and calendars English and Persian documents dealing with British rule and publishes a journal which is one of the best of its kind. Many volumes of records and calendars in English have also been published by local governments: the gazetteers also are replete with historical information not absorbed in formal histories: and the *Journal* of *Indian* History, the proceedings of the annual Indian History congress and the organs of the Bengal Historical society, the Punjab Historical society and the Uttar Pradesh Historical society are composed of original matter.

Biography, including autobiography, is now popular in India. The best-known are the autobiographies of Mohandas K. Gandhi (originally written in Gujarati) and Jawaharlal Nehru. but there are also memoirs of many other well-known personages. Biographies of historical figures and important religious leaders are also increasing in number. D. G. Tendulkar's 8-vol. *Mahatma; Life* of *Mohandas Karamchand Gandhi* was published in 1951–52. The number of short "lives" of popular heroes, such as B. G. Tilak, G. K. Gokhale and Gandhi. is beyond counting. A very favourite form, of which there are old examples, is the serial biography. containing lives of saints, lives of famous women and hierarchical, dynastic and family biographies. Valuable work of this kind has been done in regard to the Tamil and Telugu saints and poets, and the poets of Bengal and Gujarat. The old form of biography in verse is still favoured in relation to saintly and historical characters; naturally. it has aims other than information and research. Many Indians have written accounts of their travels abroad: but India itself furnishes rich material and occasions for travellers' experiences, especially with its shrines and pilgrimages. Jawaharlal Nehru's Discovery of India is no isolated phenomenon.

See M. Winternitz, *A* History *of* Indian Literature (Calcutta, 1927 ff.) ; H. N. Das Gupta, The Indian Stage, 4 vol. (Calcutta, 1934–44).

(S. GL.)

INDIAN **MUSIC.** The music of India has a double interest. It offers the most complete example. in theory and practice, of melody untouched by harmony; hence. it provides a key to the problems of ancient Greek music, which have fascinated scholars and musicians.

Musical literature refers not seldom to the "laws of melody," but makes no attempt to formulate them. because European melody is always harmonized. and it is nearly impossible to say what part of it belongs to harmony and what to melody. From a system innocent of harmony, like the Indian, we realize that: (1) Melody swings. in the first instance, on two pivots — the vocal tonic (amsha), a sort of "ecclesiastical" dominant. at a pitch that varies nith the mode, and the tonic in our sense of the word supported by a drone (kharaj) and, secondarily, on notes related as fourth or fifth to either of these On this varying distance between the two tonics depends mainly the character of the mode (*rāg*), poignant, if the *amsha* is high, festive or placid, if low. (2) There is a general contrast of major and minor, but the third of the scale is no more decisive of this than the seventh. sixth or second: the ethos of the minor is not so much sad as elaborate and reflective, and is graduated or intensified by shades of intonation nhich we do not possess (3) **A** melody is conceived as lying within, or round, the tetrachord though the second part of it may spring to the upper octave. just as. with us, it would adjourn to a key of contrast. (4) The motion is mainly conjunct; intervals which strike us as odd (augmented second or augmented fourth) are justified as motion to or from the *amsha*. (5) The octave contains. like ours, seven notes (it is called *saptaka*, a set of seven), with possibly an eighth or ninth as an alternative. not an addition. The "quartertones" (shruti) have been entirely misconceived by European uriters. They do not provide a scale of 22 notes through which the voice threads its precarious path. but are in use as increments of intervals well-known to us, and lend them an exhilarating or pathetic colouring. (Thus, from a tonic C, the sixth. A will have 884 accents in one mode, 906 in another, B flat, similarly. 996 or 1.018.) The Indians have. in fact preserved distinctions which we have merged by our "temperaments." and non employ them for a musical purpose; just as grammar will sometimes employ different forms (nosco and *novi;* ken, can and know) for different meanings. (6) Melody centres in the mode. The amateur knons a dozen of them, the professional at least five. perhaps ten, dozen. (It is customary to say that we have only tao modes, major and minor; but for those who consider the history and the implications of the Neapolitan sixth. the German and diminished sevenths. etc., there are more than two.) The modes are differentiated

by *(a)* their amshas, (b) the flat (komal) and sharp (tivra), or the very flat and very sharp notes (*atikomal, atitivra*) and (*c*) the amount of transilience, *i.e.,* whether they are of five, six or seven notes in all. The various admixture of these elements gives each mode its flavour (raga), and this is emphasized by assigning the mode to a particular hour of the day or season of the year.

We conceive musical times as multiples, they as sums. We take $\frac{6}{8}$ as 3×2, and $\frac{9}{8}$ as 3×3; they, as $3+1+2$ and $5+2+2$ (or $4+2+3$, or in some other way). In these three instances, to go no farther, they are representing the dactyl (– ∪ ∪) of their prosody, and allowing for (a) different lengths of short syllable and (b) different proportions of long to short. They have dealt similarly with trochee (– ∪), iambic (∪ –) and anapaest (∪ ∪ –). The tribach (∪ ∪ ∪) they treat as three crotchets and a crotchet rest, thus arriving at common time, which they call "three-time." Such procedure soon becomes far too elaborate to follow out here, though, in practice, they confine themselves to only a dozen kinds of time.

But, in whatever time it may be, the essence of an Indian melody it that it employs cross rhythm. Singer and drummer converge upon a point; one sings seven bars of ten units perhaps, while the other drums ten bars of seven units; or the drummer's two hands beat different times, one $2+2+2$ and the other $3+3$; or one hand starts at the beginning and the other in the middle of the bar, in different times, and they converge half a dozen bars later. The audience appreciates such a point, and waits for it.

In the absence of harmony, grace-notes are important, to emphasize one moment as against another. The couple of dozen graces that are practised are, in principle, two—the slide (as on the violin) and the "deflect" (as produced by the tangent of a clavichord). The eminence of a performer is largely decided by his skill in these, and he uses them to accentuate the essential notes of the mode.

The chief instruments are (1) ***vim,*** with three drone strings, and four fretted strings on the finger board, plucked like, and with the tone of, the guitar; (2) sitar, a simpler form of guitar, more easily played, with less noble tone, native to Bengal; (3) *sārangi,* an elementary violin, used for the nautsch; (4) *surnai,* a hautboy of strident tone; (5) various drums, the most important being the tabla, a small pair, played one by each hand; and, in the jungle (6) the *banshri,* bamboo flute, of varying size, scale and compass. Concerted music, vocal or instrumental, is rare, and is in unison. (A. H. F. S.)

INDIAN MUTINY, THE, the great revolt of the Bengal native army in 1857 which led to the transference of the government of India from the East India Company to the Crown in 1858. This mutiny, accompanied by rebellion of the population in many parts and of some of the chieftains of India, was due to many causes, some of which remain a matter of controversy to this day. Whatever were the ultimate political and psychological reasons underlying the rebellion, the increasing of the native army to implement the holding of the newly acquired territories of Oudh, the Punjab and Sind, out of all proportion to the European garrison, together with a reduction of that small garrison during the Crimean and Persian campaigns, made a mutiny possible and sufficiently attractive to catch up into its whirlwind the discontented political elements.

During the 100 years which had elapsed since the battle of Plassey, the East India company had risen, through the crumbling of the central power of the Mogul empire, from being the mandatory of that empire for the government of certain coastal tracts, to the control of the whole of the Indian peninsula. In overcoming the various warring principalities into which the Mogul power had broken up, the instruments were largely Indian soldiers themselves, who had eagerly followed the British who were proud to lead them. A vast army modelled on the British Line[1] and clothed to resemble it had sprung up, with all the complicated machinery and traditions of a regular standing army. Elated at the success which attended the British arms, the martial races eagerly enlisted under the Union Jack, and served gallantly and faithfully, fighting more than once against the French and sailing as far as Mauritius, Egypt and Java to take part in the wars against Napoleon. But ever behind this great native army marched as a hammerhead European corps, some enlisted for the service of the company, but chiefly consisting of the British Line. The European units always bore the brunt of the hardest service. The vast native army was organized in three distinct lines, under the presidencies of Bengal, Madras and Bombay. The native army of Bengal was by far the largest, and the three armies, in addition to the line, had developed many local corps, regular and irregular, while the larger native states also maintained contingents under treaty, trained as a rule after the manner of the Bengal army and officered by British officers, which enlisted in many cases the same races as furnished the Bengal Line.

[1] Line—an *organized regular army.*

The Bengal army and indeed the whole of India were shaken by the disasters which, for the first time, overcame the company's forces in Afghanistan in 1841–42. In the wars with the Sikhs (1846–49) the fighting and the nature of the foe were far more formidable than previously experienced; the European troops had to bear a more forward part than ever in the great battles of that war, and the prestige of the Bengal army was to some extent threatened.

There had been several untoward military incidents in the 50 years preceding 1857. As early, indeed, as 1764 it had been necessary to quell mutiny by the usual oriental punishment of blowing away the offenders from the guns, when 30 sepoys (*i.e.,* soldiers, from *sipahi;* cf. the form *spahi* in the French African army) were so disposed of.

In 1806 a serious mutiny was brewing in the Madras army, partly born of the overintroduction of European-pattern clothes and accoutrements. In 1824 the 47th Bengal native infantry refused to march when it was ordered for active service in Burma and, after being somewhat severely handled by European artillery, was disbanded. In 1844 no less than seven battalions of the Bengal army broke into open mutiny over the question of allowances when garrisoning newly acquired provinces. It was to be noticed that the sterner measures of earlier days were not taken and the corps involved for the most part remained in the service.

But there were not wanting those who saw further and thought harder. Lord Ellenborough often said that a general mutiny of the native army was the only real danger with which the British empire in India was threatened. His warning was solemnly repeated by Sir Charles Napier as commander in chief, who based his warning on the many defects which had gradually crept into the military system.

General John Jacob of the Bombay army uttered still more forcible warnings during the years immediately preceding the mutiny.

Sir Henry Lawrence, than whom no greater authority existed, frequently warned all and sundry that things were not right and that what had occurred at Kabul might happen at Delhi.

There can be little doubt that the social reforms of Lord Dalhousie and his predecessors had disturbed many men's minds. The prohibition of suttee (*q.v.*) and female infanticide, the subordination of Brahmans to the ordinary criminal laws, all tended to cause bitterness and alarm. The landowning class, especially among the Mohammedans, found that British rule meant curtailment of inordinate privileges and fair .treatment for the poor, while at times British zeal for justice pressed unduly on these ancient classes.

The Greased Cartridge and the **Chappattis.**—To this accumulation of inflammatory material a spark was put in 1857 by a strange but intelligible oversight on the part of the authorities responsible for the manufacture of ammunition. The use of the Minie or Enfield rifle involved a cartridge with a heavily greased patch at the end, The use of the cartridge for muzzle-loading muskets had always demanded the biting of the end and the pouring of the powder thus released into the barrel. Then occurred an altercation at Dumdum between a high-class Bengal sepoy and a low-caste employe of the arsenal and the hurling of a gibe by the latter as to the utter defilement involved in the use of the

new cartridge. The news spread. Officers, when they heard of the trouble, took the matter up; and it was decided that whatever material had been used, clarified butter was to be the future ingredient. It was also arranged that men Should grease their own materials. But the mischief had been done, and the clever brains which had been plotting against the British found a stimulant. There is no doubt that the first cartridges did contain material that would be entirely unclean, and there is no doubt that the fears of the sepoys were genuine.

At this time, too, when half India was agape and looked for a portent, the strange phenomenon of the *chappattis* occurred. The ordinary unleavened cakes of household use seemed to be passing round. A village watchman arrived at a village, distributed a cake, saying, "To the north, the south, the east and the west," with injunctions to make four more and increase the snowball. No one knew why they came. The watchmen only knew that someone had brought them. But it was known that in the past similar appearances had taken place in time of trouble.

The first signs of the approaching upheaval were displayed at the great military station of Barrackpore, 16 mi. from Calcutta, in Jan. 1857. The rumour regarding the cartridges, which had originated at the adjacent Dumdum, had much inflamed the minds of the sepoys quartered there. The well-known sign of unrest, incendiary fires, broke out in the lines. Fortunately General Hearsey was perhaps the best known and most experienced sepoy general in India, and active withal. Trouble was for the time laid by his judicious handling, but he warned the government that he was sitting at Barrackpore on a mine ready for explosion. A month later the 19th Bengal infantry at Berhampur refused to receive their percussion caps, on the ground that to use the new cartridge meant defilement. The absence of any European troops necessitated a temporizing policy. The battalion was, however, ordered to march to Barrackpore for disbandment. Two days before its arrival, on March 29, a sepoy named Mangal Pandi[1] endeavoured to provoke an outbreak in his regiment, the 34th native infantry, shooting the adjutant who interfered and cutting down the European sergeant major of the battalion. The regimental guard failed to take action, but General Hearsey, who happened to be riding by, rode at the mutineer.

At this juncture, the gravest which had ever befallen the British in India, the commander in chief and his office, with all the military heads, were separated from the governor general and the government by many hundreds of miles. Calcutta was the headquarters of government, and though on occasion the governors general had summered at Simla during the wars with Afghanistan and the Sikhs, the offices and the ministers did not move. The commander in chief, finding that the major portion of his army was in the north, had made Simla his headquarters. The absence of the commander in chief and the adjutant general from the seat of government at this period made any concerted policy impossible.

The Outbreak at Meerut.—By May 10 the situation developed in grim earnest, and what had fizzled at Berhampur and Barrackpore broke into flame at Meerut. Meerut was the largest station south of the Punjab, commanded by Major General Hewitt and containing a considerable European garrison; viz., the carabineers, the 60th rifles and two troops of Bengal horse artillery, with the headquarters and principal depot of the Bengal artillery, commanded by Brig. Archdale Wilson. Meerut was originally instituted to watch Delhi and the Maratha frontier. The native troops were the 3rd light cavalry (a regular and nonsilladar corps) and the 11th and 20th Bengal native infantry.

The officer commanding the cavalry, who had lately returned from leave, decided that the cartridge question must be faced and ordered the sharpshooters of his regiment to receive the cartridge and practise the new loading drill. Eighty-five of the men refused, were tried by a native court-martial and sentenced to long terms of imprisonment for mutiny. At a general parade of the garrison the convicts were degraded and put in irons.

Just before dusk on the day succeeding the punishment parade, a Sunday, the native garrison broke out into open mutiny. The cavalry saddled and mounted and galloped to the jail to release their comrades. The 11th infantry shot the colonel of the 20th and fell on any of their own officers who came their way. The European and Indian barracks lay some distance apart. At Meerut the two portions of the cantonment, divided by a deep watercourse, were especially distinct. While the mutineers were murdering all Europeans that they came across, aided by all the ruffians who inhabit an Indian bazaar, the British troops, unaware of what was happening, were about to turn out for church parade which, at that season, was held in the evening, when the sound of firing broke on their ears. Fortunately the rifles were not in church and hurried to get under arms. The regimental sergeant major ordered the men to change from white cotton to their green clothing. When the British troops marched to the scene of the conflagration the mutineers were gone. A few rounds in the direction of the native lines cleared out any stragglers. The scenes of outrage did not continue. The cantonment was surrounded with woods and villages, and there were large numbers of women and children to be collected in a central place of refuge. The carabineers themselves were hardly a regiment in fact. Just out from Europe to replace a regiment sent to the Crimea, they were largely young soldiers, mounted on walers[1] as yet only half trained. No one thought that the excited rabble of soldiers without their leaders was going to march straight to face the orderly brigade at Delhi, or that anyone could think of restoring the Mogul dynasty.

Delhi.—Whether, had the situation been grasped and correctly interpreted, Delhi could have been saved, can only be a matter of opinion. It has, however, been said that matters had gone too far for any local action to prevent the rebellion and that Delhi, acting as a focus of the disease in the north, served a valuable purpose and contributed to its eventual suppression in a manner that could not have been foreseen. Early in the morning the mutinous cavalry reached Delhi, to be followed by parties of tramping redcoat sepoys. Attempts were made to prevent their entering the city and palace, but troops sent cheering from the cantonment three miles away soon fraternized with the mutineers; officers were shot down on all sides. The city and palace rabble hastened to massacre all Europeans and Christians. Those who took refuge in the palace were soon butchered. The whole of the civil lines which lay within the city wall became a shambles. Up on the ridge which lay between the cantonment and the city the brigadier with half his garrison stood to arms till dusk, the Europeans clustered at a small tower, the troops muttering and restless. Within the city walls, one of the most famous incidents in British history was taking place. Between the Kashmir gate and the fortress-palace stood the great arsenal of upper India, left by some strange folly entirely in the hands of Indian troops and within the city. Sir Charles Napier, when commander in chief, had protested, and the magazine itself had been moved to the end of the ridge in the cantonment. Within the arsenal there was an immense park of cannon, with a small "expense" magazine in which small-arms ammunition was made up. After defending the arsenal for as long as possible the resolute young artillery officers and warrant officers of the arsenal establishment, under Lieutenant Willoughby, blew up their magazine, causing great damage to their assailants. This act, however, had not the effect generally supposed, for unfortunately Sir Charles Napier's forethought in moving the main magazine had but resulted in its falling into the mutineers' hands. Without its contents (3,000 bbl. of powder) the defense of Delhi by the mutineers would have been impossible. At sunset the remnant of the Europeans left Delhi for Meerut and Umballa as best they could. The Mogul former king was proclaimed by the soldiery and was put at the head of the rebellion.

One hundred and twenty miles north of Delhi lay the great military station of Umballa, the headquarters of a large military district commanded by Maj. Gen. Henry Barnard of Crimean fame, which being in the newly occupied Punjab had many European troops. Of these, three battalions of European infantry were in the Simla hills for the summer, 60 to 80 mi. farther away. At Umballa itself were the 9th lancers and two troops of European artillery with several native units. The commander in chief, Gen. George

[1]From whose name, a common patronymic of Oudh Brahmans, the mutineers became known as "Pandies."

[1]Australian horses from New South Wales.

Anson, at once ordered all the Europeans in the Simla hills to march to the plains; the commander at Umballa was to get ready his force to march to Delhi. It was some days before the troops could be got down from the hills and supplies and transport collected.

It must be remembered that there were practically no railways in India in 1857 and that the mutiny occurred in the height of the hot season. On May 17, six days after the outbreak at Delhi, the leading portion of the commander in chief's forces left Umballa for Kurnal, about 50 mi. down the Grand Trunk road, followed by a stream of detachments. The commander in chief proceeded to Kurnal on May 23 and died there of cholera four days later.

With the rising at Delhi and the proclamation of the former king of Delhi to the throne of his fathers, the whole of the Bengal army, from Calcutta to Delhi, broke into revolt. At some stations the influence of individual officers held the regiments for a time, but with a few exceptions the whole of the Bengal army and the contingents of the central Indian states caught the contagion. Scenes of tragedy and horror were enacted all over the Bengal presidency, especially along the great waterways of the Ganges and the Jumna. But from Calcutta to Meerut, a marching distance of 1,000 mi., the European garrisons were extremely small.

At Lucknow, with one British battalion, Sir Henry Lawrence kept his troops in hand for weeks. At Cawnpore Sir Hugh Wheeler, experienced but aged, tried to maintain a bold face with a few Europeans sent him by Lawrence. At Agra one European battalion held the great fortress and became a refuge for all the neighbouring provinces. As soon as the gravity of the situation was realized by Lord Canning, the governor general, attempts were made to apply the only remedy, reinforcements of European troops. A battalion from Burma had been brought over when the trouble at Barrackpore had occurred. An expedition on the way to China was now summoned to help, and the European portion of the Persia expedition now returning to India was hurried to Calcutta.

With the upper provinces isolated and telegraphs cut, with the commander in chief dead at Kurnal, it was necessary to organize a new chief command. Gen. Sir Patrick Grant, the most famous of the Bengal sepoy officers of the day, was summoned from Madras, where he was provincial commander in chief. The pacification of the lower provinces first demanded the dispatch of such small columns as could be organized to relieve the two officers in the greatest danger—Sir Hugh Wheeler at Cawnpore and Sir Henry Lawrence at Lucknow.

To help the small stations was impossible. The restoration of order at the centre would automatically relieve them. Only in the Punjab, the most important of all the provinces, was the situation reassuring, and this for four reasons: first and foremost, the presence of a far larger number of European troops in the newly acquired provinces; second, the commanding character of the ruler, Sir John Lawrence; third, the fact that the Punjabis had recently been beaten by the British and liked their new masters; fourth, the pick of the young men of the Indian services were in civil and military employment in the north. Maj. Gen. Thomas Reed, the senior general in the Punjab, went off to Delhi to assume the provisional chiefship when Anson died, to break down immediately from his exertions. But at Peshawar, the brigadier, Sidney Cotton, was a tower of strength.

The eagerness, indeed, of Lawrence caused him to overlook the problem of moving Europeans in the Punjab summer and the want of carriage and equipment, nor did he at first realize the character of the revolt. Seeing that Delhi was the focus and should be recovered at all costs, and finding that even the combined Meerut and Umballa force could not take the city, he poured his British troops down, raising also innumerable levies to replace the Bengal troops, who were disarmed at many stations. His boldness and that of Sidney Cotton, Neville Chamberlain and John Nicholson charmed the wild Afghan and frontier tribes, who flocked to serve and share in the loot of Delhi. The amir of Kabul, contrary to expectation, held by his alliance and refrained from attacking the British. Lawrence gambled and won. But it required every man he could raise before Delhi could be taken.

By June the combined forces from Meerut, under Gen. Sir Henry Barnard, the commander of the Umballa division, and Brig. Gen. Archdale Wilson from Meerut, defeated the rebels in three engagements and found themselves once again in the cantonment of Delhi.

The final reinforcements reached the ridge from the Punjab late in August, under Brig. Gen. John Nicholson, who had hitherto passed rapidly up and down the Punjab disarming Bengali garrisons. With him came the last supplies of siege guns and ammunition. The siege batteries then opened an intense fire on a short front of wall and bastion. At dawn on Sept. 14 three columns moved against the city, two attacking the breaches and the third blowing in the Kashmir gate. The walls on the ridge side were soon in British hands, but Nicholson was mortally wounded. Days of severe fighting were necessary to clear out the city and gain the fortress-palace. This finally done, the former king was captured at Humayun's tomb outside Delhi and the sons shot to avoid a rescue. The fittest of the troops then started south to relieve Agra.

Relief of Lucknow.—The course of the mutiny had four distinct phases: (1) that of the outbreak, and the recapture of Delhi with the British garrison and Punjab troops which were chiefly stationed in the north of India; (2) the coming of reinforcements and the restoration of order along the course of the Ganges, with the relief of Lucknow; (3) the final capture of Lucknow in the spring of 1858 and the destruction of the second great centre of rebellion; and (4) the pacification of the country.

Sir Patrick Grant on his arrival had found a government in a military crisis, with no military headquarters. Not one high official of the staff of the army nor any of its machinery was available. It was necessary to improvise and reconstruct an army machinery which would handle the large forces arriving for what was now clearly seen to be the reconquest, not only of Bengal, but of most of central India, to which the conflagration had now spread. Very soon came the news that government at home had appointed Sir Colin Campbell to succeed Anson, and Grant could occupy himself only with making a machine for Campbell to use. He did, however, push forward as soon as possible a column to relieve General Wheeler at Cawnpore and Sir Henry Lawrence at Lucknow, pushing up first Col. J. G. S. Neill and his Madras fusiliers and then, as soon as he arrived, Gen. Sir Henry Havelock with more reinforcements.

The trunk road up country from Calcutta led straight across country to Benares on the Ganges, a distance of about 380 mi., of which the first 100 mi. could be travelled on the recently opened commencement of the railway. Eighty miles farther lay the Mogul fortress of Allahabad at the junction of the Ganges and Jumna, and 120 mi. beyond was the important military centre of Cawnpore, which had long watched the adjacent state of Oudh. At Cawnpore was Sir Hugh Wheeler's headquarters, with four native regiments and one European field battery. At Lucknow, 45 mi. distant, the headquarters of Sir Henry Lawrence and the administration of Oudh, was a European battalion and a large native force. Wheeler, greatly experienced in the sepoy army, realized that his troops were likely to mutiny and that it must be a race against time. He was encumbered with a large number of women and children. It was essential to find a place of refuge, and choice lay between a fortified magazine a long way from the cantonment at the other side of the native city and some disused hospital buildings, still unfortified, on the parade ground. Because it would have been difficult to move to the magazine and in order to be easily accessible to the reinforcements expected early from the south, Lawrence decided on the hospital buildings. A company of the 32nd foot from Lucknow came in to help garrison the entrenchment, into which most of the Europeans moved on May 21. On May 31 about 150 men of the 84th foot from Burma and a few Madras fusiliers arrived. Believing that the crisis was passing, Wheeler sent a company of the 84th on to Lucknow. The total force of possible combatants in the entrenchment now was about 450 men, including civilian Europeans and Eurasians, with

six guns, but there were 330 women and children. On June 4 and 5, the sepoys mutinied and marched for Delhi. But there lived, near Cawnpore, one Dandu Panth, the Nana Sahib, adopted son of the former peshwa,[1] who prevailed on the mutineers to return and attack the entrenchment, which they did on June 6.

From June 6 to June 24 the garrison held out against heavy bombardment and at last, worn out with heat and sickness, surrendered on promise of safe conduct by boat to Allahabad. Then followed the infamous massacre at the boats and the collection of women and children to be murdered later. Neill and his Madras fusiliers, pushing up from the railhead by bullock train and route march through great heat and heavy rain, first reached Benares in time to quell a mutiny there and then threw themselves into Allahabad, still garrisoned by a few artillery invalids and some Sikhs. There Neill collected supplies, pushed parties up the road and awaited Havelock, who was able to leave Allahabad on July 7, some of his troops moving by road and some by steamer. After several engagements with the mutineers Havelock heavily defeated their main force outside Cawnpore on July 16, to find that all the women and children had been hacked to death in a small house known as the Bibi-ghar the night before.

Their bodies, some still breathing, were thrown down a well, on which now stands a monument. No act in the mutiny raised so fierce a storm of anger.

At Lucknow, the headquarters of Sir Henry Lawrence and the administration of Oudh, the British still held out. Up till June 30, though there had been mutinies in Lucknow and in the neighbourhood, the garrison was not beleaguered. On June 30 Lawrence, moving out to attack the mutineers at Chinhut, immediately incurred disaster, which not only severely crippled the force of Europeans but compelled Lawrence to abandon outlying positions and concentrate in the group of houses known as the residency. The garrison, 1,720 fighting men, of whom 712 were loyal sepoys and 153 civilian volunteers, was now hotly beleaguered. Unfortunately Sir Henry Lawrence was fatally wounded by a shell on July 4, the command devolving on Brig. John Inglis. Havelock at Cawnpore was compelled to wait for reinforcements, and to collect carriage and supplies. It was not till late in September that he was able to advance to Lucknow. By Sept. 25 he had reached the residency, a reinforcement enabling the garrison to hold a less restricted area; but it had to remain for many weeks before the actual relief could come up.

In the meantime Sir Colin Campbell had arrived. By Nov. 3 he reached Cawnpore and was ready with 4,500 men to advance on Lucknow. That city had become the focus of rebellion of all who had not hurried to Delhi, and 60,000 armed men were collected round the devoted Lucknow garrison and its reinforcements.

By Nov. 12 the force reached the Alumbagh, and by Nov. 14 it advanced on Lucknow. On Nov. 16 the Sikandrabagh was stormed and Campbell joined hands with Sir James Outram and Havelock. The commander in chief had decided to withdraw the garrison and all its helpless folk at once and to leave a strong force outside the city till he was prepared to attack the whole of the Lucknow rebel concentration. The success was marred by the death of Havelock, who was buried in the Alumbagh, in mhich Outram with 4,000 men was left to face the masses of the rebels till Sir Colin was ready.

The Campaign in Oudh and Central India.—Returning to Cawnpore with the rescued people, the chief was in time to save that important place from a sudden attack by the Gwalior rebels. The second phase of the mutiny, that of the coming of the reinforcements and the reopening of the Great Trunk road, had now been accomplished. Caanpore had been avenged and Lucknow relieved, while in the far north Delhi had fallen and the Delhi troops nere marching south. It was not, however, till March 1858 that Sir Colin had enough troops for his purpose, when Jang Bahadur, the prime minister of Nepal, had also arrived with 10,000 Gurkhas. The attack on the masses entrenched at Lucknow began on March 9 and partook of the nature of a siege, lasting till March 16, when the city was in British hands and the whole rebel army routed. It was the brilliant campaign of Sir Hugh Rose in central India mhich destroyed the last mutinous forces in being and clinched the suppression of the mutiny.

Though the two great princes of central India, Sindhia and Holkar, remained true to the British, troops belonging to both of them joined the mutineers. The Gwalior contingent of Sindhia's army mutinied in the middle of June, and on July 1 Hoikar's troops revolted at Indore and the resident, Henry Durand, was forced to leave the residency. The rani of Jhansi also rose in rebellion, to become known as "the best man upon the side of the enemy." The rising in this quarter received little attention until Jan. 1858, when Sir Hugh Rose was given the command of two brigades, to act in concert with Sir Colin Campbell; he immediately began a campaign which for celerity and effectiveness was rarely equalled in India. Advancing rapidly from Bombay, Rose relieved Saugor on Feb. 3, after it had been invested by the rebels for almost seven months. On March 3 he forced the pass of Madanpur and took the whole of the enemy's defenses in rear, throwing them into panic. On March 21 he began the siege of Jhansi, the stronghold of the mutineers in central India, with a garrison of 11,000 men. During the course of the siege Tantia Topi, the most capable Indian leader of the mutiny, arrived with a fresh force of 20,000 men and threatened the British camp; but Rose, with a boldness which only success could justify, divided his force and, while still maintaining the siege of the fort, attacked Tantia Topi with only 1,500 men and completely routed him. This victory was won on April 1, and two days later Rose carried Jhansi by assault. On May 1 the battle of Kunch was fought and won in a temperature of 110° in the shade, many of the combatants on both sides being struck down by heat apoplexy. On May 22 the battle of Kalpi was won. In five months he had beaten the enemy in 13 general actions and sieges and had captured some of the strongest forts in India. News now arrived that the rebel army under Tantia Topi and the rani of Jhansi had attacked Sindhia, whose troops had gone over to the rebels and delivered Gwalior into their hands.

Rose marched against Gwalior at once, captured the Morar cantonments on June 16 and carried the whole of the Gwalior positions by assault on June 19, thus restoring his state to Sindhia within ten days of taking the field. This was the crowning stroke of the central India campaign and practically put an end to the mutiny, though the work of stamping out its embers went on for many months and was completed only with the capture and execution of Tantia Topi in April 1859.

Nature of the Mutiny.—The Indian mutiny was in no sense universal. In the first place it practically occurred only in Bengal, central India, the northwest provinces along the Ganges, Oudh and the Punjab; viz., those provinces garrisoned by the Bengal army and its offshoots. The Madras Line stood firm as did almost all that of Bombay. Seditious movements among the Marathas were kept in hand. Even in the affected districts the great mass of the people either stood neutral or helped the British troops with food and service, in many cases also sheltering British fugitives to the best of their ability. The attempt to throw off the British yoke was confined to a few disaffected former rulers and their heirs, with their numerous clansmen and hangers-on, besides the badmashes and highwaymen who saw their way to profit by the removal of the British administration under which their peculiar talents found no outlet. The Bengal native army was their tool. But the fighting races of the Punjab saw no reason for casting in their lot with the mutineers, and the great majority of the independent princes who had nothing of which to complain, like Patiala and Jhind in the Punjab, preserved a loyal or at least an interested friendship. The Sikhs kept faith with their recent conquerors, and the Gurkhas of Nepal did yeoman service for their fathers' enemies.

The chief result of the Indian mutiny was the end of the government of India by the East India company. It was felt that a system of administration which could permit such a catastrophe was no longer desirable. On Aug. 2, 1858, the queen signed the act which transferred the government of India to the crown. On Nov. 1 Lord Canning, then viceroy of India, published the

[1] The deposed and pensioned chief of the Maratha confederacy who lived in exile near Cawnpore.

proclamation in which the change was announced, and a full amnesty was offered to all the rebels who had not been leaders in the revolt or were not guilty of the murder of British subjects.

INDIAN OCEAN, the name applied to the region bounded on the north by India, Pakistan and Iran (Persia); on the west by the Arabian peninsula and Africa; on the east by the Malay peninsula, the Sunda Islands of Indonesia, and Australia; and on the south by Antarctica. An arbitrary separation from the Atlantic is made at the longitude of Cape Agulhas (20° E.) and from the Pacific at the longitude of Tasmania (147° E.).

The ocean is more than 6,200 mi. wide between the southern points of Africa and Australia and narrows steadily toward the north, where it is separated by India and Ceylon into the Arabian sea and the Bay of Bengal. Two adjoining seas connect with the Arabian sea, the Red sea through the Strait of Bab el Mandeb and the Persian gulf through the Strait of Hormuz. Because of the concentration of maritime traffic in low latitudes, the Indian ocean is often considered to be a tropical ocean but actually it extends to latitude 70° S. and the Red sea and Persian gulf reach to 30° N.

The Indian ocean has an area of 25,300,000 sq.mi. and is the smallest of the oceans, comprising only 20.7% of the ocean-covered portion of the earth. The two adjoining seas included in these figures are relatively small, the Red sea covering 169,000 sq.mi. and the Persian gulf 92,300 sq.mi.

The Indian ocean receives few large rivers, the chief being the Zambezi, the Shatt-al-Arab (formed by the junction of the Tigris and Euphrates), the Indus, the Ganges, the Brahmaputra and the Irrawaddy. J. Murray estimated the total land area draining to the Indian ocean at 5,050,000 sq.mi. (1.3 the area of Europe), more than two-thirds that draining to the Pacific. The Pacific, however, is more than twice as large as the Indian ocean. In addition to the rivers mentioned, the southwestern and northwestern monsoons in the tropical regions on the eastern side of the Indian ocean bring heavy rains, and there is heavy rainfall also in the neighbourhood of the equatorial calms. Therefore, the salinity of the surface water in these regions is relatively low, particularly in the Bay of Bengal into which flow the great rivers from the mainland.

Relief of the Ocean Floor.—Large portions of the ocean bed remain unexplored. In the latter part of the 19th century, H.M.S. "Challenger" and the German "Gazelle" and "Valdivia" provided a general understanding of the topography which was later expanded by the expeditions of the "Sealark" and many British cable ships. The "Discovery II" made extensive cruises, beginning in 1929, in high latitudes and in the western part of the ocean. The oceanographic vessels "Willebrord Snellius" and "Dana II" worked in the open ocean, and the "Ammiraglio Magnaghi" in the Red sea. The "Mabahiss" explored the northwestern part of the ocean in 1933–34, the Swedish "Albatross" the equatorial regions in 1948 and the Danish "Galathea" selected deeper waters in crossing from southern Africa to India to Indonesia in 1951.

A longitudinal ridge, the mid-Indian ridge, extends from India to Antarctica and separates the Western Indian and Eastern Indian troughs. Although similar in general location to the Atlantic ridge, it is much wider and does not extend so near the surface. In the northwestern part of the ocean the ridge is divided with two elevations extending toward the coast of Africa and separating the Arabian, Somali and Mascarenes basins. The longitudinal ridge is continuous at depths less than 13,000 ft. Although the western part of the ocean is divided into a series of basins, the Eastern Indian trough extends from the Bay of Bengal to Antarctica with but one major break at depths of less than 13,000 ft. This transverse ridge occurs near 50° S. and lies between the mid-Indian and Macquarie ridges. The latter is continuous at depths less than 13,000 ft. over most of the distance from Tasmania to Antarctica and is one of the barriers separating the deeper waters from those of the Pacific. West of the Kerguelen ridge, which forms the southern part of the longitudinal ridge, there is deepwater connection with the Atlantic. These features influence the deepwater circulation and the distribution of properties.

The greatest depths are found in the Sunda trench, a narrow depression paralleling the Sunda Islands, where soundings of 24,460 ft. have been obtained. Depths of about 21,300 ft. exist in the central part of the Eastern Indian trough (Wharton deep, 19° S., 100° E.). The Red sea, with an average depth of about 1,600 ft. and maximum depth of 9,200 ft. is separated from the open ocean except for a narrow channel only 330 ft. deep. In contrast, the Persian gulf is a shallow sea with an average depth of only 80 ft. The mean depth and volume of the Indian ocean are 12,700 ft. and 70,000,000 cu.st.mi.

Islands.—Madagascar, the largest of the ocean's islands, rises from a plateau about 4,900 ft. deep extending out from Africa. Ceylon and Socotra are continental islands. The Laccadive, Maldive and Chagos islands rise from the central part of the Indian ridge, while those extending from the Seychelles to Mauritius rise from the westward extension of the ridge and are separated by deep water from Madagascar. The Andaman and Nicobar islands rise from a ridge extending southward from Cape Negrais. Between the ridge and the Malay peninsula lies the Andaman basin opening only to the south. Many oceanic islands, such as Mauritius, Crozet and St. Paul's, are volcanic. Those in tropical seas are often coral formations or possess coral reefs.

Bottom Deposits.—The characteristics of sea-bottom sediments are described in OCEAN and OCEANOGRAPHY: *Marine Sediments* because they are common to all oceans. The greater part of the Indian ocean north of 50° S. is covered with globigerina ooze. At depths greater than 16,000 ft. the calcium carbonate content is small and the deep basins, especially the Eastern trough, are covered with red clay. However, sediment cores up to 36 ft. long collected by the "Albatross" show a considerable quantity of globigerina ooze even at the greatest depth, and also pronounced stratification of sediments near the equator. Radiolarian ooze is found in some of the deeper basins, and diatom ooze covers a broad band in higher southern latitudes. Eighty-six per cent of the main basin (excluding adjacent seas) is covered with pelagic sediments, globigerina ooze covering 47%, red clay 22%, diatom ooze 17% and radiolarian ooze 0.4%. The remaining 14% of the bottom and the adjacent seas are covered with terrigenous sediments or shallow-water calcareous deposits (coral sands and muds). Glauconite is abundant in sediments off the African coast and calcareous sediments predominate in the Persian gulf and on many of the coasts and oceanic islands in tropical latitudes. Southeast of Ceylon an extensive flat area is apparently underlain by lava.

Compared with the Atlantic and the Pacific oceans, the high proportion of pelagic siliceous oozes is quite striking, but this is the result of the shape of the ocean and the relatively large extent of the diatom ooze band in the south.

Meteorology.—In no oceanic division does the regular half-yearly alternation of all the factors in weather conditions and particularly the winds play such an important part as in the monsoon regions from 10° S. northward of the Indian ocean. From Oct.–Nov. to March–April northeast winds prevail in the north latitude and northwest winds in the south latitude; from May–June to Sept.–Oct. south and west winds prevail. In the Arabian sea between Socotra and the Maldives these southwest monsoons are very violent and are dangerous even to modern steamship traffic. From the earliest times the voyages of the native sailing vessels between India and Africa have been regulated by these alternating winds. The southwest monsoon brings rain to the whole of India; the northeast monsoon is predominantly dry. Southward from the latitude of the Seychelles-

Chagos-Cocos islands, the southeast trade wind prevails throughout the year, and south of 30" S. the west winds which are generally particularly strong between 40" and 55° l., and of which in the 19th century the fast sailing ships bound for Australia and China took advantage.

The tropical storms, especially of Mauritius, are much dreaded; they follow a parabolic course from east to west then southward and back to the southeast, and occur in the summer season. In the Arabian sea and the Bay of Bengal these hurricanes are. fortunately, rare and occur only once or twice a year, in April–May and Oct.–Nov., that is to say, at the periods when the monsoons change. In the Hooghly delta off Calcutta the high waves which accompany the storms are dangerous and have caused the loss of thousands of lives.

Surface Currents. — Over the northern part of the Indian ocean the surface currents change with the monsoon. During the northeast monsoon the currents flow toward the southwest and west, crossing the equator, and between the easterly current maintained by the monsoon and the westerly current maintained by the southeasterly trade wind a strong countercurrent flows east in about 10° S. The southwest monsoon appears as a continuation of the southeast trade wind of the southern hemisphere which in crossing the equator turns from a southeasterly to a southwesterly direction. In the season of the southwest monsoon westerly currents prevail to somewhat north of the equator and turn then around toward the north. A strong northerly flow is found particularly off the Somali coast and the southeast coast of Arabia, where upwelling lowers the temperature near shore.

In the southern part of the Indian ocean a counterclockwise circulation prevails with westerly currents to the north of 20° S. and easterly currents maintained by the prevailing winds to the south of 40° S. These easterly currents represent part of the large antarctic circumpolar flow. The south equatorial current divides when reaching the coast of Madagascar, sending one branch north and another branch to the south. The northern branch turns around the northern end of Madagascar and flows south through the Mozambique channel and continues as the Agulhas current to Cape Good Hope. Only a small fraction of the waters of the Agulhas current continues into the Atlantic ocean, and by far the greater body of water mixes with the waters of the circumpolar current and is carried to the east with that current. In the region of mixing, the surface temperature shows a great variability with alternating streaks of cold and warm water.

Deep Water and Its Circulation.—No large amount of deep water is formed in the Indian ocean by sinking of surface water, but the deep basins are filled by water which enters the Indian ocean to the south of Africa and is therefore similar to the deep water of the South Atlantic.

The deepwater circulation appears to be very slow compared with that of the Atlantic. Along the bottom the coldest water advances to the north and at a depth of about 3.300 ft. Antarctic intermediate water of low salinity also flows north and can be traced nearly to the equator. Between these two northerly flows deep water returns to the south and rises toward the surface near the antarctic continent. To the north of the equator the movement of the deep water is probably extremely slow.

Conditions are somewhat complicated by the outflow of high salinity water from the Red sea along the bottom of the Strait of Bab el Mandeb. This Red sea water sinks! mixes with the surrounding water and spreads at depths of 3,300 ft. to 4,900 ft. To the north of the equator it can be traced as far as Ceylon, and to the south of the equator to about 25° S. off the coast of Africa. The Red sea water corresponds to the Mediterranean water in the Atlantic ocean, but since the outflow from the Red sea is relatively small it exercises a less widespread influence upon the salinity distribution at moderate depths.

Below a depth of about 6.600 ft. the temperature of the deep water decreases from about 3° C. (37° F.) to about 1.5° C. (35° F.) at the bottom and the salinity remains nearly constant at 34.8 $^{0}/_{00}$ (per mille).

Temperature. — North of the southern tropics the temperature of the surface waters is at all times higher than 20° C. (68" F.) and in the equatorial latitudes over 25° C. (77° F.); in the eastern half it is generally above 27.5° C. (81.5° F.); in the Red sea and the Persian gulf the temperature often rises to above 30° C. (86" F.). South of 40° S. the water quickly cools so that off Kerguelen (49" S.) even in summer the temperature has been found to be no more than 2° C.–3° C. (36° F.–37° F.). The isotherms run mainly from west to east, and their course is not diverted by currents to so great a degree as in the Atlantic.

Salinity. — The saltiest surface water is found in the Arabian sea and along a belt extending from southwest Australia to south Africa, the highest salinity in this belt occurring at the Australian end. In both regions the salinity exceeds $36^{0}/_{00}$ (per mille). In the monsoon region west of Sumatra and throughout the Bay of Bengal. because of rainfall and the inflow of rivers, the salinity is diminished to $34^{0}/_{00}$ and at the mouth of the Hooghly channel, below $30^{0}/_{00}$. In the northern portions of the Red sea and the Persian gulf, on the other hand! the salinity is sometimes as high as $40^{0}/_{00}$. South of New Amsterdam and St. Paul the salinity, as also the temperature, quickly diminishes, and south of Kerguelen as far as the antarctic shelf there is a uniform antarctic water of salinity $33.7^{0}/_{00}$.

Ice. — In the extreme southern part of the Indian ocean, pack ice and icebergs from the Antarctic are encountered in all seasons. In October the northern limit of the pack ice lies in about latitude 58° S. and in March it closely follows the coast of the antarctic continent in about latitude 65° S. The average northern limit of icebergs lies in about 45° S.

INDIANOLA, a city of Iowa. U.S., 17 mi. S. by E. of Des Moines; the seat of Warren county. Farm machinery is manufactured and corn. oats and wheat are grown in the vicinity. It is the seat of Simpson college (Methodist), founded in 1860 and chartered as a college in 1867. Indianola was laid out in 1849. incorporated in 1864 and chartered as a city in 1884. For comparative population figures see table in IOWA: *Population.*

INDIAN PAINTBRUSH or PAINTED CUP (*Castilleja*) is a large genus of plants which are partial parasites on the roots of other green plants; they are most abundant in the central and western states of the U.S. The leaves are alternate. and those immediately beneath the flower cluster are brightly tipped with red or yellow. The corolla and calyx of the flower are flattened! the former being two lipped. Indian paintbrush is a member of the Scrophulariaceae or figwort family.

See PAINTBRUSH; SCROPHULARIACEAE.

INDIAN PHILOSOPHY is a singularly manifold philosophic development. It is impossible to touch in this article on all the special points of interest or doctrinal variations. For these the student must consult special works (see *Bibliography*).

It is not possible to determine exactly the dates of the Indian systems of philosophy, but for the broad divisions the dates may

be taken as follows: for the Vedic period, c. 1500–600 B.C.; for the Epic period, 600 B.C. to A.D. 200; and for the period of the Six Systems, A.D. 200.

This article is divided into the following sections:

I. Vedic Period
A. The Rig-Veda
1. Monotheism
2. Monism
3. Cosmology
4. Future Life
B. The Upanishads
1. Metaphysics
2. Subjective Analysis. Atman
3. The Doctrine of Maya
4. Ethics
II. Epic Period
1. Materialism
2. Jainism
3. Early Buddhism
III. Six Systems
A. Nyaya
1. Inference
2. Induction
3. Causation
4. Comparison
5. Metaphysics
B. The Vaiseshika
1. Categories
2. Atomic Theory
C. Sankhya
1. Theory of Evolution
2. Plurality of Souls
D. Yoga
E. Purva Mimamsa
F. Vedanta
1. Shankara's Non-Dualism (Advaita)
2. Doctrine of Maya
3. Ramanuja's Theism
4. Madhva's Dualism

I. VEDIC PERIOD

The Vedic literature comprises (1) the four Vedas, which consist of hymns, prayers and spells addressed to the gods; (2) the Brahmanas (*q.v.*) or ritual treatises; (3) the Aranyakas, or the forest treatises, the concluding portions of the Brahmanas; and (4) the Upanishads, which form the basis of much of the later Indian philosophy. The religion of nature of the hymns, the religion of law of the Brahmanas and the religion of spirit of the Upanishads correspond in a very close way to the three great divisions in the Hegelian conception of the growth of religion.

A. The Rig-Veda

The Rig-Veda represents the thought of successive generations of thinkers, and so contains different strata of thought. In it may be seen the development of religious ideas from the animistic to the absolutistic stages. "Where is the sun by night?" "Where go the stars by day?" "Why does the sun not fall down?" "Of the two, night and day, which is the earlier, which the later?" "Whence comes the wind, and whither goes it?" These are some of the questions which harassed the mind of the early Aryan. His first efforts to answer them resulted in naturalistic polytheism. There is a deity which makes the strong wind to blow, the lightning to flash and the thunder to roll. While some of the chief Vedic deities like Indra and Varuna, are completely emancipated from connection with the phenomena of nature which originally suggested them, others, such as Surya (Sun) and Agni (Fire), are conceived on the lines of the actual phenomena whose names they bear. In some later hymns appear abstract deities which show no traces of connection with natural phenomena, as Prajapati ("lord of creatures"), or personifications of pure abstractions, as Faith and Wrath. The conception of Varuna, the lord of physical and moral order, reaches a high level and is majestic enough both in its cosmical and ethical aspects. Varuna is the lord of rta: rta refers to the physical order in the universe, the order of the sacrifice and the moral law of the world. On account of rta, the sun pursues his daily, and the moon her nightly, journey across the sky, and the silent procession of the seasons moves regularly in light and shadow, in cloud and sunshine across the earth. The doctrine of karma (discussed under Ethics below) is a reformulation of this principle of rta.

When mythical conceptions from beyond the limits of the Aryan world belonging to a different order of thought entered into the Vedic pantheon skeptical tendencies developed. There were men who were harassed by doubts: "Who is Indra? whoever saw him?" "To what god shall we offer our oblation?" (x, 121). Some men were devoid of faith. An undercurrent of satire may be noticed in some of the hymns (ix, 112; x, 119; vii, 103).

1. Monotheism. — The crowding of gods and goddesses proved a weariness to the intellect. Attempts were made to identify one god with another or to throw all the gods together. The close connection of the elements in nature helped the growth of syncretism. An orderly system of nature signified by the conception of rta has no room for miraculous interferences in which alone superstition and confused thought find the signs of polytheism. Besides, religious consciousness is naturally inclined to believe that the supreme is one. What is called henotheism, or the worshiping of each divinity in turn as if it were the greatest and even the only god, is the expression of the logic of religion. When the same functions of establishing the earth and sustaining the air and the sky are assigned to the different deities we tend to drop the peculiarities and make a god of the common functions. This becomes easy when the several gods are not clear-cut individuals but cloudy and confused concepts. The supreme is identified with Prajapati (x, 85. 43, 184. 4, 189. 4), sometimes with Hiranyagarbha (x, 121), sometimes with Brihaspati (x, 72).

2. Monism. — Those dissatisfied with monotheism argue that there is one impersonal reality of which Agni, Indra, Varuna are the names or forms. "The real is one, the learned call it by various names." This one is the soul of the world, the reason immanent in the universe (x, 129. 2). "Priests and poets with words make into many the hidden reality which is but one" (x, 114). Our minds seem to be satisfied with inadequate images of this reality, "the idols which we here adore."

3. Cosmology. — At the pluralistic stage the deities are looked upon as the authors of the universe who create it by a process of manufacture or organic development or through the power of the sacrifice (x, 123. 1). When we rise to the monotheistic level the one god creates the world with the help of pre-existent matter (x, 121). Sometimes the dualism of the creator and the pre-existent matter is overcome and God is said to create the world out of his own nature. In the Purusha-sukta (x, 90) the world is produced by the gods from the sacrifice of a primeval *purusha* (person). This person is all that has been, is, and shall be. But the most advanced theory of creation is suggested in the Nasadiya hymn (x, 129). It starts with the assertion that in the beginning there was neither being nor nonbeing, neither air nor sky, neither death nor immortality, neither night nor day. There was nothing else save the one which breathed breathless, of its own power. This is the poet's way of describing the primal unconditional ground of all being, which is beyond our categories. The third verse states that through the power of tapas (austerity), the first antithesis of being and nonbeing, the active energy and the passive matter is produced. Through desire (kama), which is the germ of mind (manasoretah), the rest of the development takes place. Desire, which is the sign of self-consciousness, is the bond binding the existent and the nonexistent. We cannot say why the original being develops into an active creator and the passive chaos. The hymn concludes with an expression of doubt. Creation is a mystery. *Ko* veda? ("who knows?")

4. Future Life. — A healthy joy in life dominates the Rig-Veda. The worshiper asks not for immortality or heaven but a long life for a full 100 years. There is belief in future life, a heaven for the good and a hell for the wicked. Reward follows righteousness and punishment misconduct.

B. The Upanishads

The Upanishads form the concluding portions of the Veda and are therefore called Vedanta or the end of the Veda. Their aim is not so much to reach philosophical truth as to bring peace and freedom to the anxious human spirit. They represent free and

bold attempts to find out the truth without any thought of a system. Notwithstanding the variety of authorship and the period of time covered by them, a unity of purpose and a vivid sense of spiritual reality may be discerned in them. They are distinguished from the Vedic hymns and the Brahmanas by their increased emphasis on monistic suggestions and subjective analysis as well as their indifference to Vedic authority and ceremonial piety.

1. Metaphysics. — The Taittiriya Upanishad (iii) gives an account of the gradual evolution of ideas regarding the ultimate basis of things. The seeker tries to find out the one comprehensive principle from which "all things are born, by which they are sustained and into which they return at death." His first answer—that matter (annam) is the basic principle—is discarded in view of its inadequacy to vital phenomena. The second answer of life (prana) is found unsatisfactory when sentient entities are considered. The third suggestion of mind (*manas*) is incapable of accounting for logical phenomena. The fourth formula of logical intelligence (*vijnana*) cannot be regarded as the highest reality, since there are aspects of being which cannot be reduced to intellectual terms. Thought as ordinarily understood deals with objects viewed as beyond or other than the process of thinking. Reality can be reached in the state of highest immediacy which transcends thought and its distinctions, which is *ananda* or bliss. Ananda is Brahman.

2. Subjective Analysis. Atman. — The Chandogya Upanishad (viii, 3. 12) institutes an enquiry into the nature of the self. The body which is born, grows up, decays and dies cannot be the true self which persists throughout the changes of birth and death. The dreaming self, subject as it is to the accidents of experience, must not be confused with the true self. The self is not the unity of the evergrowing and changing mental experiences. The self in dreamless sleep cannot satisfy our need, since it is empty of all content and is a bare abstraction. The true self is said to be the universal consciousness existing both in itself and for itself. The Mandukya Upanishad observes that the three states of the soul — waking, dreaming and sleeping — are included in a fourth (turiya) which is intuitional consciousness, where there is no knowledge of objects, internal or external. It is the unchanged and persistent identity which continues in the midst of all change. It is the Atman.

Brahman and Atman are one. The inmost being of universal nature is the same as our innermost self. Tat *tvam* asi: "that art thou." The nature of this ultimate reality cannot be defined. It can be grasped, however, through intuition. This intuition is not objective like perceptual experience or communicable to others like inferential knowledge. A formal exposition of it cannot be given. To any suggested definition of reality we can only say, "not this," "not this" (Brihad-aranyaka, iv, 2. 4). Contradictory accounts are given to show that negative descriptions do not mean negation of all being but only the poverty of intellect.

We cannot, however, remain long at this high level. We insist on framing intellectual pictures of the absolute. When the Atman is identified with the self-conscious individual, Brahman is described as a personal being (Isvara). When the Atman is identified with the mental and the vital self, Brahman becomes the cosmic soul (Hiranyagarbha). When the Atman is taken for the body, Brahman is taken for the cosmos (Virat). Brahman is the sole and the whole explanation of the world, its material and efficient cause. The metaphors of the spinning of the web by the spider, the bearing of the child by the mother, the production of notes from musical instruments point to the oneness of Brahman and the world. There is, however, no logical deduction of the world of multiplicity from the ultimate cause. At the theistic level the world is regarded as the self-limitation of the Supreme. The power of self-expression possessed by the personal Isvara (God) is sometimes called Maya.

3. The Doctrine of Maya. — There is hardly any suggestion in the Upanishads that the entire universe of change is a baseless fabric of fancy. The dominant note of pantheism goes against this view. The assertion 'of the sole reality of Brahman denies duality and traces all change to Brahman but does not suggest that change is illusion. The frequent emphasis on the oneness of the world and Brahman need not be repudiated as a mere concession to common-sense ideas. The texts which declare that the variegated universe is due to the development of name and form from out of the one Brahman warn us against getting lost in the world of multiplicity. The passing semblance of life is in no wise its immortal truth. The theory of the world-illusion is inconsistent with the conception of degrees of reality, or, to be more accurate, unreality which is found in the Aitareya Aranyaka (ii, 3. 2 et seq.). When Yajnavalkya contends that duality is necessary for empirical consciousness and suggests that the world of duality is not real by the use of the particle '*iva*' (Brihad-aranyaka, ii, 4. 14; iv, 3. 31), he refers to the non-ultimate character of the world of duality.

4. Ethics.—*Moksha* is release from the bondage to the sensuous and the individual. The morality of the Upanishads is, in a sense, individualistic as it emphasizes self-realization. The term "individualistic," however, ceases to have any exclusive meaning. To realize oneself is to identify oneself with a good that is not private to any one. Insistence on the knowledge of God (jnana) is tempered by the recognition of the need for moral life.

When the moral striving ends in religious realization the individual is said to be freed from all moral laws. This does not mean that the free can do what they choose with perfect impunity. Laws and regulations are necessary for those who do not naturally conform to the dictates of morality. For those who have risen above the selfish ego and who have died to sin, morality is the very condition of their being.

Those who have not reached the highest perfection will have other chances for striving. Sansara offers a succession of spiritual opportunities. The hypothesis of rebirth is formulated in this period (Chandogya Upanishad, v, 3. 10; Brihad-aranyaka, vi, 3.), though there are still compromises with the Vedic views. Good and evil actions experience a twofold retribution, once in the other world and again by a renewed life on earth.

Moral striving is governed by the law of karma (*q.v.*). Our life carries within it a record that time cannot blur or death erase. The soul that sinneth, it shall decline. Though we cannot efface the results of our acts on the outer universe, its effects on us can be wiped away by strenuous exertion. Karma emphasizes individual responsibility. It is more favourable to self-culture and meditation than to prayer and petition.

In every sphere the Upanishads indulged in inconsistent compromises with the Vedic views. The chaos of the Brahmanical religion reached its climax in the post-Upanishad or pre-Buddhist, period when truth hardened into tradition and morality stiffened into routine. The need for reconstruction was clear.

II. EPIC PERIOD

The systems of materialism, Jainism and Buddhism, belong to the Epic period. which is the age of reconstruction.

1. Materialism. — Materialism is called Lokayata (directed to the world), as it holds that only this world (loka) is real. According to it, perception is the only source of knowledge. Inference which assumes universal relations, testimony and analogy are all defective. Matter is the only reality, of which the elements are earth, water, fire and air. Consciousness is a function of matter. There are different opinions about the nature of the soul. It is identified with the gross body or the senses or breath or thought. There is no future life. As the soul is an attribute of the body, it comes into being when the body is formed by the combination of the elements even as the power of intoxication arises from the mixture of certain ingredients. When the body is destroyed the soul disappears. The world is born of itself. God is a myth which we accept — thanks to our ignorance and incapacity. Pleasure and pain are the central facts of life. Virtue and vice are conventions.

2. **Jainism.**—Vardhamana (c. 599–527 B.C.), the founder of Jainism, is a slightly older contemporary of Buddha. He is said to have systematized the faith held by a succession of 23 other sages, of whom the chief was Parsvanatha (c. 776 B.C.). (For the historical development see JAINS.)

Jainism assumes that truth is relative to our standpoints. The

Jains are fond of quoting the old story of the six blind men who each laid hands on a different part of the elephant and tried to describe the whole animal. The man who caught the ear thought that the creature resembled a winnowing fan; the holder of the leg imagined that he was clinging to a big round pillar, and so on. It was he who saw the whole that perceived that each had only a portion of the truth. The doctrine of *nayas* (particular ways of looking at things) brings out this relativity of thought. The most important application of this doctrine is the theory of *Syadvada* or *Saptabhangi*. Every proposition gives us only a perhaps, a may be, or a *syat*. We cannot affirm or deny anything absolutely of any object, owing to the endless complexity of things. Being is not of a persistent unalterable nature. Every statement of a thing is necessarily onesided and incomplete. If we take it as true and complete we make a mistake. There are seven different ways of speaking of a thing or its attributes according to the point of view. All things, *i.e.*, substances *(dravya)*, are divided into lifeless *(ajiva)* and living *(jiva)*. The former are again divided into (1) space *(akasa);* (2) and *(3)* two subtle substances called *dharma* and *adharma;* and (4) matter *(pudgala)*. Space, *dharma* and *adharma* are the necessary conditions for the subsistence of all other things, viz., souls and matter. Space affords them room to exist; *dharma* makes it possible for them to move or be moved, and *adharnza* to rest. Time is recognized by some as a quasi-substance beside those mentioned. Matter is eternal though it may assume forms as earth, air and so on. It exists in the two forms of atoms *(anu)* and aggregates *(skandha)*. The changes of the physical universe are traced to atomic aggregation and disintegration. The atoms are not constant in their nature but are subject to change or development *(parinama)*, which consists in their assuming new qualities. There are not different kinds of atoms answering to the different elements of earth, water, fire and air. Homogeneous atoms produce different elements by varying combinations. While things which we perceive are made of gross matter, there is matter beyond the reach of our senses in subtle form which is transformed into the different degrees of *karma*. This kind of matter fills all space. The soul by its commerce with the outer world becomes literally penetrated with the particles of this subtle matter. *Karma* works in such a way that every change leaves a mark which is retained and built up into the organism to serve as the foundation for future action.

The characteristic essence of the soul is consciousness *(cetana)*, which is never destroyed, however much it may be obscured by external causes. The souls are said to possess size, which varies with the nature of the bodies with which they happen to be connected. Subtle matter coming into contact with the soul causes its embodiment. Being then transformed into eight kinds of *karma* and forming, as it were, a subtle body, it clings to the soul in all its migrations. The individual soul *(jiva)* is a composite of consciousness and matter or body. Jainism believes that there are souls even in inorganic objects, though they lie dormant in them.

Jainism does not believe in God, though the souls can reach a divine status. The souls and the world are self-existent and eternal. The chief means to the end of *nirvana* is the performance of austerities. By it we destroy the old *karma* and prevent the formation of the new. Right faith, right knowledge and right conduct are recommended. The peculiarity of the Jaina ethics is its insistence on avoidance of taking life of any kind.

3. Early Buddhism. — This also falls within the Epic period. *See* BUDDHA AND BUDDHISM.

For the *Bhagavad-Gita* (part of the epic Mahabharata) *see* BHAGAVAD-GITA and INDIA: *Hinduism and Its Offshoots*.

III. SIX SYSTEMS

The revolt of Buddhism and Jainism helped to bring about a critical point of view and led to the great movement of philosophy which produced the six systems of thought, where criticism and analysis take the place of poetry and religion. The different systems are not antagonistic but are complementary. They are regarded as an evolutionary chain, a single series, rather than as destructive of one another. Each of them is a metaphysics and a religion, an explanation of the world and a method of salvation.

A. NYAYA

Logic as epistemology may be called a critical reflection on metaphysics. The *Vaiseshika*, which deals with the analysis of nature. is earlier than the *Nyaya*, which discusses the problem of knowledge; yet we start with the latter, as it gives the main logical principles assumed by the *Vaiseshika* as well.

Assuming that the account of the world which our minds afford us is, in the main, a trustworthy one, the *Nyaya* analyzes the different ways in which our knowledge is acquired. They are said to be intuition *(pratyaksha)*, inference *(anumana)*, comparison *(upamana)*, and verbal testimony *(sabda)*. Though *pratyaksha* originally meant sense-perception, it soon came to cover all immediate apprehension whether through the aid of the senses or otherwise. It is knowledge whose instrumental cause is not knowledge *(jnanakaraṇakaṁ jnanam)*. In inference, comparison, etc., we require a knowledge of premises or of similarity, but such knowledge is not an antecedent condition of intuition. The word is used for the result or the apprehension of the truth as well as the process or the operation which leads to the result.

Sense-perception follows on the modification of the self produced by the contact of the senses with their objects. Two kinds of perception are distinguished, determinate *(savikalpaka)* and indeterminate *(nirvikalpaka)*, which correspond roughly to knowledge about and acquaintance with an object.

1. Inference. — Inference operates "neither with regard to things unknown nor with regard to those known definitely for certain; it functions only with regard to things that are doubtful." It derives a conclusion from the ascertained fact of the subject possessing a property which is constantly accompanied by another. We ascertain that the hill is on fire from the fact that the hill has smoke and smoke is universally accompanied by fire. Inferential reasoning is stated in the form of a syllogism of which the five members are (1) proposition *(pratijna)*: the hill is on fire; (2) reason *(hetu)*: because it smokes; *(3)* example *(udaharana)*: whatever shows smoke shows fire, *e.g.*, a kitchen; *(4)* application *(upanaya):* so is this hill; and (5) conclusion *(nigamana)*: therefore, the hill is on fire. The first member states the thesis to be established. It is only a suggestion. It ccntains a subject or what is observed, which is generally an individual or a class, and a predicate which is to be proved. The subject is the minor term *(paksha, dharnzin)* and the predicate the major *(sadhya, dharma)*. The second member of the syllogism states the presence in the minor of the middle term called ground *(hetu)*. The third takes us to the basis of inference, the major premise. Though Gautama Buddha and Vatsyayana may not have regarded the example as the illustration of a general rule, later Nyaya looks upon it as the statement of an invariable concomitance between the mark and the character inferred *(vyaptipratipadikaṁ vakyam)*. The conclusion restates the proposition as grounded. Nagarjuna is given the credit for dispensing with the last two members of the syllogism as superfluous.

2. Induction. — Universal propositions are reached through enumeration, intuition and indirect proof. Uninterrupted agreement *(niyata sahacarya)* reinforced by absence of exceptions *(avina-bhāvarūpasambandha)* leads to unconditional concomitance~. Nature does not always supply us with positive and negative instances of the necessary type. In such cases indirect proof *(tarka)* may be used. By pointing out the absurdities in which we are landed if we deny a suggested hypothesis, we indirectly prove its validity. Even when we observe all possible cases and strengthen our conclusion by indirect proof we cannot reach absolute certainty. Experience of sensible particulars, however thorough and exhaustive, cannot give rise to universal relations. Gangesa recognizes the nonsensuous *(alaukika)* activity involved in the apprehension of universals *(samanyalakshana)*.

3. Causation. — A cause is that which invariably precedes the effect. It is not merely accessory to but is necessary for the production of the effect. Two things cannot be causally related unless there is the positive-negative *(anvayavyatireki)* relation between them, such that the presence of the cause means the presence of the effect and vice versa. Three different kinds of causes are distinguished, material *(upadana)*, nonmaterial or formal

(*asamavayi*) and efficient (ninzitta). The appearance of plurality of causes is traced to defective analysis. When the effect is understood in its uniqueness (karyavisesha) it will be seen to have only one cause.

4. Comparison. — By means of comparison (upanzana), we gain the knowledge of a thing from its similarity to another thing previously well known. Hearing that gavaya (wild ox) is like a cow, me infer that the animal which we find to be like the cow is the gavaya. This argument involves knowledge of the object to be known and perception of similarity. Comparison relates to the problem of identification. The problem of sabda or verbal knowledge is mainly of theological interest. Certain questions of logical value are incidentally discussed. Regarding the import of words, the Nyaya holds that a word denotes an individual (vyakti), or a form (akrti) or a genus (jati) or all these. It depends on our interest at the moment. The validity of knowledge is not self-established but is proved by something else (*paratah* pramana). If every cognition were self-evident there would be no possibility of doubt. We discover the truth by the test of action.

5. Metaphysics. — The individual self is a real substantive being possessing the qualities of knowledge, feeling and desire and aversion. It is different from the body, the senses and the understanding. It is all-pervading though it does not cognize many things simultaneously on account of the atomic nature of *manas* or the inner sense. It is unique in each individual, and we have an infinite number of souls. The soul is an unconscious principle capable of being qualified by consciousness.

B. The Vaiseshika

The system takes its name from visesha or particularity. It is in the particulars of the world. pre-eminently in the particular imperceptible souls and atoms, that true individuality is found.

1. Categories. — The Vaiseshika adopts a sixfold classification of *padarthas* (objects which can be thought and named) into substance (dravya), quality (guna), movement (karma), generality (samanya), particularity (visesha) and inherence (*samavaya*), to which later thinkers add a seventh, nonexistence (abhava). That something is, is the first principle; but nothing can be without possessing certain qualities. Some of the qualities reside in a plurality of objects, while others are confined to individuals. The former are general qualities (sanzanya), while the latter are distinguished into permanent (guna) and transitory (karma). Inherence is a special kind of relation distinct from occasional or separable conjunction. When the scheme became logical in scope, nonexistence was included. Later Nyaya develops this idea with great subtlety. The first three categories possess a real objective existence, while the other three are products of intellectual discrimination.

2. Atomic Theory. — The atomic theory is developed in connection with the substances of earth, water, light and air. The things that we experience are made up of parts. They are therefore noneternal. Noneternal has no meaning apart from eternal. The component particles are eternal. The atom marks the limit of division. If it were endlessly divisible, then material things would be products of an equally endless number of constituent parts, and differences in the dimensions of things could not be accounted for. Though the atoms have no extension, their heterogeneous nature is the cause of the extension and visibility of the combinations of atoms. Though Kanada is not clear about where the visibility of the combinations begins, his later followers suggest that an aggregate of three atoms (tryanuka), others of three double atoms, produces extension, and it is visible in the shape of the dust mote (trasarenu) dancing in the sunlight. Ans ering to the four kinds of material objects — earth, water, light and air, we have four kinds of atoms producing the four senses of touch, taste, sight and smell. This is why each special sense reveals a single quality, however excited. Though the qualities of earthly things, as colour, taste, smell and tangibility, vanish on the destruction of the thing itself, they are always found in their respective atoms, though in earth and atoms of earth new qualities are produced by heat (pakaja). Water, light and air do not suffer a similar change. There can never come a time when there will be an utter annihilation of things. The atoms will abide for ever.

C. Sankhya

The *Sankhya* is a reaction against the idealistic monism of the Upanishads. It believes in a real matter and an infinite plurality of individual souls which are not emanations of a single world soul.

The Sankhya adopts the view that the cause and the effect are the undeveloped and the developed states of one and the same substance. Development is the coming to light of what is latent or hidden even as destruction is disappearance into the original cause. There is no such thing as utter annihilation. Applying this principle, the ultimate basis of the empirical universe is said to be *prakrti* (nature). The world is the transformation of prakrti (nature), which cannot be equated with any one of the stages of its evolution.

Prakrti (nature) is a string of three strands or *gunas*, sattva or potential consciousness, rajas or activity and *tamas* or restraint. They are called *gunas* (qualities), as they are factors in the substance of prakrti (nature). They represent different stages in the evolution of any particular phenomenon. Sattva signifies the essence or the form which is to be realized, *tamas* the obstacles to its realization, and rajas the force by which the obstacles are overcome. The *gunas* are always changing, but when they are held together in a state of equilibrium (*samyavastha*) there is no action. The tendencies to manifestation and activity are held in check by that of nonmanifestation and nonactivity. When the tension is relieved development results. Prakrti (nature) evolves under the influence of purusha (subject) into the apparatus of thought as well as the objects of thought.

1. Theory of Evolution. — The first product of the evolution of prakrti (nature) is *mahat*, "the great" or buddhi (intelligence). Self-sense (ahankara), or the principle of individuation, arises next. From this, in its sattva aspect, arise the *manas* (internal organ), the five organs of perception and the five of action; from the same in the *tamas* aspect the five fine elements (tanmatras) arise. The rajas element helps both. From the five fine elements, by a preponderance of tanzas, the five gross elements are produced. The account is probably suggested by the subject's experience and transferred to a cosmic plane. In the state of dreamless sleep the self is present, though it does not apprehend the world. So, in the case of world dissolution, the selves are not distinguished and prakrti (nature) is unperceived. When one wakes from sleep there is, first, the rise of consciousness. followed immediately by the sense of selfhood and the restlessness of desire. The senses begin to function until the world is perceived. This order is followed in the Sankhya theory of evolution.

2. Plurality of Souls.—*Purusha* is the intelligent self, for whose experience prakrti (nature) evolves. It is a mere witness, a solitary indifferent spectator. It is pure consciousness while prakrti (nature) is unconscious. It is inactive, unalterably constant, and devoid of the *gunas* while prakrti is active, alterably constant and consists of them. Prakrti and its products depend for their manifestation on the light of *purusha* (self), which does not depend on anything else for illuminating objects. The Sankhya believes in a plurality of selves. If the self were one all should become free when one attained freedom, which is not the case. Freedom is not coalescence with the absolute spirit but isolation from prakrti.

The empirical individual is not the pure self but the self distinguished by the conjunction of the senses, etc., and limited by the body. While the pure self remains beyond the intellect the reflection of the self in it appears as the ego. Activity belongs to the intellect, and on account of its union with purusha (self) the indifferent self appears as an actor. Though not an agent, the self appears as an agent through confusion with the agency of nature, even as the latter through proximity to the self appears to be conscious. Every ego possesses within the gross material body, which suffers dissolution. a subtle body formed of the psychical apparatus including the senses. This subtle body is the basis of rebirth as well as the principle of identity in the various existences.

The evolution of nature is adapted to the ends of the self. The spiritual centres are, however, incapable of exerting any direct influence on nature, though they are said to excite it to activity. The union of self and nature is compared to a lame man of good

vision mounted on the shoulders of a blind man of sure foot.

The real self has relations with a real world on account of a fancied relation between the two. When the self recognizes its distinction from the ever evolving and dissolving world of nature the latter ceases to operate towards it. The efficient cause of the development of nature is not the mere presence of the selves but their nondiscrimination. Freedom is the result of discrimination. No cause is assigned for the original entanglement of the free spirits in the bonds of ignorance.

D. Yoga

The Yoga differs from the Sankhya in its insistence on mental discipline and acceptance of theism, though its connection with belief in God is somewhat loose. God does not create, reward or punish. Union with God is not the goal of Yoga endeavour. God is only a particular soul not essentially different from other souls co-eternal with him. He stands in an eternal connection with the most refined constituent of matter and is endowed with supreme power, wisdom and goodness.

Our bondage is due to nondiscrimination. The true light of the spirit will shine if the obscuring mental activities are suppressed. The method of Yoga consists in the suppression of all mental activities, conscious as well as unconscious. The eightfold path is a means of it. The first two, *yama* (abstention) and niyama (observance), refer to the ethical preparation. The next two, asana (posture), *pranayama* (regulation of breath), insist on the discipline of the body so as to make it flexible. We can control involuntary muscles as well by the breathing exercises. The next step of pratyahara or the withdrawal of the senses from their natural outward functioning answers to what modern psychology calls introversion. While these five are only accessories, dhyana (fixed attention), dharana (contemplation), and samadhi (concentration) are integral elements of Yoga. Through concentration we get into direct touch with the reality of the things and obtain intuitional knowledge. The process of concentration is to be continued until the mind is dissolved and self-illumination results. Samadhi is the perfect life of spirit.

E. Purva Mimamsa

The Purva Mimamsa has for its special object the ascertainment of duty (dharma). It is not a philosophical system, though it refers to philosophical topics incidentally. It believes in the reality of the world and the individual souls. As it deals with ritual specially, it points out how every act produces its effect sometime or other through the principle of apurva or the link between the act and the result. While the earlier writings do not admit the existence of God, the later ones do.

A chief writer of this school, Kumarila, argues for the theory of self-evidence (svatah *pramana*). Truth is its own guarantee. Cognitions are by themselves valid and their validity can be set aside only by the contrary nature of their objects or by the recognition of discrepancies in their causes. When we are in doubt about the true nature of a thing perceived at a distance or in faint light, we can resolve the doubt by a second cognition obtained under improved conditions. Even in the most difficult cases we can obtain an absolutely true cognition after a series of three or four. Correspondence and coherence theories do not produce validity but only test it.

F. Vedanta

The Vedanta Sutra attempts to set forth the teachings of the Upanishads in a consistent way. Its short aphorisms are unintelligible by themselves. Many different systems ranging from pure nondualism to explicit dualism attempt to interpret the Sutra. The chief of them are those of Shankara, Kamanuja and Madhva.

1. Shankara's Non-Dualism **(Advaita).**—Shankara in his system asks whether there is anything in experience which may be regarded as foundational and discusses the claims of the different factors of experience to that title. Our senses may deceive us and our memory may be an illusion. The waking tracts may not be different from dream worlds, where also we visit places, handle shadows and battle with ghosts. Though all objects of experience may be open to doubt, there is something which is beyond all doubt. Everyone is conscious of the existence of one's own self and no one thinks "I am not." The self cannot be doubted or denied for "it is the essential nature of him who denies it." Though we cannot know it by thought, it does not entirely escape us. It is the object of the notion of self (*asmat-pratyayavishaya*) and is known to exist on account of its immediate presentation (*aparokshatvat*). This self is distinct from the body, the senses and the understanding. It is the principle of consciousness which is unaffected when the body is reduced to ashes and the mind perishes. It is one, universal and infinite.

Logical knowledge based on the distinction of subject and object is not final. The real excludes all relations, but logical knowledge is relational in character. The real simply is, but we attempt to characterize it in knowledge and no predicate is found adequate to it. In judgment, we equate the real with the unreal, the subject with the object. We attribute to the Atman activity, agency and enjoyment: All our knowledge is strictly speaking nonknowledge (*avidya*). The ascertainment of the ultimate reality by the exclusion of all that is imposed (adhyasta) on it is wisdom (vidya). Avidya is another name for our finitude. When its roots are cut our bondage is broken. Shankara admits the reality of intuitional consciousness where the distinctions of subject and object are superseded.

Shankara adopts the distinction between truth (paravidya) and empirical truth (aparavidya). The latter is not illusory or deceptive but only imperfect or relative. The empirical world is not self-existent or real. Yet there must be a reality on which it rests. Even if we regard the whole universe as merely imaginary there must be something which is the basis of all imagination. That reality is Brahman. As it is opposed to all empirical existence, it is given to us as the negative of everything that is positively known. We cannot even call it one (ekam). It is to be called nondual (advaitam). It is the wholly "other" but not nonbeing. When we are not content with such negative accounts we describe it as the personal God (Isvara). God is the absolute cast through the molds of logic.

2. Doctrine of Maya.—Every object in the world tends to pass away from itself to something else. The categories of time, space and cause which bind experience are self-contradictory. Our knowledge of the world is inconsistent. When intuitional experience arises the pluralistic universe is sublated. The term maya (appearance) registers the imperfection and relativity of the world. It does not mean that the world is a mere illusion. Shankara's refutation of Buddhistic subjectivism is decisive on this question. While he traces the world to avidya (ignorance) he takes care to point out that this ignorance is cosmic in character. The phenomenal self and the phenomenal world are mutually implicated facts. The mind with its categories on the one side and the world which it construes through them on the other hang together.

We cannot conceive the relation between the world and the absolute. The question of relation has meaning only if we have two "distincts," but the world is not distinct from Brahman. The finite is the infinite hidden from our view through certain barriers. When we intuitively recognize the absolute the relative disappears; when we discuss about the relative there is no absolute to which it has to be attached. The problem arises on account of a confusion of standpoints. If Brahman is to be viewed as the cause of the world it is only in the sense that the world cannot be explained apart from Brahman, though the latter is in no way touched by the world of appearance. Brahman is the basis of the apparent existence of the world (vivartopadana).

The individual soul is different from the Atman. Its divine nature is concealed by the external adjuncts (upadhis) of the sense organs and vital airs which form the subtle body. These, together with karma, accompany the soul in its migrations. Moksha or salvation is the lifting of the veil of ignorance which conceals from the soul the truth that it is and always has been one with Brahman. The road to realization lies not through something done or accomplished but through knowledge or the sweeping aside of the delusive veil of ignorance. Shankara is clear that this insight cannot be attained without the discipline of moral life. Insight is not

so much an answer to a riddle as a victory in a battle.

3. Ramanuja's Theism.—Ramanuja endeavours to show that the God of religious faith is not the unconditioned abstraction of Shankara but a personal being whose reality need not be doubted simply because our knowledge of him is imperfect. The sense of personal communion with God involves a real fellowship with an other. The supreme Brahman has internal differences (*svagatabheda).* Souls and matter are comprehended within the unity of the supreme as attributes to the substance or parts to a whole or body to the soul which animates it. Though attributes of God, souls and matter are in themselves substances possessing qualities with their own distinct modes, energies and activities. Souls, matter and God are different on account of their natural differences *(svarzrpabheda)* but one on account of their identity *(aikyam)* of the modes and substance. Identity means only inseparable existence *(aprthaksiddhi).*

For Ramanuja, causation is only an alteration of state. The creation of the universe from Brahman is not a production of something new but only a change of condition. It is a modification of that which is subtle into that which is gross. In the causal condition Brahman has for his body or mode the conscious (*cit*) and unconscious *(acit)* entities in their subtle form, while in the effect condition they are in a gross form.

Ramanuja does not accept the explanation of the world and of the individual souls as mere productions of ignorance enveloping the nature of Brahman. If the multiplicity is due to human ignorance, then there should be no such world for God. But Scripture tells us of God's creation, etc., which means that God reckons with the world of multiplicity. We cannot regard the world as unreal, like the mirage, for while the activity prompted by the latter is unsuccessful, that based on the knowledge of the objects is successful. The reality of the world established by perception cannot be sublated by Scripture as the spheres of perception and Scripture are different. Simply because objects do not persist we cannot conclude that they are unreal.

While for Shankara, freedom consists in the removal of a barrier and the entering into the secure realization of a permanent and inalienable truth, for Ramanuja, it is communion with God to be reached by devotion and faith. The individual is not effaced when the goal is reached but maintains his self-identity and enjoys the fruit of his faith in unending felicity.

4. Madhva's **Dualism.**—Madhva stands out for unqualified dualism and insists on the five great distinctions of God and soul, God and matter, soul and matter, one soul and another and one part of matter and another. Reality is of two kinds, independent *(svatantra)* and dependent *(paratantra).* God is the only independent reality; matter and souls are dependent. God controls souls and matter though he does not create or destroy. He is the efficient but not the material cause of the universe. Though absolutely dependent on Brahman, the individual souls are essentially active agents and have responsibilities to bear. While God is all-pervading, the souls are said to be of atomic size. They yet pervade the body because of the quality of intelligence. No two souls are alike in character.

INDIAN PIPE *(Monotropa uniflora)*, a saprophytic herb of the wintergreen family (Pyrolaceae), called also corpse plant, American ice plant and ghost flower, found in moist, rich woods almost throughout temperate and warm North America and also in the Himalaya mountains and Japan. It is a smooth waxy-white plant, of unusual appearance, which grows on decaying vegetable matter and is somewhat parasitic on roots. The erect, usually clustered stems, four to ten inches high, bear small scales representing leaves and terminate in a single nodding flower, about one inch long, blossoming from June to Aug., followed by a many-seeded capsule which becomes erect in ripening. Occasionally the flower, or more rarely the whole plant, has a pinkish or reddish tinge. All parts of the plant turn blackish in drying. There are two other species of the genus, both north temperate, one of which, M. *hypopytis,* the yellow bird's-nest or pinesap, with flowers in a drooping cluster, widely distributed in Europe, Asia and North America, occurs in the British Isles.

INDIANS: *see* INDIAN, LATIN-AMERICAN; INDIAN, NORTH AMERICAN.

INDIANS, NORTHWEST COAST. The Indians of the coast of southern Alaska, British Columbia. Washington, Oregon and northern California formed an areal grouping of tribes with a common cultural foundation. The principal tribes and stocks comprised are the Tlingit, Haida, Tsimshian, Kwakiutl, Nutka, Bella Coola and other Coast Salish, Chimakun, Makah, Chinook, Yakonan, Kus, Takelma, Yurok, Wiyot, Karok and the Hupa and other Athabascan groups. Linguistically there was considerable diversity among these groups; otherwise their similarities exceeded their differences. Generic cultural features extending over the entire area were: dependence primarily on fish, especially salmon; coastal maritime navigation; development of woodworking, including the carver's art; wealth accumulation, with an elaborate system of economic exchange and property law; the organization of society on the basis of hereditary rank dependent on economic status; religious cults heavily influenced by proprietary rights. Particular traits exemplifying these trends were: deep-sea fishing; whale hunting; large dugout canoes with plank lashings for higher freeboard; mat sails; clothing largely of mats, with basketry hats; twined basketry with overlay decoration; villages of large, all-frame houses facing the beach or river; totem poles and wooden grave monuments; boxes for cooking, storage. etc.; clubs, spoons and most utensils, also rattles, masks, etc., elaborately carved or painted in a peculiar totemic-symbolic art style; dentalium shells, plates of native copper, boxes, etc., serving as standardized mediums of exchange, often with high fictitious credit values; potlatches or competitive socioreligious festivals with wealth distribution for prestige; loans with high rate of interest; division of society into rich nobles with titles, crests and privileges, commoners and slaves; marriage by purchase; secret religious societies with elaborate ranks and masks. The greatest concentration and elaboration of this distinctive combination of traits occurred among the Haida, Tsimshian and Kmakiutl. In several respects, however, the classic manifestations of the complex among these tribes were late and short lived. Thus, woodworking and potlatching were greatly stimulated through access to iron tools and external sources of wealth subsequent to 1800, but both practices were on the decline well before the end of the 19th century.

INDIAN SUMMER, a spell of warm, clear weather often persisting for a week or more, characteristic of middle and late autumn in central and eastern United States. It occurs in a large, stagnating, anticyclonic area; the first day or so may be cold, but under the clear skies with light winds the daytime hours of each

succeeding day become warmer and warmer, while frost, dew, hoar or valley fog may occur during each chilly night. The haziness of the air, the musty odour and glorious mordant colouring of the leaves, the smell of smoke from rampant fires in the dry woods and the relaxing physiological effect of the warmth following the previous cold snap all contribute to the distinctive and romantic stereotype of Indian summer that has been cherished by generations of Americans. In some years Indian summer spells may be brief or lacking; in others they are prolonged or recurrent. The weather-map situation for Indian summer is not so definite, or clear-cut a type as the weather itself: it may be described in general as caused by conversion of a moving, cool, shallow, polar air mass into a deep, warm and stagnant anticyclone. The strong temperature inversions that develop at low levels in the free air in such an anticyclone (*q.v.*) have the effect of concentrating the smoke and dust in the air near the ground and causing a large range of temperature between day and night. INDICATOR, CHEMICAL. An indicator is a substance that is capable of indicating the completion of a reaction. Methyl yellow, for example, imparts a yellow colour to an alkaline solution. If acid is slowly added, the solution remains yellow until all the alkali has been neutralized, whereupon the colour suddenly changes to red. Methyl yellow is therefore classified as an acid-base indicator.

Like most indicators, methyl yellow is visible even if its concentration is as low as a few parts per million parts of solution. Gsed at such low concentrations, indicators do not interfere with or have any influence on the reactions for which they are recommended. The common application of indicators is the detection of end points of titrations (see CHEMISTRY: Analytical *chemistry*).

The colour of an indicator alters when the acidity or the oxidizing strength of the solution, or the concentration of a certain chemical species reaches a critical value or, more precisely, a critical range of values. Indicators are therefore classified as acid-base, oxidation-reduction, or specific-substance indicators, every indicator in each class having a characteristic transition range. Methyl yellow is yellow if the hydrogen ion (acid) concentration of the solution is less than 0.0001 mole per litre and is red if the concentration exceeds 0.001. Ferrous 1,10-phenanthroline, an oxidation-reduction indicator, changes from red to pale blue when the oxidation potential of the solution is increased from 1.04 to 1.08 v.; and diphenylcarbazone, an indicator for mercuric ion, changes from yellow to violet when the mercuric ion concentration is increased from 0.000001 to 0.00001 mole per litre. Each of these indicators thus has a relatively narrow transition range, and each is capable of giving a sensitive, sharp indication of the completion of a reaction (the end point). In devising a new titration the chemist first calculates or empirically determines the changes in the properties of the solution that occur as the end point of the reaction is approached and passed. He then selects an appropriate indicator from tables of indicator transition ranges. Thousands of indicators have been studied, some of which have been individually synthesized to provide them with specified characteristics.

Commonly, indicators are complex organic compounds, similar in structure and optical properties to dyes. The chemical behaviour of indicators is, however, usually simple. The acid-base properties of methyl yellow (p-dimethylaminoazobenzene), for example, are entirely analogous to those of ammonia. Both compounds are weak bales which, when acid is added, combine reversibly with hydrogen ions. Moreover, the same simple mathematical equations describe the acid-base behaviour of both compounds; namely, the ratio of the concentration of the acidic form to the concentration of the basic form is proportional to the hydrogen ion concentration (see HYDROGEN IONS). The principal difference is that the basic form, NH_3, and the acidic form, NH_4^+, of ammonia are both colourless, whereas the corresponding forms of methyl yellow are yellow and red. The addition of a hydrogen ion to the methyl yellow molecule causes a redistribution of electrons and a consequent alteration in light absorption properties. This redistribution is in part made possible by the complexity of the indicator's molecular structure (see DYES).

Although the visible change of the indicator is usually a colour change, it may instead be the formation or disappearance of a turbidity. If, for example, a soluble silver salt is added to a solution of cyanide that contains a trace of iodide, the solution remains clear until all the cyanide has reacted to form the soluble silver cyanide complex ion, $Ag(CN)_2^-$. Upon the addition of more silver a turbidity of silver iodide forms. Iodide is therefore an indicator for excess silver ion in this reaction.

A peculiar kind of indicator is the adsorption indicator, the best-known representative of which is the dye, fluorescein. Fluorescein is used to detect the completion of the reaction of silver ion with chloride ion the colour change occurring in the following manner. After a quantity of silver sufficient to precipitate all the chloride has been added, additional silver ion is partially adsorbed on the surface of the particles of silver chloride. Fluorescein also is adsorbed and, in combining with the adsorbed silver ion, changes from yellow-green to red.

Until about 1935 acid-base indicators were used extensively for the colourimetric determination of the pH of aqueous solutions. (The pH is a measure of acidity and alkalinity. The pH scale runs from approximately zero—very acidic solution—to approximately 14—very alkaline solution.) The procedure was (1) to select by trial and error an indicator with a suitable transition range; and (2) to compare the colour of the sample solution with the colours of standard solutions of known pH, all solutions containing the same amount of the same indicator. After the development of the glass electrode, which permits a precise and convenient electrochemical measurement of pH, the use of indicators for this purpose was abandoned, except as it survives in the employment of the so-called wide-range or universal indicator. The wide-range indicator is actually a mixture of indicators, the transition ranges of which slightly overlap one another and in combination extend from the very acid range to the very alkaline range. The indicators of the mixture are so chosen that the colour of the mixture indicates uniquely the pH; a colour chart gives the pH corresponding to a given colour. Thus, a mixture of methyl yellow (pH range 3 to 4), methyl red (4 to 6), bromthymol blue (6 to 8), thymol blue (8 to 9.5), and phenolphthalein (8.2 to 10) is coloured cherry red at pH 1, rose at pH 2, red-orange at pH 3, orange-red at pH 4, orange at pH 5, yellow at pH 6, yellowish-green at pH 7, green at pH 8, bluish green at pH 9, and blue at pH 10.

"Indicator paper" is dry, absorbent paper impregnated with one or more indicators. An estimation of pH can be made by putting a drop of test solution on wide range indicator paper and observing the colour. This technique avoids contamination of the solution. (T. S. L.)

INDICATORIDAE: see HONEY GUIDE.

INDICTION, a period or cycle of 15 years. The word means "impost" and was first applied to publicly imposed taxes in Egypt, a system which Diocletian, following Hadrian's proposal of a 15-year period of revision of tax censuses, extended to the whole Roman empire in A.D. 297. But the first indiction is usually given as beginning with A.D. 312, being associated with Constantine's victories of that year.

Dating by the year of indiction became regular during the middle ages, particularly in ecclesiastical affairs.

INDICTMENT. England.— An indictment is a formal accusation in writing presented to the court in any criminal prosecution other than an offense to be tried summarily before magistrates, with certain exceptions that do not often occur in contemporary practice, such as impeachments before the house of lords and the trial of certain misdemeanours in the queen's bench division. Its purpose is to state the offense or offenses with which the person accused is charged, the statute, if any, which creates the offense, and such particulars as are necessary to enable the accused to know what charge he has to answer.

To give an example, the statement of offense will charge the accused with robbery with violence, contrary to section 42 of the

Larceny act, 1861; the particulars of offense will specify, naming the accused, that on a certain day of a certain month in a certain year, in a named county, he robbed a particular individual of a watch. and that at the time of or immediately before or immediately after such robbery he did use personal violence to the said individual.

Historically, there have been two lines of development that have affected indictments. The first is that they were previously drawn up in the form of a "bill" of indictment and sent before the grand jury; the grand jury then heard in private the witnesses in support of the charge, and, if satisfied that a prima-facie case had been made out, found the bill to be a true bill and returned it to the court as such, or otherwise reported to the court that they found "no true bill." This procedure was fundamentally altered by the Administration of Justice (Miscellaneous Provisions) act, 1933, s. 1 of which abolished grand juries, while s. 2 prescribed the procedure for the indictment of offenders. No bill of indictment charging any person with an indictable offense (that is, any offense other than such minor offenses as can only form the subject of summary proceedings before magistrates) can be preferred unless either (1) the person charged has been committed for trial or (2) the bill is preferred by the direction or with the consent of a judge of the high court or pursuant to an order made under s. g of the Perjury act, 1911; where a person has been committed for trial, however, the bill of indictment may include any counts founded on facts or evidence disclosed in any examination or deposition taken before a justice, being counts that may lawfully be joined in the same indictment; and a charge of a previous conviction of an offense or of being a habitual criminal or a habitual drunkard may, notwithstanding that it was not so included or in a judge's direction or consent, be included in an indictment.

The second line of development is a relaxation of the technical rules that previously obtained in the preparation of indictments, and used frequently to be a cause of undeserved acquittals. This process has been connected with the elimination of much of the old harshness of the penalties incurred on conviction! together with the greatly increased opportunities that the modern procedure in criminal trials gives to the accused of conducting his defense with the help of counsel at all stages. Since 1825 numerous enactments have been passed for getting rid of technicalities in connection with indictments, and from 1851 the courts had power to disregard technical objections to the form of indictment and to amend in matters not essential should the indictment and the evidence be at variance. The technicalities of criminal pleading were finally dealt with by the Indictments act, 1915, which made rules as to indictments and set up a rule committee under the lord chief justice having power to vary or annul the rules in the statute and to make further rules. Although the individual counts in the indictment must still relate to separate offenses and be free of duplicity or ambiguity, charges for more than one felony or more than one misdemeanour, and charges for both felonies and misdemeanours, may be joined in the same indictment. Power is given before or at any stage of trial to amend the indictment. if it can be done without injustice; to order the separate trial of separate offenses if the accused would otherwise be prejudiced or embarrassed; or to postpone a trial for amendment or separate hearing.

Scotland. — In Scotland the terms indictment or criminal letters are used to express the acte d'accusation. The indictment is filed by the lord advocate or one of his deputies; it is only by order of the court of justiciary that a prosecution can be instituted without the general assent of the lord advocate. As in England. the form of indictment has been much simplified. (W. T. Ws.)

United States. — As a general rule, an indictment must state the crime charged with sufficient certainty to fulfil three iunctions: to enable the defendant to prepare his defense; to enable the court to pronounce judgment, upon conviction, according to the rights of the case; and to prevent a second prosecution for the same offense.

Further requirements of form and rules relating to the indictment vary considerably among various jurisdictions. In many cases the indictment contains a number of counts, each charging a different version of the same offense or, subject to certain limitations, separate offenses. The modern tendency has been to shorten and simplify the form of the indictment. In addition, there frequently has been recognition of a defendant's right to obtain from the prosecution a "bill of particulars." This contains such additional details of the facts and circumstances of the offense as the trial judge determines are required for the proper defense of the accused. Under some statutes the granting of bills of particulars is mandatory upon application by the defense.

Since the indictment is a finding by the grand jury upon oath, and depends for its validity upon this fact, among others, it could not, until recent times, be amended by the court without the concurrence of the grand jury that presented it. Under modern practice, however, certain formal mistakes, such as the name or description of any place, person or thing, may be corrected by amendment at the trial on such terms as the court may deem necessary. Such amendment may not be ordered, however, to correct errors that affect the substance of the accusation.

The fifth amendment of the U.S. constitution declares that "No person shall be held to answer for a capital or other infamous crime unless on a presentment or indictment of a grand jury. . . ." This provision applies only to prosecutions in the federal courts, but in many of the state constitutions there are similar provisions applying to the state courts. Under these provisions it has sometimes been held that an indictment is absolutely essential before the court has jurisdiction to try the offender, and the accused cannot even waive the benefit of the provision by consenting to be tried without an indictment. This view was rejected, however, in the Federal Rules of Criminal Procedure, adopted in 1946 and applicable to federal prosecutions. The rules provide that a defendant "may be prosecuted by information if . . . after he has been advised of the nature of the charge and his rights, (he) waives in open court prosecution by indictment."

It has long been held that the U.S. constitution does not require the use of indictments in state criminal proceedings. Where the state constitution contains no such requirement there is nothing to prevent the legislature from providing for prosecution of all crimes. even capital offenses, by some other mode of accusation. For example, the accusation might be by information, which is a written accusation of crime preferred by the prosecution without the intervention of the grand jury. A large number of the states, by either constitutional provision or statute, authorize the prosecution of serious offenses by information, with various qualifications. In some of these states indictments are never or rarely ever employed. (F. A. A.)

INDIES, LAWS OF **THE,** in general, the whole body of law promulgated by the crown of Spain for the government of the Spanish kingdoms outside Europe; and more particularly, a series of collections of decrees. compiled and published by royal authority, culminating in the Recopilacidn de Leyes de *los* Reynos de *las Indias* of 1680. From the beginnings of American settlement, the law of Castile was regarded as the basic law of the Indies also. American conditions, however, presented many problems which had no exact parallel in Spain. An entire administrative and judicial hierarchy, civil and ecclesiastical, had to be created; and a vast native population europeanized and converted to Christian belief. Land had to be distributed and labour organized to work the land. From an early date, therefore, the crown found it necessary to legislate separately for the Indies and to adopt the principle — implicitly at first, but explicitly in the Recopilacidn — that new legislation promulgated for the Iberian kingdoms had no force in the Indies, unless given such force by explicit decree. Thus, while the subjects of the crown in the Indies continued to live, in general, according to the system of private law prevailing in Castile, they acquired a separate body of public law of their own, designed to carry over into America the spirit and intent of Spanish law, but also to adapt it to the vastly different conditions of American life.

Of the many thousands of legislative enactments issued by the crown, with the advice of the Council of the Indies in the 16th century, a small number took the form of codes of rules dealing

with particular aspects of colonial life throughout the empire. The earliest of these codes, the "Laws of Burgos" of 1512, was primarily an attempt to order the relations between Spaniards and Indians and to limit the demands made upon the conquered people. It was, in part at least, a response — a quite inadequate response — to complaints made by Dominican missionaries. The "New Laws" of 1542, which also owed much to missionary agitation. dealt with the same subject in much more radical fashion, in particular by attempting to abolish the system of *encomiendas*, whereby leading Spanish settlers were empowered to levy tribute and services from specified Indian villages in return for military service. the provision of churches and the payment of parish clergy. The "New Laws" provoked armed rebellion by the *encomenderos* in Peru and the threat of it in New Spain, and some of the clauses concerning *encomiendas* had to be repealed; though restrictions upon *encomenderos* were reintroduced, in a different form. in 1549. In 1552 a code of commercial regulations was published for the Casa de Contratación ("House of Trade") in Seville; in 1563 the constitution, procedure and powers of the colonial courts of appeal *(audiencias)* were defined; and in 1573 appeared the justly celebrated "Ordinances Concerning Discoveries," prohibiting unauthorized operations against independent native peoples and laying down rules for establishing good relations with the inhabitants of newly discovered lands. The vast majority of decrees (*cédulas*), however, were not arranged in code form but dealt empirically with matters of concrete detail, in response to specific complaints or reports. The bureaucratic paternalism of the Habsburg kings produced an extraordinary legislative profusion. Before the middle of the 16th century, the need for a general legal code was already apparent.

Attempts at codification made in the 16th century included the *Cedulario* of Vasco de Puga, published in 1563, which applied only to the viceroyalty of New Spain and contained many errors and omissions; the work oi Juan de Ovando of 1570–71, never published; and the iour iolio volumes of Diego de Encinas (1596), a roughly classified collection of decrees in chronological order, again with many mistakes — a valuable historical source but oi little use to working lawyers. None of these met the need for an authoritative code. The collection which eventually appeared as the *Recopilación* was begun by Antonio de León Pinelo in 1624, under the supervision first oi Rodrigo de Aguiar y Acuña, later of Juan Solorzano Pereira, both councillors of the Indies and both, particularly Solorzano, jurists of proiound learning and great experience. The work, extracted irom more than 400,000 *cédulas*, u-as completed in 1635 and approved by Solórzano the following year. It was not immediately published, largely because of lack oi funds; and was iurther edited and abbreviated by Fernando Jiménez Paniagua before its eventual approval in 1680 and publication in 1681. The *Recopilación de Leyes de los Reynos de las Indias* or *de Leyes de Indias* in its final iorm contains about 6,400 laws, in nine hooks of very unequal length, subdivided into *titulos* or chapters. Briefly stated, the contents of the books are: (1) ecclesiastical government; (2) the Council of the Indies and colonial *audiencias;* (3) political and military administration, viceroys and captains-general; (4) discoveries, colonization. municipalities; (5) provincial government and lower courts; (6) Indians; (7) penal law; (8) public finance: and (9) trade and navigation. Subsequent legislation, especially the far-reaching administrative and economic reforms introduced in the later part of the 18th century, rendered much of the *Recopilacidn* obsolete; but proposals made under Charles III for bringing it up to date came to nothing. It remained in force until the Spanish-American wars of independence and, in Cuba, in Puerto Rico and in the Philippines, until the end of the 19th century. It was reprinted three times in the 18th century and twice in the 19th, the last two editions containing a supplement of later legislation; but the main body of the work was never revised.

The *Recopilacidn* is a notable monument of colonial legislation. It contains, no doubt, many inconsistencies; its phrasing is not always precise; and the marginal references to original *cédulas* are often inexact. It has nonr of the organic character of a modern (or of a Roman) code. Side by side with decrees enunciating vital principles of law, it gives rulings on trivial local matters: the installation of a clock in the courtroom at Seville; the gratuities of court ushers; and so on. Much space is devoted to details of ceremonial and precedence; much, again, to restrictive commercial regulations that were not only a defiance both of geography and of common sense but also in many cases uneniorccable. The general tendency of the whole code was to retain all interpretation and decision in peninsular Spanish hands, thus cutting the creole upper classes off from the normal political functions of aristocracy and so rendering them irresponsible and, ultimately, disloyal. These deiects are more apparent. however, to the hindsight of the 20th century than they were irom the normal standpoint of the 17th or 18th. The *Recopilación* remains the most comprehensive code of law eyer devised for a colonial empire and in many ways the most humane. It is permeated by lofty moral and religious principles. This characteristic is most apparent in the sections concerning Indians, which date, ior the most part, irom the 16th century. They reflect the public influence of such men as Francisco de Vitoria, one oi the greatest theologians of his age and a iounder of modern international law; Bartolomé de Las Casas, indefatigable missionary and polemist and a passionate advocate of Indian rights; and Garcia de Loaisa, the emperor Charles V's confessor, general of the Dominican Order and president of the Council of the Indies. Their arguments reinforced the royal determination to prevent the growth of a new colonial feudalism. The *Recopilacidn*, accordingly, declared that the Indians were free men, the direct subjects of the crown, entitled to the protection of the law in their persons, lands and possessions; that they were rational beings, to be converted to the Christian iaith by persuasion, not by force; that tribute and services might be demanded from them only by public authority; and that their laws and customs, where not repugnant to Christian morality or to the laws of Castile, mere to be respected. The laws of the Indies mere often evaded or disregarded. Yet the records of the *audiencias* and of the *juzgado general de Indios* indicate that the laws, where they concerned Indians, mere by no means a dead letter. At the very least, they were an unequivocal declaration oi policy, which anticipated many ideas associated with the doctrine of colonial trusteeship in the 20th century. (J. H. Py.)

INDIGESTION (Dyspepsia) is a subjective variable sensation of discomfort associated with food intake by the person experiencing the discomfort. It may be of nervous origin, the result of poor food habits, a reflex to pain or due to disease in the gastrointestinal tract. The sensation may be a bad taste in the mouth; a burning or tight feeling in the chest; belching or frequent vomiting; heaviness, gnawing, burning or fullness in the upper abdomen; a bloating or cramping sensation in any part of the abdomen or irregular bowel habits. Nervous indigestion usually dates from youth and is associated with added stresses and strains of life as well as the intake of irritating foods. It responds well to mild sedation, antispasmodics and a bland diet. Indigestion caused by poor food habits usually can be corrected by eating in leisurely fashion, chewing the food well with the mouth closed and observing a bland diet. Indigestion may arise in reflex to pain in any part of the body, fatigue, anger or fear. This may be eliminated by elimination of the inciting cause. Similar sensations may be caused by spasms or tumours in the esophagus, inadequate valve action between the esophagus and stomach, ulcers or tumours of the stomach or duodenum, tumours or inflammation of the intestine. Therefore, such symptoms require thorough medical study in order to eliminate any such serious causes. (JE. A. S.)

INDIGO, an important and valuable dyestuff. was obtained up until the last decade of the 19th century entirely from plants, mainly those of the genus *Indigofera*, of which the **I.** *sumatrana* and *I. arrecta* were the most important. The material was known to the ancients of Egypt, Greece and Rome, and according to Julius Caesar also to the Britons who obtained it from the woad plant, *Isatis tinctoria.*

In all the plants from which it was derived, indigo occurred in the form of a colourless glucoside, indican, $C_{14}H_{17}NO_6.H_2O$ which was readily soluble in water. By a process closely akin to fermentation, the glucoside was split into glucose and indoxyl, C_8H_7NO, the latter also colourless. By mild oxidation, even by air, two molecules of indoxyl were converted by the loss of four hydrogen atoms into indigo $C_{16}H_{10}O_2N_2$, a dark blue powder. (*See* Dyes.)

The cultivation of indigo plants and the extraction of the dyestuff was an important industry in India up to the beginning of the 20th century. In 1897, for example, no less than 1,750,000 ac. of land in this country were under cultivation for this purpose, and something like 17,000,000 lbs. of indigo were exported. The introduction of comparatively cheap synthetic indigo at about this time by the Germans therefore produced an economic upheaval in India.

In 1883, the German chemist, A. von Baeyer, announced the true chemical structure of indigo, and at once a race began between the leading German dyestuff companies to develop a commercial method for its manufacture. But it was not until approximately 1j years later that a process was developed that was economically sound. Although discovered elsewhere, it was developed in the plant of Meister, Lucius and Bruening at Hoechst and consisted in the fusion of phenylglycine sodium salt, $C_6H_5.NH.CH_2COONa$,

in a mixture of caustic soda and sodium amide to indoxyl, the use of soda amide being the key to the success of the development.

Since the World War II period synthetic indigo has been made by this method in every country in the world possessing a first-rate dyestuff industry.

The cultivation of indigo-bearing plants in India has practically ceased. (J. H. Ss.)

INDIGO BUNTING (INDIGO BIRD) (Passerina cyanea), a North American bird of the finch family (Fringillidae), breeding chiefly in the northeastern United States and adjacent Canada. south to Georgia, west to Colorado and Texas. The adult male is of a deep blue nearly all over, changing to brownish in the autumn. The female is brown above and ochreous-white beneath. See BUNTING.

INDIUM, a lustrous, silvery, metallic element softer than lead and both malleable and ductile, was discovered in 1863 by Ferdinand Reich and Theodor Richter by means of the spectrograph, and because of the prominent indigo-blue spectral lines they gave the name indium to the element. It is in group IIIb of the periodic table between gallium and thallium, which it resembles in many chemical properties.

For more than 50 years after its discovery little use was made of the substance, which has since found valuable applications in the manufacture of transistors, in finishing engine bearings, as an ingredient in fusible alloys and solders and in other specialized uses, including the measurement of the thermal neutron flux of nuclear reactors (see Uses, below).

Occurrence and Recovery. — Indium is scattered widely throughout the world and is found in small amounts in many minerals, particularly those of zinc and lead. Numerous methods have been suggested or used for the extraction of indium from concentrates or residues. In one method, the zinc concentrates containing indium are roasted and leached with a solution maintained somewhat acid with sulfuric acid. The solution is treated with zinc and the indium is precipitated, together with copper, silver, etc. The precipitate is treated with sulfuric acid, and the silver is removed from the resulting solution by hydrogen sulfide. Indium is then recovered from solution by electrolysis. Aluminum can also be used, in place of zinc, for precipitating indium from acid solution.

Another process is based on the fact that indium can be precipitated selectively as a phosphate from a slightly acid solution. The method includes the precipitation of indium from the leach solution as indium phosphate, the conversion of indium phosphate to indium hydroxide by treating with strong caustic solution, filtering and heating to form the oxide, followed by the reduction of the oxide to metal. The resulting metallic indium can be further refined electrolytically if desired.

To recover indium from a zinc-lead metal, the molten bath is treated with a suitable chlorine-supplying agent or gaseous chlorine to remove selectively the zinc and indium as chlorides, using a low-melting cover slag and temperatures sufficiently low to avoid loss of indium by volatilization. The resulting chloride slag is then leached with dilute sulfuric acid and the indium is precipitated with zinc dust after removing lead sulfate by filtration. The zinc-indium sponge is then melted and the zinc is removed by means of chlorine.

TABLE.—*Physical Properties of Indium*

Atomicnumber	49
Atomicweight	114.82
Boiling point	2,046° C. (3,722° F.)
Crystal structure	Face-centred tetragonal
Density at 20° C. (68° F.), g./c.c.	7.31
Electrical resistivity, microhm-cm.	
(solid) 20° C.	2046° C.
(at melting point) 156° C. (313° F.)	29
Electrochemical equivalent for In^{+++}, mg./coulomb	0.39641
Electrode reduction potential for $In^{+++}(H_2=0.0$ volt)	0.34
Latent heat of fusion, cal./g.	6.8
Latent heat of vaporization, cal /g.	468
Linear coefficient of thermal expansion, per 1° C.	33×10^{-6}
Mechanical properties:	
Tensile strength, p.s.i.	380
Elongation, % in 1 in.	22
Brinell hardness	0.9
Modulus of elasticity, p.s.i.	1,570,000
Melting point	156.17 ± .05° C. (313.1 ± .1° F.)
Nuclear data:	
Stable isotopes	In^{113}; In^{115}
Thermal neutron cross section, 2,200 m./sec.	
Absorption (barns)	190 ± 10
Scattering (barns)	2.2 ± 0.5
Specific heat cal./g./° C.	
(solid) 20° C.	0.057
Thermal conductivity at 20° C., cal./sq.cm./cm./° C./sec.	0.057
Valence	Usually 3, but also 2 & 1

Characteristics. — Indium metal is unaffected by air at ordinary temperatures, but at a red heat it burns with a blue flame to form the oxide, In_2O_3. The metal dissolves in mineral acids but is unaffected by potassium hydroxide or boiling water. When heated in the presence of the halogens, direct combination takes place; when heated with sulfur, the two elements combine with incandescence.

Uses. — Indium is used as a coating for aircraft sleeve bearings since it improves corrosion resistance and enables the surface to retain a more adherent oil film. For fire protection indium is an ingredient of low-melting alloys used in sprinkler heads, fire door links, fusible plugs, etc. Indium has the unique property, when molten, of wetting glass and other surfaces, which makes it valuable for producing hermetic seals between glass, metals, quartz, ceramics, marble, etc. It is also used extensively in the manufacture of P-N junctions in semiconductor devices and for soldering various parts of germanium transistors and rectiiiers (see also TRANSISTOR: Fabrication Techniques: P-N Junctions).

In the nuclear field indium is used to measure the thermal neutron flux of a reactor and to monitor neutrons for the protection of personnel and equipment. This ability of indium to measure neutrons depends on the activation of the indium by neutron capture. The main stable isotope (11j), which is approximately 96% of natural indium, has a large capture cross section for thermal neutrons and the resulting isotope, In^{116}, is a radioactive beta ray and high-energy gamma ray emitter with a half life of 54 min. This activity, which is readily measured by conventional ionization instruments, gives a measure of the neutrons available for capture by indium. The characteristic of giving off intense gamma rays is the reason why serious consideration is being given to indium as a source of these rays for the preservation of food.

Organic indium compounds (particularly indium laurate) are used as additives to gasolines to give higher fuel efficiencies and to inhibit the deposition of carbon by the fuel during combustion. Another use of indium is as an anode in miniature alkaline batteries which are characterized by their long shelf life and freedom from gas evolution.

See M. *T*. Ludwick, *Indium* (1950); *A.* **A.** Smith, Jr., *Encyclopedia of Chemical Technology (1951).* (**A. A.** SH.)

INDIVIDUALISM is a term somewhat similar in meaning to liberalism (*q.v.*). Both concepts place high value on the freedom of the individual. While liberalism, changing in connotation with the times, has come to include concepts of freedom that are compatible with either governmental control or conjoint activity, individualism stresses the self-directed, self-contained and comparatively unrestrained individual or ego. In present day usage, the term sometimes lacks liberalism's suggestion of approval and may even imply disapprobation. Alexis de Tocqueville (*q.v.*), who coined the word, described it in terms of a kind of moderate selfishness, disposing men to be concerned only with their own small circle of family and friends. **A** hermit is an individualist but not necessarily a liberal.

Conceptual Bases. — As a philosophy, individualism involves a value system, a theory of human nature, a general attitude or temper and belief in certain political, economic, social and religious arrangements. The value system may be described in terms of three propositions: all values are man-centred, that is they are experienced (but not necessarily created) by human beings; the individual is an end in himself and is of supreme value, society being only a means to individual ends (held by some to be divinely ordained); and all individuals are in some sense morally equal. this equality being best expressed by the proposition that no one should ever be treated solely as a means to the well-being of another person.

The individualistic theory of human nature holds that the

interests of the normal adult are best served by allowing him maximum freedom and responsibility for choosing his objectives and the means for obtaining them: and acting accordingly. This belief follows from the conviction that each person is the best judge of his own interests and. granted educational opportunities. can discover how to advance them. It is also based upon the assumption that the act of making these choices contributes to the development of the individual and to the welfare of society.— the latter because individualism is thought to provide the most effective incentive to productive endeavour and because it is also believed to lead to variety of individual development. which itself is judged valuable. These beliefs about human nature have tended. historically. to be based upon a mechanistic and atomistic theory of psychology.— that is. the idea that behaviour is a matter of mechanical responses to sensations, directed toward maximizing pleasure and minimizing pain. Society, from this point of view, is seen as only a collection of individuals; each of which is a self-contained and ideally almost self-sufficient entity.

As a general attitude, then. individualism embraces a high valuation on self-reliance, on privacy and on respect for other individuals. Negatively, it embodies opposition to tradition, to authority and to all manner of controls over the individual, especially when they are exercised by the state. It also looks with favour upon variety rather than uniformity. and change rather than fixity; it anticipates and values progress and. as a means to this end, subscribes to the right of the individual to be different from, to compete with and to get ahead of (or fall behind) others.

The institutional embodiment of individualism follows from these principles. Liberal democracy is the favoured form of government and *laissez faire* (*q.v.*) the approved policy. The role of the state is to maximize individual freedom and opportunity. Only the most extreme individualists believe in anarchy *(see* ANARCHISM), but all believe that government should keep its interference with men's lives (including their voluntary arrangements for social life) at a minimum and that it should confine itself largely to maintaining law and order, preventing individuals from interfering with others and enforcing agreements (contracts) voluntarily arrived at. The state tends to be viewed as a necessary evil and the slogan "That government that governs least governs best" is applauded. Moreover, each individual should have equal opportunity, through the ballot, to determine the form and activity of the state and, through freedom of expression and association. to influence the beliefs and behaviour of others.

Individualism also implies a property system according to which each person (or family) enjoys the maximum of opportunity to acquire property and to manage and dispose of it as he sees fit. Freedom of association extends to the right to join (or to refuse to join) any religious organization. For some. individualism implies the belief that individuals do not stand in need of priest or church to mediate between them and God and that church organization should not be authoritarian.

History.— Both a clearer understanding of its meaning, and a better perspective for judging its value and prospects, can be obtained by examining individualism (or tendencies toward the development of an individualistic approach) in terms of its history. Primitive societies seem frequently to be characterized by a group solidarity that leaves relatively little room for individual autonomy. Within the period of a few centuries ancient Greece, in Periclean Athens, saw the development from this kind of tribal society to a degree of democracy. equality and individual assertiveness that was a far cry from the degree of subordination of the individual to the authority of a graduated social structure found in Sparta. Athenian democracy was short-lived, but it was individualism rather than the Platonic notion of the state as analogous to an organism that came to prevail in Hellenistic Greece. Epicurus. following the atomism of Democritus. developed a more thoroughgoing individualism than the world had yet known. For him the individual was the unit, the basis of society, and the sensation was the foundation of individual psychology. Not only were society and the state secondary, but the individual was encouraged as iar as possible to find his freedom and realization in withdrawal from politics and development of self-sufficiency. Justice, founded upon agreement or convention, was based upon the need of the individual for protection.

Although Epicureanism was widely adopted in the post-Xristotelian and Roman worlds. it was another and less individualistic school of thought, stoicism. that became dominant. Stoicism did develop a doctrine of moral equality. Its cosmopolitanism, however. and its insistence on an absolute standard of justice independent of the individual (and on the state as a natural institution having as its purpose the enforcement or approximation of this natural justice or natural law) constituted significant modifications of the stark individualism of the Epicureans.

Christianity, drawing upon ideas already developing in Judaism, introduced into the prevailing philosophy the emphasis on the supreme worth of the individual that had been lacking among the Greeks. Jesus' teaching also implied for many Christians the direct relation between man and God. This outlook provided a radically individualistic basis for religion that was not fully realized until the Reformation. For centuries. however. this individualistic element in Christianity was tempered by the concurrent belief that the individual most fully realizes himself by losing himself, by committing himself wholly to God and by emphasizing the importance of the life hereafter beyond that of earthly existence.

If individualism was highly qualified in the days of the Roman empire. the middle ages saw a far greater retreat into barbarian tribalism while the opening centuries of the modern period found a growing state centralism emerging from the weakness of feudal political society. Perhaps it was the very consolidation once more of political authority, freeing men from the insecurities of feudal society, that provided the condition for a rebirth of the spirit of individualism. Whatever the causes. and they were certainly complex, the Renaissance was characterized by a new spirit of inquiry, of discovery and of individual self-confidence and assertiveness. An exchange economy in which money replaced payments in kind. and in which free contract gave a new flexibility to arrangements hitherto fixed by immemorial custom, was representative of this development in the economic sphere. Similar movements toward freedom of the individual appeared throughout western culture. Science and the arts flourished. Soon the major over-all institutions found themselves under attack. The authority of the Roman Catholic Church was challenged by Luther, Calvin and their followers, and the new doctrine of the "priesthood of all believers" soon gained sway over large parts of Christendom. Partly as a result of religious strife, partly because in other ways the authoritarian secular states whose power had made possible the transition from feudalism to emerging capitalism were themselves unable or unwilling to adjust to the needs and demands of the rising commercial class. and partly because of the democratic demands inherent in the new individualism, some western European authoritarian political regimes were overthrown. Gradually the doctrine that government must be based upon popular consent implicitly or explicitly expressed in some form of a contract came to prevail.

Full-fledged individualism. as it is usually conceived to be, seems to have emerged first in England, perhaps because the English Catholicism was weaker and its ties to Rome more attenuated, and because England's insular position and consequent greater security following the Tudor era permitted a more relaxed society and a state in which it was easier for the individual to assert his demands successfully. Thomas Hobbes (*q.v.*), in the middle of the 17th century. building upon Epicurean ideas, presented a radically individualistic philosophy which was still politically authoritarian. His contemporary, John Lilburne (*q.v.*), less systematically but more effectively developed from a radically different viewpoint, that of economic "leveling." the democratic implications of the new philosophy, with emphasis on assertion of the universally accepted doctrine of natural rights (*q.v.*), including the natural right of political equality. The latter ideas were systematized and further developed later in the century by the Whig philosopher John Locke (*q.v.*), and gained support in British North America and France in the 18th century. The French Revolution, however. was characterized more by national sentiment than by

individualism.

It was again in England, through the ideas of Adam Smith and Jeremy Bentham and their followers in economic and political theory, respectively, that the 19th century saw individualism advance to new heights. Smith's doctrine of *laissez faire*, based upon a profound belief (borrowed from French Physiocrats) in the natural harmony of individual wills and Bentham's hedonistic utilitarianism, with the basic rule of "each to count for one and none for more than one," set the stage for these developments. On the economic side, Smith's "obvious and simple system of natural liberty," pictured exchange of goods and services in free and competitive markets as the ideal system of co-operation for mutual advantage. Such an organization should maximize efficiency as well as freedom, secure for each participant the largest yield from his resources to be had without injury to others and achieve a just distribution, meaning a sharing of the social product in proportion to individual contributions.

Restrictions on Economic Individualism. — While economic individualism, and political individualism in the form of democracy, advanced together for a while, eventually they proved incompatible as newly enfranchised voters increasingly came to demand, in the course of the 19th century, governmental intervention in the economic process. In point of fact the reasons for the growing demand for intervention were inherent in the attempt to adhere rigorously to an economic theory based almost solely on individualistic assumptions. In economics as in all other phases of life these assumptions are inadequate. Man is a social animal. His nature, his wants and his capacities are to a great extent the product of society and its institutions. His most effective behaviour is often through groups and organizations running the gamut from the family, through all manner of voluntary social and economically motivated associations to the state and international organizations. These units in varying ways interfere with the individualistic ideals of perfectly free association and of atomistic competition. Problems of monopoly and of technological, seasonal and cyclical unemployment, frequently associated in the public mind with individualistic economic theory, caused widespread dissatisfaction. Moreover, pure individualism, involving the institution of inheritance, tends to increase the tendency toward inequality inherent in the fact of unequal abilities. In this and other ways the individualistic society of the 19th century became more and more unsatisfactory to increasing numbers of people. Karl Marx demanded a radical departure from individualistic principles. Although his call for revolution and socialism did not succeed in the 19th century, gradually the collectivist principle gained headway, sometimes relying upon state ownership and management of business enterprises, but more frequently consisting of all sorts of state regulations limiting the freedom of the individual (and the corporation) in the management of property, for the welfare of society as a whole. The individualist state would intervene, if at all. only where it was clear that private activities. through the market or otherwise, were seriously damaging the public.

In the 20th century, even in nonsocialistic states, the presumption against state control became far weaker. If in any respect the nonpolitical institutions of society were apparently not working well, there was a strong demand that the state should intervene; and in the subsequently developed "welfare state," for instance, it was the government rather than the individual that took primary responsibility for insuring the great mass of the working population against the major hazards of life.

Organic View of Society. — Increased recognition of the need for a greatly enlarged role for the state went hand-in-hand with a modification all over the western world, of the individualistic theory of the nature of man and his relationship to the state. Contract theory tended to yield to theories that saw the state and the relationship between individual and state in less mechanical and more organic terms, while perceiving the individual himself less atomistically and more as an entity who was regarded as being as much effect as cause of society. Early examples of this emphasis were to be found in the works of Rousseau and Hegel. Even the mildly Hegelian British liberal T. H. Green, emphasized the organic relationship between individual and society. Among 20th century American democratic theorists, John Dewey exemplified a similar trend (*e.g.*, in his *Individualism, Old and* **New,** 1930).

In the extreme form of romantic (Nazi and Italian) totalitarianism all residue of individualism disappeared, the state or race became the final end of all, and the very notion of the individual as the basis of the western value system tended to fade away, along with its attendant belief in the moral equality of all men. Human reason is denigrated, and blind will or a mystical "spirit" of the group (political or racial) takes its place.

While the excesses of the 20th century totalitarianism had by mid-century produced a reaction against it in the free countries of the western world, particularly with respect to the supreme worth of the individual, there was also notable an attempt to capture certain values felt by some to have been embodied in totalitarian movements and to respond to forces that brought it about. More than this there were evidences of group-oriented thinking and values that seemed to be the unpremeditated product of innumerable conditions of modern life: large populations thrown together in tremendous metropolises, enabled by modern technology to share in each others' feelings and experiences to a greater degree than ever before; and a growing recognition of the fact that most human ends entailed group activity and group living. Psychologists discovered that men's minds seemed to perceive wholes before the parts of which they were composed. Similarly in many other fields the organic tended to displace the mechanistic approach and the whole tended to assume an importance that seemed to many men to be greater than that of the sum of its parts. In educational theory emphasis on "electives" had in some places given way to "core curricula," while much was heard of "adjustment to society" as a goal and less of the development of individuality; in criminology the idea that society was to blame for the criminal, or at least that he was not the master of his own soul, was bringing about sharp modifications in the theory of punishment; in economics "macro-economics," starting with measurement and analysis of the inputs and outputs of the economy as a whole, was supplementing if not displacing "micro-economic" analysis, which began with the individual firm; in political science the group had largely displaced the individual as the basic unit for analysis. Even physical science, with the development of the science of cybernetics, seemed to be moving from the mechanistic and atomistic approach to something more akin to the study of organisms.

The notions of the individual as the centre of value and of the moral equality of all individuals seemed to retain their fundamental position. In most other respects individualism and its corollaries appeared to be giving way to more social and organic modes of thought and endeavour although here and there, as in the field of education, there were indications of retreat from the most extreme applications of group theory. The possibilities for still further development seemed to be (1) an extension of these trends into totalitarianism; (2) a return to greater emphasis on the private; or (3) some degree of stabilization, philosophically and institutionally, at a point where the claims of the individual and the group, the private and the social, were in better balance than they had been in western civilization at least since the Renaissance. *See* also COLLECTIVISM; CORPORATE STATE; FASCISM.

INDIVIDUALITY, BIOLOGICAL. Two different meanings are associated with "biological individuality." First, it is used synonymously with "entity" or "unit." This connotation is derived from higher animals and plants which are encountered as individuals; that is. as clearly defined entities set apart from each other. They are characterized by a complex structure, but the diversity of their tissues and organs is integrated in a unit. When we speak of an individual robin or beetle, fir tree or tomato plant. we have in mind the unity in form. structure and function which enables the robin, fir tree. etc., to behave and react as a whole, in its environment. The individual. in this sense, constitutes the basic biological unit, as a self-sustaining and self-reproducing entity. Higher categories. such as species. or plant and animal communities: are composed of large numbers of such units.

In modern biology, "biological individuality" frequently has another quite different meaning. It refers to the "uniqueness" of the individual, or "individual specificity." In examining a population of robins. or of fir trees, the student is impressed. first. with the similarity of all individuals in all essential structural and behavioural features. It is this similarity on which the species concept is based. However. closer inspection brings to light another. equally significant. biological phenomenon, namely. the remarkable variability among individuals within the general framework of the species characteristics. In fact, no two individuals are completely alike, if the details of structure and function are considered. In the final analysis. the uniqueness of the individual is due to its unique hereditary constitution.

Entity. — Returning to the first-mentioned definition of biological individuality as an "integrated entity," it can be seen that this connotation is not so simple and unequivocal as it may seem. It loses its sharp focus when lower organisms. in both the animal and plant kingdoms, are considered. There exist forms of life to which the definition "integrated entity" is not applicable, and there arc others which show transitions from unindividuated to individuated organization. The difficulty that may arise in applying the term "individual" to plants, even the more highly organized, is seen when these are multiplied by mere division. When cuttings are rooted they may for practical purposes be considered distinct individuals, but theoretically they are separated portions of one. Again. a grafted apple tree is a composite unit built up of portions of two, sometimes more, individuals, termed stock and scion. mutually influencing one another. Furthermore. in the vegetable kingdom the change with lapse of time is well exemplified by the fact that in a tree new tissues are continually added at the periphery of the older, which gradually die; thus, though it is said that the age of a certain tree is to be measured in centuries, no living portion may, in fact, have survived for more than a few decades.

The unicellular organisms (many bacteria. algae and slime molds, and the protozoa) represent clear individuality on the cellular level. Other bacteria and algae and higher fungi exist in the form of cell colonies — that is. strings (filaments) or sheets of cells — which may grow and branch indefinitely and fragment fortuitously. The mycelium of fungi is an irregular, dense feltwork of such filaments. with no definite shape or boundary. and no inner organization, hence lacking the characteristics of individuality. However. the mycelium forms mushrooms (fruiting bodies), which represent the beginning of individuation.

The transition from unicellular to multicellular individuality is well represented by the small spherical green alga. *Volvox,* which any observer would designate as an individual. Actually, it is a colony of hundreds of flagellate cells embedded in a gelatinous mass. which swims and behaves as a unit. The constituent cells resemble their free-living, single-cell relatives; but there are signs of beginning organization, or division of labour, in that some cells specialize in reproduction and others are particularly active in locomotion. The slime molds (see Mycetozoa) offer another striking example of a shift from cellular to supracellular individuality. These organisms spend the major part of their life cycle as single-celled. freely moving. amoebalike cells. Under appropriate conditions. hundreds of such individuals aggregate in a tightly packed cluster. which transforms itself into an erect fruiting body of definite shape and structure. The individual amoeboid cells, like those of *Volvox,* give up their independence and become building stones in a higher unit, whereby they undergo a certain degree of specialization. The term "individual" can be applied legitimately to both levels, the cellular and the supracellular.

The evolutionary trend from cellular to multicellular organization is observed in all higher organisms: it is undoubtedly related to the greater efficiency that can be achieved through division of labour among cell groups. *Volvox* and slime molds represent early steps in this direction. At the other extreme are the highest animals and plants. in which the specialization of the individual cells has been carried to the point where they are completely interdependent and subservient to the whole. and no longer capable of a free, independent existence. Yet cellular individuality is not completely obliterated even in the highest forms. The individual cell remains the basic unit for all metabolic processes, such as energy transformation, respiration and growth. Furthermore. some cell types, such as white blood cells. are single cells, capable of amoeboid movements. Finally. living tissue cells (*e.g.,* nerve tissue or connective tissue) can be removed experimentally from an organism and grown in an artificial nutritive medium. In these so-called tissue cultures the cells not only survive for long periods, but they may regain some characteristics of free-living cells, such as the capacity for active movements. Therefore, there is some justification in viewing the higher organism as a highly integrated cell colony. In a sense, higher organisms, plants and animals, are organized in a peculiar way: they represent both levels of individuation. cellular and supracellular, in one.

In some animal groups (coelenterates, tunicates and others) a new type of individuality has been achieved on a still higher level, in the form of animal colonies: that is, groups of interconnected multicellular organisms. Successive steps in colony formation in the coelenterates may be observed. The well-known fresh-water polyp *Hydra* and its relatives. the sea anemones, are solitary beings. In the colonial corals, the polyps are linked together by a system of channels which enables them to share in a common food supply, but otherwise they retain their relative independence. In related forms, division of labour results in high specialization and modification of form of the individuals (polymorphism)! which, in extreme cases, appear merely as special organs attached to a common stem. For instance, the colourful marine siphonophores (Portuguese man-of-xvar and others) have all but lost the appearance of a colony; individuation on a supraorganismic level comes into existence.

In the two parallel series — that is, the evolution from unicellular to multicellular organisms and from there to animal colonies of the siphonophore type — may be recognized a general rule: wherever the subordinate units are strongly individualized and only loosely connected with each other, the individuality of the higher unit is indistinct; and. conversely, the more the individuality of the lower units is obscured, the more definite and distinct is the individuality of the higher unit.

Animal societies have been viewed by some biologists as supra-individuals or supraorganisms. particularly with reference to the elaborate caste systems in termite. ant and honey bee societies, where, again, division of labour has resulted in a high degree of specialization and consequent interdependence of the different types. These societies may be compared with animal colonies in which the physical linkage is replaced by communication systems, such as the elaborate language of honey bees.

The phenomenon of reproduction (*q.v.*) presents special difficulties to the individuality concept. The continuity of life is maintained by the faculty of all organisms to detach parts of their own living substance, thus giving rise to a new generation. This is done in a variety of ways: by the formation of gametes

(egg and sperm) or of seeds or spores. or by budding, as in yeast or polyps. or fission, or by still other devices. Difficulties arise when we try to determine exactly when and how the individuality of the offspring begins. Actually, one generation emerges from the other by a gradual process of individuation, and there are transitional stages during which no sharp line can be drawn between parent and offspring.

Phenomena of regeneration and regulation are closely akin to reproduction and present a similar dilemma. It is well known that a new plant can be grown from a cut-off shoot, or even from a fragment of a leaf, as in *Begonia*. Likewise, fragments of flatworms (Planaria), earthworms or starfish can regenerate a new individual (see REGENERATION). The same capacity for regulation is manifest in the early developmental stages even of higher animals and man. If eggs or very early embryos of a sea urchin, salamander or frog are cut experimentally in half, each part will regulate to form a whole individual (see EMBRYOLOGY, EXPERIMENTAL). In the armadillo, fragmentation of the egg has become the established procedure; each litter of four to eight individuals derives from a single egg. Identical tnins in man and in other forms arise in the same fashion from one egg. The difficulty of applying the individuality concept becomes insurmountable in the case of double monsters which derive from incompletely separated egg parts. There is a continuous series, from the Siamese-twin type, in which the individuality of the conjoined partners is undisputed, to those types in a-hich only the heads or the posterior body parts are dualicated.

Surveying the variety of design in the organization of living matter. it must be recognized that not all organisms are individualized. that individuality has become manifest at different levels of organization and in different degrees of distinctness, and that it is necessary to be cognizant of transitional states No rigid definition of individuality can do justice to the diversity of the biological phenomena.

Individual Specificity. — As mentioned above, "biological individuality" has a second meaning referring to the "uniqueness" of the individual with respect to the sum total of its structural, physiological, biochemical and behavioural traits. This is the result of the unique genetic constitution with which each organism is endowed, reflecting the enormous variety of recombinations and mutations of hereditary factors (genes) which occur in a cross-breeding population and are maintained by natural selection (see GENETICS OF POPULATIONS). As a result of the reshuffling of genes at fertilization and in the preceding processes of egg and sperm formation, each individual starts out with a unique constellation of hereditary factors which determine not only the structural and physiological adult characters but also the responses to its environment.

Everyday experience shows that no two human individuals are alike, but even in organisms in which the individual differences are not so obvious they can be demonstrated by appropriate methods. The most sensitive indicator of biological individual specificity is the well-known intolerance of an individual for transplants of skin (*see* PLASTIC SCRGERY) or other tissues from another individual (except from an identical twin nhich shares its genetic make-up). This incompatibility, akin to immunological reactions, is based on biochemical agents, the "individuality differentials" (Loeb). Such differentials have been detected in all vertebrates, down to fishes with the aid of the transplantation method. Of equal interest and significance are individual differences in blood groups; that is, immunological (antigenic) differences in red blood corpuscles (erythrocytes), which can be detected by their agglutination or lysis nhen combined with blood serum from other individuals. In man and several higher animals (monkey, cattle. sheep, chicken, dove) detailed studies have revealed numerous blood groups (the best knonn in man are the ABO groups, the MN group and the Rh factors) and subgroups (*see* also HEREDITY: Human *Heredity*). The possible recombinations of the blood group substances discovered so far go into the millions, and it can be assumed that each individual has its own peculiar blood type. Fortunately, many blood types are compatible with each other in transfusions, and only differences between major groups cause detrimental transfusion reactions. On the other hand, blood tests have been found to have practical applications in legal matters, and they may eventually supply a reliable index of individuality in animals, comparable to that of fingerprints in man; and assume great importance in animal breeding. It is'of interest to note that many blood group factors in animals can be referred to particular genes, whereby the genetic basis of individuality is firmly established.

The clinician is well aware of individual differences in the response to many drugs, to anesthetics and to antibiotics. The wide range of variability in the drug reaction of human individuals is illustrated in a study of the minimum concentration of mercuric chloride that is required to produce skin irritation. The sensitivity varied over a hundredfold in a small sample of individuals. Remarkably great differences among individuals have also been found with respect to the chemical composition of blood and saliva, to enzyme and endocrine patterns, vitamin needs, amino acid excretion, taste sensitivity and many other physiological and biochemical characteristics. A striking example was found in connection with the study of taste sensitivity to phenyl thiocarbamide (PTC). This substance has a bitter taste for some individuals but is tasteless for others, and this trait is due to a single hereditary factor. It was found that PTC can be tasted by "tasters" only when it is dissolved in the individual's own saliva, but not when it is dissolved in that of another person. The anatomist is familiar with corresponding individual variations in structural details. such as the shape of skeletal elements, the patterns of nerves and blood vessels, and the weight of organs. The uniqueness of fingerprints is so far the best criterion for identification of human individuals, and handwriting, when expertly analyzed, would be equally valid. The argument that in some of the instances cited above the differences may be due not to inborn diversity but exclusively to environmental factors can be met by studies of identical twins. They derive from a single egg and have therefore identical genetic constitution. In all traits that can be studied, identical twins show greater similarity. than fraternal twins or other siblings, thus demonstrating the significant part that heredity plays as the foundation of biological individuality. In man, the uniqueness of his biological heritage combines with the uniqueness of his stream of life experience to create "personality" (see PERSONALITY).

INDO-ARYAN LANGUAGES are the satem languages of the Indo-European family that are still spoken in the northern and central parts of India and in Pakistan (see INDO-EUROPEANS) and include the Sinhalese language of Ceylon.

Classification. — Inscriptions of the Mitanni country (northeast Syria) of the 14th century B.C. contain proper names of Indo-Iranian type. Otherwise, the oldest specimens of Indo-Aryan speech very closely resemble the oldest Iranian. The development of the two old forms of speech went on independently and followed some\\-hat different lines. This is most marked in the treatment of a nexus of two consonants. . While modern Iranian often retains the nexus with little or no alteration, modern Indo-Aryan prefers to simplify it.

The earliest extant literary record of Indo-Aryan languages is the collection of hymns known as the Rig-Veda. It may be taken as representing. on the whole, the particular vernacular dialect spoken in the east of the Punjab and in the upper portion of the Gangetic Doab. Later it extended between the Punjab and the modern Allahabad from the Himalayas to the Vindhya hills in the south, over the area known to Sanskrit geographers as the *Madhyadēśa* or Midland, also called *Āryāvarta* or the "home of the Aryans." There it received constant literary culture, and a refined form of its archaic dialect became fixed by the labours of grammarians during the 4th century, B.C., receiving the name of *Saṁskṛta* (Sanskrit) or "polished," "refined" in contradistinction to the folk-speech of the same tract and to the many Indo-Aryan dialects of other parts of India. all of which were grouped together under the title of *Prākṛta* (Prakrit) (*q.v.*) or "natural," "unrefined."

Sanskrit (*q.v.*) became the language of religion and polite literature, and thus the Midland, the native land of its mother dialect, became accepted as the true pure home of the Indo-Aryan speech.

Dialectal Variations. — In the time of Asoka (c. 269–232 B.C.), there were at least three dialects, an eastern, a western and another in the extreme northwest. The grammarian Patañjali (150 B.C.) mentions the existence of several dialects.

Round the Midland, on three sides — west, south and east — in Vedic times, Indo-Aryan dialects were spoken which all appear more closely related to each other than was any of them to the language of the Midlands. Thus, at an early period of the linguistic history of India there were two sets of Indo-Aryan dialects — one the language of the Midland and the other that of the dialects which form an Outer Band, according to the scheme suggested by Sir G. A. Grierson.

As time went on, the people of the Midland conquered the eastern Punjab, Rajputana with Gujarat (where they reached the sea) and Oudh. Hence in all these territories are found mixed forms of speech. The basis of each is that of the Outer Band, but the body is that of the Midland. From the Midland to the external borders of this tract, the influence of the Midland language grows weaker and weaker, and traces of the original Outer language become more and more prominent. In the same way the languages of the Outer Band were forced farther and farther afield over the Maratha country, into Orissa, into Bengal and, last of all, into Assam.

At the present day, a Midland Indo-Aryan language (western Hindi) occupies the Gangetic Doab and the country immediately to its north and south. Round it, on three sides, is a band of mixed languages, Panjabi (of the central Punjab), Gujarati, Rajasthani (of Rajputana and its neighbourhood), and eastern Hindi (of Oudh and the country to its south). Beyond these again, are the Outer Languages (Kashmiri, with its Dardic basis), Lahnda (of the western Punjab), Sindhi (here the band is broken by Gujarati), Marathi, Oriya (of Orissa), Bihari, Bengali and Assamese. The Pahari languages in the Himalaya, north of the Midland belong to the Intermediate Band, being recent importations from Rajputana, while Kohistani includes mixed dialects of the Sivat and Indus Kohistans. Thus, the Midland language is enclosed within a ring fence of intermediate forms of speech.

INDOCHINA, English equivalent of the French INDOCHINE, the name given collectively to the group of southeast Asian territories constituted by the French protectorates of Tongking, Annam, Cambodia and Laos and by the French colony of Cochin-China, bounded north by the Chinese provinces of Yunnan and Kwangsi, east and south by the South China sea and west by Siam (Thailand) and by the easternmost region of Burma. By the middle of the 20th century this unit was dissolved into three parts, Vietnam. Cambodia and Laos, the old names Tongking, Annam and Cochin-China surviving only as geographical expressions to denote northern, central and southern Vietnam respectively. (See also CAMBODIA; LAOS; VIETNAM.)

The population of the eastern area is predominantly Vietnamese, or, as it was formerly called, Annamite (the Annam of modern times being but the central zone of the earlier empire of Annam); that of Cambodia, Khmer; that of Laos, Thai. There are also, however, considerable groups representing aboriginal peoples, some of them speaking Malayo-Polynesian languages, such as the Cham (*q.v.*) of southern Annam and the Moi (*q.v.*) and Kha, whom the dominant peoples class as "savages." Finally there are peoples of northern or Chinese origin, Muong, Man, Meo and others in Tongking and Laos.

By the middle of the 20th century the racial distribution of these peoples was estimated roughly as follows: Vietnamese, 21,000,000; Cambodian, 3,000,000; Laotian, 600,000; Cham, 100,000; Muong, 200,000; Thai other than Laotian, 800,000; Man and Meo, 300,000; Moi and Kha, 1,000,000. Nonassimilated Chinese of immigrants of modem times numbered 600,000; Europeans, 40,000, of whom 36,000 were French.

The religions of Indochina are little less diverse than the peoples. The Annamite form of Buddhism is of Chinese origin and in practice resolves itself largely into ancestor-worship. Cambodian and Laotian Buddhism is very different, being of a form adopted from the Indian. The Moi and the Kha are pagan. Christian missionaries have been active in Indochina since the first quarter of the 17th century, so that there are now several Catholic bishoprics. Finally there are the eclectic sects, Cao-Daists, Hoa-Hao and Bin-Xuyen, often of a paramilitary and highly nationalistic character.

HISTORY

French political influence in Indochina dates from Nov. 27, 1787, when, through the efforts of the great missionary P. J. G. Pigneau de Béhaine (1741–99), bishop of Adran *in partibus infidelium,* a treaty was signed at Versailles between Louis XVI of France and the chua (king) of Cochin-China, Nguyen phua Anh.

As a result of this treaty, despite obstruction by the French king's Irish governor of Pondicherry, a number of French officers, notably V. C. Olivier de Puimanel, Philippe Vannier, J. M. Dayot and J. B. Chaigneau, helped the chua to recover his throne, disputed by the Tay Son rebels, in 1801 and to become, under the name of Gia Long (1802–20), the founder of the new imperial dynasty of the Nguyen. Tourane and the island of Poulo-Condore (Pulo-Condor) were ceded to France. A great ruler who did much for his country, undertaking considerable public works, a land-survey and the promulgation of a new legal code, Gia Long never forgot his obligation to the French and particularly to Pigneau, whose tomb he built in Saigon and whose epitaph he himself composed.

The Establishment of the **Colony.**—Gia Long's successors, however, began a persecution of Christian natives and missionaries in the course of which, between 1833 and 1873, 8 European bishops and 15 missionaries were put to death. In the reign of Tu Duc (died 1883), the persecution was intensified, and, as the victims included both Frenchmen and Spaniards, a Franco-Spanish expedition, under Vice-Admiral Charles Rigault de Genouilly, was eventually sent to intervene. Rigault took Saigon in 1859; but the Annamite siege of the latter place, which began in the following year, was not raised till L. V. J. Charner arrived with reinforcements for the French in 1861. By the treaty of June 5, 1862, the three eastern provinces of Cochin-China were ceded to France.

From 1863 to 1879 the newly acquired territory was governed by the "administration of the admirals" (it should perhaps be pointed out that until 1889, when they were transferred to the ministry of trade, the French colonies were under the same minister as was the navy). The first of these admirals, L. A. Bonard, was succeeded by P. P. M. de la Grandière (1863–68), during whose tenure of office three important events took place: a French protectorate was established over Cambodia (Aug. 11, 1863), secured by E. M. L. Doudart de Lagrée's occupation of the capital (1864); M. J. F. (Francis) Garnier explored the valley of the Mekong (1866–68); and the three western provinces of Cochin-China, which had been left to Annam in 1862, were annexed to the French colony (June 1867).

Tongking and the New Protectorates. — It was during the governorship of M. J. Dupré that French intervention in Tongking began, as a consequence of differences between the Annamite

authorities there and the French merchant Jean Dupuis. Sent on a mission of enquiry Garnier took Hanoi in Nov. 1873 and had subdued several other places in the Red river delta before he was killed in battle a month later, by the Black Flag brigands whom the Tongkingese had called in from Yunnan.

Dupré then concluded an agreement (1874) with Tu Duc of Annam whereby the French were to renounce Garnier's abortive conquests in return for Tu Duc's undertaking to "conform his policy to that of France" and to grant them certain trading rights in Tongking, necessary for their commerce with Yunnan. This agreement is sometimes considered as tantamount to the establishment of a protectorate, though the term itself was not used in it. Its validity, however, was called in question when in 1880 Tu Duc decided to reaffirm Annam's status of vassalage to China, which had been disregarded for many years; and the continued depredations of the Black Flag brigands in the Tongking area led to the dispatch of a new expedition under the commandant Henri Riviere, who took Hanoi in April 1882 but was killed in battle in May 1883, after which Gen. A. E. Bouet took his place in command of the expedition. Subsequent French successes in Tongking and the arrival off Hué of a squadron under Vice-Admiral A. A. P. Courbet induced the Annamite government to accept a French protectorate over Annam and Tongking (Aug. 25, 1883). Warfare continued, however, with the Black Flags, who began to receive imperial Chinese support after the French advance on Sontay.

The convention of Tientsin (May 11, 1884), signed by the French representative François Fournier, stipulated that Chinese troops would withdraw from Tongking and was followed by another treaty signed at Hué (June 6, 1884) confirming the French protectorate over Annam and Tongking. At the same time a treaty was signed confirming the French protectorate over Cambodia (June 17). But misunderstandings as to the terms of the Fournier convention prolonged the war in Tongking, as the French forces tried to occupy Langson before the Chinese were ready to withdraw: France declined the mediation of the powers; Courbet destroyed the Chinese fleet on the Min and bombarded the Foochow arsenal (Aug. 1884); then the defeat of Gen. François Négrier at Langson led to the fall of Jules Ferry's ministry in Paris (March 1885). The mediation of the British ambassador, Sir Robert Hart, led to the signing of preliminaries of peace at Peking in April 1885; this was followed by the conclusion of the treaty of Tientsin on June 9, 1885, whereby China again recognized the French position in Annam and Tongking. (The Sino-Tongkingese frontier was defined in conventions of June 1887 and June 1895.) There was rebellion in Cambodia during the first six months of 1885.

Peace with China, however, did not bring peace within the protectorates. Operations against the bandits of Tongking had to be undertaken for a further decade. In Annam the mandarins who controlled the regency for Tu Duc's short-lived successors were alarmed at France's use of the protectorate: they organized an attack on Gen. P. M. H. Roussel de Courcy when he entered Hué in July 1885; and the French had to install a new emperor, DongKhanh, in the following September. Paul Bert (*q.v.*) the first resident general for Annam and Tongking, died in Nov. 1886, seven months after his arrival.

The Union from 1887 to 1900.—The unification of Cambodia, Annam, Tongking and Cochin-China under a governor general was first undertaken by decrees of Oct. and Nov. 1887; but neither the first governor general, Jean Antoine Constans, nor his immediate successors exercised any very considerable powers over the residents general of the three protectorates. It was the decree of April 21, 1891, that gave the governor general effective authority. J. M. A. de Lanessan (*q.v.*), the first to be appointed with these new powers, was in office when Auguste Pavie saved Laos from being divided between Siam and Annam and secured the Laotian acceptance of a French protectorate over the kingdom of Luang-Prabang (Sept.-Oct. 1893). Lanessan's policy, however, which tended to restore something of the power of the mandarins (at whose disposal he put a native police force, the *Linh co*), to check the recurrence of expeditions and minor military operations and to restrict the authority of the residents superior. was objectionable to certain influential groups, who obtained his abrupt recall in Dec. 1894. For a few years after this the governor general's powers under the decree of 1891 were somewhat modified; but the decree recovered its full force shortly after the appointment of Paul Doumer (*q.v.*) as governor general. The decree of July 31, 1898, established the financial unity of French Indochina by setting up a general budget (the separate budgets for the several countries, which had survived Indochina's passing under the control of the newly created French ministry of the colonies in March 1894, were allowed to subsist); and that of Sept. 9, 1898, put the public works of Indochina "under the direct authority of the governor general as regards works entered to the general budget account." Doumer's administration (1897–1902) saw also the creation of a network of railways and, in April 1898, the leasing of the Chinese mainland territory of Kouang-Tchéou-Wan, which was placed under the governor general's authority in 1900.

The Siamese Treaties, 1904 and 1907.—By the treaty of Feb. 13, 1904 (replacing an unratified one of Oct. 7, 1902), France restored to Siam the district of Chantabun (taken in 1893 while the Laotian protectorate was being established) in return for the cession of Melupré (northern Cambodia), of Bassac (southern Laos) of Dansai (the southernmost part of the old Laotian kingdom of Luang-Prabang) and of the maritime frontier district of Krat. Dansai and Krat, however, were returned to Siam by the treaty of March 23, 1907, when the latter country ceded Battambang. Siem Réap and Sisophon, the three western provinces of Cambodia, to the French protectorate.

The 20th Century to 1940.—The history of French Indochina from 1907 to the outbreak of World War II is primarily that of its organs of government. A decree of Oct. 20, 1911 (a few months after A. P. Sarraut's first being appointed governor general), redefined the governor general's powers, making them wider as regards local budgets. In 1914 the Conseil de Gouvernement de l'Indochine was established to replace the Conseil Supérieur de l'Indochine (which had been reorganized by the decree of Aug. 8, 1898). The Grand Conseil des Affaires Économiques et Financieres de l'Indochine was constituted on Nov. 4, 1928, to deal with budgetary questions.

The governor general was the head of the administration, controlled the armed forces and represented the French republic in Indochina; he also approved the budgets of the separate countries of the union. The separate countries, however, maintained their own governments, with internal autonomy. By 1939, the structure was as follows: Cochin-China, a colony under a governor, had its colonial council (established in 1880) and sent a deputy to the parliament in Paris. Cambodia, a kingdom, and Annam, an empire, both under protectorates, had each a council of ministers, over which a French resident superior presided, as well as an assembly elected by the natives and a council for economic and financial affairs elected by the French; native affairs in each were administered by the prince; and each sent one delegate to the Conseil Supérieur des Colonies in Paris. Tongking, a protectorate, was similarly organized, except that the French resident-superior was responsible for native as well as for French administration (the Annamite emperor having agreed to withdraw his viceroy in 1897); it also sent a delegate to Paris.

Laos comprised both the kingdom of Luang-Prabang (a protectorate) and a colony; the French resident-superior being responsible for both French and native administration except where the king had jurisdiction; the country also had a consultative assembly. Ports under a regime of concession to France were Tourane in Annam and Haiphong in Tongking; there was also a concession in Hanoi.

The administration of justice throughout Indochina was based in principle on French law; but in the protectorates there were native tribunals with jurisdiction in civil cases in which no European was involved, while in Cochin-China the Annamite law could be administered in the French courts, as there were no native tribunals there. The court of appeal had four chambers (two in Saigon, two in Hanoi); its French judges had native advisers for cases affecting native law.

Before World War II, Indochina had a flourishing commercial economy: in 1939 the value of exports was 3,494,729,000 francs, that of imports 2,382,262,000. The principal exports were as follows: rice, grown mainly in Cochin-China (1,692,000 tons exported in 1939; Indochina rose to be the world's third largest exporter of this commodity); rubber, grown mainly on estates planted by the French in Cochin-China and in Cambodia (nearly 69,000 tons exported in 1939); corn (average annual production more than 500,000 tons); coal, iron, manganese and zinc from Tongking and tin from the Cammon province of Laos; fish, caught mainly off the coasts of Cambodia Cochin-China; pepper from Cambodia (between 3,000 and 4,000 tons exported annually); livestock and hides, mainly from Laos, Annam and Cambodia; and cement. Other crops included tea, coffee and various spices. The teak forests of Laos were particularly valuable. Imports consisted principally of manufactured goods and petroleum products.

World War II.—Gen. Georges Catroux was appointed governor general in Aug. 1939. Within a month World War II had broken out; and after the fall of the French republic in June 1940 Catroux was replaced by Adm. Jean Decoux, a nominee of the Vichy government. From Sept. 1940 the Japanese secured the use of bases in Tongking for their operations against China; and by the middle of 1941 they had obtained a virtual monopoly of Indochina's rice and rubber exports and a hold over the transport system. The Siamese had meanwhile attacked Laos and Cambodia and, through Japanese mediation, won the cession of the Laotian provinces lying west of the Mekong and a large portion of western Cambodia (March 1941). In July 1941 the Japanese occupied southern Indochina, from which they attacked Siam and Malaya in December. (See WORLD WAR II.)

The Rise of the Vietminh.—On March 9, 1945, the Japanese overthrew the French administration, interning or killing French officials. Proclaiming a policy of "Asia for the Asiatics," they then set up nationalist governments of their own creatures. On Aug. 19, however, after the bombing of Hiroshima, the Japanese withdrew. At Hanoi the Vietminh seized power. This was a nationalist party that had been formed on Chinese territory during the war, under the leadership of a veteran Communist, Ho Chi-minh. Soon the Vietminh had set up administrative committees throughout Vietnam (Tongking, Annam and Cochin-China, the predominantly Annamite or Vietnamese areas), in the place of the mandarins. Then they declared their country independent.

Meanwhile the Allies, at Potsdam, had decided that northern Vietnam should be occupied by the Chinese and southern by the British. The British were soon superseded by the French, who opened negotiations with Ho Chi-minh. French troops under Gen. Jacques Leclerc landed at Haiphong on March 6, 1946, and then occupied Hanoi. France recognized the republic of Vietnam as a "free state forming part of the Indochinese Federation and of the French Union." Ho Chi-minh then went to Fontainebleau for negotiations with a view to defining this formula; but agreement was reached only on points of secondary importance.

The Indochinese War, 1946–54.—On Nov. 23, 1946, the French at Haiphong took measures to halt the smuggling of arms; shots were exchanged, followed by artillery fire. In the night of Dec. 19 the Vietminh made a sudden attack on the French forces, failed to overcome them and had to take to the jungle.

This marked the beginning of a long war. The French occupied the Tongking delta, several points on the coast of Annam, the Moi and Thai countries and, in particular, Cochin-China, where Saigon became a vast city of refuge as well as the seat of government. The Vietminh controlled the hinterland of the Tongking delta, most of Annam and certain areas of Cochin-China and had moreover the support not only of secret sympathizers but also of guerrilla forces in all the French-occupied parts of Vietnam. The French could not leave the towns except in convoys; and even in Saigon attempts at assassination were frequent.

The French government tried to reach a compromise by addressing itself to the former emperor of Annam, Bao Dai. The agreements of March 8, 1949, established the independence of Vietnam within the French union. The former colony of Cochin-China, momentarily classed as an overseas territory of France, was transferred to Bao Dai's Vietnam. A Vietnamese army was gradually created, to fight beside the French forces. Yet Bao Dai's regime failed to attract the large local adherence that had been expected.

Conditions in the two other countries of French Indochina were settled more peacefully (for their postwar constitutions. see below). The authority of the king of Luang-Prabang, Sisavang Vong, was extended to cover the rest of Laos, so as to form a single kingdom of Laos, which was recognized as an iridependent state associated with the French union by the treaty of July 19, 1949. The king of Cambodia, Norodom Sihanouk, agreed to a similar treaty, signed on Nov. 8. The Issarak dissidents, however, armed first by Siam and then by the Vietminh, continued to infest some parts of Cambodia.

The year 1950 marked a turning-point in the war in Vietnam. The French had to evacuate the Langson area, on the Chinese frontier, which enabled Communist China to furnish generous supplies of arms to the Vietminh. In 1951 the French managed to clear the delta of enemy forces and to recover the initiative. thanks to the efforts of their high commissioner and commander in chief, Gen. Jean de Lattre de Tassigny. The latter's death, however, was a blow that jeopardized his successes.

In the following years the French conducted some successful diversionary operations in the Thai country of southwestern Tongking and on the coast of Annam. But in April 1953, after occupying the Thai country, the Vietminh invaded Laos, set up an independent government (Pathet Laos) in the northeast of the country and temporarily advanced almost into the suburbs of Luang-Prabang. In Jan.-Feb. 1954 they made another invasion along the same route without achieving anything further; but they succeeded in occupying central Laos (west of Annam).

Provided with heavy artillery. the Vietminh laid siege to Dien Bien Phu, a post in the Thai country that had been occupied by French parachute troops in Nov. 1953. After a heroic resistance by the defenders, Vietminh forces entered the central stronghold of Dien Bien Phu on May 7, 1954, where they took 10,000 prisoners. The French in the delta then withdrew into the Hanoi and Haiphong zones.

The Convention of Geneva.—Meanwhile an international conference had met at Geneva to reach an agreement on affairs in Asia. The French prime minister, Pierre Mendès-France, was active in negotiations both with the Chinese and with the Vietminh. The convention of July 20, 1954, for the cessation of hostilities, stipulated that the Ben-Hai river, near the 17th parallel of latitude north of Hué, should be the line of demarcation between the two zones into which either party would withdraw its armies: the French troops were to evacuate Tongking, the Vietminh those parts of southern Annam, Cochin-China and Laos which they had been holding. Supervised elections were to take place before June 20, 1956, to decide the terms on which northern and southern Vietnam should be reunited. These dispositions may be taken to mark the end of the French Indochina first unified in 1887. There were now four successor states, again wholly separate: North Vietnam, South Vietnam, Cambodia and Laos.

North Vietnam, styled the Democratic People's Republic of Vietnam, was the Vietminh state, organized on totalitarian Communist lines. The Communist party (Lao Dong) held the key industries and exercised an effective and entire control by means of a hierarchy of communal, district and provincial committees, the members of which were elected from its approved lists of candidates. The disciplinary efficiency of the party was enhanced by its wartime experience.

South Vietnam, on the other hand, could present no such consolidated front. Bao Dai, as chief of state, enjoyed but a remote authority. One prime minister followed another all too quickly, and power was divided between the powerful religious sects (Cao-Daists, Hoa-Hao and Bin-Xuyen) and the generals of the new army.

Cambodia, through a constituent assembly, had received a constitution in 1947. The prime minister was to be designated by the king and to be responsible, with his cabinet. to a national assembly elected by universal suffrage. A second chamber, the council

of the realm, was to comprise representatives of the king, of the assembly, of the provincial authorities and of the professions. After disturbances in Jan. 1953 the king dissolved the assembly and assumed power himself.

Laos, which also received a constitution in 1947, had likewise a national assembly elected by direct suffrage. The king could refer decisions back to the assembly for a second deliberation, he could act as president oi the council, and dissolve the assembly. Buddhism was recognized as the state religion. The seat of ministerial government and of the assembly mas at Vientiane; the royal palace was at Luang-Prabang. The non-Laotian tribes, especially the Meo, were practically beyond the government's control.

South Vietnam, Cambodia and Laos, as independent states, were voluntary ("associated") members of the French union, represented in Paris in the assembly of the Union and in the high council. French troops were stationed provisionally in all three of these states, the independence of which was guaranteed in 1954 by the signatory powers of the Manila agreement (Southeast Asia Treaty organization). France was represented by a high commissioner in the three "associated" states and in northern Vietnam.

INDO-EUROPEANS. The term Indo-European appears to have been invented by the well-known physician and physicist Thomas Young. In an article in the 10th volume of the *Quarterly Review* (Oct. 1813) he uses the word without any remark as to its being a new coinage. The word was devised especially to indicate a family of languages, but from the beginning it has been found very difficult to keep apart the use of the word as indicating languages and the application of the term not only to the speakers of the languages at any given period but also to the supposed original speakers of these languages. The effect of this confusion has often been serious. It is obvious that a language may be spoken by persons who have no blood relationship with the general body of speakers of the language, and that this body itself may not be all of one and the same origin. Thus the negro in Liberia or in the Southern States of America who speaks English as his mother tongue may have no drop of English blood in his veins, and even 200 years ago Daniel Defoe was certain that there was no such person as the "true-born Englishman."

Ever since it was possible to identify a separate family of languages as Indo-European, continual efforts have been made to ascertain who were the original speakers of the language from which the surviving members of the family, or those which are recorded in literature or other monuments, have sprung, where was their home, what were their surroundings and their manner of life. The first of the elaborate statements of these problems was that published by Adolphe Pictet in 1859. The more important attempts of the same kind which have appeared since are enumerated in the bibliography at the end of this article. It is hardly necessary to say that the majority of such attempts deal mainly or altogether with the evidence derived from language. This is necessarily so, because, when the question arose, the linguistic scholars were the first who were ready to carry on the investigation; but the problem can be attacked in various other ways; and it is only by an attack converging from all quarters that a certain result will ever be attained.

Fauna.—From language it is clear what were the animals, what were the plants and what were the seasons in the country whence this language was derived. The animals still familiar amongst us were well known; the sheep, the cow, the horse, the dog and the pig. The names of the goat vary much more from language to language; but it does not necessarily follow from this that the goat was not known until a later time. Animals for which there are no early terms in the Indo-European languages are the lion, the tiger, the elephant, the camel and the ass. It may therefore be safely concluded that these animals did not exist in the original habitat. The lion, at one time, certainly roamed over a much larger area than it does now. According to Herodotus lions were found as far to the west as Macedonia and the prevalence of the representation of the lion in monuments of Asia Minor and Persia is proof to some extent, that the animal was well known. It still survives in Cutch but has lost its mane and is on the way to extinction in Asia. As there is no word for the elephant and no representation of it in the more western part of Asia or in Europe it is clear that this animal also was unknown. The same is true of the tiger and the camel and the ass. In Asia the common beast of burden was the ass. The horse, though known in Mesopotamia from the time of Hammurabi before 2000 B.C., owes its introduction to the Kassite invasion of 1926 B.C., and was called the mountain ass. Palaeolithic man was able to represent in his drawings two species or varieties of horse. The name of the cow has the same origin in almost all the languages and the same is true of the sheep, the pig, the dog and the mouse; but in their wild state the same environment is not suitable to all. The horse is an animal of the prairie; it lives in the open plain and the foal is able from the day of its birth to accompany the mare. The cow, on the other hand, in the wild state lives in countries with open spaces well provided with woods or clumps of trees. When the cow travels afield to find food, the calf is unable to accompany her and has to be hidden in some brake or thicket, as it can walk but feebly and its eyesight is still imperfect. Unless it were so hidden it would fall a prey to animals like wolves or eagles, both of which seem to have been known to the first Indo-Europeans. The grass which suits horses or cows is unsuitable for sheep which prefer the short crisp grass of upland pasture. If, therefore, all these animals were well known to the early Indo-Europeans they must have lived in an area where the landscape was diversified. The country seems to have no connection with the sea; the more widely spread meanings of the word for the sea are either moor or marsh. That open water was known is shown by the fact that there were words for water birds, the swan, the goose and probably the duck, but all of these could find a resting place in very small sheets of water. From what has been said, it will be clear that the Indo-Europeans must originally have lived in the temperate zone. The bear was known, but which species we cannot tell. It is well known that the name "bruin" meant the brown bear, being cognate with the Lithuanian word *béras*, for the Lithuanian word is used as an adjective meaning brown. Other animals known were the beaver and the hare, the word for the beaver being generally a reduplicated form from the same stem as the word for the bear and the hare, meaning originally the grey beast. Its origin was the same as that of the Latin adjective *canus* from an older *cas-nos*.

Flora.—The trees and other plants are not so easy to identify because it is found that when men migrate to a new area, they carry with them the names of plants and, to some extent, also of animals and apply them to plants or animals in the new area which bear some resemblance to the plants or animals they have left behind. Thus in England the oriental plane, so well known in Asia Minor and Persia as the Chinar, grows only with difficulty north of the Trent and in northern Scotland not at all. But the name plane is preserved, notwithstanding, and applied to the sycamore which resembles the plane in being an umbrageous tree and having a leaf somewhat similar. In the same way, the English in America have given the name of robin to a much larger bird, because it has a red breast. The trees most widely spread in the temperate zone are the willow and the birch. The birch extends from the British Isles to the farthest Himalayas. Some variety of willow is the first tree to grow near streams in a country like Siberia which has not long been freed from surface ice. On the other hand, some of the commoner trees, like the beech, do not penetrate far into the southern peninsulas of Europe. The consequence is that in Greece the word corresponding to *beech* in English and to *fagus* in Latin, means oak or sometimes possibly chestnut. In the same way in Latin the word cognate with the English birch is used for the ash, *fraxinus*. The pine in some of its numerous forms was also certainly known.

Cereals and Seasons.—More important, perhaps, for the history of the race, is the existence of cereals. Within historical times, only two new cereals have been introduced into Europe, rice and maize, though a plant of another kind, buckwheat, was

brought in by the Tatars and has received its name because its fruit was ground, and treated as a cereal. Many attempts have been made to connect the Greek oryza with the Sanskrit *vrihi,* which in modern Persian appears as *birinj*. But traffic down the Red Sea was mostly with southern India and the simpler explanation is to connect the Greek word with the Tamil, *arishi*. The early names for grain are very ambiguous. The word corn connotes in England wheat, in Scotland oats, in Sweden barley, in Germany rye and in America maize. The most widely spread name for a cereal is that which appears in Sanskrit as yava, in Greek as *zka* or *zeiá,* the latter a derivative of the former, in Lithuanian *jawaĩ*. It may have meant originally barley, but is also used for spelt, a simple and ancient form of wheat, which, as being such, was long used in religious ritual.

The names for the seasons of the year help us somewhat. There **are** words widely spread for winter and for snow. The stem *hima* is found in the name of the Himalayas ("the abode of Snow") and in the Greek khezma with its adjective duskhimos, the Latin *hiems* and many others. We do not use a word from its root for winter ourselves; but notwithstanding we have a word borrowed from the Norse and much used by Cumberlanc shepherds, *gimmer,* a winterling or sheep one year old. There is less agreement about the other seasons but there is a fairly widely spread word for spring. In many countries summer is simply the hot season. For harvest the languages do not agree very well; the Latin *auctumnus* is simply the "season of increase," which we have introduced into English as autumn. The word harvest is probably the season of fruit gathering, not of corn harvest, the two being still distinguished in German as *herbst,* the fruit harvest, and ernte, the reaping time. Snow was certainly known because the stem is found in so many languages, but with lofty mountains in the neighbourhood that might well be, even in a hot climate; from the names of the animals and plants, however, as we have seen, the climate was temperate and if it was a continental climate as, from the absence of words for sea, it apparently was, the climate might be severe, even if it were tolerably far south. The areas that will satisfy the conditions require a land with a temperate climate, remote from the sea and shut off from other areas, for otherwise it seems impossible that languages with so complicated a grammatical system as the Indo-European could have developed, bearing so close a resemblance to one another and on the whole so strongly differentiated from other languages. The only area which will satisfy the conditions postulated by the languages is the great area in Europe which includes practically the former empire of Austria-Hungary. In this area are found rich corn land, great prairies for the production of horses, pasture for cattle in the plains and for sheep on the mountain slopes, while the mountains themselves contain a large supply of minerals which were later utilised by man. But when the migrations from this centre began, the use of metals had not advanced very far, the only word for metal common to many languages being that which appears in Sanskrit as ayas, in Latin as aes and in English as ore. The word at the time of the migration meant either copper or bronze which sometimes, as in Greek, are not distinguished, the first bronze probably being a natural alloy. From what has been said it is clear that much could be done on this subject by the geographers.

Migration. — Even when we have found a people using a certain vocabulary, it is necessary to discover, if they migrated from their original habitat, in what manner it was possible or probable that they did migrate. It is, for example, a common belief that migration from Europe to Asia or the reverse, was carried on largely by the steppes of Southern Russia, the shores of the Caspian and Turkistan. In ancient times, however, progress in this direction would not have been so easy as it is to-day. In the Caspian area very large and important changes in the earth's surface have taken place. The eastern end of the Caucasus, for example, has sunk till it is now far below the level of the Caspian. The northern Caspian is steadily being filled up by siit from the Volga. In earlier times, it extended much further north than it does at present, while eastwards its extent was very much greater, including within its area not only the present Sea of Aral and what is now the intervening desert, but also passing still further to the east to a distance which is not yet clearly determined. Scholars often talk lightly also of great hordes passing the Caucasus. This also would be very difficult to achieve. According to early Greek notions the Caucasus was a barrier without openings through it and in fact at the present day there is but one, the Pass of Dariel. Historical migrations, in fact, have taken place much more readily across Asia Minor than across the Steppes. The main movement from Asia into Europe which went north of the Caucasus was in early times that of the Scythians and in mediaeval times that of the Hungarians. That the migration of the Indo-Europeans was through Asia Minor is proved by the discovery in 1906–07 of a large mass of records dating from the 1 jth and 14th centuries B.C., at Boghaz Keui, an important site east of the river Halys. Here were discovered the archives of the ancient Hittite empire, recorded in eight languages of which two have a certain Indo-European element in them. The most important is called Kanisian by Dr. Emil Forrer, who has been very successful in their decipherment. The grammar of this language, its noun and verb forms, are clearly Indo-European; but only a small part of its vocabulary is so, the main part coming from an unknown tongue. The first records of this language which were discovered came not from this find at Boghaz Keui, but from two letters discovered many years before, in the archives of Ikhnaton (*q.v.*), the heretic king of Egypt at Tell-el-Amarna. The mixture of two languages might be compared to what has happened in English where the pronouns, the numerals and the few remaining inflections of noun and verb are Teutonic but the bulk of the vocabulary is of Latin, or of Greek origin. The forms of this language, particularly in the names of certain deities, and of the numerals were so like those of Sanskrit that the first investigators were of opinion that either the records proceeded from Indians advancing westwards, or that the original home of the Indo-Europeans must once more be carried back to central Asia, where it had been located by some of the early authorities. A difficulty was found in the fact that the existing remains of the ancient languages of Persia — Zend and old Persian — as represented in the dialects of the Avesta and the kindred tongue of Darius' inscriptions at Behistun were so much less archeic in sounds than either the forms of these records or of Sanskrit. The explanation, however, is simple. When the speakers of Sanskrit passed over the mountains into a new country, they found themselves faced by powerful tribes more numerous than themselves and speedily realized that if they were not to be absorbed, they must stand aloof from mixture with the native tribes. Hence the beginning of the system of caste in India, for the Sanskrit word for "caste" means colour. The changes found in the language left behind in Persia must have taken place after the migration of the emigrants to India. This is not at all unusual. In the 16th century important changes took place in Spanish, but these changes were not shared by those who had already established Spanish in America. The English settlers of New England carried with them the forms noos for news and Toosday for Tuesday, because the y sound before *u* had not developed when these settlers left England.

If the original home of the Indo-Europeans is really located in Austria-Hungary, we should expect a considerable number of the Indo-Europeans to have been pile-dwellers. For this country had at one time much more water in it than it has now, when the Platten See, a shallow marshy lake, is all that remains of what was at one time a vast expanse of slowly drying morass. That there were amongst them many pile-dwellers, we can be certain, because they carried into Switzerland and into Italy for the western migrations, the same form of habitation, and gradually extended it further to the West.

Anthropology. — What manner of men were these emigrants? In Germany many scholars contend that they were tall men with fair hair and blue eyes and they attribute to the Indo-Europeans all the characteristics of the ideal German. For this, however, there is no solid foundation. It is said by these scholars that when Homer talks of xanthos *Menelaos,* this should be translated "yellow haired Menelaos." This translation, however, is not accurate. To a Greek xanthos did not mean blond, but brown,

as is clearly shown from the use of the verb, which signifies "to change the colour of meat in roasting," so that the colour would not have been lighter than auburn. In fact, when the Greeks came in contact with German children they did not know how to describe the colour of their hair and said they had hair like old men and described them as *polioi*, "with grey hair."

The anthropologists at one time maintained that the Indo-Europeans had long heads as distinct from other people with short heads. The mixture, however, of long and short heads is not a new thing. As Sir Arthur Keith points out (*Antiquity* of *Man*, vol. i. p. 110 [1925]), the antiquary, Dr. R. R. Schmidt, found at Ofnet, fifty miles south-west of Nuremberg, a large number of skulls of the Azilian epoch (a period linking up palaeolithic with neolithic times), some of which were long and others short. There is no reason to suppose that the Indo-Europeans had only one type of skull. No records lead us to suppose that we can trace the Indo-Europeans back more than ten thousand years. In earlier Europe there were peoples of different types, some of a physical frame now confined to the natives of South Africa, others with features akin to those of native Australians, and others again of types which no longer exist. The Basque language in the Pyrenees is a last relic of languages which preceded the Indo-European in the west of Europe; and the characteristics of colouring, hair and eyes of natives of western Britain and western Ireland, which Huxley called Iberian, are probably the relics of this population which has been almost absorbed. In Persia, on the other hand, a short, very dark people (negrito), which survives only in the extreme south-west of Asia, apparently preceded the Indo-European stock. The value of the relation of length to breadth of head, to which the elder Retzius first referred, has been much exaggerated, for the total content must be of more importance than the relation of length to breadth. As has been emphasized in recent years by Mr. Griffith Taylor, the height of the brain-pan is worthy of consideration.

Pottery.—Still more recently the subject has been attacked from another point of view. In 1902 Professor Kossinna of Berlin undertook to show that pottery would be a more certain index to the history of peoples than any of the other methods proposed. But in the quarter of a century which has since elapsed, Professor Kossinna has withdrawn almost all the statements which he then made and his proposed new treatment of the Indo-Europeans has stuck fast after one part was published. That, however, evidence will be forthcoming from this side is certain. But a good deal more has still to be done in identifying the makers of particular types of pottery before this clue can be regarded as of more value than any of the others. At present the best chance of progress lies in the possibility of dating positively, and linking up with the linguistic evidence, the results which can be derived from the "Bell-beaker Civilization" and the Megalithic graves which extend very nearly over the same area which was covered by the early migrations of the Indo-Europeans The probability is that the Indo-Europeans and their civilization arose from the mixture of two earlier types, a Mediterranean and a Northern type. But Schuchhardt in the second edition of his *Alteuropa* (1926) goes further and boldly assigns (p. 282) the Indo-Europeans to a mixture of the Germans coming from the north and the Celts from the Danube area, a stock in Thuringen possibly first "indogermanizing" north Germany by settlement and south Germany by conquest. To this he has added (*Sitzungsberichte der preussischen Akademie*, Feb. 16, 1928) that it was the conquest by the Thuringians of South Germany and Switzerland that created the Celtic stock; the Thuringians afterwards wandered to the Danube and were thus the original stock of the Indo-European people.

Language Classification.—Leaving these archaeological points to be definitely decided by future investigation, we may classify the Indo-European languages according to their connections. The Indo-European languages fall into two groups distinguished from one another by their treatment of certain guttural sounds. In one group, lying mainly in Europe, these sounds remain as k, g, kh and gh, whereas in the other group they change into some form of sibilant *ç, z* and the aspirated sounds either drop the aspiration and are treated as *k* or g, or appear as *h*. The causes for this distinction are not certainly known and the distinction did not mark a deep difference between the languages at an earlier period, because the Greek, which is a *k* language, resembles in its syntax Sanskrit, which is a *ç* language, more than any other. The two series are generally named from the word for 100, in Latin *centum (kentum)*, in Zend *satem*. The languages which preserve the guttural are *centum* languages, those which change it into a sibilant are *satem* languages. Thus the Greek *kuōn* "dog," Latin *canis*, appears in Sanskrit as *çvā (n)* and in Lithuanian as *szuo*. The chief *centum* languages are (1) Greek, in three distinct groups of dialects, Aeolic, Ionic and Doric, with more archaic forms in Arcadian and Cyprian. (2) Latin and the other Italic languages of Italy, Oscan in Campania and the South, Cmbrian on the East of the Apennines. (3) The Celtic languages, which fall into two groups according to their treatment of an original combination of a guttural with a w sound like the English *qu*. One group changes *qu* into *p* (ancient Gaulish, Welsh, Cornish, Breton), the other represents *qu* by *c* (Irish and its descendants. Scotch Gaelic and Manx of the Isle of Man). Thus, corresponding to Latin *quis* is Irish *cia* and Welsh ***pwy***. (4) The Teutonic or Germanic languages which fall into three groups: (a) Gothic, (b) Norse (Danish, Norwegian, Icelandic, Swedish), (c) West Germanic, including English, Frisian, Dutch and Flemish, Low and High German. The most distinctive feature of this group is the "sound shifting" which the stop consonants and *s* have undergone, and which are catalogued under the action of "Grimm's Law" and "Verner's Law," in the treatment of Teutonic languages. (5) Very remote from these four sections which are all in Europe, is Tocharish, presumably the language of migrants from somewhere much farther to the west, though the records of this now extinct language are found in Chinese Turkestan. (6) The Indo-European section of the Hittite languages (*see* above).

The *satem* languages are (1) in northern India Sanskrit and its descendants, and in Persia and its adjacent countries the ancient dialects called Iranian, viz., Zend (of the Avesta), Old Persian, Sogdian and North Iranian; Sanskrit and Iranian together form the Aryan branch properly so-called, though in England the word has often been applied wrongly to mean Indo-European. (2) Armenian, (3) Slavonic in its numerous dialects and Baltic (Lithuanian, Lettish, and Old Prussian, which is now extinct), (4) Albanian, more probably the descendant of the Ancient Thracian than of the Ancient Illyrian which occupied in part the same area. The relation of Illyrian to the Ancient Venetic, once spoken north of the Po and to the Ancient Messapian spoken in the heel of Italy, is not yet definitely ascertained. The other important language of Italy, Etruscan, did not belong to this family, but seems to have been related to Ancient Lydian and other languages of the Levant now extinct. (*See* also HITTITES; and separate articles on various languages.)

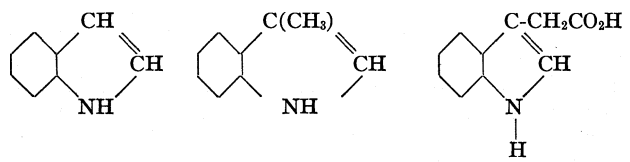
Brugmann, *Grundriss der vergleichenden Grammatik der indogermanischen Sprachen* (2nd ed., 1897–1916), of which a small additional part has been published since the author's death in 1919; a shorter work by the same author is *Kurze vergleichende Grammatik* (in 3 parts, 1902–04), dealing only with the more important languages; H. Hirt, *Indogermanische Grammatik* (the first four vols., only, are published, 1921–28); A. Meillet, *Introduction à l'étude comparative des langues Indo-Européenes* (1903, now in the 5th ed.), and *Les dialectes indo-européens* (1908). The comparative grammar of Latin and Greek is often treated separately, as by A. Meillet et J. Vendryes, *Traité de grammaire comparée des langues classiques* (1924); P. Giles, *A Manual of Comparative Philology for Classical Students* (3rd *ed.* in preparation). A complete bibliography of recent publications appears annually in the *Indogermanisches Jahrbuch* begun by *A.* Thumb and W. Streitberg in 1913.

(P. GI.)

INDOLE (BENZOPYRROLE), first prepared by A. Baeyer in 1866 and regarded by him as the parent substance of indigo. It crystallizes in colourless lustrous leaflets, melts at 52° C.. boils at 253°–254° C., is readily volatile in steam and easily soluble in water, alcohol, ether or benzene. Its odour is generally faecal, but after careful purification and in sufficient dilution indole possesses a not unpleasant odour of flowers. Accordingly it finds a limited application in perfumery. Indole occurs in the coal-tar fraction (*see* COAL TAR), boiling at 220°–260° C.; after removal of phenols and strong bases the oil is treated with sodium or sodamide to form sodium indole, which is separated mechanically and decomposed by water. It is synthesized by treatment of o-amino-w-chlorostyrene, $H_2N.C_6H_4CH=CHCl$, with sodium ethoxide, or by reduction of o-nitrocinnamic acid, $O_2N.C_6H_4.CH=CH.CO_2H$. These reactions indicate its constitution (I).



(I) (II) (III)

Scatole (3-methylindole; II) occurs in human faeces, of which it is the chief volatile constituent; it melts at 95° C. and boils at 265°–266° C. 3-Indole acetic acid, III, or heteroauxin, is one of the natural plant-growth hormones.

INDONESIA, a country of southeast Asia extending for more than 3,000 mi. across the equator between Asia and Australia. The Republic of Indonesia comprises all the islands, or parts of them, which until Dec. 27, 1949, constituted the Netherlands Indies, the only exception being Netherlands New Guinea. It includes Sumatra, Java, Bali, Borneo or Kalimantan (in part), Sulawesi (Celebes), Halmahera, Lombok, Sumbawa, Flores, Timor (in part), the Moluccas and hundreds of smaller islands of the largest archipelago in the world. (For geography see MALAY ARCHIPELAGO and separate articles on different islands.)

HISTORY

Not much is known of the prehistory of the area. Remains of Pithecanthropus or "Java man" were found in east Java. It is believed that the aboriginal inhabitants were a dark-skinned race of which the Kubu people of south Sumatra may be descendants. It seems likely, however, that the islands were populated by various waves of migrations probably from southwestern China and taking place over a long period of time and not all following the same route.

The historical record begins with a period roughly coinciding with the beginning of the Christian era, when states developed in the larger islands under strong Hindu and Buddhist influences from India. The two most important states of this period were Srivijaya (centred around Palembang in south Sumatra) from about the 7th to the 13th century, and Majapahit (with its capital in east Java) founded at the end of the 13th century. At the height of its power Majapahit claimed sovereignty not only over the Indonesian islands but also over large areas of the Malay peninsula; but outside Java it is doubtful whether its control in fact extended beyond the more important trading ports and coastal areas. Both Srivijaya and Majapahit maintained commercial and diplomatic links with other Asian states, including China. The cultural heritage of this so-called Hindu period is still preserved in the life and arts of the island of Bali (whose people remain Hindu) and in the music and dances of Palembang, Djokjakarta (Jokyakarta) and Solo; it is visible in such world-renowned temples and monuments as the Prambanan group and the Borobudur of central Java.

Islam was brought to Indonesia by Arab and Indian Moslem traders, who converted the rulers of the seaports to their faith. It reached north Sumatra at the end of the 13th century and north Java in the second half of the 15th and the early 16th century. Thence it spread along the trade routes and, more slowly, into the interior of the larger islands. By about 1j20 the Moslem ports of north Java had become independent, their attacks on the decaying state of Majapahit assisting its downfall and the eventual rise of the Moslem state of Mataram, which brought most of east and central Java under its control in the early 17th century. Balambangan in southeast Java, however, was not converted to Islam until the second half of the 18th century, and large areas of Sumatra, Borneo and the islands east of Java were still pagan until converted by Christian missionaries in the 19th century. Large numbers of Indonesian peoples retain animistic and Hindu beliefs mingled with the newly acquired observances of Islam.

The **Colonial** Period.—When the Portuguese reached the "Spice Islands" of eastern Indonesia in the latter half of the 16th century, Islam was well established on Sumatra and Java, and there was considerable discord among the princes who had succeeded to the broken-up parts of the former Majapahit empire. After the Portuguese came the British and the Dutch, likewise for the sake of the spice trade, over which quarrels broke out among the three European powers. The final outcome eliminated the British and Portuguese from any significant role in the future of the archipelago.

The Dutch East India company (*q.v.*), formed in 1602, set out to monopolize the export and import. at first of the products of the Spice Islands, but soon of the considerable trade both domestic and foreign which was already well established and centred on Java. The company obtained trading privileges from the local princes; when it became evident that political interference was necessary to enable the company to protect its monopoly, one prince was played off against another, so that the company came to exercise ever greater political as well as economic control. Political administration was achieved through increasing the power of local rulers amenable to Dutch influence, who were required to control economic activities in their domains in accordance with the company's interests.

For Indonesia this system had two consequences: not only did it result in considerable material extortion, it also upset the social organization of the areas where it was enforced. Politically it favoured an autocratic system of government; economically it almost annihilated the class of Indonesian merchants and traders through the company's promotion of the Chinese as middlemen. For the Dutch East India company this system produced great profits, but it also led to corruption which contributed to its collapse in 1789. In 1800 the entire area controlled by the company was placed under the direct authority of the Netherlands government which. however, made no sharp break with past practices of forced labour, deliveries in kind and monopolies in certain crops.

During the brief British occupation of Java and its dependencies (1811–16), which resulted from the Netherlands coming under the control of Napoleon Bonaparte, Sir Stamford Raffles, the lieutenant governor, attempted to introduce a more liberal system embodying private trade and cultivation and the abolition of compulsory services to government. But with the end of the Napoleonic wars in Europe Indonesian territories returned to the Netherlands. The opportunities for private enterprise which had begun under Raffles continued to some degree under the Dutch until 1830 when there was a return to government monopoly. The culture system was introduced, compelling cultivation of stipulated crops in stipulated quantities. Implementation of this system required also a return to strict political control. The social pattern of the company's regime was consolidated. The people were unable to acquire trading experience, their initiative was hampered and a growing proportion of agricultural land was devoted to export crops at the expense of rice and other crops for local consumption. The culture system began to be curtailed in the 1860s, after which the government's grip on export crops was progressively diminished, and the Land law of 1870 opened great opportunities for the investment of private capital. But the compulsory cultivation of coffee, the last remnant of the culture system, was not abolished until 1917.

Mitigation of the worst features of colonial policy, which began to appear in the 20th century under the so-called ethical system, proved in the event to have been too little and too late. Demands for improved conditions gave birth to demands for political self-

determination. From the first attempts at political interference the Indonesian people had never submitted placidly. The endeavours of the company to play offone prince against another had led to armed clashes of a sporadic and scattered nature. The company frequently had to use force to secure its objectives, for instance against Sultan Agung Hanjokrokusumo (Djakarta, 1629) and against Hasanmudin (south Celebes, 1653–69). The company's territories transferred to the Netherlands government did not encompass the whole of Indonesia, nor did the transfer bring greater peace. From 1825 to 1830 there was the considerable uprising led by Prince Diponegoro of central Java. Pattimura revolted in the Moluccas in 1817, Imam Bondjol in west Sumatra in 1833; there was warfare in Bali in 1846, in Banka (Bangka) in 1811 and in Lombok in 1894 as a result of attempts to extend or consolidate Dutch rule. It was only as late as 1907 that Atjeh, the northernmost part of Sumatra, was brought under Dutch control.

The Nationalist Movement. — By the end of the 19th century the backnardness of the common people began to cause concern among Indonesian intellectuals. Raden Adjeng Kartini (1879–1904) began her campaign for the emancipation of Indonesian women. A few years later Wahidin Sudirohusodo began the education of cadres as a means of raising the cultural standards of the people; as a result of his efforts,the Budi Utomo educational organization was established in 1908. In 1911 Indonesian merchants founded the Serikat Dagang Islam with the idea of protecting the last remaining field of trade, the batik industry, from the domination of non-Indonesian businessmen. However, purely nonpolitical effortssoon proved to be ineffective. The existing organizations became openly political and political parties were formed,including a Social Democratic party.

Political demands in Indonesia increased and were coupled with criticisms in the Ketherlands. In response. the volksraad was created in May 1918 as an advisory council to the Netherlands Indies government of mainly appointed representatives. In Nov. 1918 Count J.P. van Limburg Stirum, the governor general. promised both u-ider powers for the volksraad and democratic government for Indonesia. As this promise was never fulfilledthe activities and demands of the nationalist movement increased, and the government began to retaliate by imprisoning and exiling prominent leaders, becoming especially harsher after the general strike of 1926–27 called by the Indonesian Communist party. The governors general were given powers to take action under criminal law without trial; some persons were hanged, thousands were imprisoned or exiled. But the nationalist movement continued to grow. Indonesian students abroad formed associations through which echoes of the struggle in Indonesia reached the knowledge of western public opinion opposed to colonialism.

The Japanese Occupation. — When the Japanese attacked Indonesia in 1942 the Netherlands army and such Allied forces as were there were quickly overpowered. Though there were Indonesian elements in the Netherlands Indian army the people in general had never been associated in the defense of the country, and they did not feel themselves associated with the Dutch in the war against Japan. The common people were at first prepared to listen to Japanese propaganda of "Asia for Asians," believing then that the Japanese had liberated them from colonialism. But the seizure of crops, the press-ganging into forced labour, the suppression of freedom of information and the cruelty of the Japanese showed otherwise. In Blitar and some other places mutinies broke out among the Japanese-organized home defense guard.

Nevertheless the Japanese had been compelled to give Indonesians military training and appoint them to technical and administrative posts never open to them before: the Indonesian language was used officially as the national language. Some Indonesian leaders of the prewar nationalist movement, such as Sukarno (1901–) and Mohammed Hatta (1902–), accepted posts in the Japanese administration to safeguard as best they could the interests of their people; but they also kept in touch with other leaders, such as Sutan Sjahrir and Amir Sjarifuddin, who worked underground. Early in 1945 the Japanese allowed the formation of a body to prepare for Indonesia's independence. This body met from May to July 1945 and began to draft the future constitution.

Independence. — The independence of Indonesia was proclaimed on Aug. 1, 1945, two days after the collapse of Japan. The five years of revolution which followed were marked by two characteristics: major armed clashes with Allied or Dutch forces were followed by major agreements; the battle of Surabaja (Surabaya; Kov. 10, 1945), fought against occupation troops of the British southern Asia command, was followed by the Cheribon (Tjirebon) or Linggadjati agreement (initialled Nov. 15, 1946 and signed on March 25, 1947). The first large-scale military attack by the Dutch army (launched on July 21, 1947) was followed by the "Renville" agreement (Jan. 17, 1948). The second attack by the Dutch army (launched on Dec. 18, 1948) was followed by the Round Table conference agreements (signed at The Hague on Nov. 2, 1949). The periods between these events were filled with recurrent clashes and negotiations, as well as, for the republic, with some months of civil war when a Communist-led rebellion broke out in Madiun (Sept. 18, 1948). While the Indonesian people were determined to win complete independence, the Dutch were unwilling to grant it. The means used by the Indonesians were largely limited to guerrilla warfare and to appeals to world opinion. The Dutch attempted to deprive Indonesia of the world's sympathy by describing the republic as "made in Japan," while in Indonesia they endeavoured to isolate the republic both economically and politically. At the time of the 1946 agreement the republic controlled a part of Java with Jokyakarta as capital. An economic blockade was instituted by the Dutch after the attack of 1947. In parts of Indonesia which were under their administration, the Dutch sponsored the formation of separate states, such as that of East Indonesia (founded Dec. 24, 1946), East Sumatra (Dec. 29, 1947) and West Java (Feb. 26, 1948); by the end of 1948 there were altogether 15 such "states" or "special territories," each of which sent one delegate to a Dutch-sponsored federal consultative assembly. But international intervention could not be prevented. The first negotiations had been arranged with British assistance; the following two major negotiations were arranged with the help of the UN Security council. In consequence of the agreement of Nov. 2. 1949, the Netherlands transferred complete and unconditional sovereignty to Indonesia on Dec. 27, 1949.

Difficulties with the Dutch were not, houever, over. Not all Dutch elements accepted without reservation the recognition of Indonesia's sovereignty and independence. Capt. R. P. P. Westerling gathered around him troops from the Netherlands Indies army, which had not yet been disbanded, and attacked the city of Bandung (Jan. 23, 1950). Similar disturbances occurred in several parts of Indonesia for months to come, the most important being the South Moluccas rebellion (April 25, 1950). Indonesia claimed that the rebels, including some Dutchmen. dispersed to the hills and joined certain bands of irregulars, that they received support from Dutch-owned estates and enterprises and formed a subversive movement against the republic.

Another source of friction between the Netherlands and Indonesia was the latter's claim that Netherlands New Guinea (or West Irian) should be transferred to the new republic. The Dutch. however, refused to discuss this. their argument being that neither ethnographically nor geographically was New Guinea a part of the Malay archipelago.

The political consequences of the Nov. 2, 1949, agreements also proved short-lived. First the federal form of the state, described as the Republic of the United States of Indonesia, to which sovereignty had been transferred, and which had 16 member states, was accepted by the Indonesian government only as a lesser evil. In the first few months after transfer of sovereignty, all but two of the member states dissolved themselves and joined the original republic as a means toward achieving a unitary state for the whole of Indonesia. Negotiations with the two other remaining states led to the formation of a unitary state on Aug. 17, 1950, and the name of the country became again the Republic of Indonesia. Second, the union with the Netherlands never came to life and was formally dissolved on Aug. 10. 1954. Finally, certain clauses of the agreements reached at the Round Table conference, especially

those guaranteeing a favoured position to Dutch interests, proved disadvantageous to Indonesia. When negotiations of Jan.–Feb. 1956 broke down, on April 9, 1956, Indonesia unilaterally abrogated the whole of the Round Table conference agreements.

POPULATION

The population of Indonesia is composed of a large number of different peoples of varying degrees of civilization. Hunting tribes such as the Punaus in central Borneo live in the near vicinity of agricultural tribes, whose agriculture is sometimes of a very primitive nature. The highest level of civilization is found in Java, Bali and some parts of Sumatra. The islands between Celebes and New Guinea are inhabited by a population of mixed races.

The main population groups of Sumatra are the Achinese, at the northern point, the Gajo and Alas people, south of Achin; the Bataks, around Lake Toba, divided into Toba, Timur, Karo and Pak Pak Bataks in the interior; the Menangkabaus on the plateau of central Sumatra; and the Malays. Among them live the remnants of the Kubu tribe, who are descendants of the oldest-known inhabitants of the archipelago. All these peoples are Moslem except the Bataks, most of whom are Christian.

There are three main population groups in Java: the Sundanese in the west, the Javanese in the centre and east and the Madurese who migrated from the island of Madura into the eastern coastlands of Java. There are also some small groups of older stock, the Badujese in west Java and the Tengerese in east Java. The people of Java. Moslem in great majority, form about 70% of the total population of Indonesia.

The main part of Borneo's population is formed by the Dayaks. Malays have settled along the coast and the rivers; mixed with Javanese, they form the population of Banjermasin on the south coast. From the 18th century onward the Chinese began to settle in western Borneo where gold was mined. They came as miners and continued as farmers, handworkers and traders but are strongly mixed with Malays and Dayaks. On the east coast of Borneo there was immigration from Celebes, by the seafaring Buginese. The Dayaks are mainly pagans, the Chinese maintain their own culture, and the other groups are Moslem.

The southwestern part of Celebes is inhabited by Macassars and Buginese, the interior by the Toradjas and the northeastern part by the Minahassans. Among the Minahassans the Christian religion predominates, to which some tribes of the Toradjas also have been converted. The Balinese and the inhabitants of the western part of the adjacent island of Lombok have clung to the pre-Islamic Indonesian type of Hindu culture. On the other islands east of Celebes and Java the population is partly Christian (Amboina, part of Flores, the Kei Islands, etc.), partly Moslem (Ternate, Tidore, etc.).

The only population census was taken in 1930, revealing a total of 60,412,962 inhabitants, excluding Netherlands New Guinea; the estimated population in 1940 was 70,476,000 and in 1956 was 84,432,141.

Political and social unrest caused a great influx into the cities. Jakarta (Djakarta), the capital, had 533,000 inhabitants in 1930 and an estimated 1,927,788 in 1956. Jogjakarta had 280,067 inhabitants in 1956. During the same period the population of Surabaya increased from 342,000 to 980,905; of Bandung from 166,800 to 870,346; of Semarang from 217,000 to 389,970; of Surakarta or Solo from 165,000 to 380,843; of Medan (east Sumatra) from 76,000 to 307,115.

By 1955 the total number of Moslems in Indonesia, generally belonging to the Shafi'i sect, was estimated at 62,160,000 (approximately 80%), Christians at 3,400,000 (4.3%), Balinese Hinduists at 1,710,000 (2.2%), while about 2,330,000 (3%) were Buddhists, almost three-quarters of them Chinese or descendants of Chinese. Other religions were Taoism and Confucianism. Animist influences were still prevalent in certain isolated areas.

The population of Indonesia is composed of about 17 language groups. Prewar statistics of the ethnic groups were based mainly on linguistic characteristics. On this basis were established the following estimates for 1955: Javanese (inhabitants of central and eastern Java) 41,250,000; Sundanese (western Java) 13,260,000; Madurese (the island of Madura and eastern Java) 6,580,000; Jakartans 3,960,000; Menangkabaus (central Sumatra) 3,050,000; Buginese (southern Celebes) 2,350,000; Bataks (northern central Sumatra) 1,820,000; Balinese 1,720,000; Malays proper (eastern Sumatra) 1,110,000; Toradjas (central Celebes) 900,000.

The two main nonindigenous groups are the Chinese and Europeans. The Chinese were estimated in 1955 at 1,600,000, most of whom lived in Java, Sumatra and western Borneo. The majority had been born in Indonesia and was of mixed blood. The Europeans counted about 350,000 in 1940. By 1955 their number had been reduced by emigration to the Netherlands to about 60,000.

In all there are approximately 25 major languages and about 250 dialects spoken. Bahasa Indonesia, an adaptation of Malay, is the official language and language of instruction in elementary schools, at least from the third form.

The total area of Indonesia, excluding Netherlands New Guinea, is 575,893 sq.mi.

GOVERNMENT AND ADMINISTRATION

The form of government in Indonesia varied in accordance with its three successive constitutions: that of 1945 (proclaimed on Aug. 17, 1945); that of Nov. 2, 1949, drafted during the Round Table conference for the Republic of the United States of Indonesia; and that of Aug. 17, 1950, controlling the unitary Republic of Indonesia. All three constitutions were provisional until a democratically elected constituent assembly should draft a permanent one. These constitutions varied not only in providing for different forms of state, but also in powers and rights of institutions common to all three forms. In the preamble to all three constitutions were incorporated the *Pantja Sila*, the five principles upon which the state was based: belief in God, nationalism, humanism, sovereignty of the people and social justice.

The 1950 constitution provides for five instruments of state: the presidency, the cabinet, the house of representatives, the supreme court and the General Audit council. Among these the administrative, legislative and judicial functions of government are divided. The president is the supreme commander of the armed forces; as head of state his office stands outside the mutations of party politics and is outside the jurisdiction of the courts; he appoints the prime minister, upon whose advice he appoints the ministers; he has the power to dissolve parliament. The vice-president fulfils the functions of the president when the latter is unable to do so. President Sukarno and Vice-President Hatta had extraconstitutional roles in the affairs of the country by virtue of their past positions as leaders of the nationalist movement. The cabinet is responsible to parliament; the ministers, both collectively and individually, are obliged to report important matters to the president; the cabinet has the power of initiating legislation. In addition to the prime minister there are two deputy premiers, a titular minister for each of the 18 ministries and a minister without portfolio in charge of general affairs. The house of representatives, which also has the power of initiating legislation, but through the cabinet, is elected every four years. There is one representative for each 300,000 persons, with special provision for representation of the minorities. All citizens above the age of 18 years may vote at elections and may stand as candidates; the vote is direct and secret and the distribution of seats determined by proportional representation. Judges of the supreme court and members of the General Audit council are appointed for life.

Indonesia is divided into ten provinces: North Sumatra, Central Sumatra, South Sumatra, West Java, Central Java, East Java and Madura, Kalimantan, Nusa Tenggara (Lesser Sunds), Sulawesi (Celebes) and Maluku (Moluccas). West Irian or Netherlands New Guinea is described as the 11th province. Each province has an appointed governor and an elected regional council of representatives. There is a movement toward local autonomy: the "special territory" of Jogjakarta and several small areas have become autonomous.

The first general elections were held on Sept. 29, 1955, for the house of representatives and on Dec. 15, 1955, for the constituent assembly. In Table I the results are compared with the provisional

house of representatives whose members were government or party nominees. *(See* Table I.)

Education. — The estimates of illiteracy in Indonesia vary. In 1930 it amounted to 96.8% of the population; according to a 1955 estimate this had been reduced to about 40%. In the Setherlands Indies school attendance was not compulsory. The Republic of Indonesia intended to introduce compulsory attendance by 1961, but much depended on the availability of teachers, buildings and equipment. In the school year 1939–40 there were 48.206 teachers employed at the elementary schools, 542 at the secondary schools and 125 at the University of Batavia. By 1953 Indonesia had about 86.000 teachers instead of the 224,400 that were needed; many of the teachers employed since 1945 did not possess the necessary training.

The government maintained t o universities: the Gadja Mada university at Jogjakarta (about 2,500 students in 1951) and the University of Indonesia with a teaching staff of 548 and 6,754 students in 1952–53. *(See* Table II.)

TABLE II. —*Education*

Level	1939–40		1953–54	
	Schools	Pupils	Schools	Pupils
Elementary	18,091	2,348,798	27,400	4,977,304
Secondary (junior	114	21,879	1,053	236,000
Secondary (senior	17	2,232	61	22,000
Vocational and technical	86	12,525	978	168,000
Higher	5	1,635	17	14,907

Public Health. — The republican government faced from the outset a great shortage of hospitals (less than 1 bed per 1,000 inhabitants in 1950), shortage of equipment and medicines and shortage of medical personnel (about 1 doctor per 60,000 inhabitants in 1950). In addition, it was necessary to persuade the population of the desirability of public health and of the efficacy of scientific medicine. Side by side with normal educational programs, the shortage of personnel was being alleviated by training of paramedical personnel for narrowly limited purposes, A complete system of public health was being instituted as means became available, following a scheme known as "the Bandung plan," while a series of mass campaigns had been organized with the assistance of the UN World Health organization to reduce and eradicate the worst diseases endemic among the people. Because of the psychological advantages for the introduction of a thorough public health system which could be anticipated as a result of dramatic cures, yaws was chosen in 1950 as the subject of the first mass campaign, Later a beginning was made with the much more difficult campaigns against malaria, tuberculosis and venereal diseases.

ECONOMIC CONDITIONS

The 1950 constitution provided that the economy be built up by common effort on the basis of the family principle; that branches of production important for the state and affecting the daily necessities of the masses be controlled by the state; and that the land and waters with their natural resources be controlled by the state to obtain the greatest possible prosperity for the people. These principles sum up the intention to convert the colonial economy, which stressed the export of raw materials and had left the economy heavily dependent upon the world market, into a national economy which, stressing the basic necessities of the people, would secure more even development and better balance in the economic life of the country. More even development implied opening up of the virgin or underdeveloped areas. notably of Sumatra and Borneo, using the manpower from overcrowded Java, where the population rises to more than 1.000 per square mile. The migration scheme had already resettled 104.649 persons in 1951–5j. More balance in the economy implied greater production of consumers' goods, notably foodstuffs and textiles, which mould require the creation of new industries in order to lessen Indonesia's dependence upon world markets.

Agriculture and Forestry. — Agricultural production and livestock by 1951 reached more or less prewar levels, but the population was then larger by 8,000,000 than it had been in 1938. Rice imports, which in 1950–52 amounted to an annual average of 600,000 tons. were reduced to 99,000 tons in 1954. While still Indonesia's fourth largest earner of foreign exchange (after rubber, petroleum and tin), copra output was being increasingly absorbed by the domestic market. Production in 1954 was 728,000 tons, slightly higher than the pre-1938 annual average, but export during the period fell from 554,000 tons to 296,000 tons. (See Tables III, IV and V.)

TABLE III.—*Agricultural Production*

Between 1950 and 1953 timber production rose from 1,114,000 cu.m. to 1,553,000 cu.m.; that of charcoal in the same period from 36,200 tons to 61,100 tons.

Industry. — By 1951 mineral production recovered more or less its prewar level, and by 1955 the extraction of crude petroleum was 46% higher than in 1938. *(See* Table *VI.)* Between 1949 and 1953 the output of oil refineries also increased; production of motor spirit (gasoline) rose from 1,898,000 tons to 2,215,000

TABLE VI.—*Mineral Production*

tons, of aviation spirit from 123,500 tons to 384,500 tons, of kerosene from 792,000 tons to 1,256,000 tons and of heavy oils from 3,482,000 tons to 5,700,000 tons.

While the supply of electric power was only about 10 kw.hr. per

capita in 1954, there had been an increase in generating capacity of electricity from 162.609 kw. in 1949 to 227,309 kw. in 1954. Production of electricity was 362,000,000 kw.hr. in 1948 and 812,000,000 kw.hr. in 1954. About 68% of electricity produced was for lighting and other domestic uses.

In 1954 there were 6 j weaving mills in operation (47 in 1951), and their output of cotton piece goods amounted to 46,144,000 m. (22,829,000 m. in 1951).

Foreign Trade. — Indonesia's difficulties with its trade balance began with a drastic decline in export earnings in 1952 from the 1951 level. The terms of trade fell from 104 (1950=100) in 1951 to 76 in 1953. *(See* Table VII.)

Transport and Communications. — In 1954 the railway system in operation comprised about 6,700 km. of track of various gauges (75% in Java). The situation with regard to rolling stock, which suffered great losses during World War II and after, improved only slowly and by 1954 was still below the 1938 level. *(See* Table VIII.) In 1954 the Indonesian railways transported 125,744,000 passengers and 6.375,000 tons of freight.

TABLE VIII.—*Railway Rolling Stock*

Item	1938	1948	1950	1952	1954
Locomotives		584	809	1,004	1,063

Freight cars	27,036	16,690	20,910	23,560	24,041

The highway network totalled 70,300 km., of which about 30,000 km. were in Java; about one-third of the Java network was asphalted. Between 1938 and 1954 the number of motor vehicles in use rose from 70,000 to 178,300 (60% in Java).

About 90% of interinsular sea communications was conducted by a Dutch-owned shipping company which in 1954 carried 701,148 passengers and 3,312,000 tons of goods.

The Garuda Indonesian Airways (G.I.A.) flew 47,514 hours in 1954, covering 12,392,766 km. and carrying 180,100,000 passenger-km., 5,679,000 ton-km. of cargo and 1,545,000 ton-km. of mail. Most of the routes are internal, but routes to Manila, Bangkok and Singapore are also operated by G.I.A.

Finance. — By 1956 the economy of the country was still at a transitional stage. A steady rate of growth had not been achieved and the economy was not stabilized. Both the balance of payments and the national budget were in deficit. *(See* Table IX.)

TABLE IX.—*Budget Estimates*
(In millions of rupiah)

Item	1950	1952	1953	1954
Revenue	6,414	11,334	9,707	8,451
Expenditure	7,798	17,563	12,672	13,973
Deficit	1,384	6,229	2,965	

Currency circulation, which at the end of 1948 amounted to 1,520,000,000 rupiah, was 8,820,000,000 rupiah in Dec. 1955. The new monetary unit, the rupiah, was originally at par with the Dutch florin. From March 1950 and July 1952 the official exchange rate was 3.81 rupiah per U.S. dollar. This was nominal, however, with most exchange transactions being concluded at effective rates of 11.43 rupiah per U.S. dollar. From Aug. 1952 exchange transactions were conducted at four different rates; from Sept. 1955 there were five import rates from 11.48 to 57.38 rupiah per U.S. dollar, while most exports were at the 11.36 rupiah basis. From Dec. 1951 to Dec. 1955 the gold assets of the Bank of Java shrank from $280,000,000 to $81,000,000. The foreign exchange holdings stood at $231,000,000 in Dec. 1951, fell to $67,000,000 in Dec. 1954, but by the end of 1955 recovered at $226,000,000.

The cost of living index based on 12 basic foodstuffs (July 1938=100) stood at 1,463 in March 1950 and at 3,334 in Dec. 1954.

INDONESIAN ARCHAEOLOGY. This article deals first with the prehistoric background to the cultures of Indonesia and their relations with other cultures of the far east and southern Asia. The subsequent cultural development of certain areas is then treated, together with that of parts of mainland southeast Asia which have Indonesian affinities. The primary concern is with material culture. Reference should also be made to ARCHAEOLOGY: *China, Southeast Asia and Japan;* ASIA: *Anthropology; Ethnology.*

PREHISTORIC CULTURES

Paleolithic Cultures. — Although human remains are known from the Lower Pleistocene of Java *(Homo modjokertensis),* stone tools have not been found in contexts earlier than the later Middle Pleistocene. Even this date is to some extent conjectural since almost all the material comes from surface finds, but careful analysis of all the available evidence suggests that the bulk of the Patjitanian material (named after Patjitan in southern central Java) can be assigned to the later phases of the Middle or the earliest phases of the Upper Pleistocene. The association of this culture with *Pithecanthropus* species rests upon the assumption that, in the absence of other skeletal material, Java man was responsible for the artifacts. *(See* also MAN, EVOLUTION OF: *Pithecanthropus.)* These consist of pebble and chopping tools, flaked upon one side only, together with a certain number (about 6%) of hand axes which have been compared with those of the Madrasian culture of south India. Actually, the technique of manufacture is clearly related to that of the chopping tools and to be distinguished from the Madrasian. Related cultures are the Soan of northwest India, the Anyathian of Burma, the Tampanian of Malaya and that associated with *Sinanthropus pekinensis* at Chouk'ou'tien, China. Some evidence exists for the occurrence of a similar culture in Thailand, but in Indochina definite traces are lacking. The general homogeneity of this culture and its known distribution lends colour to the view that it is to be associated with the *Pithecanthropus-Sinanthropus* group of early man.

The Upper Pleistocene levels of the Solo river valley at Ngandong, central Java, have yielded a considerable number of skulls of *Homo soloensis.* The relation of this species to *Pithecanthropus erectus* is a matter of debate. In the same region numbers of artifacts were also found, though their diversity — they include picks made from the antlers of *Axis lydekkeri* (a Pleistocene deer), pointed bone tools and flakes, points, borers and scrapers of stone — and the imprecise nature of the reports make it difficult to decide whether these tools represent one or more cultures. Also from the Solo river is a bone harpoon with a double set of barbs. It is probable that the implements from Sangiran, which include small flakes, points and scrapers. as well as chalcedony cores, belong to the same horizon as H. *soloensis* (*i.e.,* to the Notopoero beds rather than to the Trinil horizon, as G. H. R. von Koenigswald proposed).

Later Stone Age Cultures. — In addition to the above cultures, various sites in Indonesia have yielded implements which, while morphologically paleoliths, are unquestionably of Holocene date. They have been classed as Mesolithic since they occur between the Paleolithic and the fully developed Neolithic, but the name must not be taken to imply either true transitional forms between these two readily distinguishable cultures or the typical European Mesolithic facies. However, while the forms are not transitional, they do, nevertheless, show a slow transformation as a result of Neolithic influences, presumably from the mainland. These cultures can be divided into four groups.

Hand Axes. — These are closely related to the Hoabinh-Bacson types of Indochina and the Malay peninsula. While most of the mainland forms are known from Indonesia, it is not possible to demonstrate their sequential development in the islands because of the unsatisfactory nature of the sites and the inadequacy of the archaeological reports. In north and northeast Sumatra typical hand axes occur, both as surface finds and in shell mounds; these are waterworn pebbles, generally worked upon one side only, and usually of oval shape, though leaf forms also occur. The *hache* courte, a transversely cut hand ax with a straight butt, a typical Hoabinh form, is also known, together with roughly chipped pebble tools, pounders, grinding stones and ruddle. The Hoabinh hache courte is also known from west Java and from an east Javanese rock shelter. The later, "proto-Neolithic," hand ax, with ground edge, which represents the final Hoabinh-Bacson stage, is also found in Java and Sumatra, and it seems probable that this represents a later cultural influence rather than a local evolution. It has been reported that all the stages are also found in the Philippines, Borneo and Celebes.

Flake Cultures. — Knives, points and scrapers are known from two caves in east Java which have also yielded bone tools. Another find of the same type is from Roti, off Timor. Both these groups are comparable with the so-called "proto-Toalian" of Celebes where they are widespread, sometimes in association with shell mounds. The subsequent Toalian culture includes, in addition to proto-Toalian types, Neolithic forms, notably arrowheads. some of which have serrated edges. In Timor the finds include tanged spearheads in jasper and chalcedony, as well as pottery. The relation between these objects and the rest of the material is not clear. It is likely that the whole represents a typical complex of survivals in a relict area.

Microliths. — Three sites in central Sumatra (two caves and a surface find near Lake Kerintji) have yielded cultures with scrapers, knives and points in obsidian; similar finds are known from Bandung, west Java. The latter sites, and that in the vicinity of Kerintji, have produced a number of microlithic forms, those from Bandung including typical geometric forms apparently comparable with western microlithic cultures. R. von Heine-Geldern has claimed, against the majority of the Dutch prehistorians, that these cultures are pre-Neolithic, but it is doubtful whether, on the present evidence, any firm conclusions as to date can be properly made. The same observation is applicable to their relation to the Capsian and Tardenoisian of Eurafrica, while an analysis of their Indian affinities has yet to be made.

Cave cultures *of* East Java. — The situation obtaining in Guwa Lawa, near Sampang, east Java, is illustrative of the complexity of Indonesian prehistory. There the lowest stratum has winged Neolithic arrowheads, while the succeeding level contains bone, deer-horn and shell implements, which in their turn are succeeded by a layer with fully developed neoliths. The middle stratum contains awls, spatulas and adzes of bone, horn tools and shell scrapers; there are no stone tools. In isolation it would almost certainly be described as Mesolithic, but the context must require a Neolithic analysis. Typically, a neighbouring site, Bodjonegoro, like those of Tuban, yields the range of the three strata of Guwa Lawa, but all in a single level.

Neolithic Cultures. — In the absence of adequate excavations and research, it is possible to analyze the Neolithic in typological terms only. So far, it seems that there are four main types.

Grooved Axes. — These are found in association with developed Mesolithic chipped hand axes and mat-marked pottery. While traces of these tools have been widely found in Indonesia, it is not yet possible to assess their distribution and importance.

Round-Ax Culture. — This culture is characterized by the occurrence of axes of oval or lenticular cross section and pointed or rounded butts. Their distribution includes the Philippines, Moluccas, Timor and the eastern islands, Celebes and Borneo, with outlying elements in Malaya, where they are rare, and a restricted region of northeast Sumatra. This seems to point to a route through Formosa and the Philippines, the outliers being an offshoot from Borneo.

Quadrangular Adzes. — Throughout Indonesia, with the exception of a few of the smaller islands and the northern half of Sumatra, are found adzes of a rectangular (more rarely trapezoid or square) cross section. These are also known from China, Laos, Thailand and the Malay peninsula. The finest specimens, in terms of workmanship, are those from Java and southern Sumatra, where the existence of numerous examples in such semiprecious stones as agate, jasper and chalcedony suggests that this type had become an object of esteem rather than a purely functional tool or weapon. If these are taken to be the end product, as the evidence suggests, it is clear that they have reached Java from elsewhere, while their uidespread distribution might indicate that they accompanied a major ethnic movement. The very large number of these adzes in Java suggests a considerable population, while the thousands of unfinished specimens in restricted localities indicate a high degree of industrialization in factory sites of considerable size.

Shouldered and Stepped Adzes. — These types, known at present only from northeast Borneo and Celebes, appear to be related to the preceding, though with Bacson elements. These latter are exemplified by crude tanged axes. The later phase shows developed shouldered neoliths and stepped adzes in which the butt is thinned as the result of the removal of the back of the upper side to make a stop ridge at right angles to the longitudinal axis.

Bronze Age. — Various elements appear to have contributed to the Bronze Age of Indonesia — socketed celts, which can be traced throughout Eurasia, ceremonial "halberds" (west Java), decorated axes with cast handles as well as blades (Roti) and the characteristic drums of the Dong-son culture. At present there is no satisfactory evidence to distinguish these various components chronologically, and only the Dong-son element seems native to southeast Asia, though the "halberds" and Roti axes may be evolved forms of this last. Some of the typical drums were imported, but the discovery of part of a stone mold in Bali provides evidence for local manufacture. There does not seem to have been a full Iron Age in Indonesia, probably because more sophisticated cultures reached the area before it could deveiop, but the practice of burial in stone cists, sarcophagi or urns seems to belong to the later Bronze-Iron period, at a time when stronger Indian and Chinese influences were beginning to appear. In eastern Java, at least, this tradition persists until the European middle ages. Beads testify to the presence of Greco-Roman trade goods, as well as to Chinese influences. The latter are more definitely attested by the vigorous Pasemah culture of south Sumatra. The dynamic stone reliefs of men and animals, riders, fighters with beasts, warriors with typical Bronze Age weapons and drums, are stylistically close to certain early Han sepulchral monuments, and Han pottery is found in the larger Indonesian islands. Some remarkable wall paintings have survived in Pasemah on the cist walls.

Prehistory: General Survey. — During the Pleistocene period Indonesia shows clear relations with other countries of eastern Asia. Both the implements and the skeletal material have affines in a wide area from India to China. There is some evidence for a development in Indonesia of a cultural pattern with a distinctive ethnic component from its beginnings with Pithecanthropus species. The Holocene saw the commencement of new cultural influences from the mainland, especially Hoabinh-Bacson elements arriving probably at various times. The relationship between this culture and the "proto-Toalian," Toalian and microlithic cultures is obscure, but it is probable that, whatever their origins, evolved "Paleolithic," flake, bone microlithic and proto-Neolithic cultures existed and persisted side by side in the islands, many surviving in relict areas until well into historical times. Racially, too, there

appears to have been a mixture of Papuan-Melanesians, Indonesians. Australoids and possibly survivors from an evolved element of basic pithecanthropoid stock. As is the case throughout Indonesian history, both the Malay peninsula and the Formosa-Philippine routes seem to have provided a way of access to Indonesia.

During the Neolithic period these same routes contributed new elements to Indonesia. The round-ax culture came via Formosa, while the quadrangular-ax culture followed the peninsula, almost certainly with peoples who spoke Indonesian languages and who brought with them many of the surviving cultural traits of Indonesia — outrigger boats, wet rice cultivation, cattle and pig rearing, bark cloth manufacture and the megalithic burial tradition. Heine-Geldern wished to date this period to 2 joo–I 500 B.C. These peoples were ancestral, both ethnically and culturally, to present-day Indonesia. Later, in the last few centuries B.C., the Bronze Age cultures of the mainland began to influence Indonesia, their bearers being in part later successors to the quadrangular-ax people, perhaps the Yueh of the Chinese texts. There is little evidence to substantiate Neine-Geldern's hypothesis of Thraco-Cimmerian influences.

Nor does the matter rest there, for while Indonesia, or at least the greater part of it, came under Indochinese influences, the cultures discussed above spread into Australasia and Oceania where many of them survive long after their disappearance in the Indonesian islands. Round axes persist in New Guinea and Melanesia; the quadrangular axes accompanied the Polynesians; Hoabinh-Bacson hand axes and "proto-Toalian" flakes reached Australia; stepped and shouldered adzes from the Philippines and Celebes are paralleled by those of eastern Polynesia and New Zealand.

The Bronze Age cultures of Indonesia penetrated northern New Guinea and survive in the decorative arts of Oceania as far as the Solomons.

CULTURES IN HISTORIC TIMES

Indonesia and the Mainland: Later Developments. — While the Pleistocene cultures of eastern Asia show a marked homogeneity, which persisted in part through the later Stone Age period and in some aspects of the Bronze Age, a divergence set in during this later period which grew as time went on. The northern areas of Indochina came under strong Chinese influence, while Indian cultures overlaid the rest of southeast Asia, modified by the cultural patterns which had already been established there in the last few centuries B.C. Some aspects of this development are noted below; *see* also CAMBODIA: *Archaeology;* EMBROIDERY; INDIAN ARCHITECTURE; INDIAN ART; JAVA: *Archaeology;* and TEXTILES.

Borneo, Celebes, Sumatra. — While the main evidence for the interaction of Indian and Indonesian culture is to be found in Java, the relatively less-explored areas of the other islands have also yielded data for the cultural historian. Thus there are early, in terms of countries outside India, Buddhist images from Sampaga (Celebes) and Seguntang (south Sumatra) and one of rather later date from east Borneo, where there are also inscriptions from the beginning of the 5th century A.D. in Sanskrit. The earliest Buddha images belong to the so-called Amaravati school, but may in fact be from Ceylon. Numbers of Brahmanical and Buddhist images are also known from eastern Borneo which seem to be related to central Javanese art of the 7th to 10th centuries. At later periods the Chinese appear to have exploited the resources of Borneo, more especially the iron ores, and have left vast quantities of pottery as evidence of their visits. (Collecting of Chinese art objects, particularly ceramics, is still characteristic of many of the peoples of Borneo.) It has been argued by a number of scholars that many of the patterns still surviving in this island are relics of the Dongson culture of mainland Indochina. In Sumatra, after the Stone Age cultures of which mention has already been made and of which some traits at least survive in the peripheral islands, notably Nias, a markedly Indianized culture developed which is connected with the kingdom of Srivijaya. Remains in the vicinity of Palembang probably belong to this epoch. These include a more than life-sized statue of Avalokiteshvara in stone, and three very fine bronzes, a Buddha, a Maitreya and another Avalokiteshvara of central Javanese type. There are also four inscriptions in Old Malay, with a considerable Sanskrit admixture, which are the earliest record of the Malay language. Three of these are dated, in the Saka era, A D 683, 684 and 686. Other finds are from the vicinity of Djambi (7th-10th century) and a fine bronze group dates from AD. 1024 and records the artist's name, an unusual event. Buildings include the Muaratukas group (?12th century), Padanglawas (?13th century), apparently a Tantric centre, and Tandjungmedang. The use of brick rather than stone is a distinctive feature of Sumatran as opposed to Javanese building.

Burma. — The Paleolithic cultures of Burma belong to the general eastern Asian complex. There is no evidence of Dong-son influence in the archaeology, but one or two references in T'ang Chinese texts suggest that at least some of the musical instruments of the 8th century survived from this culture. The earliest relics of historical Burma which we possess are the finds from Hmawza, near Prome, and Halingyi, Shwebo, which are assigned to the Pyu, a Tibeto-Burman people who occupied parts of central and upper Burma during the 5th-8th centuries. The material includes terracotta plaques, some Indian and some native, statuary and reliefs which show considerable skill in carving. and some notable metalwork. To the south of the Pyu were probably outlying groups of the Mons of the lower Menam valley and possibly settlements of Indian traders from the east coast ports. So far little is known of their archaeology, but the few pieces found show even greater affinities with their Indian originals than is the case with the Pyu remains. A survival from the earlier period of Burmese protohistory is probably to be seen in the habit of burials in stone urns, some of which bear inscriptions in the Pyu language.

At a later epoch, the Pagan period, there developed a great efflorescence of building, almost entirely religious in character. Here the sources are diverse, though mainly Indian. Much has survived in a fair state of preservation and demonstrates the skill of the masons, carvers and mural painters. Both buildings and statuary show much dependence upon India, mostly the eastern areas, while the murals derive from Bengal and Nepal, though there are also parallels with the Jain works of the Gujarati school. The most notable buildings are the Ananda, Myazedi, Thatbinnyu and Mingalazedi pagodas. In addition to carving and painting, Burmese decorative techniques included the use of glazed sandstone, in green, and glazed terra-cotta bricks. Some of these bore Jataka (*q.v.*) stories. The relief sculpture is often very fine, notably the 81 panels, telling part of the Buddha's life story, in the Ananda and the splendid Brahmanical reliefs of the Nan-paya. Little of the sculpture other than figures of deities has survived, but statues of Shin Arahan and King Kyanzittha suggest that the image maker was capable of high-quality creative work.

It seems likely, however, that it was in wood that the Burmese artist achieved his real masterpieces. Little survives from the earlier periods, but the monasteries of Mandalay and Amarapura testify to the skill of the wood carvers working in a truly Burmese tradition. Other arts of Burma include silverware, glass mosaics and the famous Burmese lacquer wares. These were, and still are, used for the adornment of buildings and for the construction of smaller objects of everyday use. The craft, Chinese in origin, probably came to Burma through the Shan states. The earliest specimens date from the Pagan period.

It is notable that there does not seem to have been a culture as strong as that of the Indonesian which could markedly adapt and modify foreign influences in Burma. Thus the Burmans themselves, relatively late arrivals in southeast Asia, seem at best to have utilized Indian and to some extent Chinese originals and to have found little else which can be claimed as a native tradition. Thus one does not find, as in Java, a recrudescence of indigenous culture as Indian direct influences wane, unless the later emphasis upon woodwork may be claimed as such.

Champa. — Linguistically the Chams appear to be related to the speakers of Indonesian languages and, if this is correct, they must represent the last main group of these people to establish a major cultural group on the mainland of southeast Asia. The archaeology of Champa is not adequate to give an account of the earlier phases of Cham culture, but a certain amount of information can

be gained from Chinese sources (cf. R. A. Stein; see bibliography). At the beginning of the Christian era they seem to have occupied a position in the vicinity of the Tongking delta and to have been forced south by pressure from the Annamites moving southward. Indian influence seems to have been a powerful factor in the formation of the classic Cham culture, and it is not surprising that the earliest evidence from Champa is the Dong-duong Buddha which belongs to the same school as those of Sempaga and elsewhere in southeast Asia. The first monuments belong to the 7th century A.D. (*e.g.*, temple E.1, Mi-son) and the last phase is represented by the temples of Po Klaung Garai and Po Rome. which can be dated to the 14th-15th centuries. This means that the Cham period is probably rather longer than that of the better-known Khmer of Cambodia, and it probably never achieved the greatness of the Khmer civilization at its apogee. The greatest period of Cham material achievement was during the 7th-9th centuries when the capital was in the neighbourhood of Trakieu, a period to which belong the main groups of Mi-son and Dong-duong. A series of Annamite attacks toward the end of the 10th century led to the transfer of the capital farther south to Quinhon where further building took place, as witness the remains of Hung Tanh and others, but the decline can already be detected. The final collapse of the Chams came in the 15th century, by which time the decline had reached its nadir.

There can be little doubt that the earliest phases of Cambodian monumental architecture owe something to the Chams, but whereas the Khmer builders proceeded to develop the single tower (prasat) into the familiar temple complex, the Chams persisted with the kalan (tower) as their principal architectural feature, nor did they often try, so far as it is possible to judge, to group their single towers into symmetrical patterns. A feature of Cham architecture which distinguishes it from that of the Khmers is their continuing use of bricks as the preferred building material. Nor do they appear to use wood so readily as their western neighbours. The complex, pyramidal base which forms so marked a feature of Khmer architecture would seem to be unknown in Champa. The earlier buildings are noteworthy for the use of sculpture as an integral part of the structure—*e.g.*, apsarases upon the corners of buildings and an ambitious treatment of the foot of the building—and the Cham decline is, in part, marked by the substitution of terra-cotta moldings for these features, as though there was a shortage of skilled craftsmen in the later stages of the kingdom.

Whatever was subject to Indian influences in Champa does not seem to have been recognizably Indonesian; Cham art at its best is sui generis. For although there is little that does not belong to India in its origin, the treatment is distinctive and, in the period of Cham greatness, of considerable aesthetic merit. The handling of movement, in the case of some of the dancing figures, or of repose in the case of ascetics, is skillful and impressive, but with the general decline of Cham culture stereotypes are substituted for creative work.

Malaya. — The Tampanian culture of the Paleolithic in Malaya belongs to the general eastern Asian group to which reference has already been made. During the later stages of prehistory, Malaya exhibits the same main features of cultural development as the rest of southeast Asia, and serves, above all, as one of the principal routes into Indonesia. This characteristic, as a transit zone, persists into historic times. While there is evidence in Chinese texts of settlements, presumably from India, in the peninsula from the beginning of the Christian era, archaeological evidence is scanty until the 7th-8th century. Certain pieces in Gupta style, and a few others which are reminiscent of Kanheri, together with a few inscriptions which are difficult to date epigraphically, form the greater part of the evidence. In the 8th century a style develops which may be called Indo-Malaysian, and which seems to be connected with the rise of the kingdom of Srivijaya with its capital in Sumatra, probably at Palembang. The origins of this style, which is concerned with Mahayana Buddhist imagery, are a matter for debate, but it is likely that they are basically eastern Indian. A splendid Avalokiteshvara from Jaya, now in the Bangkok museum, and the plan of Wat Keo at Jaya both suggest Javanese influences. Other finds are reminiscent of the earliest stages of Cambodian (almost certainly pre-Khmer) statuary, and in the north of the peninsula, Khmer and Mon influences are to be seen. It seems likely that during most of the pre-European period Malaya's importance was "strategic" rather than cultural, in the sense that it was an area of marked and distinctive cultural development.

Thailand. — The prehistory of Thailand has never been satisfactorily studied but after a Paleolithic stage, at present almost unknown, it is possible to detect three phases of the later Stone Age, consisting of crudely chipped tools, tools chipped into regular shapes and ground tools. There is little or no evidence to enable these phases to be differentiated chronologically, and it must be admitted that they give the impression of representing three cultural groups rather than three periods in time. The problem which confronts the prehistorian in southeast Asia is always one of trying to decide when morphological distinctions represent differences of time, when differences of culture. Nor is anything known of the Bronze Age of Thailand, so that its archaeological history begins in fact with the development of historical cultures, though these are unconnected uith the country's eponymous people who are late-comers into southeast Asia. The first period, known as Dvaravati, is generally considered to be due to the Mons, who occupied the Menam delta in about the 5th century A.D. The relation between this people and the Khmer, with whom they are usually associated, is by no means clear, but it is certain that they occupied at one time a very considerable area of southern mainland southeast Asia. Little or no archaeological evidence is available for the earliest Mon period or for that of their immediate predecessors, though air photographs reveal sites which may perhaps belong to the kingdom of Funan or its vassals. (See CAMBODIA.) The earliest remains are those of P'ong Tuk, where, in addition to structural foundations, a Greco-Roman lamp was found which appears to belong to the and century A.D. There was also a fine bronze Buddha which some scholars hold to be another of the Arnaravati school, of which a specimen is known from Korat, but in fact is almost certainly Gupta. The finds from Prapathom and Lopburi are certainly of the Dvaravati school, and include both Buddhist and Hindu images, which parallel those of the pre-Khmer period of Cambodia and are related stylistically to the Gupta art of India. This style, with some local development, persists until the 11th century when Khmer influences begin to take the place of Indo-Mon. The Dvaravati style has no obvious connection with that of contemporary Indonesia. The material is usually limestone, in contrast with the Khmer preference for sandstone which comes into use in Thailand with the setting up of a Khmer kingdom at Lopburi. The art of this period is unmistakably Khmer, but in the north the Thai were beginning to establish small principalities whence, in the 13th century, they expanded southward to establish sway over the central areas of modern Thailand. The Sukhothai school of sculpture is the beginning of true Siamese art and shows an interesting blend of various elements. Technical skill from the Khmer was applied to certain Dvaravati traditions, which still survived, though in attenuated forms, among the Mons of the south. To these were added fresh inspirations from Ceylon, so that by a process of what seems to have been deliberate selection the Thai evolved a characteristic art style well suited to their native abilities and taste. The rapid expansion of the northern kingdom led to a rapid dissemination of this new formula throughout the Menam valley, its development being shown by the two schools of U Thong, difficult to date and probably less homogeneous than the convenient label might suggest, and of Ayutthaya; the former is perhaps 14th century, the latter about 100 years later. Contemporary with the Ayutthaya school is that of Lan-na in the north, formerly known as early and late Chiengsen, which shows an independent development, based on the style of the Mon (Dvaravati) kingdom of Lamphun and strongly influenced by Sukhothai. Ayutthaya fell into decline. apparently largely as a result of overproduction, but at its height it was a centre of amazing virtuosity and enterprise. with considerable technical skill, as witness the colossal bronze Buddha figures, among the largest in the world. After the sacking of Ayutthaya (*q.v.*) by the Burmese in 1767, the culmination of long Burmo-Siamese wars, the capital and the art centre shifted to Bangkok, but the great days of Thai sculpture were over,

though the minor arts, lacquer, inlay, mural painting, weaving and embroidery, continued to flourish. Painting in particular, descended from a long Indian tradition which goes back to Ajanta and Sigiriya and owes something to Pagan, shows a most lively charm and a timelessness without anachronism so that tradition and modernity are happily combined and the royal palace of the Buddha's father is that of a Siamese king with sentries carrying rifles on guard. The Thai ceramic tradition owes almost everything to China and much of the ware was made there for export, but kilns were established in central Thailand at Sukhothai and Sawankalok where native skills developed a distinctive and charming tradition which persisted to the 19th century.

INDONESIAN ART. The peoples of the Indonesian archipelago exhibit a rich diversity of old Malay cultural forms. The more original forms have been most purely preserved in the remoter islands and in the mountainous interior of Sumatra, Borneo and Celebes, but there are marked traditional differences in style. In south Sumatra) Java and Bali, however, artistic forms since the 7th century have been influenced by the cultures of south Asia through political interference and the penetration of Hindu doctrines. The "grand style" of Indian architecture and sculpture overgrew the indigenous folk art and, according to modern archaeologists, Indonesian architects and artists must have received their training in India. On the other hand, this advanced culture from the mainland had been developed from mythological conceptions that were also common in Indonesia, and basic symbols such as the tree of life or the ship of death are repeatedly found.

For the Indonesian the artistic criterion is less aesthetic decoration than the potential magic of the ideal shape, but the symmetrical decoration of textures and the definite shape of specific objects strive for beauty while determining the magical value.

Ancestral figures hewn from stone are to be found on the island of Nias, in the Batak districts, in west and central Java, in north Celebes (Minahasa) and in the Timor archipelago, but examples of wood sculpture are more numerous wherever the Islamic religion (which forbids the portrayal of human beings) is not professed by the people. Characteristic is the rendering of the human figure in a squatting position (the usual position of rest among Indonesians). The inhabitants of Nias are not only admirable architects but excel at making impressive wooden ancestor images in an individual style and sometimes of considerable size. The wood sculpture of the Batak (northwest Sumatra) is impressive in its rendering of the human figure in the upper figures of the sorcerer's staff, symbolizing a tree reaching from the underworld into the upperworld. Finally, in the most easterly islands (Leti, Tanimbar and Kai) there are idols, usually of small dimensions but carefully carved out of extremely hard wood, which are carried as fetishes on lengthy sea voyages.

The oldest people on Celebes, the Toradjas, have a high reputation for weaving, in which they employ a complicated dyeing technique. Into their magnificent ceremonial ikat cloths the women weave human figures representing their ancestors, normally in red. black and white. The same technique is found among the inhabitants of the islands of Timor. Sumba and Sanu. Such cloths (in which the dead are often wrapped) are supposed to have a magical and favourable influence on descendants.

In Indonesia noven material is the symbol of woman and has its complement in the masculine symbol, the dagger or creese (kris). In the exchange of presents preparatory to an exogamous marriage, *e.g.,* among the Batak, the creese and the cloth represent the bridegroom's and the bride's clans respectively and the exchdnge is designed to preserve the cosmic balance. It has indeed been argued that the original function of the creese could have been that of a totemistic clan emblem. Such conceptions, directed at the continuation of the existing order and wealth, must have stimulated Indonesian art and, in particular, have caused the high standard of the goldsmith's art.

Masks, too, have a dynamic function. They hide the wearer's personality in order to express some supernatural idea or power, and in this way impending disasters are given a demonic shape that can be exorcized by the sorcerer. Masks used by Toba- and Timor-Batak tribes at their funeral feasts are dark and threatening; the Dayak masks on the other hand, of white overlaid with black and red spirals, recall lurid skeletons, and dancers wearing them represent evil spirits threatening the harvest after the planting of the rice. On Bali the archaic and the civilized forms exist together. Great care is taken in making the masks expressive artistic objects: in the Batak highlands the priest performed this task in the secl'usion of the forest and the masks, to which sacrifices were made, were carefully preserved. Sometimes, *e* g., among the Dayaks of central Borneo, the head-hunters' wooden shields served as magical masks in which a stylized monster's head was a central figure in the traditional decoration. The motif is similar to that on certain ancient bronze shields from southern China and is found again in the Balinese play dealing with the magical contest between the Barong (tutelary spirit of the Balinese village) and the Rangda (personification of evil).

The Javanese shadow play. which is at least 1,000 years old (and was also originally designed to ward off evil), is an art form by itself. Both the technique of employing dolls cut from leather and its meaning can be traced to an old Javanese theme: the initiation preparatory to the marriage of the mythical forebears of the Javanese people. The audience witnesses the ordeals endured by their old national hero, Pandji, before he attained to full maturity of body and spirit, and this explains why this classic drama has to be acted whenever Javanese villages are threatened by disaster or smitten by hardship. This shadow play has retained its original magical function.

It is difficult to differentiate clearly between expressionistic magic and purely decorative art. Cosmic symbols for heaven and earth are used as decorative motifs in wood, silver or bronze and woven into cloths. Pottery, cloths, bamboo containers, basketwork

and beaded headbands are often decorated with geometrical figures that can be derived from more sacred emblems. Painting alone was almost entirely used for the decorating of ships and dwellings, but on Bali the influence of Hindu myth had led at an early stage to the development of a magical tantric art of painting on canvas, showing high skill and taste in its conservative style. The amazing development and flourishing of art and handicraft on Bali was certainly helped by its geographic location and by the particular history of the people, but most of all by the innate sensibility to the great symbols and the delicate intelligence of the Balinese people.

INDONESIAN TIMOR (TIMOR RARAT): *see* TIMOR.

INDORE, a city and district of Madhya Pradesh, India; the district was formerly one of the five into which the princely state of Holkar or Indore (Central India agency) was divided. The city of Indore (pop., 1951, 310,859) is 1,738 ft. above sea level on the Saraswati river, near its junction with the Khan. It was the capital of the former princely state and is now the summer capital of Madhya Bharat. One of the most important trading centres in central India, it has flourishing cotton mills. Daly college, a fine marble building. is for the education of young noblemen; the Christian college, Holkar college and Mahatma Gandhi Memorial medical college are all affiliated to Agra university.

The DISTRICT OF INDORE had a population in 1951 of 596.622. The former princely state had an area of 9,934 sq.mi. and a population (1941) of 1,513,966. The difference in population between the territories now and formerly bearing the name Indore is accounted for by the detachment and separate absorption of the former princely state's four other districts—Nimar (pop., 1951, 758.694). Mehidpur. Nemawar and Garoth (Rampura-Bhanpura).

The territory of HOLKAR or INDORE STATE, like that of most other princely states in central India, was not homogeneous. The largest tract of territory ran south from the Vindhya hills (in which Indore city is situated) across the Narbada river to the Satpura range. This. with the large, isolated Nemawar tract to the east and three smaller areas to the west, constituted the southern division of the state (Indore, Nimar and Nemawar districts). North of the Vindhyas the detached Mehidpur and Garoth tracts and three smaller areas formed the northern division (Mehidpur and Rampura-Bhanpura districts).

The state had its origin in an assignment of lands made early in the 18th century to Malhar Rao Holkar, a peasant's son who worked his way up to a cavalry command in the army of the Maratha peshwa. Of the Dhangar or shepherd caste, he was born in 1694 at the village of Hol near Poona, and from this circumstance the family derives its surname of Holkar. Before his death in 1766 Malhar Rao had added to his assignment large territorial possessions acquired by his armed power during the confusion of the period. By the end of that century the rulership had passed to another leader of the same clan, Tukoji Holkar, whose son, Jaswant Rao, took an important part in the contest for predominance in the Maratha confederation. At first he defeated a British force that had marched against him under Col. William Monson; but when he made an inroad into British territory he was completely defeated by Lord Lake in 1804 and compelled to sign a treaty which deprived him of a large portion of his possessions. In 1818, by the treaty of Mandasor, the state transferred to the British government its suzerainty over a number of minor tributary states and acknowledged the British protectorate. For many years afterward the administration of the Holkar princes was troubled by internal quarrels, misrule and dynastic contentions, necessitating the frequent interposition of British authority; and in 1857 the army, breaking anay from the chief's control, besieged the British residency. In 1899 a British resident was appointed and changes were made in the system of administration. On June 15, 1948, Indore was merged into the United States of Gwalior, Indore and Malwa (Madhya Bharat).

INDORSEMENT or ENDORSEMENT, anything written or printed on the back of a document. In its technical sense, it is the writing upon a bill of exchange. check, or other negotiable instrument by one who has a right to the instrument and who thereby transmits the right and incurs certain liabilities. In the U.S., the usual method for indorsing a check is for the first indorser to sign the check exactly as it is made out if he wishes to convert the instrument to cash. This signature may be preceded by the words "for deposit only" if the indorser wishes to have the value of the check credited to his bank balance or by the words "pay to the order of (name)" if he wishes to transmit the check to another party. By indorsing a check a person makes himself liable to payment of it if it is not honoured, but usually retains the right to try to collect compensation from any previous indorsers. *See* also BILL OF EXCHANGE.

INDO-SCYTHIANS, a name commonly given to various tribes from central Asia, who invaded northern India and founded kingdoms there. They comprise the Sakas, the Yue-Chi or Kushans, and the Ephthalites or Hunas.

INDRA, in Vedic Hindu mythology god of the clear sky and greatest and best of deities; he is lauded in about 300 hymns (or quite a fourth of the Rig-Veda). Unquestionably of Zoroastrian origin, the Boghaz Keui inscription (*c.* 1400 in Asia Minor) mentions Indra with Varuna and Asvins, but in the Avesta he appears as a demon. In the Vedas however his paternity is ascribed to Dyaus, the Sky, and he is almost the national god of the invading Aryans. Represented as having four arms and hands, in two he holds a spear and in a third a thunderbolt, his body is depicted as Sahasrakhsha, "with 1,000 eyes." In the epic age Indra survives as one of the eight great Devas, but is gradually subordinated to Brahma, Siva and Vishnu, and in modern Hinduism he is merely vicegerent of Smarga the heaven of the gods.

INDRE, a *de'partement* of France, formed in 1790 from parts of the old provinces of Berry, Orléanais, Marche and Touraine. Pop. (1954) 247,436. Area 2,667 sq.mi. It is bounded north by the *de'partement* of Loir-et-Cher, east by Cher, south by Creuse and Haute-Vienne, southwest by Vienne and northwest by Indre-et-Loire. The *département* slopes northwestward from the Plateau Central and is drained by the Indre river. In the north is the Champagne, a land of corn and of sheep with fine wool; in the west is the Brenne, once marshy, now drained and afforested; the wooded Boischot is in the south, east and centre. The average annual temperature is nearly three degrees higher than that of Paris, but the winter on the higher Boischot is somewhat severe. The average rainfall is 23½ in. Wheat and oats are largely grown, as are beetroots and artichokes. Wool spinning and weaving and iron working are the chief industries; felt hats and parchment are made.

The *de'partement* is divided into the *arrondissements* of Châteauroux, the capital, le Blanc, Issoudun and la Chbtre, with 23 cantons and 248 communes. It is in the archbishopric of Bourges, where is the court of appeal; it is in the region of the 9th army corps (Tours), and of the *académie* (educational division) of Poitiers. At Neuvy-St. Sépulchre there is an 11th-century circular church with a 12th-century nave; at Mézières-en-Brenne a 14th-century church; at Levroux a 13th-century church and the remains of a feudal fortress; and a magnificent Renaissance chbteau at Valençay. St. Genou has an 11th-century church and a 12th-century tower. There are several dolmens in the *de'partement.*

INDRE-ET-LOIRE, a *de'partement* of France, consisting of nearly the whole of the old province of Touraine and of small portions of Orléanais, Anjou and Poitou. Pop. (1954) 364,706. Area 2.378 sq.mi. It is bounded north by the *de'partements* of Sarthe and Loir-et-Cher, east by Loir-et-Cher and Indre, south and southwest by Vienne and west by Maine-et-Loire. The department is floored by the southern outcrop of Eocene of the Paris basin, with barren shell-marl at Ste. Maure between the Indre and the Vienne; the Loire and its affluents, the Cher, Indre and Vienne, cut valleys with fertile slopes through these Eocene deposits. North of the Loire is the barren Gâtine; between Cher and Indre the vine-clad slopes of Champeigne; between the Loire and Vienne

the vine- and fruit-growing Véron sloping down to the Val d'Anjou; and in the south the Brenne (see INDRE). The climate is mild with average annual temperature 1.8° F. above that of Paris, and about 24 in. of rainfall. Cereals, potatoes, hemp, beetroot and the vine are grown, and many sheep reared. There are quarries of building and mill stones. The industries include iron and lead working. potteries, silk spinning and weaving. important tanneries and the making of famous wines.

Indre-et-Loire is divided into the arrondissements of Tours, Loches and Chinon. possessing 24 cantons and 281 communes. The chief town is Tours, which is the seat of an archbishopric; the court of appeal is at Orléans, and the dtipartement is in the region of the 9th army corps (Tours) and of the *académie* (educational division) of Poitiers. Chinon, Loches, Amboise, Chenonceaux, Langeais and Azay-le-Rideau are also important. Montbazon has the ruins of a square donjon of the 11th and 12th centuries. Preuilly has the most beautiful Romanesque church in Touraine. The Sainte Chapelle (16th-century) at Champigny is a survival of a château of the dukes of Bourbon-Montpensier. The church of Montrésor (1532) has the mausoleum of the family of Montrésor. The town of Richelieu, founded in 1631 by the famous cardinal, preserves its *enceinte* and many 17th-century buildings. Megalithic monuments are numerous.

INDRI, the largest of the existing lemurs, belonging to the family Indriidae (see PRIMATES: Lemuroidea) which includes also the avahi and sifakas. The tail is rudimentary, only two inches long, while the head and body length is about two feet. It is slender, long limbed and has large feet. The pointed face is naked, the rounded ears furry. Indris are usually blackish, with white markings on the head, throat and buttocks, but individuals may be almost white. These lemurs live in the forests of eastern Madagascar. They are diurnal in habit, feeding on shoots, berries and flowers as well as animal matter. (J. E. HL.)

INDUCTION, in logic, usually means reasoning in support of a general proposition by consideration of particular cases which fall under it. Aristotle calls induction "a passage from individuals to universals." John Stuart Mill defines it as "the operation of discovering and proving general propositions" or as "that operation of the mind, by which we infer that what we know to be true in a particular case or cases, will be true in all cases which resemble the former in certain assignable respects."

Induction is called summative (or complete) if it proceeds through an enumeration of all the cases which fall under its conclusion. Aristotle gives an example, which can be rendered as follows: Man, the horse and the mule are long lived; but man, the horse and the mule are all the bileless animals; therefore all the bileless animals are long lived. Summative induction is a conclusive argument.

Induction is called ampliative (or incomplete) if its conclusion goes beyond its premisses in the sense that the former is not a logical consequence of the latter. Ampliative induction is thus an inconclusive argument. It proceeds "from the known to the unknown" (Aristotle, Topics; Mill).

Induction is often contrasted with deduction. Induction and deduction are sometimes (*e.g.*, by W. Whewell and by W. S. Jevons) described as "inverse operations" of the mind; induction leading from less general to more general propositions, deduction leading to conclusions of a generality either equal to or less than that of its premisses. This contrast is not an altogether happy one: summative induction can properly be regarded as a type of deductive argument. The appropriate contrast is between arguments which are logically inconclusive—of which ampliative induction is one—and arguments which are conclusive.

Some logicians, following Mill, wish to restrict the term "induction" to ampliative reasoning. In the rest of this article we shall consider induction in this restricted sense only.

Ampliative reasoning need not aim at the establishing of general propositions. It may also conclude from some particular cases to other particular cases This type of inference is sometimes called eduction (W. E. Johnson).

Induction and Laws of Nature.—The conclusion of an inductive argument can often be stated in the form "everything which is a is β." If x is something of which a and β can be significantly predicated, the general proposition can be used for predicting that if x is a then x is also β. If x, on examination, turns out to be both a and β, we say that x constitutes a confirming instance of the generalization. If x is a but not β, we say that x constitutes a 'disconfirming instance.

A general proposition of the form "every a is β" is called a law of nature if it satisfies some additional requirements. The following three may be regarded as minimum requirements:

1. The scope of the generalization must not be numerically restricted; *i.e.*, the things of which α and β can be significantly predicated must not be restricted by definition to a finite number of objects. This means that a law of nature, reached by ampliative induction, cannot be subsequently established by summative induction.

2. The scope of the generalization must not be spatiotemporally restricted; *i.e.*, the things of which a and β can be significantly predicated must not be restricted by definition to a certain place or to a certain period of time. The laws of nature are valid always and everywhere.

3. The generalization must be a basis for asserting so-called unfulfilled or contrary-to-fact conditionals; *i.e.*, if a certain x, on examination, turns out not to be a, we shall be willing to assert that if it had been a it would also have been β.

Besides universal generalizations of the type "every α is β" there are statistical generalizations of the type "a certain proportion (percentage) of things which are a are β." Statistical generalizations are often established by induction from samples of a "parent" population. Induction of this kind is a species of statistical inference, which will be excluded from consideration here.

ELIMINATION THEORY

An Important Asymmetry.—A single disconfirming instance of a law of nature is a falsifying instance. If we find an x which is a but not β, then it cannot be the case that everything which is a is β. But a confirming instance of a law of nature is never a verifying instance. Since the scope of the generalization is numerically unrestricted, any number of x's which are both a and @ will be compatible with the existence of an x which is a but not β.

Laws of nature are thus asymmetrical with regard to verification and falsification. To have appreciated the importance of this asymmetry to a theory of induction and scientific method is the immortal merit of Francis Bacon (1561–1626).

Of induction which proceeds by enumeration of confirming instances Bacon says that it is "exposed to danger from one contradictory instance" and therefore "utterly vicious and incompetent." But "greater is the power of the negative instance": relying upon it we can reject false inductive conclusions and, by this negative approach, so Bacon thought, ultimately single out the true ones. Scientific induction is a selective process of elimination among a number of alternative possibilities as to a nomic relationship (law of nature). Inductive logic is elimination theory, not confirmation theory.

Elimination theory is today chiefly known in the form given to it by Mill in his System of Logic (1843). Mill distinguished four variants of induction by elimination. He called them the methods of "agreement," of "difference," of "residues" and of "concomitant variations." He regarded them as methods for ascertaining causal connections. More recent contributions to elimination theory are due to J. M. Keynes (1921), to W. E. Johnson (1922) and to C. D. Broad (1930). Broad placed the study on a new basis, abandoning the traditional causal schemas in favour of the terminology of a logic of conditions (necessary, sufficient, necessary-and-sufficient, contributory, counteracting, etc.).

The Canons of Elimination.—Suppose we are searching for a necessary condition of a. To this end we may compare different cases which agree in exhibiting the feature a. It is clear that a feature, say γ, which is missing in some of these cases, cannot be necessary for the presence of a. It is also clear that a feature, say β, which is present in all examined cases, may be a necessary condition of a. If, "varying the circumstances," we find that the

examined instances of α have only one common feature β, we can conclude that, if α has any (simple) necessary condition at all, then β is such a condition. If we are left with more than one common characteristic, we shall have to reckon with the possibility that a has several or a plurality of necessary conditions. If again the instances are found to have no common feature (beside a), we must not conclude that α lacks a necessary condition, since this condition may be complex, which here means that it is a disjunction of two or more features, say β and y, so that the presence of either β or γ is necessary for the presence of a.

The canon of elimination employed in the search of necessary conditions corresponds roughly to Mill's "method of agreement."

Suppose next that we are searching for a sufficient condition of α. To this end we compare an instance in which a is present (a positive instance) with instances in which a is absent (negative instances). Obviously any feature, say y, which is present in the absence of α cannot be a sufficient condition of a. On the other hand any feature, say β, which is absent in the absence of a, may possibly be a sufficient condition of α. If there is only one feature β which belongs to the positive instance under consideration but does not belong to any negative instance, then we can conclude that, if α has any (simple) sufficient condition at all (in the positive instance), then β is such a condition. As long as there remain more than one feature in which the positive instance differs from all the examined negative instances, we have to admit the possibility that α has a plurality of sufficient conditions. If again there is no (simple) feature in which the positive instance differs from all negative instances, we must not conclude that α lacks a sufficient condition, since this condition may be complex, which here means that it is a conjunction of two or more features, say β and γ, so that the presence of both β and γ (but not of either of them alone) is sufficient to produce a.

The eliminative procedure thus outlined corresponds roughly to Mill's method of difference. This method has a characteristic use in scientific experimentation, when the "transition" from positive to negative instances is achieved through a removal of one feature from an instance, all the other features being left intact. If this removal is accompanied by the disappearance of one other feature from the instance, we may suspect that the removed feature is a sufficient condition of the disappearing feature.

Sufficient and necessary conditions are interdefinable. The presence of a is necessary for the presence of β if and only if the absence of a is sufficient for the absence of β. If oxygen is necessary for life, then removal of oxygen from an organism's environment is sufficient to extinguish life. This interrelatedness makes it possible, in the search of determining conditions of a given phenomenon, to switch over from one method of elimination to another and is thus responsible for a wealth of possible variations and combinations in the use of inductive canons.

Induction by Elimination as Demonstrative Induction. —Mill says: "Every induction may be thrown into the form of a syllogism, by supplying a major premiss." Inductive inference, when exhibited in syllogistic form, is sometimes called demonstrative induction.

Mill thought that the major premiss, needed for making reasoning from elimination demonstrative, was a law of universal causation stating that: "Every event, or the beginning of every phenomenon, must have some cause; some antecedent, on the existence of which it is invariably and unconditionally consequent."

The necessity of assuming some kind of deterministic principle is clear from the description of the methods of elimination given above. Unless we assume that a has a necessary condition, we can conclude nothing from the fact that a number of examined instances of a agree in only one other common feature β.

On the other hand. a law of universal causation as formulated by Mill or a deterministic principle stating that every phenomenon possesses a nomic condition of a certain kind, is much too weak to serve its purpose as a supplementary premiss of all induction by elimination. This was never clearly appreciated by Mill. It becomes plain when we pay due attention to the possible plurality and complexity of conditions (as Mill and most subsequent authors on induction failed to do).

The number of attributes (characters, features) among which the nomic conditions of a given phenomenon are to be sought may be infinite, or some of them may have escaped our notice or otherwise been ignored. In order to cope with difficulties arising from these possibilities, a second major premiss is needed in addition to a deterministic principle. It may be called a selection postulate. Its function is to limit the range of alternative possibilities in eliminative induction.

Mill ignored the function of a selection postulate and acknowledged only the need of a deterministic principle. Bacon, on the other hand, took determinism for granted but was aware of the necessity of limiting the range of possibilities. He postulated that all variety in nature could be reduced to combinations of a finite number of independent elements or "generic" properties. Thus the number of possibilities with which the scientist has to count in his search of law connections is necessarily finite (and relatively small). This postulate of limited independent variety was reintroduced into inductive logic thanks to Keynes (1921).

The postulate, however, is too weak for its purpose as supplementary premiss; and so, too, are any general principles which, like Mill's law of universal causation or Keynes's principle of limited variety, profess to remain the same for all inductions. Each inductive inference requires supplementary premisses (a deterministic principle and a selection postulate) of its own in order to acquire the force of a demonstration. The first writer on induction clearly to have appreciated this "in opposition to the prevalent view" was Johnson (1922).

CONFIRMATION THEORY

Inverse Probability and the Law of **Succession.**—Ampliative induction from confirming instances admittedly does not yield certainty. But may it not establish its conclusion with a degree of probability? The advent of a mathematical theory of chances in the late 17th and the 18th century opened fresh prospects for a confirmation theory of induction.

The calculus of probability was already regarded by its early champions as being an ars conjectandi or technique for estimating the value of empirical evidence for conjectures about the unknown. One of its classical problems can be formulated as follows: If, of n examined instances of a, m instances possess the character β, what is the probability that a random instance of a is β? An answer to this and to kindred questions was provided by the doctrine of so-called inverse or inductive probability. Its foundation was laid by Thomas Bayes (1763), and it was greatly developed by Pierre Simon de Laplace (1749–1827) and his school. (*See* PROBABILITY.)

A famous formula of inverse probability is Laplace's "law of succession." It professes to answer the question: If n instances of a all agree in being β, what is the probability that the next instance of a is β? The answer given is: $\frac{n+1}{n+2}$. If n is a large number, this value is very near 1; *i.e.*, if we observed a great number of a's and found that they without exception are β, then it is "practically certain" that the next a which comes within our experience will be β too.

The formula of Laplace was long considered a most powerful means of justifying inductive inference of the type called eduction (see above). In view of the debatable and sweeping assumptions on which its derivation from the fundamental principles of probability rests, the faith accorded to the law of succession by many 19th-century writers on induction (*e.g.*, Augustus De Morgan and Jevons) was amazingly uncritical.

A critical attitude toward the doctrine of inverse probability was developed, parallel with the revival of the so-called frequency theory of probability. from the middle of the 19th century onward. The law of succession was acutely criticized by C. S. Peirce and others.

The Principal Theorem.— Although inverse probability is also traditionally called "inductive" and a branch of it was known under the name of "probability of causes," the doctrine is not

directly concerned with degrees of probability in universal generalizations (laws of nature). The foundations of a confirmation theory dealing with laws of nature were laid by Broad (1918) and Keynes (1921). These authors proved what may be called the principal theorem on confirmation. It runs:

The probability of a generalization is increased by a confirming instance, provided that the probability of the generalization prior to confirmation is greater than o and that the probability of the confirming instance, relative to the previous coniirmations, is smaller than 1.

The content of the theorem ought not to be uncritically interpreted as meaning that induction by the multiplication of instances, sometimes also called pure induction, possesses a value independently of induction by elimination. Keynes was of the opinion that the condition, according to which the confirming instance ought not to be maximally probable, can be satisfied only if this instance, at the same time as it confirms the generalization. also disconfirms (and thus "eliminates") some alternative generalization. In opposition to this view, Jean Nicod (1923) tried to show that the conditions for increase in a law's probability through confirmation can be satisfied independently of elimination.

The arguments of both authors are unconvincing. It is hardly possible to settle the controversy over the value of pure induction without giving an interpretation (definition, model) of the notion of probability in the principal theorem. Actually an interpretation can be found, on which the theorem merely reflects, in numerical terms, the working of an underlying mechanism of induction by elimination. This may be said to support Bacon's opinion on the relative value of confirmation and elimination to the systematical pursuit of inductive knowledge.

Some Other Problems of Confirmation Theory.—After Keynes and Nicod, few contributions to confirmation theory were made until the study was revived in the 1940s. To the subsequent period belong the contributions of J. Hosiasson, C. Hempel, Rudolf Carnap and others.

The concept of a confirming instance has turned out to present serious problems. Let the generalization be that every α is β. It is clear that an x which is not α cannot disconfirm the generalization. But can it be said to confirm it? Similarly, no x which is β disconfirms the generalization. But shall we say that it confirms it, irrespective of whether it is α or not? These and some related puzzles are sometimes referred to under the name of the paradoxes of confirmation.

Another problem of confirmation theory is, whether the probability attributed to laws on the basis of confirming evidence is capable of numerical evaluation or whether it is a comparative concept. Most authors seem to agree on the second alternative, but the reasons given for their views vary greatly.

A further problem is, whether the "meaning" of probability as an attribute of laws of nature is the same as the meaning of probability in some other typical uses. To indicate a distinction, some authors prefer to speak cf degree of confirmation (credibility, acceptability, reasonableness), rather than of degree of probability, in connection with laws.

THE PLACE OF INDUCTION IN SCIENCE

Induction and Hypothesis.—The framing of hypotheses and theories in science mould be arbitrary and useless. could they not be put to a test by deducing from them predictions to be confronted with the testimony of future experience. Likewise. the application of science for technical purposes essentially depends upon the predictive force of scientific laws. The very aim of science is often said to be that of making successful predictions possible: *savoir pour prkvoir pour pouvoir,* as Auguste Comte put it.

Science cannot be used for making predictions unless its results transcend the data of experience so as to contain an element of conjecture (anticipation) about the future course of events. This transcending of experience is an act of ampliative induction. In virtue of this fact, science which is predictive can rightly be called inductive science.

It would, however, be a mistake to believe that the hypotheses (theories. laws) used for prediction were reached through "mere" inductive inference. This is true only of those cases in which it is readily clear which features of a given situation can possibly lend themselves to generalization. It is not true, for example, of those cases in which, experience having provided us with a set of values of co-ordinates of points in a diagram, the "problem" is to discover the mathematical law (curve) connecting the points. The first step to the solution of the problem here is to suggest a hypothesis about the curve and to see whether values which are deduced from this hypothesis "fit" the points of observation. If they do, we may by induction extend the hypothesis to points to be observed in the future. This second step often follows as a matter of course and presents no "problem." Authors who put strong emphasis on the invention of scientific hypotheses sometimes neglect this generalizing step in their accounts of scientific method.

Thus hypothesis in science has a double function: it introduces a new concept or idea to account for observed data; and it makes a conjecture about the unobserved. To fulfill the first function is to make an invention or discovery; and discoveries are "happy guesses" or "leaps which are out of the reach of method" (Whewell). To fulfill the second function is to reason inductively. Thus the uses of induction and hypothesis in science are not to be contrasted: induction is a step in the use of hypothesis. (*See* also HYPOTHESIS.)

The Justification of **Induction.**—Ampliative induction, as has been said. is an inconclusive argument. Its conclusion does not follow "logically" from its premisses. In what sense. if any, can the use of induction and a belief in the truth of inductive conclusions be ··justified"?

David Hume was the first to appreciate the full significance of the epistemological problems which originate from the inconclusive character of inductive reasoning. The problem of justifying induction has therefore also been called the "problem of Hume." Kume's attitude to the problem is his famous "skepticism": induction, in a sense, has no rational justification. Kant's efforts in the theory of knowledge mere largely directed toward rebutting Humean skepticism. According to Kant, there exist "synthetical judgments a priori," which are amplifying in the sense of going "beyond the evidence of our memory and senses" (Hume) and at the same time known to be true prior to experience.

This attempt to solve Hume's problem encounters two principal difficulties. One concerns the notion of a synthetic a priori. This notion has been severely criticized, particularly by philosophers of a positivist turn of mind. The second difficulty is connected with the application of the synthetic a priori principles to actual cases of inductive inference. It is notorious that no such principle can, without sweeping additional assumptions, raise a single inductive conclusion to the rank of certainty.

Early in the 20th century the French mathematician Henri Poincaré (La *Science* et *l'hypothèse*, 1902, and other publications) pointed out the important role played by conventions, as he called them, in science. A well-confirmed inductive conclusion is often raised to the rank of a principle which we refuse to let become falsified in the event of (seemingly) adverse experience. For example, experiments have taught us that pieces of phosphorus, under "normal" conditions, melt at 44° C. From this we inductively conclude that all pieces of phosphorus melt at this same temperature. If later a piece of phosphorus is found not to melt at the temperature in question, we "explain" this failure by declaring either that the experimental conditions were not "normal" or that the substance was not "really" phosphorus. The inductively found melting point has been made a defining characteristic of the substance. The inductive conclusion has gained certainty and thus become "justified."

Poincaré himself did not use these ideas for offering a wholesale solution to Hume's problem. But others have made the attempt. "Conventionalism" was for some time a fashion among writers on induction. Its most serious shortcoming as a contribution to the problem of induction is that it does nothing to justify our reliance on predictions in science.

An approach to the justification problem which has found

favour among many authors (R. B. Braithwaite, W. Kneale, H. Reichenbach, J. O. Wisdom) is one suggested for the first time by Peirce in 1877. Induction is a policy which we adopt for predicting the course of events. We cannot know that this policy will be successful, but we can justify its use as being rational on the ground that it is, in a certain sense, the best way of making conjectures about the unknown. The superiority of inductive policies is in the fact that induction is self-correcting. To follow an inductive policy means to let past experience determine one's belief about the future and to let new experience correct false beliefs. If we follow this policy consistently, we cannot, so it is thought, fail to reach true inductive conclusions in the end. "The validity of an inductive argument consists, then, in the fact that it pursues a method which, if duly persisted in, must in the very nature of things, lead to a result indefinitely approximating to the truth in the long run" (Peirce).

The idea of an indefinite approximation to the truth is open to criticism. It is doubtful whether the Peircean approach can prove more than that to follow inductive policies is part of what we mean by "rationality" in action and beliefs. It is worth suggesting that no justification of induction can be based on the ground of its being rational, but that reasoning is sometimes called "rational" on the ground that it employs an inductive policy.

INDUCTION COIL, an electrical device for producing an intermittent source of high voltage. An induction coil consists of a central cylindrical core of soft iron on which are wound two insulated coils: an inner or primary coil having relatively few turns of copper wire, and a surrounding secondary coil having a large number of turns of thinner copper wire. An interrupter is used for making and breaking the current in the primary coil automatically. This current magnetizes the iron core and produces a large magnetic field throughout the induction coil.

The principle of operation of the induction coil was given in 1831 by Michael Faraday (*q.v.*), who showed that if the magnetic field through a coil is changed an electromotive force is induced whose value depends on the time rate of change of magnetic field through the coil. This induced electromotive force. is by Lenz's law, always in such a direction as to oppose the change in the magnetic field.

When a current in the primary coil is started, induced electromotive forces are created in both the primary and secondary coils. The opposing electromotive force in the primary coil causes the current to rise gradually to its maximum value. Thus, when the current starts, the time rate of change of the magnetic field and the induced voltage in the secondary coil are relatively small. On the other hand, when the primary current is interrupted, the magnetic field is reduced rapidly and a relatively large voltage is produced in the secondary coil. This voltage, which may reach several tens of thousands of volts, lasts only for the very short time during which the magnetic field is changing. Thus an induction coil produces a large voltage lasting for a short time and a small reverse voltage lasting a much longer time. The frequency of these changes is determined by the frequency of the interrupter.

After Faraday's discovery many improvements were made on the induction coil. In 1853 the French physicist Armand Fizeau placed a capacitor across the interrupter, thus breaking the primary current much more rapidly. Methods for winding the secondary coil were greatly improved by H. D. Ruhmkorfi in Paris, by A. Apps in London and by Klingelfuss in Basel, who was able to obtain sparks in air about 59 in. long. There are various kinds of interrupters. For the small induction coils a mechanical one is attached to the coil, while the larger coils use a separate device such as a mercury jet interrupter or the electrolytic interrupter invented by A. R. B. Wehnelt in 1899.

About the beginning of this century. induction coils were used to provide the high voltage for electrical discharges in gases at low pressure. and as such were instrumental in the discovery of cathode rays and roentgen or X-rays. Another form of induction coil is the Tesla coil. which generates high voltages at high frequencies. The larger induction coils for use with X-ray tubes have been displaced by the transformer-rectifier source of voltage. while the smaller ones are still used to provide the ignition spark in gasoline engines. (R. J. SN.)

INDULGENCE, a term defined by the Roman Catholic Church as "the remission before God of the temporal punishment still due to sin after the guilt has been forgiven." The doctrine is based on the same church's teaching that the remission of guilt does not necessarily imply the remission of temporal punishment and that the debt of punishment may be paid vicariously. In the case of an indulgence. the debt of punishment is paid from the superabundant treasury of Christ's merits and the satisfactory works of the saints. The payment may be made in full (plenary) or in part (partial); the indulgence may be gained by the living, or applied by way of suffrage to the souls in purgatory. The authority of the church to grant such an indulgence is derived from the power granted the apostles to bind and to loose (Matt. xvi. 18; xviii. 18) and more specifically to forgive and to retain sins (John xx, 23).

The history of indulgences is intimately bound up with the penitential discipline of the early church (see CONFESSION). The sacrament of penance was frequently referred to as a secbnd and more laborious baptism in which the penitent endeavoured to free himself not only of the guilt of sin but of the temporal punishment as well. To this end fixed penances (canonical) were assigned which were calculated to compensate the debt of punishment contracted by sin. The penitent was not, however, left to his own resources. Conscious of his solidarity with the church, the mystical body of Christ, he was encouraged to enlist the aid of the whole Christian community in making fitting reparation for his personal transgressions (cf. Caesar of Arles, *hom.* I, de *Poenitentia*). This principle of vicarious satisfaction finds striking application in the action of St. Cyprian during the Decian persecution (A.D. 250–252). At the request of the martyrs, and it would appear out of regard for their sufferings, St. Cyprian considerably curtailed and even waived the canonical penance in favour of the lapsed nho had received from the martyrs certificates of peace (St. Cyprian. epist. xvi, xxi, xxii). The essential elements of an indulgence may be recognized in this action of St. Cyprian; the practice did not, however, outlive the period of persecutions which occasioned it.

In succeeding centuries, particularly under the influence of the Celtic discipline, the procedure ti-as rather to commute the protracted canonical penance by substituting periods of fasting (usually of 40 days, a quarantine). special private prayers, almsgiving and payments of money nhich were used for religious purposes. This last substitute, a form of redemption, was efficacious in redeeming only a part of the canonical penance and the debt of temporal punishment implied. The first to grant a plenary indulgence nas Pope Urban II on the occasion of the first Crusade (1095). The pertinent section of the indulgence decree reads: "Whosoever out of pure devotion and not for the sake of gaining honour or money, shall go to Jerusalem to liberate the Church of God, may count that journey in lieu of all penance" (Council of Clermont. Mansi. Concilia, xx, 816).

After the 12th century references to indulgences became more frequent. Innocent II granted a 40-day indulgence for visiting and contributing to the adornment of the great church at Cluny (1132), and soon every church of any importance had its own indulgence to further the work of construction. The evident lack of proportion betneen the small sums of money contributed and the debt oi punishment remitted posed a problem for the great speculative theologians of the age. Their solution fixed the doctrine which was regarded as implicit in contemporary practice. Money contribu-

tions and other pious works were not to be considered as substitutes for the canonical penance but rather as conditions for gaining the indulgence. The debt of punishment was paid from the church's treasury.

While the doctrine of indulgences was sound enough, the practice of demanding an offering as a necessary condition for certain indulgences inevitably prepared the way for serious abuses. The magnificent cathedrals of Europe, its older universities, hospitals, bridges and other social and cultural projects are evidence enough that much of the money collected on the occasion of an indulgence was actually directed to legitimate purposes; not a little, however, found its way into the pockets of greedy ecclesiastics and professional collectors (quaestores). And it is at least possible that preachers in their zeal for the church (edifice) of God went beyond the limits of the doctrine, misleading the more credulous into believing that the indulgence was a substitute for true sorrow and confession.

It would appear also that the expression *"ab omni culpa* et *poena"*—from all guilt and punishment—contributed to this misconception. Whatever the original significance of this misleading phrase, it is noteworthy that during the rebuilding of the Kaiserdom in Speyer (1451) "fifty and often a hundred priests with their stoles sat hearing confessions," and this despite the fact that "on the church doors in Speyer there was written in big letters in Latin and in German: In this place is full pardon of all sins for punishment and guilt." (Eikhardt Artzt, the Chronicler, in Badissches Archiv fur Vaterlandskunde, II, 232 ff.)

It was not until the great reform council of Trent (1562) that an end was put to abuses connected with the practice of indulgences. The name and office of quaestor was abolished and with the office the privileges attached. Five years later, Pius V revoked all indulgences for which money payments or alms were prescribed and ordered the bishops to destroy all briefs in which such indulgences were granted. The church did not, however, retreat from its doctrinal position that the debt of punishment could be paid from the church's treasury; insisting on this point, it kept before the minds of the faithful the consoling doctrine of the communion of saints and of that solidarity of all its members in Christ's mystical body, which is basic to the doctrine of indulgences.

INDUNA, a Zulu-Bantu word for an officer or head of a regiment among the Kafir (Zulu-Xosa) tribes of South Africa. It is formed from the inflexional prefix in and ***duna,*** a lord or master.

INDUS (Sanskrit *Sindhu,* Greek Sinthos, Latin *Sindus*), one of the mightiest rivers of the Indian subcontinent. It rises in Tibet in the glaciers on the northern slopes of Kailas Parbat, 17,000 ft. above sea level. Its sources are within 100 mi. of these of the Brahmaputra and the Sutlej. In its upper course the river flows northwestward in the trough between the Kailas range (N.E.) and the Ladakh range (S.W.) for about 200 mi. Near Thangra it pierces the Ladakh range and continues its northwesterly course between the Ladakh range in the northeast and the Zaskar (Zanskar) range in the southwest for about 300 mi. It is joined by the Zaskar river from the southwest about 12 mi. west of Leh, the capital of Ladakh (eastern Kashmir) and the chief town on the great trade route to central Asia via the Karakoram pass. It recrosses the Ladakh range to the north near Kiris where it receives the Shyok. The combined stream is soon joined by the Shigar near Skardu, the chief town of Baltistan, and flows another 100 mi. to the northwest under the shadow of a vast snow-covered range of the Great Himalayas to the south. It flows past the Haramosh peak in a magnificent 10,000-ft. gorge, then suddenly turns southwest. It is now joined by the Gilgit river from the northwest, having dropped to 4,000 ft., and strikes across the Great Himalayas, flowing below the famous Nanga Parbat (26,660 ft.). Past Chilas it continues southwest through the Kohistan (highlands) of the northwest frontier regions of Pakistan. It debouches on to the Terbela plain near Ghazi in Hazara district (North-West Frontier Region) and ultimately comes out of the Himalayan region through a narrow gorge near Attock (2,079 ft.), where it is joined by the Kabul.

Below Attock the river flows along the western margin of the Potwar plateau and finally cuts across the Salt range in a narrow gorge to emerge into the Punjab plain near Kalabagh. From Kalabagh to the sea it flows in the west of an extremely flat plain formed by it and its tributaries. Just above Mithankot in south Punjab it receives the Panjnad ("five waters"), carrying the combined Jhelum, Chenab, Ravi, Beas and Sutlej rivers. It is joined by several smaller streams from the western mountains including the Kurram, Tochi and Gomal. All through the Punjab the Indus is broken by islands and sandbanks and in winter is divided into numerous channels.

Near Kashmor it enters Sind. From Bukkur to the Arabian sea it is familiarly known as Darya (Big river). In Sind its gradient is very gentle and it carries down enough detritus to raise its own bed above the general level of the surrounding plains. As a protection against floods, therefore, the river is confined with bunds (embankments). At Hyderabad, about 115 mi. from the sea, begins the delta, through which the river discharges along about 125 mi. of coast-line. It is almost perfectly level, but the soil is generally infertile. The marshy parts contain good pasturage and rice grows luxuriantly where cultivation is possible.

The river is about 1,800 mi. long; its total drainage area is estimated at 372,000 sq.mi. The catchment basin in the Himalayan region covers about 103,800 sq.mi., which is larger than that of any other river in the subcontinent.

Because of the general absence of firm banks in the plains bridges are difficult to construct. There are railway bridges at Attock, Kushalgarh, and Mari Indus (near Kalabagh), and spanning the river between Sukkur and Rohri and between Kotri and Hyderabad.

The volume of water in the river remains small during the cold season. The river begins to rise in March, attaining its maximum in July or August after which it begins to subside. The average monthly discharge for the decade ended 1950 at Kalabagh above the barrage was 27,244 cu.ft. per second in January when it is lowest and 409,670 cu.ft. per second in July when it is highest. For the same period the average monthly discharge above the barrage at Sukkur was 31,071 cu.ft. per second in January when it is lowest and 409,670 cu.ft. per second in August when it is highest. Unusual floods, caused by landslides, breaches or other exceptional causes are not infrequent. Because of the large volume of water it carries during summer and the flatness of the country, the river shows a great tendency to shift its course in the plains. Formerly it used to flow down in the middle of the Thal. A long lake still exists in the south of the Thal that once formed the bed of the river. In prehistoric times a branch found its way to the Runn of Cutch and the gradual shift of the river westward led to the disappearance of many old towns on its banks. One of the most important changes took place as a result of an earthquake in A.D. 962. when the stream broke through the limestone ridge between Sukkur and Rohri. Formerly it flowed through another gap. 4 mi. to the southeast of Rohri.

Almost the entire plains course of the river from Kalabagh to the sea lies in the zone of deficient rainfall, the mean annual being generally under ten inches. The cultivation. therefore, depends mostly on irrigation. The prosperity of Sind has been particularly dependent upon the water supply from the river through the perennial and inundation canals. which irrigate 7,500,000 ac. Inundation canals take off from it in southwestern Punjab and Sind. The Jinnah barrage near Kalabagh feeds the canals of the Thal project. planned to irrigate 2,000,000 ac. in the Sind-Sagar doab. The canals from the Sukkur barrage irrigate about 5,000,000 ac. The Ghulam Mohammed or Lower Sind barrage, officially opened at Kotri on March 15, 1955, was to irrigate about 2,800,000

ac. The proposed Gudu barrage in upper Sind and the Taunsa barrage in Punjab would irrigate 2,320,000 ac. and 1,400,000 ac. respectively. (K. S. AD.)

INDUSTRIA (mod. *Monteù da* Po). an ancient town of Liguria, 20 mi. N.E. of Augusta Taurinorum. Its original name was Bodincomagus, from the Ligurian name of the Padus (mod. Po), Bodincus. *i.e.,* bottomless, and this appears on inscriptions of the early empire. It stood on the right bank of the river, which has shifted more than 1 mi. to the north. It was a flourishing town, as excavations (which have brought to light streets, the forum, theatre, baths, etc.) have shown, but was deserted in the 4th century A.D.

INDUSTRIAL ACCIDENTS or work injuries include in the United States all injuries and occupational diseases suffered by workers which arise out of and in the course of gainful work, except (1) work injuries to domestic servants and (2) injuries occurring in connection with farm household chores. Because these two types of injuries arise out of circumstances which are peculiar to the home, they are considered as home injuries. Except for these two special activities, gainful work includes the full range of work activities, in manufacturing. construction, mining, public utilities, transportation, agriculture, trade and service.

Work injuries are classified, by degree of seriousness, into five general groups: (1) fatalities; (2) permanent total disabilities—loss of both eyes. both hands, etc.; (3) permanent partial disabilities—loss of one eye, one hand, etc.; (4) temporary total disabilities—no permanent impairment but loss of one or more full day's time following the day of injury; (5) medical treatment and first-aid cases.

The first four groups of injuries are referred to as disabling. In the United States injuries of these kinds totalled about 2,000,000 in 1953, of which about 15,000 were fatal, and about 85,000 resulted in some permanent disability, ranging from partial loss of use of a finger to blindness and complete crippling. No data were available on the number of medical-treatment and first-aid cases which occurred annually, but in some instances frequencies of these cases. in relation to disabling cases, were reported as high as several hundred to one.

Table I shows the total number of disabling work injuries and the number of fatalities in the United States in 1953, summarized separately for eight major industry groups.

Although fairly accurate estimates of total work deaths in the U.S. date back only to 1928, approximations have been made for as far back as 1913. For that year, indications are that work deaths totalled between 18.000 and 22.000. In relation to an estimate of employment for that year. the death rate would be between 48 and 59 deaths per 100,000 workers.

While the number of work deaths decreased by 1953 only to 15,000, this was accomplished while employment was increasing sharply; thus the death rate dropped about 50%, to 26 per 100,000 workers.

Both employment and deaths increased between 1933 and 1937, but the increase in deaths was greater, proportionally, with a resulting increase in the death rates. After 1937 the trend in the U.S. was steadily; although irregularly, down, despite an increase in the number of workers (excluding domestic servants) from about 44,000,000 in 1937 to about 58,000,000 in 1953.

TABLE I.—Work Injuries in the United States in 1953

Industry	Deaths		All injuries*	
	Number	Rate per 100,000 workers	Number	Rate per 100,000 workers
All industries	15,000	26	2,000,000†	3,450
Trade	1,400		360,000	3.120
Manufacturing	2,400	14	480,000	2.810
Service	2,300	16	380,000	2,610
Public utilities	300	22	10,000	1,400
Transportation	1,400	44	190,000	6,030
Agriculture	3,800	59	320,000	5,000
Construction	2,500	81	220,000	7,100
Mining, quarrying, oil and gas wells	900	107	60	7,140

*Includes those causing death, permanent total disability, permanent partial disability and temporary disability—the last being limited to injuries resulting in a full day's disability beyond the day or shift on which the injury occurred. †Possibility of error in the industry estimates makes it advisable to round the all-industry total to 2,000,000.

Work Accidents Compared With All Accidents.—Work accidents are one of four major classifications into which accidents are grouped. The other classifications are motor vehicle, home and public nonmotor vehicle. Accidents in all classifications resulted in about 9,600,000 disabling injuries in 1953, of which about 95,000 were fatal and about 350,000 resulted in some permanent disability (see Table II).

TABLE 11.—Distribution of Deaths and Injuries in Major Classifications, 1953

Class of accident	Deaths	Injuries
Total	95,000*	9,600,000*
Work	15,000	2,000,000
Motor vehidle	38,300	1,350,000
Home	29,000	4,350,000
Public nonmotor vehicle	16,000	2,000,000

*The motor vehicle totals include some cases which are also included in the work and home totals. This duplication amounted to about 3,300 deaths and 100,000 injuries.

In addition to accidents which workers have on the job, they are also the victims, of course, in many of the motor vehicle, home and public accidents. Fatalities of workers in these off-job accidents normally total more than twice the number that occur on the job, while injuries total nearly one-third more.

Time Lost From Work Accidents.—Time lost from work accidents falls into three categories. (1) time lost by injured workers in the year in which the accidents happen; (2) time lost by injured workers in later years; and (3) time lost by workers who were not injured (these losses occur in the year in which the accidents happen) (see below).

Time lost in 1953 totalled about 250,000,000 man-days (the sum of categories 1 and 3). About 45,000,000 of these days were lost by the injured workers (1), and about 205,000,000 days were lost by other workers (3).

Time lost by injured workers in the year in which the accident occurred (category 1) is a minimum figure and includes primarily just the actual full days lost during the year from disabling injuries. It does not include time lost on the day of the injury or time required for further medical treatment or check-up following the injured person's return to work, nor does it include the countless number of losses of less than a full day's time. Fatalities are included in the year of occurrence at an average loss of 150 days per case, and permanent impairments are included at actual days lost plus a small allowance for lost efficiency resulting from the impairment.

It was estimated that time lost in future years from accidents which happened in 1953 would total about 140,000,000 more days (category 2). Most of the future loss results from the fatalities, but a considerable amount also results from a reduction in the capacity of workers who have suffered permanent impairments. A worker with only one arm, for example, might produce less during the remaining years of his working life than a worker with two arms.

Time lost by workers other than those injured (category 3) arises when these persons stop to help the injured or to discuss the accidents. Slowdowns resulting from temporary reductions in efficiency by persons witnessing serious accidents. suspensions of work cdused by damaged equipment and the time required to replace damaged products. machinery and structures also are included in this total. Such losses are not always plainly identifiable. but they result in losses of production time as real as the losses of injured workers.

Accident Costs.—Detailed and precise figures on the cost of work accidents in the U S. were not available in the mid-1950s, but conservative estimates placed the cost to the entire nation at about $3 000.000 000 in 1953. This total was about equally divided between visible costs and indirect costs.

Visible costs included wage losses of about $900 000,000, medical expense of $250,000,000, and insurance overhead costs of $3 50,000,000. Wage losses are borne partly by the injured workers and partly by industry. The other costs are borne by industry, either directly or through payment of insurance premiums. The

indirect costs included the money value of damaged equipment and materials, production delays and time losses of workers other than those injured. The total costs to U.S. industry averaged about $45 in 1953 for every worker employed. This figure obviously would be higher in companies or industries with high injury rates, or in which little has been done about safety.

Measures of Work Accidents.—Preceding paragraphs commenting on the frequency with which work accidents occur and the losses in both time and money resulting from them indicate their impact on business activity. In a particular company, the accident experience may have an important effect on its profits or losses--even on its success or failure. The prevention of accidents, therefore, deserves the same serious consideration that is given to other phases of business activity.

In accident prevention as in other phases of business, accurate records are essential for effective planning and intelligent appraisal of progress. One purpose of such records is to measure the accident problem and indicate whether or not progress is being made in meeting that problem. This purpose can be accomplished by getting answers to such questions as these: (1) Is the volume of accidents greater or less than in other establishments or activities having similar hazards? (2) How serious are the accidents and how do they compare in this respect with accidents experienced in other establishments or activities? (3) Is the accident experience in terms of volume of cases and seriousness of cases improving or getting worse?

Obviously the answers to each of these questions involves a comparison. It is important, therefore, that the basic records be constructed so that they may be used for comparison purposes. Primarily this means that the records must be prepared in accordance with a standard procedure, and one which provides for adjusting differences in the plants or operating units which they represent. For example, if the records for one operating unit include all injuries treated or reported in the first-aid room, while the records of another unit include only injuries which are serious enough to cause lost time, obviously a meaningful comparison between the totals cannot be made. Similarly, if one operating unit has 10 employees while another has 100, it would be illogical to compare the accident totals without making some allowance for differences in the size of the two units.

A procedure for keeping accident records which accomplishes the objectives stated above, developed under a program of the American Standards association, was published as standard Z16.1, "The American Standard Method of Recording and Measuring Work Injury Experience."

Injury Frequency Rate.—Since concern centres principally on accidents which cause injury, this standard defines the injuries which should be counted for comparison purposes, and specifies a method of indicating the relative seriousness of different injuries and how the recorded experience should be expressed for comparison purposes. Specifically, the standard provides two injury rates for making the necessary comparisons: (1) the injury frequency rate and (2) the injury severity rate.

The injury frequency rate measures the volume of disabling injuries in terms of 1,000,000 man-hours of work, and is computed in accordance with the following formula:

$$\text{Frequency rate} = \frac{\text{total disabling injuries} \times 1{,}000{,}000}{\text{total man-hours worked}}$$

The frequency rate indicates the relative degree of safety achieved during the period covered by the rate and permits direct comparisons between injury volume in different establishments or activities regardless of differences in size or number of man-hours worked in these establishments or activities.

Injuries included in the standard frequency rate are those which arise out of and in the course of employment and which cause loss of a full day's time on any one or more days after the date of the accident, or which result in some permanent impairment or death. These injuries are referred to as disabling injuries. Minor injuries are not included in the rate computations because of the impossibility of obtaining standardization of such cases. Injury totals include the number of disabling injuries and not the number of accidents. For example, if five employees suffered disabling injuries in an explosion, five injuries would be included in the total number of injuries.

As itemized previously, disabling injuries are of four types: death, permanent total disability, permanent partial disability and temporary total disability. Specifically, a death is any injury which terminates fatally regardless of the time interval between the accident and the death. Permanent total disability is any injury which permanently and totally incapacitates an employee from following any gainful occupation; or in the same accident results in the loss of or complete loss of use of both eyes; or one eye and one hand, leg, or foot; both hands; or any two of the following, not on the same limb: hand, arm, foot or leg.

Permanent partial disability is any injury which results in the complete loss of any member or part of a member of the body, or any permanent impairment of function of the body or part thereof to any degree less than permanent total disability. Temporary total disability is any injury which does not result in permanent impairment or death, but which renders the injured worker unable to perform a regularly established job during his entire normal period of employment on the day after the accident, or on a later day, regardless of whether the next day is a holiday, or whether the injured worker is not employed for other reasons.

Injury Severity Rate.—The injury severity rate measures the loss resulting from disabling injuries in terms of 1,000,000 man-hours of work, and is computed by the following formula:

$$\text{Severity rate} = \frac{\text{total days charged} \times 1{,}000{,}000}{\text{total man-hours worked}}$$

Loss is the sum of actual calendar days lost for temporary total injuries, and scheduled charges for permanent impairments and deaths as set forth in the Z16.1 standard procedure. For example, the scheduled charge for a fatality is 6,000 days, while for permanent impairments the charges range from 4,500 days for loss of an arm to 75 days for loss of a part of a finger. If an injury causes permanent loss of use of a body member instead of amputation, a percentage of the scheduled charge is used which corresponds to the percentage loss of use. For injuries of these kinds, the scheduled charges are used in place of actual days lost, or even if no days are lost at all.

In the U.S. major industry groups report to the National Safety council and to the U.S. bureau of labour statistics. The National Safety council rates are based principally on the experience of council members, while the bureau of labour statistics rates cover many more reporters and probably are more representative of injury experience in general.

On the average, employees work about 2,000 hours a year; 1,000,000 man-hours, then, represents a year's work for about 500 employees, and in general terms a rate of 20.0 may be interpreted as 20 disabling injuries per year for each 500 employees, or about 1 disabling injury for each 25 employees. A severity rate of 2,000 may be interpreted as four days charged per year for each employee.

Accident Analysis.—Accidents should be analyzed to determine their basic, underlying causes, so that direct, positive action can be taken to prevent recurrence. An accident usually is the last occurrence in a series of events. Complete success in accident prevention will be accomplished only when earlier events in the series are identified and corrected. Accident analysis is a procedure for identifying these earlier events.

To use a simple example, workers frequently suffer eye injuries because they fail to wear safety goggles, and often this is given as the cause of the accident. The corrective measure usually consists of instructions to the workers to wear goggles. However, if there are basic reasons why workers do not wear their goggles, and if these reasons are not determined and eliminated, eye injuries will probably occur again and again. Perhaps the goggles are of the wrong type, or they do not fit properly, or the workers have not been convinced of the importance of wearing goggles.

The method of accident analysis is a standard procedure set forth in standard Z16.2 of the American Standards association, and titled "American Recommended Practice for Compiling Industrial Accident Causes." This procedure, which is primarily concerned with accidents which cause injury, provides for selecting, cross-

classifying, and summarizing the fundamental factors in accidents. Each essential point of information about an accident is referred to as an accident factor. These may be grouped into six major classifications: (1) agency of the injury—the tool. material, machine or substance most closely associated with the injury; (2) agency part—the particular part of the selected agency most closely associated with the injury; (3) unsafe mechanical or physical condition—the condition of the selected agency or conditions in the environment of the agency which could have been guarded or corrected; (4) type of accident—the manner in which the employee was injured; (5) unsafe act contributing to the accident—the violation of a commonly accepted safe procedure which resulted in the accident; and (6) the unsafe personal factor—the mental or bodily characteristic which permitted or occasioned the unsafe act.

Often supplementary items of information closely related to the basic factors, such as sex, occupation and type of work performed at the time of injury, are included in an analysis so that all facts are available for taking the proper preventive steps.

Experience has proved that the most effective way to reduce accidents is to concentrate on one phase of the problem at a time. Analyses, therefore, can approach the problem in many ways, any one of which should prove effective. The accident reports may be grouped by occupation of the injured person in order to determine what types of accidents are most prevalent among different occupations, the actions which contribute to the accidents, and the manner in which the accidents occur. Such information is particularly helpful in planning employee training and in developing educational materials and programs.

Injury frequency rates computed by departments may reveal that injuries occur at sharply higher rates in some departments than in others. If such is the case, an analysis could be made of the accidents in the high-rate departments to find out the sources of the accidents and their causes. This method will permit concentration of effort in the locations in which accidents occur most frequently.

If injury frequency rates reveal that a high rate of occurrence is general throughout the plant, the accident reports might be grouped by agency of the injury to find out the principal sources of the injuries; or by accident type to find out how the persons were injured; or by unsafe act, or unsafe condition. Any one of the accident factors may be used as a starting point.

Table III presents an example of one part of a typical analysis of ladder accidents showing the unsafe acts and unsafe conditions which were found to have contributed to the accidents. The complete analysis might also include information on such factors as occupation of the injured, place of the accident, etc.

Analyses of the circumstances of accidents according to the recommended standard procedure make it possible, for example, to: (1) identify and locate the principal sources of accidents by determining from actual experience the materials, machines and tools most frequently involved in accidents, and the jobs most likely to produce injuries; (2) disclose the nature and size of the accident problem in departments and among occupations; (3) indicate the need for engineering revision by identifying the principal unsafe conditions of various types of equipment and materials; (4) disclose inefficiencies in operating processes and procedures where poor layout, for example, contributes to accidents, or where outdated methods or procedures which overtax the physical capacities of the workers can be avoided, as by using mechanical handling methods; (5) uncover the unsafe practices which need special attention in the training of employees; (6) discover improper placement of personnel in instances in which inabilities or physical handicaps contribute to accidents; (7) enable supervisors to use the time available for safety work to the greatest advantage by providing them with information about the principal hazards and unsafe practices in their departments; (8) permit an objective evaluation of the progress of the safety program by noting in continuing analyses the effect of different safety measures, educational techniques and other methods adopted to prevent injuries.

TABLE 111.—Analysis *of Ladder Accidents*

Unsafe conditions and acts	No. of cases
Unsafe conditions	
Slippery rungs	6
Broken rungs	3
Weak, worn or cracked rails	1
Lack of hooks for fastening ladder at top	1
Worn ladder shoes	1
Unsafe acts	
Ascending or descending improperly	
Carrying too heavy loads	11
Improper or Insecure grip	9
Running up or down ladders	6
Jumping from lower steps to ground	5
Oily or wet shoes	3
With back to ladder	1
	35
Failure to secure ladder at top	29
Placing ladder unsafely	
On boxes or other equipment	
At too great an angle	
Near moving equipment	2
On inclined or irregular surface	2
On planking over opening	1
	22
Failure to secure ladder at bottom	12
Working in unsafe position	
Overreaching	6
Improper stance while using leverage tools	2
Straddling space between ladder and nearby object	2
	10
Using ladders known to be defective	8

Sources of Injury Statistics.—Injury rates by industries are published in the United States by the National Safety council, the U.S. bureau of labour statistics and the department of labour or compensation commissions in some states. Data concerning the cause of injury, giving such information as type of accident, type of injury, agency of injury, and in some cases unsafe acts and unsafe conditions, were published in the mid-1950s by at least the following states: California, Illinois, Iowa, Maryland, Minnesota, New York, Ohio, Pennsylvania, Rhode Island, West Virginia and Wisconsin.

Special studies giving the detailed circumstances of accidents in selected industries, or in the use of particular equipment, are published by the National Safety council, the U.S. bureau of labour statistics, and numerous trade associations and insurance companies. Because of the rapidly expanding interest in safety in recent years, it would be difficult to keep up-to-date a list of all agencies compiling data. For this reason, companies should check with their insurance carriers. trade associations and state labour departments to learn what records are available at the local level. Care must be used in making comparisons between the U.S. and other countries because of differences in such factors as industry classification, injury definition and hours worked per week.

Organized Safety Efforts.—Preceding sections have dealt primarily with the size and character of the work accident problem, how the problem may be measured and studied in any industrial unit, and the change in experience over a period of years. In conclusion, it is pertinent to review briefly the nature of efforts that are made to control and reduce work accidents.

Throughout human history work accidents have taken their toll in death, disabilities and handicaps and in wastage of manpower and materials. These undesirable, and often disastrous, results of accidents were certainly always apparent. However, the idea that a planned and sustained effort could and should be made to keep people from having accidents while at work is a relatively recent development, beginning in the United States around the turn of the 20th century. Important factors in this development were (1) the concentration of large numbers of employees in factories and other places of work where, on account of the increased exposure, the number of accidents and the seriousness of accident losses became more apparent; (2) the pioneering safety efforts of certain industries, which proved the feasibility and effectiveness of organized and sustained safety programs; (3) the passage of workmen's compensation legislation, which, by placing a sizable share of the cost of accidents directly on the employer, made clear the monetary benefits of accident control.

It has been recognized for many years that the avoidance of accidents at work depends fundamentally on two factors: (1) a safe environment, including buildings, equipment and materials; and (2) performance of the job by the worker in a safe manner.

Though stated fundamentally in these two categories—safe conditions and safe work practices—the ramifications of the modern safety program are many and varied. On the environmental side

are involved such things as properly constructed work places, use of nonhazardous materials, adequacy of lighting and ventilation, the guarding of moving machinery, proper provision for fire protection and many others.

In the second category — safe work practices — it is recognized that these can be achieved by the employee only if he knows how to work safely, why it is important for him to do so, and if he is reminded of these facts at frequent intervals. Safety-minded companies place no less emphasis on such a safety program for employees than on the maintenance of safe working conditions.

For many years a stumbling block in the path of work safety was a deep-seated idea that doing a job safely was likely to result in lower production — avoidance of accidents could be accomplished only by doing the' job less efficiently. Experience has proved, however, that the opposite is true. There is a right way to do every job, and that way is both the efficient way and the safe way. Thousands of business concerns, by organizing their plants for efficiency and safety, have prevented enormous economic losses as well as untold human suffering.

Although safety interest on the part of employers is widespread and growing every year, much remains to be done to secure universal acceptance of the importance of work safety. On the whole, the largest companies proved most successful in safety programs, whereas less progress was shown among the medium- and smaller-sized companies. This can be accounted for in part on the ground that the need for and the feasibility of doing something about accident prevention is more strikingly apparent where a large number of workers are concentrated in a single location.

It is standard practice among larger companies to assign responsibility for safety to specific individuals with special training in accident prevention work. Smaller companies, however, find it less practicable to make such assignments, often resulting in less favourable accident rates.

Public and private agencies of various kinds encourage and assist employers in promoting safety at work. The National Safety council, a private organization founded in 1913 and chartered by the U.S. congress in 1953, includes in its membership a high proportion of the nation's major industries, and makes available a great variety of publications and personal services in the industrial safety field. City and state safety councils perform somewhat related functions in the areas they serve.

Trade associations in the various industries showed an increasing tendency to make safety promotion work an important part of their activities. Their influence has proven particularly helpful in reaching and assisting smaller companies. which might not otherwise be well informed on safety methods and procedures. Insurance companies give major attention to the development and maintenance of effective safety programs and also participate with other groups in work safety programs generally.

Labour departments, industrial commissions and other government agencies, at local, state and national levels, share in the important task of work safety. Although basically concerned with law enforcement, many agencies provide assistance in accident prevention which goes far beyond the limits of legal requirements.

Labour organizations are able to exert an important influence on work safety. Through contractual arrangements with employers, support of company safety programs, and safety education among their members, they can contribute greatly to a safer work environment and safer working practices. An increasing number of safety committees in national, state and local labour groups is an evidence of a large and growing interest.

An interesting development on the part of many safety-minded employers has been the attention paid to off-job safety. For the United States as a whole, more than twice as many gainfully employed people are killed in accidents which occur away from their work as are killed in work accidents. Industries which have good job safety records find that the ratio of off-job to on-job fatalities is much higher. Faced with these facts, and realizing that the company suffers a serious loss, regardless of where an employee's accident occurs, many companies have undertaken extensive programs for the education of their employees in matters of traffic safety, home safety and general public safety.

One-quarter of all U.S. work fatalities and one-sixth of all work injuries occurred on farms in the mid-1950s. Special programs aimed at lowering the farm accident toll were developed. Farm safety committees, organized in about two-thirds of the states, carried on year-round programs aimed at reducing farm work accidents, as well as other accidents on farms. State departments of agriculture, farm youth groups and other influential agencies take an active interest in these activities. (*See* also PSYCHOLOGY, APPLIED; WORKMEN'S COMPENSATION.) (N. H. D.)

EUROPE

From mid-19th century the law of Great Britain required certain steps to be taken by employers for the protection of their employees against injuries likely to be sustained by them in the course of their work. For the second half of the 20th century, the Factories act of 1937 and 1948, together with the regulations made under the acts, provide. *inter alia*, a legal minimum of safety precautions to be taken in British industry. In many cases, however, factory owners have, on a voluntary basis, gone far beyond the legal requirements, and as a result of their efforts the number of industrial accidents is slowly decreasing: in 1937, out of every 1,000 people employed in industry, 30 were concerned in accidents; but by 1952 the proportion had dropped to 22.5%. Even so, in 1952, out of an industrial working population of approximately 9,000,000, nearly 800 were killed and 177,000 people had industrial accidents which were sufficiently serious to keep them from work for periods of more than three days. The distribution of these accidents is shown in Table IV.

TABLE IV.—*Distribution of Industrial* **Accidents,** *1952*

	Factories	Docks and warehouses	Building operations	Engineering construction	Total
Fatal	471		207	54	792
Non-fatal . .	154,995	6,969	12,325	2,325	176,718

By 1954 there were more than 237,000 registered factories in Great Britain. together employing about 7,352,000 workers. Of these factories, about 83% were small ones, employing 25 persons or less, that is, about 15.3% of the factory working population. At the other end of the scale, 24% of the working population was working in factories employing more than 1.000 workers. The conditions under which employment was held, therefore, varied very greatly indeed.

In addition to these factory workers, people employed in docks, warehouses, building operations and works of engineering construction are also subject to the Factories act; but the agricultural and mining populations are not, and no reference is made to them in this article.

The Factories act is administered by the factory department of the ministry of labour and national service, to whom reports of all accidents causing absence from work for more than three days must by law be reported. Many individual firms keep records of all accidents — however apparently trivial — and though these are not collected on a national scale, the experience of many firms who keep comprehensive records shows that they outnumber the reportable 3-day accidents by as many as 25–30 times.

At first the factory inspectors appointed by the factory department were regarded as policemen and informers by the factories under their jurisdiction, and in consequence for many years a large portion of industry was, to say the least, resentful and non-co-operative. By the 1950s, however, a great change had come about, and their duties in connection with accident prevention, considered to be their major problem, were becoming more and more advisory. The department has a staff of specialists much of whose time is engaged in research work, in providing material for the publication of technical pamphlets and in the solution of problems submitted to them by individual firms or industries.

The Factories act, accepted as a standard, is reproduced in a simplified fashion by all the members of the British Commonwealth; and in several of the British colonies (*e.g.*, the West Indies, Nigeria and the Gold Coast), factory acts have been passed and organizations similar to the factory department of the ministry of labour set up to supervise their enforcement.

Much of this progress has been the direct result of help and advice given by the factory department to the labour departments concerned in consultation with many voluntary organizations.

On the continent of Europe organizations similar to the factory department exist in most cocntries. Norway, Sweden and the Netherlands include also agriculture within their jurisdiction. The German, Swedish and Netherlands acts go into very much greater detail in their requirements than the British; and Germany, in particular, exercises a very close control over industry by a form of licence required by firms before they can start manufacture.

Legal control, however, can only reasonably be exercised in certain directions, where the specific action to be taken can be clearly stated by legal definitions; for example, the guarding of dangerous machinery and the methods of using, or protecting against, dangerous substances. However, a comparatively large proportion of accidents occur in connection with activities outside these categories (see below). To a very large extent these remaining hazards can be treated only very generally by legal definition, and a different approach has therefore to be made in regard to their prevention.

In Great Britain, the factory owner is responsible for the safety of his employees while they are at work. He is encouraged in his efforts not only by the comparatively high cost of accidents for which he is liable at common lam. having to pay compensation if the accidents occur through his negligence, but also by the social movements of the 20th century. Such influences, together with a belief in humanitarian principles, cause employers to support such organizations as the Royal Society for the Prevention of Accidents and the British Standards institution, as well as voluntary accident-prevention committees set up by industry and committees raised jointly with the government to define standards and to initiate research work on accidents. There is much evidence to show how this work has many times resulted in changes of methods and, through pressure on machine makers, in changes in the design of machine tools.

Within each industry, employers' organizations or joint organizations perform similar functions. In the more industrially developed section of the British Commonwealth, the position is similar. But on the continent of Europe there is considerable deviation from these methods; in Sweden, Norway and the Netherlands, regional committees are set up and are given statutory powers over the area that they control (the committees are sometimes employers' committees and sometimes joint committees of employers and workers); in Poland the formation of committees is usually on an industry basis. Proposals to force British industry to set up industrial accident committees by legal statute have been rejected on the grounds that voluntary work has a more effective driving force and that, where legal enforcement is used, progress is stultified and the mere letter of the law observed.

The influence exerted on accident prevention by the insurance companies differs in various countries. In Luxembourg, the work of factory inspection is done by the insurance representatives, and in Italy the insurance companies are the force behind the industrial accident-prevention movement. In the Netherlands, the insurance companies share the cost of accident-prevention research nith industry and government. In Great Britain, some insurance companies take a widely different view with regard to industrial injury risk: while suitably trained staff are engaged to act in an advisory capacity as to preventative measures to be taken by the insured in relation to the risk involved. these specialists are solely advisers and have only a limited duty with regard to undern riting.

Whatever organization of private enterprise supplements legal compulsion, the methods employed are rather similar. The case histories of industrial accident causes are first studied in careful detail and principles formulated to govern preventative methods. Information of this type, provided on a voluntary basis, is made available for the benefit of all industry by various central bodies. In Great Britain the information is generally disseminated by two principal bodies, the factory department of the ministry of labour and the Royal Society for the Prevention of Accidents. In addition, specialized knowledge for any particular industry is passed to those concerned through its particular association and made available to the two principals mentioned.

The Royal Society for the Prevention of Accidents is a voluntary nonprofit body of organizations and individuals concerned in the prevention of accidents of all kinds—on the roads and in the home as well as in industry. It is governed by a committee drawn from its members which, in regard to industrial accident prevention, consists of representatives of industrial firms and interested organizations such as insurance companies and employees' organizations.

Principles **of** Security.— The principles evolved by the Royal Society for the Prevention of Accidents deal with two facets of accident prevention. In the first place, six guiding principles have been enunciated for the organization of an effective accident-prevention campaign within individual industrial concerns: (1) that the driving force must come from the highest level of management; (2) that the direction of the campaign must be delegated to a single individual; (3) that comprehensive records and statistics must be maintained; (4) that the campaign must be directed by factual studies of inspection, investigation and job-safety analyses; (5) that much of the organization's work must be delegated to a works-safety committee; and (6) that the education of both workers and management through continuous propaganda is a vital part of the organization. These principles, evolved from the continuous experience of the society's members, have the support of the larger industrial firms in Great Britain who have organized for accident prevention successfully on these lines.

In the second place, general principles as to the method of preventing accidents have been established. If a method of work, a substance, a force, or a part of a machine or process is dangerous, then (1) the first consideration should be to do away with it and/or replace it by a safe method of work, substance, force or part of a machine or process; if this proves impossible or for the time being impracticable, then (2) the unsafe method of work, substance, force or part of the machine or process should be completely enclosed against the intrusion of any part of any worker's body, or so enclosed or controlled that any noxious substance is prevented from contact with the worker; if both these methods prove impossible or impracticable, then (3) all workers liable in any way to be adversely affected should be supplied with some form of protective clothing.

Action to be taken in accordance with the first of these latter principles would include the scrapping of mushroom-headed chisels, the use of which should be discontinued; the substitution of shot-blasting instead of sandblasting in many cases, because silica sand as dust in the atmosphere is a dangerous substance; and the substitution on occasion of gravity as a force instead of electricity which can be dangerous. Many parts of machines which have been in themselves dangerous, such as shafting, belts, spur gears, etc., have been either done away with entirely or replaced as a result of improvement in design.

In accordance with the second principle, that of enclosure, the practice of inserting blanks by hand between press dies has been almost entirely superseded by the fixing of guards which totally enclose the hazard at the time of operation and through which material to be processed is inserted either by mechanical means or by the use of a variety of holding tools. Likewise the filling of carboys with acid from drums by open pouring has been replaced by totally enclosed methods of transfer. The commonest case of a force's being totally enclosed is the insulation surrounding electric conductors.

In accordance with the third principle, an example of enclosing the worker instead of the work is to be seen when metal is ground with a portable grinder. This operation gives rise to danger to the eyes. but, as in many cases the wheel is difficult to enclose, goggles are provided for the worker. Again, the use of acid—when it cannot be enclosed—usually necessitates the workers' being totally enclosed by protective clothing of rubber or some similar material. When in exceptional circumstances it is essential to work on live electric circuits, the worker is protected by insulating mats, gloves, fuse holders, etc. Where objects may fall unexpectedly or splashes of hot metal cause injury, safety hats and boots and protective leggings or spats should be worn. These are some of the commonest examples, but it has been found that the principles apply

alone or in combination in every case in industrial practice.

Types of Accident.—Research has shown that the total number of industrial accidents may be analyzed according to the various causes as follows: handling goods, 27.8%; power-driven machinery, 16.4%; persons falling, 13.3%; use of hand tools, 8.8%; persons struck by falling objects, 8.7%; persons stepping on or striking against objects, 7.3%; molten metal or other hot corrosive substances, 4.2%; transport (other than railways), 3.3%; railway transport, 1.6%; and miscellaneous causes not specified above, 8.6%.

The handling of goods is at the top of the list because it is undoubtedly the most common industrial operation. The accidents which arise during this operation are commonly caused by lack of a clear path along which to move the goods, by lack of an intelligible direction when a gang is handling material together, by lack of accurate knowledge of the weight of the materials, by lack of knowledge of the correct way to grasp and to lift and by lack of correct placement and stacking. Obviously, the best means of preventing such accidents is not to handle goods, or at least not to handle them so much. Handling can often be reduced or obviated by studying layouts and methods of work with a view to reducing movements or improving supervision. Keeping workers better informed about weights and teaching them the best methods of lifting, placing and stacking will also reduce the number of handling accidents.

Power-driven machinery commonly causes accidents where it is not properly or adequately guarded. In Great Britain the real solution is to comply strictly with the law not only to guard machinery, but also to use the most effective guards and to maintain them properly in both condition and adjustment. In some countries, less reliance is placed on guarding and more on the training of operators. The best result will no doubt be derived from the intelligent use of both methods. Accidents other than those caused by lack of adequate guarding constitute a small proportion of those connected with power-driven machinery and are largely due to some unsafe method of using the machine; they usually can be prevented only by careful training of the operator.

Persons falling may fall on the same level as well as from one level to another. Building operations account for a high proportion of the most serious of such accidents because of the nature of the work. The most common causes are unguarded openings, platforms without guardrails; untidy, obstructed or badly maintained walkways; and slippery walking surfaces. The methods of prevention are to guard all openings, however temporary; to erect proper guardrails on all working platforms; and to ensure that walkways to working platforms are adequate and in good condition. Walkways should be designed to avoid obstacles and should be maintained in a clear condition free of obstruction.

The use of hand tools may give rise to accidents when the tools are in bad condition or misused. The preventative measures are obvious—to maintain tools in good condition and not to improvise.

Persons are most likely to be struck by falling objects, for example, when tools or materials are improperly placed on overhead working platforms or in unsuitable places where they are either shaken loose by vibration or knocked over the edge. The preventative measures, apart from the erection of toe boards where necessary, consist of careful consideration of the placement of such materials, the training of workers to use proper methods and the provision of suitable containers for tools, etc., when necessary.

Accidental stepping on or striking against objects is most often due to bad housekeeping; *i.e.*, haphazard placing of tools, materials and equipment in relation to walkways. The curative methods are better planning and insistence on maintaining the plan. Subsidiary causes which can be avoided by foresight in planning include the taking of unauthorized short cuts and unnoticeable projections into walkways from adjacent structures.

Accidents associated with molten metal or other hot or corrosive substances are usually caused by unsafe methods of handling such materials or a breakdown of the handling equipment. They are largely prevented by the redesign of methods. by the good maintenance of equipment and by provision of protective clothing for workers.

Transport (other than railway transport) tends to present an increasing problem as more handling is done mechanically. The most common cause of transport accidents is the failure to consider the movements of pedestrians when planning the movements of transport. This is to be expected because of the progressive introduction of mechanical transport vehicles within and about the factories, tending to allow their use on existing routes not originally designed for such purposes. The cure, often impossible economically, is the replanning and redesigning of the factories; the alternative is very careful training of transport operators and other workers and strict enforcement of factory traffic regulations by all grades of supervisors.

The cause of accidents associated with railways within and about factories are not greatly dissimilar from those of other vehicles. The only effective measures are: careful consideration of design and layout within the factory boundary; the introduction of a supervised compliance with operating codes; and the careful training of operators and workmen to meet the hazards in each particular factory.

To speak generally, it is not very difficult to plan preventative measures in connection with most of the causes of accidents in industry. The real problem arises when an attempt is made to put these measures into operation. Though the accident-prevention scheme may be perfect in theory, it can be put into practice only so long as it receives the co-operation of the working force. Without this co-operation on the part of the workers the best-planned safety precautions will be of no avail. (H. I. S.)

INDUSTRIAL ALCOHOL. In order to provide tax-free grain alcohol for use in industry, many governments have set up a special classification of industrial alcohol. In addition to a close watch on records to insure that industrial alcohol is not diverted to beverage production, laws provide that it be denatured, *i.e.*, made unfit for human consumption by the addition of a poisonous substance which cannot be easily distilled out. *See* ALCOHOL: *Preparation.*

INDUSTRIAL ARBITRATION AND CONCILIATION: *see* INDUSTRIAL RELATIONS.

INDUSTRIAL ARCHITECTURE, in this article, refers primarily to the design of buildings, such as factories, administration buildings, laboratories, etc., for manufacturing and related operations from the time of the Industrial Revolution to the present.

GENERAL DEVELOPMENT

Architecturally, industrial buildings can be said to have had the following sequence of phases: water power was paralleled by buildings in wood and stone; steam power by constructions in brick and metal, at first cast and wrought iron, later steel; electric power by reinforced concrete construction. Externally, the late 18th-century mills were characterized by domestic scale and academic compositions, often with cupolas like public buildings. During the 19th century the facfbry followed contemporary stylistic fashions, Greek, Gothic and Italian villa. The same details and towers appeared on them as on the owners' houses. In the latter part of the 19th century, most architects devoted their talents to public buildings and palatial residences, leaving the inartistic factories to the engineers who, however, attacked the problem creatively and produced buildings of genuine integrity. The engineers showed so much vitality that in the early 20th century, when a new architecture based on functionalism was being born, it was the engineer-designed buildings that triumphed. They were rational and scientific; they directly and economically expressed the purpose for which they had been built, and their materials did not make irrelevant concessions to good taste. Grain elevators, factories and office buildings of Chicago, Ill., were hailed as masterpieces. By 1925 a new architectural style had been created, known as modern or as the international style. Nothing so wholly independent of the past had been found in western culture since the end of the middle ages; hence a belated consequence of the Industrial Revolution was, incongruously, the creation of a new art. This was to be seen in Peter Behrens' tube company at Diisseldorf, Ger., of 1911, his chemical factory at Hochst am Main of 1920–

24, Hans Poelzig's chemical factory at Luban, Pol., of 1912, and Auguste Perret's clothing factory in Paris, 1919, with its elegant reinforced concrete arches. These reflected a vigorous expressionism, also dramatically presented in Eric (Erich) Mendelsohn's sketches of 1914–18. S. van Ravestyn's buildings for the Dutch railways combined clarity, lightness and a sensitive handling of scale and proportion.

This appeal was felt by a few discerning spirits in the 19th century, but the strangenesses of proportion and of scale became more familiar after World War I, and the aesthetic merits of the better ones were then forcefully publicized. Merz and McClellan's power station at Dunston near Newcastle, with its steel frame and glass curtain walls, seemed infinitely preferable to Sir Giles Gilbert Scott's Battersea power station with its inappropriate monumentality.

Of the thousands of meritorious industrial buildings all over the world from the U.S.S.R. to Brazil, it is possible to mention specifically only a few. However, many badly designed industrial buildings continued to be built, emphasizing mass instead of lines and planes—buildings which affected simplicity, buildings which clung tenaciously to tradition in a misguided attempt at beauty. Factories could be seen everywhere hiding behind fancy-dress Georgian or Tudor fronts.

Metal Construction.— The use of iron instead of wood for columns and beams was developing at the end of the 18th century so that by 1801 at Salford, England, the Phillips and Lee mill, designed by the engineers Matthew Boulton and James Watt, was a seven-story, fireproof building, its interior cluttered by a forest of columns spaced 9 ft. by 14 ft. The mills at Saltaire, Eng., built in 1853 by the engineer Sir William Fairbairn, marked the increased size attainable a half century later. The top floor was a single room 550 ft. by 50 ft. without any incumbrances to interfere with the most efficient disposition of the machinery. Other buildings there had saw-tooth roofs. These structures had an enclosing envelope of load-bearing masonry walls.

The first factory built without structural masonry, with all the load-bearing parts in metal, was the Menier chocolate factory of 1871 at Noisiel, Fr. In, the meantime the Crystal palace in London of 1851 by Sir Joseph Paxton had demonstrated the advantages of metal construction, glass walls and prefabricated, standardized, mass-produced parts. From 1848, James Bogardus, in the United States, developed ingenious iron-framed structural systems.

Steel, more available after the invention of the Bessemer process, was gradually substituted for iron and permitted wider rooms and larger windows. The daring use of metal trusses for wide spans in bridges, train sheds, and exhibition halls was one of the most notable developments of 19th-century engineering; spans of 200 ft. were being regularly achieved by 1860 and of more than 300 ft. by the end of the century. Masonry and wood throughout history had not often reached spans of 80 ft. These achievements did not influence industrial building until the 20th century. Meanwhile a totally new medium, concrete combined with reinforcing tension rods of steel, was being developed. After many years of experimentation, beginning about 1860, sufficient confidence was gained so that around the turn of the century the medium was being widely applied. François Hennebique's system was used at the Marconi factory at Genoa, It. After World War I, traditional masonry systems became obsolete for large buildings (See REINFORCED CONCRETE.)

20TH-CENTURY INDUSTRIAL ARCHITECTURE

Characteristics.— There were four notable developments in industrial building after 1900: (1) extensive one-story plans; (2) the use of light roof trusses in spans of 40–80 ft.; (3) the thinning down of the enclosing masonry shroud at first to glass and for some processes its elimination altogether; and (4) the dispersion of factory sites from town to open country, partly for security but chiefly because of inexpensive land costs and increased road transport.

One-Story Plants.— Great changes in production methods made possible Albert Kahn's automobile plants. The basic idea was assembly-line production in which, by means of conveyors, exactly machined parts were added until an endless stream of automobiles would roll out of the exit. This called for enormous spaces, preferably one story. The early examples occurred in Detroit, Mich., and in Turin, It., where Matte Truco's Fiat factory (1922) had an assembly line 2 km. long. The most expensive plant of this kind up to its time was built at Willow Run, Mich., during World War II.

Reduction of Roof and Wall Supports.— Although factory windows had been generous from the beginning (Stanley mill, 1813), full development of the glass wall as something separate from the structure was slow in coming. During most of the 19th century factories were long severe blocks, three or four stories high, the top floor lit by monitors, the brick walls monotonously punctured by windows at regular intervals. Toward the end of the century the columns which had been used for intermediate supports were also applied to the exterior walls, and the wall itself reduced to a thin, sometimes transparent, curtain against the weather. The structural skeleton, whether of metal or reinforced concrete, was revealed in such buildings as those of Montgomery Ward at Chicago (1909) and the Administration building of the Fagus shoe plant (1911) by Walter Gropius and Adolph Meyer. In such buildings the proportion of glass to wall was radically shifted from one-third to nine-tenths. This could also be seen in Peter Behrens' turbine factory of 1909 in Berlin, Ger., and in the later Van Nelle tobacco factory outside Rotterdam, Neth., by J. A. Brinkman and L. C. van der Vlught. There the supporting columns were set back from the plane of the wall and the glass ran practically continuously around the building. The final step in this sequence, up to mid-20th century, was the Bluebonnet plant in Corpus Christi, Tex., where it was found that some steps in the manufacturing process did not require either curtain walls or roofs because of the climate. The machines had, in a sense, become the building.

Site Dispersion.— In the early days of the Industrial Revolution factories were perforce located on river banks and at ports. Hence the industrial "cinder belt" spread along the coasts. The use of coal for power and the growth of railways opened up new sites, and finally the efficient transmission of electric power paralleled by the development of motor vehicles made the manufacturer even more geographically independent. If materials and finished articles could be shipped by truck, and if workers could be brought considerable distances by cars and buses, factories could be built on the cheap land outside cities as low, rambling, flow-line-shaped buildings. In some cases these advantages were sufficient to justify the creation of wholly new industrial towns complete with housing, stores and civic centres. This practice was accelerated during World War II when it was realized that the congested industrial area presented too vulnerable a target to long-range bombers; that camouflage was helpless against radar and that dispersion was the best defense. The atomic energy plant at Los Alamos, N.M., was an example of this trend, stimulated by the need for both security and secrecy.

A number of industrial cities had been built during the 19th century. Sir Titus Salt's Saltaire was once a model town of this kind, as was Alfred Krupp's community at Essen, Ger. Some of these offered wholesome living conditions as in the early days of Lowell, Mass.; some were in too subservient a position to the founding company, as Bournville, Eng. (1895). These industrially sponsored communities provided working models for the government-sponsored communities of the 20th century. Industrial towns of later date include Zlin in Czechoslovakia in which factories, stores, public buildings and housing were designed by one architect on one module, for one owner. One of the most important centres from the points of view of manufacturing, health and aesthetics was the group of buildings, factories, houses and stores on the island of Kvarnholm near Stockholm, Swed., designed in the late 1920s and in the early 1930s for the Swedish co-operative societies.

Among the solutions to the industrial city following World War II were the designs by Paul Lester Weiner and José Luis Sert for mining towns in the Venezuelan mountains. These towns, Puerto Ordaz and Ciudad Piar, were communities planned for the

pedestrian. They conformed to the economic and social structure of the region.

(See also CITY PLANNING.)

The **U.S.** and Great Britain. — Comparable to the magnificent factories built in the United States by Albert Kahn and the Austin company was Sir Evan Owen William's work in England. His best-known plant, that for Messrs. Boots near Nottingham, begun about 1933, was planned around a streamlined flow system, from raw materials at one side to packaged articles at the other. In post-World War II Great Britain the Brynmawr Rubber Factory at Brynmawr (1949), by the Architect's Co-Partnership, utilized a modular, domical, thin-shell concrete construction pierced by skylights to provide admirable, economical lighting and ventilation.

The postwar development of the atomic-energy industry showed that promising architectural achievements could be expected from the new requirements in this field. Plants in the U.S. at Hanford, Wash., and Aiken, S.C.. and the Windscale factory at Sellafield in England exhibited aggressive, even if utilitarian, architectural solutions. In the U.S. the postwar addition of the tower laboratory to the Racine, Wis., Johnson Wax complex (1949; earlier buildings. 1938) by Frank Lloyd Wright disclosed interesting and unusual planning and structural features. Among the other outstanding examples, special mention should be made of the General Motors Technical centre, Warren, Mich., a gigantic complex of buildings arranged on a palatial 18th-century scale with fountains that pump more water than those of Versailles. Somewhat less ostentatious, but done with equal precision, were the Heinz laboratories in Pittsburgh, Pa., by Skidmore. Owings and Merrill (1953) and the *Oregonian* newspaper plant in Portland, Ore. (1948), by Pietro Belluschi.

Elsewhere. — In the late 1940s and early 1950s Latin America and Italy excelled in the development of reinforced concrete structures. Felix Candela in Mexico was perfecting the warped shell (Rio's warehouse, 1955; Parasina textile plant, 1953; both in Mexico, D.F.), and was developing greater refinements on the catenary and barrel vault thin shell (Mexican custom's warehouse, Mexico, D.F., 1953; P.I.S.A. factory, S. Bartolo Naucalpan, 1951). In Argentina, the S.I.T. spinning shed at Pilar, by José Delpini (1950), provided exceptionally good lighting conditions by the use of curved concrete shells supported on concrete catenary arches.

In Italy. meanwhile. Pier Luigi Nervi continued the tradition of François Hennebique and Robert Maillart and converted the flat slab into a highly articulated and expressive structure (tobacco warehouse. Bologna. 1949; Lanificio Gatti factory, Rome, 1951), and invented methods for using prefabrication techniques in concrete construction (salt warehouse, Tortona, 1952; exposition hall, Turin, 1948).

Elsewhere in Europe distinguished solutions to all sorts of industrial building problems, including workers' housing. occurred in such small, integrated countries as Finland, Denmark, the Netherlands and Switzerland. In Finland, the sawmill at Varkaus, destroyed in World War II and rebuilt by Alvar Aalto (1947), was seen to be allied in its mildly expressionist phrasing to the earlier work of Eric Mendelsohn (hat factory, Luckenwalde, Ger., 1923).

INDUSTRIAL COUNCILS. By this name are usually meant joint councils formed by employers' associations and trade unions for the discussion of industrial problems. They range from general bodies intended to cover all or most industries on a national scale, through national bodies for particular industries, to regional and local bodies either for a number of industries or for a single industry. In Great Britain the name "industrial council" was used for a joint body set up in 1911 by the government to act as a general court of reference on industrial matters and also to act as a conciliator, without compulsory powers, in any particular dispute referred to it. This body never functioned effectively, and was discarded during World War I, when special machinery for compulsory arbitration was established under the Munitions of War acts, 1915 to 1917 (*see* INDUSTRIAL COURT). The name was revived in the reports of the Whitley committee on the Relations between Employers and Employed (1917), which recommended the setting up in all organized industries of joint industrial councils for the improvement of industrial relations and, in less well-organized industries, either of interim reconstruction committees, some of which grew into industrial councils. or of trade boards, later renamed wages councils. (Only these last were given any legal power to fix wages—that is, minimum wages.) The Whitley committee further recommended that under the industrial councils there should be joint regional councils similarly constituted, and also joint works committees. The original intention of the Whitley committee was that the councils should be primarily not negotiating bodies but meeting places for the joint discussion of wider economic and industrial issues. In practice, however, the councils were successful only when they turned into negotiating agencies for settling questions of wages and conditions, chiefly in lesser industries and in the public services: most of the major industries, which had already their own systems of collective bargaining, refused to set up councils of the new type. The government at first refused to introduce the system into the civil service but had to give way; and it was also successfully applied in local government. In 1919 the joint industrial councils asked for power to make compulsory settlements on wages and conditions which could be extended by order of the minister of labour to all firms in the industries concerned; but this proposal was rejected. At the same time the National Industrial conference called by the government in 1919 to consider post-World War I industrial relations proposed the establishment of a national joint industrial council representing employers' associations and trade unions in all industries; but the government did not act on this proposal. It was revived after the general strike of 1926 by a group of employers headed by Sir Alfred Mond (later Lord Melchett), who approached the Trades Union congress on the matter. The outcome was a report recommending such a body; but this was rejected in the form proposed by the main employers' organizations, and only a much reduced plan of occasional joint consultation emerged. War, however, changed the situation: in Oct. 1939 the minister of labour called a conference of representatives of the British Employers' confederation and of the Trades Union congress, which set up a National Joint Advisory council: in May 1940 this council established a smaller Joint Consultative committee, and similar bodies were set up to advise each of the main government departments concerned with labour questions. These joint councils and committees remained in being after 1945. The joint industrial councils for particular industries also continued to function, still without any compulsory powers. The joint works committees proposed in the Whitley reports were never set up in more than a few establishments, the main development of works committees taking place outside the industries covered by industrial councils. Only the post office and the royal dockyards and arsenals developed a full system of works committees on the Whitley plan. When joint production committees in particular works were set up in large numbers in the war industries from 1940 onward. they had no connection with the Whitley plan but were related to the joint consultative bodies set up at national and regional levels in the government departments concerned with war industries. These joint production committees in many cases turned into joint consultative committees after 1945, but survived mainly in the engineering, shipbuilding, electrical and coal-mining industries, none of which had joint industrial councils on the Whitley model. The establishment of joint consultative bodies at all levels was made a statutory duty of the boards set up after 1945 to administer the nationalized industries; and in these industries the national consultative committees are meant to do the work intended by the Whitley committee to be done by the joint indus-

trial councils, as distinct from negotiations about wages and conditions, which are conducted through different channels. (See also INDUSTRIAL RELATIONS; STRIKES AND LOCKOUTS.)

INDUSTRIAL COURT. The name "industrial court" has been used with a number of different meanings, including its use to describe a proposed court of justice designed to take the place of the county court in Great Britain in dealing with legal cases arising out of conditions of employment, industrial accidents, etc., and to describe tribunals set up for similar purposes in other countries. In Great Britain a particular body, the Industrial court, was set up under the Industrial Courts act, 1919, not as a law court but as an arbitration tribunal to which industrial disputes can be referred by mutual consent of the parties. This court was a successor to the government arbitration tribunal established during World War I under the name of the Committee on Production (1915), which was reconstituted in 1918 as the Interim Court of Arbitration and a year later as the Industrial court. The government continued to appoint the members, drawn from trade unions and employers' associations; but after 1919 it had no power to refer any case to the court without the consent of the parties, though the minister of labour could, under part ii of the Industrial Courts act, refer any dispute to a specially constituted court of inquiry. Such a court of inquiry could only make a report on the circumstances of any dispute referred to it, and any recommendations for a settlement had no binding character. The Industrial court, on the other hand, issued awards on the disputes referred to it, which were formally binding on the parties, though no sanctions were provided for nonobservance.

The Industrial court was used by some industries throughout the period between World Wars I and II as a regular agency for the settlement of wage and other disputes (*e.g.,* railway shopmen) and by other industries as an occasional court of reference for particular disputes. It did not, however, establish itself as a general court of arbitration for all industries: nor was it meant to, for the Industrial Courts act allowed the minister to refer disputes, with the consent of the parties, to other forms of arbitration; *e.g.,* by *ad hoc* bodies. Cases affecting civil servants were kept outside its jurisdiction, and were referred to a special Civil Service Arbitration tribunal; and the railways (traffic grades), coal mines and certain other industries set up or were given special machinery of their own.

The court continued to operate during and after World War II; but when arbitration was made compulsory in 1940 a new body, the National Arbitration tribunal, was set up, and the minister was empowered to extend the awards of this body to cover firms not directly parties to the proceedings but engaged in the same types of work. Much of the work of the Industrial court passed over to the new tribunal.

After 1945 the wartime system of arbitration was continued, and the court and the tribunal continued to operate side by side. The minister of labour also retained his power to refer disputes to special or ad *hoc* tribunals. Strikes and lockouts were prohibited, unless a dispute had been reported to the minister and he failed to refer it within three weeks for some form of settlement. These provisions were reviewed in 1951.

(G. D. H. C.)

INDUSTRIAL DESIGN. Industrial design is, properly, design of wares produced by large-scale industry for mass distribution. Designing such wares means, first, planning their structure, operation and appearance; then planning these to fit efficient production, distribution and selling procedures. Clearly appearance is but one factor in such a complex process. Nevertheless, in consumer goods especially, appearance design is widely accepted as the principal virtue of industrial design; it is that portion of the whole least subject to rational analysis, and like craft secrets of the past, advantageous in commercial competition. On the other hand, design of equipment for production, for services and for sports is expected to demonstrate utility; but in these products too, appearance design is increasingly evident.

Practice. — Industrial design is supplied to manufacturers by three kinds of designers: staff designers, fully employed by one firm; designers under contract, who may serve several clients simultaneously, generally avoiding conflicts of interest; and free lances who sell designs, often with royalty agreements, to the best-paying manufacturer. A designer may practise these last two ways simultaneously. Free lances fit least well into big industry where gradual design development through group consultation is a usual precaution against monetary risk; staff designers often have been opposed effectively by fellow employees — salesmen and engineers; the most vigorous advances have been made by designers under contract. Some large manufacturers have raised the status and salaries of staff designers to match those enjoyed by designers under contract; outside designers are frequently called to consult with staff designers. Industrial design gains economic importance when both technological advance and commercial enterprise tend to become competitively equalized within an industry.

Development. — The first known industrial designer worked under admirable conditions: Peter Behrens (1868–1940) in 1907 was hired by the Allgemeine Elektrizitats-Gesellschaft in Germany to be their architect, industrial designer and graphic designer, in fact to give unified visible character to the numerous activities of a giant enterprise. Behrens had other clients and professional duties besides. A member of the architectural profession. Behrens applied its standards and ethics to his work as industrial designer, founding in 1907 with others an important association of designers and businessmen, the Deutscher Werkbund. As a direct result, the German and Swiss Werkbunds became well-established professional organizations of industrial designers. In the United States and Great Britain industrial designers have initiated legally recognized professional associations, nith codes of conduct, educational standards. etc. In other countries practice and organization are less advanced. In London the Royal Society of Arts designates qualifying practitioners as Royal Designers for Industry; in the U.S. both the American Society of Industrial Designers and the Industrial Designers' institute grant memberships only to those subscribing to codes and limitations of practice. In Britain the Council of Industrial Design was established in 1944 to advise on design, recommend designers, provide courses in design appreciation for trade and exhibitions for the public.

Industrial design in the U.S. began to grow after the 1929 depression, in Great Britain even later. Then and since, continual change has characterized the materials, power sources and production and distribution methods of the mass market. Everywhere industrial-design educators are seeking suitable curriculums; the national organizations mentioned furnish current information about schooling. Considering the short time, shifting situations and high stakes, professional attitudes in the English-speaking countries can be considered well advanced. Disputes among designers and with nearly related professionals nevertheless are usually resolved by economic competition rather than by appeal to vested rights, as in labour unions and many professions.

Style. — Industrial design has evolved no unified style, even for industries where handwork is minimized. There have been, however, four controversial style trends. The first is impersonality; here again Behrens established the precedent. Design for industry, whether determined by one man or by a group, shows a certain neutrality of expression. This impersonality has been acclaimed as the natural aspect of mass production and marketing, of average taste in a democratic community. It has been condemned as submission to the machine, contradictory to free individual expression and in consumer goods a cold substitute for the handicraft touch. The style has, so far, persisted. Secondly, industrial design is associated with the trend to provide an envelope for a product, leaving the inner workings to engineers. Complicated mechanical and electronic assemblies which have come into common use

require protective shells for safety, cleanliness and orderly appearance. Here industrial designers are accused of superficial embellishment, suitable in package design and fashion. But, in product design, appearance! structure and operation ideally should seem fused, an ideal perhaps too stringent. The third trend, streamlining, is widespread in industrial styling. Originally the term applied to shapes efficient in fast motion through fluids. Such shapes have typical, expressive, curved surfaces and smooth transitions between parts; speeding through their mediums these shapes may leave visible tracks, extending from their extremities like comet tails. Such teardrop shapes and speed whiskers became symbols of speed in an age fascinated by ever-faster motion. These symbols were seized by industrial designers and applied to objects intrinsically unassociated with speed; hence the criticism. But symbols frequently drift away from original significations; here designers may be merely more human than logical. The fourth trend is artificially accelerated obsolescence, that is, design that intentionally tempts owners to replace goods with new purchases more frequently than would be necessary as a result of normal wear and tear or established custom. Beginning in the field of fashion, artificial obsolescence has become something of a custom itself in industrialized countries, It operates through public opinion molded by advertising. through price changes and through improvement and change in utility as well as through appearance change provided by designers. Its assessment must be established on wide social and economic considerations, not on design values alone. Especially in automobile and large home appliance design, artificial obsolescence has aroused strong emotional and rational reactions; yet, because of its demonstrable economic effectiveness, it is used increasingly. At least in fashion, and as disposability in everything to d~ with cleanliness and health, the trend has been enthusiastically welcomed.

Industrial design is a growing force, influencing and influenced by world economy, private efficacy and enjoyment, the arts, engineering and, not least, education. It has contributed more to economic activity than to achievement in the arts; here lies its most challenging future.

Notable designers for industry in the mid-20th century include in Great Britain, Wells Coates and Gaby Schreiber; in Germany, Egon Eiermann and Wilhelm Wagenfeld; in Switzerland, Emil Guhl and Max Bill; in the U.S., Charles Eames and Harley J. Earl,

INDUSTRIAL ENGINEERING is the branch of engineering technology primarily concerned with organizing and conducting the technical aspects of manufacturing operations. As a technology, industrial engineering utilizes not only mathematics and the physical sciences but also the social sciences (including economics) and the principles of engineering analysis and synthesis. Its primary tasks are to design manufacturing systems and to predict, control and evaluate the results obtained from such systems.

Three managerial groups commonly are found within an industrial organization: (1) management, a group that makes decisions directly affecting the operating divisions; (2) industrial engineers, who make plans for controlling and evaluating work in process and who also make plans for proposed work; and (3) industrial engineering technicians, or management technicians, who gather data upon which the industrial engineers' plans are based.

In addition to the primary area of activity in manufacturing the techniques of industrial engineering have been applied successfully to a wide range of activity including medical and dental work, farming, naval operations and household work.

Industrial engineering as a separate technology evolved in the 20th century. Although large-scale systems of men, materials and equipment were used previously in such instances as the construction of the pyramids, the building of the Roman roads and aqueducts, military and naval undertakings and large-scale mining, no use was made of complex equipment on such a large scale as in 20th-century industrial enterprises. Also, the economic and social factors were not as pressing in earlier times, and the degree of integration in early group undertakings was by no means as complex.

Scientific Development.—The development of quantitative measures with which to design the integration of men, materials and equipment realistically began almost simultaneously with the industrial revolution (*q.v.*). The amount of capital inherent in the machinery which then came into being required that care be exercised in using this capital effectively. Early attempts to predict accurately the man-hours of labour required for a given task reportedly were made by Jean Perronet of France in 1760 and by Charles Babbage (*q.v.*) of England in 1820; both dealt with the manufacture of pins. Early recognition of the need to pay attention to the human factor is implicit in the comments of Robert Owen (*q.v.*) in 1813 (reported in Anne G. Shaw, *The Purpose and Practice of Motion Study*, p. 1, Columbine Press, 1952):

> If then, the care as to the state of your inanimate machines can produce such beneficial results, what may not be expected if you devote equal attention to your vital machines, which are far more wonderfully constructed? When you shall acquire a right knowledge of these, of their curious mechanism, of their self-adjusting powers; when the proper mainspring shall be applied to their varied movements,—you will become conscious of their real value, and you will readily be induced to turn your thoughts more frequently from your inanimate to your living machines.

The need for the careful design of an integrated system combining men, materials and equipment toward a given objective was given greater urgency by the introduction of interchangeable manufacture by Eli Whitney and Simeon North in the United States during the 1790s. However, a statement of a method of systematically designing a time-integrated system of men, materials and equipment was not made until 1903, by Frederick W. Taylor. Taylor began the work leading to this paper in 1881 when, at the Midvale Steel company in Philadelphia, Pa., he systematically began to measure and plan the various factors related to such tasks as shovelling raw materials and machining metals. Taylor's work gave rise to a procedure later described as time study.

An analytical method of designing human tasks (with adequate consideration of the human problems—a phase neglected at times during the years which followed) was introduced by Frank B. and Lillian M. Gilbreth in *Motion Study* (1911). The Gilbreths' work was the basis for an industrial activity variously called motion study, work simplification or methods improvement.

During the period from 1903 until about 1917 the application of industrial engineering was known as scientific management. In a study of the applications of scientific management made during the period 1911–15 by C. Bertrand Russell *(The Taylor System of Scientific Management,* A. W. Shaw Co., 1917) 172 applications were reported in the twelve states between Maine, Maryland and Illinois. The author did not claim this as a definitive total; these were all on which he could obtain information. In these 172 applications, there were factories. railroad and steamship companies, public service corporations, department stores, banks, publishing houses, building and construction companies and a professional society.

It was during this same period that a group of men called efficiency experts entered the U.S. industrial scene. Lacking the full comprehension of Taylor, Gilbreth and the men associated with these two pioneers, these so-called efficiency experts created indus-

trial unrest to such an extent that in 1917 the U.S. congress added a rider to the appropriations act outlawing the use of a basic industrial engineering technique, time study, in government establishments. (This rider was last added in 1948.) The term efficiency expert was dropped from common usage in the 1930s.

Industrial engineering during the period 1910–30 achieved its primary development in the United States and Great Britain. The first university course in industrial engineering was introduced at Pennsylvania State college in 1908 under the guidance of Hugo Diemer, and the first two graduates received their degrees in 1910. By the latter 1950s approximately 33 U.S. universities offered undergraduates degrees in this field of engineering.

During World War II, methods of creating mathematical models of management problems were introduced. Under the name "operations research," these methods quickly found their way into industrial engineering activity, improving the accuracy of the design of systems and the predictions of how they would perform.

Current practice assigns much work to the industrial engineer between the time a product is designed and the time it reaches the customer. Processes must be planned, equipment physically arranged, work scheduled, workers' jobs planned, workers trained and procedures for the control of labour, production, material, quality and cost must be designed, installed and continually improved.

Industrial engineering activity commonly appears under the names of motion study, time study, production planning and control, procedure analysis, systems design, quality control, job evaluation, wage incentives, plant layout, organization analysis, work study, etc. By 1930 it was an integral and necessary part of the industrial routine in the western countries. *(See* also INDUSTRIAL ARCHITECTURE; PSYCHOLOGY, APPLIED; JOB EVALUATION; WAGES.)

Societies.—The Society of Industrial Engineers was formed in the U.S. in 1917 but merged with the Taylor society in 1936 to form the Society for the Advancement of Management. The American Institute of Industrial Engineers was formed in 1948.

(M. E. M.)

INDUSTRIAL INJURIES: *see* INDUSTRIAL ACCIDENTS.

INDUSTRIAL INSURANCE, known in Britain as industrial assurance, is a form of life insurance intended for wage earners. In the U.S. it is usually defined as life insurance under which premiums are payable monthly or oftener and in which the face value of the policy is $2,000 or less. Much the same definition holds in Britain, where the business is transacted by friendly societies and industrial assurance companies *(see* FRIENDLY SOCIETY).

Life insurance for industrial workers and their families in the U.S. originally was supplied by co-operative societies, many of which were financially unstable; in 1875 the Prudential Friendly society (later the Prudential Insurance Company of America) was organized largely after the pattern of the Prudential Assurance Company of London, and other companies soon entered the field. The number of policies in force in the U.S. passed 100,000,000 in the early 1950s. *See* also LIFE INSURANCE.

INDUSTRIAL MANAGEMENT: *see* SCIENTIFIC MANAGEMENT.

INDUSTRIAL MEDICINE. Industrial medicine is a specialized form of medical practice directed toward the prevention of disease to the industrial worker and the treatment of those diseases and disabilities which have a causal relation to the environment of the worker. In some industries workers are exposed to health hazards which may cause disease or disability. Where an illness is the direct consequence of some factor in employment or where a diseased condition can be traced to employment as the proximate cause. it is generally regarded as an industrial disease.

Loss of production because of illness and accident of workers totals millions of dollars each year and the conservation of the working capacity of the industrially employed is of major importance in maintaining a highly productive economy.

The most commonly recognized industrial diseases are those resulting from absorption of or from contact with poisonous or deleterious substances which may be in the form of liquids, vapours, gases. solids or oils. Most of these materials are inert, some are only slightly harmful, and a few are definitely poisonous. These substances enter the body through the respiratory system, through the mouth and gastrointestinal tract or by absorption through the skin. Although the healthy individual is able to eliminate most of the harmful substances nhich enter the body, acute poisoning takes place if the material is particularly toxic. For example, carbon tetrachloride is a clear, colourless liquid used extensively as a cleaning detergent. In industry it is used as a degreaser for metal parts, as a dry-cleaning agent and as a solvent for crude rubber, tar and resin; it is also used in fire extinguishers. in insecticide sprays and in certain soaps and fumigating solutions. The chemical may cause toxic effects by inhalation of the fumes, by contact with the skin or by oral intake. Poisoning may result from a single brief exposure to a high concentration of the vapour or from repeated small exposures. Alcoholics are particularly susceptible to the poisonous effect5 of carbon tetrachloride. Permanent damage to the liver and kidneys may occur or death may result within a few days after inhaling a heavy concentration of fumes.

One of the earliest recognized industrial health hazards was the toxic effects of lead absorption. This heavy metal has a wide variety of uses in industry, and workers who handle or use lead in any of its various forms should be alert against the dangers of lead poisoning.

The United States department of labour lists more than 150 occupations where lead poisoning might occur. The inhalation of fumes containing lead and ingestion through the mouth are the main sources from uhich poisoning occurs. Smelting, refining and burning of products in which lead is an ingredient give rise to fumes. Lead is used in most paints. and acetylene cutting of metals which previously have been painted may generate toxic fumes. The melting of old storage batteries has given rise to a number of cases of lead intoxication. The other dangerous source of absorption is by ingestion which might arise from the careless use of litharge. in mixing of paints, or inhalation of fumes through the mouth where the lead mixes with the saliva and is swallowed. When lead is inhaled or enters the body through the gastrointestinal tract it is carried by the blood stream and deposited in the bones where it exerts a harmful effect on the formation of new blood cells. Some workers are particularly susceptible to the effects of lead absorption and early in the disease suffer from abdominal cramps, headaches, constipation and a persistent metallic taste in the mouth. Mercury, arsenic, chromium, benzene and radioactive paints are a few of the other recognized poisonous materials used in industry which may cause an industrial disease and disability.

By the 1950s, the great increase in industrial uses of radioactive materials, and in the number of workers exposed to them, had added another difficult problem to the practice of industrial medicine. The monitoring of such plants must be extremely rigid, because no completely satisfactory treatment of irradiation sickness had yet been discovered

Numerically, skin affections form the most prevalent type of occupational disease. More than 50% of all disease claims filed with the industrial commission in some industrial states pertain to occupational dermatitis. Workers vary considerably in a sensitiveness to skin irritants, and frequently an allergy of the individual is a dominant influence in the cause of a dermatitis Many of the skin lesions are the results of direct contact in the handling of oils. chemicals. dyes. paints, solvents, metals, rubber or plastics and produce a characteristic type of skin condition. However, there are other types of dermatitis which do not take on a distinctive appearance, and the aid of an allergist and dermatologist is needed to determine the exact cause. Various protective creams and skin lotions are available for workers who show sensitiveness to mild irritants It is seldom that occupntional dermatitis causes a permanent disability and most cases clear up when the worker is removed from contact with the irritating substance.

In some types of industry dust is generated in large quantities within confined spaces or in the general atmosphere of the workshop. Fine particles sometimes become imbedded in the terminal

air sacs of the lungs of workers and remain there. Most dusts are inert and produce no change in the lungs other than a pigmentation that is characteristic of the colour of the dust inhaled—these include cement, carbon, talc and alumina. There are some. however, which cause a reaction or irritation in the lung cells and give rise to disease and disability.

Pneumoconiosis is the inclusive term applied to describe the effect of dust in the lungs. Diseases of the lung caused by dust are also designated by specific name; *e.g.,* silicosis, caused by the inhalation of silica dust. The hazards of silicosis are recognized in such occupations as quarrying of granite, quartz and slate, glass manufacturing, sandblasting, ceramic and pottery making or any occupation where fine silica dust is present in the air breathed into the lungs of the workers. Silicosis develops after years of exposure and is recognized by characteristic X-ray findings. The inhalation of asbestos dust such as might occur in the mining of chrysolite and the manufacture of asbestos products may cause asbestosis, which resembles silicosis and is also recognized by characteristic X-ray findings. In some occupations the dust generated is a combination of silica and other matter. In anthracite mining, for example. inhalation of this dust over long periods of time may cause anthrasilicosis, sometimes known as miner's asthma. These industrial lung diseases are not always disabling. but they may become complicated by tuberculosis of the lungs which greatly increases the seriousness of the illness. In any occupation where the inhaled dust has a high silica content the worker should be protected by a filter mask or a positive pressure helmet.

Cancer, alleged to be caused by substances originating in work, is of course a problem of major importance to industrial medicine. **A** few substances such as carbon black, aniline dyes, certain coal tar and petroleum products long have been suspected as carcinogenic agents. Considerable study is being given to all factors in the industrial environment which might have some relation to the cause and prevention of cancer.

Noise in the working environment has also received particular attention as a cause of impaired hearing and lowered working efficiency. It is the function of the industrial physician to conserve the hearing of workers and institute protective measures in industry to prevent occupational deafness. This requires audiometric testing as a part of the preplacement examination as well as periodic examinations of workers exposed to hazardous noise.

Medical Service.—The passage of state workmen's compensation laws placing responsibility upon the employer for medical care of the injured or ill worker was the major influence in the development of U.S. industrial medicine. Employers realized that the prevention of disability had an actual monetary value. In addition, management found that medical service in industry made an important contribution to the health and efficiency of the individual worker, to the effectiveness of the groups of workers in a plant and even to the standards of health in the community. The Council on Industrial Health of the American Medical association endorsed the following responsibilities within the scope of industrial medical service: (1) adequate medical care for workers disabled by reason of accidents or injury caused from work; (2) proper control over industrial environment for the prevention of disease or injury in industry; and (3) education of employees on problems of health by consultation, advice or guidance.

To a major extent the pattern of medical care in industry was developed by the employers of large groups, 5,000 or more workers in a unit. In addition to the care of cornpensable accidents and illness the medical departments of large industries render in-plant treatment for minor illnesses, preplacement examinations to determine fitness of applicants for work. periodic examinations of workers in hazardous occupations, medical opinions on questions of job fitness, disability retirement, etc.; and they also advise management and labour on questions relating to health. sanitation, hygiene and preventive medicine. An important function of an industrial medical program is the education of workers on such subjects as nutrition, personal hygiene and other aspects of accident and disease prevention.

Many small plants of less than 100 workers maintain a first-aid room under the care of a registered nurse, trained in industrial nursing, and working under the direction of a part-time physician. The doctor issues the standing orders and assumes responsibility for the medical program as set up by management. By the 1950s there were more than 2,000 physicians and 10,800 registered nurses working full or part time in industrial medical service. A number of both large and small companies were providing visual care, dental care and home visits by a plant nurse as a part of the medical program. It is significant to note that many companies, through the co-operation of their medical department had come to participate in community health programs such as mass X-ray surveys. cancer detection clinics, rehabilitation clinics and venereal disease control.

A few railroads and isolated plants operate hospitals for the care of employees disabled at work, with additional facilities for the care of employees' dependents under company insurance plans. In some instances companies provide medical service to employees beyond the recognized scope of industrial medicine; for example, where X-ray and laboratory facilities are maintained in a company medical department diagnostic study of disease or injury that has no causal relation to employment will be made upon request of the employee's personal physician. Where in many instances these various services were once entirely under the control of the employer, there was a later tendency to include the provisions of these benefits in the labour-management contracts of each company.

The prime purpose of these broad medical activities is not to replace or supplant the family physician, but rather to work in co-operation with him. Any procedure that will shorten the period of lost worktime, decrease the cost to the worker for necessary medical care and maintain a closer relationship between sick employees and the company medical department is consistent with sound business practice.

Another phase of industrial medicine is the rehabilitation of injured or disabled workers, applied as soon as possible to shorten the period of disability and restore the injured workman to employment suitable to his disability. This often requires assistance of consultants representing social service, clinical psychology, vocational counselling, as well as physical and occupational therapy.

A study of absenteeism resulting from nonoccupational illness and accident made management aware of one of the important causes of lost man-hours and decreased employee earnings. In some years of the 1950s, for example, it was estimated that 400,000,000–500,000,000 man-days of work were lost because of disability as a result of accident and sickness. Of this enormous loss, only 10% was attributed to occupational causes.

Such important organizations as the National Association of Manufacturers and the Cnited States public health service became interested in the establishment of industrial medical service throughout the country.

GREAT BRITAIN

The adverse effects of employment on the physical, mental and social well-being of the individual. and through him on his family and the community. have been recorded throughout British industrial history. But the extent and seriousness of the problems did not impress the public until steam power was applied to the development of the factory system toward the end of the 18th century. Recurrent outbreaks of grave infectious diseases, including typhus. cholera and smallpox, especially among child apprentices in textile mills, compelled the attention of local justices. In Manchester the reports of the board of health. a group of physicians and leading citizens, forced the magistrates to take action not

merely to safeguard the health of child labourers but that of the whole community.

Amelioration was effected through legislation, and the Health and Morals of Apprentices act. 1802. was the first of a long series of statutes collectively named the Factory acts. The early legislation referred to cotton and woollen mills, but gradually other textile and nontextile factories and industries were brought in and benefits extended—largely indirectly—to adult male workers.

The Factory act, 1833, is noteworthy for the appointment for the first time of inspectors of factories and for the requirement that children between the ages of 9 and 13, employed in factories, should attend school for two hours each weekday. This was the beginning of compulsory education in Great Britain. Under the act of 1844 an attempt was made to remedy dirty conditions by requiring the limewashing of the interior of factory premises. Even more significant was the power given the inspectors to appoint certifying surgeons to examine persons for the "surgical certificates" of age required by the act. This was the beginning of statutory medical supervision in industry, which in considerably extended form came to prevail under the purview of the inspectors of factories and the appointed factory doctors. Meanwhile Edwin Chadwick's report, *The Sanitary Condition of the Labouring Population* (1842), had advanced the cause of public sanitation. As the apostle of the "sanitary idea" he may be regarded as the founder of the modern public health system, which is concerned with the prevention rather than merely the cure of disease and with the application of preventive measures to the group rather than to the individual.

Deaths and serious injuries, largely resulting from the use of horizontal shafting and unguarded machinery, led to the Employers' Liability act. 1880, and so to a series of workmen's compensation acts culminating in the National Insurance (Industrial Injuries) act, 1946. T. M. Legge was appointed the first medical inspector of factories in 1898. During his 28 years in this office he made outstanding contributions to industrial medicine, particularly to the control of lead poisoning and anthrax. Following the inquiries of Charles Booth in London and Seebohm Rowntree in York into the social circumstances of the working classes, and later those of the inspector general of recruiting into the defective physique of recruits during the South African War, compulsory medical inspection of schoolchildren, supplemented by the provision of school meals, was instituted in 1908. On July 15, 1912, the first National Health Insurance act came into operation and almost concurrently the new tuberculosis service.

The large number of ex-servicemen disabled in World War I focused attention on the employment problems of the disabled. Orthopaedic surgeons, notably Sir Robert Jones, concentrated on the restoration of function to injured limbs, while at Papworth village settlement P. Varrier-Jones concentrated-on the employment of tuberculous patients. The advances in the rehabilitation of all substantially handicapped persons were finally given statutory effect in the Disabled Persons (Employment) act, 1944.

From all the developments described above emerged, almost inevitably, the national health service—which included provisions for dealing with industrial injuries—on July 5, 1948

In 1937 existing factory legislation was consolidated in the Factories act, amended and extended in 1948. Whereas the earliest enactments were restricted in their application, the act as amended in 1948 was comprehensive in its general and particular provisions for health. safety and welfare and applies to many premises and outdoor places of employment not previously defined as factories. While the act itself prescribed minimum requirements and standards generally applicable to all factories (as defined), special preventive measures referring to particular processes and conditions were imposed through specific orders and regulations. The duty of enforcing the legislation constitutes the work of the inspectors of factories.

Industrial Medicine in Coal Mining.—Coal mining is the basic industry in Great Britain. Miners' work has always involved a high incidence of fatal and crippling accidents and such diseases as pneumoconiosis, nystagmus. rheumatism and a group of conditions known collectively as the "beats." Furthermore, all underground workers are subject to the adverse influences of high temperatures, humidity. bad air conditions resulting from mine gases, and the strain of arduous work in cramped conditions. It is therefore remarkable that the statutory provision of health, safety and welfare arrangements in coal mines lagged so far behind those made for factories. The hlines and Collieries act. 1842, prohibited underground work by women and young children. Thereafter, mostly as a result of the recommendations of various commissions, there was a series of acts culminating in the Coal Mines act, 1911, which with amendments, regulations and orders codified the law governing coal mining. This code of legislation imposed a duty on the employers—the National Coal board from Jan. 1, 1947—to provide and maintain in efficient order adequate supplies of materials and appliances (including ambulance transport) for first-aid and rescue work, and to train a suitable number of men in that work. At various centres specially trained full-time resident rescue brigades are maintained as mobile squads to operate in disasters resulting from explosions, flooding, fire or other causes. An important regulation permits the administration of morphia, in emergency, by certain nonmedical persons. The Miners' Welfare fund established by the Mining Industry act, 1920, marked a great advance in welfare arrangements not only for the miner but for his dependents and the local community. The act provided for a levy on all coal produced, the proceeds to be used for "purposes connected with the social well-being, recreation and conditions of living of workers in or about coal mines, and with mining education and research." The most generally acceptable innovations were pit head baths and changing houses and institutes for social recreation. Convalescent homes were established. and these became pioneer rehabilitation centres. Concurrently rehousing of miners in modern council houses was greatly advanced, while bus transport largely removed the need for them to live in isolated villages around the pit head. The growth of industrial estates provided more opportunities of employment near home for the miners' families and for aged and handicapped miners. Enforcement of mining legislation is the duty of mines inspectors under the ministry of fuel and power. The first permanent medical inspector of mines was not appointed until 1927. From 1943 additional medical inspectors were appointed to the separate mining divisions throughout the country.

Health and Welfare in Nonindustrial Employment.—Regulation of the working conditions of persons engaged in nonindustrial employment (for example, work in shops. offices, places of entertainment and domestic employment) is more difficult and correspondingly restricted. There are a number of shop acts regulating hours and conditions of work; these are enforced by the public health authority. Under the Merchant Shipping acts provision is made through the ministry of transport and civil aviation for the health and welfare of seamen. In Jan. 1956 parliament introduced a bill to safeguard the health, safety and welfare of agricultural workers.

Medical Supervision in Industry.—Medical supervision in industry is of two kinds, statutory and voluntary. Statutory supervision is limited to the enforcement of the law. In factories it is comprised in the duties of the appointed factory doctor—originally the certifying surgeon—covering the various administrative districts into which the country is divided. The work includes the examination of young persons—that is, those up to the age of 18 years—on engagement and thereafter annually until their 18th birthday; periodical examination of workers in certain prescribed dangerous processes, such as the manufacture and handling of lead compounds, chemical processes involving nitro and amino derivatives of benzene. the use of radioactive materials as in luminizing, and workers engaged in chromium plating; and, uhen requested by the inspector of factories, investigation into the circumstances attending cases of industrial accident and disease *(see* also DANGEROUS OCCUPATIONS).

Under the Coal Mines (Medical Examination) general regulations, 1952, all persons under the age of 21 years first employed, or about to be employed, in or about a coal mine were required to undergo medical examination, including X-ray examination of the chest, to ascertain their fitness for mining work. The ex-

aminations are completed by the full-time doctors of the National Coal board. The pneumoconiosis panels of the ministry of national insurance were made responsible for the initial and periodic medical examination of certain workers in the refractories, sandstone, pottery and asbestos industries. A grave defect of these examinations was that radiographic examination of the lungs was not made compulsory but entirely at the discretion of the examining doctor. Fitness examinations. specially directed to the nature of their duties, were also required for public transport drivers and for officers and men of the mercantile marine.

Voluntary Medical Services.—Whereas statutory medical services are strictly limited by prescription, the extent and scope of voluntary services are entirely at the will of the individual employer. Thus he may be satisfied that the statutory services are adequate. or he may supplement these by medical, nursing and ancillary services such as physiotherapy, dental examination and treatment, chiropody, ophthalmic examination and treatment and general welfare. The motive may be simply a general humanitarian interest in the workers; a recognition that a high incidence of accidents and disease leads to absenteeism and loss of output; or a realization that efficient production and good labour-management relations can be enhanced by regular care and attention to the fitness of the men as well as to the machines they operate.

From the beginning of the factory system the local doctor assisted during emergencies occurring at work. However, it was during the late decades of the 19th century that the increasing toll of machinery accidents made calls on his services at the factories more extensive and frequent. The employer found it expedient to retain the services of the doctor in claims for compensation in respect of injury from these accidents. Thus the doctor came to be looked upon as the employers' man and so was regarded with suspicion by the workmen and their unions. Even after the introduction of state insurance this attitude persisted, hindering the extension of private medical services in industry.

Modern Industrial Medicine.—The modern practice of industrial medicine in Great Britain probably originated during World War I when David Lloyd George formed the Health of Munition Workers' committee. This phase ended with the end of the war, but a few enlightened leaders of industry, realizing the importance of health in the factory, sought to promote this by the appointment in their organizations of full-time or part-time medical officers. The movement. however, was restricted and slow in advancing. In 1935 a group of 35 doctors employed full time in industry (almost all those so employed) formed themselves into the Association of Industrial Medical Officers, a body which by the mid-1950s had a membership of about 900, of whom 400 were full-time medical officers. A great forward impetus was given by the Factories (Medical and Welfare Services) order, 1940, which required the occupiers of factories engaged in munitions manufacture to provide, if so directed by the inspector of factories, such medical, nursing and welfare services as were deemed necessary by him for the health supervision of the workers.

During World War II the ministry of supply established medical departments in all government ordnance factories. This service not only made a great contribution to the war effort but provided tested patterns for medical units, staffing and organization suitable for adoption by industry as a whole. There was subsequently some expansion of the movement but chiefly in the large organizations. At the inception of the national health service in July 1948, the Trades Union congress strongly recommended the inclusion of an industrial health service, but chiefly for financial and administrative reasons such a plan had to be deferred. A comprehensive picture of services existing in early 1949 appears in the Report of a committee of inquiry on industrial health services (command paper 8170, H.M.S.O., London [1950]). Altogether there were 243,769 factories. and of the 4,884 factories with more than 250 workers, 2,018 (41.32%) had definite voluntary medical services, whereas only 845 (0.42%) among 202,868 factories with fewer than 26 workers had any such service. The report (generally known as the Dale report) recorded that medical services in industry do not overlap the national health service but are complementary; they must be regarded as a normal function of enlightened management and important by reason of the contribution they make both to the health of the workers and to productivity. The committee recommended that employers. individually and collectively, be encouraged to provide industrial medical services and that eventually there be some comprehensive provision (presumably through legislation) for occupational health covering not only industrial establishments of all kinds, both large and small, but also the nonindustrial occupations dealt with in the report of another committee of inquiry, Health, Welfare and Safety in Non-Industrial Employment: Hours of *Employment* of Juveniles (command paper 7664, H.M.S.O., London [1949]). Despite agitation for implementation of these recommendations there was still in the mid-1950s no prospect of a comprehensive industrial medical service. However, government pronouncements foreshadowed some statutory extension based on priorities determined by surveys of occupational conditions and hazards directed by the Industrial Health Advisory committee appointed in 1955.

Meanwhile private industry had shown a limited response toward expansion of such services. By contrast the National Coal board established a medical service in every mining district in the country, comprising 65 doctors, 300 nurses and 20.000 first-aid assistants. Similar schemes commencing about 1950 were instituted in other nationalized undertakings, such as dock, transport, electricity and gas services; and in the Atomic Energy authority.

Although the number of industrial medical officers is comparatively small, there is a much larger number of nurses (about 9,000 in the mid-1950s), of whom a large proportion was state registered; 900 hold the special certificate in industrial health.

The Industrial Medical *Officer.*—Experience proves that an efficient casualty service gains the confidence of management and workers more than any other type of service. Particularly acceptable to employers is the reduction of avoidable sickness absenteeism, and. in conjunction with other experts, the provision of a job placement system, based on job analysis, for newly engaged workmen and persons returning to work after illness or injury, thereby reducing labour wastage and turnover. For workmen temporarily or permanently handicapped for normal work by injury, disease, age or other cause, schemes for rehabilitation and resettlement are recognized as invaluable. Excellent examples of these were developed by the Austin and Vauxhall motor companies, and their methods were followed by government industrial rehabilitation units. The industrial doctor also provides advisory services to management on industrial hygiene, on conditions affecting the health of workers and on the location, cause and prevention of industrial diseases and accidents. Up to the 1550s practice tended to emphasize the clinical functions, while the environmental problems were somewhat neglected. However, this defect began to be removed along the lines of the work of P. Drinker and his associates at Harvard.

Industrial Health Services.—British industry is largely composed of small units employing only a few workers. It is recognized that these small groups could benefit from industrial medical services, but difficulty arises in organizing such a service. An experimental group service—the Slough Industrial Health service —was established in 1947. By the 1950s the service comprised a central health polyclinic, a mobile dressing station, an occupational hygiene team, a social service department and a residential rehabilitation centre. At Birmingham a special hospital was established to deal entirely with accidents, and the staff subsequently made outstanding contributions to the study of traumatic shock, the treatment of burns, the application of no-touch technique in the care of wounds and the development of dressings suitable for use under varying working conditions. Roffey Park Rehabilitation centre. Horsham, Sussex. treats patients from offices and factories suffering from subhealth, maladjustment and emotional problems. Haven Products Ltd . Glasgow, established an outstandingly successful experiment in the employment of severely handicapped workers—cardiac cases, paraplegics and amputees. The government through "Remploy" factories tried to provide sheltered work for similar cases at various industrial centres. But this project proved very expensive and not very successful in dealing with the problem. Elderly and tuberculous workers constitute two very

difficult groups for employment. Progress was made, however, and modern advances in chemotherapy and thoracic surgery gave promise that more and more tuberculous patients might be enabled to return, after treatment, to ordinary employment.

Industrial Accidents and Diseases.—An increasing number of firms in the 1950s were employing safety engineers, and in the design and construction of new machines greater emphasis was being placed on accident prevention. Among devices for use by the workman one of the most effective was the safety boot to prevent toe accidents. Despite the expansion which took place both in dangerous processes and in the use of noxious materials, the small number of authenticated cases of specific industrial disease emphasizes the effectiveness of measures of control and prevention. Pneumoconiosis, dermatitis, various cancers and the risks to health from radiation continued to present serious problems for study.

Teaching and Research.—Several of the large chemical firms maintain their own research departments. Generally, however, this work is undertaken through the various groups of the Medical Research council and the universities. Pneumoconiosis, poisonous insecticides used in agriculture, ionizing radiations and the rehabilitation of disabled workers have been main subjects of study. Departments of industrial medicine were instituted in the medical schools of the universities of Manchester and Glasgow and at King's college, Newcastle upon Tyne (Durham university), while the subject is comprised in the teaching of social medicine at most other medical schools. Postgraduate courses—full time for one year—are designed to prepare doctors for the diploma in industrial health. For state-registered nurses there is similar instruction leading to the nursing certificate in industrial health. The real need is ior continuous instruction of undergraduates by clinical teachers on the significance of occupation and fitness for work in relation to disease.

For employers and workers the Industrial Welfare society, through leaflets, a journal and special conferences, provides education in health and saiety. The Royal Society for the Prevention of Accidents undertakes similar propaganda in relation to accidents. Special problems are focused by the British Council for Rehabilitation, the British Epilepsy association and the Empire Rheumatism council. Special journals devoted to industrial medicine are the *British Journal of Industrial Medicine,* the *Transactions* of the Association of Industrial Medical Officers and the *Journal for Industrial Nurses.*

The designation industrial medicine was being replaced at mid-20th century by occupational health, signifying that this branch of medical practice is concerned with the care of all workers, whether employed in factories or not, and with the maintenance and promotion of health, physical, mental and social, in the individual and the group, as opposed merely to the treatment of patients suffering from accident or disease arising out of employment. (Aw. M.)

INDUSTRIAL RELATIONS. This is a general term for the relations of all those associated in productive work, including industry, agriculture, mining, commerce, finance, transport and other services. The main aspects are establishment of the conditions under which work shall be done, and the settlement of the ways by which the proceeds of the work are divided as dividends, salaries and wages between shareholders, employers, management and workpeople of various grades, manual, clerical and technical. Working conditions are not determined solely by direct relations between employers and workpeople: in many countries there began during the 20th century a growing participation by the state in the regulation of conditions in industry and in the prevention and settlement of industrial disputes. Because of their interest in the legislation enacted for these purposes and in the economic and social policies of governments. industrialists and trade unions undertook political as well as industrial action. The subject of industrial relations therefore includes individual relations and joint consultation between employers and workpeople at the place of work, collective relations between employers and their organizations and the trade unions, and the part played by the state in regulating these relations.

HISTORICAL DEVELOPMENT

Industrial relations as understood in modern times developed first in Great Britain, where the Industrial Revolution had its earliest impact upon relations between employers and workpeople. In mediaeval times businesses were small, contacts between masters and workmen were close and many craftsmen had opportunities to become masters, so that there was no sharp line of division between them. By contrast, many modern factories are large, capital is costly (and with minor exceptions workpeople do not share in its ownership) and few workers become employers. This separation of interests was accentuated when the limited liability system of investment in industry was introduced in the mid-19th century, thereby frequently distinguishing between the owners of a company's capital, its management and its workpeople. In these circumstances workpeople came to regard themselves as in a separate class from employers and shareholders. They recognized their weakness in individually negotiating conditions of work with employers, and they began to form trade unions to strengthen their bargaining power and to protect their interests. Until 1824 trade unions were illegal in Great Britain, and for the next half century they were handicapped by many legal restrictions, such as the laws on conspiracy and the common-law principle by which action in restraint of trade was illegal.

Not only were trade unions hampered by such laws and by the hostility of the courts, but they encountered bitter opposition from employers, many of whom refused to recognize unions and to enter into negotiation with them. In consequence, though many unions were formed, they were mostly short-lived; but from the middle of the 19th century unions of craftsmen in several British industries succeeded in establishing themselves permanently, first locally and then nationally. These unions were formed partly to secure better wages and working conditions by negotiation with employers but partly also to provide sickness and unemployment benefits and old-age pensions for their members and protection against unfair dismissal and other forms of victimization. Being relatively well-paid these skilled craftsmen could make considerable contributions for such benefits, and they were eager to retain membership in order to keep their rights to benefits. The craft unions were well administered, were generally opposed to violence and extreme demands, and were cautious in the use of the strike weapon. As a result of this moderation public opinion favoured the removal of some of the legal disabilities of the unions, and there were great improvements in their legal position during the years 1867–75.

Usually in the early stages of development the unions of skilled craftsmen did not admit unskilled workpeople to membership. The neglect and the low wages and poor conditions of work among unskilled labourers led in Great Britain to attempts to organize them into unions. This movement became significant during the last decade of the 19th century and the early years of the 20th century. In their struggle for recognition and for improved working conditions such unions adopted more aggressive policies than the craft unions. At this time also unions began to show interest in political action in the belief that working conditions could be substantially improved by legislation as well as by collective bargaining. Similar developments occurred in other countries. though often a decade or two later than in Britain. The British trade union movement gave support to the Labour party, with which it became organically associated, whereas in some other countries (*e.g.,* the United States) the unions kept free from party attachments, preferring to use their influence as pressure groups to obtain the best results possible from the political party in power.

By the beginning of the 20th century the three main methods by which workpeople can organize — the craft unions, industrial unions and general labour unions — were in use. These alternatives caused division in the movement, and conflicts arose between unions in recruiting members in disputed territories. During World War I membership of trade unions grew rapidly, while in the decade 1910–20 many employers' organizations were formed or increased their membership. In this period in most European countries national unions or federations of unions were formed, as were also industry-wide national organizations of employers, and negotiations and agreements were arranged in many industries. In Great Britain the Trades Union congress, formed in 1868, began in the 1920s to exercise a more effective co-ordinating influence on the trade union movement and to represent its views on policy to the government, and in international labour matters. In 1919 the National Confederation of Employers' Organizations (later renamed the British Employers' confederation) was formed as the counterpart of the Trades Union congress. Similar central bodies were formed in France, Belgium, Germany, Sweden, Denmark and other countries.

During the last years of the 19th century, consultation between trade unions in different countries led to the formation of international trade secretariats for each of the main industries. Early in the 20th century the International Federation of Trade Unions was formed; this brought together representatives of the central trade union organizations of many countries. In 1919 an international organization was formed of the national central bodies of employers. The establishment of the International Labour organization in the same year provided an official meeting place for representatives of the governments. employers and workpeople of more than 60 countries, and international standards of labour conditions were adopted which influenced labour legislation in many countries.

In Russia, where trade unions had hitherto been suppressed as criminal conspiracies, a trade union movement with a large membership was formed under government control after the Russian Revolution, the industrial basis of organization being adopted. In Germany in 1933 the Nazi government suppressed the trade unions and employers' organizations, and the government became responsible for the regulation of working conditions. After the collapse of the Hitler regime, however, trade unions, employers' organizations and collective bargaining mere re-established in western Germany. .In ltaly the Fascist government brought trade unions and employers' organizations under go ernment control in the corporative system in the 1920s, and this method was introduced in several other countries, including Spain and Portugal. After the fall of Benito Mussolini, the system was abandoned in Italy and freedom of association and collective bargaining were restored.

The close consultation established during World War II by governments in many countries with representatives of employers' organizations and trade unions was continued after the war. National advisory bodies in which these interests were represented were set up for consultation on industrial, economic and social matters. There was also a tendency for trade unions to recognize that higher standards of living depend upon increased production, and therefore more discussions than formerly took place with managements about ways of increasing the efficiency of industry while safeguarding the interests of the workers. High levels of employment in many countries during the early years after the end of World War II, by contrast with severe unemployment in the inter-war years, were associated with rising costs of living and increases in money rates of wages; inflation was feared by governments, employers and workers alike: and policies of wage restraint together with limitation of dividends to shareholders were sometimes voluntarily applied in critical periods.

RELATIONS AT THE WORKPLACE

The foundations of industrial relations are laid in the day-to-day association between employers, management and workpeople at the place of work. It is there that management and workpeople are in close continuous relations throughout their working lives, and a constant problem is to promote mutual understanding and co-operation between them. The basic relationship is the individual agreement or contract, whether written or not, between the employer and each worker, specifying wages and other conditions of employment. General conditions applicable to all workpeople in the undertaking may be set out in a booklet on work rules, a copy of which is given to each worker. The individual contracts must embody standards not less favourable to the worker than those in legislation applicable to the industry or in collective agreements to which the employer and the worker, through his membership in a trade union, are parties.

Employers in increasing numbers came to recognize the value of establishing and maintaining good relations with their workpeople. The adoption by management of enlightened methods of labour relations spread only slowly, though progress became more rapid during and after World War II, being marked by the establishment in increasing numbers of personnel and welfare departments with officers expert in the human problems of industry.

Personnel Management. — The main personnel functions in an undertaking are recruitment and selection, training, transfers, promotions and dismissals; conditions of employment and methods of wage payment; grievance procedures; consultations to increase productive efficiency; and welfare provisions. Though often undertaken by some member or members of management in addition to other duties, in many progressive firms they are the responsibility of the personnel department, headed by a personnel officer, which in large companies may include an employment officer, an education officer and a welfare officer. The department works in close co-operation with experts in time and movement studies and with the doctor and nursing staff in those companies which have established a factory medical service.

Minimum standards of health, safety and welfare for workpeople in factories. mines, merchant ships and other occupations, are defined by legislation, and observance is supervised by government inspectors, but many firms go far beyond the legal requirements. On the welfare side many firms help to create a sense of community by providing social clubs, sports grounds and facilities for hobbies and other forms of recreation. There are also financial schemes to provide sickness benefits and old-age pensions, while thrift is encouraged by providing favourable conditions for saving. Profit-sharing and copartnership were introduced voluntarily by firms in France, Belgium, Great Britain and other countries, but the number of workers employed by these firms is usually only about 1% to 2% of the total number of workers in the country, and the trade unions have usually shown suspicion or hostility. These social, recreational and financial schemes are generally administered by joint committees of representatives of workpeople and management, and committees similarly composed are set up for prevention of accidents.

Joint Consultation. — In small undertakings employers and workpeople are in frequent personal contact, and grievances, suggestions and other matters can be discussed informally, but in undertakings with more than 200 to 300 workpeople arrangements for consultation between representatives of the workpeople and of management have been found valuable. Consultation began by a spokesman or small deputation from the workpeople going to the employer or manager to request remedies for grievances or provision of welfare amenities, and this method became widespread. Often the shop steward or other active trade unionist is the spokesman for the workpeople of a department or shop. The need for more regular and systematic consultation led to the formation of works committees or councils. These may be of two main kinds! (1) committees consisting only of representatives of the workpeople who meet by themselves to decide what matters they shall raise with the employer; (2) joint committees of representatives of the workpeople and of management. Committees of the first kind were made compulsory by legislation in Germany, Austria, Czechoslovakia and other .European countries shortly after the end of World War I. But committees of the second kind were set up voluntarily, in Great Britain and France for example, in various firms. Joint committees were also set up voluntarily by firms in the United States (see below), where they

were often called employee representation schemes.

In undertakings and industries in which trade unionism is established, rates of wages, hours of work and other working conditions are fixed by collective agreement, and works committees should not interfere with these arrangements; but, as was indicated by the Whitley committee (appointed in Great Britain during World War I) in its report on works committees, "there are also many questions closely affecting daily life and comfort in, and the success of, the business, and affecting in no small degree efficiency of working, which are peculiar to the individual workshop or factory." These are the questions which can usefully provide a basis for joint consultation in works committees. The Whitley committee urged that such committees should be set up with the co-operation of employers' organizations and trade unions.

In some works committees the representatives of the workpeople consist entirely of individuals elected by ballot, secret or otherwise, by occupations or departments. Some are composed entirely of members of trade unions so elected. In large undertakings there is often a general committee comprising delegates from departmental committees. It is usual for meetings to be allowed during working hours and for wages to be paid for time so lost. Among subjects which are dealt with by works committees are welfare, benevolent, holiday (vacation) and loan funds, pension schemes, sports and recreation, accident prevention, share-purchase schemes. piece-price fixing and education. In some cases dismissals of individuals or, in case of slackness of business, of numbers of individuals are subject to review by works committees. This is greatly valued as it gives individuals greater security of employment and protection against victimization. At a time of depression prior consultation enables plans for the sharing of work or regularization of employment to be discussed. Methods of production, regularity of output and prevention of waste are other matters dealt with by committees. They are in some cases informed regularly of the state of business.

During and after World War II many firms in Great Britain and other countries set up joint production committees for consultation between management and workpeople on ways of increasing productive efficiency. In some works such committees exist alongside works councils. This seemed desirable where works'councils had the habit of dealing mainly with grievances and welfare and of giving little attention to productive efficiency; representatives with a different outlook were found to be more effective on questions of production.

The works council system in Germany differs from that in most other countries not only in being compulsory but in providing that on specified matters councils have the right of codetermination. This was accorded to them by an act passed in 1952. If, on specified issues, the employer and the works council disagree, the matter goes to mediation or arbitration by a mediation committee or by the labour court of the district. The act also provided for the setting up of economic committees in undertakings with more than 100 workpeople, consisting of from four to eight members employed in the undertaking, half of them being nominated by the works council and half by the employer, at least one of them being a member of the works council. The act further required that one-third of the members of the supervisory board (*Aufsichtrat*) of joint stock and limited liability companies shall be representatives of the workers elected by them.

The success of works councils and joint production committees depends upon a genuine belief by management and workpeople in the value of joint consultation. Where this is inadequate, apathy results and discussions are limited to trivial matters.

COLLECTIVE RELATIONS

Employers' Organizations. — The main reasons for the formation of employers' organizations were to ensure greater strength in dealing with claims by the unions and especially to deny to unions the opportunity of using piecemeal tactics with demands and pressure exerted successively on individual employers. The formation of employers' organizations and the development of collective bargaining between them and the unions proved more widespread in Great Britain, the countries of western Europe and in Australia and New Zealand than in the United States, where working conditions were more often determined by agreements between unions and individual companies. In Great Britain recognition of trade unions by individual employers and employers' organizations was almost universal at mid-20th century.

Collective Bargaining. — In its widest sense collective bargaining is negotiation between an employer or group of employers and a group of workpeople to reach agreement on working conditions. If negotiations are between an employer and a group of his own workpeople the dependence of the workpeople on the employer for their jobs weakens their bargaining power, and therefore collective bargaining is more usually understood to be negotiation between one or more trade unions and an employer or group or association of employers. Trade union organization gives the workpeople greater bargaining strength, providing means for the expert presentation of demands by skilled officials not dependent on the employers for their jobs. Further, a union has funds and means of obtaining information outside any one undertaking and can secure for the workpeople at any one firm the support of their fellows in other firms.

If negotiations result in an agreement the parties mutually undertake to apply'its provisions. In some countries, Great Britain for example, collective agreements are not legally binding but depend fbr their application on the good will of the signatories. In other countries, however, agreements may be registered with a government department or other authority, when their terms become binding. This system operates, for example. in France and Germany, whereas in Australia and New Zealand collective agreements registered with the arbitration courts have the binding force of arbitration awards. Collective agreements have effect beyond the membership of the signatory organizations as their provisions influence the terms of employment of nonmembers. Arrangements are made in some countries for the government or an arbitration court to extend to a whole industry the provisions of agreements reached between employers' organizations and trade unions representative of a large part of the industry. This extension of agreements is known as the "common rule" and prevents the agreements from being undermined by outsiders adopting lower labour standards. Agreements may be local, regional or national according to the range of membership of the negotiating parties. In small countries national agreements are more frequent than in big countries with widely separated undertakings.

National agreements often include procedure and general matters such as length of working hours, relation of piece rates to time rates, overtime and night-shift rates of payment, general adjustments of wages, sliding scales, holidays, apprentice questions, training and employment of workers. Detailed conditions of wages are sometimes settled nationally but it is more usual for them to be settled locally, the national organizations confining themselves to general changes and to acting as the co-ordinating and appeal authority. Thus the conditions in industries which are carried on in many parts of a country are adjusted both to local circumstances and to the required degree of uniformity. Wage-rates fixed by national bodies are often graded according to area. The existence of different types of unions with conflicting interests adds to the complexity of collective bargaining. The craft unions, for example, seek to obtain, as far as possible, similar conditions in each industry in which their members are employed. Where there are several unions having members in an industry there are sometimes federations of unions which act as a unit for negotiating purposes.

The adjustment of wage rates to changing conditions is a central problem in collective negotiations, and account is taken of the capacity of the industry to pay, changes in the cost of living and the relation between wages in different occupations and industries, unions in one industry often demanding a raise in wages because of increases in other industries. The cost of living is almost always a factor in wage negotiations, but in some industries agreements provide that wages be adjusted periodically by a sliding scale based on the cost of living index; the basic wage, however, is also changed at intervals to allow for other factors. In Great Britain the system has the advantage of reducing the frequency of

wage negotiations. Another form of sliding scale adjustment of wages is that based on the selling price of the product of an industry, this being for some industries a rough measure of capacity to pay. For many years collective agreements in the British iron and steel industry provided for sliding scales of wages based on the selling price of rails, bars and other representative products. In coal mining, wages in some districts were adjusted by sliding scales to changes in the selling price of coal, but in the period between World Wars I and II they were varied at intervals of two or three months according to the net proceeds of the industry, taking into account not only the selling price of coal but the quantity sold and also wages and other costs. In New Zealand the wages of sheep shearers have been adjusted by sliding scale based on the export price of wool, and in Malaya the wages of rubber plantation workers have been adjusted to changes in the price of rubber.

The enormous number of questions which arise is shown by the complexity and length of collective agreements. The constant association, however, of representative persons of experience, responsibility and negotiating ability on both sides increases the chance of reaching amicable settlements of the most difficult problems, and this, together with the adaptability and freedom from rigidity of the system, causes it to be recognized as the main means of regulating working conditions.

Collective bargaining demands for its efficient operation the possession by representatives of adequate authority to bind their members. Although some union executives have considerable authority. it is often necessary to take the opinion of the members either by a ballot or through a delegate conference before agreements are made. The effectiveness of a voluntary agreement depends upon its terms being in general accord with the views of those who are bound by it. In practice the recommendations of leaders carry great weight.

Collective agreements usually provide for a settled procedure for dealing with disputes in order to obviate stoppages of work. A common procedure is for the matter to be discussed first within the establishment. Failing settlement it may then be discussed between the local employers' association and representatives of the union, and then by the national executives, work continuing in the meantime. When action is taken in breach of an agreement, the organization whose members are at fault is expected to restore the status quo pending discussion of the matter in dispute. Stoppages without the sanction of an organization are called unofficial.

The rules of many unions provide that a strike shall not be called unless a ballot of members shows a two-thirds or three-quarters majority in favour. Many collective agreements provide that, if negotiations fail, the differences shall be referred to conciliation boards or in the last resort to arbitration machinery set up by the parties or to state arbitration tribunals. Agreements usually require that there shall be no stoppage of work during these proceedings.

STATE INTERVENTION

State intervention varies according to a nation's political doctrine, traditions and economic and social conditions. In the Soviet Union and other Communist countries the centralized political, economic and social controls involve government intervention in all aspects of industrial relations. Less complete but still widespread is the regulation of industrial relations by the governments of Fascist countries. The policy in many other countries is for governments to leave employers, workpeople and their organizations free to regulate their own relations, and to intervene only when they fail to do this satisfactorily. The countries in which this policy is applied in varying degree include Great Britain and other countries of western Europe, Canada. India, Pakistan. Australia and New Zealand. In most of these countries intervention was slight throughout the 19th century, but it increased substantially during the 20th century.

Intervention or participation by the state is undertaken to promote the health, safety and welfare of workpeople, to define the legal relations between employers and norkpeople and the legal status and functions of employers' organizations and trade unions, to facilitate the settlement of disputes, to provide for the regulation of wages and working conditions where this is not done effectively by the parties themselves. and to take a direct part in industrial relations as the employer of persons in the public services and in nationalized industries. In many countries the state also maintains consultative relations with employers' organizations and trade unions on questions of economic, industrial and social policy which affect their interests.

Conciliation and Arbitration. — In every country conciliation and arbitration are undertaken by the state, though with many variations. The main differences are between voluntary and compulsory systems. Compulsory arbitration is limited in some countries to public utilities and other industries in which stoppages would seriously affect the public interest. A further distinction is between systems of compulsory arbitration with awards binding on the parties and with prohibition of strikes and lockouts, and those under which the parties are free to reject awards and can engage in a strike or lockout after the end of the arbitration without incurring legal penalties. Conciliation is usually compulsory in countries which have compulsory arbitration, notably in Germany, Sweden, Australia, New Zealand, and in Venezuela and some other countries of Latin America. In Australia the parties in disputes must have made full use of the processes of conciliation before compulsory arbitration is applied.

Conciliation officers and arbitration tribunals may be appointed specially for each dispute, or a permanent system with full-time conciliators and arbitrators may be set up to whom successive disputes are referred. The latter has the advantage of continuity, and principles are evolved which make the settlement of disputes easier and may influence the parties themselves in their direct negotiations. Most governments appoint conciliation or industrial relations officials to assist in the settlement of disputes before they become acute. If the parties fail to agree, the next stage is usually for the dispute to go through a more formal conciliation procedure with equal numbers oi representatives from the two sides meeting under an impartial chairman who may be either a full-time conciliation commissioner or a person selected from a panel established by the government. If conciliation fails the dispute may go to arbitration either by a single arbitrator, or by a tribunal, which may consist of impartial persons only, usually three in number, or may include also assessors acquainted with the standpoints of employers and of workpeople. These assessors are not, however, from the industry involved in the dispute. Although arbitration has been highly successful in many countries. there are practical difficulties. One is to satisfy the parties in dispute that the tribunals are impartial, a difficulty which is greatest in small and especially underdeveloped industries where members of tribunals are often accused of having an interest in favouring one side or the other. Then if awards are binding there is the difficulty of enforcing awards by penalties where large numbers of workpeople are involved. Moreover, the fact that either side can force the other to arbitration tends to make direct negotiations and conciliation procedures less effective.

British policy is based on acceptance of the principle of regulation of working conditions by collective agreements and of minimum government intervention. Also, the government does not refer a dispute to arbitration unless agreed arrangements within the industry for the settlement of disputes have been fully used. Provision is made for voluntary conciliation and arbitration by the Conciliation act, 1896. Conciliators or arbitrators are appointed separately for each dispute, there is no continuity of tribunals and arbitration takes place only with the consent of both parties. In 1919 the Industrial Courts act, based on recommendations of the Whitley committee. provided for the setting up of a standing or permanent industrial court. This ensured continuity, and arbitration became voluntary (the consent of both parties being required) and awards were not made binding on the parties. The act, however, empowered the minister of labour and national service to set up a court of inquiry on his own initiative in any dispute. A court may consist of one or several members, and it can require any persons who appear to have relevant information to furnish such information and, where necessary, to

give evidence on oath, though there is no penalty for failure to do so. The value of these courts of inquiry is that their recommendations based on a thorough impartial examination of the facts are likely to lead to settlements. Their recommendations have no binding force but only rarely have the parties failed to reach agreement on their basis. The governments of many other countries have similar powers to use this method of courts of inquiry.

Compulsory arbitration. with binding awards and with strikes and lockouts illegal. was applied during both World Wars I and II in Great Britain and in many other countries. After World War II, with the agreement of the British Employers' confederation and the Trades Union congress, this system mas continued in Great Britain during the early years of postwar reconstruction. but in 1951 the general council of the Trades Union congress asked for modifications, particularly for removal of the provision making strikes illegal. The principle of compulsory arbitration was retained, but awards of the Industrial Disputes tribunal, which succeeded the National Arbitration tribunal, were not binding, and strikes and lockouts ceased to be illegal.

Regulation of Wages.—A main purpose of state intervention in wage regulation is to fix minimum rates in industries in which organization among workpeople and employers is inadequate for regulating wages by collective agreements and where in consequence wages in some undertakings are unduly low. In France, Germany, Norway and other European countries the earliest intervention was limited to home workers, while in Ontario and other provinces in Canada it was restricted to women and young persons. In Great Britain and in Victoria, Tasmania and other Australian states these restrictions to home workers or to women and young persons had not been applied by the mid-1950s.

The establishment of a wage board or council for each industry, or a central wage commission covering a group of industries are the most widely adopted methods for fixing statutorily enforceable minimum rates. In Great Britain, under legislation in 1909 and 1918, a trade board was set up in each of a number of separate branches of industry. This method was continued by the Wage Councils act, 1945, under which about 76 councils recommend minimum rates for the various grades of workers in more than 50 branches of industry employing nearly 2,000,000 workpeople; these rates are applied by orders of the minister of labour and national service. Each council consists of three impartial members together with representatives of employers and workpeople in the industry. A similar system applies to British agriculture, the road haulage industry and the catering trades.

In countries where a central wage commission is used it consists of three or five impartial members together with members representing equally the interests of employers and of workpeople, and the commission is often assisted by a committee in each of the industries in which wages are fixed, the committees having one or more impartial members and representatives from the industry. In a few countries, France and the United States for example, minimum rates of general application are announced periodically by the government, and in Australia and New Zealand the arbitration courts, in addition to dealing with disputes! periodically fix basic wages that apply to all industries. Wages fixed by statutory bodies are enforceable by law, and fines and other penalties can be imposed for failure to observe them. Also, statutory rates apply to all firms and workpeople in a defined industry, whereas rates fixed by collective agreements apply only to those firms which are parties to the agreements.

UNITED STATES

The long-term drift in the evolution of labour-management relations in the United States gave way in the mid-1930s to a cataclysmic change. The labour-management problem was catapulted to a peak of public concern which, in the past, it had reached only on brief occasions. Since the mid-1930s trade unions have been an important feature of U.S. society. The growing strength of the unions carried with it many significant consequences. Enhancement of the worker's sense of dignity and of psychological well-being and the elevation of his role in the community at large was made possible by according to him increased participation in the decision-making processes which affect the terms and conditions of his employment, by affording him increased job security, by providing him with an arsenal for mutual protection in his attempts to mitigate some of the abuses of industrial competition or to counteract some of the tyrannies which inhered in the use of employer weapons such as the black list, the lockout, the yellow-dog contract, the company union, labour espionage and the injunction.

But growing strength meant, too, that the consequences of the policies and practices of organized labour could have more than localized impact. Labour-management relations assumed a more intense and momentous aspect when unrest in the industrial relations arena could affect the health and welfare of the country's population or the operations of an entire industry; when success or failure in collective bargaining could reflect upon the entire economy's industrial output, technical progress or economic stability; when growing bureaucratization accompanying growing numbers could threaten internal union democracy; or when "accommodation" between labour and industry could mean collusion against the consuming public. The increasing importance of organized labour as a factor making for progressive change in U.S. society was accompanied, thus, by a host of issues real and alleged, which focused a variety of attempts at public control on the practices and procedures in labour-management relations. Throughout the pageantry of violence and battle and the turbulence of shifts in the balance of power and prestige there has none the less been emerging an unmistakable ray of reason to illuminate the path toward peaceful mutual survival. The many thousands of contracts negotiated without pitched conflict and the innumerable grievances adjusted peacefully and lawfully attest to the steady growth of mutual acceptance by two parties grown strong and well organized.

In attempting to understand the history of the growth of trade unionism and collective bargaining, the ideological orientations of labour and of management, the shifts and varieties in the structural arrangements and substantive scope of collective bargaining, the role of government in industrial relations and the consequences and issues emanating from this growth and development, it should be kept in mind that the evolution of industrial relations in the United States occurred against an environmental backdrop which has been in many respects unique. The strong tradition of political democracy and the achievement in the early 19th century of practically universal manhood suffrage helped to stave off the early radical tendencies which are inherent in a labour movement which has yet to achieve civil and political rights for its adherents. The pervasiveness of the "Protestant ethic," the emphasis on independence

and equality, the relative abundance of economic resources and o p portunity and the early fluidity and mobility among social and economic classes all imparted a flavour of individualism which helps to explain the belated appearance of social legislation and the more than a century of slow-gaited growth. This growth of the labour-movement was slowed by the fierce hostility of the individualistic employer, by the disinclination to join a union of the individualistic worker oriented to the chance to advance, and by the repressive interpretations of a judiciary which carried the individualistic strain to great lengths.

The alternations of prosperity and depression which marked the dynamics of industrial evolution in the United States were accompanied by an ebb and flow of proposed social panaceas and radical reform movements, but the remarkably successful progress of industrial productivity and the abundance of material goods and services which U.S. capitalism produced certainly helped to sustain the basically conservative, limited-ends, business-union credo which still characterized dominant sectors of organized labour in the early 1950s.

Growth and Extent of Trade Unionism.—Trade unionism grew from the several thousand members of its sporadic beginnings at the end of the 18th century to a force numbering approximately 15,000,000 in 1953. Trade union membership pursued a long and slow secular climb up past the 5,000,000 mark in 1920, but declined to less than 3,000,000 in 1933, largely as a result of the great depression. This membership trough was followed by a steep climb to 15,000,000 members by the end of World War II, and membership was stabilized at about that level in the postwar years.

Superimposed on these secular tendencies were numerous fluctuations around this upward trend. Before the Civil War there was no continuously functioning trade union movement. A series of revivals and collapses of organized trade unionism, generally of a craft nature, local in scope, restricted to relatively skilled artisans and emphasizing narrow economic objectives, alternated with an ebb and flow of a variety of political movements and social reconstruction programs during the pre-Civil War years. The peak in trade union membership for this period came in 1836 when 300,000 workers were members of trade unions.

The second half of the 19th century, despite the nationalization of the trade union movement, continued to witness these economic-political cycles. By 1872 the previous peak of 300,000 members had once again been attained only to be cut to no more than 50,000 under the impact of the 1873–79 depression. This peak was regained by 1884. The spectacular heights reached by the polyglot Knights of Labor with a membership of 700,000 in 1886 (achieved after remarkably successful strikes against the railroads) were surrendered almost as precipitously as they had been scaled. With the firm establishment in 1886 of the American Federation of Labor with its business union creed, total union membership began to expand steadily and multiplied fourfold, from about 500,000 in 1897 to more than 2,000,000 in 1904 (of which about 80% was affiliated with the new federation), and increased by another 700,000 in the following decade. Under the impact of World War I, membership spurted past the 5,000,000 mark by 1920, but the decade of the 1920s reversed the trend and the ensuing depression accentuated the decline. By 1933 trade union membership had declined to 3,000,000.

Two observations concerning the areas of employment included in this development may especially be noted. First, the fluctuations in membership from the 1890s through 1933 (with the exception of the World War I period) touched only a relatively few categories of industrial employment, particularly coal mining, the railroads, the building trades, and printing. With the exception of the miners, the vast majority of unskilled and semiskilled workers were still unorganized. Second, even the peak membership figure attained (1920) represented organization of less than 20% of the country's nonagricultural employees. In 1930, as in 1910, trade union membership accounted for only 10% of nonagricultural employment.

Social mobility, the pre-1842 application of the conspiracy doctrine to combat trade unions, the post-1842 judicial interpretations which stripped labour of many of its tactics, the recurrence of business depressions, the internecine clashes of ideology, the hostility of employers (whether manifested in the violence of a Ludlow massacre or in the open-shop drives and welfare capitalism plans of the 1920s), the divisions made possible by a stream of immigrants drawn from diverse backgrounds, the reluctance of leaders of labour to adapt trade union structure and policy to the dynamics of a rapidly changing industrial technology, and the continuing rise in real earnings and adverse popular sentiment were all factors in the retardation of trade union growth in that period.

Other factors, however, such as increasing mechanization, increasing concentration of industry accompanied by a loss of individual bargaining power, restriction of immigration and reduced social fluidity, were pressing for an eventual growth of large-scale industrial unionism. These factors were abetted by the New Deal environment of the 1930s in reversing the preceding decline and in stimulating the rapid resurgence of the labour movement. Favourable government legislation, a more hospitable judicial attitude and popular sympathy, all reflecting a disposition to permit the power of labour to grow to match that of business, and the birth of a new militance in labour's ranks pushed total membership from the 3,000,000 mark of 1933 to almost 9,000,000 in 1940 and to the 15,000,000 mark by 1946. As the growth of bona fide unions proceeded, the number of company unions declined. In 1929 less than one-fifth of union members were affiliated with industrial or quasi-industrial unions, by 1950 more than half were.

The extent of this new growth is reflected in the expansion of the areas of employment embraced by organized labour during the early 1950s. Between 80% and 100% of the workers employed in 22 major manufacturing industries (*e.g.*, steel, electrical machinery, meat packing, aluminum) and in 14 nonmanufacturing industries (*e.g.*, coal mining, building trades, maritime transportation, trucking) were covered by collective agreements. The number of unorganized workers, however, still far exceeded the number of trade union members. Barely one-third of all workers gainfully occupied in nonagricultural establishments were organized. The bulk of white collar workers, farm labourers and government employees and labour in the south generally were still unorganized. Total trade union membership was not concentrated in a single unified federation but split between the American Federation of Labor (with about 8,000,000 members), the Congress of Industrial Organizations (5,000,000) and several unaffiliated independent unions (2,000,000).

Ideologies of Labour and Management.—Although U.S. working class organization never constituted a unitary phenomenon motivated by a single ideology, the basic creed formulated in the days of the founding of the A.F. of L. continued dominant and largely unchanged. There were several short-lived rival ideologies as, for example, that of the Industrial Workers of the World, a few temporary abberations such as support of the Robert LaFollette presidential candidacy in 1924, and some changes in emphasis. But the core of the credo survived intact.

Before 1890, U.S. labour, encouraged by middle-class intellectual advisers, had (especially in periods of depression) advocated a variety of utopian programs and political panaceas which sought to implement the workers' faith in social, political and economic equality. Many of the pressures for political and social reform which were brought to bear upon government between 1827 and 1833 bore fruit in subsequent years. Free public education, mechanics' lien laws, reforms in the compulsory militia service regulations and abolition of imprisonment for debt were all achieved. But later interests in co-operatives, in self-governing workshops and in communistic colonies offered no satisfactory response to the challenge of an emerging industrialization.

Samuel Gompers, first president of the A.F. of L., read the lessons of these failing political panaceas and faltering utopian schemes very clearly, and his substitute program for the workingman well appraised the tone and temper of labour. After Gompers' ascendance to leadership, labour was motivated by a pragmatic, gradualist, "no ultimate ends," "here and now" philosophy seeking, within the framework of a capitalist society, to advance the interests of particular groups of workers organized in trade unions. It placed primary emphasis on economic methods such as collective

bargaining and the trade agreement rather than upon independent political action or co-operatives in making "today better than yesterday and tomorrow better than today."

For Gompers the natural unit of organization was the craft; later the growth of mass production industries called forth a shift in emphasis which made the industry as important a jurisdictional unit as the craft. The fear of hostile government and of unfavourable judicial attitudes evoked reliance on voluntarism or self-help; but the New Deal dispelled to some extent this fear of state intervention and left labour relying more than in the past upon government aid and legal enactment. The later expansion of political activity with the formation of the Political Action committee (C.I.O.) and the Labor's League for Political Education (A.F. of L.) indicated less skepticism about utilizing political action but still did not supplant the established policy of "rewarding friends and punishing enemies."

At mid-20th century the United States had only one significant form of working class organization — the trade union — and the important business of the day for the unions was collective bargaining within a capitalist framework. Labour's ideology, matured and grown with exigencies of internal and external changes, continued to define trade unionism as a bulwark of the fundamental institutional structure of the United States rather than as a revolutionary menace.

The strong Puritan ethic and the tenacious entrepreneurial adherence to a *laissez faire* philosophy led to an unrelenting and vigorous employer opposition to trade unionism which generally prevailed up to the decade of the 1940s. Employer techniques designed to quell the trade union threat ranged from crude violence to a velvet-gloved paternalism, from enlisting government troops to the use of public relations experts. After 1933 trade unionism and collective bargaining were gradually accepted by most employers as a permanent feature in labour-management relations. The sharp decline in the number of strikes for union recognition as a percentage of total strikes (from almost 60% in 1937 to less than 15% in 1951) was only one of several quantifiable affirmations of this acceptance. The transition toward such managerial acceptance was facilitated by government's externally imposed stimulus, but the gradual recognition of benefits deriving from collective bargaining further abetted this transition although there were still a number of exceptions to this conversion to collective bargaining during the early 1950s.

Despite labour's general acceptance of capitalism and management's increasing recognition of the collective bargaining process, there continued to persist separate union and business ideological conceptions of "workable" labour-management relationships which, taken together, might in fact not be consistent with permanent workability at all. Management, for example, might conceive of industrial relations as a matter relating to its own workers; might see the primary objective of workeble industrial relations as the enhancement of efficient and profitable operation of the enterprise; might feel that the capacity to exercise managerial responsibilities must be left unimpaired; and might expect unions to behave in "businesslike" or "responsible" fashion.

But these managerial guideposts might not be fully consistent with the simultaneous sovereignty and survival demands of the trade union. The union might be unwilling to limit its scope to issues which reflect only the particular problems of a particular company, holding that it must consider also the welfare of its entire membership and the security and strength of the union, Moreover, although few union leaders seek to "run the business," unions are employer-discretion regulators and the heart of unionism lies in the standard rule. Unionism inevitably imposes rules on management and reduces worker competition.

Such divergent orientations are giving way to revised and expanded conceptions of collective bargaining which permit mutual sovereignty, mutual security and mutual survival.

Role of Government. — The role of government in U.S. industrial relations may be described in terms of four general periods: ineffective legal repression, reluctant tolerance, encouraging support, and increasing control of trade unions and collective bargaining. Until the *Commonwealth* v. *Hunt* decision in Massachusetts in 1842, judicial common law doctrine held that trade unions were in restraint of trade and therefore illegal, although, as noted previously, they did exist. Between 1842 and the 1930s collective bargaining was given minimum legal recognition. The ability and occasional willingness of the courts to vitiate unionism's means of self-help (organization, the strike, picketing, the boycott) by declaring either the ends sought or the means utilized to be illegal coupled with the use of the injunction, damage suits, criminal prosecutions and obstructive presidential intervention stood as obstacles in the path of growth. The supreme court sustained in 1930 the constitutionality of the Railway Labor act of 1926 which enumerated a series of unfair practices as interfering with bona fide collective bargaining and established dispute-settlement machinery in the railroad industry, and this, along with the passage of the Norris-LaGuardia anti-injunction act by congress in 1932, presaged a reversal of earlier policy.

The National Industrial Recovery act in 1933 (invalidated by the supreme court in 1935) and the National Labor Relations (Wagner) act in 1935 (sustained in the Jones and Laughlin decision in 1937) were turning points in U.S. industrial relations history. They established, as a matter of national policy, that strong independent trade unions were desirable; that workers should be encouraged "to organize and bargain collectively through representatives of their own choosing"; and that employers should be prevented from interfering with such organization. Accompanying these legislative props to a hitherto weak trade unionism, the Social Security act of 1935 and the Fair Labor Standards act of 1938 improved and extended social security and protective minimum wage and hour legislation. This was the high water mark in governmental recognition of and assistance to organized labour in the United States. It marked the shift to the federal government of concern with the conduct of labour-management relations in industries in "interstate commerce," a boundary most broadly interpreted.

The Labor Management Relations (Taft-Hartley) act of 1947 marked a new trend toward more direct government intervention in and restriction of the collective bargaining process. Deriving from the efforts of those who had opposed the philosophy of the Wagner act and from public concern over the wave of strikes of the prior decade which reached a peak in 1946 when a total of 113,000,000 man-days lost due to work stoppages posted an all-time high, the Taft-Hartley act sought, by a variety of controls, once again to "redress" the balance of power among a now grown labour movement, the individual employee, the employer and the government. The provisions of the act (which restricted the collective bargaining area, controlled the internal affairs of trade unions, made illegal a number of union techniques, provided for direct government intervention in disputes threatening the public welfare, and limited the degree of trade union institutional security which legally could be obtained) made government a participant in industrial relations as well as an umpire.

Structural Scope of Collective Bargaining. — No standard structural caste developed in U.S. unionism. Historically, organization by a single union ranged from inclusion of members of a single craft to attempted coverage of "all productive labour." Structural forms also followed the lines set forth by coverage of amalgamated crafts, single or related companies, parts of industries, whole industries or related industries. Geographically, units (or amalgamations of individual units) embraced city-wide. statewide and regional areas and the nation itself. The distribution of power among locals, national unions and federations of national unions also varied greatly from authoritative influence residing in an all-powerful federation, to virtual autonomy for centralized national unions linked in a relatively weak federation, to great independence for the locals in a national union. This diversity in structural form persisted in the early 1950s, although the trend was toward a reduction in the number of separate national unions, an expansion of industrial (relative to craft) unions and a centralization of power in strong, relatively autonomous national unions. In 1951, of 172 national unions, 10 were craft (6%), 30 industrial (17%) and 132 intermediate between these classifications (77%) as compared with the 28 craft (21%), 5 industrial (4%) and 100

intermediate (75%) national unions which existed in 1915.

Because structure is intimately related to function and policy, diversities and shifts in structural form mirrored the diversities and shifts in the ideological, social, industrial and political environments with which union organizations were confronted. The Knights of Labor, for example, with its emphasis on "one big union," reflected the great social mobility of its era and the absence of a working class permanently delineated by craft or industry; the early craft emphasis of the American Federation of Labor, on the other hand, reflected the development of specialized groups of skilled workers surrounded by a heterogeneous mass of semiskilled and unskilled workers.

Changes in the industrial environment also resulted in structural adaptations: increasing concentration of industry encouraged combination and centralization in labour organization; secular changes in technology, mechanization and division of labour reduced the average degree of skill required and helped encourage the shift from local craft unions to national industrial unions. The nature of employment (whether casual or steady) in the industry, the stage of an industry's development or decline, the ease of substituting capital for labour, the nature of the product market and the proportion of total production costs which labour constitutes helped determine the preference for one structural form rather than another. The standard structural form, however, came to be a multicraft or industrial union which centralizes substantial authority in the hands of its national officers and which is affiliated in a loose multiunion federation.

The structural hierarchy within both the C.I.O. and the A.F. of L. runs from the local union to the national to the federation. The locals of the A.F. of L. unions generally exercise greater autonomy than do those of C.I.O. unions. National unions, perhaps because of the size of the country and the lack of class consciousness, are almost completely autonomous. The national federations are still "ropes of sand" limited in authority to a variety of activities (such as research, education and determination of jurisdictional boundaries) which do not usually restrain the autonomy of the affiliated national unions. Attempts at organic unity between the A.F. of L. and C.I.O., faced with severe jurisdictional and vested interest hazards: proved unsuccessful.

Common to all unions, despite the variations in form, is their essential political nature. Trade unions are more political than economic institutions. Trade union structure and policy are shaped by the union's concentration on maintaining and extending its institutional life, and by the union leader's attempt to balance and reconcile the variety of conflicting pressures imposed upon him by his own rank and file, the employers, rival leaders, internal factions, the state and the consumer. This aim of achieving institutional and leadership security is the most formidable moulder of trade union structure, policy, function and internal government. If trade unions attempt to maximize anything, it is more the security of the institution and its leaders than some economic variable such as money wage rates or employment opportunities.

Union structure largely determines the structure of collective bargaining. Local autonomy leads to local contracts with employers; concentration of power in the national union leads to nation-wide contracts. Craft unions cover the craft with their contracts; industrial unions, the industry. No "national bargain" was possible in the United States at mid-20th century because, first of all, there were two federations and, moreover, neither federation had disciplinary power over its constituent national unions.

Substantive Scope of Collective Bargaining.— Issues bargained over in the United States traditionally encompassed union security, job security, working conditions, hours and wages. The long historical tradition of employer hostility and the lack of working class solidarity made the union security provision in the collective contract of special importance in the United States. Consisting of some provision that the worker, as a condition of his continued employment, either must be a member of the union when hired (the closed shopj, or must join and remain a member once hired (the union shop), or may elect to join or not to join, but once having affiliated must agree to remain a member (maintenance of membership), a union security clause became the cornerstone of most contracts. After the enactment of the Taft-Hartley act, which banned the closed shop form of agreement (although many tacit closed shop provisions continued to be mutually enforced), the union shop gained relative to other forms.

Job control provisions which seek to define and make more secure the worker's tenure on the job include rules controlling entrance to the trade, rate of output, transfers, layoffs, discipline and dismissal of workers, the introduction of new equipment or methods, and even a guarantee of volume of employment. With the shift from craft to industrial unionism, rules governing apprenticeship (to control a skilled labour supply), excluding new equipment and limiting the volume of output became less important, and rules concerned with the distribution of work according to the principle of seniority more important. Make-work rules had their greatest impact in seasonal or declining industries. Guaranteed employment provisions had by the early 1950s affected less than 1,000,000 workers (mostly in small companies operating in stable or predictably fluctuating demand industries), but several large C.I.O. unions started in the post-World War II period to campaign for a guaranteed annual wage.

Diverse working conditions produced a wide range of specific work-rule provisions seeking to improve health, comfort, sanitary and safety conditions on the job. Wages and hours, of course, were significant issues from the earliest incursions into collective bargaining, and a steady pressure to reduce work-day and work-week hours was exerted. Once the 8-hr. work day and the 40-hr. work week were achieved, there was a strong tendency to include provisions for holidays and vacations with pay.

Wage objectives of unions encompassed efforts to establish systematic wage structures, to take individual wages out of competition by establishing standard rates for comparable work, and to improve real wages by seeking to negotiate ever higher money wage increases. Slogans and criteria for justifying wage demands have varied and have been called upon at propitious moments: "a living wage," "a fair day's pay for a fair day's work," "adjustment of inequities," "the cost of living," "ability to pay," "productivity"—all have been used to rationalize the justifiability of the wage demand.

A significant shift from wage to nonwage demands, especially toward bargaining for health and welfare and pension plans, began during the 1940s. Wartime restrictions on money wage increases encouraged negotiation for fringe benefits to which the National War Labor board generally acceded. By 1950 this conversion of the older unilateral union or management paternalisms into a jointly administered paternalism had progressed quite far. More than 5,000,000 workers were covered by various health and welfare plans in 1950 as compared with about 500,000 in 1945. The increased coverage of pension plans was about the same in scope.

Management-imposed contractual obligations continued to be concerned primarily with guarding against new or further encroachments into the domain of historical managerial perogatives and functions, and particularly with maintaining discipline and efficiency on the job.

Varieties of Collective Bargaining Patterns and Experience.— The heart of all collective bargaining lies in the joint negotiation and administration of a trade agreement. The trade agreement establishes working rules; describes worker; union and management rights and obligations; determines rewards and penalties; and clarifies the procedures to prevail in the effective administration of this mutually agreed upon code of behaviour.

Because the labour-management relationship treats with such important rights and obligations which shift over time, so severe a conflict may develop that no agreement results without battle. Even when open warfare is avoided. the trade agreement is not a final, static resolution of all conflicting differences or objectives but rather a better or worse compromise derived from the preceding "exercise in skilful retreat.'!

Differences in market conditions, the security of the trade union, face-to-face relations, origins of the relationship. dominant union or management personalities, ideological views and selection of bargaining techniques (*i.e.*, differences in the surrounding environment) resulted in a great variety of bargaining patterns and experi-

ences in the United States. The scope of a bargain may range irom coverage of an entire competitive area under a single agreement negotiated between the union and an employer association to coverage of only a single plant of a single employer. A grouping of bargaining patterns according to the scope of the agreement (with illustrations of industries in the United States in which each variety became prevalent) includes the following basic varieties: contracts relating to a single plant (machinery, precision instruments): contracts relating to more than one plant of the same employer (automobiles. steel, rubber, communications); and contracts negotiated with a group of employers bargaining as a formally organized or informal association (printing and publishing, clothing. coal, railroads, services). Within these categories, bargaining may be craft by craft (building), multicraft (railroads), or industrial (meat packing, aluminum). It may be local (baking, service trades), regional (Pacific coast longshoring) or national (railroads, coal). Within particular industries, key bargains may be struck which serve as a pattern for subsequent negotiations with other companies.

The trend in the United States was toward an increasing importance of multiemployer agreements, of locality-wide and company-wide bargaining, and toward a greater importance of the key bargain in the more important basic mass-production industries. The bureau of labour statistics found, in a study of more than 3,000 agreements, that, in 1950, although two-thirds of all agreements related to a single plant, less than one-third of all workers were covered by such contracts. Multiplant bargains, while involved in only one-eighth of all contracts surveyed, covered two-fifths of all workers. Multiemployer agreements (one-fifth of all agreements) covered about one-third of all workers. Association bargaining was especially important in the Pacific coast area, where about half the agreements negotiated were of the multiemployer variety.

Grouping bargaining systems according to the tone of the relationship, as contrasted with its scope, scholars identified a variety of patterns of experience in U.S. labour-management relationships: (1) containment-aggression, where ceaseless management attempts to contain in a narrowly restricted area or to eliminate the trade union result in persistent and intensified union aggression; (2) conflict marked by reluctant management recognition and a constantly combative attitude; (3) conflict emerging from basic ideological incompatibilities; (4) price-list bargaining, where terms of the agreement are unilaterally determined (illustrated in the case of a craft union offering its skilled labour to miscellaneous, minor or occasional purchasers who hire the labour according to an announced price list); (5) deal bargaining, involving a high degree of co-operation between top leaders but limited understanding or participation at the root levels of the relationship; (6) power bargaining between strong secure unions and well-organized employer associations; (7) mutual accommodation and real tolerance in negotiating the traditional terms of the trade agreement; (8) active co-operation and conscious promotion of relationships extending mutual concern and accommodation beyond the customary range of wages, hours and working conditions to include attempted improvement of managerial efficiency or solution of problems of solvency and permanent disposition of union security and stability issues; (9) collusive relationships involving mutually contrived supply or price controls to the advantage of producer interests over consumer.

Bargaining systems tended to move from some form of conflict (the first three types noted above) through tolerance (the second three types) to accommodation or co-operation (the last three). Co-operation frequently meant either retreat or market restrictions. Many of the pre-1933 union-management co-operation schemes were really equivalent to trade union retreats or concessions in the face of unemployment or nonunion competition; and co-operation, after the extended growth of trade unionism, tended in the collusive-restrictionist direction at the expense of the consuming public.

Consequences of Growth and Development.— The consequences of trade unionism and of collective bargaining before 1933 had only localized significance. Subsequent growth made the character and results of collective bargaining nationally significant. After 1933 repercussions of industrial conflict, of the interaction of trade union wage policy and general economic stability, and of restrictionist or collusive tendencies, provoked and sustained greater public concern over the conduct and consequences of labour-management relations than had existed at any time in the past. These and other real or alleged by-products of the growth of trade unionism have evoked both vigorous indictments and ardent defenses of collective bargaining and have bequeathed a much disputed range of remedial or ameliorative proposals and policies.

The minimizing of industrial conflict and the more positive goal of achieving industrial peace (where industrial peace refers to a continued state of mutually agreeable but noncollusive relations freely and amicably negotiated by parties of relatively equal strength) assumed a greater importance as collective bargaining became more pervasive. Though it may be true that as free collective bargaining systems mature they proceed toward a more accommodative or co-operative level, this did not resolve the immediate issue of minimizing the sometimes substantial transitional residuum of conflict. Nor did this theory offer even longer-run hope for industrial sectors which seemed not to be governed by this behavioural rule at all (*e.g.,* water transportation, coal mining). Varying emphases on causes of conflict resulted in different policy proposals to promote and maintain accord. Those who emphasized better "human relations" in industry as the crucial lubricant in the procession from conflict to co-operation sought to improve interpersonal relationships and communication lines within the factory social structure. This method of approach, which gained its impetus from the experiments conducted at the Western Electric company in the late 1920s and early 1930s sought the reform of management personnel policies and increased managerial concern with personnel relations.

Others stressed fundamental external as well as internal environmental circumstances and proceeded to describe typically favourable environments which prevailed where industrial peace had developed. These environmental forces, however, are essentially permissive rather than compulsive; and where environments are compulsive they may compel toward conflict as well as peace. Where workers, for example, form a relatively homogeneous group which is unusually isolated from the general community and which is capable of cohesion (*e.g.,* in maritime transportation and coal mining), they will be exceptionally strike-prone. Those industries where workers are integrated into the larger society are comparatively strike-free. This hypothesis, which singles out the location of the worker in society at large as the most significant variable in explaining interindustry differences in strike-proneness, suggests, as the greater strategy in reducing intensity of conflict, the fuller integration of the worker, his associations and the employer into the general society. Increasing vertical and horizontal mobility, the encouragement of many limited-function mixed associations, the substitution of the mixed community for the isolated mass become the gates to industrial peace.

Government implicitly accepted the conflict-to-co-operation generalization insofar as it generally sought to rely on voluntary instrumentalities to encourage labour-management co-operation and compromise. Reliance on state and federal mediation and conciliation services and on fact-finding boards which attempt to recommend to the disputing parties some reasonable basis for settlement reflected the prevailing belief in the potential harmony of interests. In attempting to avert the consequences of conflict in areas where interruption of operations resulting from a strike would endanger the 'public welfare or national safety, however, government employed more compulsive sanctions and penalties which remain the subject of much debate and controversy. Some states, in disputes involving public utilities, required compulsory arbitration; and for strikes designated by the president as national emergency disputes, the Taft-Hartley act established an injunctive procedure which was not always effective in settling or even in averting strikes. Within the realm of union-management self-government itself, there was widespread acceptance of voluntary arbitration in the settlement of grievance disputes. None of these measures, how-

ever, eliminated industrial conflict and the appropriate handling of emergency disputes remained an unresolved issue.

The issue of minimizing conflict is matched in importance by the issue which revolves about the consequences of trade union wage policy upon national employment and price levels. The more exaggerated indictments have charged collective bargaining with the ultimate destruction of the free enterprise system. It is alleged that unions, by exerting constant and apparently limitless upward pressure on the wage level, must create serious unemployment and or severe inflation which in turn are but preludes to the inevitable demise of a free "competitive" pricing system. Employer and government resistance are regarded as utterly ineffective in stemming the devastating consequences of the omnipotent union leaders' demands for "more, more and more." Collective bargaining, in brief, is viewed as simply not compatible with capitalism. Equally ardent defenders have, on the other hand, maintained that negotiated wage increases will almost always have a favourable impact on employment and price stability; that the roots of inflation never lie at the trade union's door; and that extended collective bargaining, resulting finally in a national bargain which will stabilize prices and wages, is absolutely essential to the proper functioning of a capitalist society since it is a key technique for preventing both mass unemployment and injurious inflation. Less extreme views have not entirely dismissed the problem of constant inflationary tendencies as a result of trade union wage pressures under conditions of full employment, but recognition is accorded the fact that power may beget power, that strong unions bargaining with strong employer groups have historically led to wage structures which tend toward a two-directional inflexibility as well as to generally more moderate demands, and that the rate at which wages spiral upward may be retarded by the increasing internal bureaucratization in union hierarchies. If it is true that union leaders do not seek to exploit the maximum economic monopolistic powers which they possess but rather seek the minimum gains requisite for political security and stability, then an ever more secure and self-perpetuating leadership may feel less pressured to secure maximum wage gains during periods of general economic prosperity.

The growth and development of collective bargaining provoked still other important grounds for concern. Is it not possible that equalization of power, instead of serving a stabilizing function, may result in collusive price fixing against the consumer and in higher wages for a restricted number of workers, and thus in a less efficient utilization of resources? May not increased internal centralization of leadership coupled with union security provisions and other restrictions on entry threaten a loss of freedom for the individual worker? How severely will the effects of various contractual provisions, such as pension and health and welfare plans and seniority rules, obstruct the mobility of the labour force and the fluidity which a dynamic economy requires? These several issues are the focal points for the continuing debate over the form and the performance of collective bargaining in the United States.

INDUSTRIAL ARBITRATION

Industrial or labour arbitration is the process by which a labour dispute is submitted to an impartial person, or to a board of three or more, for a final and binding decision. When the parties agree to settle a dispute in this manner it is known as voluntary arbitration; where a law prohibits strikes and requires such arbitrament, it is compulsory arbitration. In the United States most arbitration is voluntary, but some states enacted laws making it obligatory to arbitrate controversies which threaten to shut down public service industries.

The parties to industrial arbitration are normally trade unions and employers or organizations of employers. Because they make collective agreements governing terms and conditions of employment, such arbitration (whether voluntary or compulsory) is necessarily of two distinct kinds. One deals with disputes arising out of grievances, or out of interpretation or application of agreements, the other with differences that arise when new agreements or proposed changes in existing agreements are being negotiated.

The first kind of arbitration adjudicates "rights," *i.e.,* the rights of employees, managements and unions established by the agreements. The second settles controversies about "interests," so-called because it deals with proposed new terms of employment when the parties are free to pursue their respective interests. They are not bound by any existing agreement, and the arbitrators, having no such agreement to control their decisions, are free to support, reject or compromise the proposals of either party. Such arbitration is, in effect, legislation rather than judicial determination, for the decisions fix rates of pay, rules and working conditions to be embodied in agreements on the basis of which future disputes about rights are adjudicated.

Adjudication. — This is the most frequent and successful form of industrial arbitration. It did not develop on any considerable scale until the last quarter of the 19th century when skilled craftsmen succeeded in establishing more or less continuous organizations. As these forced employers to make collective agreements with them, the practice developed of including a provision for a joint standing committee, equally representative of employees and the employer, to adjust differences as to the requirements of the agreements. If the representatives were unable to settle a dispute, they were authorized to select a neutral or impartial person to sit as a member of the committee so that a decision could be made by majority vote.

In the early years of the 20th century this form of arbitration spread to other trades and industries. Provisions were made for the appointment of the impartial arbitrator by some public authority when the party representatives were unable to agree on a neutral. A collective agreement in the anthracite coal industry in 1903 set up a conciliation board which, like the standing committees, was composed of an equal number of representatives of the miners' union and the mine operators. This agreement provided for the designation of the neutral chairman by a U.S. court of appeals. Later other boards with arbitrators similarly appointed were established in various districts of the bituminous coal industry. In other industries the more common practice was to have the arbitrator designated by the federal or a state labour department.

In 1910 an agreement known as the "protocol of peace," in the New York ladies garment industry, established a board of arbitration, and the parties agreed on an impartial chairman of the board at the time the agreement was made instead of waiting to select a temporary chairman for each case as it arose. A year later such a board was established in the men's clothing industry of Chicago, and during the 1920s impartial chairmen were presiding over arbitration boards made up of labour and employer repre-

sentatives in all clothing manufacturing centres and in other needle trades as well. In that decade the number of agreements providing for joint standing committees, with temporary arbitrators chosen for disputes they could not settle, also continued to grow. On the railroads such committees were known as adjustment boards, the practice being for each road to set up a separate board for each class of employees covered by an agreement with a union.

The Railway Labor act of 1926 extended this practice by authorizing such boards to be "created by agreement between any carrier or group of carriers or the carriers as a whole, and its or their employees." But while it stipulated that a majority of the members of an adjustment board should be competent to make a final and binding award, the act made no mention of a neutral member or arbitrator designated to sit with the board. In 1934, however, the law was amended to create a National Railroad Adjustment board to which grievances or disputes about rights not settled on the individual roads could be referred; and it further provided for appointment of a referee by the administrators of the act when the party members were unable to settle a dispute and could not agree on a neutral arbitrator.

The amended act also obligated the railroad managements to bargain collectively and to "exert every effort" to make and maintain working agreements with unions representing their employees. The following year (1935) congress adopted the first National Labor Relations act, which placed a similar obligation to bargain collectively on employers in all other industries engaged in interstate commerce. Thereafter arbitration became the normal method of settling disputes about grievances or rights under agreements in most U.S. industries. Studies by the U.S. department of labour in 1950 and 1952 showed that almost 90% of the agreements prescribed arbitration as the final step in the process of handling grievances or disputed claims under agreements (*Monthly* Labour ***Review,*** July 1951 and March 1953). Arbitration of this kind is a direct substitute for strikes or lockouts which collective agreements generally prohibit during the periods for which they are written. It largely eliminated work-stoppages as a result of differences about interpretation or observance of agreements; such arbitration became so common that decisions were regularly published in volumes like reports of court cases.

Legislative Arbitration.— Much less frequent and much slower in growth has been arbitration of disputes about new terms and changes in agreements, or disputes about "interests." But such arbitration was resorted to increasingly after the U.S. congress began to equalize bargaining power of employees and employers by the labour relations legislation of 1934 and 1935. It is a characteristic of this form of arbitration that the stronger party is usually inclined to oppose and the weaker to favour it. But as their strength approaches equality, both are more willing to accept arbitration as a lesser evil than a strike when they cannot settle disputes by collective bargaining, as they do most frequently.

Thus there was little of this arbitration in the 19th century, when trade unions were weak and employers generally had the upper hand. But after 1890 the American Federation of Labor (*q.v.*) (formed in 1881) devoted itself to building strong unions with ample treasuries, and in the early years of the 20th century, when these were able to match their strength with employers in protracted strikes, many arbitrations were arranged as a means of settlement and also to forestall work stoppages. The anthracite conciliation agreement mentioned above was the result of an award by an arbitration commission appointed by Pres. Theodore Roosevelt in 1903 after a long and bitter strike; and arbitrators' efforts were largely responsible for the so-called protocol of peace in the ladies' garment industry in 1910. Major labour disputes were similarly settled by arbitration during that period in the printing and building trades, on the railroads and in other industries. The International Typographical union made an agreement with the American Newspaper Publishers association in 1901 to arbitrate future disputes for five years, and it was renewed several times. About the same time the International Printing Pressmen's and Assistants' Union of North America entered into a similar agreement which, renewed from time to time, was still functioning in the early 1950s. During World War I the federal government established a National War Labor board to arbitrate disputes affecting war industries in return for a "no strike-no lockout" agreement entered into by representatives of the A.F. of L. and of national associations of employers.

These developments gave an impetus to arbitration of "interest disputes" which lasted through most of the 1920s and was stopped by the depression that began in 1929. It was revived again on a larger scale by the labour relations legislation of the Franklin Roosevelt administration in the 1930s; and during World War II it was greatly extended by another National War Labour board which arbitrated disputes in war industries pursuant to a no-strike pledge. The awards of this board, however, were technically only recommendations; they could be enforced only if the president used his war powers to seize a plant and put their terms in effect. But in most cases they were accepted by the parties, or formed the basis of settlements.

The method by which a government board hears the parties to a dispute, determines its merits and makes recommendations for an equitable settlement is rarely referred to as arbitration. It is variously known as fact-finding, investigation or emergency proceedings by boards of inquiry or emergency boards; but essentially it is arbitration without binding decisions. In the Transportation act of 1920 congress provided for a Railroad Labor board with authority to hear and decide disputes, and left its awards unenforceable. Nevertheless, during the six years of its existence, most of its 4,000 decisions were accepted by the parties. The board had jurisdiction over both disputes about rights and disputes on interests, and this proved a source of confusion, causing dissatisfaction among railroad managements and employees alike.

The Railway Labor act of 1926 clearly distinguished between the two kinds of labour disputes; for the first it provided arbitration with final and binding decisions by the adjustment boards previously mentioned; for the second it authorized legally enforceable agreements to submit such disputes to arbitration, but either party could refuse to arbitrate. After such refusal, however, if any dispute threatened substantial interruption of interstate transportation, the law empowered the president to appoint an emergency board to inquire into the dispute and make recommendations for an equitable settlement. After this law was passed several hundred such boards were appointed, and in a large majority of the cases strikes were prevented by the parties' accepting what was recommended.

In other industries where labour controversies threatened or created emergencies, the president appointed similar temporary boards on his own initiative, and in most of those cases, too, recommended settlements either prevented or ended strikes. Not infrequently, moreover, the parties themselves submitted their differences to an individual or a board of their own selection with instructions to make recommendations rather than binding awards, and usually these brought about peaceful settlements. (See also LABOUR LAW; TRADE [LABOUR] UNIONS.)

INDUSTRIAL RESEARCH: **see** RESEARCH, INDUSTRIAL.

INDUSTRIAL REVOLUTION, THE. When we say that a society has passed through the industrial revolution we have in mind a definite picture of its life and power. We are thinking of a society that makes great use of machinery and conducts its operations in industry and commerce on a large scale. The creation of any such society must be in some respects a gradual development. Certain features of our modern economic life can be traced back to the days when Columbus and the great sailors of his time put Europe in touch with the new world and the far east; others to the earlier history of Europe when classical Greece, and the Roman empire in turn exploited the wealth of the Mediterranean basin. There was large capital invested in industry as well as in commerce before the 18th century, and even so modern a phenomenon as mass production was not altogether

unknown before the industrial revolution. No people and no age could pass directly from a primitive and simple economy to a life so complicated as that of modern Britain or modern Germany. Some critics, surveying these earlier tendencies. doubt whether the term industrial revolution is appropriate, arguing that revolution implies sudden and catastrophic change. But a closer examination shows that the great inventions which distinguished the 18th and 19th centuries played so decisive a part in creating the new kind of society that the term industrial revolution, invented by a Frenchman and made familiar by Arnold Toynbee (1852–83), is not too violent a description of the changes they produced. It is now an established phrase. like the Renaissance, or the middle ages, with a well-understood meaning and content.

England the Pioneer.—We mean, then, by the industrial revolution the change that transforms a people with peasant occupations and local markets into an industrial society with world-wide connections. This change has come to different peoples at different times. It came first in England because the English people had favourable political institutions, internal free trade, advantages of climate and geographical position, considerable experience of foreign trading. special connections with the new world and abundance of coal. In the first phases of the revolution coal mattered much less than it did afterward, for the first great mechanical inventions in the textile industries were worked by water power, and rapid industrial development was possible at this stage without coal. This explains why France made such rapid progress as an industrial nation before the French Revolution. France had great inventors like J. M. Jacquard and Jacques de Vaucanson. and it had a richer foreign trade than Great Britain. But when a series of inventions had made coal the chief source of economic power, France was at a great disadvantage. As late as 1847 it produced only 5,000,000 tons of coal, whereas the English production so early as 1800 was 10.000.000 tons, and from 1845 it was over 34,000,000. If France had kept the frontiers established by the treaty of Amiens (1802), its history would have been different, for that treaty left it with the Belgian coal fields.

The Revolution in Iron.—The inventions which gave this predominant importance to coal began with the discoveries by the two Abraham Darbys and by Henry Cort of methods of using coal instead of charcoal in blast furnaces and forges. Before these discoveries iron manufacture depended on charcoal. It was therefore carried on mainly in counties like Sussex with extensive woodlands. But by the early 18th century the industry was in great difficulties, for the supplies of fuel were giving out. When the Darbys, Cort, John Wilkinson and James Watt had revolutionized the industry the difficulties vanished, coal took the place of charcoal, and the iron manufacturer could set up his plant in the neighbourhood of coal fields. So the industrial revolution created the black country. and enabled England to turn to account the good fortune which had given it abundance of coal, and coal conveniently placed near its ports. Between 1720 and 1788 the production of pig iron in England grew from 25,000 to 68,000 tons; between 1788 and 1839 it grew from 68.000 to 1,347.000 tons.

The Textile Revolution.— The revolution in the manufacture of iron which created the black country was accompanied by a revolution in the textile industries which transformed Lancashire and the West Riding of Yorkshire. This revolution was started by a series of inventions in the 18th century. The flying shuttle was invented by John Kay in 1733; the spinning jenny was patented by James Hargreaves in 1770; a roller spinning frame, worked by water power was patented by Richard Arkwright in 1769 and 1775; the mule which enabled English mills to match the delicate muslins produced by Indian fingers was invented by Samuel Crompton in 1779. The cotton industry established by these discoveries was conducted at first by water power, but before the end of the century its progress and its power received a great stimulus from the most important of all the discoveries of the industrial revolution.

Steam Power.—Profiting by the earlier pioneer work of Thomas Savery and Thomas Newcomen, Watt learned how to make steam the servant of man's will. By his invention of the separate condenser, patented in 1769, he produced a new type of engine. In his early engines steam was used to force a piston up and down, and they were mainly used for pumping water in mines, but Watt went on to devise a method by which steam could be applied to rotary movements as well, and this was in some respects the most important of his discoveries. From that time there was scarcely any limit to the range of the invention, which revolutionized one industry after another. In the textiles the new power was first applied to spinning; later it was used for weaving, as the result of a series of inventions, beginning with the imperfect power loom patented by the Rev. Edmund Cartmright in 1785, The effect was to give new freedom to the industry, which was now independent of water power, just as the iron industry was independent of woodland. The growth of the cotton industry was the most sensational event of the early revolution. In 1764 England imported 4,000,000 lb. of cotton wool, in 1833 it imported 300,000,000 lb. A table drawn up by the Chamber of Commerce at Mulhouse in 1835 shows that in that year England produced over 60% of the cotton goods consumed in the world; France 16%; the United States 7%; Switzerland, Saxony, Prussia and Belgium between them a little less.

This expansion of the industry involved, of course, a great increase in the demand for raw cotton. When first the industry began to grow England and France competed for a deficient supply. At that time the West Indian islands provided more cotton than the continent of North America. The United States had a great deal of short stapled cotton, which could not be exported profitably, because the cotton adhered so closely to the seeds that it was difficult and costly to prepare it for export. But in 1793 Eli Whitney invented a saw gin which enabled this cotton to be cleansed, and from that time the United States became the chief source of supply. This invention led incidentally to a great extension of slavery in the southern states, for slaves were especially suitable for the task of growing cotton in the river beds.

The woollen and worsted industries were older than the cotton industry, and in their case these technical improvements were introduced more gradually. They led to the concentration of both industries in the West Riding, the worsted industry declining in the eastern counties, and the woollen in the southwest.

Canals.— It is important to notice that the cotton industry was established on a large scale while England was still dependent on canals and roads for transport. There had been a great development of road making and canal making in the 18th century, in consequence, partly, of the agrarian revolution. This revolution, nhich increased rapidly the system of large tenant farming, with landlords applying their capital to improvement, made farming much more productive. It was effected partly by Enclosure acts which were passed through parliament, setting up commissioners to enclose the common fields and the common wastes. Under the old system individual freedom was limited by the rights of the commoners. By this change enterprising landlords could apply the lessons taught by Jethro Tull and other agricultural pioneers, who had discovered how to improve crops and stock. But the roads were in a bad state, much worse than in contemporary France, and it was necessary to construct new roads and reconstruct old ones, in order to enable corn and other agricultural products to be taken to the towns. So the governing class threw itself into road development, and turnpike trusts were set up all over the country for that purpose. Similar motives led to canal building. The most famous of the inventors in this field was James Brindley, who was commissioned by the duke of Bridgewater in 1759 to make a canal to connect his coal field with Manchester. His success gave a stimulus to the movement, and the industrial districts of the north and the midlands were rapidly connected with each other and with the ports by a network of waterways.

Railways.— But man's new servant. steam, was soon brought into use for the purpose of transport. The first steam locomotive was tried at the Merthyr Tydfyl iron works in the early days of the 19th century. The founder of the British railway system was George Stephenson, the engineer of the Stockton and Darlington railway, opened in 1825, and the designer of the engine which

won the prize in the competition held at Rainhill in 1829. The success of the Liverpool and Manchester railway opened in 1830 led to an age of feverish activity in railway building. and by 1848 nearly 5,000 mi. of railway line had been laid in Great Britain. This in its turn had a powerful influence on the metal industries. Sea transport changed more slowly; the first steamship crossed the Atlantic in 1819, and, by 1847, 60 or 70 steamships were turned out every year.

Engineering. — In some respects the most important of the results of Watt's discoveries was the use of machines for making machines. Mechanical engineering began to be important in English history about 1820 (the first textile machinery was made of wood), and with the rapidly growing demand for machinery from all parts of the world its importance grew at a rapid rate. The scope and power of the industry were increased by a series of inventions such as James Nasmyth's steam hammer in 1838, and by discoveries associated with the names of Henry Bessemer (1856), the brothers Werner, Sir William, Frederick and Carl Siemens (1866) and Sidney Gilchrist Thomas (1879), which created the modern steel manufacture. All the metal industries were helped further by the chemical discoveries of which Michael Faraday had made a beginning in 1826, discoveries that created in their turn the successful chemical industries of Lancashire and Cheshire.

The effect of all this energy in scientific pursuits and industrial enterprises was to make England the leading representative of the new civilization: the workshop of the world. Its early progress was all important. For, as we have seen. England had an industrial revolution before the railway era. In the two countries where industrial expansion was most rapid in the latter half of the 19th century, Germany and the United States, the industrial revolution began with the introduction of the railway. In earlier ages the chief obstacle to industrial development was the difficulty of land transport. In Germany and America this difficulty was resolved by the railways. In England, on the other hand, where the sea was nowhere very far distant, an industrial revolution was possible aithout the railways, because canals and roads could give access to the ports. It was mechanical engineering that received the greatest stimulus from the railways. Therefore, when the world wanted railways and docks, England was ready with the plant, the experience, the capital and the skill. Hence it was to English capital and English labour that the world turned for this task. But there was a difference between the early days of the revolution, when England sold piece goods all over the world, and the later days, when it sold railways; for the railways it sold sometimes helped to turn agricultural into industrial societies, and it was certain that when this change had taken place, England's preponderant share in the trade of the world would decline. When the 20th century opened England had ponerful industrial rivals both in and out of Europe, many of them with far greater natural resources to exploit, and one of them, the United States, with far greater supply of capital per worker.

After 1900 the industrial revolution went through new phases, many of them providing greater opportunities and affording more serious challenges than the early industrial revolution. New sources of power, such as electricity, the use of new and synthetic materials, the increased application of science both to techniques and to management, transformed industry in many parts of the world, particularly in the United States, which took the place of England as a world leader. Hitherto underdeveloped societies felt the impact of this new revolution, which took a planned form in the Soviet Gnion. The consumer has often benefited as much as the industrialist from the enormous increase in production.

Electricity. — The 19th century was the century of steam. Before its close man had discovered in electricity an even more valuable servant. A new industrial revolution was thus set in train, a revolution of which we cannot yet forecast the consequences. One effect is seen in the growth of motor industries in the home counties. The great industrial revolution concentrated industry in certain districts; Lancashire is the home of cotton, the West Riding of wool, Staffordshire of pottery, the great metal industries are found near the coal fields. Electricity gave industry again a wider choice, and the factory inspectors' reports for 1926 drew attention to the development of industries in the south of England. Transport was easier, and power could be made available in the country districts.

Social Results. — The conversion of an agricultural to an industrial society brings with it great changes in a nation's habits and manner of life. Of the changes that followed the first development of the new system, those that made the greatest impression on the thinkers and observers of the time were the great improvement in production, and the opportunities this new world offered to individual talent and character. The great cheapening of commodities made life easier, and the first impression made by this improvement led to a belief that the secret of progress was to allow every enterprising person to make what profit he could by any means that he chose. The revolution also gave great opportunities to the workman who could save a little money and was shrewd and daring in investing it. Most of the early cotton spinners were men who had made their way. Robert Omen, for example, one of the most successful of them, owed his success to a loan of £100.

The exhilarating atmosphere of a world in which men could make their own careers helps to explain the optimism of the time, and the disregard of evils which called for action.

Problems of Urbanization. — The industrial revolution created social problems as well as economic advances. In particular the new industrial towns, like Manchester and Birmingham, which grew rapidly in the early 19th century as the textile and metal industries expahded, were unable to handle the tasks of maintaining public health and law and order. Equipped with obsolete administrative apparatus, they were uncontrolled in their growth. Frequently the new town life was tough and squalid, in Edwin Chadwick's phrase, "in respect to cleanliness almost as bad as that of an encamped horde, or an undisciplined soldiery." The accumulation of numbers, however, frequently directed attention to social problems which had been concealed in villages and preindustrial communities, and the movement for reform was itself as much a product of the industrial revolution as the black spots on the map. In the 1840s, when a spirit of inquiry was active and philanthropists and statisticians were directing attention to the "condition of England" question, the state of towns was examined by committees and commissions, such as the Health of Towns commission, and their appalling condition was revealed. A national effort to reform these conditions was made by the Public Health act of 1848, but the problem proved difficult for technical, political and administrative reasons. The long history of urban improvement in the 19th and 20th centuries shows how heavy a social burden was imposed by early uncontrolled economic development.

Industrial Relations. — The revolution not only made the problems of urban life acute and pressing: it created industrial relationships which brought social conflict into the open. Before the textile industries passed into the factory, spinning and weaving were done either in the workers' homes or in the house of a small master. Spinning was woman's work and weaving man's work. In the mill, spinning was mainly men's work and weaving women's work, but both Beavers and spinners depended on the help of children. The early mills had difficulty in getting labour, for they were built on streams in districts where there was little population. The difficulty was surmounted by the supply of children from the workhouses. The hardships of these children led to an agitation and it was made illegal to apprentice children 40 mi. from home. But by this time the use of steam power had made it possible to put up factories in or near towns, and the apprentice children were no longer needed. The campaign against the long hours of children became a campaign against the long hours of the factory, for it proved in practice impossible to shorten the hours of children without restricting the hours of the factory, and this campaign was brought to success in 1847, when parliament passed the Ten Hours act, for which the 7th earl of Shaftesbury (then Lord Ashley) had fought since 1833. Factory legislation and factory inspection were gradually extended to other industries in the course of the century.

After 1900, and particularly after 1919, many industrial firms enormously improved their own factory conditions, although in new industrial countries, such as Japan, labour conditions remained unsatisfactory even in the mid-1950s.

Trade Unions.— Large-scale industry in engineering and mining as well as in the factory created a different relationship between employer and employee than the sort of relationship which existed in the days of the craftsman. The place of the guild was taken by combinations of employers and employees. Strikes and combinations were not unknown beiore the industrial revolution, but the revolution gave a new importance and a new scope to trade unions. Their rights and their liabilities became one of the acute questions of politics. The Combination act passed in 1799, modified in 1800, and repealed in 1824, hindered trade union development. The next year a new act defined the powers of the trade unions in such a way as to make effective combination difficult. Trade unions did not obtain full recognition until after the workmen had been enfranchised in 1867. After World War I they were given a new place in public life by the institution of Whitley councils and similar bodies, composed of representatives of organizations of employers and workpeople. By the middle of the 20th century they had become a powerful iorce in industrial relations both at the factory and the national level.

Unemployment.— Another result of the industrial revolution was periodic mass unemployment, a consequence of mass production. The revolution made industries interdependent, and by bringing the whole world into close economic relationships it made the industries of one country dependent on the conditions in remote places. A coal strike hits the textile industries; a deadlock in engineering holds up shipbuilding. The poverty or the quarrels of the continent affect all British export industries; a political or commercial crisis in the United States may throw the cotton industry of Lancashire or the engineering industries of Newcastle into distress. In addition cyclical fluctuations in the volume of investment and failures of effective demand lead to changes in the level of employment.

It is sometimes said that the industrial revolution has substituted unemployment for famine as the nightmare of mankind. The growth of planning and the welfare state has been the 20th-century response to this situation.

Problems of Industrial Civilization.— The industrial revolution has not had exactly the same consequences in all countries. For those consequences depended partly on the conditions preceding the revolution and those conditions varied. English experience has been peculiar in one important respect. In England peasant farming disappeared with the agrarian revolution that began in the 16th century and ended in the 19th century. In other countries the peasant survived. France, for example, possesses important industries, but its people are mainly rural. Germany, much more industrial than France, has still a large peasant population.

But the industrial revolution has produced certain results that are common to industrial civilization. Thus one country after another has been obliged to legislate for social welfare. Asia has followed Europe. Provision against unemployment by state or municipal insurance was first made in certain continental countries, notably Germany and Belgium. In almost every industrial country policies to protect labour have been adopted since 1919. If we want to realize how much the industrial revolution has done to create common problems and to suggest common remedies we have only to glance at the publications of the International Labour office or to consider what reforms it pursues by conference and convention. In every country the same problems and the same remedies are under discussion: unemployment insurance, factory acts, hours of work, minimum rates of wages, the rights of trade unions, family endowment. One effect of the all-embracing system which the revolution has established has been to standardize the occupations, the cares and even the amusements of man.

The movie theatre is as much the mark of the modern world as the factory; the railway as the football or baseball field; the radio and television as the trade union. It is by these institutions that the modern traveller is reminded, as the mediaeval traveller was reminded by cathedrals and monasteries, that he can leave his own country without passing into a wholly strange and separate world.

The institutions, however, are in constant flux. If it is difficult to say exactly when industrial revolutions begin. it is clear that they never end. The introduction of automation and the preoccupation with the use of atomic energy were likely at mid-20th century to produce far bigger social and economic transformations than the rise of factories and the invention of steam power.

INDUSTRIAL WELFARE AND MEDICINE: **see** INDUSTRIAL MEDICINE.

INDUSTRIAL WORKERS OF THE WORLD, THE, commonly known as the I.W.W., a revolutionary labour union organization which played in the early 20th century a considerable part in U.S. and world labour history. It was founded in July 1905 at Chicago, Ill., as a result of a conference of Socialists and trade union leaders, of whom the most outstanding were E. V. Debs (*q.v.*), William D. Haywood, Daniel DeLeon, W. E. Trautmann, Vincent St. John and the Rev. T. J. Hagerty.

At the time of the formation of the I.W.W., there had been growing pressure among revolutionary elements in the labour movement both for independent political action and for industrial unionism, as opposed to the craft lines of organization followed by the American Federation of Labor (*q.v.*) and other existing unions. It was argued that without industrial unionism to match the growing concentration of control among the ownership class, the workers were helpless. As things were, they felt, the workers of any one industry were split up into the various craft unions with their own narrow interests and goals, and if the members of one craft or occupation went on strike, those of other crafts in the same industry were still attending their jobs so that the plant was still more or less able to function. Only an industrial union, they contended, could successfully exercise pressure for labour's demands by all workers' leaving the job together no matter which part of their ranks had demands at stake at the moment. It was further argued that under the existing craft union type of organization, no provision was made for the vast number of unskilled workers who could neither benefit by trade union membership nor lend the support of their numbers to the struggles of labour, either in the industrial arena or the field of political action.

Most firm and articulate in opposing these arguments were the spokesmen of the A.F. of L., headed by Pres. Samuel Gompers (*q.v.*). Trade unionism, they countered, would mean the suppression of all gains won by labour thus far, and an end of trade unions themselves. It was their belief that such a reorganization of unions on an industrial basis would bring about confusion and injury to themselves when force was pitted against force. In defense of their position they claimed that in the past it had been largely the craft union strikes which had brought gains, while most all-out industrial strikes known to them had ended in failure and were followed by repressive measures.

The backbone of the revolutionary union leadership at that time lay in the Western Federation of Miners, with a membership of about 27,000. Impatient with the slow methods of the more conservative unions, a convention was called in June 1905 for the purpose of forming a new and more militant organization. Other unions represented were the American Labor union, the United Metal Workers, the Journeymen Tailors' union of Pueblo, Colo., the United Brotherhood of Railway Employees and the Socialist Trade and Labor alliance. The convention lasted 12 days, with Haywood, then secretary and treasurer of the Western federation, as permanent chairman. It was Rev. Hagerty who provided the first organizational plan of the union (known by Gompers' derisive nickname of "Father Hagerty's wheel of fortune"). All workers of every trade were to be accepted by the union, which was to be subdivided into 13 industrial sections, craft unions not being allowed. That is, workers of a given industry in a given city would unite to form a local industrial union. These, in turn, would unite with the local industrial unions of the same industry in other cities to constitute a national industrial union. The national industrial unions of related industries would then make up a department. And, finally, the departments and their constituent unions comprised the national Industrial Workers of the World. The 13 industrial sections, such as the division of mining, the division of building, etc., were felt to encompass the basic industrial activities of the time, and of times to come. The methods to be followed by union members were to be "any and all tactics" that would "get the results sought with the least expenditure of

time and energy." It was felt that the long strike was no longer an effective technique and they sought no agreements with employers beyond what their own bargaining strength could secure in terms of concessions gained. In the event of the failure of a strike, they advocated a return to work for the purpose of resuming sabotage and forcing the employer to concede to their demands.

The initial growth of the organization matched all the optimism of its founders. Before its second convention in 1906, it numbered about 100,000 members and issued its own weekly, the *Industrial Union Bulletin.* But the I.W.W. comprised many varying factions of political thought, including Socialists: anarchists, syndicalists and trade unionists, and factional rifts within the organization on the question of political action led to a splintering of the group. As a result of the first split, the Western federation withdrew in 1907 on the unseating of Pres. Charles O. Sherman, its nominee, leaving the strength of the I.W.W. seriously undermined. Two years later the syndicalist element thrust out the followers of DeLeon. This second split resulted in two separate I.W.W.s, one of which had its headquarters in Detroit, Mich., and the other in Chicago, but the former soon became nonexistent. In the same year, the I.W.W. (*i.e.,* the remaining Chicago faction), altered its platform to eliminate all reference to a political base of action, and the preamble was rephrased as follows: ". . . Between these two classes a struggle must go on until the workers of the world organize as a class, take possession of the earth and the machinery of production and abolish the wage system." After the withdrawal of the Western federation, the strength of the I.W.W. varied greatly; the figures of paid-up membership in 1906 were 60,000 and in 1919, 35,000, but these figures give no reliable indication of its strength. After the defection of the miners, the I.W.W. membership became more and more predominant among the nomadic workers (partly foreign born) such as lumbermen, longshoremen and "hoboes," for whom the American Federation of Labor made no provision. This class of worker rarely paid dues, except on the occasion of first taking out an I.W.W. ticket. Of the innumerable strikes directed by the I.W.W. the Lawrence, Mass., strike of 1912 was the most famous and first brought the organization into prominence. About 30.000 textile operatives were involved and for the first time large bodies of non-English-speaking workers were led together to ultimate victory, their spirits being kept up partly by the use of the I.W.W. "red book" songs, of a coarse but vigorous character, which travelled across the world. In addition, many "free speech fights" mere undertaken; *e.g.,* in 1909 at Missoula, Mont., Spokane, Wash., Newcastle, Pa., and later more important struggles at Paterson, N.J., Aberdeen, S.D.., Old Forge, Pa., San Pedro, Calif., etc. These were mostly cases in which the municipalities objected to I.W.W. propaganda and arrested the "wobbly" (the slang name for I.W.W.) speakers, the I.W.W. replying by providing a continuous stream of speakers "until the jails burst." More than 5,000 "wobblies" were imprisoned. Elsewhere, especially in the western states, the history of the I.W.W. was violent and sanguinary. The facts which led, for example, to the shooting of the organizer and poet Joseph Hillstrom (Joe Hill) in Utah are greatly disputed; the murder of organizer Frank Little in Butte, Mont., was dealt with in a federal enquiry. (*See* the *Sixth Annual Report* of the secretary of labour.) In some of the states attempts were made to drive the I.W.W. out of existence.

During World War I, the I.W.W. was the only labour organization to oppose the war vigorously, and it was said to be one of the major targets of the antiespionage act passed by congress in 1917. After the war, the general attack on "red" organizations, together with a quarrel with the Communist International (*see* INTERNATIONAL, THE) gravely weakened the I.W.W. A large number of states passed "criminal syndicalism" laws, mostly held constitutional on appeal to the supreme court, with the object of suppressing the I.W.W. altogether. A mass trial of approximately 100 prominent I.W.W. members at Chicago in Aug. 1918 resulted in a number of heavy sentences. The less important position of the I.W.W. after the war may have been due to the immigration laws which cut off the influx of unskilled labour, its most fruitful source of recruits. But whatever the cause, its influence dwindled until by the end of the 1920s it had ceased to be of social consequence. Nevertheless, in 1949, it became the first labour organization to appear on the government's subversive list, although there were only about 1,500 workers. most of them in Cleveland, O., who still bargained with their employers through the medium of the I.W.W.

Australia.—I.W.W. locals existed in nearly every industrial country, especially in the ports. In Great Britain they appeared in London, Liverpool and Glasgow. But they only achieved importance, outside the U.S., in Australia between 1911, when the first local (Adelaide) was chartered from Chicago, and 1917–18, when the organization faded away.

INDUSTRY, the quality of steady application to work, diligence; hence, employment in some particular form of productive work, especially of manufacture; or a particular class of productive work itself, a trade or manufacture.

INDUSTRY AND TRADE, WAR CONTROL OF. Government control of industry has appeared sporadically in every major war of modern times. It has taken the form of commandeering supplies and means of transport and production, and occasionally of price control. Except in rare cases of cities under siege, however, government control before World War I never assumed the form of a general system dominating the economic life of a belligerent nation. The conditions which made such control of industry essential were:

1. Universal conscription, with its tendency to disorganize all industries, essential and unessential alike, by withdrawing the most energetic workmen and key technicians and administrators;
2. The vast consumption of materials and equipment in modern warfare;
3. The insatiate demand for financial resources for maintaining and supplying armies in the field and their auxiliaries:
4. The maintenance of the health and morale of the civilian population by the provision of the necessities of life at reasonable prices.

GREAT BRITAIN

The control of trade and industry in Great Britain developed gradually through attempts to solve particular difficulties of supply as they emerged during World War I. For the first year of that war the service departments relied on the ordinary forces of the market for the provision of their requirements. Their competition with private demand, and also the competition between individual branches of the services themselves, led to congestion of order books, serious delays in deliveries and rising prices. The difficulties of industry were increased by the loss of workmen, both skilled and unskilled, to the services. These problems led to the establishment of the ministry of munitions in June 1915 with responsibility for organizing the production and delivery of munitions. including the setting up of state factories; the war office continued to procure its own supplies of food, clothing. etc., as distinct from munitions. The increasing demands of the services for men and equipment and weapons, the resulting shortage of manpower and difficulties of importing led to extensions of control to cover all the chief raw materials and many prices, and to intervention in the use of manpower and methods of production. By 1917 the service departments absorbed, directiy and indirectly, so large a proportion of the output of industry that special steps had to be taken to safeguard essential supplies for the civilian population. It was in this year that the ministry of food was set up, food rationing developed and the production of standard clothing at reasonable prices arranged. Extension of control continued, partly in the interest of civilians, until by mid-1918 virtually no industry was entirely free.

Preparations for World War 11.—In Great Britain preparation for World War II included provision for immediate control over some key economic activities. It was thought that, although

comprehensive control might ultimately become necessary, most economic resources would be relatively plentiful in the initial stages. Imports. for instance. were expected to be maintained at about the peacetime level. It was also assumed that the change-over from production for peace to production for war would come about automatically as the result of losses of export markets, changes in domestic demand and the incentive of government contracts. Finally, since there was a reserve of labour shown by persistent unemployment, no general shortage of manpower was feared.

The plans for those controls which would most directly affect industry may be summarized briefly. Resources of foreign currencies nere to be conserved by means of exchange control administered by the banks on instructions from the treasury. Imports and exports would be subject to licence by the board of trade, and responsibility for sea and inland transport was to be divided between a new ministry of shipping and the existing ministry of transport, respectively. The use of machine-tools and certain raw materials for which wartime demand would be abnormally great was to be controlled by another new ministry, the ministry of supply; the latter would also be responsible for the royal ordinance factories. All the controls would be recruited in part from the trades concerned in order to obtain both their co-operation and the advantage of expert knowledge. Matters concerning manpower would be the responsibility of the ministry of labour, to be transformed into a ministry of labour and national service to organize the call-up for the fighting services according to the schedule of reserved occupations; this had been drawn up to prevent undue loss by industry of essential types of workers. Plans were also made to establish a ministry of food.

Taken as a whole, these plans provided for departmental responsibility for many important sections of trade and industry. The actual extent of control to be exercised was, however, very limited. For instance, the ministry of shipping was to control ships by individual licensing and chartering and not by requisitioning shipping in general; and the control of raw materials was intended to cover only the most obviously important such as iron and steel, timber, industrial alcohol, etc.

First Nine Months of War, Sept. 1939–May 1940.—These plans were put into force either just before. or immediately after, the outbreak of World War II. Outside the limited sector specifically included in the controls planned, producers and consumers were free to do as they liked. Even within the controlled sector regulation was very loose for a number of reasons. Personnel had to be built up and experience gained; the necessity for rigid control was not accepted even for shipping, imports or raw materials; and raw material control was hampered by the existence of stocks already distributed to the users.

Already before the fall of France in the summer of 1940, however, there were signs that this stage of "business nearly as usual" was coming to an end. The serious falling short of actual imports compared with estimated imports was causing anxiety and hastening the depletion of stocks of every kind. Contracts placed by the war departments were already absorbing the slack in the economic system. For instance, by March 1940, progress on building and civil engineering contracts was far behind schedule owing to bottlenecks of particular types of labour and materials. The difficulties experienced by the air ministry in obtaining essential supplies led to the establishment in April of the ministry of aircraft production to take over its procurement work. The first step to impose a check on the output of consumers goods, other than food, was also taken in that month by the issue of the first Limitation of Supplies order; this order, issued by the board of trade, prohibited manufacturers of cotton, rayon and linen goods from supplying more than 75% of prewar quantities to the home market; supplies for export and government contracts were not restricted.

The entry of Italy into the war and the fall of France in June, 1940, cut off an important area of material supplies and also increased the difficulty of transporting them. Europe and French North Africa together had previously provided, for example, about two-thirds of Great Britain's supplies of iron ore; these were no longer available. The control by the axis of the whole west coast of Europe except Spain and Portugal and of much of the Mediterranean provided many more bases for attacks on British shipping and forced diversion from the Mediterranean route to the east. Dependence on North America for supplies was thus greatly increased and, with it, the problem of finding dollars became acute until the introduction of lend-lease in the autumn of 1941.

These difficulties in the supply situation which followed the fall of France, together with the new strategic situation necessitated complete mobilization of British industrial resources. Nothing could be imported or produced that was not essential for the pursuit of the war. To achieve this object, a system of interlocking controls of industry from the procurement of raw materials to the finished product was developed during the next 18 months from the foundations of limited control already established.

Development of Full Control, May 1940–Dec. 1941.—Control over raw materials by licensing was extended rapidly, and the ministry of supply also became responsible for their purchase and import in many cases. Pressure on the steel and timber controls for licences for purposes with high departmental priorities became so excessive, however, that responsibility for licensing was transferred to the user departments who were obliged to keep within total allocations made to them individually. Control over the demand for machinery for civilian production was also introduced by means of a licensing system operated by the board of trade.

The difficulties caused by excessive competing demands on the building and civil engineering industry has already been mentioned. To deal with this, a special ministry of works and buildings was set up in May 1940, responsible for arranging priorities and for licensing all civilian work. It also became the controlling authority for any building materials not already controlled. Control of the use of existing buildings was introduced at the same time, by requiring the consent of the board of trade for any requisitioning of premises. Later, board of trade approval was also required for changes in the use of buildings.

It was realized during 1940 that, however complete the controls over the use of machine tools, materials, machinery and buildings might become, this would not be sufficient. Control of the final product was also needed in order to prevent the restriction of civilian supplies caused by the war effort which deprived civilians of real necessities. The first step, the Limitation of Supplies order of April 1940, has already been mentioned; by the end of the year a wide range of consumers' goods had been covered by similar orders and the permitted quotas had become much smaller. To ensure fair distribution of declining supplies of textile and leather goods, clothes rationing was introduced in the summer of 1941 and extended at various times to cover household textiles such as sheets. Special permits were required for some particularly important goods as, for example, furniture. In order to ensure that the civilian goods produced were really essential, licensing was extended to production itself, making the production of certain types of goods illegal without a licence. Thus the board of trade, the licensing authority, was able to specify the quantity and quality of goods for which a licence to produce would be granted, and to prohibit entirely the production of others. This system was carried a stage further with the introduction of "utility" goods. Manufacturers' quotas of materials, and later of labour also, were made dependent on the production of utility goods designed according to specifications laid down by the board of trade to economize in materials and labour and strictly price controlled.

To avoid waste of the labour and the factory premises made redundant by these restrictions, many of the industries affected were concentrated. Suitable firms were chosen by the industry, or in consultation with it, to take over the remaining production of all other firms on a quota basis. The latter then ceased production for the duration of the war and as much as possible of their labour, equipment and buildings was used for war work.

Thus by the end of 1941 a method for the complete control of industry had been worked out. It proved capable of extension and adaptation in the changing conditions caused by Japan and the U.S. becoming belligerents and provided the main framework of control for the rest of the war. The development of manpower

control had been parallel to the development of control of industry and culminated in conscription and direction of the whole population of working age to industry and the fighting services.

The Problem of Central Planning. — Effective control of industry presupposes a coherent scheme of requirements. The overall strategic disposition of resources remained, of course, the responsibility of the war cabinet Translation of the strategic plan into quantities of goods and services involved the difficult task of reconciling departmental programs and priorities. This function was performed by a frequently changing group of interdepartmental committees of all types from the defense committee (supply) of the war cabinet to committees with purely official membership. Early in 1942, after much discussion, the ministry of production was established to provide for easier and more effective co-ordination of production programs and also to co-ordinate British with Allied programs. It must not be thought that the elaborate system of determining requirements and controlling industry was operated merely by instructions from London. From an early stage all the departments concerned with production set up regional organizations to watch over and help to organize production, to administer the controls and to maintain close contact with industry and deal as far as possible with the difficulties that inevitably arose. In this way the consent of industry to, and its co-operation in, control could be secured at each stage.

EUROPE IN WORLD WAR II

In Europe the problems of industrial control during World War II differed among the various belligerents not only because of strategic differences, but also because of differences in their prewar economic systems.

U.S.S.R.—At the one extreme, the U.S.S.R. before the war had not merely a completely controlled economy, but one in which the state owned the means of production. Russia's problem was, therefore, that of re-orientating its plans to the requirements of actual war rather than of evolving methods of control. The invasion of the U.S.S.R. by Germany led to the interruption of the third five-year plan, to the evacuation of as much equipment and labour as possible from the Ukraine, including the Donbas, to beyond the Urals, and to the loss of important factories, mines and productive resources generally. The strain thus placed on the economy necessitated severe consumer rationing and the disappearance of many consumer goods from the market. It also led to further emphasis being placed on incentives to increased output; the use of piece-rates, premiums and bonuses for exceeding production targets was extended and longer working hours became common. The extra earnings thus made possible would, however, have provided little incentive unless it were possible to spend them on goods. For this purpose an uncontrolled market was permitted on which extra rations and other goods could be bought at entirely uncontrolled prices. This most interesting, but not entirely new, feature in some ways resembled a legal black market.

Germany. — The German problem differed again. Although the German economy was based on private enterprise and private property, state intervention, direct and indirect, was much greater in peacetime than it was in the western nations. Foreign exchange control. price and wages control had been established in the years before the outbreak of World War II. Moreover, total government expenditure had been absorbing a large and growing proportion of the national income since 1936, so that German industry was more dependent on the government than was the case elsewhere. The extensive trade associations and cartels also formed an easy channel for government influence. When war broke out considerable use was made of existing cartels and new ones were formed compulsorily, so that by placing nominees on their governing bodies the government could secure complete control of individual industries. In other respects the steps taken to extend control of industry were not dissimilar in purpose to those used in Great Britain; but they wereintroduced earlier and many were highly developed early in 1940. Thus raw materials and labour were controlled and allocated, industries were concentrated, production of many goods was prohibited, specifications were laid down for others and consumers were severely rationed.

The severity with which the controls were administered was, of course, determined by the development of the war. Thus the first year of the war cut Germany off from the most important producers of such materials as oil, rubber and some textiles. Rigid economy in motor transport was therefore essential from an early stage and also diversion of resources to produce substitutes of many kinds. Since Germany was the centre of a continental system it was peculiarly dependent on inland transport, on which the course of the war placed a severe strain; this led to zoning of markets and numerous restrictions on private travel.

Occupied France. — In the case of Germany, occupation of other countries offered considerable addition to its economic strength provided that the occupied countries could be suitably organized. Direct benefit could be obtained by the transfer of equipment (e g., rolling stock for railways) and conscripted labour, as well as prisoners of war, to Germany itself; but use of the main factories and natural resources required control of output in the occupied countries themselves. In the case of France, the German government attempted to build up an elaborate system for the complete control of the economy on a corporstive method under the central office for the distribution of industrial products. Under this central authority, responsible to the minister of production, organization committees were established to control the various industries. The committees had extensive powers of supervision of individual businesses, means of production, stocks, manpower and programs. Terms of employment were laid down under the Labour Charter law of 1941, administered by a hierarchy of joint committees of both sides of industry and outside representatives. The difficulties of controlling the use of materials and production were greatly increased by two causes inherent in occupied territories: the ordinary inflationary tendencies of war were enhanced by the spending of the army of occupation troops and officials, and unwillingness to co-operate with the occupying government became a patriotic duty. A close study of the history of control in France would show, by contrast, how important was the basis of consent both of consumers and producers to the effective working of industrial control in the other countries referred to.

BIBLIOGRAPHY.—World War I. There is no book adequately covering the whole field of war control of trade and industry. Brief contemporary surveys are contained in the Reports of the war cabinet for 1917 and 1918 (Cd. 9,005 and Cmd. 325). Different aspects of war control are dealt with in the volumes contained in the Economic and Social History of the World War (British Series), *e.g.*, J. A. Salter, *Allied Shipping Control,* E M H. Lloyd, *Experiments in State Control;* H. D. Henderson, *Cotton Control Board.* The unpublished and official *History of the Ministry of Munitions* may be consulted at the London School of Economics and some other libraries.

UNITED STATES

In both World Wars I and II, the U.S. economy had to meet the problem of supporting the war economies of allied powers in addition to supplying the U.S. armed forces. Since industry and trade had to be engaged in the single purpose of winning the war, consumer and business demands had to be conditioned to a schedule of wartime requirements. Control was essential to effect maximum production and the best practicable distribution of supplies among the military, allied and essential civilian uses.

While World War I brought the first experience in wartime control of industry and trade under the War Industries board headed by Bernard M. Baruch, that experience paled before the far greater challenge of World War II. Steering the largest and most diversified industrial system of the world into full wartime per-

formance, balancing it under ever changing requirements of warfare and preparing for its release from war duty was a staggering task of statesmanship and administration. In 1940–41 neither organizational nor material preparations were abreast of the complexity to which the United States economy—in technical and social respects—and the task of war itself had grown. The experience of the government in economic controls, although enhanced by the recovery efforts of the 1930s, nevertheless was inadequate to the management of the all-out effort. The size of the armed forces, their equipment, the consumption of supplies in battle were vastly greater, the supply lines longer. In addition to oil, steel, copper, cotton and wheat that made up the bulk of supplies to the Allies of World War I, vast amounts of finished aircraft, tanks, trucks, electrical equipment, dehydrated foods and all types of highly fabricated products were supplied to the Allies in World War II, chiefly under the lend-lease system. The industrial effort required was correspondingly greater and more complex. In the beginning it staggered the imagination of the most sanguine production men.

The first measures to create a munitions industry and give economic support to friendly nations were taken through regular government departments and a set of new auxiliary agencies without effective control powers, on an economy that was beginning to enjoy prosperity after a decade of underemployment. Prior to the attack on Pearl Harbor, it had proved impossible to join industry and armed forces in a big common effort. Neither the National Defense Advisory commission of May 1940 nor the Office of Production Management of Dec. 1940 and their associated agencies succeeded in creating ample stockpiles of strategic materials, expanding the industrial capacity for basic products (steel, aluminum) and war goods (ships, planes, tanks, etc.), and effecting a conversion of mass-production manufacturing to military production. They laid the foundation of the priority, conservation and price control systems and the elementary statistical groundwork for the planning of munitions productions, and created a useful system of railroad traffic control. They also helped develop in 1940 the financial arrangement prerequisite to enlisting private capital in plant expansion—the five-year amortization deduction which permitted concerns to charge off the value of new plant in five years against income under the income tax law. But while congress was pruning military appropriations and armament plans were uncertain, industry could not be diverted from its peacetime pursuits.

The lack of preparation came to bedevil war production from 1941 through 1943. Steel plants, synthetic rubber plants and merchant ship construction were then to compete with tanks and fighting ships for steel. But the "all-out" war economy inherited unemployed resources that facilitated its expansion, and experience in pilot war production gained in co-operation with Britain. When there was an urge to produce for war, industry lived up to the startling demands for "45,000 tanks and 60,000 planes in 1942, 75,000 tanks and 125,000 planes in 1943" that President Franklin D. Roosevelt put forward shortly after the attack on Pearl Harbor.

Organization of Controls.—The wartime control of industry was placed chiefly in the hands of the War Production board (WPB), Donald M. Nelson, chairman, created by the president in Jan. 1942. With powers to requisition property, to stop production of nonessentials and to force the acceptance of essential orders by producers, the board's chief task was to weave the labour, material resources and business leadership of the American people into a new production pattern. Its governmental powers over the economy were of a degree unknown in peace; but to succeed it had to rely on the initiative of managers, designers and workers in independent industrial units.

In the transition to a full war economy, most of the control power was applied to divert production from civilian to military end uses, to keep the dangerously short stocks of certain materials from being frittered away and to stop waste. Tire sales to civilians and passenger car production were stopped at once. Conversion of the huge automobile industry to tank, jeep, aeroplane and gun production was a first necessity. Orders limiting the production of other civilian goods and housing were to follow, and under the direction of the Office of Price Administration (OPA), created in Feb. 1942 with Leon Henderson as head, the curtailment of supplies was carried to the consumer through the rationing of gasoline, fuel oil, tires, bicycles, meat, coffee, sugar and other products. But the stress on war production for the U.S. and allied forces had to be balanced by emphasis on essential civilian production to assure the people necessary food, clothing, shelter and transportation. Waste of production and scarce resources, the real plague of all-out effort, had to be dealt with in both the military and civilian fields, industrial needs to be screened by the commodity groups of WPB allocating materials to factories, and consumer needs by rationing boards composed of volunteers working under the direction of OPA, which had to tailor rations to fit individual conditions. Fortunately the vast expansion of productivity in industry and agriculture prevented any serious threat to the people's health and vigour. To many it brought more material goods than they had enjoyed before.

The primacy of military demands for goods and services could not fail to act as a continual challenge to civilian control. Throughout the war the army and navy did their own procurement and controlled specifications and inspection. Centralized procurement under civilian direction was not attempted and probably would have failed, but the power to contract tended to be the power to control. There was competitive procurement by the military authorities. Conflicts were unavoidable; many were solved productively, others were not. The preference of procurement agencies for large industrial concerns tended to leave large numbers of smaller concerns outside the war production program. By encouraging pooling of production capacities, subcontracting and other methods, however, WPB redressed the balance. Fluctuations in army procurement, delays, rush orders, over-ordering, then cutting back were a more serious problem, since they upset the complex time schedules and the balance of supply streams and output. Industry wanted stable designs of products for mass production; but battle experience repeatedly led the military men to change the designs of tanks and planes.

In 1944, after war production had passed its peak and some unemployment appeared in a few places, the problem of starting reconversion to peacetime production while the war was still on caused a sharp clash of views between WPB and the army. Experience showed that real differences of outlook based on differences in background and tasks were compromised and adjudicated, or fought out between agencies, but could not be resolved by the device of merging military and civilian control bodies. The task of settling the more basic conflicts fell in the last instance on the president.

Production Control Techniques.—The control devices used by the War Production board were varied and changing. Individual priority actions issued by WPB or the procurement agencies fixed the preference ratings of specific orders. Blanket priorities expressed preferences to be given to the orders of certain classes of users, say, to steel orders coming from machine tool makers. But priorities, once called by Bernard Baruch "the synchronizing force of war industry," showed a dangerous tendency to get in their own way. In the rush of army, navy, maritime commission and lend-lease orders. A-I priorities were superseded by AA-I priorities. Soon jobs rated AAA slipped in ahead of the AA ones. Of course a developing war program required the frequent readjustment of priorities to bring about the acceleration of some activities and the slowing down of others. But the upgrading and downgrading of orders by the various agencies, sometimes deliberate, sometimes the mere result of the invention of a new symbol of higher urgency, and the overissuance of high priority ratings caused much confusion in industry.

In July 1942, the organization of the priority system was somewhat improved; but the remaining complexity was apparent in an agreement between the WPB and the Army and Navy Munitions board (ANMB) then concluded:. "The ANMB continues as the primary military body for reconciling and presenting to the WPB the army and navy supply requirements. Acting in this capacity the ANMB is the 'advocate' for the allocation and priority needs of the military program. The ANMB will continue to exercise the

responsibility for granting priorities to the military services and their contractors, subject to the directives of the WPB." Simultaneously, a new control device, called the Production Requirements plan was put in motion to dam up the stream of priority orders emanating from the military procurement agencies. Contractors were forbidden to attach the military ratings for their products to their own orders of supplies. Instead they had to use the ratings set by WPB. Finally, in Sept. 1942 the War Production board took over the assignment of preference ratings on military contracts.

The Production Requirements plan called for periodic applications from each of the large metal consuming plants to WPB, listing the kinds and quantities of products made in the plant and the preference ratings against which they were to be shipped. Having established the importance of each claim the plant then had to demonstrate what it would amount to in terms of materials, and taking account of the stocks of materials on the spot, what new supplies it would need and when. After having attempted to match the total demand for and the total supply of each critical material, WPB would authorize the plant to buy materials in specific quantities over a period of time. But even before the plan had become the principal machinery of materials distribution, it was earmarked for replacement; for the flood of high-rating requirements that it brought down on the War production board stood in no reasonable relation to available supplies of production goods. The procurement actions of the services and the accumulation of priorities issued earlier made requirements run far ahead of supplies. The WPB was not in a position to rule between the services and to cut their procurement to fit supplies. Therefore, many of its authorizations to buy were invalidated by shortages and delays. The plan did not work.

To cope with these problems a new plan was developed — the Controlled Materials plan. After a short trial period it became the basic materials control system in July 1943. This plan designated a number of "claimant agencies," chiefly the army, navy, maritime commission, Aircraft Resources Control board, Foreign Economic administration, Office of Lend-Lease Administration, Office of Defense Transportation, War Food administration and the Petroleum Administration for War. Each claimant agency was required to translate its procurement program for a three-month period ahead into the common tender of the "controlled materials," carbon and alloy steel, copper, brass and aluminum. Programs for ships, tanks, ammunition and other military and civilian products were expressed in these units and presented to WPB. After total claims had been balanced against total supply, which often required the reduction of some claims, each claimant agency was allotted a share of the controlled materials. These allotments covered all programs of the agencies and were to be passed on to their prime contractors and by them in turn to the suppliers of components under a system of budgetary accounting.

The accounting in a few common units and the allotment of materials within the limits of supplies were of great value, and so was the decision to attach the control levers to programs rather than products. The distribution of materials outside of the controlled group and of components was expected to adapt itself more or less automatically to the allocations of the controlled ingredients. It did so to a fairly high degree; but contractors were often found to buy uncontrolled items in excess of their allotments of controlled ones, sometimes with the encouragement of the procurement agencies who hoped to stretch the supplies of controlled materials through savings in production or to obtain revisions of allocation subsequently. Thus lumber, textiles, chemicals, bolts, nuts and metal stampings were overordered and hoarded by shipbuilders, synthetic rubber producers, etc. This compelled WPB to introduce detailed scheduling controls over components and accessories, which probably meshed the control agency more deeply into the gears of industry than any other measure. The Controlled Materials plan was, at least in principle, the last word in industry control in World War II. It was never felt to be a perfect instrument and was criticized for regimentation and ineffectiveness; but it worked.

Price and Wage Controls. — Besides directing quantitatively the flows of essential goods and services, the control of industry and trade had to deal with the terms of exchange, prices and wages affecting all economic circulation. The vast demands meeting limited supplies had to be kept from causing a cumulative inflation of prices, wages and profits which would have proved disruptive to the pursuit of the war by causing hoarding, strikes and discontent in the armed forces. At the same time, stability had to be kept from impeding war production. In specific situations, price and wage increases were needed to provide the production incentive. Genuine costs of production had to be met, and in meeting them a great effort had to be made to keep the increases from breaking stability in general.

The first purpose was served by the General Maximum Price regulation of OPA (May 1942), which made it illegal for sellers to charge prices in excess of those in existence in March 1942. The broad price freeze replaced the piecemeal system by which individual commodity prices had been kept in check since 1940 while the economy moved toward full employment; but it did not cover most of the basic farm products which remained under the control of the department of agriculture, sales to the United States government under the control of the procurement agencies, and wages and salaries. The price ceiling was wide but not complete, and the pressure of the uncontrolled factors often came near to breaking it. This was particularly true in the field of farm prices where a strongly entrenched policy of price support inherited from prewar days often won out over stabilization.

The government's approach to wage control was less administrative, more judicial and political than was its approach to industrial prices. At first it relied on the restraining efforts of the trade unions which gave a no-strike pledge after Pearl Harbor. A National War Labor board (NWLB) was created in Jan. 1942 to settle disputes, and in July 1942 this board provided a valuable rule of thumb for wage control in its "little steel" decision. This decision limited wage increases to workers whose wages had not kept pace with the 15% rise in the cost of living that had taken place between Jan. 1941 and May 1942 (the date of the price freeze), or whose earnings were substandard or out of line. In Oct. 1942, the wage and salary stop was strengthened. The NWLB and the 12 corresponding regional boards, composed of representatives of employers, labour and public, assumed the function of wage stabilization, and an Office of Economic Stabilization under James F. Byrnes was created to co-ordinate all the price and wage controls of the various government departments.

These measures greatly slowed down the upward move of price and, reinforced by the president's "hold the line" order in 1943, prevented the repetition of the general price inflation of World War I. A rigid general freeze at the outset was neither politically nor economically practical. As it was, control probably reached too far into the field of nonwage civilian goods. Fuller employment and higher productivity often provided opportunities for production incentives even under price restraints.

Various rules and techniques were developed to cope with the price tensions. OPA gave subsidies to some producers (particularly in agriculture and mining) and traders whose cost had risen and whose prices were to remain stable. It "rolled back" the prices of goods that were about to force up other prices or wages. It fixed standards for profit margins and admissible price increases and developed methods of price supervision. While unable to prevent black markets entirely, OPA was effective in keeping the great bulk of essential supplies flowing through legal channels. The effectiveness of price and rationing controls was rather remarkable in view of the great excess of purchasing power over available supplies, generated by rising income and lagging taxation. It rested on the people's willingness to save increasing portions of their incomes, and in turn strengthened the will to save.

In the field of armaments and their specific components, price controls were chiefly exercised by the military agencies, the only purchasers of such products. Costs were analyzed and argued, risks examined and to a large extent assumed by the government. A large number of contracts were made on a "cost plus fixed fee" basis, a form well adapted to the widespread system of

government owned, privately operated production facilities; other contracts particularly for new types of products were made in terms of maximum prices, to be redetermined after some time. Renegotiation of contracts provided an instrument for the government to cut excessive profits that had arisen in past operations.

OPA controls, however, governed a large part of military purchases; *i.e.*, of goods that were not exclusively of military use, textiles, food, etc. To expedite procurement of such goods, OPA allowed more liberal policies for their pricing. But the problem of competence over prices in the war goods field was acute often between the civilian and military agencies. (See also RATIONING; WAR CONTROL OF FOOD; WAR CONTROL OF SHIPPING.)

BIBLIOGRAPHY.—Official histories of the two most important control agencies are given in *Industrial Mobilization for War, History of the War Production Board,* vol. i of which appeared in 1947, and in *A Short History of OPA,* (1947). Among a number of authoritative studies and reviews, the following are of special interest: Donald M. Nelson, *Arsenal of Democracy* (1946); D. Novick, M. Anshen and W. C. Truppner, *Wartime Production Controls* (1949); Thomas B. Worsley, *Wartime Economic Stabilization and the Efficiency of Government Procurement,* with an extensive bibliography (1949); J. K. Galbraith, "The Disequilibrium System," *American Economic Review* (June 1947). For World War I, *see* Bernard *M.* Baruch, *American Industry in the War* (1941). (Ho. ME.)

INE, West Saxon king, of the line of Ceawlin, succeeded Ceadwalla in 688. In the earlier part of his reign he was at war with Kent, but peace was made in 694, when the men of Kent gave compensation for the death of Mul, brother of Ceadwalla, whom they had burned in 687. In 710 Ine fought in alliance with his kinsman Nun against Gerent of West Wales and was victorious, and in 715 he repulsed an attempted invasion by Ceolred, king of Mercia. In 721 Ine slew the rebel Cynewulf, and in 722 his queen Aethelburg destroyed Taunton, which was held by Eadbriht, another rebel. In 725 Ine fought with the South Saxons, who had previously been subject to him, and slew their leader Aldbryht. In 726 he resigned the crown and went to Rome where he died shortly afterwards, being succeeded by Aethelheard in Wessex. Ine is said to have built the minster at Glastonbury. He issued a written code of laws for Wessex, which is still preserved.

INEBOLI, a town on the Black sea coast, Turkey, 70 m. W. of Sinub (Sinope). Ineboli represents the ancient *Abonouteichos,* famous as the birthplace of the false prophet Alexander, who established there (2nd century A.D.) an oracle of the snake-God Glycon-Asclepius. Alexander obtained leave from the emperor Marcus Aurelius to change the name of the town to *Ionopolis,* whence the modem name is derived. (See ALEXANDER THE PAPHLAGONIAN.) It is the first place of importance touched at by vessels going eastwards from Constantinople. The roadstead is exposed and landing difficult. The exports are chiefly wool and mohair. Population 47,538.

INEBRIETY, LAW OF. The legal relations to which inebriety gives rise are partly civil and partly criminal.

I. Civil Capacity. — The law of England as to the civil capacity of the drunkard is practically identified with and has passed through substantially the same stages of development as the law in regard to the civil capacity of a person suffering from mental disease (see INSANITY). Unless (see III. *inf.*) a modification is effected in his condition by the fact that he has been brought under some form of legal control, a man may, in spite of intoxication, enter into a valid marriage or make a valid will, or bind himself by a contract, if he is sober enough to know what he is doing, and no improper advantage of his condition is taken (cf. *Matthews* v. Baxter, 1873, L.R. 8 Ex. 132; Imperial Loan *Co.* v. Stone, 1892, 1 Q.B. 599). The law is the same in Scotland and in Ireland; and the Sale of Goods Act, 1893 (which applies to whole of Great Britain), provides that where necessaries are sold and delivered to a person who by reason of drunkenness is incompetent to contract, he must pay a reasonable price for them.

Under the Roman law, and under the Roman Dutch law as applied in South Africa, drunkenness, like insanity, appears to vitiate absolutely a contract made by a person under its influence (Molyneux v. Natal Land and *Colonization Co.,* 1905, A.C. 555).

In the United States, as in England, intoxication does not vitiate contractual capacity unless it is of such a degree as to prevent the person labouring under it from understanding the nature of the transaction pending (see *infra*). The same rule is by implication adopted in the Indian Contract Act (Act ix. of 1872, s. 12). In some legal systems, however, habitual drunkenness is a ground for divorce or judicial separation (Sweden, Law of April 27, 1810; France, Code Civil, art. 231, Hirt v. Hirt, Dalloz, 1898, pt. ii., p. 4, and n. 4).

II. Criminal Responsibility. — Under the law of England, until early in the 19th century, voluntary drunkenness was never an excuse for criminal misconduct. Sir Matthew Hale (P.C. 32) took a fairly moderate view, viz., that a person under the influence of this voluntarily contracted madness "shall have the same judgment as if he were in his right senses." But the law on the subject was ultimately defined by the House of Lords in 1920, in the case of Director of Public Prosecutions v. Beard (1920, A.C. 479), in which all the earlier decisions were reviewed in the following terms: (1) Insanity, whether produced by drunkenness or otherwise, is a defence to the crime charged; (2) evidence of drunkenness which renders the accused incapable of forming the specific intent essential to constitute the crime should be taken into consideration with the other facts proved in order to determine whether or not he had this intent; (3) evidence of drunkenness falling short of a proved incapacity in the accused to form the intent necessary to constitute the crime, and merely establishing that his mind was affected by drink so that he more readily gave way to such violent passion, does not rebut the presumption that a man intends the natural consequences of his acts; (4) the test of criminal responsibility is not the same in the case of drunkenness as in the case of insanity, and upon a plea of drunkenness where insanity is not pleaded, the jury should not be asked to consider whether, if the accused knew what he was doing, he also knew that he was doing wrong.

The law of Scotland accepts, if it does not go beyond, later developments of that of England in regard to criminal responsibility in drunkenness. Indian law on the point is similar to English (Indian Penal Code, Act. xlv. of 1860, ss. 85, 86; Mayne, *Crim.* Law of India). See also the Criminal Code of Queensland (No. g of 1899), art. 28; the Penal Code of Ceylon (No. 2 of 1883), art. 79; the Criminal Code of Grenada (No. 2 of 1897), art. 51; and the Criminal Code of St. Lucia (1920, s. 22). Under the French Penal Code (art. 64), *il n'y* a *ni* crime, *ni* de'lit, *lorsque le prévenu était* en *état* de *démence* au temps de *l'action.* According to the balance of authority (Dalloz, *Rép.* tit., Peine, ss. 402 et seq.) intoxication is not assimilated to insanity within the meaning of this article, but it may be and is taken account of by juries as an extenuating circumstance (Ortolan, Droit *Pénal* i. s. 323: Chauveau et Hélie i. s. 360). Nor is it assimilated to insanity in Germany (Clunet, 1883, p. 311); but in Germany, as in France, intoxication may apparently be an extenuating circumstance. Under the Italian Penal Code (arts. 46–49) intoxication — unless voluntarily induced so as to afford an excuse for crime — may exclude or modify responsibility. In the United States the prevalent legal doctrine is similar to the English legal view.

There remains the question how far drunkenness itself is a crime. Mere private intoxication is not, in England, indictable as an offence at common law; but in all civilized countries public drunkenness is punishable when it amounts to a breach of the peace (see LIQUOR Laws) or contravention of public order; and modem legislation in many countries provides for deprivation of personal liberty for long periods in case of a frequent repetition of the offence. Reference may be made in this connection to the Inebriates Acts, 1898, 1899 and 1900 (see III. inf.), and also to similar legislation in the British colonies and in foreign legal systems (*e.g.,* Cape of Good Hope, No. 32 of 1896; Ceylon, Licensing Ordinance, 1891, ss. 23, 24, 29; New South Wales, Vagrants Punishment Act, 1866; Massachusetts, Acts of 1891, c. 427, 1893, cc. 414, 44: France, Law of Jan. 23, 1873, art. 6).

III. State Action in Regard to Inebriety. — This assumes a variety of forms. (a) Measures regulating the punishment of occasional or habitual drunkenness by fines or short terms of imprisonment. (b) Control in penal establishments for lengthened periods. (c) Laws prohibiting the sale of liquor to persons who are known inebriates: *e.g.,* in England (Licensing Act, 1902); Ontario (Rev. Stats., 1897, c. 245, ss. 124, 125); New South Wales (Liquor Act, 1898, ss. 52, 53); Cape of Good Hope (No. 28 of 1883, s. 89). (d) Laws regulating the appointment of some person or persons to act as guardian or guardians, or who may be endowed with legal powers over the person and estate of an inebriate. Thus in France (Code Civil, arts. 489 et seq.) and Germany (Civil Code, art. 6 [3]), an inebriate may be judicially interdicted if he is squandering his property and thereby exposing his family to future destitution. (*e*) Control for the purpose of reformation. Legislation of this character provides reformatory treatment: (1) for the inebriate who makes a voluntary application for admission; (2) by compulsory seclusion for the inebriate who refuses consent to treatment and yet manages to keep out of the reach of the law; (3) for the inebriate who is a police court recidivist or who has committed crime caused or contributed to by drink. The legislation of Great Britain (Inebriates Acts, 1879–1900) deals both with voluntary application and with the committal of criminal inebriates or of police court recidivists. A brief sketch of the English system must suffice.

The Inebriates Acts of 1879–1900 deal in the first place with non-criminal, and in the second place with criminal, habitual drunkards.

For the purposes of the acts the term "habitual drunkard" means "a person who, not being amenable to any jurisdiction in lunacy, is notwithstanding, by reason of habitual intemperate drinking of intoxicating liquor, at times dangerous to himself or herself, or incapable of managing himself or herself and his or her affairs," although when sober no such danger or incapacity exists (*Eaton* v. *Best,* 1909, 1, K B. 632). A person would become amenable to the lunacy jurisdiction not only when habitual drunkenness made him a "lunatic" in the legal sense of the term, but where it created such a state of disease and consequential "mental infirmity" as to bring his case within s. 116 of the Lunacy Act, 1890. Any "habitual drunkard" within the above definition may obtain admission to a "licensed retreat" on a written application to the licensee. stating the time (the maximum period is two years) that he undertakes to remain in the retreat. When an habitual drunkard has once been committed to a retreat, he must remain in the retreat for the time that he has fixed in his application, subject to certain statutory provisions similar to those prescribed as to leave of absence and discharge from mental homes; and he may be retaken and brought back to the retreat under a justice's warrant. The term of detention may be extended on its expiry, or an inebriate may be re-admitted on a fresh application, without any statutory declaration, and without the attesting justice being required to satisfy himself that the applicant is an habitual drunkard.

Licensed retreats are subject to inspection by an inspector of retreats appointed by the home secretary, to whom he makes an annual report. There are also statutory provisions as to offences — (~)by licensees failing to comply with the requirements of the acts; (2) by persons ill-treating patients, or helping them to escape or unlawfully supplying them with intoxicating liquor; (3) by patients refusing to comply with the rules. The home secretary may (1) authorize the establishment of "State inebriate reformatories," to be paid for out of moneys provided by parliament; and (2) sanction "certified inebriates' reformatories" on the application of any borough or county council, or any person whatever, if satisfied concerning the reformatory and the persons proposing to maintain it.

Miscellaneous. — Any person convicted on indictment of an offence punishable with imprisonment or penal servitude (*i.e.,* of any non-capital felony and of most misdemeanours), if the court is satisfied from the evidence that the offence was committed under the influence of drink, or that drink was a contributing cause of the offence, may, if he admits that he is, or is found by the jury to be, an habitual drunkard, in addition to or in substitution for any other sentence, be ordered to be detained in a State or certified inebriate reformatory, the managers of which are willing to receive him. Again, any habitual drunkard who is found drunk in any public place, or who commits any other of a series of similar offences under various statutes, after having within 12 months been convicted at least three times of a similar offence, may, on conviction on indictment, or, if he consent, on summary conviction, be sent for detention in any certified inebriate reformatory. Habitual drunkenness has been held to be a ground for the refusal of restitution of conjugal rights (Fisk v. Fisk, 122 L.T. 803). Where the husband of a woman is an habitual drunkard, she may obtain a protection order; where the wife is an habitual drunkard, the husband may obtain an order equivalent to a decree for judicial separation (Licensing Act, 1902, s. 5). A convicted inebriate of 60 years or upwards may be disqualified for an old age pension (Old Age Pensions Act, 1908, s. 3). A parent who is convicted of an offence under the Children Act, 1908, may be sentenced to detention in a certified inebriate reformatory (s. 26).

BIBLIOGRAPHY.—As to the history of legislation on the subject see Parl. Paper No. 242 of 1872; 1893 C. 7008. See also Wyatt Paine, Inebriate *Reformatories* and Retreats (1899); Blackwell, Inebriates Acts, *1879–1898* (1899); Wood Renton, Lunacy (1896). An excellent account of the systems in force in other countries for the treatment of inebriates will be found in Parl. Pap. (1902), cd. 1474.

(A. W. R.)

United States. — In the United States, by the decided weight of authority, the contract of a completely intoxicated person is voidable. It is capable of repudiation or ratification when the party becomes sober, and the ratification may be express or implied, the burden being upon him to take action within a reasonable period after he becomes sober to disaffirm it; otherwise ratification is presumed from his silence. The rule is the same in the United States as in England that a man may, in spite of intoxication, bind himself by contract, if he knows what he is doing and comprehends the consequences of his acts. If his intoxication utterly and entirely deprives him of his reason and understanding he may set his contract aside on the ground of drunkenness.

Voluntary intoxication carries with it the assumption by the drunkard of all criminal responsibility, while if the criminal act was committed when the intoxication was involuntary this is a complete defence to a criminal charge based on the act. However, the condition known as delirium tremens, when it has progressed to a degree establishing permanent insanity, which renders the person incapable of distinguishing between right and wrong, relieves him from criminal responsibility for his acts, even though the condition was voluntary in its inception. The theory and reason for the rule is that the man is insane, and his insanity is a defence even though it was produced by the voluntary excessive use of intoxicating liquors. (People v. Rogers, 18 N.Y. g; Flanigan v. The People, 86 N.Y. 554; State v. Haab, 195 La. 230.) Intoxication, even though voluntary, may be adduced in evidence in those acts which become crimes when done knowingly or *with* a specific intent or purpose, and the courts have held that in such cases the fact of intoxication is admissible to negative the existence of such knowledge or intent, which is a necessary element of the crime.

The manufacture and sale of intoxicating liquors for beverage purposes in the United States was controlled first under sanction of the war powers of Congress and later (from Jan. 16, 1920 to Dec. 5, 1933) under the eighteenth amendment to the Constitution. The prohibition act of Nov. 21, 1918, was upheld by the federal supreme court (Hamilton v. Kentucky *Distilleries,* etc. Co., 251 U.S. 146; United States v. Standard *Brewery,* 251 U.S. 210, *Ruppert* v. *Caffey,* 251 U.S. 264), on the ground that it was within the war powers granted by the Constitution. The act of Oct. 28, 1919 (known as the Volstead Act), elaborating upon the previous act and providing for the enforcement of the amendment as soon as it came into effect, forbade the manufacture, sale, and transportation of intoxicating liquors for beverage purposes, and narrowly defined the meaning of that term. The Supreme Court (*Ruppert* v. *Caffey,* supra) held that the provisions of this act

extending prohibition to malt liquors, with an alcoholic content of 0.5% by volume, whether actually intoxicating or not, was a proper exercise of the discretion of congress. The act made certain exceptions under a permit system, stating lawful uses of liquor; *i.e.,* for scientific, sacramental, medicinal, and mechanical purposes. (See PROHIBITION.) (J. P. EA.)

INERTIA MOTION. In meteorology and oceanography, inertia motion refers to the motion of air or water moving horizontally without horizontal forces. With respect to a co-ordinate system fixed to the rotating earth, such motion is circular, provided that the variation of latitude is small. This "inertia circle" can be most easily explained in terms of the fictitious Coriolis force (see MOTION, LAWS OF).

As long as no other forces act, and the variation of latitude can be neglected, a particle is deflected uniformly (to the right in the northern hemisphere) and describes a circle in the clockwise sense. The size of the circle depends on the initial velocity, and the period to complete the circle is one-half day divided by the sine of the latitude. In the southern hemisphere, the corresponding circle is counterclockwise.

The effectof varying latitude is to increase the trajectory curvature at high latitudes relative to that at low latitudes. Hence, under large latitudinal displacements, inertia circles are modified to spirals, in which a westward drift is superimposed on the inertia circle.

Pure inertia motion has been observed in the ocean, but not in the atmosphere. However, air motion subject to a uniform pressure gradient without friction can be described by the vector sum of geostrophic motion and inertia motion. Indications of damped inertia motion have been obtained from constant-level balloon trajectories.

Because of inertia motion, the atmosphere has a natural period of oscillation, which at latitude 30° is exactly one day. When daily heating causes a periodic force on the atmosphere, resonance occurs at this latitude, and the resulting motions are amplified. Such periodic forces occur at coast lines and cause land-sea breezes with large amplitude near latitude 30°. Over the interior of continents friction caused by momentum exchange is strongly enhanced by daytime heating; at night it nearly disappears. This periodic variation of frictional force results in large diurnal wind variations near latitude 30° with maximum amplitude about 2,000 ft. above the ground. At this height the nocturnal wind speed is substantially in excess of the geostrophic value. Therefore, the wind between midnight and sunrise frequently increases with height to about 2,000 ft. and decreases above, forming the so-called low-level jet stream near 2,000 ft.

Inertia Instability.—A configuration is stable when a particle has a restoring force acting on it after displacement. In meteorology or oceanography, inertia instability denotes the stability of geostrophic flow for displacement at constant entropy (nearly horizontal in most cases). (See also GEOSTROPHIC WIND.)

Geostrophic flow is unstable when the geostrophic current of air or water increases poleward more rapidly than $2\omega \sin \phi$, where ω is the angular velocity of the earth and ϕ the latitude. On the other hand, a poleward decrease of current is stable, no matter how great the variation of the current.

Inertia instability has been used to explain the observations that both for the atmospheric jet streams, and for fast ocean currents, the current profiles are asymmetrical: the poleward variation of speed can have extreme gradients, whereas on the equatorward side, the gradient of current rarely exceeds $2\omega \sin \phi$.

Some meteorologists believe inertia instability to be important in the formation of storms (cyclogenesis). There exists some doubt, however, about whether the motions set up by inertia instability are of sufficient scale and magnitude to be important in this connection.

Inertia instability is further enhanced for anticyclonic curvature of air trajectories (see GRADIENT WIND).

(H. A. A. P.)

INFALLIBILITY, the fact or quality of not being liable to err or fail (Med. Lat. *infallibilitas, infallibilis,* formed from *fallor,* to make a mistake). At the present time the idea of infallibility in religious matters is most commonly associated with the claim of the Roman Catholic Church. and more especially of the pope personally as head of that Church, to possess the privilege of infallibility, and it is with the meaning and limits of this claim that the present article deals.[1] The substance of the claim to infallibility made by the Roman Catholic Church is that the Church and the pope cannot err when solemnly enunciating, as binding on all the faithful, a decision on a question of faith or morals. The infallibility of the Church, thus limited. is a natural outcome of the fundamental conception of the Catholic Church and its mission. Every society of men must have a supreme authority, whether individual or collective, empowered to give a final decision in the controversies which concern it. A community whose mission it is to teach religious truth, which involves on the part of its members the obligation of belief in this truth, must, if it is not to fail of its object, possess an authority capable of maintaining the faith in its purity, and consequently capable of keeping it free from and condemning errors. To perform this function without fear of error, this authority must be infallible in its own sphere. The Catholic Church has expressly claimed this infallibility for its formal dogmatic teaching.

The infallibility of the pope (*q.v.*) was first defined in 1870 at the Vatican council. The exact formula for the papal infallibility is given by the council in the following terms (Constit. Pastor aeternus, cap. iv): "we teach and define as a divinely revealed dogma, that the Roman Pontiff, when he speaks ex *cathedra—i.e.,* when, in his character as Pastor and Doctor of all Christians, and in virtue of his supreme apostolic authority, he lays down that a certain doctrine concerning faith or morals is binding upon the universal Church—possesses, by the Divine assistance which was promised to him in the person of the blessed Saint Peter, that same infallibility with which the Divine Redeemer thought fit to endow His Church, to define its doctrine with regard to faith and morals; and, consequently, that these definitions of the Roman Pontiff are irreformable in themselves, and not in consequence of the consent of the Church." A few notes will suffice to elucidate this pronouncement.

a. As the council expressly says, the infallibility of the pope is not other than that of the Church; this is a point which is too often forgotten or misunderstood. The pope enjoys it in person, but solely qua head of the Church, and as the authorized organ of the ecclesiastical body united with him.

b. The late date at which the dogma was defined is explained by the fact that the mode of exercising authority on the part of the Church has varied since the time of Christ; but it is affirmed that the dogma was already contained in that of the papal primacy established by Christ himself in the person of St. Peter. A certain dogmatic development is not denied. nor an evolution in the direction of a centralization in the hands of the pope of the exercise of his powers as primate; it is merely required that this evolution should be well understood and considered as legitimate.

c. Infallibility is the guarantee against error, not in all matters, but only in the matter of dogma and morality; everything else is beyond its power, not only truths of another order, but even discipline and the ecclesiastical laws, government and administration, etc.

d. Again, not all dogmatic teachings of the pope are under the guarantee of infallibility ; neither his opinions as private instructor, nor his official allocutions, however authoritative they may be, are infallible; it is only his ex cathedra instruction which is guaranteed; this is admitted by everybody.

e. The last phrase of the definition is aimed at Gallicanism and kindred doctrines, political rather than theological, which placed the authority of the Church above that of its head.

But what is the extent and limit of an ex cathedra pronouncement? The direct and immediate object of this infallible teaching concerns those truths of faith and morals, revealed by Christ and passed down by Scripture and tradition. Of its nature, this deposit of faith is so intimately bound up with other truths, either by a historical or logical relation, that to deny these latter would destroy

[1] On the idea of infallibility in reference to a written revelation, see INSPIRATION.

the practical religious purpose of the deposit itself. This principle, that infallibility is extended to truths that are directly connected with the deposit of faith, is upheld by all theologians. In this category of connected truths or secondary objects of infallibility are: (1) logical conclusions drawn from premises, of which one is a revealed truth and the other a truth known with certitude by natural reason, *e.g.*, Christ had a human body and soul; (2) natural truths insofar as connected with revealed truths, *e.g.*, idea of person, substance, etc.; (3) facts historically connected with dogmas which, though not revealed as such, would, if denied, destroy the revealed dogma, *e.g.*, ecumenicity of a council; (4) ecclesiastical laws and precepts for the regulation of worship or guidance of the entire body of the faithful, *e.g.*, law of communion under one species. Further, not every official decree of the pope is protected by his infallibility. In the bull of Pius IX on the Immaculate Conception, the strict infallibility is confined to a sentence or two. There, as in every ex cathedra definition, the pope declares positively that the faithful must believe a definite proposition under pain of heresy.

The controversies occasioned by this question had started from the beginning of the council, and were carried on with bitterness on both sides. The minority, among whom were prominent Cardinals Rauscher and Schwarzenberg, Hefele, bishop of Rottenburg (the historian of the councils), Cardinal Mathieu, Mgr. Dupanloup and Mgr. Maret, did not pretend to deny the papal infallibility; they pleaded the inopportuneness of the definition and brought forward difficulties mainly of an historical order. The majority, in which Cardinal Manning played a very active part, took their stand on theological reasons of the strictest kind; they invoked the *tu* es Petrus and the *pasce* agnos of Christ; they showed the popes, in the course of the ages, acting as the guardians and judges of the faith, arousing or welcoming dogmatic controversies and authoritatively settling them, exercising the supreme direction in the councils and sanctioning their decisions; they argued that the few historical difficulties did not involve any dogmatic defect in the teaching of the popes; they insisted upon the necessity of a supreme tribunal giving judgment in the name of the whole of the scattered Church; and finally, they considered that the definition had become opportune for the very reason that under the pretext of its inopportuneness the doctrine itself was being attacked.

The definition once proclaimed, controversies rapidly ceased; the bishops who were among the minority one after the other formulated their loyal adhesion to the Catholic dogma. The last to do so in Germany was Hefele, who published the decrees of April 10, 1871, thus breaking a long friendship with Dollinger. In France, though no bishops abandoned it, a few priests, such as Father Hyacinthe Loyson, refused their adhesion. The most distinguished among the German dissentients was Dollinger, who resisted all the advances of the archbishop of Munich, was excommunicated on April 17, 1871, and died unreconciled, though without joining any separate group. After him must be mentioned Friedrich of Munich, several professors of Bonn, and Reinkens of Breslau, who was the first bishop of the "Old Catholics" (*q.v.*).

Butler, *Life and Times of Bishop Ullathorne* (2 vols., London, 1926); H. E. Manning (card.), *Petri Privilegium,* 1871, and *The Vatican Decrees in their Bearing on Civil Allegiance,* 1875; *J. H.* Newman, *Letter to the Duke oj Norfolk,* 1875.

INFAMY, public disgrace or loss of character. Infamy occupied a prominent place in Roman law, and took the form of a censure on individuals pronounced by a competent authority in the state. Such a censure involved disqualification for certain rights both in public and in private law. In English law infamy as a cause of incompetency was abolished by 6 & 7 Vict. c. 85. The same has occurred in most of the codes which followed the Roman law in this relation; *e.g.*, the Spanish penal code of 1848.

The word "infamous" is used in a particular sense in the English Medical act of 1858, which provides that if any registered medical practitioner is judged by the General Medical council, after due enquiry, to have been guilty of infamous conduct in any professional respect, his name may be erased from the medical register. The General Medical council are the sole judges of whether a practitioner has been guilty of conduct infamous in a professional respect, and they act in a judicial capacity, but an accused person is allowed to appear by counsel.

See *Pratt* v. *British Medical Association,* 1919, 1 *K.B.* p. 270 and cited cases. As to dentists, *see* the Dentists act, 1921, establishing a dental board.

INFANCY. Infancy is usually regarded as extending through the first year of life or until the child begins to walk alone, at which time he is often referred to as a toddler.

In the mid-20th century infants were healthier and had a better chance of survival than they had at any previous time in recorded medical history. In England and Wales in the 1870s the infant mortality rate was approximately 150 per 1,000 live births; by mid-20th century it had been reduced to 25. The rate in the United States stood at approximately 150 as late as 1900; this had been reduced to less than 27 at mid-century. In Europe infant mortality rates range from as low as 18.2 per 1,000 in Sweden to 110.2 in Yugoslavia.

Important among the reasons for the greatly improved chance of survival was the advance in knowledge of foods and nutrition. Clean milk alone greatly reduced gastrointestinal diseases that formerly were the chief killers. Chemistry and biology contributed chemotherapeutic and biological agents to combat many infectious illnesses.

Any discussion of infant care must include a consideration of the mother and the unborn baby. It is often said that a fetus is a parasite on the mother. Unless the mother is a healthy person and unless the maternal diet is adequate, the fetus may not receive the essential nutrients necessary for optimum development. It has been demonstrated also that certain infectious illnesses during the early months of pregnancy can unfavourably influence the developing fetus. Good health and good nutrition thus are of utmost importance for motherhood, not only throughout pregnancy but presumably even before conception occurs. (See also PREGNANCY; MATERNAL AND CHILD HEALTH.)

DEVELOPMENT, HEALTH AND COMFORT

Newborn Infant. — The length of a normal male infant born at full term averages about 20.0 in.; females 19.5 in. The average boy baby weighs about 7.5 lb. and the average girl slightly less, about 7 lb The circumference of the head of a boy baby is approximately 13½ in., that of a girl approximately ½ in. less. The head grows rapidly during infancy. At the top of the head is a soft spot, the fontanelle, which is well protected by a very tough layer of dense protective tissue which is gradually replaced with bone; usually the spot is completely closed by the end of infancy.

Infants are usually, but not always, born without visible teeth. The first tooth erupts at about six months. The time of appearance of the first tooth may vary considerably but the place of its appearance is remarkably uniform: it usually appears just at one side of the middle of the lower jaw. By the end of the first year six teeth usually have erupted — four upper incisors and two lower incisors.

The skin of newborn white babies is reddish but rapidly fades to a light pink. Other babies have skin colourings characteristic of their races. By the third or fourth day the skin often takes on a slightly yellowish colour, which normally tends to disappear during the next ten days to two weeks. The skin of well-nourished babies soon takes on a smooth pink velvety appearance and is elastic to the touch. The amount of hair on the heads of newborn babies shows great variation in amount, colour and texture, although it tends to be much more delicate in texture than it is in later life.

Newborn babies are incapable of visual focus; their eyes are likely to move in any direction and their motion is not co-ordinated. Strong light causes discomfort. By the end of a month babies begin to focus momentarily on objects and during the next two months they gradually develop greater skill and begin to recognize objects; their eyes will follow a moving object.

Newborn babies are often quite deaf, but this tends to correct itself rapidly and soon they respond to noise, words and music.

Babies are readily disturbed when jarred or touched. Newborn babies are relatively less susceptible to pain than are older infants and children.

Sucking is a reflex act which is fully developed in babies born at full term but weak in premature infants. The ability to continue sucking is influenced by muscle fatigue. Rest periods and artificial assistance are sometimes necessary when the sucking reflex of a weak baby does not permit the taking of adequate nourishment. The ability to swallow, well developed at birth, is related to the sucking reflex.

The neaborn baby cries when hungry or cold or otherwise uncomfortable. When appetite is satisfied and the infant is warm and in a comfortable position he sleeps much of the time.

Progress of Development. — During the first year normal development follows a fairly uniform pattern but with considerable individual variation. It is generally not until the age of six weeks or two months that the baby smiles in response to a pleasant approach. Purposeful smiles are not to be confused with facial contortions apparently associated with abdominal distress in the young baby. At about three months the baby begins to use his fingers with purpose and by four months some skill has been acquired with arm movement. The baby laughs, turns his head in response to being spoken to and holds his head up well at about three months. Often he can roll himself over on a hard surface; this is an important point to remember. A baby should never be left on a table or a bed without due precautions to ensure that he will not push himself off and fall to the floor. At five months the baby reaches for objects and soon learns to pick them up. At about seven months he begins to sit alone. From ten months to a year the baby begins to use a few one- or two-syllable words, and his comprehension of words begins to be shown in response to a few simple commands. Toward the end of the first year he learns to pull himself to his feet and in about one year he begins to take a few steps with support.

Bowel habits and bladder control are matters that may be considered in relation to the child's general development. There is little use in trying to teach infants bowel and bladder control until their development has reached a point where it is possible for them to have enough success to be encouraged. It is often reported that babies have been trained to control bowel movement at the age of two or three months, but one must consider the possibility that this may be a trained mother rather than a trained child. It is seldom advantageous to start bowel habit training before a baby can sit alone comfortably and before he can understand the idea his mother is attempting to convey to him. Training with reference to bladder control habits is generally started after success has been obtained with bowel control. Physical punishment or scolding should never be the technique used to establish toilet habits. The alertness of the mother to create situations that will ensure successes that can then be praised is by far the most satisfactory method and least time consuming. Failures on the part of the child should be treated as unfortunate accidents.

Parental Love and Affection. — The importance of beginning early to develop in the child a sense of security can scarcely be overestimated. This sense of security is dependent on a feeling of being loved and wanted. Behaviour problems of childhood can be minimized or reduced by giving fully of parental love. Babies soon learn to enjoy being held by their parents; they enjoy play that is suitable for their age and they respond to the multitude of other little evidences of parental love.

However, there are a few cautions to be observed and suggestions that may be made. Babies cannot stand rough play with their fathers immediately after eating; it usually causes regurgitation of food, and, furthermore, this is the time for sleep. Infants should be protected from tickling. The morning bath can be a happy time for both mother and baby. Feeding time should be a pleasant experience without tenseness. The urgency that some mothers feel about the necessity of giving their infants a measured amount of food at each feeding time creates unnecessary tension and establishes bad eating habits. Well babies should not be forced to eat. Late afternoon is a suitable time for play; some regularity is desirable, for the baby must learn that he cannot be played with at any or every time he fancies.

Cleanliness. — Once a day a baby should be given a bath in water at normal body temperature (between 95° and 100" F.). The temperature should always be tested (using the mother's elbow) before placing the baby in the water; this will prevent accidents and enhance the baby's pleasure. There are a variety of acceptable tubs. It is essential, however, that the tub be firmly placed and incapable of being tipped over, and it should be of a kind that can be readily cleaned. In bathing an infant another point to remember is that the skin of a wet baby is slippery and that the mother must always have a firm hold of her baby when he is in the tub. First she lowers the baby's buttocks into the water. One hand firmly grasps the baby's right arm above the elbow near the shoulder; the remainder of her hand supports his back and her wrist and forearm support his neck and head. The mother's other hand is then free to cleanse the baby's body nith a dampened wash cloth and a small amount of a mild soap. A minimum amount of soap should be used. When baths are skillfully given babies soon learn to enjoy them.

Since it is a characteristic of infants to put objects in their mouths and since the mouth is one of the most common portals of entry for disease-producing microorganisms it is essential that hands, toys and eating utensils be kept clean.

Keeping a Well Baby Well. — Barring accidents or the occurrence of the few diseases of unknonn cause or those for which there is no known treatment, it is entirely possible through the application of known knowledge to maintain a baby in a state of optimum health throughout the first year and beyond.

The rules for keeping a well baby well are simple but important, as follows:

1. Proper feeding (see below).
2. Preventing infectious disease.

The rules governing the prevention of exposure of infants to infectious diseases are a direct application of techniques established years ago in contagious disease hospitals for the prevention of spread of infectious disease from one patient to another. The success of antibiotics has often led to carelessness in these matters; however, to ignore well-established, effective rules of sanitation because cures are available is comparable to being careless with matches because the city has a good fire department. The baby should have a room or a corner that belongs to him and him alone. The most convenient place in the daytime is a room adjoining the place where the mother spends most of her time, usually the kitchen. No one is permitted in the baby's room except well people with washed hands and clean clothes. If any member of the family is suffering from a common cold or other infectious illness he must stay out of the baby's room or corner.

In case the mother has a cold and it is necessary for her to take care of the baby during this period, she can prevent the baby from contracting the cold if she will observe the simple aseptic technique that is known to all pediatric nurses, modified for home use. While caring for the baby the mother wears a mask of gauze over her nose and mouth; she washes her hands with soap and water and dries them on a clean towel, and without touching contaminated objects outside the baby's room, she enters the room and slips into a loose cotton gown with sleeves which cover her clothing. With these precautions she is ready to take care of the baby, and it is perfectly possible for her to do so without transmitting her cold. The gown used in the baby's room should never be used for any other purpose than that for which it is intended and should be kept in the baby's room except when it is washed. After scrubbing her hands and getting into her gown the mother does not touch her face or things that she has handled with unwashed hands.

Young babies do best when kept at home; traveling with small babies invites the possibility of exposure to infections. Visitors are invited to look at but not handle babies. If the visitor has a cold the baby is not brought out for inspection. Persons with infectious disease should not come closer than six feet to a well infant and must cover coughs and sneezes.

3. Immunizations. These are available for diphtheria, tetanus,

whooping cough and poliomyelitis. Babies under six months are not susceptible to measles providing the mother had measles before she became pregnant. After babies lose their natural immunity they may be protected by the use of proper immunization technique, but known exposures must be promptly reported to the baby's physician with a request for assistance.

4. Cleanliness (see above). It is important to remember that not all bacteria are harmful and that it is not necessary to observe absolute surgical asepsis in order to prevent the occurrence of illness of infectious origin. Absolute cleanliness (asepsis) is necessary, however, when persons in the household are suffering from or have recently suffered from colds or other infectious illness, or when the baby may be exposed to persons whose state of health is unknown to the mother. When all members of the household are well and free from illness simple cleanliness suffices for all health purposes.

5. Preventing accidents (see below).

6. Good hygiene. This requires provision of opportunity for restful sleep, frequent changes of linen, daily outdoor airing (weather permitting), sun baths when recommended by the baby's own physician, opportunities for free play consistent with the age of the infant, an abundance of love and affection, together with the application of all the foregoing rules.

7. Pediatric care. The mother and the father can act sensibly and with good judgment only when they are informed concerning the above rules. The pediatrician will assist them with problems they do not understand.

Accident Prevention. — Accidents that can happen to the infants are relatively few, and if the subject is given a little thought most of them can be prevented. A thoughtful mother can invent most of her rules and they can be effective. However, the following are given as examples: (1) when carrying a baby always be sure to have a firm hold — babies wriggle, squirm and jump at unpredictable times; (2) never leave a baby alone on a bath table or examining table or any other surface from which he might fall; (3) when bathing a baby always hold him securely; (4) never hold or carry hot objects above a baby; (5) remove pointed or sharp objects from the baby's reach; (6) be sure the slats on the side of the baby's crib are close enough to prevent the baby from getting his head through; (7) do not give the baby easily breakable toys; (8) very small toys are to be avoided; the baby may choke on them; (9) toys covered with lead paint or water-soluble stains are to be avoided; (10) plastic sheets and bags must be kept completely out of reach of babies and small children, since they may be slipped over the head and may then cling to the face and cause suffocation.

Sun Baths. — When weather and temperature permit, sun baths are usually recommended, since exposure to the sun's rays, and to skyshine for that matter, transforms substances in the skin to materials which have vitamin D activity. While vitamin D preparations can be given by mouth when sun-bathing is impossible or impractical, it is believed that sensible exposure to the sun is beneficial. While there is no agreement with reference to the precise age at which sun-bathing can best be started, it is probable that most babies can be safely exposed outdoors, temperature permitting, after the age of two or three months. The baby's eyes should be protected from direct exposure to sunrays, and direct exposure to the glare of a cloudless sky on a summer day is also evidently unpleasant for the infant.

The time of exposure naturally varies with the season of the year, the time of day, the age of the infant and character of skin. It is safer to avoid exposure in midday when the sun is hottest. It is often recommended that first exposure be for as short a time as two minutes. Succeeding exposures can be gradually increased until tanning occurs. It must be remembered that babies do not tan so deeply as adults do and that they burn much more easily. The physician should be consulted on how much sun each baby needs.

Clothing. — The chief object of clothing is comfort. Babies should wear only a sufficient number of garments to keep them warm and comfortable. In newborn babies the temperature regulating mechanisms may not be fully developed and therefore they may need extra clothing to maintain body temperature. If there is doubt in the mother's mind that her infant is wearing too many clothes, it is usually possible to tell by observing the presence or absence of perspiration on the baby's back. The mother may pass her hand over the baby's back under the shirt and if she finds the skin wet with perspiration it is almost certain that the child is overclothed; if on the other hand the skin is warm and dry to touch and the baby is otherwise apparently comfortable and happy, the amount of clothing is probably appropriate. Cotton clothing is generally most comfortable next to the baby's skin and is easier to wash than most other materials. The baby should wear a hat or a bonnet on cool days out of doors.

Sleeping Out of Doors. — Fresh cold air is stimulating and invigorating even to quite small babies. However, good judgment must be used in placing babies out of doors to sleep. Weak or very small babies require control of external temperature and are best kept in the house. A healthy, vigorous baby gradually can be accustomed to cool or cold air provided that he is appropriately covered. Some overzealous mothers have permitted frostbite to occur in babies' cheeks and on the backs of their hands. While these usually are not serious, they are to be avoided. After frostbite hard lumps may appear beneath the skin of the frostbitten area and persist for weeks.

INFANT FEEDING

Breast Feeding. — The ideai food for the young infant is human milk. It supplies all of the nutrients in amounts and variety necessary for good growth and development provided the mother is in good health and is eating a nutritionally satisfactory diet. One possible exception to the nutritional adequacy of human milk is vitamin D, but this can be obtained from exposure to sunlight.

The yellowish fluid that is secreted before breast milk makes its appearance is known as colostrum. The amount varies greatly. Colostrum alone is secreted for a period of from two to four days; after this comes a transition to breast milk which is complete at the end of about three weeks.

It has long been held that colostrum may confer some degree of immunity on infants, but however that may be, its removal from the mother's breast by the infant is of importance to the establishment of lactation. Early nursing also encourages early contraction of the mother's uterus.

The composition of human milk varies, as does that of other foods, within a rather wide range. According to P. C. Jeans the approximate percentage composition of human milk is as follows: fat 3.5%; sugar 7.5%; protein 1.25%; lactalbumin 0.75%; casein 0.50%; total ash 0.20%; calcium 0.032%; magnesium 0.004%; potassium 0.041%; sodium 0.011%; phosphorus 0.013%; sulphur 0.014%; chloride 0.032%; iron 0.0001%; copper 0.00003%. In addition breast milk contains traces of other minerals plus identified and unidentified vitamins. In fact milk from healthy mothers who are themselves on a nutritionally adequate diet supplies all of the nutrient needs of the infant with the exception of vitamin D. The amount of breast milk is usually suited to the needs of the infant. Some mothers can nurse two babies when necessary.

Successful nursing implies that the mother must be free from debilitating disease, that she eat adequately (but not excessively so that she gains unneeded weight) and that she be emotionally adjusted. Adequate rest is necessary. Exercise should be moderate. Home surroundings should be as pleasant and as congenial as possible, and in all these things the husband plays no small part. Professional medical attention is also sometimes required and is always helpful.

In addition to the other good reasons for encouraging breast feeding it is emotionally satisfying to both the mother and infant. Nursing time is often the one time when the mother can relax and enjoy her baby. When she nurses her baby there is no formula to worry about and there is no concern when the infant does not take all of an alloted formula.

Cow's Milk. — When the nutritional needs of infants cannot be met with human milk, other means of supplying these needs are available. Infants who do not receive human milk, however, may require certain nutrients in amounts greater than are present in

breast milk. Cow's milk approaches a perfect food only for the baby calf. Furthermore, in no species of animal is milk alone the sole source of food for more than a relatively short period after birth. Soon infants require supplementary foods just as young animals do.

The milk formula for the newborn baby is generally made up of milk, added water and a carbohydrate (one of several sugars or mixtures such as lactose, maltose-dextrin mixtures, glucose and sucrose). It is common practice in the calculation of formulas to give from 1 to 1½ oz. of milk per pound of body weight. One and one-half ounces of milk supplies approximately 3.4 g. of protein and 0.12 g. of calcium per kilogram, together with other minerals, lactose, fat (apparently sufficient for the infant's needs), water and vitamins — notably vitamin A, riboflavin and some thiamine and niacin.

At first the total fluid volume of the formula is in the neighbourhood of 2½ to 3 oz. per pound of body weight. Later the volume is diminished. Thus after determining the amount of milk required, the difference between the calculated amount of milk and the calculated volume of the formula is made up by adding boiled water.

Babies need approximately 50 cal. per pound of body weight. This is easily calculated. The amount supplied by the milk in the formula is calculated on the basis of the fact that average cow's milk supplies 20 cal. per ounce. The difference between the total caloric need and the caloric value of milk in the formula represents the number of calories that need to be added to the formula to make it supply the necessary energy value. This is usually done by adding an appropriate amount of carbohydrate in the form of one of the sugars. Most sugars contribute approximately 120 cal. per ounce. More than 1½ or 2 oz. of sugar is seldom required.

The rapidly growing healthy infant soon is able to take whole undiluted pasteurized milk or unsweetened evaporated milk diluted to the equivalent of whole milk by the addition of an equal amount of water. Full-strength powdered whole milk also may be used.

In bottle feeding infants it is essential to observe strict cleanliness in the preparation of formulas and to refrigerate all bottles whose contents are not consumed at once. There are many ways of preparing formulas, but the object of all of them is to attain a clean (pasteurized or sterilized) product and to keep it safe until the time of use.

Goat's milk approximates cow's milk in nutritive value and generally may be used as a substitute, particularly if the infant is allergic to cow's milk. When using goat's milk it is especially important to be certain of the cleanliness of the supply and that it has been properly pasteurized. Powdered and evaporated goat's milk are also available. Soybean preparations may also be used as substitutes for cow's milk.

Supplemental Foods. — Except in the case of breast feeding, and then only for a short time, the infant can rely on no single food to supply his total nutrient needs. The early supplementation of the diet with nutrients known to be essential for good growth and development is necessary. Furthermore, it is desirable to start early the cultivation of good food habits with relation to foods other than milk.

The first supplement for babies fed both human and cow's milk is vitamin D. It may be started in the first week with the addition of vitamin D concentrates or the pure vitamin. The infant apparently needs no more than 350 units of vitamin D per day, although the dose usually given is 400 units. Doses above 1,500 units per day tend to inhibit the appetite when given over a period of time, with the result that the growth rate is impaired.

Because the vitamin C content of cow's milk decreases on storage it is necessary to supplement the infant's diet at an early age with foods containing this vitamin. In North America it is a common practice to use orange juice, tomato juice or other fruit juices blended with acerola (West Indian cherry) juice, which is by far the richest of all fruits in vitamin C. In Australia, black currant juice and papaw juice sometimes replace citrus juices. Orange juice can be started a few days after birth and increased rapidly up to two or three ounces at the age of three months. Advances in the technique of canning and freezing orange juice make it possible for these juices to supply an abundance of vitamin C at all times of the year, even during the season when fresh oranges are not easily obtainable.

In addition to supplying natural vitamin C, fruit juices contain other valuable nutrients.

Iron-bearing food supplements are also essential for the infant fed on cow's milk, because a baby fed on this type of milk alone will tend to develop an iron deficiency anemia after a period of several months. (See ANEMIA.) For this purpose and to encourage the baby to learn to like a variety of foods it is common practice to start strained vegetables and fruits, meat, egg yolk and cereal at an early age. All these supply needed iron. Good cereal sources of iron are the whole grain cereals, notably oatmeal, and specially fortified cereals.

Home-prepared strained fruits and vegetables for infants have been replaced largely by specially prepared, high-quality, commercially processed foods, available in jars and cans and, after 1960, also as instant dry frozen foods requiring only the addition of water before feeding.

The supplementation of the cow's milk diet with food sources of thiamine and possibly other members of the B-complex group of vitamins is generally regarded as desirable. Strained meat, whole grain cereals (oatmeal or specially fortified cereals) and many fruits and vegetables all provide supplements of thiamine. Egg yolk is a good source, and fruits and vegetables are better sources than highly refined cereals.

At about six months the baby has often developed sufficient skill with his hands to permit him to start feeding himself with a spoon. At this time he sits easily and comfortably and should be encouraged to feed himself. Supplemental foods have the added advantage of assisting in the cultivation of a taste for a variety of foods that later on are even more important in the diet. The smooth strained foods of early infancy may be gradually changed to coarser foods beginning at about six or seven months and to distinctively coarser foods soon after the baby is a year old. While it would appear that most babies tend to demand coarser foods voluntarily when given a choice, failure on the part of the mother to supply them sometimes results in the persistence of the desire for smooth foods long beyond the end of the first year.

It is important also to mention the fact that the parents' attitude toward foods is unquestionably recognized by infants at an early age. Thus it is very helpful for the parents to adopt the habit of regarding all good foods as pleasing and pleasant to eat. The opposite attitude often results in refusal on the part of the infant.

Water should be available at all times for drinking purposes and can be given at any time to satisfy thirst. Generally speaking it is desirable not to give water within 15 minutes before a regular feeding time.

A good working philosophy is to regard eating as a pleasure and not a duty. Well babies should never be forced to eat.

INFANT, in law, a person who has not attained his full age or majority and is therefore subject to disabilities entailed by nonage or minority. At common law the age of legal majority for both sexes is 21 years. The same rule has been adopted generally in the United States, except in a small group of states which have fixed the age of majority for females at 18 years. See CHILDREN, LAWS CONCERNING. (M. DN.)

INFANTE, a title of the sons of the sovereigns of Spain and Portugal, the corresponding *infanta* being given to the daughters. (From Lat. *infans,* young child.) The title is not borne by the eldest son of the king of Spain, who is prince of Asturias, *il principe de Asturias.* While a son or a daughter of the sovereign of Spain is by right infante or infanta of Spain, the title, alone, is granted to other members of the blood royal by the sovereign.

INFANTICIDE. In sharp contrast with the modern anxiety to lessen child mortality is the extent, as vouched for by sound historical evidence, of the practice of infanticide or of putting newborn infants to death or of allowing them to die.

Thus it is recorded of the Nandi that "children are buried alive in cow-dung if they cry in their mother's womb or if at birth they present their legs first, or are born with teeth. as these events are considered unlucky." From every quarter of the world comes evidence of similar practices, supported by similar reasons. The horror of the abnormal explains many of the cases. Breaches of the rules regulating sexual intercourse may, as with the Nandi, lead to the immediate death of the offspring because the ancestral spirits seeking reincarnation can achieve their desire only by regular marriage. The birth of twins, as an abnormal occurrence, may be viewed as either an indication of future prosperity or of impending misfortune, and social attitudes conform with the view taken in the community of the incident. Some welcome twins as proof of divine favour, others deem them akin to animals and therefore to be destroyed.

Among the Tuski, Ahts, western Eskimo and the Botocudos newborn children were killed now and then if they were weak and deformed, without distinction of sex. Among the Dakota Indians and Crees female infanticide was rare. The Blackfoot Indians believed that a woman guilty of such an act would never reach the "Happy mountain" after death. but would hover around the scene of her misdeed with branches of trees tied to her legs. The Aleutians held that child murder brought misfortune on the whole village. Among the Abipones it was common, but boys were usually the victims, because it was customary to buy a wife for a son, whereas a grown daughter would always command a price.

Infanticide is sometimes practised for economic reasons, as when an Australian mother thinks she is unable to rear the newborn babe. In Africa, where a warm climate and abundance of food simplify the problem of existence, the act is not common. In Polynesia, while the climate ensures food in plenty, the relative smallness of the islands imposed the custom on all families without distinction. In the Hawaiian Islands all children, after the third or fourth, were strangled or buried alive. At Tahiti fathers had the right (and used it) of killing their newly born children by suffocation. The chiefs were obliged by custom to kill all their daughters. The society of the Areois, famous in the Society Islands. imposed infanticide upon the women members by oath. In other islands all girl children were spared, but only two boys in each family were reared.

Cases are known were a child has been killed in order that its soul may pass to a woman desirous of offspring. In India female infanticide was attributed to the custom of hypergamy (*q.v.*). To some superstition related to the social order is also attributed the rule of the Wataveta requiring the destruction of every child born to a woman after her daughter's marriage. The system of age grades which forms an essential part of the structure of that tribe is perhaps the factor in this connection.

Children, especially the first-born, were killed to cure barrenness. to ensure health, good fortune and general fertility. Reincarnation beliefs play a part, since if the son is the reincarnation of his father the son is put to death and the father lives. Again special sanctity, special virtue attached to the first-born and therefore the sacrifice of the first-born had special efficacy. In certain conditions the legitimacy of the first-born is dubious and his destruction may then be regarded as a special case of illegitimacy. There are many proofs of infanticide in religions possessing ethical potentialities such as druidism and Semitism as well as in advanced communities such as Egypt. Greece and Rome.

That the destruction of weak, deformed and unsightly children at birth mould have favourably affected the quality of the community is highly probable. Eugenic motives, however, were not present, and the destruction of such children was conditioned by the superstitions attached to them.

INFANTILE PARALYSIS (ANTERIOR POLIOMYELITIS) is an acute infectious disease caused by a filterable virus and characterized by symptoms which range from a mild nonparalytic infection to an extensive flaccid paralysis of voluntary muscles.

History. — There is evidence that the disease has existed for many centuries. However, the first clear description of it came from Jakob von Heine in 1840. It was not recognized in its epidemic form until nearly a half century later, when Oskar Medin in 1887 reported observations on an outbreak in Sweden. In addition to the usual spinal form, he recognized the bulbar and certain less common types of the disease. C. S. Caverly, in 1896, recognized that the disease may occur in an abortive or nonparalytic form, a fact confirmed by others later.

While earlier outbreaks centred largely in Sweden, epidemics have occurred in many parts of the world and became particularly prominent in the United States after the beginning of the 20th century.

Incidence. — Severe epidemics have been reported in many countries and islands including North, Central and South America, Europe and Africa. The disease reached epidemic proportions in some region of the U.S. almost every year after the beginning of the 20th century. The greatest recorded sustained incidence in the United States was in 1942–53; in 1950, for example, there were 33,344 cases in the U.S. In 1952 severe epidemics occurred in Denmark, Germany and Belgium. In Asia outbreaks have been reported in Bombay. Singapore. Japan, Korea and the Philippines.

Symptoms. — The commonest early complaints consist of mild headache, fever, sore throat. nausea, vomiting, diarrhoea, restlessness and drowsiness. The temperature rises slowly, reaching its peak in two to three days, and then rapidly subsides. Fortunately more than two-thirds of the patients who develop these early symptoms recover and remain well without any signs of muscle weakness. When the disease is severer, the patient develops pain in the back and limbs, muscle tenderness, stiff neck, irritability and fretfulness.

Spinal Poliomyelitis. — This is the commonest type of paralytic poliomyelitis and is caused by infection of the spinal cord. At about the third day of the illness, the patient develops weakness of the limbs. The paralysis may be of all grades of severity from transient weakness which soon disappears to complete and permanent paralysis. The lower limbs are more often affected than the upper limbs. Within a few months after the development of paralysis, the involved muscles begin to atrophy.

Respiratory Poliomyelitis. — The muscles of the chest that control breathing receive their nerve supply from the upper part of the spinal cord. When the virus injures this part of the spinal cord, the patient develops difficulty in breathing. Acts such as coughing, sneezing and sniffing cannot be carried out. When there is a definite loss of function to these muscles, it is essential that some mechanical device be used to aid respiration.

Bulbar Poliomyelitis. — That part of the nervous system situated just above the spinal cord is called the bulb or brain stem. In this region are situated the nerve centres that control swallowing and talking and when poliomyelitis affects this area the patient has difficulty mith these actions. Secretions pool in the throat. The voice becomes hoarse and develops a nasal twang. The accumulation of secretions in the throat may block the airway, causing the patient to suffocate. If this obstruction to the airway is not relieved, the patient loses consciousness and will die.

Diagnosis. — In the preparalytic stage of the disease, the diagnosis must depend on strong clinical suspicion supported by certain laboratory observations on the spinal fluid. This is particularly true of patients who become ill in the late summer and fall in an area where infantile paralysis is prevalent. In 1951 a rapid method for identifying the infection became available, based on the direct inoculation of tissue cultures with stools of ill patients. Virus growth is manifested within 24 hours by a breakdown of the growing tissue culture cells.

Prognosis. — Of all patients who develop infantile paralysis, more than 80% recover within three to four days without the development of paralysis. When paralysis has occurred, consider-

able restoration of normal muscle powers results under proper treatment, although some residual weakness remains in almost half these patients. The over-all fatality rate in the United States was estimated in the 1950s at 5%, while a death rate of 30% had been reported in Europe during periods of low prevalence.

Treatment. — Treatment during the preparalytic stages includes complete bed rest, isolation and careful observation. The patient should be permitted to assume whatever position he wishes. It is important to check carefully for evidence of limb paralysis or breathing or swallowing difficulty.

If paralysis occurs, good nursing care is of primary importance. The bed should be firm with a board under the mattress. Passive movement of the limbs can be used to avoid deformities. Moist heat usually makes the patient more comfortable. As muscle strength returns, exercises are increased. (See below, *Orthopaedic* Aspects.)

When there is paralysis of the breathing muscles, some form of mechanical breathing aid is necessary. The commonest one used in the United States is the tank respirator, or "iron lung." The patient is placed in the tank respirator with only his head emerging. and by a rhythmical increase and decrease of the pressure within the tank his chest is expanded and relaxed. In less severe cases it is possible to use a respirator that fits to the chest only (cuirass respirator) or a rocking bed.

When the patient develops difficulty in swallowing, with accumulation of secretions in the throat, it is important that the airway be kept open by removal of the secretions. This can be done by a mechanical suction machine. If suction of the machine is not adequate an artificial airway must be made from the outside into the throat (tracheotomy).

Aetiology.—In 1909 Landsteiner and Constantin Levaditi showed that the causal agent of infantile paralysis is a filterable virus (see VIRUSES). This virus cannot be cultivated on ordinary lifeless media but only in media containing living tissue cells. It is fairly resistant to physical and chemical agents and able to survive for some time in water, milk and sewage.

When the virus comes in contact with the defense mechanism of the body it elicits the formation of specific antibodies which act to neutralize its infectivity. Of importance, however, is the fact that not all strains are antigenically or immunologically alike. Many strains have been isolated from patients with infantile paralysis from all parts of the world; they can be divided into three immunologically distinct types, and infection with one type does not protect against reinfection with one of the other types. The three types are known as type I, or Brunhilde, type II, or Lansing, and type III or Leon.

Up to 1939 the virus could be transmitted to monkeys only. In that year, however, Charles Armstrong succeeded in transmitting the Lansing strain to eastern cotton rats and from these animals to white mice. In 1949 J. F. Enders and his associates demonstrated that the virus could be isolated and grown in tissue culture on non-nervous tissue cells, thus making it possible to study and grow this virus without the use of living animals. This inexpensive method of working with the virus greatly facilitated research and was directly responsible for the development of a vaccine against infantile paralysis (see below).

Pathology. — The virus probably enters the body through the throat and intestinal tract, since large quantities are excreted in the stools for a number of weeks before and after an attack of infantile paralysis. The disease is probably spread from person to person by intimate human contact. The virus possesses a marked affinity for the nervous system and migrates from the throat and intestines to the central nervous system along the peripheral nerves. Within the central nervous system also it spreads along nerve pathways (axonal transmission), and eventually reaches the more sensitive motor nerve cells in the spinal cord, medulla or brain. These are destroyed in varying numbers, and the destroyed cells are not replaced since nerve cells lack the power of regeneration. Not all cells attacked are destroyed, however, and those not severely injured recover their normal function in time. To the extent that they do recover a corresponding restoration of muscle function may be expected to take place.

Predisposing Factors. — Individual differences in the degree of natural susceptibility appear to exist. Many persons have acquired antibodies in their blood without having knowingly gone through a poliomyelitic infection. The disease commonly attacks those who seem to be in the best of health, so that undernutrition or faulty health do not appear to be predisposing factors.

It is generally held that a lasting immunity follows recovery from the disease. Second attacks are known to occur, however, some of which may be caused by strains differing immunologically from those which caused the first attack.

Among other predisposing factors, age has always been considered the most important. In earlier epidemics, most cases occurred in children under ten years of age. Later, however, there was a definite shift to the beginning of adult life.

Geographic areas appear to play little role in the disease. Although the majority of cases do occur in temperate climates, the disease has a world-wide distribution and has been reported in the tropics as well as in Iceland and Alaska.

Epidemics of infantile paralysis recur with considerable regularity during the summer in temperate areas. Although the disease persists throughout the year, the highest incidence is in the late summer and early fall. Active cases may extend into early winter.

Strenuous exercise, sudden chilling and pregnancy all seem to predispose to the disease. It is generally accepted that removal of the tonsils at the time when the disease is prevalent predisposes to the severer forms of the disease. There is also suggestive evidence that injections of any type (vaccinations) may predispose to the disease, particularly when it is prevalent.

Control. — The ultimate in the control of this disease is the development and use of a vaccine which can protect against infection (see The Salk Vaccine, below). Control measures must depend upon avoiding contacts so far as possible. This is exceedingly difficult, since during epidemic periods there are likely to be many who unknowingly spread the virus. There is no practical way of detecting these persons. All that is possible, therefore, is to avoid unnecessary contacts and especially new ones. A child in school may actually have fewer new and intimate contacts than one out of school.

Inasmuch as the stools of patients and of contacts have been found to contain the virus, often in large amounts, it seems clear that the same general sanitary precautions should be followed as those followed in the prevention of typhoid fever and dysentery. This includes, of course, rigid protection of food and water against possible faecal contamination, including contamination by flies, and the strictest personal and culinary cleanliness. Swimming, especially in public pools, should be avoided. The more serious late effects of infantile paralysis can be materially reduced by prompt medical attention. Proper treatment from the beginning is essential to this end.

The Salk Vaccine. — The state of immunity to paralysis that follows infection with poliomyelitis virus is associated with the presence of antibody specific against the infecting virus. Antibody, which is one of the normal serum proteins modified to possess antiviral activity, is present in the blood stream and acts by combining with virus, thereby rendering it ineffective. Thus, invasion of the cells of the spinal cord and brain is intercepted.

Antibody formation can be induced not only by infection but by inoculation with a killed-virus preparation; the latter is made in such a way that the virus no longer can multiply but does retain the property of stimulating antibody formation. Since there are three distinct immunologic types of poliomyelitis virus that affect man (see above), it is necessary for immunity to be induced to each. The diseases produced in man by viruses of the three immunologic

types are indistinguishable. In the 1950s type I virus accounted for approximately 80% of the paralytic cases, types II and III for about 10% each.

Since a rich source of virus is needed for the preparation of an immunizing agent, and since virus is propagated only inside living cells, the ultimate requirement for the immediate raw material—namely, the virus—is a rich source of susceptible cells. The latter is available in the form of cultures of monkey kidney cells that can be prepared in large flasks. Tissue from such cultures is prepared by reducing the monkey kidney substance to small fragments by cutting or further reducing these to small cell clusters or to individual cells. Then approximately 500 ml. of a dilute tissue or cell suspension is placed in a rectangular-shaped five-litre flask. The cells will settle and will attach to the flat glass surface, grow and then multiply. A suitable nutrient fluid is used, among the principal components of which are amino acids, salts and vitamins, as well as carbohydrates, proteins and fatty acids. Maximum cell yield develops in about one week. Since maximal virus yields are derived from cultures containing the greatest quantity of susceptible cells, the virus is inoculated into cultures at about this time. Infection of cells takes place promptly, soon after which the individual cells are disrupted and the cell sheet on the side wall of the flask is destroyed completely. As a result of the destruction of the cells in which virus multiplied, the fluid phase is then rich in virus. The virus is separated from the cell debris by passage of the fluid through filters that retain particles of the size of bacteria, yeasts and moulds. The virus, being much smaller in size, will pass through such filters, leaving behind the larger particles. This. then, is the starting material that is subjected to chemical treatment for destruction of virus infectivity.

The polio vaccine tested in the field in 1954 and first used for mass immunization in the United States in 1955 is composed of viruses killed by treatment with formaldehyde in which a concentration of 1:4,000 formalin (37% formaldehyde) is used at *p*H 7.0 and at approximately 37° C. for sufficient time to destroy all infectivity. This requires at least six to seven days, but in practice nine or ten days (sometimes longer) is employed to provide for a margin of safety. An entirely safe vaccine is created in this way, so long as precautions are taken to assure complete contact between virus particles and formaldehyde during the virus inactivation process. Since safety is dependent not only upon the absence of virus from samples of the final vaccine but also upon the reliability with which satisfactory vaccine is produced consistently, tests are made at several stages in the course of processing. First a determination is made of the rate of destruction of virus so that adequacy of treatment time can be established as a guide to provision of the desired margin of safety. Then, when it is believed that the process has resulted in the killing of all the virus, a sample is removed and. after an additional three days of treatment, still another sample is removed for test. These are examined for the absence of infective virus by inoculation into cultures of monkey kidney cells such as are used for multiplication of virus for vaccine. After the application of sufficient treatment to destroy infectivity, the material is then stored at refrigerator temperature. The three virus types. treated separately for killing the virus. are then combined in equal amounts and a sample is again tested to make certain that no infective virus is detectable. At this point. further action of the formalin is arrested by the addition of sodium bisulphite, or any other substance that combines with formalin, to prevent further action by this chemical. Further tests for safety are made by inoculation of monkeys, as well as a variety of other animals, and cultures. A test is made to establish potency by inoculating monkeys or other suitable animals in which antibody responses can be measured. Acceptability of vaccine for use depends upon its performance in this test and is indicated by the relative potency of the manufactured vaccine as compared with the performance of a reference vaccine that has been standardized for antibody-producing capacity in fully susceptible children.

Vaccine prepared and tested in the manner described is then administered to potential susceptibles to achieve protection for a number of years—the full extent of which had not yet been determined in 19jj. The objective is to create an immune state which will persist for life. This is approached by the use of two injections spaced not less than two weeks apart and preferably four to six weeks apart, follon-ed by a third not less than seven months later. Yearly booster shots have been advocated. Such divided doses induce much higher levels of antibody than could be achieved if the same quantity of vaccine were to be administered all at one time. Indications are that the prompt re-emergence of antibody, when the immunologic mechanism is restimulated by booster injections or upon later exposure to infection, provides the mechanism for resistance even when antibody has declined to low or to nonperceptible levels. (J. E. Sk.)

Live-Virus Vaccines.—Advances continued to be made and more effective vaccines constantly sought. Live-virus preparations. such as the Sabin, Cox and Koprowski vaccines, which can be given by mouth. are inexpensive to produce, theoretically confer long-lasting immunity and show promise of greater effectiveness over killed-virus preparations: Experiments, especially in the U.S.S.R., Great Britain and elsewhere, indicated the relative safety of such vaccines. (X.)

Orthopaedic Aspects.—The orthopaedic management of a paralytic patient is directed toward the prevention of deformities, correction of those which cannot be prevented and restoration of bodily function. Actually, 80% of patients with poliomyelitis require little more than general nursing care and recover without significant paralysis. Of the remaining 20%, not all require intensive orthopaedic care. During the acute phase of the disease the patient must be kept at absolute bed rest. Attention is given to the prevention of joint contractures by proper positioning of the extremities. As long as the patient is bedridden care must be taken to prevent the development of decubitus ulcers (pressure sores).

As muscle pain subsides active motion is begun. Frequently patients require assistance in certain movements to neutralize the opposing force of gravity. However, it is only through active contraction by the patient himself of those muscle groups which are still intact that sufficient strength can be restored to permit normal function of the part. In selected cases, supported walking or exercise in a water tank is of value. Other aides to the restoration of muscle power may occasionally be utilized. The relatively small group of patients who fail to regain enough muscle power to function independently can usually be taught to walk with the support of braces or crutches.

It is not until a permanent plateau of function is reached—usually 12 to 18 months after the acute illness—that surgical measures are considered. Surgery in poliomyelitis may be undertaken to (1) stabilize an unsupported joint, (2) correct fixed deformities, (3) adjust leg length inequalities or (4) restore function. A common stabilizing procedure involves arthrodesis (fusion) of a joint. In such cases motion is sacrificed for position and strength. Extensive fusion is sometimes the treatment of choice in scoliosis (spinal curvature) resulting from postparalytic imbalance of the spinal musculature. Another useful type of surgical operation involves transplantation of one end of a functioning but expendable muscle in the region involved to a new insertion where its contraction will then produce a movement or perform a joint-stabilizing function formerly the property of a paralyzed muscle group. Leg length inequality, rarely considerable enough to require treatment, may, when necessary, be compensated for by a growth-arresting procedure on the uninvolved extremity at an age calculated to permit equalizing but not excessive growth of the shorter leg. Clearly the purpose of surgical treatment, whatever the type, is to restore the paralytic patient to as nearly normal function as possible and free him from the use of artificial supports. (J. Dy.)

INFANTRY, the backbone of land forces throughout history, includes troops which fight on foot, even though transported to battle by horses, ships, aircraft, tanks, skis or other means. Troops armed with such hand weapons as the spear and sword in ancient times and with automatic rifles and rocket launchers in modern days; troops assisted in combat on land by cavalry, tanks and artillery, by air force fighter-bomber planes and by naval forces in amphibious warfare are all parts of infantry. As foot soldiers their objective has always been to seize and hold ground and, when necessary, occupy enemy territory. In the period following

World War II, infantry came to include elements of the former supporting arms of artillery and tanks as an integral part of Its organization. (See ARMY.)

Since ancient times the infantry has been the largest single element in armies, except during the feudal period. Infantry has fought on foot, on mountain and plain, in desert and jungle, in swamps and on landing beaches. This article will include a history of infantry from the time of Greece and Rome through World War II, and the special characteristics of infantry in the immediate postwar years.

A study of the history of infantry must take into account the social system which produced the armies of the period. At different ages in history, the same nation may produce an army which carries all before it, or fails to meet history's demands. Greece and Rome in classical history supply excellent examples of the changing character of soldiery.

In more modern times the difference between the French of the Revolutionary period and in World War II, or between Spain of the 15th and 19th centuries exhibits the importance of analyzing the social character of a people when discussing their army and its infantry.

The history of infantry through the ages should therefore include both the military factors of organization, strength, tactics, leadership and armament, and the social factors of the position of the soldier in the society. Two brief examples will serve to illustrate the point.

The Roman legion's battle formation—an interesting geometric design—could have been copied by other nations. Its tactics were not startlingly different from those of the Greek phalanx; its weapons were almost identical. The strength of the armies of the Roman republic was not greater than that of its enemies, and its leadership suffered by comparison with that of many of its adversaries. Yet again and again the Roman legion chalked up victories. The answer must lie outside the province of the purely technical military considerations, and probably in the social character of the people.

Napoleon's infantry was unbeatable during the first 15 years of his campaigns. Its organization, armament and tactics were duplicates of those in other armies. Its strength was usually less than that of its enemies; its leadership superior. However, during the early years of the Napoleonic campaigns the veterans of the grande *armée* were good, solid peasant and urban French stock, imbued with the glory of their part in the Revolution. When their numbers were decimated, and polyglot nationalities took their place, Napoleon caused the tactics to be changed to meet the lessened capabilities of the new levies.

EARLY INFANTRY

Infantry in a sense goes back to the first men who fought with clubs. When men fought on foot in groups, against other men or animals, they were fighting as infantry. Infantry undoubtedly existed in all the early tribes since they were an accepted part of the fighting force in the first nations such as Egypt and Assyria. Seven castes existed in Egypt at the time of the Pharaohs and the second caste were the warriors. They fought as infantrymen and were armed with bow and slings and, at one time, with bronze swords. In the Assyrian armies the predominant arm was cavalry which was reserved for the highest caste, the nobility. Lesser men served as foot soldiers.

From the beginning of organized warfare the infantryman appeared armed with sword and bow. As weapons improved and multiplied, tactics became more complex. But the general object of all change was to balance infantry capabilities more evenly in attack and on defense. Following the breakup of the Roman empire and the obliteration of European roads there was a 1,000-year period in which cavalry dominated the battlefield.

The history of infantry begins with masses of armed men trained to move and fight shoulder to shoulder. Its modern battle array in attack and defense is a succession of thinly deployed lines. The evolution of infantry formations, superinduced by changes in weapons, has required corresponding changes in infantry spirit. When ranks were closed, unity was achieved through the rule of blind obedience. With their thinning, infantry came to depend for cohesiveness on the inculcation of higher initiative and resourcefulness in its individuals. Charged with the basic mission of seizing and holding ground, the infantry has borne the brunt of human conflict through the ages and has been called Queen of Battles.

Persia.—In their heritage from the Egyptians and the Assyrians, the Persians utilized much the same method of warfare. The foot soldiers were armed with short spears and wicker shields but they depended upon the bow as their principal weapon. The Persians divided their infantry into heavy- and light-armed groups. The latter operated as a skirmish line ahead of the main force, expecting to be driven back on first contact with the enemy. On occasion. the light infantry fought on the flanks with the object of harassing the enemy flanks or rear.

Greece.—Mountains cut Greece into many cantons, preventing the growth of despotism. Hardy people, knowing both mountain and sea. the Greeks were natural infantrymen. The terrain of Thrace was more suitable for infantry than cavalry. Oddly, nature's advantages were the seed of civil conflict. Civil war led to self-destruction, the best men being killed in an irrational series of petty wars. The golden age of Pericles fell into ruin through the elimination of the elite in the Greek city-states.

The Greeks, being near the sea, were also traders. Their weapons and armour were borrowed from other Mediterranean peoples, skill in metal work being learned from others like the Phoenicians.

In the Greek city-states, the infantryman was a heavily armed pikeman, or hoplite. Spear and sword were his weapons. His protection was provided by shield, helmet, breastplate and greaves—the last a guard for the legs. The men fought in the phalanx, a mass formation created by the Greeks, which was also the basis for their tactics.

The military glory of the Greek city-states was ephemeral. and lasted for a mere century and a half before Alexander of Macedonia conquered them. In the interim, the Greeks won a great victory over the Persian invaders at Marathon (490 B.C.) on the plains north of Athens. Ten years later another Persian force invaded Greece with the aim of taking Athens. Though stopped momentarily at the pass of Thermopylae by the rear guard action of a valiant band of Spartans, Thebans, Phocians and Thespians, they were aided by treachery to reach Athens, which they sacked. A naval battle at Salamis compelled the withdrawal of the Persians, however.

Military service at that time was the duty and privilege of the city-state citizen-soldiers. The great proportion of the residents of states such as Athens and Sparta were not citizens, and therefore were not permitted to become members of the army. As each of the city-states attempted to spread its influence over the remainder of Greece, a warlike spirit became common throughout the peninsula.

Sparta was best known for the development of its warrior class, every effort of the state being devoted to turning out the finest infantry soldiers. For 13 years after being sent to a military camp at the age of 7. Spartan males were trained in military duties in preparation for entrance into the army at the age of 20 years. As long as they remained physically fit, they followed that calling.

The Athenian warriors were not trained in such a rigorous system, but they were liable to army service from the ages of 16 to 60. The other city-states like Thebes followed the Athenian system.

Constant civil war drained the Greek states of their best manpower, its place being taken by mercenaries and by slaves who fought to merit citizenship. Athens grew wealthy from its trade, and utilized that wealth to provide mercenaries as substitutes for its citizen army. Despite the high intelligence of the Greeks, their contributions to warfare were meagre: the phalanx, and the stepladder oblique tactics of the Theban commander, Epaminondas. The phalanx was a mass formation of heavily armed hoplites. initially eight ranks deep, who moved forward with their long spears waist high and straight ahead in a solid

bank of spear points. Spartan and Theban phalanxes met at the battle of Leuctra (371 B.C.). Against a Spartan army of 10,000, Epaminondas had a force of only 6,000, half of them doubtful allies.

Epaminondas, from his knowledge that previous battles had followed a set course with each side successful on the right wing, weak on its left, decided to align his forces in a new tactical formation. He placed his strength on the left, employing his Theban hoplites in a phalanx 50 ranks deep, and echeloning his remaining troops to the right and to the rear. His cavalry was placed well to the front of the weaker and "refused" right wing. This tactic was based on the simple fact that each Greek warrior instinctively sought to gain the protection of the shield on his right. As a consequence. the line inevitably dropped back on the left wing. Epaminondas' tactics were to strike the strong Spartan right with a greater-than-usual shock effect, while sending his cavalry to roll up the left of the Spartans. The Spartan right was thrown back, its demoralization being communicated to the left wing simultaneously under cavalry attack. Panic ensued. and the Thebans won a quick, overwhelming victory.

The traditional enemies, Athens and Sparta, leagued against Thebes, engaging its army ten years later in a battle in which Epaminondas died. His tactics shattered the Spartan right, but in the moment of victory he was killed and his troops left the field demoralized. Philip of Macedonia, having learned military art from Epaminondas in Thebes. returned home to train his own hardy mountaineers. He brought them south against Athens and Thebes, winning a total victory over the mercenary and inferior troops of these two states.

The Greek infantry and the Greek system of fighting reached the highest point under Philip and his son, Alexander (see ALEXANDER III, THE GREAT; PHILIP II of Macedonia). The latter placed his army, as was the custom of the time with the phalanx of heavily armed Greek and Macedonian infantrymen, in the centre preceded by slingers and archers; the cavalry protected the flanks.

The phalanx was modified by Alexander so that the human fortress nas 16 men deep and had 16 men on the front. Alexander armed his hoplites with a spear between 18 and 21 ft. long. With this weapon the heavily armed infantrymen, shoulder-to-shoulder, were able to present a solid front of spear points to an enemy. The first five ranks held their spears horizontally or with the points slightly depressed while the remaining ranks carried their spears vertically or rested them on the shoulders of the men in front. Though Alexander's phalanx mas an improvement over that of his predecessors, its close formation of 256 men was broken when marching over rugged ground. Alexander drilled his phalanx constantly, teaching them to form wedges or "V's" upon signal, and to make a flank movement or a countermarch as if they were a solid mass.

Alexander's battles with the Persians in Asia Minor and in Persia followed a similar pattern. His army of 30,000 to 40.000 was more manoeuvrable than the bulky forces of Persians numbering in the hundreds of thousands. At Granicus. Issus and Arbela. he struck with his strong right, employing heavy infantry as the holding force in the centre. He himself led the cavalry on the right flank in a tactic uniformly successful.

The campaigns in Asia Minor gradually used up the Macedonian and Greek forces, their plàces being taken by subject races and mercenaries. Alexander's successors, recognizing the deterioration of the infantry, concentrated their better soldiers in the cavalry, and built their tactics around flank attacks by horsemen.

Later wars between the Greeks and Romans indicated that heavy infantry was still the backbone of forces, honever. Dependence was placed upon the shock attack of the phalanx, and the available Greek soldiers were concentrated in that formation. The quality of the Greek armies steadily declined until the unimproved. inflexible Macedonian phalanx was defeated at Pydna (168 B.C.) by the legions of the great power of the west, Rome.

Rome.—The Italian peninsula, like Thrace, presented natural barriers to invasion; mountains cut it into isolated areas where city-states grew. Rome, one of these city-states, was originally the home of a peaceful people, but constant strife and a natural aptitude for military life eventually made them extremely warlike.

The Italian countryside, like that of Greece. was not conducive to the development of cavalry. The people depended upon their feet for mobility, and became in time a hardy foot soldiery. Like Athens' army, Rome's was composed originally of citizen-soldiers, who believed it their privilege to serve as warriors. Every citizen was liable for military service, but freedmen and slaves were not accepted in the army.

The history of Roman infantry may, for convenience, be divided into three periods: (1) the Punic Wars and the struggle with Greece; (2) the period of civil war from about 146 B.C. to the formation of the empire in 29 B.C.; and (3) the long period of empire.

For six centuries the Roman legion, an infantry organization, was supreme in warfare. Its composition changed from the citizen-soldier to the professional and eventually to the mercenary and barbarian. The weapons—the two-edged Roman sword and the lance—changed but little; the tactics were revised to suit the capacity of the various elements which made up the legion.

In the early period of the Roman republic, the legion was made up of the finest men in the state. Unlike the Athenian army, the Romans furnished their own arms and equipment. Wealth, usually in property, determined which one of the five classes of infantry a man might enter. The wealthiest class, other than those who joined the cavalry, were the infantry élite with good weapons and heavy armour. The last class was practically unprotected though armed with sword and spear.

Because of the constant warfare, the Roman militia became strong in veteran soldiers. In addition the recruits, eligible at the age of 17. had been trained from boyhood for the profession of arms. Active service, required until the age of 45, was followed by service in the home guard. Though the Romans of the early republican period were imitators of the Greek infantry and the Carthaginian cavalry, their basic organization, the legion, was superior to the phalanx. However, it was tailored to the spirit of the Romans, allowing them more freedom of movement and more flexibility in combat.

At the time of the Punic Wars, the Roman legion formed for battle in what looked like three rows of a checkerboard. Groups of legionaries, comprising 120 men each on a 12-man front and 10 files deep, formed in three lines 250 ft. apart. The width of ten of these maniples. as they were called, was 1,200 ft. The vigorous young Romans were in the front line (hastati), the battle-nise veterans in the second line (principes), and the oldest men in the third line (triarii). The maniples of the last line had a strength of 60 men. The recruits, from 17 to 2j years of age (velites), normally occupied a post in front of the hastati, until driven back by enemy attack. They then fell back to occupy the intervals between the maniples of the triarii.

From a tactical standpoint, the Roman legionary was in a loose formation compared with the Greek phalangite. His place in the maniple was about five feet from his nearest neighbour. When under heavy attack, the maniples of the hastati could fall back into the intervals of the principes, or conversely, on the offensive, the principes could move forward to utilize the intervals between the front-line maniples.

In combat an enemy would often filter through the Roman front line and become engaged with the second line. The Romans usually threw their javelins upon their first contact with an enemy and then resorted to swords for close fighting.

Normally the strength of the legion was about 4,200 infantrymen and 300 cavalrymen. However, since the term "legion" usually meant one Roman and one allied legion, the combined consular army of four legions numbered almost 20.000. This army employed the two Roman legions in the centre, flanked by the allied legions. and with cavalry on either of the wings. A small reserve and the general's bodyguard were in the rear.

Command of the Roman army was centred in two consuls, serving on alternate days. This system, while it gave Rome weak

leadership and was greatly responsible for such defeats as that by Hannibal at Cannae, was a safeguard against the rise of an Alexander.

Ordinary legionaries commanded the legion in battle, these men having risen slowly through experience to the positions of leadership. They were not aristocrats but the best disciplined and most competent professionally of the citizen-soldiers who made up the legion. The Roman centurion, or small unit commander, became famous for his bravery and his willingness to die fighting at his post.

Discipline among the legionaries was extreme; cowardice was punishable by crucifixion. Disobedience on some occasions also received the same punishment. For instance, wherever the legion moved throughout Europe its camp was laid out in exactly the same formation at all times. No matter when the legion was called to action every man knew where his tent and his equipment were located. Failure to conform to this rigid system and to appear at the bugle call was punishable by death.

The Punic Wars were fought by Roman legions manned by this middle-class militia. Opposed to them was the Carthaginian army, superbly led in the field and built around a modified Greek phalanx. Aside from the excellent cavalry which was Carthaginian, the remainder of the army was a mixture of Gauls, Iberians and Liby-Phoenicians. Hannibal, poorly supported at home by a merchant people who placed the army a poor second to the navy, led these undisciplined, plundering soldiers to a number of magnificent victories. Unaware of patriotic motives for fighting, the Carthaginian army won battles from the Roman legions but lost the three Punic Wars. After the destruction of Carthage, Rome became affluent, and the citizen-soldiers, mostly of the farming class, lost their land to the wealthy who brought in slaves to do the work.

In the second period, that of the civil wars and the wars against the Gauls, the Roman legion became a professional force. Impetus was given to the professionalization of the legion when citizenship was granted to Italian allies. Voluntary enlistments, replacing compulsory service, brought in freeborn Romans and even slaves. Capacity for soldiering and willingness to garrison the outposts of Rome became the criteria for service. The Roman infantryman thought of plunder and fought for his own legion, while giving allegiance to his commander.

Such were the infantry soldiers of Julius Caesar who conquered the Gauls. Men of stamina and patience, wedded to soldiering, they fought well whether in the open, in sieges, or in outpost fortresses. The heavy infantry continued to form the main line of battle in their centre position, with cavalry and light infantry on the wings. Under Caesar, the Roman legion extended the bounds of the republic to its greatest extent. Hardship was the lot of the soldiers, whether fighting in long-drawn-out campaigns or engaging in the building of the great Roman roads and garrison forts at the outposts.

In the period of the empire, the nature of military service was changed by the requirements for long-term garrison duty on the frontiers. The objective was to protect the empire from barbarian forays. In this new service, barbarians were increasingly enlisted in the legion; the Roman legion became a polyglot band of infantry, relying more upon cavalry and upon new tactics. Consequently formations and weapons were changed. The pike was adopted in lieu of the javelin, and the tactical formation became tighter. The three lines gradually disappeared until the Roman army was a combination of infantry, cavalry and garrison units protecting the frontier.

For six centuries the Roman legion was the supreme foot soldiery but it was annihilated by the heavy cavalry of the Goths at Adrianople (A.D. 378). For the better part of 1,000 years infantry was replaced by cavalry as the heart of armies, though the infantry of the east Roman, or Byzantine, empire lived on until A.D. 1071. (See CAVALRY.)

MIDDLE AGES

The **Feudal** System.—Rome's greatness in developing the legion was passed to the Frankish tribe of Germany whose soldiers had been trained by the Romans. Here again every man was responsible for military service. The Franks under Charles Martel defeated the Moslems at Tours in A.D. 732. Under the Franks a system of landholding and military service developed into what became known as feudalism (*q.v.*). The conquerors were lords; the conquered, serfs. As in ancient Rome individual wealth was a mark of the soldier's class; the serf became the despised, unwanted foot soldier, more servant than fighter. His service for 40 days a year was required by the lord of the manor, each lord being the vassal of other lords on up to the king. All eyes were upon the knight in armour mounted on horseback. The foot soldiery was poorly armed and its part in conflict almost negligible. The serf as foot soldier fought in the sieges and defense of castles and many of them accompanied their lords to the crusades.

England remained the last country where foot soldiers predominated. Behind the barrier of the channel the islanders retained the old military customs, supplementing their weapons with the two-handed axe adopted from the Viking invaders. At the battle of Hastings (A.D. 1066), the Norman cavalry assisted by infantry archers drove the English infantry from the battlefield in panic. However, as feudalism neared its end, the age of gunpowder opened. It "made all men alike tall." The serfs became peasants and burghers. Infantry regained its supremacy and the armoured knights gave way to the more numerous and better armed yeomanry.

During the long centuries of feudalism, the English people maintained a feeling for independent action. English kings understood that feudal levies produced a poorly trained, undisciplined infantry, whose service in the field was limited to 40 days a year. The alternative of accepting money payments in lieu of service and using it to hire foreign mercenaries was checked by Magna Carta. Eventually English kings found it desirable to pay wages to the fighting men.

Military service became the acknowledged duty of freemen, the foot soldiery being drawn by county levies. By the beginning of the 14th century, the English foot soldier was a man of some independence of spirit, assured of payment by acts of parliament.

Likewise on the continent, the burghers found that they possessed the capacity for combat on foot against the knights, particularly when money would hire mercenaries as crossbowmen to support them. French knighthood, in attempting to put down a revolt in Flanders, found the Flemish burghers a worthy foe at Courtrai in 1302. Armed with a clublike staff and the pike and protected by a marsh to their front and streams on the flanks, the Flemish infantry cut the knights to pieces when they waded in disorder in the swamp.

Historians generally date the downfall of the mounted man from the battle at Crécy (1346) when the English longbowmen defeated French cavalry. For the following century the English longbow, which was five or six feet long and shot arrows a yard in length, dominated the field even after the appearance of the first firearms. Though the French cavalry was defeated by the longbow, the latter weapon did not of itself restore the supremacy of infantry. The bowmen were dependent upon the shock action of massed infantrymen to defeat cavalry. It was the Swiss pikeman who confirmed the decision in favour of the foot soldier. The pike brought about the return of the Greek phalanx in a Swiss model which was later developed into what became known as the Spanish square.

For the infantryman it meant that his firepower and the shock of massed action had been substituted for the mobility which had given the cavalry predominance for 1,000 years. The Swiss, a well disciplined people, copied the phalanx of Alexander, utilizing pikes 20 ft. long as their shock weapons. At this time many of their opponents still wore armour and were mounted. To cut these men down the Swiss used a halberd, an axe with a handle about eight feet long. This style was much imitated, and Swiss troops were readily hired as mercenaries throughout Europe.

The Swiss were rugged mountaineers, unused to horses, and unaccustomed to knightly armour. Peasants and townsmen rose up to protect their cantons from the invasions of the Austrians.

Courage, endurance and patriotism were their main strengths, though their tactical formations and weapons were admirably suited to the character of their infantry. Not only did they defeat the Austrians but they also were victorious over the duke of Burgundy. As a result of these wars, the Swiss peasants became renowned throughout Europe as the ablest fighters. Their capacity in battle without armour and fighting on foot established infantry as predominant over the last of the feudal knights.

It being proved that foot soldiers could win in combat, the relatively inexpensive foot soldier came into demand throughout Europe. But because the kings were constantly at war, the burghers and peasants found such service distasteful. Mercenary forces grew in favour since the people preferred to pay for a trade guild of war rather than take time from their own occupations. The Swiss helped meet the demand by supplying foot soldiers for hire.

Free Companies.— Trade in mercenary soldiers became a major business in Switzerland, the youth being trained and desirous for strife. Their services were offered either in independent bands or through the cantons. Their rules required that no Swiss mercenary could fight against his own banner. Other free companies sprang up in competition, and the German *Landsknechts* demonstrated their abilities as did the Italian *condottzeri.* From the 14th century to the Thirty Years' War, free companies of mercenaries. fighting under a commander and ready to sell their services. were present on practically every battlefield in Europe. Their purpose was to prolong wars, while engaging in as little bloodshed as possible. In time they reaped the scorn of governments, though not before French cannons at Marignano (1515) destroyed the invincibility of the Swiss.

The free companies brought to warfare the value of drill in infantry combat. the importance of *esprit de corps,* and the first beginnings of organization. Since they fought in the Swiss phalanx or Spanish square, their usefulness declined when fire and movement brought an end to that method of fighting.

Gunpowder and the early matchlocks were becoming improved though it took something like 95 operations to load and fire one of them. After the battle of Pavia in 1525 in which the Spanish musket defeated the French there was a slow development in firearms until the next improved version, the arquebus, became a common weapon. This lighter firearm marked the end of both the longbow and the crossbow, though the pike still held its place along with the sword and halberd as battlefield weapons. The Spanish armies grafted the new firearm onto the Swiss phalanx in developing a Spanish square with 50 men on a side. Its claim to distinction was its combination of the pike, sword and arquebus. Behind the front rank pikemen were the usual number of swordsmen while at the corners of the formation were the musketeers. One single laborious shot was all they could get off; the musketeers would then file to the rear to reload.

TO WORLD WAR I

Spanish and Dutch Infantry.— In the 16th century, the Spanish and Dutch infantry were imbued with the spirit of professional soldiers. The excellence of the Spanish infantry was ascribed to the strong sense of discipline, good leadership and the capacity for withstanding fatigue and privation. A hardy, temperate and apt people furnished recruits for the Spanish army, one that refused to concede defeat. Spain had just been through the long struggle against the Moors, had discovered America and was animated by a passion for church and king.

The wealth of the new world passed through the hands of the Spaniards into those of the Dutch burghers. The Spanish army, which had become increasingly filled with mercenary troops while the command and hard core remained Spanish, was unable to put down insurrection in the Low Countries. Though the Dutch were unable initially to confront the Spanish troops in the open, they fought with indomitable courage behind the walls of their cities. Artful in the creation of practical fortifications, the Dutch burghers formed a citizen-soldiery reminiscent of the classical age. Antwerp, for example, held off the duke of Parma's Spanish army for 14 months, and Ostende for 3 years. City after city defied the Spanish in aggressive defenses which included sorties on ice skates, in ships and by land.

The hardy spirit of the Dutch was utilized to advantage by Maurice of Nassau. Establishing the first standing army in Europe, he schooled it in tactics similar to those of the Romans and employed the latest types of firearms. Long-term enlistments, strong discipline and superb battlefield strategy enabled him to employ his Dutch forces in warfare that avoided pitched battles. Capturing city after city which had been taken by the Spaniards, he was vindicated in his confidence in his rugged Dutch infantry. The independence of the nation was won by Maurice and his foot soldiers.

Standing Armies.— The Dutch and Spanish had given armies a new appreciation for organization into battalions and regiments. Both nations had also placed their country's security in the hands of standing armies composed largely of infantry troops drawn from substantial middle-class and peasant stock. The combination of good soldiers and well led fighting organizations had changed the character of armies and warfare.

Meanwhile, the free companies were disappearing and cavalry was no longer dominant over infantry. The pike was rapidly being replaced by firearms; cannon were becoming important. All these new developments were drawn together by the Swedish king, Gustavus Adolphus. With an expeditionary force of 13,000, largely infantry, he arrived in Germany in 1631 to assist the Protestant north against the Catholic south in the Thirty Years' War (1618–48). His sturdy foot soldiers were organized into companies, 4 to a battalion; 2 battalions of 400 men each comprised a regiment.

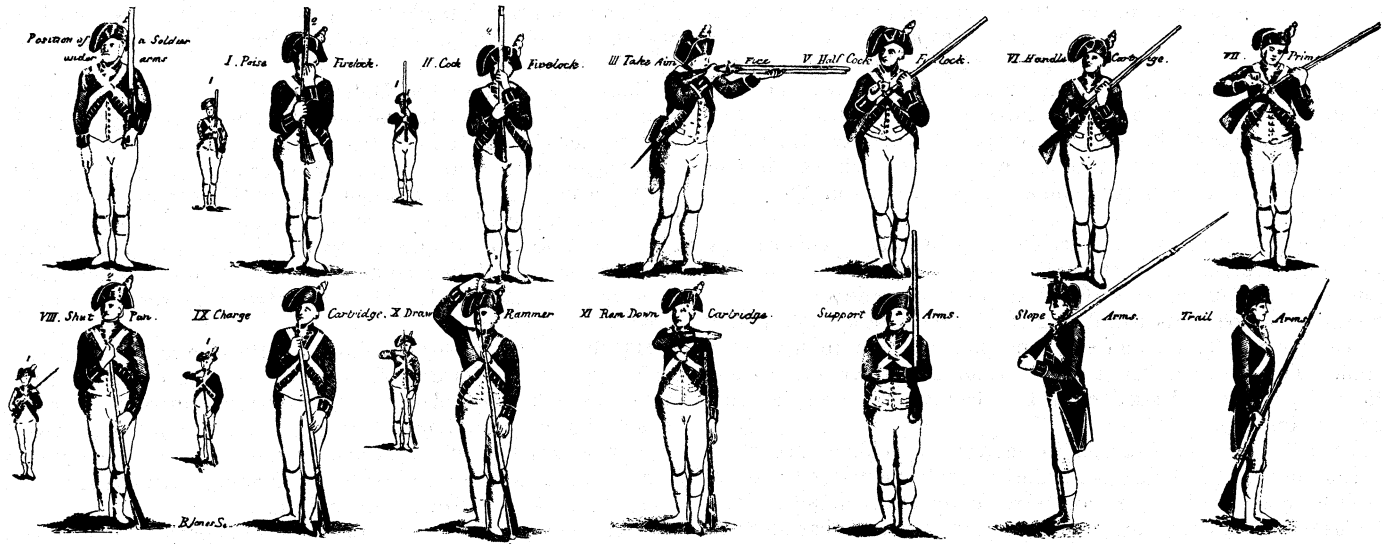
Gustavus also brought to the battlefield a lighter musket, capable of speedier loading through the use of a paper cartridge containing a prepared charge of powder and ball. For the first time. artillery was combined with infantry and cavalry. His tactics included an artillery preparation to soften up an enemy, followed by a cavalry charge to crack resistance, and an infantry assault to mop up a disorganized enemy.

Later in the 17th century Louis XIV replaced the matchlock with the firelock and his great siege engineer Sebastien de Vauban introduced the bayonet. He produced a socket bayonet which did not prevent firing or loading since it was attached around the barrel of the firearm. It had none of the disadvantages of the earlier bayonet which was fixed in the muzzle of the weapon. This contribution enabled the infantry to employ volley fire; troops would move forward, fire a volley, repeat the process and use the bayonet on the final assault.

The opportunity of marching close to an enemy while firing volleys, reloading and then moving to the bayonet assault resulted in heavy losses. Understandably, military leaders sought some new tactical formation which would prove less costly if compelled to meet an adversary in the field. The science of fortification underwent a revision, stress being put upon the desirability of safeguarding troops from the firepower of new weapons. Among the European nations long-service enlistments and the greater professionalization of armies relieved citizens of the necessity of military service. Only in one country, Prussia, were citizens required to perform compulsory service.

Modern Foundation.— Three celebrated soldiers of the 18th century made a permanent imprint on infantry tactics, training and organization, leaving an inheritance of knowledge and understanding which formed the basis of modern methods.

Maurice de Saxe (*q.v.*), marshal of France, rediscovered cadenced marching, lost since Roman days. It changed European armies from straggling mobs into disciplined soldiery. De Saxe also became the first advocate of conscription, the first great opponent of volley fire, the initiator of the company mess, the pioneer of sniper tactics and the first reformer to insist that infantry dress should be designed for field utility rather than show effect. Far in advance of his age in tactical concepts, with deeper insight into leadership than any soldier since the Romans, Saxe also knew the heart and mind of the fighter as profoundly as any general since his day.



CULVER SERVICE

THE MANUAL OF ARMS FOR AN INFANTRYMAN FROM A RECRUITING POSTER OF THE AMERICAN REVOLUTION

Data on the caption was: "Position of a Soldier under arms: I. Poise Firelock, II. Cock Firelock, III. Take Aim (and) Fire, V. Half Cock Firelook, VI. Handle Cartridge, VII. Prime, VIII. Shut Pan, IX. Charge Cartridge, X. Draw Rammer, XI. Ram Down Cartridge, Support Arms, Slope Arms, Trail Arms." The notice offered a "truly liberal and generous" encouragement to enlist

Gen. Sir John Moore (*q.v.*), British soldier, extended what Saxe had taught. Unexcelled as an infantry trainer, he brought to it an enlightened humanism. In an age when other disciplinarians favoured the lash and the gallows, Moore stood for methods which won loyalty and heightened the moral qualities. The system gradually bent to his influence.

Frederick the Great of Prussia took over the pattern set by Gustavus. His infantry was recruited by compulsory service. Frederick scorned the individuality of his infantrymen, preferring to mould them in a mechanical form, held by fear of their officers. His major tactical contribution was greater firepower on the battlefield. Iron ramrods and constant drill doubled the fire of his infantry.

Prussian drill was imitated throughout Europe and was taken to America by Baron von Steuben, who became George Washington's drillmaster at Valley Forge, Pa. Steuben's system, however, excluded Frederick's iron-handed discipline and sought to mould infantry spirit and unity by adhering to the humane principles that guided Moore and Saxe. The influence was permanent. What Steuben taught became the cornerstone of American military discipline.

Napoleon's Infantry. — The infantryman in France, like his American predecessors, was a citizen-soldier in contrast to the professional soldier of Prussia, Austria and Britain. Napoleon's idea of battlefield tactics was to formalize what became known as the holding attack, while employing reserve infantry and artillery in an assaulting flank manoeuvre. Thus he utilized initiative common to his men and obtained a flexibility in the employment of small columns.

Napoleon's men were formed into three ranks in the infantry and placed trust in the bayonet as a good French method of making the final thrust at an enemy. As the war continued and the citizen-soldiers were replaced by more and more impressed soldiers from other European nations, Napoleon had to rely increasingly upon massed infantry.

While the tactical operations in battle were excellent, the reason for the spirit of the troops was more than one of good leadership. The infantry of the French republic had an *élan* inspired by republican enthusiasm; they had the mental and physical alertness and the initiative to make any system of tactics workable. Though their discipline was not one of fear of their officers, nor the habitual kind of the Prussian, it was a higher form later to become common in democratic armies. Discipline included the will to anticipate orders, to do the necessary things on the battlefield to make victory more assured. Rewards and honour were the reasons impelling soldiers to fight.

Conscription produced Napoleon's armies. At the age of 20 all Frenchmen became liable for four years' service, but the backbone of the army was the old soldiers induced by various means to remain. Nor could his men forget that free men could rise through promotion to become marshals of France. The infantryman was released from the bonds of his servitude common to standing armies of the previous century. But as incessant war wiped out the solid French peasant and townsman in the armies of Napoleon, their place was taken by nationals of conquered countries impressed into service. The infantry of Napoleon became debased, its morale declining steadily as Napoleon suffered his great defeats, particularly in the invasion of Russia.

The 19th Century. — For 99 years from Waterloo to the German thrust into the Low Countries in 1914 there were relatively few changes in the tactical organization and administration of infantry. The main change was in infantry weapons: first the substitution of the rifle for the smoothbore musket, then the invention of the percussion cap. (*See* SMALL ARMS, MILITARY)

Increased weapon range made untenable the old battle order in which artillery worked within, or forward of, the infantry line, with cavalry disposed to the flank. These other arms were forced back to save the guns and the horses. From this separation of the lines arose the new command problem of controlling all forces of the battlefield when no longer joined immediately under the eye of the commander.

In the American Civil War the northern armies were gradually armed with breech-loading rifles which multiplied the fire of each soldier. The course of that conflict, with its futile bayonet charges, established the reign of the bullet on the battlefield before the first appearance of automatic weapons. Cannon played their part in supporting or resisting attack but it became almost impossible for infantry to close on infantry while the defense was sustained by steady, aimed rifle fire. Every range increase in infantry weapons widened the displacement between artillery and the covering infantry line, thereby inducing the development of cannon with greater range. Yet the battle crisis was still resolved at close range. Taking to ground, the infantryman became more elusive. Even so, better protection and increased range did not give him commensurate effectiveness. Such were his human limits that massed rifle fire did not have stopping effect beyond 300–350 yd.

Approach to World War I. — During the years from 1870 to 1914 it became common practice to make every able-bodied man liable for regular army service. Since this continental system brought most men into uniform it made the infantry soldier the symbol and the prototype of the common or average man in

European nations. In some ways he was a common denominator of the people of his country. His reactions to service, his ability to handle new weapons, and his like or dislike of organizational methods became increasingly important. He was not a professional soldier in the full sense of the term, nor was he a mercenary.

In the relatively minor wars of this period—such as the Russo-Turkish, the Boer, and Russo-Japanese wars—military leaders had an opportunity to analyze the effects of new weapons, tactical and organizational changes and technical improvements. Unfortunately, the lessons taught by these wars were not wholly assimilated by major nations. In spite of successful defensive stands, the attack was still expected to dominate the battlefield. The ghosts of Frederick the Great and Napoleon still hovered over the infantry of the great powers.

The rifled breechloader in the hand of the Turks assured defensive success against the Russians. who closed their skirmish lines to form a mass target as they advanced. They attempted to advance at Plevna, Bulg., in a close formation without firing their rifles or without taking advantage of the natural cover of the ground.

In the Boer War, the British found their adversaries an unseen foe. Again and again the lines of British infantry assaulted positions against Boers hidden in the folds of the ground and behind vegetation. Smokeless powder made them a cunning enemy safeguarded from easy detection. On the other side of the world, open-order tactics and improvised field fortifications employed by both the Japanese and the Russians were a preview of the infantry combat of succeeding years.

Open-order tactics and the increasingly devastating firepower of breech-loading rifles augmented by machine guns altered tactics to some extent, though mistakenly in favour of the offense rather than the defense. The inclination toward close formations still existed in the major armies. Seemingly, the preponderance of the new potential in firepower coupled with movement was to assure victory to the attacker. As further evidence, the field telephone and telegraph would assure the control necessary for the co-ordinated attack of the immense numbers of infantry troops in the pre-World War I armies.

Organizationally, armies were becoming changed in this period with the increase in strength of technical troops and staffs. Signal, quartermaster and engineer troops were needed in growing numbers as an adjunct to the combat iniantrymen. Furthermore. larger staffs were needed to co-ordinate the complex armies totalling close to 1,000,000 men in France and Germany, and even more in Russia. The basic purpose of all such augmentations was to further the infantry battle and reduce infantry losses, but only a relative few shared infantry danger.

Developments in all arms in the wars before World War I called for increased individual initiative from the infantry, with emphasis on personal mobility and protection, according to a few writers and soldiers of that period. They argued that quick-firing artillery and the automatic rifle would wither the infantry assault and defeat control. Whereas safety lay in spreading and moving, from fear infantrymen would converge and huddle. The new weapons could be countered only by a rifleman who would guard. move and fire on his own, exploiting any opening, but using protection when needed. The warning went unheeded. Every general staff remained convinced that a conquering will in the iniantry mass could prevail over the new multiplied fires and would insure victory.

WORLD WAR I INFANTRY

The defensive power of modem firearms had been underestimated by the infantry combatants at the outset of World War I. In a short time tactics were altered by the need for defense against machine guns. Each nation had its own machine gun which fired bullets of the same calibre as its rifle, at a rate of 250 or more a minute. Though this rate could not be maintained, short bursts of 10 or 15 rounds aimed knee-high across a field in a scythelike sweep made exposure by the infantry extremely hazardous. Tremendous efforts were made to break through the power of the machine gun and the modern rifle at the cost of high casualties. On both sides commanders added machine guns to their infantry units as fast as they could be procured. Failing of decision in repeated efforts to win by mass manoeuvre, confronted at last by a solid enemy array from Switzerland to the sea, the two sides settled to trench warfare. Artillery numbers and ranges were multiplied in the hope of smashing the dominance of automatic fire and countering the opposing artillery build-up. This thickening of supporting fires only clamped the vise tighter by making indecisive the infantry's closing power.

In the four years of drawn battle the two sides persistently sought new methods to insure infantry survival and restore its mobile and decisive role. To minimize artillery effects. defending infantry fought in small groups separated by the bays of deep, heavily revetted and traversed trenches. Infantry lived in dugouts 20 ft. below ground. In the attack under fire, riflemen advanced in short individual rushes, looking for defilade or the unguarded flank of the opposing weapon. Their own main weapons were often mounted in concrete emplacements called pillboxes.

At first the commanders tried to break the deadlock by sheer weight of preparatory artillery fire, thousands of guns firing millions of rounds for days prior to the infantry jump-off. This proved futile because of the great depth in the entrenched systems and the diffusing of the infantry attack before it could cut through. Later came the tactics called infiltration, the artillery pounding the main bastions in the line opposite, the infantry seeking the weak spots and advancing over indecisive ground in an effort to envelop or take in rear main positions. Infantry tactics have adhered to this pattern down to the present.

The Germans introduced the use of poison gas with the object of neutralizing infantry defense. The British invented the tank, or land battleship, so that infantry could advance behind a strong shield and breach the line. In both cases the new weapon was first used experimentally on a small-scale with only marginal effect. Subsequently, both weapons were put into full-scale development and use by the two sides. These changes compounded battlefield danger and radically altered the problem of infantry survival and movement. They were not decisive until toward the close of the war the authority of massed armour restored mobility to the accompanying infantry.

To blast the opposing infantryman out of his trench. the lightweight infantry mortar mas added to the weapons family. It provided high-angle fire. The grenade was brought back into use for much the same reason, though it was also useful for trench and dugout mop-ups.

The supply function in World War I gathered tremendous proportions in order to fill the need ior ammunition and equipment for the entrenched millions living underground between Switzerland and the channel. The long supply line of the U.S. forces across the sea into French ports and by railroad and truck to the front-line units required much man power. For the first time, total warfare made it possible for a man to go to war and, in the wartime expression, "never hear a shot fired in anger." Understandably the infantrymen who lived under the tension of the battlefield, its dangers. and its grime took offense at the recreational facilities and more normal life of the rear echelon serviceman. The gap between the soldier and the technical or administrative serviceman widened rapidly.

BETWEEN TWO WORLD WARS

By the end of World War I, however, iniantry prestige was higher than ever before. Historians took note that the tide had not turned until the winning side could at last muster superior strength in infantry divisions. General staffs drew the broad conclusion that automatic fire and the ne reinforced structure of direct support artillery had made the infantry defensive array all but invincible. Among the victors, the armies suffered from postwar neglect, but in such development as took place, infantry fared better than did armour and air power, although compared with these infant but promising arms, its potentials were proved and well understood. Only the vanquished state. Germany. saw the main lesson that infantry, hitting in combination with armour, had restored mobility to the offensive order. The British tactician-

historian, Maj. Gen. J. F. C. Fuller, originated this theory and became its most powerful world advocate. The idea won some backing in France and became accepted doctrine in the Russian army. But only in postwar Germany existed the will and the means to build upon this pattern a wholly new military foundation which in time would transform infantry usage.

Infantry weapons and tactics in the armies of the world changed little during the two decades between World Wars I and II, but firepower was increased severalfold. The automatic rifle, a self-loading weapon, larger calibre machine guns and bigger mortars were added to the hand weapons of the infantry. Great changes were going on around him, most of them affecting his combat potential considerably. Motor transportation delivered him to the combat area, and armoured tanks supported him closely. Artillery guns could be moved on their o n vehicles, or were towed by trucks.

In the skies the fighter-bomber supported the tank in breaking holes in an enemy line. The job of the infantry was still to be the exploitation of the attack, by employing the usual tactics to push back the enemy on the shoulders of the breakthrough. Also in the air there was some hint of the possibilities of parachute infantry flown to battle in air transports. Before World War II the future for the infantry soldier was much obscured, and the magnitude and extent of infantry combat was unforeseen even by the prophets.

WORLD WAR II INFANTRY

World War I had proved difficult for the infantry soldier but the new devices, new weapons and increased firepower developed during the second world conflict made his job tougher. In the prior war. artillery calibres were extremely large, but the tanks were lightly gunned and the infantry soldier had to undergo little bombardment from the air. The trenches and the pillboxes which had offered some shelter to the doughboys of all armies in the previous war gave less protection because of the bazooka, flame thrower and mortar fire. The infantryman's lot was a rugged one since everything was being done to weaken his will, induce him to surrender or annihilate him. No other group in the armed forces took the sustained beating which was expected of the doughboy. Day after day he remained in the line, and added to his burden were all the new developments in tanks, rockets and land mines. Not only did he undergo isolation and loneliness, great physical discomfort, constant danger as was expected of most other soldiers but he had also to fight aggressively under all kinds of conditions.

In some ways it was a marvel that infantry survived. Because of new developments in weapons it steadily changed its mode of fighting. No longer did a massed infantry unit go forward under its commander with sabre held high as was common in the wars of the 19th century and as occurred even in World War I. The infantryman needed to be constantly alert to act instantaneously and be mentally ready to meet any new situation. He was under constant strain of the pressure brought by artillery fire, the incessant danger and certain death for some of his comrades. He withstood the burden of being wet, muddy and tired most of the time. While soldiers in other forces went into the danger zone in tanks, planes and ships, they could return readily from the battle zone to comparative comfort. The difference was that the doughboy had to wade in the mud, eat in it, sleep in it and oftentimes die in it.

No matter what army, the problem for the infantryman was similar.

Organization. — Infantry units in all armies during World War II were organized similarly. The potential power on the march or in the line was centred in the tremendous firepower which had been given by new weapons. The infantry regiment (brigade in the British army) was normally the basic fighting unit and varied from 2,100 to 3,300 men. the soviet army having the lower figure and the U.S. the higher. In practically all armies the strength of the regiment was in its three rifle battalions, varying in size from 550 to 900 men each. The triangular type of organization was carried out through all infantry organizations to include the division with its three infantry regiments. The difference in the numbers in a battalion and regiment was usually in the number of rifle companies and the weight of the artillery weapons assigned to the unit.

All armies had infantry divisions composed of three regiments, the total strength varying from 11,000 in the soviet army to 15,000 in the United States army. For supply and all maintenance functions, infantry divisions were almost wholly motorized in western armies. German and soviet armies continued to have divisions with some horse-drawn equipment. In all armies the infantryman remained afoot. Technical troops invariably accompanied him. Medical aid men, signallers, engineers and supply troops shared with him the dangers of the forward zone of fire—the first 2,500 yd. from the enemy. Mines, artillery and armour made movement anywhere in this zone hazardous for supporting troops. But these were small risks compared with infantry danger.

Gen. George C. Marshall, in his *Biennial Report* (1945), stated that the United States infantry sustained 70% of all casualties in the nation's armed forces. though it comprised only one-fifth of the forces overseas. But even within the infantry division, there were degrees of hazard. The rifle and heavy weapon companies suffered the heaviest losses, followed by the artillery, signal, engineer and other supporting units.

To return to the organization of the infantry division, its regiments usually comprised three battalions, and each battalion three or four rifle companies and a headquarters company which included heavy weapons like mortars and large-calibre machine guns, or the heavy weapons were grouped in a heavy weapons company. The triangular system was further carried out in that infantry companies contained three rifle platoons, and each platoon three rifle squads (sections in the British army).

All armies included some heavier weapons in the rifle platoons or added an additional machine gun unit. The squads (sections) of nine or ten men were the real fighting soldiers of the infantry—the shock elements of the men first in line in battle. Their perennial job was to seek out the enemy. The British rifle section comprised ten men—a leader, a light machine gunner, a submachine gunner and seven riflemen. The soviet army and U.S. army had five riflemen in their squads, the machine gunner or automatic rifleman having an assistant. While the U.S. army squad had an assistant leader, the soviet army made up its nine-man team with a *Panzerfaust* infantryman.

There was no relaxation for these forward infantrymen; they had to seek cover and concealment, know how to handle a large array of weapons and how to work together as a team. In the U.S. army the weapons platoon armed with 60-mm. mortars and light machine guns stayed up close to give fire support to the infantrymen, who were armed with automatic rifles and submachine guns. Again this organization was common to practically all armies of the world, slight variations occurring in the types of weapons and in the number of men assigned to the platoons and squads.

In the battalion of most armies supporting fire was furnished by a heavy weapons company containing mortars and heavy machine guns. As a family, infantry weapons had the dual purpose of defense against tanks and against aeroplanes. Likewise, in combination, they were suitable for either defense or attack, though the heaviest mortars and machine guns could not be hand-carried forward.

Task Forces. — World War II fighting required tremendous firepower. Even with all his organizational weapons, the battalion commander needed more fire to assist his infantry. On his call, or assigned, were artillery units which worked closely with the infantry battalion. The system used in the U.S. and in several other armies was to group a combination of infantrymen and artillery along with tanks and engineer troops into battalion combat teams.

In like manner the regiment was assisted by such additional firepower units as the cannon and antitank companies. Here again the infantrymen's 75- and 105-mm. guns were often augmented by other artillery batteries assigned to the regiment. In the western armies the regimental combat team was strong enough and complete enough in service units to be sent off on missions as a separate force. This was also true of the German and Japanese armies, but the soviets incorporated the artillery, engineers and service units

as an integral part of their rifle regiment.

This grouping of infantry battalions and regiments with additional elements into task forces for the accomplishment of a specific task was one of the significant developments of the war. A task force could be tailored to fit each special operation, the infantry battalion or regiment being assisted by attached tank units, artillery, engineers, all drawn together under the control of the basic headquarters. When the operation was completed, the task force elements were returned to their former commands.

Training. — The preparation of infantry soldiers for the intense, often prolonged combat of World War II required an elaborate training system. Universal liability for service produced a steady flow of physically fit recruits, usually between the ages of 18 to 3j years. The universal system was to train the recruits in the basic knowledge of weapons and orientation to military life at a gigantic training centre. After from 8 to 14 weeks, the soldiers were then incorporated into divisional units where tactical training progressed from that of the squad and platoon to the regiment and division.

When the infantryman had been thoroughly trained in his own tactics. training was expanded to include artillery, tank and air support. Realism was given to training through manoeuvres in which live ammunition was used. Not only did this require that the infantryman learn to seek cover instinctively but also made him aware of the sound of battle.

Throughout the war entirely new divisions were introduced into combat, preferably in a quieter part of the front. A gradual introduction to warfare gave the infantryman an opportunity to acclimate himself to battle. Later in the war when the full supply of divisions had been committed to combat there was a constant requirement for replacements. Individuals who had been trained in the centres mere sent in groups to join battlewise divisions.

The human factor in the placement of the right man in the right job was considered in most armies. Aptitude for combat was determined for individuals entering the infantry and the other fighting services. Men were given a military occupational specialty (MOS) but, unfortunately, the fighting tasks were not so labelled that infantry profited greatly by the workings of the classification system. That was its main shortcoming. It did not permit tapping the erstwhile bookkeeper or truck driver who potentially was a born platoon leader or weapons mechanic.

Infantry Weapons. — In number and size the weapons of the infantry steadily had increased through both world wars. Whereas in World War I the doughboy had only a rifle, pistol, machine gun, grenade and bayonet, he added in the second war submachine gun, carbine, automatic rifle and rocket-firing tubes known as bazookas in the United States army and as *Panzerfausts* in the German army. Other infantrymen fired mortars, large calibre machine guns and antitank guns. Later in the war the flame thrower, used in World War I, was restored to infantry usage. The bangalore torpedo, a long explosive tube, used to cut through obstacles, first developed in the 19th century, was brought back. The average infantry company employed 20 different weapons. The average rifleman was expected to be master of at least four or five; relatively few were the men in line who could operate all. As in all wars past, infantrymen also utilized captured enemy weapons, the German Schmeisser automatic pistol becoming highly favoured by United States troops. The "Molotov cocktail," a glass bottle filled with gasoline and supplied with a burning wick, was used to incinerate tank crews. There were numerous variations of this armour-stopping grenade, both handmade and formalized. One thing remained unchanged: the basic infantry arm was still the bolt-operated rifle.

In the combat zone the infantryman had to be able not only to use his weapon but to know what to do to get through wire entanglements and around pillboxes. His fighting was against tanks, in mountains and in the jungle. The unexpected was normal for him and his weapons had to be usable against anything that moved on land, or that flew in the air. Therefore his weapons, though best suited to a particular use in battle, had to be effective for general use.

The picture of the infantrymen had been for many years the man with the firearm and a bayonet. For hundreds of years he had been a complete fighting unit, abie to take cover, move anywhere, and stand up under difficult conditions. His courage and brains and his weapons made him a one-man army. This was the great difference between the foot soldier and all other men who fought in warfare. It was his individual will and his movements which won battles.

Some armies continued during World War II to use rifles designed before World War I. Others turned to more modem, semi-automatic, rapid-fire weapons such as the U.S. army M-I. The carbine came back into use as the arm of personnel likely to need a quick burst of rapid fire at-close range; its performance was not conspicuously successful. The bayonet was rarely used except for guard duty; as a weapon of the attack it virtually vanished from operations. The grenadier was no longer the highly trained specialist of World War I days, and in all western armies the art of the sniper also visibly declined.

During the early part of the war the infantryman had to fight tanks at a great disadvantage, armed only with rifle and grenade. The answer to this problem was the bazooka or *Panzerfaust*—a lightweight arm which could be handled by one man. It was capable of stopping light armour at 40 yd. or less and was effective against medium armour at close range when fired from the rear or flank. The automatic rifle and the submachine gun provided the fire base of the infantry squad, the action of individual riflemen developing around the heavier volume of these weapons. Of the two, the automatic rifle was more accurate but less demoralizing in night action.

The armament of an infantry division of approximately 15,000 men included 7,000 rifles, 375 automatic rifles, 327 machine guns of .30- and .50-calibre, 60 37-mm. antitank guns, 117 mortars, 8 75-mm. guns and 48 105- and 1 jj-mm. howitzers. While these totals differed in armies and even within the same army, it was representative of the firepower available to the U.S. infantry division commander in World War II.

With the above armament, and helped by minefields and other obstacles which canalized the armoured attack, the infantry could occasionally make a successful stand against tanks by the mid-period of the war. Infantry weapon power did not permit engaging armour directly on a broad front. The infantry either sought foxhole cover or folded flankward, allowing the penetration, then attacked the tanks from flank or rear. Until war's end the infantry array remained vulnerable to armour attacking in line.

Despite the increased firepower of weapons, however, and their greater mechanical convenience, many infantrymen did not fire in combat. S. L. A. Marshall, in Men Against Fire, explored the psychological aspect of modem war. and concluded that in the isolation of the battlefield of World War II men were gripped by a fear and an inertia which he believed prevented them from employing their weapons to capacity. He stated that 75% of the trained, seasoned troops would not fire or persist in firing against the enemy. In the light of his conclusions, training establishments in western armies re-examined the problem of stimulating maximum fire rates in the infantry line by new methods. The undertaking was phenomenally successful. By the time of the Korean war infantry fire rates had approximately doubled.

SPECIAL TYPES OF INFANTRY IN WORLD WAR II

Air-borne. — During the 1930s the soviet army had a number of air-borne units, but they were never used as such; rather they were employed as infantry in the defensive battles of 1941 when Moscow was almost taken. Air-borne units were present in all armies of the major powers, though it was not until late in the war that the U.S. and British armies produced the most spectacular and largest drops.

Air-borne units were usually smaller than their counterparts mainly because they did not have the trucks, guns and heavy equipment common to infantry units. The soviets and the British had air-borne brigades of four parachute battalions totalling approximately 3,500 and 5,000, respectively. In the U.S. and German armies the organization was similar to that of the infantry division, with three regiments of three battalions each. Air-borne regiments

were either parachute or glider types with the proportion varying from two parachute and one glider regiment as the normal formation, to be replaced later by the reverse. The main weapons of the paratroopers were automatic rifles, machine guns and mortars. The air-borne troops were handpicked men and considered themselves the élite infantry in all armies. They were highly trained physically and knew how to employ their weapons. They were trained to jump from planes, usually at an altitude of 1,000 ft., or to drop in gliders which rode to earth and skidded to a stop. The gliders carried some supplies and in the U.S. army included the jeep for transportation. Other supplies were dropped by parachute to be reassembled by the men who had dropped ahead of them. Air-borne troops once they had jumped fought like their line infantry comrades. They were basically infantry, in weapons and tactics, but. with higher small-group initiative.

The Allied air drop in Sicily was made at night. Many units were misdropped and far scattered. In srnall bands, wherever men collected, they hit the enemy, thus widening his disorganization. In the Allied drop in the Netherlands (Operation "Market-Garden") the invasion was staged in daylight. British air-borne troops were dropped north of the Neder Rijn at Arnhem. The United States divisions dropped south of the river between Nijmegen and Eindhoven. All assemblies were achieved in rapid order. But the Arnhem landing became trapped by a German armoured division and was smashed. South of the Rijn the U.S. air-borne consolidated its corridor and held firm. The most ambitious air-borne undertaking of the war, the Netherlands invasion failed of its strategic purpose, capture of a bridgehead into Germany's western plain. In air-borne operations during World War II the length of time which the air-borne troops were expected to hold out was estimated at 72 hr., at which time their ammunition and food were exhausted. They needed the support of the heavy firepower of regular infantry units in order to continue to operate effectively.

Armoured Infantry. — The setting up of armoured divisions brought about the creation of a specialized armoured infantry to accompany tanks. It was armed and attired as any other infantry. Its particular missions were to outguard tanks, fight off foot forces threatening the tank encampment and temporarily hold ground which the armour had captured. However, these were relatively small components within the armoured organization and their separate character was not strongly expressed. Line infantry also accompanied tanks into battle, riding on the armour and providing local security for it when the situation favoured such tactics.

In the soviet army infantry was used behind tanks on sleds both in snow and on normal ground. Other units which might be called a type of armoured infantry operated on skis in conjunction with tanks. In some ways the tank of World War II became a battering-ram for use against enemy infantry in trench positions or foxholes much like the battering-ram of old against soldiers in a fortress. Another development which came out of the improvised use of tanks by infantry was the personnel carrier, a low-silhouetted, tracked vehicle with a box on top. A number of infantrymen carried in such a tank-type vehicle operated with the same mobility as the tank and yet dismounted and fought as infantry in holding ground or in assistance to a tank attack.

Mountain Infantry. — Practically all armies of World War II contained a few specialized mountain infantrymen. Recruited from mountain areas where they had learned how to live on snowshoes and skis, these men had the rugged physique developed in an outdoor life. Like the paratrooper their arms mere necessarily light weight so that they could be carried by skiers. However, some sled-type vehicles were developed which could be moved by man power to carry mortars and machine guns as well as ammunition. Mountain infantry tactics varied considerably from those of regular infantry units because of their increased mobility and their usefulness in small groups for isolated attacks. Except in the Russo-Finnish war during the 1939–40 winter, there were no large-scale operations staged by ski troops. The western mountain divisions were used as other line troops.

Commandos, Rangers and Raiders. — World War II saw the development of special infantry units which quickly adopted the traditions of historic units of Indian fighters and guerrillas. In the Soviet Union after the German advance had bitten deep into the Ukraine. the soviet army organized partisan units behind the German lines. From swamps and forests and in snow-covered wastes they operated in small groups under the direction of soviet army leaders. They were rugged, hardy infantrymen and infantrywomen, who utilized only light weapons such as the rifle and carbine, though occasionally machine guns were found in the larger guerrilla bands. Their tactics, rooted in Russian history, mere based upon the idea of a split-second move against the enemy, the carrying off of a few prisoners, the killing of a few soldiers, and a quick disappearance. They were extremely effective against small units or the rear echelons of larger units, but they avoided regular infantry battles as a matter of course.

The special infantry of the British and U.S. forces were the commandos, rangers and raiders. The British commandos, trained to the peak of efficiency, employed the swoop tactics of the guerrillas but stayed to fight an infantry battle when they chose to do so. They were especially adept at amphibious raids behind the enemy lines in the Mediterranean area where they implanted fear in the German and Italian forces fighting in Africa. The greatest commando raid of the war was at Dieppe, where 7,000 Britishers landed on the shores of France, scaled the town walls, and fought a pitched battle against the German defenders. The commandos lost heavily in getting into the city and in so doing alerted the German supporting troops so that the defenders were stronger than anticipated. After a night ashore the commandos slipped through to their landing craft after suffering heavy losses; but they had demonstrated that a heavy amphibious assault against the German defenders on the channel approach might be successful if supported by sufficient firepower.

The U.S. counterparts of the commandos were known as the rangers. In battalion strength, they participated in all the major landings in the Mediterranean and were the first to go ashore. In addition they made several forays in Tunisia, striking miles behind the axis lines with the objective of taking prisoners in a manner reminiscent of Indian warfare in America. The rangers were lightly armed and possessed practically no transportation in combat. They did, however, increase their firepower by efficient use of the 4.2-in. mortar. In their campaigns they fought in amphibious operations. in deserts and in mountain warfare, exemplifying the flexibility of the infantry and its weapons.

In the Pacific there were U.S. marine raider units, amphibiously trained, which carried out operations similar to those of the commandos. The Allies other than the Soviet Union seemed to specialize in these extraordinary infantry units including in addition to those mentioned, other units fighting in Burma and China knonn as Wingate's raiders and Merrill's marauders, both of which were trained in jungle warfare as a speciality.

OFFENSIVE TACTICS IN WORLD WAR II

The infantry, of all land forces, had the primary mission in combat of coming to grips with the enemy, capturing him, defeating him. Their weapons, tactics and role in the combined land team were designed to bring about victory on the battlefield.

The uncertainties of infantry combat called for moral strength. Normally infantry fought where fire was most intense; tactical formations, even in the squad, were spread over a considerable area. No matter how excellent his training, nothing prepared the infantry soldier for battle where he saw practically nothing moving and had no sense of large numbers of men being engaged in combat. Local clashes made up the battle; each leader carried forward his own particular part of the panorama of modern battle. Consequently, infantry action demanded fighting spirit and initiative.

Offensive action was needed to obtain decisive results in infantry combat; the spirit of attack was basic to good fighting. But in World War II, local actions by infantry units rarely were continuous attack or defense. While neighbouring units were attacking, some infantry formations were on the defensive. However, for sound and spirited defense, the swift, disorganizing counter-attack was essential. In this particularly testing aspect of opera-

tions, German World War II infantry was unexcelled.

Rapid movement on the offensive made it possible to exploit the effect of firepower. This was one of the key principles of infantry action. If an infantry platoon or company reached its objective before the enemy reserves had been brought into battle, it saved itself casualties. As a result every wile and stratagem was employed to concentrate against an enemy weak point, or to conceal the time and place of attack.

When the advancing infantry unit, large or small, met strong resistance, overwhelming fire superiority was a necessary adjunct to movement and surprise. Infantry action was made over all kinds of ground. Accordingly, terrain had to be made to serve the interests of the fighting foot soldier. In the attack, every fold in the ground. every tree and bush became important in his mission of advancing by bounds while other soldiers kept up fire against the enemy. The picture of the battlefield was therefore one of small groups constantly moving forward, firing their weapons, seeking cover preparatory to the next dash. In all these attacks there was a common pattern.

Attack Manoeuvres.— The triangular organization of infantry from the regiment to the squad was peculiarly adapted to the offensive. The normal formation was to place two units in the main attack, with one in reserve or support. Such attacks were rarely frontal, in the tradition of the close formations of the 18th- and 19th-century infantry, but always sought to slide around enemy strong points by enveloping them from both flanks, or by striking on the flank. Therefore, the main attack most often was a hitting operation by one or more units while the elements to the flanks supported the movement with a pinning fire, thus creating a holding effort such as that used by ancient phalanxes. The reserve or support unit was used at an appropriate time to drive home the flank attack or to back up the holding force if it was counter-attacked in strength. In some ways the offensive tactics of infantry were similar to those of a prizefighter, always striking with the left or right hand at the side of the opponent's jaw.

Infantry offensive tactics, like those of entire armies, did not always effect an envelopment aimed at an enemy flank or his rear. On occasions, the terrain did not permit such a tactic for every unit in the combined army or army group offensive. Consequently, a frontal or penetration attack had to be made. This required careful preparation, like the envelopment, and demanded a follow-through. Small infantry formations often entered this type of battle by placing their three units in a column, the infantrymen being of course deployed as in other offensive fighting. The first unit attacked. If it broke through, the second unit was available to exploit the breakthrough. If the first unit was held up, the second unit was brought up to add to the firepower, or even passed through the lead unit to make a fresh assault on an enemy position. These tactical methods applied to divisions and other units down to even the infantry squad. In all these manoeuvres, the infantry was almost never left to fight alone; artillery, tanks, and even fighter-bombers were available to add power to the team attack.

Preparation for Attack.— In all armies the sequence of moving to the attack followed a similar pattern; the U.S. method used in World War II was typical. The battalion or the regiment was the basic infantry combat unit. Orders came from the next higher headquarters to prepare for an attack. Subordinate commanders were gathered together to receive the attack order, which included the objective to be taken, a line of departure or jump-off line, a zone of action, a direction and time of attack and information about supporting artillery and heavy weapons fire.

Having received the order from the superior headquarters, the commander then had to develop his own method of attack. Before he could analyze the many factors of importance to his own attack plan, he had to make a reconnaissance of the ground. Without the information thus obtained, he could not know the dispositions of the enemy or the approaches which would best serve his own advance. Very rarely was battlefield intelligence more detailed than that. Usually the scheme of manoeuvre was determined without having exact knowledge of strong points in the enemy line, although in some notable instances, such as the Normandy invasion, the defensive pattern was developed with almost blueprint accuracy. The actual situation of the enemy, in contrast with what had been surmised, was most often revealed in the preliminary phase of battle when forces began to exchange flat trajectory fires. So general was this rule that initial skirmishing, aimed to develop the enemy profile, was called reconnaissance by fire.

This and all other forms of reconnaissance were the keys to infantry combat success. Lacking knowledge of the intermediate ground and of the general use made by the enemy of the high ground or any fortified area, the infantry commander was not properly prepared. Familiarity with the scene was the touchstone of efficiency. One method of gaining information was to send out patrols at night, either to capture enemy soldiers or to examine ground beyond the area surveyable from an observation point during daylight. Failure to reconnoitre led almost invariably to wrong estimates, unsound deployments and tactical failure.

Having gained information from all available sources, the infantry commander issued his own attack order, which included a map designation of the objective, the line of departure, the zone of action, the scheme of manoeuvre, the location of the reserve, the protection of the flanks and the avenues of approach to be utilized by the subordinate units. In addition the fire support plan of the heavy weapons was worked out. This included the emplacement of mortars and antitank guns, and designation of priority targets. Certain key spots in the zone of attack were given to the supporting artillery as possible targets so that they might calculate their firing data and thus be prepared for instantaneous shelling of those points when a telephone call for assistance was received.

The zone of action of an infantry unit in attack gave it a frontage for which it was responsible. A regiment, for example, might be responsible for a frontage of from 1,000 to 2,000 yd., with each succeeding subordinate unit responsible for a front half that extent. The company usually had a frontage of from 100 to 200 yd., and the squad from 50 to 75 yd.

While a battle reconnaissance was in progress, the units of the attack were made ready. If located in assembly areas too far rearward they were moved forward by motorized transport.

During World War II, in the average situation, the infantry assembly, preparatory to attack, was already within light artillery range, or less than 6,000 yd. from enemy weapons. When advanced to the line of departure, where they deployed for the attack, the formations usually came within enemy small arms range. Sometimes the final lunge was made under cover of dark. More times than not, it was in broad daylight. Frequently assemblies had to be made under observation and small arms fire.

Usually a successful infantry attack was conducted in a sequence which obviously required changing to fit the situation. As in World War I, artillery concentration was normally the first move. Artillery also included air bombardment and the infantry mortars so that concentration on the enemy came from three unco-ordinated or partially co-ordinated directions. The infantrymen moved forward during the concentration, keeping under cover as much as possible until they got within a few hundred yards of the enemy. Not only were they faced with wire entanglements similar to those of World War I but also mine fields. They had to send ahead groups to clear mines or at least make a path through them. The mine field had become one of the primary aids to defense since great quantities of them could be put a few inches under the ground in a field which blocked normal access to the defensive positions. Mine fields not only forced attacking troops into unfavourable terrain but also brought them under the fire of presited machine guns, artillery concentrations and defense lines in depth. When they got within a short range of the enemy the attacking troops brought up all possible firepower in mortars and machine guns and obtained the help of the artillery which placed its shells upon the enemy infantry. In many cases tanks were brought up to the line of departure and led the infantrymen through the gap or prepared lanes in mine fields. The last few yards were gained by the infantry, on its own, using the automatic rifle and covering machine gun fire to bound forward and kill final resistance with rifle and grenade fire.

At the time set for attack, the infantry assault units crossed the line of departure and moved aggressively ahead toward the objective. After the attack was launched the commander had only moderate control over his men. Their individual initiative and abilities determined in large measure how well the attack went. However, the infantry commander had partial control over the action by radio and telephone, with which he endeavoured to manoeuvre his units, direct supporting fire and seek help from the elements to his flank and rear. His hold upon his reserve was final insurance against the battle crisis.

Infantry assault units were in many cases assisted by tanks, which fired their artillery guns from concealed positions in extremely close support of the infantry, or preceded the infantry from the line of departure and acted as a land battleship for their protection. On some occasions tanks followed the infantry units, passing through them just before the assault on the objective, or perhaps, moving down other avenues, arrived simultaneously from the flank to assist in the assault.

When enemy resistance was too strong, the infantry advance was halted while neighbouring units assisted by attacking the objective from a flank. Meanwhile, the infantry in attack had to dig in and attempt to build up enough fire superiority to beat down the enemy. In such a situation, the ability of the infantry soldier was put to the test to improvise means of getting the attack under way even if it meant altering the plan. Sometimes, the support unit was brought in on a wide flanking movement, while the main attack continued to move forward aggressively.

Before the final assault on the enemy was made, the infantry commander called off the supporting fires by a prearranged signal. It was the task of the infantry to move through the enemy position so as to work through its complete depth and prevent reorganization and counterattacks.

After the assault, the attacking infantry had to reorganize its own units before swinging into a pursuit, a tactical action often made by truck or by infantry carried on the tanks.

This entire system of the conventional infantry attack, as presented in sequence, was rarely so well ordered. The "fog of war" often obscured what later was obvious. At such times the aggressive action of a few infantry riflemen or machine gunners pushed the attack through to success. There were also many variations in this conventional sequence and form of infantry attack, particularly where the action took place in towns, or mountains, or desert. The special characteristics of infantry action in such cases is noted below.

DEFENSIVE TACTICS IN WORLD WAR II

Infantry tactics were almost as often defensive as offensive in World War II; even a spirited attack called for momentary defensive tactics by certain units in the line. Even when there was a general advance on a portion of a front, other units were in a holding or defensive position. Also, whenever a rifle unit had made an advance, it was compelled to dig in temporarily to gather itself for the next move forward. A defensive position properly laid out was a safeguard against counterattack; selection of a position on the ground was of great importance though often the infantry commander had no choice but to make the best possible use of the front assigned for defense.

As in the attack, co-ordination of troop locations and firepower with respect to the ground to be defended was the best assurance of success. The position was organized in a group of key points, the intervals between them and the approaches covered by the maximum fire. The selection and preparation of these key points into an integrated system was the crux of defensive infantry tactics.

Any defensive position could be penetrated if the enemy wanted to pay the price. Therefore, defense in depth was the solution since it often made the price of attack too high. When an enemy penetrated the main line of resistance, he was certain that he would be met by fire and by reserve infantry units from other defensive key points to the rear. Other principles in the establishment of a defensive position were the necessity of assuring mutual support, a co-ordinated plan for firing all available weapons, an antitank defense and flexibility.

Units across the front of a defensive position and from front to rear were charged to dispose men and site weapons to provide mutual support. The aim was to have all units so placed as to assist any unit with fire. Thus stated, the object was elementary. But because of irregularities of terrain and the chronic overextension of infantry forces, the ideal was seldom achieved.

In World War II. because of armoured mobility, attacks often came from the rear as well as from the front and flanks. This was particularly true of air-borne operations and of desert and jungle fighting where the defense was often a closed perimeter or hedgehog. Troops likely to be cut off or enveloped attempted to secure an all-around defense. But because automatic firepower was seldom sufficient to complete the tight-knit circle, the rear continued weak.

A co-ordinated plan for firing weapons on signal was absolutely essential to a good defensive position. Not only was the fire of unit machine guns, mortars, and antitank weapons co-ordinated, but they were supplemented by additional artillery support on call of the infantry commander. The objective was to be able to bring down the maximum fire on a certain area where an enemy attack was being organized, or prepared to make an assault.

The antitank defense was all-important for the infantry, even after bazookas became a regular weapon. Against tanks, the defense included the co-ordinated fire mentioned above, assisted by mine fields and obstacles like antitank ditches.

A combination of the foregoing methods of defense did, oi course, provide for flexibility. Other than the massing of supporting fires, and the withholding of a reserve or support force, one of the greatest aids to flexibility was in the preparation of alternate positions. For example, it was common practice for units to have different positions for day and night. In general, however, western forces did not prove adept at forest fighting, and the tactics of using or refusing forest cover advantageously remained unclarified.

In defense, the infantry commander studied the ground by reconnaissance, seeking high points for observation, noting covered avenues of approach open to an enemy, looking for places to emplace his heavy weapons, and assuring supply routes to the rear.

The infantry defense order took into account the amount of time available before an attack was expected, giving emphasis to the most essential elements of defense when time was short. In addition to information of the enemy and of neighbouring friendly infantry units, the order gave the defensive mission, areas assigned to each subordinate force. the tasks for the heavier weapons, the plan for control of fire, security of flanks and rear, priority of construction, location of mine fields and other obstacles already in existence or to be set down and administrative details.

Frontages for defense were usually from two to five times the width of attack frontages, contingent on the nature of the ground. An infantry company was usually assigned a front in rolling country of 600 to 1,200 yd., and was expected to defend in depth to whatever limit the fight required.

If time was available, extensive defensive preparations were usually taken, not only to dig foxholes but to link them with shell-resistant tunnels, prepare deep shelters covered over with earth for safety from artillery barrages, and dig several alternate positions for each key point in the defensive system. Similarly, the heavy weapons were first dug in, then the hole covered over with just a firing slit remaining, and then brush and tree branches on the lines of fire cut so that maximum effect was attained.

Ditches, obstacles, mine fields and wire entanglements were added, their number and complexity increasing the longer an infantry unit was located in a defensive position. Time and machinery were the main limitations on the organization of a defensive area. While the infantry was digging foxholes and trenches and laying out obstacles, artillery observers in the front line arranged their schedules for fire support. They selected danger areas such as a valley leading into the position and gave it a number on their map which in turn was communicated to the artillery batteries. In this way artillery support could be called

for rapidly without mentioning map co-ordinates.

Defensive positions in many areas were complicated by the soil. On many of the atolls in the Pacific, for example, the matting of tropical roots made digging foxholes impossible. In addition, the jungles raised new problems for the defensive formations of infantrymen. Night noises and the various methods used by the Japanese to prevent sleep made life extremely difficult in the jungle. Defensive positions were fluid, and the men had to be kept fairly close together because of the dangers of losing contact.

Early in World War II infantrymen came under heavy fire from strafing aeroplanes though anti-aircraft weapons attached to an infantry division later made such attacks costly. Ground fire by the infantry from its multiplicity of weapons sometimes brought down enemy planes. As the war wore on the infantry paid less and less attention to dive bombing and strafing aircraft, leaving protection to their own anti-aircraft. Also it was found that infantry firing against aircraft gave away positions to enemy artillery. It became common practice in all armies for the infantryman to dive for a foxhole in a plane attack, which was normally short-lived and did little damage to him.

The conduct of the defense offered greater opportunity for control by the infantry commander than did the attack. Usually, he retained the heavy weapon support, the reserve troops, and the antitank guns under his central direction so that the entire weight of the defense could be thrown against a critical enemy penetration.

SPECIAL OPERATIONS IN WORLD WAR II

Infantry offensive and defensive tactics were not always as conventional as indicated in the foregoing description. However, the principles for such tactics were applicable in special operations, revisions being made as directed by the judgment of the infantry commander.

Attack of Fortifications.— During World War II, the normal infantry action was against enemy field fortifications. Their strength depended largely on how long the infantry had had to prepare the defensive position, on the will of the defenders, and on the combined support obtained from the other land forces and from the air forces. In many cases German and Japanese machine gunners held out until infantrymen had actually killed every man. Japanese infantry were also adept at cover and concealment, particularly in cave warfare, and normal infantry weapons were insufficient to dislodge the defenders. Grenades and 25-lb. explosive blocks called satchel charges were used against these refuges, as were flame throwers, but they sometimes failed to shake the enemy's will to resist. After outposting such obstacles, the infantry assault waves usually advanced past them, leaving the task of destroying them to the support elements.

The 1940 attacks by the German army against Low Country fortresses were carefully planned manoeuvres carried out by task forces comprising engineers and paratroops as well as line infantry. The most famous attack was against the Belgian fort at Eben Emael, where flame throwers, artillery, and air-borne and ground infantry were employed in a co-ordinated, overwhelming effort. Rehearsals against a mock-up of the fort had assured the task force of co-operation on a split-second attack schedule.

Infantry in Inhabited Communities.— Advances inevitably brought infantry troops in contact with villages and towns which seldom could be by-passed since all armies utilized such communities as fortresses, By sandbagging windows and doorways, setting up machine guns in rubble, laying mines under debris, or preparing booby traps in unoccupied buildings, a town was made into a fortress. Air attacks and artillery only increased the amount of rubble, and tanks were at a disadvantage in enclosed areas. Consequently, small infantry teams were the most potent attacking force. Usually one infantryman proceeded ahead to open doors, pry into heaps of rubble under cover of the guns of his fellow soldiers. Grenades and submachine guns were the preferred weapons in villages. Grenades could be thrown into open windows, and tommy guns were employed to spray an area with bullets.

House-to-house fighting was the most dangerous kind of combat, since at any moment enemy fire might come from front or flanks, or from the rear. A systematic attack was used to take building after building, establishing a general line through a city. Then moving forward on a wide front, the advance in time reached the far edge.

Combat in Woods and Jungles.— Wooded areas were also left to infantry combat. Occasionally a small wood could be by-passed, to be mopped up later by forces following the advance elements. However, large woods like that of the Hurtgen forest in Germany west of the Rhine had to be taken by infantry troops. It was slow going, complicated by lack of control and observation. Artillery and air bombardment were not usually effective.

The edge of large woods was usually the first objective, followed by later attacks when the infantry were organized to move forward. Trench systems, mines and ambush were common to fighting in woods. Much of the battle consisted of man-to-man fighting, with grenades and submachine guns of the greatest use as in towns.

Jungle warfare demanded the greatest resourcefulness of infantry. The dense growth compelled foot soldiers to remain on the roads and trails where there was the greatest danger from enemy attack. The heavy rainfall, debilitating climate, and the noises of the jungle were added impediments to the infantryman. Cover and concealment were afforded the enemy, and often a strong point was by-passed unknowingly. Advance elements, after moving forward, were surprised by firing in their rear, usually against larger parties moving up in support or bringing supplies. Painstaking efforts had to be made by infantry in outflanking resistance and, when halted, to assure all-around defense of their position. Again the hand weapons were the main reliance of the infantry, artillery and tanks being useful only when the jungle area was not a mass of dense undergrowth.

Amphibious Assaults.— Prior to World War II amphibious attack by infantry had been limited largely to battalion assaults against relatively light opposition or none at all. There was no considerable doctrine for amphibious attacks by units of a division or larger. The foot soldier was put ashore from landing craft and fought his way inland in typical infantry fashion. Training for amphibious assault was a long and involved process in which the armies of the western Allies necessarily took the greatest interest. There were two types of movements by water for the infantryman, one known as ship-to-shore and the other as shore-to-shore.

In the former case the infantrymen and their supporting arms were sent into the combat zone in ships especially loaded so that all their necessary supplies and equipment were immediately available. At the appointed hour the ships dropped anchor several miles offshore and let down their small boats. The infantrymen then climbed down huge rope nets which covered the sides of the ship and dropped into the landing boats. They were escorted ashore by navy boats and landed in a number of assault waves. The primary objective of the troops was to get inland as quickly as possible since in many cases the landing beaches were under the fire of infantry weapons on the heights above them and from artillery several miles to the rear.

In some respects the landing was similar to land attack since there was an artillery concentration ahead of the landing troops, furnished by aircraft bombardment and by naval gunfire. Later in the war the landing boats were supplemented by small rocket ships which fired dozens of rockets simultaneously from what: the troops called "the organ" since it was a mass of pipes.

The other type of amphibious operation, the shore-to-shore, began at a port or beach where the infantry troops walked onto landing craft, the various sizes holding from 20 to 500 soldiers. A World War II development which revolutionized the sea-to-shore assault, outdoing all previous amphibious progress, was these craft, small and large, which were capable of moving onto a beach and virtually dry landing their companies. Some of the smaller types had wheels that enabled them to continue with the attack as it moved inland. They were used mainly for supply, communications and casualty evacuation. It was no longer necessary to

attack a well-armed port, for expeditions could be both landed and supported across a beach. However, the weakest point in attack continued to be at the water line. The defense resorted to elaborate obstacle building. Once ashore, infantrymen took up a line. dug in and then, as beachhead supply became firm, attacked inland.

Infantry attacks across rivers were similar in some respects to shore-to-shore amphibious operations. Reconnaissance for the best crossing area was absolutely essential. Usually these operations were commenced at night so that leading elements could get established on the far bank before daylight. A further build-up of forces was then essential so that the attackers could fan out and obtain a bridgehead. Later, various types of prefabricated steel bridges, as well as the pontoon bridge, were used to facilitate movement.

Mountain Warfare.— Throughout World War II there was considerable fighting in mountains. It developed mainly into dogged infantry combat, advances being slow and painful. Artillery and air attacks were useful in bombarding enemy strong points, and the infantry flanking tactics were particularly adaptable.

Though most armies had mountain-trained troops, they were insufficient in number for the widespread fighting in mountainous areas. Usually infantry divisions were given this combat duty, and expected to improvise their tactics to suit the situation. Supply was a continuous problem, though pack mules were found in considerable numbers in such areas.

Night Operations.— Infantry combat was replete with night operations, usually involving small patrols and combat teams. In the jungle. the Japanese had a special liking for infiltration at night. Furthermore, all armies found that incessant artillery and small weapon firing served to unnerve the opponent by causing loss of sleep. Night attacks were often necessary to consolidate ground won the previous day, to initiate an operation by the seizure and occupation of an enemy strong point which might hold up a general attack. Night operations required resourceful infantry, well rehearsed in what was expected of each man. Control was obtained by keeping men close together, and by the wearing of a distinguishing armband or headband.

Arctic-type Operations.— There were no true arctic operations in World War II. though winter combat was common throughout Europe and in the Aleutians. It was true infantry combat, with camouflage by white clothing and the wearing of warm equipment absolutely essential.

The mobility of machines was considerably decreased in cold-weather operations, shifting greater dependence on the foot soldier. In a few cases skis and snowshoes were used, but generally the infantry soldier fought the same kind of warfare he did under more favourable conditions. However, it was much more difficult to dig in, compelling the infantry to depend for cover on trees and walls.

Desert Operations.— The British, German and Italian infantry fought in the North African desert for the better part of two years. Desert combat was sometimes compared with naval combat. Forces were visible for long distances by the dust clouds they raised. Long sweeping flank movements were common, vehicles being utilized almost entirely. Only when halted did the infantrymen dig into the sand or build up a rock breastwork for protection. Surprise through deception was particularly useful in desert warfare. Water supply was always deficient, and many of the battles were fought for the possession of waterholes. There was no particular finesse possible in this type of warfare, most attacks becoming slugging matches in which the force with the greater strength and staying power was victorious.

Partisan Operations.— The partisan, or guerrilla, warfare behind the German lines in Europe was a special adaptation of infantry tactics. The basic principle was never to stand up and fight a pitched battle. Rather the best tactics were raids conducted against supply columns, trains and against small parties of the enemy. In the occupied areas, Russians, French, Belgians, Dutch, Norwegians and Danes conducted an incessant partisan warfare, utilizing the small-unit tactics of infantry. The principal weapons of the partisans were submachine guns, rifles and grenades, supplies being smuggled inside the German lines or dropped by aircraft.

In the Pacific, the Chinese and Filipinos had similar success in disrupting Japanese supply lines, and in conducting a campaign of fear among the occupying forces.

Commando, Ranger, and Raider Tactics.— The organization and objectives of these peculiarly British and U.S. forces were discussed earlier. Their tactics were a combination of typical infantry tactics, of partisan methods of silent warfare, of amphibious assault techniques and of jungle tactics. These specialist infantry groups served a useful purpose during the early years of the war to show that any physically fit individual, highly trained in the use of weapons and in stealth, could become a superb infantryman. Later the fighting qualities of these special units became the goal in all infantry units, the great mass of infantrymen approaching close to the high standards set by the commandos, rangers and raiders.

Air-borne Tactics.––Parachute and glider infantry were organized and equipped as mentioned earlier in this article; their tactics were somewhat different from those of regular infantry, since they did not have available the supporting heavy weapons. The individual fighting capacity of each soldier had, in part, to make up for this lack. Also, admission of the necessity for such heavy weapon support, as well as by tanks, was made in operations where the air-borne infantry was relieved as soon as possible, or heavy weapon support furnished them.

The soldierly abilities of the air-borne infantry, their *esprit* de *corps,* ability to fight and to fire their weapons steadily and accurately, made them the Clite infantry.

Supply.— The usual system of supplying the front-line infantrymen was to bring up food, ammunition and other requirements at night by truck or horse-drawn wagon from regimental dumps several miles behind the line. At dusk each night the U.S. and British troops used jeeps to rush supplies forward to the troops before complete darkness set in. The jeeps were often able to bring supplies to within roo yd. of the front. Eventually however, supplies had to be carried by man power the last few yards. The rifle companies in many cases furnished their own members to bring forward supplies. Horses and mules were used wherever possible. particularly in the mountains of Sicily and Italy. The bringing up of supplies was usually a difficult job because routes soon became known to the enemy. A heavy shelling could be expected during the time the enemy reckoned supplies would be moving forward.

Morale.— In all armies greater efforts were made to keep up the spirit of the soldier. particularly those in front-line combat, than in any previous war. Radio programs, motion pictures, newspapers and theatrical shows were brought to the soldiers overseas. Even the front-line troops got their news by radio. They also were the subject of enemy interest, being propagandized by the playing of nostalgic music and reporting of news items stressing events at home which would make the soldier lonelier or would cause him to ask himself the question "Why do I fight when others at home have an easy and safe life?" These broadcasts became so persistent that in all armies efforts were made to educare the soldier to the justice of his nation's cause and the necessity to continue the fight until victory was won.

The soviet army through its political commissars featured a system of indoctrination so persuasive that even the soviet leaders of the fighting units claimed that their authority was subverted by the political representatives. Though commissars were withdrawn when the fighting was particularly severe on the defensive they returned when the soviet forces took up a general offensive.

The U.S. army had particular difficulty early in the war in the assignment of men to the infantry. The majority of draftees preferred the other arms and services. Moreover, the early policy was to deny the infantry a fair proportion of superior men. At one time the disequilibrium was such that 72% of the ranks in the air force were educationally qualified for infantry commission while only 16% of infantrymen were so qualified. The system was changed and infantry prestige was raised when finally it was

realized that infantry was still the decisive arm. Infantrymen were given additional combat pay and a special identifying badge. The British and German armies had difficulty with the same problem but in lesser degree.

CHARACTERISTICS OF INFANTRY AFTER WORLD WAR II

Organization. — The triangular organization throughout the infantry from platoon to division was maintained as it had been at the close of World War II. Such changes as were made had either the object of further increasing infantry firepower against other foot forces or of giving it better protection against infantry fire. Bulletproof vests and jackets were perfected for combat issue. Organic armour was brought into the infantry division. A new family of infantry weapons, the recoilless rifles, was developed. These relatively light tubes could be man-carried and gave infantry the equivalent of a highly mobile light artillery, invaluable for point-to-point firing in rugged country. *(See* ORDNANCE).

Other weapons developments included an infra-red device called the sniperscope, designed to enable the firer to see his target at night. It proved only moderately successful. More helpful was the addition of the large-size rocket launcher which for the first time enabled infantry to attack medium armour with a fair chance of destroying it at ranges up to roo yd.

Tactical reform and organizational change did not keep pace with the over-all advance in weapon power which threatened the existence of the conventional defensive order. For at least five years after the first atomic bomb was dropped in World War II, western general staffs took scarcely a step to measure what changes the new conditions required in infantry training, structure and theory to insure success, or even survival. There was talk among infantry tacticians about the necessity of achieving maximum spacing between deployed men and units, while making infantry more elusive, mobile and aggressive. But no exercises were held and little staff work was done to bring doctrine and practice abreast of the new realities in total war.

From the experience of World Wars I and II had come two dominant tactical ideas, the flankless front in defense and the breakthrough by massed armour on the offense. These defined and limited the infantry approach in future operations. The military schools continued to emphasize the avoidance of open flanks, the correctness of the closely joined order of battle and the preponderant mobility of armour as an offensive shield covering infantry. In this brief twilight period, military thinking proceeded as if nothing had changed radically.

Korean War. — Although the doctrinal lag incurred no immediate penalty, the first limited war of the atomic era, in Korea, 1950–53, presented unique problems for all infantry forces. Not only did the Communist armies possess at all times superior infantry numbers, some of which were always in position to harass the rear of the United Nations army and cut its communications, but the latter side was never in strength sufficient to form a continuous, closely knit forward line, supported in depth.

During the highly fluid operations of the first year, the Communist armies, after their initial drive, used little artillery, air power or armour. But in all operations they made prodigious use of ground protection and night cover. In the attack, they advanced against the entrenched ridge tops with hand-carried weapons, relying heavily on the machine gun and slightly less on the mortar. Or else, under cover of darkness, their infantry moved forward through openings in the main line of resistance, either to attack artillery and other rear installations or to set up roadblocks behind forward infantry battalions to compel their withdrawal. These were the chief unorthodoxies in their method of making war.

Against a strongly armed opponent, with ample air and artillery weapons. the defensive system ultimately developed by the United Nations forces to counter these tactics would not have availed. Perimeter defense, by infantry blocks of battalion size or larger, proved to be the correct solution. Its success derived primarily from organic unity within the position, combined with maximum union-by-communications with all higher headquarters and co-equal tactical bodies to the right and left. Mutual fire support was supposed to exist between each block and its nearest neighbours. Such was the infantry shortage and the resultant stretching of the rifle line — understrength battalions sometimes covering 4,000 yd. of front — that this defensive technique was more theory than fact.

In the attack by UN forces, air and artillery preparation and the thrust by armour opened the way for infantry wherever possible. Because the Communist defense was hinged usually to the higher and rockier ridge tops, distant from the valley roads and beyond reach by any vehicle, much of the time infantry had to make its closing rush with little or no effective support except the fire of its own machine guns, recoilless rifles and rocket launchers. For infantry on both sides, it was an infighting war, with an extraordinary incidence of hand-to-hand combat. The hand grenade was heavily used by both sides as a finishing weapon. Because the rugged terrain limited fields of fire and because morale needed stimulating in the crisis of the first winter, the UN command restored active use of the bayonet as an attack weapon. The war saw more bayonet charges than any conflict since the American Civil War.

Tactical Change. — Basically there was little change in infantry weapons use or the tactics of fire and movement except as old methods were modified in conformity to the difficulties of the terrain. The main advance tactically came in the form of new and greatly diversified forms of support provided to the infantry by the younger services. When defensive perimeters became cut off and besieged, infantrymen were sustained by air resupply and their casualties were taken out by helicopter. On many occasions battalions and larger units were saved by flying prepackaged supplies from Japan. More numerous were the incidents in which a platoon or company was rallied in a desperate situation by one or two liaison planes coming in to make a free drop. The rifleman wounded in a fight for a distant and unroaded mountain peak frequently was flown to a base hospital within 10 min., receiving plasma and first-aid while still air-borne. Such innovations came of the inspiration of the moment, but they were characteristic of a new tendency under pressure to find wider use for all equipment.

The light liaison plane became a jack-of-all-trades in support of infantry. It served in artillery direction, did observation work over enemy lines, acted as relay and guide for long-range infantry patrols, led in the air strike and became an intermediary in long-range radio communication.

The employment of armour was not less diversified, and many of its most decisive services to infantry ran counter to the orthodox teachings of the schools. In night defense, it formed roadblocks covering critical approaches to the main infantry positions. In the face of fire, it ferried infantry onto the ridge tops when the slopes were negotiable. It acted as escort to patrols. It worked as artillery from within the infantry defensive circle, firing its cannon from 20 yd. or less behind the rifle line. When the infantry was hard worn and the night situation uncertain, armour occasionally outposted the position. If the position became lost, armour was used to retrieve the infantry dead and wounded. When the infantry numbers became too thin, tanks were spliced directly into the rifle line.

During the last two years of position warfare, armour was consistently employed in that role because of the infantry shortage. Armour was set up to enfilade main roads running laterally behind the key ridges; it mounted guard over first-aid stations and supply points. The conservation of both forces was most perfect only when there was perfect reciprocity between them, and the commander considered one just as expendable as the other when the position became threatened as a whole.

Infantry hardship in Korea was not more than in the earlier wars of the century but on the whole less, though the subject was more fully publicized. Viewing the extraordinary work load which devolved upon mfantry, there was obvious need for a pioneer or engineer company within the infantry regiment. The rifle companies always had their hands full, if supply was to be moved

forward, if telephone lines were to be laid, if foxholes were to be dug. Still. the wounded had better prospects for survival than ever before and the terrain which made every advance arduous also proved a shield against the heaviest fires. Infantry losses from nervous exhaustion, combat fatigue and desertion became minimal.

Communist Chinese Infantry. — Historically the salient military development of the war was the proof of tactical and moral competence in Communist China's almost unlimited infantry mass. Its trained formations could withstand the shock of massed fire despite the fact that its own tactical methods in attack and defense were inflexible. Except for the machine gun and mortar, which the Chinese used expertly, the use of organic weapons, while persistent, was not markedly skilled. Their physical endurance proved adequate.

During the final two years of position warfare, the Chinese Communist defensive system had far greater depth and elaboration than the UN line. The army lived and concealed itself in deep subterranean works, using the surface trench system as an alarm net to rally forces to the ridge tops when attacked. Artillery also was tunnelled into the ridge tops. Bombproof, these works, unlike the opposing defenses, would have been strongly resistant to atomic weapons. Operations consisted mainly of infantry patrolling. By keeping divisions in line until troops were thoroughly seasoned, Chinese Communist forces became unexcelled in this furtive and essential activity.

Tactics tried and proved in Korea by the Communist forces were exported to north Indochina during the concluding phase of a war which until then had been a struggle between elusive guerrilla bands and a conventional army basing on blockhouses along fixed lines of communication. The new methods made firm and decisive the Communist counter to the French invasion by airhead at Dien Bien Phu.

Atomic Exercises. — On Nov. 1, 1951, the first test of the behaviour of infantry in the vicinity of an atomic explosion was held at Yucca Flat, Nev. It was not a tactical exercise designed to work out specific infantry problems, such as mass evacuation, preliminary reconnaissance and reorganization of ground forces following atomic attack. The object was to determine whether normal infantry suffers an abnormal psychological or physical reaction when within sight of but at a safe distance from a nuclear explosion. The findings were negative. Since then all tests of infantry forces when disposed toward an atomic explosion have had similar limitations, and the results bear only marginally upon the main question of battlefield reactions.

Atomic exercises, in which corps and armies manoeuvred and a number of atomic strikes against the battle order were simulated, were conducted regularly by western armies after the summer of 1953. During the first years of experiment, no radical change in conventional organization and practice resulted. Getting a late start, the development of theory about the character of the front, the regulation of movement and the problem of infantry deployment under the new conditions remained in a highly fluid state, awaiting further exercises, more committee study and a breaking down of traditional resistance to change.

By 1957 came the first clean break with infantry structure in the pre-atomic age. In the U.S. army the change preceded systematic field testing to determine what form infantry organization should take to meet the new conditions. Regiments and battalions were eliminated and for the old triangular division was substituted a five-sided structure composed of battle groups. Each battle group was formed of five heavy companies, both within air-borne and line infantry divisions. By this reform both types of division became reduced in size. The general purpose of reform was to make the holding structure less rigid, thereby increasing the elusiveness of its parts on the atomic battlefield. Supporting organic artillery was greatly reduced in numbers of men and guns, thereby placing greater reliance on heavy mortars and rocket batteries. Communications (signals) support was heavily increased by the addition of a new division group which was to maintain wire nets, etc., for the fighting groups. The combat supply problem was similarly handled through the forming of a logistical support group which would carry the load for the infantry fighters. With the ordering of this change, it was not expected that the weapons requisite to it would be more than 25% complete by 1960.

INFANT SCHOOLS (GREAT BRITAIN). The first significant landmark in the development of infant education in Great Britain was the pioneer effort of Robert Owen at New Lanark in Scotland. As managing partner of cotton mills there he was determined to provide a happy, healthful upbringing for the young children of his employees and with this object he established a school in 1816. His two ideals — pleasant, harmonious conditions and a life of interesting activity — had a profound influence in spite of many setbacks.

The circumstances of the industrial revolution tended to encourage the provision of schools for infants because early legislation prevented the employment of young children while the factories took their parents and older brothers and sisters away for long hours. In 1824 the London Infant School society was founded with Samuel Wilderspin as superintendent; another notable pioneer was David Stow, who in 1836 founded the Glasgow Normal seminary in which teachers were trained for service in infant schools. Wilderspin and Stow attached importance to memory drill and moral training, and the restricted playgrounds and fixed galleries in large classrooms, characteristic of schools in which their methods were used, reflected an attitude quite different from that of Robert Owen.

Soon other and more wholesome influences intervened. In 1837 the Home and Colonial society was founded to train teachers in methods advocated by J. H. Pestalozzi. Much influenced by Jean Jacques Rousseau, this great Swiss educator revolutionized ways of infant teaching, stressing nature study and learning by doing. But his disciple, Friedrich Froebel, made an even deeper impression on British educational tradition; rejecting the term infant school because he did not believe that little children should be schooled, he coined the name kindergarten (*q.v.*), later widely used in the United States for the first unit of primary education, to describe an environment in which children grow freely like plants tended by a good gardener.

In 1854 the prince consort opened in London an exhibition of Froebel's "gifts and occupations," and ever since there have been training colleges and schools in which his principles have been held in high regard. It was not until the 1920s, however, that the last of the galleries, characteristic of the Wilderspin technique, disappeared from infant classrooms.

Several influences contributed to make the modem infant school the happy community that it usually is. Most important, perhaps, was the growing appreciation of the psychological and physical attributes of childhood. Child study associations came to flourish on both sides of the Atlantic, and there was increasing co-operation between parents and teachers. Maria Montessori's emphasis on self-education and her criticism of old-fashioned classroom rigidities won her many adherents in Great Britain, although there was some dislike of her graded apparatus. About the same time support for new methods reached Great Britain from the United States as a result of John Dewey's powerful influence, especially his stress on the educative value of practical activities and experience. The Dalton plan also came from the United States reinforcing conceptions of freedom and self-learning. A most effective contribution to the new outlook was that of Rachel and Margaret Macmillan who, appalled by the ill effects of bad housing conditions upon young children, set to work at Deptford, London, in 1911 where three years later they established a nursery school consisting of well-warmed open-air shelters grouped round a garden. The nursery school movement became an influence which also affected the infant school.

Administratively it is often difficult to provide satisfactorily

for the education of infants. The aim in Great Britain is to have a separate school or department for infants. But, especially in villages, numbers are frequently too small to justify separation, and there are many primary schools which infants as well as juniors attend. Less defensible were the many all-age unreorganized schools. There are also many schools outside the state system with various age ranges. *See* also ELEMENTARY EDUCATION.

INFANT WELFARE: *see* INFANCY; MATERNAL AND CHILD HEALTH.

INFECTION: *see* BACTERIAL AND INFECTIOUS DISEASES; PARASITIC DISEASES. For infection in the sense of boils, abscesses, etc., *see* INFLAMMATION.

INFECTIOUS FEVERS: *see* CHICKEN POX; MEASLES AND GERMAN MEASLES; SCARLET FEVER; TYPHOID AND PARATYPHOID FEVERS; WHOOPING COUGH; etc.

INFECTIOUS MONONUCLEOSIS (GLANDULAR FEVER) is a common infection of man. The cause is probably a virus (still unknown by the 1950s). The disease, which has been observed in most areas of the world, occurs predominantly in people from 10 to 35 years of age but may appear at any age.

Glandular fever is probably contagious and usually appears about 5 to 15 days after contact. Malaise and sore throat are the commonest symptoms. Enlargement of the lymph nodes in all parts of the body is frequent; the "glands" in the neck are most often affected. Fever of varying degree is usual. In some cases the only signs of the disease are fever and generalized discomfort; in these, the diagnosis is made by study of the blood.

In about one-third of patients with the disease, the spleen is enlarged. A rash consisting of multiple, small hemorrhages or resembling that of measles or scarlet fever sometimes appears. Pneumonia is present in about 2% of the cases. Severe involvement of the liver with jaundice, which is rare, may persist for several weeks. Encephalitis, meningitis or peripheral neuritis occur; death has followed the encephalitis. The heart is rarely affected. Swelling of the upper eyelids is observed occasionally, and a small amount of blood may be present in the urine. Glandular fever usually lasts for about 5 to 10 days. In some instances, it may persist for several weeks, especially when the liver or nervous system is affected.

Glandular fever is suspected, therefore, when fever, sore throat and enlarged lymph nodes are present. A presumptive diagnosis is made from study of the blood. The white blood count is usually elevated; there is an increase in the relative number of lymphocytes, a varying percentage of which appear abnormal. In from two to seven weeks after the disease begins, there appears in the blood a substance which causes clumping of sheep red blood cells. This is responsible for the "heterophile agglutination reaction" which is diagnostic and positive in about 95% of the cases.

There was still no specific therapy for glandular fever in the 1950s. Antibiotic agents proved of value only for the commonly occurring secondary infections of the throat. (*See* also BLOOD.)

INFERENCE: *see* INDUCTION; PROBABILITY. For oblique inferences *see* LOGIC, HISTORY OF: *Modern Logic: Jungius.*

INFERIORITY COMPLEX, a term used by some psychiatrists and psychologists, particularly the followers of Alfred Adler, to denote a feeling of inferiority that is wholly or in part submerged in the unconscious. The term "inferiority feeling" was used frequently by Adler, who held that many outstanding achievements, some antisocial behaviour, and other continuing aspects of the personality could be traced to overcompensation for this feeling. The use of "complex" later gained acceptance to denote the group of emotionally toned ideas, partially or even wholly repressed, organized around and related to such feelings of inferiority. The term "inferiority complex" has lost much of its significance through imprecise, popular misuse—for example, as an attempt at a facile explanation of any show of ambition by a man of small physical stature. *See* ADLER, ALFRED.

(H. F. HT.)

INFINITE PRODUCTS. The expression $a_1a_2a_3\ldots$ formed by multiplying together in a definite order numbers a_1, a_2, a_3, ... is called an *infinite product.* If at most a finite number of factors vanish, so that $a_p \neq 0$ for $p \geq n$, where n is sufficiently large, and if the limit

$$\lim_{p=\infty} a_n a_{n+1} a_{n+2} \cdots a_p$$

exists and is a finite number different from zero, then the infinite product is said to *converge.* Otherwise it is said to *diverge.* In case the infinite product converges, then the limit

$$\lim_{p=\infty} a_1 a_2 a_3 \cdots a_p$$

is its *value.* According to this definition of convergence, the value of an infinite product is zero only when a factor is equal to zero. Infinite products such as $(1/2)(2/3)(3/4)\ldots$ are counted as divergent since the product of the first n terms, namely $1/(n+1)$, has the limit 0 for n infinite. In case of convergence, if n is sufficiently large we must have

$$\lim_{p=\infty} \frac{a_n a_{n+1} a_{n+2} \cdots a_{n+p+1}}{a_n a_{n+1} a_{n+2} \cdots a_{n+p}} = \lim_{p=\infty} a_{n+p+1} = 1.$$

Hence, if we put $a_p = 1 + b_p$, the infinite product takes the *normal form* $(1+b_1)(1+b_2)(1+b_3)\ldots$, and $\lim_{p=\infty} b_p = 0$ if the infinite product converges. The notation $\prod_1^\infty (1+b_p)$ or simply $\prod(1+b_p)$ may be used for an infinite product. The product of consecutive factors from the nth to the mth inclusive, $m > n$, is denoted by $\prod_n^m(1+b_p)$. One may suppose for the sake of convenience that $|b_p| < 1$, $p = 1, 2, 3, \ldots$. This can always be realized for any convergent infinite product by omitting at most a finite number of factors and renumbering those which remain. There are several important convergence theorems.

(A) *If the b_p are real and positive, then the infinite product $\prod(1+b_p)$ converges* if *and only if the infinite series $\sum b_p$ converges.*

For

$$\sum_{p=1}^{n} b_p < \prod_{p=1}^{n} (1+b_p) = \prod_{p=1}^{n} \operatorname{Exp} \log(1+b_p)$$

$$= \operatorname{Exp} \sum_{p=1}^{n} \log(1+b_p) < \operatorname{Exp} \sum_{p=1}^{n} b_p.$$

The statement follows at once from this inequality.

Example. The infinite product $\prod(1+\frac{1}{p})$ diverges inasmuch as the product of the first n factors is $n+1$ and therefore tends to, ∞ as n tends to ∞. From (A) it therefore follows that the series $\sum \frac{1}{p}$ is divergent.

(B) If the infinite product $\prod(1+|b_p|)$ converges then the infinite product $\prod(1+b_p)$ converges.

In accordance with an earlier remark, we assume that $|b_p| < 1$, $p = 1, 2, 3, \cdots$. Let $P_n = \prod_1^n(1+|b_p|)$, $Q_n = \prod_1^n(1+b_p)$. Then,

$$|Q_{n+m}-Q_n|=|Q_n|\cdot\left|\prod_{p=n+1}^{n+1}(1+b_p)-1\right|$$
$$\leqq P_n\left(\prod_{p=n+1}^{n+m}(1+|b_p|)-1\right)=P_{n+m}-P_n.$$

Since, by hypothesis, $\lim_{n=\infty}P_n$ exists and is a finite number, it follows that for every $\epsilon>0$ there exists an N depending only upon ϵ such that for $n>N$, $m=1, 2, 3, \cdots$, $P_{n+m}-P_n<\epsilon$, so that $\lim_{n=\infty}Q_n=Q$ exists and is finite. To prove that $Q\neq 0$, consider the infinite product $\Pi(1+c_p)$, where $c_p=-b_p/(1+b_p)$. Clearly $\Sigma|c_p|$ converges, so that $\Pi(1+|c_p|)$ converges by (A). Hence, from what we have just proved, it follows that $\lim_{n=\infty}\Pi_1^n(1+c_p)$ exists and is finite. But this limit is equal to $1/Q$. Therefore $Q\neq 0$, as was to be proved.

When $\Pi(1+|b_p|)$ converges, then $\Pi(1+b_p)$ is said to be absolutely convergent. From (A) we have:

(C) The *infinite* product $\Pi(1+b_p)$ is absolutely convergent *if* and *only if* the *infinite* series Σb_p is absolutely convergent.

The notion of absolute convergence furnishes one reason for introducing the normal form of the infinite product. The infinite product $\Pi|a_p|$ has no interesting relationship to the infinite product Πa_p. In fact, the former may converge when the latter diverges, *e.g.* if a, $=(-1)^p$.

An infinite product may converge without converging absolutely. This is shown by the following theorem.

(D) If the b_p *are* real and the infinite series Σb_p and Σb_p^2 are convergent, *then the infinite* product $\Pi(1+b_p)$ *is* convergent.

For, supposing that $0\leqq|b_p|<1$, we have $1+b_p=\mathrm{Exp}[\log(1+b_p)]=\mathrm{Exp}(b_p-b_p\theta_p)$, where $|\theta_p|<M$, a constant independent of p. Therefore, $\Pi_1^n(1+b_p)=\mathrm{Exp}(\Sigma_1^n b_p-\Sigma_1^n\theta_p b_p^2)$, and consequently $\Pi(1+b_p)$ converges.

If the series Σb_p is non-absolutely convergent, then its sum may be made any assigned value by suitably rearranging the order of the terms. We then conclude from the preceding that the value of an infinite product depends in general upon the order in which the factors are taken.

The problem of convergence of an infinite product can always be reduced to the problem of convergence of an infinite series, in accordance with the following theorem.

(E) *The* infinite *product* $\Pi(1+b_p)$ converges *if* and only *if* the infinite series $\Sigma\log(1+b_p)$ *converges*. This holds also for complex b_p provided we take the principal values *of* all the *logarithms*.

Supposing the b_p are real, $|b_p|<1$, put $P_n=\Pi_1^n(1+b_p)$ $L_n=\Sigma_1^n\log(1+b_p)$. Then $P_n=\mathrm{Exp}\,L_n$, $L_n=\log P_n$, and hence if $L_n\to L$ then $P_n\to\mathrm{Exp}\,L>0$; and if $P_n\to P>0$, then $L_n\to\log P$, and the theorem is proved for this case. If the b_p are complex, some further considerations are needed.

One of the most important theorems on infinite products is the *Weierstrass* factor theorem. This theorem concerns functions $f(x)$ having power series expansions $\Sigma a_p x^p$ convergent for all values of x, and having infinitely many zeros $x_1, x_2, x_3, \ldots$ The theorem states that any such function is equal to a convergent infinite product made up of one nonvanishing factor, and one factor corresponding to each zero x_p, vanishing if and only if $x=x_p$. This generalizes the analogous theorem on polynomials. If $f(x)=\sin\pi x$, then the infinite product is $\pi x(1-x)(1+x)(1-\frac{1}{2}x)(1+\frac{1}{2}x)(1-\frac{1}{3}x)(1+\frac{1}{3}x)\cdots$. If, in particular, $x=\frac{1}{2}$, this gives Wallis' famous formula

$$\frac{\pi}{2}=\prod\frac{(2p)^2}{(2p-1)(2p+1)}=\frac{2\cdot2\cdot4\cdot4\cdot6\cdot6\cdots}{1\cdot3\cdot3\cdot5\cdot5\cdot7\cdots}.$$

An important function which can be conveniently represented as an infinite product is the *gamma function*, $\Gamma(x)$. This function serves to define $n!=1\cdot2\cdot3\cdots n$ when n is not a positive integer. We have: $\Gamma(n+1)=n!$ if n is a positive integer, while $\Gamma(x)$ is defined and continuous for all positive values of x as well as for all other values with the exception of $x=0, -1, -2, \ldots$. This function is given in terms of an infinite product by the formula

$$\Gamma(x)=\frac{e^{-Cx}}{x\Pi(1+\frac{x}{p})e^{-\frac{x}{p}}},$$

where C is *Euler's* constant.

Infinite products of the form $\Pi(1-x^{n_p})$, $n_1<n_2<n_3<\cdots$ being positive integers, occur frequently in mathematics. One of the most interesting is $\Pi(1-x^p)$. Euler found a remarkable theorem on the sum of the divisors of n involving the exponents in the power series for this infinite product.

Knopp, Theorie *und* Anwendung der *unendlichen* Reihen (available also in English translation) contain sections on infinite products. For the Weierstrass factor theorem, see E. Borel, *Leçons* sur *les* Fonctions *Entières* (Paris, 1921). Philip Franklin, *A* Treatise on Advanced Calculus (1940), has a chapter on the gamma function. (H. S. WL.)

INFINITESIMAL, a number or magnitude which, though not zero, is less than any finite number or magnitude. This rather vague definition may be rendered more precise by denying the axiom of Archimedes. This axiom states that, if A and B are any two numbers or any two measurable magnitudes such that zero is less than A and A is less than B, then there is a natural number n such that nA is greater than B. The denial of this principle yields the following definition of infinitesimal: if A and B are any two numbers or any two measurable magnitudes such that zero is less than A and nA is less than B for every natural number n, then A is infinitesimal relative to B.

Prior to the 19th century it was generally believed that infinitesimal~were necessarily involved in the notion of continuity and of the infinite, and hence were essential to the development of the differential and integral calculus. When, in the 19th century, adequate definitions for irrational numbers were discovered and an arithmetical theory of limits was worked out, it was possible to show that no real number is infinitesimal with respect to any other; but, on the other hand, it was found that the calculus could be based on the real numbers and the arithmetical theory of limits.

After it had thus been shown that the earlier view was erroneous, the use of the term infinitesimal began to disappear from the writings on the calculus, being used only occasionally to describe a variable (not a number) whose limit is zero.

The proof of the absence of infinitesimals from the system of real numbers and the subsequent discussions of the subject inspired the German mathematician David Hilbert to seek systems in which infinitesimals could occur. He succeeded in defining systems for which the axiom of Archimedes is false. In these systems one element can be infinitesimal with respect to another. (R. W. BD.)

INFINITESIMAL GEOMETRY: see DIFFERENTIAL GEOMETRY.

INFINITY AND THE INFINITE. These terms (from Latin in, "not," and finis, "end" or "limit") in common usage express our felt inability completely to carry out the procedures of counting, measuring. comparing, etc., by means of which size, number or degree can be assessed. Thus we say that there are an infinity of stars in the heavens or of colours on a bird's wing, that someone has been infinitely kind, etc. With this inability to assess go strong emotional overtones; the infinite usually astonishes, wearies or confounds us. In stricter contexts a predication of infinity implies a considered belief that the repeated application of procedures of counting, measuring, comparing, etc., will always be demanded by the material on hand and will never lead to a final assessment of size, number or degree. Thus we say that there are an infinity of fractions between 0 and 1, implying that we shall always be able and obliged to discover new fractions between these limits. In more religious and metaphysical contexts, the notion of the absolutely infinite is developed, the idea of something whose size, number. degree, etc. cannot be assessed in any respect whatsoever and which is therefore omnicomprehensive and omnicompetent: this notion is obviously of greater difficulty and of more doubtful consistency than that of the simply infinite. We may note that there are always both positive and negative aspects to our notion of the infinite: a predication of infinity is. from one point of view. negative. being a confession of our inability to assess size, number or degree; but it tends also, from another point of view, to be regarded as a positive as-

sessment, one demanded by the character of our object and one that is, in many respects, extremely hard to understand or to justify.

The Infinite in Ancient Thought.--Infinity appeared to ancient Greek thought in two contradictory guises. To the thinkers of Ionia it was attributed to the boundless environment of our cosmos and was an object of honorific assessment. Thus Anaximander (*q.v.*) set our world, together with countless other similar worlds, in a boundless environing material medium, "that becoming might not fail"; he also spoke of this medium in laudatory and religious terms. Even Melissus the Samian, whose notion of unchanging Being was Italian rather than Ionian, felt obliged to hold that "that which is" was infinite in magnitude, while Anaxagoras (*q.v.*) of Clazomenae constructed his world out of an infinity of particles called "seeds," which were also infinite in variety and in "smallness." As opposed to this positive, favourable attitude to the infinite, the Italian attitude (represented by Pythagoras) was unfavourable and negative: the infinite was put into the class of things obscure, variable, unfinished and therefore bad. It stood in essential opposition to the "limit," whose work was the simplifying ratio or the precise mathematical proportion. The infinite showed itself in the "boundless breath" of darkness from which the starry units were separated, in the boundless variability of the crooked line or of the oblong as opposed to the constancy of the straight line or of the square, in the irrational and in the incommensurable of which the Pythagoreans (in search of a simple ratio between the diagonal of a square and its side) had had bitter experience. This unfavourable view of the infinite was passed on to Parmenides of Elea (*q.v.*), who refused to make his unchanging Being infinite "since it is in need of nothing, and since what is infinite is in need of everything"; and to Parmenides' disciple Zeno, who found a sufficient reason for denying that "things are a many" in the fact that, if such plurality were admitted, it would lead to the admission of an infinity of units between any two distinct points, and that such an infinity was not a number at all. Zeno also based his famous proofs of the impossibility of movement on the fact that it involves passing through and completing an infinity of successive stages.

This negative, Italian view of the infinite was adopted by Platonism, for which the infinite was essentially the irrational, flowing or formless principle, capable of indefinite increase and diminution which has to be subordinated to the "one" or the "limit" in order to give rise to whatever is intelligible and good. It is the indefinite element in the ideal world, which has to be bounded by the One in order to give rise to those precise, quantitative patterns with which Plato ultimately identified his "ideas." It is also the indefinite element in the world of the senses, whose bounding by numerical ratios gives rise to whatever is healthful, strong, musical or visibly excellent. In itself, however, it admits only of a contradictory characterization: it is essentially "the others," "the great and small." It shows itself, particularly, in the way in which quantitative parts evanesce into other parts without end and in the way in which a new beginning, middle or end always appears before, within or after any beginning, middle or end that we try to fix. (For Plato's attempt to describe the continuum, see his Parmenides. For further interpretation of his doctrine, see the works cited in the bibliography below.)

This mystical Platonic view of the infinite was replaced by the clear formulations of Aristotle which have, to a large extent, remained definitive for western thought. For Aristotle the infinite exists only "after a fashion": after another fashion it does not exist at all. It never exists in the sense that we ever actually have an infinitely large number of things or of parts of things or anything which exceeds in size all things of limited bigness. The infinite is something potential or facultative: its presence in a field means that one always can go on to ever larger sizes, divisions or number in that field, that one can go outside of any given size or number to one that lies beyond it. So understood the infinite is incompatible with wholeness and perfection; for something to be infinite means that one never can have 'all of it, only more and more of it. Mathematicians, Aristotle observes, talk as if they needed infinite quantities in their calculations; in reality they need only finite quantities, but as large as they require. Nor can our world contain anything infinitely great, since Aristotle shows it to be finite and spherical, It is not actually, but only potentially infinite by division: this fact is used by Aristotle to refute Zeno's "disproofs" of the possibility of motion. Time, indeed, goes on endlessly in either direction but it is not infinite in the sense of ever being there all at once. Even the potential being of the infinite is. for Aristotle, a queer sort of potentiality: unlike the potentiality of the statue in the block of stone, it can never be translated into actuality.

The Infinite in Modern Philosophy.—Modern post-Renaissance thought shows the same tension as does ancient thought between the acceptance of an actual and a merely facultative view of the infinite. In the main, the continental European rationalists espoused the former, while the British empiricists favoured the latter. Thus Descartes held infinity to be a positive notion: it is only by contrast with the infinity involved in my inborn idea of God that I can become conscious of my own finitude. In Spinoza the infinite becomes the omnicomprehensive or absolutely infinite: reality or substance is for him infinite in a sense which renders illusory any division of it into clear-cut finite parts and which entails its including, not merely infinitely many finite "modes," but also all possible modes in each basic kind or attribute. In Leibnitz, too, there is a ready acceptance of the view that in every organized part of nature there is an actual infinity of subordinate parts, each expressing a governing monad or entelechy. He is careful to explain, however, that (apart from God) he does not believe in a single substance which is infinitely great or infinitely small: the infinitely great and small (as employed by him in the calculus) are for him merely useful mental fictions not admissible in philosophy (see his letter to B. des Bosses, March 11, 1706). But if Leibnitz had reserves in this regard, his contemporaries or successors had none: they talked without scruple about infinitely small or vanishing quantities and spent much time over such problems as that of the value of the infinite sum $1-1+1-1+1-\ldots$.

As opposed to this uncritical acceptance of an actual infinite, the British empiricists were more wary. Thus Locke spoke of our idea of infinity as an "endless growing idea" and denied, as against Descartes, that we could ever form a positive and distinct idea of infinite magnitude In like fashion Berkeley, in The Analyst, subjected contemporary mathematical treatments of the infinitesimal to a devastating critique. Hume, too, refused to allow that we had an impression, and could consequently form an idea, that admitted of the infinite division demanded by the mathematicians. It is this critical approach to the infinite which is, in the main, characteristic of the German idealists. Thus Kant gets round his antinomies involving infinite series—the antinomy, for instance, as to whether the world ever had a beginning in time or not, or as to whether its series of events goes back to a first cause or admits of an infinite regress in causation—by holding that, while we are obliged to go back indefinitely from any empirical feature of the world to other features presupposed as its conditions, it makes no sense to try to sum up the totality of conditions thus involved. For Kant as for Aristotle. infinity is incompatible with completeness. The same point of view is given a somewhat mystical expression by Hegel, when he contrasts his own "true infinite" with the "bad infinite" of the mathematicians, the bad infinite being characterized by an endless vain effort to transcend the finite, which it only succeeds in reinstating, whereas the "true infinite" is achieved when the finite is seen in its place in the whole system of finites, as expressive of a unity which pervades them all.

The Mathematical Infinite.— Modern mathematical thought has devised various conceptions which have enabled it to avoid confused and self-contradictory views of the infinite. Thus the useful phrases "tending to zero" and "tending to infinity" have been, since the time of Augustin Cauchy (1789–1857) (*q.v.*), so interpreted that they no longer seem to involve a reference to single quantities which are infinitely large or infinitely small. To say, for instance, that a certain function of a variable x "tends to infinity" as x "tends to zero" is merely to say that one can make

the value of that function of x exceed any finite number, however large, provided that x is given a value sufficiently close to zero. In the same way, useful geometrical talk about points, lines and planes "at infinity" involves no reference to anything infinitely remote. Thus to say that parallel lines intersect at a point at infinity is only to say that the point of intersection of lines which are *not* parallel will recede to any finite distance, however remote, the more nearly such lines approach the parallel.

In another region, however, modern mathematical thought has tended to reinstate the actual infinite; *i.e.,* the field of Georg Cantor's transfinite numbers. This development rests on a view of number which connects it with the establishment of one-one correlations between the members of different classes and which applies this notion to the case of series or progressions which lack a final term; *e.g.,* the series of positive integers 1, 2, 3, 4, etc. If we now ask ourselves what number can be assigned to the whole set of terms belonging to such a series or progression, it will be plain that we cannot assign to it the number of any subset reached in the successive running-through of such a series or progression. We shall have to widen our notions of number and assign to it a number differing from, and also exceeding, any such successively reachable number. It will have to be the number of an ordered progression lacking a final term, not any number exemplified *in* such an ordered progression. Though such a number cannot be reached through stepwise increases by unity (which Cantor calls his first principle of the formation of numbers), it can be reached by considering the whole set of terms which are reachable by such stepwise procedures (this Cantor calls his second principle of the formation of numbers). The functioning of this new type of number will be in many ways peculiar. Thus a transfinite aggregate will not be increased by the addition of a unit or by that of a finite number of such units: it can even have infinitely many units added to it or taken away from it, while remaining as infinite as ever. Thus the series of odd integers can be put into one-one correlation with the complete series of integers and is therefore of the same number. This capacity to have proper parts which are equal in number to the whole can be taken as definitory of transfinite aggregates. It can, however, be shown that not all transfinite aggregates can be put into one-one correlation with one another: there are some (*e.g.,* that of the real numbers in the continuum) which elude reduction to an ordered list or progression and which must therefore be said to be of a higher, nondenumerable type of infinity. The theory of Cantor deals with many distinct orders of nondenumerable infinity.

The Cantorian theory has built up an account of transfinite number in which no inconsistency is discoverable. There are, however, profound obscurities in regard to the precise meaning of the theory: it gives rise to problems deeply involved with questions concerning the foundations of mathematics and the analysis of numerical statements. On certain views (*e.g.,* the somewhat different views of Ludwig Wittgenstein and L. E. J. Brouwer), we can make use of the idea of infinity only in cases where we have a rule to guide us through its labyrinth: it is senseless to talk as if we could ever have an infinite aggregate before us or could ever complete a process involving an infinite number of steps or cases. Such views give small meaning to Cantor's denumerable type of infinite and no obvious meaning at all to his higher, nondenumerable types of infinity. On other views (*e.g.,* that of Bertrand Russell), talk about the infinite involves us in finding some actual class somewhere in the universe, correlation with which will constitute the infinity of any class; such an "axiom of infinity" is, however, profoundly dubious, more particularly in view of the findings of modern physics, which make the world finite in extent and in divisibility. It may, however, be argued than there is no more to the "existence" of transfinite numbers than the *possible* existence of aggregates exemplifying any and every finite number in their proper parts, and that we perfectly understand what this means. On such a view, the main use of Cantorian concepts is to dispel the atmosphere of awe and mystery attaching to the mathematical infinite and to restore it to those ethical, aesthetic and religious objects to which it more properly belongs.

INFLAMMATION. Inflammation is the characteristic response of animal tissue to injury Whenever tissue is injured, whether by burning, tearing, chemicals. bacteria, viruses or parasites, there follows a series of reactions at the site of injury. Certain portions of the inflammatory reaction are common to all types of injury. Thus redness, heat, swelling and pain are known as the cardinal signs of inflammation and as such were first clearly recognized and described by Celsus (A.D. 34). Although there is a fundamental similarity in the pattern of the response to injury. there is also a nide range of variation in the appearance and course of events following trauma. The four cardinal signs are all evident in cuts, burns, insect bites and boils. The duration, the amount of tissue destruction and proliferation and the residual disability, however, differ in each instance. These differences are functionally related to the following factors: (1) the nature of the irritant (burn, chemical, bacteria, etc.); (2) the structure of the tissues in nhich the event occurs; (3) the condition of the host at the time of injury and during the subsequent process. All three factors, each complex in itself, must be accounted for in arriving at an understanding of the inflammatory process. The general pattern of the inflammatory response can be divided into four major parts: (1) cell and tissue injury; (2) the blood vessel (vascular) response; (3) the exudate; and (4) restitution or repair.

Tissue Injury.— The amount of tissue injury and cell death (necrosis) which occurs depends upon the nature of the irritant. This injury or death may be brought about by physical agents, chemical substances or living agents, including microorganisms and parasites. Physical agents include violent force. heat, ultraviolet and X-irradiation. Chemical poisons may be the salts of simple inorganic substances, such as mercury, silver, arsenic. acids and alkalies, simple organic molecules such as formaldehyde and turpentine or complex organic molecules such as bacterial toxins, enzymes. etc. Viruses are essentially large complex organic molecules which grow only in living cells and operate by interfering with cell metabolism. Bacteria and parasites produce, as a result of their metabolism, substances chemical in nature which kill or injure cells. This cell injury or death leads to the release and degradation of materials normally contained within the cells. These substances in turn produce effects on local tissue structures and. nhen absorbed into the blood stream. affect distant organs. This is illustrated in the following situation: When the blood supply to an area is shut off. as in thrombosis of an artery, the local tissue supplied by the artery frequently dies. The dead cells release substances which diffuse into the adjacent living tissue and into the blood stream. In the marginal zone the characteristic changes of inflammation occur. Similar phenomena occur when physical agents, chemical agents or living pathogenic organisms cause tissue damage or death

Blood Vessel Response.— The redness, suelling and heat in an area of injury are an expression of alterations in the blood vessels —dilation of the smallest vessels, capillaries, arterioles and venules, accompanied by leakage of the blood plasma and its proteins into the surrounding space. The redness is accounted for by the increased quantity of blood in the dilated vessels, the heat is an indication of the associated increased blood flow. while the swelling is caused by the excess fluid in the tissue spaces. More severe alteration in the vessels is associated with accumulation of formed elements and coagulation of the blood.

Exudate.— In some inflammations simultaneous with or shortly following the alterations in the blood vessels the white blood cells and sometimes the smaller structures known as platelets begin to adhere to the walls. The white blood cells. particularly the polymorphonuclear leukocytes, are capable of amoeboid movement and migrate through the endothelium of the blood vessels.

Other white blood cells — lymphocytes, monocytes and eosinophiles — also migrate from the blood stream in some conditions. Additional cells are contributed from the local site by elements in the connective tissue associated with the blood vessels. The combination of cells and fluid containing the various plasma proteins is called the exudate.

The exudate has a variable composition, in terms of its protein and cell population. which is related to the nature of the irritant. Thus the mild irritants lead to a serous exudate composed mainly of fluid and smaller blood plasma proteins. Some irritants cause rupture of blood vessels with leakage of red blood cells; these are called haemorrhagic exudates. Pus is an exudate composed of dead tissue, many white blood cells in various stages of disintegration. and a small quantity of plasma. It is associated usually with bacterial infection.

The cells of the exudate have several functions. The polymorphonuclear leukocytes engulf (phagocytose) bacteria and digest large numbers of them. The monocytes do likewise. The polymorphonuclear leukocytes when lysed rclcase enzymes capable of digesting various products of dead tissue. The lymphocytes also produce enzymes: plasma cells produce antibodies. The plasma component of the exudate has many constituents including fibrin. antibodies, enzymes, nutrients, hormones and products derived froni degraded cell structures. Of particular importance are the opsonins, which occur normally or are formed in response to the presence of an infectious agent. These substances, one class of which is known as antibody, enhance the effectiveness of the engulfment (phagocytosis) of bacteria by the white blood cells. In the absence of sufficient numbers of polymorphonuclear leukocytes, infection may become rampant. Likewise the absence of sufficient opsonin or antibody is associated with lack of usual control of infection and inflammation.

Restitution and Repair. — In situations in which cell death and tissue destruction are nil or minimal the return to the normal state is by resorption of exudate. This process is known as resolution. When cell destruction is extensive there may be regeneration of those tissues which are capable of regeneration. such as epithelium. liver cells. certain types of tissue fibres and bone. In general the more complex a tissue the less likely it is to regenerate. Certain tissues such as nerve cells do not regenerate, although the nerve processes may if the cell body is not injured. In those tissues n-here regeneration does not occur the repair is by fibrous tissue replacement and is known as scar formation.

VARIATIONS IN THE INFLAMMATORY RESPONSE

Properties of the Irritant. — Irritants may be physical or chemical. or they may be living biological organisms, including bacteria. viruses. fungi and parasites such as worms of various types. The character of the irritant is important in conditioning the type of reaction which ensues. An important difference between living and nonliving agents is in the fixed quantity of the latter as opposed to the reproductive capacity of the former. Thus a sufficiently small amount of chemical substance lethal in larger quantities may produce only a mild reaction. but even a single bacterium may, in a susceptible host, multiply and cause overwhelming disease.

Direct physical trauma, a blow or cut, damages and kills tissue cells. The damaged cells then release chemical substances, some of which are excitants of the inflammatory reaction. The types of substances released are ions of the cell sap. products of the degradation of cell proteins, and cell metabolites not normally present in any large quantity in the cxtracellular space. These liberated materials affect small blood vessels either directly or through the activation or release of such substances as histamine or by way of the nerves which control the vessels.

The cardinal signs of inflammation can be reproduced by injecting into the skin a small amount of histamine. The mosquito bite and nettle sting produce a similar phenomenon. Such reactions can he prevented wholly or in part by an antihistaminic. Histamine is present in most body tissues in special cells known as mast cells. Damage to these cells by substances liberated from bacteria, from damaged tissue cells or from extraneous sources liberates histamine and probably other substances. Several chemical substances have been isolated from inflammatory exudates which are capable of causing capillary dilation and increased permeability, of inducing elevation of the white blood cell concentration. of producing fever and of causing damage and death to other cells. These appear to be partially hydrolyzed derivatives of protein and other tissue substances. Thus simple mechanical tissue damage of sufficient extent may produce the total constellation of inflammation including both the local and general manifestations.

Heat applied for a sufficient time and at a sufficient intensity (about 45° to 50° C. [113°–122° F.] for a few minutes depending on size of part. rate of blood flow insulation, etc.) will cause the appearance of pain. redness, heat and smelling. This results from the liberation of chemical substances from the injured tissue. Higher temperatures and more prolonged exposures (scalds, oil burns, etc.) cause more extensive tissue injury and death. Blistering is the result of the accumulation of fluid exudate between the layers of epidermal (superficial skin) cells. Sunburn is due mainly to the effects of the ultra-violet in the sun's radiation. Mild exposure causes only the redness and slight swelling associated with mild injury. Longer exposure or exposure to more intense radiation causes a more severe reaction. which on the skin is seen as blistering. Ionizing irradiation such as X-ray or other products of nuclear fission can also elicit reactions varying from simple erythema (the redness reaction, to extensive tissue destruction. From the standpoint of the inflammatory reaction the process is similar to the others. In addition subtler changes occur in irradiated cells.

Chemicals such as mustard gas, strong acids or alkalies applied to the skin surface or injected into tissue cause alteration in cells which may vary from mild, microscopically indiscernible changes to necrosis. Associated with this there may be mild reactions such as erythema or more severe reactions including tissue death, blistering and formation of a purulent exudate.

Bacterial incitants of inflammation are ubiquitous in the environment and within animals. They are in the soil, floating in the air. on the skin surface and in the gastrointestinal tract from mouth to anus with the possible exception of the stomach (in the stomach the high acidity and digestive enzymes provide an inclement milieu for bacteria). Many bacteria are normal inhabitants of the skin surface and gastrointestinal tract; under ordinary circumstances they do not cause inflammation unless there is an alteration in the balance between the animal host and the bacterium. Such is the case for example with many staphylococci and streptococci and with the colon bacillus. The factors which maintain this balance are in two categories: those of the host which prevent excessive multiplication of the bacteria, and those of the bacteria which promote its virulence or invasiveness. The host factors involved will be considered later.

Bacteria produce a variety of chemical substances which in part account for their virulence or invasiveness. Some of these substances are enzymes, complex sugars. proteins and fats. while others are simpler derivatives of amino acids such as histamine. These substances formerly were classed together under the term toxins. It later became clear, however, that all these chemical agents can. each in a relatively specific fashion. alter the structure or the metabolism of the host cells. Thus the protein toxin of diphtheria bacillus interferes with the formation of certain respiratory pigments of tissue cells, the cytochromes. This leads in turn to impairment of cell metabolism or death, or both. Some bacteria (streptococci and pneumococci) produce an enzyme known as hyaluronidase. which causes breakdown of hyaluronic acid. an important constituent of the ground substance of connective tissues. This allows spreading of bacteria and other substances through the tissue spaces. Many microorganisms produce enzymes capable of attacking and splitting the proteins of the cells and tissues; including the collagen and reticulin fibres of the connective tissue. Such enzymes also liberate fragments of protein which in themselves are capable of inciting portions of the inflammatory reaction including the vascular injury and the ingress of leukocytes.

Viruses are obligatory intracellular parasites; that is, they need

a complete cell such as a tissue cell or a bacterium in which to grow. In this respect they differ from many bacteria. which if supplied with a simple or complex set of nutrients in a cell-free medium will multiply. Viruses damage tissue by interfering with the metabolic processes of the cells which they parasitize. The reaction of tissue to viruses and other agents involves cell damage or death with the attendant vascular, exudative and reparative phenomena.

Site of Inflammation. — The nature of any inflammatory process depends in part upon the site of occurrence in the host; the site depends in turn upon the nature of the organism and its portal of entry into the host. Certain organisms are air-borne and usually are inhaled or taken in with food or other objects introduced into the nose or mouth. The pneumococcus, streptococcus, meningococcus and many of the viruses enter the body in this way. They are specially adapted to invade the membranes of the nose, throat and tracheobronchial system. Some organisms taken in with food or other objects are capable of surviving passage through the stomach with its acid digestive secretions and of invading the mucosa of the bowel; included in this group are the organisms causing typhoid fever and the various dysenteries. The virus of poliomyelitis likewise survives passage with the food and invades via the gastrointestinal tract. In contrast with typhoid and dysentery bacilli. the polio virus finally causes its main disease manifestations after passage through the blood stream to a distant site, the central nervous system. Many disease-producing microorganisms exhibit this predilection for principal growth in a certain tissue.

Inflammation in a tightly confined tissue, such as the marrow of the bones or the pulp of a tooth, produces more extensive necrosis than does inflammation in a soft tissue. This is due to the pressure of the confined exudate. which restricts the flow of blood. In certain spaces such as the peritoneal and pleural cavities the exudate spreads freely and may be voluminous. In the meninges of the brain the exudate may spread freely on the surface but its volume is restricted by the cranial bones.

The site of an inflammatory process conditions not only the character of the local reaction but also its consequences. An abscess in the brain leading to destruction of a small vital area may spell severe disability or even death. On the other hand, a lesion of the same extent in skin, muscle or even liver may have little serious consequence.

General Host Factors Conditioning Inflammation. — Normally there are chemical substances in the sweat and sebaceous secretions of the skin which prevent bacteria from excessive multiplication and invasion of the body. Saliva and other secretions and cellular activities of the gastrointestinal tract act similarly. Changes in the physiological state of the host may lead to alterations in the host's tissues and secretions which allow proliferation and invasion of bacteria such as staphylococci. This happens. for example, in adolescent acne. Similar though usually less drastic changes may occur at other times with appearance of crops of boils. Some of these changes are due to alterations in endocrine gland secretions; the amount of antibody formed in response to an infectious agent can be important in conditioning the pattern of inflammation. Practically all humans and animals have the capacity to form antibodies. Some persons. however. are unable to form antibody to certain types of agents. Severe starvation or dietary deficiency of protein may restrict antibody formation. Hormones of the adrenal cortex in sufficient amounts depress formation of certain types of antibody.

The adrenal cortex secretions are capable of altering the inflammatory reaction in several ways: excessive amounts of the hydrocortisone type of secretion reduce the quantity of exudate formed and the amount of fibrous tissue and capillary proliferation. The adrenal cortex is under the control of the pituitary secretion and the pituitary is controlled by many factors both humoral and nervous. Thus many factors which regulate the general state of a person can modify inflammation.

SPECIFIC EXAMPLES OF INFLAMMATION

Boils.—A typical and common inflammation is the boil, occurring on the skin following invasion of bacteria through a natural channel such as a hair follicle or sweat gland or through a break in the surface. The type of bacterium most frequently causing boils is the staphylococcus, which multiplies and induces death of a few cells locally. Both bacteria and dead tissue cells then liberate materials which engender formation of exudate. In this case large numbers of polymorphonuclear leukocytes are the main cellular elements. From the vessels come plasma and its fibrinogen which clots and forms a fine fibrin network which helps prevent spread of bacteria in the local tissues. With the formation of more exudate the boil progressively enlarges and follows the path of least resistance toward the skin surface. Finally. in most instances, it ruptures, and the pus and bacteria are evacuated. The walls of the cavity collapse and, if the growth of bacteria is sufficiently checked by the combination of antibodies and phagocytes, repair by fibrous tissue replacement occurs.

Abscesses.—When a similar focus in deeper tissues is started the reaction is similar to that in a boil and is called an abscess. This may reach considerable size and last for some time, becoming chronic. There is a central focus of necrosis and pus. Around the pus is a layer of fibrin which lies upon a surface of newly proliferated and dilated capillaries known as granulation tissue. In a chronic abscess this is encapsulated by fibrous tissue. With time the bacteria may become attenuated, either spontaneously or with the help of administered antibacterial agents, and die off. The dead material is absorbed slowly unless evacuation occurs spontaneously or by surgical incision and drainage. The result again is repair by scarring.

Ulcers. — An ulcer is an inflammation on a surface — the skin or the lining of the gastrointestinal tract. It may be acute (of recent onsetj or chronic. The open surface or crater of an ulcer usually contains a mixture of dead tissue cells, leukocytes and fibrin, resembling the pus of an abscess. In an acute ulcer there is a characteristic congestion of blood vessels in the underlying live tissue. In a chronic ulcer there is also granulation tissue and fibrous tissue with some inflammatory cells. In the inflammatory cell population lymphocytes and plasma cells usually predominate. When the stimulus to ulceration is removed the fibrous tissue fills in the gap and epithelium grows from the margins to cover the surface.

Fever Blisters; Common Cold. — The virus which causes fever blisters is present in the body in the epithelial cells of skin and mucous membranes; when conditions in the host are altered by the presence of a mild infection such as a cold. or a severe infection such as pneumonia. the virus proliferates and produces obvious inflammation. The chief manifestation is blistering due to changes which include death of some epithelial cells and fluid separating the layers of cells in the skin. Associated with it is a mild hyperaemia and an exudate composed of white blood cells. A secondary bacterial invasion may occur with pus formation.

The agent of the common cold, presumably a virus, causes redness and swelling of the nasal mucous membranes and an abundant watery exudate containing, in addition to plasma constituents. considerable quantities of dilute mucus and a sparse population of exudate cells. This process is usually self-limited in a few days. Frequently it becomes secondarily invaded by bacteria, and pus is then formed. No serious tissue loss occurs and the return to normal is by resolution and regeneration of lost epithelium.

Allergic Inflammations. — Hay fever induced by pollens, house dust, horse dander and other stimuli is a source of great discomfort to a substantial proportion of the population. Many persons are sensitive to the products formed following ingestion of certain foods. In these cases another injury mechanism is introduced; the appearance of certain kinds of foreign materials in the body engenders the formation of antibodies. Foreign proteins are the main stimulants to antibody formation (antigens), but complex sugars and fats and certain chemicals which react with proteins will also cause formation of antibodies. The latter circulate in the blood and are frequently deposited widely in the body tissues. When the specific, or a very closely related, foreign substance is reintroduced it reacts with the antibody. In the process of this reaction substances including histamine are set free from

the tissue cells and produce the inflammatory process. Thus the irihalation of pollen causes hay fever; another type is allergic asthma. Urticaria (hives) is produced in a similar manner by antigen which is absorbed and distributed via the circulation or applied locally to the skin. In some instances (for example, following local reinjection of foreign protein), the antigen-antibody (allergic or hyperergic) reaction can be severer. with extensive tissue and cell destruction. Formation of antibody and the attendant allergic reaction appear in the later stages of some chronic bacterial and fungous infections; *e.g.*, tuberculosis and ringworm. The exudates in allergic inflammation characteristically contain a large number of eosinophilic leukocytes.

An aberrant antigen-antibody reaction is thought to be involved in rheumatic fever and glomerulonephritis. A factor common to both diseases is the occurrence two to three weeks before their onset of an upper respiratory infection, usually with β-haemolytic streptococcus. This infection is long past its peak when the disease makes its appearance. The inflammation of rheumatic fever involves the joints. heart and lining of small blood vessels. In its acute or early phase there is small blood vessel dilatation and an exudate with leukocytes. Characteristically there appear in certain sites Xschoff's nodules. special forms of the inflammatory process in which there are no demonstrable bacteria. There is swelling and fragmentation of the connective tissue fibres (collagen bundles) and the appearance of large, frequently multinucleated cells. Similar formations. called verrucous vegetations, form on the heart valves and have a large component of fibrin and platelets from the blood. Excessive proliferation of the fibroblasts of the connective tissue of the valves frequently occurs: this leads to thickening and stiffening of the normally thin and flexible heart valves and fusion of their separate parts or cusps. The result is restriction of valve function — one form of heart disease.

In glomerulonephritis there is a somewhat similar process with swelling of the blood vessel tufts of the glomeruli and later fibrous tissue proliferation which may destroy some glomeruli.

Pneumonia. — In pneumonia of the lobar type. caused by pneumococci. an exudate is formed in the air spaces of the lung. At first the exudate cvntains many red blood cells (haemorrhagic exudate). Later a large population of polymorphonuclear leukocytes move in and are enmeshed in a fibrin network. There is little tissue destruction. and when the body produces a sufficient concentration of antibodies or when sufficient antibiotic or chemotherapeutic agent is administered to stop bacterial proliferation the fibrin is digested by enzymes from the white blood cells; the exudate is removed as sputum by coughing. At this time another class of phagocytic cells makes its appearance, the macrophages, and these ingest and dispose of residual debris. The end result is resolution of the pneumonic process, usually without evidence of alteration of lung structure or impairment of function.

Tuberculosis. — Tuberculous inflammation differs in certain respects from the acute pyogenic inflammations described above. Here there is a minimal early exudation with polymorphonuclear leukocytes. Very soon monocytes appear and become transformed following ingestion of the bacteria into epithelioid cells. These. along with some lymphocytes and giant cells. are the common cells of a fully developed tuberculous exudate. Tubercle bacilli proliferate much more slowly than do staphylococci and streptococci and related bacteria: tuberculosis is a disease with a slower tempo than the diseases caused by the pus-producing bacteria. It falls in the class of inflammations known as granulomatous because of the abundance of granulation tissue and fibrous tissue usually present. The tubercle bacillus produces no soluble exotoxins of the kind which kill tissue cells. Substances have been extracted. including some fats. some complex sugars and some proteins, which when injected into animals produce the various cellular responses.

The course and outcome of tuberculous infection has been clearly shown to be highly conditioned by the host. Experimentally strains of rabbits have been bred with a high, low or intermediate resistance to this infection. Given the same strain of bacterial organism in the satne dose, one strain produces a moderate degree of inflammation and considerable fibrous tissue and the lesion becomes arrested: another strain of host gets a rapidly progressive, tissue-destroying inflammation with little fibrosis and dies quickly. The same pattern can be seen in humans. Groups of men who have lived in close quarters and in the presence of tuberculous infection for centuries are usually relatively resistant, whereas those who have not been in contact with the organism or have lived in uncrowded areas have a more rapidly progressive disease and a higher death rate. Susceptibility to tuberculosis is not only an inheritable trait but can be modified by the endocrine system. Xdministration of adrenal cortical steroids of the type of cortisone causes an apparent improvement of the patient's symptoms and a sense of well-being but a more rapid progression of the disease process.

INFLATION AND DEFLATION. There is no single, generally accepted definition of inflation. Following World War I the term was widely applied to the enormous increases in money arid prices in central and eastern Europe, notably Germany, Austria and Russia. Inflation thus connoted a breakdown in the value of the monetary unit. arising from a vast increase in the supply of money issued to finance government spending in excess of tax revenues. Until the 1930s inflation was generally defined as an abnormal increase in the supply of money without a corresponding increase in goods and services available for purchase, resulting in a rapid rise in the price level (fall in the purchasing power of the monetary unit.)

Following the work of John Maynard Keynes during the 1930s, however, economists placed less emphasis on the quantity of money as the major determinant of total spending and prices. Instead. current consumer and business spending was considered to be largely a function of income received. Wide variations in total spending and in prices could thus result from changes in the public's decisions to invest or consume, quite apart from changes in the quantity of money. More money would not necessarily lead to higher prices.

Definitions of inflation thus focused on the rise in the price level itself. Many but not all writers continued to emphasize the increased money supply .underlying inflation and to dissociate price increases from monetary expansion. Inflation was now often used to describe slow or moderate. as well as rapid, increases in the price level. Violently rising prices, with a rapid decline in the value of the monetary unit. were often termed runaway, hyper- or open inflation, in contrast with creeping or repressed inflation (the latter referring to prices held down by direct government controls on prices and wages). Serious inflation seldom occurs until substantially full employment is reached, and sometimes price rises in underemployment periods are excluded. Disapprobation almost invariably attaches to inflation, but confusion often arises because of failure to define the term precisely.

Measurement. — If inflation is defined as a rise in the price level, and deflation as a corresponding decrease. a price index or average of individual price movements is needed to measure these changes. Diiferent prices change at different rates in inflation and deflation. Thus. any price index provides only a central tendency of the many individual price changes in inflation and deflation. The change indicated by the index number may be markedly influenced by the particular prices included in the average. If the index is intended to measure changes in the value of the monetary unit. it should ideally include all prices on which the monetary unit is spent, but this breadth of coverage is never attained. (See INDEX NUMBERS; PRICE.)

Causes. — All the major inflations of moder'n history have been associated mith large increases in the quantity of money. created to finance government expenditures in excess of tax receipts during or following major wars. The severest inflations have occurred in defeated countries. suffering from serious disruption of productive capacity, from postwar disillusionment and from lack of confidence in the government's ability to restore economic stability. Faced with the problem of financing large war or post-

war rehabilitation and reparations expenditures, the government needs to collect taxes roughly comparable with its expenditures in order. to avoid inflation. Under such circumstances, however, it is difficult to obtain popular support for increased taxes, especially from a public already impoverished by a long war effort. Thus the government resorts to borrowing to cover its excess of expenditures over tax receipts.

Borrowing from the banks creates new money, whose expenditure represents a net increase in total spending in the economy. Unless production can be increased; this leads to higher prices. Higher prices in turn require higher government outlays and further increase the deficit which must be financed by borrowing. Tax collections lag behind rising incomes. Recourse to more money creation further increases the inflationary pressure. Such an upward spiral of hyperinflation is very difficult to check unless the government can somehow restore confidence by establishment of a new, generally accepted monetary unit. as was done with the rentenmark ending the great German inflation after World War I. Whether the government resorts to direct printing of new paper currency or borrows from the banking system (thereby creating additional bank deposits) is of no major importance in the inflationary process. The type of new money created depends largely on the financial institutions and habits of the country concerned.

In the great German hyperinflation, for example, the quantity of paper marks in circulation increased from about 2,000,000,000 marks in 1914 to about 500 quintillion (500,000,000,000,000,000,000) at the end of 1923. At the peak of the inflation in 1923, 1,000,000,000,000 paper marks had about the same purchasing power as 1 prewar German mark—about 24 U.S. cents. Postage for a local letter cost 100,000,000,000 marks. To conserve paper and printing press time, notes were printed in billion- and trillion-mark denominations. Prices rose so rapidly in late 1923 that paper money lost half or more of its value in an hour, and wages and salaries were paid daily or oftener to facilitate quick spending of earnings. Rising prices outdistanced increases in the money supply as people greatly increased the rate at which they spent their receipts. With the introduction of the new German rentenmark to re-establish confidence in 1924, the preceding paper currency was in effect completely repudiated.

Similar, though less severe, inflations occurred after World War I in Russia, Austria, Hungary, Poland and other nations. Other great inflations in modern history were that in China during the 1940s, in the United States following the Revolutionary War (where the paper Continental fell to one-thousandth of its previous value) and in France during the 1790s (when the paper assignat fell to about one five-hundredth of its former value). Such hyperinflations were comparatively rare, but milder inflations have been commonplace throughout modern history. Price-level fluctuations as part of business booms and depressions have never reached the magnitudes of the major inflations associated with large government deficits, and modern economists emphasize the favourable impact of rising prices in helping to end depressions.

In nearly all countries, control over the supply of money (paper currency and bank deposits) is directly or indirectly under the government. Thus important inflations can occur only with the acquiescence or active support of the government. In business cycles, however, variations in the money supply may arise out of private decisions on borrowing, if the government permits a banking system that expands and contracts its loans in response to varying public demand for borrowed funds. Price fluctuations also reflect variations in the rate at which money is spent. Such milder price fluctuations are particularly disruptive when deflations are accompanied by mass unemployment, which is usually the case if prices fall sharply.

During part of the 19th and early 20th centuries, the prevailing gold standard limited the issue of paper money and bank deposits to the amount the public would hold instead of gold; gold could be obtained freely in exchange for other money. With the virtual elimination of free domestic gold conversion following World War II, this provision was replaced in some nations by legislation limiting the amount of money allowable per dollar of gold reserve held. Elsewhere, there was no formal metallic limit on money issue. As long as either free gold convertibility or a fixed money-to-gold ratio prevails, there is an ultimate limit on the government's power to acquiesce in runaway inflation. though substantial inflations and deflations have occurred under both types of gold standard. Under the war and postwar pressures which have led to hyperinflation, public support for government adherence to any metallic standard has not been strong enough to make the metallic standard a serious barrier to inflation. From the end of World War I onward there was a strong world-wide tendency to place major reliance on discretionary government control over the supply of money, instead of on a rigid metallic system, to attain the economic ends desired by the country.

Governments. whether democratic or dictatorial. almost invariably find inflationary policies easier than deflation. Strong deflationary pressure on total spending generally causes unemployment and reduced output as well as lower prices; this leads to strong political pressures for expansionary measures. Many observers feel that, particularly in the democratic nations, the political process is likely to produce gradual inflation as a continuing development; labour, business and agricultural voting blocs put pressure on legislative bodies to obtain larger money incomes, through such politico-economic devices as minimum wage laws, supported commodity prices and other indirect income subsidy or support measures. Modern business and labour mores lead to strong resistance to substantial price cuts. The increased power of organized labour in many nations also increased the likelihood of strong upward "cost-pushes" on the price level, as union wages are bid upward in bargaining with management.

Effects.—The economic effects of inflation and deflation can be analyzed by considering the effect on the current and future levels of total output, on the current distribution of income and on the distribution of wealth (claims on future income).

Moderately increasing prices are generally considered a stimulant to employment and output in periods of less than full employment of resources. As such, they are widely supported by economists and businessmen. Once substantially full employment is reached, however, inflation can have little effect in stimulating greater current output. There is, on the other hand, little evidence that inflation has seriously disrupted and reduced total production until hyperinflation is reached. In the German inflation, for example, total output continued to rise until 1923, when rising prices finally led to disruption of business relationships and to great speculative rather than productive activity. Many observers believe, however, that even moderate speculative, price rises during business booms increase the likelihood of a quick downturn in business activity and prices. There is some supporting evidence for this position, but little evidence that deflations correspond in size to immediately preceding inflations.

Hyperinflation produces a violent redistribution of income and wealth, in general away from fixed to flexible income receivers and away from creditors to debtors. Landlords, bondholders and fixed income middle-class employees have been the most drastically injured large groups. Entrepreneurs in business and agriculture generally, and adept speculators in particular, are the major gainers. The income share of wage earners, the largest income group, appears often to have remained relatively stable, though with wide variations between individuals depending on the type of wage contract and on adeptness at bargaining up wages with rising prices. Over-all, it is not clear whether inflation substantially alters the shares of the national income going to the rich and the poor. Creditors, who are largely in higher income groups, suffer directly while debtors gain. The superior understanding and speculative opportunities of higher income groups and large entrepreneurial incomes provide strong countereffects.

The extent to which expectations become adjusted to continuing inflation largely controls inflation's impact on the distribution of income and wealth. Money contracts tend to be adjusted to expected inflation. Except for long-term contracts, terms restricted by government policies and cases where some individuals or groups have superior anticipations or bargaining power, the redistributional aspect of inflation is greatly mitigated.

The effects of deflation are generally the converse of those of inflation. except that substantial deflation has seldom occurred without mass unemployment and falling total output. Deflation is thus socially and economically painful. and is unlikely to be followed for long as a conscious government policy.

INFLORESCENCE, the arrangement of the flowers on the axis, or the ramification of the floral axis, composed of the rachis, which forms the stalk supporting the flower or cluster of flowers, called the peduncle. A flower having no stalk is called sessile. The floral axis may be shortened, assuming a flattened convex or concave form and bearing numerous flowers as in the artichoke, daisy, etc. There are two distinct types of inflorescence: (1) indeterminate, indefinite or axillary; and (2) determinate, definite or terminal.

A third series of inflorescence is termed mixed. In the compound indefinite inflorescence the lateral shoots develop centripetally upon a primary axis into a group of racemes or compound racemes. *See* FLOWER.

INFLUENZA is an acute infectious respiratory disease caused by a filterable virus. The disease commonly occurs in epidemics; they develop quickly, spread rapidly to as much as 25% to 40% of the population, with low fatality, and terminate abruptly. Within a short period of years the illness reappears in the same geographic area. It is abrupt and of brief duration. characterized more by prostration and aching than by obvious signs of respiratory disease. Complications of bronchitis and pneumonia are common. At times the epidemics become world-wide or pandemic, and during these periods. as in 1918, the severity of the disease and the frequency of complications may attain terrifying proportions. Some authorities have considered the severe pandemics a different disease from those of intervening years. but the resemblances between the two are so great as to suggest that they are of the same basic nature. The specific cause of epidemics previous to 1933 was not known. After that time, however, viruses (*q.v.*) were identified as the primary agents of influenza A and influenza B. Snine influenza, studied extensively by R. E. Shope, is caused by a virus related to type A influenza virus, in conjunction with a bacterium. *Hemophilus influenzae.*

History of Epidemics. — Influenza has a long history. An epidemic described by Hippocrates in the 5th century B.C. has been called influenza, but the first clear description is that of the epidemic of 1610. The descriptions of numerous outbreaks through the succeeding centuries reveal a tendency to surprising uniformity of behaviour but considerable variation in time of occurrence and severity. The severer outbreaks have been the most completely described, culminating in the extensive reports of the pandemics of 1889–goand 1918.

Many of the epidemics were thought to have arisen in Russia. where a reservoir of influenza was said to exist and to have spread into Europe by the routes of travel. As rates of travel increased it became more and more difficult to trace a progressive extension until in 1918 the disease seemed to erupt almost simultaneously in widely separated geographic areas. In Oct. 1889 influenza was recognized in Siberia; in November it had reached Berlin, Ger., and Paris. Fr.. and in December extended to Spain. Italy and England. In the same month the cities of the Atlantic seaboard of the United States were involved; in early January the cities of the middle west and. somewhat later, San Francisco, Calif., on the Pacific coast, had their peaks of incidence. In the autumn of 1918 much of the northern hemisphere was blanketed by influenza in approximately one month. Australia and certain rather isolated areas were not affected until later. These examples clearly illustrate the rapid, widespread distribution of the severe outbreaks; evidence indicates that in its milder forms the same tendency exists.

Epidemics of influenza commonly affect a high percentage of the population although accurate data have been uncommon. In pandemic times incidence rates as high as 30%–40% were repeatedly reported; in milder epidemics estimates of 10% were common. The frequency of illness is greatest in children, although the impression widely prevails that adults are most commonly attacked. It is true, nevertheless, that young adults are prominently affected.

Despite the high incidence, mortality is commonly low, and deaths from uncomplicated influenza are infrequent. On the other hand, there is usually an increased mortality from complications such as pneumonia, and excess mortality among patients with cardiac or other debilitating disease, especially at ages over 50 years. The 1918 epidemic was the most destructive in history; in fact it ranks with the plague of Justinian and the Black Death as one of the severest holocausts of disease ever encountered. It was estimated by E. O. Jordan that more than 20,000,000 persons perished of influenza in a few months and more than 50 times as many were sick. In India 12,500,000 persons, or 4% of the total population, are said to have been killed by influenza in the autumn of 1918. In the United States 548,000 died. In contrast, the pandemic of 1889–90, which also had a high attack rate, had a mortality of less than one-tenth that of 1918.

Influenza is most commonly a disease of the colder half of the year, but it is not strictly limited. The severer episodes appear to be less controlled by season than those of intervening years. In tropical and subtropical areas, epidemics occur with a frequency similar to that seen in the temperate zones.

Another feature encountered prominently in the pandemics of 1889–90 and 1918, as well as in earlier ones, is the tendency toward "waves" of infection. This is seen by the appearance of an epidemic, the first wave, in the winter of 1889–90; the second wave, a severer episode, 14 to 1j months later in the spring of 1891; a third mild disease in the late fall and winter of 1891–92. A mild, world-wide epidemic in the spring and early summer of 1918 was followed by the astoundingly severe epidemic in the autumn; a third rise in the spring of 1919 was quite irregular and was of doubtful relation to the preceding two. Reports are confusing as to whether an attack in the first wave gave resistance to the second.

Later Epidemics. — In 1933 influenza virus, type A, was first isolated by W. Smith, F. W. Andrewes and Patrick Laidlaw in London, and the following year in the U.S. by Thomas Francis, Jr. Thereafter a number of outbreaks of influenza A were observed at intervals of two to three years. There was variation in the extent of the epidemics; some were extremely mild and irregularly encountered, but those of 1936–37 and 1940–41 spread throughout the world. In most instances the influenza A epidemics were sharp and brief, beginning in the late autumn or winter of the temperate zones, while areas such as Hawaii and the West Indies were often affected earlier. Data of the percentage of population attacked are inexact, but 8% to 15% appears to be a reasonable estimate in the more clear-cut epidemics. It was shown, however, that the disease may be encountered in small, localized, almost sporadic outbreaks which sometimes precede the epidemic wave. The mortality has been low; scarcely 1 case in 1,000 was fatal. Nevertheless, an excess in mortality from pneumonia and in the general mortality accompanies the disease.

Influenza B was first identified in the U.S. in 1940 by Francis, who demonstrated also that an epidemic in that country early in 1936 was caused by the same virus. It also gave rise to an extensive epidemic in 1945. Influenza B seems to have been more scattered in its distribution, and the epidemics, which recurred at intervals of four to five years, were less sharply defined in scope. The incidence tends to be somewhat lower than with influenza A, and the accompanying mortality is proportionately reduced.

In some epidemics a proportion of cases have not been identified as influenza A or B, but no definite epidemic has been observed which might be attributable to still another type of influenza. Swine influenza virus has not been reported in the human population. The fact that these two types recur at intervals of a few years offers a possible explanation of the so-called three waves of a pandemic period.

It seems likely, with the appearance of these diseases in the

northern and southern hemispheres in alternate halves of the year and with the recognition that they may exhibit limited, spotty tendencies. that influenza is maintained by a constant circulation in the human population, reaching epidemic proportions only when a sufficient number of susceptibles has reaccumulated to furnish fuel. (*See* BACTERIAL AND INFECTIOUS DISEASES: *Virulence.*) Chronic carriers of the virus have not been demonstrated. Under this interpretation the severer pandemics represent variations in scope of a basic disease and may be related to the circulation of modified strains of virus and to the frequency and virulence of bacterial accompaniments. Laidlaw suggested in 1936, and the suggestion was supported by Shope. that swine influenza represents the human disease of 1918, which became established in hogs and persisted there. Shope presented evidence that the swine disease is maintained in a concealed form in worm parasites of that animal from which it erupts when the animal's physiology is disturbed.

The idea that there are geographical foci in Russia and the east in which influenza is maintained is a similar concept of a limited reservoir.

The epidemic of Asian influenza of 1957 apparently began in China early in the year. It was detected in Hong Kong among refugees early in April and extended soon to Singapore and Taiwan. From there the distribution became quite wide and by June 10 the disease had circled the globe. Its course was readily traced along lines of transportation and numerous foci were described developing from affected groups.

The incidence was high. particularly in crowded areas of the orient; it was generally mild although, as usual, an increased mortality from respiratory disease took place. It appeared that the highest frequency was in adolescents and in people generally under 30 years of age.

In the United States a distinct increase in respiratory disease was noted beginning in August; the peak, both of incidence and excess mortality was reached by the end of October, after which a progressive decline took place. A significant proportion of the deaths apparently was associated with staphylococcus, and also cases of rheumatic heart disease with mitral stenosis.

The severity of the disease was reported to vary somewhat in different countries, but experience generally was that of a mild illness with high incidence and low mortality. In all regions crowding appeared to have been a significant factor in morbidity.

The virus, belonging to type A influenza virus, exhibited antigenic characteristics different from those of recent years, but serological evidence indicated that it is related to strains circulating earlier. Sera from the older segments of the population contained antibodies to the strain, suggesting that it may possibly have been prevalent in the 1889–90 pandemic period.

Intensive efforts were made in the United States in 1957, through the collaboration of all agencies concerned, to prepare for the epidemic. Large scale production of specific vaccine was instituted and became available in significant amounts before the epidemic developed. Data indicated that with the proper concentration of virus, protection of 80% could be obtained. Much illness and mortality were prevented by widespread use of vaccine.

Aetiology.—The name influenza was introduced by John Huxham in 1743, apparently derived from the Italian phrase which ascribed the origin of the disease to *un influenza* di *freddo*, the influence of the cold. It was not until 1890 that the idea that influenza was borne by the prevailing winds was dispelled. In 1892 Richard Pfeiffer described the influenza bacillus. *Hemophilus influenzae,* commonly a tiny organism, but of varied forms, which requires for its proper growth substances present in blood. Subsequent studies appeared to support Pfeiffer's conclusion that this organism was the cause of influenza. The pandemic of 1918 resulted in extensive studies of its role. It was generally concluded that while this organism was of considerable importance, perhaps greater than that of other bacteria. it did not satisfy the requirements of a primary causative agent. The concept of a filterable virus gained in prominence, and as a result studies in England, France! Germany, Japan and the United States were made in an effort to transmit the disease to human subjects and experimental animals. Results were quite variable, and. even in instances which were apparently successful, no agent was well established. As a result the cause of that epidemic was not clearly demonstrated.

In 1931 Shope demonstrated that swine influenza. hog flu, was caused primarily by a virus which in conjunction with a bacillus similar to that of Pfeiffer's produced extensive disease in hogs throughout the United States.

In 1933 Smith. Andrewes and Laidlaw produced an experimental infection in ferrets with a virus from the throats of influenza patients. This was confirmed in 1934 in the United States by Francis. It was then found that the virus infection could be transmitted to mice. In both species of animals continued transfer gave rise to extensive fatal, nonbacterial pneumonia. The virus produced infection only when given by the respiratory route. Animals which recovered were immune for a period of months to reinfection. and their blood serum contained immune substances (antibodies) capable of protecting normal animals. It was shown that a high percentage of the human population had immune bodies in the blood as a result of earlier infection and that the recovered person developed more. This fact could be used for diagnosis and studies of the distribution of the disease. designated influenza A. After 1939, following studies of F. M. Burnet, the incubating egg containing the embryonic chick was an increasingly effective tool for isolation of virus and studies of the disease. G. K. Hirst. L. McClelland and R. Hare observed that influenza virus caused clumping of the red blood cells of chickens and that the phenomenon could be applied to the measurement of virus and antibodies.

The virus of influenza B was isolated in 1940 by both Francis and T. P. Magill. Its general characteristics are similar to those of influenza A. It is. however, more difficult to establish experimental disease in ferrets, mice and frequently in eggs than with type A virus. Aloreover. infection with one gives no immunity to the other. so that in this sense they represent two different diseases. The strains of type A or of type B also differ among themselves. Swine influenza virus is related to type A.

Infection does not give permanent immunity. but in experimental animals it can be renewed by reinoculation. In the general population there appears to be a decline of immunity between epidemics and thus an increase of susceptibles. Even after induced infection under experimental conditions the immunity may be of only a few months' duration. However, a good percentage of the population develops a resistance effective for a much more prolonged period. as shown by the fact that only a minority takes sick during epidemic periods.

Clinical Features. — Influenza spreads through a population by the transfer of virus by sneezing. coughing. etc.. of the excretions from the respiratory tract of the infected person to that of a susceptible. In the majority of instances the process is a direct infection. although indirect transfer through contamination of hands, handkerchiefs or eating utensils is obviously possible. There is little reason to consider the disease air-borne except in crowded, poorly ventilated quarters when contamination of the air may be marked. As the virus gains entrance to the respiratory tract of the susceptible. it selectively attacks and destroys the cells lining the respiratory tract. These cells are superficially situated. not intimately bathed in the fluids of the blood stream, and apparently protected to a great extent by their own physiologic mechanisms. Following injury of the cells. fluid from the blood is poured out, and the supporting tissues give evidence of acute, inflammatory changes. The changes are essentially limited to the nose and the larger respiratory passages. When pneumonia ensues, the type of subsequent injury will depend upon the character of the bacteria encountered. If the pneumonia is related to virus iniection alone. which is uncommon, the injury is usually an extension of that previously mentioned with a considerable amount of fluid accumulating in the lungs. areas of collapse and a few cells of a large type. Specific changes in other organs are not ordinarily observed although toxic effects are evident.

Symptoms and Clinical Course.—The incubation period of epidemic influenza is one to two days. The majority of cases present a striking uniformity of symptoms and clinical course. The onset

is abrupt with sudden chilliness or distinct chill. fatigue and achiness. Severe prostration is noted early. The temperature rises rapidly in 12 to 24 hr. to a level of from 101° to 104° F. Diffuse headache and severe muscular aches throughout the body become prominent features. Whereas the patient may experience a feeling of nasal irritation or a sense of rawness in the nasopharynx, symptoms referable to the respiratory tract are few. In this respect the disease is sharply different from the usual common cold in which congestion and runny nose with little or no fever are customary. Sore throat similar to that of acute tonsillitis is rare. In the next 24 hr. the temperature reaches a sustained level. Aches and pains may be the chief complaint. Laryngitis and hoarseness may be present and a short, hacking, unproductive cough may become annoying. Symptoms referable to the gastrointestinal tract are ordinarily no more common than in other acute upper respiratory infections. and the so-called intestinal flu is a misnomer. A nervous form has been described which seems to be essentially a designation of the severe prostration or delirium which may occur.

In three to four days as the temperature begins to fall the patient's general symptoms improve and recovery from the acute phase begins. In 90% to 95% of the cases. even in the severest outbreaks, the disease is a "three-day fever" followed by relatively rapid convalescence; but protracted weakness and exhaustion in adults are traditional. In children. except infants, the disease is generally mild. while in older persons it is severer than the average. When the temperature remains elevated beyond the fourth or fifth day. involvement of the loner respiratory tract is usually present and is ordinarily evidence of complications resulting from associated bacterial infection.

In addition to the usual course of the disease, a number of cases present a much severer infection from the onset. In these there is early evidence of respiratory distress and pulmonary disease. The course is stormy and unpredictable. On the other hand! there is a large group of cases in which the evidence of infection is negligible. These patients may experience nothing more than a mild apathy and a slight discomfort in the upper respiratory passages for a period of 24 hr. The temperature is either not elevated or elevated slightly. In others the symptoms may be so slight as to be unnoticed. Nevertheless, these inapparent infections constitute a serious menace in that they can transmit infection. In some instances, by appropriate tests it was shown that during the course of an epidemic 20% to 25% of persons were actually infected with influenza virus without significant signs of illness.

Complications.—By far the greatest number of and most important complications of epidemic influenza involve the respiratory tract. The various forms of bronchitis and pneumonia may ensue, and in some instances pneumonia apparently begins with onset of the disease. They are usually associated with invasion by pneumococci, streptococci. H. *influenzae* or other bacteria which invade the lungs. In the U.S. army camps in 1918 purulent or capillary bronchitis was observed in as many as 35% to 40%, and pneumonia occurred in 10% to 20% of the cases. The incidence of complications varies in different epidemics; it is usually low but the frequency may depend upon the amount of virulent bacterial infection prevalent at the time. Paranasal sinusitis is not uncommon. Otitis media similarly occurs. Influenza acquired during pregnancy often results in miscarriage or abortion. There is consequently an increase in both maternal and infant mortality. In many respects influenza is one of the most dangerous complications of pregnancy.

Treatment.—There is no specific treatment for influenza virus infection. Drugs are used to relieve discomfort or control fever. Confinement of the patient to bed in a warm room conserves his resources and limits the possibilities of complicating infections. Although sulfonamides, penicillin and streptomycin have no effect upon the virus disease, they do have a therapeutic, possibly some prophylactic, effect upon the bacterial pneumonias which are the chief causes of death.

Control.— The continued recurrences of influenza clearly demonstrate that there has been no effective procedure for control. Rigid isolation may limit infection under special conditions. But under epidemic conditions the amount of infection to which the person may be exposed and the high infectiousness of the virus clearly nullify minor precautions. In the presence of virulent influenza. crowding may increase the risk of picking up secondary infections as well.

Efforts to control respiratory disease through sterilization of the air by installations of ultra-violet light or by bactericidal vapours (aerosols) were investigated.

Prophylactic Inoculation.—The fact that influenza virus produces disease only when it enters the body by the respiratory tract led to the demonstration that if given subcutaneously or by other routes. illness did not occur in animals or humans but that in the former a resistance developed and in both the accumulation of immune substances in the blood was stimulated. Various studies were undertaken to ascertain the effect upon susceptibility to the natural disease with no more than suggestive results.

The ready growth of influenza virus in the chick embryo results in the accumulation of virus in the allantoic fluid surrounding the embryo. This has served as a bountiful source of virus for vaccine. In 1943 the commission on influenza of the U.S. army epidemiological board carried out studies with a vaccine of virus concentrated from the egg fluid. The virus was obtained from the fluid by permitting it to become attached to the red blood cells of the chicken and then removing it into a reduced volume of sodium-chloride solution. The virus was inactivated by treatment with formalin. Both type A and type B influenza viruses were incorporated into a dose of one cubic centimetre to be given subcutaneously to adults. The results of the study showed that the incidence of influenza A in a vaccinated group of 6,250 men was about one-fourth that observed in a similar group of unvaccinated men. In 1945 the entire U.S. army was vaccinated with this material. Observations during the epidemic of influenza B that winter showed that 1% or less of vaccinated army personnel took sick while 10%–13% of unvaccinated service groups were affected.

The duration of resistance induced by vaccination is not known. It seems improbable that available preparations would have a uniform effect beyond three to four months. The antibodies developed from vaccination reach their peak in two weeks, decline somewhat in four months and still further in one year, but it is not established that the resistance is retained to the same extent as the immune substances. Moreover, the strains of virus encountered in different epidemics vary in chemical constitution, and this may limit the efficacy of vaccine until more strains or a collection of suitable ones are placed in the vaccine. Nevertheless, the information points to the probability that prophylactic vaccination would be effectively developed for use in the control of influenza—a disease which has been called the last of the unconquered scourges.

INFORMATION, in English law, a proceeding on behalf of the crown against a subject otherwise than by indictment is either criminal or civil. Criminal informations are ex officio or by the master of the crown office. An-ex officio information is a proceeding in the queen's bench by the attorney general without the intervention of a grand jury.

The attorney general or, in his absence, the solicitor general has a right ex officio to file a criminal information in respect of any misdemeanour, but not for treason, felonies or misprision of treason. It is, however, seldom exercised, except in cases which might be described as "enormous misdemeanours," such as those peculiarly tending to disturb or endanger the government; *e.g.,* seditions, obstructing the queen's officers in the execution of their duties, etc.

There are informations also which are the first step in proceedings in permits of summary jurisdiction leading to the issue of summonses or warrants. They relate to proceedings of a criminal nature as opposed to complaints which are the initiatory steps to proceedings of a civil nature in these courts.

Civil informations are of two kinds and are filed on the revenue side of the queen's bench division. The Latin information is the way in which the crown recovers money or other chattels. and these informations are either *in* rem or *in personam.* Informations *in rem* are used chiefly where the crown lays a claim to property and are usually resorted to where such property is alleged to have become forfeited under customs or inland revenue statutes. Informations *in personam* are largely used to recover a debt to the crown whether such debt is payable by penalty or in another way.

The other form of civil information is the English information and is generally used to recover corporeal or incorporeal hereditaments and also debts to the crown where discovery and an account are sought

In the United States the federal constitution (amendments. art. v) forbids the use of informations by providing that "no person shall be held to answer for a capital, or otherwise infamous crime, unless on a presentment or indictment of a Grand Jury," with certain exceptions in the land or naval forces and the militia. Attempts at evasion of the revenue laws and other minor offenses are sometimes prosecuted by information in the federal courts. In a number of states all misdemeanours except misprision of treason may be prosecuted by information. This process may also be used in civil cases. such as a proceeding against a corporation for violation of charter.

INFORMATION AGENCY, THE UNITED STATES, was created on Aug. 1, 1953 to conduct the overseas information program of the U.S. government. Foreign information activities formerly conducted by the International Information administration and the Technical Cooperation administration of the department of state and by the Mutual Security agency were consolidated in the new agency. The foreign information program was established to promote support among other peoples for the foreign policies of the United States. Field operations of the agency were carried out by the U.S. Information service, which established posts throughout the world. The posts, under the general direction of the U.S. chief of mission in each country, were staffed by public affairs officers and specialists in news, radio, film, library and other cultural activities.

The agency provided field posts with various services: the "Voice of America", which broadcast on a world-wide network in many languages and serviced field needs for recorded film and television programs for use by local stations; the press service, which provided news and prints; the motion-picture service. which prepared documentary films on the United States in various languages; the information centre service, which supplied materials for library programs and community activities and also was responsible for the translation and distribution of U.S. books overseas. The agency also co-operated with private U.S. organizations and individuals.

INFORMATION THEORY. One of the most prominent features of 20th-century technology is the development and exploitation of new communication mediums. Concurrent with the growth of devices for transmitting and processing information, a unifying theory was developed and became the subject of intensive research.

This theory, known as communication theory, or, in its broader applications. information theory, is concerned with the discovery of mathematical laws governing systems designed to communicate or manipulate information. It sets up quantitative measures of information and of the capacity of various systems to transmit, store and otherwise process information.

Some of the problems treated relate to finding the best methods of utilizing various available communication systems, the best methods of separating signals from noise and the problem of setting upper bounds on what it is possible to do with a given channel. While the central results are chiefly of interest to communication engineers, some of the concepts have been adopted and found useful in such fields as psychology and linguistics.'

Information is interpreted in its broadest sense to include the messages occurring in any of the standard communication mediums such as telegraphy, radio or television, the signals involved in electronic computing machines, servomechanism systems and other data-processing devices, and even the signals appearing in the nerve networks of animals and man. The signals or messages need not be meaningful in any ordinary sense. This theory. then, is quite different from classical communication engineering theory, which deals with the devices employed but not with that which is communicated.

Central Problems of Communication Theory.— The type of communication system that has been most extensively investigated is shown in fig. 1. It consists of the following:

1. An information source which produces the raw information or "message" to be transmitted.
2. A transmitter which transforms or encodes this information into a form suitable for the channel. This transformed message is called the signal.
3. The channel on which the encoded information or signal is transmitted to the receiving point. During transmission the signal may be changed or distorted. In radio, for example, there often is static, and in television transmission so-called "snow." These disturbing effects are known generally as noise, and are indicated schematically in fig. 1 by the noise source.
4. The receiver, which decodes or translates the received signal back into the original message or an approximation of it.
5. The destination or intended recipient of the information.

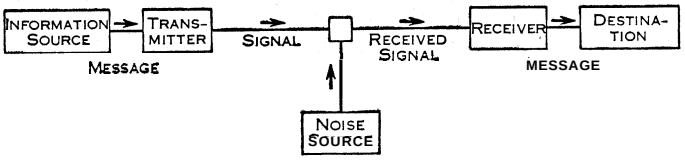

FIG. 1.— DIAGRAM OF GENERAL COMMUNICATION SYSTEM

It will be seen that this system is sufficiently general to include a wide variety of communication problems if the various elements are suitably interpreted. In radio, for example, the information source may be a person speaking into a microphone. The message is then the sound that he produces, and the transmitter is the microphone and associated electronic equipment which changes this sound into an electromagnetic wave, the signal. The channel is the space between the transmitting and receiving antennas, and any static or noise disturbing the signal corresponds to the noise source in the schematic diagram. The home radio is the receiver in this system and its sound output the recovered message. The destination is a person listening to the message.

A basic idea in communication theory is that information can be treated very much like a physical quantity such as mass or energy. A homely analogy may be drawn between the system in fig. 1 and a transportation system; for example, we can imagine an information source to be like a lumber mill producing lumber at a certain point. The channel in fig. 1 might correspond to a conveyor system for transporting the lumber to a second point. In such a situation there are two important quantities: the rate R (in cubic feet per second) at which lumber is produced at the mill, and the capacity C (in cubic feet per second) of the conveyor. These two quanti-

ties determine whether or not the conveyor system will be adequate for the lumber mill. If the rate of production R is greater than the conveyor capacity C, it will certainly be impossible to transport the full output of the mill; there will not be sufficient space available. If R is less than or equal to C, it may or may not be possible, depending on whether the lumber can be packed efficiently in the conveyor. Suppose, however, that we allow ourselves a sawmill at the source. This corresponds in our analogy to the encoder or transmitter. Then the lumber can be cut up into small pieces in such a way as to fill out the available capacity of the conveyor with 100% efficiency. Naturally in this case we should provide a carpenter shop at the receiving point to fasten the pieces back together in their original form before passing them on to the consumer.

If this analogy is sound, we should be able to set up a measure R in suitable units telling the rate at which information is produced by a given information source, and a second measure C which determines the capacity of a channel for transmitting information. Furthermore, the analogy would suggest that by a suitable coding or modulation system, the information can be transmitted over the channel if and only if the rate of production R is not greater than the capacity C. A key result of information theory is that it is indeed possible to set up measures R and C having this property.

Measurement of Information. — Before we can consider how information is to be measured it is necessary to clarify the precise meaning of "information" from the point of view of the communication engineer. Often the messages to be transmitted have meaning: they describe or relate to real or conceivable events. However, this is not always the case. In transmitting music, the meaning, if any, is much more subtle than in the case of a verbal message. In some situations the engineer is faced with transmitting a totally meaningless sequence of numbers or letters. In any case, meaning is quite irrelevant to the problem of transmitting the information. It is as difficult to transmit a series of nonsense syllables as it is to transmit straight English text (more so, in fact). The significant aspect of information from the transmission standpoint is the fact that one particular message is chosen from a set of possible messages. What must be transmitted is a specification of the particular message which was chosen by the information source. The original message can be reconstructed at the receiving point only if such an unambiguous specification is transmitted. Thus in information theory, information is thought of as a choice of one message from a set of possible messages. Furthermore, these choices occur with certain probabilities; some messages are more frequent than others.

The simplest type of choice is a choice from two equally likely possibilities; that is, each has a probability $\frac{1}{2}$. This is the situation, for example, when a coin is tossed which is equally likely to come up heads or tails. It is convenient to use the amount of information produced by such a choice as the basic unit and this basic unit is called a binary digit or, more briefly, a "bit." The choice involved with one bit of information can be indicated schematically as in fig. 2A. At point b either the upper or lower line may be chosen with probability $\frac{1}{2}$ for each possibility.

If there are N possibilities, all equally likely, the amount of information is given by $\log_2 N$. The reason for this can be seen from fig. 2B, where there are eight possibilities each with probability $\frac{1}{8}$. The choice can be imagined to occur in three stages, each involving one bit. The first bit corresponds to a choice of either the first four or the second four of the eight possibilities, the second bit corresponds to the first or second pair of the four chosen, and the final bit determines the first or second member of the pair. It will be seen that the number of bits required is $\log_2 N$, in this case $\log_2 8 = 3$.

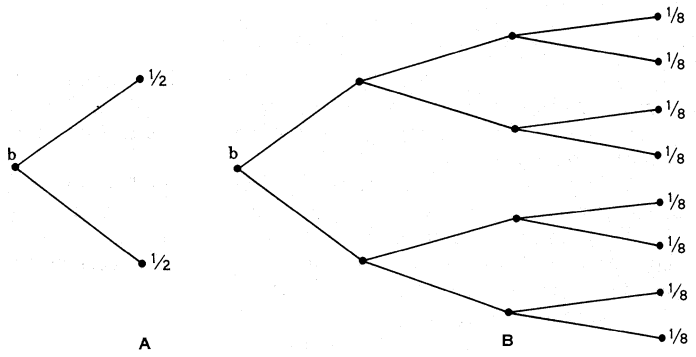

FIG. 2.—A CHOICE FROM (A) TWO POSSIBILITIES (B) EIGHT POSSIBILITIES (*see* TEXT)

If the probabilities are not equal, the formula is more complicated. When the choices have probabilities $p_1, p_2, \ldots, p_n$, the amount of information H is given by:

$$H = -(p_1 \log_2 p_1 + p_2 \log_2 p_2 + \ldots + p_n \log_2 p_n).$$

This formula for amount of information gives values ranging from zero — when one of the two events is certain to occur (*i.e.*, has a probability of 1) and all others are certain not to occur (probability 0) — to a maximum value of $\log_2 N$ when all events are equally probable (probability $\frac{1}{N}$). These situations correspond intuitively to the minimum information produced by a particular event (when it is already certain what will occur) and the greatest information or the greatest prior uncertainty of the event.

The parlor game "Twenty Questions" illustrates some of these ideas. In this game, one person thinks of an object and the other players attempt to determine what it is by asking not more than 20 questions that can be answered "yes" or "no." According to information theory each question can, by its answer, yield anywhere from no information to $\log_2 2$ or one bit of information, depending upon whether the probabilities of "yes" and "no" answers are very unequal or approximately equal. To obtain the greatest amount of information, the players should ask questions that subdivide the set of possible objects, as nearly as possible, into two equally likely groups. For example, if they have established by previous questions that the object is a town in the United States, a good question would be, "Is it east of the Mississippi?" This divides the possible towns into two roughly equal sets. The next question then might be, "Is it north of the Mason-Dixon line?" If it were possible to choose questions which always had the effect of subdividing into two equal groups, it would be possible to isolate, in 20 questions, one object from approximately 1,000,000 possibilities. This corresponds to 20 bits.

The formula for the amount of information is identical in form with equations representing entropy in statistical mechanics, and suggests that there may be deep-lying connections between thermodynamics and information theory. Some scientists believe that a proper statement of the second law of thermodynamics requires a term relating to information. These connections with physics, however, do not have to be considered in the engineering and other applications of information theory.

Most information sources produce a message which consists not of a single choice but of a sequence of choices; for example, the letters of printed text or the elementary words or sounds of speech. The writing of English sentences can be thought of as a process of choice: choosing a first word from possible first words with various probabilities; then choosing a second, with probabilities depending on the first; and so on. This kind of statistical process is called a stochastic process, and information sources are thought of, in information theory, as stochastic processes. A more general formula for H can be given which determines the rate at which information is produced by a stochastic process or an information source.

Printed English is a type of information source that has been studied considerably. By playing a kind of "Twenty Questions" game, suitably modified, with subjects trying to guess the next letter in an English sentence, it can be shown that the information rate of written English is not more than about one bit per letter. This is a result of the very unequal frequencies of occurrence of different letters (for example, E is very common in English while Z, Q and X are very infrequent), of pairs of letters (TH is very common and QZ very rare), and the existence of frequently re-

curring words, phrases and so on. This body of statistical data relating to a language is called the statistical structure of the language. If all 26 letters and the space in English had equal frequencies of occurrence (*i.e.*, each had probability $\frac{1}{27}$) and the occurrence of each letter of text was independent of previous letters, the information rate would be $\log_2 27$, or about 4.76 bits per letter. Since only one bit actually is produced, English is said to be about 80% redundant.

The redundancy of English is also exhibited by the fact that a great many letters can be deleted from a sentence without making it impossible for a reader to fill the gaps and determine the original meaning. For example, in the following sentence the vowels have been deleted:

MST PPL HV LTTL DFFCLTY N RDNG THS SNTNC.

As might easily be deduced, redundancy in a language plays an important role in the science of cryptography.

Encoding Information. — An important feature of the measure of information, H, is that it determines the saving in transmission time that is possible, by proper encoding, due to the statistics of the message source. To illustrate this, consider a model language in which there are only four letters — A, B, C and D. Suppose these letters have the probabilities $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$ and $\frac{1}{8}$. In a long text in this language, A will occur one-half the time, B one-quarter of the time, and C and D each one-eighth of the time. Suppose this language is to be encoded into binary digits, 0 or 1, as for example in a pulse system with two types of pulse. The most direct code is the following:

$$A = 00;\ B = 01;\ C = 10;\ D = 11.$$

This code requires two binary digits per letter of message. By proper use of the statistics, a better code can be constructed as follows:

$$A = 0;\ B = 10;\ C = 110;\ D = 111.$$

It is readily verified that the original message can be recovered from its encoded form. Furthermore, the number of binary digits used is smaller on the average. It will be, in fact,

$$\tfrac{1}{2}(1) + \tfrac{1}{4}(2) + \tfrac{1}{8}(3) + \tfrac{1}{8}(3) = 1\tfrac{3}{4},$$

where the first term is due to the letter A, which occurs half the time and is one binary digit long, and similarly for the others. It may be found by a simple calculation that $1\frac{3}{4}$ is just the value of H, calculated for the probabilities $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{8}$.

The result verified for this special case holds generally — if the information rate of the message is H bits per letter, it is possible to encode it into binary digits using, on the average, only H binary digits per letter of text. There is no method of encoding which uses less than this amount.

This important result in information theory gives a direct meaning to the quantity H which measures the information rate for a source or a language. It says, in fact, that H can be interpreted as the equivalent number of binary digits when the language or source is encoded in 0 and 1 in the most efficient way. For instance, if the estimate of one bit per letter, mentioned above as the rate for printed English, is correct, then it is possible to encode printed English into binary digits using, on the average; one for each letter of text; and, furthermore, no encoding method would average less than this.

Capacity of a Channel. — Now consider the problem of defining the capacity C of a channel for transmitting information. Since the rate of production for an information source has been measured in bits per second, we would naturally like to measure C in the same units. The question then becomes, what is the maximum number of binary digits per second that can be transmitted over a given channel? In some cases the answer is simple. With a teletype channel there are 32 possible symbols. Each symbol therefore represents 5 bits, provided the possible symbols are used with equal probability. If we can send n symbols per second, and the noise level is not high enough to introduce any errors during transmission, we can send $5n$ bits per second.

The problem of calculating the capacity of a channel is usually more complex than this example because of disturbing noise. As an example, suppose there are two possible kinds of pulse that can be transmitted in a system, a 0 pulse and a 1 pulse. Suppose further that when 0 is transmitted it is received as 0 nine-tenths of the time, but one-tenth of the time noise causes it to be received as 1. Conversely, suppose a transmitted 1 is received as 1 nine-tenths of the time but distorted into a 0 pulse one-tenth of the time. This type of channel is called a binary symmetric channel. It and other noisy channels have definite capacities that can be calculated by appropriate formulas. In this particular case, the capacity is about 0.53 bits per pulse.

The meaning of the capacity of such a noisy channel may be roughly described as follows: It is possible to construct codes that will transmit a series of binary digits at a rate equal to the capacity. This can be done in such a way that they can be decoded at the receiving point with a very small probability of error. These codes are called error-correcting codes, and are so constructed that the type of transmission errors likely to occur in the channel can be corrected at the receiving point. Finally, it is not possible to transmit at a higher rate than the channel capacity and retain this error-correcting property.

The functioning of error-correcting codes can be likened to the ability of a person to correct a reasonable number of typographical errors in a manuscript because of his knowledge of the structure and context of the language. Much of the work in information theory centres around the theory and construction of such error-correcting codes.

Band-limited Channels. — A frequently occurring restriction on communication channels is that the signals must lie within a certain band of frequencies W cycles per second wide. A result known as the sampling theorem states that a signal of this type can be specified by giving its values at a series of equally spaced sampling points $1/2W$ seconds apart. Thus it may be said that such a function has $2W$ degrees of freedom, or dimensions, per second. If there were no noise whatever on such a channel it would be possible to distinguish an infinite number of different amplitude levels for each sample. Consequently, in principle, an infinite number of binary digits per second could be transmitted, and the capacity C would be infinite. In practice, there is always some noise, but even so if no limitations are placed on the transmitter power P, the capacity will be infinite, since at each sample point an unlimited number of different amplitude levels may be distinguished. Only when noise is present and the transmitter power is limited in some way does the capacity C become finite. This capacity depends on the statistical structure of the noise as well as the nature of the power limitation.

The simplest type of noise is resistance noise, produced in an electrical resistor by thermal effects. This type of noise is completely specified by giving its average power N.

The simplest limitation on transmitter power is the assumption that the average power delivered by the transmitter is not greater than P. If a channel is defined by these three parameters W, P and N, the capacity C can be shown to be

$$C = W\log_2 \frac{P+N}{N} \text{ (bits per second).}$$

The implication of this formula is that it is possible, by properly choosing the signal functions, to transmit $W\log_2 \frac{P+N}{N}$ binary digits per second and to recover them at the receiving point *with as small a frequency of errors as desired.* It is not possible to transmit binary digits at any higher rate with an arbitrarily small frequency of errors.

Encoding systems in current use, pulse-code modulation and pulse-position modulation, use about four times the power predicted by the ideal formula. Unfortunately, as one attempts to approach more closely this ideal, the transmitter and receiver required become more complicated and the delays increase.

The relation

$$C = W\log\left(1 + \frac{P}{N}\right)$$

can be regarded as an exchange relation between the bandwidth W

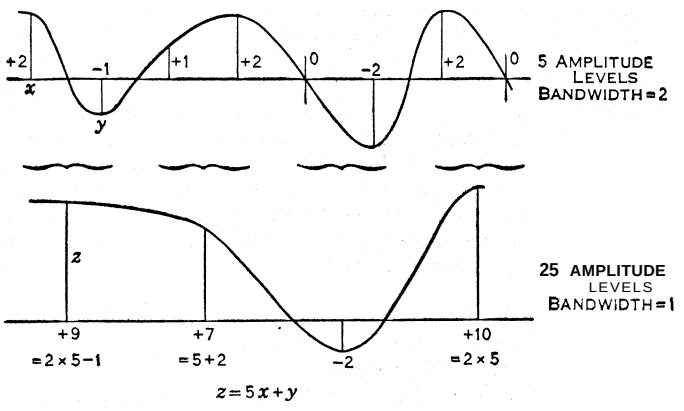

FIG. 3.— THEEXCHANGE OF BANDWIDTH FOR SIGNAL-TO-NOISE RATIO

and the signal-to-noise ratio P/N. Keeping the channel capacity fixed, the bandwidth can be decreased provided the signal-to-noise ratio is sufficiently increased. Conversely an increase in bandwidth allows a lower signal-to-noise ratio in the channel.

One method of exchanging bandwidth for signal-to-noise ratio is shown in fig. 3. The upper curve represents a signal function whose bandwidth is such that it can be specified by giving the samples shown. Each sample has five amplitude levels. The lower curve is obtained by combining pairs of samples from the first curve as shown. If the pair of samples from the upper curve have amplitudes x and y, a single amplitude z for the lower curve is computed from the formula

$$z = 5x + y.$$

The five possible values of x combined with the five possible values of y produce 25 possible values of z which must be distinguished. However, the samples now occur only half as frequently; consequently the band is reduced by half, at the cost of increasing the signal-to-noise ratio. Operating this in reverse doubles the band but reduces the required signal-to-noise ratio.

To summarize, there are three essentially different ways in which bandwidth can be reduced in a system such as television or speech transmission. The first is the straightforward exchange of bandwidth for signal-to-noise ratio just discussed. The second method is utilization of the statistical correlations existing in the message. This capitalizes on particular properties of the information source feeding the channel. Finally, particular properties of the ultimate destination of the messages can be used. Thus in speech transmission the ear is relatively insensitive to phase distortion. Consequently, phase information is not as important as amplitude information, and need not be sent so accurately, resulting in a saving of bandwidth or of power. In general, the exploitation of particular "sensitivities" or "blindness" in the destination requires a proper matching of the channel to the destination.

Filtering and Prediction Problem.— Another type of problem that has been studied extensively in the field of information theory is that of determining the best devices for eliminating noise from a signal and predicting the future value of the signal. These are known as the filtering and prediction problems. The two problems may also occur in combination if it is desired to predict the future value of a noisy signal. Possible applications of the filtering problem occur in the detection of various types of communication signals which have been corrupted by noise or in the smoothing of data subject to observational error. The prediction problem, with or without filtering, may arise, for example, in weather or economic forecasting or in the control of gun directors, where it is desired to predict the future position of a moving target.

The most successful work in this general field has been carried out under the following two assumptions. First, the best prediction or filtering is interpreted to be that which minimizes the mean-square error between the computed value and the true value. Second, the devices performing these operations are assumed to perform linear operations on the signals which they filter or predict. Under these conditions, substantially complete solutions have been found specifying the characteristics of the predicting or filtering device in terms of the power spectra of the signal and of the noise.

Cryptography, Linguistics and Other Applications.— Some applications have been made in the fields of cryptography and linguistics. It is possible to formulate a theory of cryptography or secrecy systems in terms of the concepts occurring in information theory. When this is done, it appears that the information rate R of a language is intimately related to the possibility of solving cryptograms in that language. The smaller this rate, the easier such a solution becomes and the less material is necessary to render such a solution unique. Indeed, within limits, the theory becomes quantitative and predictive, giving means of calculating how much material must be intercepted in a given language and with a given cipher in order to ensure the existence of a unique solution.

A study has been made of the distribution of lengths and frequency of occurrence of the different words in a language such as English. It has been found, for example, that the relative frequency of the nth most frequent word may be expressed quite closely by a formula of the type $P(n+m)^{-b}$, with suitable constants for P, m and b. Experimental data of this type can be explained as consequences of the assumption that a language gradually evolves under continued use into an efficient communication code. *(See* CRYPTOLOGY; LINGUISTICS.)

Psychologists have discovered interesting relationships between the amount of information in a stimulus and reaction time to the stimulus. For example, an experiment can be set up in which there are four lights and four associated push buttons. The lights go on in a random order and the subject is required to press the corresponding button as quickly as possible after a light goes on. It develops that the average time required for this reaction increases linearly with an increase in the amount of information conveyed by the lights. This experimental result holds true under a wide variety of changes in the experiment: the number of lights, the probabilities of different lights, and even varying correlations between successive lights.

These results suggest that under certain conditions the human being, in manipulating information, may adopt codes and methods akin to those used in information theory.

INFORMER, the term applied to a person who prosecutes in any of the courts of law those who break any law or penal statute, without any direct injury having been done to himself. Such a person is called a common informer when he furnishes evidence on criminal trials or prosecutes for breaches of penal laws solely for the purpose of obtaining the penalty recovered, or a share of it. An action by a common informer is termed a *popular* or *qui tam* action, because it is brought by a person *qui tam pro domino rege quam pro se ipso sequitur.* A suit by an informer must be brought within a year of the offense, unless a specific time is prescribed by the statute. The term informer is also used of an accomplice in crime who turns what is called "king's evidence," or "state's evidence" in the United States *(see* ACCOMPLICE). In Scotland, informer is the term applied to the party who, in criminal proceedings, sets the lord advocate in motion. *See* also DELATOR.

INGE, WILLIAM **RALPH** (1860–1954), English theologian and dean of St. Paul's, was born June 6, 1860, at Crayke, Yorks., the son of William Inge, sometime provost of Worcester college, Oxford, and was educated at Eton, and at King's college, Cambridge. From 1884 to 1888 he was an assistant master at Eton, and during the last two years of that time was fellow of King's college, Cambridge. From 1889 to 1904 he was fellow of Hertford college, Oxford. In 1907 was made Lady Margaret professor of divinity at Cambridge, and in 1911 he became dean of

St. Paul's. His sermons attracted attention because of their criticism of modern life and their pessimistic tone, which earned him the sobriquet "the gloomy dean." Inge died Feb. 26, 1954, at Wallingford, Eng.

Among Inge's numerous theological and devotional works may be mentioned *Christian Mysticism* (Bampton lectures; 1899); *Types of Christian Saintliness* (1915); *Philosophy of Plotinus* (Gifford lectures; 2 vol., 1918); *Outspoken Essays* (1919, 2nd series 1922); *Personal Religion and the Life of Devotion* (1924); *The Platonic Tradition in English Religious Thought* (Hulsean lecture; 1926); and *Christian Ethics and Modern Problems* (1930).

INGEBORG (INGEBURGE, INGELBURGE, INGELBORG, ISEMBURGE, Danish INGIBJÖRG) (*c.* 1176–1237 or 1238), queen of France, was the sister of Canute VI. king of Denmark. She married in 1193 Philip II Augustus, king of France, but on the day after his marriage the king took a sudden aversion to her. The French council of Compiègne acceded (Nov. 5, 1193) to his demand for a declaration of nullity, but the popes Celestine III and Innocent III successively took up the defense of Ingeborg. Philip, having married Agnes of Meran in June 1196, was excommunicated; and, as he remained obdurate, the kingdom mas placed under an interdict. Agnes was finally put aside, but Ingeborg was shut up in the chbteau of Étampes until, in 1213, Philip, hoping perhaps to justify by his wife's claims his pretensions to England, acknowledged her again as queen of France. She survived him more than 14 years, highly respected by all.

INGELOW, JEAN (1820–1897), English poet and novelist, was born at Boston, Lincs., on March 17, 1820, and died in London on July 20, 1897. Jean Ingelow, who was the daughter of a Boston banker, is famous for one poem, "High Tide on the Coast of Lincolnshire"; many of her ballads and songs were set to music in the '70s and had a great vogue. Her works include *Poems* (1863); *The Story of Doom and other Poems* (1867); *Poems* (1885); several novels, of which *Sarah de Berenger* (1880) is perhaps the best known; and a number of excellent children's books, including *Mopsa the Fairy* (1869).

INGEMANN, BERNHARD SEVERIN (1789–1862), Danish poet and novelist, was born at Torkildstrup. Falster, on May 28, 1789. He was educated at the grammar school at Slagelse, and entered the University of Copenhagen in 1806. All his early and unpublished writings were destroyed when the English burned the town. In 1811 he published his first volume of poems, and in 1812 his second, followed in 1813 by a book of lyrics entitled *Procne* and in 1814 the verse romance. *The Black Knights.* In 1815 he published two tragedies, *Masaniello and Blanca,* followed by *The Voice in the Desert, The Shepherd of Tolosa,* and other romantic plays. In 1818 he went to Rome, where he wrote *The Liberation of Tasso.* In 1820 he began to display his real power in a volume of delightful tales. His last comedy. *Magnetism in the Barber's Shop,* appeared in 1821. In 1822 the poet was nominated lector in Danish language and literature at Sorö college, and in 1846 director. *Valdentar the Great and his Men,* an historical epic, appeared in 1824. The next few years were occupied with his best and most durable work, his four great national and historical novels of *Valdemar Seier* (1826); *Erik Menved's Childhood* (1828); *King Erik* (1833); and *Prince Otto of Denmark* (1835). He then returned to epic poetry in *Queen Margaret* (1836) and in a cycle of romances, *Holger Danske* (1837). His last publication was *The Apple of Gold* (1856). Ingemann died on Feb. 24, 1862.

INGENHOUSZ (INGEN-HOUSZ), **JAN** (1730–1799), Dutch physician and chemist, was born at Breda on Dec. 8, 1730 and educated at the University of Louvain, obtaining the degree of M.D. in 1752. Two years later he entered the University of Leyden to study natural history and continued his studies in Paris and Edinburgh. He travelled extensively in Europe, practising medicine and pursuing his scientific studies and published some works in which he displayed unusual insight and originality of thought. In 1772 he became physician to the empress Maria Theresa and a member of the Aulic council at Vienna. He finally settled in London, where he published in 1779 his remarkable small book *Experiments Upon Vegetables, Discovering Their Great Power of Purifying the Common Air in the Sun-shine,* etc. (Ger. trans., 1780; Fr. trans., 1787–89), introducing the concept of the balance between the animal and the vegetable world which became the foundation of the whole modern conception of the economy of living things. The appreciation of the importance of the work of Ingenhousz, and the fact that the power of plants to absorb carbon dioxide and give off oxygen is the most significant activity in nature, came much later with the development of plant physiology. Ingenhousz was also a talented engineer, and the invention of an electrophorus and the plate electric machine is attributed to him.

His other publications include *An Essay on the Food of Plants and the Renovation of Soil* (1796, Ger. trans., 1798); *Nouvelles expériences et observations sur divers objets de physique,* 2 vol. (1785–89); *Vermischte Schriften physisch-medicintschen Inhalts* (1782, 1784) and *Anfangsgründe der Electricitiit* (1781).

See J. Wiesner, *Jan Ingen-Housz, sein Leben und sein Wirkrn als Naturforscher und Arzt* (1905); C. Singer, *The Story of Living Things* (1931) and *Nieuw Nederl. Biogr. Woordenboek,* vol. vi (1924).

INGERMANLAND (Russian: *Ingermanlandia, Ingria,* formerly: *Izhora;* Finnish: *Ingerinmaa),* is the region on the Gulf of Finland between the lakes Ladoga and Peipus. Its terrain is flat except for the slight hill formations along the Luga and Oredezh rivers. The city of Leningrad is situated in this region.

INGERSOLL, ROBERT GREEN (1833–1899), U.S. orator, politician and lawyer, who popularized the higher criticism of the Bible, a humanistic philosophy, and a scientific rationalism which qualified him as the "bull dog" for Charles Darwin in the United States, was born in Dresden, N.Y., Aug. 11, 1833. The self-educated son of a peripatetic Congregational minister, he had little formal education. Admitted to the Illinois bar in 1854, Ingersoll subsequently enjoyed a lucrative law practice in Peoria, Washington, D.C., and New York city. His Civil War service as a colonel of Illinois volunteer cavalry was terminated in 1862 when he was captured and paroled by Confederate General Nathan Bedford Forrest. As an orthodox Republican he was attorney general of Illinois, 1867–69, the "big voice" of the party in the presidential campaigns of 1876 and 1880 (he gave James G. Blaine the soubriquet "The Plumed Knight"), and leading counsel for Republican defendants in the Star Route Scandal of 1882. In spite of his contributions to the party as a speaker, his unorthodox religious views deterred Republican administrations from appointing him to the cabinet or diplomatic posts which he desired. Nationally known as a lecturer, he was in great demand and received as much as $3,500 for a single evening's performance. He died at Dobbs Ferry, N.Y., July 21, 1899. His principal lectures and speeches—which bear such titles as *Some Mistakes of Moses* and *Why I Am An Agnostic*—*are* found in *The Works of Robert G. Ingersoll,* edited by Clinton P. Farrell, 12 volumes (1902).

See C. *H.* Cramer, *Royal Bob,* a biography (1952). (C. H. CR.)

INGERSOLL, ROBERT HAWLEY (1859–1928), U.S. merchant and manufacturer, was born at Delta, Eaton, Mich. Dec. 26, 1859. He spent his youth on his father's farm and had a very limited formal education. At the age of 20 he went to New York city and, with his savings of $1,600, established a business manufacturing and selling rubber stamps. With his two brothers he expanded it to include a wide variety of novelty products including the dollar Ingersoll watch. This became known as "the watch that made the dollar famous," about 70,000,000 being sold by 1919. He lost control of the firm in 1921 but in 1924, in a new venture, successfully introduced a dollar razor strop. Ingersoll died in Denver, Colo., Sept. 4, 1928. (H. J. SG.)

INGERSOLL, ROYAL EASON (1883–), U.S. naval officer, was born in Washington. D.C., June 20. 1883, son of Rear Adm. Royal Rodney Ingersoll. He graduated fourth among 114 in 1905 at the Naval academy. He became a rear admiral in 1938, a vice-admiral in Jan. 1942 and an admiral in July of that year. As commander in chief of the Atlantic fleet from Jan. 1942 to Nov. 1944 he had the responsibility of conducting antisubmarine warfare, escorting convoys and transporting both troops and supplies to Europe and north Africa. In Nov. 1944 he became deputy

commander in chief U.S. fleet and commander of the western sea frontier, in which post he continued until Dec. 1945. He retired on Aug. 1, 1946. (J. B. HN.)

INGLEWOOD, an industrial and residential city in west-central Los Xngeles county, Calif., U.S., a part of the Los Angeles metropolitan area and site of the Los Angeles International airport. Inglewood's industry includes aircraft manufacturing, metal products, pottery production and oil refining. An additional feature is the large race track, Hollywood Park.

The first settlers to enter the area were attracted by the *Aguaje de la Centinela* ("Sentinel Springs"). In 1822 Antonio Avila was given permission by the Mexican government to keep stock around the springs. The Avila family continued to hold the springs area until 1855, when the grant was confirmed by the California state government after a three-year land-claim survey. In 1887 it was acquired by the Centinela-Inglewood Land company, made up of seven Los Angeles real estate investors. Surveyors laid out the townsite during August and September. A railroad connecting Inglewood with Los Angeles was completed the next spring. By that time several small businesses and a hotel were already in operation. Inglewood was incorporated as a California city in 1908 and gained a freeholder charter in 1927. Its greatest proportional growth came between 1920 and 1925. The 1960 census showed a population of 63,390. (J. M. Wo.)

INGLIS, SIR CHARLES EDWARD (1875–1952), British professor of engineering distinguished as a teacher and for his researches into bridge vibrations, was born at Worcester on July 31, 1875. His early researches concerned mechanical vibrations, but in 1913 he published an important paper on the stresses in a plate due to the presence of cracks. He investigated railway bridge vibration from 1923 to 1934. During World War I he designed an easily transportable bridge, bearing his name, which was adopted by the British army and much used in 1917–18. In 1919 Inglis was appointed professor of mechanical sciences and head of the department of engineering, Cambridge university, in succession to Bertrand Hopkinson. On his retirement in 1943 the department had become one of the most important engineering schools in the world. He died in Suffolk, April 19. 1952. (J. F. BR.)

INGLIS, SIR JOHN EARDLEY WILMOT (1814–1862), British major general, son of John Inglis, third bishop of Nova Scotia, was born in Nova Scotia on Nov. 15, 1814. In 1833 he joined the 32nd foot, in which all his regimental service was passed. He saw active service in Canada (1837) and in the Punjab (1848–49), being in command at the storming of Multan and at the battle of Gujrat. In 1857, on the outbreak of the Indian mutiny, he was in command of his regiment at Lucknow. Sir Henry Lawrence being mortally wounded during the siege of the residency, Inglis continued the defense for 87 days against an overwhelming force. He was promoted to major general, made K.C.B. and, in 1860, given command of the British troops in the Ionian Islands. He died at Hamburg, Sept. 27, 1862.

INGOLD, CHRISTOPHER KELK (1893–), English organic chemist, born Oct. 28, 1893, at Ilford, Eng., was educated at Cniversity college, Southampton, and the Imperial College of Science and Technology, London, where he received a Doctor of Science degree in 1922. After lecturing at the Imperial college. Ingold became professor at Leeds, 1924–1930, University college of London university, 1930–37, and director of the chemical laboratories at University college in 1937. Ingold excelled in studies of resonance, mesomerism, electronic interpretations, clarification of constitution of organic substances and their reactions. developments of steric hindrance and use of deuterium in research. He received many honours and awards, including the royal medal of the Royal society (1952) for investigations of the mechanism and factors affecting organic reactions. He was Baker lecturer at Cornell university, Ithaca, N.Y., in 1950. and published *Structure and Mechanism in Organic Chemistry* (1953), authoritative for stereochemistry and reaction mechanics. (V. BW.)

INGOLSTADT, a town of Germany, in the *Land* of Bavaria, on the left bank of the Danube at its confluence with the Schutter, 52 mi. N. of Munich, at the junction of the main lines of railway, Munich, Bamberg and Regensburg-Augsburg. Pop. (1950) 40,523. Ingolstadt, known as *Aureatum* or *Chrysopolis,* was a royal villa in the beginning of the 9th century, and received its charter of civic incorporation before 1255, and later became the capital of a dukedom which merged with that of Bavaria-Munich. The fortifications were erected in 1539. In 1800 the French, under General Moreau, took the town, and dismantled the fortifications. They were rebuilt on a much larger scale under King Louis I, and after 1870 Ingolstadt ranked as an important fortress. The principal buildings are the old palace of the dukes of Bavaria-Ingolstadt; the remains of the earliest Jesuits' college in Germany, founded in 1555; the former university buildings, now a school; and the large Gothic Frauenkirche, founded in 1425, with two massive towers, containing the tomb of Dr. Eck, Luther's opponent. In 1472 a university was founded in the town by the Bavarian duke, Louis the Rich, which at the end of the 16th century was attended by 4,000 students. In 1800 it was removed to Landshut, whence it was transferred to Munich in 1826. The industries are metal founding and the manufacture of locomotives and machinery. The town suffered some damage during World War II.

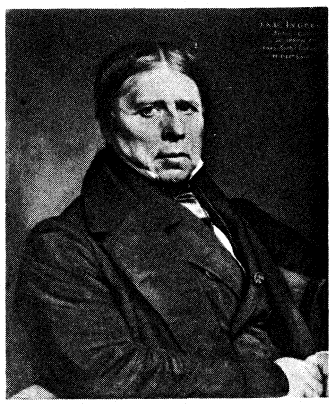
INGRAM, JOHN KELLS (1823–1907), Irish scholar and economist who made a reputation in the fields of literature, philosophy and science, as well as political economy was born in County Donegal, Ireland, on July 7, 1823, and educated at Newry school and Trinity college. Dublin. Elected fellow of his college in 1846, he became successively professor of oratory and English literature (1852–66), regius prufessor of Greek (1866). and librarian (1879). Remarkable for his versatility, he contributed a historical and biographical article on economics to the 9th edition of the *Encyclopedia Britannica* which was translated into many European languages. He died in Dublin on May 1, 1907. His principal works are *Greek and Latin Etymology in England; The Outlines of the History* of *Religion* (1900); *Human Nature and Morals According to A. Comte* (1901); *Practical Morals* (1904); and *Sonnets and Other Poems* (1900).

INGRAM, JONAS HOWARD (1886–1952), **U.S.** naval officer who during World War II supervised the convoy of thousands of U.S. troops to the European theatre, was born in Jeffersonville, Ind., Oct. 15, 1886. He entered the Naval academy in 1903 and graduated in 1907. He became a rear admiral on Jan. 10, 1941, vice-admiral on Feb. 2, 1942, and admiral on Nov. 15, 1944. In 1941 he commanded a cruiser division in the Atlantic, and afterward he became commander 4th fleet and commander South Atlantic force with headquarters in Brazil. He was most successful in his dealings with the South American nations and with Brazilian naval units serving under his command. His fleet was very efficient in antisubmarine warfare. On Nov. 15, 1944, he became commander in chief U.S. Atlantic fleet, and continued in this post until Sept. 1946. He retired April 1, 1947, and died at San Diego, Calif., Sept. 10, 1952. (J. B. HN.)

INGRES, JEAN AUGUSTE DOMINIQUE (1780–1867), French painter, the leader of the classical tradition in French 19th-century painting, was born at Montauban in Gascony on Aug. 29, 1780. His father was an impecunious ornamental sculptor, painter and drawing master who encouraged his eldest child from the very early moment that the boy's gifts for drawing and music became apparent. In 1791 Ingres first attended classes at the academy at Toulouse. The personalities of none of his early teachers left their mark, though Ingres' lifelong love of Raphael dates from his boyhood. In Aug. 1797 he went to Paris and entered the atelier of J. L. David. moving two years later to the Ecole des Beaux-Arts. After no more than a few weeks there he won the torso prize; and in 1800 he was equal second in the Prix de Rome, which he won outright the following year with a painting in the style of David's "Sabine Women," "The Envoys From Agamemnon Before Achilles" (École des Beaux-Arts, Paris).

Unsettled political and economic conditions led to the postponement of the award, and Ingres had to wait until the autumn of 1806 before he could leave for Rome. In the meantime he was given important official portrait commissions, and was provided with a studio in the old Capucine convent, now state-owned, where A. Gros, A. L. Girodet and Ingres' student friends François Granet

and Lorenzo Bartolini worked. "The Envoys From Agamemnon" was warmly praised by John Flaxman, whose influence may be seen in several of Ingres' early works, among them the sketch "Venus Wounded by Diomedes" (c. 1803, Hirsch collection, Basel) and "Jupiter and Thetis" (1811, Aix-en-Provence). Flaxman was at this time famed throughout Europe as a vase painter for Josiah Wedgwood and as an illustrator of Homer, and his friezelike compositions and bold use of unshaded line were regarded as quintessentially classical qualities by Ingres and his friends. They found Flaxman's style more convincing than the new "Greek" manner of their master David.



ALINARI

"SELF PORTRAIT– BY J. A. D. INGRES. IN THE UFFIZI GALLERY. FLORENCE

Ingres borrowed freely from Flaxman's illustrations and from contemporary engravings of Greek sculpture and vase designs. He was deliberately building up a repertory of forms that he continued to use in classical compositions throughout his life Perhaps aware of the poverty of his imagination, Ingres made a virtue out of copying.

Apart from the classical figure compositions the young Ingres was also painting portraits Several were shonn at the Salon of 1806, where they were met with incomprehension and ridicule. Ingres' portrait style was indeed an unusual one, owing much to Raphael. In self-portraits and portraits of friends, the sitters are strongly individualized and given a mysterious, almost tormented air—the touch of romanticism often found in Ingres. But in commissioned works, like the three Rivikre portraits (Louvre, Paris) or Mme. Aymon (Rouen), the artist does not attempt to express the character of his sitters, though their bourgeois origins are plain.

Ingres is not concerned with naturalism of any sort, but with the creation of an abstract design in which the forms of the natural norld are shaped into an eloquent surface pattern. His remarkable natural feeling for line allows him to describe form by contour alone.

In the most revolutionary portraits, like that of Mme. Rivikre, an arabesquelike pattern of lines dominates the picture, and Ingres seems to have abolished space, reducing body, clothes and cushions to a single unified plane. Natural forms are given an unreal near-geometrical smoothness, and are then held in perfect equilibrium by the linear pattern of the picture. Colour is always subservient to line, though Ingres has a strong feeling for texture and delights in rendering rich stuffs. These same qualities may be found in the great series of female nudes which begins in 1807 with the Bonnat and Valpinçon "Baigneuses" ("Bathers," Bayonne and Louvre) and reaches its climax in "Le Bain Turc" ("The Turkish Bath," Louvre).

The "Baigneuses" were painted in Rome; Ingres had finally left Paris in 1806 and did not return when his scholarship expired in 1810. He stayed in Rome, earning a living from the portraits and portrait drawings in pencil, now so admired. which to Ingres were a form of drudgery that prevented his working on the large history pieces he wished to paint. Ingres was planning both classical (Homeric) and historical (Raphaelesque) compositions: two distinct manners that persist in his work. The first large Homeric composition, "Jupiter and Thetis." met only with disapproval when sent back to Paris in 1811. Because he disliked all Italian painting after Raphael, Ingres was accused of archaizing tendencies.

In 1814 and 1819 Ingres again sent work to the Paris Salon, including some pictures in the new "troubadour" style—scenes of medieval history depicted in quasi-realistic manner (events in the lives of Henri IV, of Aretino, of Raphael; and a series of great lovers). He was still much criticized. In 1820 he moved from Rome to Florence; his altarpiece, "Christ Giving the Keys to Peter" (Louvre). had won some favour, and he mas now at work on another religious picture, "The Vow of Louis XIII," commissioned for Montauban cathedral. Ingres returned to France in 1824 to show this at the Salon. It met with universal approbation, appealing to classicist, romantic and troubadour taste alike. A rnost ambitious design, it represents the culmination of Ingres' Raphaelesque manner.

After 18 years' absence in Italy, Ingres became a Parisian celebrity overnight. He was given the cross of the Legion of Honour by Charles X, elected to the French Academy, and asked to paint "The Martyrdom of St. Symphorian" for Autun cathedral and "The Apotheosis of Homer" for the ceiling of the ne museum in the Louvre. He opened a studio and quickly had more than 100 students. The Louvre picture was completed by 1827. It celebrated an early enthusiasm of Ingres', one that also inspired the "Homer Deified" on which he was working at the time of his death. In the "Apotheosis" Ingres' Raphaelesque and Homeric manners are combined. The second commission, for Autun, gave Ingres much difficulty and when exhibited at the Salon of 1834 it was adversely criticized. Greatly upset, Ingres vowed never to show at the Salon again. He stopped painting for a time and left Paris to become director of the French academy in Rome.

He returned to Paris in 1840 and the last 26 years of his life were comparatively uneventful. The most considerable project was a decorative scheme for the chbteau of Dampierre, which occupied Ingres from 1843 until 1850 when work was abandoned. "The Golden Age," unfinished and ruined as it is, marks the revival of mural painting in France which culminates in the work of T. Chassériau and Puvis de Chavannes.

Ingres also continued to paint portraits, religious pictures, nudes and figure compositions, of which "Le Bain Turc" (Louvre), completed 1863, is the most important. Into it he introduced, almost without change, the figure of the "Valpinçon Baigneuse" which he had painted in 1808. Ingres was never against imitation or copying, and replicas by his own hand abound. In 1846 and 1855 retrospective exhibitions of his works were arranged. Ingres died in Paris on Jan. 14, 1867.

Charles Baudelaire, although as the champion of Eugène Delacroix he cannot be regarded as unbiased, laid the foundations of later estimations of Ingres. He perceived that Ingres was a draftsman of genius, who, seeing colour as no more than an inessential prettifying ornament, ruthlessly subordinates it to line. He noticed Ingres' lack of creative imagination, and the way in which he develops little, but switches from style to style. The entire production of Ingres' long output is implicit in the impressionable early years; and, as Baudelaire says, *comme il n'a* pas *progressé, il* ne vieillera pas ("because he has not progressed, he will not age").

Though affected by romanticism, the David-trained Ingres was a classical artist. His classicism made him abstract from the natural world for the sake of pictorial composition. This and his powers of draftsmanship help to explain why he has never lacked admirers, and why Degas, Gauguin, Matisse and Picasso were all profoundly influenced by his work. Many of Ingres' major works are now in the Louvre museum; he bequeathed the contents of his studio, including 4,000 drawings and 30 paintings, to his native town of Montauban.

INGRESS, entrance as opposed to exit or egress; in astronomy, the apparent entrance of a smaller body upon the disk of a larger one, as it passes between the latter and the observer; in this sense it is applied especially to the beginning of a transit of a satellite of Jupiter over the disk of the planet.

INHERITANCE. The expression inheritance in its broad sense comprises the devolution of property on death, whether real property (land) or personal property, whether effected by will or by operation of law upon intestacy. In its technical sense the expression is derived from Latin *heres,* an heir.

United States.—U.S. law borrowed its rules of descent of real estate considerably more from the civil lam than the common law.

"The 118 novel of Justinian has a striking resemblance to American law in giving the succession of estates to all legitimate children without distinction and disregarding all considerations of primogeniture. There is one particular in which the American law differs from that of Justinian, that while generally in the United States lineal descendants if they stand in an equal degree from the common ancestor share equally per *capita;* under the Roman law regard was had to the right of representation, each lineal branch of descendants taking only the portion which their parent would have taken had he been living, and the division being per stirpes and not per capita. But in some of the state's the rule of the Roman law in this respect has been adopted and retained." When such lineal descendants stand in unequal degrees of consanguinity the inheritance is per stirpes and not per capita (In re Prote, 1907; 104 N.Y. Supplement 581). This became the rule in practically all 'the states.

The entire subject of descent, substantially, became statutory. The principal changes were in uniformity of rules as between real and personal property and a more substantial provision for the wife. An important feature at common law—"the blood of the ancestor"—lost its importance.

But as in no two states are the rules of descent identical, the only safe guides are the statutes and decisions of the particular state in which the property to be inherited is situated. In most states the rules for the descent of real and personal property are the same, but in several states they continue to differ. The law of primogeniture as understood in England is abolished throughout the U.S., and male and female relatives inherit equally.

The distinction between relatives of the whole and half blood is not ordinarily in force. In a few states it is abolished by statute. In several others those of full blood are preferred.

The English rule that natural children not subsequently legitimated have no inheritable blood has been greatly modified. In several states inheritable blood exists between a natural child and its mother. In some states a subsequent marriage removes the bar as does recognition by the father in some states. In Arizona an illegitimate heir may inherit from and through both parents. Common-law dowers have been largely regulated by statutes which give certain rights to the surviving wife in lieu thereof—usually more favourable to her than her common-law dower. In several states she takes a third interest in fee in land alienated by her husband in his lifetime without joining her in the deed—usually one-third; in Kansas one-half interest in fee.

Curtesy has likewise been very generally abolished and certain statutory rights given to a surviving husband instead. In the states which came in through the Spanish or French titles, dower and curtesy had no place.

In default of issue and subject to the share of the spouse, the parents usually take, and failing parents, collaterals take. A usual form of statute gives the wife one-half where there is but one child; if there be more than one child, the wife takes a child's share.

Degrees of kindred in the United States generally are computed according to the civil law; *i.e.,* by adding together the number of degrees between each of the two persons whose relationship is to be ascertained and the common ancestor. Thus, relationship between two brothers is in the second degree; between uncle and nephew in the third degree; between cousins, in the fourth; etc. In a few states such degrees are computed according to the common law; *i.e.,* by counting from the common ancestor to the more remote descendant of the two from him—thus, brothers would be related in the first degree; uncle and nephew in the second; etc. In most states representation among collaterals is restricted—in some to the descendants of brothers and sisters, in others to their children only.

In eight states (California, Louisiana, Texas, Arizona, Idaho, Nevada, New Mexico and Washington) the law of "community property" of husband and wife prevails. This is derived from the French and Spanish law existing in the territories out of which those states were formed as the result of the Spanish and French occupation. The foundation idea is an equal division at the death of either party of all property acquired during their marriage except by gift, devise or descent. In general the husband has the control and management thereof during the marriage, and the survivor has the administration of the moiety of the one deceased.

(F. R.; X.)

England.— The heir in English law was the person on whom the real property of a deceased person devolved by operation of law. Until 1926 such descent was regulated by the rules and canons of descent. All existing modes, rules and canons of descent were abolished by section 4j of the Administration of Estates act, 1925, which went into operation in 1926. Before 1926 the devolution of personal property upon an intestacy depended upon a complex body of law which was likewise superseded by the provisions of the Administration of Estates act, 1925.

The act contains a composite body of law governing the devolution of both real and personal property. It provides that on the death of a person intestate as to any real or personal estate, such estate shall be held by personal representatives appointed by the court upon trust for sale. The personal representatives have the duty of realizing the estate and applying the proceeds first to satisfy the liabilities of the deceased and then to distribute the residue when realized to the next of kin of the deceased as defined by and in the manner provided by the act. The first person to be considered is a surviving spouse. Subject to the interests of the surviving spouse the residuary estate is held upon the statutory trusts for any issue of the deceased. If the intestate leaves no issue the residuary estate is to be held on trust for the father and mother of the deceased, and if there are neither issue nor parents upon trust for the brothers and sisters of the whole blood; failing whom for brothers and sisters of the half blood. Then come grandparents, then uncles and aunts. If there are none of the aforementioned relatives the surviving spouse takes the whole of the estate absolutely. If no person can be found within the above categories the residuary estate passes to the crown. (See INTESTACY.)

For the inheritance of property by will, see WILL.

In many of the commonwealth countries and British colonial territories the English law of inheritance has been greatly modified by legislation.

Scotland.— Inheritance is that which descends to the heir of the owner on his death intestate. On the death of the person his property. so far as it is not regulated by deed and subject to certain prior claims. devolves on his heir or heirs according to rules of intestate succession.

The rules are the same for both heritage (land) and movable estate. The estate devolves in the first instance, subject to the rights of a surviving spouse, upon the descendants of the deceased, first children, failing them grandchildren and so on. If there are no descendants the estate devolves on relations in the collateral line, that is, brothers and sisters of the deceased, and failing these it passes to the ascendants, the father and his collateral relations, whom failing it passes to the grandfather and his collaterals and so on.

There are, however, important differences between succession in heritage and succession in movable property. In heritage, for instance, males are preferred to females in the same degree and the rule of primogeniture obtains. In movable estate all who are related in the same degree to the deceased share in the estate irrespective of age or sex.

By the Legitimacy act an illegitimate child or, if he is dead, his issue are entitled, if the mother dies intestate and without legitimate issue, to the same interest in her estate as would be the case if the child had been legitimate; and the mother takes the same interest in the intestate estate of her illegitimate child as would have fallen to her if he were legitimate and she were the only surviving parent.

The position of the father, after the brothers and sisters of the deceased, will be noticed as an important point of difference from the English axioms; so also is the total exclusion of the mother and the maternal line. Half blood is either consanguinean, as between children by the same father, or uterine, as between children having the same mother. The half blood uterine is excluded altogether. Half blood consanguinean succeeds thus: if the issue is by

a former marriage, the youngest brother (being nearest to the deceased of the consanguinean) succeeds first; if by a later marriage than that from which the deceased has sprung, the eldest succeeds first.

See also INTESTACY; **WILL.** (P. **E. L.**)

ECONOMIC ASPECTS

There are no concepts of inheritance which can be shown to be "natural," as may well be seen by comparing the ideas prevailing in different countries at the same time, or in the same country at different times. Absolute rights of inheritance and, bequest are mutually exclusive. In general, by an absolute right of bequest is meant the freedom to leave one's possessions exactly as one pleases, whereas an absolute right of inheritance is an inalienable right to possess what someone has left. An Englishman or an American, finding that his parents have left their wealth to some stranger, may be pardoned for emphasizing the moral rights of inheritance. A Frenchman, finding that a substantial part of his accumulated fortune must go, whether he likes it or not, to a son who has by his conduct no moral claim upon it, may be excused for advocating the right of bequest. One who has neither wealth to leave nor to receive may be pardoned for questioning a system which perpetuates through the accident of birth the concentration of economic power inherent in wealth status.

Inheritance and Income Inequality.— Inheritance of wealth is one factor among many affecting the pattern of income distribution in a society. Wealth as well as poverty tends to be self-perpetuating, even in countries where consciousness of social classes is not acute and opportunities are many for the advancement of the astute and the ambitious. Progeny of high-income families usually have better educations as well as better opportunities for early placement in promising positions than do those of low-income families. Occupation is a main source of income differences, and family background continues to be an important influence in occupational selection. Even if inheritance in the form of wealth could be eliminated, differences in the investment made in the training of children would be sufficient to perpetuate income inequality.

It is a common error to overemphasize the effect of wealth ownership alone on the pattern of income distribution. According to estimates made by Simon Kuznets in 1953, a redistribution of all property income in the United States on an equal per capita basis would reduce the income inequality between the top 5% of income recipients and the lower 95% by, at most, only one-third. Since wages and salaries are a large part of total incomes, inequality in their distribution assures inequality in the distribution of all incomes, and the inequality from service incomes in large.

Inheritance and Taxation.— Two sets of taxes have grown around the event of death—estate duties and succession or inheritance taxes. An estate tax is levied on a base defined as the net assets of the estate, whereas a succession or inheritance tax is computed on the share obtained by the beneficiary. At proportional rates, the two types of taxes are equivalent; the total tax liability is the same regardless of how finely an estate may be divided. In practice, however, both taxes are ordinarily levied at progressive rates and therefore they are not equivalent. Estate taxes are usually believed to provide more revenue than succession or inheritance taxes. However, their comparative yields depend upon the exemptions and the rate structures imposed.

The estate tax is found in English-speaking countries. The inheritance tax is, with few exceptions, the only death tax device used throughout the rest of the world. Estate and gift taxes are imposed by the federal government of the U.S. The states also employ estate taxes, and a few have both estate and inheritance taxes. The trend in the 1950s was away from the employment of inheritance taxes in the United States, and the estate tax was the only form of death duty in the United Kingdom. (For history, detailed tax provisions, rates, etc., see ESTATE AND INHERITANCE TAXES.)

From the point of view of reducing the concentration of economic power, both estate and inheritance taxes, as ordinarily designed, are rather crude tools at best. If it is public policy to impose obstacles to the perpetuation of fortunes, there is no compelling reason for imposing a tax only once each generation. A more direct and effective method of reducing wealth concentration is annual net worth taxation. Such a tax was introduced in Japan after World War II as a result of the suggestions of the Shoup commission. The tax was based on the value of assets owned minus debts of living persons. Such a tax may be viewed as a substitute for high rates on large incomes under a personal income tax as well as a substitute for a death tax. Even with a high exemption, such as the first $500,000 of net assets, a system of initially low but progressive rates on net worth could substantially reduce the large fortunes over relatively short periods of time. Tax liabilities could be made to exceed income, and for the few very wealthy families, greatly exceed income.

Another substitute for death taxes is an accessions tax (also introduced into Japan). The base of the tax is the cumulative total of gifts, bequests and inheritances received by any one person from all sources during his lifetime. An accessions tax is a form of inheritance tax, and its employment would call for a marked departure from the traditional form of transfer tax in the United States or the United Kingdom. Such a tax comes close to another proposal advocated by Henry Simons (*Personal* Income Taxation) to include gifts, bequests and inheritances in the income of the recipient and to tax such gains like other gains under an individual income tax. The theory behind this proposal is that the income of a person consists of any gain he receives regardless of its source, and thus a gift or an inheritance is income to the recipient and should be treated as such for tax purposes. No insuperable technical obstacles exist to both an annual net worth tax and the inclusion of gifts, bequests or inheritances under the individual income tax if it is public policy to prevent inheritance from perpetuating wealth concentration.

Incentive Problems.— Death taxes have been called "ideal" taxes from an economic point of view because they merely take away a portion of a windfall gain from the recipient, thus having no effectson economic incentives. This theory is defective because it directs attention to the recipient, whereas the incentive effects, if any exist, apply to the predecessor. A simple tax on dying would have no incentive effects, since a person would know that at his death a flat sum would need to be paid and this sum would be independent of any action he or his beneficiaries might take. The incentive effects of an estate tax may be discovered by comparing such a flat-sum tax on dying with a tax of equal revenue based on the size of the net estate at death. Viewed in this way, the extra anticipated tax cost of an extra dollar added to one's estate is the discounted value of the future rate of tax to be imposed on the added dollar. The alternative to adding to one's estate is spending more money on consumption, making gifts (unless gifts are also subject to tax) and, in the case of an active person, retiring from work at an earlier age. Whether or not high marginal rates of a death tax actually induce wealthy people to consume more had not been systematically investigated at mid-20th century. Some presumption exists that wealthy people, by the time they have reached their middle years, will have settled upon their consumption habits, and the prospect of a tax will have little if any influence on their consumption behaviour. Dissipation of estates by gifts does occur. The gift tax in the United States and the requirement in the United Kingdom that gifts made within a specific number of years prior to death be included in the taxable estate were attempts to prevent this method of avoidance. The evidence suggests that people are rather cautious about giving away their wealth prior to death. According to a U.S. treasury study, even those with estates exceeding $5,000,000 made gifts of only about 12% of their total wealth prior to death. Few people of wealth are apparently willing to part finally with their assets on a substantial scale prior to death, suggesting that the desire to own and control property is deeply rooted in human motivation. The same evidence suggested, but did not prove, that the willingness of people to accumulate wealth is not affected in any marked degree by the prospect of taxes levied upon the size of their estates.

The prospect of heavy taxation of net estates or of the shares

of possible beneficiaries may undermine the inducement of older people to continue to work, where they had the opportunity. Many of course have no choice because of poor health or compulsory retirement plans. In other cases, an estate tax (or an inheritance tax) becomes one possible motivation for early retirement. If the rates under an estate tax were 100%, the dissipation of assets by earning less without consuming less mould be almost costless for people of advancing years. Some might retire earlier by living off their accumulated assets. The rate structure of the U.S. federal tax becomes high only for very large estates, and the number of persons affected is, correspondingly, very small. If the exemptions were greatly reduced and the rates advanced on modest estates, the possible negative effect of death taxes on the incentive to work might have more importance.

Inheritance and Investment.—Inheritance has been defended on the grounds that wealth concentration favours investment and any governmental interference with transfers at death slows the pace of progress through new investment. What justification there might have been favouring wealth concentration as a means of achieving mass-production techniques has long been made obsolete by the industrial corporation. There is, however, some substance to the belief that heavy death taxes may retard the rate of new capital formation. Clarity of thought on this point has been severely handicapped by the popular misconception, shared by legislators, that because a death tax is a tax on capital, it must "come out of capital." Actually, the form of a tax gives no information about the source of the funds which the government obtains. It has been observed that a tax on beer does not mean that the tax is paid out of beer. Likewise a tax levied on persons with respect to the size of their assets does not imply that the tax is paid out of capital. In a literal sense, taxes are paid in money, an asset, and in this respect tax payments do not differ from other payments. The issue of substance is the adjustment which people make in their personal consumption and asset-acquisition expenditures under the impact of a tax. Whether a tax reduces private consumption or expenditures on assets depends primarily on the distribution of the burden of the tax among people classified by the size of their wealth or by the size of their incomes. A revenue system which forces low-income groups to pay taxes will, almost regardless of the type of tax. reduce aggregate consumption expenditures because low-income groups spend what money they have mainly for personal consumption items. Likewise, a tax system nhich hits high-income groups heavily mill reduce their expenditures upon assets because a larger portion of their current expenditures goes for investment. Thus heavy death taxes may be expected to curtail the amount of individual thrift. Its effects in this regard are much smaller than those of progressive income taxes for the reason that death taxes yield less revenue.

There is a school of thought which holds that taxes, including death taxes. need not reduce expenditures on new physical assets. In substance, this position rests upon the theory that actual investment is not restricted in any significant degree by inability to acquire the necessary funds. Large corporations make a substantial portion of total new investment. They obtain funds by plowing back earnings and, on a smaller scale, by borroning. The relevant limitations on their expenditures for new facilities are those connected with the marketing of the product, the rate at which engineering and scientific research points to new profitable investments and, most important, expectations concerning future business developments. Accordingly, a government might virtually equalize the distribution of income by tax and subsidy measures without affecting the ability of business to finance new investments. Taxes are relevant to the scale of investment mainly as they affect the demand for products of a corporation rather than as they may affect the demand on the part of private groups for corporate shares of stocks or bonds. Noncorporate investors can finance themselves also without depending upon wealthy lenders by using the facilities of financial organizations including those sponsored by governments.

Thus it may be claimed that the rate of new investment is not affected in any significant degree by heavy taxation of high-income groups, whether the form of such taxes consist of once-a-generation capital levies, annual net worth taxation or highly progressive income taxation. Accordingly, taxes reduce expenditures for new facilities only if they directly discourage investment expenditures, sometimes alleged to be true of corporate net income and excess profits taxes. Death taxes are mainly irrelevant in this regard because corporations are, for obvious reasons, not subject to such taxes, and individuals who may acquire new physical assets are affected only to the extent that loss possibilities, occasioned by forced liquidation in the settlement of an estate, may be anticipated. Such considerations as these remove almost any economic objections to heavy individual progressive taxes because of their effects on capital formation.

The view that ability to obtain cash is not a limiting factor in the creation of new resources was the dominating, though not the exclusive, implication of the views of British economists as well as a large group of U.S. students in the 1950s. The contrary view, commonly labeled "orthodox" (historically, the great thinkers in economics held that saving limits capital formation), had been gaining more support, partly because the experience of post-World War II inflations was interpreted as experimentally verifying the theory that lax financial policies contribute to price inflations, and that stringent policies, where practised, were, in fact, effective in reducing inflationary pressures. Such evidence supported but did not conclusively establish that greater thrift induces a higher rate of investment in industrial countries without resort to inflation.

If the cost of financing does limit investment, estate taxation does so also, not because the tax is levied on "capital" but because it is imposed on people who spend much of their money for assets. The payment of the tax absorbs funds which in part would otherwise have financed the holding of assets, including new physical resources, and thus tends to advance interest rates. Only the most extreme view of the role of finance in investment, however, would support the conclusion that progressive death taxation reduces expenditures for capital formation on a dollar for dollar basis. In the United States the yield of death taxes was too small in the 1950s to have any quantitatively significant effect on the rate of new investment.

INJECTOR, an induced current apparatus which by means of a jet of steam feeds water to a boiler. The invention of Henri Giffard, its introduction in 1859 created great interest, because it seemed impossible that a jet of steam from a boiler could force itself and the water back into the boiler. Yet not only was this done, but later researches proved that exhaust steam at atmospheric pressure could be utilized, and it became possible later to deliver against a pressure of 150 lb. per square inch. The Davies and Metcalfe exhaust injector will do this, and with the help of a small supplementary jet of live steam it will feed against a pres-

sure of 250 lb. per square inch. Exhaust steam has no velocity in the atmosphere, but if issued into a vacuum it acquires a very high velocity. Hence, by condensing the steam by contact with the feed water such a vacuum is produced, and the resulting velocity of the steam, imparted to the water, produces sufficient force to carry the latter into the boiler.

See also EJECTOR; STEAM.

INJUNCTION, in English law, the name for a judicial command whereby a party is required to refrain from doing a particular thing according to the exigency of the writ. Formerly it was a remedy peculiar to the court of chancery, but under the modern constitution of the judicature, the injunction was made equally available in all the divisions of the high court of justice and it could no longer be used to prevent an action in any of them from proceeding in the ordinary course. Although an injunction is properly a restraining order, there are instances in which, under the form of a prohibition, a positive order to do something is virtually expressed by what is known as a mandatory injunction. The injunction was used to stay proceedings in other courts "wherever a party by fraud, accident, mistake or otherwise had obtained an advantage in proceeding in a court of ordinary jurisdiction, which must necessarily make that court an instrument of injustice." As the injunction operates personally on the defendant, it may be used to prevent applications to foreign judicatures; but it is not used to prevent applications to parliament or to the legislature of any foreign country unless such applications be in breach of some agreement and relate to matters of private interest. The jurisdiction of the court to prevent breaches of contract has been described as supplemental to its power of compelling specific performance; thus, *e.g.*, in the case of an agreement of a singer to perform at the plaintiff's theatre and at no other, the court, although it could not compel her to sing, could by injunction prevent her from singing elsewhere in breach of her agreement.

An injunction may as a general rule be obtained to prevent acts which are violations of legal rights, except when the same may be adequately remedied by an action for damages at law. Thus the court will interfere by injunction to prevent waste, or the destruction by a limited owner, such as a tenant for life, of things forming part of the inheritance. Injunctions may also be obtained to prevent the continuance of nuisances, public or private, the infringement of patents, copyrights and trade-marks. Trespass might also in certain cases be prevented by injunction. Purely temporary injunctions may be obtained ex parte but others only on notice to the other side. An injunction obtained on interlocutory application during the progress of an action is called an "interim" injunction, which is superseded by the trial. It may be continued either provisionally or permanently. (See PRACTICE AND PROCEDURE.) (X.)

United States.—Despite the administration of law and equity by a single court, as is true of most U.S. states, the remedy by injunction retains its essentially equitable character. Its issuance is governed, in the main, by the accepted precedents of equity. An extension of the injunction on the principle of equitable jurisdiction over nuisances was the use of the remedy to aid in the enforcement of criminal laws. The fact that the proceedings relating to the issuance and enforcement of injunctions are conducted before a judge alone eliminates the inevitable discretion that under the common law system is vested in a jury. Consequently, when the enforcement of a particular law becomes difficult because of the opposition of a particular community as manifested in the tendency of juries to acquit in criminal prosecutions, resort has been made to this head of equity jurisdiction.

Peculiar to the U.S. federalist system is the problem of federal courts' enjoining proceedings in state courts and vice versa. The general principle is that no such injunctions shall issue; but being courts of concurrent jurisdiction either court that first obtains jurisdiction of the subject matters regards itself as entitled to retain that jurisdiction to the exclusion of the other court and employs the injunction in aid of this purpose. The friction that might result from a liberal use of the injunction was foreseen at an early date, and in 1793 congress prohibited the use of the injunction by the federal courts for this purpose save in bankruptcy cases. The federal courts have, however, by a series of judicial decisions established numerous exceptions to this broad statutory provision among which is that noted above and the principle that the injunction will issue in aid of the exclusive jurisdiction of the federal courts. A second ground of irritation concerned the use of the injunction by the federal courts to restrain the enforcement of state statutes on the ground of their constitutionality. An appeal from such action lay to the U.S. supreme court, but during the interim a single federal judge was able to set at naught the entire administrative authority of a state. The incongruity of this result led congress by a series of statutes beginning in 1910 to prohibit the issuance of such injunctions before a court consisting of less than three judges, one of whom should be a circuit judge, and to provide for expediting an appeal therefrom to the supreme court. Limitations have also been imposed upon the power of federal judges to issue ex parte restraining orders pending an application for a temporary injunction. (J. M. LA.)

INK is a liquid or semifluid medium in which colouring matter is dispersed. The fluid serves as the vehicle for transferring the colouring matter to the paper or other surface from the pen, rubber stamp, type or other mechanism for making the characters.

Writing Inks are solutions of colouring material and other substances in water. The first inks, dating from about 2500 B.C. and used in the early Egyptian and Chinese civilizations, consisted of lampblack ground with a solution of glue or gums. This mixture was moulded into sticks and allowed to dry. The sticks were mixed with water before use. Coloured juices, extracts and suspensions of many plant, animal and mineral substances have been used as inks, including dragon's blood, alizarin, indigo, pokeberries, cochineal and sepia. A soluble iron salt forms a dark-coloured solution with an extract of tannin. Such mixtures have been used as writing ink for many centuries, and are the basis of modern blue-black inks.

General Properties.—Writing ink should leave a neat, legible mark on the paper. If a permanent ink, the marks on paper should remain legible after soaking in water, and after exposure to strong light. The ink mark should not accelerate deterioration of the paper. The ink should dry fairly quickly on paper and not smudge. It should not produce a feather-edged line or penetrate clear through the paper, or offset onto the adjacent sheet. The ink should have good writing qualities, including free and even flow from the pen without flooding or clogging. It should resist drying up and thickening on the feed and point of fountain pens. The liquid should be stable on standing; it should not form scum or sediment or permit the growth of mould or other microorganisms. It should be inert to steel pens, and to the rubber, plastic and other parts of fountain pens. Numerous special materials, in addition to the colour, are added to inks to modify their properties for the purposes outlined above.

Blue-black inks usually contain ferrous sulphate as the iron salt. At one time the tannin for inkmaking was obtained by extracting oak galls with hot water as part of the process. In the United States, however, most inkmakers adopted purified gallic and tannic acids. A small amount of a mineral or organic acid is usually added. Such a solution has a light bluish-black colour, and the writing on paper is faint initially but on standing becomes darker and insoluble in water. The latter property gives the ink its permanent quality. If the record becomes wet, the characters do not wash out but remain legible. Blue dyes are added to blue-black inks to enhance the appearance and to make the writing initially legible. The addition of black dyes produces permanent black inks. The following formula is from Federal Specification for Writing Ink, no. TT–I–563b:

Gallic acid crystals	5.0 g.
Ferrous sulphate crystals	7.5 g.
Tartaric acid	1.0 g.
Soluble blue (Colour Index no. 707)	3.5 g.
Distilled water, to make (25° C.)	1 l

Aqueous extracts of logwood with various metal salts, principally those of chromium, were extensively used as inks for many years, but by mid-20th century were little used in the United States. A small amount of ink which uses colloidal Prussian blue for the colour is produced.

Coloured inks contain soluble dyes as the sole colouring matter. Such inks are for school and home and such business use as does not require a permanent record, because the writing on paper fades in strong light and washes out if immersed in water. However, the writing on paper will last for many years if protected from such deteriorating effects.

Among the classes of dyes which have been used in writing inks are derivatives of triphenylmethane, azine, thiazine, monoazo, disazo and anthraquinone.

Washable inks are dye-base inks which may be washed from washable fabrics more readily than permanent inks if accidentally spilled, A typical washable ink:

Soluble blue (Colour Index no. 707)	5.0 g.
Glycerine	10.0 g.
Thymol	0.5 g.
Water, to make	1 l.

Quick-drying permanent inks consist of certain substantive dyes dissolved in an alkaline solution. The caustic solution wets the paper readily, which results in rapid penetration below the surface. Dyes are chosen which have strong affinity for the cellulose fibres of the paper, so that the writing on the paper cannot be washed out by soaking in water.

India ink is a dispersion of carbon black in water. Numerous substances have been s'uggested for stabilizing the suspension, including various alkaline solutions, shellac dissolved in borax solution, soap, gelatin, glue, gum arabic and dextrin. It is used mainly as drawing ink, though some is used as writing ink.

Technology.—The manufacture of writing ink consists of purifying the water by distillation or deionization, dissolving the ingredients in large tanks, clarifying the resulting solution by decanting, filtering or centrifuging, and packaging.

The packaging is usually done by a series of automatic machines which put the right amount of ink in each bottle, put on caps and screw them down, attach the label and insert each bottle in the individual carton. Such an automatic production line can produce more than 50,000 small bottles per eight-hour day. Economically, the package and the handling, storing and shipping are by far the most important parts of ink manufacture, because they represent a large fraction of the total cost.

Ballpoint Pen Inks; Other Types.—In writing with ballpoint pens the ink is transferred from the reservoir to the paper by a rotating ball, about one millimetre in diameter, held in a socket at the writing tip of the pen. Ballpoint pen inks consist of dyes or pigments, or both, dispersed in oils, resins, etc., and are essentially printing inks or lithographic varnishes. Cellulose fibres are preferentially wetted by most ballpoint pen inks, hence the latter will write on paper which is wet.

Stamp pad inks, for rubber stamps, are solutions of dyes in glycerine or glycol and water.

Inks for various duplicating processes contain a high concentration of colouring matter.

Inks for numbering and cancelling machines, which use metal type, are dispersions of dyes or pigments, or both, in an oil base.

Printing **Ink** consists in general of a pigment dispersed in a vehicle. Many vehicles are used, the principal ones being linseed oil, raw, boiled and heat bodied to different viscosities. Synthetics of the alkyd type! mineral oil (petroleum derivatives) and petroleum fractions, tung oil raw and polymerized, soy oil and dehydrated castor oil are also used. All these oils, by themselves or in combination with each other or in the form of varnish (cooked with synthetic resins) have their uses for the different types of printing.

Ink made with linseed or alkyd varnish is used for the better types of printing. Mineral oil and mineral oil varnish are the components of the black and colours used in newspapers. The alkyd varnishes are used in lithographic inks for tin decorating, outdoor signs, toys, etc., because of their hardness after baking Mineral oil fractions or petroleum solvents in combination with synthetic resins provide the vehicle for heat-set inks, used mainly in the printing of magazines. Dihydric alcohols (glycols) and alcohol-soluble synthetic resins provide the vehicle for the steam-set type ink used mainly in bread wrappers, chewing gum wrappers, milk cartons and any other uses where lack of odour is a desirable feature.

Methyl alcohol and plasticizers, alcohol-soluble synthetic resins and shellac provide the vehicle for aniline inks. This ink, which is liquid, is used in printing cellophane, wrapping paper, paper bags, glassine paper and plastic materials. Naphthas and other coal-tar solvents in which synthetic and natural (fossil) resins are dissolved provide the vehicle for rotogravure ink. This ink, like aniline, is liquid and is used in printing soap cartons, labels, rotogravure supplements and cellophane and in other uses where quick drying is essential.

Diethyl phthalate and glyptal resin provide the vehicle for hot-wax ink. This ink has the property of drying when the printed matter is dipped in hot wax. It is used in the printing of milk bottle caps and hoods, the printed paper going directly through the hot-wax bath. The drying is accomplished by the molten wax taking the diethyl phthalate away from the ink film, leaving the resin to bind the pigment.

Inks are made to fit specifications such as proofness to alkali, alcohol, grease, lactic acid, odour, rub or scratch, water and soap and fastness to light. Here the pigments used play a leading part even though in some cases the vehicle also has to be made to meet the specifications. For instance, tung oil is almost always one of the components of an ink which has to stand a stiff alkali test. Rubber is used to obtain special results such as binding on metal, quick setting on paper, hardness, etc. Only small quantities of these specialty inks are used.

The pigments used in the manufacture of printing ink are many and varied. These include: (1) for yellow, various shades of chrome yellow, benzidine yellow, yellow lake, hansa yellow and cadmium yellow; (2) for red, the lithol toners from light to dark (the sodium being the lightest, the barium medium and the calcium darker), para toners (light and dark), toluidine, phloxine red, cadmium red, rhodamine and others; (3) for blue, iron blues, peacock blue, phthalocyanine blue, reflex blue and tungstated blue; (4) for green, phthalocyanine green, tungstated green and chrome green; (5) for purple, methyl violet, molybdate purple and tungstated purple; (6) for orange, molybdate orange, Persian orange and ortho orange; (7) for opaque whites; titanium dioxide, zinc sulphide, zinc oxide and lithopone; and (8) for transparent whites, calcium carbonate, magnesium carbonate, alumina hydrate, blanc fixe and clay. The transparent whites are used mainly as extenders to weaken the intensity of the straight pigments. All colours are opaque, semiopaque or transparent in nature. Some are not fast to light, alkali, alcohol, water, soap; others are fast to one and not another; and still others are proof against all tests. "Earth colour" pigments such as raw sienna, burnt sienna, raw umber and burnt umber are rarely used; even though they have good light fastness, they are poor working pigments and are very abrasive, tending to wear down printing plates.

Drying.—The drying action of printing ink is achieved by oxidation, penetration, evaporation or coagulation and penetration. Typographic and lithographic inks contain driers such as cobalt, lead and manganese, sometimes only one and sometimes the three.. Each has the property of absorbing oxygen from the air. This action upon the drying oil which is the vehicle is the film-forming chemical action known as drying.

Newspaper inks or any ink printed on a very absorbent uncoated paper usually contains no drier, the drying being accomplished by

penetration of the ink into the fibres of the paper.

Heat-set inks. the type used in magazine printing, utilize evaporation, while steam-set inks utilize coagulation and penetration. Both types are discussed more fully below.

Steam-Set *Inks.*—When moisture in some form comes in contact with a sheet printed with steam-set ink, the latter dries almost instantly. This is caused by the vehicle or varnish in which the pigment is ground; the vehicle is compounded of glycol (dihydric alcohol) and a resin soluble in the glycol. Most of the different glycols are used, including propylene, dipropylene, diethylene, etc. The resin can be a fumaric, maleic, phenolic or zein (a protein found in maize). The combination of the different glycols and resins gives different rates of drying.

The drying principle is that glycols, being hygroscopic, become saturated and throw the resin out of solution, giving the ink surface a dry feeling. If rolled out on a steel or glass plate when the moisture content of the atmosphere is about 45%, an ink made with diethylene glycol will become dry if the moisture in the room is increased. It will become wet again if the moisture is decreased to the original percentage. This, of course, does not follow when the ink is applied to paper, for when the resin is thrown out of solution by moisture, the combination of glycol and moisture has a chance to soak into the sheet, leaving the resin to act as the binder for the pigment.

Relative humidity is of much importance when printing with this ink. If the humidity is too high it will cause the ink to dry on the printing press. Inks are usually made so they will stand from 70% to 80% relative humidity. Where there is humidity control the ink is made accordingly.

Steam-set inks are used mostly in printing corrugated paper containers and bread wrappers, with or without the application of live steam to the printed sheet. In most cases it is not necessary to apply moisture artificially; the ink absorbs enough from the paper and from the air to dry. An important feature of this ink is that it is almost odourless.

Heat-Set Inks.—The latest development in printing ink is the use of the plastic resin polyvinyl chloride. This resin in finely pulverized form is mixed with a plasticizer. The plasticizer can be made up of the following: tricresyl phosphate, dioctyl phthalate, dihexyl phthalate, santicizer. The mixture is modified with diluent to give the proper flow, and a pigment is ground into it.

This ink is perfectly stable at room temperatures but when used on printing presses equipped with heaters or ovens, it turns from a semi-liquid to a hard, tough solid, by the solution of the resin into the plasticizer when subjected to a temperature of 350° F. or more.

This type of ink is used similarly as the "heat-setting" ink that has been in use for a number of years and which consists of pigment ground in a varnish, made with a resin and hydrocarbon solvent. The resin is any of a series which are soluble in a solvent of a very low kauri butanol value (from 23 to 28); the most commonly used are zinc resinate, calcium resinate, limed rosin and some soluble phenolics of the terpene type or a combination of various of these resins. Solvents of high boiling points, from 230° C. to 320° C., are used. Narrow cuts of these solvents are then used in making the varnish according to the speed of the press and the type of form being printed. Most magazines are today printed with ink which is formulated in such manner so that it will dry instantly under the application of heat.

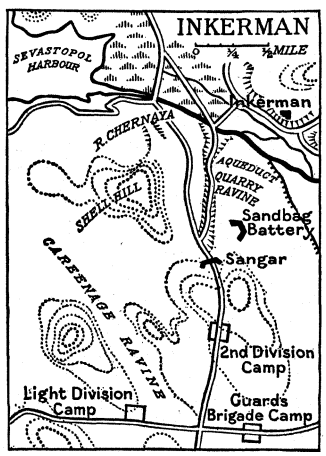
Fast rotary printing presses are equipped with heaters, burners or large steel steam-heated drums which dry this ink by evaporating the solvent. After the printed sheet passes through the burners or over the heated drums it passes over cooling rollers to get it back to almost normal temperatures.

It will be noted by the foregoing that the two types of printing ink have altogether different composition. The drying is affected in one case by the action of the heat melting the plastic and putting it into solution in the plasticizer with the resultant increase in viscosity which turns it from a liquid to a solid compound. In the other case, it merely evaporates the solvent, attaining this way the same purpose. (Jo. P.)

INKBERRY (*Ilex* glabra), a North American shrub of the holly genus (family Aquifoliaceae), known also as evergreen winterberry and Appalachian tea, native to sandy soil from Nova Scotia to Florida and west to Louisiana, mostly near the coast. It is a small shrub, 2 ft. to 6 ft. high, with leathery, evergreen, oblong, usually slightly toothed leaves; small white flowers, solitary or sometimes two or three together, borne on short slender stalks in the axils of the leaves; and small black berries (drupe), about $\frac{1}{5}$ in. in diameter, ripening in autumn. Among other plants called inkberry are the West Indian indigo berry (Randia *aculeata*) and the widely distributed pokeberry (Phytolacca decandra). The Australian or Queensland inkberry is *Mollinedia macrophylla*, a plant of the family Monimiaceae. (See HOLLY; POKEBERRY.)

INKERMAN, BATTLE OF, fought on Nov. 5, 1854, between a portion of the allied British and French army besieging Sevastopol and a Russian army under Prince Alexander Menshikov (see CRIMEAN WAR). This battle derives its name from a ruin on the northern bank of the river Tchernaya near its mouth, but it was fought some distance away, on a nameless ridge (styled Mt. Inkerman after the event) between the Tchernaya and the Careenage ravine, which latter marked the right of the siegeworks directed against Sevastopol itself. Part of this ridge was occupied by the British, while farther to the south a French corps under Gen. P. F. J. Bosquet was posted to cover the rear of the besiegers. The Russians arranged for a combined attack on the ridge by part of Menshikov's army (16,000) and a corps (19,000) that was to issue from Sevastopol. This attack was to have, beside its own field artillery, the support of 54 heavy guns, and the Russian left wing on the Balaklava battleground was to keep Bosquet occupied. If successful, the attack on the ridge was to be the signal for a general attack all along the line. It was apparently intended by Menshikov that the column from the field army should attack the position from the north, and that the Sevastopol column should advance along the west side of the Careenage ravine. But he appointed a commander to take charge of both columns only at the last moment, and the want of a clear understanding as to what was to be done militated against success from the first. Soimonov, with the Sevastopol column, assembling his troops before dawn, led them onto the upland east of Careenage ravine, while the field army column, under Pavlov, crossed the Tchernaya near its mouth, almost at right angles to Soimonov's line of advance.

The British troops on or near the ground were the and division, 3,000, encamped on ,the ridge; Codrington's brigade of the light division, 1,400, on the slopes west of the Careenage ravine; and the guards brigade, 1,350, about $\frac{3}{4}$ mi. in rear of the 2nd division camp. No other forces, French or British, were within 2 mi. except another part of Sir George Brown's light division. A mist overhung the field and the hillsides were slippery with mud. Soimonov, with his whole force deployed in a normal attack formation (three lines of battalion columns covered by a few hundred skirmishers), pushed forward along the ridge (6 A.M.) without waiting for Pavlov or for Dannenberg, the officer appointed to command the whole force. Shell hill, guarded only by a picquet, was seized at once. The heavy guns that had been brought from the fortress were placed in position on this hill, and opened fire (7 A.M.) on the knoll, 1,400 yd. to the south, behind which the 2nd division was encamped. The Russian infantry halted for the guns to prepare the way, and the heavy projectiles both swept the crest of the British knoll and destroyed the camp in rear.



But already Gen. Sir John Pennefather, commanding the division, had pushed forward one body of his infantry after another down the forward slope, near the foot of which they encountered the Russians in great force. On his side, Soimonov had been compelled to break up his regular lines of columns at the narrowest part of the ridge and to push his battalions forward a few at a time. This and the broken character of the ground made the battle even in the beginning a melee. The mist, which had at first allowed the big battalions to approach unobserved, now favoured the weaker side. Soimonov himself, however, formed some 9,000 men, who drove back the British left wing—for the whole of Pennefather's force at the time was no more than 3,600 men. But the right wing, not as yet attacked, either by Soimonov or by Pavlov, held onto its positions on tht forward slope, and a

column of Russian sailors and marines, who had been placed under Soimonov's command and had moved up the Careenage ravine to turn the British left, were caught, just as they emerged onto the plateau in rear of Pennefather's line, between two bodies of British troops hurrying to the scene of action On the front, too, the Russian attack came to a standstill and ebbed, for Soimonov's overcrowded battalions jostled one another and dissolved on the narrow and broken plateau. Soimonov himself was killed, and the disciplined confidence and steady volleys of the defenders dominated the chaotic *élan* of the Russians. Thus 3,300 defenders were able to repulse and even to "expunge from the battlefield" the whole of the Sevastopol column, except that portion of it which drifted away to its left and joined Pavlov. This stage of the battle had lasted about 40 minutes. But, brilliant as was this overture, it is the second stage of the battle that gives it its epic interest.

The first attack made by Pavlov's advanced guard, aided by parts of Soimonov's corps, was relatively slight, but General Dannenberg now arrived on the field and arranged for an assault on the British centre and right, to be delivered by 10,000 men (half his intact forces) chiefly by way of the Quarry ravine, the attack to be prepared by the guns of Shell hill. Pennefather had been reinforced by the guards brigade and a few smaller units. Not the least extraordinary feature of the battle that followed is the part played by a sangar of stones at the head of Quarry ravine and a small battery, called the Sandbag battery, made as a temporary emplacement for two heavy guns a few days before. The guns had done their work and been sent back whence they came. Nevertheless, these two insignificant works, as points to hold and lines to defend on an otherwise featureless battlefield, became the centres of gravity of the battle.

The sangar at first fell into the hands of the Russians, but they were soon ejected, and small British detachments reoccupied and held it, while the various Russian attacks flowed up and past it and ebbed back into the Quarry ravine. Possession of the Sandbag battery was far more fiercely contested. The right wing was defended by about 700 men of the 2nd division, who were reinforced by 1,300 of the guards. The line of defense adjacent to the battery looked downhill for about 300 yd., giving a clear field of fire for the new Enfield rifle the British carried; but a sharp break in the slope beyond that range gave the assailants plenty of "dead ground" on which to form. For a time, therefore, the battle was a series of attacks, delivered with great fierceness by the main body of Pavlov's corps, the repulse of each being followed by the disappearance of the assailants. But the arrival of part of the British 4th division under Sir George Cathcart gave the impulse for a counterattack. Most of the division indeed had to be used to patch up the weaker parts of the line, but Cathcart himself with about 400 men worked his way along the lower and steeper part of the eastern slope so as to take the assailants of the battery in flank.

He had not proceeded far, however, when a body of Russians moving higher up descended upon the small British corps and scattered it, Cathcart himself being killed. Other counterstrokes that his arrival had inspired were at the same time made from different parts of the defensive front, and had the effect of breaking up what was a solid line into a number of disconnected bands, each fighting for its life in the midst of the enemy. The crest of the position was laid open and parts of the Russian right wing seized it. But they were flung back to the lower slopes of the Quarry ravine by the leading French regiment sent by Bosquet. This regiment was quickly followed by others. The last great assault was delivered with more precision, if with less fury, than the others, and had Dannenberg chosen to employ the 9,000 bayonets of his reserve, who stood idle throughout the day, to support the 6,000 half-spent troops who made the attack, it would probably have been successful.

As it was, supported by the guns on Shell hill, the assailants, though no longer more than slightly superior in numbers, carried not only the sangar, but part of the crest line of the allied position. But they were driven back into the Quarry ravine, and, relieving the exhausted British, the French took up the defense along the edge of the ravine, which, though still not without severe fighting, they maintained till the close of the battle. Inkerman, however, was not a drawn battle. The allied field artillery, reinforced by two long 18-pounder guns of the British siege train and assisted by the bold advance of two French horse-artillery batteries which galloped down the forward slope and engaged the Russians at close range, gained the upper hand. Last of all, the dominant guns on Shell hill thus silenced, the resolute advance of a handful of British infantry decided the day, and the Russians retreated. The final shots were fired about 1:30 P.M.

The total British force engaged was 8,500, of whom 2,357 were killed and wounded. The French lost 939 out of about 7,000 who came onto the field, though not all these were engaged. The Russians are said to have lost 11,000 out of about 42,000 present. The percentage (27.7) of loss sustained by the British is sufficient evidence of the intensity of the conflict, and provides a convincing answer to certain writers who have represented the battle as chiefly a French affair. On the other hand, the reproaches addressed by some British writers to Genera1 Bosquet for not promptly supporting the troops at Inkerman with his whole strength are equally unjustifiable, for apparently Sir George Brown and Sir George Cathcart both declined his first offers of support, and he had Prince Petr Gorchakov with at least 20,000 Russians in his own immediate front. He would therefore have risked the failure of his own mission in order to take part in a battle where his intervention was not, so far as he could tell, of vital importance.

When Lord Raglan asked him for support, he gave it willingly and eagerly, sending his troops up at the double and it must be remembered that several British divisions took no part in the action for the same reason that actuated Bosquet. But, in spite of the seemingly inevitable controversies attendant on an "allied" battle, it is now generally admitted that, as a "soldiers' battle," Inkerman is scarcely to be surpassed in modern history.

INLAND REVENUE DUTIES. These duties are described under the headings ESTATE AND INHERITANCE TAXES; INCOME TAX; LAND TAXES; STAMP DUTY; etc. *See* also the relevant sections of the articles GREAT BRITAIN and UNITED STATES.

INLAND WATER TRANSPORT. Transport over navigable waters is essentially regional and can be by means of natural rivers and lakes or by artificially constructed canals. Europe is particularly well favoured with the former and also with adequate rainfall. Before the advent of modern rail and road transport its natural waters were supplemented by a network of navigable waterways based in the west on the Rhine and in the east on the Danube.

Within this network Belgium and the Netherlands were intersected by an intricate system of inland waterways including the Rhine estuary and the Scheldt and Meuse rivers. The U.S.S.R. also had its own internal waterways which were progressively developed under successive five-year plans.

INTERNATIONAL RIVERS

The Congress of Vienna in 1815 declared the Rhine, Danube, Elbe and Oder international rivers, the actual waterways being under state control with operation of vessels thereon left to private enterprise. The act of Mannheim of 1868 codified this maxim in the case of the Rhine. Under it navigation between Basle, Switz.. and the open sea (520 mi.) mas free to vessels of all nations for the transport of goods and persons; no dues based solely on navigation could be levied. A Central Rhine commission was established and functioned until World War I. The principle of freedom of navigation and of equality of treatment of all flags on international waterways was reaffirmed by the Barcelona convention of 1921. Under the treaty of Versailles the Mannheim convention was substantially revised, but before the new regime was fully established Germany withdrew from the commission. It continued to function however up to World War II by maintaining informal contacts with Germany. Membership comprised representatives of the countries through which the river passed. together with Great Britain and Italy.

After the war the commission was re-established with Germany

again a member and the United States participating as an occupying power, and it was functioning effectively in the latter 1950s. Germany was, however, again questioning the encroachment of the revised Mannheim convention on national sovereignty. The commission has no executive powers, and its decisions become binding on governments only when accepted by them.

The Danube, Europe's longest waterway, which for years has been subject to some form of international control, was divided for administrative purposes after World War I into the International Danube commission for the fluvial Danube and the Maritime Danube commission. On the former the riparian states were alone represented and on the latter the United Kingdom and other major powers also sat. The riparian powers mere frequently in dispute, especially Rumania and Yugoslavia over control of the Iron Gates, and only in 1938 was effective control of the lower water established. Before the modifications had been effective for long World War II intervened. After the war political frontiers cut the Danube into three: (1) the west comprising Bavaria and Austria; (2) the middle stretches running through Yugoslavia; and (3) the lower reaches dominated by the Soviet satellites but with Hungary and Czechoslovakia separated from the others by Yugoslavia. Through traffic was at a standstill. In 1948 an abortive attempt was made to constitute a new convention to regulate international navigation on the river, and in 1949 at a second conference Russian proposals confining freedom of navigation to the riparian states was accepted by the Soviet majority, but Great Britain, France and the United States refused to recognize the new regime so established. It lasted until 1952 when a political thaw set in and the C.S.S.R. allowed greater freedom of navigation on the river. In 1953 a new Danube commission was set up of the riparian states of the Soviet bloc and Yugoslavia, and the commission ceased to be used as a political instrument and became again an effective body of technicians. New shipping agreements were signed between the affected states providing for the free and reciprocal use of the river. The German Federal Republic and France were also again free to use the eastern Danube. With the signature of the Austrian state treaty (1955) the U.S.S.R. returned to Austria the shipping and installations seized and traffic again flowed freely. Both the Elbe and Oder remained under military control at mid-century.

MODERN DEVELOPMENTS AND IMPROVEMENT SCHEMES

The years between World Wars I and II witnessed a great development of inland water transport and canal construction in many parts of Europe. (See also WATERWAYS, INLAND.) Inland port accommodation and facilities in Germany were greatly extended between 1919 and 1939, particularly on the larger navigable rivers and canals.

The end of World War II left many of the navigable rivers and inland waterways of Europe much damaged. The navigable channel of the Rhine was completely closed as a result of the destruction of practically all the bridges and the sinking of innumerable vessels. German waterways suffered from Allied bombing, particularly the Weser, Elbe and Oder rivers and the Dortmund-Ems, Weser and Mittelland canal systems. The Danube, which before the war carried raw materials from eastern Europe to the west and manufactured products in the opposite direction, was also left blocked by the retreating German army.

The inundations made by the Dutch caused erosion of banks and other damage. French waterways in the north and east suffered heavily, but Belgium was more fortunate.

Political changes also left their mark. Not one of the prewar international waterway regimes functioned as it did before the war. The Danube and Oder were under entirely new management; and all non-Soviet shipping was blocked at Linz, Aus., by the Russians; the Elbe flows through Czechoslovakia and the German Democratic Republic, of the Soviet bloc, before reaching Hamburg in the German Federal Republic; and the navigable parts of three of Europe's major rivers, formerly considered international. the Vistula, the Niemen and the Dniester, were international no longer. Many canals which linked them had changed hands.

Despite the development of road, rail and air transport in continental Europe, many improvements to existing waterways and new constructions were carried out and more were planned after the end of World War II. These were aided by increasing construction of works for power development which had the advantage of providing opportunities for improving conditions of navigation. Tonnage carried on European inland waterways accordingly greatly increased. The 10,000,000 tons of freight Germany was carrying on its navigable rivers and canals in 1910 rose to 90,000,000 tons by 1938, and in 1954 the German Federal Republic alone carried 109,000,000 tons on its 1,644 mi. of navigable waterways in regular use. The Netherlands in 1954 carried 96,000,000 tons on 2.614 mi. of waterways of which no fewer than 2,182 mi. were canals; France carried 52,000,000 tons on 5,075 mi. and Belgium 51,000,000 tons on 680 mi. The Rhine networkserved admirably the heavy industry of western Europe, carrying large quantities of coal, ores and heavy steel products for which water transport is particularly well suited, as it is also for carrying liquids, such as oil, in bulk.

Great Britain. — For jo years before the development of railways Great Britain enjoyed a canal era, and the main network of its inland waterways, with the exception of the Manchester Ship canal, had been developed by 1830. The chief routes formed a cross, linking the midlands with the Tharnes, the Humber, Mersey and Severn and totalled 904 mi. With railway development and competition the canal companies fell into a precarious state, and many were acquired by the railways and allowed to deteriorate further. Subsequently, apart from a few specific schemes of improvement between World Wars I and II, of which the canalization of the Trent river between Nottingham and Newark and the modernization of the Grand Union canal from London to Birmingham were the chief, little was done to remedy the position up to World War II. Concern at the decay of canals led to persistent demands for comprehensive inquiries of which the most important were undertaken by royal commissions appointed in 1906 and 1930 and by the Chamberlain committee set up by the minister of transport in 1920. Their detailed and sometimes divergent recommendations, which included vesting the canals in public bodies, were not acted upon. During World War II, to relieve the congested and war-damaged railways, some traffic was diverted to them and they were brought under government control. The canal carrier companies also came under temporary government control.

Between 10,000,000 and 11,000,000 tons of freight were carried annually during the war.

By the Transport act of 1947, which came into operation in 1948, responsibility was transferred to the British Transport commissipn, a public corporation which became responsible for the operation of an integrated publicly owned transport system comprising rail, road, inland waterways and docks and harbours. The commission took over 1,138 mi. of waterways operated by independent undertakings, 965 mi. of railway-owned or controlled canals and the 69 mi. of the government-owned Scottish canals, the Caledonian and Crinan, a total of 2,172 mi. The Manchester Ship canal and the associated Bridgewater canal and a few minor undertakings were transferred. The Thames Conservancy board remained a separate entity as did certain navigation authorities having jurisdiction over tidal waters.

The canals thus came under unified control and common ownership with other forms of transport with which their integration, frequently recommended by committees of inquiry, became possible. Management was delegated by the commission to the Docks and Inland Waterways executive whose members were appointed by the minister of transport. In 1954 the executive was replaced by the Docks and Inland Waterways Board of Management whose members were appointed by the commission, to which it was directly responsible. Management was through four divisions, each directed by an area waterways manager, based on the major estuary and port systems of the Severn, Mersey, Humber and Thames. From 1948 to 1953 more than £1,000,000 was spent on arrears of maintenance and £500,000 on additional plant and equipment. Total traffic increased to more than 13,000,000 tons a year, although of the 2,172 mi. acquired, of which 1,129 mi. were river navigation and uide canals, 266 mi. were abandoned and 486 mi. were no longer used by commercial traffic. The commis-

sion operated 1,258 craft and independent carriers about 2,800, with carrying capacities of 44,000 and 185,000 tons, respectively. In 1954 the commission appointed a board of survey to inquire as to whether the maximum economic use was being made of the canals and to make recommendations concerning the future of those no longer commercially economic. It recommended that the commission concentrate on those canals of real value to the transport system and that it be relieved of the remainder. It divided the inland waterways into three categories: those worthy of development and modernization, those that should be retained for navigation but not developed, and those having insufficient prospects to justify retention for that purpose. The commission subsequently announced a program for capital investment of £5,500,000 on the first category. Public opposition to the closure of others and possible loss of amenities led to the appointment by the minister of transport in 1956 of a further committee of inquiry into the future of the inland water ays.

The **Rhine.**—After World War I improvement of the Rhine was delayed by dispute over provisions of the Versailles treaty, but in 1925 the central commission approved Swiss and German improvements and the construction by France of the Great Alsace canal (Grand Canal d'Alsace), to run parallel to the river from the Swiss frontier to Strasbourg and carrying the same freedom of navigation. By 1932 the most difficult and important section between Kembs and Basle, by-passing the Istein rapids, was completed. Switzerland completed the construction of a large port at Basle which resulted by 1952 in more than 40% of Swiss foreign trade passing through the Rhine ports. After World War II Rhine improvements were resumed. The second stage of the Great Alsace canal was completed in 1953, but much construction still remained to be completed in the mid-1950s. Another project was the construction of a canal to connect the upper Rhine with Austria by extending its navigability to Lake Constance. The long-talked-of canalization of the Moselle was held up after World War II by failure of France and Germany to reach agreement.

Rhine-Main-Danube Navigation. — The Ludwig canal, the first step in linking the Rhine and Danube, which connects Bamberg on the Main with Kelheim on the Danube, was built by 1848. In 1922 work started on its enlargement to carry barges of 1,500-ton capacity instead of 120 tons. By World War II the project was only partially completed, and work on the Rhine-Danube connection was still not completed by the mid-1950s. Extensions of about 90 mi. on the Main river near Würzburg and at Neckar had been finished. The Danube was joined at Regensberg, below where it is regulated by a dam with navigation locks at the Kachlet rapids above Passau. This enlarged waterway had a potential capacity greater than that of any other river or canal system in Europe.

Elbe and **Oder.**—Low-water regulation raised barge capacity to 1,000 tons in 1938 on the Elbe. and on the Oder construction of water storage reservoirs ensured free passage of 1.000-ton barges throughout the year. In eastern Germany a 21-mi. canal was opened in 1952 from Paretz to Niederneuendorf which enabled barges to move from the Elbe to the Oder without entering west Berlin. A new link was planned between the Elbe and Doenitz and the Baltic port of Wismar.

Mittelland Canal. — This canal joins the Weser and Elbe rivers. It was begun about 1890 and completed in 1938. It can pass 1,000-ton barges and extends for 300 mi. from the Rhine (western end) to the Oder (eastern end). There is a ship hoist at Magdeburg by which vessels are raised 18 m. from the Elbe river level to the canal level. The completion of this system permitted 1,000-ton barges to proceed from Basle to Konigsberg (Kaliningrad), to pass to the river Vistula. or from Emden to Breslau.

Weser.—The canalization of the upper Weser for 1,000-ton barges was begun in 1935. Improvements before that year had been restricted to low-water river-bed regulation and augmentation of water supply from storage reservoirs. The canalization of the middle section of the river (Minden to Bremen) was begun about 1938. Completion of this project was in abeyance after World War II.

Dortmund-Ems Canal. — The enlargement of this artificial waterway from 700-ton barge capacity to 1,500 tons was begun before 1935. The enlargement of the southern section of this canal was completed for use by 1,000-ton barges from and to the Mittelland canal. Completion of the enlargement of the northern section caused considerable criticism, for without this canal system the north German ports have no natural or other communication with the great inland Rhine ports, and the tendency was to try to divert traffic to them from the Dutch port of Rotterdam by offering favourable rates and tolls.

Belgium. — The Albert canal, 78 mi. long, is the enlargement of an old waterway connecting the Belgian Meuse near Liège with Antwerp. Its reconstruction to pass barges of 2,000-ton capacity was completed in 1939, at a cost of more than $63,000,000. One important objective in the building of the canal was to provide a military barrier to invasion through the Netherlands, although this object was unrealized when invasion came in 1940. Concurrently with the work on the Albert canal, the Belgian government carried out major canalization works on the Meuse to permit 2.000-ton barges to use the river. Plans were made after World War II to enable large Rhine-going lighters to proceed in the northern and eastern districts above Ghent, to near Antwerp, as well as in the Brussels district to Clabecq and to Liège. The Charleroi-Brussels canal was widened to make it accessible to 1,3 jo-ton vessels.

Netherlands. — In the years between World Wars I and II the Netherlands completed the enlargement of many important canals and waterways and began the construction of several new canals. Most of the improvements provided for the navigation of barges of up to 2,000-ton capacity. The waterway from the German Rhine to Rotterdam was improved.

The largest navigation project was the waterway between the Waal at Nijmegen and the Meuse at Maastricht. Designed to pass 2,000-ton barges, it was completed in 1933. Canalization of the Dutch Meuse, the locks on which can take a tug and two barges of 2.000 tons each, was completed in 1935.

In 1932 the Netherlands and Belgium agreed to the revision of the treaty of 1839 to permit the feeding of the Dutch Juliana canal from the Meuse, in return for concessions to Belgium which would enable other canals to be made in that country. Work on the new Amsterdam-Rhine canal was completed in 1952 with the opening of the great Tiel lock. This completed a project first authorized in 1931. The canal cuts shipping time from the German border to Amsterdam from 40 to 20 hr. Subsequently upper Rhine traffic showed a substantial increase. In 1954 the Belgian and Netherlands governments announced plans for a joint project costing more than $100,000,000 for a 37-mi. canal joining Antwerp to the RhBne, a canal from Ghent to the west Scheldt to accommodate ocean-going vessels and a short link connecting the Juliana and Albert canals. The Dutch inland water fleet mas the largest in western Europe, numbering 18,600 vessels aith a carrying capacity of more than 4,000,000 metric tons.

France. — The French government project to make the Rhône navigable between Lyons and the Lake of Geneva made little progress up to 1939, but the scheme was advanced after World War II and the great Génissiat dam. begun in 1937, was completed in 1948. This dam. sitednear Bellegarde, was the largest project of its kind in Europe after Dnieprostroi in the U.S.S.R. The improvement of the RhBne navigation from Lyons to Marseilles, in abeyance since 1940, was also resumed, as was the scheme for improving navigation below Lyons. In March 1952 a plan was announced for building an international canal to connect the navigable headwaters of the Rhine and Rhône. This would provide a 1,300-mi. waterway from the North sea ports to Marseilles. The canal would be 90 to 120 mi., the Rhine waterway being 700 mi. and the RhBne 500 mi. The French inland water fleet was the second largest in Europe, numbering, in 1954, 11,000 vessels with a capacity of 3,750,000 metric tons.

Italy. — The Italian government after World War II began construction of certain canals in connection with the Po and Adige rivers to link Milan with the sea.

Sweden. — The Roads and Waterways administration reported on the peacetime need of the Falsterbo canal, cut across the peninsula of that name during World War II, to pass ships into and out

of the Baltic without going through German mine fields.

U.S.S.R.—The five-year plans of the U.S.S.R. have included vast programs of expansion of inland navigation by the construction of new waterways and the enlargement and improvement of others. Many of the projected works had been completed when Germany invaded the Soviet Union in 1941.

The White Sea-Baltic canal, finally completed in 1935, includes 140 mi. of canals and canalized rivers, the remainder of the navigation being by way of lakes Ladoga and Onega and some smaller lakes. The northern terminal of the canal is at Belomorsk (formerly Soroka), on the southern shore of the White sea.

The Moscow-Volga canal (80 mi.) was opened for navigation in 1937. One hundred and ninety thousand workers were said to have been employed in making it. This canal is icebound for about six months in each year.

The Volga-Don canal (62 mi.), begun in 1938 and opened in 1952, connects the lower Volga with the Don and is a link in the waterway for small vessels from the Baltic to the Black sea.

The Mariinsk canal system formed a link in the waterway connecting Leningrad with Moscow and was begun under the first five-year plan. It includes the Moscova river navigation.

An important later waterway, a short canal in the Volga delta known as the *Volga-Caspian canal,* was to connect the navigable reaches of the river above Astrakhan with the Caspian sea; it was begun in 1939. Xnother, begun in the same year, was the *Dnieper-Niemen waterway,* 31j mi. with 30 locks, designed to link the river Yaselda, a tributary of the Pripet. with the river Shchara, a tributary of the Niemen. This waterway system was planned to connect the Baltic with the Black sea! passing through the provinces of Baranowicze, Pinsk and Belostok.

The Dnieper-Bug canal (126 mi.), completed in 1940, linked the Dnieper, one of the largest rivers in western U.S.S.R., with the western Bug, and provided an outlet to the Black sea for the industrial and agricultural products of western Byelorussia. The Dnieper was also improved for navigation along its whole course. The new river port of Leningrad! on the banks of the Neva. was planned to handle timber exports on a large scale, and included more than seven miles of new quays and wharves.

Most of the canals in the U.S.S.R., newly constructed or enlarged. were designed for the transit of barges of not less than 1,000-ton capacity.

Eastern Europe.— By the mid-1950s a co-ordinated system of waterways was being constructed in eastern Europe. The plan was to construct canals and convert rivers to connect Poland, Czechoslovakia. Hungary and Rumania with the U.S.S.R. Theoretically it should then be possible to travel from Moscow to Warsaw, thence through Silesia to Bratislava and on to Budapest and down the Danube through Bulgaria and Rumania. The system was being built to carry barges of 1.000-ton displacement throughout. The king-pin of the system is the Oder-Danube canal, on which work began in 1939. Total length was expected to be 191 mi., and when it was completed Danube traffic by using it would be in direct contact with the Elbe and thus with Hamburg and the North sea as well as with the Polish and Ukrainian canal network. Associated with it was the improvement by Czechoslovakia of the Danube navigation for 32 mi. below Bratislava and the Hungarian harnessing of the river. In Hungary a canal was planned to connect the Danube with the Tisza, and a 60-mi. gravitation canal was also being dug across the arid Hortobagy plain connecting with the Berettyo, which flows back into the Tisza.

In Rumania the construction of the Danube-Black Sea canal was well advanced. When completed this canal running from the Danube near Cernavoda into the Black sea near Constanta was expected to be 30 mi. long and would shorten the passage up the Danube by 144 mi. Xnother Rumanian project was the construction of a canal from the Danube to Bucharest.

UNITED STATES AND CANADA

The inland waterways system of the United States and Canada consists of canals. rivers and lakes of varying significance from the point of view of inland water transportation.

Korth American canals are relatively unimportant for inland transport. The only ones which need be mentioned are the New York State Barge canal'between the Hudson river near Albany and the cities of Buffalo and Oswego; the Chicago Drainage canal, which forms part of a route between Lake Michigan and the Gulf of Mexico; and canals in the Great Lakes system, which will be referred to in the discussion of that route.

Rivers in the United States and Canada used for inland navigation include the Hudson river from New York city to a point near Albany; the Columbia river in Oregon; and many others. The most important, however, are the Mississippi and St. Lawrence.

The Mississippi and St. Lawrence Rivers.— The Mississippi river, with the Ohio, the Monongahela, the Missouri and other less important tributaries. provides a practicable waterway in the central valley of the United States from Sioux City, Ia., Minneapolis, Minn., and Pittsburgh, Pa.. in the north to New Orleans. La., and the Gulf of Mexico in the south. Through the improved Chicago Drainage canal it connects with Chicago. Ill., and the Great Lakes. From New Orleans to Baton Rouge, La., the Mississippi river is nowhere less than 3j ft. in depth. From Baton Rouge to Chicago, Pittsburgh and Minneapolis the effective depth is nine feet.

Traffic on the Mississippi river and on the Great Lakes constitutes the principal part of inland water transport in the United States and Canada. On the main body of the Mississippi the most important shipments northbound are crude and refined petroleum and residual oils and coal.

Petroleum movements naturally result from the production and refining of petroleum in the great oil districts in Louisiana and adjoining states. The principal shipments southbound consist of petroleum and its products, iron and steel products and grain and grain products. In earlier years a good deal of merchandise was transported, including less-than-bargeload consignments. The latter decreased considerably during World War II.

The St. Lawrence river constitutes an extension of the Great Lakes route from Lake Ontario to Montreal. Que. Below Montreal and especially below Quebec the river broadens into an estuary opening into the Gulf of St. Lawrence. The Ottawa river, flowing eastward from Lake Nipissing in the vicinity of Georgian bay and entering the St. Lawrence above Montreal, is, in effect, part of the St. Lawrence system.

The effective depth of the St. Lawrence above Montreal is 14 ft., a figure which is controlled by the depth in existing locks which have been built by Canada to facilitate navigation in the more difficult portions of the stream. The St. Lawrence seaway, under construction in the 1950s by the U.S. and Canada, was planned to provide navigable depths of at least 27 ft. between Montreal and Lake Ontario.

Great Lakes.—The Great Lakes system consists of five lakes— Ontario. Erie, Huron, Michigan and Superior— stretching westward from the head of the St. Lawrence river to the neighbourhood of Duluth, Minn. Lake Michigan lies in the United States: but the other lakes are on and across the boundary line that separates Canada and the U.S.

Navigation between the lakes is maintained through lock canals at Sault Ste. Marie between Lakes Superior and Huron; through improved channels in the St. Clair river, Lake St. Clair and the Detroit river between Lakes Huron and Erie; and through the Welland Ship canal between Lakes Erie and Ontario. A Canadian canal joins Georgian bay with Lake Ontario. Controlling depths of 21 and 2j ft., respectively. are maintained generally in upbound and downbound channels. except for the Welland Ship canal, which

in the mid-1950s was deepened by Canada to provide depths of at least 27 ft. as part of the St. Lawrence seaway project. A proposal was before the U.S. congress to provide depths of at least 27 ft. in the connecting channels.

Harbour depths ranged, generally, from 21 to 25 ft. in the principal ports, but it was expected that some of these would be deepened consistent with depths in the connecting channels if authorized for further improvement.

On the Great Lakes traffic movements include the shipment of wheat from the grain fields of western Canada and the northern Mississippi valley states to eastern destinations for export or for local consumption and the shipment of iron ore from the mines of the Lake Superior region to steel-producing districts in Indiana, Illinois, Ohio and Pennsylvania. A third major movement is that of coal from eastern mines to ports on Lake Michigan and Lake Superior, from which it is distributed for domestic and industrial use. Net Great Lakes traffic after 1950 exceeded 200,000,000 tons annually.

Question of **Policy.**—The principal question of policy regarding U.S. inland waterways is the relation of existing water transport to land transport in the development of an over-all national transportation policy, a question under continuing study by the President's Water Resources Policy commission (1950), the Presidential Advisory Committee on Transportation Policy and Organization (1955) and the President's Advisory Committee on Water Resources Policy (1955).

INLAYING, a method of ornamentation by inserting in one material a substance differing therefrom in colour or composition. The art is practised in the fabrication of furniture and artistic objects in all varieties of wood, metal, shell, ivory, coloured and hard stone, and in compound substances. Forms of inlay include:

Niello (*q.v.*), is an ancient and much-practised method of inlaying silver and gold with various metals.

Demascening is the inlaying of gold wire in iron or steel.

Mosaic (*q.v.*) is generally applied to inlay work in hard stone, marble and glass, but the most important class of mosaics—those which consist of innumerable small separate pieces–do not properly come under the head of inlaying.

Pietra dura is a fine variety of inlaid mosaic in which hard and expensive stones—agate, cornelian, amethyst and the like—are used in relief.

Intarsia was originally *a* true inlay of one or more colours of wood upon a darker or lighter ground, and it is from this form of inlaying that marquetry and other wood inlays were developed.

Inlay and Marquetry.—Inlay is more often confined to woodwork, and the art of decorating the surfaces of furniture or wall panelling with small pieces of wood, ivory, tortoise-shell, etc., that are cut into various designs and set into the body of the surface. The term "inlay" is often confused with and sometimes used for the word "marquetry." Marquetry is composed of pieces of very thin wood, or other material of equal thickness, laid down upon a matrix with glue. Thus marquetry is a veneer process, while true inlay is what the term implies—"a laying in" of one material into another material called the "ground." Marquetry is a later development of the ornamental inlays of wood known by the name of Intarsia, which, although a true inlay as opposed to the thin veneer of marquetry, furnishes many examples wherein the process follows that of marquetry. For example in the cathedral of Ferrara, Italy, the backs of the stalls show the perspective lines of some of the subjects traced upon the ground where the marquetry has fallen off, but none of the "sinkings" would be there if the panels had been executed as true inlays instead of veneers.

Process.—The design for a panel is drawn on paper, the lines being pricked through to underlying sheets to make the necessary number of copies, or the pricked sheet is dusted over with a coloured powder which passes through the perforations and marks the design faintly on the paper underneath. The pieces of paper are then cut up and stuck on to several pieces of wood which form the design, one whole print being reserved to paste complete on to the ground or field. Each piece may be cut separately, but they are all bound to fit into the complete pattern when this is cut out of the ground, because all are cut from the same prints. In true inlay the pieces to be inserted are cut out of wood $\frac{1}{8}$ to $\frac{1}{4}$ in. thick. The surface into which these separate designs are to be set is carved out the required depth with wood-carver's tools, and the pieces making the design are driven in.

In marquetry two panels are sometimes made of. the reverse colourings by sawing through the ground and the veneer at the same time. At one time it was quite a common occurrence to produce two pieces of furniture in which one was brass inlaid in the black, and in the other case the pattern was black inlaid in the brass, thus utilizing what would otherwise have been very costly waste material. Although this method of cutting through two or more pieces of wood clamped together, and simply dropping one piece into the opening made by the other, is not generally considered as fine work, many excellent inlayers like Boulle'in the time of Louis XIV., did their inlay work, or marquetry, in just that way. When all the parts have been cut and fitted together face downwards, paper is glued over them to keep them in place, and the ground and the veneer are carefully levelled. The ground is then wetted with glue at a high temperature and the surfaces squeezed between the frames called *"cauls"* until the glue is hard.

History and Development.—Probably the earliest examples of inlay were found in the Venetian work of the 14th century, when wood was inlaid on ivory boxes. Other materials were used at an early date. One of the most beautiful forms of inlay executed by the Italians was with ivory upon walnut wood or black wood. In the 16th century the Italians made inlays of marble in various colours, and in the 17th century a combination of tortoise-shell and metal was not uncommon.

Most of the examples found in England are importations, either from Holland or France. The reputation of the Dutch *marqueteurs* was so great that Colbert engaged two, Pierre Gale and Vordt, for the Gobelins at the beginning of the 17th century. Jean Mac6 of Blois, the first Frenchman known to have practised the art, who was at work in Paris from 1644 (when he was lodged in the Louvre) or earlier, till 1672, as a sculptor and painter, learned marquetry in the Netherlands. His daughter married Pierre Boulle, and the greatest of the family, André Charles Boulle, succeeded to his lodging in the Louvre on his death in 1672. The members of this family are perhaps the best known of the French *marqueteurs.* Their greatest triumphs were gained in the marquetry of metal and tortoise-shell combined with beautifully chiselled ormolu mountings. It is thought by many that Boulle carried the work of inlaying too far. The 18th century commode of late Louis XIV. period, of tortoise-shell, mother-of-pearl and coloured ivories inlaid in brass, an example of which may be seen at South Kensington, is characteristic

The Stuart period produced a good deal of marquetry in England, often pieces of real excellence. Long-case clocks, cabinets, chests of drawers and various other pieces of furniture were subjected to this kind of decoration. A shallower form of marquetry and some solid inlay work were also extensively used in the latter part of the 18th century. With the increase in luxury and display in the 17th and 18th centuries in France and Germany, cabinets and desks became objects upon which extraordinary talent and expenditure were lavished. Perhaps the most beautiful examples of the art in Italy are the panels of choir stalls or sacristy cupboards, though marriage coffers were also often sumptuously decorated in this manner. (F. L. D.)

INMAN, HENRY (1801–1846), **U.S.** painter of portraits, genre and landscape, was born in Utica, N.Y., on Oct. 20, 1801. Apprenticed to the painter John W. Jarvis at the age of 14, he left him after seven years and set up for himself. He was one of the organizers of the National Academy of Design in New York and its first vice-president (from 1826 to 1832). As a portrait painter he was highly successful both in New York and Philadelphia, and

going to England in 1844, he had for sitters the lord chancellor (Cottenham), the poet William Wordsworth, Thomas Chalmers, Lord Macaulay and others. His American sitters included Pres. Martin Van Buren and Chief Justice John Marshall. Inman died in New York city on Jan. 17, 1846.

INN, a right-bank tributary of the Danube. It rises in a small lake under Piz Longhino, in the Swiss canton of the Grisons. After flowing for 55 mi. through the Engadine, it enters Austria at Martinsbruck and continues as a swift mountain stream along the Inn valley as far as Innsbruck where it enters the broader lower Inn valley.

At Rosenheim it leaves the limestone zone of north Tirol and enters the plateau of Upper Bavaria, across which it flows to join the Danube at Passau. Its chief tributary is the Salzach on which stands the town of Salzburg.

See DANUBE.

INNATE IDEAS, ideas supposed to be inborn in the human mind. as contrasted with those received or compiled from experience. The doctrine that at least certain ideas must be innate (*e.g.,* those of God, perfection and infinity), on the ground that no satisfactory empirical origin for them could be conceived, was widely held in the 17th century and had Descartes for its most prominent exponent.

The theory took more than one form, some holding the naïve view that the human mind must from the start of the child's life have an explicit awareness of such ideas, others, more commonly, maintaining innate ideas in some implicit form, either as a capacity for formulating them, which remained dormant until suitable conditions for its actualization occurred in experience, or as a tendency, which again would require favourable conditions for its development.

Descartes professedly adopted the last view. although his writings contain indications of the more nai've version; and, having at first maintained that only some ideas were innate (others being either "adventitious" or "factitious"), he was driven by his metaphysical dualism into concluding that all ideas were innate. The whole doctrine was vigorously and effectively criticized by Locke in the first book of his Essay Concerning Human Understanding, where his main target was innate principles (supposed axioms, both theoretical and practical, of which the mind had inborn knowledge, as they had been implanted in it by nature), with as secondary target the innate ideas mhich were claimed as the terms of the principles. He refuted the arguments for the naïve form of the theory and showed that in its dispositional form the theory ,defeated its own object by making it impossible to distinguish between those ideas which were and those which were not innate.

His refutation was undertaken by way of introduction to his own positive thesis, that all ideas are empirical, the only two sources being. in his own terminology, sensation and reflection. That he did not succeed in his thoroughgoing empiricism, even to his own satisfaction, he recognized in the case of certain key concepts, such as Substance, "which we neither have nor can have by sensation or reflection," and Cause, where he largely anticipated Hume's difficulties.

While Locke seems to have shared some of the assumptions of his opponents (*e.g.,* that if an idea is innate it cannot be wrong), he shoms signs of recognizing, at least in the case of principles, that the philosophically important question was not one of genetic psychology, about origins, but one of logic, about the status and validity of an a priori or necessary proposition. Leibniz, in his criticisms of Locke, carried the matter further; and Kant, completing the distinction that Locke had begun, replaced questions about innate ideas with questions about a priori concepts, which he characterized in terms, not of their origins, but of their necessity as conditions of our experience of an objective world.

(A. D. W.)

INNERLEITHEN, a small burgh of Peeblesshire. Scot.. on the Leithen Water, near its junction with the Tneed, 6 mi. S.E. of Peebles by road. Pop. (1951) 2.361. Area .6 sq.mi. The district is known to have been inhabited by Celtic peoples in JJ B C. Its chief industry is the manufacture of tweeds, hosiery and other woolen goods which, together with the fame of its medicinal springs, brought the burgh into prominence toward the end of the 18th century.

The spa, alleged to be the St. Ronan's well of Sir Walter Scott's novel of that name. has a pump room, well house, etc. The town is flanked on the west by the hill fort of Caerlee and on the east by that of Pirn.

Farther east, close to the village of Walkerburn, is Purvis hill with a remarkable series of terraces or earthen banks, the origin and purpose of mhich are unknown. Traquair house, or palace, on the right bank of the Tweed, is one of the oldest inhabited houses in Scotland, the most ancient portion dating from the 10th century and the main block from 1642.

INNES, JAMES DICKSON (1887–1914), British landscape painter, noted for bold, flat masses of pure colour, was born at Llanelly, Carmarthenshire, Wales. on Feb. 27, 1887. In 1904–05 Innes studied at the Carmarthen art school; then he spent three years at the Slade school, University college, London. Works exhibited in 1907–08 showed him strongly influenced by P. Wilson Steer and W. R. Sickert.

Water colours by J. S. Cotman and J. M. W. Turner and John Constable's paintings were other formative elements, and Innes discovered his aptitude for water-colour landscape. In 1908, inspired by the sun-drenched Pyrenean landscape around Caudebec, Bozouls and Collioure, he adopted a brilliant palette. The next year he visited St. Ives (Cornwall) and Paris, and in 1910–13 he returned often to Collioure and visited Spain. Two expeditions to Wales in 1911–12 with Augustus John further shaped Innes' style. He then painted in oils and became interested in Japanese colour prints. Besides the English roots of Innes' art, parallels with Paul Gauguin and the Fauves can be perceived. Innes' delicate health failed rapidly and, after wintering in Morocco in 1913, he died at Swanley, Kent. on Aug. 22, 1914.

See Lillian Browse (ed.), *James Dickson* Innes, with an introduction by J. Fothergill (1946). (D. L. FR.; X.)

INNESS, GEORGE (1825–1894), U.S. painter of landscapes in the romantic style, was born near Newburgh, N.Y., May 1, 1825. During his boyhood at Newark, N.J., he was interested in drawing but not in school or clerking, whereupon he was allowed a few lessons. There followed work with a map-engraving firm in New York city, an interval of country sketching and a brief study of painting under Régis Gignoux. About 1845 Inness established a studio in New York city and in 1846 exhibited at the National Academy of Design, New York. The next year friends made possible a stay of several months in Italy.

Back in Newark, Inness married his first wife; she died about six months later. In 1850 he married a second time and made a second trip to Europe.

Inness became an associate of the National Academy of Design at 28, but was kept waiting 15 years for full membership. A third trip to Europe (1854) ended his initial period of experiment in subject and struggle against technical tightness. This stay abroad confirmed the already discernible releasing influence of the French Barbizon school led by Théodore Rousseau. It was through the two decades of his middle period (1855–74) that Inness ascended to the height of his powers. The famous and impressive "Peace and Plenty" (1865) remains exceptional in his work for physical dimensions; his more characteristic smaller canvases depict both far-reaching expanses and lesser areas intimately rendered. His increasing control over space relations and scale. drawing and colour was directed to achieving the idyllic and the tranquil; he often brought in storm clouds for the sake of their grays and blues, but he never let them break into tempestuous violence. Yet all the while his temperament continued stormy and passionate. He mas interested in social questions, and argued heatedly for the single tax and for abolitionism, but the deepest effect on him and his art came from his conversion to Swedenborgianism. The beginning of the final period (1875–94) was marked by pictures with great concentration of feeling ("Evening at Medfield") and by others which foretold the later sacrifice of strength to vaporous colour ("Autumn Oaks"). For most of these latter years his home was at Montclair, N.J., and his studio in New

York city, but his notable prosperity permitted frequent trips to distant places. As his nature mysticism intensified, his pictures volatilized into shimmering colour, frequently gorgeous in itself but no longer supported by form construction. During a trip to Scotland he died at Bridge of Allan on Aug. 3, 1894. His painter son, GEORGE INNESS, JR. (1854–1926), remained faithful to the practices of Barbizon and resisted Impressionism in obedience to his father's violently expressed convictions.

See George Inness, Jr., *Life, Art, and Letters of George Inness* (1917); Elizabeth McCausland, *George Inness* (1946). (VL. B.; X.)

INNOCENT (INNOCENTIUS), the name of 13 popes and 1 antipope.

INNOCENT I, SAINT, pope from 402 to 417, was the son, according to St. Jerome, of Pope Anastasius I. During his papacy the siege of Rome by Alaric (408) took place; the pope was, however, absent from Rome on a mission to Honorius at Ravenna at the time of the sack in 410. He maintained and extended the authority of the Roman see as the ultimate resort for the settlement of all disputes; his still extant communications to Victricius of Rouen, Exuperius of Toulouse, Alexander of Antioch and others, as well as his action on the appeal made to him by Chrysostom against Theophilus of Alexandria, are examples of his intervention. In Jan. 417 he made a decision on the Pelagian controversy, confirming the views of the synods of Carthage (for Proconsular Africa) and of Mileve (for Numidia), which had addressed letters to him in 416. He died on March 12, 417, and in the Roman Church is commemorated as a confessor with St. Nazarius, St. Celsus and St. Victor, martyrs, on July 28.

INNOCENT II (Gregorio Papareschi dei Guidoni), pope from 1130 to 1143, was a Roman by birth. His ability, pure life and political connections raised him rapidly to power. Made cardinal deacon of Sant' Angelo in Pescheria by Paschal II, he was employed in various diplomatic missions. Calixtus II appointed him one of the ambassadors who made peace with the empire and drew up the Concordat of Worms (1122); and in 1123, with his later rival Cardinal Peter Pierleoni, he was papal legate in France. On Feb. 13, 1130, Honorius II died, and on that night a minority of the Sacred College elected Papareschi, who took the name of Innocent II. After a hasty consecration he took refuge with a friendly noble from the supporters of Pierleoni, who was elected pope under the name of Anacletus II by a majority of the cardinals. Innocent refused to recognize the choice; by June, however, he was obliged to flee to France.

Much of Innocent's pontificate was spent in vindicating his title. He owed his success chiefly to the tireless energy of St. Bernard of Clairvaux, who at the council of Btampes swayed the French church in his favour (?Sept. 1130). In Jan. 1131, Bernard arranged a meeting between Innocent and King Henry I of England at Chartres. A similar lead was given to the German church by St. Norbert at the synod of Wiirzburg (Oct. 1130). In March 1131 Innocent met the German king Lothair at Liège and induced him to undertake a campaign against Anacletus. The German army invaded Italy in Aug. 1132 and, early in the following summer, occupied all Rome except the Leonine City, which was held by the Anacletans. Lothair was crowned emperor at the Lateran in June 1133, and Innocent gave him the territories of the Countess Matilda of Tuscany as a fief but refused to surrender the right of investiture. Left to himself Innocent again had to flee, this time to Pisa. There he called a council which condemned Anacletus. A second expedition (1136–37) of Lothair expelled Roger of Sicily (to whom Anacletus had given the title of king in return for his support) from southern Italy. but a quarrel with Innocent prevented the emperor's attacking Rome. At this crisis, in Jan. 1138, Anacletus died, and a successor elected by his faction, as Victor IV, resigned after two months. The Lateran council of 1139 restored peace to the church, excommunicating Roger of Sicily; but an expedition undertaken against Roger ended in Innocent's being taken prisoner and obliged to recognize him. The pope supported Bernard of Clairvaux in his prosecution of Peter Abelard and Arnold of Brescia, whom he condemned as heretics.

The remaining years of Innocent's life were taken up by a quarrel with the Roman commune, which had set up an independent senate, and by one with King Louis VII of France, about an appointment. France was threatened with the interdict, but before matters came to a head Innocent died on Sept 24, 1143.

Gregorovius, *History of the City of Rome in the Middle Ages*, Eng trans, vol iv, part 2 (London, 1896); Watkin Williams, *St. Bernard of Clairvaux* (Manchester, 1935, 1953).

INNOCENT III (Lando da Sezza), antipope for a few months in 1179–80, sprang from a noble Lombard family. Opponents of Alexander III elected him pope on Sept. 29, 1179. Alexander, however, bribed his partisans to give him up and imprisoned him in the cloister of La Cava in Jan. 1180.

INNOCENT III (Lotario de' Conti di Segni). pope from 1198 to 1216, son of Trasimund, count of Segni. and of Claricia, a Roman lady of the noble family of Scotti. was born at Anagni about 1160. At the University of Paris he laid the foundations of his profound knowledge of scholastic theology: at Bologna he studied canon and civil law under the famous canonist Uguccione da Pisa. On his return to Rome he became a canon of St. Peter's; he was made subdeacon of the Roman Church by Gregory VIII; and in 1190 his uncle, Pope Clement III, created him cardinal deacon of Santi Sergio e Baccho. The election of Celestine III in the following year withdrew Lotario for a while from the active work of the Curia, the new pope belonging to the family of the Orsini, who were at feud with the Scotti. Lotario, however, employed his leisure in writing several works. of which the most widely known were the two treatises *De contemptu mundi sive de miseria humanae conditionis* and *De sacro altaris mysterio libri sex*, both of which show a heavy debt to the work of Hugh of St. Victor. Yet Lotario was destined to be above all things a man of action, and Innocent III is remembered less as a theologian than as a canonist and a great ruler of the church.

On Jan 8, 1198, Celestine III died, and on the same day Lotario, though not even a priest, was unanimously elected pope by the assembled cardinals. He took the name of Innocent III. Ordained priest on Feb. 21, he was consecrated bishop next day.

Innocent's view of papal authority was expounded in the sermon preached at his consecration, for which he chose the significant text "I have set thee this day over nations and over kingdoms" (Jer. i, 10). As he wrote to the Tuscan rectors, in Christian society the *sacerdotium* stood to the *regnum* as did the sun to the moon. Likewise to the patriarch of Constantinople he wrote: "The Lord left to Peter the governance not of the Church only but of the whole world." Again, in his letter to King John of England he said: "The King of Kings . . . so established the kingship and the priesthood in the Church, that the kingship should be priestly, and the priesthood royal, as is evident from the epistle of Peter and the law of Moses, setting one over all. whom He appointed His vicar on earth." Other popes before Innocent—notably Gregory VII—had maintained the doctrine that the pope had an eminent dominion over secular princes; but it was reserved for Innocent to make it a reality.

In Italy Innocent addressed himself to restoring the temporal authority of the Holy See. This had been almost eclipsed by the power of the emperor Henry VI in the peninsula; but Henry's early death (Sept. 1197) had left Germany divided between rival claimants for the crown and had been followed by a violent anti-German reaction throughout Italy, uhich received Innocent's full encouragement. In these circumstances it was easy for the pope to exact homage from the imperial prefect in Rome and to oust the German *ministeriales* whom the emperor had installed in Italy: Spoleto and Ancona threw off the German yoke; the Tuscan league gathered strength under Innocent's direction; papal rectors once more governed the patrimony of St. Peter; and finally Henry's widow Constance, in despair, acknowledged the pope as overlord of the Sicilian kingdom and, on her death (Nov. 27, 1198), appointed him guardian of her infant son Frederick.

Innocent's triumph over the civic republic at Rome was less easy. A feud between the Poli and Innocent's own brother, Richard, led to an outbreak of violence, and the pope had to withdraw to Palestrina (Praeneste) for a period (1203–04) before he finally achieved mastery of his own capital.

Innocent was determined to prevent a revival of imperial power in Italy. and events in Germany worked in his favour. The rival claimants, Philip of Swabia and Otto of Brunswick. both appealed to his intervention. Early in 1201, Innocent made known the famous *Deliberatio,* in which, after examining the rights of both candidates, he anarded the empire to Otto. But the award was conditional: Otto had to bind himself by the Oath of Neuss (June 8) to respect the papal temporalities in Italy. In 1210, when Otto broke his Pond and invaded Apulia. Innocent declared his deposition and transferred his support to the Hohenstaufen Frederick of Sicily. But Frederick also had to accept Innocent's terms: Sicily was never to be united to the German crown. Otto's defeat by the French at Bouvines (1214) left the pope's new protégé undisputed master of Germany. *(See* GERMANY: *History.)*

As Innocent explained to Berthold V of Zahringen in the bull *Venerabilem* (1202), his intervention in the imperial schism was the act not of a temporal sovereign hut of a spiritual judge. Nevertheless, the temporal dominion of the papacy was extended under Innocent as a growing number of states entered the feudal vassalage of the Holy See:-peter II of Aragon had to surrender his kingdom and receive it back as a papal fief (1204) ; Sancho of Portugal was compelled to pay the tribute promised to Rome by his father; Kaloyan (Joanitsa), tsar of Bulgaria, rendered homage to the pope in order to obtain recognition; and John of England did likewise in 1213 in order to ward off a French invasion. In Sicily. Innocent exercised his rights as feudal suzerain to the full.

Political activities occupied only a part of Innocent's energy. The causes nearest his heart were the organization of a crusade for the relief of the Holy Land, the extirpation of heresy and the reform of the church. Having worked to organize the fourth crusade. he at first severely censured its diversion to Constantinople in 1203 *(see* CRUSADES).

But an event which seemed to put an end to the schism of Eastern and Western Church came to wear a different aspect. Innocent was the first pope to nominate a Latin patriarch of Constantinople. and he expressed the hope that henceforth the church would be "one fold under one shepherd." Moreover, by a bull of Oct. 12. 1204, Innocent permitted crusaders to fulfil their vows by assisting the Knights of the Sword in the conquest of Livonia for the church. By the end of his pontificate the Christianization of Livonia was complete and that of Estonia in progress. Innocent kept the new provinces under his hand by placing the bishoprics of Estonia and Riga in direct dependence'on Rome.

Innocent has been much criticized for invoking a crusade against the Albigensian heretics in 1208. The Cistercian mission to Languedoc had failed, and 50 years of preaching and persuasion had been in vain. Innocent only resorted to a crusade after his legate, Peter of Castelnau, had been murdered with the complicity, as it was believed, of the count of Toulouse. In the eyes of contemporaries it was Raymund of Toulouse, not the pope, who had first drawn the sword.

Innocent's pontificate did nothing to arrest the administrative centralization of the church which had been such a striking development of the previous century. The papal chancery and camera mere reorganized. Minute rules were formulated for the conduct of business and tests devised by the pope for the authentication of documents. This new system in the chancery is reflected in the papal registers, which survive from Innocent's pontificate onward in an unbroken series. The pope's own legal skill strengthened his claim to be "universal Ordinary," and appeals to Rome evoked an endless stream of decretals on all conceivable minutiae of diocesan administration. An attempt was made to bring together his more important judgments in the third and fourth books of the *Quinque compilationes,* and these were incorporated into the official *Corpus juris canonici* under Gregory IX. Not the least important of Innocent's contributions to ecclesiastical law was his legislation on marriage, which reduced the forbidden degrees of consanguinity from seven to four.

Another aspect of this centralizing tendency was the application of the doctrine of the pope's *plenitudo potestatis* to the disposal of benefices: it was under Innocent that the system of provisors began, whereby the pope conferred benefices directly, overriding the rights of the normal patrons, a system that was later to lead to serious abuse. On the other hand: Innocent was inflexible in upholding the canonical election of bishops. for only thus could the standards of the episcopate be maintained. Over this issue he fell foul of King John of England. who sought to impose his own nominee on the vacant see of Canterbury instead of the candidate elected by the chapter. Innocent settled the dispute by nominating to the chapter the English cardinal Stephen Langton (*q.v.*) over the heads of both candidates. John's resistance was broken by an interdict which lay on England from 1208 until 1213 and finally by the threat of deposition.

Innocent's plan for the reform of the church was embodied in the canons of the fourth Lateran council, which he summoned for 1215. This, the greatest of the mediaeval councils, was attended by 412 bishops, by about 800 abbots and priors and by the ambassadors of kings and princes. While several of its canons reenacted those of the third Lateran council of 1179, many new acts had a far-reaching effect on the development of Latin Christianity. Thus a new impetus was given to synodal activity in the dioceses, a steady effort was made to improve the education of the diocesan clergy, and the obligations of the laity were emphasized by the 21st canon, *Utriusque sexus,* which made annual confession obligatory. (See LATERAN COUNCILS.) If the council did not achieve all that Innocent hoped, its canons are a worthy epitaph to the breadth of vision and nobility of purpose of a great pope. It was perhaps the finest hour of the mediaeval papacy.

In the midst of organizing another crusade, Innocent was struck down by a fever and died at Pemgia on July 16, 1216. He was still only 55 years of age.

INNOCENT IV (Sinibaldo Fieschi), pope from 1243 to 1254, belonged to the noble Genoese family of the counts of Lavagna. Born at Genoa, he was educated under the care of his uncle Opizzo, bishop of Parma. After taking orders at Parma, when he was made canon of the cathedral. he studied jurisprudence at Bologna. His first recorded appearance in political affairs mas in 1218–19, when he was associated with Cardinal Ugolino (later Gregory IX) in negotiating a peace between Genoa and Pisa. Pope Honorius III gave him a benefice in Parma in 1223 and established him at the Curia as *auditor contradictarum literarum* in 1226; and Gregory IX promoted him to be vice-chancellor of the Roman Church in July 1227 and made him cardinal priest of San Lorenzo in Lucina in September. He was papal *rector* (governor) of the March of Ancona from 1235 to 1240. On June 25, 1243, he was elected pope by the cardinals assembled at Anagni.

When Innocent was raised t o the Holy See, the emperor Frederick II lay under excommunication. Frederick hoped great things from the elevation of a member of a family favourable to the imperial cause; but it was soon clear that Innocent intended to pursue the traditions of his predecessors. Embassies and courtesies were, indeed, interchanged, and on March 31, 1244, a treaty was signed at Rome, whereby the emperor undertook to satisfy the pope's claims in return for his own absolution from the ban. Neither side, however, was prepared to begin to carry out the agreement, and Innocent began to feel unsafe in Rome, where the imperial partisans had the ascendancy. He left Rome in June, arranged to meet the emperor but fled by night on horseback, pursued by the emperor's cavalry, from Sutri to Civitavecchia, whence he took ship for Genoa and proceeded to Lyons, at that time a merely nominal dependency of the empire. Thence, close

to French soil and confident in the sympathy of Louis IX, he issued a summons to a general council, before which he cited Frederick to appear. The council, which opened on June 28. 1245, was attended by about 1jo bishops, most of the German and all the Hungarian bishops being absent. Though Frederick was defended by the jurist Thaddeus of Suessa, the judgment was a foregone conclusion; in the session of July 17, Innocent renewed sentence of excommunication against the emperor and declared him deposed.

Frederick retorted with a circular letter, appealing to the opinion of all Christian princes, and threatened reprisals on clergy who obeyed the papal sentence. But Innocent pursued the war relentlessly. The Mendicant orders mere mobilized to preach against the emperor The German electors were invited to elect a new king and, under the lead of the Rhenish archbishops who had already deserted Frederick. chose Henry Raspe. landgrave of Thuringia, in May 1246. But the *rex clericorum* died in Feb. 1247, and William II. count of Holland, was elected to succeed him in October. Those who fought against Frederick were granted crusading indulgences, and the papal legate took all vacant German benefices into the pope's hand and disposed them on papal partisans. The turning point mas Frederick's failure of the siege of Parma in 1248. The conflict was still unsettled when Frederick died, at Fiorentino in the Regno, on Dec. 13. 12 jo.

Innocent left Lyons for Italy in April 1251. He continued the struggle with Frederick's son and successor. Conrad IV, who in 1252 descended into the Regno, reduced the rebellious cities and claimed the imperial crown. Innocent now offered the crown of Sicily in turn to Richard of Cornwall, Charles of Anjou and Henry III of England. the last of whom accepted the doubtful gift for his son Edmund. After Conrad's capture of Naples. Innocent feared that Rome itself might fall into the hands of the German king. But Conrad died on May 21. 1254, leaving his infant son Conradin under the pope's guardianship. Innocent posed as the champion of the infant king He held, indeed, to his bargain with Henry III and exercistd his rights over the Sicilian kingdom by nominating his own relations to its 'most important offices. Finally. when Manfred. who by Frederick's will had been charged with the government of the two Sicilies, felt obliged to acknowledge the pope's suzerainty. Innocent threw off the mask, ignored Conradin's claims and. in October, announced the annexation of Sicily and Calabria to the States of the Church. He entered Naples on Oct. 27; but meanwhile Manfred had fled and had raised a considerable force; the news of his initial successes reached Innocent as he lay sick and hastened his end. He died on Dec. 7. 1254.

Deep legalistic in outlook. Innocent went beyond his predecessors in claiming for the papacy a direct temporal sovereignty over all earthly kingdoms. Innocent III had been more cautious, preferring to base his political interventions on the spiritual authority of the pope in the matter of sin *(ratione peccati).* But for Innocent IV, the church was not merely the judge of temporal sovereigns but the necessary author of their power. In the church itself, the prestige of the papacy began to suffer as spiritual resources were diverted to political ends. Under the strain of war, papal fiscality became increasingly oppressive. In particular, Innocent's exploitation of the system of papal provisions to benefices aroused a growing body of complaint. Robert Grosseteste, bishop of Lincoln, nho led the English delegation to Lyons, denounced the abuse before the pope's face, and a strong protest was made by Louis IX of France. The abuse had become so great that Innocent's successor was obliged to revoke large numbers of mandates of provision on the ground that in some churches the number of '.expectants" awaiting provision exceeded the total number of benefices in existence.

Innocent IV was a canon lawyer of some eminence. His small work *De exceptionibus* was probably written before he became pope; but the *Apparatus in quinque libros decretalium,* which displays practical sense and a mastery of the materials, was written at Lyons immediately after the council. His *Apologeticus,* a defense of the papal claims against the empire. was lost. Innocent was also a notable patron of learning; he encouraged Alexander of Hales to write his *Summa universae theologiae,* did much for the universities, notably Paris, and founded *studia generalia* at Rome and Piacenza.

INNOCENT V (Pierre de Champagny or de Tarentaise), pope from Jan. 21 to June 22, 1276. was born about 1225 in a dependency of the county of Savoy and entered the Dominican order at an early age. He studied theology at Paris, probably under Albertus Magnus, and incepted as a master in 1259 From 1260 to 1267 and again from 1269 to 1272, he was provincial of his order in France. He was made archbishop of Lyons in 1272 and cardinal bishop of Ostia and Velletri. and grand penitentiary in 1273; and. partly through the influence of Charles of Anjou, was elected to succeed Gregory X. As pope he established peace between the republics of Lucca and Pisa and confirmed Charles of Anjou in his officeof imperial vicar of Tuscany. He was seeking to carry out the Lyons agreement with the Eastern Church when he died.

Before he became pope, he had prepared. in conjunction with Albertus Magnus and Thomas Aquinas, a rule of studies for his order, which was accepted in June 1259; and he was the author of several works in philosophy, theology and canon law. He is sometimes referred to as *famosissimus doctor.*

INNOCENT VI (Etienne Aubert), pope from Dec. 18. 1352, to Sept. 12, 1362 was born at Monts in Limousin. He became professor of civil law at Toulouse and subsequently chief judge of the city. Having taken orders he was raised in 1338 to the see of Noyon and translated in 1340 to Clermont. He was made cardinal priest of SS Giovanni e Paolo in 1342 and cardinal bishop of Ostia and Velletri, grand penitentiary and administrator of the bishopric of Avignon ten years later.

As pope, Innocent revoked the reservations and commendations of his predecessor Clement VI and prohibited pluralities. urged upon the higher clergy the duty of residence in their sees, and diminished the luxury of the papal court. Largely through the influence of Petrarch. whom he called to Avignon, he released Cola di Rienzo. who had been sent a prisoner in Aug. 1352 from Prague to Avignon, and used the latter to assist Cardinal Albornoz, vicar-general of the States of the Church, in tranquillizing Italy and restoring the papal power at Rome.

Innocent established good relations with the German king Charles IV. whom he caused to be crowned emperor at Rome in 1 The following year Charles published the famous Golden Bull (*q.v.*), which prescribed a method for the election of the German kings and passed over in silence the claims of the papacy to approve the election. Contrary to statements sometimes made, Innocent raised no objection to the bull. He had other matters in hand. In 1360 he arranged the treaty of Brétigny between France and England, a success which redounded on his head, for the peace released roving armies of mercenaries. One of these "free companies" occupied Pont-Saint-Esprit and threatened Avignon. In the end Innocent was constrained to buy them off. In the last years of his pontificate he was busied with preparations for a crusade and with negotiations for the reunion of Christendom.

See G. Mollat, *Les Papes d'Avignon,* 9th ed. (Paris, 1949), which contains an exhaustive bibliography

INNOCENT VII (Cosimo de' Migliorati), pope from Oct. 17, 1404, to Nov. 6, 1406, was born at Sulmona in 1336. He was made papal vice-chamberlain and archbishop of Ravenna by Urban VI and cardinal priest of Sta. Croce in Gerusalemme, bishop of Bologna and papal legate to England by Boniface IS. He was unanimously chosen to succeed Boniface. The election was opposed at Rome by a considerable party but peace was maintained by the aid of Ladislaus of Naples, in return for nhich Innocent agreed not to come to terms with the antipope Benedict XIII, except on condition that he should recognize the claims

of Ladislaus to Naples. Innocent issued at the close of 1404 a summons for a general council to heal the schism, but the council never assembled. as the Romans rose in arms to secure an extension of their liberties and finally, maddened by the murder of some of their leaders by the pope's nephew Ludovico de' Migliorati, compelled Innocent to take refuge at Viterbo (Aug. 6, 1405). Later, recognizing the pope's innocence of the outrage, they made their submission to him in Jan. 1406. He returned to Rome in March, and, by a bull of Sept. 1, restored the city's decayed university. He died on Nov. 6, 1406.

See N. Valois, *La France et le grand schisme d'Occident* (Paris, 1896–1902).

INNOCENT VIII (Giovanni Battista Cibb), pope from Aug. 29, 1484, to July 25, 1492, successor of Sixtus IV. was born at Genoa (1432), the son of Arano Cibb, who under Calixtus III had been a senator of Rome. Through the favour of Cardinal Calandrini, half-brother of Nicholas V, he obtained from Paul II the bishopric of Savona. Sixtus IV translated him to the see of Molfetta and created him cardinal priest of Sta. Balbina in 1473 and of Sta. Cecilia subsequently.

Innocent VIII was not a successful pope. His summons to a crusade against Islam went unheard, and he ended by making a treaty with the sultan Bayezid II (1489), agreeing, in return for an annual payment of 40,000 ducats and the gift of the Holy Lance, to detain the sultan's fugitive brother Jem in confinement in the L'atican. Innocent's manoeuvres in Italian politics were equally unscrupulous and unsuccessful. He deposed Ferdinand (Ferrante) king of Naples in 1489 for failure to pay arrears of tribute. But the papal arms were worsted. and Innocent had to abandon his project of incorporating Naples into the ecclesiastical state. He is remembered as the persecutor of Pico della Mirandola. The capture of Granada from the Moors (Jan. 2, 1492) gave a borrowed lustre to his pontificate. Innocent died on July 2j. 1492. A man of lax private morals, he was a weak and unworthy pope. He left the papal camera empty and States of the Church in anarchy.

INNOCENT IX (Giovanni Antonio Facchinetti), pope from Oct. to Dec. 1591, was born in 1519. After taking part in the council of Trent. he became nuncio at Venice and was employed on important duties at Rome by Gregory XIII. who made him a cardinal in 1583. Under the invalid Gregory XIV he assumed almost the entire direction of affairs. He was a supporter of the Catholic League in France and of the policy of Philip II of Spain, and it was with the latter's support that he succeeded Gregory on Oct. 29, 1591. He died on Dec. 30 of the same year.

INNOCENT X (Giambattista Pamfilij, pope from 1644 to 1655, was born in Rome on May 7, 1574. He was made auditor of the Rota by Clement VIII. nuncio at Naples by Gregory XV and legate apostolic to Spain and cardinal by Urban VIII. He was elected pope on Sept. 1j. 1644. through the support of those cardinals who had opposed his predecessor Urban VIII's domestic administration and diplomatic policy, both of which he proceeded to reverse. The most emphatic and significant demonstration of this change is to be seen in Innocent's condemnation of the peace of Westphalia (1648), for which papal mediators had worked under Urban; and in the fact that practically no notice was taken of his protest by either side. In support of a pro-Habsburg policy, cardinals favoured by Spain were promoted and recognition of the independence of Portugal. then at war with Spain, was refused. In Rome, the Barberini (relatives of Urban and protégés of Cardinal Mazarin) were attacked and their property confiscated. Much of the initiative in these events was taken not by Innocent but by his sister-in-law, the notorious Olimpia Maidalchini, by whose advice he was almost completely dominated. While her diplomatic policy had the praiseworthy aim of keeping the papacy aloof from international entanglements. her greed for money led her to adopt devices which destroyed the very prestige upon which such a policy depended for its success. In doctrine. Innocent intervened in the quarrel between the Jesuits and the Jansenists and, in the bull Cum *occasione* (1653), condemned five propositions concerning the nature of divine grace said to be in Cornelius Jansen's *Augustinus.* The quarrel thereupon entered a new phase, in which it was contended that papal infallibility did not extend to matters of fact and that the propositions were not in fact implicit in the Augustinus, so that the teaching of Jansen had not been condemned by the bull. On all scores, therefore, papal prestige had seriously declined by the time that Innocent died, on Jan. 7, 165j.

See J. Ciampi, *Innocenzo X Pamfili, et la sua corte* (Rome, 1878), a standard work; also H. Coville, *Études sur Mazarin et ses démêlés avec le pape Innocent X* (Paris, 1914).

INNOCENT XI (Benedetto Odescalchi), pope from 1676 to 1689, was born on May 19, 1611, at Como, where he was educated by the Jesuits. He studied law in Rome and Naples, entered the Curia under Urban VIII and became successively protonotary, president of the apostolic chamber, governor of Macerata and commissary of Ancona. Innocent X made him a cardinal (1645), legate to Ferrara and, in 1650, bishop of Novara. He was elected pope on Sept. 21, 1676, against the opposition of Louis XIV of France. On grounds of moral character he was the outstanding pope of the 17th century, being entirely free from nepotism and invariably refusing to diverge for reasons of expediency from the policy that he considered right. He averted bankruptcy by abolishing sinecures and introducing economies. As a result he was able to finance the war against the Turks and, in particular, to subsidize John Sobieski (King John III of Poland) and the emperor in the campaign which led to the relief of Vienna in 1683.

Innocent XI had to face, in Louis XIV, a man with entirely opposite principles. Their quarrel began when two French bishops resisted an edict of 1673 which extended the *régale* (*i.e.*, the king's right to administer both the temporalities and the spiritualities of vacant sees). Innocent upheld their objection, refused the offer of a compromise and, when Louis replied by having a French synod issue the famous declaration of Gallican liberties (see GALLICANISM) in 1682, refused to confirm the promotion of any of the clergy who had taken part in it.

The deadlock that resulted was made worse in 1687, when Innocent took action against the abuse of ambassadorial privileges by the French representative in Rome. Something approaching a schism threatened, and the deadlock was still unresolved when Innocent died. In addition, Innocent opposed Louis's candidate for the archbishopric and electorate of Cologne (1688) and would not help his plans for James II of England.

In doctrinal matters, Innocent had some sympathy with the Jansenists. On the occasion of an appeal to him by the Jesuit Tirso Gonzalez, whose rigorist theories were being suppressed by his superiors, Innocent showed his disapproval of the lax probabilism taught by many Jesuit casuists (1680); and in 1687 he had Gonzalez made general of the Jesuits. On the other hand, he was personally favourable to the Quietist Miguel de Molinos, most of whose propositions he condemned in 1687.

Any general appreciation of Innocent XI's pontificate must take into account the problems created by the ambitions of Louis XIV at a time when the church was passing through a period of doctrinal discord. Innocent's greatest contribution was perhaps his domestic reform, both moral and administrative. His integrity was unquestioned. He died on Aug. 12, 1689, and was beatified by Pius XII on Oct. 7, 1956.

BIBLIOGRAPHY.—The best modem life is M. Immich, *Papst Innocenz XI, 1676–1689* (Berlin, 1900). For his correspondence *see* G. Colombo, *Notizie biografiche e lettere di Papa Innocenzo XI* (1878); and F de Bojani, *Innocent XI: sa correspondance avec ses nonces* (Rome, 1910–12) For affairs with France *see* E. Michaud, *Louis XIV et Innocent XI,* 4 vol. (Paris, 1882–83); and J. Orcibal, *Louis XIV contre Innocent XI* (Paris, 1949).

INNOCENT XII (Antonio Pignatelli), pope from 1691 to 1700, was born in Neapolitan territory on March 13, 1615; was educated at the Jesuit college in Rome; entered upon his official career at the age of 20; and became successively vice-legate of Urbino, governor of Viterbo and nuncio to Tuscanp, to Poland and to Austria He was made cardinal in 1681 by Innocent XI. whose pontificate he took as a model for his own, which began on July 12, 1691. Nepotism was officially condemned in a bull of 1692 and justice was administered in the papal states without regard for

the status of the persons involved. The deadlock with France was broken in 1693 when both the French bishops of the synod of 1682 and Louis himself wrote letters disavowing the declaration of Gallican liberties of 1682 and Innocent agreed to the extension of the *régale* enacted in 1673 *(see* above. *Innocent XI)* Typically, Louis first assured himself that his repudiation was invalid, since a letter could not annul an edict registered by the *parlement*. In doctrinal matters, Innocent allowed the uneasy peace between Jansenists and Jesuits to continue; condemned the archbishop Fénelon's *Maximes des saints* at Louis XIV's instigation in 1699; but refused to condemn Celestino Sfondrati's book on predestination, which Jacques Benigne Bossuet had denounced as Quietistic in 1697 but nhich was still "under consideration" when Innocent died. on Sept. 27, 1700.

INNOCENT XIII (Michelangelo Conti), pope from 1721 to 1724, the son of the duke of Poli. and a member of a family that had produced several popes. among them Innocent III, was born at Poli on May 13, 1655. He served as nuncio in Switzerland and Portugal and was made cardinal and bishop of Osimo and Viterho by Clement XI. He was elected pope, after a long conclave, on May 8, 1721, as a result of the exclusion by the emperor of the candidature of Cardinal Fabrizio Paolucci One of his first acts was to invest the emperor Charles VI with Naples (1722); he protested in vain against the imperial investiture of Don Carlos with Parma and Piacenza He recognized the Stewart pretender "James III" and promised him subsidies conditional upon the re-establishment of Roman Catholicism in England. Moved by deep-seated distrust of the Jesuits and by their continued practice of "accommodation" (whereby missionaries might modify Christian usage to attract converts) despite Clement XI's express prohibition. Innocent forbade their society to receive new members in China and nas said to have meditated its suppression. This encouraged the French Jansenist bishops to press for the revocation of the bull *Unigenitus;* but the pope commanded its unreserved acceptance. Innocent died on March 7, 1724. (I. F. B.)

INNOCENTS' DAY or CHILDERMAS, a festival celebrated in the Latin Church on Dec 28 and in the Greek Church on Dec. 29 (O S.) in memory of the massacre of the children by Herod. The church early regarded these little ones as the first martyrs. It is uncertain when the day was first kept as a saint's day. At first it seems to have been absorbed into the celebration of the Epiphany, but by the 5th century it was kept as a separate festival In Rome it was a day of fasting and mourning

The boy-bishop (q v.), whose tenure of office lasted till Childermas. had his last exercise of authority then. the day being one of the series of days which were known as the Feast of Fools. Parents temporarily abdicated authority, and in nunneries and monasteries the youngest nun and monk nere for the 24 hours allowed to masquerade as abbess and abbot. These mockeries of religion were condemned by the Council of Basel (1431). The day is still observed as a feast day and merrymaking for children in Catholic countries, and particularly as an occasion for practical joking.

The society of Lincoln's Inn specially celebrated Childermas, annually electing a "king of the Cockneys."

Innocents' day was accounted unlucky, and Louis XI prohibited all state business on the day. The coronation of Edward IV, fixed for a Sunday. was postponed till the Monday when it was found that the Sunday fell on Dec 28

In rural England it was deemed unlucky to do housework put on new clothes or pare the nails. At various places in Gloucestershire. Somerset and Worcestershire muffled peals were rung. In Northampton the festival was called "Dyzemas day," and there was a proverb "What is begun on Dyzemas will never be finished."

The Irish called the day *Lu Crouste na bliana,* "the cross day of the year." or *Diar dasin darg,* "blood Thursday," and many legends attach to it.

In mediaeval England the children were reminded of the mournfulness of the day by being whipped in bed on Innocents' morning. This custom survived to the 17th century.

INNS AND INNKEEPERS. An inn is a hostelry. hotel or public house kept for reward, for the lodging and entertainment of travellers or of any who need temporary accommodation. The name is also given, in a specialized sense. to the institutions set apart for the study and practice of the law. *(See* INNS OF COURT AND CHANCERY.)

English Law.—The term inn includes any house of public entertainment where beds and food are furnished to all persons paying for them, although the prices charged may, of course, vary between one inn and another, according to the character of the accommodation and services provided. The name used—hotel, public house, temperance hotel or whatever it may be—is immaterial. but a lodging house or boarding house is not an inn. because there is a distinction at law between a guest and a boarder—the latter of whom makes a contract to stay for a certain period, the landlord being as free to accept or reject him as is any other party to a contract.

The law enforces on the innkeeper, on the other hand, the provision of certain services for the benefit of travellers. An innkeeper has no right to select his guests or refuse shelter at any hour of the day or night, provided he has vacant accommodation and the traveller is not obviously objectionable; nor can he refuse to serve food at reasonable hours if he has it available. (See R. v. *Higgins* 1948 1 K.B. 165 and *Constantine* v. *Imperial Hotels Ltd.* 1944 K.B. 693.)

By the common law of England an innkeeper is responsible for the personal property of a traveller so long as the relationship of landlord and guest continues between the parties unless the goods are destroyed by the act of God or the queen's enemies. No special contract is necessary in order to create this obligation, which was reaffirmed by the house of lords in *Shacklock* v. *Ethorpe Ltd.* (1939 3 A.E.R. 373). The innkeeper's liability is not founded upon the law of negligence. he is responsible to his guests. except in so far as they may fail to take the ordinary care which a prudent person would take. This rule is qualified by the limitation stated by Lord Justice Asquith in *Williams* v. *Linnitt* (1951 1 K.B. 565 at 580), namely, that "The absolute liability of the innkeeper for the safety of the plaintiff's goods only attaches where such goods are *infra hospitium,* namely, within the inn buildings themselves or within precincts so intimately related to those buildings as to be treated for this purpose as forming part of them." The question of what is *infra hospitium* mas also raised in *Watson* v. *People's Refreshment Houses Ltd.* (1952 1 K.B. 318). On the other hand, where a question is raised of a guest's being injured through the condition of the property the duty of the innkeeper has been held to be to make the premises reasonably safe, not as safe as reasonable care and skill can make them. *(Bell* v. *Travco Hotels* 1953 1 A.E.R. 638).

The common law liability of an innkeeper (except for horses, harness and carriages, which term includes motorcars) for the safe custody of the goods of a guest is limited by the Innkeepers' Liability act, 1863, which provides that an innkeeper shall not be liable to a greater amount than £30 for loss of goods unless the loss is caused by the neglect or default of himself or his servants. This limitation of liability only applies if the words of the first section of the act are exhibited prominently in the hall or entrance to the inn. The law gives the innkeeper a lien over his guest's goods for the amount of the bill, but this lien only attaches to goods brought to the inn by the guest and housed by the innkeeper. (See *Marsh* v *Commissioner of Police* 1943 K.R. 99).

By the Innkeepers act, 1878, goods held under such a lien may be sold after six weeks on the expiry of one month from the publication of advertisements in one London and one local newspaper.

(W. T. Ws.)

Scotland.—In Scotland the law is in most respects the same as in England but injury due to the queen's enemies or to the act of God does not render the innkeeper liable He is moreover bound to receive and house the goods of a traveller, other than personal effects, provided they are not very exceptional or dangerous.

(A. D. *G.)*

The United States.—In the United States the common law follows that of England. and laws of the various states of the union have diminished the liability of the innkeeper in much the same manner as in England.

INNSBRUCK, the capital of the Austrian Bundesland of Tirol, is a beautiful town situated at a height of 1,880 ft. in a wide plain formed by the Inn and its right-bank tributary, the Sill, and mainly on the peninsula between these streams. Surrounded by lofty mountains that seem to overhang the town, it occupies a site strategically and commercially important at the junction of the highway from Germany proper to Italy over the Brenner pass with the great thoroughfare from western Europe to Vienna, Aus., and the east over the Arlberg pass. As the name implies, this is a famous crossing place of the Inn guarded in Roman time by the station of Veldidena, which was succeeded by the Premonstratensian abbey of Wilten.

The town is first recorded by its present name in 1187, and in 1233–3 j it was fortified. About 1420 the archduke Frederick IV built a new castle there, and the town replaced Meran as the capital of Tirol

Innsbruck's history has been generally uneventful, and it always manifested a strong loyalty to the ruling house of Austria, particularly during the revolution of 1848. With Austria, it was annexed to Germany in 1938. In 1945 it became the headquarters of the French zone of occupation.

Within the town there is a striking contrast between old and new. The narrow arcaded streets of the old town, with fine old frescoed houses of the 17th and 18th centuries, give place to the regularly built blocks and open spaces of the more modern accretions, yet without disturbing the sense of unity. One of the finest of the older buildings is the Franciscan or Court church (1553–63), mainly in Italian Renaissance style. Within was preserved the remarkable cenotaph of the emperor Maximilian I (d. 1519), count of the Tirol from 1490 onward, a gigantic marble sarcophagus with 28 bronze statues of his ancestors and favourite heroes and 24 marble reliefs depicting scenes from his life. The church contains also a number of other tombs of notable historic figures.

The university of Innsbruck, formally founded in 1677, suspended during 1782–92 and 1810–26, was refounded in 1826 and makes the town a centre of intellectual life. Well staffed and equipped with fine buildings and a library of about 400,000 volumes, the university influence spreads far beyond the borders of Tirol and Austria. Before the Anschluss of 1938, more than 1,500 students attended its courses, 39% coming from Tirol, 27% from other parts of Austria and 34% from foreign countries including 2% from the Cnited States. After World War II, more than 4,200 students were enrolled. The building for internal medicine and anatomy, which was damaged during the war, was later remodelled. There is also a well-stocked museum, the Ferdinandeum, with rich collections, some illustrative of the Tirolean life.

Other interesting and historic buildings and monuments combine with the surrounding scenic and climatic attractions to make Innsbruck a centre for tourists, whereby its functions as the regional capital and market are strengthened. In the 20th century thousands of visitors were catered for annually, their needs forming the basis of a large trade in foodstuffs and other necessities of daily life. Improved facilities for travel swelled this tourist traffic, a fact that was reflected in the growth of the town after 1900, when its population numbered 26,866. By the census of March 1923 it was 56,365, and the census of 1939 reported 80.084, mainly German-speaking Roman Catholics. The population was 103.503 according to the census of 1961. See also TIROL.

See H. Bobek, *Innsbruck, eine Gebirgsstadt, ihr Lebensraum und ihre Erscheinung* (Stuttgart, *1928).*

INNS OF COURT AND CHANCERY. The four inns of court seated in London — Lincoln's inn, Gray's inn, the Inner Temple and the Middle Temple — have frequently been referred to as "colleges in a university of law," and in their general structure, system of government and functions this analogy holds good. In Coke's *Reports* they are described as "the most famous Universitie for profession of law only" and they are referred to by Fortescue, Coke and Selden as universities for the study of the law on the same footing as the universities of Oxford and Cambridge. Just as the universities are responsible for the preparation of students for a degree and for their discipline, so the inns of court are responsible for the education and discipline of their students; and their respective governing bodies, the benches, exercise the exclusive right of admitting persons to practise by a formal call to the bar.

They are voluntary societies, unchartered, unincorporated and unendowed Hence their early history is very obscure and the date of their respective foundations cannot be precisely determined, for they did not own land, but only leased it, and records of such transactions are much more difficult to trace than dealings with a fee simple. Since the inns were not endowed by any benefactor, there was no foundation charter, and no statutes, to be preciously preserved.

Since the inns were primarily concerned in the middle ages with legal education, attempts have been made to connect them with the early educational establishments of London. No doubt the city was well furnished with schools where the rudiments of Latin, grammar, logic, etc., were taught, possibly with those odd tags of law which often appeared as illustrative material in the course of rhetoric. But this is not sufficient to account for the rise of the inns of court, which were devoted to the technical study of English, not Roman, law and which seem to have been concerned from the first with students well beyond the schoolboy stage.

There is nothing to suggest that while the common law was still young, its administrators had any systematic education in English law; it was learned in the course of service, the first rudiments possibly as private clerk to some official. These conditions persisted well into the 13th century. By about 1256 Henry de Bracton's massive book on the laws and customs of England and the bulk of the plea rolls both show that the common law was extensive and intricate, conducted by numerous skilled men in courts which had considerable establishments.

This law had little in common with Roman and canon law; whence it followed that there was no question of the universities teaching English law. Moreover, there arose a class of men, literate but lay, who took an interest in law. They dominated, and created, the legal profession, and faced and solved the problem of English legal education. The inns of court were the answer they supplied.

This emergence of the literate layman is clear from the appearance (contemporary with Bracton's last years) of treatises on English law in French instead of Latin. From them and other sources it seems clear that already English law was being taught. Many were studying — the surviving manuscripts of these manuals are numerous — and the teachers were able enough to write quite good little books.

The students listened to arguments in court, and discussed law among themselves. That does not mean that there was any permanent inn; the students may well have made their own private arrangements both for teaching and lodging.

The general educational history of the city of London does not seem to show any genuine relevance to all this. It is usual to mention the writ of 1234 whereby Henry III ordered that "no regent of law schools in the said city shall teach laws (leges) there henceforth." This language suggests teaching of academic standards, and leges without further qualification must mean Roman law. F. W. Maitland's suggestion that the schools in question were perhaps the schools of St. Paul's cathedral is attractive, were it not for the fact that one would not expect the civic authorities to exercise jurisdiction over them.

Whatever its meaning, the writ of 1234 cannot be taken as having anything to do with the teaching of English law, whether at inns of court or elsewhere.

By about 1260 laymen were taking up law studies, and didactic manuals were written in the vernacular French for them; law students attended arguments in court and discussed points of law among themselves, from which it is a fair inference that the students not only met in court but almost certainly congregated out of court.

It could be assumed that the students were well-to-do — in 1305 the chief justice suspected that a knotty case before him had been manufactured by some apprentice who bought the land in order to see how it would fare in court. Finally, by about 1300, law-

yers of various sorts were numerous and needed regulation. The city made orders for practitioners before the London courts in 1280, and in 1292 the king commanded his judges to select from different counties 140 apprentices and attorneys and to allow no other to meddle with legal business.

Bearing all this in mind, it is a natural inference that law students should have acted like university students elsewhere, hiring hostels or inns where they could live together. It might even be an established practitioner who leased a house, taking in students and guiding their studies. This system was common in English and foreign universities among such men as could afford to live on such a scale. To assist the poor university student. benefactors often founded colleges (or conferred endowments upon some existing inn or hall) to enable poor scholars to stay. This did not happen in London; law students had the means (sometimes borrowed) to keep themselves at an inn without the aid of collegiate endonments It is not surprising that the inns were at first liable to move as leases expired or more suitable premises were found, and in time leases would be given (or renewed) for long terms; in the Tudor period the growth of the trust enabled the inns to acquire the ownership of their quarters.

Aspirants to practice in the superior courts were only a small proportion of all those needing a legal education. There was a keen demand for stewards and legal advisers to landowners everywhere, conducting general business and keeping manorial courts. These men needed the rudiments, but not the refinements, of the common law, and they too came from the class of literate laymen. There was likewise the large class of attorneys, and a growing class of bookkeepers and correspondence clerks. Some part of their knowledge could be got from *dictatores,* professional teachers of letter writing; more still by joining an inn of chancery.

Chancery clerks (being then clergy in at least minor orders) had long lived as part of the household of the chancellor. but in the 14th century they had become too numerous, and the household broke up as groups of clerks either combined to take inns or married. Many seem to have taken in students for training and, since the penning of writs and other legal documents was a prominent part of their work, a good grounding in law could be obtained in an inn of chancery. By the end of the 14th century these inns were in danger of being submerged by a flood of attorneys-to-be and of students who used a stage at an inn of chancery as a preparation for entering an inn of court. Eventually each inn of court secured control of one or more inns of chancery and supervised its affairs, appointed readers to teach in it and later often bought its premises, thus becoming its landlord.

By the beginning of the 15th century the four inns of court were established bodies with tradition behind them. They were governed by their benchers, who had previously given at least two courses of lectures (readings), and who presided over mock arguments (moots) in which students argued before them difficult points of law. The standard was high and the teaching thorough. A number of manuscript reports of readings and moots survive.

Since the law was highly technical, proficiency could only be acquired by following the severe studies of the inns, so that in practice the inns had a *de facto* monopoly. This soon became recognized. and when benchers called certain students to the bar of their inn, those students were regarded as qualified apprentices or barristers. The inns steadily remained organizations of students. When the crown conferred the degree of serjeant-at-law upon a few outstanding barristers, they at last ceased to be apprentices and withdrew from their inn to the Serjeants' inn. The judges were always serjeants and so remained in Serjeants' inn. In spite of the severity of their studies, there were in the 15th and 16th centuries many students of the inns who had no legal ambitions but joined them for the purpose of general education (which was by no means neglected there). Since the universities were still strongly ecclesiastical, the inns were much frequented by the sons of wealthy families who had no intention of becoming lawyers.

By the end of the 16th century the inns of court began to exclude attorneys and solicitors and refused to call them to the bar. with the result that attorneys especially fell back upon the inns of chancery, and were finally in a profession distinct from that of the barristers.

The golden age of the inns of court may well have been from the middle of the 15th century (as Sir John Fortescue described it) to the early years of the 16th century. The inns (by the end of that period) had acquired the freehold of their sites and began the building of splendid halls which continued through the reign of Elizabeth I. Their material prosperity was also shown by their magnificent feasts and the entertainment offered to the sovereigns. If a man left an inn to become a serjeant, feasting on the scale of a coronation was expected. The system of legal education was at its best and most vigorous during that period.

Various causes brought about its decline. The great activity of the printing press led students to suppose that they could learn more quickly and more easily from printed books, and so they neglected attendance at readings and moots. Indeed, students performed moots by deputy. If students were reluctant, so were the readers, who were unpaid and lost much time from their practices in preparing and delivering readings, and latterly had to provide very costly feasts; many paid heavy fines to escape the office. The judges, who had assumed vague powers of giving directions to the inns, often tried to compel observance of the old system, but it was clearly on the decline. It broke down completely during the Civil War, and the desperate efforts at the Restoration to revive it were abandoned. Readings ceased in 1677. Only the fees survived, and having paid them, the student was deemed to have fulfilled all his duties.

During the 18th century the cessation of the old system left a void which was slowly filled by new arrangements. There had been no readers to recommend students for call to the bar since 1677, so the four inns finally agreed (in 1762) to call students who had kept a stated number of terms; later it was settled that eating three dinners was equivalent to keeping the whole term. The benchers kept their position as the sole governing body of each inn and stoutly resisted the claim that king's counsel should become benchers as of right. It was also settled that the head of the inn was the bencher holding the office of treasurer, which passed by rotation in order of seniority. Since the Judicature acts of 1873, 1874 and 1875 the grade of serjeant-at-law has been extinct, with the result that judges, no longer being serjeants, can remain members of their inns and in fact are benchers.

The inns of chancery were not fitted to become the professional organ of so large a body as the attorneys and solicitors, if only because these practitioners were not congregated in London. They therefore created their own society, and the inns of chancery one by one were sold.

The common law commissioners of 1854 investigated the inns of court, and, thus stimulated, the inns took steps to resume their educational functions. Readerships were established and eminent lawyers engaged in teaching with a view to examinations conducted by the Council of Legal Education, representing all four inns.

Lincoln's Inn.—The legends connecting this inn with Henry de Lacy, earl of Lincoln (d. 1311), and with John Thavie the armourer (d. 1348) have no historical foundation and rest on misunderstandings. It is certain that Lincoln's inn was lessee of the bishops of Chichester on land west of Chancery lane by 1422. It was also shown by G. J. Turner and E. Williams that it once occupied land on the east side of the same lane which had been accumulated between 1331 and 1348 by Thomas de Lincoln, king's serjeant. It is presumably there that Lincoln's inn first came into existence, being known, as often, by the name of the landlord whose "inn" the lawyers rented.

By 1369 Thomas de Lincoln had conveyed the whole of the freehold to the abbey of Malmesbury. It does not follow that the lawyers were already in possession by 1369, for the house may still have been called by Lincoln's name even after he had disposed of it. But it is quite certain that in 1399 the abbey was receiving rent for "the new inn at London called Lincoln's inn." The bishops of Chichester ceased to reside at their house on the other side of Chancery lane in 1412, and evidently the inn moved across the street between 1412 and 1422 to the present site.

The earliest records of Lincoln's inn, the Black *Books,* commence in 1422. The control of the society was vested in the coun-

cil, which consisted of the masters of the bench. Next in rank came the utter-barristers, those who had been called to the bar, and the inner-barristers or students, so called because at the moots held in the hall of the inn the former sat on the outermost part of the form which represented the bar of the court and the latter sat inside and between them. Formerly attorneys and solicitors also might be members of the inn. It is interesting to note that Sir Thomas More's grandfather was chief butler prior to his call in 1470. The chief butler at this period acted rather as clerk to the council than as butler in the modern sense. He was clearly an educated man. The bishop of Chichester's palace and the chapels of Our Lady and of St. Richard sufficed for the needs of the society for nearly a century. The Bishop's hall was pulled down in 1491 and the present Old hall erected in its place in 1506. When this proved insufficient for the growing membership the present New hall was built in **1843.** The present chapel. constructed by Inigo Jones, was completed in **1623,** Thavie's inn (which had no connection with the armourer) has existed since **1376** as an inn of chancery, and its site was acquired by Lincoln's inn in 1550. It was sold by the benchers in **1769** and thus erased as a legal institution. The other inn of chancery attached to Lincoln's inn, Furnival's inn. dates from about **1406.** Its ancient hall, in Holborn, still exists.

Gray's Inn. — The site of Gray's inn formed part of the manor of Portpoole, which passed in 1294 to the dean and chapter of St. Paul's. who let it to Reginald de Grey, chief justice of Chester and first Lord Grey of Wilton. There is little doubt that the judge lived there with his clerks and other officers of his court and law students. The Greys had for a century been connected as officials with both the court of exchequer and the chancery. Gray's inn continued in the de Grey family till the conveyance of the manor of Portpoole in 1503 to the prior and convent of the charterhouse at Sheen, from whom the benchers held the inn until the dissolution of the monasteries in 1**539** when the rent became due to the crown. In 1733 the benchers acquired the freehold. The existing records of the inn only commence with the year 1569, but Chief Justice Sir Thomas Billing told William Paston in 1454 that he had been a fellow in Gray's inn; that would imply that the inn was in existence about **30** years earlier. The constitution and officers of the inn are similar to those of the other inns. When the records open, governors had ceased to be elected. The control of the inn was vested in the masters of the bench. The office of pensioner was abolished in 1630, but the name survives in the *Pension* Book *of Gray's Inn* and in the old and new pension chambers, where the masters of the bench meet for the discussion and transaction of the business of the society and for relaxation. Of the servants of the inn the chief were in 1**j**70 the steward, the master butler, the priest and the master cook. Whether anything of the old hall of the de Greys remains cannot be determined. It was rebuilt or re-edifyed under the supervision of Nicholas Bacon and Gilbert Gerard in 1**jj6.** It was a particularly fine specimen of Tudor architecture and may be compared with the Middle Temple hall, which it much resembled, although on a smaller scale. In 1941 the hall and much else perished in an air raid, but the screen and heraldic glass had been removed to safety. The oak screen is said to have been presented by Elizabeth I. The chapel was reconstructed or re-edifyed in 161**j** and finally restored in **1893.** The library is first mentioned in 1j55.

The inns of chancery affiliated to Gray's inn were Staple inn and Barnard's inn. The former was an inn of chancery in the reign of Henry V and later became the property of the Actuaries society. Barnard's inn, named after Lionel Barnard who leased it from the dean of Lincoln, became an inn of chancery at least before 1451. The inn was later the property of the Mercer's company.

The Inner and Middle Temples. — As far as the history of the Inner and Outer Temples can be traced, they have always been separate societies. Writing about **1387,** Geoffrey Chaucer describes the "Manciple of a Temple" who had **30** lawyers as his masters, which suggests something like an inn, perhaps more than one, as already existing. The Temple had been the seat in England of the Knights Templars, on whose suppression in 1312 it passed after an interval of some years to the Knights Hospitallers of St. John of Jerusalem The first mention of the Middle Temple as a distinct society occurs in a will dated 1404, and of the Temple as an inn of court in the *Paston Letters*, where, under date Nov. 1440, the Inner Temple is spoken of as a college, as is also subsequently the Middle Temple. The two societies continued as tenants to the Knights Hospitallers of St. John until the dissolution of the order in 1**539;** they then became the lessees of the crown and so remained until **1609,** when James I made a grant by letters patent of the premises in perpetuity to the benchers of the respective societies on a yearly payment by each of £10. a payment bought up in the reign of Charles II. In this grant the two inns are described as "the Inner and the Middle Temple or New Temple." Excepting the church and the priests' hall at the west end of the hall, nothing remained in modern times of the edifices belonging to the Knights Templars, the present buildings having been almost wholly erected since the reign of Queen Elizabeth I or since the Great Fire (1666), in which the major part of the Inner Temple perished. The Temple suffered heavy destruction by air raids during World War II. The church has been in the joint occupation of the Inner and Middle Temple from time immemorial—the former taking the southern and the latter the northern half. The round portion of the church was consecrated in 1**18j,** the nave or choir in 1240. The largest and most complete of the four remaining round churches in England, it is built on the plan of the church of the Holy Sepulchre at Jerusalem. Narrowly escaping the ravages of the fire of **1666,** this beautiful building is a perfect specimen of early Gothic architecture in England. The constitution of both societies is similar to those of the other inns, but the meetings of the benchers are in both styled a "parliament," which is further evidence of their antiquity.

The Inner Temple comprehends a hall, parliament chamber, library and other buildings often rebuilt and extended, the present buildings being completed in 1870. The library owes its existence to William Petyt, keeper of the Tower records in the time of Queen Anne, who was also a benefactor to the library of the Middle Temple. Belonging to the Inner Temple. Clifford's inn was the most important of the inns of chancery and numbered among its members Sir Edward Coke and John Selden. Clement's inn was an inn of chancery before the reign of Edward IV. taking its name from the parish church of St. Clement Danes; it was the inn of William Shakespeare's Master Shallow, and the Shepherd's inn of William Makepiece Thackeray's *Pendennis*.

The Middle Temple possesses in its hall one of the most stately of existing Elizabethan buildings. It was completed in 1572, the richly carved screen at the east end in the style of the Renaissance being erected in 1575. The hall, which was preserved unaltered and survived the air raids of World War II, has been the scene of numerous historic incidents, from the time of Queen Elizabeth I. The library, which contains about **70,000** volumes, dates from **1641.** In civil, canon and international law, as also in divinity and ecclesiastical history, the library is rich; it contains also some curious works on witchcraft and demonology. There was only one inn of chancery connected with the Middle Temple, New inn, the buildings of which were razed. *See* also DOCTORS' COMMONS; LEGAL PROFESSION: *England and Wales*.

The King's Inns, Dublin. — The legal school in Ireland, the King's inns, corresponds closely to the English inns of court and is in many respects in unison with them in its regulations with regard to the admission of students into the society and to the degree of barrister-at-law, as also in the scope of the examinations enforced. Formerly it was necessary to keep a number of terms at one of the inns in London — the stipulation dating as far back as 1542 (**33** Henry VIII, c. 3). Down to **1866** the course of education pursued at the King's inns differed from the English inns of court in that candidates for admission to the legal profession as attorneys and solicitors carried on their studies with those studying for the higher grade of the bar in the same building under a professor specially appointed for this purpose — herein following the usage anciently prevailing in the inns of chancery in London. This arrangement was put an end to by the Attorneys and Solicitors act (Ireland) of **1866.** The origin of the King's inns may be traced to the reign of Edward I, when a legal society designated

Collett's inn was established outside the walls of the city; it was destroyed by an insurrectionary band. In the reign of Edward III, Sir Robert Preston, chief baron of the exchequer, gave up his residence in the city to the legal body, which then took the name of Preston's inn. In 1542 the land and buildings known as Preston's inn were restored to the family of the original donor, and in the same year Henry VIII granted the monastery of Friars Preachers for the use of the professors of the law in Ireland. Thenceforward the legal body was known as the King's inns.

In discipline and professional etiquette the members of the bar in Ireland differ little from their English brethren. The same style of costume is enforced, and the same gradations of rank are observed. The King's inns does not provide chambers for business purposes; there is consequently no aggregation of counsel in certain localities, as is the case in London around the inns of court.

Scotland. — The corporation known as the Faculty of Advocates in Edinburgh corresponds with the inns of court in London and the King's inns in Dublin and, like them, regulates the admission of barristers. (See ADVOCATES, FACULTY OF.)

INONU, ISMET: *see* ISMET INÖNÜ.

INOUYE, KAORU, MARQUESS (1835–1915), Japanese statesman, mas born in 1835, a samurai of the Choshu fief. He was a friend of his fellow-clansman Ito (later Prince Ito), and they visited England together in 1863, serving as common sailors during the voyage. At that time all travel abroad was forbidden on pain of death, but the veto did not prove deterrent in the face of a rapidly growing conviction that, as a matter of self-protection, Japan must assimilate the essentials of western civilization. Shortly after the departure of Inouye and Ito, the Choshu fief, having fired upon foreign vessels passing the strait of Shimonoseki, was menaced by war with the Yedo government or with the insulted powers, and Inouye and Ito, on receipt of this news, hastened home hoping to avert the catastrophe.

They repaired to the British legation in Yedo and begged that the allied squadron, then about to sail for Shimonoseki to call Choshu to account, should be delayed that they might have an opportunity of advising the fief to make timely submission. Not only was this request complied with, but a Britsh frigate was detailed to carry the two men to Shimonoseki. and, pending her departure. the British legation assisted them to lie perdu. Their mission proved futile, however, and Inouye was subsequently waylaid by a party of conservative samurai. who left him covered with wounds. This experience did not modify his liberal views, and, by the time of the Restoration in 1867, he had earned a high reputation as a leader of progress and an able statesman.

In theory the 1867 Restoration meant the return of all political power to the emperor. In point of fact, real control over the newly established government came to rest in the hands of a little group of about 85 samurai drawn from the four western clans, or fiefs, known as Tosa, Hizen, Satsuma, and Choshu. The Choshu samurai soon became especially influential. Among the Choshu contingent were Yamagata (later Field Marshal Prince Yamagata) who later became the head of the military bureaucracy and Ito who later became the head of the civilian bureaucracy. Because of his intimate friendship with Ito, Inouye was given a high place in the civil bureaucracy. At various times he held the portfolios of home affairs,agriculture and commerce, foreign affairs and finance. He became noted as an outstanding authority on public finance. In 1885, when the new peerage was created, he was given the title of count. He retired from active politics in 1898 but became an elder statesman whose advice was frequently sought by the imperial court. During the war with Russia he was designated special adviser to the minister of finance and by order of the emperor he attended all important state councils. In 1907 he was raised to the rank of marquess. It is generally agreed that Inouye was one of the five outstanding Japanese statesmen during the Meji era, the others being Princes Ito and Yamagata and Marquesses Matsukata and Okuma. (W. M. McG.)

INOWRACLAW (HOHENSALZA), town of Poland, in the province of Bydgoszcz, 21 mi. S.W. of Thorn (Torum). Pop. (1950) 38,000. It has an agricultural trade. Iron founding and the manufacture of machinery and chemicals are important. In the vicinity are important salt works and a sulphur mine. Inowraclaw is mentioned as early as 1185, and in 1772 it passed to Prussia. It became a part of Poland after World War I, was taken by Germany in World War II and was returned to Poland in 1945.

INQUISITION, THE. The name given to the ecclesiastical jurisdiction dealing both in the middle ages and in later times with the detection and punishment of heretics and all persons guilty of any offense against Catholic orthodoxy. (Lat. *inquisitio,* an inquiry.)

It is incorrect to say that the Inquisition made its appearance in the 13th century complete in all its principles and organs. It was the result of, or rather one step in, a process of evolution, the beginnings of which are to be traced back to the fourth century at least.

Opinions **of the** Fathers. — During the first three centuries of the Church there is no trace of any official persecution, and the earlier Fathers, especially Origen and Lactantius, reject the idea of it. Constantine, by the edict of Milan (313), inaugurated an era of official tolerance, but from the time of Valentinian I and Theodosius I onwards. laws against heretics began to appear, and increased with astonishing regularity and rapidity. Heretics are subjected to exile or confiscation, disqualified from inheriting property, and even, in the case of a few groups of Manichaeans and Donatists, condemned to death; but it should be noticed that these penalties apply only to the outward manifestations of heresy, and not, as in the middle ages, to crimes of conscience. Within the Church, St. Optatus alone *(De schtsmate Donatistarum,* lib. iii cap. iii) approved of this violent repression of the Donatist heresy; St. Augustine only admitted a *temperata severitas,* such as scourging, fines or exile, and at the end of the 4th century the condemnation of the Spanish heretic Priscillian, who was put to death in 38j by order of the emperor Maximus, gave rise to a keen controversy. St. Martin of Tours, St. Ambrose and St. Leo vigorously attacked the Spanish bishops who had obtained the condemnation of Priscillian. St. John Chrysostom considered that a heretic should be deprived of the liberty of speech and that assemblies organized by heretics should be dissolved, but declared that "to put a heretic to death would be to introduce upon earth an inexpiable crime."

The Middle Ages. — From the 6th to the 9th century the heterodox, with the exception of the Manichaean sects in certain places, were hardly subjected to persecution. They were. moreover. rare and generally isolated, for groups of sectaries only began to appear to any extent at the time of the earliest appearances of Catharism. But from the latter part of the 10th century until the beginnings of the 12th there were numerous executions of heretics, either by burning or strangling, in France, Italy,

the Empire and England; and during this period it is not easy to determine what part was taken by the Church and its bishops and doctors in this series of executions. In many cases the people, supported by the crown, were responsible for the death of the heretics; the historians give only the faintest indications of any direct intervention of the clergy, except perhaps for the examination of doctrine. The theory in these matters was at first as uncertain as the practice; in the 11th century one bishop only, Theodwin of Liége (d. 1075), affirms the necessity for the punishment of heretics by the secular arm (1050). His predecessor, Wazo, bishop of Liége (1041–44), had expressly condemned any capital punishment and advised the bishop of Chalons to resort to peaceful conversion. In the 12th century Peter the Cantor[1] protested against the death penalty, admitting at the most imprisonment; and in dealing with the heretics of Cologne, St. Bernard, who cannot be accused of leniency where heterodoxy was concerned, recommended pacific refutation, followed by excommunication or prison, but never the death penalty *(see* BERNARD, ST., OF CLAIRVAUX).

But it must be noticed that from the opening years of the 12th century date the beginnings of a decided evolution in the canon law, continuing up to the time of Innocent III., which substituted for arbitrary decisions according to circumstances an organized and particularized legislation, in which judgment was given *secundum canonicas et legitimas sanctiones,* Anselm of Lucca and the *Panormia* attributed to Ivo of Chartres reproduced word for word under the rubric *De edicto imperatorum in damnationem hoereticorum,* law 5 of the title *De hereticis* of Justinian's code, which pronounces the sentence of death against the Manichaeans; and we should remember that the Cathari, and in general all heretics in the West in the 11th and 12th centuries were considered by contemporary theologians as Manichaeans. Gratian in the *Decretum* proclaims the views of St. Augustine (exile and fines). From the beginning of the 12th century the death penalty for impenitent heretics was frequently demanded in influential quarters. In 1184 Pope Lucius III. and the emperor Frederick Barbarossa agreed on the penalties of exile, confiscation, demolition of their houses, *infamia,* and loss of civil rights. The usage, then, was already quite clear; but the death penalty had not as yet been inflicted. It was probably Peter II. of Aragon who was the first to decree, in 1197, the punishment of death by burning against the heretics who should not have left his kingdom within a given time. But it was Innocent III. who gave the most powerful impetus to the anti-heretical movement in the secular world by his frequent exhortations (beginning in 1198) to the secular princes (letters of March 25, 1199, and Sept. 22, 1207).

Beginnings of the Inquisition. — From the foregoing it is clear that the Inquisition did not arise out of, and at the time of, the crusade against the Albigenses. These executions *en masse* certainly created a definitive precedent for violent repression, but there was still no regular organization: the council of Toulouse, held in Nov. 1229 by the Roman legate after the treaty of peace, attempted to organize one, and constituted itself the tribunal. But the procedure was still uncertain. The emperor Frederick II. defined his jurisprudence more clearly: from 1220 to 1239, supported by Pope Honorius III., and above all by Gregory IX., he established against the heretics of the Empire in general a legislation in which the penalties of death, banishment and confiscation of property were formulated so clearly as to be henceforth incontestable. Gregory IX. felt his influence, and also that of the Dominican Gualo, bishop of Brescia, who had subjected his episcopal town to the full rigour of the imperial laws. The pope no longer hesitated as to the principle or the degree of repression; but introduced new methods of inquiry and judgment: he created out of the material furnished by the mendicant orders, and especially the Dominicans, the monastic inquisition, which was more elastic, more constant in its activities and more numerous than the inquisition by legate, and better disciplined than the episcopal inquisition. In Nov. 1232 the Dominican Alberic went round Lombardy with the title of *Inquisitor kaereticae pravitatis.* In 1231 a similar commission was given to the Dominicans of Friesach and to the terrible Conrad of Marburg, whose zeal in Germany even exceeded the pope's wishes. In 1233 Gregory IX. addressed a letter to the bishops in the south of France, in which he announced his intention of employing the preaching friars for the discovery and repression of heresy. The inquisition was now regularly instituted, but its jurisprudence was elaborated by successive additions or limitations by the force of custom and the detailed prescriptions added by the papal constitutions. The pope's commissioners "in the matter of heresy" at first travelled from place to place. On arriving in a district they addressed its inhabitants, called upon them to confess, if they were heretics, or to denounce those whom they knew to be heretics: a "time of grace" was opened, during which those who freely confessed were dispensed from all penalties, or only given a light penance; while those whose heresy had been openly manifested were exempted from the penalties of death and perpetual imprisonment. But this time could not exceed one month. After that began the inquisition. As soon as their mission was at an end, and heresy was considered to be stamped out, the inquisitors left the country. Later, inquisitorial districts were formed. The seat of the Inquisition in each district was the monastery of the order (Dominican or Franciscan) to which the inquisitors for that part belonged. There was never any special court or prison: the *murus* (prison) was lent to the Inquisition by the ecclesiastical or secular authorities. The maintenance of the prisoners and the duty of providing the prison fell in principle upon the bishops (council of Toulouse, 1229), but they tried to evade it. The kings of France, and in particular Louis VIII., granted subsidies to the inquisitors. For each district the inquisitors were chosen by the provincials of their order, approved or rejected by the pope, and removable by him only. Their discretionary powers were absolute. They conducted their interrogations before two persons (laymen or ecclesiastics) and only pronounced their sentence after consultation with leading men in the district. This was the only protection for the accused. It was in vain that the civil lawyers tried to prove that the secular authorities had a right to see the documents bearing on the case; the Inquisition always succeeded in setting aside these claims. The share taken in the proceedings by the bishops, the accused or their representatives, though admitted in principle, was as a rule merely illusory.

Procedure of the Inquisition. — Bernard Guy (Bernardus Guidonis), Dominican, 1261–1331, one of the earliest and most complete exponents of the theory of the Inquisition, admits distinctly that in its procedure *multa sunt specialia.* The procedure was secret and in the highest degree arbitrary, proceeding *sine strepitu et figura judicii,* its object being to ascertain not so much particular offences as tendencies: the murderers of the inquisitor Peter Martyr (Dominican, d. 1252) were tried, not as assassins, but as guilty of heresy and adversaries of the Inquisition; and on the other hand, external acts of piety and verbal professions of faith were held of no value. Moreover, the Inquisition was not bound by the ordinary rules of procedure in its inquiries: the accused was surprised by a sudden summons, and as a rule imprisoned on suspicion. All the accused were presumed to be guilty, the judge being at the same time the accuser. Absence was naturally considered as contumacy, and only increased the presumption of guilt by seeming to admit it. The accused had the right to demand a written account of the offences attributed to him, but the names of the witnesses were withheld from him (Innocent IV.; bulls *Cum negocium* and *Licet sicut accepimus),* he did not know who had denounced him, nor what weight was attached by the judges to the denunciations against him. The utmost that was allowed him was the unsatisfactory privilege of the *recusationes divinatrices, i.e.,* at his first examination he was asked for the names of any enemies of whom he knew, and the causes of their enmity. Heretics or persons deprived of civil rights (*infames*) were admitted as witnesses in cases of heresy. Women, children or slaves could be witnesses for the prosecution, but not for the defence, and cases are even

[1] Pierre de Beauvoisis (?), choir-master *(grand-chantre)* of the university of Paris (1184), bishop of Tournai (1191), of Paris (1196); died as a Cistercian in 1197. He was beatified.

to be found in which the witnesses were only ten years of age. Langhino Ugolini states that a witness who should retract his hcstile evidence should be punished for false witness, but that his evidence should be retained, and have its full effect on the sentence. No witness might refuse to give evidence, under pain of being considered guilty of heresy. The prosecution went on in the utmost secrecy. The accused swore that he would tell the whole truth, and was bound to denounce all those who were partners of his heresy, or whom he knew or suspected to be heretics. If he confessed, and denounced his accomplices, relatives or friends, he was "reconciled" with the Church, and had to suffer only the humiliating penalties prescribed by the canon law. If further examination proved necessary, it was continued by various methods Bernardus Guidonis enumerates many ways of obtaining confessions, sometimes by means of moral subterfuges, but sometimes by a process of weakening the physical strength. And as a last expedient torture was resorted to. The Church was originally opposed to torture, and the canon law did not admit confessions extorted by that means; but by the bull *Ad extirpanda* (1252) Innocent IV. approved its use for the discovery of heresy, and Urban IV. confirmed this usage, which had its origin in secular legislation (cf. the Veronese Code of 1228, and Sicilian Constitution of Frederick II. in 1231). In 1312 excessive cruelty had to be suppressed by the council of Vienna. The next step was the torture of witnesses, a practice which was left to the discretion of the inquisitors. Moreover, all confessions or depositions extorted in the torture-chamber had subsequently to be "freely" confirmed.

The procedure was of course not litigious; any lawyer defending the accused would have been held guilty of heresy. The inquiry might last a long time, for it was interrupted or resumed according to the discretion of the judges, who disposed matters so as to obtain as many confessions or denunciations as possible. After the different phases of the examination, the accused were divided into two categories: (1) those who had confessed and abjured, (2) those who had not confessed and were convicted of heresy. There was a third class, by no means the least numerous, namely, those who having previously confessed and abjured had relapsed into error. Next came the moment of the sentence: "there was never any case of an acquittal pure and simple" (H. C. Lea). The formula for full and complete acquittal given by Bernardus Guidonis in his Practica, should, he says, never or very rarely be employed. The sentences were solemnly pronounced on a Sunday, in a church or public place, in the presence of the inquisitors, their auxiliaries, the bishops, the secular magistrates and the people. This was the sermo generalis. The accused who had confessed were reconciled, and the penalties were then pronounced; these were, in order of severity, penances, fasting, prayers, pilgrimages, public scourging, the compulsory wearing on the breast or back of crosses of yellow felt sewn on to the clothes or sometimes of tongues of red, letters, etc. The inquisitors eventually acquired the right of inflicting fines at discretion. In 1244 and 1251 Innocent IV. reproved them for their exactions. All these minor penalties could be commuted for payments in money in the same way as absolution from the crusader's vow, and the council of Vienna tried to put an end to these extortions. Beyond these minor penalties came the severer ones of imprisonment for a period of time, perpetual imprisonment and imprisonment of various degrees of severity (*murus* lnrgus, murus *strictus vel strictissimus*). The murus *strictus* consisted in the deepest dungeon, with single or double fetters, and "the bread and water of affliction"; but the severity of the prison régime varied very much. The murus *largus*, especially for a rich prisoner, amounted to a fairly mild imprisonment, but the mortality among those confined in the murus *strictus* became so high that Clement V. ordered an inquiry to be made into the prison régime in Languedoc, in spite of Bernard Guy's protest against the investigation as likely to diminish the prestige of the inquisitors. After the sentences had been pronounced, the obstinate heretics and renegades were for the last time called upon to submit and to confess and abjure. If they consented, they were received as penitents, and condemned on the spot to perpetual imprisonment; if they did not consent, they were handed over to the secular arm. When the heretic was handed over to the secular arm the agents of the secular po er were recommended to punish him debita animadversione, and the form of recommending him to mercy was gone through. In effect, handing over to the secular arm was equivalent to a sentence of death, and of death by fire. Jacob Sprenger, Dominican provincial in Germany (1494) and inquisitor, does not hesitate to speak of the victims quas *incinerari* fecimus ("whom we [the inquisitors] caused to be burnt to ashes"[x]). But we must accept the conclusions of H. C. Lea and Vacandard that comparatively few people suffered at the stake in the mediaeval Inquisition. Between 1308 and 1323, Bernard Guy, who cannot be accused of inactivity, only handed over to the secular arm 42 persons, out of 930 who were convicted of heresy.

Punishment by Confiscation of Goods.—From the point of view of jurisprudence of the Inquisition, the confiscation of the condemned man's property by the ecclesiastical and secular powers is only the accompaniment to the more severe penalties of perpetual imprisonment or death; but from the point of view of its economic history the importance of the confiscation is supreme. The practice originated in the Roman law, and all secular princes had already, in their own interest, recognized it as lawful (Frederick Barbarossa, Decree of Verona; Louis VIII., ordinances of 1226, 1229; Louis IX., ordinance of 1234; Raymond VII. of Toulouse, etc.). In the kingdom of France there was a special official, the *procureur* des encours (confiscation in the matter of heresy), whose duty it was to collect the personal property of the heretics, and to incorporate their landed estates in the royal domain; in Languedoc crying abuses arose, especially under Alphonse of Poitiers. Soon the papacy managed to gain a share of the spoils, even outside the states of the Church, as is shown by the bulls ad *extirpanda* of Innocent IV. and Alexander IV., and henceforward the inquisitors had, in varying proportions, a direct interest in these spoliations. In Spain this division only applied to the property of the clergy and vassals of the Church, but in France, Italy and Germany, the property of all heretics was shared between the lay and ecclesiastical authorities. Venice alone decided that all the receipts of the Holy Office should be handed over in full to the state. Clement V., in his attempted reform and regularization of inquisitorial procedure, endeavoured to reduce the confiscations to a fairly reasonable minimum, and in 1337–38 a series of papal inquiries was held into this financial aspect of the matter. The Assize of Clarendon, the Constitutions of Frederick II. (1232) and of Count Raymond of Toulouse (1234) had also come to a joint decision with the councils on this question. Charles V. of France prevailed upon the papacy to abolish this regulation (1378). Confiscation was, indeed, most profitable to the secular princes, and there is no doubt that the hope of considerable gain was what induced many princes to uphold the inquisitorial administration, especially in the days of the decay of faith. The resistance of the south of France to the Capetian monarchs was to a large extent broken owing to the decimation of the bourgeoisie by the Inquisition and their impoverishment by the extortions of the encours. The same was the case in certain of the Italian republics; while in districts such as the north of France, where heretics were both poor and few, the Inquisition did not easily take root, nor did it prove very profitable. These confiscations, the importance of which in the political and economic history of the middle ages was first shown fully by H. C. Lea, were a constant source of uncertainty in transactions of all kinds; there was, for instance, always a risk in entering into a contract in a place where the existence of heretics was suspected, since any contract entered into with a heretic was void. Nor was there any more security in the transmission of inheritances for posthumous trials were frequent; the Liber *sententiarum inquisitionis* of Bernardus Guidonis (1307–23) records sentences pronounced after death against 89 persons during a period of 15 years. But not only was their property confiscated and their heirs disinherited; they were subject to still further penalties. Frederick II extended to heresy the application of the Roman law disqualifying from holding office, and even included under its operation the children and

grandchildren of the guilty man. Alexander IV. and Boniface VIII. lightened the severity of this law, and removed certain disqualifications, notably in the case of ecclesiastical offices and property.

The sphere of action of the Inquisition was gradually extended by the theologians and casuists until sorcery and magic ranked with doctrinal heresy *(see* Hansen, *Inquisition, Hexenwahn,* u. *Hexenverfolgung,* 1900). With regard to Jews, they might profess their religion and observe its rites without being in a state of heresy; they were only heretic when they attacked the Christian faith or community, made proselytes, or returned to Judaism after being converted. But those who practised usury were "suspected of not holding orthodox doctrine as to theft" (Vacandard), and on this account the Inquisition gained a hold on them (the special case of Spain is described on page 381).

TREATMENT OF HERESY

England. — The Inquisition was primarily the instrument for the repression of all kinds of breaches of orthodoxy. Its work in this capacity we will now outline for each of the great countries of mediaeval Christendom. England, whether before or after the establishment of the Inquisition, had few trials for heresy and, particularist in this as in all her religious activity, judged them according to her own discipline, without asking Rome for laws or special judges. But orthodoxy remained almost unimpaired until the time of Wycliffe. Apparently neither the Catharist, Waldensian nor pantheistic heresies gained any footing in Great Britain. The affair of the Templars in France, which was quite political, was repeated in England: Clement V. having ordered their arrest, Edward II., after much hesitation, gave orders to the sheriffs to execute it and then decided that the *ecclesiastical law* should be applied. The papal inquisitors sent to England met with a bad reception, and the pope was obliged to forbid them to use torture, which was contrary to the laws of the kingdom. It was found impossible to establish the Templars' guilt and only canonical penalties were inflicted on them. The rising of the Lollards having alarmed both the church and the state, the article De *haeretico comburendo* was established by statute in 1401, and gained a melancholy notoriety during the religious struggles of the 16th century; it seems to have been not so much a measure for the safeguarding of dogma as a violent assertion of the secular absolutism. It was not till 1676 that Charles II. caused it to be abrogated, and obtained a decision that in cases of atheism, blasphemy, heresy, schism and other religious offences, the ecclesiastical courts should be confined to the penalties of excommunication, removal from office, degradation and other ecclesiastical means of censure, to the exclusion of the death penalty. Scotland was much later than England in giving up persecution and bloodshed; and so late as 1696 a student of medicine aged eighteen named Aikenhead was accused of heresy and hanged in Edinburgh.

France. — The activities of the monastic Inquisition in France lay chiefly in the south. The repression of the Albigensian heresy went on even when its importance had disappeared. The chronicle of the inquisitor Guilhem Pelhisso (d. 1268) shows us the most tragic episodes of the reign of terror which wasted Languedoc for a century. Guillaume Arnaud, Peter Cella, Bernard of Caux, Jean de St. Pierre, Nicholas of Abbeville, Foulques de St. Georges, were the chief of the inquisitors who played the part of absolute dictators, burning at the stake, attacking both the living and the dead, confiscating their property and land, and enclosing the inhabitants both of the towns and the country in a network of suspicion and denunciation. The secular authorities were of the utmost assistance to them in this task; owing to the confiscations, the crown had too direct an interest in the success of the inquisitorial trial; not to connive at all their abuses. There were frequent attempts at retaliation, directed for the most part against the inquisitors, and isolated attacks were made on Dominicans; but the work of repression culminated under Bernard Guy, and completed the destruction of Catharism, the appearances of which after the middle of the 14th century are rare. Afterwards the efforts of the Inquisition were directed against the Spirituals, who were a branch of the Franciscans, and were remote disciples of Joachim, abbot of Floris (*q.v.*), and whom their rigid rule of absolute poverty led, by a reaction against the cupidity of the ordinary ecclesiastics, to repudiate the papal hierarchy. On Feb. 17, 1317 John XXII. condemned all these irregular followers of St. Francis, and the Inquisition of Languedoc was at once set against them. Four *spirituales* were burnt at Marseilles in 1318, and soon the persecution was extended to the Franciscan *beguins* or *tertiarii,* many being burnt about 1320. The Waldenses (*q.v.*) were more difficult to destroy: originally less dangerous to the church than the Cathari, they resisted longer, and their dispersal in scattered communities aided their long resistance.

In the north of France the workings of the Inquisition were very intermittent; for there were fewer heretics there than in the south, and as they were poorer, there was less zeal on the part of the secular arm to persecute them. At its outset, however, the Inquisition in the north of France was marked by a series of melancholy events: the inquisitor Robert le Bougre, formerly a Catharist, spent six years (1233–39) in going through the Nivernais, Burgundy, Flanders and Champagne, burning at the stake in every place unfortunates whom he condemned without a judgment, supported as he was by the ecclesiastical authorities and by princes such as Theobald of Champagne. The pope was forced to put a check on his zeal, and, after an inquiry, condemned him to imprisonment for life. We know that there were inquisitors settled in fle de France, Orléanais, Touraine, Lorraine and Burgundy during the 12th century, but we know next to nothing of what they did. In the 14th century, the Flemish and German heresies of the Free Spirit made their appearance in France, and some executions resulted. But in the 15th century, with the exception of a few condemnations aimed against the Hussites, the Inquisition acted but feebly.

From the middle of the 14th century onward, the *parlement* had taken upon itself the right of hearing appeals from persons sentenced by the Inquisition. And the University again, by its faculty of theology, escaped the jurisdiction of the Inquisition. These two great bodies at the time of the Reformation took the place of the Inquisition in dealing with heresy.

Italy. — In Italy heresy not infrequently took on a social or political character; it was sometimes almost indistinguishable from the opposition of the Ghibellines or the communalist spirit of independence. Lombardy, besides a number of Cathari, contained a certain number of vaguely-defined sects against whom the efforts of the Apostolic Visitors sent by Innocent III. were not of much effect. From the very earliest days of the Inquisition, John of Vicenza, Roland of Cremona and Rassiero Sacchoni directed their persecutions against Lombardy, and especially against Milan. St. Peter Martyr, who was conspicuous for his violence, was assassinated in 1252. On March 20, 1256 Alexander IV. ordered the provincial of the friar preachers of Lombardy to increase the number of inquisitors in that province from four to eight. At Florence both heresy and Ghibellinism were alike crushed by the severities of Fra Ruggieri, and indulgences were promised to all who should aid in the extinction of heresy in Tuscany. Certain districts revolted against this violence, which threatened to devastate Italy as it had devastated Provence; in 1277 Fra Corrado Pagano was killed on an expedition against the heretics of the Vattelline, and two years after the people of Parma rose against the inquisitors. Besides, this reign of terror only raised to a furious pitch the passionate and independent piety of the Italian peoples. The Inquisition had a hard struggle against the successes of Gerard Legarelli, and especially Dolcino *(see* APOSTOLICI), which only came to an end after a long and difficult trial of the adepts of the Messianist sect of Guglielma, some of whom belonged to the noble families of Lombardy. Zip till the beginning of the 14th century, however, the power of the Inquisition steadily increased, and at this period Zanghino Ugolini appeared as the most skilful exponent of its theory and procedure. About the same time Charles of Anjou introduced the Inquisition into the Two Sicilies, but it could rarely effect anything there; the religious cohesion of the country was weak, and refugees were sure of safe hiding, both Waldenses and Fraticelli being frequently

harboured there.

Venice always preserved its autonomy as regards the repression of heresy; she was perfectly orthodox, but remained independent of Rome; Innocent IV. sent inquisitors there, but the heretics continued actually to be subject to the secular tribunals. In 1288 a compromise was arrived at, and the papal Inquisition was admitted into the republic, but only on condition that it should remain under the secular power; thus there was established a mixed régime which survived till the last days of the Venetian state. In Savoy the Inquisition constantly carried on severe measures against the Waldenses of the Alps. During the 14th and 15th centuries there was an uninterrupted succession of trials.

As regards the papal states, "it was in the nature of things that, by a confusion of the two personages, the pope should consider all opposition to him qua Italian prince as resistance offered to the head of the church, *i.e.*, to the church" (Langlois). The Colonna had a personal animosity against the Gaetani; therefore Boniface VIII., a Gaetano, declared the Colonna to be heretics. Rienzi was accused of heresy for having questioned the temporal sovereignty of the pope at Rome. The Venetians, who in 1309 opposed the annexation of Ferrara by Clement V. to the detriment of the house of Este, were proclaimed heretics and placed under the ban of Christendom. Savonarola was attacked because he interfered with the policy of Alexander VI. at Florence. It was this same desire for the hegemony of Italy which inspired the attitude of the popes throughout the middle ages, causing them to excommunicate, apparently without reason so far as doctrine was concerned, the Visconti of Milan, the Della Scala of Verona, the Manfredi of Faenza, etc., and prompting them to lay under an interdict or preach a crusade against certain rebellious great towns (Clement V. against Venice, John XXII. against Milan).

Germany. — In Germany heresies, especially of a mystical character, were numerous; some of them affected the people, and led to religious and social movements of no little importance. The repression of heresy went on by fits and starts, and the Inquisition was never exercised so regularly in the Germanic as in certain of the Latin countries. At the outset of the 13th century persecutions of the Waldenses and Ortlibarii (followers of Ortlieb of Strassburg, c. 1200) took place at Strasbourg; measures were taken locally, until, in 1231, Gregory IX. issued definite instructions to the German prelates with a view to a regular repression of heresy, and gave to Conrad of Marburg full powers to execute them. In Feb. 1234 the Diet of Frankfort decided, in spite of the pope's injunctions, that the destruction of heresy should be entrusted to the ordinary magistrates. Moreover, owing to the struggle between the Empire and the papacy, the German prelates always limited the prerogatives of the papal Inquisition. Marsilius of Padua, the theoretical exponent of the imperial rights, attributes to the secular judge the right and obligation to punish heresy, the priest's rôle being merely advisory. In 1353 Innocent VI. tried to implant the papal Inquisition in Germany once for all; its success was but short, and Urban V.'s attempt in 1362 succeeded little better, in spite of the fact that Charles IV. (edicts of Lucca, June 1369) gave him the support of the secular power. Towards 1372, however, Gregory XI. succeeded in regularizing the exercise of the powers of the papal inquisitors on German soil; and the latter, notably Kerlinger, Hetstede, etc., set to work to destroy the communities of the Beghards (who had developed with extraordinary rapidity), to burn their books, to close those *beguinages* which were under suspicion, and to check mystical epidemics such as those of the "flagellants," "dancers," etc. But these measures provoked protests from the people, the secular magistrates and even the bishops, so that Gregory XI., perceiving that he was face to face with the popular party, invited the bishops to control the inquiries of his own envoys. At the end of the 15th century the two inquisitions were acting concurrently.

Bohemia. — In Bohemia and the provinces subject to it the Waldenses had found their chosen country, and by the middle of the 13th century their propaganda was very flourishing. In 1245 Innocent IV. ordered the bishops to prosecute them with the aid of the secular arm, and in 1257, at the request of King Premysl Ottokar II., Alexander IV. introduced the Inquisition into Bohemia. But from this date till 1335 inquisitorial missions succeeded one another without effecting any sensible diminution in the material and moral strength of the heresy. The Waldenses had been joined by other sectaries, the Luciferani, and especially the Brethren of the Free Spirit. It was in vain that the bishops of Bohemia and Silesia carried on during the second half of the 14th century an active campaign against heresy; the spirit of criticism which had arisen with regard to the morals, and even to the dogmas of the Church, was already preparing the way for Hussitism.

The Balkan States. — In the regions east of the Adriatic, Catharism, the first communities of which had very probably settled here, was supreme in the time of Innocent III. and Honorius III. The first Dominicans who established themselves in these parts had much to suffer from the aggression of those very heretics whom they had come to convert. Gregory XI., implacable in his persecution of Catharism, preached a crusade against them in 1234, and Bosnia was laid waste by fire and sword. But in spite of these violent measures Catharism only gained strength in the churches of Bulgaria, Rumania, Slavonia and Dalmatia. In 1298 Boniface VIII. tried to organize the Inquisition there, but the project remained fruitless. The attempt was revived in 1323 by John XXII. with doubtful success. The persecutions undertaken in the 14th and 15th centuries merely resulted in binding the Cathari to the invading Turks, with whom they found more tolerance than with the Slav princes converted to Roman orthodoxy.

Spain. — In Spain the papal Inquisition only very slowly gained a footing. Spain had been, in turn or simultaneously, Arian under the Visigoths, Catholic under the Hispano-Romans, Mohammedan by conquest, and under a régime of religious peace Judaism had developed there. After the reconquest its heresies had been of minor importance. At the end of the 12th century Alphonso II. and Peter II. had on principle promulgated cruel edicts against heresy, but the persecution seemed to be dormant. By the bull *Declinante* of May 26, 1232 inquisitors were sent to Aragon by Gregory IX. on the request of Raymond of Penaforte, and by 1237–38 the Inquisition was practically founded. But as early as 1233 King James I. had promulgated an edict against the heretics which quite openly put the Inquisition in a subaltern position, and secularized a great part of its activities. The people, moreover, showed great hostility towards it. In Castile Alphonso the Wise had, by establishing in his Fuero *Real* and his *Siete Partidas* an entirely independent secular legislation with regard to heretics (1255), removed his kingdom from all papal interference. At the opening of the 14th century Castile and Portugal had still no Inquisition. It was not against heresy that the church had to direct its vigilance. A mutual tolerance between the different religions had in fact sprung up, even after the conquest; and for a long time past both the decisions of councils and papal briefs had proclaimed their surprise and indignation at this ominous indifference. Sporadic cases of violent measures against Jews and Mohammedans occurred during the 13th century and increased in frequency and severity during the 14th and 15th centuries. Massacres *en masse* and forced baptisms were carried out, instigated by the clergy. A class of "converted" Mohammedans and Jews arose, and increased after the conquest of the kingdom of Granada and the completion of the conquest by Ferdinand and Isabella, and after the pacification of the kingdoms of Aragon and Valencia by Charles V. The Mahommedans and Jews in these parts were given the choice between conversion and exile. Being of an active nature, and desiring some immediate powers as a recompense for their moral sufferings, the Jewish or Mohammedan *Conversos* soon became rich and powerful. In addition to the hatred of the church, hatred and jealousy arose also among laymen and especially in the rich and noble classes. *Limpieza, i.e.*, purity of blood, and the fact of being an "old Christian" were made the conditions of holding offices. And a combination of secular jealousy, national pride, and religious bigotry led to the foundation of an essentially national Inquisition, directed against local heretics, and founded without the help of the papacy. It was created in 1480 by Ferdinand and Isabella

Sixtus IV. had wished the papal Inquisition to be established after the form of the middle ages; but Ferdinand, in his desire for centralization wished to establish an inquisition which should be entirely Spanish, and entirely royal. Rome resisted, but at last gave way. Sixtus IV., Alexander VI., Innocent VIII., Julius II. and after them all the popes of the 16th century, saw in this secular attempt a great power in favour of orthodoxy, and approved it when established. The Inquisition took advantage of this to claim an almost complete autonomy. The decisions of the Roman Congregation of the Index were only valid for Spain if the Holy Office of Madrid thought good to countersign them; consequently there were some books approved at Rome and proscribed in the peninsula, and some which were forbidden at Rome and approved in the peninsula. The Spanish Holy Office perceived long before Rome the dangers of mysticism, and already persecuted the mystics, especially the *Alumbrados* and afterwards the Molinists, while Rome still favoured them. There was even a financial dispute between the Inquisition and the papacy. The Roman Penitentiary sold exemptions from penalties (involving loss of civil rights), such as prison, the galleys and wearing the *sanbenito,* and dispensations from the crime of *Marrania* (secret Judaism). The inquisitors tried to gain control of this sale, and at a much higher price, and were seconded in this by the kings of Spain, who saw that it was to their own interest. The struggle continued throughout the first half of the 16th century, the Curia finally triumphing, thanks to the energy of Paul III. Since, however, the Inquisition continued to threaten the holders of papal dispensations, most of them found it prudent to demand a definite rehabilitation, in return for payments both to the king and the Inquisition. As a national institution the Inquisition had first of all the advantage of a very strong centralization and very rapid procedure, consisting as it did of an organization of local tribunals (established in all parts of the country) with a supreme council at Madrid, the *Suprema*. The grand inquisitor was *ex officio* president for life of the royal council of the Inquisition.

From the very beginning the papacy strengthened the organization by depriving the Spanish metropolitans, by the bull of Sept. 25, 1487, of the right of receiving appeals from the decisions given jointly by the bishops of the various dioceses, their suffragans and the apostolic inquisitors and by investing the inquisitor-general with this right. And, more than this, Torquemada actually took proceedings against bishops; for example, the accusation of heresy against Don Pedro Aranda, bishop of Calahorra (1498); while the inquisitor Lucero prosecuted the first archbishop of Granada, Don Ferdinando de Talavera. Further, when once the Inquisition was closely allied to the crown, no Spaniard, whether clerk or layman, could escape its power. Even the Jesuits, though not till after 1660, were put under the authority of the Suprema. But the descendants of Moors and Jews, though they were good Christians, or even nobles, were most held in suspicion. A family into which a forced conversion or a mixed marriage had introduced Moorish or Jewish blood was almost entirely deprived of any chance of public office, and was bound, in order to disarm suspicion to furnish agents or spies to the Holy Office.

The Spaniards were very quick to accept the Inquisition to such an extent as to look upon heresy as a national scourge to be destroyed at all costs, and they consequently considered it as a powerful and indispensable agent of public protection. As had happened among the Albigenses, commerce and industry were rapidly paralysed in Spain by this odious régime of suspicion, especially as the *Conversos,* who inherited the industrial and commercial capacity of the Moors and Jews, represented one of the most active elements of the population. Besides, this system of wholesale confiscations might reduce a family to beggary in a single day, so that all transactions were liable to extraordinary risks. It was in vain that the counsellors of Charles V., and on several occasions the Cortes, demanded that the inquisitors and their countless agents should be appointed on a fixed system by the state; the state, and above all the Inquisition, refused to make any such change. The Inquisition preferred to draw its revenues from heresy, and this is not surprising if we think of the economic aspect of the Albigensian Inquisition.

The political aspect of the work and character of the Inquisition had been very diversely estimated, it is a serious error to attribute to it, as has too often been done, extreme ideas of equality, or even to represent it as having favoured centralization and a royal absolutism to the same extent as the Inquisition of the 13th and 14th centuries in Languedoc. "It was a mere coincidence," says H. C. Lea, "that the Inquisition and absolutism developed side by side in Spain." The Suprema did not attack all nobles as nobles; it attacked certain of them as *Conversos,* and the Spanish feudal nobles were sure enough of their *limpieza* to have nothing to fear from it. But it is undeniable that it frequently tended to constitute a state within the state. At the time of their greatest power, the inquisitors paid no taxes, and gave no account of the confiscations effected; they claimed for themselves and their agents the right of bearing arms, and it is well known that their declared adversaries, or even those who blamed them in some respects, were without fail prosecuted for heresy. It was, however, only the Bourbons, who had imbibed Gallican ideas, who by dint of perseverance managed to make the Inquisition subservient to the Crown, and Charles III., "the philosopher king," openly set limits to the privileges of the inquisitors. Napoleon, on his entry into Madrid (Dec. 1808), at once suppressed the Inquisition, and the extraordinary general Cortes on Feb. 12, 1813 declared it to be incompatible with the constitution, in spite of the protests of Rome. Ferdinand VII. restored it (July 21, 1814) on his return from exile, but it was impoverished and almost powerless. It was again abolished as a result of the Liberal revolution of 1820, was restored temporarily in 1823 after the French military intervention under the duc d'Angoulême, and finally disappeared on July 15, 1834, when Queen Christina allied herself with the Liberals It was not, however, till May 8, 1869 that the principle of religious liberty was proclaimed in the peninsula; and even since then it has been limited by the constitution of 1876, which forbids the public celebration of dissident religions (S. Reinach). In 1816 the pope abolished torture in all the tribunals of the Inquisition It is a too frequent practice to represent as peculiar to the Spanish Inquisition modes of procedure in use for a long time in the inquisitorial tribunals of the rest of Europe. There are no special manuals, or *practica,* for the inquisitorial procedure in Spain; but the few distinctive characteristics of this procedure may be mentioned. The Suprema allowed the accused an advocate chosen from among the members or familiars of the Holy Office; this privilege was obviously illusory, for the advocate was chosen and paid by the tribunal, and could only interview the accused in presence of an inquisitor and a secretary. The theological examination was a minute proceeding; the "qualificators of the Holy Office," special functionaries, whose equivalent can, however, easily be found in the mediaeval Inquisition, charged those books or speeches which had incurred "theological censures," with "slight, severe or violent" suspicion. There was no challenging of witnesses. The torture, to the practice of which the Spanish Inquisition certainly added new refinements, was originally very much objected to by the Spaniards, and Alphonso X. prohibited it in Aragon; later, especially in the 15th, 16th and 17th centuries it was applied quite shamelessly. But by the end of the 18th century, according to Llorente, it had not been employed for a long time; the *fiscal,* however, habitually demanded it, and the accused always went in dread of it. The punishment of death by burning was much more often employed by the Spanish than by the mediaeval Inquisition.

With the extension of the Spanish colonial empire the Inquisition spread throughout it almost contemporaneously with the Catholic faith. Ferdinand IV. decreed the establishment of the Inquisition in America, and Jimenes in 1j16 appointed Juan Quevedo, bishop of Cuba, inquisitor-general delegate with discretionary powers. Excesses having been committed by the agents of the Holy Office, Charles V. decreed (Oct. 15, 1538) that only the European colonists should be subject to the jurisdiction of the Inquisition; but Philip II. increased the powers of the inquisitors' delegate and, in 1541 established on a permanent basis three new provinces of the Inquisition at Lima, Mexico and Cartagena The first *auto-da-fe'* took place at Mexico in 1574, the year in which Hernando Cortez died. The Inquisition of Portugal was no less

careful to ensure the orthodoxy of the Portuguese colonies. An Inquisition of the East Indies was established at Goa, with jurisdiction over all the dominions of the king of Portugal beyond the Cape of Good Hope. Finally Philip II. even wished to establish an itinerant Inquisition, and at his request the pope created, by a brief of July 21, 1571, the "Inquisition of the galleys," or "of fleets and armies."

During the 16th and 17th centuries the Inquisition in Spain was directed against Protestantism. The inquisitor-general, Fernando de Valdés, archbishop of Seville. asked the pope to condemn the Lutherans to be burnt even if they were not backsliders, or wished to be reconciled, while in 1560 three foreign Protestants, two Englishmen and a Frenchman were burnt in defiance of international law But the Reformation never had enough supporters in Spain to occupy the attention of the Inquisition for long. After the *Marranes* the mystics of all kinds furnished the greatest number of victims. Here again we should not lose sight of the tradition of the mediaeval Inquisition; the mysticism of the Beghards, the Brethren of the Free Spirit and the innumerable pantheist sects had been pitilessly persecuted by the inquisitors of Germany and France during the 14th and 15th centuries The Illuminati *(alumbrados),* who were very much akin to the mediaeval sectaries, and the mystics of Castile and Aragon were ruthlessly examined, judged and executed. Not even the most famous persons could escape the suspicious zeal of the inquisitors Valdés and Melchior Cano. St. Ignatius de Loyola was twice imprisoned at the beginning of his career; St. Theresa was accused of misconduct, and several times denounced; one of her works, *Conceptos del amor divino,* was prohibited by the Inquisition, and she was only saved by the influence of Philip II. Countless numbers of obscure visionaries were accused of Illuminism and perished. Miguel de Molinos, one of the leaders of the Quietist movement, was also arrested and condemned to perpetual imprisonment (1685–87), and during the 18th century, till 1781, several of Molinos' followers were burnt.

The Inquisition also attacked Jansenism, freemasonry (from 1738 onward; *cf.* the bull *In eminenti*) and "philosophism," the learned naturalist José Clavigo y Faxarcho (1730–1806), the mathematician Benito Bails (1730–97), the poet Tomas de Iriarte, the ministers Clavigo Ricla, Aranda and others being prosecuted as "philosophers." Subject also to the tribunal of the Holy Office were bigamists, blasphemers, usurers, sodomites, priests who had married or broken the secrecy of the confessional, laymen who assumed ecclesiastical costume, etc.

Two features of the Spanish Inquisition are especially noteworthy: the prosecutions for "speeches suspected of heresy" and the censure of books. The great scholar Pedro de Lerma, who after fifty years at Paris (where he was dean of the faculty of theology) had returned to Spain as abbot of Compluto, was called upon in 1537 to abjure eleven "Erasmian" propositions, and was forced to return to Paris to die. Juan de Vergara and his brother were summoned before the Inquisition for favouring Erasmus and his writings, and detained several years before they were acquitted. Fray Alonso de Virues, chaplain to Charles V., was imprisoned on an absurd charge of depreciating the monastic state, and was only released by the pope at the instance of the emperor. Mateo Pascual, professor of theology at Alcala, who had in a public lecture expressed a doubt as to purgatory, suffered imprisonment and the confiscation of his goods. The censure of books was established in 1502 by Ferdinand and Isabella as a state institution. All books had to pass through the hands of the bishops; in 1521 the Inquisition took upon itself the examination of books suspected of Lutheran heresy. In 1554 Charles V. divided the responsibility for the censorship between the Royal Council, whose duty it was to grant or refuse the *imprimatur* to manuscripts and the Inquisition, which retained the right of prohibiting books which it judged to be pernicious; but after 1527 it also gave the licence to print. In 1547 the Suprema produced an Index of prohibited books, drawn up in 1546 by the university of Louvain; it was completed especially as regards Spanish books, in 1551, and several later editions were published. Moreover, the *revisores* de *libros* might present themselves in the name of the Holy Office in any private library or bookshop and confiscate prohibited books. In 1558 the penalty of death and confiscation of property was decreed against any bookseller or individual who should keep in his possession condemned books. The censure of books was abolished in 1812.

BIBLIOGRAPHY.—A critical bibliography was drawn up by P. Fredericq in the preface to the French translation (1900) of H. C. Lea's important work: *History of the Inquisition in the Middle Ages* (3 vols., 1888). *See* also J. Havet, *L'Hérésie et le bras séculier au moyen âge jusqu'au XIIIe siècle in the Oeuvres complètes,* vol. ii. (1896); Ch. V. INSANITY. Although formerly a part of scientific nomenclature, the word "insanity" is today employed principally as a term of legal significance. So used, it denotes those conditions of mental disorder or defect which modify certain of the legal relations, rights and obligations of afflicted persons. For discussions of mental disorder in its medical and psychological aspects, *see* ABNORMAL PSYCHOLOGY; MENTAL DEFICIENCY; PSYCHIATRY; PSYCHOANALYSIS; PSYCHOLOGY; PSYCHOSIS.

In general, the legal rules which define the rights, privileges and obligations of persons assume the existence of a degree of mental capacity sufficient to enable the person to manage his conduct and affairs in the ordinary contingencies of life. When, by reason of mental disease or defect, such capacity is lacking, however, the law applies special regulations which deny to the insane person some of the rights and privileges enjoyed by other members of the community, and, at the same time, relieve him of certain obligations and responsibilities. These various rules are encountered both in the criminal and civil law. The degree of mental incapacity required to be found and the modes of proof vary from situation to situation. There is, thus, no single legal test of insanity. Reference must always be made to the particular purpose for which the inquiry is made. Even with respect to the same rule, legal authority is sometimes sharply divided.

INSANITY IN THE CRIMINAL LAW

The most dramatic application of the insanity concept, though not necessarily of the greatest practical importance, is that which relieves the afflicted person of criminal responsibility for his conduct. It is important to understand that the legal tests of responsibility are not, and are not intended to be, scientific definitions of mental disorder. Rather, the legal tests are expected to identify those persons whose incapacities, produced by mental disease or defect, are of such character and extent that criminal responsibility should be denied on grounds of social expediency and justice. The inutility and moral incongruity of holding seriously disordered persons to the criminal consequences of their acts have been recognized in the development of the Anglo-American law for at least seven centuries. Responsibility assumes capacity to make elementary moral discriminations and power to adjust behaviour to the commands of the law. One lacking such capacities is conceived as ineligible for the moral condemnation inherent in a criminal conviction. Such persons, also, are not likely to be deterred from the commission of criminal offenses by the threat of penal sanctions.

Early History. — Beginning with the writings of Henry de Bracton in the 13th century, discussion of the legal consequences of mental disorder appear in the work of several early commentators. The 17th-century treatise of Lord Hale, however, contains perhaps the first systematic effort to state a legal test of criminal responsibility in the English law. Hale wrote: ". . . such a person

as labouring under melancholy distempers hath yet ordinarily as great understanding, as ordinarily a child of fourteen years hath, is such a person as may be guilty of treason or felony." This observation was made the basis of the so-called child of 14 years test in later cases.

In *Arnold's Case* (16 How. St. Tr. 695), decided in 1724, Judge Robert Tracy, relying on a suggestion of Bracton, announced a formulation sometimes referred to as the "wild beast test." Not every kind of "frantic humour," said Judge Tracy, exempts a man from punishment; "it must be a man that is totally deprived of his understanding and memory, and doth not know what he is doing, no more than an infant. than a brute, or a wild beast, ..." In *Hadfield's Case* (27 How. St. Tr. 1282), tried in 1800, Thomas Erskine, the brilliant criminal advocate, induced the court to accept the proposition that "delusion . . . , where there is no frenzy or raving madness. is the true character of insanity."

McNaghten **Rules.**—But it is the rules announced in the famous case of *McNaghten* (10 Cl. and Fin. 200) which constitute unquestionably the most important pronouncement on the subject of criminal responsibility in the Anglo-American law. Though formulated in 1843, the McNaghten rules still provide the basis for the modern lam in most English-speaking jurisdictions. Daniel McNaghten, acting under a delusion that he was being persecuted by Sir Robert Peel, shot and killed Peel's secretary. Edward Drummond, believing him to be Sir Robert. McNaghten was brought to trial on a charge of murder, but was acquitted by a verdict of not guilty on the ground of insanity. The public interest and outcry were of such proportions that the house of lords was induced to employ the unusual procedure of addressing a series of questions to the judges of England on the subject on insanity. The answers to these questions, announced by Lord Chief Justice Nicholas Tindal, constitute the McNaghten rules. It has been suggested that the judges' answers, since submitted in response to hypothetical questions and not in the course of adjudicating an actual case, have no binding legal effect. As a practical matter, however, the rules have been accepted as authoritative in most Anglo-American jurisdictions. A portion of the judges' answer to the second and third questions is most important for the purposes of modern law: ". . . to establish a defence of insanity. it must be clearly proved that. at the time of the committing of the act. the party accused was labouring under such a defect of reason, from disease of mind, as not to know the nature and quality of the act he was doing; or if he did know it, that he did not know he was doing what was mrong." It will be observed that it is the mental condition of the accused at the time of commission of the act which is crucial and that the incapacity must be the result of mental "disease." There have been many widely diverging interpretations of the other important terms of the formulation. Thus, in the United States, "wrong" is frequently understood in the sense of moral wrong, while in Britain mid-20th century cases have held that the accused is not entitled to exculpation if he knew his act was contrary to law.

The McNaghten rules have been the source of sharp and sometimes intemperate controversy for over a century. The range of criticism has been wide and the points made have possessed varying degrees of cogency and relevance. It is said, for example. that the McNaghten rules, by their exclusive reliance on the criterion of knowledge, emphasize unjustifiably the cognitive or intellectual elements of human personality, at the expense of the will and emotions, and, consequently. incorporate an obsolete conception of the nature of mental disorder. Since the rules are founded on conceptions foreign to modern medical science, the psychiatric witness finds it difficult or impossible to translate his learning into the terms of the legal formula, thereby depriving the court and the jury of the full benefit of his expert insight. Also, it is said that the rules require a total incapacity to distinguish wrong from right, although even grossly disordered persons may possess at least rudimentary powers of moral discrimination.

Changes From the McNaghten **Rules.**—Although the attack on the McNaghten rules has received much less than unanimous support, an important segment of opinion has held for many years that drastic changes in the legal tests of criminal responsibility are required. In the United States the adoption of the irresistible impulse test by the federal courts and those of about one-quarter of the states is one important consequence of this dissatisfaction. The irresistible impulse test is accepted in no jurisdiction as a total substitute for the McNaghten rules. Rather, it is intended to supplement the right and wrong test by relieving from criminal responsibility those who may have power to discriminate intellectually between right and wrong but who, because of mental disorder, are unable to act on that knowledge and to control their behaviour. As expressed by a Utah court: "Volitional ability to choose right and avoid wrong is as fundamental in the required guilty intent . . . as is the intellectual power to discern right from wrong and understand the nature and quality of his acts" (78 Utah 580, 6 P. 2d 177).

The irresistible impulse test has also received its share of criticism. and the critics have included both supporters and opponents of the McNaghten rules. Some have urged the difficulties of distinguishing between the irresistible impulse and the impulse which is merely unresisted. More fundamentally, others have complained of the emphasis on "impulse" as erroneously suggesting that volitional disorders are manifested only in sudden or momentary inclinations to commit unlawful acts. Still others have urged that a proper interpretation of the McNaghten rules renders the irresistible impulse test unnecessary, since serious volitional disorders are always accompanied by impairment in the cognitive capacities of the afflicted person.

In recent years the movement to reform the legal tests of criminal responsibility has received increased impetus. A majority of the Royal Commission on Capital Punishment (1949–53) urged the abrogation of the McNaghten rules in England and Wales and the substitution of a test which would submit to the jury simply the question "whether at the time of the act the accused was suffering from disease of the mind (or mental deficiency) to such a degree that he ought not to be held responsible." In the United States the most important recent judicial development was the 1954 decision in Durham v. *U.S.* (214 F. 2d 862) by the U.S. circuit court for the District of Columbia. That decision, applicable only to the District of Columbia and not to the federal courts generally, rejected the McNaghten rules as supplemented by the irresistible impulse test, which had formerly been applied in the jurisdiction. and adopted a new formulation derived from opinions of the New Hampshire court. the only American jurisdiction which had theretofore rejected the McNaghten rules. The Durham test, as it has come to be known, is "simply that an accused is not criminally responsible if his unlawful act was the product of mental disease or mental defect."

The decision was hailed by many in the medical and legal professions as an event of profound importance. It was pointed out that the formulation, by avoiding reference to any particular symptom of mental disorder, eliminates the danger of incorporating into the legal test conceptions of mental disease which are or which may shortly become obsolete. It was also urged that the test provides the psychiatric expert with greater freedom in conveying his scientific evaluation of the accused's condition to judge and jury. It is clear that, in casting aside the McNaghten rules, the court rejected a series of propositions which has constituted for many a symbol of the law's ignorance and obduracy. This is a matter of no small importance. But the Durham formulation suggests problems which may require future attention. Some commentators have pointed to the difficulties in the notion of causation inhering in the phrase "the product of." As Judge Paul Brosman pointed out, it is doubtful "that a criminal act may be committed which is *not,* in some sense, a product of whatever mental abnormality may coexist" (*U.S.* v. *Smith,* 5 U.S.M.C.A. 314, 17 C.M.R. 314). Since the Durham formulation does not state any requirements with reference to the degree of incapacity produced by the mental disorder, and indeed, does not define the concepts "mental disease or defect,"there is considerable question as to the breadth of the exculpation it may at least theoretically authorize.

Trial Practice.— The mode of trying the insanity issue in criminal trials has provoked very nearly as much criticism as the tests of responsibility. The use of the lay jury to decide the issue of

responsibility, the adversary nature of the judicial proceedings, the use of partisan expert witnesses, the elaborate "hypothetical questions" which may be put to the psychiatric witness and other procedural matters have been attacked frequently and with considerable asperity.

While some of the criticism reveals misunderstanding of the purposes and function of legal proceedings in these cases, it cannot be denied that many of the complaints point to weaknesses which can and should be remedied. In the United States, provisions of state constitutions, such as those relating to the right of jury trial, place certain limitations on innovation. Thus, statutes of Washington and Mississippi, which entirely eliminated the defense of insanity from the trial of criminal cases, were held unconstitutional. A California statute has been sustained, however, which requires the insanity issue to be tried in a separate proceeding, after it has been determined in the original trial that the accused committed the criminal acts charged.

Partial Insanity. — Mental disorder may affect criminal liability even though the incapacity of the accused is not of such degree as to relieve him entirely of criminal responsibility. The definitions of certain offenses require proof of particular mental states on the part of the accused. In some jurisdictions, the doctrine of "partial" insanity entitles the defendant to a jury instruction on the issue whether his mental disorder rendered him incapable of entertaining the particular mental state included in the definition of the crime. Thus, in a prosecution for murder in the first degree, the issue would be whether the accused was, by reason of mental disorder or deficiency, rendered incapable of premeditating or deliberating the killing, which is an essential element of the crime. If the jury determines that the accused was incapable of premeditation, it may return a verdict holding him guilty of second-degree murder or some lesser degree of criminal homicide. The U.S. supreme court has refused to reverse a criminal conviction for first-degree murder where the trial judge refused such an instruction (Fisher v. U.S., 328 U.S. 463). But the trend of judicial authority in the United States appears to be toward the contrary result.

Continental European Tests. — Tests of responsibility are included in the criminal legislation of countries whose legal systems are not derived from the English common law. These tests typically give consideration to both cognitive and volitional incapacities. Thus, article 85 of the Italian penal code relieves a person of responsibility when he "is deprived of the capacity of understanding or volition." The factors which most significantly distinguish the continental law of insanity from that of the English-speaking jurisdictions are procedural, not the least important of which derive from the fact that in continental Europe no provision is ordinarily made for the use of lay juries to resolve the issue of criminal responsibility. In some but not all the continental codes, mental disorder, which is insufficient in degree to relieve the accused of responsibility, may be taken into account by the sentencing authority to mitigate punishment.

"Present Insanity." — The significance of mental incapacity in the criminal law is not restricted to the question of the mental condition of the accused when the criminal act was committed. At the common law a person afflicted with what is sometimes called "present insanity" cannot be required to plead to an indictment or stand trial on a criminal charge.

The legal test of "present insanity" is wholly distinct from the tests of criminal responsibility. While the test of "present insanity" has been expressed with some variations in language, "present insanity" consists in essence of that degree of mental disorder which denies the accused understanding of the nature of the proceedings against him or renders him incapable of making or assisting in his own defense. The principle which protects such persons from standing trial has been widely adopted in modern legislation. Indeed, under U.S. constitutional provisions, the principle has been recognized as part of the concept of fair trial and due process of law. The question of "present insanity" may be raised by the defense, the prosecution or the trial judge. It has been held that the judge has not only a privilege to raise the issue, but, when he reasonably suspects the mental capacity of the accused, he is under duty to do so. At common law the issue of "present insanity" was tried before the trial judge, with or without a jury at the judge's discretion. Some of the statutes in the United States preserve the common-law powers of the judge in this matter, others require the summoning of a jury and still others require the trial judge to obtain the assistance of psychiatric specialists in determining the issue. It is important to understand that a finding of "present insanity" only postpones the criminal proceedings until such time as the accused has sufficiently recovered from his incapacities.

One of the important problems in the administration of criminal justice is the detection of mentally disordered persons among those apprehended and brought to trial on criminal charges. Although the right to raise the issue of "present insanity" is clearly established, there is reason to believe that substantial numbers of persons are tried who should not be subjected to criminal proceedings. Even larger numbers of seriously disordered persons are arrested and released from custody who, in their own interests and those of the community, should be confined in mental institutions. In response to these needs, court clinics and other facilities have been established in many localities for the purpose of providing pretrial psychiatric examinations, either on a routine basis or when requested in special circumstances. Most observers agree that such facilities have made a substantial contribution to the effective administration of the criminal law. Perhaps the most interesting statute on this subject is the famous Briggs law of Massachusetts. The law, enacted in 1921, requires the routine examination of all persons charged with certain specified criminal offenses. The examinations are conducted by specialists employed in the state department of mental health. A report of the examination is forwarded to the court and may be introduced in evidence if the accused is brought to trial. The procedure not only assists in the detection of those who are presently insane, but, it is claimed, the tendency of juries to regard the reports as impartial and to give them great weight has done much to eliminate the "battle of the experts" when the issue of criminal responsibility is raised at the trial.

Insanity After Sentence. — There are other situations in which mental disorder has important consequences in the administration of criminal justice. One of these is presented by cases in which a prisoner under sentence of death is found to be incapable, by reason of mental disorder, of understanding the nature and purposes of the punishment about to be inflicted upon him. At common law, the death penalty may not be inflicted in such situations, so long as the mental disorder persists. The reason for the rule, suggested by Lord Coke, is that the execution of a disordered person "cannot be an example to others." Another reason, sometimes advanced, is that the disordered prisoner is incapable of communicating facts to his counsel which might be useful in securing executive clemency. There is a wide variety of statutes in the United States regulating the mode of determining insanity in these cases. Many require a jury trial of the issue. Others authorize the issue to be determined in the courts, with or without juries in the judges' discretion. Still others have eliminated judicial trial of the issue and place its determination, after some species of administrative hearing, in the governor or other executive personnel. Such a state statute has been upheld by the U.S. supreme court (Solesbee v. Balkcom, 339 U.S. 9). Questions may arise, also, as to whether the prisoner has sufficiently recovered his faculties to permit the execution to proceed. Although there is no definitive constitutional ruling on the point, this determination probably must be preceded by a hearing, though not necessarily by a judicial hearing.

Insanity and Acquittal. — A procedural problem of some importance relates to the disposition of defendants who are acquitted on the criminal charge by reason of insanity. If the defendant is still suffering from mental disorder, his interests and those of the community may require that he be confined in a mental institution until his recovery. In the United States this problem has been the subject of a wide range of statutory provisions. The prevailing legislative pattern confers discretion on the trial judge to order the civil commitment of the defendant in such cases, though in many statutes the order of committal can be entered only after the judge has conducted an investigation into the defendant's pres-

ent mental condition. Some of the states require the jury at the criminal trial to consider the defendant's present mental condition. If the jury finds that the accused at the time of acquittal is still afflicted with mental disorder. the trial judge must order the defendant committed to a mental institution. A fen states have so-called "automatic commitment" statutes, which require the immediate confinement of defendants acquitted on grounds of insanity without any further hearing or investigation. These laws. in effect, create a presumption of continuing mental disorder, and have been upheld as constitutional in the state courts. A person who has, in fact, recovered from the mental illness may be released by the hospital authorities, or may challenge the legality of his confinement in the courts, ordinarily in a habeas corpus proceeding in which recovery from the mental disease is alleged. In England, no provision was made for civil commitment of such persons before 1800, and a defendant acquitted on grounds of insanity was permitted to go at large. After that date the trial judge had power to detain the defendant "during His [or Her] Majesty's pleasure." The Trial of Lunatics act, 1883, authorized a new form of verdict—"guilty. but insane"—in cases in which the defendant successfully maintains an insanity defense, and, in effect. directed the automatic commitment of such defendant to the custody of the home secretary. The form of verdict authorized by the 1883 act is inaccurate and illogical; it is, in fact, a verdict of acquittal on the criminal charge, from which an appeal by the prosecution may not be taken. The Royal Commission on Capital Punishment (1949–53), following the recommendations of the earlier Atkin committee, urged an amendment to the law "so that the verdict may again be one of acquittal in language as well as in substance."

INSANITY IN THE CIVIL LAW

Questions relating to the legal consequences of mental disorder are encountered throughout the civil law. These problems may be roughly classified into two broad categories: those relating to the protection and care of the disordered person in the interests of his well-being and the safety of the community, and those relating to the capacity of the insane person to perform certain legal acts and to enter and avoid certain legal relations. As in the criminal law. there is no single legal test of insanity applicable to all situations in which the mental capacity of a person may be in issue

Protection of the Well-being of the Insane and of the Community.— The obligation to afford care and protection for seriously disordered persons has long been recognized by the states. But involuntary commitment to a mental institution subjects the person to loss of liberty. Many of the problems relating to commitment procedures stem from the necessity of reconciling the needs for protective measures and for reasonably adequate procedural safeguards. The degree of mental incapacity justifying civil committal of the disordered person is variously defined in U.S. legislation. The definition of a "mentally ill person" included in the Illinois act is: "any person afflicted with mental disease to such an extent that for his own welfare, or the welfare of others, or of the community. he requires care, treatment, detention and training, and which renders him incapable of caring for and managing his own estate." It was not until 1827 that any state enacted legislation relating specifically to the commitment of mentally disordered persons, and most of the earlier legislation dealt principally with the commitment of the criminally insane. Even 20th-century legislation retains many of the incidents of criminal proceedings both in the language employed and the procedures actually authorized, though the trend is clearly in the direction of lessening the resemblances to criminal actions. During the 1860s many states added the requirement of jury trial in commitment proceedings as a result of certain well-publicized cases, including the famous Packard case in Illinois. involving allegedly improper commitment of sane persons to mental hospitals. At mid-20th century only one state, Texas. retained the mandatory requirement of jury trial, and in about half of the others a jury might be employed at the option of the judge or on demand of the person proceeded against. The dominant legislative pattern places the determination of the issue in the judge, after examination of the person by one, or more frequently, two physicians. In some states; the commitment is ordered by a special or standing commission composed of doctors or lawyers or both. In still others, commitment is almost entirely separated from judicial or administrative proceedings, being authorized on the certification of physicians. Under such statutes a judicial hearing is afforded only if an appeal from the commitment is taken.

In addition to the formal commitment procedures, more than half the states authorize summary commitments, ordinarily on the certificate of a health officer, where, by reason of emergency, immediate hospitalization is deemed necessary. These laws strictly limit the period of time a person may be held, typically between five and ten days. After expiration of the period, the person must be released unless a formal commitment order has been obtained in the interval. Release after formal committal ordinarily follows an administrative finding by hospital authorities that the patient has recovered from his illness. In the mid-1950s several states experimented with so-called "family care" releases, a procedure authorizing the patient to be placed in the care of a private family for an indefinite period of time, under the general supervision of the mental institution. A patient, alleging that he has recovered from his mental disorder, may resort to the courts in an effort to compel his discharge. Habeas corpus proceedings are frequently employed for this purpose.

Another device for the protection of mentally disordered persons is the appointment of a guardian by a court of equity or other court designated by statute. The guardianship may relate either to the person or the property of the insane individual, or both. The test of mental incapacity authorizing the appointment of a guardian is ordinarily said to be whether the person, by reason of mental disorder, lacks capacity to manage his own affairs or to care for his estate. All U.S. jurisdictions have enacted statutes governing, with greater or lesser particularity, the procedure for the appointment of guardians. Most of the statutes authorize the guardianship proceedings to be instituted on petition of a relative or friend of the afflicted person. Some also give this privilege to certain specified public officers, and a few to any inhabitant of the county in which the person resides. Most statutes expressly require that the person be given advance notice of the hearing in order that he may prepare a legal defense. In many states the issue of insanity is determined by the judge, but in others juries must be employed, either in all cases or when demanded by or on behalf of the person alleged to be insane. The older authority takes the view that the property of a ward is vested in the guardian and any conveyance made by the ward is absolutely void. Contrary results have been reached in more recent cases where it was shown that the nard had regained his sanity and that the guardianship had fallen into disuse, although not formally terminated. In any event, the insane person, like the minor, may be held to pay for articles and services necessary to life. if not supplied by the guardian.

Legal Capacity of Insane Persons.—As to persons not under guardianship. the insanity which destroys legal capacity to contract or to convey property must be of such advanced degree as to prevent the person from understanding the nature and effect of the particular transaction. Thus. contractual capacity may exist even though the person is mentally defective or is seriously disordered in the medical sense. Despite language to the contrary in the early cases, it is now generally held that a contract or conveyance made by an insane person is voidable rather than void. This means, among other things. that the insane person may ratify the transaction when he recovers his reason and hold the other contracting party to the bargain, or that, after the death of the insane person, his representatives may ratify the transaction or disaffirm it. Another consequence is that, if the transaction is executed and the bargain is not unfair or unconscionable, the insane person must offer to return the consideration furnished by the other contracting party before he is permitted to rescind. Most states provide by legislation that persons of unsound mind lack capacity to dispose of property by will. The relevant test is nhether the testator is of sufficiently sound mind and memory to understand the nature of his act. to comprehend the character and extent of his estate and to recollect the natural objects of his

bounty. With reference to marriage, a special application of the tests of contractual capacity is made; hence a marriage may be annulled when one of the parties, at the time of the ceremony, was unable to understand the ordinary incidents of the marital relationship. Some state statutes also extend prohibitions of marriage to other classes, such as epileptics and the feeble-minded. Prolonged and incurable insanity, occurring after marriage, is recognized in some states as a ground for divorce.

Insane persons are generally held liable for their torts; *i.e.*, harm they inflict on others. It is apparent that the proposition results in the imposition of civil liability on those who, by reason of mental disorder, may be incapable of avoiding the torts. This rule may be explained, in part, as a historical survival from a period in which tort liability was generally imposed without regard to the fault of the actor. A number of additional reasons have been advanced, none of which appear wholly satisfactory. It is said that since insanity may be feigned, a contrary rule of law might be used improperly by a sane person to escape liability. Also, placing responsibility on the insane person may induce the guardian, or others interested in the person's welfare, to exercise closer supervision of his activities. Finally, public policy requires that, as between two innocent persons, loss should be borne by the one who occasioned it.

In the adjudicated cases, insane persons have been held liable for a wide variety of torts including assault and battery, trespass on land and even alienation of affections. An insane person is liable for negligent harms, and the standard of care is that which is required of a sane person. One exception to the rule of liability relates to certain wrongs requiring proof of a "specific" intent, which a disordered person may be incapable oi forming. These include such torts as deceit, malicious prosecution and defamation.

Finally, mental disorder may have important consequences as it relates to the capacity of insane persons to give testimony in judicial proceedings. The early common-law rule rendered any person of unsound mind totally incompetent as a witness. Although a literal reading of some modern statutes would require the same result, it appears that nowhere is the rule applied in its original rigour. The broad principle generally applied today would exclude a witness only where the disorder substantially impairs the trustworthiness oi the particular testimony. Some oi the cases suggest that a person of unsound mind is competent to testify if it is found that he understands the nature and signlficance of his oath and has sufficient possession of mind and memory to recollect and relate what he saw and heard.

INSCRIPTIONS are documents incised on some hard or permanent material in the form of letters or other conventional signs, for the purpose of conveying some information or preserving a record. (Although inscriptions come from many parts of the world, *e.g.*, India, Mexico. Turkey. China. this article deals only with those from the ancient near east. Greece and Rome. since these have been by far the most thoroughly studied.) Inscriptions are to be distinguished on the one hand from manuscripts. or documents written on papyrus, parchment, paper or other more or less smooth surfaces by means of a brush, reed or pen and some coloured fluid (see PALAEOGRAPHY; PAPYROLOGY), and on the other hand from pictures or reliefs intended to convey information or to record events (see PICTOGRAPHY), though inscriptions were often combined with such pictures or reliefs, especially in primitive times. There are also some classes of documents which are intermediate between inscriptions and manuscripts. such as writing incised with a stylus or sharp-pointed instrument upon tablets covered with a thin coating of wax or scratched upon pottery or other hard materials (ostraka). But as the forms of the letters and the character of the writing in both these cases approximate to what is found in manuscripts, they are usually considered to belong to that class of document; but graffiti, or casual scratching on walls, rocks or fragments of pottery, are sometimes included in the study of inscriptions because they often fill gaps and, in early times at least, did not differ in form or character from ordinary inscriptions. A good example is offered by the names and other records scratched by Greek mercenaries at the time of Psammetichus on the legs of the colossal statues at Abu Simbel in Egypt. As one of the earliest examples of the use of the Greek alphabet, these find their place in the history of inscriptions. On the other hand, casual notes as nell as receipts, accounts, etc., are found scratched upon potsherds or ostraka, which nere merely a cheap substitute for more expensive material such as papyrus; the study of such ostraka cannot be separated from that of manuscripts on papyrus, and really forms a branch of palaeography rather than of epigraphy.

Inscriptions were studied and quoted by authors in ancient times, by orators and by historians — notably Thucydides and Polybius — as records of political. economic and social interest; they also contributed to the history of art, and Polemon had the nickname of *stelokopas* given him for his studies of such documents. His nork is now lost. Some of the great scholars of the Renaissance were interested both in Greek and Roman inscriptions. But the gigantic task of collecting and editing all known ancient inscriptions has been undertaken only since the 19th century.

FORM

Materials and Technique. — Inscriptions were commonly incised on stone or marble, on metal or on wood (though this last material has hardly ever survived except in Egypt) or on terra cotta. In Egypt and Mesopotamia hard stones were frequently used for the purpose, and the inscriptions are therefore well preserved and easy to read. In Greece the favourite material, especially in Athens, was white marble, which takes an admirably clear lettering but is liable to weathering of the surface, if exposed, and to wear, if rebuilt into pavements or similar structures. Many other kinds of stone, both hard and soft, were often used, especially crystalline limestones, which do not easily take a smooth surface and nhich, therefore, are often difficult to decipher, owing to accidental marks or roughness of the material.

The metal most commonly used for inscriptions was bronze; flat tablets of this metal were often made for affixing to the walls of temples and other buildings. Occasionally such tablets were made of silver or gold, and inscriptions were often incised on vessels made of any of these metals. Inscriptions on metal were nearly always incised, not cast. An important class of inscriptions are the legends on coins; these were struck from the die (See NUMISMATICS.) Clay was very extensively used for inscriptions in the near east and in Crete. In this case the symbols were incised or impressed on specially prepared tablets when the clay was soft, and it was subsequently hardened by fire. In Greece many inscriptions on vases were painted before firing (especially when they had reference to the scenes represented), or incised after firing: potsherds (ostraka) were often used as a cheap writing material. Inscriptions were also impressed from a mold upon net clay before firing; this frequently was the case with tiles, amphora handles. etc., objects which often supply valuable information as to the buildings to which they belong or the place from which they took their origin.

The tools used for making inscriptions varied with the material; most of them were chisels of some sort. usually nith a square blade; early inscriptions were sometimes made on hard rock by successive blows with a punch or pointed hammer. Sometimes a circular punch was used for *O* or a letter of which *O* formed a part.

Early inscriptions. which were often amateur work. are frequently very irregularly cut. But in almost all examples of later work the inscriptions were evidently cut by professionals and there are definite styles and methods belonging to various places and periods In Egypt, for instance. the hieroglyphs (q *v.*) mere carefully and delicately cut in early times, but became more careless and conventional in later periods. In Greece the best work was done in the 5th and 4th centuries B.C. in Athens. The letters were all exact and regular in shape, nith no adventitious ornaments, and, especially in the 5th century, were usually aligned

exactly with the letters above and below as well as with those on each side. The result is a beauty and simplicity of effect that has never been surpassed. At that time all the strokes were made of equal thickness, but in the 4th century B.C. and later there arose the custom of holding the chisel obliquely to the surface, thus producing a wedge-shaped stroke. A similar custom in Mesopotamia gave rise to the cuneiform (*q.v.*) system. In Greece this effect appears earlier on metal inscriptions than on stone or marble. In the 3rd century and later it became common to introduce apices, or ornamental ends, to the strokes, a custom which prevails to the present day in ordinary capital letters. The custom of making different strokes and different parts of curves of varying thickness became common in Roman inscriptions, which developed a monumental style of their own, varying from period to period. Inscriptions can often be dated approximately by the style of the cutting as well as by the shapes of the letters; skill in doing this can only be acquired by a careful and minute study of originals and facsimiles.

Inscriptions vary greatly in size according to their intended position, their purpose and the skill of the cutter. Some inscriptions are of great length, the longest—a statement of accounts of the temple at Delos under Athenian administration—being nearly half as long as a book of Thucydides; and many other inscriptions approach this in length.

Symbols and Forms of Writing.—The origin of writing (*q.v.*) and the evolution of the alphabet (*q.v.*) need not be discussed here. For the present purpose it is sufficient to note that most of the known forms of writing originated in some system of picture-writing. Such systems appear independently in different parts of the world—in Egypt, Mesopotamia, Crete, among the Hittites and in China and America. The evidence for all of these is to be found mainly in inscriptions. The development from ideograms (or direct representation of an object or idea) to symbols of phonetic value, and so to syllabaries or alphabets, took place in many different systems to various degrees. The Greeks borrowed the Phoenician system of writing, with certain modifications and improvements. From the Greek was derived the Latin; and from the two, all the later alphabets of European peoples. It is still a matter of dispute whether the Phoenician was derived from the Egyptian.

The pictographic shapes naturally tended to be conventionalized and simplified for convenience of cutting, in accordance with the materials and tools employed. In many cases they developed from a pictorial to a linear form. It is possible that some of these linear forms may not be derived from pictograms at all, but from purely conventional geometrical forms, such as were aidely used at all periods and places as owners' or masons' marks. The tendency of linear forms to become wedge-shaped is most conspicuous in cuneiform, but the same tendency occurred in Greek inscriptions of the 3rd and 2nd centuries B.C., and earlier in inscriptions incised on bronze.

In the north of Europe the Ogham inscriptions are alphabetic, and are apparently an independent invention on arbitrary lines, like the Morse code; but Runes, which were extensively used in the same region, are derived from the Greek or the Latin alphabets.

Certain symbols which are not strictly alphabetic or phonetic in character are also found in inscriptions of most alphabetic systems. The commonest of these are the various systems of numerals that were used in different times and places. It is impossible to give any full description here of these different systems, but a brief account may be given of the principles underlying them. Most of them are based upon a decimal system, doubtless owing to the habit of counting on the fingers. In some cases the symbols are simple and obvious, as in the Cretan script where circles and short horizontal and vertical strokes are used for hundreds, tens and units, each being repeated as often as necessary; and a similar system for the lower denominations was used at Epidaurus in the 4th century B.C. In Athens the usual system was to indicate each denomination by its initial, M for *myrioi* (10,000), X for chilioi (1,000), H for *hecaton* (100), Δ for deca (10), Π for *pente* (5) and I for units. The other Greek system followed that derived from the Phoenicians, using the letters of the alphabet in their conventional order from one to nine, 10 to 90 and 100 to 900; in this arrangement obsolete letters were retained in their original places so as to give the requisite number of 27 symbols. The Roman system of numerals—M, D, C, L, X, V, I (for 1,000, 500, 100, 50, 10, j and 1)—is generally supposed to have arisen from the adaptation of certain symbols in the Greek alphabet.

Apart from numerals, the use of initials in the place of complete words was not common in early times. However. it became very frequent in Roman inscriptions, which sometimes are made up almost entirely of such abbreviations and can only be understood by those familiar with the formulae. Compendia or monograms also occurred in later Greek and Roman times, and became very common and difficult to interpret in early Christian and Byzantine inscriptions.

Some kind of punctuation is often found in inscriptions of all kinds. In Greek inscriptions a vertical line or a dot (or group of dots) sometimes indicates the separation between sentences or words; but words are seldom separated by spaces as in modern printing, so that the text is continuous and no division of words exists. This is particularly the case with Greek inscriptions of the best period. In Roman inscriptions it was usual to separate the words by dots. In certaip inscriptions a cross (+) was used to indicate the beginning of an inscription, especially when its direction was erratic. Christian inscriptions sometimes began with a cross, which doubtless had a symbolic meaning, and a leaf or other device was often placed at the end.

The direction of the writing varies greatly in different places and times. The letters or symbols may be arranged vertically below one another, reading from top to bottom, or horizontally, reading either from right to left or left to right; they may also be arranged in a kind of pattern—in which case their order may be indeterminate, or follow a wandering or curved line, or read left to right and right to left alternately (*boustrophedon*, or as an ox in plowing). Most Semitic alphabets, including Phoenician, read from right to left; and the earliest Greek inscriptions follow the same direction. But the direction from left to right became regular in Greece after the 6th century B.C., and consequently was adopted by the Romans and in all European systems. The individual letters or symbols usually face in the same direction as the writing as a whole.

Position or Place.—When they have a direct relation to the sculptures, reliefs or paintings with which they are associated, inscriptions often form a kind of pattern to fill the background or vacant spaces between the figures. Sometimes, however, and especially in Mesopotamian statues or reliefs, they are cut right across the figures without any regard to the artistic effect. In late Greek or Roman work it was usual to cut any inscription relative to a statue or relief upon the base on which it was mounted, but short inscriptions such as dedications or artists' signatures were often placed in some inconspicuous position upon the work itself. In the case of painted vases the inscriptions relative to the subject represented were usually painted; but dedications and other inscriptions were often incised after the vase had been fired.

In Egypt, inscriptions were often inscribed or painted upon the inner walls of tombs, whether they referred to religious belief or ritual or to the honours and possessions of the deceased. They were intended for his benefit and convenience rather than for the information of others—to perpetuate his familiar surroundings, not to make him live in the memory of his successors. The information which is derived from such inscriptions is invaluable, but such was not the intention with which they were made. On the other hand, inscriptions which were intended to be seen by the public and to perpetuate a record of events or to supply useful information usually occurred in places of common resort, above all in temples and sacred precincts. Sometimes they were cut on convenient rock faces, sometimes upon the walls of temples or other buildings. Most frequently the slabs of marble (stelae), stone, metal or other material upon which the inscriptions were incised were set up in convenient positions to be read in places of public resort. This was the method of publication of all laws,

decrees and official notices, of treaties and contracts, of honours to officials or private citizens, of religious dedications and prescriptions of ritual. Inscribed tombstones were set up over graves, nhich were usually placed along the chief roads leading out of a town; the most familiar example is the sacred way from Athens to Eleusis. Inscriptions commemorative of victories or other great events were erected upon the spot only in exceptional cases; more often such memorials were set up in some great religious centre such as Delphi or Olympia. But boundary stones were necessarily placed on the line which they defined.

Chief Periods and Nationalities. — The study of inscriptions supplies an important contribution to the history of many lands and peoples. In some cases, as in Egypt and Mesopotamia, it forms almost the only source of first-hand written information; in others, as in Greece and Rome, it offers a most valuable supplement and comment to what is otherwise recorded.

Both Egyptian and Mesopotamian inscriptions go back to an extremely early date; it is uncertain which is the earlier but both show, as early as 3000 B.C., a complete, organized system of writing which implies many centuries of development behind it. The Egyptian hieroglyphic script, as used in inscriptions, continued without any essential change of character until Roman times, though various cursive hieratic and demotic types were also in use. On the famous Rosetta stone in the British museum, which first gave the clue to the interpretation of Egyptian writing, hieroglyphic, demotic and Greek versions of the same decree are given side by side. Its date is 19j B.C. The Mesopotamian linear symbols developed, mainly for technical reasons, into a wedge-shaped or cuneiform system which was adopted in modified forms and applied for millennia to different languages: Sumerian, Babylonian, Assyrian, Hurrian, Hittite and Old Persian. An independent hieroglyphic system, which also developed into various linear scripts, appeared in Crete around 2000 B.C. (*see* MINOAN LINEAR SCRIPTS). The Hittite hieroglyphs date from the period of Hittite domination in northern Syria and Asia Minor, from about 1600 to 700 B.C.

The earliest known Phoenician inscriptions date from about the 10th century B.C., and the alphabet remained in use down to the 3rd century B.C. It was modified and adopted by the Greeks at an uncertain date; the earliest Greek inscriptions are generally dated in the 8th century B.C.

In early times each Greek state had its own alphabet; but in the year 403 B.C. (the archonship of Eucleides) the Ionian alphabet, which is the one used now for Greek capital letters, was officially adopted by Athens and soon became universal in Greece. From the various Greek alphabets were derived the different local Italian types. including the Etruscan, with sundry modifications. The Roman alphabet was among these. There are a few very early Roman inscriptions. They did not become common until the 3rd century B.C.; from that time the letters took much the same forms as they preserve to the present day.

The custom of putting inscriptions in Greek and in Latin on buildings and other monuments continued through medieval times and is still customary, classical forms being frequently imitated. The latest dated inscription in the Greek Corpus records the building of a bridge in Sicily in A.D. 1121; the series of Byzantine inscriptions continues practically without interruption to the present day; and Latin retains its use as a universal language in religious, public and private inscriptions.

Methods of Dating. — It is often possible to date an inscription approximately by the style of the lettering. or even by the alphabet used. Thus at Athens the Ionic alphabet was adopted in place of the early Attic alphabet in 403 B.C. But the change was already in process in private inscriptions, Ionic forms are sometimes found earlier, even in official documents. Inscriptions are dated in various ways, mostly by giving the name of a king, magistrate or priest. In the case of kings, they only give an approximate date, unless the year of his reign is given also. But in the case of most independent cities the date is given by the name of an annual magistrate, and thus the year is indicated precisely. At Athens, the name used was that of the Eponymous Archon and, since an almost complete list of these has been drawn up from inscriptions and other sources, this means of dating is quite satisfactory. The custom of dating by Olympiads, which is familiar from later Greek and Roman writers, was rarely used in early Greece, except in connection with athletic victories. Many inscriptions are dated from various local eras, often based upon historical events such as the foundation of a town or festival, the organization of a province or even the visit of an emperor. The number of these eras in later times, especially in Asia Minor, becomes very bewildering. In Attic decrees, and some others, it also was usual to give the day of the month.

In Greek inscriptions of the Roman period, the year of the emperor is defined by the number of his consulate or other indications or titles, as in the corresponding Latin inscriptions. In later times, the dating is commonly by "Indiction," but as this only gives the number of the year within the 15-year period, while leaving that period undefined, such dating is very inconvenient, except for merely temporary use. In the Eastern empire the date from the creation of the world (5509 B.C.) is sometimes given; but the date of the Christian era is hardly ever used.

CONTENT

Purpose of Inscriptions. — Inscriptions may be divided roughly into two main classes: (1) those in which the inscription was subservient to the object on which it mas inscribed or, at any rate, had a direct relation to that object (*e.g.*, the name of the owner or the record of dedication to a god); and (2) those in which the inscription existed for its own sake, or for the sake of the information which it recorded, the object on which it was inscribed being either made for the purpose, as a slab of marble or plate of bronze, or made use of, as in the case of a convenient wall or the surface of a rock or even a potsherd. The walls of buildings are often covered with such inscriptions, especially if they are in a conspicuous or convenient position, and so offer an obvious means of publicity.

For those accustomed to a vast mass of books, newspapers and other printed documents. it is difficult to realize the extensive use and great convenience assigned to inscriptions in ancient times. Not only were public announcements of all sorts, such as should now be made known by advertisements or posters, thus placed before the public, but all kinds of records and enactments — codes of law and political decrees; regulations for all matters, civil and religious; accounts and contracts, public and private; treaties between states; records of public and private benefactions and dedications, and all matters of administration; honours to the living and to the memory of the dead. Many of these were intended to preserve for all time the records which they contained; but others must have been of only temporary interest. It seems, therefore, the more remarkable that they should have been incised on permanent material such as bronze, marble or stone — and incised in the first instance, with a care and perfection of technique nhich have led to their survival to the present day, so as to preserve invaluable evidence as to the life and institutions of the people who made them. Temporary and permanent value are thus often combined in the same inscription. For instance, an Athenian citizen, visiting the Acropolis or the market place, could satisfy himself at first hand as to treaties or decrees of the people, public accounts or state income and expenditure. In the near east and Helladic Greece vast archives of clay tablets were kept in royal palaces and temples.

Relative Inscriptions. — Inscriptions having a direct relation to the object, or representation, on which they are inscribed vary greatly in their contents. Those relating to picture or relief chronicles of the victories or exploits of kings, as in Egypt and Mesopotamia, serve as a record of the events and help to interpret the scenes. Such inscriptions are not common in Greek or Roman work; but frequently, especially in early Greek times and on vases, the names of persons and even of objects are written beside them for the purpose of identification, and sometimes a speech issues from the mouth of a figure. On the carved wooden chest of Cypselus, of about 600 B.C.. hexameter verses were written. curving about among the figures and giving a description of each scene. The bases of statues and reliefs often had inscrip-

tions cut upon them for identification and record, This was particularly the case with honorary statues and tombstones. In other cases, where there is an evident relation between the artistic representation and the inscription, the figures are subordinate and seem merely to illustrate the text, such as a treaty between Athens and Samos with a relief at its head representing the goddesses Athena and Hera clasping hands, as representatives of their respective cities. In other cases the arms or device of a city is carved on an inscription, almost like a seal on a document. In all these cases the figures and the inscription are part of a common design, whether carried out by the same hand or not. But in the case of owners' marks, or names cut on vases or other objects, or of the dedication of such objects, the inscription is not necessarily contemporary; it may indeed be misleading, as in the case, mentioned with disapproval by Cicero, of re-using old Greek statues and placing new dedicatory inscriptions on them in Roman times; for instance, one of the statues of Athenian knights of the 5th century B.C., placed at the entrance of the Acropolis, had a later inscription cut on its base to make it serve as an equestrian statue of Germanicus, probably in 18 A.D. when he visited Athens. In Egypt and Mesopotamia also it is not unusual to find the name of a later king or official cut upon an earlier work.

Independent Inscriptions. — The majority of inscriptions are of independent value and interest, the object on which they are cut being either provided for the purpose or utilized as convenient and suitable. Such inscriptions may be classified as *(a)* religious and (b) political and social. The distinction between the two is not always easy to draw; for in almost all ancient civilizations religion was a part of the established service of the state and was under public control, or at least was closely bound up with political administration. It follows that many inscriptions relating to religious matters take the form of political decrees or state documents, and therefore might, especially as far as form is concerned, be included in either category; but it is usually possible to classify them according to their contents and intention.

Greek Inscriptions

Religious. — Temples. — A temple was often a kind of religious corporation under the control of the state, and its accounts and details of administration were made public at frequent intervals, usually annually, by means of inscriptions, exhibited to public view in its precinct. Many such inscriptions have been found and they supply a great deal of information that can be obtained from no other source. Some great temples, such as that of Apollo on the island of Delos, held great amounts of property, both real and portable, the latter taking the form either of more or less precious offerings dedicated in the temple and its surrounding buildings, or of coined money. The inscriptions accordingly record gifts and acquisitions of landed property, leases and assignments, payments of rent and fines for default, loans and interest and many other business transactions suitable to a great landed proprietor or to a bank. They therefore throw much light upon the social and economic conditions of ancient life, such as are nowhere else recorded. The lists of offerings dedicated in the temple and other buildings almost recreate their appearance. These offerings are described as being on the floor, on the walls, on shelves or in cases; they consisted of vases and other objects suitable for use in the temple service; ornaments and jewels; statuettes, mostly in gold and silver; weapons and tools; coined money; and bullion, mostly melted down from old offerings. The detailed care that was taken to ensure that the full weight of melted objects was preserved, whether made into a new vessel or not, is recorded in other inscriptions. These elaborate inventories were checked and revised by each successive board of administrators, and gave the best possible security against any robbery or peculation. In addition to such general lists, there are also innumerable records of various gifts and acquisitions, whether of land and houses, or of movable property of all sorts. Buildings and repairs, sometimes by the state, sometimes by individuals, whose piety and generosity are suitably honoured, are also recorded. In form, these are often hardly to be distinguished from public works of a secular character, which must be mentioned later.

The inscriptions on or belonging to special dedications are often of great historical interest — there need only be quoted the inscription on the famous snake column from Delphi, with the list of the Greek states which took part in the Persian War, and that relating to the Roman arms dedicated by Pyrrhus of Epirus at Dodona after his victories. Most of the great temples being of immemorial sanctity, it is hardly to be expected that any records of their foundation should be found in inscriptions. But on the other hand there are many accounts of the dedication of new temples, either by states or communities or by private individuals. In almost all such cases it was necessary to obtain sanction for the foundation from the State; thus the inscription often takes the form of a decree of the people authorizing the foundation of the temple, and often giving some privileges to the founder or founders.

Officials. — Inscriptions give much information as to priests and other religious officials. There are, in the first place, lists of priests, some of them covering long periods and even going back to mythical times; there are also lists of the treasurers and administrators, who were usually lay officials appointed for the purpose either by election or by lot. The duties and privileges of priests are recorded in many inscriptions, and vary considerably from place to place. It is recorded, for instance, what portions of a victim at any sacrifice were to be received by the priest. In any important temple this must evidently have been far more than the priest or his family could consume; accordingly, it must have been sold, and so constituted a considerable source of income. Consequently a priesthood was an office well paid and much sought after; and in later Greek times, especially in Asia Minor, priesthoods were frequently sold, under proper guarantees and with due sureties as to the duties being carried out. Sometimes a fee to the priest had to be paid in cash; in some cases a priest or priestess was allowed to take up a collection on certain days. On the other hand, the duties of a priest are often recorded; he had to see to the cleaning and care of the temple and its contents, to provide flowers and garlands for decorations and to supply the regular daily service. Sacrifices on great occasions were usually provided by the state, as also were important repairs; but in some cases a priest undertook these on his own account, and was honoured accordingly — for instance, by being allowed to inscribe his name in the restored temple.

Besides priests, many other officials of various ranks were attached to temples and recorded in inscriptions. Some of these, especially those who were concerned with buildings or constructions, or with the inventories of temple treasures and the accounts of administration, were lay officials appointed by the state. as in the case of political officers. But many others had specialized sacerdotal functions; for instance, in many places there were manteis or prophets, often of special families with hereditary skill in divination; at Eleusis records were found of the hierophant, the torch-bearer and others who took part in the celebration of the mysteries. At Olympia, in later Greek times, was found a remarkable list of officials. viz.: three priests, three libation pourers, two prophets, three custodians (of keys), a flute-player, an interpreter, a priest for the daily sacrifice, a secretary, a wine-pourer, three dancers at libations, a woodman (to supply wood for the sacrifices) and a steward and cook — the last being no sinecure, in view of the numerous sacrificial feasts.

There were also many more menial offices in the service of temples which were carried out by slaves. Such slaves were often presented to the temple or acquired in some other way. There is a whole class of inscriptions, found on many sites, in which the sale of slaves to a temple or to the god of a temple is recorded. It is often difficult to know whether such slaves were intended for the service of a temple, or, on the other hand, such service was either purely formal or was not required at all, the sale to the temple being intended as fictitious, so as to enable a slave to acquire his own freedom and at the same time to secure the protection of the god in his free status.

Ritual. — The ritual appropriate to different divinities and temples varied greatly from place to place, and it was therefore neces-

sary or desirable to set up notices in all public places of worship for the information and guidance of worshipers. The commonest and most essential act of worship was sacrifice; an example of the simplest form of prescription is to be seen in the inscription on the relief from Thasos in the Louvre: "To the Nymphs and to Apollo the leader of the Nymphs, the worshiper may, if he so choose, sacrifice a male and a female victim. It is not permissible to offer a sheep or a pig. No paean is sung. To the Graces it is not permissible to offer a goat or a pig."

It is to be noticed that this order of service contains a prohibition as well as a prescription. Such prohibitions are frequent, and often relate to the need of ceremonial purity in all worshipers entering a sacred precinct. They must, for a certain time, have abstained from certain prescribed means of pollution, varying from place to place. The officials are sometimes ordered to erect notices giving information on this point; for instance, at the precinct of Alectrona at Ialysus, it was prescribed that "no horse, ass mule, nor any other animal with a bushy tail should enter, and that nobody should bring such animals in or wear shoes or any article produced from pigs. There is also a fine for driving in sheep." Other precincts were protected in a more general manner from any invasion or violation. It was prohibited to cut wood or to remove earth and stones or to drive any beasts into some precincts; the right of erecting booths was either restricted or denied altogether. Sometimes more detailed prescriptions are given for the whole organization of a festival; thus at Andania, in Messenia. the arrangements for the celebration of the local Eleusinia—the dress of the participants, the officials and policing—are very fully described. Similarly, in the hall of the Iobacchi, at Athens, the order of proceedings, the officers and the characters in the sacred play and various administrative details are ordered.

When there mas any doubt about a ritual or procedure, divination was often resorted to, and the results of such divination were recorded in inscriptions as a guidance for the future. It was also a common practice to consult Delphi or some other oracle in doubtful or difficult cases; in such cases the exact method of procedure nas sometimes recorded, as well as the response of the oracle. Forms of worship were often prescribed or recorded, especially hymns, which were sometimes inscribed together with their musical notation. The performance of songs or hymns and dances was also a matter of constant reference, especially in connection with lyrical or musical contests; the victorious band or performer often dedicated the prize in honour of the god. A special form of contest was that in dramatic performances, of which many records have survived, both from Athens and from many other parts of the Greek world. The regulation of athletic festivals and the records of victors in their contests also form a numerous class of inscriptions. As regards mysteries, though there are numerous regulations affecting the arrangement of celebrations and the conduct of those participating, there is, as was to be expected, very little concerning the actual performances.

Another interesting phase of Greek religion known mainly from inscriptions is offered by the shrines of healing. The most notable of these was the precinct of Asclepius at Epidaurus. where lists of the cures effected by Apollo and Asclepius have been found on large slabs of inscription, compiled, in all probability, from earlier documents. The cures are of the most varied kinds, ranging from painful diseases or surgical cases to a lost boy and a broken cup. The formula is the same in almost all cases: the consultant comes to Epidaurus, sleeps in the abaton, has dreams or sees visions and comes out whole. In later times, when such faith healing had probably become less efficacious, elaborate prescriptions of diet and hygiene are recorded.

A special form of prayer consisted of curses, which mere often buried in the ground, probably nith the intent to reach the infernal gods. Such curses often give the reason for their being made, usually some injury done to the author of the curse; sometimes they devoted the offender to the infernal gods.

Private Associations.—Another element in Greek religion which is known almost exclusively by means of inscriptions is to be found in the religious associations that existed in many Greek cities, apart from the organization of state religion, though sometimes recognized by it. Each association had its own regulations, which were duly recorded in inscriptions; the associations varied greatly both in purpose and in character. Many of them had a definitely religious purpose, in the worship of certain gods; sometimes an alien community mas given special permission to worship its own god or gods in its own way. Other associations were more social in character and served as clubs, or as burial societies. A remarkable feature about such associations is that the lists of members of many of them include the names of women and of slaves, thus contrasting with the civic basis of established religion in Greece and anticipating a religion in which "there is neither Jew nor Greek, there is neither bond nor free, there is neither male nor female."

Political and Social.--Codes and Regulations.—Ancient writers state that the earliest laws of Athens were inscribed upon tablets of mood. put together in a pyramidal shape. These, owing to their material, have perished; but there are some very early codes of law preserved on stone, notably at Gortyna in Crete. There an inscription of great length is incised on the slabs of a theatre-shaped structure in 12 columns of 50 lines each; it is mainly concerned with the law of inheritance, adoption, etc. Doubtless similar inscriptions were set up in many places in Greece. An interesting series of inscriptions deals with the conditions under which colonists were sent out from various cities, and the measures that were taken to secure their rights as citizens. A bronze tablet records in some detail the arrangements of this sort made when the Locrians established a colony in Naupactus; another inscription relates to the Athenian colonization of Salamis in the 6th century B.C.

Decrees.—A large number of inscriptions are in the form of decrees of various cities and peoples, even when their subject matter suggests that they should be classified under other headings. Almost all legislative and many administrative measures took this form; often a decree prescribed how and where the inscription should be set up. The formulae and preambles of such decrees vary considerably from place to place, and from period to period. Those of Athens are by far the most exactly known, oning to the immense number that have been discovered; and they are so strictly stereotyped that they can be classified with the precision of algebraical formulae and dated, often to within a few years, by this test alone. It was usual to record the year (by the name of the Eponymous Archon), the day of the month and of the prytany (or presiding commission according to tribes), the various secretaries, the presiding officials and the proposer of the decree. It is also stated whether the resolution mas passed by the senate (Boule), by the assembly of the people (Ecclesia), or by both. The circumstances or the reason of the resolution are then given, and finally the decision itself. Some other cities followed Athens in the form of their decrees. with such local variations as were required; others were more independent in their development, and different magistracies or forms of government had various results. In the Hellenistic age and later, the forms of independent government were kept up to a great extent, though little real power remained with the people. On the other hand, it is a common thing to find letters from kings, and later from Roman emperors. inscribed and set up in public places.

Public Accounts.—It was customary to inscribe on stone all records of the receipt. custody and expenditure of public money or treasure, so that any citizen could verify for himself the safety and due control of the state in all financial matters. As in the case of temple accounts, it was usual for each temporary board of officials to render to their successors an account of their stewardship, and of the resources and treasures which they handed over. In all cases of public works the expenditure was ordered by the state. and detailed reports were drann up and inscribed on stone at intervals while the work nas being carried out. In many cases there is a detailed specification of building work which makes it possible to realize not only all the technical details and processes employed. but also the whole plan and structure of a building. A notable instance is the arsenal of Philon. which has been completely reconstructed on paper by architects from the building

specification. In the case of the Erechtheum, there is not only a detailed report on the unfinished state of the building in 409 B.C., but also accounts of expenditure and payments to the workmen employed in finishing it. Similar accounts have been preserved of the building of the Parthenon, spread over 15 years; in the case of both the Parthenon and the Erechtheum, there are included the payments made to those who made the sculptures.

Naval and military expenditure is also very fully accounted for; among other information there are records of the galley slips at the different harbours, and of the ships of the Athenian navy, with their names and condition. In short, there is no department of state economy and financial administration that is not abundantly illustrated by the record of inscriptions.

Tribute Lists.—A set of records of high historical value are the tribute lists, recording the quota paid to Athens by her subject allies during the 5th century B.C. These throw much light on her relations with them at various periods. (See DELIAN LEAGUE.)

Ephebic Inscriptions.—An institution as to which knowledge is mainly derived from inscriptions is the ephebic system at Athens. There are not only records of lists of ephebi and of their guardians and instructors, but also decrees in honour of their services, especially in taking their due part in religious and other ceremonies, and resolutions of the ephebi themselves in honour of their officials. It is possible to trace in the inscriptions, which range over several centuries, the gradual transformation of what was originally a system of physical and military training for Athenian youths from the age of 18 to 20, with outpost and police duties. In later times there were added to the instructors in military exercises, others who gave lectures on what should now be called arts and science subjects; thus in Hellenistic and Rornan times, when youths from all parts of the civilized world flocked to Athens as an intellectual centre, the ephebic system became a kind of cosmopolitan university.

Political *and Commercial* Agreements.—In addition to inscriptions which are concerned with the internal affairs of various cities, there are many others recording treaties or other agreements of an international character between various cities and states. These were incised on bronze or stone and set up in places of public resort in the cities concerned, or in common religious centres such as Olympia and Delphi. The simplest form of treaty is merely an alliance for a certain term of years, usually with some penalty for any breach of the conditions. Often an oath was prescribed, to be taken by representatives on each side; it was also not unusual to appeal to the god in whose temple the treaty was exhibited. In other cases a list of gods by whom the two parties must swear was prescribed. Commercial clauses were sometimes added to treaties of alliance, and commercial treaties are also found, agreeing as to the export and import of merchandise and other things. In later days, especially in the time of the Hellenistic kings, treaties tended to become more complicated and detailed in their provisions.

Another series of records of great historical interest is concerned with arbitration between various states on various questions, mainly concerned with frontiers. In cases of dispute it was not uncommon for the two disputants to appoint a third party as arbitrator. Sometimes this third party was another state, sometimes a specified number of individuals. Thus, in a frontier dispute between Corinth and Epidaurus, 151 citizens of Megara were appointed by name to arbitrate, and when the decision was disputed, 31 from among them revised or confirmed it. In all such cases it was the custom for a full record to be preserved on stone and set up in the places concerned. In this case the initiative in referring the matter to arbitration came from the Achaean league.

Proxenia Decrees.—A very large class of inscriptions deals with the institution of *proxenia*. According to this, a citizen of any state might be appointed proxenos of another state; his duties would then be to offer help and hospitality to any citizen of that other state who might be visiting his city, and to assist him in any dispute or in securing his legal rights. The office has been compared to the modern appointment of consuls, with the essential difference that the proxenos was always a citizen of the state in which he resided, not of that whose citizens and interests he assisted. The decrees upon this matter frequently record the appointment of a proxenos and the conferring on him of certain benefits and privileges in return for his services; they also contain resolutions of thanks from the city served by the proxenos and record honours consequently conferred upon him.

Individual Honours.—This class of inscription is, in form, not unlike the last, except that the honours recorded were given for all sorts of services, private and public, to the state and to individuals. A frequent addition is an invitation to dine in the Prytaneum at Athens. Some were inscribed on the bases of statues set up to the recipient. In early times these inscriptions were usually brief and simple. The bust of Pericles on the Acropolis held nothing but the names of Pericles himself and of the sculptor Cresilas. Later it became usual to give, in some detail, the reasons for the honours awarded; in Hellenistic and Roman times these became more and more detailed and fulsomely laudatory.

Artists' Signatures.—These inscriptions are of special interest for the light they throw upon the history of art. The artist's name was usually carved upon the base or pedestal of a statue. especially in earlier times, and consequently was easily separated from it if the statue was carried off or destroyed. An instance in which both statue and pedestal are preserved is the Victory, signed on its pedestal by Paeonius at Olympia. Occasionally, and more frequently in later times, the artist's signature was carved upon some portion of the statue itself. But in later copies of well-known works it has to be considered whether the name is that of the original artist or of the copyist who reproduced his work.

A special class of artists' signatures is offered by the names signed by Attic vase painters and others upon their vases. These have been made the basis of a minute historical and stylistic study of the work of these painters and unsigned vases also have been grouped with the signed ones, so as to make an exact and detailed record of this branch of Greek artistic production.

Historical Records.—The great majority of these fall into one of the classes already referred to. But there are some instances in which an inscription was set up merely as a record, *e.g.*, a list of athletic or other contest victories. The most famous historical record is the autobiographical account of the deeds and administration of Augustus, which was reproduced and set up in many places; it is generally known as the Monumentum Ancyranum because the most complete copy of it was found at Ancyra. The Marmor Parium at Oxford, found in Paros, is a chronological record of Greek history, probably made for educational purposes and valuable for the traditional dates it gives of events from the earliest times.

Tombs.—This is by far the most numerous class of inscriptions, both Greek and Latin. In early Athens often no record was left beyond the name of the deceased, the name of his father and his deme. Sometimes a word or two of conventional praise was added, such as "a good and wise man." Occasionally the circumstances of death were alluded to, especially if it took place in battle or at sea. Such epitaphs were frequently in metrical form, usually either hexameters or elegiacs. Many of them have been collected and they form an interesting addition to the Greek anthology. In later times it became usual to give more elaborate praise of the deceased; but this was hardly ever so detailed as on more modern tombstones. The age and other facts about the deceased mere occasionally given on Greek tombstones, but not nearly so often as on Latin ones, which offer valuable statistical information in this respect.

LATIN INSCRIPTIONS

Latin inscriptions may be classified on much the same lines as Greek; but certain broad distinctions may be drawn at the outset. They are generally more standardized as to form and as to content, not only in Rome and Italy, but also throughout the provinces of the Roman empire. One of the chief difficulties in deciphering Latin inscriptions lies in the extensive use of initials and abbreviations. These are of great number and variety, and while some of them can be easily interpreted as belonging to well-known formulae, others offer considerable difficulty, espe-

cially to the inexperienced student. A mere list of such initials and abbreviations occupies 68 pages in R. Cagnat's *Cours d'epigraphie latine*. Often the same initial may have many different meanings according to the context. Some common formulae such as V.S.L.M. (votum solvit *libens* merito, "according to justice he discharges his vow willingly"), or H.M.H.N.S. (*hoc monumentum* keredem *non sequetur*, "this monument is not to pass to the heir") offer little difficulty, but there are many which are not so obvious and leave room for conjecture. Often the only way to determine the meaning is to search through a list of initials, such as those given by Cagnat, until a formula is found which fits the context.

Most of mhat has been said about Greek inscriptions applies to Roman also. The commonest materials in this case also are stone, marble and bronze; but a more extensive use is made of stamped bricks and tiles, which are often of historical value as identifying and dating a building or other construction. The same applies to leaden water pipes which frequently bear dates and names of officials. Terra-cotta lamps also frequently have their makers' names and other information stamped upon them. Arms, and especially shields. sometimes bear the name and corps of their ox-ners. Leaden disks were also used to serve the same purpose as modern identification disks. Inscriptions are also found on sling bullets — Roman as well as Greek; there are also numerous classes of tesserae, or tickets of admission to theatres or other shons.

As regards the contents of inscriptions, there must evidently be a considerable difference between the records of a number of independent city states and an empire including almost all the civilized world; but municipalities maintained many of their independent traditions in Roman times. and consequently their inscriptions often follow the old formulas.

The classification of Roman inscriptions may, therefore, follow the same lines as the Greek, except that certain categories are absent and that some others, not found in Greek, are of considerable importance.

Religious.—*Temple* Dedications. — These are very numerous; and the custom of placing the name of the dedicator in a conspicuous place on the building was prevalent, especially in the case of dedications by emperors or officials, or by public bodies. Restoration or repair was often recorded in the same manner. In the case of small objects the dedication is usually simple in form; it usually contains the name of the god or other recipient and of the donor, and a common formula is D.D. (dedit, *donavit*, "he gave," "he has given"). often with additions such as L.M. (*libens* merito, "willingly according to justice"). Such dedications are often the result of a vow, and V.S. (*votum solvit*, "he discharges his vow") is therefore often added. Bequests made under the wills of rich citizens are frequently recorded by inscriptions; these might either be for religious or for social purposes.

Officials.—A priesthood was frequently a political office and consequently is mentioned along with political honours in the list of a man's distinctions. The priesthoods that a man had held are usually mentioned first in inscriptions. before his civil offices and distinctions. Religious offices, as well as civil, mere restricted to certain classes. the highest to those of senatorial rank, the next to those of equestrian status; many minor offices, both in Rome and in the provinces, are enumerated in their due order.

Regulations. — Among the most interesting of these is the ancient song and accompanying dance performed by the priests known as the Arval brothers. This is, however, not in the form of a ritual prescription, but a detailed record of the due performance of the rite. An important class of documents is the series of calendars that have been found in Rome and in various Italian towns. These gave notice of religious festivals and anniversaries, and also of the days available for various purposes. The bronze tablets from Iguvium contain extensive ritual instructions in the Umbrian dialect for a cult association known as the Atiedian brethren.

Colleges. — The various colleges for religious purposes were very numerous. Many of them, both in Rome and Italy and in provincial municipalities, were of the nature of priesthoods. Some were regarded as offices of high distinction and were open only to men of senatorial rank; among these were the Augurs, the Fetiales, the Salii and, in imperial times, the Sodales Divorum Augustorum. The records of these colleges sometimes give no information beyond the names of members. but these are often of considerable interest. Haruspices and Luperci were of equestrian rank.

Political and Social. — Codes and Regzrlations — Information as to these is not drawn mainly from inscriptions and, therefore, they need not be considered here. On the other hand, the word *lex* (law) is usually applied to all decrees of the senate or other bodies. whether of legislative or of administrative character. It is best, therefore, to consider all together under the heading of public decrees.

Laws and Decrees.—A certain number of these dating from republican times are of considerable interest. One of the earliest relates to the prohibition of bacchanalian orgies in Italy; it takes the form of a message from the magistrates, stating the authority on which they acted. Lans all follow a fixed formula, according to the body which passed them. First there is a statement that the legislative body was consulted by the appropriate magistrate in due form; then follows the text of the law; and finally the sanction, the statement that the law was passed. In decrees of the senate the formula differs somewhat. They begin with a preamble giving the names of the consulting magistrates, the place and conditions of the meeting; then comes the subject submitted for decision. ending with the formula Q.D E.R.F.P. (quid de ea re fieri *placeret*, "what does the senate determine to be done concerning this matter?"); then comes the decision of the senate, opening with D.E.R.I.C. (de ea re ita *censuerunt*, "concerning this matter they have resolved thus"). C is added at the end, to indicate that the decree mas passed. In imperial times the emperor sometimes addressed a speech to the senate, advising them to pass certain resolutions: or, especially in later times, he would give orders or instructions directly, either on his own initiative or in response to questions or references. The number and variety of such orders is such that no classification of them can be given here.

One of the most famous is the edict of Diocletian, fixing the prices of all commodities. Copies of this in Greek as well as in Latin have been found in various parts of the Roman empire.

Building Records. — A very large number of inscriptions record the building or repair of public buildings by private individuals. by Roman or provincial magistrates and by emperors. In addition to the dedication of temples, inscriptions recording the construction of aqueducts, roads, especially on milestones. baths, basilicas, porticos and many other works of public utility are found. In early inscriptions often nothing nas given but the name of the person who built or restored the edifice and a statement that he had done so. But later it was usual to give more detail as to the motive of the building, the name of the emperor or a magistrate giving the date. the authority for the building and the names and distinctions of the builders; then follows a description of the building, the source of the expenditure (e g., S.P.-*sua pecunia*, "his money") and finally the appropriate verb for the work done, whether building, restoring, enlarging or otherwise improving. Other details are sometimes added, such as the name of the man under whose direction the work was done.

Military Documents.—These vary greatly in content, and are among the most important documents concerning the administration of the Roman empire. "They are numerous and of all sorts — tombstones of every degree, lists of soldiers' burial clubs. certificates of discharge from service, schedules of time-expired men, dedications of altars, records of building or of engineering works accomplished. The facts directly commemorated are rarely important." But when the information from hundreds of such inscriptions is collected together, "you can trace the whole policy of the imperial Government in the matter of recruiting, to what extent and till what date legionaries were raised in Italy; what contingents for various branches of the service were drawn from the provinces, and which provinces provided most: how far provincials garrisoned their own countries, and which of them,

like the British recruits, were sent as a measure of precaution to serve elsewhere; or, finally, at what epoch the empire grew weak enough to require the enlistment of barbarians from beyond its frontiers." (F. Haverfield, Authority and Archaeology, p. 314.)

Treaties and Agreements.—There were many treaties between Rome and other states in republican times; but as a rule, knowledge of these does not derive from inscriptions, which are very rare in this earlier period. In imperial times, to which most Latin inscriptions belong, international relations were subject to the universal domination of Rome, and consequently the documents relating to them are concerned with reference to the central authority, and often take the form of orders from the emperor.

Proxeny.—This custom belonged to Greece. What most nearly corresponded to it in Roman times was the adoption by a city or a state of some distinguished Roman as its patron. The relation was then recorded, usually on a bronze tablet placed in some conspicuous position in the town concerned. The patron probably also kept a copy in his house, or had a portable tablet which would ensure his recognition and reception.

Individual *Honours.*—Honorary inscriptions were extremely common in all parts of the Roman world. Sometimes they were placed on the bases of statues, sometimes in documents set up to record some particular benefaction or the construction of some public work. The offices held by and the distinctions conferred upon the person commemorated are enumerated in a regularly established order (*cursus honorum,* "order of honours"), either beginning with the lower and proceeding step by step to the higher, or in reverse order with the highest first. Religious and priestly offices are usually mentioned before civil and political ones. These might be exercised either in Rome itself, or in the various municipalities of the empire.

There was also a distinction drawn between offices that might be held only by persons of senatorial rank, those that were assigned to persons of equestrian rank and those of a less distinguished kind. It follows that when only a portion of an inscription has been found, it is often possible to restore the whole in accordance with the accepted order.

Artists' Signatures.—When these are attached to statues it is sometimes doubtful whether the name is that of the man who actually made the statue or of the master whose work it reproduces. Thus there are two well-known copies of a statue of Hercules by Lysippus, of which one is said to be the work of Lysippus and the other states that it was made by Glycon. Another kind of artist's or artificer's signature that was commoner in Roman times is to be found in the signatures of potters upon lamps and various kinds of vessels; they are usually impressed on the mold and stand out in relief on the terra cotta or other material. These are of interest for the information they give as to the commercial spread of various kinds of handicrafts and the conditions under which they were manufactured.

Historical Records.—Many of these inscriptions might well be assigned to one of the categories already considered. But there are some which were made expressly to commemorate an important event or to preserve a record. Among the most interesting is the inscription of the Columna Rostrata in Rome, which records the great naval victory of Duilius over the Carthaginians; this, however, is not the original, but a later and somewhat modified version. A document of high importance is a summary of the life and achievements of Augustus, already mentioned, known as the Monumentum Ancyranum. The various sets of Fasti constituted a record of the names of consuls and other magistrates or high officials, and also of the triumphs accorded to conquering generals.

Tombs.—These are probably the most numerous of all classes of inscriptions. Though many of them are of no great individual interest, they convey, when taken collectively, much valuable information as to the distribution and transference of population, as to trades and professions, as to health and longevity and as to many other conditions of ancient life. The most interesting early series is that on the tombs of the Scipios at Rome, recording, mostly in Saturnian metre, the exploits and distinctions of the various members of that family.

About the end of the republic and the beginning of the empire, it became customary to head a tombstone with the letters D.M. or D.M.S. (dis *manibus sacrum,* "sacred to the shades of the gods"), thus consecrating the tomb to the deceased as having become members of the body of ghosts or spirits of the dead. These are followed by the name of the deceased, usually with his father's name and his tribe, by his honours and distinctions and sometimes by a record of his age. The inscription often concludes aith H.I. (*hic* iacet, "here lies") or some similar formula, and also. frequently, with a statement of boundaries and a prohibition of violation or further use—for instance, H.M.H.N.S. (*hoc monumentum heredem* non sequetur, "this monument is not to pass to the heir").

The person who erected the monument and his relation to the deceased are often stated; or if a man has prepared the tomb in his lifetime, this also may be stated, V.S.F. (vivus sibi fecit, "while living he made this for himself"). But it is obvious that there is an immense variety in the information that either a man himself or his friends might wish to record.

Milestones and Boundaries.—Milestones (*miliaria*) have already been referred to, and may be regarded as records of the building of roads. Boundary stones (termini) are frequently found, both of public and private property. A well-known instance is offered by those set up by the commissioners called "III. viri A.I.A." (*agris iudicandis* adsignandis, "for assigning boundaries of farms") in the time of the Gracchi.

INSECT, a class (Insecta) of animals usually defined as those members of the phylum Arthropoda in which the body is divided into three parts: head, with mouth parts and sense organs; thorax, with locomotor organs, legs and wings; and abdomen, with the digestive, reproductive and excretory organs. As insects usually possess six legs, they have at times been termed the class Hexapoda (see fig. 1).

To the casual observer they comprise the pests, from bedbugs, houseflies and clothes moths to the gardener's potato beetles and plant lice; the aggressive attackers, such as the biting flies, ants, bees and wasps; and such conspicuous beauties as the butterflies that idle the summer away on flowers. Few observers comprehend the great variety and number of individual insects. The majority of even adult insects are in size below that which attracts the human eye. Many are microscopically minute. For every adult, visible or not, there are a hundred or more young even less visible. In numbers of species, in the vast numbers of individuals and in the social organization of many of the higher forms, they are eminently successful. They have been a great group of such numbers since the middle Coal age, 300,-

000,000 years before man appeared.

Variety in Insects.—No other class of animals even approaches the class Insecta in the great variety of species. Within many species the individual has two or three forms. The butterfly has emerged from a chrysalis; the chrysalis is preceded by a caterpillar. All three forms are butterfly. The housefly has been a pupa in a brown capsule in the ground; the capsule and its contents just previously were a maggot crawling in filth. Insects are known with 21 forms (Phylloxera quercus).

All living and many dead organisms appear to be fed upon by insects. They are adapted to every land and fresh water habitat where food is available. Many live in brackish water up to one-tenth the density of sea water, a few in sea water and some fly larvae can live in pools of crude petroleum where they eat other insects that fall in. Knowledge of one sex may give little clue as to the appearance of the other sex. In some, the female is a mere inactive bag of eggs, while the male (Strepsiptera; figs. 115, 117) is winged and one of the most active insects known. Some insects feed only in the larval stage (Ephemeroptera; figs. 23-26) and go without food as adults. Some insects (queen ants) live 16 years as adults, some mayflies only 20 minutes.

The insects that advertise their presence to the other sex by flashing lights, and some larvae well lighted to no apparent purpose, are as unexpected as are the many forms which imitate other insects in colour and form and thus avoid trouble, or which make sneak attacks in the guise of something harmless.

Behaviour is equally diverse, from the almost inanimate parasitic forms where the larva lies in the nutrient blood stream of its host and feeds by absorption, to dragonflies which pursue victims in the air and dytiscid beetles that out-swim prey in the water.

Insects have gone much farther. On their line of evolution they have developed care of the young, a family life, where the mother lives to defend or feed her young and from this the insect society, where in many tropical areas cities of termites and ants may reach populations of millions of inhabitants. These are true co-operative societies with some in a more advanced stage of co-operative behaviour (more truly a society) than is the human society. Among ants many farm mushrooms or oversee herds of other insects for a living, or do little themselves but have slave ants work for them.

Numbers of Insects.—Entomologists have described more than 625,000 kinds of insects, and estimates of the total of living forms vary from 2,000,000 to 4,000,000. These are kinds or species and are not estimates of individuals. No scientist familiar with insects has attempted to estimate individual numbers beyond areas of a few acres or a few square miles in extent. Figures soon get beyond the grasp of the mind. Large populations and great numbers of kinds are related to small size, a high rate of reproduction and numerous small, suitable food supplies.

Because of small size, insects retain a distinct advantage in being able to develop from egg to adult in a minimum of time as compared with other animals of equal brain capacity. Only minimal volume of tissue has to be developed to produce an adult. The minimal volume of tissue can be produced on a very small amount of food. This speed of reproduction on a per capita small amount of food permits great populations of insects within even small areas. A commonly used method in teaching entomology is to count all insects in and on a square yard of rich moist soil. Including the young and adults of all forms from microscopic young Collembola to all large adults, 500 are easily found and 2,000 are not unusual. This is roughly 4,000,000 insects which live normal insectean lives in comfort on one moist acre. The untrained observer could tramp through such an area and would notice only an occasional butterfly, bumblebee or large beetle, supergiants among insects. Only a few thousand species touch man's living seriously enough to rate retaliatory measures—those that attack his crops, herds and products, and those which carry disease. However, when they do appear as enemies of man, they can build up populations with speed and attack in incredible numbers. In spring the few houseflies which winter over are rare insects. In August their descendents occur in great numbers. Thus man moves about in a world of insects but is virtually unconscious of their vast numbers.

Insects and Man.—Insects injure nearly every organic material possessed or produced by man, and even puncture lead-covered telephone cables which wood-boring beetles mistake for hard, dead tree limbs. The millions of dollars poured into research by the Allied armies and navies, in the protection of the armed forces of World War II gave the world the first broad view of the immediate human danger from disease-carrying insects. The armed forces for the first time in human history were given planned protection by the very best scientific control that could be devised, protection against typhus, typhoid, plague, malaria, jungle typhus and various other deadly and prostrating diseases transmitted by insects and their immediate relatives the ticks and mites. A survey (C. L. Metcalf and W. P. Flint, Fundamentals of Insect *Life*, 1932) of the annual account of the United States against insect damage to crops, products, livestock and health amounted to $1,606,164,000. Our present knowledge gained by war research on army and navy health would increase this figure many million dollars. Because of the inadequacy of surveys of this kind the estimate must be far below the total actual damage, perhaps 50%. We do not know what a forest tree, a field crop or livestock might be like entirely free from such damage. Greenhouse flowers as compared with field-grown flowers give some suggestions. The remarkable crops on newly irrigated areas before insect pests have been introduced are also suggestive.

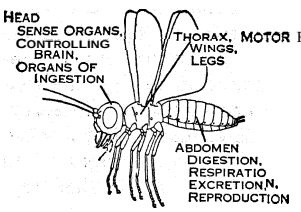

FIG. 1.—DIAGRAM OF BASIC BODY PLAN OF THE INSECT

Speed and Diversity of Insect Evolution.—The subclass Vertebrata of the Chordata has an age of 480,000,000 or more years, the Insecta, 250,000,000 years. (A. S. Romer, Vert. Paleontology, 2nd. ed., 1945). But in numbers of species the insects are more than ten times as great. The advantage in the evolutionary speed of insects is due largely to the great numbers produced as against the low reproduction rate in the vertebrates. Evolution is based largely on mutations, but also on recombinations, chromosomal abberations, and on gene fluctuation in relation to environment. Mutations generally occur in the order of once in 10,000 births. Insects usually lay from a few hundred to a thousand eggs per female in each generation. Generations are short, sometimes several a year. The vertebrate female reproduces very slowly and generations are usually several years long. A special mutable germ plasm for the insects need not be invoked.

The small size of the insect plus diversity of small environments are probably involved in diversity of forms in insects. A new form of insect can not survive without a reciprocal environment into which it can fit. Because of small size, many more such environments (microenvironments) per acre or per square mile are available to new insect forms than to the large vertebrate forms. Two acres are required for one horse or cow. Eight million insects can live on an equal area.

Flight is a great factor in insectean success in that it permits the insect quick and easy access to the numerous small environments and particularly to scattered food supplies.

Another factor enters into the diversity of insects, the phenomenon of metamorphosis which finally divides the insect into two insect forms—larva and adult—each of which, somewhat conditioned by the attachment to the other, can evolve in certain directions peculiar to each. In some insects four lines of evolution in one species are recognizable; (1) larva of male, (2) adult of male, (3) larva of female and (4) adult of female (see scale insects in section Order XV. Hemiptera). Evolution has dealt lavishly with the insects.

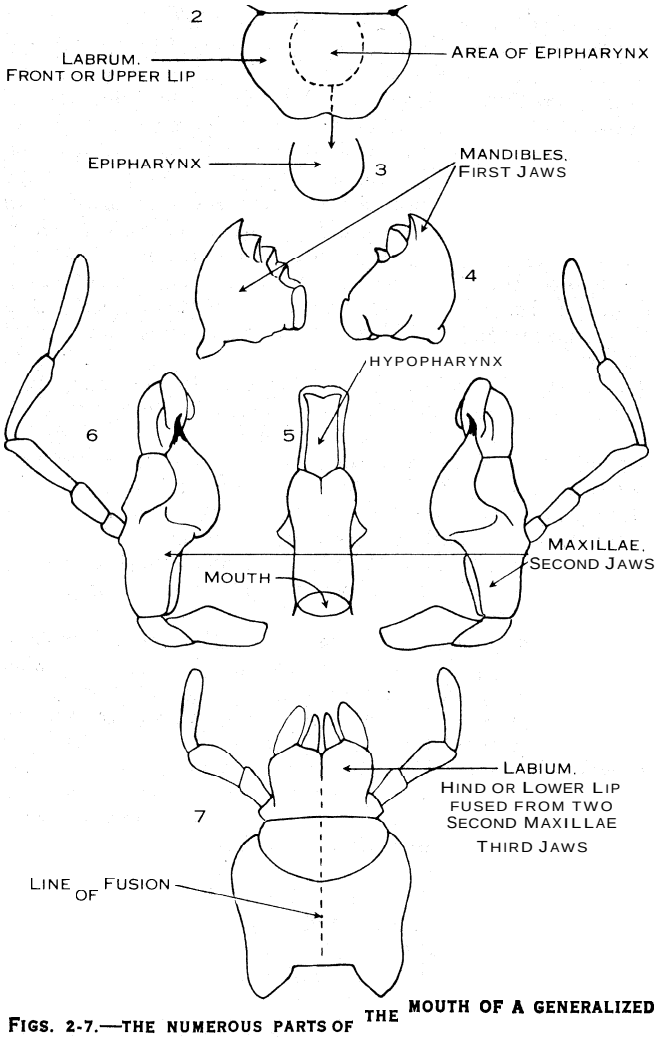
Insect Evolution Guided by Limitations Imposed by the Exoskeleton (C. H. Kennedy, "Exoskeleton a Factor in Limit-

ing and Directing Evolution of Insects," *Jour. Morph.* and Physiol., 48 [1927]).—Being arthropods, insects have an external skeleton (exoskeleton), a basic feature of that phylum as contrasted with the internal skeleton (endoskeleton) of the phylum Chordata (vertebrates and allies). For movement in a stiff exoskeleton, the appendages (mouth-parts, antennae and legs) are jointed, while the body itself is segmented, with movable joints at the neck and in the abdomen (fig. 1). In the evolution of the world of insect species, the hard covering skeleton has been in some ways an advantage and in other ways a handicap. As an impermeable covering it has prevented desiccation in dry environments and so has permitted the aquatic crustaceanlike ancestors of insects to invade dry land and their descendants, the insects, to penetrate even hot, dry deserts. But the disadvantages of an exoskeleton are great because, in growth, it has to be shed regularly. This series of rebirths, 4 to 20 or more in number, is a series of critical events. Even the linings of the breathing tubes (tracheae), which penetrate to every muscle and internal organ, have to be pulled out through the spiracles (respiratory openings). The critical danger is the loss of body shape. The insect, without a hardened exoskeleton while shedding, is a soft white object which has to retain its form through inflation with blood and air until the succeeding skeleton hardens. To secrete the new skeleton, which is a liquid plastic (chitin) that hardens to shape, the whole body wall is a continuous gland—one of the most delicate tissues known. The slight inflation pressure possible against such delicate tissues restricts all insects to small size. An animal of even the size of a dog or cow, if it had to shed an exoskeleton for further growth, would have to lie down as its soft legs could not support it, and could not arise until the skeleton had hardened. If it did have this arthropod process of growth, it would harden on the ground and the animal would arise plano-convex in shape, or, if enough pressure had been developed to retain symmetry, the pressure must have ruptured the delicate, glandular body wall. The body wall at time of shedding (ecdysis) is not only glandular, to secrete the new skeleton, but also frail from the fast growth. Thus the basic arthropod design of body wall, by physical law, limits insects to small size. Few weigh as much as a tenth of an ounce. The few giant Crustacea shed while floating in water. Insects are essentially land animals.

Locomotion, Sense Organs and a Steering Brain.— Through arthropod-pattern, insects have locomotion and with it, the concurrent steering behaviour which locomotion makes necessary. Sedentary and drifting animals (sponges, polyps, some molluscs) without locomotion never develop complex behaviour. The insects move about by undulation (larvae), by walking and, in higher forms, by flying. Locomotion is dangerous except where evolution has provided a guiding nervous system which contacts the environment through perfected sense organs and directs locomotion from dangers, and to profits. The insects have locomotion and the accompanying highly developed guiding sense organs and brain, but lack size and, with lack of size, the possibility of a large elaborately developed brain. In large animals (Aves, Mammalia) the large brain gives elaborate instinctive behaviour and, in later evolution, thought and reason. The insect brain is microscopic in size. It lacks the many storage cells for memory and the many cross fibres which in large brains permit the comparison of memories which forms the basis of plastic behaviour. However, the elaborate instinctive behaviour of such higher insects as the ants, bees and wasps indicates that the minute brain is most intricately and elaborately organized. It appears to be the most elaborately organized bit of matter of its minute size in the world. Thus insects have rigid instinctive behaviour, as compared with the plastic behaviour based on memory of experience and its sequential education as found in animals (birds and mammals) of large brains.

The Structural Design.—The insect's anatomical design can be traced from marine annelid worms with a segmented chitinous exoskeleton but without jointed appendages. They crawled and swam by undulation. From this design was evolved the trilobite-like form by the addition of jointed appendages along the side of the body. Annelids and worms had a variable number of body segments; but in the next stage, the crustacean, the body is divided definitely into 19 or 21 segments, depending on whether 4 or 6 are allotted to the head. Exceptions occur in the trilobites and millepedes (sens *lat.*). Insects of the order Collembola have only six segments in the abdomen.

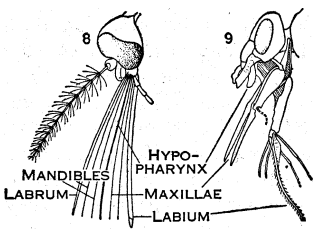
The Value of the Arthropod Structural Design lies largely in the fact that the mouth-parts and locomotor organs



FIGS. 2-7.—THE NUMEROUS PARTS OF THE MOUTH OF A GENERALIZED BITING INSECT, THE COCKROACH

are in series of pairs. The mouth-parts (figs. 2–7) have three pairs of jaws: the biting mandibles, the holding maxillae, with the third pair or second maxillae fused into a lower lip or labium (fig. 7). Added to these are an anterior lip, the labrum and internally a hypopharynx and an epipharynx, nine parts. The insect has six legs where most active animals have two or four. It is a redundancy of parts until the possibilities of evolution are considered, then it appears as a mine of material on which evolution can act. Animal evolution has its difficulties one of which is a radical change of function in a single essential organ while that organ continues to operate. It may account for some of the slowness of evolution in the vertebrates and the comparative paucity of forms in that group as compared with the vast number of forms in the insects. In the insects the many specialized organs, mouth-parts and locomotor organs mainly, have been evolved through change in a part of a previously homogeneous series. In the bee, (fig. 9), the maxillae and labium have become a very effective nectar-gathering tongue of three parts, while the first pair of jaws, the mandibles, have not changed function except toward greater strength. In the beetles (Coleoptera) the forewings have become perfect waterproof covers for the delicate hindwings which have kept the function of flight. In the praying mantis the forelegs have become prey-grasping

organs, while the four remaining legs continue as walking organs. In the grasshopper the hindlegs change into vaulting organs for instantaneous movement, while the other two pairs retain their function of slow walking and of perching. Students of evolution term this process as differentiation in a series. The structural design with parts in series permits evolution to change structures and add new habits with the greatest of evolutionary ease. The insect continues with its previous habits plus the advantages of the new structure and new habits or under evolutionary pressure to save energies, loses the outmoded parts by degeneration and depends nholly on the newly evolved more advantageous organs. The many things insects can do with the extra pair of legs (only four are needed for support) and with the extra two pairs of jaws make a long list.



FIGS. 8-9

Mouth-parts of the female mosquito evolved from biting mouth-parts, used in piercing and sucking blood (from Snodgrass). (9) Mouth-parts of a eucerid bee used for biting, digging and lapping

On this jointed body design are evolved all types of insects. It is rich in possibilities. The addition of wings has made greater speed possible, an advantage in mating and in finding the scattered microhabitats suitable to each species, and speed has necessitated better sense organs and more elaborate behaviour. On ecdysis (the shedding of the skeleton and periodic growth) is evolved metamorphosis.

Metamorphosis is a sudden change in form during ontogeny, *i.e.*, the development of the individual. In insects it is obviously involved with ecdysis and is probably a physiological mechanism very similar to, or a part of, the mechanism of rapid growth at such periods. Only too little study has been given the mechanism of ecdysis and its co-mechanism metamorphosis. It occurs in three forms, with many variants of each: early metamorphosis, as in the Prometabola (Ephemeroptera); incomplete metamorphosis, as in the Hemimetabola; and complete metamorphosis, as in the Holometabola. Metamorphosis in insects revolves around the nature of the development of wings in ontogeny where wing development is different in each of the great groups. Any striking metamorphosis does not occur in the earliest insects, the Ametabola, which have never possessed wings, or in lice which have lost their wings.

CLASSIFICATION BY THE FORMS OF METAMORPHOSIS

The names for the forms of metamorphosis and their classification are a perennial argument among entomologists. The present system is logical etymologically and embodies the ideas of leaders who have worked over the whole field of classification. Eventually the palaeontologists and physiologists will give a satisfactory classification. Subclass names for insects based on metamorphosis, or the lack of it, are of two derivations, (1) structural, usually with the subclass name ending in the Greek *pterygota* (=bearers of wings), or, (2) functional, with a subclass name ending in the Greek *metabola* (=change). As metamorphosis is a change or function, though almost immediately expressed in structure or form, for direct discussions of metamorphosis, as in this review, terms compounded on *metabola* are preferred. The structural series of terms is equally valid.

Metamorphosis started in the earliest winged insects, the Palaeodictyoptera of the Coal age, as a restriction of functional wings to late life stages. Late larval stages (fig. 10) in that order may have had functional gliding wings. While eventually many organs went through metamorphosis, the process is usually defined by the stages of the evolution of the metamorphosis of the easily observed wings.

Ametabola (=no change) is the subclass name applied to the group of orders of insects which do not have metamorphosis. These are the Collembola, Protura and Thysanura[1], where immature forms have the shape of the adult. There are no wings in present species and have been none in their ancestry (metamorphosis occurs only in winged insects). These are the most primitive forms of insects known, though not yet identified positively among early fossils.

The Protura (fig. 20) are an anomalous group in that the basic design of the body changes after hatching. The adult proturan has 12 full abdominal segments, but it hatches with 9 (segs. 1–8, plus seg. 12). Later segments 9, 10 and 11 are interpolated between segments 8 and 12. It might be termed metamorphosis in the broad zoological sense, but it is not a part of the mechanism of insect metamorphosis which later was initiated as a restriction of wings to late instars (see *Prometabola*, below) and then evolved to the development of a highly differentiated pupa in the highest Holometabola (p. 404). The proturan change in form resembles the lengthening of the body in species of the arthropod class Chilopoda, the centipedes, which also acquire segments after birth.

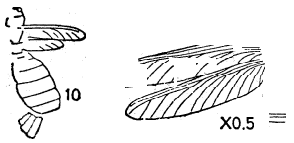
Leach *(Brewster Edinburgh Encyclopedia,* vol. 9 [1815]) proposed the term Arnetabolia (now Ametabola[2]), a functional term for the Thysanura including the Collembola and the lice. The Protura were discovered later by F. Silvestri in 1907. Lang *(Lehrbuch der vergleichende Anatomie,* 1889) proposed the name Apterygota (=not carriers of wings) a structural term to displace the awkward term Apterygogenea of Brauer ("Systematische-Zoologioche Studien," *Sitz. math. Naturw., Akad. Wiss.,* Wien, 91 [1885]). Brauer's research, the first from an evolutionary standpoint, is the basis of all present classifications by forms of metamorphosis.

Prometabola (Greek, pro- in the sense of early) was proposed by Heymons ("Die verschiedenen Formen der Insecten Metamorphose," *Ergebnisse* u. *Fortschr. Zool.,* 1:137–188 [1909]) for Ephemeroptera (mayflies) (figs. 23–26), which insects pass through four stages, egg, nymph (aquatic), subimago (a sexually immature form with wings) and imago (adult, sexually mature with wings). Wings develop in the nymph as external wing pads. Metamorphosis takes place between the nymph and the subimago, which by zoological definition is a larval or immature form.

The mayflies thus have functional wings in a last larval instar (subimago) as well as in the adult (imago). The development of functional wings has not yet reached complete suppression up to the imago as in all later insects. This may be a hangover from the earliest winged insects, the Palaeodictyoptera (figs. 10, 11).

A structural term such as Propterygota, parallel with Prometabola, does not appear available in the literature. Its use is suggested.

Metamorphosis began in the first winged insects, the Palaeodictyoptera, known only as fossils from the lower Upper Carboniferous age on into the Permian. Evidence suggests that some of these may have had functional wings in late larval stages, *i.e.*, immature sexually, as well as in the adult (Handlirsch, 1908, 1925). The Ephemeroptera are now classed as an order closely related to the Palaeodictyoptera with a similar venation (R. J. Tillyard, 1922, 1923). The Prometabola then include the Ephemeroptera by venation and metamorphosis and may include some fossil orders when there is a better knowledge of fossil history.



FIGS. 10-11

Fossil larva *Stenodictya* (10); and fossil adult of *lobata* (11), a palaeodictyopterous or earliest winged insect, showing gliding wings on a late larval (10) stage (from Handlirsch)

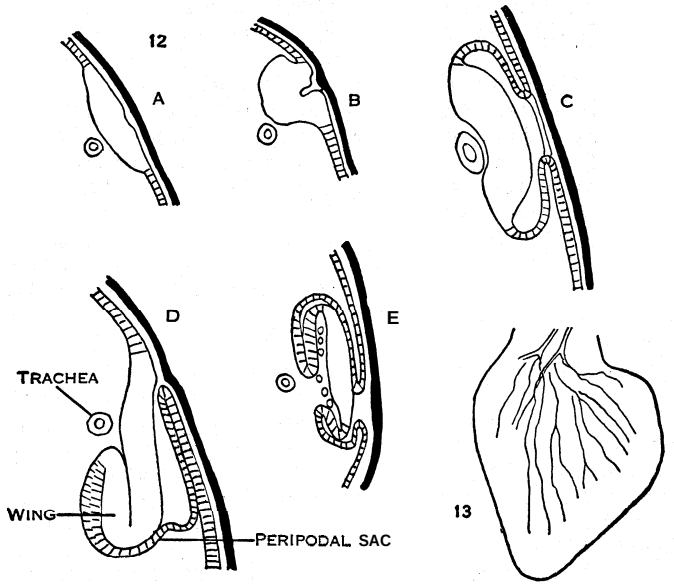
Hemimetabola (=half change) is the subclass proposed by H. C. C. Burmeister (*Handbuch der Entomologie* for a congeries of orders the majority of which had no pupal stage, and thus when winged had "incomplete" metamorphosis. For various reasons he included the Thysanura, Ephemeroptera, the Neuroptera, *sens lat.* and the Trichoptera, the latter two with

[1] For serial arrangement of Ametabolic orders this review follows A. D. Imms, *Trans. Soc Brit Ent*, 3 5, fig 2 (1936); and H. E. Ewing, *Ann. Ent. Soc. Amer.*, 33:513, fig. 5 (1940)

[2] J H Comstock, *Manual of Entomology* (1898), shorteoed Ametabolia to Ametabola and used it for Ephemeroptera plus Hemimetabola (*lc*).

pupa and complete metamorphosis. R. J. Tillyard (1926), who studied classification as profoundly as any 20th century author, accepted the term with the exclusion of the Thysanura, Neuroptera, sens *lat.* and the Trichoptera. Except for the removal of the Ephemeroptera to the Prometabola of Heymons, the present discussion of this subclass follows Tillyard. Hemiinetabola then includes the Odonata, the Plecoptera, Orthoptera, Isoptera, Dermaptera, Embioptera, Zoraptera, Corrodentia, Mallophaga, Anoplura (variously placed) and the hemipteroid series, Thysanoptera and Hemiptera.

The term Hemimetabola (=half change) is functional. The widely used term from the view of structure is Exopterygota of David Sharp ("Classification of the Insecta Hexapoda," Proc. *4th* Internat. Congress of *Zool.,* 4:246–249 [1898]), in reference to the external development of the wings in the wing pads. Tillyard (1926) proposed Ectopterygota, "pure Greek," for Exopterygota which he thought hybrid, Latin plus Greek, but the latter is still in use and appears to be properly compounded.



FIGS. 12-13

Diagrams of cross sections of the developing internal wing pad of an Insect (Lepidoptera) with complete metamorphosis: (A) in early stage of the caterpillar; (B) later stage; (C) peripodal or wing-pad sac forming; (D and E) wing-pad (prepupal stage) with peripodal sac shrinking and soon to free wing-pad (from Mercer). (13) Wing-pad of caterpillar dissected out of the internal peripodal sac (from Mercer)

In this series of orders metamorphosis occurs between the last immature (nymphal) stage and the adult stage (imago). There is no subimago and no true pupa with wings developed internally. In the Hemimetabola wingless genera and wingless orders, Mallophaga, Anoplura, have virtually no metamorphosis as the adult without wings has the nymphal form. Ample anatomical evidence shows that such are descended from winged insects. The nymph is usually an active long-legged campodeiform type (body form of Campodea, order Thysanura, figs. 21, 22), in most orders, with the details of body structure those of the adult. In some of the orders, Isoptera, Thysanoptera and some Homoptera, the last nymphal stage is a quiescent one but has wing pads developed externally and is not a true pupa (figs. 14–17, 72, "pupa" of thrips). (Compare next, "pupa," Holometabola.)

The widely followed use in America of the term Hemimetabola by J. H. Comstock (1918) for the aquatic orders, Ephemeroptera, Odonata, Plecoptera, falls before the recent discoveries in fossil insects as discussed by Tillyard and F. M. Carpenter. They show that the Ephemeroptera have a palaeodictyopterous venation. Tillyard and Carpenter show that the Odonata retain in the wings the primitive vein MA, lost in all other recent orders except Ephemeroptera and perhaps in the Plecoptera, still in doubt. The Odonata have no winged subimago stage and, except for vein MA, fall in the Hemimetabola, as the preseht review follows metamorphosis as more pertinent than structure. The Odonata then are an early branch from the very base of winged insects while the Plecoptera have structures which make them aquatic orthopteroid insects, such as the great development of the anal area of the hind-wing, uhile E. M. Walker (1931) has shown the low placement of antennae as in Grylloblatta. The three orders could not have originated from a common aquatic stem. Each is an independent aquatic adaptation in the most important feature of aquatic adaptation, the gills. In the Ephemeroptera (fig. 24), they are paired on abdominal appendage bases (R. E. Snodgrass, *Morphology* of the Insect Abdomen, Part 1:77, Smithsonian Inst. [1931]); in the Odonata the gills are rectal in Anisoptera, with caudal plate gills in some Zygoptera (fig. 30), and in others paired abdominal gills on the sternites (P. P. Calvert, 1911). In both Anisoptera and Zygoptera breathing is by rectum in early instars, and by rectum in Zygoptera when external gills are lost. In the Plecoptera, when present, they are thoracic and cephalic or anal (Leuctra and *Megaleptoperla,* New Zealand). The emphasis placed by Comstock on the term naiad for the aquatic nymphs in these orders as a character of a group of orders has a suggestion of ecology. Classification on metamorphosis is based on phylogeny and ontogeny. Thus the three orders are not a consistent group structurally (*i.e.,* in gills) and can not have a common inheritance of function (metamorphosis). They are not a close phylogenetic group in metamorphosis, and not at all in venation.

Holometabola (complete change), a name proposed by Burmeister, 1839, Handbuch der Entomologie, includes those insects which have a resting stage (prepupa and pupa) between the larva and adult (butterfly) (figs. 138–140). The wings are developed internally in sacs (peripodal sacs) (figs. 12, 13), in the prepupal stage, which is also the last larval stage, and are everted from the sacs to external position on the pupa. The pupal skin splits off, the adult emerges, which frees the crumpled wings in the external wing pads of the pupa to expand into adult wings. Metamorphosis is not between two stages. as in the Prometabola and the Hemimetabola, but makes two changes between the last three instars, between prepupal stage and pupa and between pupa and adult. The larvae are different also from the nymphs of the preceding group, as they have no external wing pads and may be campodeiform (lower Coleoptera, fig. 82); eruciform (fig. 139, Lepidoptera and lower Hymenoptera); maggots (fig. 147, muscoid Diptera); and grubs (figs. 97, 98, lower Coleoptera, Micromalthidae, and higher Coleoptera, fig. 101, and higher Hymenoptera, with many variants).

The structural term for the Holometabola is Endopterygota, of David Sharp ("Classification of the Insecta Hexapoda," Proc. *4th* Internat. Congress of *Zool.,* 4:246–249 [1898]), in reference to the development of the wing pads within the larva. By the nature of the larvae and the adult structure, the orders fall into three groups: (1) the coleopteroid series, Coleoptera and Strepsiptera; (2) the neuropteroid series, Neuroptera, Mecoptera, Trichoptera, Lepidoptera, Diptera and Siphonaptera; and (3) the hymenopteroid series, Hymenoptera. The Hymenoptera were later classed as Neuropteroidea by Tillyard; in Panneuroptera by G. C. Crampton.

The beginning of the coleopterous series is lost in Permian or earlier times. Even then it was a well-defined group. Modern remnant groups, Cupesidae, Micromalthidae, the suborder Adephaga and perhaps the Lymexylidae, show two types of larvae, legged campodeiform (Adephaga) and legless larvae (Micromalthidae). Larval legs in the campodeiform larvae are usually slender and weak, which suggests a possible redevelopment from short legs in an earlier eruciform larva, a boring type. In general, campodeiform larvae occur in the free-living Adephaga, the Carabidae (ground beetles) and relatives, in the lower Polyphaga, Staphylinoidea (rove beetles) and relatives, and tend to be displaced by legless boring types in the higher families, the Curculionoidea (weevils). The weevils have evolved into the degeneracies of parasitism on plants. Another great branch ending in the Meloidea have evolved into degeneracies of parasitism on animals (insects). The Scarabaeoidea (scarabs) are probably the tip of another great branch, as some have achieved family (semisocial) life. Next to the Hymenoptera, the Coleoptera are most instructive in the several great evolutionary series. (See A. G.

Böving and F. C. Craighead, *Larvae of Coleoptera* [1931] and C. W. Leng, *Catalogue of the Coleoptera of America . . .* [1920]).

The neuropteroid series of orders shows a similar reduction of locomotion and concurrent reduction in larval legs as the evolution of metamorphosis progresses to the highest forms such as the maggot of the highest Diptera. Metamorphosis is under an evolutionary guidance or pressure which arrives at similar structural and functional results over two or more independent paths. In the Seuroptera, Rlecoptera, Trichoptera and Lepidoptera the larva is campodeiform in the first three orders and is eruciform in the Lepidoptera. In the Diptera it is legless from lowest to highest forms. In free living forms some elongate active larvae may develop false legs, as in the Lepidoptera, and even in dipterous legless larvae, those of the Ephydridae.

The order Hymenoptera of the Holometabola shows evolution of the larva from an eruciform type (caterpillarlike) through various legless parasitic types to the final legless grub of the highest social forms in the ants, bees and wasps.

The origins of these great modern groups with the highest form of metamorphosis is yet unsettled. The coleopteroid series has structural characters which suggest an orthopteroid origin near the base of that group. The neuropteroid series is equally old by fossil record but shows fewer orthopteroid characters. The Hymenoptera were thought by Tillyard (1926), on the discovery of a wing of *Protokymen,* to have been descended from a Permian group he termed the Protohymenoptera; but more complete fossils have shown this to be a Megascopteron, a mayfly-like insect (F. M. Carpenter, 1930). Comstock (*Wings of Insects,* 1918) associated the primitive Hymenoptera with primitive Diptera on wing characters. The fact that three groups have evolved similar types of metamorphosis with a pupal stage, an exceedingly complex mechanism of metamorphosis, allows one of two explanations: (1) that the three are descended from a common ancestry which had a pupal stage or (2) that within the limits of the basic arthropod structure and physiology, and the similar limits in subsequent winged insects, metamorphosis can only evolve in one direction, touard a pupal stage and a helpless larva. This raises the question why it has not done so in the great orders composing the Hemimetabola. In fact, it has paralleled this evolution in the production of a pupalike stage but with wing pads developed externally in the Isoptera, Thysanoptera, male Coccids and elsewhere. Even the primitive Odonata have a week of inaction in the last larval stage before the emergence of the adult.

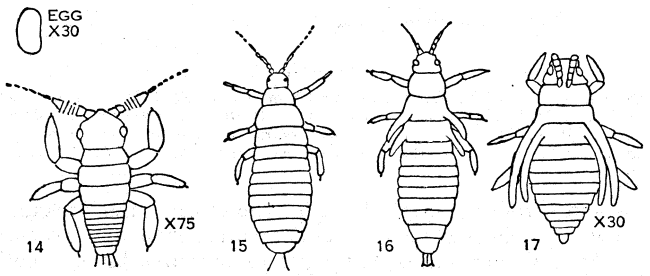
The Meaning of Metamorphosis.— This outstanding physiological phenomenon, one of the strangest developments in animal life, runs all through the evolution of the winged insects. Its beginning was associated with the evolution of wings. In the restriction of the wings to the reproductive adult it preserved them for that very active stage where they can be of most benefit to the species. Because of small size the insects use small environments, temporary wet spots as with mosquitoes, individual scattered plants of the host species, individual hosts for parasitic insects, to locate which wide and capable locomotion is most advantageous. In insects, wings are fragile and irreplaceable. Thus the problem of the development and protection of the wings is the basic or central palingenetic thread about which all other phases of metamorphosis have been evolved. The use of wings is locomotion at its best, and bound up with locomotion the evolution of brain and habits, and so becomes the necessitous central advantage in metamorphosis. Its forms define the great groups based on type of metamorphosis, except where wings are lost in parasitism and social life.

The inhibition of wing development in the larva, and the sudden release of that development at a late ecdysis, is the first evidence of a physiological mechanism of metamorphosis. However it operates, it was established as a feature of the period of sudden growth at ecdyses. Having once been established physiologically, its further development in many other directions became a matter of mutation, evolution and the fitting of the wingless larva and winged adult, two discrete or even antithetic entities in evolution of metamorphosis, to the many diverse waiting microenvironments. Once established, metamorphosis itself evolved on its own.

With this saving of the wings for uses more advantageous in the adult, with fully developed sense organs, came in a second advantage: the larva no longer burned up precious energy in locomotion but could devote more energies to eating and groning. Larval growth processes were separated from adult reproduction activities. Neither function was reduced physiologically by the operation of the other. A winged insect without the adolescence in the growth of the endoskeletoned vertebrate could waste no precious energies sowing. "wild oats." The winged insect goes to sleep at the end of larval life and wakes up at the end of pupation into reproductive maturity. Adolescence is not needed. for education of the minute brain and is discarded.

Having separated the tno somewhat antagonistic phases of individual development, growth and reproduction, in the lower Hemimetabola of incomplete metamorphosis, the already established mechanism of metamorphosis in an independent line. the Holometabola, evolved into the next step, the reduction of the development of the adult body structures to one period of differentiation, the prepupal and pupal stages, the period of differentiation of new parts. This is complete metamorphosis with the life history divided into (1) a period of growth (larva), (a) a period of differentiation (prepupa and pupa), (3) a period of reproduction (imago). This was not an evolution out of the advanced Hemimetabola. Fossil evidence indicates it was out of lower Hemimetabola, or an even lower group, and more or less in point of geological time a parallel evolution.

While complete metamorphosis was evolving, two other phases of metamorphosis were evolving which accentuate its appearance of change at the pupal stage.



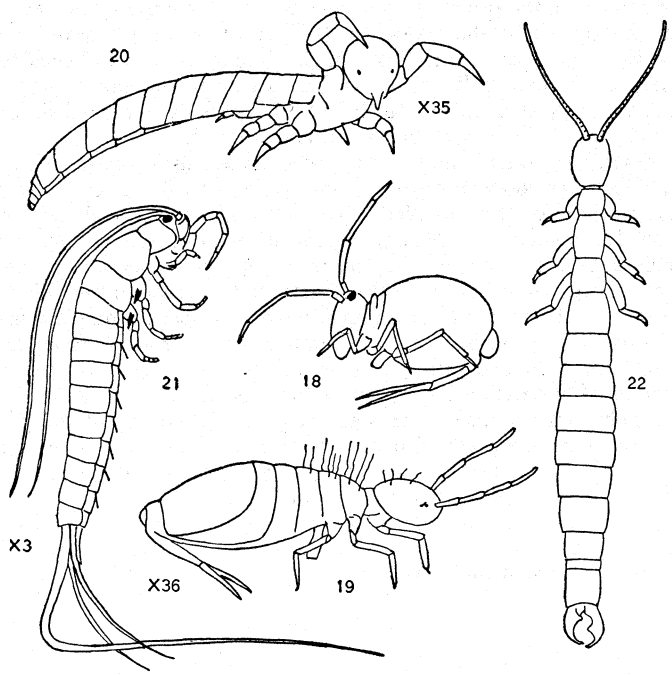
FIGS. 14-17

Egg and immature stages of the bean thrips (adult, see fig. 72): (14, 15) first and second larval stages; (16) third larval or prepupal stage which does not feed; (17) fourth immature or "pupal stage." Not a true pupa as in insects with complete metamorphosis because the wing pads are developed externally in the "prepupa" (16) (from Bailey)

As metamorphic change increases, the larva appears to hatch from the egg at earlier stages in its embryonic development. It tends to carry the embryonic form of hatching time through the larval stages to pupation. The Neuroptera, Mecoptera, Trichoptera and Lepidoptera of the Holometabola hatch as legged larvae. They hatch so in the lower Coleoptera and Hymenoptera, but in the highest forms of these they hatch before legs develop in the embryo. In the latter two orders the larvae of the higher forms are legless and vermiform. In the Diptera all larvae hatch at this very early stage. All dipterous larvae are legless. This increasing retrogression in the larva as holometamorphosis evolves was first pointed out as a matter of hatching in earlier embryonic stages by A. Berlese (1913). (*See* A. D. Imms, *Recent Advances* in *Entomology,* and ed. [1937] for a review.) The opposed theory is that the larva, after the evolution of metamorphosis, has had its larval evolution detached from the evolution of the adult and proceeds to degenerate in the abundant and better food supplies used among the highest insects. It is an aberrant form of parasite degeneration. Legs and sense organs are no longer needed by larvae living in or on more good food than they can consume. This degeneration is very apparent in larvae of parasitic Hymenoptera where they merely lie in the blood stream of the insect host, where the larvae of the social forms are fed by nurses, and in the weevils (Coleoptera) where the larva merely eats its way

through cambium, nuts or fruits. Imms (1937, pp. 51–64) suggests that both types of retrogression may fit into the picture of larval degeneracy.

The second accent to complete metamorphosis, apparent rather than a phase of metamorphosis itself, is the fact that the adult continues the evolution of form after complete metamorphosis has been established. It evolves farther toward many specializa-



FIGS. 18-22

Collembola: **(18)** *Papirius unicolor* (from Jackson); **(19)** Entomobrya *laguna*, California (from Bacon); (20) Protura: Acerentomon *doderoi* (from Berlesi); **(21)** Thysanura: *Nesomachilis maoricus*, New Zealand (from Tillyard); **(22)** Evalljapyx *propinquus*, California (from Bacon)

tions away from the original active type of early Hemimetabola. It is in the Holometabola that more often evolution produces such diverse types out of the series of primitive biting mouthparts, out of the series of three pairs of legs, and from the series of two pairs of nearly similar wings (pointed out in the section, *The* Value *of the Arthropod Structural Design*, above).

Secondary Adaptive Features. — So far only the basic features of metamorphosis, those which define the Prometabola, Hemimetabola and the Holometabola, have been reviewed. In every group, but most often in the Holometabola, larvae in special small groups within the greater classification show special adaptations to special larval habitats. These are larval organs and larval habits that are not carried over into adult organs and adult behaviour, but which disappear at the time of metamorphosis or earlier as in parasitic larvae. Some examples which have been compared in the classification of metamorphic processes are the independent development of larval gills in the aquatic larvae of Ephemeroptera, Odonata and Plecoptera. In each case the gills are on a different part of the body and evolved independently. The larval silk glands which produce the silk cocoon protecting the pupa are larval mouth organs in the Lepidoptera, Hymenoptera, etc., but are Malphigian glands emptying through the anus in the Neuroptera and some Coleoptera. The parasitic larvae of the great number of families of parasitic Hymenoptera show endless larval specializations.

Thus metamorphosis, along with the saving of the locomotor wings, separates the periods of growth, differentiation, and reproduction from each other by separation of the life history into larva, pupa and adult, so that each period can speed up with the least physiological interference of the other two processes. This is metamorphosis in the Holometabola.

This view that metamorphosis in its final holometabolic form separates the life history into a growth stage (larva), a oeriod of differentiation (pupa) and one of reproduction (imago), appears to have been minimized by recent writers studying limited phases of the subject. It was proposed by Fritz Müller (1864), was enlarged upon by P. Deegener (1909) and accepted by David Sharp (1895). After the first reduction of the wings to late stages, these trends to separation of physiological processes develop independently in each group of orders and even independently within each of the four large orders.

This separation of the three great physiological processes of life prevents each from hindering the others. Life itself is speeded up. Early forms of insect life went through 12 to 40 instars (growth periods), consuming time from several months to a year or more. Very modern insects have the number of instars reduced to about five or six, and in many higher flies and bees a generation may take from a few days (the housefly) to three or four weeks (the honeybee worker). This means elastic adaptation of populations to temporary food supplies, such as the quick build-up of workers in a hive during flowering seasons. It means also more generations with the accompanying mutations and thus the speeding up of evolution itself.

Value of Metamorphosis. — The most striking evidence of the value of metamorphosis is the increasing number of species from the Ametabola to the Holometabola. With each step up, from the Ametabola with no metamorphosis to the Holometabola with final complete metamorphosis (with exception of the Prometabola), the number of species described has increased enormously. They are:

Ametabola	1,420
Prometabola	1,270
Hemimetabola	83,650
Holometabola	537,960
Total described	624,300

With the evolution of the larva in the Holometabola into a wormlike form, we find the great series of parasitic families, where the insect as a larva can be wholly endoparasitic and in the imago retain all the benefits of wings and sense organs. In the most masterful of all insects, the social wasps. bees and ants, we find the same wormlike larva filed in pidgeon-holes, in wasp and bee combs, or corded in piles in ant nests, and fed and cared for in rotation, where reproduction is completely production-lined. Nearly the same ants are found as fossils in the Baltic amber, where the production line was probably in operation 50,000,000 years before it was thought of in America, in Detroit. Complete metamorphosis makes it possible.

This suggests, results from the evolution of metamorphosis which parallel the very greatly increased output of the production line in the automobile factory. The thought can be referred further to the auto plant design. The latter is a saving of energies. Metamorphosis becomes an energy-saving device in separating growth, differentiation and reproduction. After having been evolved up to this level, it steps forward again by making use of the growing larva in internal parasitism and again using the larva to the benefit of social organization as a convenient production-line form. Production-line methods in the hymenopterous society are probably of almost as much value as the co-operative behaviour usually thought of as spelling success. The two go together. Energy values have become so necessitous in the insect society that it burns out labour. The worker bee. at the height of the midsummer honey-flow, works every daylight hour and lives only two or three weeks. One of the English bumblebees works all night, as well as all day, on warm June moonlight nights The bald-faced hornet in America works in warm weather from early dawn, to the human eye, until after dark by the same meter of light. The social wasps, social bees and ants work on cool days when the sun passes under a cloud, when most other flower-loving insects disappear. The production-line behaviour mechanism takes all the energy the workers can deliver.

The Insect as an Evolving Energy-Transforming Mechanism. — The insect is the tip of a line of evolution of protoplasm. Protoplasm is an energy-transforming mechanism. The animal takes in food and oxygen. They unite, releasing the energy in the

food. The energy and by-products give growth and supply material and the greater part of the energy of all the living processes. Apparently evolution constantly improves the animal mechanism. Better energy-transforming mechanisms displace (survival of the fittest) poorer ones.

Insects start out as "selfish" individualists with heavy losses in battling the environment. Then the "selfish" behaviour of the individualist gives way to a second level in the evolution of behaviour. The female loses "selfish behaviour" which is displaced by mother care of her young (see ANT, BEE, WASP). Mother care is a great advance in that it helps the insect in its weak young stage to master the environment vicariously through its mother's strong adult organs and more complex adult behaviour. Mother care is the great second level in the evolution of animal behaviour (*q.v.*). Finally a third level is reached in evolution of the insect where the offspring, usually females, assist the mother. Co-operation has appeared and we have the family-society, characteristic of most social insects (*q.v.*). (See TERMITE; WASP; BEE; ANT.) This is the third and final level of insect evolution.

The production-lined insect society, with its exhausted working class, emphasizes the evolving energy values in the whole evolution of insects (see later section on The Ants).

The insect society has evolved out of mother care for the young (family life). In its highest form (wasps, bees and ants) it is a society of females with the elimination of the maie except for fertilization (see later section on The Ants: The Problem of the Male). In the highest form, the honeybee, even all traces of the family are eliminated (see HYMENOPTERA). The social organism is an energy-transforming mechanism which demands all from the co-operative working class which have become slaves to the social mechanism, slaves to exhaustion and death. In the honeybee, the queen mother degenerates to mere egg production. The slavelike workers rule and operate the society. The queen saves her energies by dodging work and lives several years. The worker-slaves of the system burn their energies out by hard labour and live a few weeks only in the highest co-operative societies.

CLASSIFICATION

By decision of the Committee on Zoological Nomenclature of the International Congress of Zoology, technical classification of the insects starts with that given by the Systema naturae of Carolus Linnaeus in 1758. Linnaeus proposed the class Insects and divided it into seven orders based on the presence or absence and nature of the wings. F. Brauer (1885) gave the present general arrangement of orders based largely on metamorphosis. Entomologists have revised this classification until at present the highly technical lists of orders run to 30 or 40, much of which revision has been based on the extensive publications of Anton Handlirsch of Vienna on fossil insects which, for the first time, gave entomologists a good picture of the evolution of the group and the relationships of modern orders to each other. One classification uses 55 orders (G. C. Crampton, Entomologist, 61:82, 1928). The simplified classification usually used for convenience in textbooks and general work contains 23 to 25 orders.

INSECTA

SUBCLASS I: AMETABOLA

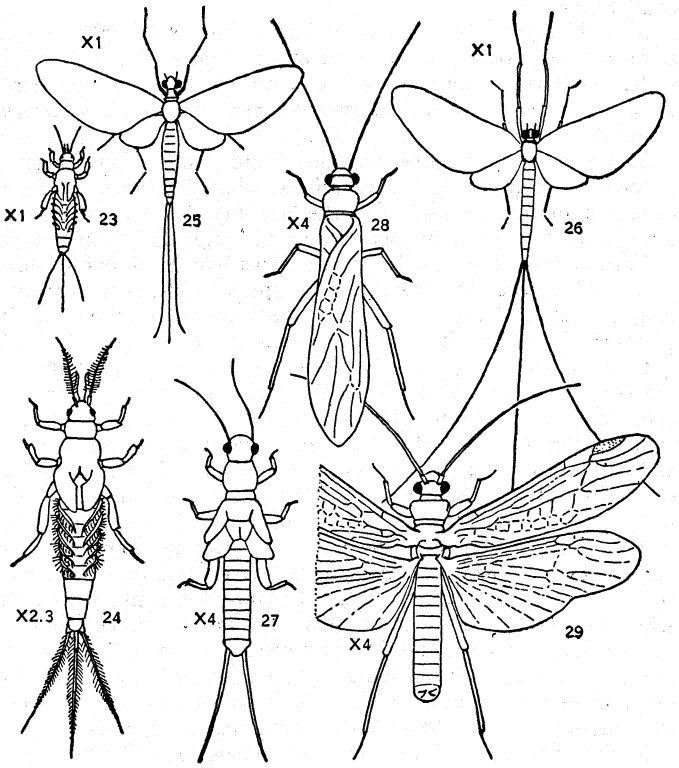
Primitively wingless insects with no true metamorphosis: abdominal appendages present other than gonopophyses (sexual appendages) and cerci.

Order I. Collembola (Figs. 18, 19).—Springtails; 1,100 species in 5 families. Very small, soil insects, with four-jointed antennae; abdomen of 6 segments. Because at no time in the embryo are there more than six segments, the question arises whether these should be classed as true insects. The first segment of the abdomen has a ventral tube with a glandular sucker-like tip considered an adhesive organ, segment four or five usually has a forked springing organ, while on segment three is a hook that holds the spring in place when not jumping. Hence the name Springtail (see footnote 1, above).

Pseudosinella has an egg stage of five days and goes through six instars in ten days. Hence Collembola can build up an enormous soil population following a heavy rain, or in western America following one deep irrigation, where on the surface of an irrigating trough they may appear as a black soot for hundreds of feet. This is an outstanding example of the myriads of microscopic insects usually unnoticed in moist soil.

Order II. Protura (Fig. 20).—Sixty-two species in three families. Minute insects without antennae; with eyelike spots (pseudoculi) which may be vestigial antennae; abdomen of 12 segments, no cerci; mouth-parts piercing, fore-legs held above head like antennae and probably used as tactile organs.

These insects on hatching have nine segments in the abdomen; three are added, by interpolation between the last and next to the last, during larval growth. (See Classification by the Forms of Metamorphosis: Ametabola, above.) The three pairs of small appendages on segments one to three of the abdomen, and the development of abdominal segments by interpolation, are characteristic of chilopodlike forms. Protura are found in humus-filled moist soil.



FIGS. 23-29

Ephemeroptera: *Ephemera* sp.; (23, 24) nymph showing external wing-pads and lateral abdominal gills; (25) subimago, the winged "larval" stage; (26) imago or adult; (27-29) Plecoptera: Nemoura *vallicularia*, a species without the usual thoracic gills in the nymph (from Wu)

Order III. Thysanura (Figs. 21, 22).—Bristletails; 270 species in 6 families. Small insects with many-jointed antennae and biting mouth-parts. Abdomen of ten segments with vestiges of abdominal legs on six or more segments, and prominent cerci.

Because of their external mouth-parts, long antennae, cerci and general shape of body, the Thysanura have usually been considered closely related to the wingless ancestors of the winged insects. While associated with the soil, many are found, for the first time in insects, in very dry places—dry stumps, dry rocky ridges and, as household pests, occupying dry closets and warm areas about stoves and hearths. In insect evolution it is the first order to show a definite adaptation to dry conditions. The number of instars is indefinite, each lasting from four to eight days, and may reach more than 40 instars (Thermobia). The female in Thermobia reproduces at half of her full growth at about one-fourth of the 40 or so instars (H. L. Sweetman, 1938). In later life one lot of eggs is laid during each instar, and the female may

double in size after the first deposition of eggs.

With Thermobia the male in mating deposits a spermatophore in front of the female. She moves forward and attaches it to her sexual organs and then, turning her head, eats it. It is not known by what route the sperms reach the eggs (see Order *V. Odonata;* bedbug, Suborder *Heteroptera* and Order *XVIII. Strepsiptera*).

In technical literature Thysanura are split into two suborders, Ectognatha and Entognatha, or into two orders, Thysanura and Diplura.

Subclass II: Prometabola

Winged insects with functional wings in a subimaginal (immature) stage as well as wings in the imago. Nymph aquatic in the one recent order Ephemeroptera.

Order IV. Ephemeroptera (Figs. 23–26).—May flies; 1,270 species in 5 families. Small to medium sized, soft-bodied insects, inconspicuous setiform antennae, large eyes; vestigial mouth-parts; one or two pairs of many-veined, fanlike wings, hind pair reduced or wanting; slender legs, tarsi one to five segmented; very long filiform segmented cerci and usually a similar median caudal filament.

Nymph aquatic, with pairs of lateral abdominal gills, but in some species extra gills on head or on thorax. External wing-pads, and biting mouth-parts with which it feeds on fragments of plant tissue, algae and diatoms; 27 instars in Baetis *posticatus* of America.

Subimago, an immature stage not found in other living insects, follows the nymph. It has functional wings but does not feed: as it is immature sexually, it is the last stage larva (in zoological sense). It may be homologous with the pupa in Holometabola.

In the larger may flies the aquatic larva lives from one to three years. It does all the feeding for the species. The subimago lives long enough to expand its wings (*Potamanthus*) or over night (Ephemera). The adults live long enough to mate and oviposit.

In the emergence of *Potamanthus* the active nymph swims to the surface of the water. its back splits and from it arises the subimago, which immediately sheds its skin, releasing the final imago which continues the flight but almost immediately mates and scatters its eggs on the water, all within a half hour of the emergence of the subimago of the nymph at the surface of the water. This is one of the shortest known adult lives among insects. In most may flies the process covers 24 hours. In this order the relationships of the species to the environment are carried nearly 100% by the nymph. The larva, the active food gathering stage of the insect, shows many special adaptations to swift waters, to quiet ponds and, in many species, to burrowing through the bottom mud. The imago is reduced to mating and egg laying, and in some species, with males unknown, mating has been lost and eggs hatch without fertilization (parthenogensis).

In the parthenogenetic species the female loses the behaviour of mating and has her activity reduced to mere emergence from the water and a short flight while dropping her eggs. This is one of the most abbreviated behaviour patterns known in adult winged insects. It shows an equally reduced brain activity. The female in such species is one of the most reduced, if not the most reduced, mentally of any insect except the female in the more degenerate families of the order Strepsiptera (order XVIII, below). Evolution in this archaic insect, one of the first structural patterns with wings, has not yet seized upon the opportunities opened up for the development of brain and behaviour to accompany this new and better mechanism of locomotion. It has survived on the vast food supplies opened to it by an aquatic nymph.

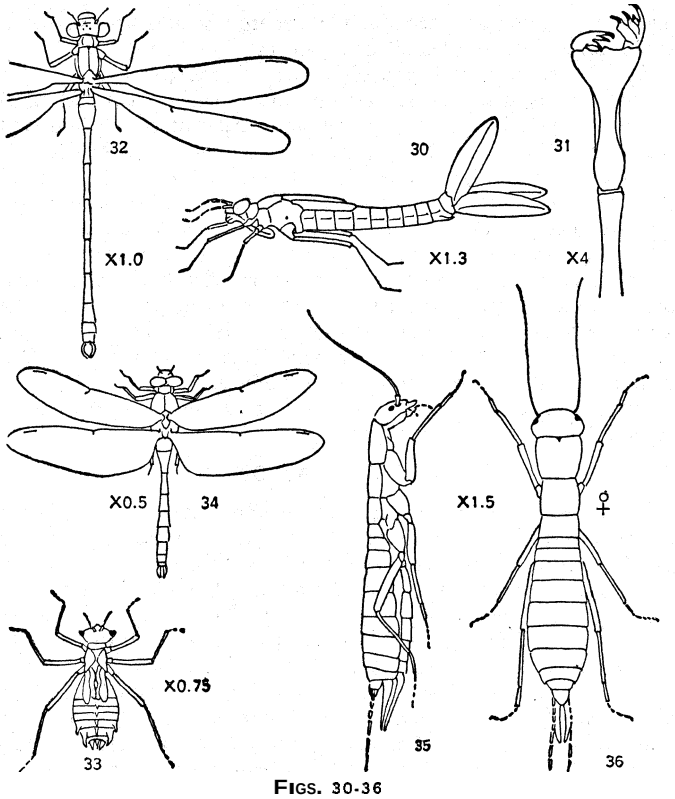
In this order the restriction of wings to a late developmental stage saves them for reproduction, a more critical function of locomotion than that of feeding. It is the first appearance in insect evolution of the physiological mechanism of metamorphosis (*q.v.*). The may flies are one of the most beneficial groups of insects as they, in their vast numbers, transform aquatic vegetation into fish food.

Subclass III: Hemimetabola

Winged insects, but including many secondarily wingless through parasitism or other life habits where wings would be an incumbrance; wings restricted to imago. Larva a nymph usually resembling the adult in form and habits. No true pupa, as wing-pads are developed externally. but in some groups a quiescent "nymphal" period preceding adult. Metamorphosis is incomplete. Both nymph and imago gain their own livelihood, with adult life and larval life nearly equal in length, that of the adult somewhat shorter through greater activity; exceptions in social and over-wintering forms.

Order V. **Odonata** (Figs. 30–34).—Dragonflies; 4,500 species in 17 or more families. Large insects with long slender bodies, very large eyes and vestigial antennae. Two pairs of equal, membranous, net-veined, narrow wings. Biting mouth-parts; tarsi three-jointed, cerci small, one-jointed, males with a secondary copulatory organ on abdominal segment two, suborder Anisoptera (figs. 33, 34), or on two and three, suborder Zygoptera (figs. 30–32).

Nymphs usually aquatic, breathing basically by rectum but in later stages of the nymph of the suborder Zygoptera by abdominal gills: labium a long, hinged prey-grasping organ (fig. 31).



Figs. 30-36

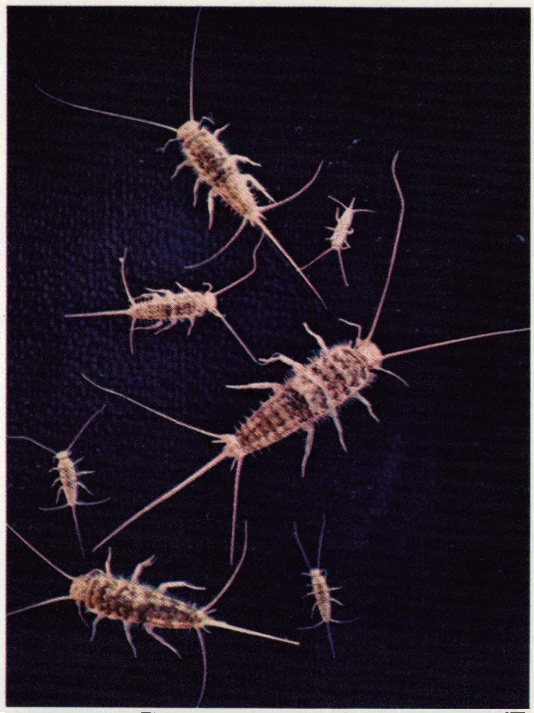
Odonata, suborder Zygoptera. Archilestes *californica:* (30) nymph with three caudal gills; (31) prehensile lip of nymph, the labial palps evolved into raptorial jaws; (32) imago; (33-34) Odonata, suborder Anisoptera. Somatochlora *metallica*, Europe; (33) nymph which breathes by drawing water into large gill-filled rectum (from Cabot); (34) imago (from Jacobson and Bianchi); (35, 36) Orthoptera: *Grylloblatta campodeiformis*, British Columbia (from Walker). See figs. 37-40 for other Orthoptera

Because of the preservation of the vein MA in dragonfly wings, they have split off from all other winged insects at the very bottom of the evolution of such (see Dragonfly).

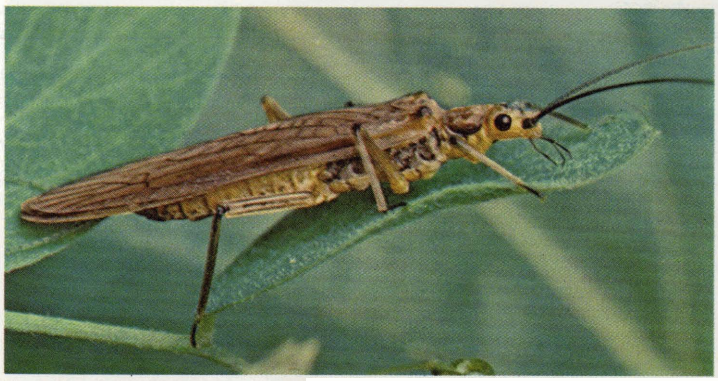
The Odonata are the earliest of the existing orders in which the evolution of the brain and behaviour has progressed to equal the evolution of the wings, the new and vastly better locomotor organs. The more primitive existing Odonata, such as *Tachopteryx thoreyi* of Mesozoic evolutional level, are stupid to the point of alighting on the collector when he is in pursuit of them as compared with the alert modern Libellulidae which arose in the Cenozoic.

The aquatic larvae are active, with good eyesight, and hunt active prey; but a few (Petaluridae, Gomphidae) burrow for prey, while some (Pseudostigmatinidae) live in tropical rain forests in mud collected at the bases of leaves. Dragonfly adults

Dragonfly, order Odonata. Dragonflies are found throughout the world, nearly everywhere there is fresh water. This species was photographed in central Africa



Firebrats, order Thysanura. Wingless insects, in some species eyeless; firebrats are household pests



Stone fly, order Plecoptera. Medium-sized to large insect with well-developed eyes and wings. The nymphs are aquatic

May fly, order Ephemeroptera. Another flying insect found near bodies of fresh water where eggs are laid and nymphs mature

Termites, order Isoptera. Portrait of three of the castes of a *Reticulitermes* species: winged individuals are kings and queens, large yellow-headed individuals are soldiers, others are workers

REPRESENTATIVES OF INSECT ORDERS

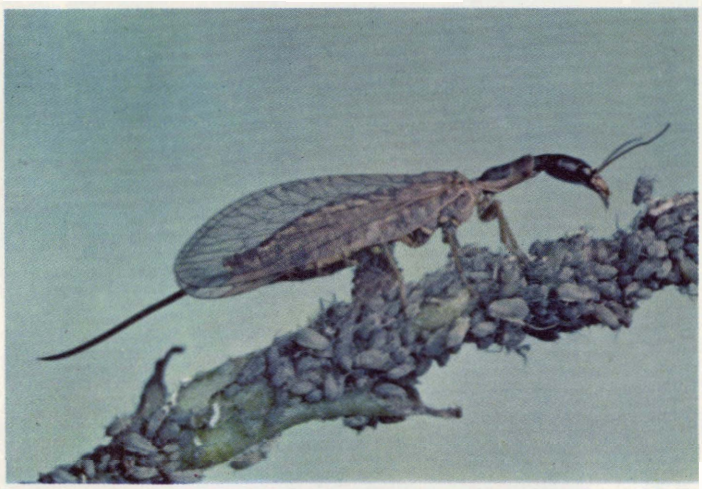
PHOTOGRAPHS, (TOP LEFT, CENTRE LEFT, BOTTOM LEFT, BOTTOM RIGHT) E. S. ROSS, (TOP RIGHT) ROMAN VISHNIAC—PUBLIX

INSECT

Brown lacewing, order Neuroptera. Soft-bodied insect with extremely elaborate venation of its large wings. Larvae are beneficial to man as aphid eaters

Earwig, order Dermaptera. A hard-bodied insect characterized by a pair of "forceps" (cerci) at the end of its abdomen

Paraphagadochir trachelia, a web spinner, order Embioptera. A social insect that lines its subterranean tunnels with silk produced from glands in its front tarsi (leg segments)



Snake fly, order Raphidiodea (considered by some a superfamily of Neuroptera). Photograph shows the long, slender ovipositor of a female as she rests on a plant stem covered with aphids

Stylops, order Strepsiptera. Twisted wing flies, a small, parasitic order. This unusual photograph shows a male in the act of feoundating a female that lives within the abdomen of a boo (note wings at top centre) that is feeding on a flower

REPRESENTATIVES OF INSECT ORDERS

PHOTOGRAPHS, E. S. ROSS

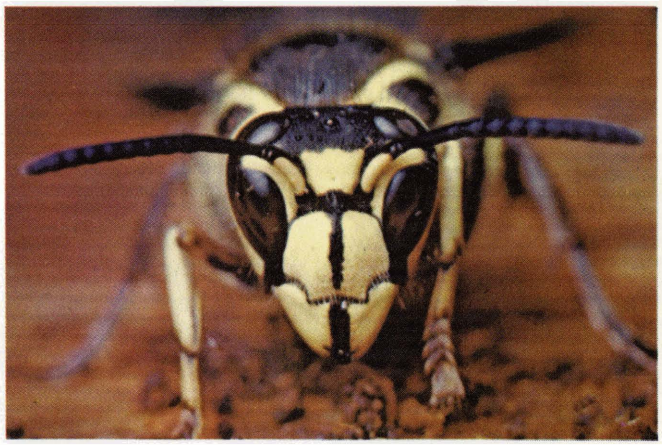
Horsefly, ***Tabanus*** species, order DIptera. Colour patterns of the compound eyes are used **in identifying species** of ***Tabanus.*** Houseflies and **mosquitoes are also** members of **this order**

A velvet ant, a **mutillid** wasp, the female of which is wingless and **antlike, order** Hymenoptera. This is the great order of social insects, including bees and ants. Velvet ants are parasites on other insects

Bush katydid, ***Microcentrum rhombifolium*, order Orthoptera.** The **leaflike colour, shape** and **pattern** of venrtlon **serve to camouflage** the katydid from predators

Long-horned meadow grasshopper, ***Orchelimum*** species, another member of the Orthoptera, related to the katydids and crickets

Cockroach, order **Blattaria** (considered by some a family *of* Orthoptera). **Flattened,** quick-running **scavengers,** some **species** have **become** household **pests.** Most are tropioal, such as **this** onr from Peru



Close-up of the head of a queen bald-faced hornet ***(Vespula maculata),*** order **Hymenoptera.** This wasp is related to the common yellow jacket

INSECT

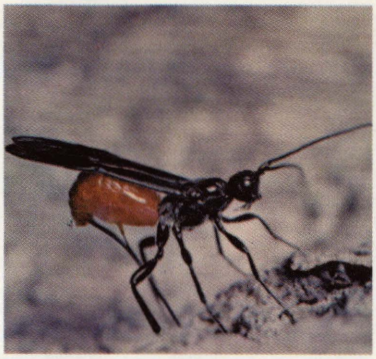
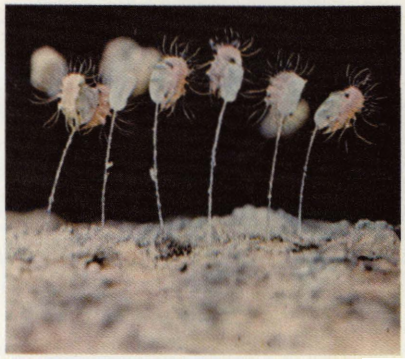
Cicada, *Tibicen* species, just emerged from its nymphal **shell, completing a metamorphosis that lasts as** long **as** 17 years in some **species**



Braconid, a parasitic wasp, laying eggs. Note long ovipositor **extended** from abdomen



Lacewing larva (family Chrysopidae) **hatching** from eggs. Each egg **is** borne on the **end of a** hairlike stalk formed of a hardened seoretion

Arctiid eggs hatching on a **leaf. Grown** larvae **are the familiar "woolly bear" caterpillars** that become nocturnal moths

Newly-hatched stink bugs (family Pentatomidae) and their empty egg cases on a leaf

Aphids being born **alive** by **parthenogenetic reproduction** of **wingless females.** Note individual emerging from mother at right

Short-horned grasshoppers or locusts **(Acrididae)** mating. Eggs are laid in the **soil in** large masses enclosed in a capsule

Praying mantis ***(Stagmomantis carolina)*** with egg mass. Egg laying takes place in autumn, the eggs hatch early the following summer. Each capsule contains about 200 eggs

REPRODUCTION AND METAMORPHOSIS

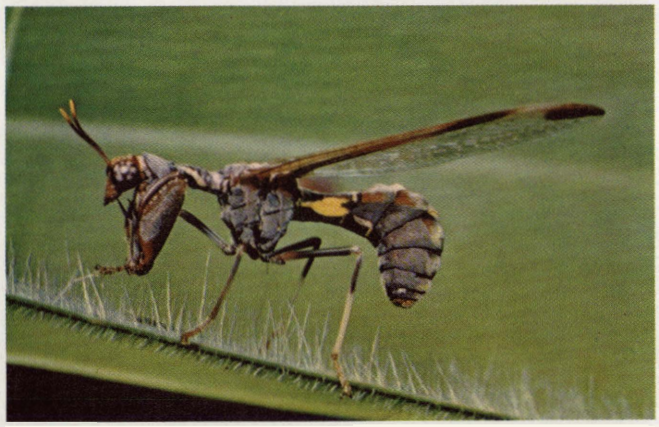
PHOTOGRAPHS, (TOP LEFT. BOTTOM RIGHT) JOHN H. GERARD, (OTHERS) E. S. ROSS

INSECT

Parasitic fly of central Africa with the body shape and markings of a bee, features that serve to protect it from the bees which it parasitizes

Cryptic pygmy locust (family Tetrigidae), a tiny insect that resembles the bark of a tree

Nymph of orchid mantis (*Hymenopus* coronatus). The form and coloration of the nymph serve to conceal it from its prey. The adult of this species bears little resemblance to the nymph



A mantidfly or mantispid (related to lacewings) with wings and abdomen like those of a wasp, and enlarged front legs like those of a mantis

Larva of the spicebush swallowtail butterfly (*Papilio troilus*). Large eyelike spots are merely protective coloration

A walking stick, *Diapheroma* femorata, a phasmid, related to the rnantids, coloured and shaped like a twig. These insects also assume positions that further enhance their disguise

PROTECTIVE COLORATION AND MIMICRY

PHOTOGRAPHS (TOP LEFT, TOP RIGHT CENTRE RIGHT) E. S. ROSS. (CENTRE LEFT) J. R. HENDRICKSON FROM D DWIGHT DAVIS, (BOTTOM RIGHT) D. DWIGHT DAVIS, (BOTTOM LEFT) JOHN H. GERARD

are agile on the wing, with probably the best vision of all insects, and catch gnats and mosquitoes. Hence the common name "mosquito hawk": an order with very agile locomotion, unusual vision and the accompanying agile behaviour. The beat of the long wings is slow, due to primitive slow muscles, which are long for power, giving the thorax housing them a backward slant termed skewness of the thorax. The sense of smell is greatly reduced.

Order VI. Orthoptera (Figs. 35–40).—*Grylloblatta,* cockroaches, grasshoppers, katydids, crickets, mantids and phasmids, 21,000 species in 7 families. Forewings leathery, hind-wings membranous with a large posterior lobe folded up fan-wise; mouth-parts for biting; cerci present.

The nymph resembles the winged adult, with usually five to nine instars.

Eggs are frequently laid in packets or oofheca formed from secretions of abdominal glands. For the first time mother care of the young begins to appear in a few groups. The majority have a life of at least one year and some even longer. With this increasing length of life of the adult, the mother has opportunity to contact her young. Family life in insects usually appears where the species is gregarious, with old and young living together in a crevice or enclosed space, as in the log-inhabiting roach *Cryptocercus* (L. R. Cleveland, 1934).

Family life is also associated with life on the ground. The surface of the ground is the most intense animal environment known. A ground insect never knows whether it will meet friend or enemy around the corner, behind a tuft of grass or hidden in the ground. Man himself had a slow simian mind until he adopted walking on the ground among tigers, wolves and such. Only the quick-witted or otherwise protected insect survives in a ground environment. This means that surviving ground insects in general have a more complex and intelligent behaviour than flying insects, tree insects or subterranean insects. In Orthoptera the ground-inhabiting roaches develop a family life in occasional species. Crickets and grasshoppers, when disturbed, vault to safety. Such radial locomotion in a group is antisocial. Survival in such species is by a behaviour of disassociation. Also many live only six months, so that generations do not overlap where a mother can associate with her offspring. Walking sticks are nearly all tree insects, with the young usually hatching on the ground from eggs dropped from a tree, which disassociates mother and offspring. Further, walking sticks depending on the camouflage of their shape, are exceedingly slow, and possess the stupidity that is associated with the lessened locomotion. Mantids, where the female usually eats the male after mating, are carnivorous with a savage behaviour, a type which seldom evolves into mother love. Thus, except for a few ground-inhabiting cockroaches, the behaviour of most Orthoptera is very simple. They are at the evolutional level where in a few species for the first time behaviour has become complex enough to show reversal from primeval "selfish" behaviour to mother care.

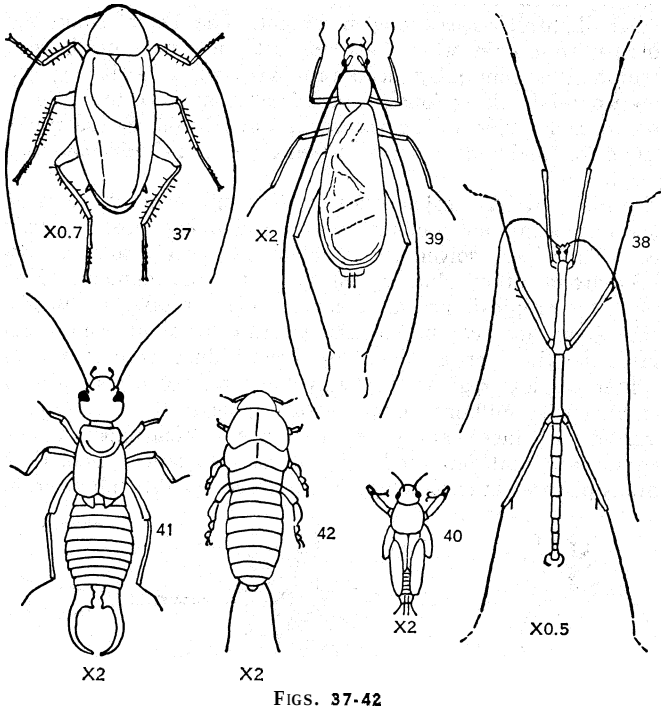
In technical publications the Orthoptera are usually split into five orders, adding Grylloblattodea, Phasmida, Blattaria and Mantodea.

Order VII. Plecoptera (Figs. 27–29).—Stone flies, 1,260 species in 8 families. Roachlike insects, but more slender, with long antennae; wings membranous, folded in repose, the hind-wings with a large posterior area folded roughly fan-wise as in many Orthoptera. Mouth-parts for biting but generally degenerate; a few records of having chewed flower buds. Tarsi three-jointed, cerci often elongate.

Nymphs aquatic with biting mouth-parts. The smallest forms without gills, but usually with tufted gills on the thorax and jaws, and in a few species, with gills about the anus. The nymphs of the more primitive species herbivorous, slow; of the higher species carnivorous and more active. This is another but minor beneficial group that transforms aquatic vegetation into fish food.

A group with probable orthropteroid relationship, but with no immediate relationship to Odonata and Ephemeroptera, and with behaviour little above that of may flies. The adult lives several days but without food.

Order VIII. Dermaptera (Figs. 41, 42).—Earwigs, 1,050 species in 7 families. Small to medium-sized insects. Usually elongate with the body terminating in a pair of large forceps. Usually heavily chitinized, hard. Filiform antennae, good eyes, biting mouth-parts. Fore-wings are short hard covers for the much-folded, fanlike hind-wings.



FIGS. 37-42

Orthoptera (also figs. 35, 36): (37) *Periplaneta americana*, cockroach (from Marlatt); (38) *Diapheromera femorata*, walking stick; (39) *Oecanthus nigricornis*, tree cricket (from Fulton); (40) *Tridactylus apicalis*, pigmy cricket (from Morse); (41, 42) Dermaptera, earwigs; (41) *Forficula auricularis*, European earwig (from Tümpel); (42) *Hemimerus talpoides*, a louselike external parasite of African rats (from G. H. Carpenter)

Nymphs resemble adults, but in some species the cerci (forceps) are long threadlike filaments.

Earwigs are gregarious ground insects, usually omnivorous. The eggs are laid in a cluster and guarded by the mother until hatched, when the young wander away. This is the second and independent development of family life in insects. It arises in species that live on the ground—the most dangerous environment—and congregate under logs, stones and other safe spots with the mother living to see her young.

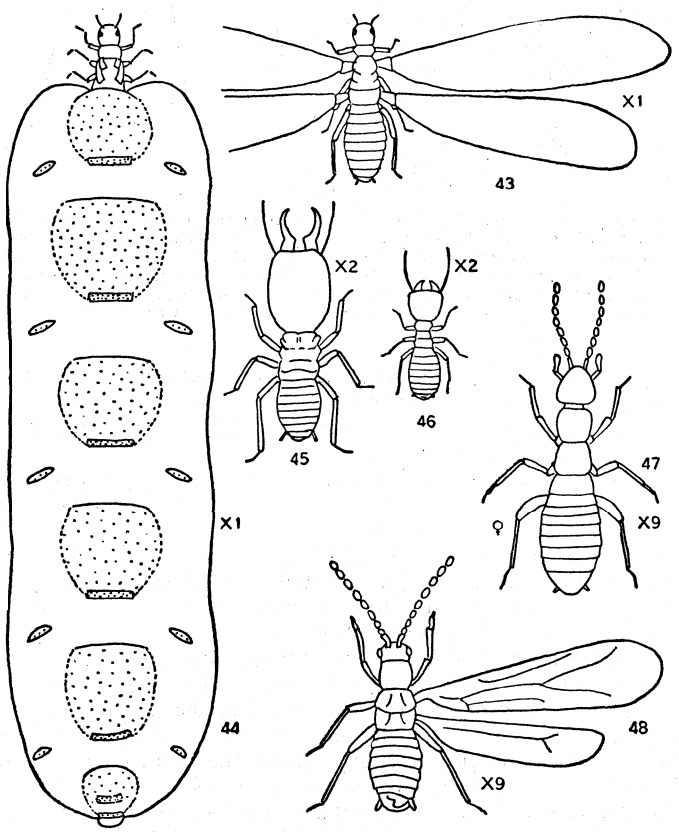
Two species of *Hemimerus* are wingless, have two filamentous cerci instead of forceps, and are external parasites on African rats. Two species of the related *Arixenia* of the East Indies live with bats. These forms are truly viviparous. The eggs hatch and the young mature partially within the mother's oviducts. where they are nourished by a placentalike organ which connects the abdomen of the embryo to the ovarian tissues of the mother (see *Order XV. Hemiptera, Suborder Heteroptera*, below: Polyctinidae, viviparity with placenta on neck of embryo). Largely because of the great differences between the semisocial habits of true earwigs and the external parasitism of *Hemimerus,* almost as wide apart as habits can be in insects. these have at times been given an order of their own, Diploglossata, of four species. the smallest proposed order of insects.

Order IX. Isoptera (Figs. 43–46).—Termites, white ants, over 2,000 species in 5 families. Social insects usually with four long feeble wings in the males and females. numerous wingless workers derived from both sexes. In some species neuter, soldier. nurse and other castes; reproductive males and queens dark; nonreproductive castes usually white and soft.

The primitive Australian species *Mastotermes darwinensis,* which lays eggs in an ootheca as do roaches, shows by structure, intestinal protozoan fauna and habits, that the termites are an

order of social roaches with modifications (far reaching degeneracies usually) in structure and behaviour for a social life. Because the female lacks a special sperm receptacle, the male lives with her and fertilizes her from time to time. Most termites eat wood, which in many forms is digested for them by a fauna of special ciliate protozoa living in the gut. The diet of wood lacks proteins, to obtain which termites eat their own dead, re-eat faecal matter containing dead protozoa and, in a few species, grow wood-inhabiting fungi. There is also much regurgitation of food to each other among the socii, trophallaxis, or the trading of food for food and for services (see Order XXV. Hymenoptera: Bees, below).

Termites live in sealed nests, which cut them off from the numerous behaviour problems which free-living insects have to face. They have solved the problem of difficult contacts with the environment by shutting off the outer environment. However, some tropical species forage for plant products. Because of the wood diet, they become dangerous pests about wood structures. In the wet tropics they help reduce forests to soil. In drier tropical regions they may build mound nests up to 20 feet high with millions of inhabitants. The earth of the mound is mixed with faecal and other substances, which makes its surface so hard that few predators can gain entrance. One of the famous pictures in entomology is a railroad cut through a termite



FIGS. 43-48

Isoptera, termites or white ants; Termes *natalensis*, Africa: (43) winged virgin queen (male closely similar); (44) aged queen, dealiated (wings off) and abdomen distended with eggs, immobile; (45) soldier; (46) worker (from Hegh); (47, 48) Zoraptera, rare, semisocial termitelike insects; Zorotypus *hubbardi*, U.S.; (47) female; (48) male (from Caudell)

nest at Katanga, Belgian Congo (Y. Sjöstedt, Revue *Zool. afric.*, 2:354–391, Bruxelles, 1913). Once a year in temperate species the termite nest is opened by the workers and the winged queens and males have a colonizing flight. Those which survive start new nests. In such flights they are easy prey to numerous birds, lizards and insectivorous mammals. The queen in some of the tropical species becomes enlarged to three or four inches (fig. 44) and is thought to live six or more years and to lay as many as 1,000,000 or more eggs. The population of a small nest of *Nasutitermes* when counted totalled 3,600,000.

Such enormous aggregations of a single species thoroughly protected from outside enemies become extremely desirable living places for numerous other insects, termitophiles (lovers of termites), thousands of species of which live with the termites themselves as parasites, as predators, but more often as symbiont~.Many of these are glandular and secrete substances which are eaten by the termites in return for housing and food. (See later sections on Hymenoptera: Bees, Trophallaxis.)

These great social complexes are built on mother behaviour, for the life of the mother is long enough to associate her with the young where the association has been more or less compulsory from living in cracks and crevices and where there has been built up a great caste of workers. These, both male and female, by some twist of heredity, have inherited mother behaviour but do not have mother reproductive ability. Rigid inherited mother instinct, stepped up by trophallaxis, compels them to care for the young (see later sections on Hymenoptera: Social Wasps, Bees and Ants). Social behaviour of the termites began in their ancestors, the roaches. This is the third development of social behaviour.

Order X. Zoraptera (Figs. 47, 48).—An order of minute insects of wide distribution but of one family, Zorotypidae, and one genus Zorotypus of 12 species. Some species have wings with two to four veins, others are wingless; biting mouth-parts; simple antennae, two-segmented tarsi, cerci short.

They occur in small colonies frequently near termite nests. They appear to be social, perhaps with castes, but there are only fragmentary notes on habits. By some they are thought to be related to termites, by others related to the book lice and psocids; very rare.

Order XI. Embioptera (EMBIIDINA, Figs. 51, 52).—One hundred species in eight families. Small slender campodeiform insects with biting mouth-parts, filamentous antennae, moderate eyes. Wings occur only in males of certain species.

Peculiar in having silk glands on first tarsal segment of forelegs in all instars of both sexes (the male dolichopodid fly thus spins web); in having femur of hind-legs large, housing enlarged depressor muscles for hind tibiae which probably give them their ability to run backward as well as forward. Some species are parthenogenetic (true eggs, but developed without fertilization).

Embiids are semisocial in that adults and young live in silk tunnels under stones, in grass tufts, under bark and similar places. The silken tunnels are spun from the glands in the forefeet, and help keep the nest atmosphere moist and entangle enemies. The species are inhabitants of the warm temperate zones and the tropics. Food mostly dead plant matter; little is known of colony habits. This is the fourth development of social behaviour.

Order XII. Corrodentia (Figs. 49, 50).—Psocids and book lice, 875 species in 15 families. Minute to small insects. Body short, compact; head large, prothorax necklike, eyes large, beaded antennae which may be short or long; no cerci.

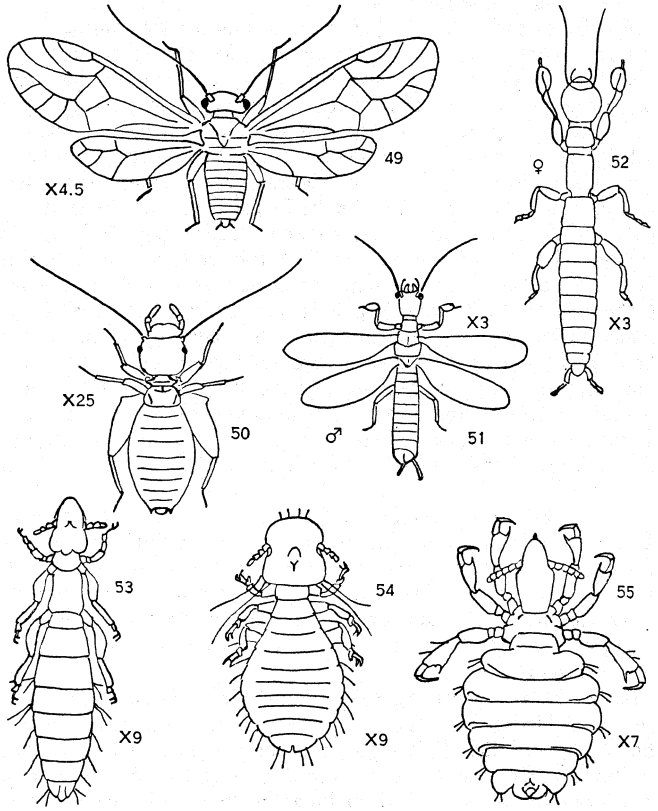
Corrodentia fed on dead plant and animal matter. They are ground and bark insects, frequently gregarious and in many species the young are associated with parents though none are known to be social. They have a simple behaviour, as do many insects which succumb to living on dead matter, which is usually abundant and of course does not have to be out-witted by superior intelligence. The bark-inhabiting psocids may be the progenitors of the Mallophaga, the biting bird lice (see next order). Book lice (fig. 50) are pests in libraries, where they eat paste and glue.

Order XIII. Mallophaga (Figs. 53, 54).—The biting lice of birds, with a few on mammals; 2,500 species in 9 families; of the shape and size of psocids and book lice, but usually tough-bodied against the pecking and biting of the host. Wingless; antennae and eyes reduced; biting mouth-parts; body with long smooth hairs reducing friction in crawling through feathers and hairs; legs short; claws, if present, adapted to grasp feathers or hairs.

No metamorphosis, as there are no wings. The species spread by contact between hosts as both birds and mammals have mating, and frequent family contacts.

This order is usually associated with the Corrodentia on the theory that psocids as bark insects crawled onto perching birds for warmth and were able to subsist on feathers, epidermal scales and dried blood about wounds. As ectoparasites, louse locomotion degenerates and with it the sense organs and any complex behaviour. Insects parasitic as adults do not later develop family or social behaviour. (See *Order* XXV. *Hymenoptera* where larvae become parasitic, the adults remain free-living and finally both become social.)

Order XIV. Thysanoptera (Figs. 14–17, 72).—Thrips. Minute, slender insects, mouth-parts of needles for piercing and sucking: 2,500 species in 17 or more families. Slender antennae, narrow hair-fringed wings; tarsi one- or two-jointed, with bladderlike organ on tip; no cerci.



FIGS. 49-55

Corrodentia (Psocoptera or Copeognatha), psocids, and book lice: (49) Psocus *fasciatus*, psocid, England (from McLachlan,); (50) *Lipocelis divinitoria*, book icuse (from Howard and Marlatt); (51, 52) Embioptera (Embiidina, Embiaria), web spinners, semisocial, a small tropical group, *Embia* major, Himalayas: (51) male; (52) female (from Imms); (53, 54) Mallophaga, biting bird lice: (53) *Liperurus squalidus*, duck louse; (54) *Goniocotes* compar, pigeon louse (from Osborn); (55) Anoplura, sucking or mammalian lice: Hematopinus *suis*, hog louse (from Osborn)

Metamorphosis with a pupalike stage. Thrips are strange insects of obscure relationships, but usually associated with the Homoptera and Heteroptera (hemipteroid orders) on account of the piercing mouth-parts.

One to seven generations a year. Nymphs with four instars, the third and fourth with wing-pads and do not feed (figs. 4–7). In some forms instar three is inactive in a cell in the ground and is called a "prepupa." Its antennae are free. and body movement is possible when disturbed. Instar four has antennae folded back over head and is more quiescent, called the "pupa." The "pupa" is not a true pupa because its wing-pads have been developed externally in the prepupa. (See earlier discussion under *Classification by the Forms of Metamorphosis: Holometabola*.)

The wings (fig. 72) are very narrow with one or two parallel veins. The wing surface is extended to three or four times the original area by wide fringes of hairs. by which the weight of the wing is reduced in such minute insects. Minute insects of other orders have similar wing structure, as in the minute moths termed Microlepidoptera, in minute wasps (Hymenoptera) parasitic on insect eggs and in very minute beetles, Trichopterygidae, Sphaeridae and Ptiliidae. It is convergent evolution in independent lines, common in insects, where the best mechanical design is produced that can be evolved from the insect material and basic design available.

Some thrips are carnivorous blood suckers, some herbivorous sap feeders. While they may become very abundant, they show no tendency of family or social behaviour. Insects with piercing and sucking mouth-parts have a basic behaviour of attack not easily modified to the tender care of young. Also the smaller forms have a very simple behaviour. Some are pests on pear blossoms, on onions and tobacco.

Order XV. Hemiptera (Figs. 56–71, 73–So).—Insects with needlelike mouth-parts which suck sap and blood; commonly called bugs. This great group falls into two such distinct subgroups that they are frequently treated as two distinct orders. The present tendency is to unite them. A similar situation occurs in the Odonata but there union is closer because of an intermediate mostly fossil suborder. This review treats the two hemipteroid suborders, Homoptera and Heteroptera, individually because of the great distinction of habits; the first feeds on plants wholly, the second on animals, except for a few families of sap feeders.

Suborder Homoptera (Figs. 56–71).—Cicadas, tree hoppers, leaf hoppers, aphids, scale insects; 34 families. Insects with piercing mouth-parts, living almost altogether on plant juices. Head small, because small muscles can operate the piercing needles of the mouth-parts. Wings membranous, with fore- and hind-wings similar and held sloping, roof-shaped, over body. Size large (cicadas) to minute (scale insects and aphids).

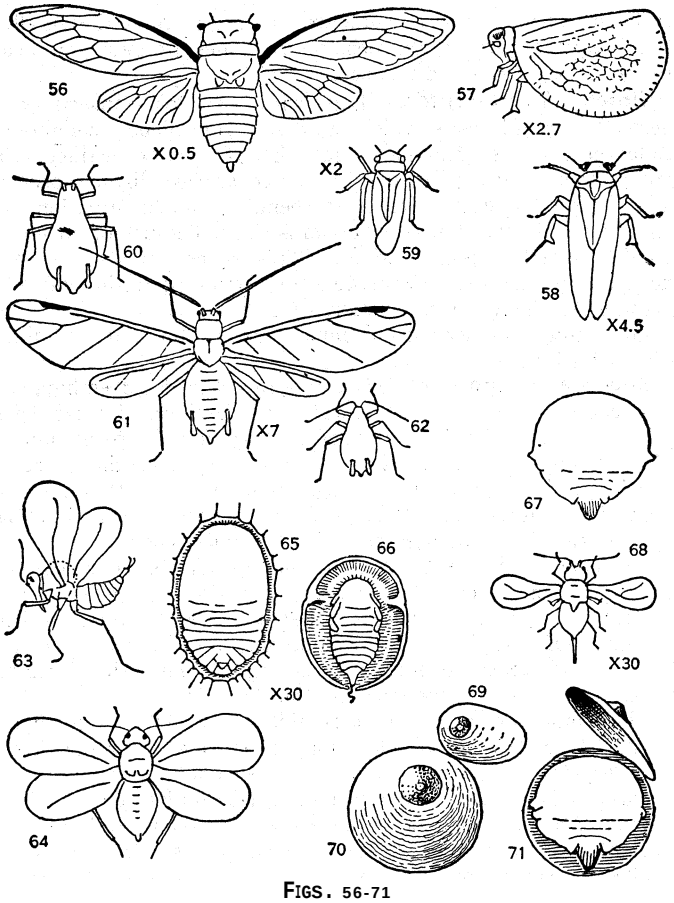
Behaviour is simple, but the life history may be very complex in the higher species (Phylloxera) parasitic on plants. The Homoptera form a very large order and are the least studied of any. Of the hemipteroid suborders, the Homoptera are simpler and appeared earlier in geological time, the Permian period. Heteroptera appeared in the Triassic.

The Homoptera appear to lack ability to imbibe or to digest animal blood. An anticoagulant may be lacking, or proper digestive enzymes, or proper excretion of poisonous animal proteid products. Those considered primitive (Cicadidae, fig. 56, Fulgoridae. Membracidae, etc.) are large, but show tendencies to obligate feeding on one or a few host plants. This tendency evolves to the more highly specialized minute forms (Aleurodidae, Coccidae, Aphidae), many of which are wholly confined to one plant species for food and which show some of the highest phases of parasite degeneracy of sense organs and locomotion found among insects. Conversely, the life history, as in many parasites. may become very complex. Complex life histories, an adaptive development in parasitism, reach their peak for insects in the higher Homoptera. In the life cycle of the plant louse, *Phylloxera quercus* of Europe. as many as 21 forms occur. The earlier and simpler phase of insect parasitism on particular plants with degeneracy of sense organs and locomotion has a parallel in the higher Coleoptera with degeneracies in the families of weevils.

Rfetamorphosis is incomplete, with a nymph which also has piercing mouth-parts. The number of instars. including adult, decrease from the cicada (fig. 56) with nine to the scale insects (figs. 67–71) where the male has four and the female three. The male scale insect passes through a quiescent "pupal stage" but one in which the wing-pads have been developed externally as in the "pupa" of thrips. The female (figs. 67, 70, 71), an immobile scale in the higher forms of Coccidae with only three instars, and never reaching winged adult form. .thus produces viable eggs in a late nymphal form In the aphids (figs. 60–62) metamorphosis is incomplete, but is involved uith the production, in nymphlike wingless forms (figs. 60, 62), of eggs which, without fertilization (parthenogenetically). develop within the mother who gives birth to active nymphs. At such periods in this life cycle all may be females, which in a few days after birth reproduce in the same manner. This is a production-line reproduction that can build up an enormous population in a few

days. It is only equalled by queen termites, queen bees and queen ants. Because of this, aphid pests require speed in control.

The scale insects as pests are almost as difficult to control as aphids. Many secrete a waxy "scale" cover (figs. 70–71) impervious to water. Some of their products have commercial value. The body of the cochineal scale on cactus has furnished the food-colouring dye carmine. Various other dyes are derived



FIGS. 56-71

Hemiptera, suborder Homoptera, cicadas, fulgorids, cicadellids, aphids, white flies, scale insects: (56) *Cicada marginata* (from Davis); (57) *Acantholomia bivittata*, fulgorid (from Dozier); (58) *Perkinsiella saccharicida*, sugar cane leafhopper, fulgorid, Hawaii (from Kirkaldy); (59) *Exitianus obscurinervis*, a ciccadellid, the commonest American pasture leafhopper (from Osborn). (60-62) *Myzus persicae*, peach aphid, three forms of the female, holarctic (from Theobald). (63-66) *Aleyrodes citri*, an aleyrodid, the citrus white fly; (63) male; (64) female; (65) "prepupa"; (66) male "pupa" (from Morrill). (67-71) *Lindingaspis rossi*, auricaria scale; (67) mature female freed from wax scale: (68) male: (69) male scale; (70) female scale; (71) female with wax scale lifted (figs. 67, 68, 70 from Ferris). Male "pupa" of Lindingaspis not shown

from the bodies of scales, while shellac and waxes from the scale-cover of oriental species have furnished the basis of lacquers and varnishes.

Nearly all Homoptera pass in large quantities a sweet diarrhoea called honeydew used as food by Hymenoptera. Ants are particularly dependent on it for sugars. Some ants cultivate and rear aphids and scales ("ant cows") as domestic animals for the honeydew. When bees use it in making honey, government authorities label the product "honeydew honey." It is used in cheap cookies and other 'bakery products. Many leafhoppers and other Homoptera transmit plant diseases which are as destructive as the direct sucking of plant juices.

Suborder Heteroptera (Figs. 73–80).—A group of varied forms, water bugs, plant bugs, bedbugs, stink bugs; 43 families. True bugs are insects with piercing mouth-parts. The form varies, but with small head, short wings—if such are present—held flat over body; the fore-wings thickened at the base as covers which protect the hind-wings. Size usually larger than in the Homoptera. Behaviour and life history simple, but in predatory species behaviourwis much more advanced than in the plant-sucking Homoptera.

Metamorphosis is incomplete, usually with five instars in the nymph, which resembles the adult in both structure and habits.

Some Heteroptera are suckers of blood, while others suck plant juices. In many, digestive enzymes are injected into the prey where they act as a noncoagulant to prevent the delicate beak from being plugged by clotting blood, and where the injected enzymes actually digest the internal parts of the prey. which predigested food is then sucked up. A meal leaves the insect prey an empty sack. A "bite" or sting by a bug is usually painful, since the tissue around the wound is partially digested. Thus bugs are able to use animal proteins, as compared with the plant-feeding Homoptera.

A series of families are aquatic, breathing air by coming to the surface (see fig. 73, water boatman). Authorities usually consider these a primitive group, which may explain the thickened fore-wings as an adaptation which prevents wetting of the flying hind-wings. A parallel evolutionary situation occurs in the lower Coleoptera, where hard fore-wings could have been an adaptation to aquatic life. The order shows much peculiar specialization in family groups. In the bedbugs (fig. 80), parasitic in nests of mammals and birds, the copulatory pouch (organ of Berlese) lies in the ventral wall of the abdomen and has no direct connection with the female's sexual organs. Sperm travel to the eggs through the internal tissues. In the bat bugs, Polyctinidae (fig. 79), also parasitic, the egg develops within the female; the embryo gro s through food supplied by a placental organ connecting the neck of the embryo with the ovarian tissues. In insects one other such organ is found in the Hemimeridae, order Dermaptera (see above), parasitic on African rats. Here the placental organ is attached to the abdomen of the embryo.

Various Hemiptera as blood feeders are carriers of diseases. Hemiptera seldom build up the enormous populations found in the vegetarian Homoptera and other herbivorous insects. All carnivores occupy the apex of a "food-pyramid." Each requires many victims, while each of the victims requires an even more numerous food-pyramid base. (C. S. Elton, Animal Ecology, London, 1935).

Order XVI. Anoplura (Fig. 55).—Sucking lice of mammals and some birds; 280 species in 5 families. Similar in form to the biting bird lice (Mallophaga), but the head small because of the smaller muscles operating the needles of the piercing mouth-parts. All are blood sucking; no wings, hence no metamorphosis.

The sucking lice are a compact group in general structure, but have no connecting forms indicating to what order they might be related. External parasitism with similar degeneracies and general appearance suggest relationship to the Mallophaga, while the piercing mouth-parts suggest relationship to the Hemiptera. However, recent study of the piercing mouth-parts (see Stozanovich, Jr., in *Microent.*, 1945, G. F. Ferris [ed.]) indicates that they are very different from those in the latter order. Being feeders on blood, they transmit various human diseases, such as trench fever and typhus.

SUBCLASS IV: HOLOMETABOLA

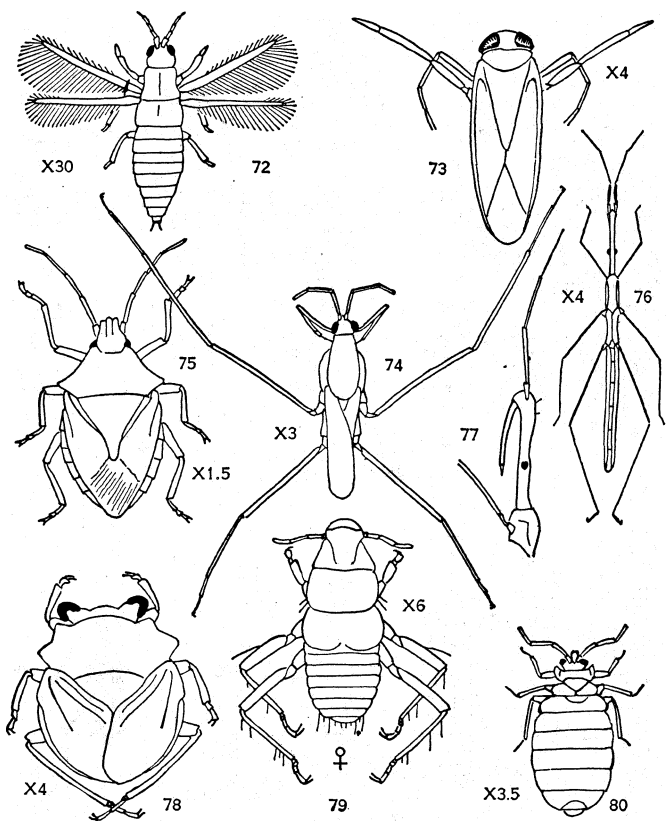
Winged insects, but including many secondarily wingless through parasitism, social life or other life habits where wings would be an encumbrance. Metamorphosis complete, with a true pupa with its wing-pads developed internally (figs. 12, 13) in the last larval instar (prepupal stage). Larvae, from degeneracy of locomotor and sense organs, are unlike imago. Larval life frequently shortened to a few days, adult life lengthened to weeks, months or years. In higher forms, larva usually associated with ample food supply and limited largely to mere eating and growing in size.

Order XVII. Coleoptera (Figs. 81–109).—The beetles; 154 families, 250,000 species. Minute to large insects, usually very hard-shelled, the fore-wings modified into horny elytra which meet

tightly in a straight line down the back; hind-wings, if not lost, membranous and folded beneath them. Prothorax large; mouth-parts for biting; cerci absent.

Larvae of many types, from campodeiform to legless grubs; pupa free. Rfetamorphosis complete, usually in a hard-shelled cell in the ground, occasionally in a silk cocoon spun from the anus.

The beetles in number of species comprise one-half of all described insects. They form the most numerous order of all animals from Protozoa to S'ertebrata. No satisfactory explanation of their unparalleled success as animals has ever been given. In general they do not evolve into high specializations in structure or habits. Modern beetles are very similar to the earliest fossil forms in the Permian, the last Coal age The general evidence suggests that they are evolved from an early orthopteroid type of insect near the cockroaches; that perhaps they have developed complete metamorphosis more or less independently from that evolved in the neuropteroid series of orders. The evidence is conflicting as to which families are the oldest in the order, Boving and Craighead (Larvae of Coleoptera, Brooklyn Ent. Soc., 1931) place the families Cupesidae and Micromalthidae as the oldest of all living Coleoptera. These have cylindrical larvae, some of which in *Micromalthus* (figs. 97–99) are legless (*Cupes*, figs. 94–96). If these are the oldest types the Coleoptera probably have evolved from boring (aquatic?) insects with cylindrical larvae.



Figs 72-80

(72) Thysanoptera, thrips; *Hercothrips fasciatus*, bean thrips, California. See also figs. 14-17 (from Bailey). (73-80) Hemiptera, suborder Heteroptera, true bugs: (73) *Arctocorixa alternata*, water boatman (from Hungerford); (74) *Gerris* buenoi, water strider (from Garman); (75) *Apateticus cynicus*, stink bug (from Htckman in Garman); (76, 77) Hydrometra *martini*, (77) side view of head showing piercing beak (from Garman); (78) *Gelastocoris* barberi, toad bug (from Garman); (73-78 American); (79) *Hesperoctenes impressus*, parasitic on bats, Neotropical (from Ferris); (80) *Cimex lectularius*, bedbug, cosmopolitan (from Marlatt)

The suborder Adephaga, with such families as Cicindelidae, Carabidae and Dytiscidae (figs. 61–84), is rated as the lowest of the larger groups. These are aquatic or shore-loving groups. They have campodeiform larvae, active and predaceous, but the larval legs are generally slender and weak as though redeveloped from previously reduced legs. All remaining beetles are usually grouped in the suborder Polyphaga, nhich contains five or more radiating lines of evolution. These lines arise in forms generally with campodeiform larvae and end in forms with cylindrical or even legless grublike larvae. In some of the higher families, the first stage larva is active and campodeiform, the full-grown larva cylindrical and nearly legless, uhich ontogeny suggests a recapitulation of ancestral forms.

The higher groups tend to evolve into (1) parasitism either on plants, the weevils, Curculionoidea and Platystomoidea, or on animals (other insects) the Meloidea; or (2) social life, the tumblebugs of the Scarabaeoidea and the ambrosia beetles of the Scolytidae. In either parasitism or social life the partially-grown larva does not need legs to find food.

Hypermetamorphosis occurs in the Meloidae (figs. 104–109), *Epicauta vittata* (figs. 104–107), E. *cinerea* (figs. 108, 109), species parasitic on clusters of grasshopper eggs. The meloid egg hatches into a campodeifnrm larva (fig. 104), very active, which runs about and finds a buried cluster of eggs. It burrows into these and changes into the short-legged form (fig. 105), which fattens up into the later form (fig. 106). The next, a full-fed stage (fig. 107), is fat and inactive and is called a prepupa; this sheds its skin turning into the true pupa (fig. 108) from which the adult (fig. 109) emerges. A similar series of forms (hypermetamorphosis) occurs in the family Mantispidae, order Neuroptera, parasitic on spider egg-clusters.

Parasitism on plants occurs all through the higher families of the Coleoptera, especially in the weevils, where many species are obligate or limited to feeding on one species of plant. In the highest forms of this obligateness, the larva, legless and inactive, spends its life feeding in a nut, fruit or similar very nourishing plant part. As in all parasitism, locomotor and sense-organs disappear and other degeneracies appear. In weevils even the adult may lose flying uings and the species may be reduced to one of females only, that do not need fertilization by a male.

Beginning social life appears in six families (W. M. Wheeler, Insect Societies, 1928). No social forms appear in the active carnivorous series of families. Here behaviour is too vigorous and abrupt to be easily evolved into the slow and more gentle behaviour necessary in the care of young.

In the Scarabaeidae, in the section of the dung beetles (scarabs) the young are fed on manure of the hoofed mammals (cattle, sheep, etc.). In one species of the tumblebug (*Copris hispanus*) studied by Fabre, the manure is rolled into a marble-sized ball by the parents, a hole is dug, the ball of manure is dropped into the hole, then cut into four parts in each of nhich an egg is laid. The mother remains in the chamber keeping the pellets free from fungus while the larvae develop. She then accompanies the young adults to the surface, where the family breaks up. In other species in this group the male lives with the female, helping her care for the young. In the Passalidae, which bore tunnels in and feed upon rotten wood, both parents live with the young, chew the wood up for food for the young, and both parents and young have sound-producing organs by nhich they call each other. The parents also help the young, at the time of pupation, build a sawdust cocoon. The adults of *Passalus* have pockets of live fungus in the colon. These may help digest the wood as do protozoa in the termite intestine and in that of *Cryptocercus*, the social cockroach. No study has been made of the fungal pockets.

In the highest level of the Coleoptera (the weevils) the larva, being immersed in an abundant food supply, needs little mother care beyond selection of the food medium. However, in the family Platypodidae and in some genera of the Ipidae, food habits have shifted from that of eating general plant tissues in which the tunnels lie, to the cultivation and eating of fungi grown on the wood walls of the tunnels. The fungal food is tended by the mother, as it needs special care in planting and harvesting to prevent fast growth. which sometimes chokes the tunnels and smothers the family. From the nature of the food, these weevils are called ambrosia beetles. The mother carries live fungus from her home burrow to that she makes for her eggs and young. After

establishing fungus beds in the burrow, she gathers the crop and places it before the larvae.

It appears unusual for intelligent behaviour to develop in a group which has shown broad parasitic degeneration, but it is associated with a shift from normal plant food to the growth of fungi by the adult. In insects, evolution of social life is largely the evolution of the behaviour of the adult, coincident with degeneration of behaviour in the young.

Order XVIII. Strepsiptera (Figs. 110–117).—Stylops or twisted-winged insects; 170 species in 6 families; size small to minute; mostly with the female endoparasitic; female as a primary larva, free, active, spiny, long-legged; after boring into host, she becomes an egg-producing sac without eyes, antennae or legs. Her head and thorax fuse into a cephalothorax (probably a pupal stage); at maturity she is enclosed in the larval skin, at the anterior end of which is a brood-passage opening, which is also used by the male in coitus. Sperm pass between female and larval skin case to a series of genital openings on venter of female, as her sexual organs are degenerate. Male with flabellate antennae, eyes wide apart, in some species stalked; fore-wings reduced to a pair of short flaps (pseudohalteres); thorax large; abdomen short.

The male has a pupal stage within last larval skin within host. The female larva changes into a pupa with head and thorax fused, from which form she develops no further. In the most primitive family Mengeidae, the female (fig. 114) has small eyes, antennae, mouth-parts and short legs, and has been found living free under stones. In all higher families she is an endoparasite in the abdomen of host insects, mostly Homoptera and Hymenoptera. Here the cephalothorax protrudes between two abdominal sclerites (fig. 116). She feeds by osmosis.

The Strepsiptera are considered a highly specialized parasitic offshoot from the Coleoptera. The fore-wings of the male (fig. 117) appear to be rudimentary elytra. The six distinct families, and world distribution with hosts in several orders of insects, indicate an old group well considered an order. The life history, habits and structure of larvae somewhat parallel those in the Rhipiphoridae (Coleoptera). In both, the primary larva is active and the later larva becomes an endoparasite.

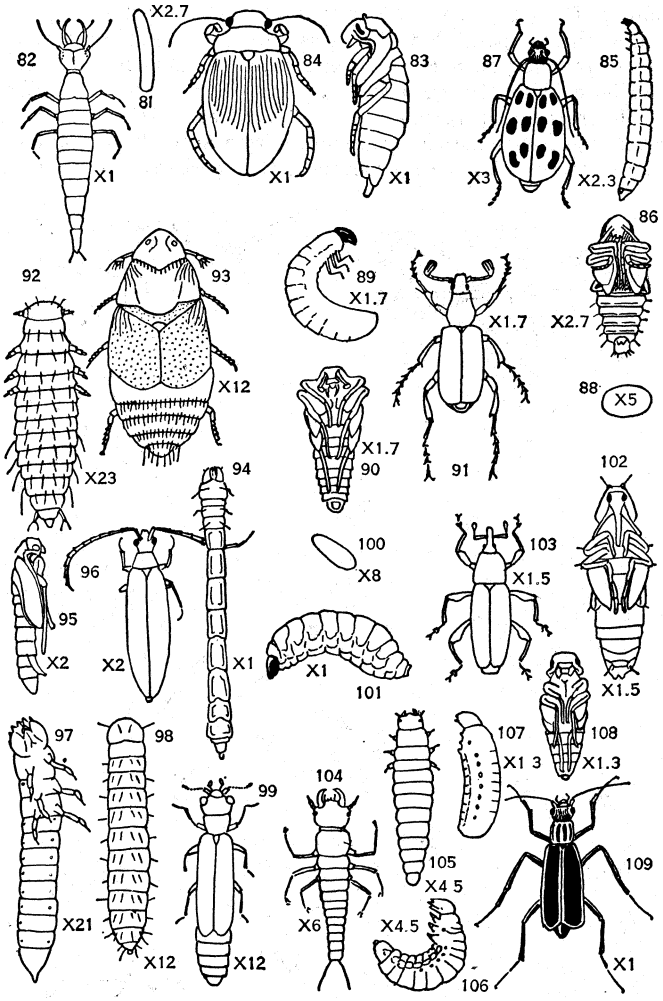
To entomologists the Strepsiptera form one of the most interesting groups of insects. Metamorphosis has reached an almost explosive development. The primary larvae (fig. 111) has legs and is intensely active in search of a host, finding which it bores in, lives by absorption of food (osmosis) through the body wall, becomes legless and quiescent. It pupates in the last two larval skins. The female evolves into a mere sac of eggs (fig. 115), with head and thorax fused into a cephalothorax which is apparently a pupal stage, while the male evolves into one of the most intensely active insects known, in his search for a mate. This life history is one of the more striking examples of how metamorphosis divides a life history into four parts by an interpolated pupal stage: (1) male larva, (2) male adult, (3) female larva, (4) female adult, when each can evolve radially in an independent direction.

Order XIX. Neuroptera (Figs. 118–121).—Fish flies, ant lions, aphis lions, mantispids and many others; 20 or more families, 4,350 species. Small to large soft-bodied insects, with long subequal net-veined wings which are folded rooflike over the body. Venation dense and elaborate in the higher forms. Tarsi five-jointed. Mouth-parts with raptorial jaws, usually modified into tubular blood-sucking organs; no cerci.

Larva various, campodeiform, eruciform, gilled in the aquatic Sisyridae. Metamorphosis complete, hypermetamorphosis in the Mantispidae. A cocoon is spun from silk produced by the normally excretory Malpighian tubules and passed out the anus.

The Neuroptera appeared in the Permian Coal age and are as old as the Coleoptera. The 20 or more families are relic, highly specialized tips of a great Mesozoic order, from which the connecting links between families have become extinct Structure and habits of the living forms are very different from family to family. They show evolution from a fairly simple venation, Sialidae and Coniopterygidae, to some of the most elaborately-veined wings known, in such families as the Myrmeleonidae, Ascalaphidae and Dilaridae. The term lacewings is a common name for many of these.

The majority are voracious wandering predators that stalk their prey. But the larva of the ant lion, Myrmeleonidae, digs a circular pit in sand or dust in which it lies in wait for any insect that slides to the pit bottom. The larva of the spongilla fly (Sisyridae) is parasitic in fresh-water sponges, while that of the Mantispidae is parasitic in egg sacs of spiders where it undergoes a hypermetamorphosis. The lacewings of the Hemerobiidae (figs. 118–121) and Chrysopidae eat aphids and scale insects, making themselves very beneficial insects. Because they are soft and shrink out of shape on pins in collection, few collect Neuroptera, but they are of great interest to students of insect evolution and habits. They are primitive and queer of habit.



FIGS. 81-109

Coleoptera, beetles, comprising one-third of all insects, the largest order of animals in the world. (81-84) *Dytiscus marginalis*, dytiscid diving beetle, European; egg, larva, pupa, imago (from *Korschelt*), notice the primitive campodeiform larva (82); (85-87) *Diabrotica 12-punctata*, chrisomelid, corn rootworm, American (from Riley); (88-91) Macrodactylus *subspinosus*, scarabaeid, rose chafer, egg, larva, pupa, imago (from Riley); (92-93) *Platypsyllus* castoris, platypsyllid. parasitic on the beaver (from Riley); (94-96) Cupes conocolor, cupescid, a very primitive borer in wood (from Snyder); (97-99) *Micromalthus debilis*, micromalthid, legged and legless larvae, a very primitive borer (from Barber); (100-103) *Sphenophorus* obscurus, a weevil, the sugar cane borer, Hawaii. Notice completely legless larva (from Riley); (104-109) Epicauta, 2 spp.: E. *vittata*, blister beetles parasitic on grasshopper eggs. Notice hypermetamorphosis (four types of larva); (104) campodeiform, active first-stage larva; (105, 106) second stage larva which changes from form 105 to form 106; (107) Quiescent prepupal form; (108) E. *cinerea*, pupa; (109) adult. (Figs. 104-109 from Riley)

Order XX. Mecoptera (Figs. 122–126).—Scorpion flies; 7 families, 310 species; small to medium sized, slender predacious insects with biting mouth-parts in an elongated head held vertically; antennae long; eyes large, widely separated: legs

long; four long slender wings, when such are present. Larvae eruciform (caterpillarlike).

The common forms of damp woods, *Panorpa* and *Bittacus,* look like four-winged crane flies (Diptera). The venation of the aings is similar to that of the crane flies, but with more cross veins. The name comes from the great bulb of male genitalia in some genera, appearing as a stinging organ to the ignorant, as on the tail of a scorpion. The caterpillarlike larva is a voracious predator (fig. 124) that wanders among the dead leaves of the forest floor. The adult *Bittacus* hangs from bushes with his long fore-legs and catches passing gnats with his grasping hind feet (fig. 126). This requires remarkable binocular vision to the rear, very unusual in animals. Good binocular vision which judges distance is associated with good eyes wide apart, characteristic of this order.

The order Mecoptera is of special interest to students of the evolution of insects, as by anatomy it appears to be ancestral to the Trichoptera and Lepidoptera and to the Diptera and Siphonaptera, and closely related to the Neuroptera. The five orders have been termed the panorpid complex or mecopteroid orders by Tillyard.

Order **XXI.** Trichoptera (Figs. 127–133).—Caddis flies, case worms: 16 families, 3.600 species. Small to medium mothlike insects, nocturnal or crepuscular; feeble biting mouth-parts, long antennae, large eyes; wings folded over body rooflike, covered with hairs and scales.

Larvae aquatic, living in a silk case to which usually are attached sand grains, sticks or pebbles (figs. 129–133); eruciform and most species with filamentous abdominal gills (fig. 127)

Larvae of the primitive family Rhyacophilidae scramble among the stones in torrents or many build silken tunnels. The larva of the Hydropsychidae build a hammocklike silk net on water falls, which sieves prey out of the running water. The majority build silk tubes or cases which may be free, so the larvae can crawl about by extending head and legs, or are attached solidly to a rock or log in the stream bed. Nearly all cases are variously camouflaged by sand grains, pebbles, sticks or bits of leaves glued to their surface. As the larva grows, it crawls out and builds larger cases. Its taste may change. Some species use one type of case ornament when young and another at an older stage. They pupate in a silk or gelatinous cocoon within the case. The pupa has no gills, but breathes air by spinning a sieve across the opening of the case. The air dissolved in the water running through the case forms a permanent air bubble within the case against the spiracles of the pupa. When ready to emerge, the pupa with its special free jaws gnaws out, the pupal skin splits and the adult flies up from the water. With defective mouth-parts, the adult lives but to mate, oviposit and die.

Caddis flies are general feeders, some herbivores, other omnivores. Except when flying in swarms in a mating dance, they show little associative behaviour. No aquatic insect shows any tendency toward family or social life. and but few even show any tendency to larval or adult aggregations. Exceptions are water striders, Gerridae (Hemiptera), whirly-gig beetles, Gyrinidae and the mating dances of caddis flies, and of some aquatic Diptera. In all these the larvae are aquatic, the adults aerial (except Gerridae of the Heteroptera, where both larva and adult are water-surface forms) which prevents mother care of the young.

Caddis flies rate as beneficial insects. They are one of the few animals which convert the great areas of aquatic vegetation into attractive fish food. They occur in enormous numbers.

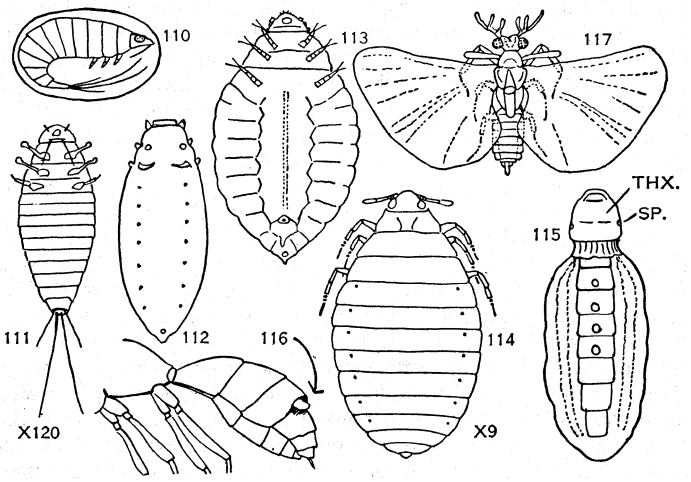
Order **XXII.** Lepidoptera (figs. 134–141).—Moths and butterflies; 190 families, 105,000 species in 1,000 genera; small to large insects with mandibles lacking, the two maxillae with galeae developed into a hollow nectar-sucking proboscis, coiled at rest; wings usually fanlike and covered with overlapping scales.

Larva eruciform, or caterpillar (figs. 134, 136, 139), with none to four pairs of abdominal prolegs; compound eyes reduced to a semicircle of 4–12 ocelli on each side of head; antennae vestigial; mouth-parts for biting; usually herbivorous.

The Lepidoptera divide into two great groups, the moths, Heterocera and the butterflies, Rhopalocera. The butterflies have antennae thickened, clubbed at the tip and sometimes (skippers, Hesperoidea) hooked at tip. The moths have many-jointed antennae, but plumose or not, and never clubbed. Moths are usually crepuscular or nocturnal, though there are many brightly-coloured forms which are diurnal, some of which have the appearance and habits of large butterflies.

The form of life history is monotonously alike through this great order. The caterpillar is herbivorous. except in a few Lycaenidae (butterflies) where it feeds on aphids and other small insects. It is carnivorous in moth larvae in ant nests, in the clothes moth, the wax-moth of bees and a few others. Some are borers in plant stems and wood, while others are aquatic with filamentous gills. The adult usually feeds on sugar as found in the nectar of flowers, in sweet sap, at times in fruit injured first by a bee, wasp or bird. Some of the most gorgeous South American *Morpho* butterflies are baited by faecal matter.

Except in the very primitive Micropterigidae, the pupa is obtected with all appendages glued to its surface, one of the highest forms of pupa in evolution (fig. 140). In the moths the last instar of the caterpillar usually spins a silk cocoon about itself from its temporarily modified salivary glands, which cocoon serves as a protective case while the caterpillar changes into a pupa and while the pupa transforms. In the butterflies there is no silk cocoon. The use of silk is reduced to a pad from which



FIGS. 110-117

Strepsiptera, the twisted-winged insects in reference to the folding of the male's wings, internal parasites of other insects (Fig. 116). (110-114, 117) Eoxenos *laboulbenia*, Menoeidae, the, most primitive family with active adult female (Fig. 114); (110) first stage larva in egg dissected from mother; (111) first stage larva or active triungulin; (112) last stage male larva; (113) last stage female larva; (117) adult male, notice rudiments of forewings. (115, 116) Xenos *pallidus*, female; (116) with cephalothorax projecting from abdomen of the wasp *Polistes* sp.; (115) dissected out, showing the fused, pupalike, cephalothorax. The male copulates with the cephalothorax. The sperm enter the female through the four circular openings on the abdomen. Because of copulation with the neck region of the female it was thought until recently this was the tip of the abdomen. (Figs. 110-114 and 117 from Parker and Smith; 115 from Bohart)

the pupa (chrysalis) hangs with a silken loop about its middle (fig. 140). The oriental silk worm with its moth, *Bombyx mori,* is the only insect fully domesticated by man. It can not live without his care in daily feeding and is not known in a wild form.

In spite of the simple behaviour of larvae and adult, the Lepidoptera show a definite tendency to aggregations: (1) of caterpillars, as in the army worms (Noctuidae), the various tent caterpillars (Lasiocampidae), the fall webworm (Arctiidae) and a few others; (2) aggregations of adults about water holes and moist places, where each species tends to form its own group. However, the food habits of adult and caterpillar are so different the mother could not feed her young. She has lost her main household tools. biting mouth-parts. in place of which she has a perfected sucking proboscis of little home use. Further, the

large awkward nature of the wings prevents the use of a family nesting cavity. Lepidoptera can not retain present body design and evolve on into the top level of insect evolution, social life.

Protective coloration and mimicry in these large and conspicuous insects rates as one of the most argued problems in entomology. Many caterpillars are green, brown or gray, the colour of the host plant. This seems a logical protective coloration. But the adult butterflies in motion-except a few which alight when in danger, fold their wings, and appear as dead leaves with markings like leaf veins—are to the human eye the most conspicuous objects in the landscape.

Order XXIII. Diptera (Figs. 142–149).—Two-winged flies such as gnats, mosquitoes, midges, horseflies, houseflies, sheep tick, bat tick and others; 138 families, 73,000 species. Adult; size that from minute, "no-see-um midges" *(Culicoides)* to crane flies, with wing expanse up to 100 mm. Antennae and eyes large; mouth-parts for sucking and lapping; one pair of wings, on mesothorax; second pair reduced to knobs (halteres) and present when fore-wings are absent. Abdomen long and wings narrow in lower families (suborder Orthorrhapha), wings and body shorter in higher families (suborder Cyclorrhapha).

Larva legless, wormlike in the Orthorrhapha, but *a* maggot with a few specialized exceptions in the Cyclorrhapha, in which suborder it has no well defined head (fig. 147).

Pupa obtected (appendages glued down) in the Orthorrhapha, coarctate in the Cyclorrhapha. In the latter the insect pupates within the last larval skin, which forms a tight hard cover for the true pupa within (fig. 148). The names of the two suborders are based on how the adult escapes from the pupa. In the Orthorrhapha (straight seam) the adult escapes from a straight longitudinal dorsal slit. In the Cyclorrhapha (circular seam) the anterior end of the pupal case opens by a circular seam. This outer shell, the last larval skin, covering the true pupa in the Cyclorrhapha, is termed a puparium (fig. 148).

In the Diptera (*q.v.*) metamorphosis has reached its greatest specializations in body structure other than that of the nervous system, as behaviour remains throughout the order comparatively simple. Metamorphosis has taken over completely. The larva feeds and grows, the prepupa and pupa are for differentiation, and the adult merely eats and reproduces. In the higher forms, mother care goes no further than laying the eggs on an attractive medium. The larvae throughout the order with a few exceptions are thin-skinned wormlike creatures (figs. 143, 147), which have locomotion reduced to wormlike undulation, and with the co-ordinate reduction of sense organs and behaviour which accompanies reduced locomotion. In the higher flies they are maggots and degenerate to a final extreme. They lie in the moist food medium and eat and grow. Many do a few hours labour at the end of larval life when they desert the food medium, crawl to a place favourable for pupation and dig in to safety.

The larval life is almost an aquatic or semiaquatic one throughout the order (always with exceptions). They live in water (mosquitoes) (figs. 142–145), in mud (horseflies), in damp wood (many syrphids), in moist earth (gnats), in the blood of hosts as parasites (tachinid flies), in wounds (screw-worm maggots), in carcasses and faecal matter (muscoid flies). In the highest, a parasitic group, the sheep tick and relatives (Pupipera), the larvae live in the moist tubes of the mother fly (viviparous), where they are nourished on a milk produced by the greatly enlarged accessory glands and are born to pupate immediately, the larvae parasitic in the mother, the mother a blood-sucking parasite of birds and mammals.

The carnivorous larva in the phantom gnats has caudal gills, is transparent in *Chaoborus* and floats in the water with four swim-bladders. The larvae of aquatic forms are beneficial in that nearly all are herbivores and serve to transform microscopic plant life into fish food.

The pupa in some of the lower Diptera (mosquitoes) (fig. 144) is an active wiggler. As with the larva, it breathes by coming to the surface. It swims to the surface, gets a breath of air and sinks. It does the same in the related family of phantom gnats (Chaoboridae).

Metamorphosis in the pupa has reached its most extreme form in the higher Diptera. In the maggot (fig. 147) at the prepupal stage the antennae, eyes and mouth-parts of the pupa are formed from embryonic buds (groups of cells, histoblasts) on the concave inner surface of a cavity opening into the pharynx of the maggot. When partially formed, the sac turns inside out like turning a stocking, whereupon the parts of the head are on the convex outer surface of a head which is the everted sac. No comprehensive study of this curious process throughout the Diptera has been made. Head formation appears to be normal in the Orthorrhapha. The wings and pupal legs are formed in peripodal sacs as in other Holometabola.

The ptilinum is another curious organ formed only in the higher flies. It is a sac within the head of the newly formed adult which can be filled with blood by body pressure and extruded through an opening in the front of the head, an opening which closes in later adulthood. This organ is used to push off the cap of the puparium, to push off the cap of bee and wasp cells in flies parasitic on such, and to push a hole up through the soil after pupation in the ground. The young fly braces itself, extrudes the ptilinum, and shoves a hole into the ground ahead of itself. The ptilinum is withdrawn and the fly crawls forward into the cavity, when the process is repeated. A housefly can dig its way up through seven feet of loose sand by this process.

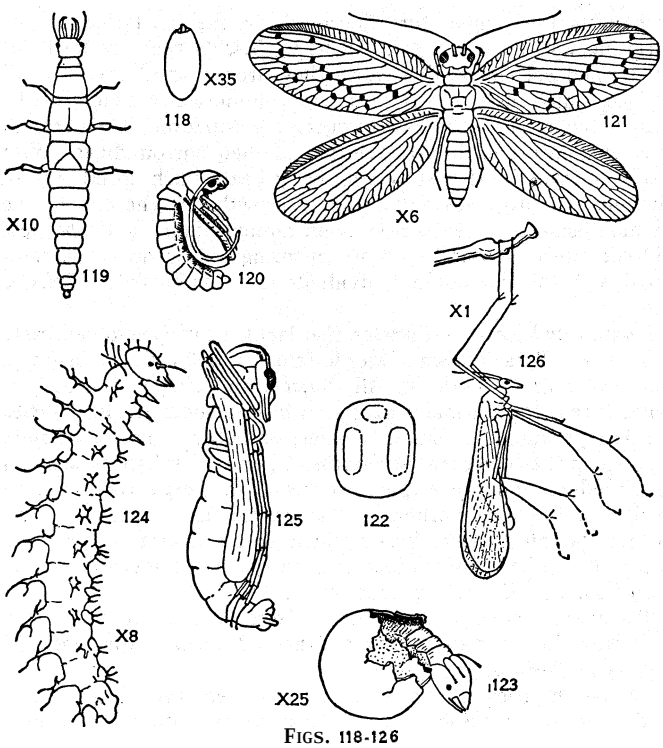
The adult flies of the majority of the higher families are some of the most active insects known, but do not have the endurance on foot or on the wing of that of the wasps, bees and ants. Some estimates give them a reasonable speed of 50 miles an hour. They are seldom taken on the wing by birds and other insects. Evolution has streamlined the body by rounding the head, folding the antennae in a groove down the face, shortening the body and shortening and speeding up the wings. Instead of attaching the front edge of the hind-wings to the trailing edge of the fore-wings to clear air eddies, the hind pair has been discarded, hence the name Diptera (two wings).

Whole families of flies as larvae are parasitic on other insects. The Tachinidae are all so, and are one of the most beneficial groups of insects. They keep down outbreaks of Lepidoptera by attacking the caterpillar. The egg is usually laid on the caterpillar, back of the head. The maggot bores in but leaves its posterior end, which has the spiracles for breathing, sticking out of the host's body, or it may attach the spiracular end to a large tracheae or spiracle of the host while it devours the viscera. In the Apioceridae, which are parasitic on spiders, the female spurts thousands of microeggs over weeds and bushes where spiders may lurk. These hatch minute very active larvae, which may wait for a spider to come by or may crawl to a likely spot. Some finally find and attack the spider in its web. The maggots of other flies (blue bottles, Calliphoridae) help to reduce the carcasses of birds, mammals and dead fish to soil. But the housefly whose maggot is reared in filth, excrement, spreads intestinal diseases when it walks on human food. The many blood-sucking families of flies from mosquitoes (Culicidae) to horseflies (Tabanidae) only add to the discomfort of man and his domestic animals. DDT has given the first easy control of the housefly. The mosquitoes which transmit malaria, yellow fever and other dread diseases make one of the greatest health problems over large areas.

Metamorphosis in the Diptera has almost completely separated the life of the larva from that of the adult, permitting evolution to operate on each form structurally in adaptation to utterly different environments. It is the highest form of metamorphosis we find in insects. The adult has been separated from the larva. In none is there mother care of the young beyond instinctively depositing eggs on the specific larval food medium. The larvae are ground insects in general, but with simple larval behaviour. The extraordinary development of the adult for speed in flight has removed it from the ground and its dangers, so there has been less need for the survival of the quick-witted and the evolution of elaborate behaviour which is a precursor of the elaborate mother care which can evolve on into social life. The Diptera can not become social. They are too simple-minded.

Order **XXIV.** Siphonaptera (Figs. 150–154).—Fleas; 6 families, 900 species, adults minute to small, apterous, laterally compressed insects, blood-sucking, ectoparasitic on mammals and some birds.

Larva wormlike; biting mouth-parts, toothed mandibles; vestigial antennae; eyeless; without legs; they feed on organic debris, usually in the nests or dens of their hosts. Metamorphosis



FIGS. 118-126

(118-121) Neuroptera. Fish flies, lacewings, ant lions, etc. *Hemerobius stigmaterus,* lacewing: egg, larva, pupa, adult (from Smith). (122-126) Mecoptera. Hanging flies, scorpion flies. *Bittacus pilicornis:* (122) freshly laid egg; (123) swollen egg, hatching; (larva, 124, pupa, 125, and imago, 126) the last in usual hanging position ready to grab passing gnats with middle and hind feet (from Setty)

complete and having features resembling that of the lower Diptera (Nematocera).

The fleas are a compact group of species of similar structure, life history and behaviour. They are Holometabola by metamorphosis, and by elimination remain nearest the lower Diptera in larval structure and adult mouth-parts. But the latter do not compare easily with any found even in the Diptera. The pupa (fig. 153), is exarate with free appendages as in lower Holometabola. The larva is legless, and in a coiled position transforms within a silken, disk-shaped cocoon flat on the surface of attachment (fig. 152).

Being blood sucking, they transmit various blood diseases, particularly bubonic plague. This is the basis of the many campaigns against rats and other rodents, the carriers of fleas and plague. The complete life cycle for most species falls within four to ten weeks. The use of the recently introduced DDT will probably be very effective in the temperate zones where freezing kills any fleas out-of-doors, but in tropical areas they can breed in yards the year around.

Order XXV. Hymenoptera.— Sawflies, parasitic wasps, true wasps, bees and ants; 118,000 species. Insects which have two pairs of membranous wings, if not lost in social and parasitic forms; hind wings locked to front wings by hooklets: mouth parts for biting, but in higher forms adapted also to lapping and sucking; antennae and eyes very highly developed (with exceptions). In the lowest forms of sawflies, abdomen with ten segments as in other higher insects; but above the sawflies, abdomen constricted at posterior end of first segment. with that segment fused onto the hind end of thorax. Female with ovipositor modified for sawing, piercing or stinging.

Larva eruciform in sawflies; vermiform, and usually without legs and developed sense organs, in the higher forms. Metamorphosis complete, with a cocoon of silk in most families.

Metamorphosis is less involved and apparently has not developed as high a mechanics of metamorphosis in the Hymenoptera as in the higher Diptera *(see Order XXIII. Diptera:* metamorphosis of the muscid fly head).

"If the Hymenoptera be judged By their intelligent behavior they must be regarded as including the highest members of their class" (A. D. Imms, A *General Textbook of Entomology, E. P.* Dutton & Co., Inc., N.Y. [1925]). They include the great series of parasites on insects, which constantly keep other insects from outbreaks disastrous to man, and many of which have strange special adaptations to parasitic life. They include the many kinds of fossorial (digger) wasps. The females of some of these are the most intelligent individualists in the insect world. But above all they include the great series of social wasps, bees and ants, where family life has evolved into social life, and this has evolved in the honeybee beyond any comparable level in human evolution, to a level where family life has disappeared completely and the whole social structure is a pure co-operative society Judged by the evolution of intelligent behaviour, the social wasps, bees and ants outrank all other insects in evolution. They do not hide from the dangers of the environment as do the termites, but face the environment openly and with intelligence boldly master it. *(See* SOCIAL INSECTS.)

The Sawflies and Parasitic Ichneumons (sens lat.).—The evolution within the Hymenoptera from sawflies to social forms has been one of the evolution of adult locomotion and adult sense organs, with concurrent evolution of the best brain and most elaborate behaviour found in any group of insects. The evolution of locomotion and the evolution of mental ability and behaviour go hand in hand. The sawflies are slow, stupid herbivores who live in and on extensive areas of food (leaves) where they do not need high intelligence to find more. Out of these evolve the great series of families of parasitic wasps, from the large Ichneumonids to the microscopic insect-egg parasites, the Chalcids. The majority are parasitic on insects, usually on larvae and eggs. In parasitism, means must be evolved for the parasite to find the scattered hosts. This is a constant pressure for the perfection of locomotion and sense organs. From the later sawflies on to the ants, the first segment of the abdomen has been transferred to the thorax. The new design improves locomotion in two ways: more room is given in the enlarged thorax for the great flying muscles and an extra pair of spiracles is transferred. giving the thorax of Hymenoptera three pairs instead of one or two, which makes a mechanism that pours air directly into the wing muscles. Sugar, a most energy-producing food, is used heavily by ants, bees and wasps. The lower Ichneumonids have long bodies, frequently dragging a long ovipositor, long legs which impede flight, and fairly long wings all of which mean slow motion. Within the parasitic series, evolution has shortened the wings; and, to give balance, has shortened the body; and, to lessen drag, has shortened the legs and the ovipositor, or has folded the latter against the body in a groove. The antennae have been shortened and folded against the face. This is evolution for speed and endurance on the wing. Speed without good sense organs and mental ability is dangerous to the individual. The preceding diagnosis applies more especially to forms parasitic on insects. Scattered through this long series of parasitic wasps are individual genera and even families in which the larva is herbivorous, such as cynipid gall wasps with simple behaviour, and *Harmolita* (Chalcidae), a pest of grains, where slower and even wingless forms may occur. Herbivorous forms living in great areas of their food do not need precision flight to find the hosts.

Transition from Parasitism to Family Life.—*In* spite of a widely accepted view among zoologists that a parasitic line can not retrace its steps and evolve back into a free life, there evolved out of this group of parasitic forms the great advanced group of the Aculeata or Hymenoptera with the ovipositor modified into a sting. This evolution is apparently based on the highly evolved locomotion, sense organs and habits of the adult which itself is

not parasitic. In the parasitic forms the larva had already degenerated to a point with the minimum of locomotion and sense organs. The habit of the adult of chewing and feeding on the host (malaxation) and a second ability, that of stunning the host with a poisoned ovipositor or evolving sting, may have been the evolutionary bridge which made for a contact of the mother with her young so that care of the young and family life could evolve as it has all through the stinging Hymenoptera. (See W. M. Wheeler, Social Insects, chap. 3 [1928].) From this point on, locomotion of speed and endurance, acute sense organs and intricate, intelligent behaviour of the adult evolved hand in hand. From this point on, by provision of nest and food for the larva, the latter had from the time of emergence from the egg the advantage of the use, vicariously, of adult tools and adult behaviour. Thus physiologically in its relationship to the environment the larva is vicariously an adult from emergence from the egg. This vicarious use of adult organs by larvae from birth is one of the great advances in insect evolution.

A group of a half dozen families such as the Evaniidae, parasitic on cockroaches; the Chrysididae, parasitic on wasps and bees; the Tiphiidae, parasitic on beetle larvae; and the Mutillidae, parasitic on wasps, carry the parasitic habit over from the true parasitic Hymenoptera into the great group of aculeate Hymenoptera. However, parasitism, that other way of living, continues to crop out up to the social parasitism found in wasps, bees and ants.

Digger *Wasps* and Mud Daubers.—Except for shorter hours of work, the amount of intelligent work done by the individualistic mother females of the next great series (the digger wasps), which include many genera in the Vespidae (senslat.) and the Sphecidae (sens lat.), is probably the greatest done by the individual in any order of insects. However, they do not work the long hours found in the day of the social Hymenoptera. In the usual life history, the queens and males emerge from the nest in the fall, mate and the male dies. The fertilized queen hibernates, and in the spring can range for miles in her hunt for a particular type of nesting site, but usually chooses a vacant spot in her home area, as the nests are commonly in close groups. She digs a hole in the ground one or more feet deep. She hunts a particular type of insect or spider, usually a caterpillar, which she paralyzes by a sting near the victim's nervous system, after which she flies away with the doped prey to the nest, alighting within a few steps of its opening, by which she shows a remarkable homing ability—the recognition of a half-inch opening, frequently camouflaged, in an area many acres in extent. Usually she places the victim near the nest, reopens the nest, carries the victim down to the bottom of the tunnel, lays an egg on it and packs dirt over it. She then emerges from the ground and closes the opening. She then seeks another victim. In a branch of this group the mud daubers, instead of digging a hole in the ground, manufacture a hole by building a mud cell in some protected place. The queen digs mud in some wet spot, transports it to the nest site and plasters it on layer by layer, a job of many hours' labour. She provisions it usually with spiders which have been paralyzed, places an egg in the cell and closes it with a mud cap. No two species in this great group have exactly the same sequence of habits, but all are intelligent and complex.

Social Wasps.--Out of these groups have evolved the family-minded papermaking wasps and the bees and ants; the bees from sphecoid ancestry, the social wasps and ants from vespoid forebears. In these the queen lives to take care of the young.

Polistes of the Vespidae. The queen constructs an open comb with the hexagonal cells hanging down. The paper is made of soft wood chewed from fence rails or dead timber. Paper is a nonconductor of heat which, when the nest is filled with brood, holds the latter at a higher temperature than would a mud nest. The mother queen feeds her young on chewed insects and nectar. The first reared are stunted females who from then on help with nest duties. Later in the season, with the increasing household help of these worker females, the food improves in quantity and the females reared have the size and reproductivity of queens, the queens for the succeeding year's nests. In late summer the males appear, fertilize the young queens and die. The aueens hibernate, each to start a new nest in spring.

Vespa, the hornets and yellow jackets. The nest is paper, but is surrounded by two to four layers or walls of paper, with a small guarded entrance. Within are tier on tier of pendant paper comb. As the nest grows, an inner layer of wall is torn off, chewed up and plastered on the outside until the late summer nest will range in size from that of a grapefruit to that of a large pineapple, the great hanging nests of the bald-faced hornet. In such nests the temperature is raised by the insulation of the enclosing wall to above 90°. All living insects generate heat but are termed cold-blooded because they are so small the ratio of surface, which dissipates the heat, to volume which generates the heat, is too greatly in favour of surface dissipation. They remain at a temperature slightly above that of their surroundings. With insulation the Vespa nest retains body heat which speeds up all physiological processes pertaining to growth. At the end of the six months' season (each nest is an annual affair) a Vespa nest will contain a thousand or more offspring of the queen as compared with the few dozen individuals in an uninsulated Polistes nest.

Polistes and *Vespa.—Polistes* also lacks a highly evolved caste of workers. These are small sterile females, but with the instincts and behaviour of mothers. All Polistes and Vespa socii are females except for the males produced in late summer. In Polistes the first produced are small females, probably a matter of food shortage in the cooler spring months. They are probably too small to reproduce and are termed workers. In Vespa these are so small that they are workers in size as well as habits. All work to feed the late summer brood which produces large queens and males. Vespa has evolved into a caste system of society. At the end of summer the nest is abandoned.

The males produced in the fall are from unfertilized eggs. They mate with the summer's young queens and die with the first cold day, as in Polistes.

Bees.—The bees by structure have evolved from digger wasps of the superfamily Sphecoidea. These wasps with a few exceptions use mass provisioning of the young. Enough food, paralyzed insects, spiders, etc., is stored in the larval cell to feed the larva until maturity. The cell is sealed, and in many species the digger wasp female never sees her young. Some primitive bees are close to such conduct but as far as known the queen remains with the nest and she and the young queens use it jointly before the latter mate and scatter. All bees are anthophilous, i *e.*, live on pollen and nectar. The more primitive forms, *Allodape* of Africa, practise mass provisioning. In some species of *Allodape* all young are in one cavity, but each with its own ball of pollen. In later evolution a cell is made for each larva, but mass provisioning is practised in Xylocopa (carpenter bee), Cerattna (little carpenter bee), Megachila (leaf cutter), Prosopis, *Colletes*, etc. However, the mother queen usually remains in the nest until her offspring appear. These may help clean the nest out or may help to provision the later young before they mate and disperse. At this level there is no worker caste of nonreproducing females. These species of lower semisocial bees retain the ancestral wasp habit of mass provisioning but do not feed the young animal protein as do the wasps.

Social Bees.—The truly social bees comprise only a few genera, the best known of which are *Bombus* the bumblebee, *Apis* the honeybee and two tropical genera *Melipona* and *Trigona.*

Bumblebee.—With the bumblebee the nest is usually a one-season affair. The fertilized queen winters over by hibernation. In the spring she finds a mass of fibres, usually on the ground, which most often is a deserted mouse nest. Then follows a short period of two or three weeks when very few queen bumblebees are to be seen. The queen has hollowed out a cavity in the bed of fibre, has built a wax honey pot, filled it with honey and has built near it a mass of pollen wet with honey on which she lays her first batch of eggs. She builds over this a cover of wax secreted by glands on the ventral side of her abdomen. She then sits on this mass of pollen, wax and eggs, keeping it warm with her own body heat until the eggs hatch. The larvae eat their bed of pollen and honey, and more pollen and honey which is brought to them

by the queen. She feeds the larvae by injecting this liquid mixture of pollen and honey through the wax roof of the larval chamber. As the larvae grow larger, she feeds each one individually. On the 11th day after the eggs are laid, in one species carefully observed by F. W. L. Sladen, the larvae each spins a silken cocoon. These stand side by side like barrels on end; the queen keeps them warm by covering them with her body. She faces her honey pot from which she can sip from time to time. From these first cocoons emerge a half dozen or so minor workers, which then appear in the field where they gather honey and pollen for the succeeding brood. In late summer in most species, large virgin queens and males are produced. These mate at the end of the summer, the males die and the fertilized queens hibernate, each to establish its own nest the following spring.

The habits of the bumblebee form one of the most instructive items in the evolution of social life in insects.

1. The nest is an annual affair.

2. It starts in the spring as a family mother-nest with all the work in its early stages done by the mother.

3. Mass provisioning is employed, which is characteristic of the provisioning in the digger wasps and in the lower bee families.

4. It changes to progressive provisioning, with many daily contacts between the mother and the young during the lifetime of the first brood.

5. The early brood of the season are smaller than the later brood; probably do not reproduce, so that a caste system appears in its incipiency. With the co-operative help of the workers, the family becomes a society and the mother becomes the queen of the society.

6. A nest reproduces the next spring after the pattern of the reproduction of the nest in the digger wasps and primitive bees, by each over-wintering fertile queen starting her own nest.

Three other items appear which are not specific to the bumblebees. They are found in all social Hymenoptera:

7. Nearly the whole social structure is one of adults using adult behaviour, adult powers of locomotion, adult sense organs and adult social tools, the mouth parts and highly modified legs. The larvae are completely degenerate and have lost all direct contacts with the environment of the nest. In the larvae locomotion has disappeared, sense organs have degenerated to the mere appreciation of food placed before them, so that larval behaviour is reduced to a minimum. However, the contacts of the larvae with the environment are made not by the weak and degenerate mouth parts, and behaviour of larvae, but vicariously by the fully mature contactual organs of the adults, those of the mother and nurse workers. Thus, for all practical purposes, the larva from birth has contact with the environment through the mature organs and mature behaviour of the adult. This is one of the greatest steps forward in the evolution of insects. So longer does a larva have to face a hostile environment with its weak organs and undeveloped behaviour.

8. Up to the level of the bumblebee society, particularly in those forms where the mother does not at any time associate with her young, as in the fossorial (digger) wasps, the care of the mother for the young has been a complex instinctive behaviour. Nothing about the young has attracted the mother, as she does not actually contact them. W. C. Allee would ascribe an aggregating factor to the fossorial wasps and the lower bees which nest sometimes densely in restricted areas, a principle of co-operation exhibited particularly in the defense of the group of nests by any one or all the mothers. The slight co-operation shown in the semisocial bees, where the young queens help clean out the old nests, would be a similar aggregating factor; but with the introduction of progressive provisioning, as in mid-growth of the bumblebee larvae, there enters another aggregating factor, trophallaxis.

9. Trophallaxis is the exchange of foods between members in an insect society. (See W. M. Wheeler, Social Insects, chap. 9 [1928].) Presumably in the bumblebee and the older larvae of the honeybee, and throughout the ants, there are developed glandular secretions (usually connected with the salivary organs in the larvae), and perhaps a regurgitation of digested food, which secretions are delectable to the worker nurse so that when the latter feeds the larva the larva gives the worker a tasty bit of food in return—a personal secretion which operates as a reward for mother love. Trophallaxis is especially developed in the many other insects associated with ants, usually spoken of broadly as myrmecophiles. It appears also in the insects associated with the termites, where they are termed trematophiles. Many of these

have enormous development of various body glands which secrete delectable substances by which they pay for their room and board. Termites also regurgitate partially digested food to friends. Thus the basic behaviour on which such a society exists is extraordinarily complex, is almost wholly adult behaviour up to the evolution of trophallaxis, when even the larvae do something for the adults.

Honeybee.—The society of the honeybee differs from all other insect societies (with the suspected exception of some ants whose habits are imperfectly known) in that the family life of the mother queen starting her own nest and taking care of her first brood has completely disappeared. The honeybee nest reproduces a new colony by the forcing of the mother queen out of the home colony by a young, vigorous queen, her own daughter. The mother takes with her a numerous band of faithful workers. This process is called swarming. and apparently may occur several times in the life of one queen bee, which is several years. Thus we arrive at a society in its final stage of evolution. Family life, the care of the young by the mother, has completely disappeared. The mother queen is reduced to mere egg-laying. The whole complex is a co-operative society of workers and larvae completely and thoroughly social. Students (K. von Frisch) of the honeybee

assure us that the young bees go through a routine of education, and that the honeybees have a simple series of signals, "a bee language," by which scouts inform the hive of the discovery of new areas of nectar and other simple incidents in bee life. The young worker bee functions first as a hive nurse, then as a water gatherer, and finally as a honey and pollen gatherer. The only immature behaviour left is that of trophallaxis, which helps to hold the society together.

The Ants.—The great majority of ants have a social system somewhat similar to that of the bumblebee. The food in different

species is almost anything edible. They are the scavengers which pick up all dead insects for the bits of meat they contain. They collect nectar on flowers, but prefer to operate wholesale by gathering the enormous quantities of honeydew, the sweet diarrhoea of the Homoptera. Nests are usually perennial affairs which operate indefinitely with the same queen, some of which have Seen known to live 16 years. In nests with several queens, the life is indefinite until some major catastrophe wipes out the whole colony. In the temperate zones at some time during the warm period of the year, at a time usually specific to each species, males and queens are produced. These have wings, and swarm and mate. Each daughter a potential queen then, after mating, casts off her wings and hunts a suitable place for a nest. By her own mother etiorts she excavates a simple chamber in which she rears her first half dozen minor workers. During that period she lives largely by absorption of her own large wing muscles. She is supposed to lay extra eggs which she chews up and feeds her young. Up to this point she is merely a mother caring full time for her family. The minor workers, on maturity, are wingless, nonreproductive females which take over the further care of the nest and the gathering of food. At this point the mother usually ceases interest in her young and becomes a mere egg-laying female, a queen of a co-operative society fed and cared for by the workers. Many variants of this type occur among ants especially in predatory and parasitic species. New colonies are formed (1) by young queens and (2) by swarming of extra queens with a considerable group of workers. Such ants are *Formica exsectiodes, F. truncicola* and *F. rufa clivia*

The Problem of the Male.—In the protoplasmic organic world the male has developed in both plant and animal kingdoms. In the evolving protoplasmic mechanisms he integrates heterozygous populations and also helps in the production of new better adapted species. He is needed, but in animals at large is useful only once, at mating. In the animal scheme the two sexes appear to have about the same amount of chemical energy in the total lifetime. In the female it is used up in the production of eggs and, in social forms, in the care of the young. The male has an unused excess of energy in the Hymenoptera. He is the nervous fast caste of the ant society. The female possesses a seminal receptacle which, filled once, in mating. lasts during her lifetime. Evolution permits the male to retain his excessive activity, as it is needed to find and fertilize the slower female. Mother care of the young is not inherited by the male ant. After mating he would become an expensive nonpaying guest. Evolution gives him death. (In the termites the female is without a seminal receptacle and has to retain the male throughout life.) The problem of the male is a real one in the animal world. In most birds he inherits mother care of the young and helps in domestic affairs. He contributes as much toward the care of the young as does the female in most instances. In *Homo sapiens* he disposes of his excess energy in art, science, literature, horse racing and war. Evolution in the Hymenoptera lets him die. The ant world is a female mother-world.

Fully social bees are few compared with the ants, all of which are social and live in colonies which continue from year to year. The major differences between ants and bees are:

Ants and Bees.—Ants are generally omnivorous while bees use only pollen and nectar. With live brood in the nest which must be fed regularly and often, the social bees store honey and pollen. The ants store seeds *(Pheidole)* and a few (*Myrmecocystus, Prenolepis*) store honey in repletes, which are workers fed honey until the distended body renders them immobile. In periods of food shortage a worker contacts a replete and is given a meal regurgitated from the replete's honey crop. Because most ants are omnivorous, they can live in areas with few nectar-producing flowers. For sweets they use honeydew, the sweet diarrhoea of sap-sucking homopterous bugs which live in both grasslands and forests. The bees tend to be limited to flowering seasons, and to flowering areas.

Ants walk; even the queen walks after mating; bees fly. In walking, ants can gather food at night and in cool weather, because the slower walking muscles do not need the high temperatures to operate that are needed by high-speed wing muscles of bees.

Ants walk in moisture and low temperature, which is reflected in nursery moisture and temperature. Bees fly at higher temperatures, which is reflected in warm dry nurseries. Ants at little cost of excavation use any kind of a cavity for brood. Wasps and bees at great expense of time and energy build elaborate warm, dry combs. The ant expense comes with constantly carrying brood from one part of the nest to another to keep larvae and cocoons at optimum moisture and temperature levels. The ant nest is a slum in architectural design as compared with the regular combs of wasps and bees. The mediocre design of an ant nest is very plastic, adapted to every advantage or disadvantage in the nest medium, a reflection of the more plastic temperature and behaviour of the ant, who survives on the dangerous ground by his/her more plastic behaviour. Perhaps ants do not see well enough to be interested in regular design as in bee and wasp comb.

Ants walk, which keeps them constantly in the most dangerous of environments, the surface of the ground. This tends to weed out the stupid ones. Survival of the fittest in ants is toward the development of acute senses and a rich behaviour. This is reflected in the greatly varied modes of life found among ants and in the constantly varying care of the brood.

Slowing the speed of ants down to a walk has made them better nurses in that contacts between mother or nurse and the young have to come down to the slow level of the activity of the young. With ants all common nest activity is at the calm social level.

Walking, however, has acted as a minor handicap in that evolution has kept the ant legs slender and trim for walking. They do not evolve into pollen baskets, pollen combs and wax shears, the social tools available to the bees.

Life on the ground has minimized vision and emphasized smell as a sense. In ultimate analysis smell is more specific and a better ground sense than the poor mosaic vision conditioned by a hard exoskeleton. It operates as well in an intricate totally dark nest as out in the light.

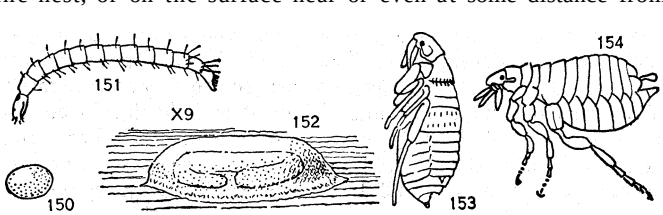
Determination of Castes.—In the higher Hymenoptera the male caste is determined by parthenogenesis, *i.e.*, he comes from an unfertilized egg. Queens and workers come from fertilized eggs and all are females. In the honeybee, queens are from fertilized eggs (as are the workers), but from such eggs placed in a large cell and from a larva given extra food which apiarists term royal jelly. In the honeybee, queens or workers which arise from the same type of egg differ in development because of full feeding with full development in the queen and more limited feeding with stunted stature in the worker caste.

No definite data has ever been advanced that castes in ants are produced in this manner. Finally Neal Weber, 1935, found a tropical ants' nest, *Cephalotes atratus quadridens,* with a mosaic caste in which one side of the body might be worker while the other side would be soldier. This evidence indicated trouble in the chromosomes, in the heredity mechanism. The conclusion was that in C. *atratus quadridens* the soldier caste was determined by the heredity mechanism. Wheeler, 1937, discusses this case with bibliography. *See* also S. F. Light, 1942–43, 1944, S. E. Flanders, 1944, and P. W. Whiting's 1941 review of Wheeler, 1937.

Population Limitations in the ants are mainly: (1) loss of life when the young queen goes abroad to establish a new nest; (2) loss of the whole colony by parasites, disease and the attack of predatory ants and other animals; (3) loss of the whole colony through minor climatic changes, drouth, cold winters and floods, also the growth of forest in new areas which shades out a nest that needs the warmth of the sun to mature brood and (4) the death of the queen in a one-queen nest.

Sanitation.—No great congeries of animals can live together without cleanliness of the habitation. Ants have evolved from parasitic forebears where the larva becomes an internal parasite. Such must not kill the host with poisonous faecal matter until the parasite has used the host as food, to the extent necessary. The larvae of the parasitic Hymenoptera (Ichneumonidae to Chalcidae) eat such pure food, the blood and viscera of the host, that little faecal matter is produced. The stomach is closed during larval life so that faecal matter can not pass into the intestine. At pupation the passage opens and the faecal matter is passed into the cocoon or it is retained as in the honeybee until the first flight from the hive.

Ants are very careful housekeepers. In an abandoned area of the nest, or on the surface near or even at some distance from



FIGS. 150-154

Siphonaptera, fleas. *Ctenocephalus felis*, cat flea: egg, larva which lives in organic dirt in floor cracks, the disk-shaped silk cocoon, pupa and imago which lives on mammals (from Howard and Marlatt)

the nest, they establish a garbage pile. All household refuse and the bodies of the dead are carried to this kitchen midden.

Domestic Animals.—Hundreds of species of insects have been described which apparently can not live except in ant colonies with the care given them by the ants. The relationship of guest to host is usually one of trophallaxis. The guest has some secretion delectable to the ant. The aphids or plant-lice (Homoptera) which pass sweet honeydew are oftenest met with.

In the forms of *Lasius niger,* the common yard ant, aphids are nursed on the roots of plants. In one species of aphid the ants collect the fall eggs of the aphid, store them in the nest piled like cannon balls in a fort, and when they hatch in the spring the young are placed on knot weed roots and later transferred to the more succulent corn roots where such are available. Many aphids that winter as adults and live on roots are wholly dependent on ant care especially in digging long tunnels that follow the roots and permit the exploitation of the aphids and the spread of the latter along the roots. Such ants are fully in *a* pastoral stage of social evolution.

Many small beetles live only in ant nests. Such give off secretions or odours "which ants appear to enjoy as a cat enjoys catnip" (W. M. Wheeler, *Ants,* 1913). Such are fed and otherwise cared for by the ants.

Slavery.—Slave-making ants, species of the *sanguinea* group of *Formica,* and of the genus *Polyergus* are among the common ants of Europe and North America. The sanguineas, as an army, raid a nest of *Formica fusca,* or in America a nest of either F. *fusca* or *pallide fulva,* carry home the larvae which are reared in the sanguinea nest, where they grow up as workers for the slavers. *Polyergus* has evolved into slavery to where mandibular teeth are lost. Slaves have to chew the masters' food and feed them. Many variants of this behaviour pattern occur between other ant species.

Harvesters.—Various ants, the cosmopolitan genus *Pheidole* and the American genus *Pogonomyrmex,* collect seeds usually of grasses, which are eaten and stored against nonharvest seasons. In *Pheidole* are giant-headed lady "soldiers" which hull the seeds rather than fight. In some species the soldier's head is larger than her entire body.

Farmers (Fungus Growers, Leaf Cutters).—In the Americas from Tennessee south to the tropics occur several related genera of the Myrmecine tribe Atti which cut leaves, carry these to their nests, where the leaves are chewed up and worked into subterranean fungus beds. The beds are started by the queen on founding the nest, who brings a mouthful of fungus from her home nest. The Atti live entirely on the fungus crop. The shape and style of the fungus beds is specific for each species.

Sewing with Silk.—The preceding examples of complex instinctive or rigid behaviour are outdone by nest building in the oriental genus *Oecophila,* which gets its name from its home of leaves, which are sewn together with silk thread. The sewing is a triple co-operation: (1) A group of workers line up along the edge of a leaf, hook their tarsal claws in the leaf on which they stand, reach across and with their mandibles pull the edge of a parallel leaf to the edge of the one occupied. (2) Another group goes into the brood chambers and collects a number of full grown larvae whose silk glands are gorged with liquid silk ready to spin cocoons for pupation. (3) The second group carry the larvae to the scene of the work, touch the mouth of each larva to the edge of one leaf then to the other. The silk sticks and dries while the first group holds the leaves. Co-operation is in each of two groups then between the two groups.

The Ant Patrol.—The ants, not numerous in species, patrol the insect world. Every square yard has from one to half dozen colonies with obscure openings overlooked by the human occupants. In the temperate and warm regions of the globe they daily patrol every square foot of soil that can produce vegetation, and carry home probably as much as 90% of all dead insects of the ground's surface and of the standing vegetation. Ants occupy the very peak of insect evolution. They patrol the world.

The Peak of Insect Social Evolution.—Both termites and ants have reached the level of farming which in each case is the cultivation of fungi. Certain wide-spread forms of *Formica sanguinea* live as slavers, perhaps a slightly higher social level, as they rear the young of other animals, those of the related forms of *Formica fusca,* into slavery. But the most wide-spread and commonest insect in the northern hemisphere from Yokohama to London, from New York to San Francisco is *Lasius niger* in its several forms and closely related species whose wide-spread success is based on its behaviour at a pastoral level. It rears and tends great herds of "ant cows" (aphids) for the sweet honeydew they produce. Some of its strains of aphid stock are unknown except in ant nests, except as cared for from egg to aphid old age. Such strains of "ant cattle" are completely domesticated. Such is the top level of insectean social evolution as gauged by

wide-spread success.

But the forms of *Lasius niger* and relatives have never been successfully monographed. They are so similar, so abundant and commonplace, so uninteresting in their cloudy colours, dirty yellows, browns and grays, that ant students pass them by for the obvious rarities. In appearance of mediocre size, of colour, of structure they are merely uninteresting drudges in smelly nests. The brilliant colours, the size and above all the dash and resourceful individualistic behaviour of their distant digger-wasp ancestors has disappeared. All are alike. 411 have sunk in evolution to mediocrity of appearance and behaviour. They work in gangs and succeed as gangsters. Thus in the highest level of insectean social evolution brilliant individualism has vanished. 'If'ide-spread mediocrity has supplanted it—a mediocrity that is successful in co-operative groups. Is this mediocrity the certain fate of protoplasm in its evolution as a steadily improved energy-transforming mechanism? Will the mediocre gang in the final social evolution of other animals eventually supplant brilliant individualism?

The Use of Tools.—The use of the silk-gorged larva as a shuttle or bobbin of silk by the workers of the ant *Oecophylla* (a near relative of *Lasius*) is the only known instance of the use of a separate tool by any ant worker. The other instance among insects is the pebble held in the mouth and used to hammer dirt into a plug to close the door of her burrow as used by the digger wasp *Ammophila,* a habit which recently has been questioned. The basic arthropod design of the foot, as well as the limitation to a minute brain, stops the evolution of the insect society at the threshold of the next great advance in social evolution, the use of detached and later the use of powered tools. The insect foot is closed by one tendon operated by one muscle located in the tibia above. As compared with the five-fingered hand of the mammal it is a defective single finger. The ant can not hold a tool firmly in its front foot.

Ants and many other animals use the mouth-parts as tools. Such are defective as tools in two ways: (1) The manipulator of the mouth tool is limited in range to the length of neck and head. (2) The mouth-parts are so close to the guiding binocular eyes that the distances are so short, and angles of vision are so narrow at the short distances from eye to tool, that the latter can not be precisely directed except at the zero angle of straight ahead.

In ants the range-finder eyes are structurally on the base of the tool itself. They can not in present basic arthropod design be detached from the mouth-part tool without a redesign of foot and mouth-parts. The basic arthropod design of limited minute brain and of tools tied directly to the guiding Binocular vision apparently forever stops the evolution of ant and other insectean societies at the slave-making and pastoral level of social evolution. The fossil ants perfectly preserved in the Baltic amber of 50,000,000 years ago are so nearly identical with present backyard species that experts assume they had then completed the evolution of the pattern of their present social behaviour.

Evolution in insects, however, is continuing at the present, as is shown in field work on the fruit flies by J. T. Patterson and students, by T. Dobzhansky and Warren Spencer; by A. E, Emerson in work on termites; by Richard Goldschmidt on *Lymantria;* and by the work in economic entomology where pests develop immunity to control measures.

BIBLIOGRAPHY.—Articles on insects appear each year in several hundred entomological and other biological journals. A thousand or more separate bulletins, books memcirs and popular treatises are published annually. The iollowing will open the various subjects indicated, and have comprehensive bibliographies.

General textbooks.— *G. H,* Carpenter, *Insects* (1924); W. H. Wellhouse, *How Insects Live* (1926); *D.* Sharp, "Insects," *Cambridge Natural History,* vols. V, vi (1895, 1898); L. F. PHYSIOLOGY

Insects are highly organized creatures; they are small in size and mainly terrestrial in habit, those insects which live in water being derived from terrestrial ancestors. They are therefore extremely subject to desiccation; and the success of the insects as a class in the colonization of almost every type of environment, including the hottest and driest portions of the earth's surface, is a result of the many ways in which their physiology is adapted for the conservation of water.

The Egg.—Most insects begin their development within an egg which is covered by a hard shell, the chorion, composed chiefly of a scleroprotein "chorionin." Eggs laid in exposed places are completely waterproof and can withstand exposure in the open for months without drying up. Eggs of other insects, such as locusts, which are laid in the earth, or of some which attach their eggs to leaves or insert them into the stems of plants, are able actively to absorb moisture from their surroundings. Many insects pass the winter in the egg stage. In these, embryonic development is arrested at a certain point and the organism goes into a state of dormancy or "diapause." It is often necessary, as in the silkworm, for the egg to be exposed to a low temperature before development is resumed. When it is fully developed, the young insect may chew its way out of the egg if it has biting mouth-parts, as in the caterpillar; or it may force off an egg cap or cut an opening in the shell by means of "hatching spines" of varying types. The young insect aids itself in this process by swallowing air and when it is free from the shell it distends itself with still more air so that the newly hatched insect is always much larger than the egg from which it has come.

The Integument. — The insect is covered by a "cuticle" which is laid down by a single layer of epidermal cells sometimes called the "hypodermis." The cuticle is a remarkable structure which plays a most important part in the physiology of the insect. It is at once flexible to allow movement of the parts, rigid to serve as a skeleton to which the muscles are attached, and waterproof to protect the insect from desiccation. Its best known constituent is "chitin." Chitin resembles the cellulose of plants, but instead of being composed of chains of glucose molecules it is made up of chains of acetyl-glucosamine residues. It is associated and perhaps chemically combined with protein; in this form it is colourless, tough and elastic, and composes the innermost layer or "endocuticle." In the outer parts of the rigid areas of the cuticle
