HYDROZOA *TO* JEREMY, EPISTLE OF

HYDROZOA. The Hydrozoa (sometimes called Hydromedusae) are a class of animals, the vast majority of which are marine, and which belong to the still greater assemblage known as the Coelenterata (*q.v.*). The Hydrozoa include not only polyps, but also medusae or jellyfish (these terms are defined in the article COELENTERATA). They are, in fact, that group of Coelenterata in which neither the one nor the other of these two forms of body predominates, and in this respect they contrast strongly with the other main classes (Scyphozoa and Anthozoa). Moreover, both polyp and medusa have a simpler plan of structure than in the other classes. The polyp itself is frequently (though not always) small. Its mouth leads directly into the internal cavity of its body (coelenteron), without the intermediary of a definite throat or gullet of any kind, and the ectoderm and endoderm (*see* COELENTERATA) meet at the lips. The coelenteron is a simple cavity lined by endoderm; it is not subdivided by partitions into lesser cavities, nor does it contain definite organs of any kind. With these limitations the actual form of the polyp varies very greatly. The medusa presents infinite variety of form, but it too lacks a throat, and although its coelenteron sends out radiating canals which run from the central cavity through the solid tissues of the bell, it is otherwise simple in that it contains no definite organs. The medusae of Hydrozoa are, generally speaking, smaller and more slightly built creatures than the medusae belonging to the related class, Scyphozoa, although in certain cases they attain a larger size than the average, which is a matter of millimetres. The Hydrozoa are also characterized by the fact that the sex cells, when they ripen in the clusters known as *gonads*, typically lie in or under the ectoderm. although the site of their original formation may be in either ectoderm or endoderm. It is among the Hydrozoa above all other Coelenterata that the phenomenon, briefly characterized elsewhere (article COELENTERATA), and known as *polymorphism*, attains its height. The details of this condition are described in parts of the present article and a summary of the question is given after the section on Siphonophora.

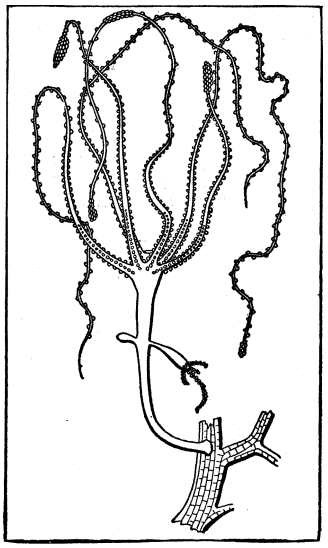
The infrequency of brackish or fresh-water forms among the Coelenterata makes their occurrence of interest. The ordinary marine Hydrozoa are either pelagic (swimming or floating organisms) or sedentary, according to their nature, and many of either kind exist. The brackish and fresh-water forms exhibit the same diversity, though few in number. One of the most interesting is a minute creature, *Protohydra*, the length of which is about 3 mm. This organism inhabits the surface layer of mud, rich in diatoms, which is to be found in the bottom of pools in certain tidal marshes: it also occurs in oyster beds and similar places. It is carnivorous, and reproduces freely by transverse fission. It possesses no tentacles, and is as simple in structure as any known Coelenterate.

The best known of the nonmarine Hydrozoa, however, are the genera *Limnocodium, Limnocnida, Cordylophora* and *Hydra*. Of *Hydra* more details are given below, and the chief interest of *Cordylophora* lies in the fact that it may flourish in water of different degrees of salinity as well as in fresh water; it is otherwise ordinary. *Limnocodium ryderi* possesses a feebly developed polyp generation (up to about 2 mm. long) which produces small colonies containing about 2–7 individual polyps without tentacles. These colonies can produce buds of two kinds; some become separated from the parent, form polyps and produce new colonies, others develop into medusae, and these are liberated and swim away. The species of *Limnocodium* (with which is now included *Microhydra*) are not very clearly recognized; but representatives of the genus occur in lakes, millstreams and similar places in the United States, Germany, China and Japan, and have appeared in water lily tanks at various botanic gardens, and in other tanks and aquaria. The genus *Limnocnida* contains medusae which have been found in several river systems in Africa and in some of the great lakes, as well as in India. The Hydrozoa comprise three large orders which from this point will be treated separately.

ORDER I. HYDROIDA

The Hydroida are, roughly, those Hydrozoa which possess a definite alternation of the polyp and the medusa in their life history, and in which one generation (the polyp) is sedentary and usually constructs a fixed colony, the other being free-swimming when fully developed. There are exceptions to this general statement, but they are not characteristic of the group as a whole. The variety of form and life history exhibited, however, is great The common and well-known but quite untypical fresh-water genus *Hydra* (fig. 1),

is the only thoroughly successful freshwater Coelenterate: *Hydra,* of one species or another, occurs in ponds and ditches and similar situations in many parts of the world. It consists of small isolated polyps, each with a pillar-like body and a limited number of tentacles. The length of the body is a matter of millimetres, and the tentacles in some species may be longer when stretched out than the body, although both they and the body can contract into rounded knobs. The *Hydra* attaches itself to stems and water-weeds, or floats beneath the surface film. It catches prey, often of a large size compared with its own bulk, in the manner characteristic of the Coelenterata (this is described in the article COELENTERATA) by stinging and then swallowing it. From the body of the *Hydra* there grow out buds, each of which acquires tentacles of its own and ultimately becomes separated from the parent; but no medusae whatever are produced, this being quite exceptional among the Hydroida. There are usually developed separately, on different parts of the body, ovaries and testes which give rise to the sex-cells. Whether this represents a degenerate condition, and there was once a medusa-stage in the life-cycle, or whether it is a primitively simple condition, cannot be determined.



FROM DELAGE AND HEROUARD, "ZOOLOGIE CONCRÈTE" (REINWALD) (COPR BONNAIRE)

FIG. 1.—FRESH-WATER POLYP (HYDRA), ENLARGED

The specimen is shown attached to a plant-stern. Its tentacles are well extended and it bears two buds on its side, one of which has acquired tentacles of its own

The few other simple genera which are known, such as *Protohydra,* may be related to *Hydra,* or may be primitive or degenerate forms of separate origin. With the above preliminary, the characteristics of the group as a whole, without reference to these special forms, may be considered.

Structure.— The following is a description of the structure of a typical Hydroid, provided by the genus *Obelia* (fig. 2). *Obelia* begins its life, after the embryonic stages which succeed fertilization of the egg have transpired, as a single polyp, possessing a number of simple tentacles in a circlet around the base of its conical *peristome* or *manubrium.* The polyp sends out roots which attach it to the surface of a stone, the frond of a sea-weed, or other suitable support, and grows a stalk which raises it somewhat in the water. From this stem a bud arises from which, although it is at first a mere knob, a new polyp is gradually developed. This process of growth proceeds in a definite and regular manner, until a small tree-like colony, from less than an inch to several inches in height, is formed; the branches are definitely arranged, and all bear polyps. If one of the colonies be examined in detail, it will be found that each of the polyps possesses, outside its body, a little transparent cup of relatively stiff, horny material, into which it can withdraw when alarmed; and that not only are the polyps connected with each other by a stem composed of soft tissues, but the cups also are connected by a horny layer, outside the soft stem, which stiffens and supports the latter. The cups are known as *hydrotkecae,* the soft stem as *coenosarc,* and the horny layer (including stem and cups) as the *perisarc.* The new polyps develop only from the tips of a branch of coenosarc, and not from one another; and in a well developed colony it will be seen that some additional branches have grown out, mostly in the lower part of the colony, each of them similar in structure to a developing polyp, and usually regarded as representing one. These branches (known as *blastostyles)* do not develop a mouth and tentacles; instead each produces a number of buds which gradually develop into small medusae, and which are known as *medusoid buds.* The blastostyle, like an ordinary polyp or *hydranth,* has a covering of perisarc known as a *gonotheca,* but this is at first imperforate. In due course it becomes open at the end, and the medusae separate off from the blastostyle and swim away into the sea, where, after a period of free life, they produce eggs and sperms which, after fertilization, develop into new polyps.

FIG. 2.—OBELIA (ENLARGED) SHOWING PART OF A COLONY OF THE POLYP GENERATION AND ALSO A MEDUSA. THE COLONY BEARS BOTH ORDINARY POLYPS AND BLASTOSTYLES, THE LATTER PRODUCING MEDUSOID BUDS

The structure of one of these fully developed medusae must now be considered in more detail (fig. 3). The body has the form of an umbrella, with a manubrium similar to that of a polyp hanging down inside it and bearing the mouth at its end. The manubrium is lined by endoderm, and contains a cavity, the main part of the coelenteron. The substance of the umbrella consists of mesogloea with ectoderm on both external surfaces; but the layer of mesogloea is penetrated. by four narrow tubes or canals. lined by endoderm, which run out from the base of the manubrium like the four arms of a cross. Connecting these *radial canals* with each other is a flat sheet of endoderm like a web *(endoderm lamella)* and also a *circular canal* which runs round the edge of the umbrella close to the bases of the tentacles. The latter are solid, both in medusa and polyp. At the edge of the bell, on the inner side of the ring of tentacles, is a little circular shelf (the *velum*) which projects inwards and slightly narrows the opening of the bell. Round the margin of the bell, at the bases of certain of the tentacles, lie the sense organs, minute sacs, formed by the ectoderm, and each containing a calcareous particle (the *statolith).* They are known as *sfatocysts* (fig. 5), and are eight in number, two being definitely placed in each of the quadrants between the radial canals; they probably initiate and control the swimming-contractions of the bell. The sex-cells of the medusa ripen in the ectoderm of four gonads which occur on the course of the four canals, and which, when ripe, shed their products into the sea. The fertilized eggs develop into new polyps

HYDROIDS AND HYDROID CORAL

1. *Aglaophenia,* showing featherlike form of the colonies which bear the minute polyps along the side branches
2. *Millepora, a* hydroid coral, bearing the polyps in minute tubular pits in the hard calcareous skeleton
3. Colonies of ***Pennaria,*** showing polyps borne on small lateral branches
4. Colonies of ***Obelia,*** showing complex tree-like branching

which initiate fresh colonies.

The story of *Obelia* is typical of the Hydroida, with modifications of one kind and another. In some cases the polyp-generation includes a single nutritive individual only, but usually it forms a colony. The form of the individual polyps and medusae, as also that of the colony, undergoes great modification however.

The polyps sometimes possess cups of perisarc as does *Obelia;* but often they are without these. Their tentacles are sometimes simple, sometimes knobbed at the tip or branched; sometimes arranged in one circlet, sometimes in two (one round the lip, one at the base of a conical manubrium), in other cases arranged irregularly over part or most of the surface of the polyp.

FIG. 4.—MEDUSA OF CLADONEMA (ENLARGED)

This is an example of a jellyfish with branched tentacles. The gonads here form swellings on the manubrium; and the medusa adheres to surfaces through knobs on the basal branches of its tentacles

The medusae vary even more than the polyps, both in shape and structure, and some idea of the diversity which occurs among them may be gained by reference to figs. 2–4 and 7–8. The shape of the bell may be shallow or almost flat, or on the other hand may be a high dome, and naturally varies with the movements of the animal. The number, arrangement and structure of the tentacles is widely various. The living medusae are some of the most beautiful of marine creatures. Their transparency, which is often touched with definite colour in given parts, and the regularity of their structure are responsible for this, and in some cases their movements also are extremely graceful. The sense organs vary from one kind of medusa to another. Statocysts are present in a number of cases, and these exhibit varying degrees of complexity of structure, with this in common to all of them—that the epithelium of the statolithic sac or pit (for the simplest of statocysts consist of an open pit) is derived from the ectoderm, and no endoderm takes part in its formation. Many medusae possess sense-organs of another nature, known as *ocelli,* and these are sensitive to light. In their simplest condition they consist of a clump of sensory cells mingled with pigment cells; but the more complicated ones possess a definite lens. These ocelli may be situated close to statocysts, but many medusae possess ocelli only, and others statocysts only. Another important variation in structure is, that in some medusae, as in *Obelia,* the gonads are situated on the radial canals; but in many others the sex-cells ripen instead on the manubrium.

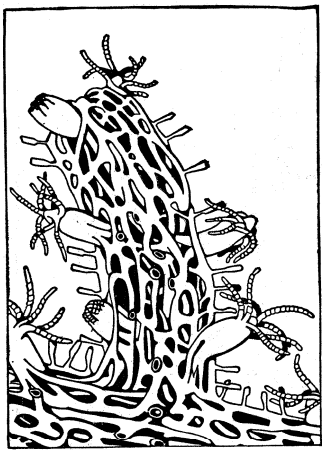
Colonies.—The next consideration must be that of the kinds of colonies which Hydroids construct. These colonies are frequently small and relatively soft, the horny perisarc giving a considerable amount of support, but not constituting a really rigid skeleton. Many such colonies are an inch or less in height, although colonies several inches long are common. Only rarely does the colony become actually large, but in a few cases it achieves a size and solidity which give it rank with the reef-forming corals; in these cases the skeleton is massive and calcareous, and is in fact "coral."

Hydroid colonies are roughly speaking of two kinds—mat-like and tree-like structures. The mat-like forms consist of a network of rootlets, attached to a stone, sea-weed or other support, from the upper surface of which arise the polyps. The network is sometimes straggling, sometimes compact, and may form *a* continuous sheet.- The tree-like forms are mostly delicate feathery structures, resembling rather the fronds of a finely divided sea-weed than any animal. The general aspect of some of them is shown in the accompanying Plate. The size of the whole colony, the exact way in which it branches, and the way in which one polyp after another is added upon a branch, affect the general appearance of the ultimate result. Sometimes the branches themselves are thick and are composed of a dense network of branching rootlets *(Clathrozoon,* fig. 6), the polyps projecting at the surface. This condition, which is achieved in a manner different from that which produces the average tree-like colony, leads on to the state of affairs found in the massive, limy colonies.

These massive forms deserve special mention. They have been considered in time past as a separate group of Hydrozoa, the *Hydrocorallina;* but it has become evident that they may be simply Hydroids with a more than usually solid skeleton, and that some of them are probably related to one series of Hydroid ancestors, others to a different series. A good example of these creatures is found in *Millepora.* This animal constructs a colony containing innumerable minute individual polyps, which are connected with each other by a continuous surface-sheet of ectoderm and by a network of ramifying tubular rootlets. The colony secretes a massive, limy skeleton which may become a foot or more in height, and which, though varying in form in different species, is often branched somewhat like the antlers of a stag, but in more compact fashion. The polyps inhabit little pits in the surface of the skeleton, and can retire into these completely when alarmed. The network of rootlets is lodged in a network of canals in the surface layers of the skeleton, the deeper parts consisting of coral only and containing no soft parts; this internal portion was secreted by the soft parts originally, but as growth proceeded and further skeleton was formed, these retired to the surface-layers. One can imagine that a similar state of affairs would be produced if a colony such as that of *Clathrozoon* were to secrete limy material into the meshes between its network of rootlets. *Millepora* is extraordinarily interesting in one respect. When the time comes for sexual medusae to be produced by the colony, these are not formed from buds as in *Obelia* and other Hydroids. Instead the sex-cells, which are migratory, move from the rootlets into one or other of the polyps. Each polyp so affected loses under their influence its characteristic structure, and becomes transformed by degrees into a medusa. The pit surrounding it enlarges and becomes closed in, so that it forms a cavity cut off from the outer world, and until the medusa is ready to escape it remains so; finally the cavity opens again and the medusa comes out. It is a weak swimmer and cannot feed; it swims a very little distance before shedding its ripe eggs or spermatozoa, the union of which gives rise to a polyp so that the life-cycle begins once more.



FROM KUKENTHAL, "HANDBUCH DER ZOOLOGIE" (DE GRUYTER)

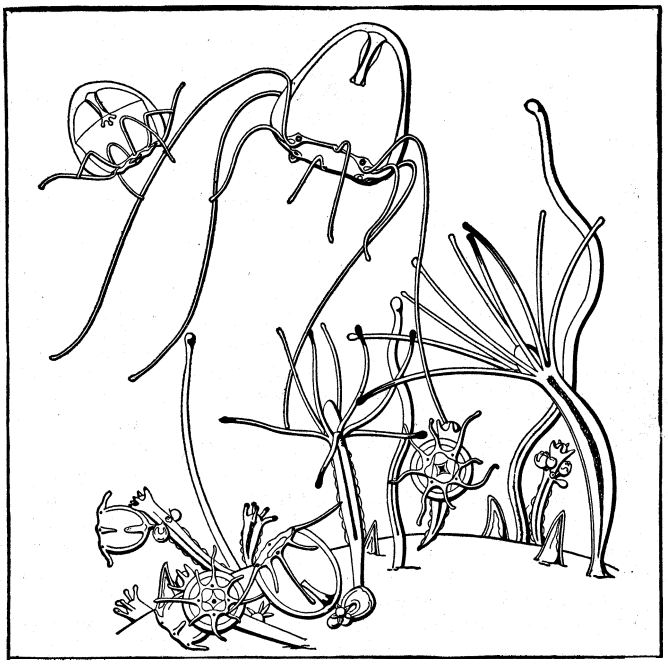
FIG. 6.—**PART OF A** COLONY OF **CLATHROZOON**

Diversities Exhibited by the Polyps and Medusae.—We may now pass on to some of the interesting diversities which the polyps and medusae exhibit. To begin with, in certain colonies, such as those of *Millepora* and *Hydractinia* (fig. 7), the hydranths are not all alike. Some of them *(gastrozooids)* possess mouths as well as tentacles, and inside these polyps digestion of food takes place. Other polyps on the contrary possess no mouths, but may have tentacles and are well provided with stinging capsules such as are described in the article COELENTERATA. These polyps themselves cannot feed, but they play a defensive part in the colony and assist the others in the capture and paralysing of food; they are known as *dactylozooids.* This is

a simple example of the phenomenon of polymorphism, which has been previously mentioned and which will be further discussed later. It is carried to greater lengths in *Hydractinia* than in *Millepora,* since in this case the colony produces also *blastostyles* similar in principle to those of *Obelia.* These may be regarded as modified polyps with a body but without mouth or tentacles, which produce sexual buds. Therefore a Hydractinia colony possesses four kinds of individuals — gastrozooids, dactylozooids, blastostyles and sexual buds.

To turn to the medusae, we find here a most curious state of affairs. To begin with, medusae may arise from blastostyles or direct from ordinary polyps; and the blastostyles may arise from the root or stem of a colony or from a polyp itself. Moreover, a medusa may itself bud off others from its manubrium, or from its tentacle-bases or other parts. The most remarkable fact connected with the medusae, however, is that despite the fact that a medusa is obviously an advantageous development, in that it can swim away and spread the eggs and spermatozoa over an area vastly wider than they could otherwise reach, there is yet a strong tendency among the Hydroida toward a condition in which the medusa not only remains permanently attached to the colony whence it sprang, but also becomes much reduced and simplified in structure. A series of medusae can be traced, in which at one end there is found the fully formed free-swimming jellyfish, at the other end a degenerate sac-like structure, devoid of any medusa-like features, and resembling the gonad of an active medusa, such as that of *Obelia.* This degenerate formation, which remains attached to the colony, is known as a *sporosac,* and consists of a layer of ectoderm containing or covering the sex-cells, and surrounding an endodermal core. Between these two extremes all intermediate stages may be found.

It has been considered by some authors that the sporosacs represent, not a reduced but a primitive condition, and that the other stages are to be regarded as developments leading up to the fully formed medusa. This would seem reasonable from the



FROM KUKENTHAL, "HANDBUCH DER ZOOLOGIE" (DE GRUYTER)

FIG. 7.—PART OF A COLONY OF HYDRACTINIA (ENLARGED), SHOWING GASTROZOOIDS, DACTYLOZOOIDS, BLASTOSTYLES AND MEDUSOID BUDS, AS WELL AS FREE MEDUSAE

point of view that the roving medusa is 'an obvious gain to a fixed colony; but the facts of the case do not seem to support it. From the structure and mode of occurrence of the various grades of medusae, and from the fact that in the development of certain of the reduced forms, medusoid features appear for a time and are subsequently lost, it is judged that they are not primitive but degenerate. The precocious development of the sex-cells may be the factor which leads to the reduction of the medusae; the gain being increased fertility.

The Coelenterata are singularly free from parasitic members. Of the few that are known, one is particularly interesting. This is *Hydrichthys boycei,* a species referred to the Hydroida but which may be an unusual siphonophore. The colony is one of the mat-like kind, and the mat, instead of being affixed to a stone or weed,

FIG. 8.— STAGES IN THE DEVELOPMENT OF A TRACHYLINE (MUCH ENLARGED)

The figures show the direct transformation of a polyp-like larva, with a long proboscis, into a medusa

is attached to the fins or body of a fish. The underside of it sends roots into the integuments of the fish, and under its growing edge are cells which are able to destroy the surface of the fish's skin and expose the vascular layer beneath. The polyps, which have no tentacles, bend down over the edge of the mat, apply their mouths to the wound made by the latter, and obtain blood from the vessels of the fish. Another parasite, better known than *Hydrichthys,* is *Polypodium;* this is parasitic at one stage of its life in the eggs of a sturgeon, which it destroys.

Classification. — The classification of the Hydroida is instructive, though as yet imperfect. 'The connection between medusae and polyps was at first not understood by naturalists, since it could not be deduced from observation of one of these types only, without a study of the whole life history. Even now there are polyps and medusae which have not yet been linked on to their corresponding alternative form. Consequently a double classification has grown up, dealing with the two sets independently, and the two systems can be correlated with each other so far as the inter-connections are known.

The polyps are divided into: —

1. Gymnoblastea. Here the polyps are not enclosed in cups of perisarc (hydrothecae), nor are the blastostyles enclosed in gonothecae.
2. Calyptoblastea. Here the polyps possess hydrothecae and the blastostyles gonothecae.

The medusae are classified as follows: —

1. Anthomedusae. Medusae in which there are no statocysts (though there are usually ocelli) and in which the gonads develop on the manubrium. These are the medusae belonging to the Gymnoblastic polyp-generation.
2. Leptomedusae. Medusae in which there are typically statocysts and sometimes ocelli, and in which the gonads are arranged on the radial canals. These medusae belong to the Calyptoblastic polyp-generation.

In the above scheme *Hydra* and its relatives would be considered Gyrnnoblasts by some authors, by others they would be placed in an independent group, the *Hydrida.*

ORDER II. TRACHYLINA

The Trachylina are an assemblage of Hydrozoa which differ sufficiently from any of the Hydroida or Siphonophora to warrant their inclusion in a separate group.

Among the Trachylina the medusa is the dominant form, and many reach a considerable size (*e.g.*, 10 x 3cm.). In accordance with this fact the Trachylina are mostly oceanic forms, pelagic throughout life; whilst the Hydroida are tethered, so far as their polyp-generation is concerned, to the bottom or to sea-weed, and include many characteristic shore-forms. The cleavage of the fertilized egg of the Trachylina typically produces a planula (see COELENTERATA), which develops into a more or less distinctly polyp-like larva; the latter is transformed directly into a medusa (fig. 8). In certain forms (Cuninidae) the polyp-larva is parasitic within medusae of its own or other kinds. In such cases it reproduces by budding, and both the parent and daughter polyps become transformed into medusae; or, the larva may form a stolon from which medusae are budded.

Beyond the facts thus outlined the Trachylina contribute little of general interest to the study of the Coelenterata, although their structure and life-histories are in themselves extremely interesting. For this reason they are dealt with very briefly here, and the only part of their structure calling for further mention is that of the sense organs. Ocelli (eye-spots) are rare amongst them, but all possess organs containing statoliths. These are of a different grade from those of the Hydroida, in that they exhibit the structure, not of ectodermal pits or sacs containing statoliths, but of small tentacles containing an endodermal core in which lie one or more statoliths, and covered by ectoderm. These modified tentacles are known as tentaculocysts (fig. g), and they may, like tentacles, project freely at the surface, or may themselves become embedded in a pit or sac formed by the surrounding tissues.

ORDER III. SIPHONOPHORA

The Siphonophora constitute one of the most interesting groups of the animal kingdom, since they illustrate the lengths to which an organism may go in the direction of stringing together a number of different kinds of individuals in a single chain. In scientific terminology they exhibit at its height the phenomenon of polymorphism.

The Siphonophora, unlike the Hydroida, are essentially pelagic animals: they are exclusively marine, and most characteristic of warm seas. They one and all form colonies, but the colony is unattached and either floats or swims. It produces sexual medusae comparable to those of a hydroid, and these may or may not be set free from the colony; consequently there may be an alternation of generations, both pelagic, or the medusa-generation may never gain independent existence. There is however this difference from the state of affairs among the Hydroida, that a medusa which is set free as such is an exception, and that it has never the full structure of a Hydroid medusa, possessing no mouth or sense-organs. Most siphonophore medusae remain attached to the colony or to a segment of it, and many of them exhibit grades of reduction in structure. These are known as gonophores, but they are never as degenerate as a Hydroid sporosac. From the eggs produced by the medusae or gonophores a planula larva of a curious type develops, and this by budding produces a colony. The siphonophore contrasts with a trachyline in that it is here the colony, and not the sexual medusa, which is the dominant form; and in addition to this a new factor is introduced which is not found either in the Trachylina or in the Hydroida. This is the production by the colony not only of more than one kind of polyp (as in *Hydractinia*) but also of more than one kind of medusa. In addition to the sexual medusae corresponding to the sole medusa-form in the other groups, there are found here medusae of modified structure which neither feed nor produce gonads, but which act as swimming-bells for the whole colony; and other structures which are also probably modified medusae. Of these latter one is a medusa transformed into a gas-containing float.

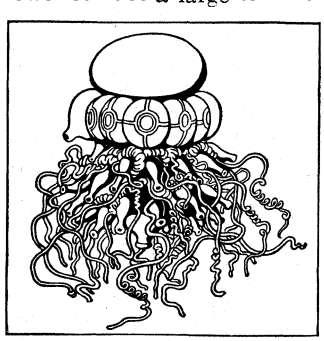
Structure of Colonies. — It will be impossible to understand or to visualize the siphonophore organization, without first con-

sidering the structure of several typical colonies; these are so diverse in constitution that a general statement at the present stage would be unprofitable.

The first colony to be described will be that of *Halistemma* (figs. 10 and 11). At the upper end of this lies a small float, and depending from it a long thin string which is tubular and contractile. This is the *coenosarc* and corresponds to the stalk of an *Obelia.* Arranged on the string just below the float are a number of swimming-bells; each of these is a medusa attached to the coenosarc by a short stem arising from the outer side of its bell, and possessing radial canals and a velum but no manubrium or mouth. At intervals along the coenosarc are found little knots or clusters of individuals. These are not all alike, larger and smaller ones alternating regularly. Each cluster *(cormidium)* contains a certain number of individuals, but not the same selection in each case. The types of individuals comprised in the whole series are leaf-like protective structures, the *bracts,* together with digestive polyps *(gastrozooids)* each with a mouth and with a single tentacle which is attached to it at the base; other polyps *(dactylozooids)* with no mouths, each with a single tentacle at its base, which act as feelers and stingers; and lastly *blastostyles* upon which male and female gonophores are produced. The tentacles of the gastrozooids, which act as fishing-lines, are branched, the branches bearing terminal stinging-batteries; those of the dactyloeooids are unbranched

A type of colony similar in principle to that of *Halistemma* is formed by *Physophora.* Here we begin as before with a small float bearing a tubular string of coenosarc with swimming-bells. But below these bells, the rest of the coenosarc, instead of forming a long string, is short and compact, with the result that all the other individuals of the colony (which include dactylozooids, gastrozooids and blastostyles) are concentrated into a group with the dactylozooids forming a protective circlet round the outside. The same principle is further exemplified in a still more modified degree by *Stephalia* (fig. 12), in which the same essentials are present but the proportions and shapes of all the parts have changed. In this case the float is large and prominent and it opens to the exterior through a special spout-like structure (*aurophore*) at one side. The swimming-bells are restricted to a single circle below the float, instead of being strung out as in *Halistemma* and *Physophora,* and the coenosarc bearing the cormidia is neither the long string of the former nor the insignificant vesicle to which it is reduced in the latter, but is a bulky mass bearing in the middle of its lower surface a large terminal gastrozooid, and supporting the cormidia on its sides. This mass is penetrated by a number of tubes lined by endoderm, which run into each other and communicate with the digestive cavities of the gastrozooids.

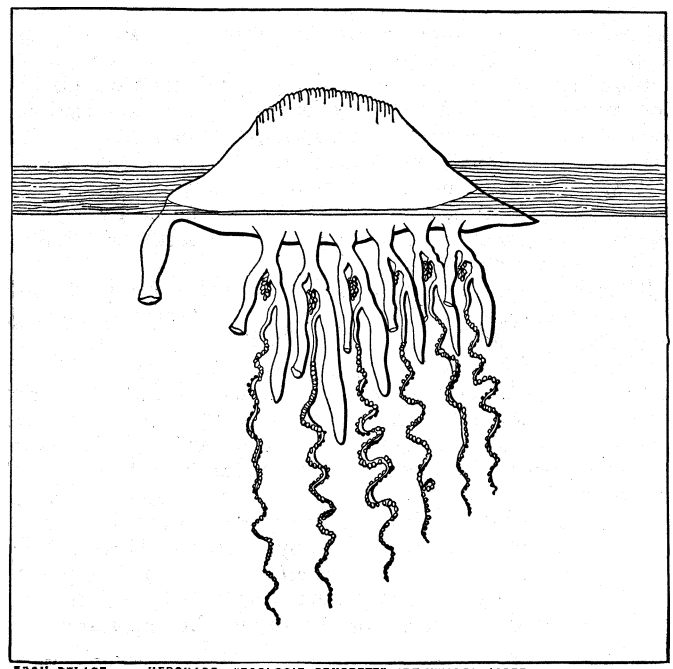


FROM E. RAY LANKESTER, "TREATISE ON ZOOLOGY," BY PERMISSION A & C BLACK

FIG. 12.—COLONY OF STEPHALIA
The swimming-bells are restricted to a single circle and not strung out as in *Halistemma* and *Physophora*

From *Stephalia* to *Physalia* (fig. 13) is a natural transition. Here there are no longer any swimming-bells, but there is a large crested float opening to the outside by a pore, and bearing a gastrozooid at one end. In a young *Physalia* the underside of the float bears directly half a dozen cormidia, each containing a gastrozooid without a tentacle, a dactylozooid with a long unbranched fishing-line, and a branching blastostyle bearing small dactylozooids upon it, and also male and female gonophores. As the colony increases in size new individuals are added somewhat irregularly upon the stalks of the old, and the simple early arrangement is lost. The colours of *Physalia* (blue, orange, etc.) are of great brilliance, and it is a well-known denizen of the Atlantic, Pacific and Indian Oceans, often occurring in fleets, and commonly known as "Portuguese Man-of-War." One of its fishing-lines reaches a greater length than all the others, attaining more than a yard; and the stinging powers of these lines are extremely powerful, producing serious conditions after contact with them even in man. The colony is not bound to float at the surface; it can deflate the float and sink, reforming the gas within it and so rising once more, within a quarter of an hour.

A colony quite unlike any so far described is formed by *Velella.* Here the whole organism has the aspect at first sight of a single flat medusa bearing a sail on its upper side and tentacles round its margin (fig. 14). On closer examination it is found, however, that the apparent tentacles are really a circle of long dactylozooids, and that the underside of the disc-like colony is covered by a number of curious blastostyles which, unlike an average blastostyle, possess mouths. In the centre of these is a single large gastrozooid, the only one which the colony possesses. The disc-like portion of the animal to which all these polyps are attached is complex in structure. It is thick and contains below the skin-layers of its upper side an internal horny float, below which is a mass of soft tissue, a concentrated coenosarc. The float is itself flattened in shape, is subdivided into chambers, bears a vertical extension in the centre stiffening the "sail," and is prolonged into the soft tissues as fine *air-tubes.* The coenosarc contains a ramifying system of endodermal tubules, in communication with the cavities of the various polyps, which is probably both absorptive and excretory in function. The coenosarc also contains a massive concentration of nematocysts, doubtless a nursery whence they migrate when sufficiently developed into the parts where they can function. Very similar to *Velella* but without a sail, is *Porpita.* In these creatures we have reached a stage in which the colony has become so compact and the parts so markedly subordinated to the whole that their interrelation resembles rather that of organs than that of independent beings; but free medusae are liberated by the colony.



FROM DELAGE AND HEROUARD, "ZOOLOGIE CONCRETE" (REINWALD) (COPR BONNAIRE)

FIG. 13.— DIAGRAM OF A YOUNG COLONY OF PHYSALIA
From the crested float depend several cormidia. At the left end of the colony is a single large gastrozooid

Finally it may be mentioned that there are a number of siphonophore colonies which differ from any so far mentioned in that they possess swimming-bells but no float.

We may now summarize the state of affairs in this very curious group of animals. In the course of the above descriptions mention has been made of a number of structures — gastrozooids, blastostyles, dactylozooids; swimming-bells, floats, bracts; and sexual medusae (fig. 11). It remains to comment on the status of these various entities. Continuing the view which is taken throughout the articles on Coelenterata in this Encyclopædia, most or all of these structures represent individuals, modifications

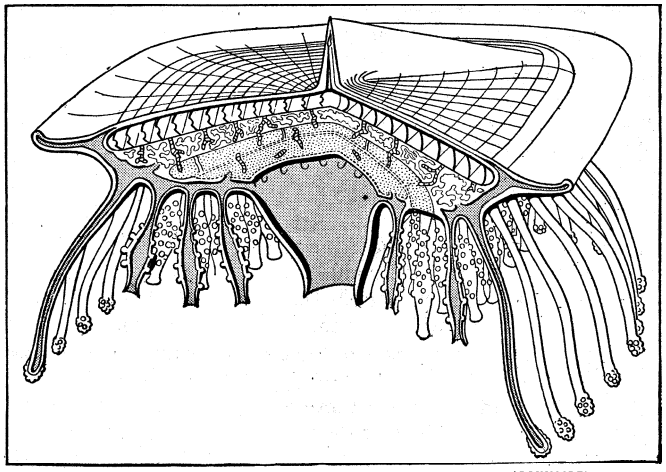
of either the polyp or the medusa form of body, or independently developed entities of equivalent standing. The gastrozooids and dactylozooids are varieties of polyp, the sexual medusae, the swimming-bells and probably the bracts are modifications of medusae. The float is sometimes regarded as the invaginated upper end of the stem of coenosarc and sometimes as a modification of a medusa. The status of the blastostyles is uncertain; they represent polyps in *I'elella,* in other cases they are perhaps the present day substitute for bygone polyps.

It should be mentioned in conclusion that the Siphonophore is regarded by Moser not as a colony of individuals but as an individual animal with division of labour between organs and "on the way to alternation of generations and to colony-formation"; and that the medusae of *Velella* are regarded by this author as free-swimming gonophores leading up to true sexual medusae. The work of Moser has thrown considerable light on the morphology and the development of the Siphonophora and has made clearer than formerly the homologies of parts throughout the group, especially that of the float, which may fairly be regarded as equivalent to the apical adult bell of the forms with no float. This work also forms a valuable contribution to the question of evolution within the Siphonophora, but in the view of the present writer it hardly establishes the claim that a siphonophore is an individual animal *(see* also the following section on Polymorphism).

POLYMORPHISM

In the articles COELENTERATA and ANTHOZOA, and in the accounts of the groups of Hydrozoa already dealt with in the present article, references will be found to the phenomena known as *polymorphism* and *alternation of generations (metagenesis).* Since these phenomena are aspects of one and the same thing and are of general interest and importance, a summary of the subject is indicated. In the following remarks it is taken for granted that the articles above mentioned are familiar to the reader.

Firstly it must be made clear that alternation of generations as found in *Obelia* is simply an example of polymorphism, which may be defined as the ability of a single species of animal to exist



FROM PELAGE AND HEROUARD, "ZOOLOGIE CONCRETE" (REINWALD) (BONNAIRE)

FIG. 14.— DIAGRAM ILLUSTRATING THE STRUCTURE OF VELELLA

A sector of the disc-shaped coenosarc has been cut away so as to reveal the internal structure

under more than one form—in this instance as polyp and medusa. In a clear-cut case of alternation of generations one of these forms is sexual and *succeeds* the alternative non-sexual form, the two co-existing on a single colony only for the period during which the medusae are developing from buds. It may be noted that some writers no longer regard the polyp and medusa as alternate ('generations," but the polyp as a persistent larva and the medusa as the adult. This view has its difficulties, however, and for purposes of the present argument the older terminology is retained. In any case the polyp phase is very persistent and has the general status of an adult organism.

The other type of polymorphism is that which is exhibited by such colonies as *Hydractinia* and in far higher degree by the Siphonophora, and in which there is not only the distinction of individuals into sexual and nonsexual forms, but the nonsexual polyps are themselves divided into kinds (gastrozooids, dactylozooids, etc.). This is exemplified even in *Obelia* by the distinction of the polyps into hydranths and blastostyles. In the Siphonophora there is the additional development that here there exist nonsexual as well as sexual medusae, and probably more than one kind of these (swimming bells, bracts and float).

In other words there exists: *(a)* a differentiation into sexual and nonsexual forms and *(b)* a division of labour between the nonsexual forms by virtue of which they become, for practical purposes, reduced to the condition of organs.

It must be noted, however, that the sexual forms tend to lose their independence; and the separate free-swimming generation so obvious in *Obelia* and similar forms becomes at the other end of the series a degenerate sporosac attached to the colony as permanently as any nonsexual individual. In fact it has become a sex-organ or gonad, and "alternation of generations" has been transformed into "division of labour."

Interesting divergences from the ordinary kinds of polymorphism typical of the Hydroida and Siphonophora are found among the Trachylina, Scyphozoa and in forms such as *Millepora.* In *Millepora* a polyp, be it a gastrozooid or a dactylozooid, becomes directly transformed under the influence of the immigrating sex cells into a medusa, instead of the medusa being formed from an independent bud. The polyp is a changeling. In the Trachylina the same process takes place, but in this case it is a pelagic or parasitic larval polyp which turns into a jellyfish, not an adult member of a colony. Among the Scyphozoa a unique condition exists; here the alternation of generations is very marked, and the medusa arises from the polyp direct; but in this case the polyp divides itself transversely into a series of superimposed saucer-like sections, which separate from it one by one, each becoming a medusa. A single polyp has therefore produced not one but several medusae. This is partly paralleled by a blastostyle; for if the latter be a polyp, it produces by *budding,* several medusae; but the scyphozoan polyp achieves the same end quite differently.

The Anthozoa are the least interesting of the Coelenterata from the point of view of polymorphism. They possess no medusoid form and among their polyps little polymorphic variation in form occurs. In, certain colonial forms ordinary polyps and siphonozooids co-exist, and there is also a distinction in some colonies between an original axial polyp and those subsequently formed. In the coral *Fungia* part of the life cycle in some respects resembles the strobilization of the Scyphozoa.

Polymorphism is chiefly interesting as an example of the extraordinary ability of animals to produce an almost infinite number of variations upon a given theme. It has also been much employed as a subject for argument, however. The argument frequently adopted has been that a siphonophore or a compound Hydroid is a *colony* and that its parts represent, morphologically speaking, *individuals* connected by a common intermediate tissue. the coenosarc. This view may appear to be far-fetched when one contemplates a sporosac, which is in effect a gonad, since it involves the claim that this structure represents not an organ but an animal. It is also true that in some cases, such as those of meandrine corals, it is difficult to decide whether a polyp with a dozen mouths represents one polyp or twelve. But taking the whole story, as presented to us throughout the Coelenterate series, as a unity, the interpretation of the systems encountered as colonies of individuals appears to be the soundest working hypothesis. The alternative view, that everything which results from the development of a single egg is an individual animal, however much it may subdivide asexually, and that gastrozooids, bracts and the rest are nothing more than the organs of this animal, seems relatively satisfactory when applied to such a form as the adult *I'elella.* But when one applies it to a free-swimming medusa it becomes reduced to an absurdity—is a jellyfish, an organism provided with mouth and stomach, canals, velum, tentacles and sense organs. simply a moving *organ* and not an animal at all? Further one may meet on many shores hosts of sea anemones. none of which have developed from eggs—each is an independent organism. not

part of a colony, and each has been produced asexually by fission. Are these anemones then "organs"? To reduce the term "organ" to such a level is to remove its actual meaning. Moser combines the two theories by regarding the Coelenterata other than Siphonophora as colonies of individuals, but the Siphonophora themselves as relatively primitive organisms, individuals comprising organs and the forerunners of true colonies.

In this connection it should however be noted that in the above paragraphs the term "individual" has been used in a purely morphological sense—*i.e.*, the individuals of a Siphonophore represent morphological individuals which have suffered a loss of independence similar to that of the component cells of any multicellular animal, which latter may be regarded as having been derived originally from a colony of individual single-celled animals (protozoa). In a physiological sense on the other hand the Siphonophore colony is a unity and may be regarded as an individual system. The status of such a system in relation to the wide general question of individuality is discussed in INDIVIDUALITY, BIOLOGICAL.

HYENA, the name applied to members of the family Hyaenidae, a group of Carnivora (see CARNIVORE) distinguished by the four toes on each foot, the comparative length of the forelegs, the nonretractile claws, and the enormous strength of the jaws and teeth, enabling them to crush hard bones. Three species are known; two belong to the genus Hyaena, while the other is Crocuta.

The striped hyena (H. striata) has the widest distribution, being found in India, Persia, Asia Minor, North and East Africa. About the size of a wolf, the animal is grayish-brown in colour, marked with indistinct longitudinal stripes of a darker hue. There is a mane along the neck and back. The animal is nocturnal in habits and has an unearthly cry, aptly compared to demoniac laughter. It feeds mainly on carrion, but occasionally carries off sheep, goats and dogs. It is a solitary and cowardly animal.

The brown hyena (H. *brunnea*) is South African, and about the size of the striped species. It is ashy brown in colour, with a lighter collar, chest and belly. The spotted form (C. crocuta) ranges from Abyssinia to the Cape, and is yellowish-brown, with darker spots. Both spotted and striped hyenas have been found fossilized in the Pliocene of Europe.

HYÈRES, a town in the *département* of the Var in S.E. France, 11 mi. by rail E. of Toulon. Pop. (1954) 15,649. The town of Hyères was founded in the 10th century, as a place of defense against pirates, and takes its name from the *aires* (hierbo in the Provencal dialect), or threshing-floors for corn, which then occupied its site. It passed from the possession of the viscounts of Marseille to Charles of Anjou, count of Provence. The château on the summit of the hill was dismantled by Henri IV, but the town resisted in 1707 an attack made by the duke of Savoy. Hyères is celebrated (as is also its fashionable suburb, Costebelle, nearer the seashore) as a winter health resort. The town is situated about 23 mi. from the seashore on the sheltered southwestern slope of a steep hill (669 ft. of the Maurettes chain) but is exposed to the Mistral. To the southwest, across a narrow valley, is the suburb of Costebelle. The older portion of the town is surrounded, on the north and east, by remnants of its mediaeval walls, and has steep and dirty streets. The more modern quarter has broad boulevards and villas, with gardens, filled with semitropical plants. The parish church of St. Louis was built originally in the 13th century by Franciscan friars, and restored in the 19th century. The plain between the new town and the sea has large nurseries, an excellent *jardin* d'acclimatation and many market gardens, which supply Paris and London with early fruits and vegetables, especially artichokes and roses in winter.

HYGIEIA, in Greek mythology, the goddess of health. The oldest traces of her cult, so far as is known at present, are to be **found** at Titane in the territory of Sicyon, where she was **worshipped** together with Asclepius, to whom she appears completely assimilated, not an independent personality.

Her cult was not introduced at Epidaurus until a late date, and therefore, when in 420 B.C. the worship of Asclepius was introduced at Athens coupled with that of Hygieia, it is not to be inferred that she accompanied him from Epidaurus, or that she is a Peloponnesian importation at all, but rather a new invention, an offshoot of the already existing worship of Athena Hygieia. At first no special relationship existed between Asclepius and Hygieia, but gradually she came to be regarded as his daughter, the place of his wife being already secured by Epione. Later Orphic hymns, however, and Herodas, iv, 1–9, make her the wife of Asclepius. The cult of Hygieia then spread concurrently with that of Asclepius, and was introduced at Rome from Epidaurus in 293, when she was gradually identified with Salus (*q.v.*). While in classical time Asclepius and Hygieia are simply the god and goddess of health, in the declining years of paganism they are protecting divinities.

VOTIVE RELIEF FOR AN AESCULAPIUM, OR TEMPLE OF AESCULAPIUS; GREEK SCHOOL. EARLY 4TH CENTURY, B.C.; ORIGINAL IN NATIONAL MUSEUM AT ATHENS

See H. Lechat in Daremberg and Saglio's *Dictionnaire* des *antiquités,* and E. Thramer in Roscher's *Lexikon* der Mythologie.

HYGIENE, the science of preserving health. The subject embraces all agencies affecting the physical and mental well-being of man, and requires acquaintance with physics, chemistry, geology, engineering, architecture, meteorology, epidemiology, bacteriology and statistics.

On the personal side it involves consideration of food, water and other beverages; clothing; work, exercise and sleep; personal cleanliness, special habits, such as the use of tobacco, narcotics, etc.; and control of sexual and other passions. In its public aspect it deals with climate; soil; character, materials and arrangement of dwellings; heating and ventilation; removal of waste matters; medical knowledge on incidence and prevention of disease; and disposal of the dead.

These topics are treated in such articles as BACTERIOLOGY; CREMATION; DIET AND DIETETICS; FOOD PRESERVATION; HEALTH AND SAFETY LAWS; HEATING AND VENTILATION; HOUSING; INDUSTRIAL MEDICINE; MATERNAL AND CHILD HEALTH; PSYCHIATRY; SEWER CONSTRUCTION; SOCIAL HYGIENE; WATER; etc. See also PREVENTIVE MEDICINE; PUBLIC HEALTH.

HYGINUS, SAINT (d. c. 140), eighth pope after Peter. It was during his pontificate (c. 136–140) that the gnostic heresies (see GNOSTICISM) began to appear in Rome.

HYGINUS, GAIUS JULIUS (fl. c. 25 B.C.), Latin author and scholar who, according to Suetonius (De Grammaticis, 20), was appointed by Augustus superintendent of the Palatine library. He went to Rome from Spain or Alexandria as a slave or perhaps a prisoner of war and was freed by Augustus.

He was a pupil of the learned Cornelius Alexander Polyhistor and a friend of Ovid. Of his numerous works, including topographical and biographical treatises, commentaries on Helvius Cinna and the poems of Virgil, and disquisitions on agriculture and beekeeping, nothing has survived.

Two works incorrectly attributed to Hyginus, however, are extant: (1) Fabulae or Genealogiae (ed. by H. J. Rose, with commentary, 1934), about 300 mythological legends and celestial genealogies, valuable for the use made by the author of the works of Greek tragedians since lost; (2) De Astronornia, usually called *Poetica* Astronomica (ed. by B. Bunte, 1875), an elementary treatise on astronomy and the myths connected with the stars, derived chiefly from Eratosthenes (*q.v.*). Although the Fabulae are in an abridged form with later accretions, there is some evidence that both works are by the same hand, but the style and the elementary mistakes (especially in the rendering of the Greek originals) are held to prove that they cannot have been the work of so distinguished a scholar as Hyginus; nor can they have been by another Hyginus of Trajan's time, who wrote only on land tenure and kindred subjects. Both probably belong to the 2nd century A.D.

See H. J. Rose, ***A Handbook of Latin Literature, (1936).***

HYGROMETER, an instrument for determining the humidity of the atmosphere (Gr. hygros, "wet"; metron, "a measure"). These instruments can be classed according to the method employed for detecting moisture, namely: (1) evaporation, the most common instrument consisting of two thermometers mounted together, one of which has a wet cloth sleeve over its bulb. The less humid the air, the greater the evaporation from the wet bulb and the greater the difference in reading between it and the standard (dry-bulb) thermometer; (2) dew point apparatus, making use of cooling devices to cause the water vapour to condense from the air and measuring the temperature at which the condensation occurs; (3) hair or strips of goldbeater's skin (ox gut), making use of the principle that these organic substances will increase in length as the relative humidity is increased; (4) chemical absorption, making use of chemical drying agents which extract the moisture from the air, and the increased weight of the dryer noted; (5) electrical. making use of the principle that changes in the electrical resistance of a chemically treated coil of wire can be related to changes of relative humidity. See HUMIDITY, ATMOSPHERIC.

(B. G. H.)

HYKSOS or "SHEPHERD KINGS," the name of the earliest invaders of Egypt. Josephus (c. *Apion.* i, 14), who identifies the Hyksos with the Israelites, preserves an account of them from bk. ii of Manetho. According to it, in the days of King Timaeus, Egypt was invaded from the east by a destructive band who elected a king named Salatis. He made all Egypt tributary and established garrisons and fortresses in various parts of the country. His successors Beon, Apachnas, Apophis, Jannas and Asses reigned c. 199 years, and all aimed at extirpating the Egyptians. Their race was named Hyksos; *i.e.*, "shepherd kings," and some say they were Arabs (another explanation found by Josephus is "captive shepherds"). When their successors had held Egypt for 511 years, a rebellion began at Thebes. Misphragmuthosis confined the "Shepherds" in Avaris; and his son Thutmosis, failing to capture the stronghold, allowed them to depart; uhereupon they established themselves, 240,000 in number, in Judea and built Jerusalem. In Manetho's list of kings, the six above named form the 15th dynasty and are called "six foreign Phoenician kings." The 16th dynasty is made up of 32 "Hellenic shepherd kings." the 17th is of "shepherds and Theban kings" (reigning simultaneously). The lists vary greatly in different versions, but the above seems the most reasonable selection of readings. For "Hellenic" see below. In 1847 E. de Rougé proved from a papyrus of the British museum that Apopi was one of the latest of the Hyksos kings, corresponding to Aphobis; he was king of the "pest" and suppressed the worship of the Egyptian gods in favour of his god Setekh or Seti. In 1850 a record of the capture of Hawari (Avaris) from the Hyksos by Ahmosi, founder of the 18th dynasty, was discovered by the same scholar. A large class of monuments was afterwards attributed to the Hyksos. Some statues, found in 1861 by Mariette at Tanis, had peculiar "un-Egyptian" features. One of these bore the name of Apopi engraved lightly on the shoulder, and on other grounds it was concluded that the features were those of the Hyksos. In 1893 Golenischeff produced an inferior example bearing its original name, which showed that it represented Amenemhe III. In consequence it is now generally believed that they all belong to the 12th dynasty. Meanwhile a headless statue of a king named Khyan, found at Bubastis, was attributed to the Hyksos, the soundest arguments being his foreign name and the boastful un-Egyptian epithet "beloved of his ka." His name was afterwards recognized on a lion found in Baghdad. Flinders Petrie then pointed out a group of kings named on scarabs of peculiar type, which, including Khyan, he attributed to the period between the Old Kingdom and the New, while others were in favour of assigning them all to the Hyksos, whose appellation seemed to be recognizable in the title Hek-khos, "ruler of the barbarians," borne by Khyan.

HYLAS, in Greek legend, son of Theiodamas, king of the Dryopians in Thessaly, the favourite of Hercules and his companion on the Argonautic expedition. Having gone ashore at Kios in Mysia to fetch water, he was carried off by the nymphs of the spring in which he dipped his pitcher. Hercules sought him in vain; and ever afterwards, in memory of the threat of Hercules to ravage the land if Hylas were not found, the inhabitants of Kios every year on a stated day roamed the mountains, shouting aloud for Hylas (so Apollonius Rhodius I, 1207 et seq., and later authors). But, although the legend is first told in Alexandrian times, the "cry of Hylas" occurs long before as the "Mysian cry" in Aeschylus (Persae, 1054); and in Aristophanes (Plutus, 1127) "to cry Hylas" is used proverbially of seeking something in vain.

HYLOZOISM, in philosophy, a term applied to any system which explains all life, whether physical or mental, as ultimately derived from matter (Gr. hyle, "matter"; zoe, "life"). Such a view of existence has been common throughout the history of thought and especially among physical scientists. Thus the early Greek thinkers of the so-called Ionian school of philosophy sought for the beginning of all things in various material substances, water, air, fire, which were regarded as being in some sense alive and taking some active part in the development of being. This primitive hylozoism reappeared in modified forms in medieval and Renaissance thought. For later developments see MATERIALISM.

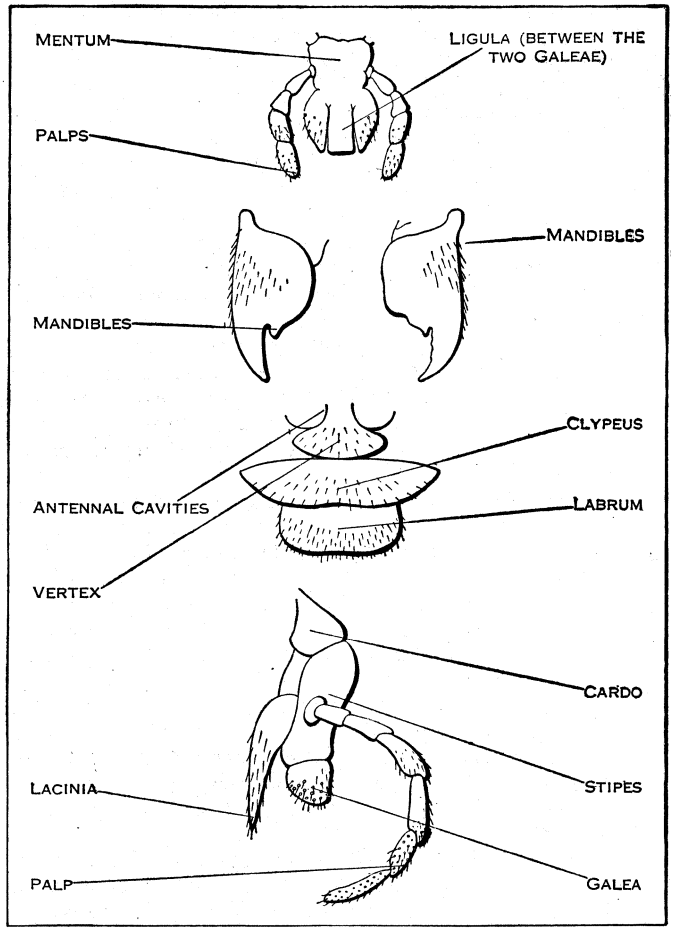
HYMANS, PAUL (1865–1941), Belgian statesman, was born at Ixelles, Brussels, on March 23, 1865. He became a barrister in 1885, and from 1898 to 1914 was professor of comparative parliamentary history at Brussels university. From 1900 he was deputy for Brussels and soon became the Liberal leader. After a mission to President Wilson in Aug. 1914 he was plenipotentiary in London, 1915–17, when he became head of the ministry of economic affairs. From 1918–20 and 1924–25 he was minister for foreign affairs. In Nov. 1918 he attended the Inter-Allied council at Versailles; he also represented Belgium at the peace conference in 1919 and on her behalf signed the peace treaty. In the same capacity he attended the conferences at San Remo, Boulogne, Brussels and Spa. He played a leading part in the settlement of the Ruhr question, the Dawes plan, the Security pact and the economic union of Luxembourg with Belgium. In Jan. 1920 he was appointed Belgian representative on the League of Nations and in the same year was made president of the first assembly at Geneva. He was again minister for foreign affairs, 1927–34 and 1934–35, and member of the council of ministers, 1935–36. A member of the Académie Royale de Belgique, Hymans continued *L'histoire parlementaire* de la Belgique (1875, etc.) and wrote *Frere-Orban* (1905, etc.), Portraits, *essais et discours*

(1914), and *Pages libérales* (1936).

HYMEN or HYMENAEUS, originally the refrain of the song sung at marriages among the Greeks. As usual, the name gradually produced the idea of an actual person whose adventures gave rise to the custom of this song. He occurs often in association with Linus and Ialemus, who represent similar personifications, and is generally called a son of Apollo and a muse. As the son of Dionysus and Aphrodite, he was regarded as a god of fruitfulness. In Attic legend he was a beautiful youth who, being in love with a girl, followed her in a procession to Eleusis, disguised as a woman, and saved the whole band from pirates. As reward he obtained the girl in marriage, and his happy married life caused him ever afterwards to be invoked in marriage songs (Servius on Virgil. *Aen.* i. 651).

See J. A. Hild in Daremberg and Saglio's *Dictionnaire* des *antiquités.*

HYMENOPTERA, the term used in zoological classification for that order of insects comprising ants, bees, wasps, and their allies the sawflies, gall wasps and ichneumon flies. These insects all exhibit the following characters: (1) The presence of two pairs of stiff membranous wings often with the venation reduced



FROM MARLATT, "ENTOMOLOGICAL BULLETIN," U.S. DEPT. OF AGRIC.

FIG. 1.— HYMENOPTERA: MOUTH PARTS OF SAWFLY (PACHYNEMATUS)

These are used principally for feeding, but in the bee the ligula is modified for sucking nectar

or almost absent: the hind wings are smaller than the fore pair and are interlocked with them by tiny hooklets. (2) The mouth parts have biting jaws, but the labium is usually modified into a kind of tongue for lapping or sucking. (3) The abdomen is generally constricted at the base to form a waist and its first segment forms a part of the thorax: an ovipositor is present and used for sawing, piercing or stinging. (4) Metamorphosis is complete and the larvae are either caterpillars or more often vermiform: the pupae may be in cocoons; their appendages are free.

Hymenoptera form one of the largest and most highly developed orders of insects and are of great interest, not only on account of the perfection of their structure but also with regard to the remarkable development of their instincts. In the latter respect they stand at the head of all invertebrate animals and their behaviour has been the subject of studies by many famous naturalists. About 80,000 species were known by 1945, but many thousands more still awaited discovery, and even in the British Isles it is only the ants, bees and wasps that have been adequately collected

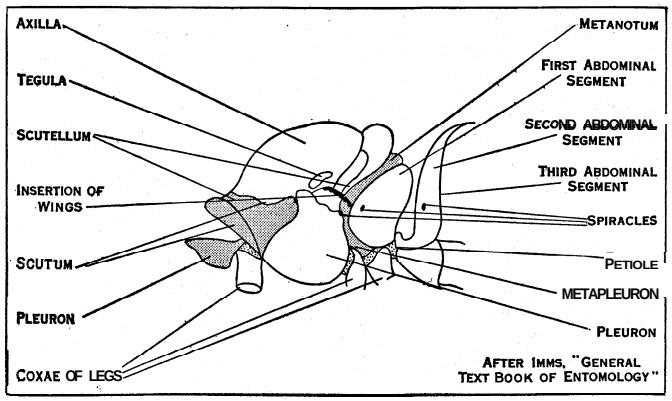


FIG. —.— LATERAL VIEW OF THE THORAX AND BASE OF ABDOMEN OF HONEYBEE

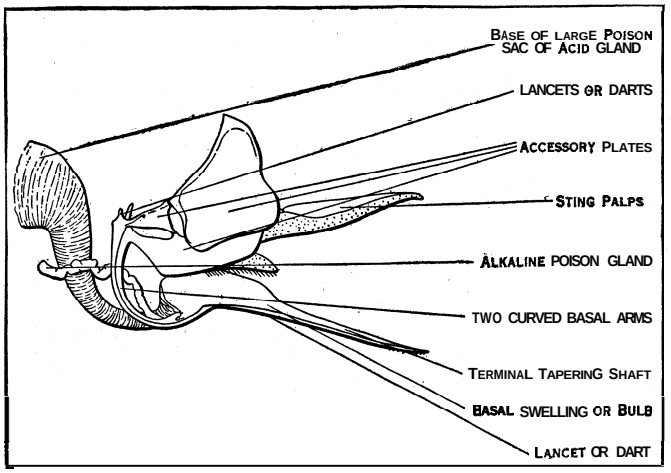
The thorax is chiefly characterized by its fusion with the first segment of the abdomen. The parts of the pre- and metathorax are shaded; mesothorax and abdomen are plain

and studied. Although the vast number of species are solitary like other insects, individuals of some species have acquired the habit of living together in great societies as is the case in ants and certain bees and wasps: their social life and behaviour is fully discussed in the article SOCIAL **INSECTS.** Hymenoptera are also remarkable for the highly evolved condition parasitism has reached in the order: tens of thousands of species betray this habit, and although they confer immense benefit to man as agents destroying other forms of insect life, they have been little collected, and in many parts of the world are very slightly known.

General Structure.— Hymenoptera have acute vision; the compound eyes are consequently large and there are usually three ocelli or simple eyes. The antennae are sometimes dimorphic in



FROM SNODGRASS, "ANATOMY OF THE HONEY BEE," U.S. DEPT. OF AGRIC.

FIG. 3.— SEMI-DIAGRAMMATIC VIEW OF LEFT SIDE OF STING OF WORKER HONEYBEE

the two sexes and in the bees and wasps they are generally composed of 13 joints in the males and 12 joints in the females. The mouth parts exhibit their simplest form in sawflies (fig. 1) where they depart but little from the generalized biting type. In most other Hymenoptera the mandibles are used for what may be termed industrial purposes more than for feeding, and the ligula is modified into an organ for lapping or sucking nectar. In the higher types of bees this organ is elongated into a kind of tongue which, in some cases, exceeds in length that of the entire insect. In these instances the labial palpi and maxillae are also correspondingly lengthened and form, with the ligula, a definite proboscis

(fig. 1). The thorax (fig. 2) is chiefly characterized by the fusion of its last segment with the *propodeum* or first segment of the abdomen. In the sawflies this union is not complete, but in all other Hymenoptera it is a pronounced feature and the second abdominal segment (or first apparent segment) is constricted to form a waist or *petiole*. The wings have departed very widely from the primitive type of venation and almost every transition can be found from the well developed condition seen in sawflies to some of the parasitic forms where there is only a single vein to the fore wings or even no vein at all. At the bases of the fore wings are small scalelike plates or *tegulae*, which afford important characters used in classification. Most members of the order fly with the wings of a side interlocked by a row of hooklets. In the female the abdomen bears an elaborate ovipositor, typically composed of three pairs of valves. The first pair arises from the eighth segment and forms the lancets, while the other pairs arise from the ninth segment and form the lancet sheath and the so-called sting palps respectively (fig. 3). In addition to functioning as an egg-laying instrument the ovipositor is used in sawflies for sawing niches in plants into which the eggs are lodged: in ichneumon flies and their allies it is often employed in stabbing their insect hosts preparatory to laying their eggs within the bodies of the latter: in bees, wasps and some ants it is used for stinging, a habit which is found in no other insects.

Classification. — Hymenoptera are grouped into two main suborders and these, along with their chief subdivisions, are enumerated below.

SUBORDER I. CHALASTOGASTRA

Abdomen with no definite basal constriction or waist: trochanters 2-jointed. Larvae generally caterpillars with a variable number of Legs.

Superfamily Tenthredinoidea. Included in this division are all the more primitive members of the order: they do not exhibit the specialized habits and instincts of the Clistogastra and their larvae are almost exclusively plant feeders. The best known family is the Tenthredinidae or sawflies (*q.v.*) which are distinguished by two large spines or spurs to each fore tibia. Their larvae are caterpillars which feed upon the leaves of plants, and those of a number of species are injurious to cultivated plants and forest trees. The ovipositor is usually elaborately toothed,

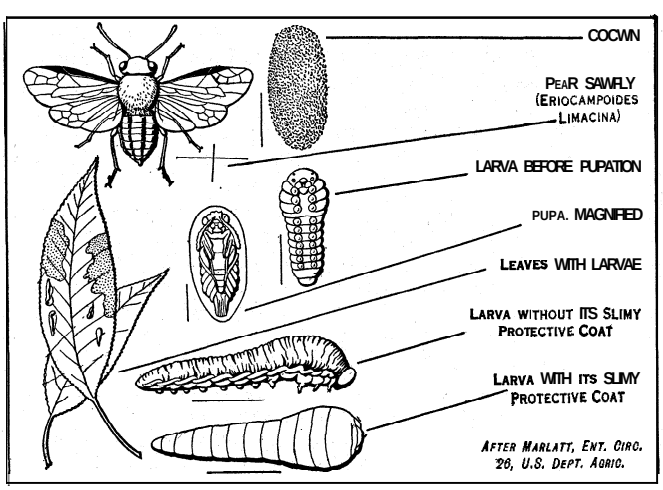


FIG. 4.—LIFE HISTORY OF PEAR SAWFLY (ERIOCAMPOIDES LIMACINA)
The larvae are plant feeders, those feeding openly on leaves being caterpillars. often with six or more pairs of feet

and is used for sawing notches to enable the eggs to be laid in plant tissues. The Cephidae or stem sawflies are a small group whose larvae feed in the stems of various plants, while those of the Siricidae or wood wasps bore into the wood of trees.

SUBORDER II. CLISTOGASTRA

Abdomen with a basal constriction or waist: trochanters 1- or 2-jointed. Larvae embryonic or vermiform without legs.

The great group is divisible into the *Parasitica* which generally have 2-jointed trochanters and the *Aculeata* or stinging forms in which the trochanters are single-jointed. The *Parasitica* include the following superfamilies.

The Ichneumonoidea have the pronotum extending back to the tegulae, the antennae are not elbowed and the fore wings have a

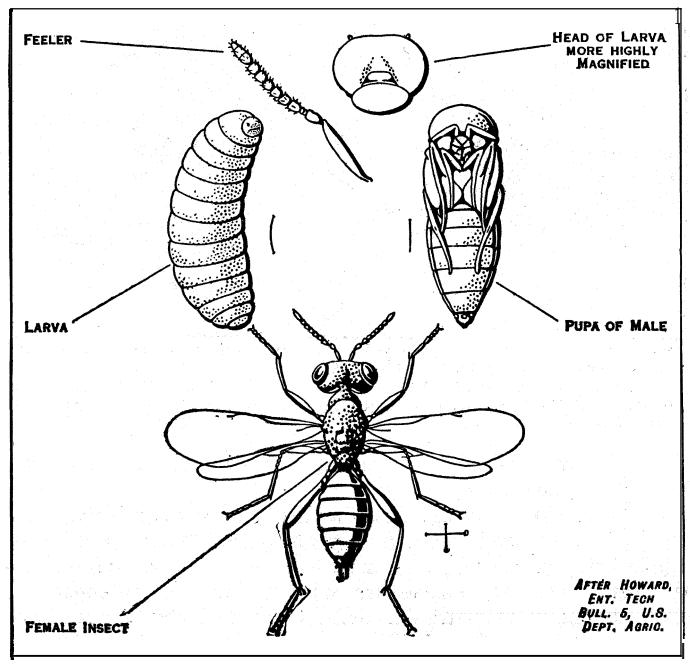

FIG. 8. — LIFE HISTORY OF CHALCID (DIBRACHYS CAVUS)
The suborder Clistogastra is chiefly characterized by the narrowly constrioted waist of the adult and by the legless condition of the larvae

dark mark or stigma (fig. 7). The larvae of all members of this group are parasites preying upon some stage in the life cycle of other insects or spiders and are consequently of great economic importance. (*See* ICHNEUMON FLY.)

The Cynipoidea include the gall wasps or gallflies which differ from the ichneumons in the absence of a stigma to the fore wings and in the usually single-jointed trochanters, unlike most other Parasitica. In the family Cynipidae many of the species lay their eggs in various plant tissues which react in such a way that galls are produced wherein their development is completed. These galls are of characteristic form for each species. the oak apple and bedeguar of the rose being familiar examples. Other members of the family are inquilines, living within the galls and bearing a close resemblance to the true makers of the latter. The Figitidae are parasites, usually attacking fly larvae and aphides.

The Chalcidoidea or chalcid wasps (fig. 5) are very small insects with elbowed antennae and with the pronotum not extending back to the tegulae. The group includes more than 16 families, most of the members of which are either parasites of the eggs, larvae or pupae of other insects, or are hyperparasites. A small number are plant feeders living in seeds, in figs, cr forming galls on cereals and grasses. The fig insects are very numerous; certain of these are important agents in the pollination of the flowers, and have been introduced for economic purposes into lands where they were absent. The parasitic forms are of great practical value, in that they destroy vast numbers of injurious insects: certain of these exhibit the phenomenon of polyembryony, which is dealt with in the article INSECTS. Chalcids often exhibit beautiful metallic coloration, and can be recognized by the wing veins being reduced to a single stem.

The Serphoidea resemble the Aculeates in that the ovipositor issues from the apex of the abdomen, but the trochanters are usually 2-jointed. This character, together with the fact that the pronotum reaches back to the tegulae, separates them from the chalcids (fig. 5). They are all very small or minute insects with greatly reduced venation, and many are wingless. They live as parasites of other insects. or of spiders, and frequently in the eggs, which they destroy in large numbers. The largest of the

eight chief families are the Platygastridae which mainly parasitize gall midges, their larvae often living in the brain or stomach of their hosts. Like the chalcids, the Serphoidea are beneficial.

The succeeding superfamilies form the series Aculeata or stinging Hymenoptera and in these the ovipositor issues from the apex

FIG. 6.—A FEMALE PROCTOTRYPID (PLATYGASTER DRYOMIAE) On the right the female is seen in the act of oviposition in an egg (O), of a gall midge, on a leaf

of the abdomen, whereas in the Parasitica it issues some distance in front of the extremity.

The Formicoidea or ants form a very natural assemblage which are easily recognized by the greatly constricted "waist" and by the petiole being marked by one or two nodes: the pronotum extends backward, but the tegulae are uanting and the antennae are elbowed. The females are differentiated into winged "queens" and wingless workers of varied forms; each species of ant leads a complex social life which presents many phases of surpassing interest. (See ANT and SOCIAL INSECTS.)

The Sphecoidea or digging wasps (fig. 8) are marked off from the Vespoidea by the fact that the pronotum forms a collar and does not reach back to the tegulae. For the most part they are to be regarded as beneficial insects from the fact that they are predators seizing other insects, which they carry off to their cells as food for their larvae. All are solitary insects which construct cells for their brood either below ground or in dry wood or stems. There are 12 families, the largest being the Sphecidae.

The Vespoidea include a large number of other digging wasps together with the social wasps. The pronotum generally reaches back to the tegulae but there are exceptions. Among the solitary species, some Mutillidae are parasites in bumblebees' nests and their females are wingless. The Pompilidae provision their cells with spiders: they are often large insects with slender bodies and elongate hind legs. The Scoliidae are robust, hairy wasps which often deposit their eggs in chafer larvae and chiefly inhabit warm countries. The Chrysididae or ruby-tailed wasps are beautiful metallic green or green and blue or ruby insects, which lay their eggs in the nests of bees and wasps where their larvae either prey upon those of their hosts or devour their food. In this family only three or four abdominal segments are visible, the remainder forming a retractile tube containing the ovipositor. The true wasps have their wings folded length ise in repose and the fore legs are of normal build—not specialized for digging as in the fossorial groups. The Vespidae or social wasps have "queens" and "workers" as in ants, but both forms are winged, while the Eumenidae or solitary true wasps have no such differentiation into castes. (For the habits of these two families see WASP and SOCIAL INSECTS.)

The Apoidea include the solitary and social bees which agree with the Sphecoidea in the pronotum not extending back to the tegulae but differ from them in having the hind tarsi dilated, while the hairs of the head and thorax are feathery or plumose. The glossa or tongue is well developed and often exceedingly long and the food consists of nectar and pollen. The larvae are fed upon a similar diet. except that the nectar is regurgitated as honey before being served to them. These substances are stored in the cells and the latter are never provisioned with animal food. Most bees are solitary in habit, but those of the families Bombidae, Meliponidae and Apidae are social insects resembling ants and wasps in the occurrence of a worker caste. (See BEE and SOCIAL INSECTS.)

Reproduction and Development. — One of the most interesting facts with regard to reproduction in Hymenoptera is the wide occurrence of parthenogenesis which obtains among members of all the great groups. The best known instance is in the honeybee, in which the unfertilized eggs produce males (drones) : in the gall wasps or Cynipidae both sexes may be produced from unfertilized eggs and the generations which arise in this way alternate with those produced by the usual sexual method. In other of the gall wasps males are unknown: parthenogenesis is also very frequent in sawflies and chalcid wasps.

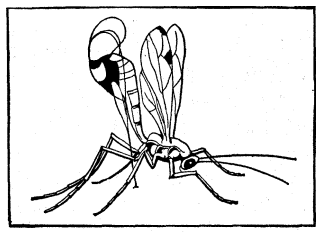
The larvae of the Chalastogastra are plant feeders: those which feed openly on leaves are caterpillars, often with six or more pairs of abdominal feet (fig. 4), but in the stem and wood borers these appendages are absent and the thoracic limbs are reduced to mere tubercles. Among the Clistogastra the larvae are usually hatched in immediate contact with an abundance of food: they are in consequence degenerate creatures devoid of limbs and of almost all traces of organs of special sense (fig. 5). In the parasitic groups hypermetamorphosis (see INSECTS) is very frequent, the larvae being hatched in forms very different from that assumed in the final instar. In a few cases the eggs are laid away from the hosts and the larvae upon hatching are active creatures of the type termed a planidium. The planidium seeks out its host, and having found it, assumes the legless maggot-like form common to all Clistogastra. Some of the parasitic species live externally on their hosts and feed by piercing the integument with their mouth parts, but the largest number are endoparasites. In the latter case the female parent drives her ovipositor into the host and lays one or more eggs wherever the larvae will find abundant food. Many of the minute Chalcidoidea and Serphoidea complete their development within the eggs of other insects: others parasitize the larvae or pupae or, more rarely, adult insects, and death of the host finally supervenes. The digging or fossorial wasps feed their brood with captured insects, which are stored away in cells along with a single egg: the wasp larva, upon hatching, thus finds its life's food supply immediately at hand. The true wasps feed their brood with animal food including many insects, from time to time, very much as a bird does her fledglings, while bees entirely resort to honey and pollen. Thus, we find throughout the order a degree of care for the offspring, not attained in other insects, which has led to the development of social life in certain groups. When fully fed most Hymenoptera pupate in cocoons formed of silk secreted for this purpose; and among the ichneumon flies and their allies, these cocoons are often elaborate and beautiful objects.

Geographical Distribution. — Hymenoptera are found in all except the most inhospitable regions of the globe, but the order, as a whole, has not penetrated to such remote parts as have the Apterygota and Coleoptera. Bees, for example, are dependent upon the existence of flowering plants and are not found outside their range: some, such as the giant *Xylocopa* or carpenter bees are mainly tropical or subtropical, while bumblebees are essentially creatures of temperate climates and are generally confined to the mountains in the tropics; they are absent from almost the whole of Africa, the plains of India and none are indigenous to Australia or New Zealand. The honeybee (*Apis mellifica*) has been introduced into most countries of the world, and some of the injurious sawflies enjoy a very wide distribution, mainly through the agency of commerce. Among the chalcid wasps the family Agaonidae, or fig insects, occurs wherever trees of the fig kind flourish, but are not found outside that limit: certain other chalcids (Eucharidae) are mainly tropical and are confined to where their particular ant hosts flourish. Perhaps the most interesting fact concerning the distribution of Hymenoptera is the great paucity of forms found in New Zealand, where they are represented by little more than 300 species, as compared with more than 6,000 found in Australia.

Geological Distribution. — The first members of the order to appear in geological history are wood wasps of the genus *Pseudosirex* from the Upper Jurassic of Bavaria. Certain parasitic Hymenoptera appeared soon afterward and some very highly specialized types occur in the Cretaceous of Canada. In Baltic

amber of Oligocene age many species have been described. In Tertiary times the order is represented by ants, bees and other forms which differ relatively little from those found living today.

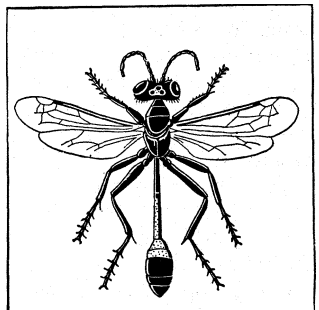
Natural History.— Hymenoptera are mostly of small or moderate size: only a few members of the order are very large insects, like the carpenter bees and spider wasps of the family Pompilidae. On the other hand, many of the parasitic forms are among the smallest of all insects, notably those which live as egg parasites; certain chalcid wasps of family Mymaridae or "fairy flies" measure only .21 mm. in length.



FROM RILEY AND HOWARD, "INSECT LIFE" U.S DEPT. OF AGRICULTURE

FIG. 7.—ICHNEUMON FLY (RHYSSA PERSUASORIA) OVIPOSITING

Hymenoptera are essentially terrestrial and aerial in habit. The only exceptions are those which parasitize the larvae or eggs of aquatic insects: the "fairy fly" *Polynema natans* swims readily beneath the water by means of its wings and seeks out the eggs of the water boatmen (Notonecta) as the host for its larvae. In number of species the parasitic groups greatly exceed the remainder of the order. No order of terrestrial insects escapes their attacks, and even larvae deep in the soil or boring in the solid wood of trees are by no means immune. As a rule the length of the ovipositor is greatest in those parasites such as Megarhyssa and Rhyssa which have to force this organ through a depth of wood, in order to reach their hosts (fig. 7). One of the most remarkable cases of parasitism is found in a proctotrypid, *Rilea* manticida which, according to L. Chopard, passes its development in the eggs of the praying mantis. The adult parasites, upon emergence, make their way to a mantis, upon whose body they settle down: in this situation they cast off their wings and live ectoparasitically. If the mantis be a female which has commenced egg laying, the *Rilea* migrates to the extremity of the body, in order to lay its eggs in the viscid mass of the mantis' egg capsule as it is being formed. Parasites which settle upon male mantids are probably short-lived and perish. The digging wasps store their cells with other insects or spiders and as a rule they sting their prey first and reduce it to a condition of immobility without actually killing it: in other cases the prey is killed, but since it retains its fresh condition up to several weeks, it is presumed that the injected venom exercises an antiseptic influence. Jean Henri Fabre's observations upon the Sphex (*Ammophila*), which stings its caterpillar prey in successive segments of its body, have often been quoted. The French observer maintained that this insect (fig. 8) had a sort of intuitive knowledge of the inner anatomy of its victim, the stings being administered in the ganglionic nerve centres, thereby inducing paralysis, a conclusion which is scarcely warranted by the facts at his disposal. The number of times a prey is stung appears to vary from once up to about a dozen: in addition to being stung the victim is vigorously pinched by the jaws of the *Sphex*, particularly when it has been stung only a few times and subsequent paralysis occurs in each case. The nature of the prey of digging wasps is often very constant for particular species. Thus *Philanthus triangulum* stores its nest with honey bees, while species of *Bembix* prey upon large Diptera, and the large species of the *Pepsis* store burrows with great tarantula spiders.



FROM IMMS, TEXT-BOOK OF ENTOMOLOGY" (METHUEN & CO.)

FIG. 8.—FEMALE SPHEX (AMMOPHILA SABULOSA) (TWICE ACTUAL SIZE)

The genus sphex includes digging wasps, which store their cells with caterpillars and other insects. The prey is paralyzed by stinging and remains fresh during the time the sphex devours it

Among bees, wasps and some ants, the capacity for stinging is employed for defensive purposes, and the usual glands which are found at the base of the ovipositor are especially large in these insects. Their secretions have irritating properties to which the sting is due, the venom containing formic acid.

The nest-building habit is another feature of Hymenoptera. Digging wasps make simple burrows in the ground, and many burrowing bees make branched tunnels. Other bees excavate wood or make their brood chambers in hollow stems, while the true wasps work up chewed fragments of wood with saliva to form a sort of paper with which they construct the cells of their nest. The social bees secrete wax from their own bodies with which they build up the combs of their nest. There are numerous Hymenoptera that are inquilines — insects which construct no nests of their own and utilize, instead, those of other species: in some cases their larvae consume the food provided by the rightful owners for their own brood, and in others, they devour the larvae of the host, thus becoming true parasites. The most interesting of all features associated with Hymenoptera is their social life, which forms the subject of a separate article. (See SOCIAL INSECTS.)

Economic Importance. — The chief injurious members of the order belong to the Chalastogastra and the larvae of many sawflies are exceedingly destructive. Thus, the turnip sawfly *Athalia spinarum* destroys the foliage of the turnip crop in Britain and many parts of Europe: the pear slug sawfly (*Eriocampoides limacina*) skeletonizes the leaves of pears in Europe, North America, Australia and New Zealand and Lygaeonematus *erichsonii* is destructive to larch on both sides of the Atlantic. The gooseberry sawfly (*Nematus* ribesii) is a well known pest of gooseberries in gardens in many parts of Europe, as well as in North America, and the larvae of various species of *Lophyrus* are destructive to pines. Wood wasps (Siricidae) bore into timber in many parts of the world and the stem borers (Cephidae), are especially injurious to cereals. The Clistogastra are almost wholly beneficial insects, the honeybee yields beeswax and honey, while the important role played by the parasitic forms in destroying injurious insects, has already been dilated upon. The introduction of the chalcid wasp *Aphelinus mali* into New Zealand is an example of the practical utilization of parasitic Hymenoptera, and the species in question has now largely controlled the woolly aphis of the apple in that territory. Among other chalcids the presence of certain fig insects (*Blastophaga*) is needed to pollinate the flowers of the fig; they have been previously mentioned. On the other hand, a small number of chalcids are injurious, notably those whose larvae live in seeds such as species of *Megastigmus* which attack those of conifers, while larvae of *Harmolita* form stem galls on grasses.

BIBLIOGRAPHY.—In an order so extensive and diverse as Hymenoptera the reader will find very few comprehensive works, the literature mainly dealing with individual groups. The European species are monographed by E. and E. André, *Species* des *Hyménoptères d'Europe* et *d'Algérie* (1879–1913), and the world's species are catalogued by C. G. de Dalla Torre, *Catalogus Hymenopterorum* (Leipzig, 1892–1902). A useful guide to the North American forms is provided by H. L. Viereck and collaborators in The Hymenoptera or *Wasp*-like Insects *of* Connecticut (Bull. 22 State Geol. and *Nat. Hist.* Survey: Hartford, Conn., 1916). One for Europe is Schmiedeknecht, Hymenopteren Mitteleuropas (Jena, 1930). For the sawflies and gallflies the accounts given in C. Schroder's Insekten *Mitteleuropas*, vol. iii (Stuttgart, 1914) are concise and well illustrated, while the British species are described by P. Cameron, British Phytophagous *Hymenoptera* (London, Roy. Soc., 1882–92), which is provided with accurate coloured plates. A useful popular account of the galls produced by Cynipidae is E. T. Connold, *British* Plant Galls (1909). For the North American galls *see* E. P. Felt, Plant Galls and the Insects *That Produce* Them (1940), and A. Cosens, A Contribution to the Morphology and Biology of Insect Galls (Trans. *Canad. Inst.* vol. ix, 1912). For parasitism and the forms exhibiting this habit the following works are important: W. H. Ashmead, Classification of the Chalcid Flips (Mem. *Carnegie Mus.* 1, 1904) and the same author's *Monograph* of the *North American Proctotrypidae* (Bull. 45, U.S. Nat. Mus. 1893); L. O. Howard, The Biology of the *Hymenopterous* Insects of the *family* Chalcididae (Proc. US. Nat. Mus., xiv, 1891); L. O. Howard and W. F. Fiske, *The* Importation into the United States of the Parasites of the *Gipsy* Moth, etc. (U.S. Dept. Agric.. Entom. Bull. 91: 1911); other references are given in the article ICHNEUMON-FLY.

The Aculeata have a very extensive literature and among the more important works are: E. Saunders, *Hymenoptera* Aculeata of the British Islands (1896); H. St. J. Donisthorpe, British Ants (1927); W. M. Wheeler, Ants (1910); P. and N. Rau, Wasp Studies Afield (Princeton, 1918); G. W. and E. G. Peckham, Wasps, Social and

Solitary (1905); for other references see SOCIAL INSECTS.

In addition to the foregoing numerous observations on the habits and behaviour of Hymenoptera are given in J. H. Fabre, *Souvenirs Entomologiques* (1879–1905), many of which are translated into English. (A. D. I.)

HYMETTUS, a mountain in Attica, bounding the Athenian plain on the south-east (3,370 ft.), has always been famous for its honey. The spring mentioned by Ovid (*Ars Amat.* iii. 687) is probably near the monastery of Syriani or Kaesariani on the western slope and identical with that known as Κύλλον Πήρα said to be a remedy for childlessness. The marble of Hymettus, which often has a bluish tinge, was used for building in ancient Athens, and even for sculpture; although the white marble of Pentelicon was preferred for both purposes.

See E. Dodwell, *Classical* and *Topographical* ***Tour*** (1819), i. 483.

HYMNS. The word "hymn" (ὕμνος) was employed by the ancient Greeks to signify a song or poem composed in honour of gods, heroes or famous men, or to be recited on some joyful, mournful or solemn occasion. But hymns are actually much older than any Greece can show; the ancient Chinese "hymned" the Ruler of Heaven; Assyria, Egypt and India have all left us records of early hymns. The Athenian dramatists (Euripides most frequently) use the word and its cognate verbs of odes in praise of conquerors at the public games; they also describe by them metrical oracles and apophthegms, martial, festal and hymeneal songs, dirges and lamentations or incantations of woe.

Hellenic hymns, according to this conception of them, have come down to us, some from a very early and others from a late period of Greek classical literature.

The Romans did not adopt the word "hymn"; nor have we many Latin poems of the classical age to which it can properly be applied. There are, however, a few—such as the simple and graceful "Dianae sumus in fide" ("Dian's votaries are we") of Catullus, and "Dianam tenerae dicite virgines" ("Sing to Dian, gentle maidens") of Horace—which approach much more nearly than anything Hellenic to the form and character of modern hymnody.

Hebrew Hymnody.—For the origin and idea of Christian hymnody we must look, not to Gentile, but to Hebrew sources. St. Augustine's definition of a hymn, generally accepted by Christian antiquity, may be summed up in the words, "praise to God with song" ("cum cantico"); Bede understood the "canticum" as properly requiring metre; though he thought that what in its original language was a true hymn might retain that character in an unmetrical translation. Modern use has enlarged the definition; Roman Catholic writers extend it to the praises of saints; and the word now comprehends rhythmical prose as well as verse, and prayer and spiritual meditation as well as praise.

The modern distinction between psalms and hymns is arbitrary (see PSALMS).

In the New Testament we find our Lord and His apostles singing a hymn (ὑμνήσαντες ἐξῆλθον), after the institution of the Lord's Supper; St. Paul and Silas doing the same (ὕμνουν τὸν θεόν) in their prison at Philippi; St. James recommending psalm-singing (ψαλλέτω) and St. Paul "psalms and hymns and spiritual songs (ψαλμοῖς καὶ ὕμνοις καὶ ὠδαῖς πνευματικαῖς) St. Paul also, in the 14th chapter of the first epistle to the Corinthians, speaks of singing (ψαλῶ) and of every man's psalm (ἕκαστος ὑμῶν ψαλμὸν ἔχει), in a context which plainly has reference to the assemblies of the Corinthian Christians for common worship. All the words thus used were applied by the LXX. to the Davidical psalms; it is therefore possible that these only may be intended, in the different places to which we have referred. But there are in St. Paul's epistles several passages (Eph. v. 14; 1 Tim. iii. 16; 1 Tim. vi. 15, 16; 2 Tim. ii. 11, 12) which have so much of the form and character of later Oriental hymnody as to have been supposed by Michaelis and others to be extracts from original hymns of the Apostolic age.

Eastern Church Hymnody.—The hymn of our Lord, the precepts of the apostles, the angelic song at the nativity, and "Benedicite omnia opera" are referred to in a curious metrical prologue to the hymnary of the Mozarabic Breviary as precedents for the practice of the Western Church. Philo describes the Therapeutae (*q.v.*) of the neighbourhood of Alexandria as composers of original hymns which were sung at their great religious festivals.

The practice, not only of singing hymns, but of singing them antiphonally, appears, from the well-known letter of Pliny to Trajan, to have been established in the Bithynian churches at the beginning of the 2nd century. This agrees well, in point of time, with the tradition recorded by the historian Socrates, that Ignatius (who suffered martyrdom about A.D. 107) was led by a vision or dream of angels singing hymns in that manner to the Holy Trinity to introduce antiphonal singing into the church of Antioch, from which it quickly spread to other churches.

The Greek hymnody contemporary with Ephraem followed, with some licence, classical models. One of its favourite metres was the Anacreontic; but it also made use of the short anapaestic, Ionic, iambic and other lyrical measures, as well as the hexametet and pentameter. Its principal authors were Methodius, bishop of Olympus, who died about A.D. 311, Synesius, who became bishop of Ptolemais in Cyrenaica in 410, and Gregory Nazianzen, for a short time (380–381) patriarch of Constantinople. They have found an able English translator in the Rev. Allen Chatfield (Songs and Hymns of Earliest *Greek Christian* Poets, 1876). Among the most striking of their works are μνήμεο Χριστέ ("Lord Jesus, think of me"), by Synesius; σὲ τὸν ἄφθιτον μονάρχην ("O Thou, the One Supreme") and τί σοι θέλεις γενέσθαι ("O soul of mine, repining"), by Gregory; also ἄνωθεν παρθένοι ("The Bridegroom cometh"), by Methodius. There continued to be Greek metrical hymn-writers, in a similar style, till a much later date. Sophronius, patriarch of Jerusalem in the 7th century, wrote seven Anacreontic hymns; and St. John Damascene, one of the most copious of the second school of "Melodists," was also the author of some long compositions in iambic trimeters.

Period of Arian Controversy.—An important development of hymnody at Constantinople arose out of the Arian controversy. Early in the 4th century Athanasius had rebuked, not only the doctrine of Arius, but the light character of certain hymns by which he endeavoured to make that doctrine popular. When, towards the close of that century (398), St. John Chrysostom was raised to the metropolitan see, the Arians, who were still numerous at Constantinople, had no places of worship within the walls; but they were in the habit of coming into the city at sunset on Saturdays, Sundays and the greater festivals, and congregating in the porticoes and other places of public resort, where they sang, all night through, antiphonal songs, with "acroteleutia" (closing strains, or refrains), expressive of Arian doctrine, often accompanied by taunts and insults to the orthodox. Chrysostom was apprehensive that this music might draw some of the simpler church people to the Arian side; he therefore organized, in opposition to it, under the patronage and at the cost of Eudoxia, the empress of Arcadius (then his friend), a system of nightly processional hymn-singing, with silver crosses, wax-lights and other circumstances of ceremonial pomp. Riots followed, with bloodshed on both sides. This led to the suppression, by an imperial edict, of all public Arian singing.

Melodists.—The controversies and persecutions of the 8th and succeeding centuries turned the thoughts of the "melodists" of the great monasteries of the Studium at Constantinople and St. Saba in Palestine and their followers, and those of the adherents of the Greek rite in Sicily and South Italy (who suffered much from the Saracens and the Normans), into a less picturesque but more strictly theological course; and the influence of those controversies, in which the final success of the cause of "Icons" was largely due to the hymns, as well as to the courage and sufferings, of these confessors, was probably the cause of their supplanting, as they did, the works of the older school.

Among the "melodists" of this latter Greek school there were many saints of the Greek church, several patriarchs and two emperors—Leo the Philosopher, and Constantine Porphyrogenitus, his son. Their greatest poets were Theodore and Joseph of the Studium, and Cosmas and John (called Damascene) of St. Saba. Neale translated into English verse several selected portions, or centoes, from the works of these and others, together with four

selections from earlier works by Anatolius. Some of his translations — particularly "The day is past and over," from Anatolius, and "Christian, dost thou see them," from Andrew of Crete — have been adopted into hymn-books used in many English churches; and the hymn "Art thou weary," which is rather founded upon than translated from one by Stephen the Sabaite, has obtained still more general popularity.

Western Church Hymnody. — It was not till the 4th century that Greek Hymnody was imitated in the West, where its introduction was due to two great lights of the Latin Church — St. Hilary of Poitiers and St. Ambrose of Milan.

Hilary was banished from his see of Poitiers in 356, and was absent from it for about four years, which he spent in Asia Minor, taking part during that time in one of the councils of the Eastern Church. He thus had full opportunity of becoming acquainted with the Greek church music of that day; and he wrote (as St. Jerome, who was thirty years old when Hilary died, and who was well acquainted with his acts and writings, and spent some time in or near his diocese, informs us) a "book of hymns," to one of which Jerome particularly refers, in the preface to the second book of his own commentary on the epistle to the Galatians. Isidore, archbishop of Seville, who presided over the fourth council of Toledo, in his book on the offices of the church, speaks of Hilary as the first Latin hymn-writer; that council itself, in its 13th canon, and the prologue to the Mozarabic hymnary (which is little more than a versification of the canon), associate his name, in this respect, with that of Ambrose.

Of the part taken by Ambrose, not long after Hilary's death, in bringing the use of hymns into the church of Milan, we have a contemporary account from his convert, St. Augustine. Justina, mother of the emperor Valentinian, favoured the Arians, and desired to remove Ambrose from his see. The "devout people," of whom Augustine's mother, Monica, was one, combined to protect him, and kept guard in the church. "Then," says Augustine, "it was first appointed that, after the manner of the Eastern churches, hymns and psalms should be sung, lest the people should grow weary and faint through sorrow; which custom has ever since been retained, and has been followed by almost all congregations in other parts of the world." He describes himself as moved to tears by the sweetness of these "hymns and canticles."

It is not, however, to be assumed that the hymnody thus introduced by Ambrose was from the first used according to the precise order and method of the later Western ritual. To bring it into (substantially) that order and method appears to have been the work of St. Benedict. Walafrid Strabo, the earliest ecclesiastical writer on this subject (who lived at the beginning of the 9th century), says that Benedict, on the constitution of the religious order known by his name (about 530), appointed the Ambrosian hymns to be regularly sung in his offices for the canonical hours. Hence, probably originated the practice of the Italian churches, and of others which followed their example, to sing certain hymns (Ambrosian, or by the early successors of the Ambrosian school) daily throughout the week, at "Vespers," "Lauds" and "Nocturns," and on some days at "Compline" also — varying them with the different ecclesiastical seasons and festivals, commemorations of saints and martyrs and other special offices. The national rituals were probably the "Ambrosian" and the "Mozarabic" (of Spain).

The hymns of which the use was thus established and authorized were those which entered into the daily and other offices of the church, afterwards collected in the "Breviaries"; in which the hymns "proper" for "the week," and for "the season," continued for many centuries, with very few exceptions, to be derived from the earliest epoch of Latin Church poetry — reckoning that epoch as extending from Hilary and Ambrose to the end of the pontificate of Gregory the Great. The "Ambrosian" music, to which those hymns were generally sung down to the time of Gregory, was more popular and congregational than the "Gregorian," which then came into use, and afterwards prevailed.

In the 5th and early in the 6th century the priest Sedulius, whose reputation perhaps exceeded his merit; Elpis, a noble Roman lady (considered, by an erroneous tradition, to have been the wife of the philosophic statesman Boetius); Pope Gelasius I.; and Ennodius, bishop of Pavia, were hymn-writers. Sedulius and Elpis wrote very little from which hymns could be extracted; but the small number taken from their compositions obtained wide popularity, and have since held their ground. Gelasius was of no great account as a hymn-writer; and the works of Ennodius appear to have been known only in Italy and Spain. The latter part of the 6th century produced Pope Gregory the Great and Venantius Fortunatus, an Italian poet, the friend of Gregory, and the favourite of Radegunda, queen of the Franks, who died (609) bishop of Poitiers. Eleven hymns of Gregory, and twelve or thirteen (mostly taken from longer poems) by Fortunatus, came into general use in the Italian, Gallican and British churches, Eleven metrical hymns are attributed to Bede and there are also in one of Bede's works (Collectanea et *flores*) two rhythmical hymns of considerable length on the Day of Judgment, with the refrains "In tremendo die" and "Attende homo," both irregularly rhymed, and, in parts, not unworthy of comparison with the "Dies Irae." Paulinus, patriarch of Aquileia, contemporary with Paul, wrote rhythmical trimeter iambics in a manner peculiar to himself. Theodulph, bishop of Orleans (793–835), author of the famous processional hymn for Palm Sunday in hexameters and pentameters, "Gloria, laus, et honor tibi sit, Rex Christe Redemptor" ("Glory and honour and praise be to Thee, King Christ the Redeemer"), and Hrabanus Maurus, archbishop of Mainz, the pupil of Alcuin, and the most learned theologian of his day, enriched the church with some excellent works.

Sequences. — The invention of "sequences" by Notker (d. 912), may be regarded as the beginning of the later mediaeval epoch of Latin hymnody. In the eucharistic service, in which (as has been stated) hymns were not generally used, it had been the practice, except at certain seasons, to sing "laud," or "Alleluia," between the epistle and the gospel, and to fill up what would otherwise have been a long pause, by extending the cadence upon the two final vowels of the "Alleluia" into a protracted strain of music. It occurred to Notker that, while preserving the spirit of that part of the service, the monotony of the interval might be relieved by introducing at that point a chant of praise specially composed for the purpose. With that view he produced the peculiar species of rhythmical composition which obtained the name of "sequentia" (probably from following after the close of the "Alleluia"), and also that of "prosa," because its structure was originally irregular and unmetrical, resembling in this respect the Greek "troparia," and the "Te Deum," "Benedicite" and canticles. That it was in some measure suggested by the forms of the later Greek hymnody seems probable, both from the intercourse (at that time frequent) between the Eastern and Western churches, and from the application by Ekkehard, in his biography and elsewhere (*e.g.*, in Lyndwood's *Provinciale*), of some technical terms, borrowed from the Greek terminology, to works of Notker and his school and to books containing them.

The "Golden Sequence," "Veni, sancte Spiritus" ("Holy Spirit, Lord of Light"). is an early example of the transition of sequences from a simply rhythmical to a metrical form. Archbishop Trench, who esteemed it "the loveliest of all the hymns in the whole circle of Latin sacred poetry," inclined to give credit to a tradition which ascribes its authorship to Robert II., king of France, son of Hugh Capet. Others have assigned to it a later date — some attributing it to Pope Innocent III., and some to Stephen Langton, archbishop of Canterbury.

Dies Irae and **Stabat** Mater. — But the two most widely celebrated of all this class of compositions — works which have exercised the talents of the greatest musical composers, and of innumerable translators in almost all languages — are the Dies Irae ("That day of wrath, that dreadful day"), by Thomas of Celano, the companion and biographer of St. Francis of Assisi, and the *Stabat Mater* dolorosa ("By the cross sad vigil keeping") of Jacopone, or Jacobus de Benedictus, a Franciscan humorist and reformer, who was persecuted by Pope Boniface VIII. for his satires on the prelacy of the time, and died in 1306. Besides these, the 13th century produced the famous sequence Lauda Sion salvatorem ("Sion lift thy voice and sing"), and the four other

well-known sacramental hymns of St. Thomas Aquinas, viz. *Pange lingua gloriosi corporis mysterium* ("Sing, my tongue, the Saviour's glory"), *Verbum supernum prodiens* ("The Word, descending from above"—not to be confounded with the Ambrosian hymn from which it borrowed the first line), *Sacris solemniis juncta sint gaudia* ("Let us with hearts renewed our grateful homage pay"), and *Adoro Te devote, latens Deitas* ("O Godhead hid, devoutly I adore Thee")—a group of remarkable compositions, written by him for the then new festival of Corpus Christi, of which he induced Pope Urban IV. (1261–1265) to decree the observance.

Before the time of the Reformation, the multiplication of sequences (often as unedifying in matter as unpoetical in style) had done much to degrade the common conception of hymnody. In some parts of France, Portugal, Sardinia and Bohemia, their use in the vernacular language had been allowed. In Germany also there were vernacular sequences as early as the 12th century, specimens of which may be seen in the third chapter of C. Winkworth's *Christian Singers of Germany*. Scoffing parodies upon sequences are said to have been among the means used in Scotland to discredit the old church services. After the 15th century they were discouraged at Rome. They retained for a time some of their old popularity among German Protestants, and were only gradually relinquished in France. A new "prose," in honour of St. Maxentia, is among the compositions of Jean Baptiste Santeul; and Dr. Daniel's second volume closes with one written in 1855 upon the dogma of the Immaculate Conception.

German Hymnody.—Luther was a proficient in and a lover of music. He desired (as he says in the preface to his hymn-book of 1545) that this "beautiful ornament" might "in a right manner serve the great Creator and His Christian people." The persecuted Bohemian or Hussite Church, then settled on the borders of Moravia under the name of "United Brethren," had sent to him, on a mission in 1522, Michael Weiss, who not long afterwards published a number of German translations from old Bohemian hymns (known as those of the "Bohemian Brethren"), with some of his own. These Luther highly approved and recommended. He himself, in 1522, published a small volume of eight hymns, which was enlarged to 63 in 1527, and to 125 in 1545. He had formed what he called a "house choir" of musical friends, to select such old and popular tunes (whether secular or ecclesiastical) as might be found suitable, and to compose new melodies, for church use. His fellow labourers in this field (besides Weiss) were Justus Jonas, his own especial colleague; Paul Eber, the disciple and friend of Melanchthon; John Walther, choirmaster successively to several German princes, and professor of arts, etc., at Wittenberg; Nicholas Decius, who from a monk became a Protestant teacher in Brunswick, and translated the *Gloria in Excelsis*, etc.; and Paul Speratus, chaplain to Duke Albert of Prussia in 1525. Some of their works are still popular in Germany. Weiss's "Funeral Hymn," *Nun lasst uns den Leib begraben* ("Now lay we calmly in the grave"); Eber's *Herr Jesu Christ, wahr Mensch und Gott* ("Lord Jesus Christ, true Man and God"), and *Wenn wir in hochsten Nöthen sein* ("When in the hour of utmost need"); Walther's "New Heavens and new Earth" ("Now fain my joyous heart would sing"); Decius's "To God on high be thanks and praise"; and Speratus's "Salvation now has come for all," are among those which at the time produced the greatest effect, and are still best remembered.

Followers of Luther.—The principal hymn-writers of the Lutheran school, in the latter part of the 16th century, were Nikolaus Selnecker, Herman and Hans Sachs, the shoemaker of Nuremberg, also known in other branches of literature. They were succeeded by men of another sort, to whom F. A. Cunz gives the name of "master-singers," as having raised both the poetical and the musical standard of German hymnody:—Bartholomäus Ringwaldt, Ludwig Helmbold, Johannes Pappus, Martin Schalling, Rutilius and Sigismund Weingartner. The well-known English hymn, "Great God, what do I see ana hear," is founded upon one by Ringwaldt. Of a quite different character were two of great beauty and universal popularity, composed by Philip Nicolai, a Westphalian pastor, dunng a pestilence in 1597, and published by him, with fine chorales, two years afterwards. One of these (the "Sleepers wake! a voice is calling," of Mendelssohn's oratorio, *St. Paul)* belongs to the family of Advent or New Jerusalem hymns. The other, a "Song of the believing soul concerning the Heavenly Bridegroom" *(Wie schon leucht't uns der Morgenstern* —"O morning Star, how fair and bright"), became the favourite marriage hymn of Germany.

The hymns produced during the Thirty Years' War are characteristic of that unhappy time. In point of refinement and graces of style, the hymn-writers of this period excelled their predecessors. Their taste was chiefly formed by the influence of Martin Opitz, the founder of what has been called the "first Silesian school" of German poetry, who died comparatively young in 1639, and who, though not of any great original genius, exercised much power as a critic. Some of the best of these works were by men who wrote little. In the famous battle-song of Gustavus Adolphus, published (1631) after the victory of Breitenfeld, for the use of his army, *Verzage nicht du Häuflein klein* ("Fear not, O little flock, the foe"), we have almost certainly a composition of the hero-king himself, the versification corrected by his chaplain Jakob Fabricius (1593–1654) and the music composed by Michael Altenburg, whose name has been given to the hymn. This, with Luther's paraphrase of the 67th Psalm, was sung by Gustavus and his soldiers before the battle of Lützen in 1632. Two very fine hymns, one of prayer for deliverance and peace, the other of trust in God under calamities, were written about the same time by Matthäus Lowenstern, a saddler's son, poet, musician and statesman, who was ennobled after the peace by the emperor Ferdinand III. Martin Rinckhart, in 1636, wrote the "Chorus of God's faithful children" *(Nun danket alle Gott*—*"Now* thank we all our God"), introduced by Mendelssohn in his *Lobgesang,* which has been called the *Te Deum* of Germany, being usually sung on occasions of public thanksgiving. Weissel, in 1635, composed a beautiful Advent hymn ("Lift up your heads, ye mighty gates"), and J. M. Meyfart, professor of theology at Erfurt, in 1642, a fine adaptation of the ancient *Urbs beata Hierusalem.*

The most copious, and in their day most esteemed, hymn-writers of the first half of the 17th century, were Johann Heermann and Johann Rist. Heermann, a pastor in Silesia, the theatre (in a peculiar degree) of war and persecution, experienced in his own person a very large share of the miseries of the time, and several times narrowly escaped a violent death. His *Devoti musica cordis,* published in 1630, reflects the feelings natural under such circumstances. Next to Heermann and Rist in fertility of production, and above them in poetical genius, was Simon Dach, professor of poetry at Konigsberg, who died in 1659.

Gerhardt.—The fame of all these writers was eclipsed in the latter part of the same century by three of the greatest hymnographers whom Germany has produced—Paul Gerhardt (1607–1676), Johann Franck (1618–1677) and Johann Scheffler (1624–1677), the founder of the "second Silesian school," who assumed the name of "Angelus Silesius." Gerhardt is by universal consent the prince of Lutheran poets. One of his hymns is well known and highly appreciated in English through Wesley's translation, "Commit thou all thy ways"; and the evening and spring-tide hymns ("Now all the woods are sleeping" and "Go forth, my heart, and seek delight") show an exquisite feeling for nature; while nothing can be more tender and pathetic than Du *bist zwar mein und bleibest mein* ("Thou'rt mine, yes, still thou art mine own"), on the death of his son. Franck, who was burgomaster of Guben in Lusatia, has been considered by some second only to Gerhardt. It was after his conversion to Roman Catholicism that Scheffler adopted the name of "Angelus Silesius," and published in 1657 his hymns, under a fantastic title, and with a still more fantastic preface.

The Pietists.—Towards the end of the 17th century, a new religious school arose, to which the name of "Pietists" was given, and of which Philipp Jakob Spener was esteemed the founder. He and his pupils and successors, August Hermann Francke and Anastasius Freylinghausen, all wrote hymns. Spener's hymns are not remarkable, and Francke's are not numerous.

Joachim Neander, a schoolmaster at Diisseldorf, and a friend:

of Spener and Schütz (who died before the full development of the "Pietistic" school), was the first man of eminence in the "Reformed" or Calvinistic Church who imitated Lutheran hymnody. The Summer Hymn ("O Thou true God alone") and that on the glory of God in creation ("Lo, heaven and earth and sea and air") are instances of his best style.

With the "Pietists" may be classed Benjamin Schmolke and Dessler, representatives of the "Orthodox" division of Spener's school; Philipp Friedrich Hiller, their leading poet in South Germany; Gottfried Arnold and Gerhard Tersteegen, who were practically independent of ecclesiastical organization, though connected, one with the "Orthodox" and the other with the "Reformed" churches; and Nikolaus Ludwig, Graf von Zinzendorf. Schmolke, a pastor in Silesia, called the Silesian Rist (1672–1737), was perhaps the most voluminous of all German hymn-writers. He wrote 1,188 religious poems and hymns, a large proportion of which do not rise above mediocrity.

Gellert and **Klopstock.**—The transition from Tersteegen and Zinzendorf to Gellert and Klopstock marks strongly the reaction against Pietism which took place towards the middle of the 18th century The *Geistlichen Oden und Lieder* of Christian F. Gellert were published in 1757, and are said to have been received with an enthusiasm almost like that which "greeted Luther's hymns on their first appearance." It is a proof of the moderation both of the author and of his times that they were largely used, not only by Protestant congregations, but in those German Roman Catholic churches in which vernacular services had been established through the influence of the emperor Joseph II. They became the model which was followed by most succeeding hymn-writers, and exceeded all others in popularity till the close of the century, when a new wave of thought was generated by the movement which produced the French Revolution. Klopstock, the author of the *Messiah,* cannot be considered great as a hymn-writer, though his "Sabbath Hymn" (of which there is a version in *Hymns from the Land of Luther)* is simple and good. Generally his hymns (ten of which are translated in Sheppard's *Foreign Sacred Lyre)* are artificial and much too elaborate.

The "Romantic" School.--Of the "romantic" school, which came in with the French Revolution, the two leading writers are Friedrich Leopold von Hardenberg, called "Novalis," and Friedrich de la Motte Fouqué, the celebrated author of *Undine* and *Sintram*—*both* romance-writers, as well as poets. The genius of Novalis was early lost to the world; he died in 1801, not thirty years old. Some of his hymns are very beautiful; but even in such works as "Though all to Thee were faithless," and "If only He is mine," there is a feeling of insulation and of despondency as to good in the actual world. which was perhaps inseparable from his ecclesiastical idealism. Fouqué survived till 1843.

The later German hymn-writers of the 19th century belong, generally, to the revived "Pietistic" school. Some of the best, Johann Baptist von Albertini, Friedrich Adolf Krummacher, and especially Karl Johann Philipp Spitta (1801–59) have produced works not unworthy of the fame of their nation.

British Hymnody.—After the Reformation, the development of hymnody was retarded, in both parts of Great Britain, by the example and influence of Geneva. Archbishop Cranmer appears at one time to have been disposed to follow Luther's course, and to present to the people, in an English dress, some at least of the hymns of the ancient church. In a letter to King Henry VIII. (Oct. 7. 1544), among some new "processions" which he had himself translated into English, he mentions the Easter hymn, *Salve, festa dies, toto memorabilis aevo* ("Hail, glad day, to be joyfully kept through all generations"), of Fortunatus. In the "Primer" of 1535 (by Marshall) and the one of 1539 (by Bishop Hilsey of Rochester, published by order of the vicar-general Cromwell) there had been several rude English hymns, none of them taken from ancient sources. King Henry's "Primer" of 1545 (commanded by his injunction of May 6, 1545 to be used throughout his dominions) was formed on the model of the daily offices of the Breviary; and it contains English metrical translations from some of the best-known Ambrosian and other early hymns. But in the succeeding reign different views prevailed. A new direction had been given to the taste of the "Reformed" congregations in France and Switzerland by the French metrical translation of the Old Testament Psalms, which appeared about 1540. This was the joint work of Clément Marot, valet or groom of the chamber to Francis I., and Theodore Beza, then a mere youth, fresh from his studies at Orleans.

The translation commonly known as the "Old Version" of the Psalms, was begun by Thomas Sternhold, whose positirn in the household of Henry VIII., and afterwards of Edward VI., was similar to that of Marot with Francis I., and whose services to the former of those kings were rewarded by a substantial legacy under his will. Sternhold published versions of nineteen Psalms, with a dedication to King Edward, and died soon afterwards. A second edition appeared in 1551, with eighteen more Psalms added, of Sternhold's translating and seven others by John Hopkins, a Suffolk clergyman. The work was continued during Queen Mary's reign by British refugees at Geneva, the chief of whom were William Whittingham, afterwards dean of Durham, who succeeded John Knox as minister of the English congregation there, and William Kethe or Keith, said by Strype to have been a Scotsman. They published at Geneva in 1556 a service-book, containing fifty-one English metrical psalms, which number was increased, in later editions, to eighty-seven. On the accession of Queen Elizabeth, this Genevan Psalmody was at once brought into use in England—first (according to a letter of Bishop Jewell to Peter Martyr, dated 5th March 1560) in one London church, from which it quickly spread to others both in London and in other cities. The first edition of the completed "Old Version" appeared in 1562.

In this book, as published in 1562, and for many years afterwards, there were (besides the versified Psalms) eleven metrical versions of the *Te Deum,* canticles, Lord's Prayer (the best of which is that of the *Benedicite);* and also *Da pacem, Domine,* a hymn suitable to the times, rendered into English from Luther; two original hymns of praise, to be sung before morning and evening prayer; two penitential hymns (one of them the "humble lamentation of a sinner"); and a hymn of faith, beginning, "Lord, in Thee is all my trust." In these respects, and also in the tunes which accompanied the words (stated by Dr. Charles Burney. in his *History of Music,* to be German, and not French), there was a departure from the Genevan platform.

Scottish Psalms.—In Scotland, the General Assembly of the kirk caused to be printed at Edinburgh in 1564, and enjoined the use of, a book entitled *The Form of Prayers and Ministry of the Sacraments used in the English Church at Geneva, approved and received by the Church of Scotland; whereto, besides that was in the former books, are also added sundry other prayers, with the whole Psalms of David in English metre.* This contained, from the "Old Version," translations of forty Psalms by Sternhold, fifteen by Whittingham, twenty-six by Kethe and thirty-five by Hopkins. Of the remainder two were by John Pulleyn (one of the Genevan refugees, who became archdeacon of Colchester); six by Robert Pont, Knox's son-in-law, who was a minister of the kirk, and also a lord of session; and fourteen signed with the initials I.C., supposed to be John Craig; one was anonymous, eight were attributed to N., two to M. and one to T. N. respectively.

So matters continued in both churches until the Civil War, During, the interval, King James I. conceived the project of himself making a new version of the Psalms, and appears to have translated thirty-one of them—the correction of which, together with the translation of the rest, he entrusted to Sir William Alexander, afterwards earl of Stirling. Sir William having completed his task, King Charles I. had it examined and approved by several archbishops and bishops of England, Scotland and Ireland, and caused it to be printed in 1631 at the Oxford University Press, as the work of King James; and, by an order under the royal sign manual, recommended its use in all churches of his dominions. In 1634 he enjoined the Privy Council of Scotland not to suffer any other psalms, "of any edition whatever." to be printed in or imported into that kingdom. In 1636 it was republished, and was attached to the famous Scottish service-book, with which the troubles began in **1637.** When the Long Parliament

undertook in 1642, the task of choosing between the rival translations of the Psaims by Rouse and Barton, Rouse's version was chosen and was received in Scotland with great favour, which it has ever since retained. The "New Version" of the Psalms, by Dr. Nicholas Brady and the poet-laureate Nahum Tate (both Irishmen), appeared in 1696, under the sanction of an order in council of William III. The relative merits of the "Old" and "New" versions have been very variously estimated. Competent judges have given the old the praise, which certainly cannot be accorded to the new, of fidelity to the Hebrew.

Wither, **Cosin,** Milton and Taylor. — Conspicuous among the sacred poets of the first two Stuart reigns in England was George Wither. His *Hymnes and Songs of the Church* appeared in 1622–1623, under a patent of King James I., by which they were declared "worthy and profitable to be inserted, in convenient manner and due place, into every English Psalm-book to metre." His *Hallelujah* (in which some of the former *Hymnes and Songs* were repeated) followed in 1641. John Cosin, afterwards bishop of Durham, published in 1627 a volume of "Private Devotions," for the canonical hours and other occasions. The hymns of Milton (on the Nativity, Passion, Circumcision and "at a Solemn Music"), written about 1629, in his early manhood, were probably not intended for singing. During the Commonwealth, in 1654, Jeremy Taylor published at the end of his *Golden Grove,* twenty-one hymns.

Restoration Period. — The epoch of the Restoration produced in 1664 Samuel Crossman's *Young Man's Calling,* with a few "Divine Meditations" in verse attached to it; in 1668 John Austin's *Devotions* in *the ancient way of offices, with psalms, hymns and prayers for every day in the week and every holyday in the year;* and in 1681 Richard Baxter's *Poetical Fragments.* In these books there are altogether seven or eight hymns, the whole or parts of which are extremely good.

Dryden, Ken, Patrick and Addison. — Dryden's translation of "Veni Creator" a cold and laboured performance, is to be met with in many hymn-books. Abridgments of Ken's morning and evening hymns are in all. These, with the midnight hymn, which is not inferior to them, first appeared in 1697, appended to the third edition of the author's *Manual of Prayers for Winchester Scholars.* Bishop Patrick's hymns were chiefly translations from the Latin, most of them from Prudentius. The best is a version of *Alleluia dulce carmen.*

Of the five attributed to Addison, not more than three are adapted to public singing; one ("The spacious firmament on high") is a perfect and finished composition, taking rank among the best hymns in the English language.

From the preface to Simon Browne's hymns, published in 1720, we learn that down to the time of Dr. Watts the only hymns known to be "in common use, either in private families or in Christian assemblies," were those of Barton, Mason and Shepherd, together with "an attempt to turn some of George Herbert's poems into common metre," and a few sacramental hymns by authors now forgotten, named Joseph Boyse (1660–1728) and Joseph Stennett. Of the 1,410 authors of original British hymns enumerated in Daniel Sedgwick's catalogue, published in 1863, 1.213 are of later date than 1707; and, if any correct enumeration could be made of the total number of hymns of all kinds published in Great Britain before and after that date, the proportion subsequent to 1707 would be very much larger.

The English Independents, as represented by Dr. Isaac Watts, have a just claim to be considered the real founders of modern English hymnody. Watts was the first to understand the nature of the want, and, by the publication of his *Hymns* in 1707–1709, and *Psalms* (not translations, but hymns founded on psalms) in 1709, he led the way in providing for it. His immediate followers were Simon Browne and Philip Doddridpe. Later in the 18th century, Joseph Hart, Thomas Gibbons, Miss Anne Steele, Samuel Medley, Samuel Stennett, John Ryland, Benjamin Beddome and Joseph Swain succeeded to them.

Isaac Watts. — Among these writers, most of whom produced some hymns of merit, and several are extremely voluminous, Isaac Watts and Philip Doddridge are pre-eminent.

Of the other followers in the school of Watts, Miss Anne Steele (1717–1778) is the most popular and perhaps the best. The influence of Watts was felt in Scotland, and among the first whom it reached there was Ralph Erskine. This seems to have been after the publication of Erskine's *Gospel Sonnets* which appeared in 1732, five years before he joined his brother Ebenezer in the Secession Church. The *Gospel Sonnets* became as some have said, a "people's classic"; but there is in them very little which belongs to the category of hymnody.

Scottish Paraphrases and Methodist Hymns. — Of the contributions to the authorized "Paraphrases" (with the settlement of which committees of the General Assembly of the Church of Scotland were occupied from 1745, or earlier, till 1781), the most noteworthy, besides the two already mentioned, were those of John Morrison and those claimed for Michael Bruce. The obligations of these "Paraphrases" to English hymnody, already traced in some instances (to which may be added the adoption from Addison of three out of the five "hymns" appended to them), are perceptible in the vividness and force with which these writers, while adhering with a severe simplicity to the sense of the passages of Scripture which they undertook to render, fulfilled the conception of a good original hymn. The "Methodist" movement. which began about 1738, afterwards became divided, between those who esteemed Arminian, under John Wesley, those who adhered to the Moravians, when the original alliance between that body and the founders of Methodism was dissolved, and the Calvinists, of whom Whitfield was the leader, and Selina, countess of Huntingdon, the patroness. Each of these sections had its own hymn-writers, some of whom did, and others did not, secede from the Church of England. The Wesleyans had Charles Wesley, Robert Seagrave and Thomas Olivers; the Moravians, John Cennick, with whom, perhaps, may be classed John Byrom, who imbibed the mystical ideas of some of the German schools; the Calvinists, Augustus hfontague Toplady, John Berridge, William Williams, Martin Madan, Thomas Haweis, Rowland Hill, John Newton and William Cowper.

Among all these writers, the palm undoubtedly belongs to Charles Wesley. In the first volume of hymns published by the two brothers are several good translations from the German, believed to be by John Wesley, who, although he translated and adapted, is not supposed to have written any original hymns; and the influence of German hymnody, particularly of the works of Paul Gerhardt, Scheffler, Tersteegen and Zinzendorf, may be traced in a large proportion of Charles Wesley's works.

The Moravian Methodists produced few hymns now available for general use. The best are Cennick's "Children of the heavenly King" and Hammond's "Awake and sing the song of Moses and the Lamb," the former of which (abridged), and the latter as varied by Madan, are found in many hymn-books, and are deservedly esteemed. John Byrom, whose name we have thought it convenient to connect with these, was the author of a Christmas hymn ("Christians awake, salute the happy morn") which enjoys great popularity.

The contributions of the Calvinistic Methodists to English hymnody are of greater extent and value. Few writers of hymns had higher gifts than Toplady, author of "Rock of ages," by some esteemed the finest in the English language.

Berridge, William Williams (1717–1791) and Rowland Hill, all men remarkable for eccentricity, activity and the devotion of their lives to the special work of missionary preaching, though not the authors of many good hymns, composed, or adapted from earlier compositions, some of great merit.

Cowper and Newton. — If, however, the number as well as the quality of good hymns available for general use is to be regarded, the authors of the *Olney Hymns* are entitled to be placed at the head of all the writers of this Calvinistic school. The greater number of the *Olney Hymns* are, no doubt, homely and didactic; but to the best of them, and they are no inconsiderable proportion, the tenderness of Cowper and the manliness of John Newton (1725–1807) give the interest of contrast, as well as that of sustained reality. *The Remains of Henry Kirke White,* published by Southey in 1807, contained a series of hymns, some of which are

still in use; and a few of Bishop Heber's hymns and those of Sir Robert Grant, which, though offending rather too much against John Newton's canon, are well known and popular, appeared between 1811 and 1816, in the *Christian Observer.* In John Bowdler's *Remains,* published soon after his death in 181j, there are a few more of the same, perhaps too scholarlike, character. But the chief hymn-writers of that period were two clergymen of the Established Church—one in Ireland, Thomas Kelly, and the other in England, William Hurn—who both became Nonconformists, and the Moravian poet, James Montgomery (1771–1854), a native of Scotland.

Collections of Hymns.—During this period, the collections of miscellaneous hymns for congregational use, of which the example was set by the Wesleys, Whitfield, Toplady and Lady Huntingdon, had greatly multiplied; and with them the practice (for mhich, indeed, too many precedents existed in the history of Latin and German hymnody) of every collector altering the compositions of other men without scruple, to suit his own doctrine or taste; with the effect, too generally, of patching and disfiguring, spoiling and emasculating the works so altered, substituting neutral tints for natural colouring, and a dead for a living sense. In the Church of England the use of these collections had become frequent in churches and chapels, principally in cities and towns, where the sentiments of the clergy approximated to those of the Nonconformists.

Two publications, which appeared almost simultaneously in 1827—Bishop Heber's *Hymns,* with a few added by Dean Milman. and John Keble's *Christian* Year—introduced a new epoch, breaking down the barrier as to hymnody which had till then existed between the different theological schools of the Church of England. In this movement Richard Mant, bishop of Down, was also one of the first to co-operate. It soon received a great additional impulse from the increased attention which, about the same time, began to be paid to ancient hymnody, and from the publication in 1833 of Bunsen's *Gesangbuch.* Among its earliest fruits was the Lyra *apostolica,* containing hymns, sonnets and other devotional poems, most of them originally contributed by some of the leading authors of the *Tracts for the Times* to the *British Magazine;* the finest of mhich is the pathetic "Lead, kindly light, amid th' encircling gloom." by Cardinal Kewman—well known, and universally admired. From that time hymns and hymn-writers rapidly multiplied in the Church of England, and in Scotland also. Works, critical and historical, upon the subject of hymns, also multiplied; and collections for church use have become innumerable—several of the various religious denominations. and many of the leading ecclesiastical and religious societies, having issued hymn-books of their onn, in addition to those compiled for particular dioceses, churches and chapels, and to books (like *Hymns Ancient and Modern,* published 1861, supplemented 1889, revised edition, 1905) which have become popular uithout any sanction from authority. Among the best known American hymn-writers are John Greenleaf Whittier, Bishop Doane, Dr. W. 4. Muhlenberg and Thomas Hastings; and it is difficult to praise too highly such works as the Christmas hymn. "It came upon the midnight clear," by Edmund H. Sears: the Ascension hymn, "Thou, who didst stoop below," by Mrs. S. E. Miles; two by Dr. Ray Palmer, "My faith looks up to Thee, Thou Lamb of Calvary," and "Jesus, Thou joy of loving hearts," the latter of which is the best among several good English versions of *Jesu, dulcedo, cordium;* and "Lord of all being, throned afar." by Oliver Wendell Holmes.

The more modern "Moody and Sankey" hymns *(see* MOODY, DWIGHT LYMAN) popularized a new Evangelical type, and the Salvation Army has carried this still farther.

The object aimed at in this article has been to trace the general history of the principal schools of ancient and modern hymnody, and especially the history of its use in the Christian church. For this purpose it has not been thought necessary to give any account of the hymns of Racine, Madame Guyon and others, who can hardly be classed with any school, nor of the works of Caesar Malan of Geneva (1787–1864) and other hymn-writers of the Reformed churches in Switzerland and France.

HYNDMAN, HENRY MAYERS (1842–1921). founder of British socialism, was born in London on March 7, 1842. the son of a wealthy man. He was educated at Trinity college, Cambridge and traveled extensively. He was deeply influenced by the Paris Commune and in 1881 joined with several extreme radicals in forming the London Democratic federation which advocated views which were practically socialist. For its first conference (June 1881) he wrote *England for All,* the first socialist book published in England since the collapse of Owenism. In this he expounded the views of Karl Marx, which he now finally adopted. But as he omitted to make what Marx ,felt was the necessary acknowledgment of his indebtedness, Marx was offended and Engels. who disliked Hyndman, deliberately widened the breach. The chief. and indeed only exponent of Marxism in the country where Marx lived was thus not on speaking terms with his leader. This, however, did not stop the spread of Marxist socialism. The

Democratic federation in 1884 became the Social Democratic federation (S.D.F.) and nearly all the prominent socialists of the new generation, except J. Keir Hardie, were molded by Hyndman. William Morris, John Burns, Tom Mann, H. H. Champion, George Lansbury and Harry Quelch were among his colleagues and pupils. But it was significant of Hyndman's failings that of these named above only one succeeded in working with him for any long space of time. Hyndman remained always an aristocrat among the Socialists. He was proud and dominant in his manners, intellectually intolerant, and resentful of criticism or disagreement. Even when distributing leaflets announcing meetings he always wore a top hat and frock-coat, and he frequently in Trafalgar square or elsewhere, taunted his ragged audiences with being such fools as to provide the money on which such as he could dress so well. But the qualities of his defects were also present—his indomitable energy which enabled him to create a Socialist movement almost from the void, his self sacrifice and patience, and his uprightness and hatred of compromise and of loose thinking. In the late 1880s the Socialist and unemployed movement blew suddenly up to an enormous size; the riots in Trafalgar square mere succeeded by the famous dock strike (1889); and for a short while public opinion, hostile or friendly, magnified the importance of the S.D.F. and its leader, whom it credited with the control and inspiration of these occurrences. With the return of better trade in the 1890s the explosive period of Hyndman's career ended, though he incurred plenty of hostility by his denunciation of the Boer War.

Hyndman was severely critical of the policy of both the Independent Labour party and the Labour party, and till 1914 was the acknowledged chief of a small, but hard working and influential party of doctrinaire revolutionaries. But on the outbreak of World War I, to the surprise of his followers, he became a strong nationalist, and later on equally vehement anti-Bolshevik. For the first time he was unable to carry his party with him: in 1915 the British Socialist party (as it had become) ousted him and his sympathizers from control. They formed a small group known as the National Socialist party. He expounded his new views in *The* Evolution of Revolution (1920). Hyndman died on Nov. 22, 1921.

HYOGO, a former town of Japan in the prefecture of Hyogo, on the western shore of the bay of Osaka, 21 mi. W. of Osaka. Pop. (1955) 211,414. The town is now incorporated in Kobe (*q.v.*) Hyogo has several temples of interest, one of which has near it a huge bronze statue of Buddha, while by the Minatogawa, which flows into the sea between Hyogo and Kobe, a temple commemorates the spot where Kusunoki Masashige, the mirror of Japanese loyalty, met his death in battle in 1336. The temple of Ikuta was, according to tradition, erected on the site of the ancient fane built by Jingo on her return from Korea in the 3rd century.

MYOSCINE: see SCOPOLAMINE.

HYOSCYAMINE, the chief alkaloid occurring in the leaves and tops of henbane, deadly nightshade (belladonna) and Jimson weed. It is a powerful poison and the major natural source of atropine, its racemic form (see STEREOCHEMISTRY). Hyoscyamine occurs in the plant sources almost entirely as the levorotatory form l-hyoscyamine, which is converted to atropine, containing both levorotatory (l) and dextrorotatory (d) molecules, during the process of extraction or by the action of dilute alkali. The d-isomer does not exist free in nature. In its action on nerve endings, l-hyoscyamine is about twice as potent as atropine, the *d*-isomer being almost inactive; the two isomers, however, exert almost equal effects on the brain and spinal cord. Thus *l*-hyoscyamine is almost entirely responsible for the peripheral actions of atropine, but the two isomers contribute equally to the action on the central nervous system. The difference in potency between d- and l-hyoscyamine is attributed to differences in their rates of chemical breakdown in the body, as well as to differences in their ability to reach the sites in the body where they exert their effects.

See also ALKALOIDS; ATROPINE; HENBANE. (V. E.)

HYPAETHRUS, an architectural term used by Vitruvius for an opening in the roof to admit light. Alternative forms are hypaethros and hypaethrum. Many students of Greek temples, especially James Fergusson and T. J. Hittorff, basing their conclusions upon the Vitruvian reference to such a hypaethrus in the temple of Zeus Olympius at Athens, and upon coping tiles found in the temple at Aegina, have concluded that all Greek temples had some such method of admitting light. Moreover, late Greek tombs at Cyrene and Alexandria show raised copings in the centre of the roof as if for such an opening. And according to Strabo (c. 50 B.C.), the temple of Apollo Didymaeus at Miletus (second half of 4th century B.C.) had its entire vast cella open to the sky and planted with groves of laurel. Pausanias, however, states that this temple was never completed; if this is so a roof may have been planned originally.

Modern consensus is counter to the idea that the hypaethrus was a common feature. No arrangements for drainage have been found in connection with Greek temples, and the very reference of Vitruvius on which the speculations of Fergusson, Hittorff and others are based seems to point to the arrangement as exceptional enough to warrant mention, and used only in the largest buildings. Thus the ordinary temple would be lighted only by the enormous doorway; certainly light thus obtained would furnish a more beautiful and impressive illumination than any direct glare from above. (T. F. H.)

HYPATIA (d. A.D. 415), who was a typical representative of Alexandrian Neoplatonism (*q.v.*), was the daughter of Theon of Alexandria, a writer on mathematics from whom she seems to have derived an interest in the subject. She is said to have occupied the chair of Platonic philosophy at Alexandria and to have lectured on Plato, Aristotle and other philosophers. Her most notable pupil was Synesius of Cyrene, who became bishop of Ptolemaïs *c.* 411 and whose affectionate and admiring letters to her are the main source of information about her personality. This close friendship between the pagan Neoplatonist teacher and the Christian Neoplatonist pupil illustrates one aspect of the complex relationship between Christians and pagans at Alexandria under the Christian Roman empire, the close and fruitful contact, so important for later developments, of Christianity with pagan philosophy.

Hypatia's cruel murder in 415, by a Christian mob in the course of a characteristic Alexandrian riot, shows another. The notice of Hypatia in Suidas gives the titles of several of her works. all now lost. They are mathematical and astronomical commentaries: the existence of any strictly philosophical works is not known. Available information about her suggests that her philosophy was the embodiment of Alexandrian Neoplatonism, which was more scholarly and more scientific in its interests, less given to metaphysical elaboration and less intransigently pagan than the Athenian school. whose greatest philosopher was Proclus.

See F. Ueberweg, ed. by K Praechter, *Die Philosophie* des *Altertums (1926)*; also K. Praechter, "Hypatia," in Pauly-Wissowa, *Real Encyclopädie der classichen Altertumswissenschaft,* vol. ix (1914). Charles Kingsley's historical romance *Hypatia* (1853) is to be recommended rather as an illustration of the mentality of the author and his period than as a source of reliable information about Hypatia and 5th-century Alexandria. (A. H. AG.)

HYPERBOLA. This geometric. two-branched curve is a conic section (*q.v.*) obtained by the intersection of any circular cone with a plane cutting both nappes of the surface (fig. 1). It may be defined as the locus of a point whose distances from two fixed points F and *F′*, the foci, have a constant difference. This difference is equal to segment *2a* (fig. 2), which is the transverse axis cutting the hyperbola.

Let *O* be the midpoint of the focal segment FF'. The points *A*, *A′* defined by the relation:

$$OA = OA' = a$$

lie on the curve, for

$$AF' - AF = AF' - A'F' = AA' = 2a,$$

and similarly for *A′*. The points *A*, *A′*, called the vertices of the curve, lie inside the focal segment FF' = $2c$; for, if M is any point of the curve, we have in the triangle MFF':

$$2c = FF' > (MF - MF') = 2a.$$

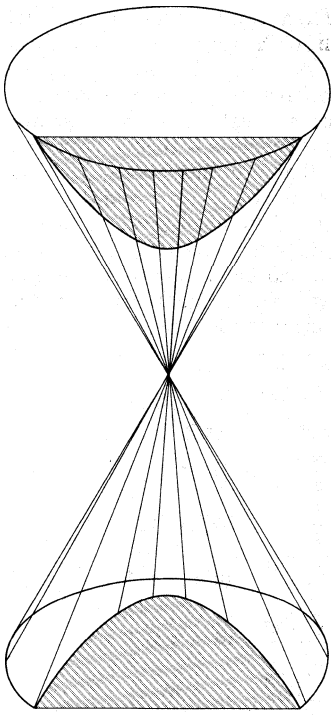

FIG 1.—THE HYPERBOLA AS A CONIC SECTION

Let L be any point on the line FF', outside the segment FF'. The two circles (F, LA), (F', LA') centred at F, F and having for radii LA, LA', respectively, intersect in two points, P, P', belonging to the curve, since

$$PF' - PF = P'F' - P'F = LA' - LA = AA' = 2a.$$

The points of intersection Q, Q' of the circles (F, LA'), (F', LA) are another pair of points of the curve From this construction by points the following properties of the hyperbola are derived: The two infinite branches have no point in common. The line FF' (fig. 2) lies on an axis of symmetry, the transverse (real) axis. The point O is a centre of symmetry and the perpendicular to FF' at O is another axis of symmetry, the conjugate axis, which does not cut the curve, since the difference of the distances of any of its points from the foci is equal to zero. More generally if a point S lies inside either of the two branches of the hyperbola, then $SF - SF' > 2a$; if S lies between the two branches, then $SF - SF' < 2a$.

If the tno axes of symmetry of the hyperbola are taken as co-ordinate axes, the co-ordinates of the foci F and F are, respectively, $(-c, 0)$ and $(c, 0)$. If $M(x, y)$ is a point on the curve, the definition of the curve given above may be translated into the equation:

$$\sqrt{(x-c)^2 + y^2} - \sqrt{(x+c)^2 + y^2} = 2a,$$

which, after simplification, becomes the standard equation of the hyperbola:

$$(1) \qquad x^2/a^2 - y^2/b^2 = 1,$$

where $b^2 = c^2 - a^2$; and, by analogy with the case of the ellipse (*q.v.*); $2b$ is taken as the length of the conjugate axis of the hyperbola.

Two tangents may be drawn from the centre O to the curve. The chord of contact of these two tangents is the line at infinity; in other words, the points of contact of these tangents recede indefinitely. and the tangents are thus the asymptotes of the curve. The equations of the asymptotes are

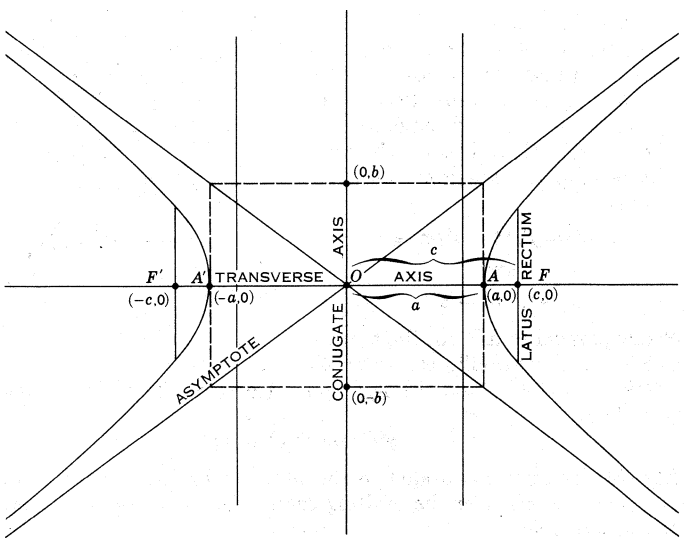

FIG. 2.—GRAPH OF THE HYPERBOLA

$$(2) \qquad ay + bx = 0; \quad ay - bx = 0.$$

The equation

$$y^2/b^2 - x^2/a^2 = 1$$

represents the *conjugate* hyperbola of the one considered, and vice versa. Conjugate hyperbolas are so related that the transverse axis of one is the conjugate axis of the other, and they have common asymptotes.

The tangent to the hyperbola at a point M is the bisector of the external angle formed by the focal radii MF, MF' of the point of contact M. The chord through a focus and perpendicular to the transverse axis is called the *latus rectum*.

The locus of the symmetric of a focus F of the hyperbola with respect to the tangents of the curve is the circle $(F', 2a)$, centred at the other focus F and having for radius the length $2a$ of the transverse axis. The asymptotes of the hyperbola are the perpendiculars dropped from the centre O upon the tangents drawn from the focus F to the circle $(F', 2a)$, or vice versa, from F' to the circle $(F, 2a)$.

The locus of points from which pairs of mutually perpendicular tangents may be drawn to the hyperbola is a circle whose centre coincides with the centre of the hyperbola and the square of whose radius is equal to $a^2 - b^2$.

In equation (1) above, if $b = a$ then that equation becomes

$$x^2 - y^2 = a^2,$$

and the hyperbola is said to be equilateral. with major and minor axes equal. The equations (2) above become $y - x = 0$, $y + x = 0$, showing that the asymptotes of an equilateral hyperbola are perpendicular to each other. If those asymptotes are taken for co-ordinate axes, the equation of the curve takes on the form $xy = k$, k being a constant. Since this equation shows that x and y are inversely proportional, the equilateral hyperbola may be said to be the graph of two inversely proportional variable quantities. *See* also CONIC SECTION; ANALYTIC GEOMETRY; ELLIPSE; PARABOLA; PROJECTIVE GEOMETRY. (N. A. CT.)

HYPERBOLE (Gr. *hyper,* "over", and *ballein,* "to throw"; hence. "in excess"), a figure of speech exaggerating the qualities or importance of a thing or person, used in satire and serious eulogy. Shakespeare's Cleopatra, lamenting Anthony's death, declares. "His legs bestrid the ocean . . ." See FIGURES OF SPEECH: *Figures of Degree of Emphasis.* (G. W. A.)

HYPERBOLIC FUNCTIONS, six functions related to the equilateral hyperbola in a manner analogous to the relation of the trigonometric functions to the circle, as explained later in this article. Two are usually defined by means of the exponential function e^x as follows:

$$\sinh x = \frac{e^x - e^{-x}}{2},$$

$$\cosh x = \frac{e^x + e^{-x}}{2}.$$

The number e is the base of natural logarithms (*2.71828 . . .*). The remaining four functions are defined in terms of sinh x (read "hyperbolic sine of x") and cosh x so that relations analogous to those for the trigonometric functions are obtained. The definitions are:

$$\tanh x = \frac{\sinh x}{\cosh x} = \frac{e^x - e^{-x}}{e^x + e^{-x}},$$

$$\operatorname{ctnh} x = \frac{1}{\tanh x} = \frac{e^x + e^{-x}}{e^x - e^{-x}} \qquad (x \neq 0);$$

$$\operatorname{sech} x = \frac{1}{\cosh x} = \frac{2}{e^x + e^{-x}};$$

$$\operatorname{csch} x = \frac{1}{\sinh x} = \frac{2}{e^x - e^{-x}} \qquad (x \neq 0).$$

The fact that ctnh x and csch x are undefined for $x = 0$ is indicated to the right of their definitions.

Of the six functions, two, cosh x and sech x, are even and the other four are odd. These properties of the functions are ex-

pressed by the equations:

$$\sinh(-x) = -\sinh x;$$
$$\cosh(-x) = \cosh x;$$
$$\tanh(-x) = -\tanh x;$$

and the three that are obtained from these when the reciprocals of the members are taken. Four of the functions have simple values when the argument is zero:

$$\sinh 0 = \tanh 0 = 0, \cosh 0 = \operatorname{sech} 0 = 1.$$

In addition to these relations there are three fundamental identities involving the squares of the functions, viz.,

$$\cosh^2 x - \sinh^2 x = 1;$$
$$1 - \tanh^2 x = \operatorname{sech}^2 x;$$
$$\operatorname{ctnh}^2 x - 1 = \operatorname{csch}^2 x;$$

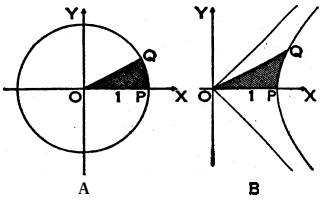
and three important addition formulas:

$$\sinh(x \pm y) = \sinh x \cosh y \pm \cosh x \sinh y;$$
$$\cosh(x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y;$$
$$\tanh(x \pm y) = \frac{\tanh x \pm \tanh y}{1 \pm \tanh x \tanh y}.$$

From these basic identities many others are readily derivable. They all bear the same striking resemblance to trigonometric identities. This is a consequence of the fact that all identities in the trigonometric and hyperbolic functions are valid when the variables are complex and in the domain of complex numbers the functions are related as follows:

$$\sin ix = i \sinh x;$$
$$\cos ix = \cosh x;$$
$$\tan ix = i \tanh x;$$
$$\operatorname{ctn} ix = -i \operatorname{ctnh} x;$$
$$\sec ix = \operatorname{sech} x;$$
$$\csc ix = -i \operatorname{csch} x$$

If in any trigonometric identity the variables x, y, . . . are replaced by ix, iy, . . . , respectively, and substitutions are then made from these equations between the two sets of functions, the trigonometric identity is transformed into an identity for hyperbolic functions. In like manner a hyperbolic identity is transformed into an identity for trigonometric functions by the six relations that are obtained from the above six when sin and sinh, cos and cosh, etc., are interchanged. Corresponding formulas may have different signs in some of the terms because of the occurrence of i^2 which is -1.



ILLUSTRATIONS OF THE PARAMETRIC EQUATIONS OF THE CIRCLE (A) AND THE EQUILATERAL HYPERBOLA (B). *See* TEXT FOR FURTHER EXPLANATION

Trigonometric and hyperbolic functions of complex numbers may be evaluated by means of the addition formulas and the relations between the hyperbolic and trigonometric functions. For example:

$$\sin(a+bi) = \sin a \cosh b + i \cos a \sinh b;$$
$$\cos(a+bi) = \cos a \cosh b - i \sin a \sinh b;$$
$$\sinh(a+bi) = \sinh a \cos b + i \cosh a \sin b;$$
$$\cosh(a+bi) = \cosh a \cos b + i \sinh a \sin b.$$

The quantities in the right members are obtainable from tables for the trigonometric functions and from similar tables for the hyperbolic functions. Another interesting consequence of the relation between the two sets of functions is that, although the hyperbolic functions have no real period, they are nevertheless periodic with an imaginary period πi for tanh x and ctnh x, and $2\pi i$ for the other four functions.

The inverse hyperbolic sine of x is written $\sinh^{-1}$ x. It is defined in the usual manner as the function for which $\sinh(\sinh^{-1} x) = x$ is an identity in x. In the domain of reals, the inverse exists as a continuous, real, single-valued function for all real values of its argument. There are two continuous, real, single-valued functions for which $\cosh(\cosh^{-1} x) = x$ is an identity in x. One is positive-valued and the other negative. It is customary to denote the positive-valued inverse function by $\cosh^{-1} x$, which is defined for all real values of x greater than or equal to 1. The other inverse function is then $-\cosh^{-1}$ x. Likewise sech x has two inverses that are continuous, real and single-valued; the positive one is denoted by $\operatorname{sech}^{-1} x$ and the negative one by $-\operatorname{sech}^{-1}$ x. Both are defined on the interval $0 < x < 1$. Each of the remaining three functions has one continuous, real, single-valued inverse defined on the real domain that is indicated at the right in the equations below. These equations relate the inverse hyperbolic functions to the logarithmic function.

$$\sinh^{-1} x = \ln(x + \sqrt{x^2+1});$$
$$\cosh^{-1} x = \ln(x + \sqrt{x^2-1}) \quad (x \geqq 1);$$
$$-\cosh^{-1} x = \ln(x - \sqrt{x^2-1}) \quad (x \geqq 1);$$
$$\tanh^{-1} x = \tfrac{1}{2} \ln \frac{1+x}{1-x} \quad (|x| < 1);$$
$$\operatorname{ctnh}^{-1} x = \tfrac{1}{2} \ln \frac{x+1}{x-1} \quad (|x| > 1);$$
$$\operatorname{sech}^{-1} x = \ln \frac{1+\sqrt{1-x^2}}{x} \quad (0 < x \leqq 1);$$
$$-\operatorname{sech}^{-1} x = \ln \frac{1-\sqrt{1-x^2}}{x} \quad (0 < x \leqq 1);$$
$$\operatorname{csch}^{-1} x = \ln \frac{1+\sqrt{1+x^2}}{x} \quad (x > 0);$$
$$\operatorname{csch}^{-1} x = \ln \frac{1-\sqrt{1+x^2}}{x} \quad (x < 0).$$

For complex values of x the inverse hyperbolic functions have infinitely many complex values.

Parametric equations for the circle $x^2 + y^2 = a^2$ are $x = a \cos u$, $y = a \sin u$. Likewise, parametric equations for the equilateral hyperbola $x^2 - y^2 = a^2$ are $x = a \cosh u$, $y = a \sinh u$. When $a = 1$ the variable u has, for the circle, three possible geometric interpretations. The usual one is the angle POQ in figure **(A).**

It may also be taken as the length of the arc PQ and as twice the area of the sector POQP in the same figure. The latter is the trigonometric analogue of the geometric interpretation of u in the parametric equations for an equilateral hyperbola $x^2 - y^2 = 1$. For the hyperbola, u in $x = \cosh u$, $y = \sinh u$ is twice the area of the sector POQP, see figure (B). The formulas for the derivatives, integrals and power series expansions of the hyperbolic functions are obtainable from standard mathematical tables. See also TRIGONOMETRY: Trigonometric Functions. (R. W. BD.)

HYPERBOLOID, in geometry, either of two open centric surfaces of the second degree (conicoids, quadrics). The general equation of such centrics takes the form

$$Ax^2 + By^2 + Cz^2 = 1,$$

where A, B, C may have four orders of signs: $+\ +\ +$ (ellipsoid) and $-\ -\ -$ (a nowhere ellipsoid, with no real points); the other two, $+\ +\ -$ and $+\ -\ -$, yield hyperboloids of one sheet or two sheets. The central rectangular equations may be written

$$x^2/a^2 + y^2/b^2 - z^2/c^2 = 1$$

and

$$x^2/a^2 - y^2/b^2 - z^2/c^2 = 1.$$

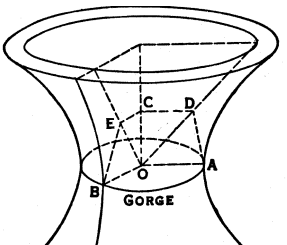


FIG. 1

Planes parallel to XY cut the hyperboloid in similar ellipses, $x^2/a^2 + y^2/b^2 = z^2/c^2 + 1$, and the hyperboloid of two sheets in similar hyperbolas

$$x^2/a^2 - y^2/b^2 = z^2/c^2 + 1;$$

likewise for sections parallel to the other co-ordinate planes. It is simplest to consider the limiting cases, when $a = b = c$. Then the hyperboloid

$$x^2 + y^2 - z^2 = a^2$$

is plainly the "revolute" of the rectangular hyperbola $x^2 - z^2 = a^2$ rotated round the Z-axis, each point (x, z) tracing a circle $x^2 + y^2 = a^2 + z^2$. For $z = 0$, $x^2 + y^2 = a^2$ becomes the minimal circle. The general surface (fig. 1) is found, as in the ellipsoid (*q.v.*), by compression (or expansion) of ally's and *z's* in the ratios b/a and c/a respectively, which yields

$$x^2/a^2 + y^2/b^2 - z^2/c^2 = 1.$$

The "revolute" has as tangent at ∞ the central cone $x^2 + y^2 - z^2 = 0$, which remains tangential in the form

$$x^2/a^2 + y^2/b^2 - z^2/c^2 = 0,$$

after the affine transformation. Rotating the same hyperbola $x^2 - z^2 = a^2$ around X yields the conoid $x^2 - y^2 - z^2 = a^2$, whose asymptotic cone is $x^2 - y^2 - z^2 = 0$. On compression (or expansion) parallel to Y or Z in the ratio b/a, c/a respectively, there results the general hyperboloid of two sheets

$$x^2/a^2 - y^2/b^2 - z^2/c^2 = 1,$$

with its asymptotic cone $x^2/a^2 - y^2/b^2 - z^2/c^2 = 0$ (fig. 2).

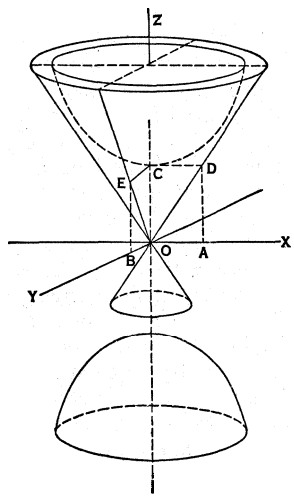

FIG. 2

Surfaces of the second degree are all ruled; *i.e.*, traceable by a right line moving in a definite way. For, combining the two equations of a line and the one of such a surface, we may eliminate two co-ordinates and obtain a resultant equation in one co-ordinate, and this equation, which is of the second degree, vanishes identically when its three coefficients reduce each to 0; and since the equations of the line have four parameters, this reduction is possible in an ∞ of ways; hence, there are ∞ many lines lying on a conicoid, like line elements forming a cone. In the ellipsoid and the hyperboloid of two sheets these lines are imaginary, but in the hyperboloid of one sheet they are real, forming two systems, each line of each system meeting all lines of the other system but none of its own (fig. 3).

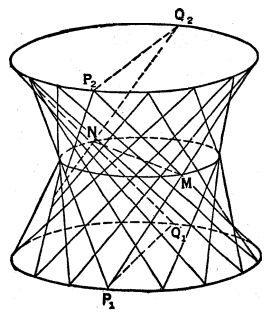

FIG. 3

See MATHEMATICAL MODELS.

HYPERBOREANS, a mythical people intimately connected with the worship of Apollo. Their names do not occur in Homer, but Herodotus (iv, 32) states that they were mentioned in Hesiod and in the Epigoni, an epic of the Theban cycle. According to Herodotus, two maidens, Opis and Arge, and later two others, Hyperoche and Laodice, escorted by five men. called by the Delians Perpherees, were sent by the Hyperboreans with certain offerings to Delos. Finding that their messengers did not return, the Hyperboreans adopted the plan of wrapping the offerings in wheat straw and requested their neighbours to hand them on to the next nation, and so on until they finally reached Delos. The likeliest explanation of their name is "those who carry over." The home of the Hyperboreans was placed in a paradisiacal region beyond the north wind. The duration of their life was 1,000 years, but if any desired to shorten it, he decked himself with garlands and threw himself from a rock into the sea. The close connection of the Hyperboreans with the cult of Apollo may be seen by comparing the Hyperborean myths, the characters of which by their names mostly recall Apollo or Artemis (Agyieus, Opis, Hecaergos, Loxo), with the ceremonial of the Apolline worship.

HYPEREIDES (*c.* 390–322 B.C.), one of the ten Attic orators, was the son of Glaucippus, of the deme of Collytus. He belonged to a wealthy family, was probably a pupil of Plato and of Isocrates and started as a forensic speech writer. His defense of the courtesan Phryne is famous. In 362 B.C. he accused the influential Aristophon of Azenia; he also prosecuted Diopeithes of Sphettos. From 346 to some time before 324 he firmly supported Demosthenes in the struggle against Macedon. In the affair of Harpalus he appeared as one of the ten public prosecutors of Demosthenes. He had probably come to consider Demosthenes too tame an opponent of Alexander. During the Lamian war Hypereides was the leader of the patriotic party and pronounced the funeral oration over the men who fell for Athens. After the defeat of Crannon (322) he fled but was captured and put to death by Antipater.

Hypereides was an ardent pursuer of "the beautiful": his temoer was easygoing and humorous. In his development of the periodic sentence he followed Isocrates, but the essential tendencies of his style are those of Lysias, whom he surpassed, however, in the richness of his vocabulary and in the variety of his powers. His diction nas plain and forcible and his composition simple.

See editions by F. G Kenyon (1906) and by F. Blass and C. Jensen (1917). G. Colin's edition (1946) is provided with a French translation. See also F Blass, *Attische Beredsamkeit,* 2nd ed, vol. iii (1898) ; R C. Jebb, *Attic Orators,* 2nd ed, vol. ii (1893). (A. D. Mo.; X.)

HYPERION, in Greek mythology, one of the Titans, son of Uranus and Ge and father of Helios, the sun-god. The name is often used as an epithet of Helios, who is himself sometimes called simply Hyperion. Its meaning may be "son of Hyperos"; *i.e.,* of him who is above (heaven).

HYPERSTHENE: see PYROXENXTE.

HYPERTROPHY AND HYPERPLASIA are descriptive terms commonly used in medical terminology with no uniformly accepted precise meaning. They are used in both noun and adjective forms to describe changes in cells, tissues, organs and structures. Hypertrophy generally implies excessive size of a cell, tissue, organ or structure, whereas hyperplasia implies an increase in number of cells, with no connotation of cell abnormality. These terms are not commonly used to describe tumours or inflammatory swellings.

The causes are varied and manifold and the resultant hypertrophy and hyperplasia may be within physiologic limits, but ordinarily some abnormal condition exists. (F. L. A.; X.)

HYPNOSIS (HYPNOTISM) is the term applied to a unique, complex form of unusual but normal behaviour which can probably be induced in all normal persons under suitable conditions and also in many persons sufiering from various types of abnormality. It is primarily a special psychological state with certain physiological attributes, resembling sleep only superficially and marked by a functioning of the individual at a level of awareness other than the ordinary conscious state; for convenience in conceptualization, this is called unconscious or subconscious awareness. Functioning at this special level of awareness is characterized by a state of receptiveness and responsiveness in which inner experiential learnings and understandings can be accorded values comparable with or even the same as those ordinarily given only to external reality stimuli.

When hypnotized, or in the hypnotic trance, the subject can think, act and behave in relationship to either ideas or reality objects as adequately as. and usually better than, he can in the ordinary state of awareness. In all probability this ability derives from intensity and restriction of attention to the task in hand, and the consequent freedom from the ordinary conscious tendency to orient constantly to distracting, even irrelevant, reality considerations.

The subject is not. as is commonly and wrongly believed, without will power, or under the power of the hypnotist. Instead, the relationship between the subject and the hypnotist is one of interpersonal co-operation based upon mutually acceptable and reasonable considerations. Hence, the subject cannot be forced, as a function of hypnosis itself, to do things against his will, as is sometimes claimed. He can be aided in achieving possible desired goals, but frequent failures in hypnotherapy attest the limitations of hypnosis in accomplishing even wanted purposes. and extensive and reliably controlled studies discredit the possibilities of antisocial use of hypnosis.

The history of hypnosis is as ancient as that of sorcery, magic and medicine, to the armamentaria of which it belonged. Its scientific history began in the latter part of the 18th century with Franz Mesmer (*q.v.*), a Viennese physician who used it in the treatment of patients. Because of his mistaken belief that it was an occult force, which he termed "animal magnetism," that flowed through the hypnotist into the subject, he was soon discredited; but mesmerism, as it was named after him, continued to interest medical men. Extensive use was made of it by a number of clinicians, without adequate recognition of its nature until the middle of the 19th century when the English physician James Braid studied its phenomena and coined the terms hypnotism and hypnosis.

Thereafter many scientifically trained men studied hypnosis, but not until after World War I was much progress made. This progress derived from the recognition of the re-educative possibilities afforded by hypnosis. World War II gave further impetus to its study, greatly extended its recognition and utilization and freed it from many of the superstitions, fears and misconceptions that had hampered its scientific acceptance and investigation. The next significant developments in the history of hypnosis occurred in the mid-1950s when both the British and American Medical associations formally approved its medical use and discountenanced its use by the laity. At that period also was organized the American Society of Clinical Hypnosis, with international scientific societies.

Hypnotic Technique.— Popular belief still ascribes significance to magical devices and rituals such as "making passes" or stroking the body, the use of "hypnotic crystals," the "eagle eye" and the "hypnotic command," all of which belong to the charlatan's stock in trade. Actually, the important consideration in inducing hypnosis is that the subject be willing, co-operative and interested in learning a new experience. To such a subject a trusted operator can progressively, persuasively and repetitiously suggest tiredness, relaxation, eye closure, loss of interest in externalities and an increasingly absorbing interest in inner experiential processes, until the subject can function with increasing adequacy at the level of unconscious awareness. The length of time required to induce a trance differs greatly with subjects and with trance situations, and the time spent should be in reasonable accord with both the importance and the specific character of the hypnotic work to be done. The charlatan boasts of his speed; the scientist considers time an important variable. Thus, the dentist might need only a few minutes to induce the trance state requisite to permit a simple tooth extraction; the psychologist might need an hour to effect those psycho-neuro-physiological responses needed for a long, involved laboratory experiment; and the hypnotherapist, because of his patient's needs, might distribute over a period of months the development of a trance state otherwise possible in a short period of time.

Another essential element in technique—for either investigative or therapeutic work—is the utilization of the subject's own patterns of learning and response, rather than an attempt to force upon him by suggestion the hypnotist's limited comprehension of what constitutes experiential validity for the subject. Failures in hypnotic experimentation and therapy often derive from treating the subject as an automaton, expected to execute commands in accord with the hypnotist's understanding, rather than as a personality with individual patterns of response and behaviour.

Hypnotic Phenomena.— Hypnotic phenomena differ from one subject to another and from one trance to another, depending upon the purposes to be served and the depth of the trance. Hypnosis is a phenomenon of degrees, ranging from light to profound trance states but with no fixed constancy. There are, however, certain basic manifestations, the extent and clarity of which vary. Foremost among these is rapport, which signifies the limitation of the subject's awareness to that which is included in the hypnotic situation. Usually the subject responds only to stimuli from the hypnotist, who may limit or direct the subject's awareness or responsiveness as is desired or needful. However, in accord with personality needs or the demands of the situation, the subject may remain in or actively establish contact with part or all of the circumstances surrounding the trance.

Catalepsy. another hypnotic manifestation, is properly tested only indirectly, since direct tests may elicit it as a responsive rather than as a spontaneous phenomenon. Catalepsy is a state of balanced muscle tonicity which permits great economy of effort, allowing the subject to maintain postures and positions for unusually long periods of time.

Suggestibility. a state of greatly enhanced receptiveness and responsiveness to suggestions and stimuli, constitutes the central phenomenon of hypnosis. It is characterized by the remarkable facility with which the subject can respond to either external stimuli or those deriving from inner experiential acquisitions. However, suggestions must be acceptable to the subject, and rejection of them can be based upon whim as easily as upon sound reasons. By acceptance of and response to suggestions. the subject can become psychologically deaf, blind, hallucinated, amnesic, anesthetic or dissociated, or he can develop various special types of behaviour regarded by him as reasonable or desirable in the given situation.

The psychological processes involved are essentially those of vivification of memories, ideas. understandings, emotions—indeed, any type of experiential acquisition—so that they are experienced subjectively as deriving from external events rather than from internal processes. This is the feature of hypnosis most often abused by the charlatan, and it is also the feature that permits the greatest accomplishments in psychology, dentistry and medicine. (See also SUGGESTION AND SUGGESTIBILITY.)

A most fascinating manifestation, also of great scientific importance, is that of posthypnotic suggestion and behaviour. By this is meant the execution, at some later time, of instructions and suggestions given in a trance and intended to become a part, either interpolated or integrated, of a later activity. For example, a pregnant patient may be instructed posthypnotically to develop, at some future time when labour begins. an obstetrical anesthesia to meet the needs of childbirth. Such use of posthypnotic phenomena offers extensive opportunities for direction and guidance of behaviour in terms of the individual's needs and patterns of response without dependency upon immediate guidance and relationships.

Amnesia of any degree of selectiveness or comprehensiveness may be developed in hypnosis, either spontaneously or by instruction. It may include all the events of the trance state or only selected items, or it may be manifested in connection with matters unrelated to the trance. Hypnotic amnesia is reversible; it may be induced. abolished, reinduced or altered by the operator or by the subject if adequate personal motivation develops. It is very useful in both experimentation and therapy and can be used in a variety of ways. For example, otherwise uncontrollable pain in malignant disease has been partially controlled by use of amnesia.

Conversely, hypermnesia, an ability to remember that transcends the everyday ability is another aspect of hypnotic behaviour that is valuable experimentally and therapeutically. For example, in the trance state, the subject, by virtue of an uncritical willingness to make the effort and a freedom from inhibitions deriving from preformed judgments, can remember vividly long-forgotten, even deeply repressed experiences, recount them in extensive detail and still maintain an amnesia for them at the ordinary level of consciousness. This remarkable ability permits the recovery of memories otherwise unavailable, makes possible extensive exploration of the experiential past, and offers opportunities for studies of basic processes underlying learning and memory.

A striking phenomenon of the profound trance is somnambulism. This is a state of deep hypnosis in which the subject can present the outward appearance and behaviour of ordinary awareness but is able to manifest readily and often spontaneously any type of hypnotic behaviour within his personal capabilities. Some subjects never achieve this state, some reach it with a minimum of effort. It is of great value in certain specialized procedures and studies. Experience and training are often required even to recognize the somnambulistic state, and even more experience is necessary to induce it readily and to utilize it adequately.

Ordinarily all trance behaviour is characterized by a simplicity,

a directness and a literalness of understanding, action and emotional response suggestive of childhood. This is the phenomenon of regression, which can be enhanced so that the subject experiences a retrogressive loss of memories, ,learnings and responses, and those belonging to an earlier age are re-established. When developed carefully, this regression is not a re-enactment or a revivification of the past in terms of current understanding, but a restoration of previous response patterns through a process of amnesic loss of subsequent learning. This manifestation permits extensive exploration of the developmental aspects of the subject's experiential past.

Dissociation. a detachment or separation of subjective from objective values, another highly complicated phenomenon, is of particular significance in effecting specialized learnings (for example, anesthesia or emotional objectivity) without arousing impeding or obstructing subjective reactions—the hypnotized subject, that is, can be made insensitive to a needle prick because the dissociation phenomenon prevents a subjective reaction (pain) from occurring.

Time distortion, first elaborated as a specific scientific concept in the mid-1940s, has proved to be useful in both hypnotic therapy and experimentation. It is essentially a function of speed of cerebration, as a result of which the passage of time is perceived subjectively in terms of inner experiential processes and events. As a consequence, time as a personal experience may be "expanded" or "condensed" with resulting alterations in subjective values and psychological and physiological functioning.

Among other interesting hypnotic manifestations are enhanced visual and auditory imagery, automatic writing, depersonalization. various types of disorientation, and acceleration or inhibition of physiological functions.

Autohypnosis.—Autohypnosis, or self-hypnosis, is both possible and feasible, but it is often a sterile procedure because of misconceptions of its nature and use. Usually the autohypnotist tries too hard to direct *consciously* the activities he wishes to take place at the hypnotic level of awareness, thus nullifying the effort.

Acceptance of autohypnotic processes, rather than attempted direction of them. leads to productive results. Usually autohypnosis is best learned through supervised instruction.

Related Questions.—Certain questions are repeatedly asked about hypnosis. Among these is the possibility of employing hypnosis to commit crimes. The better scientific studies deny this possibility and therapeutic experience discredits it, but a few experimental studies, either inadequately controlled or in protective situations. have resulted in pretended crimes. However, pretense is not reality. nor is hypnosis an essential in pretense.

Concerning harmful effects, none have been reported by earnest students of long experience. but the inexperienced and the armchair theorist are often emphatic in affirming such possibilities. Occasionally an amateur will hypnotize a person suffering from a personality disorder and mistake the evidence of that disorder for hypnotic effects. In this connection may be mentioned the harmfulness of lay hypnosis. This derives not from the hypnosis itself but from the misconceptions promulgated and from the discredit and disrepute that always attend dabbling by the uninformed in. and exploitation by the charlatan of, any field of beneficial learning.

Can hypnosis be induced without the subject's willingness or awareness? Hypnosis is based upon willingness and co-operation. but this may be concealed behind a superficial attitude of unwillingness; similarly, superficial willingness may conceal deep-seated unwillingness; with a consequent failure of trance induction. A trance state cannot be maintained without the subject's consent, actual or implied.

Then there is the question of what would happen if the subject could not be awakened, or if in some way the hypnotist were to be removed. leaving the subject in a trance state. The reply is simply that the trance state, being dependent upon an interpersonal relationship of mutual co-operation, would terminate upon the cessation of that relationship. It is possible to arrange with a subject to remain in a trance in the absence of the hypnotist. but this is merely a form of continued co-operation. Occasionally a subject may refuse through a whim to arouse immediately from a trance, but this is a problem only for the inexperienced and is not significant.

HYPOCAUST, in architecture, an open space below a floor to allow the passage of hot air and smoke in order to heat the room above. This type of heating was developed to a high degree by the Romans who used it not only in the warm and hot rooms of the baths (*q.v.*), but also almost universally in private houses in the northern provinces. Many examples of such hypocausts exist in villa and house foundations in Roman centres in Germany and England. The usual custom was to lead the smoke from a hypocaust into a single vertical flue through which it escaped into the open air. Where greater warmth was desired, several flues would lead up from the hypocaust in the side walls of the room; at times these wall flues consisted of hollow oblong tiles, set close together, entirely around the room. The usual construction of a hypocaust consisted of a layer of tiles, two feet square, laid continuously in a bed of concrete for the bottom surface. Piers approximately eight inches square and about two feet apart were used as the supports. A floor above was made of concrete or of large square tiles supporting a bed of concrete, on which the finished floor of marble, tesserae or mosaic was laid.

HYPOCHONDRIASIS, a medical term, given by the ancients and early physicians to derangements of the abdominal viscera. It is not now used to refer to any actual disease but to a morbid mental symptom which consists in an undue preoccupation in one's own state of health with a tendency to find evidence of disease from insignificant signs. There may arise a settled conviction that disease exists even in their absence. The idea of ill health, however, relates essentially to the internal organs and predominantly to the functioning of the heart. intestinal canal, or genital structures. Such a symptom may occur in many forms of mental illness. It is not infrequently noted in hysterical anxiety and neurasthenic neuroses; in melancholic states, especially those of later years; in dementia praecox; and in the initial stages of such organic psychoses as arteriosclerotic dementia and general paresis.

In other cases hypochondriasis seems to present itself without any other symptom. and though examination reveals no physical abnormality, the assurance of that fact has usually only a temporary effect on the false belief which may lead to self-centredness, depression and insomnia.

It is probable that the hypochondriacal type has a greater sensitivity to sensations emanating from the internal organs, is therefore more easily aware of any change that may occur therein, and so more affected by any possible alteration in their functioning.

Any treatment naturally depends on the associated disease. In its more pure manifestation some form of psychotherapy is indicated. but results are often disappointing. (C. S. R.)

HYPOTHALAMUS is the inferior part of the diencephalon, the portion of the brain that forms a bridge between brain stem and cerebral hemispheres. The pituitary body is attached to its middle portion. The hypothalamus contains nerve fibres and neurons, the latter forming nuclear groups that have elaborate and extensive fibre connections. Information on the physiology of the hypothalamus is largely based on animal experiments, but many of these findings have support from clinical observations in human beings. There is evidence that some of its neurons produce substances that theoretically regulate the secretory activities. of the anterior pituitary, as well as provide the antidiuretic and oxytocic (childbirth-hastening) hormones of the posterior pituitary. After certain specific hypothalamic lesions there may be increased appetite and obesity, while lesions in other areas of the hypothalamus reduce appetite. The hypothalamus is concerned in

regulation of blood pressure, gastrointestinal activity, dilatation of the pupils, etc., as well as other autonomic manifestations that are characteristic of emotional states. It is also concerned with bodily behaviour patterns of emotional type (*i.e.*, rage and fear), and is at the upper end of the reticular formation of the brain stem, which, together with the sensory systems, aids in maintaining the cerebral cortex at a level of activity consistent with consciousness.

Experimental work indicates further that the hypothalamus is connected with the little-known rhinencephalic systems as well as with more recently developed cerebral regions. This adds weight to theoretical concepts that this small region is involved in very extensive neural patterns concerned with the regulation of autonomic and endocrine activity as well as emotional expression.

(W. R. IM.)

HYPOTHEC. It is a general principle of the law of Scotland, recognized also by the law of Rome, that a security over movables cannot be constituted without transfer of possession of the movable object from the debtor to the creditor. (The law of England is different: thus the floating charge, so well known in English law, is not recognized in Scotland, since the property covered does not change hands but remains in the possession of the debtor.)

To this general rule the law of Scotland recognizes some exceptions. and most prominent among them is the "hypothec." This may be described as a security constituted over movable property which remains in the possession of the debtor. The cases, however, in which a hypothec arises by force of law—cases of so-called legal hypothec—are limited, although it is competent for the parties covered to assent by express contract to a "conventional" or contractual hypothec. The following paragraphs relate only to legal hypothecs.

The best-known legal hypothec is that of the landlord over movables in leased premises. Similar is that of the superior for his feu-duty. A solicitor has a hypothec, for expenses incurred by him, over expenses awarded to his client by the court. His rights have been extended by statute to cover also property recovered in the action.

In maritime hypothecs a ship and its cargo may be hypothecated by bond granted by the master—a bond of bottomry over the ship and a bond of respondentia over the cargo. Hypothecs, more comtnonly called liens, also exist over a ship for seamen's wages, salvors' claims, repairs and necessaries incurred abroad, and collision damage.

See also LIEN; MORTGAGE. (A. D. G.)

HYPOTHESIS, something supposed or taken for granted, with the object of following out its consequences (Gr. *hypothesis,* "a putting under," the Latin equivalent being *suppositio*).

In planning a course of action, we may consider various alternatives. working out each in detail. Though the word hypothesis is not actually used here, our procedure is just the same as that of an investigator of crime considering various suspects or of a scientist working out various possible explanations of some set of facts. however different the methods used for deciding betneen the various alternatives may be. What is fundamental is the consideration of a supposal as if it were true, without actually accepting it as true.

One of the earliest uses of the word in this sense was in geometry. It is described by Plato in the *Meno* (86e–87a). The most important modern use is in relation to scientific investigation. A scientist is not merely concerned to accumulate such facts as he can discover by observation: he wants to discover the linkages between facts. He is guided by some problem nhich puzzles him; but he needs to have some clue as to what facts will help him to solve his problem.

His best guide is a tentative hypothesis, which fits in with the existing body of doctrine and which is so framed that with its help he can deduce that under certain factual conditions ("initial conditions") certain other facts would be found if the hypothesis were

The concepts involved in the hypothesis need not themselves refer to observable objects. But the initial conditions should be able to he observed or to be produced experimentally, and the deduced facts should be able to be observed. William Harvey's researches on the motion of the heart and blood in animals show how greatly experimental observation can be helped by a fruitful hypothesis.

While a hypothesis can be partially confirmed by showing that what is deduced from it with certain initial conditions is actually found under those conditions, it cannot be completely proved in this way. What would have to be shown is that no other hypothesis would serve.

Hence. in assessing the soundness of a hypothesis, stress is laid on the range and variety of the facts which can be brought under its scope. Again, it is important that it should be capable of being linked systematically with hypotheses which have been found fertile in other fields.

If the predictions derived from the hypothesis are not found to be true. the hypothesis may have to be given up or modified. The fault may lie, however, in some other principle forming part of the body of accepted doctrine which has been utilized in deducing consequences from the hypothesis; or it may lie in the fact that other conditions, hitherto unobserved, are present beside the initial conditions, affecting the result. Thus the hypothesis may be kept, pending further examination of facts or some remodeling of principles.

A good illustration of this is to be found in the history of the corpuscular and the undulatory hypotheses about light.

HYPOXANTHINE: *see* PURINES.

HYPOXIA (also called ANOXEMIA or ANOXIA) is a general term comprising those conditions of the body under which the tissues are starved of oxygen. There are four types: (1) The hypoxemic type, in which the oxygen pressure in the blood going to the tissues is too low to saturate the hemoglobin. (2) The anemic type in which, though the hemoglobin is fully charged, there is too little of it, and hence the capacity of the blood to carry oxygen is too low. (3) The stagnant type in which the blood is or may be normal but in which the quantity of blood running through the organ is too small. (4) The histotoxic type in which—as the term suggests—the tissue cells are poisoned (for example, by cyanide) and are, therefore, unable to make proper use of the oxygen.

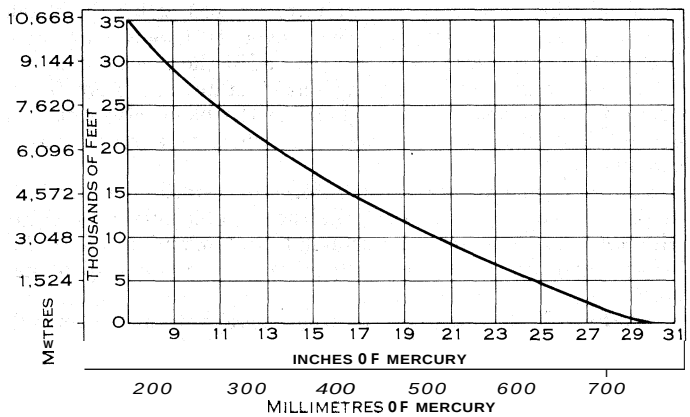
Diseases of the blood, the heart and circulation and the lungs may all produce some form of hypoxia.

Hypoxemia.—Apart from disease conditions, hypoxia is frequently encountered at high altitudes, either in airplanes or on mountains. Between the two there is this distinction—the aviator reaches the rare air suddenly, the mountain climber gradually. Moreover. the aviator reaches it without physical effort, the mountain climber usually as the result of considerable muscular effort. For these reasons the symptoms from which the two classes suffer are different.

The airman loses his faculties if he goes too high. This may amount merely to a loss of judgment or manipulative power, or it may extend to complete loss of consciousness. Because the brain symptoms are the first and most baffling, the use of some system to maintain oxygen pressure is universal in high-flying aircraft.

A person traveling to a high altitude suffers from a somewhat different series of symptoms comprising the condition known as mountain sickness or, in the Andes, *seroche.* In the case of a person traveling by train up to the mining districts about Cerro de Pasco in Peru or up Pikes Peak in Colorado (both 14,000–15,000 ft.) the symptoms usually appear a few hours after arrival, frequently during the night. They are generally a selection from the following: (1) symptoms of the brain—headache, lassitude, fatigue, sleeplessness, visual and auditory impairment and mental depression—symptoms very much like those of an acute attack of migraine; (2) cardiac symptoms—pain in the chest. palpitation, sinus arrhythmia (*i.e.*, irregularity of heart beat); (3) circulatory

symptoms—cold hands and feet, blueness, throbbing; (4) respiratory symptoms—shortness of breath on exertion, change in pattern of breathing, sighing; (j) gastrointestinal symptoms—nausea, vomiting, anorexia. After a residence of two or three days these acute symptoms usually pass off—that is, the subject becomes acclimatized—but no amount of acclimatization makes the human frame at 14,000 ft. as efficient as at sea level. Persons born and raised at this altitude approach sea-level efficiency, but visitors, no



BY COURTESY OF THE CONTROLLER OF H M STATIONERY OFFICE

FIG 1 — CHART SHOWING MEAN ATMOSPHERIC PRESSURE AT DIFFERENT ALTITUDES

The ordinate and abscissa are given both in the metric system and in feet and inches. Ordinate is altitude. Abscissa is atmospheric pressure

matter how long their stay, probably never reach the performance of which they are capable at lower altitudes.

The hurtful results of ascent to high altitudes, whether on a mountain or in an aircraft, are governed by condition of the blood. The processes of oxidation on which life and health depend take place within the tissues of the actual organs concerned—the heart, the brain, the muscles, the glands, etc. Of these, undoubtedly the most vulnerable is the brain. It not only carries out the processes of thought but governs the condition of the rest of the body; *e.g.*, the rate of the pulse, the depth of respiration, etc. Therefore the study of the conditions that produce trouble at high altitudes resolves itself into a study of the adequacy of the oxygen supply of the brain.

Oxygen is transported from the lungs to the brain by the blood. The hemoglobin or red pigment has the ability to form a loose compound with oxygen. Of each 100 g. of hemoglobin leaving the lung, the number of grams that transport oxygen depends upon the pressure of oxygen in the alveoli (air cells of the lung), nhich in turn depends upon its pressure in the air. Oxygen at any altitude is 21% of the local atmospheric pressure, hence the higher the subject ascends the lower will be the oxygen pressure in the air cells of his lungs.

At ordinary atmospheric pressures the oxygen pressure is sufficient nearly to saturate the hemoglobin.

Acclimatization.—The human body is able to make adjustments to a hypoxic condition provided it is not too severe. These adjustments are best understood in relation to hypoxemic hypoxia, most simply seen in ascent to altitude. Some of the adjustments to hypoxia begin the moment the ascent from sea level is started; others appear as the height or the duration of exposure increases. Adaptation enables the organism to withstand better the stress of the hypoxic condition. There are persons in the Chilean Andes who have their homes at 17,500 ft. altitude and who uork in the mines at 19,000 ft. In these persons the process of adaptation has gone more or less to its completion, and it can be said that they are well acclimatized to their hypoxic environment. It is possible that the Andean residents represent not only an individual adjustment but also represent the nearly complete acclimatization of a people.

In the process of acclimatization the disturbing symptoms of exposure to hypoxia disappear as the acclimatization becomes complete. The latter state is characterized by a few simple properties: a normal appetite and with it the maintenance of growth in the immature and stable body weight in the adult; a normal reproductive capacity; and finally, the general well-being common to all healthful living.

In the adjustment to hypoxia of altitude, and in those illnesses associated with hypoxia, processes are set into motion that eventually raise to more compatible levels the low oxygen pressure of the body tissues. The ventilation of the lungs in breathing becomes more effective as acclimatization develops, and this, directly or indirectly, involves the kidneys, the adrenals and the nervous system. Even before ventilation increases, the heart is required to pump more blood in order to compensate for the lower tension of oxygen in the blood. As the respiratory adaptation proceeds, the demands on the heart and circulation diminish, but whenever the demand on the body is increased, as in exercise, the circulatory system has a heightened capacity. Part of the latter apparently is due to an improved distribution of blood to the tissues consequent to either an increase in the calibre of the small vessels or an increase in their number or both.

One of the earlier adjustments to hypoxia is the increase in the oxygen-carrying compound of the blood—hemoglobin. Low oxygen tension stimulates the red bone marrow (the blood-making tissue) to heightened activity, resulting in increases in the number of circulating red blood cells with their hemoglobin. The end result is that each millilitre of blood can carry more oxygen than it did before, and therefore compensate for the deficient oxygen supply.

The average number of red blood corpuscles in each cubic millimetre of blood at various altitudes is given by Maj. R. W. G. Hingston (1924 Mt. Everest expedition) for the people living on the Pamir plateau:

Altitude (in 000 ft.)	7	8	12	15.6	18.2
Red corpuscles (in 000,000 per cu.mm. of blood)	4.5	6.0	6.8	7.8	8.3

The increased ventilation of the lungs, mentioned above as one of the early adjustments to hypoxemic hypoxia, causes the pressure of oxygen in the lungs to rise. Concomitantly the carbon dioxide in the lungs is blown off at a rate greater than normal, and as a

FIG. 2.— EFFECTS OF THE ADJUSTMENT TO CHANGES IN ALTITUDE IN SUBJECTS BREATHING AIR OR 100% OXYGEN

(A) Acclimatized subject breathing air; (B) unacclimatized subject breathing air; (C) theoretical response in absence of adaptation of subject breathing air: (D) unacclimatized subject breathing oxygen; (E) theoretical response in absence of adaptation of subject breathing oxygen

consequence the carbon dioxide pressure in the lungs falls. This in turn reduces the carbon dioxide pressure in the arterial blood, which lowers the hydrogen ion concentration.

Since the normal stimulation to breathing is derived from normal carbon dioxide pressure and hydrogen ion concentration in the

blood, the stimulation due to the hypoxia will be less effective. However. as the duration of exposure to hypoxia continues. the kidneys secrete increased quantities of alkali in the urine, so that the hydrogen ion condition of the blood is gradually returned to normal. The hypoxic stimulation of breathing then becomes more effective, so that the lung ventilation is increased and the oxygen pressure heightened.

The above points are illustrated in fig. 2. On the left the lines trace the course of the oxygen pressure in the lungs with ascent to increasing altitude. It is apparent that for the higher altitudes, particularly, the oxygen pressure in the lungs is increased by the heightened lung ventilation in those acutely exposed (compare line B with line C). It may be seen also that for these same altitudes the acclimatized person (line **A)** has a still higher oxygen pressure. The pressure of oxygen in the arterial blood is quite dependent upon that in the lungs. The respiratory adaptation just outlined ensures that the supply of oxygen to the working tissues of the body is improved as the process progresses.

The lines on the right of fig. 2 (D and E) illustrate that ascent can be made to much higher altitudes while breathing 100% oxygen rather than air. Advantage was taken of this fact by the members of the ninth British Everest expedition in 1953—indeed it made possible the reaching of the peak.

Lines D and E also show that the altitude to which ascent can be made by the use of auxiliary oxygen is definitely limited. The lung oxygen pressure (approximately 40 mm. Hg) is about the same at 44,000 ft. breathing oxygen as it is at 17,000 ft. breathing air. In the unacclimatized person either exposure is hazardous because the alveolar oxygen tension is so low.

For airmen who must ascend to altitudes above 44,000 ft. pressurized cabins or suits must be used to provide sufficient air and oxygen pressure.

Anemic **Hypoxia.**—In this condition there is too small a quantity of functional hemoglobin in the blood to supply the oxygen needs. (1) The most obvious form is anemia in which the actual quantity is too small (see ANEMIA). In severe anemia, such as pernicious anemia, the red blood cells may be so reduced in number that the normal complement of oxygen cannot be carried. (2) After severe bleeding there may not be enough blood in the body to support its needs adequately. Under such circumstances the body makes the effort to maintain the blood supply to the brain; other organs are in a measure denied their share. In other areas of the body there is a general narrowing of the vessels (vasoconstriction) that brings this about.

Three important conditions exist in which the hemoglobin present is temporarily put out of action: carbon monoxide (coal gas) poisoning, methemoglobinemia and sulfhemoglobinemia. Of these the first two are the most important.

Carbon monoxide is found in many gases other than coal gas. It is a frequent source of danger in underground mines of all kinds. Incompletely combusted gases, particularly those from the exhaust of internal-combustion engines, have been a cause of numerous fatalities.

Most cases of accidental carbon monoxide poisoning, however, are due to poorly adjusted, unflued space heaters, which can produce fatal concentrations of carbon monoxide from the incomplete combustion of gas which contains none.

In order for a person to lose consciousness, over half of all the hemoglobin in the body must be united with carbon monoxide, thus preventing oxygen transport. A concentration of less than 0.1% of the gas in the atmosphere can bring this about. (See fig. 3, based on the observations of John Scott Haldane.) However, the absorption of an absolute volume of about 500 c.c. of carbon monoxide is required; this will take perhaps 60 minutes. The effect on different persons varies greatly, but speaking in rough terms a saturation of 30% to 40% means a headache afterward, 50% to 60% means unconsciousness and 75% saturation is probably fatal.

Carbon monoxide in the blood is gradually eliminated when air free from the gas is breathed, and is eliminated at a much greater rate when pure oxygen is inhaled. If a subject has been exposed to a dangerous concentration of carbon monoxide, but recovers consciousness, some cells in the brain may have sustained irreparable damage, and, depending upon the amount of cellular destruction, he may later experience noticeable changes in personality or suffer a grave mental disorder. *(See* also CARBON MONOXIDE POISONING.)

Methemoglobinemia is another condition in which a part of the hemoglobin is thrown out of action. The simplest form is produced by the inhalation of aniline, volatile nitrites, nitrobenzene, etc., causing a conversion of oxyhemoglobin into methemoglobin (which has no respiratory value) within the blood, with injury to the corpuscles. The conversion is only temporary if the impure air ceases to be inhaled and if the poisoning is not too severe. Some other drugs such as chlorates and bromates in addition to producing methemoglobin in the blood also cause an actual destruction of red blood cells, which is a much graver condition.

Sulfhemoglobin is still another form of hemoglobin which is inactive as an oxygen carrier. Sulfhemoglobinemia may occur with the administration of acetanilid, sulfanilamide and other benzene derivatives. Occasionally it may even occur spontaneously.

Stagnant **Hypoxia.**—This may be general or local. If general, it may result from very different causes: (1) In cases of heart disease, the heart may be unable to pump the blood around the body at the required rate. (2) In cases of impairment of venous return, the back pressure may prevent the blood from circulating as it should. (3) Following severe abdominal wounds or surgical operations that have entailed considerable exposure of the internal organs, a condition known as surgical shock may supervene. The circulation of the blood is greatly reduced, and the tissues, therefore, are not supplied with sufficient oxygen. In the conditions mentioned the difficulty lies in the fact that the blood moves so slowly (or not at all) that practically all the oxygen leaves the blood, and there is not enough freshly oxygenated blood flowing along to sustain the tissues.

Local stagnant hypoxia may be due to any condition that reduces or prevents the circulation of the blood in any area of the body. Examples of this condition are Raynaud's disease and Buerger's disease, which restrict circulation in the extremities; the application of a tourniquet to control bleeding; ergot poisoning; and exposure to cold.

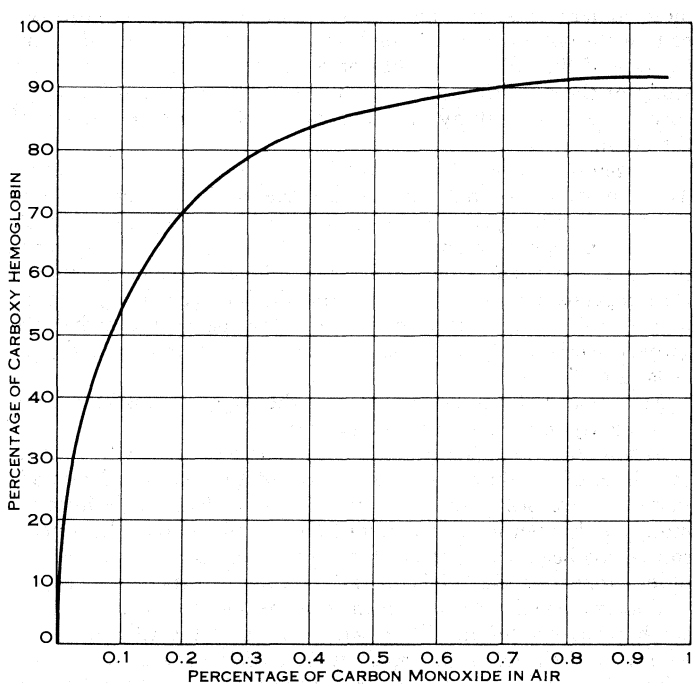

FIG. 3.—CHART SHOWING EFFECTS OF CARBON MONOXIDE SATURATION
Curve shows the percentage of carbon monoxide in the air which, if breathed indefinitely, is capable of saturating the blood to any given degree

Histotoxic **Hypoxia.**—In this case the body cells are unable

to use the oxygen, although the amount of oxygen in the blood may be quite normal and under normal tension. Although characteristically produced by cyanide, theoretically any agent that depresses cellular respiration may cause it. Some of these agents are narcotics, alcohol, formaldehyde, acetone and certain anesthetic agents. This form of hypoxia has, perhaps, somewhat less clinical significance than do the others; nevertheless, fatal poisonings by some of the above-mentioned agents are not uncommon.

HYPSOMETER, an instrument for measuring heights (Gr. *ypsos,* "height," *metron,* a "measure"), which employs the principles that the boiling point of a liquid is lowered by diminishing the pressure *(see* HEAT) and that the barometric pressure varies with the height of the point of observation. *(See* METEOROLOGY.) The instrument consists of a cylindrical vessel in which the liquid, usually water, is boiled, surmounted by a jacketed column in the outer partitions of which the vapour circulates while in the central one a thermometer is placed.

Foresters use other types of hypsometers, operating on the principles of triangulation, to determine the heights of trees.

HYRACOIDEA, a group of small hoofed mammals, including the biblical cony. The name cony or coney originally referred to the rabbit but has also ,come to be used for the related pikas, and for the present quite distinct animals. There is no unambiguous popular term for members of the Hyracoidea. They are usually called hyraxes (or hyraces). Rock rabbits, also sometimes used, is objectionable because they are not rabbits and many of them have nothing to do with rocks. In appearance the living hyraxes. with their plump, pointed heads. short necks, relatively short, slender legs, and squat. almost tailless bodies, look much more like rodents than ungulates. Nevertheless their anatomy clearly shows they are related to the hoofed mammals.

Living hyraxes are confined to Africa south and east of the Sahara and extreme southwestern Asia. They may be divided into two groups. One, the genus, *Procavia,* includes the ground-living forms, especially characteristic of deserts, hills and mountains up to about 10,000 ft., living in holes and fissures among the rocks. The other group is similar but is best separated as *Dendrohyrax.* These forms, confined to Africa, are almost entirely tree-dwelling, the only true arboreal hoofed mammals. They live in holes in trees and move readily along the trunks and branches. Both types climb easily, clinging even to almost vertical surfaces by the pads on their feet.

The hyraxes have numerous structural peculiarities which separate them sharply from any other mammals. The normal adult dental formula is $i.\frac{2}{2}$ $c.\frac{0}{0}$ $p.\frac{4}{4}$ $m.\frac{3}{3}$. The upper incisors are large, curved in a semicircle longitudinally, and grow continuously throughout life like those of rodents. Canines are absent. The premolars and molars are in pattern surprisingly like those of some of the typical ungulates, especially the rhinoceros. The dorsal and lumbar vertebrae are unusually numerous (up to 30 in *Procavia*). On both front and hind feet the three middle toes are well developed. In the forefeet the other two toes are also present, although the first is much reduced; in the hind ieet the first toe is absent, the fifth vestigial. The hoof of the inner (second) toe of the hind foot is clawlike, but on all the other toes the hooves are normal, although small. The wrist bones are arranged serially, the individual bones generally coming in contact with only one bone of the opposite row—an arrangement typical of the most primitive extinct ungulates but lost in the more specialized modern forms. The alimentary canal is unique in having a pair of large coeca opening into the large intestine some distance below the usual one at the junction of large and small intestines. There is a gland on the back marked by light hair.

The relationships of the hyraxes are doubtful. There is no question that the numerous resemblances to the rodents are all superficial and that the fundamental characters indicate affinities with the ungulates, but these affinities must be distant so far as any living forms are concerned. In addition to their many very primitive characters, the hyraxes show some special resemblance to primitive or extinct members of several groups, particularly the Proboscidea, Perissodactyla, some Condylarthra (*Meniscotherium*) and the peculiar South American fossil ungulates. This confusing series of resemblances suggests that the group is an ancient and unprogressive offshoot derived from the ungulate stem at a time when the modern groups of ungulates were not well differentiated.

Fossil Hyracoidea.—Numerous extinct hyracoids are known and they indicate that the group was formerly much more diversified than at present. Ten extinct genera are recognized, chiefly from the Oligocene of Egypt (Faiyum), Miocene of east and southwest Africa, and Pliocene of Greece (Pikermi and Samos). The earliest forms are characterized generally by having a full complement of teeth, $i.\frac{3}{3}$ $c.\frac{1}{1}$ $p.\frac{4}{4}$ $m.\frac{3}{3}$ with the last molars relatively larger than in recent forms. In some cases, for instance *Geniohyus* from Faiyum, the skull was strikingly elongated. Most of these extinct forms were larger than the recent hyraxes and some, such as species of *Megalohyrax* or *Titanohyrax* from Faiyum or *Pliohyrax* from Greece, were relatively gigantic. The largest must have been as big as a horse. *(See* UNGULATA.)

HYRAX: *see* HYRACOIDEA.

HYRCANIA. (1) An ancient district of Asia, south of the Caspian sea, and bounded on the east by the river Oxus, called *Virkana,* or "Wolf's land," in Old Persian. It was a wide and indefinite tract. Its chief city is called Tape by Strabo, Zadracarta by Arrian. The latter is evidently the same as Carta, mentioned by Strabo as an important city. Little is known of the history of the country. Xenophon says it was subdued by the Assyrians; Curtius that 6,000 Hyrcanians were in the army of Darius III. (2) Two towns named Hyrcania are mentioned, one in Hyrcania, the other in Lydia. The latter is said to have derived its name from a colony of Hyrcanians. transported there by the Persians.

HYRCANUS (*Yrcanos*), a Greek surname, of unknown origin, borne by several Jews of the Maccabaean period.

JOHN HYRCANUS I, high priest of the Jews from 135 to 105 B.C., was the youngest son of Simon Maccabaeus. In 137 B.C. he, with his brother Judas, commanded the force which repelled the invasion of Judaea led by Cendebeus, the general of Antiochus VII Sidetes. On the assassination of his father and two elder brothers by Ptolemy, governor of Jericho, his brother-in-law, in 135, he succeeded to the high priesthood and the supreme authority in Judaea. While still engaged in the struggle with Ptolemy, he was attacked by Antiochus with a large army (134) and compelled to shut himself up in Jerusalem. Peace was secured at last on condition of a Jewish disarmament and the payment of an indemnity and an annual tribute. He confirmed the alliance which his father had made with Rome, and at the same time availed himself of the weakened state of the Syrian monarchy under Demetrius II to overrun Samaria. and also to invade Idumaea, which he completely subdued. About 109 B.C. his sons took Samaria and by his orders razed it to the ground. He died in 105 and was succeeded by Aristobulus, the eldest of his five sons. The external policy of Hyrcanus was marked by considerable energy and tact, and, aided by favouring circumstances, was so successful as to leave the Jewish nation in a position of great independence and influence.

JOHN HYRCANUS II, high priest from 78 to 40 B.C., was the eldest son of Alexander Jannaeus by his wife Alexandra, and was thus a grandson of the preceding. When his father died in 78 he was appointed high priest, and on his mother's death in 69 he claimed the succession to the supreme civil authority. After a troubled reign of three months he was compelled to abdicate both

dignities in favour of his more ambitious younger brother Aristobulus II. In 63 Pompey restored him to the high priesthood, with some semblance of supreme command. He was soon again deprived of his office by the arrangement of the proconsul Gabinius, according to which Palestine was in 57 B.C. divided into five separate circles. For services to Caesar after the battle of Pharsalia he was again rewarded with the sovereignty in 47 B.C., Antipater of Idumaea, however, being at the same time made procurator of Judaea. In 41 B.C. he was practically superseded by Antony's appointment of Herod and Phasael to be tetrarchs of Judaea; and in the following year he was taken prisoner by the Parthians, deprived of his ears that he might be permanently disqualified for priestly office, and carried to Babylon. He was permitted in 33 B.C. to return to Jerusalem, where on a charge of treasonable correspondence with Malchus, king of Arabia, he was put to death in 30 B.C.

See Josephus (Ant., xiii, 8–10 and xiv, 5–13; **Bell. Jud.**, i, 2 and i, 8–13). *See* also MACCABEES.

HYSSOP (Hyssopus *officinalis*), a garden herb belonging to the family Labiatae, formerly cultivated for use in domestic medicine. It is a small perennial plant about two feet high with slender, quadrangular, woody stems; narrowly elliptical, pointed, entire, dotted leaves, about one inch long and one-third inch wide, growing in pairs on the stem; and long terminal, erect, half-whorled, leafy spikes of small violet-blue flowers, which are in blossom from June to September. Varieties of the plant occur in gardens, with red and white flowers, also one having variegated leaves. The leaves have a warm aromatic bitter taste and owe their properties to the presence of a volatile oil.

Hyssop is a native of the south of Europe, ranging eastward to central Asia, and has become naturalized in North America from Maine to Ontario and southward and also on the Pacific coast. A strong tea made of the leaves, and sweetened with honey, was formerly used in lung and nose and throat affections, and externally on bruises.

The hedge hyssop comprises herbs of the genus Gratiola, which belong to the family Scrophulariaceae, and are native of marshy lands throughout Eurasia and North America. G. *officinalis*, of Europe, has smooth, opposite, entire leaves, but the stems are cylindrical, the leaves twice the size of the true hyssop, and the flowers solitary in the axils of the leaves and having a yellowish-red veined tube and bluish-white limb, while the capsules are oval and many seeded.

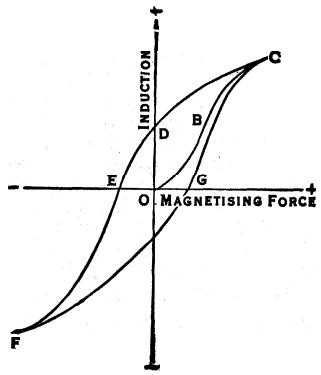
The herb has a bitter, nauseous taste, but is almost odourless. In small quantities it acts as a purgative, diuretic and emetic when taken internally. When growing in abundance, as it does in some damp pastures in Switzerland, it becomes dangerous to cattle.

The hyssop (*'ezob*) of Scriptures (Exod., xii, 22; Lev., xiv, 4, 6; Num., xix, 6, 18; 1 Kings, v, 13 [iv, 33]; Ps.. li, 9 [7] ; John xix, 29), a wall-growing plant adapted for sprinkling purposes, is not to be identified with the *Hyssopus officinalis*, which is not a native of Palestine. The most probable opinion would seem to be that it was a species of caper (Capparis *spinosa*), but it may have been Satureia thymus, a plant of very frequent occurrence in Syria and Palestine, with which *Thymus serpyllum*, or wild thyme, and Satureia thymbra are closely allied. Its smell, taste and medicinal properties are similar to those of H. *officinalis*.

HYSTASPES (the Greek form of the Persian Vishtaspa). (1) A semilegendary king (kava), praised by Zoroaster as his protector and a true believer, son of Aurvataspa (Lohrasp). The later tradition and the *Shahname* of Firdousi make him (in the modern form Kai Gushtasp) king of Iran. As Zoroaster probably preached his religion in eastern Iran, Vishtaspa must have been a dynast in Bactria or Sogdiana. The Zoroastrian religion was already dominant in Media in the time of the Assyrian king Sargon (c. 715 B.C.), and had been propagated probably in much earlier times (cf. PERSIA) ; the time of Zoroaster and Vishtaspa therefore may be put at c. 1000 B.C. (2) A Persian, father of Darius I. under whose reign he was governor of Parthia, as Darius himself mentions in the Behistun inscription (*2*, 65). By Ammianus Marcellinus (xxiii, 6, 32) and by many modern authors he has been identified with the protector of Zoroaster, which is impossible for chronological and historical reasons and from the evidence of the development of Zoroastrianism itself.

(See PERSIA: History).

HYSTERESIS. If an unmagnetized iron bar be subjected to a gradually increasing magnetizing force, and the corresponding values of the magnetic induction (flux density) in the iron be determined, then on plotting the magnetizing force against the induction a curve OBC is obtained. If now the magnetizing force is gradually decreased to zero and the values of the magnetic induction determined, it will be found that the curve obtained does not coincide with OBC but takes the form CD. If now the direction of the magnetizing force is reversed, D E F is obtained, and decreasing the magnetizing force again to zero, reversing, and increasing will give the curve FGC. It will be seen from a study of the complete curve that the magnetic induction (flux density) lags *behind* the magnetizing force. It was to this property of magnetic materials that Ewing gave the name Hysteresis. See ELECTROMAGNET ; GENERATOR, ELECTRIC; MAGNETISM ; etc.



HYSTERESIS CURVE

HYSTERIA is a term applied to a type of psychiatric disorder in which a wide variety of sensory, motor or psychic disturbances may occur. It is classified as a psychoneurosis, and is not dependent upon any known organic or structural pathology. The term is derived from the Greek hystera, meaning "uterus," and reflects the ancient notion that the disorder was the result of disturbances in uterine functions. Actually, hysterical symp, toms may develop in either sex and may occur in children and elderly people, although they are observed most commonly in early adult life.

Hysteria, in pure form, seems to occur more often among the psychologically nai've than among sophisticated persons. Studies have indicated that hysterias tend to be commoner in persons in the lower ranges of intelligence than among those in the higher ranges. There is reason to believe that the incidence of hysteria has been diminishing over the years in England and America, probably due to cultural factors which include increasing psychological sophistication, diminishing sexual prudery and inhibition and a less authoritarian family structure. Cases of classical hysteria, like those so often described by 19th-century clinicians, have become rare. Most psychoneuroses in actual clinical practice are apt to be "mixed" forms in which hysterical symptoms may be found interspersed with other varieties of neurotic disturbances. Isolated hysterical symptoms may occur in psychotic disorders also.

Manifestations. — The sensory and motor manifestations of hysteria take many forms and are designated as conversion reactions, in line with the theory that in such instances the underlying anxiety has been "converted" into a physical symptom. Sensory disturbances may range from paresthesias ("peculiar" sensations) to hyperesthesias (hypersensitivity), to complete anesthesias (loss of sensation). They may involve the total skin area or any fraction of it. In medieval times, and as late as the end of the 17th century, the finding of small discrete areas of anesthesia on the body of a person was considered to he definite proof that the person was a witch. Hysterical sensory disturbances generally do not follow any anatomic distribution of the nervous system. Thus, in "glove" or "stocking" anesthesias, the patient feels no sensation in the parts of the limbs corresponding to those covered by gloves or stockings, but such sensory loss does not follow the distribution of specific nerve pathways. Similarly, in hysterical hemianesthesia (loss of sensation over half the body). the nonfeeling area stops abruptly at the midline, while in organic hemianesthesias the transition from anesthetic to normal sensation is gradual and does not terminate at the midline. Other hysterical

sensory disturbances may encompass the special senses of vision, hearing, taste or smell; or may involve the experiencing of severe pain for which no organic cause can be determined.

Motor symptoms vary from complete paralysis to tremors, tics, contractures or convulsions (hystero-epilepsy). In each instance neurological examination of the affected part of the body reveals an intact neuromuscular apparatus with normal reflexes and normal responses to electrical stimulation. In hystero-epilepsy the electroencephalogram reveals essentially normal electrical activity of the brain, even at the height of the convulsion. Other motor disturbances which are at times hysterical in origin are loss of speech (aphonia), coughing, nausea, vomiting or hiccoughing.

Psychic symptoms may be equally varied, and are usually classified under the broad heading of dissociative reactions. Attacks of amnesia, in which the person is unable to remember who he is or anything about himself, are among the more striking of these. Occasionally the amnesia may last for weeks, months or even years, during which time the person may begin an entirely new life pattern; such protracted reactions are called fugue states. Sleepwalking (somnambulism) is also considered to be a hysterical dissociative reaction, as are also the occasional dramatic cases of multiple personality.

Causation. — Numerous theories have been advanced to account for hysteria. Prior to the work of Pierre Janet (*q.v.*), most clinicians believed it to be an essentially physiological disturbance. Janet, however, considered it to be a mental malady which he attributed to an inherent weakness in the capacity of the personality to synthesize or integrate experiences. As a result of this, he believed, certain ideas became split off from the personality. and in this "dissociated" state produced the hysterical symptoms. Janet's theory failed to explain, however, why a patient develops a particular symptom in preference to any other. The most fruitful explanation for hysterical phenomena came from Sigmund Freud (*q.v.*), the founder of psychoanalysis. Both the method and theory of psychoanalysis were derived largely from Freud's study and treatment of hysterical patients. Freud advanced the theory that all psychoneuroses are the result of conflict between unconscious wishes and prohibiting forces within the personality. The unconscious wishes are generally concerned with sexual impulses (Freud's concept of sexuality embraced all impulses concerned with biological pleasure) or aggressive ones. The forbidding or repressing forces are the result of internalizations (introjections) of parental or surrogate parental attitudes, which make the person experience anxiety in the presence of the forbidden impulse. In anxiety states this anxiety is felt by the person but he is not aware of its origin. In anxiety hysteria (phobia) the anxiety is "displaced" from its original, unconscious source to some other object, which then becomes the apparent source of the anxiety. In conversion hysteria, according to Freud, the anxiety is "converted" into a somatic symptom. This would explain the apparent lack of anxiety, *la belle indifference*, which characterizes many hysterical patients. The exact mechanism by which this conversion takes place is uncertain. The specific form taken by the hysterical symptom was attributed by Freud to the particular nature of the unconscious conflict situation. The symptom may express in disguised form either the repressed impulse, the repressing counterforce or a compromise between the two. Thus, a hysterical convulsion might be a symbolic expression of a forbidden sexual wish, a hysterical paralysis the manifestation of self-punishment for a hidden aggressive impulse, or a hysterical contracture the fusion of the wish to carry out some forbidden act with the counter-impulse which is prohibiting it.

In general it may be said that the symptoms of hysteria represent reactions to stress. They are apt to appear during life situations involving stress, and sometimes disappear spontaneously after the stress subsides. With his symptom the person is often expressing in "body language" his reaction to an intolerable life situation Thus hysterical vomiting may be saying, "I cannot stomach this any longer"; hysterical blindness, "I cannot bear to see what is going on"; hysterical false pregnancy (pseudocyesis), "I wish to have a baby," etc. Often the hysterical symptom may serve the person as a justification for avoiding certain responsibilities or for controlling and manipulating the people in his life. This is sometimes referred to as the secondary gain of the illness.

The question of why a person develops one type of neurosis rather than another is one of the major unsolved problems of psychiatry. It is probable that multiple factors. including constitutional ones, are involved. Freud believed that hysterical disorders originated in conflicts which developed in the so-called Oedipal period of personality development (ages three to five), and were due to failure adequately to resolve the Oedipus complex (based on love for the parent of the opposite sex and rivalry with the parent of the same sex). Although it is undoubtedly true that such factors can be found to be present in most hysterics in our culture, subsequent studies have indicated that this formulation is probably too narrowly based. There is reason to believe that, in many hysterics, the first roots of the personality disturbance date back to an even earlier period, the pre-Oedipal, when the basic security system of the young infant is taking form within the matrix of the primal parent-child interrelationship. Given a certain kind of constitutional predisposition, it would appear that some children, feeling unloved or insecure in their early environments, gradually develop the kind of personality structure that later, under conditions of stress, may incline them to hysterical symptom formation. This personality structure is characterized by emotional immaturity, apprehensiveness, suggestibility, feelings of inadequacy, passivity, a strong dependency on the approval of others for self-esteem, a compulsive need to be loved and admired, and an inability to express hostile or aggressive feelings directly.

Treatment. — In the treatment of hysteria a distinction must be made between the management of the hysterical symptom and that of the underlying personality disorder. The symptom is much more easily treated than is the personality disorder. Because of the suggestibility of the hysterical patient, the hysterical symptom is often responsive to any technique involving suggestion. The dramatic manipulations and theatrical equipment of medical charlatans have their greatest success with hysterical patients, as do various forms of faith healing and hypnosis. If the underlying hysterical character structure is not altered, however, there is a strong likelihood that the symptom will sooner or later return, either in its original form or in some substitutive expression. Rational therapy of the underlying personality problem requires a form of psychotherapy which is aimed at uncovering the underlying conflicts and adaptive patterns of the patient, and which, by bringing these to his awareness, will enable him gradually to learn more effective techniques of coping with his life problems and interpersonal relationships. Psychoanalysis (*q.v.*) is generally regarded as one of the most effective psychotherapeutic approaches for this purpose.

HYTHE, a market town and seaside resort, one of the Cinque Ports (*q.v.*) and a municipal borough of Kent, England, 65 mi. E.S.E. of London by road. Pop. (1951) 9,220. Area 4.7 sq. mi. It lies on the coast at the east end of Romney marsh and on either side of the Royal Military canal, built as a defensive moat when Napoleon threatened invasion. Modern Hythe extends from the canal to the coast; the old town climbs the hill inland from the canal. The church of St. Leonard is partly Late Norman, with an Early English chancel and a tower rebuilt about 1750. In a vaulted processional path under the ambulatory are hundreds of human skulls and bones believed to have been transferred from the churchyard during the 14th and 15th centuries. Lionel Lukin (1742–1834), inventor of the lifeboat, is buried in the churchyard. The guildhall was founded 1794. St. Bartholomew's hospital was founded by Hamo, bishop of Rocliester, in 1336; that of St. John (rebuilt 1802), even older, was founded for reception of lepers.

As a port Hythe owes its origin to the silting-up of the Roman *Portus Lemanis*, where Lympne (pronounced lim) and West

Hythe now stand about 2 mi. west of the town. Here is the end of the Roman Stone street from Canterbury; on the hillside substantial remains of the Roman fortress adjoin the castellated mansion known as Studfall castle. The church at Lympne is Early English and has a Norman tower with Roman material in its walls. There is an airfield at Lympne. A short distance east is Shipway or Shepway Cross, where important assemblies relating to the Cinque Ports were held. A mile north from Hythe is Saltwood castle, rebuilt in the 14th century. It was granted to the see of Canterbury in 1026 and there the murder of Thomas Becket is said to have been planned. It remained a residence of the archbishops of Canterbury until the time of Henry VIII, and was restored as a residence in 1882.

About 2 mi. north of Saltwood are remains of the fortified 14th century manor house of Westenhanger, quadrangular and surrounded by a moat.

Hythe (landing place), a port in Saxon times, was granted by a Saxon thegn to Christ church, Canterbury. In the Domesday survey the borough is entered among the archbishop's lands as appurtenant to his manor of Saltwood, and the bailiff of the town was appointed by the archbishop. King John in 1205 confirmed the liberties which the townsmen of Hythe had under Edward the Confessor. The liberties of the Cinque Ports were confirmed in 1278 by Edward I in a general charter which was confirmed, often with additions. by subsequent kings down to James II. These charters were granted to the Cinque Ports in return for the 57 ships which they supplied for the royal service (the Ports were thus "the germ of the Royal Navy"). The Cinque Ports were first represented in the parliament of 1265, to which they each sent four members. Hythe, with Folkestone, was a parliamentary borough returning one member until 1949, since when it has formed part of the Folkestone and Hythe division of the county of Kent. Hythe mas incorporated by Elizabeth I in 1575, when a fair for the sale of fish etc. was granted. With the silting-up of its harbour, Hythe lost its importance as a port. A marine parade more than four miles long links Hythe with Folkestone.

West of the town is the School of Small Arms. A miniature railway (15″ gauge) runs from Hythe to Dymchurch and New Romney.

HYTHE, CONFERENCE OF, a meeting (May 15 to 17, 1920) between the British and French prime ministers, together with the chancellor of the exchequer and the French minister of finance, in preparation for the Conference of Spa. A French proposal that France should be granted priority in reparation payments seems to have been put forward but not pressed, and the linking up of the reparation problem with the question of inter-Allied debts was proposed publicly for the first time in the official communiqué.

I THIS letter corresponds to Semitic *(yod)*, which may derive from an early symbol for hand, and to the Greek I *(iota,* whence Eng "jot"). Early Greek forms from the island of Thera were and which obviously more closely resemble the Semitic than the later single vertical stroke. In Attic inscriptions also the form appears, while in early Corinthian inscriptions the forms are found The Chalcidic alphabet had the form , and this was the form in all the Italic alphabets, including the Etruscan. The Lydian alphabet besides the form also shows a form (written from right to left).

THE DEVELOPMENT OF THE LETTER "I" FROM THE PHOENICIAN THROUGH THE CLASSICAL LATIN TO THE PRESENT FORM

The minuscule letter is merely a shortened form of the majuscule. The dot first appears in manuscripts of about the 11th century and was used to distinguish the letter and assist reading in words in which it was in close proximity to letters such as *n* or *m* *(inimicis,* for example). The dot frequently took the form of a dash, *e.g.*, . It became the custom in medieval manuscripts to distinguish an initial or otherwise prominent *i* by continuing it below the line, and it was from this habit that the differentiation of the letters *i* and j arose. The initial letter, nearly always lengthened, had most frequently a consonantal force, and this led to *j* representing the consonant, i the vowel. The two letters were not considered as separate until the 17th century.

In Semitic the letter represented a sound akin to the English y. In Greek, Latin and the Romance languages it has represented a high front vowel similar to English long *e*, as in "be." In Latin short *i* represented a considerably more open sound than long i, as is evidenced by the fact that in late Latin it ran together with long *e*. In modern English the sound of short *i* is almost identical with what it was in Latin; *e.g.,* in the word "pit." Long *i* has become a diphthong *(ai, e.g.,* in the words "ice," "hire"), its former sound as a high front vowel having been assumed by long *e* as its position shifted forward and upward. (B. F. C. A.)

In words such as "fir" the letter represents the neutral vowel, while in certain foreign words it retains its continental sound, identical with that which it represented in Middle English and previously; *e.g.,* in the words "pique," "emir." The combinations *ei* and *ie,* as in "receive," "believe," have in the great majority of cases the sound of the long *e* in "precede," although the long *i* sound of "tide" is found in many local and personal names of German origin and in a few other foreign borrowings; *e.g.,* "eider." The vowel sound in "either" is optional.

In chemistry, **I** is the symbol for iodine.

(B.F.C.A.;J.W.P.)

IAMBIC, a verse or succession of verses composed wholly or principally of the foot called an iamb or iambus (⏑ –). It is generally described by a compound name consisting of a Greek numeral and the word *metron,* signifying a group of two iambi; as, iambic dimeter, a line consisting of two *metra* or four iambi: "perunxit hoc Iasonem," or "John Gil|pin was | a cit|izen." The commonest form, and one of the most popular of Greek metres, especially in drama, is the trimeter (three *metra,* or six iambi). When "pure," *i.e.,* containing no other feet, this runs "suis et ipsa Roma viribus ruit." Classical poets, however, permitted various substitutions of other metrical feet according to well-established rules. Since the 14th century, beginning with Chaucer, iambic metre has been the principal one used in English poetry. *(See* ELEGY.) In English verse, too, substitutions have usually been permitted. One of the most common is the anapaest, which, being also a rising rhythm (from unstress to stress), blends easily with iambs. For example, in John Greenleaf Whittier's "John Underhill":

He shook/ from his feet/ as he rode/ away
The dust/ of the Mass/achu/setts Bay . . .

(John Greenleaf Whittier, "John Underhill," lines 13–14, *The Complete Poetical Works of John Greenleaf Whittier,* Boston and New York, Houghton Mifflin Co., 1904, p. 155.) In the blank verse of William Cullen Bryant's "Thanatopsis," the pyrrhic (⏑ ⏑) and the spondee (– –) are frequently substituted for the iamb:

Of the/ great tomb/ of man./ The gol/den sun, . . .

Other common substitutions are a trochee (– ⏑) in any position, but especially in the first foot, and an extra syllable at the caesura or at the end of the line. In his later dramas Shakespeare used this extra syllable frequently. Shelley in "To a Skylark" mixed

trochaic and iambic rhythms:

Hail to/ thee, blithe/ spirit!
Bird thou/ never/ wert, . . .
And sing/ing still/ doth soar,/ and soar/ing ev/er singest

IAMBLICHUS (*c.* 250–*c.* 330), founder of the Syrian school of Neoplatonism (q.v.), was born at Chalcis in Coele-Syria. He studied under Porphyry and afterward established his own school in Syria. He died at some time during the reign of the emperor Constantine the Great (306–337), before the brief court career and execution at Constantinople of his pupil Sopater. Those works of his which survive (*see* below) are of minor philosophical importance; his major metaphysical works are lost. But a fairly good idea of the main lines of his philosophy can be formed from the references to his teaching in Proclus together with the fragments preserved by Stobaeus and such philosophical ideas as can be discovered in the theurgic treatise *On the Egyptian Mysteries.* So far as can be discovered, it was Iamblichus who did more than any other single philosopher to transform the Neoplatonism of Plotinus into the stiff and complicated (though often subtle and profound) pagan scholasticism known best from the works of Proclus. He began the attempt to build up on a Neoplatonic basis a complete and coherent theology encompassing all the rites, myths and divinities of later syncretistic paganism. It was with him that theurgy, the magical conjuration of the gods, began first to play an important part in Neoplatonic religion and to push into the background the purely spiritual and intellectual mysticism of Plotinus. It was Iamblichus, moreover, who not only began but carried a very long way that process of splitting up and subdividing the great realities of the spiritual world of Plotinus and inserting intermediaries between them which produced the late Neoplatonic view of reality as a many-storied structure of complex orders of beings mirroring each other on different levels. It seems to have been Iamblichus who devised the structural principles according to which this splitting up of the spiritual world was carried out. (1) the "law of mean terms," according to which two doubly unlike realities must always be connected by an intermediate term resembling one in one respect and the other in another (AB must be connected to not-*A*-not-*B* either by *A*-not-*B* or by *B*-not-*A*), which forms a triad with them and without which they cannot be directly related; and (2) the triadic order of "remaining," "procession" and "return," according to which effects proceed from their cause and return to it again. Beyond "the one" of Plotinus which is Identical with "the good," he introduced a higher "one" which is absolutely ineffable and beyond all qualifications. He split the intelligible world of Plotinus into tao spheres of complex construction, the intelligible and the intellectual; and he introduced similar complications into his account of the sphere of soul.

In ethics Iamblichus took over Porphyry's classification (based on Plotinus) of virtues into "political," "purifying" and "exemplary" but inserted a fourth category. the "contemplative," between the last two and placed above all four the "priestly" or "unifying" virtues by which we are united in ecstasy to "the one."

Five genuine works of Iamblichus, parts of a sort of encyclopaedia or comprehensive treatise on Pythagoreanism. are extant. On *the Pythagorean Life,* ed by *L.* Deubner (1937); *The Exhortation to Philosophy* or *Protrepticus,* ed. by *H.* Pistelli (1888); *On the General Science of Mathematics,* ed. by N. Festa (1891); *On* the *Arithmetic of Nicomachus,* ed. by *H.* Pistelli (1894); and *Theologzcal Principles of Arithmetic,* ed. by V. de Falco (1922) *The Reply of Abammon to Porphyry's Letter to Anebo,* commonly knonn as the *De Mysteriis* (*On the Egyptian Mysteries*), is also accepted as a genuine work of Iamblichus. text ed. by G. Parthey (1857), Eng. trans. by T. E. Taylor (1821; new ed., 1926), Ger. trans and commentary by T. Hopfner (1922).

IAPETUS, in Greek mythology, son of Uranus and Ge, one of the Titans, father of Atlas, Prometheus, Epimetheus and Menoetius. As a punishment for having revolted against Zeus, he was imprisoned in Tartarus (according to the *Iliad)* or underneath the island of Inarime off the coast of Campania (according to Silius Italicus).

Hyginus makes him the son of Tartarus and Ge, and one of the giants. The etymology of the name is doubtful, and it may be connected with the Hebrew Japhet.

IATROCHEMISTRY (coined from Gr. *iatros,* "physician"), a stage in the history of chemistry during which the object of this science was held to be "not to make gold but to prepare medicines." This doctrine dominated chemical thought during the 16th century, its foremost supporters being Paracelsus, J. B. van Helmont and Franciscus Sylvius. But it gave way to the new definition formulated by Boyle. viz., that the proper domain of chemistry was "to determine the composition of substances."

See CHEMISTRY: *Emergence of Alchemy.*

IAZYGES, Sarmatian tribe on the Maeotis, allies of Mithradates the Great (*q.v.*). Moving westward across Scythia, they were on the lower Danube by the time of Ovid, and about A.D. 50 occupied the plains east of the Theiss. There, under the general name of Sarmatae, they were a perpetual trouble to Dacia (*q.v.*), the Roman province.

The Iazyges were divided into freemen and serfs, the latter of whom were probably an older settled population enslaved by nomad masters. They rose against their masters in A.D. 344 but were repressed.

Nothing is heard of Iazyges or Sarmatae after the Hunnish invasions.

IBADAN, a town in Ibadan province, in the Western Region of the Federation of Nigeria. 70 mi N.E. of Lagos by rail. Ibadan is the largest native city in Africa, having an African urban population of 499,000 (1957). It is the headquarters of the western regional government and the seat of the University college for Nigeria, opened in 1952. In conjunction with the medical faculty of the University college, a teaching hospital was planned. Although most of the people are Moslems, the influence of Christian missions is considerable, particularly on education. The town is surrounded by low hills and in the 19th century was a large warrior camp enclosed by mud walls. The prowess of the soldiers in intertribal wars led to a rapid growth in population, both from refugees and from captured slaves. The continued expansion of Ibadan arises from its position as the commercial centre for the Nigerian cocoa industry, a considerable proportion of Nigeria's cocoa crop being grown within a 20-mi. radius. Oil palms and citrus are also cultivated, as well as maize, cassava and yams.

The majority of the people are farmers or traders and live in single-storied, mud-built houses plastered with cement and roofed with corrugated iron sheets. After World War II the traditional type of dwellings were rapidly replaced by double-storied houses built of cement blocks. Local administration is in the hands of a council of 39 popularly elected councilors and 12 traditional chiefs. The traditional chiefs include the head chief of the town, the *olzrbadan,* and the leader of the women, the *iyalode.* (B. K. C.)

IBAGUÉ (SAN BONIFACIO DE IBAGUÉ), capital of the department of Tolima. Colombia. about 60 mi. W. of Bogotá and 18 mi. N.W. of the Nevado del Tolima. Pop. (1961 est.) 143.590. Ibagué is built on a plain between the Chipalo and Combeima, small affluents of the Coello, a western tributdry of the Magdalena. Its elevation, 4.300 ft. above the sea. gives it a mild, subtropical climate. The plain and the neighbouring valleys produce cacao. tobacco. rice and sugar cane. It is an important commercial centre, being on the road which crosses the Quindio pass, or *paramo,* into the Cauca valley.

Ibagué nas founded in 1550 by Andrés López de Galarza on the site of an Indian village and was moved to its present location because of Indian attacks. It aas the capital of the republic for a short time in 1854. The rapid expansion of coffee planting on the slopes above the city contributed to its growth, especially after 1890. It is the seat of the Colegio San Simon. (Js. J. P.)

IBAN (SEA DAYAKS), a proto-Malay people of southwest Borneo. The name Sea Dayak (though still in official use) is a misnomer, for the Iban are primarily a riverine and hill people. The local name Iban was introduced to anthropological literature by A. C. Haddon in 1901. Haddon classified the Iban as Oceanic Mongols. They are brachycephalic (average cephalic index. 83), of short stature (average height, 5 ft. 2½ in.), with dark eyes, broad noses, full lips, black, lank hair and cinnamon-coloured skin. The Iban of Sarawak (pop., 1961, approximately 235,000; about one-third of the mixed population) are scattered throughout the undeveloped, interior zone of the colony, major areas of settlement being the Lupar, Saribas and Rajang rivers. Other Iban tribes live in the headwaters of the Kapuas river in Kalimantan, or Indonesian Borneo.

The Iban are an agricultural people; their subsistence economy is based on shifting cultivation, dry rice being grown on hillside clearings in the tropical rain forest. By the second half of the 20th century, rubber had been widely adopted as a cash crop. Settlements are scattered (average density of population about ten per square mile) and almost invariably built on the banks of rivers navigable by dugout canoes. Many of these canoes are nowadays equipped with outboard engines. The Iban live in long houses, each consisting of from under 10 to as many as 50 or more privately owned one-family apartments joined together. Each family (containing an average of six persons) is an independent unit, owning land and property. Iban society is classless and egalitarian, and its members marked individualists; their kinship system is cognatic. There is general equality between the sexes.

The Iban language is closely akin to Malay. Although the majority of the Iban people are still preliterate, education services have been greatly extended during the past ten years: schools have been established, an Iban newspaper, *Pembrita,* is published monthly by the government of Saramak and Radio Sarawak broadcasts daily programs in Iban. The highly developed and complex indigenous religion of the Iban is still widely practised. There is an extensive pantheon of named, anthropomorphic gods and goddesses who are invoked in poetic language and concerning whom there is a rich "oral literature." Elaborate rituals, which confer social prestige, are a main activity. However, following mission activity, many Iban have become Christians.

Formerly the Iban were the most inveterate head-hunters in Borneo; martial virtues are still prized, and many young Iban men have served with British Commonwealth forces in Malaya. The traditional Iban are a virile, spirited, self-confident people, immensely proud of their own distinctive culture. The necessary but difficult transition from their traditional culture to the modern world, by which the Iban are taking their proper place with Chinese. Malays and others in the "plural" society emerging in Sarawak, mas still in process at the beginning of the 1960s. *See* also BORNEO: *Anthropology;* DAYAK.

See E. H. Gomes, *Seventeen Years Among the Sea Dayaks of Borneo* (1911); J. *D.* Freeman, *Iban Agriculture* (1955). (J. D. FE.)

IBÁÑEZ, VICENTE BLASCO: *see* BLASCO IBÁÑEZ, VICENTE.

IBÁÑEZ DEL CAMPO, CARLOS (1877–1960), Chilean politician and soldier, commonly referred to as Chile's "Man-on-Horseback," was born at Linares, Chile, on Nov. 3, 1877. After a military career, which he began in 1894, he became involved in politics in 1924. In September of that year he participated in a revolt against the government of Arturo Alessandri Palma and four months later led a coup that ousted a conservative military junta. In 1927 he became minister of interior and vice-president, from which posts he forced the resignation of Pres. Emiliano Figueroa Larrain and had himself elected president, a position he held until 1931. His regime was directed to material development, financed by heavy borrowing from abroad. Discontent with his authoritarianism and the economic depression led to his overthrow and exile. He returned from exile in May 1937 and with Chilean-Nazi support attempted a coup against the government. He was involved in numerous plots and failed as a presidential candidate (1942) before he was elected to the Chilean senate in 1949. He ran successfully for the presidency in 1952 under the slogan "Larger Loaves of Bread," an appeal directed to the depressed urban elements and the emergent rural workers.

He attracted foreign capital in an effort to create a viable economy, but this objective failed and at the end of his regime (Nov. 1, 1958) Chile was in desperate straits. Ibáñez died at Santiago on April 28, 1960.

IBARAKI, a prefecture *(ken)* in the northwest of the Kanto district, central Honshu, Japan. Area 2,351 sq.mi.; pop. (1960) 2,047,024. The prefecture is basically agricultural, the chief products being cereals, potatoes and tobacco. Mechanization of agriculture is advancing rapidly.

Coal is produced at the Ibaraki mines in the Jôban coal field, and copper at the Hitachi mines.

Many of the cities were castle towns. Mito, the prefectural capital, was developed under the Mito branch of the Tokugawa family; its Kairaku-en is one of the most celebrated gardens in Japan. (R. B. H.)

IBARA SAIKAKU: *see* IHARA (IBARA) SAIKAKU.

IBERIANS, an ancient people inhabiting parts of the Spanish peninsula. The name was applied by the earlier Greek navigators to the peoples who inhabited the eastern coast of Spain; originally those who dwelt by the river Iberus (mod. *Ebro).* The river's name itself may represent the Basque phrase *ibay-erri,* "the country of the river." In older Greek usage the term Iberia embraced the country as far east as the Rhone and by the time of Strabo it was the common Greek name for the Spanish peninsula. Iberians thus meant sometimes the population of the peninsula in general and sometimes one element in that population. In Spain, when this element first became known to the Greeks and Romans, there existed many separate and variously civilized tribes connected by at least apparent identity of race, and by similarity (but not identity) of language, and sufficiently distinguished by their general characteristics from Phoenicians, Romans and Celts.

1. Numismatic.— Knowledge of ancient Iberian language and history is mainly derived from a variety of coins, found widely distributed in the peninsula, and also in the neighbourhood of Narbonne. (For the prehistoric civilization of the peninsula as a whole ***see*** SPAIN.) They are inscribed in an alphabet which has many points of similarity with the western Greek alphabets, and some with the Punic alphabet, but retains a few characters from an older script. The same Iberian alphabet is found also rarely in inscriptions. The coinage began before the Roman conquest was completed; the monetary system resembles that of the Roman republic, with values analogous to *denarii* and *quinnrii.* The coin inscriptions usually give only the name of the town; *e.g., Plplis* (Bilbilis), *Klaqriqs* (Calagurris), *Seqbrics* (Segobriga), *Tmaniav* (Dumania). The types show late Greek and perhaps also late Punic influence, but approximate later to Roman models. The commonest reverse type, a charging horseman, reappears on the Roman coins of Bilbilis, Osca, Segobriga and other places. Another common type is one man leading two horses or brandishing a sword or a bow. The obverse has usually a male head, sometimes inscribed with what appears to be a native name.

2. Linguistic.— The survival of the Basque language (*q.v.*) around the west Pyrenees suggested the attempt to interpret by its means a large class of similar-sounding place names of ancient Spain, some of which are authenticated by their occurrence on the inscribed coins, and to link it with other traces of non-Aryan speech round the shores of the western Mediterranean and on the Atlantic seaboard of Europe. K. W. von Humboldt contended that there existed once a single great Iberian people, speaking a distinct language of their own; that an essentially "Iberian" population was to be found in Sicily, Sardinia and Corsica, in southern France, and even in the British Isles; and that the Basques of the present day were remnants of this race, which had elsewhere been expelled or absorbed. He adduced explanations of a vast number of the ancient topographical names of Spain, and of other asserted Iberian districts, by the forms and significations of Basque.

3. Anthropological.— This "Iberian theory" depended partly on the widespread similarity of physical type among the popula-

tion of southwestern Europe. Anthropological researches have proved the existence in Europe, from Neolithic times, of a race, small of stature, with long or oval skulls, who buried their dead in tombs. Their remains have been found in Belgium and France, in Britain, Germany and Denmark, as well as in Spain; and they bear a close resemblance to a type common among the Basques and all over the Iberian peninsula. This Neolithic race has consequently been nicknamed "Iberians," and the racial characteristics of "Iberians" have been identified in the "small swarthy Welshman," the "small dark Highlander" and the "Black Celts to the west of the Shannon," as well as in the typical inhabitants of Aquitania and Brittany. Thus a race with fairly uniform characteristics was at one time in possession of the south of France (or at least of Aquitania), the whole of Spain from the Pyrenees to the straits, the Canary Islands (the Guanches), a part of northern Africa and Corsica. Whether this type is more conveniently designated by the word "Iberian" or by some other name ("Eur-African," "Mediterranean," etc.) is a matter of comparative indifference, provided that there is no misunderstanding as to the steps by which the term "Iberian" attained its meaning in modern anthropology.

IBERO-AMERICAN ARCHITECTURE. In Spanish America the high quality as well as the great quantity of colonial architecture establish it as a major contribution of the new world to civilization. The zeal and power of the Spanish church were abetted by the wealth of the colonies in the construction of sumptuous ecclesiastical buildings. Skilled Indian labour also contributed to the early development of large-scale programs in both religious and domestic architecture. Types of buildings and styles were Spanish in origin, although local conditions produced modifications. In centres of European culture, such as Santo Domingo, Mexico City, Quito, Lima and Cuzco, architectural styles were contemporary with those in Spain. Medieval traditions survived, however, especially in monastic structures; even in the 17th century, late Gothic ribs persisted in the vaults of churches.

Spanish-Moorish elements (Mudejar), such as wooden ceilings in geometric patterns, coloured tiles, the rectangular frame of an arch (*alfiz*), and the trefoil arch, were popular throughout Spanish-American architecture.

Spanish America.—16th Century.—In Santo Domingo, site of the first Spanish settlement, is preserved the earliest cathedral (1514–40), which has a superb Spanish Renaissance façade and a Gothic interior. In Mexico large building campaigns (c. 1550–1600) were carried out by Franciscan, Augustinian and Dominican friars. Their monasteries generally have a huge vaulted church, cloister and monastic buildings, based upon Spanish prototypes. The large atrium yard and the "open chapel" for outdoor religious services are special features developed in America to accommodate crowds of Indians, as at Acolman, Cuernavaca and Huejotzingo. Portals display a wide variety of styles, including medieval and Renaissance elements and occasional Indian influences. The largest Mexican cathedrals, those of Mexico city (1563–1813) and Puebla (1575–1690). have the rectangular basilican plan and other features of the Andalusian Renaissance.

Important early monuments of Peru were destroyed by earthquakes; the surviving structures, of modest character, are found in Ayacucho, on the shores of Lake Titicaca and in Sucre, Bol. Vaulted churches were virtually unknown in South America until the 17th century. In Quito, Ecuador, the Franciscan and Dominican monasteries are notable for their cloisters and Mudejar ceilings, and the cathedral (1562–72) is an example of Andalusian Gothic-Mudejar construction.

17th *Century*.—The architecture of the first half of the 17th century preserves the late classical style of the Spanish architect of the Escorial, Juan de Herrera. Austerity characterizes San Agustin and Santo Domingo in Puebla, as well as the faqade of the cathedral.

Most awesome is the cathedral (1598–1654) of Cuzco, Peru, rectangular in plan, and Herreresque in its sobriety except for the early baroque portal. The Jesuit church in Cuzco, whose handsome faqade was designed in 1664 by Diego Martinez de Oviedo, constituted the first late baroque architecture in the Americas. The city abounds in handsome churches and palaces, built of Andean stone in the second half of the 17th century, and it is in many respects unrivaled in America. At Lima, Peru, the rebuilding of the monastery of San Francisco (1657–73) brought a new wave of Hispano-Mauresque (Mudejar) influence in the geometric designs of the plasterwork. The main portal (1674) of the church inaugurated in that city the late baroque type of faqade, closely resembling a carved altarpiece.

In Bolivia the chief architectural centre was Sucre, where Gothic vaults persisted, but otherwise both religious and domestic buildings adhered to simple classical designs. The Jesuit church in Bogotá, Colombia, owes its Italianate classicism to the Italian architect Father Coluccini. The greatest masterpiece of Jesuit architecture in America is, however, the church in Quito. There the Mudejar patterns, which stand out in gold against a red background, make the interior (1605–89) of the church unforgettably sumptuous. More provincial though extremely colourful Mudejar interiors are characteristic of the monastic churches of Tunja, Colombia. Due to the splendid designs of its monastic buildings, Quito stands with Cuzco as one of the major schools of architecture in South America.

18th *Century*.—The first stage of baroque architecture in Spanish America is generally distinguished by richly sculptured façades, whereas the interiors often remain sober settings for resplendently carved and gilded altarpieces. The late baroque altar of spiral columns was imported from Spain about 1650–60. Its translation into stone on the faqade of a church first occurred (1697–1704) in South America in La Merced at Lima, to be followed by San Agustin there and three churches in Cajamarca, Peru.

In this period appeared in southern Peru and Bolivia a school of architectural decoration characterized by native Indian contributions in the primitive manner of carving and in the introduction of non-European ornament. The crossbred style is known as mestizo, because it, like the people, is compounded of European and native Indian stock. Evidences of Indian contribution are also found in Mexico throughout the colonial period, and there exist parallel phenomena in Central America. The first examples of the independent Peruvian-Bolivian style are preserved in Arequipa, Peru, where the faqade (1698) of the Jesuit church is carved like a tapestry in stone. Other famous examples are Santiago at Pomata, Peru (c. 1690–1722), San Lorenzo (1728–44) and the Jesuit church (1700–07) at Potosi, Bol., and San Francisco (1753–72) at La Paz, Bol.

Argentina lay in the outer periphery of the Spanish colonies, and its early architecture consisted of provincial chapels of rubble and adobe, with the exception of the Jesuit monastery (1654–79) at Córdoba. In the 18th century two Italian Jesuit architects, Blanco and Primoli, established the spacious style of the Italian baroque in the Jesuit estates of Alta Gracia and Santa Catalina near Cordoba and in El Pilar at Buenos Aires.

Baroque architecture reached its climax in Mexico with lavishly carved faqades in which the tapering pilaster (*estipite*) was a distinguishing feature. Introduced in the capital in the Sagrario faqade (1749–68) under the architect Lorenzo Rodriguez, it spread rapidly and appeared in La Santisima, in the Jesuit seminary at Tepotzotlán, in the churches of Guanajuato, and elsewhere. The school of Puebla maintained independence in producing an extraordinary array of brilliantly coloured exteriors of glazed tiles, both in churches and in countless palaces. Mixtilinear contours in doorways, windows and roof levels created highly picturesque effects in Mexican buildings of this period.

Throughout Spanish America, cities were built on a gridiron plan, with a rectangular plaza in the centre and covered sidewalks (portales) of Mediterranean tradition. Houses, large or small, were arranged about a central patio. Handsome domestic buildings exist throughout the continent; special mention should be made of those in Mexico city, Puebla, Tunja, Potosi and Cuzco. Most remarkable civil edifices, such as the customhouse and viceregal palace, survive in Mexico city, whereas elsewhere only the royal mint at Potosi (1753–73) and the government palace (1764) in Antigua, Guat., are comparable in importance. Spanish colonial

architecture came to an abrupt end with the triumph of neoclassicism (1800).

Brazilian architecture. — The Colonial Period (*1530–1822*). — The architecture, language and culture of Portugal were transplanted to Brazil, which was the only major area of non-Spanish origin throughout Latin America. The first cities were built upon hills in medieval style, unlike the unified Spanish settlements. Little of importance survives from the 16th century, when buildings were mostly of wattle and palm thatch.

The Jesuits brought to Brazil the first significant ecclesiastical style, a severe and undecorated architecture, in which the rectangular façade with angle pilasters has a pedimental gable and windows in the second story (Olinda, 1592). This type with variations persisted in Brazil until 1750. Plans are rectangular with square sanctuary and sacristy directly behind, and basilican structures are few. Long lateral chapels parallel with the nave are an unusual feature, derived from Portugal. Vaults and domes are rare, and decoration is limited to the occasional use of imported blue glazed tiles.

Salvador, the viceregal capital until 1763, had the closest ties with Lisbon, and its architecture reflected contemporary Portuguese models. The former Jesuit church, now the cathedral of Salvador (1657–72), has a late Mannerist façade of stone in two principal stories, decorated with Doric pilasters and topped by a large attic story. The prominent windows in the second story are typical of Portuguese and Brazilian ecclesiastical and domestic design.

The more exotic church façades began in the 18th century; great volutes over the centres between square towers created extraordinarily ingenious effects. This development can be traced at Salvador, Deodoro, Penedo, Olinda, João Pessoa, and elsewhere, in a series of Franciscan churches with arched open narthex, three windows in the second story, and fantastic volutes crowning the top.

In the last period of Brazilian colonial architecture (1750–1822) the court style of Lisbon took hold in Belém and the new viceregal capital (1763) at Rio de Janeiro. The neo-Palladian church of the Candelaria (177j) there is the most important monument in the early neoclassical style. The late rococo was, however. still well entrenched, and in the mining country of Minas Gerais it found its most original expression after 1750. Here the great sanctuary of the Bom Jesús at Congonhas do Campo is approached by terraces, a provincial version of the shrines at Braga and Lamego in Portugal.

The oval and octagonal plans, which had been earlier introduced at Rio and Recife, reached a new development in São Pedro dos Clérigos at Mariana and in the double oval plan of the Rosario at Ouro Preto (1785), where they are combined with round towers and curving facades. Curving exteriors in various forms in the Franciscan churches at Ouro Preto (1766) and São João del Rei by Aleijadinho and in other monuments established the keynote of this late period.

Extreme decorative luxuriance characterized the altars and church furnishings in the 18th century, and often the walls of chapels and churches were overlaid with carved ornament. Rio, Salvador and Minas Gerais became the chief centres of interiors in which gilding, spiral columns, late baroque ornament, and illusionistic painting combined to create extraordinary decorative ensembles. An equal flowering of late rococo ornament distinguished portals, windows and profiles of both ecclesiastical and domestic buildings. With the arrival of the French commission in 1816 to establish an academy of fine arts the neoclassical style was definitively implanted in Brazil, and French taste prevailed thereafter.

Ibero-America.—*20th* Century. — Revivals of traditional historical styles of building held sway throughout the 19th century in Ibero-America and well into the early years of the 20th century. In the 1930s North American skyscrapers and modern functionalism in homes and apartment buildings were introduced at Buenos Aires. However, the great development of modern architecture in Ibero-America occurred in Brazil in the same period. The Swiss architect Le Corbusier was invited to Rio de Janeiro in 1936, and under his direction the Brazilian architects Lúcio Costa and Oscar Niemeyer worked upon plans for the ministry of education (1937–43). A great rectangular structure raised upon exposed cylindrical piers in pure Le Corbusier style, it established the new Brazilian school. The invention of adjustable blinds to counteract the intensity of the sun was a feature which was also widely adopted subsequently. The rapid expansion of the cities of Rio and São Paulo as well as smaller centres, such as Belo Horizonte was one of the great phenomena of the first half of the 20th century. Office buildings and apartment houses in the form of skyscrapers abound. Private houses, schools, hospitals and airports all followed the traditions of the international style of Le Corbusier, with Brazilian variations in the extensive use of tiles and stucco exteriors and in a propensity to curving plans.

Brasilia (*q.v.*), on a vast remote plateau 600 mi. N.W. of Rio, was an epoch-making event of contemporary architecture. The city plan, shaped like two great wings, with complicated levels, terraces and approaches, was conceived by Lucio Costa; and construction began in 1957 under the direction of Oscar Niemeyer, who designed the presidential palace and the government buildings, which were largely completed in 1960.

After World War II, numerous tall buildings were built everywhere in Ibero-America, notably in Caracas, Venez., and Mexico City. In the expansion of the former alone was a uniform city plan followed. Remarkable new university cities were built at Santiago de Chile, Rio de Janeiro, Caracas and Mexico City. The last (1950–52) was designed by a group of artists collaborating on the vast complex of buildings, including the Olympic stadium. The use of mosaics on exteriors and the adoption of pre-Columbian architectural traditions, especially in the stadium, gave the Mexican style a high degree of individuality within the general conventions of the modern international style of glass and concrete. Domestic architecture of the luxurious region of Pedregal also incorporated similar native elements.

IBERO-AMERICAN LITERATURE. With the discovery of new lands beyond the ocean sea, Iberian Spain and Portugal embarked on a Christian crusade three centuries long that was to stamp its colonial seal on vast sprawling areas of the Americas. This bold adventure mas chronicled fully from the very day Christopher Columbus set sail out of Palos, Spain. His letters to King Ferdinand and Queen Isabella marked the beginnings of a rich body of colonial writings. Conquerors of the sword and cross alike spelled out the story of the discovery and the conquest, of natural wonders and ancient civilizations, in countless letters, chronicles, histories, polemic tracts, dictionaries, grammars, religious pieces and epic poems that comprise this "literature of the conquest." The most fascinating and the most vital of these writings are those vibrant still with the high hopes and lusty spirit of the men who participated actively in the great crusade for church and crown.

This article is divided into the following sections:

I. The Colonial Years (1492–1826)
  A. Literature of the Conquest (1492–1600)
  B. The Flowering of Colonial Letters (1600–1808)
  C. Literature of Rebellion (1808–1826)
II. The Formative Years (1826–1910)
  A. The Romanticists (1826–1870)
  B. The Realists and the Naturalists (1855–1900)
  C. The Modernists (1888–1910)
III. The Mature Years (1910–)

A. Vanguard Literature (1918–1930)
B. Literature of Social Protest (1930–)

Biographies of many Ibero-American writers mentioned below may be found in articles under their names.

I. THE COLONIAL YEARS (1492–1826)

A. Literature of the Conquest (1492–1600).—For the thrill of first contacts, of epic adventure and of new vision there are the five dispatches, or *Cartas de relactdn,* sent by Hernán Cortés (1485–1547), the courageous, calculating conqueror of the Aztecs, to his emperor Charles V; the inimitable and disarming account of the indignant and doughty Bernal Diaz del Castillo (1492–1584), who spoke for the common soldier in his *Verdadera historia de la conquista de la Nueva España;* the incredible odyssey of the first white man to cross America on foot from Florida to the Mexican Pacific as told by Alvar Núñez Cabeza de Vaca *(c.* 1490–1564) in his *Naufragios* y *comentarios;* the impassioned pages of that impetuous "apostle of the Indies" the Dominican friar Bartolomé de las Casas (1474–1566), whose *Brevísima relación de la destruicidn de las Indias* (1552) became the cornerstone of the "black legend" of colonial Spain; and finally, the nostalgic reminiscences of a mestizo born of an Inca princess and a Spanish conqueror, (Inca) Garcilaso de la Vega (1540?–1616), embodied in his imaginative and exciting history, *Los comentarios reales que tratan del origen de los Incas* (1609–17).

The conquerors were not content. however, with chronicling their deeds in prose alone. Fired by the heroic fervour of their age and by the example of Ariosto, Tasso and the Latin masters, they sang in epic measures the nhole story of adventure that lured them from distant Antarctica to the upper reaches of the Rio Grande. *La araucana* (1569–89), the first of these epic poems and the best of the many written in the closing years of the 16th century, and sporadically throughout the later colonial period, mas begun on scraps of paper and bark by the young captain and courtier Alonso de Ercilla y Zúñiga (*q.v ;* 1533–94) while with the Spanish armies pitted against the indomitable Araucanians of Chile. Tremendously popular in its time, this national epic inspired other participants elsewhere to do for northern South America what Ercilla had done for Chile: Juan de Castellanos (1522–1607?), *Elegías de varones ilustres de Indias* (1588); for the Plate river region, Martin del Barco Centenera *(c.* 1535–1605), *La argentina;* and even for the northern outposts of New Spain, Gaspar Pérez de Villagrá *(c.* 1; 55–1620), *Conquista de la Nuevo México* (1610). These later poems pale in poetic import as they gain in documentary significance. Only the *Arauco domado* (1596) of Pedro de Oña (1570–1643), Chile's first outstanding native poet, approaches the Ercilla epic in artistic achievement. In *La cristiada* (1611), written in Lima (Peru) by the Dominican Diego de Ojeda (1571–1615), America was also to produce the best sacred epic in the Spanish language. And finally there is the brilliant and ambitious Bernardo de Balbuena (1562–1627) whose work best represents the rich and varied literary expression of the dawning Baroque age. His vast epic, *Bernardo, o victoria de Roncesvalles* (1624), and his eclogues are overshadowed by his *La grandeza mexicana* (1604), an effusive paean that placed him among the best descriptive poets of colonial America.

The discovery and conquest of the tropical heartland of America did not produce a like rich body of Brazilian counterparts to the spirited epics in prose and verse of the Spanish conquerors. The Portuguese found no centuries-old native civilizations upon nhich to build a new society. Indians were few. Rather than resist, they retreated into the interior, leaving the invaders to settle at nidely scattered points along the extended narrow coastal plain. There was, then. no epic clash of nhich to sing. But there was the beautiful and bountiful land and nature's children of coast and forest. and these, beginning nith the very day of discovery, nere described and extolled by the Portuguese explorers and missionaries and by others of many lands. Brazil's "literary baptism." like that of colonial Spain. is to be found in the letter of discovery sent to Dom Manuel I of Portugal by the scribe Pero Vaz de Caminha nho accompanied the explorer Pedro Álvares Cabral in 1500 The missionary labours nere largely in the hands of the Jesuits. and to one of their number, José de Anchieta (1534?–97), linguist. historian, poet, dramatist and educator. befell the distinction of being hailed as the father of Brazilian literature. For the period, however, there is only one epic, and this, except for some descriptive passages that give voice to *brasilidade,* or love for the new land of Brazil. sings of Portuguese exploits against the Moors in feeble imitation of Luis Vaz de Camões. The epic *Prosopopéa* (1601). by Bento Teixeira Pinto *(c.* 1540–1618), is commonly regarded as the first book by a Brazilian-born writer.

B. The Flowering of Colonial Letters (1600–1808).—By 1600 the day of the conqueror was past and the new world began to adjust to a less spectacular development for two more long centuries under Spanish-Portuguese dominion. Institutions and manners evolved and flourished under patterns already set in the latter half of the 16th century. The first printing press in the Americas was established in Mexico City about 1539, to be followed by another in Lima in 1584, and both cities were granted university charters as early as 1551. Such, however, was not the case in Brazil where not a single university was founded during colonial years and where printing was not permitted until the close of the period. But everywhere in the Americas a growing leisure class could devote more time to intellectual and artistic pursuits, and close ties maintained with the homeland through men and books encouraged the development of parallel literary patterns. In convent and court, life and letters became a pallid reflection of trends across the Atlantic, and there was little in these two centuries that could lay claim to originality or to distinction as the product of a genuine American art.

The theatre, barely emerging from its medieval forms at the time of the conquest, served largely during the 16th century as a missionary medium in the Indian tongues for the conversion of the native masses. But for the creoles and the growing mestizo class the dramatic repertoire was mainly Spanish and Portuguese, and even those plays that were written in America, but rarely published, were patterned after the flourishing drama of the Golden Age. The plays of the greatest of these native dramatists, the Mexican Juan Ruiz de Alarcón (1580?–1639), more properly belong to Spain.

No true novel was written during the entire colonial period. Prose fiction as such continued to yield to works of historical and biographical import. One of the most readable of these pieces is the entertaining travelogue, *El lazarillo de ciegos caminantes,* written sometime about 1773, by the still unidentified Calixto Bustamente Carlos Inga, of Peru, better known under his pseudonym Concolorcorvo.

That poetry was the most popular form may be inferred from a contest held in Mexico in 1585 in which more than 300 versifiers took part. But these rhymesters did little more than produce a flood of mediocre poetry as indifferent disciples of the cult of the Cordovan genius Luis de Góngora y Argote (1561–1627). Most of their work remains mercifully buried and almost forgotten. Samplings of their blighted art may be found in the curious and entertaining anthology, *Ramillete de varias flores poéticas* (1675), gathered by Jacinto de Evia (b. 1636) of Ecuador. One name alone stands out above them all, that of the famed Mexican nun and "tenth muse," Sor Juana Inés de la Cruz (*q.v.;* 1651–95). Thirsting after knowledge, she had at 16 sought refuge in a convent where she hoped to be able to dedicate her talents entirely to meditation and writing. But her admirers all over the western world kept her in the intellectual and social limelight, where she added further to her stature as Mexico's first feminist. Her fame was enhanced not a little through her critique of one of the sermons of the most eloquent Jesuit missionaries of the day. Antônio Vieira (1608–97). Vieira's vigorous writings in defense of the Indian and Negro and against the exploitation of Brazil by Portugal attest to the fact, that protest as he did against current literary licence, he too like Sor Juana and others could not free himself entirely of the fateful attraction of Góngora. Sor Juana's plays, religious tracts. a revealing autobiographical piece (the product of her contact with Vieira). but above all her sacred and profane lyrics of simple beauty and emotional appeal, amazingly free of

Góngorist excesses, constitute one of the greatest single colonial literary legacies of Ibero-America.

As the colonial period ended only an occasional voice protested against the artificiality and decadence of viceregal life and letters. Among the earliest of these were the mordant Peruvian wit Juan del Valle y Caviedes (*c.* 1652–92) and his contemporary Gregório de Mattos Guerra (1633–96), the epigrammatic "devil's mouthpiece" of Brazil. Both stemmed directly from the Quevedo tradition in Spain and both were extremely popular, their verse circulating widely from manuscript to manuscript, not to be collected and published until long after their deaths.

C. Literature of Rebellion (1808–1826).—Protest and general political unrest began to spread as the 18th 'century advanced and French letters and ideas broke through the relaxed controls indifferently held by Spain and Portugal over new world thought and expression. Early stirrings became more purposeful when French revolutionary doctrines were put to the test by the bold action of Britain's colonies to the north. Printing presses and periodicals sprang up everywhere to convey the new ideas and ideals quickened in the flourishing literary societies founded by Ibero-America's young liberals returning from fruitful contacts abroad.

One of the earliest, most immediate fruits of these contacts with foreign thought was the abortive Brazilian *Inconfidência Mineira* of 1789, a "conspiracy of poets," headed by Joaquim José da Silva Xavier, called Tiradentes (the "toothpuller"), and supported by a number of exceptional writers who were members of the *escola mineira.* This "Minas school" of epic and Arcadian (neoclassic) poets had no equal in the Spanish colonies of that day. Inspired by Camões and Ercilla, José Basilio da Gama (1740–95), author of *O Uruguay* (1769), and Friar José de Santa Rita Durão (*c.* 1720–84), author of *Caramurú* (1781), composed two great native epics of Brazil. Love of country and the appearance of the Indian as a literary character stamped both works as forerunners of Brazilian intellectual independence. The outstanding lyrist, Tomás Antônio Gonzaga (*q.v.;* 1744–1807), author of the delicate love songs to *Marília de Dirceu* (1792), is still the most popular love poet in the Portuguese language. Gonzaga was to die in exile in far-off Mozambique and a somewhat similar fate awaited most of the conspirators of that ill-starred revolt. When, after a bloodless victory in 1822, Brazil finally emerged as an empire under Dom Pedro I (1822–31) and Dom Pedro II (1840–89) only one literary figure, José Bonifbcio de Andrada e Silva (1763?–1838), stood out as the patriarch of Brazil's struggle for independence. As the author of such vigorous, passionate verse as *Poesias,* published in Bordeaux (1825), he clearly reveals his affinity to Byron; he is also acclaimed Brazil's first romantic poet.

The pioneer Venezuelan Francisco de Miranda (*q.v.;* 1750–1816) left a remarkable journal that reveals how he profited from firsthand contacts in the United States with the "great American experiment." His compatriot. the liberator Simón Bolivar (1783–1830), was later christened "the thinker of the Revolution." Through his prophetic analyses of the sociopolitical scene filtered some of the best and most applicable of French thought. particularly that of Montesquieu and Rousseau. Bolivar's dream of a confederation of Ibero-American states received ardent support from the fiery Argentine pamphleteer Bernardo de Monteagudo (1785–1825). onetime secretary of his country's national hero, José de San Martin.

But brilliant and decisive as was their contribution to the cause, the Mexican propagandist and journalist José Joaquin Fernandez de Lizardi (1776–1827), referred to as *el pensador mexicano* (the Mexican thinker) after the revolutionary journal founded by him in 1812, was the only one of that patriotic band of "liberators" to be remembered as a man of letters. His present fame rests largely on the picaresque tale *El Periquillo Sarniento* (1816). generally conceded to be the first authentic Ibero-American novel.

The revolution found its most popular form of expression in balladry and heroic verse. Only an occasional national anthem, such as that of Argentina written in 1813 by Vicente López y Planes (1784–1856), remains as a symbolic reminder of that time. The more enduring patriotic poetry came with the flush of victory and represents but a phase of the total output of three outstanding poets whose significance transcends the brief violent period of the struggle for independence. Only the work of the Ecuadorean José Joaquin de Olmedo (*q.v.;* 1780–1847) was limited almost exclusively to the themes and spirit of revolutionary years. His best-known poem, "La victoria de Junin, Canto a Bolivar" (1825; London and Paris, 1826), composed at Bolivar's request, is generally considered to be the finest example of heroic poetry in the classical style written in America. In his Virgilian "Silva a la agricultura de la zona tórrida" (1826), worthy companion piece to Olmedo's battle-inspired ode, the serene and encyclopedic poet and scholar Andrés Bello (*q.v.;* 1781–1865) of Venezuela, exhorted his fellow Ibero-Americans to turn their swords into ploughshares and live the good and abundant life that rich tropical America held out to all free men. In his later years Bello was to distinguish himself as a grammarian, literary critic, translator, lawgiver and educator and as the revered father of Chile's own first intellectual generation.

José Maria de Heredia (1803–39), Ibero-America's first great lyric poet and romanticist, lived most of his life in exile (Venezuela, New York, Mexico) where nature in its grander moods inspired the rebellious nostalgic poet of enslaved Cuba to write his widely acclaimed poems "En el teocalli de Cholula" (1820) and "Niágara" (1824). In Mexico, as was the case with Bello in Chile, Heredia was to participate actively in the new literary movement of romanticism with which the young Ibero-American nations were born to political independence.

II. THE FORMATIVE YEARS (1826–1910)

A. The Romanticists (1826–1870).—Victory brought immediate political independence from Spain and Portugal (except for the island countries of the Caribbean) but not freedom from the despotism of political anarchy that beset the young nations in their early formative years. Economic and political stability would not be realized for most of the new nations until the closing years of the century. American themes had fired the imagination of the "liberators," but neoclassic forms were still too sacred to be violated even by the tempestuous romantic Heredia. European romanticism was to show the political liberals the way to cultural independence also, even though that way lay largely along the route marked out by France (Chateaubriand, Lamartine and Hugo). England (Scott and Byron), and Spain (Espronceda and Zorilla). Neoclassic form and restraint yielded to the romantic tenets of freedom, individualism and emotional intensity, tenets ideally suited to fit Ibero-American temperaments and conditions.

The most illustrious group of early romanticists was that of the Argentine political refugees who fled from the tyranny of Juan Manuel Kosas (1793–1877). Their leader was Esteban Echeverria (1805–51), who shortly after his return from a four-year stay in France (1826–30) when romanticism was at its height, indicated the way by writing "La cautiva" (1837), his best poem and the earliest example of the wedding of native themes and scenes to new and more appropriate verse forms. The pampa had been discovered. It remained for Domingo Faustino Sarmiento (*q.v.;* 1811–88), who rose from rural schoolmaster to be his country's first civilian president, to present in *Facundo* (1845), written in Chile in passionate denunciation of Rosas, the first serious study of the pampa and of gaucho lore. It was this emphasis on the national scene that gave birth to an indigenous literary genre without European prototype, the so-called gaucho literature of Argentina and Uruguay. The gaucho had long been the subject of folk tale and ballad. He then became the subject of some of the best verse of the century, his romantic story finding, in part, its highest artistic expression in Rafael Obligado's (1851–1920) three poems (1887) on the legendary minstrel Santos Vega. He was acutely portrayed in the humorous gem *Fausto* (1866) by Estanislao del Campo (1834–80). And, finally, he aroused the national conscience and received epic treatment in the classic *Martín Fierro* (1872–79) by José Hernández (1834–86).

These "primitive" poems written in imitation of the gaucho minstrel's ballads and speech are one of two of Ibero-America's original contributions to western letters. The other springs from

the romanticist's interest in the search of national roots: the past of the "noble savage" of Utopian pre-Colombian days and of the victim of Spanish colonial tyranny, the past of a hardy epoch of discovery and of clash of conqueror and conquered, the past of the romance and intrigue of later viceregal days and finally the past of the glorious epic of the struggle for self-determination and self-expression. Echeverria was one of the first to exploit this past in *La cautiva,* the poetic narrative of the legend of the ill-starred lovers of the pampa. This romantic evocation mothered a growing brood of poems and plays that reached its poetic climax in the elegiac *Tabard* (1886) in which the Uruguayan Juan Zorrilla de San Martin (1855–1931) sings of the sad fate of the aboriginal Charrúas forever vanquished by the Spanish invaders. In prose this past produced the *tradicidn,* the other unique Ibero-American genre patterned after the historical anecdote and perfected by the Peruvian Ricardo Palma (1833–1919), one of the greatest Ibero-American masters of piquant, humorous prose. Palma's *Tradiciones peruanas* (1872–1910) have been imitated by many, but no one has yet succeeded in matching his entertaining and artistic re-creation of the past, especially of colonial years.

The Brazilian romantics had no great Indian past and a relatively uneventful colonial era. They therefore continued to extol the beauties of their tropical homeland and to exalt the simple living of the idealized Indian, always with languid nostalgia, or *saudades,* and not infrequently with marked religious fervour. Domingos José Gonçalves de Magalhães (1811–82) is generally credited with having launched the romantic movement in 1836 with the publication of the patriotic and deeply religious poems, *Suspiros poéticos e saudades.* The earlier phases of the movement found their best and most representative expression, however, in the inspired and richly variegated writings of Antônio Gonçalvez Dias (1823–64), one of Ibero-America's truly outstanding poets of the romantic period. Later phases of romanticism are best exemplified in the poetry of doubt and despair of the would-be Byronic, soul-sick, short-lived Manuel Antônio Alvares de Xzevedo (1831–52) of the so-called "Satanic school" and author of *Uma noite na taverna (c.* 1851) and in the Hugoesque sociopolitical verse of the abolitionist and intensely Brazilian Antônio de Castro Alves (1847–71), author of *Os escravos* (1876).

B. The Realists and the Naturalists (1855–1900).—The romanticist's interest in the picturesque and unusual helped him discover types and customs in the living present that gave evidence of a budding national way of life. The sketch of contemporary manners, or *cuadro de costumbres,* closely modeled after those of the Spanish *costumbristas*—*Larra,* Estébanez Calderón, Mesonero Romanos—developed into the realistic novel of manners shortly after mid-century. From that date on, the novel began to assume a more commanding role in Ibero-American letters. Contrary to its development elsewhere. homever, it appeared almost concurrently in the several types representative of successive literary trends in Europe whose masters (Scott. Dumas, Balzac, Pereda, Galdós, Eça de Queiroz) provided the molds in which were poured Ibero-American themes. José Mármol (1817–71), the most virulent anti-Rosas poet of the Argentine exiles, is remembered for *Amalia* (1851–55), a highly romantic novel of contemporary political events that afforded the outside world a dramatic depiction of life in Argentina under the tyranny of Rosas. Across the Andes the realist Alberto Blest Gana (1830–1920) began producing a series of *cosfumbrista* novels on Chilean life of which *Martin Rivas* (1862) is generally considered his best. At about the same time, the Colombian Jorge Isaacs (1837–95) gave Ibero-America its most popular and most representative novel of the 19th century in the tragic idyll of *Maria* (1867), while Juan León Mera (1832–94) of Ecuador contributed *Cumandd* (1871) to the growing number of highly romantic fictional portrayals of idealized Indian life.

Except for a scattering of prose pieces of dubious novelistic stamp, the true novel did not put in an appearance in Brazil until 1844, the date of publication of the perennially popular and romantically sentimental A *moreninha* by Joaquim Manuel de Macedo (1820–82). From that time on, however. the form enjoyed a more orderly and more continuously progressive growth than in the other sister republics. Still one of the most widely read of his country's novelists, José Martiniano de Alencar (1829–77) initiated the vogue of the Brazilian *Indianista* novel by contributing two of the most popular works to the genre, *O Guarany* (1857) and *Iracema* (1865). But these romantic tales of love between Indian and white represent only one aspect of Alencar's varied literary activity. In attempting to novelize the whole of his country's past, he turned to the *sertão* (hinterland) to depict the life and customs of Brazil's backlands. His *O gaúcho* (1870) and *O sertanejo* (1876), although still markedly romantic in spirit, were among the forerunners of a flourishing regional genre that set the stage for the flowering of a truly national novel. Two exceptional contributors to this transitional genre were Alfredo d'Escragnolle Taunay (1843–99), whose *Inôcencia* (1872), an unusual love idyll set in the backlands of Mato Grosso. became a universal favourite. and Bernardo Guimarães (1827–84), whose frankly abolitionist *A escrava Isaura* (1875) was a decisive step forward in the direction of the novel of social protest.

True realism—with a definite leaning toward naturalism—had made an early and isolated bow in the long-overlooked *Memórias de um sargento de milícias* (1854–55), a Balzacian novel of early 19th-century types and customs by Manuel Antônio de Almeida (1831–61). But it was not until the mid-1870s that the novel began to cut deeply under the surface of rural and urban national life to expose the cankers of social and psychological maladjustments to a rapidly changing economic scene. Aluizio de Azevedo (1857–1913) was to become the forerunner of the 20th-century novelist of social protest by virtue of such favourites as *O mulato* (1881) and *O cortiço* (1890). Less concerned with the external aspects of Brazilian life, Joaquim Maria Machado de Assis (1839–1908) pried with piercing irony and refined humour into the psychological complex of the Brazilian soul to distinguish himself as a master craftsman and as his country's most original and gifted writer. His trilogy: *Braz Cubas* (1881), *Quincas Borba* (1890) and *Dom Casmurro* (1900) is a landmark in Ibero-American letters. A *carne* by Júlio Ribeiro (1845–90) and *O ateneu* by Raúl de Avila Pompéia (1863–95), both published in 1888, revealed two additional writers of note who helped set the Brazilian novel on a Course not to be similarly charted by novelists of the other Americas until almost a generation later.

The struggle against the old tyrannies that survived political separation from Spain and Portugal gave birth to a mass of polemical writing notable more for its passion and invective than for profundity of thought or style. After mid-century, homever, several of these late romantic "liberators" distinguished themselves in the manner and content of their writing, significantly distinctive in the essay form. Juan Montalvo (1832–89) became the symbol of uncompromising opposition to political tyranny. He is best remembered as the stylist and essayist of the philosophical *Siete tratados* (1882). Eugenio Maria de Hostos (1839–1903) of Puerto Rico. inspired teacher and essayist, led the way for social reform and independence for Caribbean lands. The abolitionist Joaquim Nabuco (1849–1910) and the cosmopolitan statesman Ruy Barbosa (1849–1923) were the two civic-minded intellectual giants of Brazil in mid-passage from empire and slavery to republicanism and the new way of life. It was, however, relentless attacks against all forces of repression that marked Peru's most dynamic and colourful essayist, Manuel González Prada (1844–1918), as the intellectual leader of successive generations of zealous youthful reformers. His ironic experimental verse, too, paved the way for the full-flowering of the "new" poetry that came into being with the younger rebels who sought to break once and for all with the aesthetic shackles that held them captive to old world writing.

C. The Modernists (1888–1910).—Political stability and a measure of economic security vouchsafed the emergence of a growing leisure class dedicated to cultural pursuits and to a cosmopolitan awareness of life and letters. This new attitude found its best expression in the revolt against the sentimental strains of romantic versifiers whose clichés began to fill the bulging pages of national anthologies. The romanticist's striving for national expression was largely responsible for the development of a sterile,

cloying product in which the potential of a rich new world and a complex social scene degenerated into a meaningless mass of banal lines. Ibero-American writers were suffocating in the stagnant confines of excessive nationalism. The revolt began when young writers, independently of one another over the Americas, withdrew temporarily from the local whirlpool to immerse themselves in the mainstream of world thought and writing. These new horizons broadened their perspective and afforded them a revitalized vision of how to achieve the cultural independence they had so long sought. At first, then, there were the young despondents and pessimists, those who attempted to shut themselves out from their immediate environment in artificial worlds of their own making. They were the transition group, or precursors, disparagingly labeled *modernistas* (modernists) by the older generation. They experimented in metres and in language. They wrote on themes exotic and rare—the ancient past, the distant orient, lands of childhood fancy and opiate creation. Beauty was their goddess and "art for art's sake" their creed, a creed nurtured largely in the French Parnassian and symbolist schools but one that derived strength and richness from sources representing the range of western poetics.

Foremost among the modernists of early transition years were the Mexican Manuel Gutiérrez Nájera (1859–95), whose elegiac verse and restrained rhythmical prose sketches and tales best represent the trend from romanticism to modernism; the Colombian José Asunción Silva (1865–96), whose metrical experimentation and romantic reminiscences left a small but influential body of poems that were widely imitated and even parodied; the morbid Julián del Casal (1863–93), probably the first full-fledged modernist, and his compatriot José Martí (1853–95), martyr and symbol of Cuba's struggle for freedom from Spain, whose inspired prose style and deceptively simple, sincere verse set his work above and apart from all schools and movements. Martí's life and writings have a special meaning for all Americans for all time.

But these modernists all died too young to witness the full-flowering of the movement under the leadership of Rubén Dario (*q.v.;* 1867–1916) of Nicaragua, whose collection of verse and prose, *Azul,* published in Chile in 1888, is the cornerstone of Ibero-American modernism. Dario's next significant work, *Prosas profanas* (1896), represents the high point of the escapist, cosmopolitan, "precious" phase of the movement. When Spain's empire crumbled completely in 1898 and mutual understanding and sympathy swept away much of the centuries-old distrust and antipathy between the mother country and her former colonies, Dario abandoned the ivory tower to sing new songs of life and hope for Spanish-speaking peoples everywhere. His *Cantos de vida y esperanza* (1905) are the fruit of a process of blending the best of modernist form with the more enduring and more universal themes of Hispanic lands. Dario's influence was far reaching, his imitators legion. The imitators, particularly those who exploited his early experimental escapist phase, were responsible for the emergence of a cult that bore his name, *rubendarismo,* a phenomenon that had its classic counterpart in the cult to which Góngora had given unwitting birth. But many of Dario's contemporaries stood out as individual artists of exceptional merit. The titles alone of their best-known and most appreciated individual pieces or collections often suggest the content and tone of their major contributions to the movement. This is especially so in the case of Mexico's Amado Nervo (1870–1919), whose mystic serenity is reflected in *Serenidad* (1914) and *Elevacidn* (1916); of Peru's José Santos Chocano (1875–1934), whose exalted Americanism gave birth to *Alma Amkrica* (1906); of Bolivia's Ricardo Jaimes Freyre (1872–1933), who drew upon Scandinavian mythology for the exotic measures and themes of his *Castalia bdrbara* (1899); of Colombia's Guillermo Valencia (1873–1943), whose classic bent is manifest in *Ritos* (1898); and of Uruguay's philosopher and essayist José Enrique Rod6 (1872–1917), whose overly polished appeal in *Ariel* (1900) for the cultural integrity of Hispanic lands but lately humiliated by the northern colossus, the United States, distinguished him as the leading critic and exponent of modernist ideals.

Long after Dario's death several of his contemporaries continued to contribute to the evolving trends of postmodernist years, including Leopoldo Lugones (1874–1938) of Argentina. whose philosophy and aesthetics kept pace with the vanguard of thought and expression to maintain him in a position of national leadership from early modernist days to the later phases of an arbitrarily pronounced nationalism; Enrique González Martinez (1871–1952), whose call to wring the neck of the modernist swan signaled his emergence as a serious and sensitive pace setter of later poetic trends in his native Mexico; and finally, the poet's poet, Julio Herrera y Reissig (1875–1910) of Uruguay, the outstanding symbolist of modernism, whose daring imagery paved the way for the neo-Gongorist cult of the 1920s. But such poets as Lugones and Gonzblez Martinez, who adjusted or gave direction to the trends away from modernism after 1910, were the exception. The vast majority of Spanish-American modernists, and their younger satellites, continued to be spellbound by the verbal magic and brilliance of the Dario of *Prosas profanas.*

In Brazil the reaction against romantic verse set in somewhat earlier than in the rest of Ibero-America, but it never produced the richly variegated mosaic of Spanish-American modernism. The Brazilian Parnassians owed as much to their Portuguese colleagues as they did to the French masters. They remained, then, essentially Brazilian, and though the more formal aspects of their poetry were challenged by a number of poets attracted to French symbolism, a symbolist movement as such never materialized in Brazil. Parnassianism as epitomized in the poetry of Raimundo Corréia (1860–1911). Alberto de Oliveira (1857–1937) and Olavo Bilac (1865–1918) reached its high point in the mid-1880s, and continued to dominate the stage, virtually supreme and relatively unchanged, until the "stirring 1920s" of Brazilian modernism. But the ivory tower of the escapists and the formalists was soon to topple under the pressure of world-shaking events already in the offing as the period drew to a close.

III. THE MATURE YEARS (1910-)

A. Vanguard Literature (1918-1930).—The Mexican Revolution of 1910, World Wars I and II and the Spanish Civil War served to confirm the conviction of thinking men everywhere in Ibero-America that drifting and dreaming on the roseate waters of the modernist swan would not help them to meet the multiple challenges arising out of local and international conflicts that shook their tottering social, political and economic structure to its very foundations. The horror and bloodshed of the Mexican Revolution shocked a complacent intellectual minority into a realization of the sad plight of their country's submerged masses. The Indian and the mestizo everywhere found able champions of their cause. Ardent youthful liberals broke away sharply from modernist tenets and from the wordy descriptions of local scenes and types, largely imitative of European realist and naturalist techniques, to create a body of writing that in theme, form, spirit and even language was unequivocal testimony to the fact that Ibero-American literature had at last come of age. The Spanish Civil War and World Wars I and II gave continental and international perspective to America's attempt to define her lot, place and mission among the nations of the world. World-wide depression and dollar diplomacy encouraged the emergence of radical economic philosophies that seemed to offer hope of deliverance from the bondage of imperialism. From this ferment of self-discovery and self-assertion, Ibero-America produced a literary portrait that in composition. colour and complexity was a remarkable tribute to the land and to the men whose dramatic story was told therein.

Shortly after 1900 the modernist leaders (Dario, Nervo, Lugones) turned away from the more formal and exotic aspects of the movement to initiate a return to traditional forms and to sincerity and simplicity of expression. Their followers, however, never wholly rejected the blessings of modernist experimentation —enriched versification and language and the revelation of countless new thematic sources. Of these postmodernists one group stands out sharply, an extraordinary band of women whose lyrics were more widely read and enjoyed than that of the majority of male poets in the first half of the 20th century. Love in all of

its impassioned and transcendental manifestations, maternal longing and social protest are the themes of Delmira Agustini (1886–1914), Alfonsina Storni (1892–1938), Juana de Ibarbourou (1895–) and Gabriela Mistral (1889–1957). Their contribution was recognized in the honour accorded Gabriela Mistral, winner of the Nobel prize in poetry for 1945.

Stemming directly from the modernist tradition and representative of a number of more pronounced trends are the unpretentious lyrics of Enrique Banchs (1888–); the deceptively experimental verse of the deeply subjective Mexican Ramon López Velarde (1888–1921); the wholesomely mystical expression of the Guatemalan Rafael Arévalo Martinez (1884–); the brilliant sonnet sequence of the tropical scene in *Tierra de promisión* (1921) by the Colombian José Eustasio Rivera (1889–1928); and the intensely racial rhythms of Cuba's "nativist" mulatto poet Nicolás Guillén (1904–).

While the postmodernists signaled a return to a poetic expression less markedly divorced from traditional forms and themes, other groups, caught up by the nihilistic waves of post-World War I "isms," sought to wrench poetry loose from its age-old moorings. Free verse and daring imagery that more often than not defied objective analysis and gave the mistaken impression of a coldly intellectual mood were the salient features of Ibero-American vanguard experimentation. Not a few *ultraístas,* as members of these vanguard coteries were collectively labeled, wrote with sociopolitical overtones.

Under the banners of *creacionismo,* Vicente Huidobro (1893–1948) of Chile launched one of these ephemeral movements in Spain in 1918. His continued denial of the entire poetic past was offset somewhat by the classical leanings and love of the national past that rendered the novel imagery of Argentina's Jorge Luis Borges (1900–) less vulnerable to the charges of obscurity usually leveled at all vanguard groups, including those who joined the *ultraísta* movement launched by Borges in Buenos Aires in 1921. César Vallejo (1895–1938) of Peru best represents the shift from modernism to the later Marxist emphasis of the *ultraístas* of the 1930s. It was, however, upon the intensely subjective Pablo Neruda (1904–) of Chile that the mantle of Ibero-America's most gifted living poet fell. His influence upon his contemporaries bids fair to equal that of Dario and of Gongora in their time.

Upon the auspicious occasion of the *Semana de Arte Moderna* (Modern Art week) held in São Paulo in 1922, the vanguard revolt in Brazil. usually referred to as modernism, careened off to a noisy destructive break with academicism and colonial cultural bondage until the world depression of 1929 and the new political order (1930) under Getulio Vargas (1883–1954) sobered their aggressive flaunting of all convention. Although incited by European iconoclasts, the Brazilian modernists were primarily bent on bringing national thought and life abreast of modern times. It was a high-pitched, often theatrical, self-searching period of aesthetic re-evaluation and of analysis of the immediate Brazilian present. However, as in the case of the Spanish vanguard movements, there was little of enduring value that came of it. But it did serve as a sorely needed purge and produced a number of men whose names became fixed in Brazilian literary history, such as the movement's high priest, the gifted and many faceted poet and musicologist Mario de Andrade (1893–1945); his lieutenant, the genial and unpredictable Oswaldo de Andrade (1890–1954); the perceptive critic and Whitmanesque bard Ronald de Carvalho (1893–1935); and the nation's greatest living poet Manuel Bandeira (1886–). Certain modernist techniques, a highly sensitive preoccupation with social and metaphysical problems. but above all an imperative urge for untrammeled self-expression characterize the poetry of such outstanding modernist contemporaries or followers as Jorge de Lima (1893–1953). Cecilia Meirelles (1901–) and Augusto Frederico Schmidt (1906–).

B. Literature of Social Protest (1930–).—The Spanish-American modernists, and later the Brazilian modernists as well, made their best contribution in verse and in poetic prose pieces. Contrary to its exceptional development in Brazil, the Spanish-American novel had been left largely to the unwieldy pens of uninspired realists. among them some who aspired to apprenticeship under Emile Zola and his naturalist followers. Federico Gamboa (1864–1939) of Mexico and Baldomero Lillo (1867–1923) of Chile gave both strength and a measure of artistic balance to the vehement protests of their fiction of social reform. The later novelists, essayists and short-story writers who took up the battle shortly after the turn of the 20th century developed new and more effective techniques from the modernists and from such more revolutionary stylists of other lands as Joyce. Proust, Romains. Steinbeck and Kafka. As this literature of protest moved forward from 1910 to mid-century it gained in profundity, strength, clarity and form as it continued to probe into the causes that make for injustice and inequality.

Martí and Gonzalez Prada had advanced the essay to a prominent place in the realm of ideas and effective expression. And both came to be hailed as the intellectual and literary progenitors of succeeding generations of men acutely aware of their responsibilities as leaders in the move to interpret and to guide America in a rapidly changing world. Rufino Blanco Fombona (1874–1944) of Venezuela, more widely known for his prose fiction in which he assailed his country's tyrants with more passion than poise as in *El hombre de hierro* (1907) and *El hombre de oro* (1916). became the ardent spokesman for dynamic pan-Hispanism. He was also among the first to attack "Yankee imperialism," a role in which he was abetted by the militant Argentine. Manuel Ugarte (1878–1951) whose *El porvenir de América latina* (1911) and *El destino de un continente* (1923), together with *Les démocraties latines de l'Amérique* (1912) and *La creación de un continente* (1913) by the Peruvian Francisco Garcia Calderón (1883–1953), envisioned Ibero-America as the future guardian of the Latin tradition. Ricardo Rojas (1882–1957), outstanding literary critic and historian of Argentine letters, and José Vasconcelos (1882–1959), controversial philosopher and educator of Mexico, were more concerned with racial and cultural aspects of national development within the American family of nations. Under the classic touch of Alfonso Reyes (1889–1959), poet, scholar and literary critic of Mexico, the essay has become a vital intimate force, engaging in form and universal in appeal. One of America's most representative humanists, Reyes is generally recognized as the dean of a younger generation of writers—Jorge Luis Borges (1900–) of Argentina, Germán Arciniegas (1900–) of Colombia, Mariano Picón-Salas (1901–) of Venezuela—for whom the essay gives every promise of a rich fulfillment.

It was in both the short story and the novel, however, that the panoramic grandeur of the American scene and the human conflict in all of its dramatic interest were best to be described and interpreted.

The disheartening years that followed the abolition of slavery in Brazil in 1888 and the establishment of a republic in 1889 posed a number of agonizing questions to which serious-minded Brazilians at the turn of the century sought answers through an analysis of their troubled homeland as the raw product of an extraordinary amalgam of man, land and climate. It remained for an army engineer and journalist, Euclides da Cunha (1866–1909), to lay bare the very bedrock of Brazilian life, to create in the unclassifiable epic. *Os sertdes* (1902), a work that has been called the "bible of Brazilian nationality." The author and his work became a cult. It was the first written protest in behalf of Brazil's forgotten man—the cornerstone of all later efforts, no matter what the form—to probe the nation's weaknesses and strength. Da Cunha focused *Os sertdes* on the emerging Brazilian of the backlands. In a novel of ideas, *Canaan,* also appearing in 1902, José Pereira da Graça Aranha (1868–1931) focused on the problem of the effects of recent European immigration upon this evolving Brazilian type. Somewhat later, in 1918, the publication of a remarkable collection of short stories, *Urupês,* by José Bento Monteiro Lobato (1883–1948), made it apparent that talented intellectuals were continuing to probe for native types and traits in a search that gave direction and impetus to the modernist outburst of the 1920s and birth to a new cultural regionalism that

achieved full flowering after 1930 in the fiction of Brazil's northeastern backlands. The region produced a remarkably gifted and dedicated group of prose writers. A number of them, such as Gilberto Freyre (1900–), uhose *Casa grande e senzala* (1933) is fundamental to an understanding of the region. have distinguished themselves as sociologists Two of the more prominent novelists of this "Northeastern school" are José Lins do Rego (1901–57), who in a highly personal evocative style depicted the clash of the old and new way of life in his classic "sugar cane" cycle (1932–34) and in such other novels as *Pedra Bonita* (1938) and the symbolic *Fogo morto* (1943), and Jorge Amado (1912–), whose convincing manipulation of mass minds and movements gave Brazil some of America's best "proletarian" literature in such novels as *Cacau* (1933), *Jubiabá* (1935) and *Terras do sem fim* (1943). *Angústia* (1936) by Graciliano Ramos (1892–1953) attests to the fact that the individual inner struggle has also been adroitly plumbed by these new "regionalists." Constantly experimenting in technique and ever abreast of themes that reveal deep preoccupation with the individual in time and in a changing social structure, Erico Verissimo (1905–) ranks high as one of Ibero-America's few cosmopolitan nriters of distinction. hfuch of his work is now available in English and in other languages: *Caminhos cruzados* (1935), Eng. trans., *Crossroads* (1943); *Olhai os lírios do campo* (1938), Eng. trans., *Consider the Lilies of the Field* (1947); *O resto é silêncio* (1943), Eng. trans.. *The Rest Is Silence* (1946) ; and *O tempo e o vento* (1950), Eng. trans., **Time** and *the Wind* (1951).

Mexico's bitter bloody rebellion of the masses gave birth to memoirs, chronicles, sketches, short stories and novels—kaleidoscopic. journalistic, staccato pitched—of nhich the earliest and the most widely acclaimed was *Los de abajo,* a novel conceived in 1915 over the campfire and on forced marches by Mariano Azuela (1873–1952), an army doctor of one of Villa's bands. Azuela alone chronicled almost every aspect of the revolution from its preliminary rumblings to its later social implications. From the late 1920s on, Martín Luis Guzmán (1887–) in *El águila* y *la serpiente* (1928). Gregorio López y Fuentes (189j–) in El *indio* (1935) and José Rubén Romero (1890–1952) in *La vida inútil de Pito Pérez* (1938) took up the challenge to give breadth and scope to Azuela's treatment.

The Mexican Revolution focused attention on the sad plight of the Indian. This 20th-century Indian was not the uncompromising hero of the epic *La araucana,* nor yet the symbol of colonial revolt against tyrannical Spain, and much less the "noble savage" of America's untamed romantic nilderness. More discerning minds came to realize that he was the victim of centuries-old political and economic forces that kept the masses in abject bondage to colonial institutions that would not disappear nith political panaceas alone. This new *Indianista* literature. in which the Indian is presented as a pressing social problem. had already found favour in fiction in the novel *Aves sin nido* (1889) by the Peruvian Clorinda Matto de Turner (1854–1909). And the Indian's cause had been advanced by González Prada. the spiritual precursor of the militant pro-Indian, social-reform party Apra (Alianza Popular Revolucionaria Americana) that from its founding in 1923 became a vital political and intellectual force in Andean America. Out of the early sociological novels. *Pueblo enfermo* (1909) and *Raza de bronce* (1919), by the Bolivian Alcides Argüedas (1879–1946) came the sombre short stories *Cuentos andinos* (1920) by Enrique López Albujar (1872–) of Peru; the prize-ninning novel of Indian life in the Peruvian highlands. *El mundo es ancho y ajeno* (1941) by Ciro Alegria (1909–); and the brutally realistic pages of an entire school of Ecuadorean nriters nhose internationally heralded spokesman. Jorge Icaza (1902–), skirted dangerously close to aesthetic suicide in his mass-minded. vernacular-ridden novels, *Huasipungo* (1934) and *En las calles* (193j national award).

The long struggle between man and nature became more critical as more powerful economic forces brought the primitive nay of life ınto sharper conflict with the demands of modern civilization. The clash between the forces of "barbarism" and "civilization." the pampa and the city, described by Sarmiento in his classic account, *Facundo,* had by no means receded into history with the passing of 19th-century *caudillos* (local chiefs). Subtler and less tangible international forces changed the colour and pace of the aging colonial system. Land and nature's gifts were more zealously sought after and fought over than ever before: cattle on the pampas and the llanos. tin and copper and nitrates in the mountain fastnesses and desert wastes, oil in areas long neglected by modern man. rubber and bananas in the "green hell" of the tropics. Nature resisted man's inroads into its romantically conceived domain. And the struggle between the two became more violent as man fought against man, selfishly, to possess nature alone. These same forces were at work too in the growing urban centres where modern industrial economy exerted an even more insidious control over the destiny of the masses and where the traditional way of life and man's attitude toward man and toward himself were subjected to ever increasing pressures of all kinds.

The clash between the old and the new on the pampas of Argentina and Uruguay created a rich literature that runs the gamut from the sombre descriptive pages of Uruguay's early outstanding short-story nriter Javier de Viana (1872–1926) and the keen psychological portrayal of rural types in *El terruño* (1916) by Carlos Reyles (1868–1938), also of Uruguay, to the simple humorous narrative of gaucho life so engagingly depicted in *El inglés de los güesos* (1924) by Argentina's Benito Lynch (1885–1951) and the image-studded. evocative prose epic of the gaucho, *Don Segundo Sombra* (1926), by the Argentine Ricardo Guiraldes (1886–1927), a classic and perfect example of the application of modern technique to the treatment of a regional theme. In *Doña Bdrbara* (1929) Romulo Gallegos (1884–), one of Ibero-America's masters of plot technique. gave a dramatic and poetic depiction of similar forces at work on the Venezuelan llanos.

For the tropics appeared two artists who spoke for a growing number of younger writers who discovered the *selva,* or jungle, where cotton and bananas and oil have outdistanced rubber in pitting man against nature and man ever more sharply against man: Horacio Quiroga (1878–1937) of Uruguay. consummate short-story artist and worthy disciple of Poe and Kipling, who excelled in his dramatic descriptions of the Chaco and the jungle of Misiones (Arg); and the Colombian poet, José Eustasio Rivera (1889–1928). whose sole prose work, *La vorágine* (1924)—probably the best novel on the American tropics yet written—is a powerful denunciation of the type of exploitation that marred the lives of the rubber gatherers in the upper Amazon during the boom days of the early 1900s.

Man's conflict with man in urban society has been the subject of a growing body of novels since the turn of the century when Gamboa exposed the social ills of his time. His popular *Santa* (1903), a melodramatic picture of prostitution in his homeland, is the Mexican counterpart of Zola's *Nana.* In *Nacha Regules* (1919) Manuel Gálvez (1882–), distinguished Argentine novelist of a varied and rich production, did for metropolitan Buenos Aires nhat Gamboa had done for Mexico City. And in *La maestra normal* (1914) Gálvez has captured forever the universal pettiness and monotony of life in the smaller provincial centres before the quickening pace of modern mechanized manners shattered the old colonial nays Urban Santiago and Chile's underprivileged everynhere have two powerful champions in the novelist Joaquin Ednards Bello (1888–) and in Manuel Rojas (1896–). one of Ibero-America's truly gifted short-story writers. Man's struggle nith the deeper forces within and beyond himself has found commendable expression in the psychological novels of the Chilean Eduardo Barrios (1884–) and in the existentialist approach of the Argentine Eduardo Mallea (1903–).

In their soul-searching for a key to individual and collective existence in the Americas nriters have continued to turn to a record of the past as well. La *gloria* de *Don Ramiro* (1908) by the accomplished stylist Enrique Rodriguez Larreta (1875–1961) of Argentina is generally considered the best historical novel yet nritten in the Spanish language.

Ever since colonial times the Ibero-American theatre has shown a decided preference for peninsular productions and for plays borrowed from other tongues. Only one native dramatist,

Florencio Sánchez (1875–1910) of Uruguay, succeeded in obtaining minor prominence on the international stage, and his relative success was due largely to the *criollo* (creole) content of his plays rather than to anything indicative of an emerging new world dramatic technique. The favourable reception which the outside world accorded Deus *lhe pague* (c. 1938) by Brazil's Joracy de Camargo '(1898–) only served to accentuate the fact that in spite of a rapidly swelling native repertoire and of the heartening and continued efforts of experimental groups everywhere, Ibero-America had not yet produced a dramatist who could claim the universal recognition bestowed on a growing number of her distinguished sons in the fields of poetry and prose fiction.

IBERT, JACQUES FRANÇOIS ANTOINE (1890–1962), French composer known for his skilled orchestration, was born on Aug. 15, 1890, in Paris. He was a pupil of Gabriel Fauré and Paul Vidal at the Conservatoire, and won the Prix de Rome in 1919. Among his best-known orchestral works are Escales, La Ballade de la *geôle* de Reading, based on Oscar Wilde's poem, the flute concerto, the concerto for cello and wind instruments and the suite *Paris.* "Le Petit âne blanc" from the suite *Histoires* became his most popular piano work. Ibert was director of the French Academy in Rome, 1937–61. He died in Paris on Feb. 5, 1962.

See J. Feschotte, *Jacques Ibert* (1958).

IBERVILLE, PIERRE LE MOYNE, SIEUR D' (1661–1706), French-Canadian soldier and colonizer of Louisiana, was born in Montreal on July 16, 1661. At the age of 14 D'Iberville was appointed midshipman in the French navy and sent to France. After four years' service on French ships he returned to Canada. In 1686 he led a detachment on the overland expedition under De Troyes against the English forts on Hudson bay and aided in the reduction of forts Monsipi, Rupert and Kitchichouame (later Ft. Albany), also capturing two English vessels. He was left in command of the forts, 1686–89, and in 1688 succeeded in taking two more English ships. In 1690 he was a leader of the French expedition against Schenectady, but before the end of the year returned to Hudson bay to recapture Ft. Albany, which had relapsed into English control. In 1694 he led a land expedition which captured Ft. Nelson on Hudson bay.

During the winter of 1696–97, D'Iberville captured Ft. Pemaquid and ravaged the English settlements on the coast of Ne foundland. In 1697, in command of a frigate, he again entered Hudson bay and defeated three superior English vessels in a desperate engagement. Afterward he again took Ft. Nelson, which the English had recaptured. After the peace of Ryswick D'Iberville was called to France and commissioned by the marine minister, Pontchartrain, to found a settlement at the mouth of the Mississippi. He left Brest in Oct. 1698 with four vessels and 200 colonists and reached Mobile bay in Jan. 1699. There the colonists were left while D'Iberville and a number of men searched the coast for the Mississippi, which was entered at the delta and ascended probably to the mouth of the Red river. No favourable site for a colony was found along the river, and, it being late, D'Iberville built Ft. Maurepas on the present site of Biloxi, Miss. This was the first permanent French settlement on the Gulf coast.

Returning the next year, D'Iberville built a post on the Mississippi river near New Orleans and explored much of the lower valleys of the Red and Mississippi rivers. Returning a third time in 1701, he found his colony badly reduced by disease and transferred most of the colonists to Mobile. He returned for additional colonists, but France was again at war, and D'Iberville was retained for naval service. He was given command of the West Indian fleet, and in 1706 invaded the islands of Nevis and St. Christopher, forcing them to surrender. While at Havana, D'Iberville fell ill with fever and died July 9, 1706.

IBEX, the Alpine wild goat, *Capra* ibex. Formerly common in the Alps, the ibex is now confined to the Gran Paradiso range in the neighbourhood of Cogne, Italy, and to the Swiss National park in the Engadine. It measures about 43 ft. in length and stands about 36 in. at the shoulder. In summer the short fur is ashy gray, but in winter this is concealed by long, yellowish-brown hairs. The horns are long, curved backward and ridged on the front surface. The forelegs are somewhat shorter than the hind limbs. The agility of the ibex on its native mountains is astounding. It inhabits the line of perpetual snow, descending at night to graze in the highest woods. The ibex is gregarious, living in small herds, but the old males are usually solitary. The female, after a period of gestation of 90 days, produces a single young one, which is at once able to follow her. The flesh resembles mutton, but with a flavour of game.

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

ALPINE IBEX (CAPRA IBEX)

The name ibex has been extended to include allied species, of which the Asiatic ibex (*C. sibirica*), ranging over central Asia, is the finest and may possess horns 60 in. long. Other species, differing in the thickness of and ridges on the horns, occur in Arabia, Ethiopia, the Caucasus and the Pyrenees, and the name is wrongly applied to the short-horned Indian *Hemitragus hylocrius* from the Nilgiris, really more closely related to the chamois.

IBIS, any one of 25 species of medium-large birds, kin to storks (*q.v.*) but with a slender, down-curving, curlewlike bill, comprising the subfamily Threskiornithinae in the order Ciconiiformes. Six warm continents and many islands in or near the tropics have ibis. They wade in shallow lagoons, lakes, bays and marshes, feeding on small fishes and soft mollusks. They fly with neck and legs extended, alternately flapping and sailing. Ibis often nest in vast colonies, building compact stick nests low in bushes or trees and laying three to five eggs, usually dull white mottled with brown. Oldest known and emblem of Osiris' secretary, the sacred ibis (Threskiornis *aethiopica*) of Africa, 25 in. long, white with black in its wings, has a bare black head and neck. Glossy ibis (Plegadis *falcinellus*), a rich chestnut colour, range the world, the white-faced race (P. f. guarauna) from Oregon to Argentina. The scarlet ibis (Guara rubra) lives in tropical America, white ibis (*G. alba*) north to Gulf coast lowlands.

GLOSSY IBIS (PLEGADIS FALCINELLUS) ON NEST

(G. F. Ss.)

IBLIS, in Islamic religion the personal name of the devil. In the Koran he is mentioned by name 11 times as an angel who rebelled against God when man was created; his punishment was postponed until the Judgment Day, and meantime he is allowed to tempt men to evil. He is the counterpart of the Jewish and Christian Satan; in Arabic this Hebrew word has become the generic term for devil. Iblis is identified with "the devil" (references to whom occur 68 times in the Koran), but "devils" in general are also freely mentioned. See also DEVIL.

See Koran, vii, 11 ff., and s.v. "Iblis" in the indexes; "Iblis" and "Shaitan" in *Shorter Encyclopaedia of Islam* (1953), with bibliography. (W. C. Sx.)

IBN ʿABD RABBIHI (ABU ʿUMAR AHMAD IBN MOHAMMED IBN ʿABD RABBIHI) (860–940), Arab poet, celebrated for his anthology of Arabic literature, *ʿIqd al-Farid* ("The Precious Necklace"; edited by Ahmad Amin *et al.,* 1940), which resembles the *'Uyun al-Akhbar* of Ibn Qutaybah (*q.v.*), from which it borrows largely. He was born at Cordoba in Spain in 860, and won a great reputation for learning and eloquence. Selections of his own poems are included in the *Yatimat al-Dahr,* vol. i, (1887).

IBN ABI-USAYBIAH (MUWAFFAQ-AL-DIN ABU-AL-'ABBAS AHMAD IBN ABI-USAYBIAH) (1203–1270), Arab physician, was born at Damascus, the son of an oculist, and studied medicine at Damascus and Cairo. In 1236 he was appointed by Saladin physician to a new hospital in Cairo, but resigned in 1237 to serve the amir of Damascus in Salkhad. There he lived and died. His great work, *'Uyun al-Anba* ("Lives of the Physicians"), contains biographies of over 400 physicians and scientists and is probably the most important source for the history of Islamic medicine.

IBN AL-ATHIR (IBN ATHIR), the family name of three brothers, all famous in Arabic literature, who were born at Jazirat ibn Omar in Kurdistan.

The eldest, MAJD-AL-DIN IBN AL-ATHIR (1149–1210), made a special study of the Koran, the tradition and Arabic grammar. His *Kitab al-Nihaya* ("Book of the Utmost Effort," pub. 1904) is a dictionary explaining obscure terms in the traditions. He also wrote a dictionary of family names *Kitab al-Murassa* (ed. by *C.* F. Seybold. 1896). Having long been in the service of the amir of Mosul he died at Mosul in 1210.

ABU AL-HASAN IZZ-AL-DIN IBN AL-ATHIR (1160–1234), the most distinguished of the brothers, was a historian whose chief work is *al-Kamil fi-al Ta'rikh* ("The Complete in History"; ed. by C. J. Tornberg, *Ibn al-Athiri Chronicon,* 14 vol., 1851–76). It extends to 1231, the first part, up to 923, being an abbreviation of the work of Tabari (*q.v.*) with additions. He also wrote a history of the atabegs of Mosul (pub. by the Académie des Inscriptions in *Recueil des historiens des croisades,* vol. ii. 1906); an account of 7,500 companions of Mohammed, *Usud al-Ghaba* ("The Lions of the Forest"; pub. in 5 vol., 1869–71); and a compendium of Sam'ani's *Kitab-al-Ansab* ("Book of Genealogies") entitled *al-Lubab* (pub. 1938–49; *cf.* F. Wiistenfeld, *Specimen el-Lobabi,* 1835). He died at Mosul in 1234, having also been in the service of the amir.

The youngest brother DIYA' AL-DIN IBN AL-ATHIR (1163–1239) was outstanding as a literary critic and was author of a book on rhetoric, *Kitab al-Mathal* ("The Bock of Example," pub. 1939; *cf.* I. Goldhizer, *Abhandlungen zur arabischen philologie,* vol. i, 1896). He entered the service of Saladin and later became vizier to his son al-Malik al-Afdal. He died at Baghdad in 1239.

IBN AL-FARADI (ABU-AL-WALID ʿABDULLAH IBN AL-FARADI) (962–1013), Arab historian; best known for his history of Andalusian scholars, *Ta'rikh Ulama' al-Andalus* (edited by F. Codera, 1891). He was born at Cordoba, Spain, Dec. 22, 962, and studied law and the prophetic tradition. In 992 he made the pilgrimage to Mecca and thereafter lived in Egypt and Tunis. After his return to Spain (1009) he became *qadi* (judge) in Valencia, and was killed in Cordoba. April 20, 1013, when the Berbers sacked the city. He also wrote a history of the poets of Andalusia.

IBN AL-FARID (SHARAF AL-DIN ABU HAFS 'UMAR) (1182–1235), Arab poet and mystic, whose verse is accounted the finest expression of mystical aspiration in Arabic, was born at Cairo, Egy., son of a public notary. Intended for a legal career, he abandoned his studies for the religious life and wandered about the Muqattam hills overlooking Cairo. For some years he lived in Mecca, and it was there that he met the famous Baghdadi mystic Shihab al-Din al-Suhrawardi. He spent the last years of his life in Cairo, and is buried in a mausoleum in the Muqattam hills.

The *diwan* of his poems, collected after his death, consists mainly of formal odes cast in the form of a lover's yearning for reunion with his beloved, said to reside in Arabia; their esoteric meaning is the mystic's desire to be assimilated into the pre-eternal spirit of Mohammed, the first projection of the Godhead. This idea is developed at great length and with profound metaphysical subtlety in the famous *Ta'iya,* a veritable epic in 761 couplets all rhyming in *ati.* Numerous commentaries were written on this poem and on the *diwan* as a whole, the most valuable being those of al-Farghani (d. *c.* 1300), al-Kashani (d. 1334), al-Burini (d. 1615) and 'Abd al-Ghani al-Nabulusi (d. 1730). Several Arabic editions of the *diwan* have been printed; an edition in Roman transcription, based upon the oldest extant manuscript, was published in 1952 by A. J. Arberry, who also translated and annotated *The Mystical Poems* of Ibn al-Farid (1952). Ibn al-Farid's style is highly mannered and exhibits all the rhetorical embellishments of the *badi'* school of poetry *(see* ARABIC LITERATURE); nevertheless his poems contain many passages of striking beauty and deep religious emotion.

BIBLIOGRAPHY.—C. Brockelmann, *Geschichte der arabischen Litteratur,* vol. i (1898) and suppl. i (1937); R. A. Nicholson, *Studies in Islamic Mysticism* (1921); Muhammad Mustafa Hilmi, *Ibn al-Farid wa'l-hubb al-ilahi* (1942). (A. J. AY.)

IBN ʿARABI (ABU BAKR MOHAMMED IBN ʿALI MUHYI AL-DIN AL-HATIMI AL-QAI AL-ANDALUSI IBN AL-'ARABI) (1165–1240), Moslem theologian and mystic, was born in Murcia, Spain, on July 28, 1165, and educated in Seville. He traveled in Egypt, Arabia, Baghdad, Mosul and Asia Minor, and then settled in Damascus. where he lived for the rest of his life. He died in Oct. 1240.

In law Ibn 'Arabi was a Zahirite, in theology a mystic of the extreme order, though professing orthodox Ash'arite theology and combating in many points the Indo-Persian mysticism (pantheism). He claims to have had conversations with all the prophets past and future, and reports conversations with God himself. Of his numerous works about 150 still exist. The most extensive is the 12-volume *al-Futuhat al-Makkiya* ("Meccan Revelations"; 1274, 1329), a general encyclopaedia of Sufistic beliefs and doctrines.

See C. Brockelmann, *Geschichte der arabischen Litteratur,* vol. i, pp. 441–448 (1898); R. A. Nicholson, *A Literary History of the Arabs,* pp. 399–404 (1907).

IBN BATUTAH (or BATTUTAH; Arabic, ABU ABDALLAH MOHAMMED) (1304–1368), the greatest of Moslem travelers, nhose journeys extended from the Niger basin to China from 1325 to 1355, and was born at Tangier in 1304.

He set out from his native town in 1325 to make the pilgrimage to Mecca, traveling by caravan to Alexandria and Cairo. As the Red sea crossing from Aidhab to Jidda was blocked, he returned to Cairo, journeyed to Damascus and thence to Medina and Mecca. The lure of travel had already begun to beckon him, and before the next pilgrimage he toured southern Persia and Iraq. His next journey took him to Yemen, and from Aden down the east coast of Africa to Mombasa, Kilwa and Mogadishu (Mogadiscio), received everywhere by the local sultans as an honoured guest. He sailed back to Dhofar, and thence to Oman and Hormuz (on the new island site to which it had been transferred from the mainland about 1315) and back through the pearl fisheries and Qatif to Mecca for another pilgrimage.

His ambition was now set on going to India, of the generosity of whose sultan, Mohammed Tughluq, to newcomers fabulous tales were told. But no ship was available, and for some reason he recrossed the Red sea and made through Egypt and Syria to Asia Minor, then partitioned between numerous Turkish baronies. His eyewitness account of these, including the infant Ottoman state, is of outstanding value Crossing the Black sea to the Genoese port of Kaffa (his first experience of a Christian city, in which he was at first perturbed by the church bells), he traveled to the court of the Mongol khan of the Golden Horde, Mohammed Uzbeg, in the Caucasus. At this point he inserts two detours the veracity of which has been challenged: one to the city of Bulghar, on the middle Volga, the other to Constantinople in the company of a Greek princess married to the khan. The latter is a vivid narrative, especially in describing his interviews with the emperor Andronicus III and the ex-emperor Andronicus II, but is difficult to reconcile nith his chronology. After returning to the khan's capital at New Sarai on the Volga, he crossed the steppes to Khwarizm and Bukhara, and made an extensive tour in Khurasan

before crossing the Hindu Kush into Afghanistan, whence he reached the Indus in Sept. 1333.

Sojourn in the East.—The immensity: variety and wealth of India made an indelible impression on Ibn Batutah's mind. Everything aroused his curiosity, and about one quarter of his book is devoted to descriptions of its (to him) strange customs and institution;, the diversity and abundance of its products and the manners of its rulers and peoples. On arrival at Delhi. he was in due course presented to Sultan Mohammed and appointed to the sinecure of *qadi* ("a judge in a Mohammedan court") of the Malikis. He has much to relate of the mixture of tyrannical cruelty and extravagant generosity in the sultan's character, and when he himself eventually fell under suspicion he feared for his life, with just cause. In the meantime he had made several journeys in the north, but mentions them only incidentally. In 1342 he was restored to favour and ordered to accompany an embassy to the Mongol emperor of China. The party traveled to Cambay and then by ship down the Malabar coast to the great port of Calicut, where they were to embark in junks for China; but he was accidentally hindered from embarking, and the junks were wrecked. Left destitute, he spent many months on the Malabar coast, taking part in various adventures, including the capture of Sandabur (Goa), and finally sailed to the Maldive Islands, where he again became *qadi* and a personage of importance. A year later, probably in 1345, he left for Ceylon, where he climbed Adam's peak to visit the venerated "footprint of Adam."

After a short visit to the Coromandel coast and revisiting Malabar and the Maldives, Ibn Batutah sailed to Bengal, visited a Moslem saint in Sylhet and embarked near Dacca for Sumatra. whence he sailed to the trading port of Zayton in China. He visited also Canton and claims to have been in Kinsai (Hangchow) and Cambaluc (Peking).

His Return and Later Journeys.—On his may home Ibn Batutah saw the great bird *rukh* (evidently from his description, an island lifted by refraction), passed rapidly through Sumatra, Malabar, Dhofar, Oman and southern Persia to Baghdad, where he learned of his father's death 15 years before. He gives a gruesome account of the ravages of the Black Death of 1348 in Syria and Egypt, through which he traveled to Mecca for his last pilgrimage. Back in Cairo, he decided to return to Morocco, sailed to Tunisia and then by Catalan ship to Mostaganem, calling at Sardinia on the way, and reached Fès in Nov. 1349. Then, after a brief stay in Tangier, he crossed to Gibraltar to take part in the holy war against Castile, but only visited Granada and its dependencies and returned to Marrakech. In 1352 he set out from Tafilelt in southern Morocco on his last and probably most adventurous journey across the Sahara to the Moslem Negrolands in the Niger basin. Here again his narrative'is the fullest (indeed, almost the only) first-hand account of the Mandingo kingdom of Malli and the Songhai capital at Gogo. On orders from the sultan of Morocco he returned from Gogo through the Tuareg country of Ahaggar mountains and Tuat to Tafilelt and Fès, so ending 75,000 mi. of travel. His narrative was dictated to a royal secretary, Ibn Juzayy, at Fès, and his remaining years were spent as a *qadi* in Morocco.

An English translation of later abridgments of his narrative was published by S. Lee in 1829 for the Oriental Translations fund. The complete text with French translation was issued by C. Defremery and B. Sanguinetti in 1853–59. Mahdi Husain has published an annotated translation of the travels in India and Ceylon (1953). The first volume of a complete translation by H. A. R. Gibb, published by the Hakluyt society, was issued in 1958.

See H. F. Janssens, *Ibn Batouta, "le voyageur de l'Islam,"* (1948).

(H. A. R. G.)

IBN DURAID (ABU-BAKR MOHAMMED IBN AL-HASAN IBN DURAID) (837–934), Arab philologist, was the author of a large-scale dictionary, the *Jamhara fi 'l-lugha.* He was born at Basra of south Arabian stock, but fled to Oman in 871, during the revolt of the *Zanj* or Negroes. In 883 he went to Persia, and remained there until he settled in Baghdad in 920. In his dictionary (published in Hyderabad, India, 4 vol., 1926–30) the author retained the anagrammatical arrangement of Khalil (*q.v.*) though using the normal alphabetical order of the letters. The work is, however, marred by the addition of many chapters on rare word forms, which include a large number of words listed in no particular order. Another work, the *Kitab al-ishtiqaq* ("Book of Etymology," edited by F. Wüstenfeld, 1854), deals with the etymology of Arab tribal names.

See F. Krenkow, "The Beginnings of Arabic Lexicography, Till the Time of al-Jauhari, With Special Reference to the Work of Ibn Duraid," *Journal of the Royal Asiatic Society,* centenary supplement, p. 255 (1924); Carl Brockelmann, *Geschichte der arabischen Litteratur,* vol. i, p. iii (1898), suppl. vol. i, p. 172 (1937).

(J. A. HD.)

IBN FALAQUERA (SHEMTOB BEN JOSEPH IBN FALAQUERA or PALQUERA) (*c.* 1222–*C.* 1295), Spanish-born Jewish philosopher and translator. propagated a reconciliation between Jewish orthodoxy and philosophy and defended Maimonides' *Guide of the Perplexed* against the attacks of the traditionalists. His numerous works include a *Dialogue Bet-ween a Philosopher and a Man of Piety;* an ethical treatise, *The Balnt of Sorrow;* an introduction to the study of the sciences entitled *Reshit Hokhmah* ("The Beginning of Wisdom"), which reproduces al-Farabi's *The Aims of the Philosophy of Plato and Aristotle* and was translated into Latin at the end of the 15th century; the *Sefer ha-Ma'alot* ("The Book of Degrees"), which advocates the Neoplatonic ideal of the contemplative life; a commentary on Maimonides' *Guide* under the title *Moreh ha-Moreh;* and an abstract of Ibn Gabirol's *Fons Vitae,* in Hebrew.

BIBLIOGRAPHY.—L. Venetianer, *Das Buch der Grade* (1894); M. David, *Schemtob ibn Falaqueras Rrschit Choknzah* (1902); R. Klibansky, *The Continuity of the Platonic Tradition,* p. 39 (1939); and *Alfarabius: De Platonis Philosophia,* ed. by F. Rosenthal and R. Walzer (1943), being vol. ii of *Plato Arabus.* (A. AN.)

IBN GABIROL (SOLOMON BEN JUDAH IBN GABIROL; in medieval Latin and Romance languages AVENCEBROL or AVICEBRON) (*c.* 1020–*c.* 1050 or 1070), Jewish poet and philosopher, was born at Málaga. Spain. His early years were spent at Saragossa. where he enjoyed the patronage of the statesman, scholar and poet Samuel ha-Nagid. At the age of 16 he began writing Hebrew poetry, using various Arabic metres and following both Spanish and Palestinian Hebrew tradition. Developing a style of his own, he wrote some of the finest pieces of medieval Hebrew poetry. They include the *'Anaq,* a poem on grammar, partially extant; about 400 lyric poems. religious and secular; and the *Azharot,* liturgical compositions for the festival of *Shebhu'ot.* His *Keter Malkhut* ("The Royal Crown"), a didactic poem on the nature of God, the universe and man's destiny, concluding with a confession of sin, has been adopted into the Jewish liturgy for the Day of Atonement.

Ibn Gabirol's chief philosophical work was written in Arabic and is preserved only in a Latin translation by Johannes Hispanus and Dominicus Gundisalvi entitled *Fons Vitae.* It exercised *a* considerable influence on the schoolmen but was less fortunate among Jewish medieval philosophers. It was not translated into Hebrew except for an abstract made by Ibn Falaquera (*q.v.*). The only traces left by it are found in Abraham ibn Daud's strictures upon its metaphysical doctrine and in quotations from it in Ibn Falaquera's *Moreh ha-:Wore11* and Moses ibn Ezra's *'Arugat ha-Bosem.* Isaac Abrabanel (d. 1508) and his son Judah (Leone Ebreo) knew Ibn Gabirol as the author of the *Fons Vitae,* but so much had the work fallen into oblivion that the 17th-century Joseph Solomon Delmedigo shared the schoolmen's view that its author was an Arab. This view prevailed until S. Munk discovered a manuscript of Ibn Falaquera's Hebrew abstract in 1846 and proved that Xvicebron, the author of the *Fons Vitae,* was identical with Ibn Gabirol.

Ibn Gabirol's metaphysical system is Neoplatonic but has features which according to Ibn Falaquera derive from pseudo-Empedoclean writings but would seem to be much nearer the (lost) pseudo-Aristotelian source on which Isaac Israeli and the longer (Arabic) version of the so-called *Theology of Aristotle* drew. It depicts the universe as a hierarchy of substances in the following order: universal (spiritual) matter emanates from the essence of God, and universal form from His will or word; then follow intellect (the Plotinian *nous*), soul and nature, which represent the

three spiritual or simple substances, and finally the lower world of corporeal or composite substances. Ibn Gabirol assigns to the will of God a much more dynamic role (similar to that which Philo attributes to the *Logos)* than it possesses in the literary sources before him. Another novel feature of his system is the doctrine that all beings, spiritual and corporeal, are composed of matter and form. The attribution of matter to spiritual beings such as the angels became a point of conflict between Franciscans and Dominicans and was opposed, on the Jewish side, by Abraham ibn Daud.

Texts include: the *Fons Vitae* in Latin, edited by C. Bäumker (1895), on which the Hebrew translation by J. Bluvstein and A. Zifroni (1926) and the Spanish translation by F. de Castro y Fernández (1902) are based; Ibn Falaquera's abstract, *Liqqutim,* edited by S. Munk in his *Mélanges de philosophie juive et arabe* (1859); an ethical treatise, *Kitab Islah-al-Aklzlag,* edited by *S.* S. Wise (1902); a collection of moral maxims translated from Arabic into Hebrew by Judah ibn Tibbon under the title *Mibhar ha-Peninim* and edited aith English translation by B. H. Ascher (1859); and the poems, edited by H. N. Bialik and J. H. Rawnitzki, 3 vol. (1924–29). *See* also the selected religious poems edited by I. Davidson and I. Zangwill in Hebrew and English (1923).

IBN HAZM (ABU MOHAMMED 'ALI IEN AHMAD IBN SAID IBN HAZM) (994–1064), Moslem theologian, was born in a suburb of Córdova, Spain, on Nov. 7, 994. He studied history, law and theology and became a vizier as his father had been before him, but was deposed for heresy. and spent the rest of his life quietly in the country. Little is known of his later life. In legal matters Ibn Hazm belonged first to the Shafi'ite school, but came to adopt the views of the Zahirites, who admitted only the external sense of the Koran and tradition, disallowing the use of analogy and appeal to the authority of an imam, and objecting altogether to the use of individual opinion. Ibn Hazm extended the application of these principles from the study of law to that of dogmatic theology. His chief work is the *Kztab al-fasl fi al-milal wa al-ahwa wa al-nihal,* or "Book of Sects," in which he particularly attached the Ash'arites.

IBN HISHAM (ABU MOHAMMED 'ABD-AL-MALIK IBN AYYUB AL-HIMYARI) (d. 834), Arab grammarian, whose recension of *Kitab Sirat Rasul Allah* (edited by F. Wustenfeld, 1858–1860; Eng. trans. by A. Guillaume. *The Life of Muhammad,* 1955), the chief source for the life of Mohammed, written by Ibn Ishaq (*q.v.*), is the only version extant. Ibn Hisham was born at Basra, studied in Kufa and later lived in Fostat (old Cairo), where he gained a name as a grammarian and student of language and history.

IBN ISHAQ (MOHAMMED IBN ISHAQ) (d. *c.* 768), Arab historian, author of *Kitab Sirat Rasul Allah,* the most important source for the biography of the prophet Mohammed. He lived in Medina, nhere he interested himself to such an extent in the details of the Prophet's life that he was accused of scepticism. He consequently left Medina in 733, and went to Alexandria, then to Kufa and Hira, and finally to Baghdad, where he wrote *Kitab Sirat Rasul Allah,* which is now lost in its original form and is known only in the recension of Ibn Hisham (*q.v.*). The work has been attacked by Arab writers (as in the *Fihrist* of Er-Nedim) as untrustworthy.

IBN JUBAIR (Abu Husain Mahommed ibn Ahmad ibn Jubair) (1145–1217), Arab geographer, was born in Valencia, Spain. At Granada he studied the Koran, tradition, law and literature, and later became secretary to the Mohad governor of that city. During this time he composed many poems. In 1183 he left the court and traveled to Alexandria, Jerusalem, Medina, Mecca, Damascus, Mosul and Baghdad, returning in 1185 by way of Sicily.

The *Travels of Ibn Jubair* were edited by W. Wright (1852), and a new edition of that text, revised by M. J. de Goeje, was published by the Gibb Trustees (1907).

IBN KHALDUN ('ABD-AL-RAHMAN IBN KHALDUN) (1332–1406), Arab historian and sociologist, is celebrated as a pioneer in the philosophy of history. He was born on May 27, 1332, at Tunis, the descendant of a Seville family which claimed to have come originally from the Hadramaut. In 1352 he entered the service of the sultan of Fez, but in 1356, his integrity having been suspected, he was imprisoned for two years. Later he emigrated to Granada, but returned to Africa (1364) and entered the service of the sultan of Tlemcen. After various vicissitudes, including further imprisonment and a period of residence in a monastery, he obtained employment with the sultan of Tunis. Subsequently, while on a pilgrimage to Mecca, he was persuaded by the sultan of Cairo to remain in that city and was appointed grand *qadi* (1384). He was removed from and re-installed in this office no fewer than five times. In 1400 he was taken to Damascus with the Egyptian army which vainly attempted to oppose Timur and had several interviews with him. He died in Cairo on March 19, 1406.

His *Kitab al-'Ibar,* a universal history (pub. 1867), is prefaced by one volume, the *Muqaddimah* (ed. by E. Quatremère, 1858; crit. ed. by Ali Abdel Wahid Wafi, 1957; Eng. trans. by F. Rosenthal, 3 vol., 1958). This is followed by four volumes of general Islamic history, and two of the history of the Berbers (ed. by M'G. de Slane with French trans., *Histoire des Berbères* . . . , 3 vol., 2nd ed. 1925–1934). Included in the history is an autobiography (French trans. by M'G. de Slane in his *Prolégomènes historiques d'Ibn Khaldoun,* 1862–1865). The *Muqaddimah* is more important than the history itself. In it Ibn Khaldun, with great insight and originality, tries to explain the pattern of history. Taking a scientific view of the rise and decay of human societies he argues that such phenomena obey certain laws which can be discovered empirically. According to his analysis the basis of society is group-feeling and many of his conclusions have a remarkable relevance to modern problems.

An Arab Philosophy of History (1950) consists of selections from the Prolegomena (*i.e.,* the *Muqaddimah*), translated and arranged by Charles Issawi.

IBN KHALLIKAN (SHAMS-AL-DIN AHMAD IBN MOHAMMED IBN KHALLIKAN) (1211–1282), Arab author of a famous biographical dictionary, was born in Arbela, Mesopotamia, on Sept. 23, 1211. After studying jurisprudence he went to Cairo, where he became deputy chief *qadi* ("judge"). In 1261 he became chief *qadi* of Damascus and, except for one interval (1271–78) when he taught jurisprudence in Cairo, he held this appointment until his death on Oct. 21, 1282. His *Wafayat al-a'yan* (first pub. by F. Wiistenfeld, 1835–43; incomplete edition by Ahmed Farid Rifa'i, 6 vol., 1936 *et seq.;* English translation with introduction by M'G. de Slane, 4 vol., 1842–71) is a brilliant alphabetical biographical dictionary, dealing with all types of men famous in Islamic history. Mohammed, his companions and their followers and the caliphs, were excluded, since adequate literature concerning them already existed. The work deftly sketches the characters of its subjects by interesting anecdotes.

See E. V. Lucas, *A Boswell of Baghdad* (1917). (J. A. HD.)

IBN QUTAYBAH (IBN KUTAIBA; Arabic, ABU MUHAMMAD 'ABDALLAH IBN MUSLIM IBN QUTAYBAH) (828–899); Arab writer of Khurasani stock, born in Kufa, Iraq, specialized in theology, philology and literature and spent his later years teaching these subjects in Baghdad. In philology, he is said to have drawn on both Basran and Kufan ideas *(see* ARABIC LITERATURE: *Technical and Scientific Literature: Philology)*; but his grammatical writings have been lost. His *Adab al-Katib* ("Secretary's Guide," edited by M. Grdnert, 1900) is a compendium of Arabic usage and vocabulary, classified under word patterns and subject-headings. He opposed the pro-Persian *shu'ubiya* movement, and wrote the *Kitab al-'Arab* to show the pre-eminence of the Arabs. His theo-

logical works have not been printed; but he was orthodox and old-fashioned. He disliked the subtleties of professional theologians and philosophers, and thought that the traditions (*hadith*) were the only authoritative source for Islamic jurisprudence. In his *Kitab al-shi'r wa' l-Shu'ara* ("Poetry and Poets") he laid down canons of criticism. The important introduction has been printed with French translation by M. Gaudefroy-Demombynes, *Ibn Qotaiba—Introduction au livre de la poésie et des poètes* (1947). His *'Uyun al-Akhbar* (edited by Carl Brockelmann, 1900–03) deals with such subjects as war, nobility, character, eloquence and friendship. Its chief value lies in its illustrations from history, poetry and proverb. The *Kztab al-Ma'arif* ("Book of Knowledge," edited by F. Wiistenfeld, 1850) deals with history.

See Ishaq Musa Huseini, ***The Life*** *and Works of Ibn Qutayba* (1050). (J. A HD.)

IBN SA'D (ABU ABDALLAH MOHAMMED IBN SA'D IBN MANI' AL-ZUHRI) (d. 845), Arab biographer, often called Katib al-Waqidi, "Secretary of Waqidi," after one of his instructors in the Prophetic tradition, was the author of *Kitab al-Tabaqat al-Kabir* ("The Great Book of the Classes," edited by E. Sachau *et al.*, 1904–1921). This work in eight volumes contains the life stories of Mohammed, his companions and successors down to Ibn Sa'd's own day. He lived chiefly in Baghdad.

See O. Loth, *Das Classenbuch* des *Ibn Sa'd (1869).*

IBN SA'UD, 'ABD UL-'AZĪZ IBN 'ABD UR-RAHMĀN IBN FAISAL (*c.* 1880–1953), was born at Riyadh, capital of Nejd. His father, 'Abd ur-Rahmān (d. 1928), was the youngest of four sons of the amir Faisal, sultan of Nejd from 1834 to 1867. The latter's death had plunged central Arabia into a state of anarchy and civil war owing to the contest of his two elder sons, 'Abdullah and Sa'ud, for the throne he had vacated. In 1875 the Turks occupied Hasa, while the rival dynasty of Ibn Rashīd in northern Nejd gradually extended southward until in 1891 the great amir Mohammed put an end to the Wahhabi state by the occupation of Riyadh itself. 'Abd ur-Rahmān went into exile with his family and, after a period of residence at Bahrein, arrived at Kuwait. Here he was influenced by Sheikh Mubarak ibn Sawah; and to this Ibn Sa'ud owed much of his future greatness and his friendship for Great Britain. From his father he inherited steady purposefulness.

Though 'Abd ur-Rahmān was the cadet of the Wahhabi dynasty, it was he who made the first effort to recover his father's throne in 1900. His defeat at Sarif was followed by the formal abdication of his rights and obligations in favour of his eldest son, 'Abd ul-'Azīz, who in 1901 launched into the desert with a force of only 200 men. At some distance from the capital he selected 15 of these, including his cousin 'Abdullah ibn Jiluwi (afterward governor of Hasa), for the final venture; entering Riyadh by night with his following he forced an entry into a house opposite the great fort where the Rashidian governor was lodged. A desperate struggle left Ibn Sa'ud the master of Riyadh, where he was at once proclaimed ruler of Nejd.

During the next few years Ibn Sa'ud consolidated the outlying provinces and resisted the Turks in their support of Ibn Rashīd. A Wahhabi victory at Bukairiya (1904) was followed by Ibn Rashīd's death (1906) and left Ibn Sa'ud master in the house of his ancestors with no danger of interference from the north.

Free now to show his capacity for administration Ibn Sa'ud proceeded to lay the foundations of his future greatness in a scheme remarkable both for boldness and ingenuity. He boldly seized upon the latent fanaticism of his countrymen as an instrument for the creation of a nontribal or pan-tribal element out of tribal material to leaven the mass into the semblance of a homogeneous nation. The first *Ikhwan* colony in 1912 was the first step of a deliberate program aiming at the abrogation of the patriarchal system in Arabia in favour of nationalism. At the time such an ambition was beyond the bounds of practical politics, but circumstances combined to bring it within the focus of Ibn Sa'ud's clear vision.

Al-Artāwīya, a flourishing town of 10,000 inhabitants, rapidly became the prototype of a hundred colonies which sprang up in various parts of Nejd during the next 15 years. Agriculture displaced pastoral activities as the binding force of the new organization, while the *shar'* or religious law took the place of the customary law of Bedouin society. Each colony constituted a contingent of the new Wahhabi standing army, for which circumstances have provided ample work at home and abroad. It was first put to the test in 1913 when Ibn Sa'ud turned his attention to the Turks who had been in Hasa since 1875. With a mere handful of men he suddenly appeared before Hufuf, whose astonished garrison surrendered without a blow. The garrisons at 'Uqair and Qatif followed suit and the Turks left eastern Arabia.

At the end of 1914 Captain W. H. I. Shakespear was deputed by Sir Percy Cox to visit Ibn Sa'ud with a view to enlisting his active assistance against the Turks, with whom his dynastic rival, Ibn Rashīd, had thrown in his lot. Ibn Sa'ud immediately undertook military operations; and in Jan. 1915 a battle took place at Jarrāb. The result was indecisive, but Captain Shakespear was killed and the British authorities were discouraged from further activity in Arabia. In December Ibn Sa'ud concluded a treaty of friendship with Great Britain but remained quiescent though he grew increasingly anxious as he saw King Husain ibn 'Ali in the Hejaz building up a strong position for himself with the help of T. E. Lawrence. In 1917 the Philby mission visited him at Riyadh to take stock of the situation and in the autumn of 1918 Ibn Sa'ud resumed activities against Ibn Rashīd. He reached the walls of Ha'il without being able to press home the attack, and the sudden termination of World War I found him still within the same frontiers as at its outbreak and with two powerful enemies to reckon with, Ibn Rashīd and King Husain. Relations with the latter were already strained to the breaking point. In March 1919 Lord Curzon on behalf of the British government decided in favour of King Husain and authorized him to occupy Khurma, which Ibn Sa'ud was warned to relinquish. The latter disregarded the warning; and two months later the Wahhabi army surprised and annihilated the Hashimite forces at Turaba. Having vindicated his rights by might Ibn Sa'ud retired to Riyadh. In 1920 a Wahhabi expedition added the highland districts of 'Asir to Ibn Sa'ud's dominions and in August of the following year the capture of Ha'il placed all central Arabia under a single rule. Meanwhile Bisha and Tathlith in the south were occupied, as also Khaibar and Taima northward, while in 1922 Jauf came within the Wahhabi sphere.

The British government made a belated effort to mediate at the conference of Kuwait, convened in Nov. 1923. The discussions ended without result in April 1924; and in September the Wahhabi invasion of the Hejaz began with the sudden capture of Ta'if and a massacre of its inhabitants. King Husain was forced to abdicate in favour of his eldest son, 'Ali, who evacuated Mecca. Mecca was quietly occupied by the Wahhabis in October, and the outlying districts of the Hejaz were rapidly overrun. Only Jidda and Medina remained in the hands of the Hashimites, both being subjected to a desultory siege. Ibn Sa'ud entered Mecca for the first time in Dec. 1924. In Nov. 1925 he and Sir Gilbert Clayton concluded the treaties of Bahra and Hadda which satisfactorily disposed of certain questions relating to Iraq and Transjordan. The following month Medina surrendered, while Jidda followed suit a fortnight later. On Jan. 8, 1926, Ibn Sa'ud was proclaimed king of the Hejaz in the great mosque of Mecca; and a year later his title of sultan of Nejd and its dependencies was converted to king.

Relations with Great Britain were brought up to date by a new treaty of Jidda negotiated with Sir Gilbert Clayton in May 1927; but a frontier dispute with Iraq broke out in November of the same year. In 1932 the kingdom and its dependencies was renamed "the kingdom of Saudi Arabia." In 1936 and 1939 Ibn Sa'ud granted oil concessions to a U.S. company; and the royalties derived from these concessions greatly increased the state revenues, though they caused the life of the royal entourage to degenerate considerably from its former Wahhabi austerity. Ibn Sa'ud's confidence in the survival of Britain, even in the darkest days of World War II, exercised an important influence on other Arab governments.

For political and other reasons the Wahhabi king took the fullest advantage of Islamic law in the matter of marriage and divorce

and was reputed to have been married about 150 times in the course of his career. The jubilee of Ibn Sa'ud's accession to his father's rights was celebrated in 1950. Ibn Sa'ud died Nov. 9. 1953, near hlecca; his eldest surviving son Sa'd ibn 'Abd ul-'Aziz al-Sa'ud (b. 1905), was proclaimed king. His second son, the amir Faisal, (b. 1906) minister for foreign affairs who had acted as viceroy of Hejaz in his father's absence, became heir to the throne.

IBN TUFAIL (ABU-BAKR MOHAMMED IBN 'ABD-AL-MALIK IBN TUFAIL; Lat. ABUBACER) (d. 1185/86), Moorish philosopher and medical writer, was born at Guadix, Spain, in the first decade of the 12th century. He became court physician and general adviser of the Almohade ruler Abu Ya'kub Yusuf (1163–84), to whom he introduced his younger friend Xverroes (*q.v.*). Ibn Tufail died at Marrakech in 1185/86.

Ibn Tufail wrote a number of medical works in Arabic, both in prose and in verse; but his reputation rests on the *Risalat Hayy ibn Yakzan* ("The Treatise on Hayy ibn Yakzan"), a kind of philosophical novel in which he describes the self-education and gradual philosophical development of a man who passes the first 50 pears of his life in complete isolation on an uninhabited island. The author does not follow the emanationist Neoplatonic astronomy which al-Farabi and Avicenna had introduced into their otherwise Aristotelian description of the world above the moon and which Avempace and Averroës accepted without criticism. He rather inclines toward Islamic theology in this respect and does not establish any "secondary causes" as the powers ruling the different celestial spheres. God, the highest being, is the only efficient cause. Philosophy is by no means the highest aim in life. Mystic contemplation is superior to it, and the hero of the novel succeeds eventually in staying in an almost uninterrupted mystical union with God.

Moses of Narbonne in the 14th century translated the *Risalat Hayy ibn Yakzan* into Hebrew and provided a Hebrew commentary, and Pico della hlirandola in the 15th century had a Latin version made from this translation. From the Arabic, E. Pococke made a Latin translation, *Philosophus autodidactus* (1671), and Simon Ockley an English translation, *The Improvement of Human Reason* (1708), new edition, *The History of Hayy ibn Yaqzan* (1929). For the text with French translation *see* Léon Gauthier (ed.), *Hayy ben Yaqdhân, roman philosophique d'Ibn Thofaïl*, 2nd ed. (1936).
(R. R. WR.)

IBO. A southern Nigerian tribe composing 33 subtribes, inhabiting the provinces of Benin, Ogoja, Onitsha, Owerri and Warri, whose language is related to Ibibio. The Ibo on the west of the Niger were long subject to the Edo: the rest lived in independent towns or villages under a paramount chief and a chief for each quarter. The extended family groups lived together in the same quarter. Marriage rules vary: marriage is usually prohibited between members of the same extended family and between near relations. Marriage by exchange is frequent. Descent is patrilineal. Age classes and secret societies flourish.

IBRAHIM (d. 1536), grand vizier of Turkey, was the son of a sailor at Parga, was sold into slavery and was bought by the sultan Soliman I who made him his grand vizier and married him to his own sister. Ibrahim, says a Venetian record, was "the heart and breath of the Padishah, who does nothing without consulting him; he is learned, fond of reading. and knows his law well." He was made commander in chief of the army for the invasion of Hungary, and in 1526 took Peterwardein. But his main functions were diplomatic. With the Venetian Gritti he conducted the negotiations for peace between the sultan and the emperor Ferdinand in 1533 In the autumn of that year he took command in Asia against the Persians. He occupied Tabriz on July 13; he nas then joined by Soliman, and marched against Baghdad. In both cases he prevented plunder. They returned to Constantinople on Jan. 8. 1536. He had for 14 years been the sultan's constant companion, even sharing his sleeping apartments. They retired as usual on March 30, and in the morning Ibrahim was found strangled by the sultan's orders.

IBRAHIM PASHA (1789–1848), Egyptian general, son, or adopted son of Mohammed Ali, pasha of Egypt. was born at Kavala in Thrace. During his father's struggle to establish himself in Egypt, Ibrahim, then 16 years of age, was sent as a hostage to the Ottoman capitan pasha (admiral), but when hlohammed Ali was recognized as pasha, he was allowed to return to Egypt. When Mohammed Ali went to Arabia to fight against the Wahhabis in 1813. Ibrahim was left in command in Upper Egypt. He continued the war with the broken power of the hfamelukes, whom he suppressed. In 1816 he succeeded his brother Tusun in command of the Egyptian forces in Arabia. Mohammed Ali had already begun to introduce European discipline into his army, and Ibrahim had probably received some training, but his first campaign was conducted more in the old Asiatic style than his later operations. The campaign lasted two years, and the political power of the Wahhabis was destroyed. Ibrahim landed at Yembo, the port of Medina, on Sept. 30, 1816. The holy cities had been recovered from the Wahhabis, and Ibrahim's task was to follow them into the desert of Nejd and destroy their fortresses. Such training as the Egyptian troops had received, and their artillery, gave them a marked superiority in the open field. But the difficulty of crossing the desert to the Wahhabi stronghold of Deraiya, some 400 mi. east of Medina. and the courage of their opponents, made the conquest a very arduous one. Ibrahim displayed great energy and tenacity, sharing all the hardships of his army, and never allowing himself to be discouraged by failure. By the end of Sept. 1818 he had forced the R'ahhabi leader to surrender, and had taken Deraiya, which he ruined. On Dec. 11, 1819, he made a triumphal entry into Cairo. After his return he supported the Frenchman. Colonel Sève (Suleiman Pasha), who was employed to drill the army on the European model. Ibrahim set an example by submitting to be drilled as a recruit.

When in 1824 Mohammed Ali mas appointed governor of the Morea by the sultan. who desired his help against the insurgent Greeks, he sent Ibrahim with a squadron and an army of 17,000 men. The expedition sailed on July 10, 1824. but Ibrahim was not able to land at Modon until Feb. 26. 1825. Ibrahim easily defeated the Greeks in the open field. and though the siege of Missolonghi proved costly he captured the place on April 24, 1826. The Greek guerrilla bands harassed his army, and in revenge he desolated the country and sent thousands of the inhabitants into slavery in Egypt. These measures led first to the intervention of the English. French and Russian squadrons (*see* NAVARINO, BATTLE OF), and then to the landing of a French expeditionary force. By the terms of the capitulation of Oct. 1, 1828, Ibrahim evacuated the country. In 1831 Ibrahim was sent to conquer Syria. He took Acre after a severe siege on May 27, 1832, occupied Damascus, defeated a Turkish army at Homs on July 8, defeated another Turkish army at Beilan on July 29, invaded Asia Minor, and finally routed the grand vizier at Ronia on Dec. 21. The convention of Kutaiah on May 6 left Syria for a time in the hands of Mohammed Ali.

After the campaign of 1832 and 1833 Ibrahim remained as governor in Syria. The exactions he was compelled to enforce by his father soon provoked revolts. In 1838 the Porte felt strong enough to renew the struggle, and war broke out once more. Ibrahim won his last victory for his father at Nezib on June 24, 1839. But Great Britain and Austria intervened on behalf of Turkey. Their squadrons cut his communications by sea with Egypt. a general revolt isolated him in Syria. and he was finally compelled to evacuate the country in Feb. 1841. In 1846 Ibrahim paid a visit to western Europe. When his father became imbecile in 1848, he held the regency till his own death on Nov 10, 1848

IBSEN, HENRIK JOHAN (1828–1906) Norwegian poet and dramatist. nas born at Skien on March 20, 1828. His father, Rnud Henriksen Ibsen, a merchant. was of mixed Danish. German and Scotch blood; his mother. hfaria Cornelia Xltenburg was a Norwegian, of German descent When Ibsen was eight vears old, his fdther failed in business. and recollections of the penury which followed can be found in Peer *Gynt*.

Early **Life** and Works.—At the age of 1j Ibsen was apprenticed to an apothecary in Grimstad. a small town of 800 inhabitants; it was a business he detested, and he began to express himself and relieve his misery by writing poetry in 1847.

He read widely and deeply, especially in poetry and theology, and in 1850 he went to Christiania as a student; this year also saw the publication of his first play, a blank-verse tragedy, *Cataline,* which was followed, not many months after, by *The Viking's Barrow,* which was performed at the Christiania theatre, but not published. For a few months he co-operated in the production of a weekly satirical newspaper; but in November 1851, when in September the paper's brief life of nine months had ended, he was appointed as "theatre-poet" to the new theatre at Bergen, established for the encouragement of Norwegian drama, by the violinist Ole Bull. This position Ibsen held until the summer of 1857, and this intimate connection with the theatre — he combined the duties of producer, manager, adviser and designer with that of a poet — confirmed him in his nascent desire to be a dramatist. The plays which he wrote for this theatre were *St. John's Night* (1853), *Lady Inger of Ostrat* (1855), *The Feast of Sollzaug* (1856) *and Olaf Liljekrans* (1857). He left Bergen for Christiania in 1857; and his next two plays reflect the influence of his engagement and marriage to Susanna Thoresen; *The Vikings of Helgeland* (1858) and *Love's Comedy* (1862) are the first plays — earlier signs may be found in the lyric poems — in which the unmistakable voice of Ibsen is heard clearly. Both plays were misunderstood; and the fierce anti-romantic, idealistic satire of *Love's Comedy* caused a storm of indignation in Denmark and Norway: it is Ibsen's earliest protest on behalf of the inalienable rights of the individual, his first stroke in the life-long battle against the stupidity, the weight of the majority. There is in it not a little of the spirit which we find in the satiric poetry of Arthur Hugh Clough whose lines "O let me love my love unto myself alone And know my knowledge to the world unknown," might well have been Henrik Ibsen's motto. He had accepted the position of manager of a new theatre in Christiania; but he could not get *The Vikings* produced there, and it was not acted until 1861. The next year his theatre failed, and Ibsen became adviser in aesthetics at the opposition house. In spite of his disappointment and the disgust he felt at the reception of *Love's Comedy* he wrote for this theatre *The Pretenders* (1864), the best drama of his saga period. It was a popular success; but the managers of the Christiania theatre were shy of its strangeness, and it was not until Ibsen's reputation was secure — after the publication of *Brand* and *Peer* Gynt — that it took its place as one of the masterpieces of the new theatre.

Ibsen had applied to the Storthing for a poet's pension, which had been recently given to Bjornson; but it was refused and in indignation he went into exile; for his departure to Italy in 1864 was not an ordinary tour to the sun and the south. It was undertaken with a deep sense of injustice, which was partly responsible for the two magnificent poetic dramas — Brand (1866) and *Peer Gynt* (1867). After the issue of *Brand* he was granted a poet's pension and Ibsen had no longer to fear actual penury.

Plays. — In 1869 he wrote the earliest of his modern prose dramas *The League of Youth,* a political satire that roused as much animosity as did *Love's Comedy;* he was now settled in Dresden, but he returned to Norway for a short time after the publication of one of the most ambitious dramas ever composed — the huge double play *Emperor and Galilean* (1873), an elaborate historical study of the character of Julian the Apostate, which shows wide reading and a remarkable power of re-creating familiar figures of history. It is of great interest as one of the first attempts to free the study of Greek history from that smooth, neo-classical veneer by which it was falsified; it is far nearer in spirit to the Greece of Gilbert Murray and Jane Harrison than the Hellas of Winckelmann or Shelley. These years also mark the end of Ibsen's work as a poet; his collected lyrics were published in 1871, and the occasionally exalted prose of *Emperor and Galilean* does not again reappear in his work, except in brief snatches in some of the later prose dramas. His deep interest in politics was made intenser by the growing power of Germany, and when the days of the Commune came in Paris he felt strong in him something of the hopes that had awakened in 1848, when there was promise of revolution in Europe. His only persistent political principle, to be found in every play from *The Pretenders* to *When We Dead Awaken,* was the necessity of a society which should give the amplest possible opportunity for the free growth of the individual, and he was naturally and inevitably disappointed with all movements of reform — liberal, radical, socialist — as conducted. He found that they all tended in time to subordinate the individual to the state — and to Ibsen the state, the great compact majority, was always the enemy. In 1877 he published *The Pillars of Society* — *a* title which might be taken to cover all the social dramas which succeeded that play.

Later Life. — Ibsen's life presents few points of interest except the steady production of his plays; he never had the inclination nor the necessary social exuberance for such public and political appearances as were enjoyed by his rival and contemporary Bjornson. From 1868 to 1891 his permanent home was Germany, first in Dresden, later in Munich; in 1891 he settled in Christiania where he lived till his death on May 28th, 1906; for the four years previously he had suffered from an almost complete physical and mental collapse, and was unaware of the world without. Of his marriage (1858) there was one son, Sigurd, to whose education Ibsen devoted no little care and thought. When he left his home in 1850, he ceased to communicate with any of his family except his sister Hedvig; and although he had friends in journalism and in the theatre there is little evidence that any one had any real or permanent influence on the development of his character and his genius; he was grateful to Bjornson, he was grateful to Brandes, for the support each gave him at different periods of his career, but he never showed the slightest inclination to accommodate his own thought to their ideas. No other dramatist of so immensely creative a genius has ever been so lonely: he did not need long or continuous intercourse with society. A chance word, a chance meeting, a sudden memory were enough to fertilize that powerful imagination which then, feeding on itself and nourishing the germ, gave birth, every two years, to a play which brought into the world entirely new characters, owing only an infinitesimal part of their life to any power outside the mind and spirit of the dramatist. Ibsen was first and last a great poet, and a great mystic — one of the greatest poets and the greatest mystics who ever devoted himself to the drama; the "lyrical Pegasus" may as Brandes said, "have been killed under him," but his poetic inspiration burned all the more fiercely because of the severe limits which Ibsen forced on its expression, limits which are unfortunately very much exaggerated in the best-known English versions of his social dramas. His interest in his characters, real as they are, intense as it is, is always dependent on his poetic vision of life; his vision of life is never dependent, as was Bjornson's, Strindberg's or even Goethe's, on circumstances either of his own choosing or of chance. Ibsen was never afraid that facts, however obstinate, or persons, however powerful, could detract from the truth and his grasp of it In this he showed signs of affinity to the theological outlook on the world. He knew, mystically, that his conception of life and of mankind could explain and express all the facts with which he came in contact; and if ever he met apparent contradictions, he was ready to dismiss them as irrelevant or worthless. His consummate skill as a dramatist, his influence in the making of a new European theatre must not allow us to forget that he was never of the movement which he caused, and of which he was acclaimed the leader. He was always in advance and always detached.

Main Ideas. — There are two main ideas in Ibsen's work, implicit even in the early dramas, and explicit, in different degrees of emphasis, in his theatre from *Brand* to *When We Dead Awaken.* Of this continuity in his work he was himself fully conscious, and resented the tendency to separate his work into periods, and find any contradiction — except a purely formal one — between the laughing, rapid poetry of *Peer* Gynt and the close, compact prose of the social dramas. The two ideas are these. First, the supreme importance of individual character, of personality: in the development and enrichment of the individual he saw the only hope of a really cultured and enlightened society. Second, comes the belief that the only tragedy that can be suffered, the only final wrong that can be committed, is the

denial of love. The former idea was easily grasped, and was proclaimed by most Ibsenites — Brandes, Archer, and Shaw — as the key to Ibsen's drama; the latter idea was excused in the poetic plays as a relic from an imaginary romantic phase of Ibsen's life, and ignored when it appeared again in the social dramas, especially the later ones. Archer indeed was so disturbed at its very evident intrusion in *When We Dead Awaken*, that he suggested that the dramatist's mind was already failing; while he followed Shaw in his description of the climax of *Peer Gynt* as a "crowningly unreal self-realization." The reason for this obtuseness — shared by nearly all early critics of Ibsen except Sir Arthur Quiller-Couch — is to be found in the fact that it was the lot of Ibsen, a Christian mystic with no definite allegiance to any religious body, to be interpreted to the world by men who were mostly sentimental rationalists, who noticed, what was fully obvious, that the dramatist waged an unceasing war against conventional Christianity, but failed to observe that he did so, not under the banner of rationalism, but in the name of an intenser Christianity.

The same mistake was made, and is still made occasionally, by interpreters of William Blake, in whose thought may be found not a little which would have won Ibsen's sympathy and understanding. In *Brand* Ibsen preached his first and most defiant proclamation of the need of whole-heartedness in the personality; the prophet-priest of the play with his cry of "All or nothing," is a projection of Ibsen's own character, with its stern refusal to be diverted from his work. Balancing that play is *Peer Gynt*, the richest, the most imaginative and fantastic of Ibsen's works: as Brand stands for singleness of purpose, *Peer Gynt* is the embodiment of distraction and dreaming — a parody in some sense of Ibsen's own gospel that facts do not matter, anticipating the bitterer parody of *The Wild Duck*.

In *A Doll's House* (1879) we have the first emphatic statement of Ibsen's individualistic creed. It is not a feminist play. Ibsen was at the moment pre-occupied with the struggle between society and the individual, and he chose a woman as his protagonist because he knew that, on the whole, women were more likely to take a personal view of life than men. There are two dramas in the play — one consists in Nora's discovery that she has lived for years with a strange man; but this depends on the more essential drama that for Torvald a crime against society is more important than a sin against love. The same motive inspired, in a more terrible form, *Ghosts* (1881); and when *Ghosts* roused fury throughout Europe, Ibsen retorted on his critics with *An Enemy of the People* (1882) in which he attacks the stupid majority who prefer disease to the confession of their disgrace. One of the loveliest of his plays, one in which the poet breaks out again, is *The Wild Duck* (1884). It has a tenderness and a lyrical beauty which stand out all the more strongly beside the fierce satire against those who have misinterpreted him. This play, with its quiet charm, its ironic humour and its devastating satire, is the record of Ibsen's discovery that it takes two people to tell the truth, one to speak and one to understand what is spoken — the last lesson to be learned by all prophets.

Later Works. — *Rosmersholm* (1886) written after a journey to Norway is a powerful study in ineffective idealism — and in the contrast of Rebecca West and Rosmer Ibsen reached his greatest heights in pure tragedy. *The Lady from the Sea* (1888) is the happiest of the prose dramas; it is rather weak in construction, but its characterization has a cheerful, relenting quality, and Dr. Wangel is one of the few men who can be put on a level with Ibsen's women. Of all modern plays Ibsen's come nearest, in form and sense of necessity, to the theatre of Athens; and of all his plays *Hedda Gabler* (1890) is, with the possible exception of *Ghosts*, the nearest to the Greek. If Hedda had been called Medea, her egotistic ferocity would not perhaps have so distressed those critics who pitifully complained that Ibsen's women were not womanly. *The Master Builder* (1892) is a return to the poetic, symbolic manner; and the conflict between two generations, Solness and Hilda, has become a classic statement of an age-long problem. *Little Eyolf* (1894) and *John Gabriel Borkman* (1896) are variations on his old theme, the conflict between love and the claims of other desirable things. In *Little Eyolf* love is threatened by the lust of the woman and by the vanity and incompetence of the man; the solution comes only through disaster; in *John Gabriel Borkman* love has been killed by ambition, and with love dead, there is nothing else; and the end of the play is the dramatist's consummate disclosure of the truth that Borkman, Ella and Gunhild were dead before the play opened, and that none of the other characters, except the old clerk Foldal (one of Ibsen's most exquisite minor characters) has ever been alive. Yet there is hope *When We Dead Awaken* (1900). This great final statement of the poet's invincible creed has disappointed those who had misunderstood his earlier plays, and attached too much importance to the incidental social teaching that can be extracted from them, and to their amazing stagecraft. Its form is less perfect, its external action fantastic; but in the reunion of Rubek and Irene Ibsen writes out of his very soul, repeating once more his persistent cry that, whether the world be well lost for love or no, at least that which a man thinks to gain by the sacrifice of love is not held at all.

The intense reality of Ibsen's characters, while evident at a first reading or a first hearing of any play, can only be properly appreciated by continuous study of his complete theatre. It was his habit to make more or less complete histories of the lives of his people up to the moment of the opening of the first act; and in the drafts and first version of many plays (available in the volume called *Ibsen's Workshop*) can be seen the care with which he worked, the fierceness with which he sacrificed anything, however entertaining, that was not essential, and his amazing power of getting the utmost out of a character or a situation. He made his people work for him; and there is no dramatist in whose work it would be so hard to find a single speech out of character. He could not bear either to discuss, or to disclose, the idea of a new play until it was completed. He retired into his own world with his own people, and agonized until they became and did exactly what he knew was right. When, as in *The Lady from the Sea*, he relaxes a little, the change in atmosphere is startling. This severity might be lamented as a defect did we not know from *Peer Gynt* that it was a deliberate sacrifice. The author of that supremely diverting and supremely mobile play cannot be accused of any incapacity for exuberance.

Ibsen's later abstinence from humour, from divagations and those extravagances which charm us in *Peer Gynt* was the abstinence not of impotence but a deliberately self-imposed control. It may be that he sometimes regretted his choice, for in 1900 he wrote to Count Prozor (after the publication of *When We Dead Awaken)* that, if he comes back to the old battlefields, "it will be with new weapons and in new armour"; there was, however, to be no reappearance, and it would indeed be ungracious for the world to complain of any lack of variety in the drama of the man who left us *Brand, Peer Gynt, Emperor and Galilean, A Doll's House, The Wild Duck, The Master Builder* and *When We Dead Awaken*.

IBYCUS, of Rhegium in Italy, Greek lyric poet, contemporary of Anacreon, flourished in the 6th century B.C. He lived a wandering life, and spent a considerable time at the court of Polycrates, tyrant of Samos. Plutarch *(De Garrulifate,* xiv.) preserves the legend of his death. Attacked by robbers, he called on a flock of cranes to avenge him. Later, one of the robbers, in the theatre at Corinth, saw the cranes, and said "Behold the avengers of Ibycus," thus betraying himself. The "cranes of Ibycus" became proverbial. Ibycus wrote seven books of lyrics, partly mythical, but mainly erotic (Cicero, *Tusc. Disp.* iv. *33).*

The best editions of the fragments are by F. W. Schneidewin (1833) and Bergk, *Poetae lyrici* Graeci.

ICA, a department in southern Peru, bounded on the west by the Pacific ocean. on the north by the department of Lima, on the east by Huancavelica and Ayacucho, and on the south by Arequipa. Area 8,205 sq.mi. Pop. (1940) 144,547; (1958 est.) 199,795. The capital is the city of Ica (*q.v.*).

The department comprises the western slope of the Andes, the arid coast and the north end of the coastal range. Included in the department are the Viejas and Chincha Islands (*q.v.*), famous as sources of guano.

Ica is thinly inhabited except in four separate river valleys. from north to south the Rio Chincha, Rio Pisco, Rio Ica and Rio Grande. where irrigation is practised. The largest irrigated areas are in the Chincha "and Ica valleys. Cotton occupies the largest acreage, and the Pisco valley was where Fermin Tanguis originated the indigenous white long-stapled Tanguis cotton that proved to be highly productive in the irrigated lands of the Peruvian coast. In addition to cotton, fruitgrowing and viticulture are important, the latter especially in the Ica valley. Although the grapes produce an inferior wine, this is distilled into a famous brandy, which takes its name from the port of Pisco, through which it is exported. The department also includes the iron ores at Marcona, which are brought to the port of San Juan for shipment to the new steel plant at Chimbote. There is some gold mined at Nazca, and fishing is important at Pisco and San Andrés. (P. E. J.)

ICA, a city near the coast of Peru and capital of Ica department, located 160 mi. S.E. of Lima, with which it is connected by an all-weather highway. Pop. (1940) 21,437; (1958 est.) 34,230. It is the commercial centre of the department and has numerous small industries. Its chief outlet is by rail to the port of Pisco. 46 mi. N.W. Ica is in the midst of an irrigated area about 1,300 ft. above sea level, where the chief products are grapes and cotton. The famous Pisco brandy, well known along the Pacific coast of both North and South America, is produced in Ica. The city was founded in 1563 and was twice destroyed by earthquakes. (P. E. J.)

ICE is the solid form of H_2O, the substance of water. Although practically colourless, ice often appears white as a result of included air bubbles, and in large masses—*e.g.,* glaciers—it takes on a blue or blue-green colour.

Ice in its several forms (snow, lake ice, sea ice, glaciers) occurs abundantly. Of the estimated 22,000,000 cu.km. of ice occurring on earth, 87% lies on the antarctic continent and 12% on Greenland, with only 1% elsewhere. If all this ice melted, the sea level would rise about 50 m. and change the face of the earth. This could happen if the climate of the polar regions should get much warmer. Yet melting would be slow because ice has a very high heat of fusion, equal to 79.8 cal. per gram. This is the amount of heat necessary to change ice at 0° C. to water at the same temperature. (The zero point temperature of the Celsius or centigrade scale is defined as the temperature of a mixture of water and ice exposed to ordinary air at a pressure of one atmosphere.)

Ice has a density of 0.917 g. per cubic centimetre and will float on water with about 10% of its volume above the surface. However, ice containing air or brine may have a lower or higher density and will sink to different depths. As water cools it passes through a maximum density at 4° C. before any of it will freeze, for above this temperature convection currents carry the heavier cooled water to the bottom. Ice can form on the surface only after all of the water has reached 4° C. This is the reason why shallow lakes freeze over before deeper ones.

Another unusual characteristic of ice is that its melting temperature decreases when it is subjected to pressure. Under a pressure of 134 atm. ice melts at — 1° C. The low friction of most materials on ice can be accounted for, in part, by this phenomenon, for even moderately loaded surfaces will be under high pressures in the neighbourhood of edges and irregularities. Near 0° C. melting will occur at the points of high pressure, and the water formed can provide a lubricating film. At lower temperatures

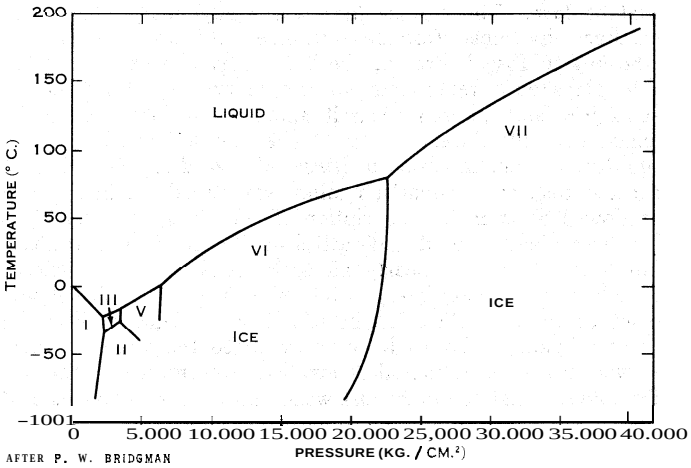

FIG. 1.— PHASE DIAGRAM FOR WATER AND ICE
Five high-pressure modifications of ice are shown along with ordinary ice (ice I). The existence of several unstable modifications, including ice IV, remains unconfirmed

ease of sliding may be due mainly to local melting by frictional heating.

The flow of ice under stress, as in glaciers, has often been explained in terms of regelation. In this process, pressure is relieved by the flow of water formed by the lowering of the freezing point. Thus, an object can pass through ice by progressive melting ahead and refreezing behind. This type of flon can occur only near to 0° C.; at lower temperatures a visco-plastic flow takes place. in which ice crystals are deformed without breaking.

Modifications. — There are several modifications of ice, one of which may be amorphous. Five different crystalline modifications were made in the laboratory of P. W. Bridgman (fig. 1); they are stable only at pressures in excess of 2,000 atm., and all have densities higher than one gram per cubic centimetre. Only one modification occurs in nature — ordinary ice — which crystallizes in a hexagonal structure; but ice crystals rarely exhibit symmetrical shape unless grown from the vapour.

Crystal Structure. — Masses of ice are aggregates of single crystalline grains. In quickly frozen ice these may be only a few millimetres to a few centimetres in size. Under slower rates of growth, as occur in temperate glaciers, single crystals are often found having dimensions of several decimetres. Although lake ice crystals may grow as large, they are less perfect. In neither case is the symmetry shown in exterior form.

Crystals, several centimetres in size and displaying the hexagonal habit, often grow from the vapour on ceilings and walls of unheated buildings in the arctic. The beautiful and varied patterns of snow crystals manifest the symmetry of ice grown from the vapour.

Boundaries between neighbouring crystals in polycrystalline ice are usually irregular and can be observed under crossed polaroids or by etching. Etching can be accomplished by evaporation of the surface or by melting with radiant heat. When the surface water is removed the grain boundaries become visible. Orientation of the individual ice crystals can be determined by X-ray crystallography. Because ice is doubly refracting, optical methods can locate the position of the C-axis (hexagonal axis), but they do not distinguish between directions in the plane normal to it. A convenient method for determining the orientation of ice is by observing the vapour (Tyndall) figures produced in the body of the

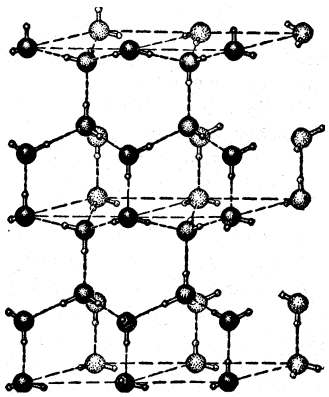

FIG 2.— CRYSTAL STRUCTURE OF ICE
Large spheres represent oxygen atoms; small spheres, hydrogen atoms

crystal by radiant heating. These flat hollow figures have the shape of snowflakes displaying hexagonal symmetry, and their axes of symmetry are parallel to those in the host crystal.

The oxygen atoms, being considerably larger than the hydrogen atoms. determine the basic structure of ice. Each oxygen atom is surrounded tetrahedrally by four others at a distance of 2.76 Å (fig. 2). The two hydrogen atoms can occupy any of the four tetrahedral directions with the limitation that only oqe can be between any pair of oxygen atoms. Because of the uncertainty concerning the position of the hydrogen atoms. the symmetry class of ice is not known. Both polar and nonpolar symmetries have been proposed.

For the manufacture of ice see REFRIGERATION AND ITS APPLICATION.

See N. E. Dorsey, *Properties of Ordinary Water-Substance in All Its Phases* (1940); P. G. Owston and K. Lonsdale, "The Crystalline Structure of Ice," *Journal of Glaciology,* vol. i (March, 1948).

ICE AGE: see PLEISTOCENE EPOCH.

ICEBERG, a floating mass of ice broken from the end of a glacier or a polar ice sheet. Icebergs drift according to the direction of the sea currents, frequently from the polar regions to navigable waters, and they are therefore occasionally encountered far beyond the polar regions. When a glacier descends to the sea and is pushed outward into water of greater depth than the thickness of the ice, the ends are broken off and the detached masses float away as icebergs. Only one-ninth of the mass of ice is seen above water. Many bergs are overturned, or at least tilted, as they set sail, as the result of the wave cutting and melting which disturb their equilibrium. The disintegration of an arctic ice sheet is a simpler matter, as the ice is already floating. The ice sheet cracks at the end, and masses break off, owing to the upward pressure of the water upon the lighter ice. This is accomplished with considerable violence. Icebergs, especially those of glacier origin, carry a load of debris which they gradually strew upon the sea floor; glacial material found in dredgings shons that icebergs occasionally transport their load for a considerable distance.

ICEBOATING: see ICE YACHTING.

ICEBREAKERS, powerfully built vessels specially designed and equipped to clear a path through ice in harbours. rivers or other navigable waters. Since late in the 19th century many maritime nations have used icebreakers to keep their ports and shipping lanes open. More recently, icebreakers have also proved valuable to exploring parties in the polar regions.

Ice encountered in the navigable waters of North America and Europe is of the annual type, which forms in sheets varying in thickness up to about 36 in. on the Great Lakes. Under the action of wind and seas such sheet ice often breaks and forms into windrows which attain great thicknesses, occasionally extending to the bottom of the lake.

Polar ice is composed of glacial ice, floes and annual ice, and is often too thick to break. Icebreakers follow open leads in navigating polar ice or force openings between floes. Modern icebreakers successfully use radar and helicopters for locating leads in the ice pack.

The design of icebreakers generally has followed the practice of developing vessels for particular areas of operation, such as the Baltic sea, Great Lakes or the Arctic. Dutch ice plows, so named because they turn ice up and out on the surrounding unbroken ice, were developed for the shallow harbours and rivers of the Netherlands.

A number of icebreakers have been fitted with bow propellers in addition to stern propellers. The action of the bow propeller creates turbulence in the water, which assists the breaking action of the bow and also moves broken ice out of the way. Bow propellers are particularly successful in breaking annual ice.

Design Characteristics. — The designs of icebreakers built during and since World War II have incorporated most of the following major characteristics.

High Beam-to-Length Ratio. — This is an important element because a short vessel performs better when forcing tortuous leads in the ice pack. Such a vessel can turn better and does not risk becoming wedged in a narrow lead as would a long vessel. The large beam is required to cut as wide a channel as possible for conventionally built merchant ships to follow. A narrow beam would require the icebreaker to make a second pass at the ice to cut a channel wide enough for a following ship.

High *Horsepower-Displacement* Ratio. — Modern icebreakers have ratios of 1.75 to 2.4 shaft horsepower per ton of ship's weight. These high ratios permit a vessel to make sustained progress in ice of varying thicknesses without the need for continually stopping, backing and ramming.

The Russian nuclear-powered icebreaker "Lenin," launched in 1957, was designed with a ratio of 2.75 shaft horsepower per ton, higher than all other icebreakers then in service. It was estimated that the "Lenin" would be able to make sustained progress in unbroken ice fields up to 6½ ft. thick and to cruise for a year nithout entering port.

Flared Hull Shape. — The use of flare-shaped transverse sections has been widely adopted in icebreaker design. The flare of the sections permits the ship to lift rather than be crushed when under ice pressure during the forcing of leads or when operating between floes. The angle of flare at midships is betneen 10° and 20°. This design feature also adds to the ship's icebreaking capability, because the sloping sides at the bow create a downward force on the ice. This characteristic, in combination with the common feature of cutaway bow or forefoot, produces a bending action on the ice. This action occurs not only as the forefoot meets the ice, but also as the hull moves along and the sloping sides of the bow and forward part of the hull meet areas of unbroken ice.

The hull shape resulting from the use of flared sections makes the icebreaker a heavy roller in open water. The absence of bilge (rolling) keels on most icebreakers. due to their vulnerability to ice. contributes to the rolling. Angles of 40° to 50° in heavy seas are not uncommon. The Canadian icebreaker "Labrador" is fitted nith retractable stabilizing bow fins to dampen the roll.

Electric *Propulsion.*—An icebreaker must be able to develop its maximum power from a standing start. This characteristic requires machinery capable of providing approximately full power at reduced propeller shaft revolutions. Electric drive has this ability and is the most common type of propulsion for icebreakers, using diesel or steam turbines to drive generators that supply the direct-current propulsion motors. Ships of the U.S. coast guard "Northwind" class (see fig. 1) and the "Mackinaw" were constructed with two stern propellers and a bow propeller. The diesel-electric propulsion plant was designed to transmit all the power developed either to the stern propellers or to divide the power betneen the stern and bow propellers. When icebreakers designed with bow propellers operate in polar regions the bow propeller is usually removed.

BY COURTESY OF U.S. COAST GUARD

FIG. 1.—THE "NORTHWIND," U.S. COAST GUARD ICEBREAKER

Rugged Hull Structure. — Heavy plating of the underwater body, with rugged framing to resist the crushing effects of icebreaking, are basic characteristics of icebreakers. Frames are spaced as close together as considerations of access for construction and maintenance permit, and by means of web frames and systems of longitudinal girders the ice loads are transferred from the frames to the decks or the bulkheads of the ship. Over-all weight considerations favour using the decks and deck beams as the major strength factors.

Shell plating, often steel of high tensile strength, usually is heaviest at the water-line areas, with a gradual reduction in thickness to the keel.

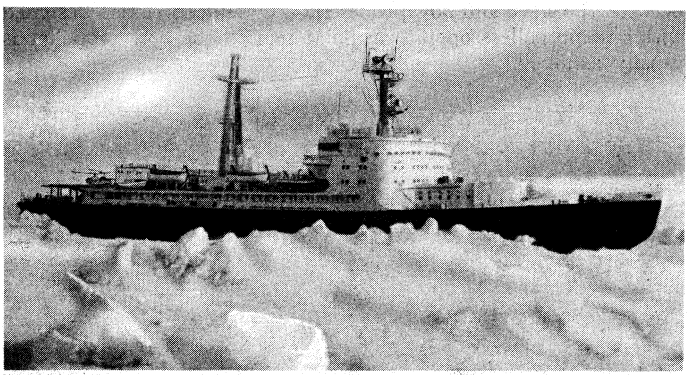
Miscellaneous Characteristics. — The rolling tendencies of icebreakers are used to advantage in connection with special heeling and trimming systems installed to induce rolling and change in fore and aft trim (the ship's position in relation to a horizontal plane). Ability to cause the ship to roll and change trim is an asset in breaking ice and in helping the ship free itself should it become stuck and be unable to move by using its propellers. Rolling and trimming are performed by using large pumps to transfer large quantities of water rapidly between the ship's tanks.

Particular attention is paid to providing rugged appendages, such as the rudder and propellers. In heavy ice the need to back off and charge the ice field requires particularly strong rudder construction, and the propellers have heavy blade sections for maximum strength. In addition to cast steels, a number of alloy steels and bronzes have been used for propeller materials to achieve the desired strength. Propellers are located as far inboard and as deep in the water as conditions permit, to give them the maximum protection.

Automatic tensioning towing machines and notched sterns to take the bow of a convoyed vessel are features included in numerous icebreakers.

A major requirement for an icebreaker designed for polar duty is large fuel capacity. The polar icebreaker operates in remote areas, where refueling facilities are deficient or do not exist at all, and the possibility is always present that the ship may get stuck in the ice and have to "winter in" until the ice conditions improve. When an icebreaker is doing its hardest work in clearing a path through heavy ice, its fuel consumption is enormous.

In the 1950s this fuel problem gave impetus to proposals to use nuclear power. A number of countries studied the feasibility of constructing nuclear-powered icebreakers, but the U.S.S.R. was the first country to build one. The keel of the atomic icebreaker



SOVFOTO

FIG. 2.— THE "LENIN," ATOMIC-POWERED ICEBREAKER OF THE U.S.S.R.

"Lenin" was laid in 1956, and the vessel was launched in Dec. 1957. (See fig. 2.) It had the following characteristics:

Length	440 ft. 0 in.
Depth of hull	52 ft. 10 in.
Maximum beam	90 ft. 6 in.
Draft	30 ft. 3 in.
Displacement	16,000 tons
Reactors	3 pressurized water reactors (1 spare) using enriched uranium fuel
Propelling machinery	Turboelectric (direct current) triple screw, 44,000 shaft horsepower

(AT. L. S.)

ICE CREAM. Water ices were known in the Roman empire, and Marco Polo is supposed to have brought a recipe for milk ices from the far east. Centuries later, chefs for the courts of Europe experimented with ice-cream recipes and tried, unsuccessfully, to keep the secret for nobility. Its commercial production became successful after the discovery that salt mixed with ice produce a lower temperature than ice alone. In the late 19th century, also, the introduction of mechanical refrigeration greatly assisted the growth of the ice-cream industry.

Ingredients. — The liquid mix, or unfrozen ice cream, for representative, good-quality vanilla ice cream contains about 80% by weight of cream and milk products and 15% sweeteners. Almost 70% of the milk or its equivalent used in ice-cream manufacture in the United States is bought during the spring and early summer months when milk production is at its peak and prices are lowest. Because this milk may be stored as frozen or concentrated milk products for use in later periods of lower milk production on farms and consequent high prices, ice cream has been called the "balance wheel" of the dairy industry.

Cream, milk, nonfat milk solids, sugar and sometimes eggs form the basis of all ice cream. Less than 0.5% of a stabilizer, of which there are several types, is generally included.

The food values of ice cream vary as compared to its ingredients. One-third pint of vanilla ice cream is about equal to one-half cup of whole milk in calcium, protein and vitamin B, and to a little more than one cup in vitamin A and calories.

The ingredients of ice cream are combined in varying proportions, but always in a way to make the solids about 38% of its weight. Milkfat in ice cream may range from 8% to 14%; nonfat milk solids from 8% to 12%, the use of the latter being limited by the amount of lactose, or milk sugar. since excessive lactose may crystallize and cause a "sandy" ice cream. In the second half of the 20th century the trend was toward the higher content of nonfat milk solids. Each U.S. state and many cities set minimum legal requirements for ice cream.

Manufacturing. — Pasteurizationin the manufacturing process and homogenization and automatically controlled freezing contribute to the quality of ice cream. Homogenization blends the fat globules with the nonfat milk solids to help form a stable emulsion and aids development of a smoother texture by retarding churning of the fat globules in the freezer. Automatic control of the whipping process produces ice cream of uniform consistency, the whipping, which incorporates air, being necessary to produce a palatable product, ice cream without whipping being like bread that has not risen.

The mix for ice cream contains all the ingredients except the fruits, nuts or other special flavouring. In a modern plant the mix is pasteurized and homogenized and then cooled rapidly to below 40° F.

At least half the ice cream made in the second half of the 20th century was frozen in the continuous type freezer, a refrigerated tube with revolving blades, or beaters, surrounded by a refrigerant. The mix moves through the freezer without stopping and comes out in less than 60 seconds as partially frozen ice cream. Fruits, nuts and similar flavourings are added at this time. Liquid flavourings are added to the mix just before freezing, except for chocolate, which is added as the mix is made.

The partially frozen ice cream is drawn off into containers, which are immediately covered, and is sent on conveyors to a hardening room with a temperature of from 0° F. to −20° F. Containers ranging from cup size to large cans of several gallons are used. The ice cream is then delivered in refrigerated trucks to dealers, who place it in refrigerated cabinets, where it is kept frozen until sold.

The ice-cream mix and the frozen ice cream are tested routinely for the amount of butterfat, total solids and bacteria. The ice cream is produced and packaged through sterilized pipes and by automatic machinery, frequent checks being made by the manufac-

turer and health authorities. Samples on the market are retested to assure quality.

Varieties. — Ice Cream. — This is a cream and milk product, variously flavoured; more than 100 flavours of ice cream have been made.

Mousses, Parfaits. — Mousse is a frozen dessert of sweetened and flavoured whipped cream or thin cream and gelatin. Parfait is a frozen dessert of whipped cream, eggs cooked with syrup, and flavouring. Both mousses and parfaits are frozen without stirring.

Fruit Sherbets. — Sherbets are made of milk, sweeteners and fruit flavouring, in many varieties.

Fruit Ices. — Fruit, fruit juices, water and sweeteners are used in water ices, and many of the flavourings used for sherbets are added. (EH. G. B.)

ICE HOCKEY. One school of thought holds that ice hockey is a development of field hockey (see HOCKEY), and another that it is a development of the old Irish game of hurling (*q.v.*). Some experts believe that the game of bandy, played with a ball and bent sticks by two teams, is a forerunner of ice hockey, while there is evidence that the Indians played some such game in Canada centuries ago.

Canada is regarded as the mother of the modern sport and was the first country to organize the game on a nationwide basis (see below), with a codified form of playing rules that has been accepted throughout the world. For long the sport was confined to natural ice, but with the advent of ice rinks its popularity spread rapidly.

INTERNATIONAL

This article will consider first the international aspects of the game, then hockey in the United States and Canada, technique and finally the game in Europe. In 1908 the International Ice Hockey federation was formed, with Great Britain, France, Belgium, Switzerland and Bohemia as founder members. In the second half of the 20th century there were 25 member nations. The international body organizes the world and European championships each year with both titles at stake although only one series of games is played. The winning team, if European, takes both titles and if non-European only the world title, in which case the European trophy is awarded to the European team gaining the most points. At one time the world championships could not be competed for unless a non-European team competed. For the winter Olympics the same system is adopted, the winner of the world title also taking the Olympic honours.

The international rules are applicable to most affiliated countries and govern the world and European championships. The governing bodies in Canada, the United States and Great Britain have, however, slight variations in the rules and slightly different interpretations for the game as played in their respective countries.

The rules of the game are comparatively easy to follow, with the possible exception of the defensive tactic known as body checking, whereby the defending player is permitted to hit with his body an attacking player in possession of the puck. Confusion also arises from the application of the offside rule (bringing the puck forward illegally) and the penalty rule. A breach of certain rules results in the offending player's being sent off the ice for a number of minutes during which his team has to play shorthanded.

Under the international rules, the number of players per team permitted on the ice at any one time is six: goalkeeper, two defense men and three forwards. In addition, the international rules allow eight others, one of whom must be a goalkeeper, to be at the disposal of the team's coach. Apart from the second goalkeeper the coach is permitted to change players as and when he chooses, provided that not more than six players are on the ice at the same time.

Before the change to six-man hockey, teams were made up of seven men, and the positions were goal tender, point, cover-point, rover, left wing, centre and right wing.

Players are permitted to wear protective equipment the specifications of which are covered by the rules. This equipment is essential because of the inherent hazards of the sport.

The puck — the term applied to the disklike object with which the game is played — is made of vulcanized rubber, or other approved material, is 1 in. thick and 3 in. in diameter and weighs $5\frac{1}{2}$ to 6 oz.

The sticks are of hardwood and must not exceed 53 in. from the heel to the end of the shaft and $14\frac{3}{4}$ in. from the heel to the end of the blade. The blade must not exceed 3 in. in width. The goalkeeper is permitted to use a special stick.

The game consists of three periods of 20 minutes each of actual playing time. The playing surface is divided into three areas, known as the defending zone, neutral zone and attacking zone. The neutral zone is again divided by the centre line. These lines govern the off sides. (J. F. AE.)

UNITED STATES AND CANADA

History. — Despite the introduction of international play in Europe, Canada took the lead in establishing the sport firmly through organization. In 1887 the Amateur Hockey Association of Canada was formed and this body soon came to be recognized. Under its guidance, hockey flourished throughout the entire dominion.

The game was not played in the United States until the winter of 1894–95. In that year a group of U.S. students visited Canada, saw some games and participated in others. On their return home, their enthusiasm prompted them to organize hockey clubs. According to the *Official* Hockey Guide of the Amateur Hockey Association of the United States,

The first official league or association ice hockey game on record in the United States was played by the St. Nicholas Skating Club and the Brooklyn Skating Club in New York's St Nicholas Rink on December 1 j, 1896, and was won by St Nick's 1 j to o The other teams in this four club circuit were the New York Athletic Club, winner of the Amateur Hockey League title for 1896–97, and the Crescent Athletic Club of Brooklyn.

In a short time many colleges were attracted to the sport with the result that it soon became an important winter game. Not long after the colleges had accepted the game, club teams were formed, and eventually hockey was organized for professional play. A number of leagues employing paid athletes were formed, the strongest of which, the National Hockey league, came into being on Nov. 22, 1917, as an outgrowth of the National Hockey association founded in Montreal, Que., Dec. 2, 1909. This league in the beginning embraced only four teams, the Toronto Arenas, Montreal Wanderers, Montreal Canadiens and Ottawa Senators. It was successful from the start and in 1924 it expanded to include teams in the United States.

At one time ten teams, representing cities in Canada and the United States, were in the circuit. In 1942 the "loop" was reduced to six — the Toronto Maple Leafs, the Montreal Canadiens, the New York Rangers, the Boston Bruins, the Chicago Black Hawks and the Detroit Red Wings. Players are purchased by the teams, with the prices running from $5,000 to $30,000. The National league season of 70 games, exclusive of the play-off games, runs from mid-October to April.

Nature of the Game. — Hockey since its inception has been an onside game, that is, a game in which forward passing is discouraged. Early in its existence all forward passing was prohibited, but this rule, despite the fact that it required the player to be more deft, tended to retard the action to some degree. To correct this shortcoming three zones were established in which the puck could be passed forward. The puck may be passed forward or, for that matter, in any direction, within zones, and can also be moved ahead from zone to zone with certain limitations described below.

In the Gnited States all schools play according to the National Collegiate Athletic association rules, which permit forward passing within the three zones and forward passing to a teammate from the defensive zone up to the attacking zone blue line. *i.e.*, a two-zone forward pass is allowed; however, no attacking player can penetrate the attacking zone ahead of the puck; if he does he is off side.

Canada and several club leagues in the United States play according to the National Hockey league rules that permit forward

DIAGRAM OF AN ICE HOCKEY RINK

passing within the three zones and forward passing to a teammate from his defensive zone up to the red line which halves the neutral zone. No attacking player can penetrate the attacking zone ahead of the puck. The object of the game is for one team to shoot the puck into its opponent's goal in the face of the opposing team's efforts to prevent such an occurrence.

Each goal counts one point. The player scoring the goal is credited one point. and the players assisting in the scoring of the goal are credited one point for each assist, but no more than two assists are credited with each goal. The last two assists prior to the actual scoring are the ones considered for credit.

Positions. — The positions on a six-man hockey team are goal tender (more commonly called goalies in the United States and goaler in Canada), left defense, right defense, centre, left wing and right wing. The wings and the centre constitute the forward positions, and they operate most frequently as an offensive unit, although there is nothing in the rules to prevent a defense man from engaging in aggressive offensive play. In fact, since the advent of the forward passing style of play, defense men play a very important part in the offensive phase of the game, in addition to their primary duty of defending their defensive zone and goal tender. Many defense men, amateur and professional, outscore their team's forwards.

The Rink. — The game is played on a surface called a rink which should measure, as nearly as possible, 200 ft. in length and 85 ft. in width. The rink sideboards and endboards should be at least 3 ft. 4 in. high and no higher than 4 ft.

A goal cage stands at each end of the rink, at least 10 ft. and not more than 1j ft. from the endboards and equidistant from the sideboards; it should be firmly fixed to the ice. The goal is 4 ft. in height, with an opening of 6 ft. facing the centre of the playing area. An area *8* ft. wide and 4 ft. deep in front of the goal is called the crease. In this area the goalie has certain privileges the other players do not. The three zones are marked on the playing surface by lines drawn across the ice, 60 ft. from the goal line.

Sticks. — Except for the goalie, each player plays with a stick terminating in a blade approximately 4j° from the shaft. The degree of the stick-blade angle to the shaft varies with the lie. Stick lies range from 3 to 10 and the players' preference for lie depends on the position in which they like to "carry the puck" in front of them. A player who likes to carry the puck in close to his skates prefers a high lie of 7, *8* or g. A player who likes to carry the puck way out in front of his skates prefers a low lie of 3 or 4. The average or normal lie used by most players is a 5 or 6.

Sticks are lefts, rights and neutrals according to the side the player shoots from. The neutral is preferred by shooters who get too much "rise" in their shot. The sticks are of standard measurements and must be made of wood.

The shafts are $1\frac{1}{4}$ in. by $\frac{3}{4}$ in. square but the blade increases in width to $2\frac{1}{2}$ in. and must not exceed 3 in. The stick used by the goalie is of different dimensions. The blade of the goalie's stick must not exceed 34 in., except at the heel, where it must not exceed $4\frac{1}{2}$ in. The widened portion of the goalie's stick extending up the shaft from the blade must not exceed more than 24 in. from the heel and must not exceed $3\frac{1}{2}$ in. in width.

The Game. — The game starts with a face-off, the referee's dropping the puck between the opposing centres, who face each other in the exact centre of the rink. Each of the centres seeks to gain possession of the puck, and the one who does contrives to advance it, either by himself or by passing to a teammate, to the region of the opposing team's goal. Passing the puck from the defensive zone beyond the opponent's goal results in a special face-off (see diagram). The passing between members of the same team may be intercepted at any time by the opponent.

The three periods of 20 minutes each have 10-minute intermissions between them. In case of a tie at the end of that time the United States National Collegiate Athletic association rules decree that at the end of the third period there shall be a 5-minute intermission. after which ends shall be changed and a "sudden death" 10-minute overtime period played. In this "sudden death" period, the team that scores first wins, and the game is ended. If no score is made in the overtime period, the game is ended and results in a draw.

The National Hockey league rules decree that if, at the end of the three regular 20-minute periods. the score shall be tied, the game is over and shall be called a tie. However, "sudden death" applies in Stanley cup play.

The Stanley Cup and Other Trophies. — The highest prize in professional hockey is the Stanley cup, a trophy put up for competition in Canada in 1893–94 by Lord Stanley, governor general of Canada. Until 1912 only amateur teams played for the cup, but thereafter professionals competed for it exclusively. The winner of the Stanley cup is regarded as the year's hockey champion.

The pattern of the National Hockey league's play-offs is an involved one. Six teams play one another through the regular season, and the teams occupying the first four places in the final standing qualify. The first-place team meets the third-place team, and the second-place meets the fourth-place. These survivors then oppose each other, strictly speaking. for the Stanley cup. All of these postseason series are decided on the basis of the best four out of seven games.

The Hart trophy, awarded to the player voted the "most useful" to his club in the league, was donated in 1923–24 by David **A.** Hart, father of Cecil Hart, who was coach of the Montreal Canadiens for many years. The Vezina trophy, awarded to the goalkeeper who allons the least number of goals to be scored on him during the regular season, was donated by the Montreal Canadiens in 1926–27 in memory of Georges Vezina, a great goal tender for the Montreal Canadiens, who suddenly collapsed in a game on the night of Nov. 28, 1925, and died a few months later of tuberculosis. The Art Ross trophy, donated in 1917 by the former manager and coach of the Boston Bruins, is given to the leading scorer. The Calder Memorial trophy, awarded to the player voted the "outstanding rookie" in his first year of professional hockey, was established in 1936–37 by Frank Calder. first president of the National Hockey league (1917–43). The Lady Bying trophy, instituted in 1927 and awarded the first time by the wife of Canada's governor general for whom it was named, is given to the player who best exemplifies clean play. The Norris trophy, awarded to the defense man who is deemed the best at that position through a season, was first presented at the end of the 1953–54 season as a memo-

TECHNIQUE

Skating. — Ordinary pleasure skating, figure skating and speed skating count for little in ice hockey. The novice must practise hours, days and months to master the stop-turn-and-start. Ice hockey is played in a series of short dashes — fast starting, sudden stopping, feinting, dodging, shifting, weaving and even hurdling being parts of the puck chaser's routine.

Stick Handling. — For fast starting and breakaway purposes, the short, choppy stride is the proper skating form and propels a player rapidly away from opponents. After getting the "jump" with short, choppy strides, the player lengthens out his stride to get the maximum speed benefit of every stride. This lengthening-out stride is more of a hip-striding movement and gives the player a smooth, rhythmic, powerful appearance. The next point is to confine the skating stride to as narrow a path of ice as possible. The professional player rushes a puck in a path as narrow as 3 ft.

After the player has learned the art of good hockey skating technique, he must learn the art of puck control. This is the almost instinctive reaction of taking a quick, wide lateral dribble with the puck as the player nears an opponent; it is known as the protective dribble, whereby the puck carrier keeps his body between the puck and the opponent so that the opponent cannot poke check the puck from the stick blade. The protective dribble is very effective when it is made with a quick, wide movement — the quickness for deception and the width for safety.

Many mediocre skaters have held positions on good teams through their clever stick handling and scoring ability. By such tricks as the delayed dribble (throwing the opponent's timing off by suddenly stopping to "shake" an opponent and then just as suddenly starting off again) a player can baffle opponents who attempt to steal the puck and thereby check the play. Years of constant practice are necessary to crown the efforts of the expert stick handler.

Professional players in the big leagues stick handle the rubber puck in a manner that is uncanny — pushing, dribbling and flipping the small rubber disk about the ice between a maze of sticks and skates with a speed and accuracy too bewildering for the human eye to follow.

Methods of rushing or "carrying" a puck along the ice vary. Some push the disk ahead at stick's length when the play is open; others play the puck from side to side as they approach dangerously close to an opponent. Some flip the rubber against the sideboards, depending on the rebound for recovery of the disk behind the opponent, while others attempt to poke the puck between the opponent's feet and skate around the man to regain possession of the disk while the opponents are off balance or too befuddled to hamper the play effectively.

Checking. — Stick checking calls for quick thinking and clever action on the part of the checker. The poke, sweep and hook checks are effective means of taking the puck away and stopping opposing forwards in their rush toward the goal.

The body check is an effective means of body blocking which, in a sense, disconnects the puck carrier from the puck and thereby interrupts his dash to the goal. A legal body check is one with the hip or upper body from the front or straight from the side and limited to two steps, and only the puck carrier can be body-checked. In the United States the National Collegiate Athletic association rules permit body checking only in the defensive zone. The National Hockey league rules permit body checking in all three zones.

Playing the Game. — With skating and stick handling perfected to a point where they are combined into one mechanical operation, the player can direct his whole attention to playing the game. A good hockey player never looks at his feet, stick or puck during the progress of the play. His eyes must be focused on his opponents at all times. He must look up in order to size up the confronting situation and thereby react intelligently. Once he comes into possession of the puck he has the three forwards, two defense men and goal tender to beat before he can register a score by shooting the disk into the goal net guarded by the opposing team.

Left wing, centre and right wing, commonly known as the forward line, should practise passing the puck from one to the other across the ice, while skating at top speed, until their combination play is perfected to a point which enables them to beat the opposing forwards, swoop past the opposing defense and set up a man in the best scoring position for a shot at the net. Individual rushes by self-styled stars seldom result in tallies going up on the scoreboard. Left- and right-wing players should at all times play their positions in their respective lanes and leave the centre lane or mid-ice section to the centre player. Members of the forward line are supposed to score goals when the opportunity is presented and never at the cost of allowing the opposing forwards to break away for a two- or three-man combination attack on the home team's net. When not participating in an offensive attack, defensive men should position themselves within a 20-yd. radius of the goal net and should never leave their goal tender unguarded. The good defense player must hold, at all times, a position between his goal tender and the opposing forwards who attempt to carry the puck close enough to the net for a shot that may mean a score. Defense players adopt various forms of checking the forward-line attack. Some use a stick check (part of the stick must be on the ice, or the foul of cross-checking is committed) or body check or a combination of the two; others crowd the incoming forwards to the sideboards; or both defense men will simultaneously body-check the puck carrier when he attempts to go between them. The purpose is to spoil the forwards' shots, keep them out of shooting range of the goal net or force them to shoot from impossible angles.

A goalkeeper has 4 by 6 ft. of open net to protect and must study the shots from all angles and positions on the ice. He must cover as much of his net as possible with his body and shift his position between the posts continuously in such a manner that he will cut down the shooting angle and thereby eliminate as much vulnerable opening behind him as possible. Such movement by an experienced goal tender hampers the target range of the opposing sharpshooters. If an opposing left-winger or right-winger goes around the defense for a shot the net guardian crowds the corner of the goal nearest to the shooting wing and edges out to cut down the far corner angle. When a forward skates through the defense and looms up directly in front of the net for a shot, the goalie edges out directly at the shooter and thereby cuts down the shooting angle on both sides. The four most vulnerable spots for scoring are the two upper corners and the two lower corners of the net. Only the most skillful shooters can hit these four vulnerable spots, and only the most skillful of goalies can block these four spots.

EUROPEAN ICE HOCKEY

The following European countries hold membership in the International Ice Hockey federation: Austria, Belgium, Czechoslovakia, Denmark, East Germany, Finland, France, Great Britain, Hungary, Italy, Norway, Netherlands, Poland, Rumania, Sweden, Switzerland, the Soviet Union, West Germany and Yugoslavia.

In the second half of the 20th century the Big Three in European ice hockey were the Soviet Union, Sweden and Czechoslovakia. Many nations with established ice-hockey tradition, such as Great Britain, France, Austria and Switzerland, fell behind the Big Three.

Czechoslovakia. — Ice hockey has been a leading sport in Czechoslovakia since its introduction in 1909 by a group of field-hockey players. During the first 25 years the sport showed a slow but steady growth. In 1933 the National league was organized

with a few teams of varying abilities competing. The calibre of play in the National league improved greatly in the late 1930s and 1940s, insuring the Czechs of strong representation in international competition.

In the second half of the 20th century. 12 teams of evenly matched ability comprised the first division of the National league. Games in this division were very popular with the public, and attendances exceeding 10,000 per game were commonplace. Senior and intermediate players numbered more than 35,000, while about 30,000 players competed in the junior and juvenile class. Formerly the sport had to depend upon the vagaries of the weather concerning natural ice, but later many artificial ice rinks were built.

Great Britain. — A bandy-type game, similar to ice hockey, was played in England as early as 1895. It was not until the winter of 1902–03, however. that ice hockey was introduced to England at the Prince's Skating club in London, primarily through the efforts of resident Canadian students.

Until about 1926 the game remained a hobby for the participants and created limited public interest. During the next decade the sport passed from the hobby stage to one supported by the public. Club competition prospered and touring Canadian and U.S. teams awakened public interest. Soon the commercial possibilities of the game were realized and teams comprised entirely of imported Canadian players were formed and organized into senior-class British and Scottish leagues The British league operated uith clubs from both England and Scotland. In addition to the top-ranked British league, there were dozens of intermediate, junior and juvenile teams composed entirely of native English and Scottish players.

Scotland's ice-hockey development closely paralleled that of England except that the Scots produced better native players than England. Both countries were hampered in the development of players because of the lack of natural ice and the limited amount of artificial ice available.

Soviet Union. — Ice hockey as an organized sport was introduced to the Soviet Gnion in 1946 and showed a phenomenal growth. As in the Scandinavian countries the time-honoured game of bandy was gradually being replaced by ice hockey. In the second half of the 20th century, according to the Soviet Ice Hockey federation, about 105,000 players were actively engaged in competition in the Soviet Union.

Although the National club of the Soviet Union began competing in world tournaments as late as 1954, it made an enviable record and threatened Canada's supremacy in amateur ice hockey. Players forming the National team were groomed through the ranks of the Group A league. The Group A league. centred in the Moscow-Leningrad area. was composed of two divisions, the first division with nine clubs and the second with six. Sixty-three teams were divided into several divisions to form Group B. In addition to the Group A and B teams there were thousands of teams in the intermediate, junior and juvenile classes.

Sweden. — Sweden was first represented by an ice-hockey team in 1920 when a group of bandy players, under the guidance of the Swedish Soccer association, entered the unofficial Olympic ice-hockey matches at Antwerp, Belg. As in other northern European nations ice hockey in Sweden was replacing bandy as the popular winter sport.

After World War II the game made tremendous progress and in the second half of the 20th century there were 4,100 teams and an estimated 60,000 players. many of whom were not registered members of the Swedish Ice Hockey federation. The construction of numerous artificial ice rinks aided considerably in fostering the sport.

The best calibre of play was in the First Division league, composed of 16 teams, divided into north and south sections. Players from this league formed the Swedish National club, which established a distinguished record in international competition.

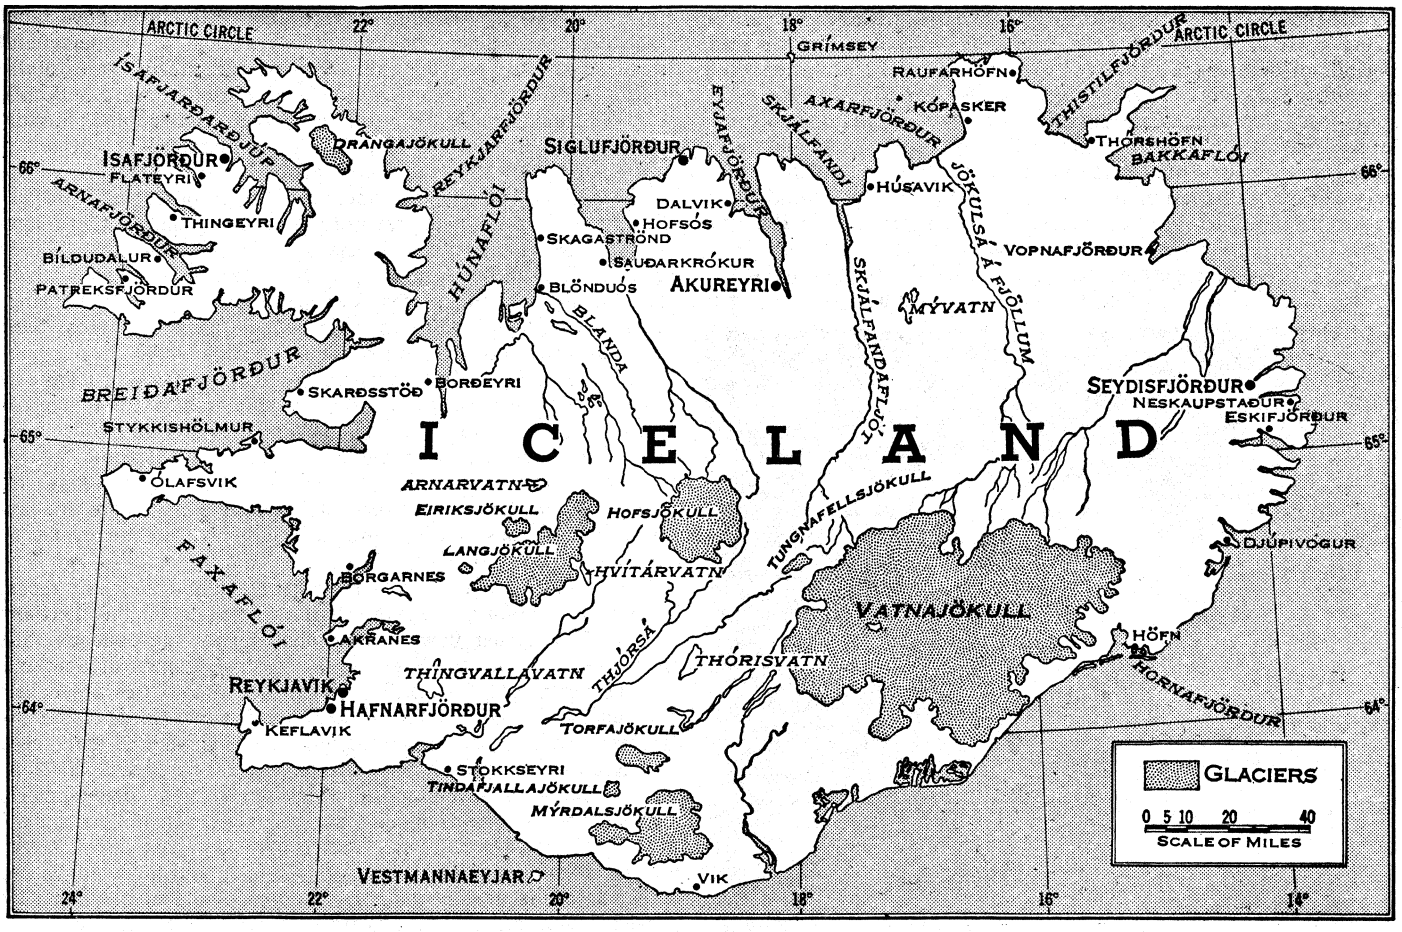
ICELAND, an island in the North Atlantic ocean (Ice. ÍSLAND). Its extreme northerly point is touched by the Arctic circle; it lies between 13° 30′ and 24° 32′ W., and between 63° 24′ and 66° 32′ N., and has an area of 39,768 sq.mi. Its length is 298 mi. and its breadth 194 mi., the shape being a rough oval, broken at the northwest, where a peninsula, diversified by a great number of fjords, projects from the main portion of the island. The total length of the coast line is about 3,730 mi., of which approximately one-third belongs to the northwestern peninsula. Iceland is a plateau or tableland, built up of volcanic rocks of older and younger formation and pierced on all sides by fjords and valleys. Compared with the tableland, the lowlands have a relatively small area, one-fourteenth of the whole; but these lowlands are almost the only inhabited parts of the island Not more than one-fourth of the area of Iceland is inhabited; the rest consists of elevated deserts, lava streams and glaciers. The northwest peninsula is separated from the main mass of the island by the bays Húnaflói and Breiðafjörður, so that there are really two tablelands, a larger and a smaller. The isthmus which connects the two is only $4\frac{1}{4}$ mi. across, but has an altitude of 748 ft. The mean elevation of the northwest peninsula is 2,000 ft. The fjords and glens which cut into it are shut in by precipitous walls of basalt, which plainly shows that they have been formed by erosion through the mass of the plateau. The surface of this tableland is bare and desolate, being covered with gravel and fragments of rock. Here and there are large straggling snow fields, the largest being Glamujokull and Drangajokull, on the culminating points of the plateau. The only inhabited districts are the shores of the fjords, where grass grows capable of supporting sheep; but most of the population gain their livelihood by fishing.

The other and larger tableland, which constitutes the substantial part of Iceland, reaches its culminating point in the southeast, in the gigantic snow field of Vatnajokull, the largest ice mass in Europe. The axis of highest elevation of Iceland stretches from northwest to southeast from the head of Hvammsfjörður to Hornafjörður, and from this water parting the rivers descend on both sides. The crest of the water parting is crowned by a chain of snowcapped mountains, separated by broad patches of lower ground. They are really a chain of minor plateaus, which rise 4,500 to 6,250 ft. above sea level and 2.000 to 3,000 ft. above the tableland itself. Numerous valleys or glens penetrate into the tableland, especially on the north and east, and between them long mountain spurs, sections of the tableland which have resisted the action of erosion, thrust themselves toward the sea. Of these the most considerable is the mass crowned by Mýrdalsjökull, which stretches toward the south. The interior of the tableland consists for the most part of barren, grassless deserts, the surface being covered by gravel. loose fragments of rock, lava, driftsand, volcanic ashes and glacial detritus.

Save the lower parts of the larger glens, there are no lowlands on the north and east. The south coast is flat next the sea; but immediately underneath Vatnajokull there is a strip of gravel and sand, brought down and deposited by the glacial streams. The largest low-lying plain of Iceland, lying between Mýrdalsjökull and Reykjanes, has an area of about 1,550 sq mi. In its lowest parts this plain barely keeps above sea level, but it rises gradually toward the interior, terminating in a ramification of valleys. Its maximum altitude is attained at 381 ft. near Geysir. On the west of Mt Hekla this plain connects by a regular slope directly with the tableland, to the great injury of its inhabited districts, which are thus exposed to the clouds of pumice dust and drift sand that cover large areas of the interior. The plain is drained by three rivers — Markarfljbt. Thjórsá and Ölfusá—all of large volume, and numerous smaller streams. There is another lowland plain around the head of Faxaflbi, nearly 400 sq.mi. in extent. As a rule the surface of this second plain is very marshy. Several dales or glens penetrate the central tableland; the eastern part of this lowland is called Borgarfjörðar, the western part Mýrar.

The great bays on the west of the island (Faxaflbi and Breiðafjorbur), as well as the many bays on the north, which are separated from one another by rocky promontories, appear to owe their origin to subsidences of the surface; whereas the fjords of the northwest peninsula, which make excellent harbours, and those of the east coast seem to be the result chiefly of erosion.



Glaciers and Lakes.—An area of about 5,000 sq.mi., or one-eighth of the total area, is covered with snow fields and glaciers. This extraordinary development of ice and snow is due to the raw, moist climate, the large rainfall and the low summer temperature. The snow line varies greatly in different parts of the island, its range being from 1,300 to 4,250 ft. It is highest on the tableland, on the north side of Vatnajokull, and lowest on the northwest peninsula, to the south of North cape. Without exception the great *névés* of Iceland belong to the interior tableland. They consist of slightly rounded domes or billowy snow fields of vast thickness. In external appearance they bear a closer resemblance to the glaciers of the polar regions than to those of the Alps. The largest snow fields are Vatnajokull (3,385 sq.mi.), Hofsjokull (520 sq.mi.) Langjokull (500 sq.mi.) and Mýrdalsjökull (390 sq.mi.). The glaciers which stream off from these snow fields are often of vast extent, *e.g.*, the largest glacier of Vatnajokull has an area of 150 to 200 sq. mi., but the greater number are small. Altogether, more than 120 glaciers are known in Iceland. It is on the south side of Vatnajokull that they descend lowest; the lower end of Breidamerkurjokull is only about 60 ft. above sea level. The glaciers of the northwest peninsula also descend nearly to sea level. The great number of streams of large volume is due to the moist climate and the abundance of glaciers, and the milky white or yellowish-brown colour of their waters (whence the common name *Hvítá,* white river) is due to the glacial clays. The majority of them change their courses often and vary greatly in volume; frequently they are impetuous torrents: forming numerous waterfalls.

Iceland also possesses a great number of lakes, some of them glacial in origin. The largest are Thingvallavatn and Thórisvatn, each about 27 sq.mi. in area. Mývatn, in the north. is well known for the natural beauty of its surroundings. Above its surface tower a great number of volcanoes and several craters, and its waters are alive with waterfowl, a multitude of ducks of various species breeding on its islands. Mývatn fills a depression between lava streams and has a depth of not more than $8\frac{3}{4}$ ft. The group of lakes called Fiskivotn (or Veiðivötn), which lie in a desolate region to the west of Vatnajokull, consists for the most part of crater lakes. The groups of lakes which lie northwest from Langjokull occupy basins formed between ridges of glacial gravel; and in the valleys numerous lakes are found at the backs of the old moraines.

Earth Movements.—Iceland is one of the most volcanic regions of the earth; volcanic activity has gone on continuously from the formation of the island in the Tertiary period down to the present time. So far as is known, there have in historic times been eruptions from 25 volcanic vents. Altogether 107 volcanoes are known to exist in Iceland, with thcusands of craters, great and small. The lava streams which have flowed from them since the Glacial epoch now cover an area of 4.650 sq.mi. They are grouped in dense masses round the volcanoes from which they have flowed, the bulk of the lava dating from outbreaks which occurred in prehistoric times. The largest volume of lava which has issued at one outflow within historic times is the stream which came from the craters of Laki at Skaptá in 1783. The largest unbroken lava-field in Iceland is Ódáðahraun ("Lava of Evil Deeds"), upon the tableland north from Vatnajokull (2 000 to 4,000 ft. above sea level). It is the accretion of countless eruptions and covers an area of 1,300 sq.mi. (or, including all its ramifications and minor detached streams, 1,700 sq.mi.).

The Icelandic volcanoes may be divided into three classes: (1) cone shaped, like Vesuvius, built up of alternate layers of ashes, scoriae and lava; (2) cupola shaped. with an easy slope and a vast crater opening at the top—these shield-shaped cupolas are composed entirely of layers of lava. and their inclination is seldom steeper than 7°–8°; (3) chains of craters running close alongside a fissure in the ground. For the most part the individual craters are low, generally not exceeding 300 to 500 ft. These crater chains are very common and often very long. The chain of Laki extends 20 mi.. and ernbraces about 100 separate craters. Sometimes, however, the lava streams are vomited

straight out of gigantic fissures in the earth without any crater being formed. Many of the Icelandic volcanoes during their periods of quiescence are covered with snow and ice. Then when an outbreak occurs the snow and ice melt, and in that way they sometimes give rise to serious catastrophes *(jokulhlaup)*, through large areas being suddenly inundated by great floods of water, which bear masses of ice floating on the surfaces. Katla caused very serious destruction in this way by converting several cultivated districts into barren wastes. In the same way in the year 1362 Öræfajökull, the loftiest mountain in Iceland (6,952 ft.), swept 40 farms, together with their inhabitants and livestock, bodily into the ocean. The best-known volcano is Hekla (4,747

BY COURTESY OF "PEPSI-COLA INTERNATIONAL PANORAMA"

THE GREAT GEYSER IN FULL ERUPTION. IT IS LOCATED IN SOUTH-CENTRAL ICELAND NEAR HEKLA

ft.), which was in eruption 23 times within the historic period down to 1947. Katla during the same period was active 14 times down to 1918. The largest volcano is Askja, situated in the middle of the lava field of Ódáðahraun. Its crater has an area of 34 sq.mi. At Mývatn there are several volcanoes, which were particularly active in the years 1724–30. On several occasions there have been volcanic outbreaks under the sea outside the peninsula of Reykjanes, islands appearing and afterward disappearing again. The crater chain of Laki has only been in eruption once in historic times, namely, the violent and disastrous outbreak of 1783.

Iceland, however, possesses no constantly active volcano. There are often long intervals between the successive outbreaks, and many of the volcanoes (and this is especially true of the chains of craters) have only vented themselves in a solitary outburst.

Earthquakes are frequent, especially in the districts which are peculiarly volcanic. Historical evidence shows that they are closely associated with three naturally defined regions: (1) the region between Skjálfandi and Axarfjörður in the north, where violent earth tremblings are extremely common; (2) at Faxaflói, where minor vibrations are frequent; **(3)** the southern lowlands, between Reykjanes and Mýrdalsjökull, have frequently been devastated by violent earthquake shocks, with great loss of property and life, *e.g.*, on Aug. 14–16, 1784, when 92 farmsteads were totally destroyed, and 372 farmsteads and 11 churches were seriously damaged; and again in Aug. and Sept. 1896, when another terrible earthquake destroyed 161 farmsteads and damaged 155 others.

Hot springs are found in every part of Iceland except the region of the eastern fjords, both singly and in groups; they are particularly numerous in the western portion of the southern lowlands, where among others is the famous Geyser (*q.v.*). There are three types of hot springs: (1) fumaroles or steam vents which are all acid; (2) acid springs; (3) alkaline springs. Acid springs occur on dry, high land in volcanic districts after eruptions; their temperature varies and there is not much water. Alkaline springs occur on low land at the foot of hills or at the bottom of lakes and rivers; their temperature is fairly constant and there is a great deal of water. Some hot springs last one day, some hundreds of years; the water at the surface is sometimes two or three degrees above the boiling point. Sulphur springs and boiling mud lakes are also general in the volcanic districts; and in places there are carbonic acid springs, these more especially on the peninsula of Snæfellsnes, north of Faxaflói.

Geology. — Iceland is built up almost entirely of volcanic rocks, none of them older, however, than the middle of the Tertiary period. The earlier flows were probably contemporaneous with those of Greenland, the Faeroes, the western islands of Scotland and the northeast of Ireland. The principal varieties are basalt and palagonitic breccias, the former covering two-thirds of the entire area, the latter the remaining one-third. Compared with these two systems, all other formations have an insignificant development. The palagonitic breccias, which stretch in an irregular belt across the island, are younger than the basalt. In the northwest, north and east the coasts are formed of basalt, and rise in steep, gloomy walls of rock to altitudes of 3,000 ft. and more above sea level. Deposits of clay, with remains of plants of the Tertiary period, lignite and tree trunks pressed flat, which the Icelanders call *surtarbrandur*, occur in places in the heart of the basalt formation. These fossiliferous strata are developed in greatest thickness in the northwest peninsula. Indeed, in some few places well-marked impressions of leaves and fruit have been discovered, proving that in Tertiary times Iceland possessed extensive forests, and its annual mean temperature must have been at least 48° F., whereas the present mean is 35.6°. The palagonitic breccias, which attain their greatest development in the south of the island and on the tableland, consist of reddish, brown or yellowish rocks, tuffs and breccias, belonging to several different groups or divisions, the youngest of which seems to be of a date subsequent to the Glacial epoch.

All over Iceland, in both the basalt and breccia formations, there occur small intrusive beds and dikes of liparite, and as this rock is of a lighter colour than the basalt, it is visible from a distance. In the southeast of the island, in the parish of Lón, there exist a few mountains of gabbro, a rock which does not occur in any other part of Iceland. Near Húsavik in the north there have been found marine deposits containing a number of marine shells; they belong to the Red Crag division of the Pliocene. In the middle of Iceland, where the geological foundation is tuff and breccias, large areas are buried under ancient outflows of lava, which bear evidences of glacial scratching. These lava streams, which are of a doleritic character, flowed before the Glacial age, or during its continuance, out of lava cones with gigantic crater openings, such as may be seen at the present day. During the Glacial epoch the whole of Iceland was covered by a vast sheet of inland ice, except for a few small isolated peaks rising along its outer margins. This ice-cap had on the tableland a thickness of 2,300 to 2,600 ft. Rocks scored by glacial ice and showing plain indications of striation, together with thousands of erratic blocks, are found scattered all over Iceland. Signs of elevation subsequent to the Glacial epoch are common all round the island, especially on the northwest peninsula. There are found strikingly developed marine terraces of gravel, shore lines and surf beaches marked on the solid rock. In several places there are

traces of shells; and sometimes skeletal remains of whales and walruses, as well as ancient driftwood, have been discovered at distances from the present coast. The ancient shore lines occur at two different altitudes. Along the higher. 230 to 260 ft. above the existing sea level, shells have been found which are characteristic of high arctic latitudes and no longer exist in Iceland; whereas on the lower shore line, 100 to 130 ft., the shells belong to species which occur amongst the coast fauna of the present day. A feature of special interest to geologists in the present conditions of the island is the great power of the wind both as a transporting and denuding agent. The rock sculpture is often very similar to that of a tropical desert.

See T. Thoroddsen, "Explorations in Iceland during the years 1881–1898," *Geographical Journal,* vol. xiii, pp. 251–274, 480–513, with map (London, 1899).

Climate. — Iceland has an oceanic climate of moderate heat and cold. The differences in temperature between the coast and the interior are not very marked. At Reykjavik the annual mean air temperature is +3.9° C. (39.0° F.), the mean temperature in January, the coldest month of the year, is −1.2° C. (29.8" F.), while in July, the warmest month, it is +10.9° C. (51.6° F.). The weather is very unsettled. Sudden changes occur from day to day, and the same season may from year to year show great fluctuations. There is rarely the same kind of weather all over the country at the same time. The relative humidity is high, averaging 80%. The wettest regions are in the south and southeast (2,175 mm. [8j.63 in.] of rain in one year at Vik); the north is the driest region (300–550 mm. [11.81 in. to 21.65 in.]) and in the mountains annual precipitation is about 2,000 mm. (about 78.7 in.). The heaviest snowfalls in the winter are in the northwest and northeast. Pressure is always low, especially in winter, but variations are great.

Iceland is situated at the outer edge of the North Atlantic drift, which warms the southern and western coasts. The rate of the clockwise movement of the coastal water is about eight nautical miles per day. Cold currents from the polar basin occasionally touch the northern and, especially, the eastern coasts. The drift ice is very irregular in its appearance; in some years there is none. When it comes, usually in April and May, it arrives on the northwest coast and drifts east. It brings cold, storms and fog. The frequent fogs on the southern coast usually occur with a seawind, those on the southeastern coast with all winds, but chiefly westerly ones. Cyclonic storms make the winds quite variable. In the fjords sudden squalls often arise. Thunder storms are rare.

Flora and Fauna. — About 375 phanerogams and vascular cryptogams, partly arctic in character and partly European, have been identified in Iceland. Most of them are sedges, grasses, composites (including some shrubs), crucifers, rushes and ferns. Other plants include about 350 species of mosses, 250 lichens and 550 fungi. The unstable climate, earthquakes, volcanoes, winds, moving glaciers, etc., all contribute to prevent the vegetation from reaching its highest development. The once large forests have been destroyed so that only about 0.44% of the total area is wooded. The trees are mainly dwarf willows, birches and mountain ash, though re-afforestation is taking place with Norwegian pine and Alaska spruce. There is a thick carpet of moss in areas not snow-covered in winter; grasses and dwarf willows dominate the regions which have a normal winter snow-cover and arctic species are found among them; cotton grass grows with rushes and sedges by the lake sides; above about 2,000 ft., where the soil is porous. lyme grass (*Elymus* arenarius) and seapinks (*Armeria* meritima) are found; and round the hot springs a dense flora often occurs, consisting of dwarf willows, grasses, eyebright, heath, etc.

Of the 30 species of mammals in Iceland, 8 are resident, 14 migratory and 8 vagrant. There are few land mammals, the arctic fox probably being the only indigenous one. The field mouse and brown rat are common everywhere (the rat was probably introduced in the mid-19th century), while the house mouse frequents all inhabited places. The polar bear is sometimes seen in the north and east but has never been known to breed in Iceland. The common seal is found round all the coasts and other seals are often seen. The white-nosed dolphin, porpoise and other whales occur in numbers in the coastal waters. Reindeer have been introduced at various times and are still to be found. Among the many birds resident in or visiting Iceland are the snow bunting, Iceland falcon (decreasing in numbers), whooper swan, red-necked phalarope (often seen near the hot springs), rock ptarmigan, divers, many kinds of duck, whimbrel, grebes, cormorants and many other sea birds. The redwing, wheatear and meadow pipit are among the summer visitors. The turnstone visits Iceland on spring and autumn migration. The hot springs have a special fauna including insects, molluscs, crustacea and a few fish. Many of the rivers abound in salmon, and trout are plentiful in the lakes and streams. There are no reptiles or amphibians. (E. Bz)

History. — Seafarers had some idea of the existence and position of Iceland as early as the 4th century A.D., but no settlement is known to have been there before the 9th century, when Irish hermits set up their dwellings in a few places. Little is known of these people and old Icelandic authorities say that they went away when pagan settlers began to arrive.

Ingolfur Arnarson, a chieftain from west Norway, began the settlement of Iceland when he moved there with his family and dependents in A.D. 874. He established himself on the site of what is now the capital, Reykjavik. For 15 years the flow of new settlers went on slowly and increased in volume toward the end of the century, probably because Harald Fairhair became king of Norway after the battle of Hafursfjörður, *c.* 885, and extended his rule over the Shetland and Orkney Islands about 890. The settlement of Iceland, followed by the discovery of Greenland and Wineland (North America) from there may be said to be consequent on the upheaval of the viking age. The earliest settlers, who were doubtless of mixed descent, came from the countries and districts where the vikings had been dominant for centuries, from the west coast of Norway, from Ireland, Scotland, Orkney, Shetland and the Hebrides.

Some of the first settlers, such as Ingólfur Arnarson, Skallagrímur Kveldúlfsson the father of Egill Skallagrimsson. Auður, the widow of Ólafur the White, king of Ireland, and her kinsman Helgi the Lean, appropriated large areas of land which they distributed later to their friends, followers and protégés. Later settlers secured smaller areas. Until the end of the 10th century the country kept the characteristics of recent settlement. the landholdings were large with few and widely scattered buildings; each homestead contained a large number of people and was practically a self-supporting, economic whole.

In the beginning, the people lived mostly by fishing, but sheep farming soon became the second most important industry. By about 1100 economic conditions were satisfactory. The population at about the time when the tithe laws were passed (1097) was between 70,000 and 80,000, a total which was not exceeded until about 1900.

Before a general system of legislation and organized government could be achieved a kind of local government was evolved by which the people of each district uho had most dealings together formed into groups under the leadership of the most important or influential man of the district; he acted as judge and mediator in the disputes of his neighbours and took the lead in communal activities such as the building of places of worship and the performing of religious rites. These leaders were called *goðar* (sing *goði*) and it is thought that the word derives from this religious function, but in the age of settlement in Iceland the word *goði* primarily means "Chief", although it occurs in its older meaning in Danish and Swedish runic inscriptions. Local assemblies such as *kjalarnesthing* and thorsnesthzng are heard of before the establishment of the *althing* (general assembly) and they show the way in which the local chiefs tried to organize law and order for their own districts, which in turn led to the co-operation of all the chiefs in founding a national parliament (*althing*) and the adoption of a general system of law for the whole country. In 930 the Icelandic commonwealth was established and the first session of the *althing* was held, probably on the site of the *kjalarnesthing,* near Reykjavik, but it was soon moved to Thingvellir by the Öxará

river. The oldest code of laws, called Ulfljóts laws from the name of the man who compiled them, may have been founded partly on the laws then in force in the Gulathing district of Norway.

The old Icelandic commonwealth was based on the first foundations of government laid in the age of settlement. Its main instrument was the *goðorð* (chieftancy). The godar became the rulers of the country and together with their advisers constituted the logrktta (legislature) of the new althing. The godar administered justice in their own districts and matters not settled there were referred to the althing. In this way they held both the legislative and the judicial power. There was no national executive power, but to the godar fell the duty of seeing that such men as accepted their leadership received their rights, and to this extent they held the executive power.

The extent of the *goðorð* was not fixed by territorial boundaries. Those who were dissatisfied with their chief could attach themselves to another *goði*. His power was therefore in direct proportion to his personal prowess and ability. As a result rivalry arose between the godar, as may clearly be seen from the Icelandic sagas. The position of *goði* could be bought and sold, as well as inherited; consequently, with the passing of time the *goðorð* for large areas of the country became concentrated in the hands of one man or a few men, This was the principal weakness of the old form of government: it led to a struggle for power and was the chief reason for the ending of the commonwealth and for the country's submission to the king of Norway (1262–64).

The old form of government became modified in the course of time. (The laws of the commonwealth that remain [the Grágás code] show organizing ability, far-sightedness and accuracy, and skill in resolving procedural and legal difficulties.) Modifications were, for instance, the division of the country into quarters and the setting up of courts of justice for each quarter after the middle of the 10th century, and the establishment of the fifth court, *i.e.*, a court of appeal, about A.D. 1000.

Towards the end of the 10th century Christian missions came to Iceland. In 1000, after great disputes which nearly led to civil war, the althing enacted a law that all inhabitants of the country should be Christian, primarily for political reasons in order to preserve the commonwealth. The old pagan gods were sacrificed to expediency but the power of the *goði* remained as before. The place of the temples of the gods was taken by the old Icelandic church, the church of the *goði*. Until the end of the 12th century it was a common practice for the lay chieftains to have a clerkly education and to receive ordination and the bishops of the country until the end of the 12th century were men of this kind. In 1056 the first Icelandic bishop Ísleifur Gissurarson of Skálaholt was ordained at Bremen; until then Iceland had only known missionary bishops. After 1106 the country possessed two bishoprics, at Skblaholt and at Hólar. In 1096, the tithe laws had been passed, thus ensuring the church's financial security. Yet even after this many churches in the country were privately owned by farmers or chiefs, and disputes arose when the clerics began to try to undermine the secular power after the end of the 12th century. These disputes were not settled until after the fall of the commonwealth, when the church emerged the victor in the struggle.

The traditional culture was fostered in the centres of learning of the old church, at Haukadalur, Oddi, Skblaholt, Hólar, and in the monasteries. Slavery was abolished before 1100. Despite the distinction conferred by power and wealth, men were honoured for their personal qualities. Sports and trials of skill and strength were popular, and from the early days of the commonwealth it was customary for all, even the chiefs themselves, to take part in the labours of husbandry. The people's daily lives were shaped by their occupations of agriculture, fishing, spinning and weaving and boat-building. There was great social activity, especially at Midsummer, in the autumn and at Christmas, when there were feasts and drinking sessions.

Lack of progress in economic life after about 1200 was chiefly due to the fact that the main industry, sheep farming, had reached its peak with the methods then followed. The climate's growing more severe also had some effect, as did the internecine quarrels, which became frequent after 1200. Trade grew more difficult for in the latter part of the commonwealth period it fell more and more into the hands of Norwegian merchants and Icelandic shipping disappeared gradually, largely because of lack of ship-building timber in the country.

In 1262-64 a treaty was made (Gamli sdttmali), bringing the country under the rule of the Norwegian king. It caused great changes. New church laws and the victory of the church in the quarrels over disposal of church property gave the church full independence and made it a state within the state. The old Icelandic chieftains yielded place to the king's officials, the governor and district magistrates. A new code of laws (*Jónsbók*, 1281) replaced the commonwealth code. The climate grew more severe and volcanic activity did more damage than ever before. Epidemic diseases took their toll. Factional brawls and fighting died down but public life lost vigour. Literature, which reached its peak in the saga writing of the 13th century, declined. Agriculture became poorer, though the fishing industry made progress. Trade was weak and there were few imports. About 1400 the arrival of English and German traders and fishermen greatly helped Iceland's trade. The fisheries flourished and fish (stockfish and fish liver oil) became the chief export, in place of skin, hides, wool and woollen goods. In 1402–4 a large proportion of the population perished in the Black Death. Wealth became concentrated in the hands of few rich men, in the monasteries and in the church, while independent farmers declined in number and the poor increased.

From 1380 Iceland and Norway were governed by Denmark. Iceland's government after 1264 had been very uneven. Foreigners were appointed as bishops and sometimes even as governors, and the country was oppressed by the heavy taxes and dues levied upon it. From 1539 to 1551 there was a struggle between the Catholic and Lutheran churches in which Lutheranism, whose cause was assisted by the Danish kings, was victorious. The king and church between them came to own half the land in the country, a state of affairs that lasted until the 19th century. The king also attacked the trade with English and German merchants so from 1602 Iceland's trade was monopolized by Danish merchants, a monopoly that was not lifted until 1787 (in part) and entirely in 1854. This monopoly paralyzed the country's economic life and conditions worsened so quickly that the census of 1703 showed only about 50,000 inhabitants, of whom one-fifth were not self-supporting. Between 1750 and 1760 Skúli Magnhsson (1711–94), with government assistance, tried to revive some forms of industry but the trade monopoly made his efforts' unsuccessful and the same fate befell proposals to improve agriculture and communications which were put forward c. 1770 by Jón Eiriksson (1728–87). In 1783–84 the country suffered severely from volcanic eruptions and earthquakes which caused great famine and the loss of sheep and cattle. When the monopoly was relaxed in 1787 conditions began to improve, especially after the end of the Napoleonic wars.

In the summer of 1809 an English merchant Phelps and his confederate Jorgen Jorgensen imprisoned the governor and proclaimed Iceland free under the protection of Great Britain. This revolt was soon crushed by the intervention of Great Britain at the instance of Magnus Stephensen.

Icelandic politics entered on a new era in 1831. The king of Denmark's move to establish a legislative parliament in his realm led to a movement for the revival of the althing, which had ceased to meet in 1800. This movement had become powerful by 1840 when a new Icelandic leader, Jón Sigurðsson (1811–79), appeared. For nearly 40 years he led his country in the struggle for greater political freedom and economic progress. The *althing* was restored in 1843 and met in Reykjavik in 1845 but it was not until 1874, the millenary of the first settlement, that Iceland was given limited self-government in home affairs.

The latter half of the 19th century was a hard time for Iceland; unusually severe weather conditions and political disappointments caused many people to emigrate to Canada and the United States. The first co-operative societies were founded after 1880 and trade turned more and more to Great Britain. The first bank was

opened in 1886, and fisheries and inland trade expanded. Home rule was granted in 1903. The new government first concerned itself with increasing industry, improving communications by sea and land and acquiring new capital for building and shipping enterprises. A marine cable was laid to Europe in 1906. Harbours and roads were improved. The Iceland Steam Shipping company was founded in 1914. A general education act was passed in 1907 and the University of Iceland was founded in 1911 on the centenary of Jón Sigurðsson's birth.

World War I delayed progress. In 1923 new agricultural laws were passed which, with the aid of modern equipment, revitalized Icelandic agriculture. After 1920 factories were erected for fish and fish products. Communications were further improved, by means of motor roads connecting most of the inhabited parts and regular coastal shipping services. After World War II communications by air both inland and overseas expanded considerably.

In 1918 the long-lasting dispute between Iceland and Denmark was settled by a treaty recognizing Iceland as an independent state under the king of Denmark. This treaty was made for 25 years and was terminable by either party. In 1937 the althing proclaimed that the treaty would not be renewed on its expiry. After the German invasion of Denmark in World War II, the British occupied Iceland in order to prevent a German occupation, and normal communication between Iceland and Denmark ceased. The executive power was of necessity taken over by the Icelandic ministry after April 9. 1940, with Sveinn Bjornsson as regent. In 1941 the althing proclaimed that it considered the treaty to be virtually terminated, as the Danes were not in a position to carry out its terms, and announced that a republic would be founded in Iceland as soon as the treaty was formally annulled. But the war continued and it was considered inadvisable to delay the matter any longer. On May 17, 1942, the althing passed two resolutions: (1) that Iceland did not intend to continue the union when it expired on Jan. 1, 1944; and (2) that Iceland intended to become a republic. On Feb. 2j, 1944, the althing proclaimed the treaty terminated and decided to hold a plebiscite with regard both to this action and to the constitution of the new republic. Of the votes cast, 97.35% supported the decision of the althing. On June 16, 1944, the althing declared the union with Denmark to be at an end and on June 17, the republic was founded at Thingvellir with Bjornsson as its first president.

From 1944 to 1950 two coalition governments were in power, each composed of three political parties. After 1950 two parties, the Progressive party and the Independence party, twice joined in forming a coalition government.

In 1948 Iceland became a member, with Denmark, Norway and Sweden, of a joint northern committee for economic co-operation, and in 1949 it accepted an invitation to join the North Atlantic Treaty organization and took part in the first meeting of the Council of Europe. Two hydroelectric power stations, begun in 1951 with the aid of European Recovery prograrn funds, were completed in 1953. In Jan. 1952 Bjornsson died, and in the presidential elections, held the following June, Asgeir Asgeirsson was elected for a four-year term of office. (T. J.)

Foreign Relations. — On May 1j, 1952, Iceland moved the limits of its fisheries outward to a perimeter four miles from lines drawn between its longest promontories and between islets and rocks offshore, enclosing many productive grounds (particularly Faxaflói and Breiðafjör ður) previously open. In retaliation British trawler owners at Hull and Grimsby refused facilities to Icelandic vessels.

The U.K. government proposed to submit the dispute to the International Court of Justice, but Iceland demanded that the retaliatory measures be lifted first. The British foreign office declared that these measures had been originated by private industries over which the British government had no control. In 1954 the Icelandic government submitted to the Council of Europe a memorandum on this dispute to which the British government replied in May 1jj asking for a compromise.

The refusal of landing facilities to Icelandic fishing vessels in English ports caused Iceland to search for new markets for its fish and fish products. The Soviet government used this opportunity to conclude on Aug. 1, 1953, a trade agreement of $12,000,000 each way, under which the U.S.S.R. was to take fisheries products in exchange for petroleum products, cement and cereals, it being stipulated that Iceland should take no other foreign petroleum products. This agreement was renewed in Sept. 1jj until the end of 1956.

Iceland, although an original member of NATO, has no armed forces. According to the U.S.-Icelandic treaty of May j, 1951. its defense is assured by the U.S. which is entitled to use the air base of Keflavik (35 mi. S.W. of Reykjavik). In Sept. 1953 the opposition Labour party introduced a resolution in the althing calling for a revision of this treaty. On May 25, 1954, the treaty was revised. The planning of defense works was slowed down; the U.S. forces agreed to employ Icelandic labour principally; U.S. military personnel were confined mainly to the air base of Keflavik and to the navy base at Hvalfjörður (30 mi. N.E. of Reykjavik). **(X.)**

Population and Towns. — The Icelanders are primarily of the Nordic race, with some early blending of Irish blood. The population, 144,263 in 1950 (*cf.* 121,579 in 1940), averages about three per square mile, almost four-fifths of the country being uninhabitable. Reykjavik, the capital and only large town, had a population of 56,096 in 1950. Akureyri had 7,143; Hafnarfjör-Bur 5,065; Vestmannaeyjar 3,699; Siglufjörður 3,052; and Ísafjörður 2,826.

During the last quarter of the 19th century there was a considerable emigration to America, chiefly to Canada.

Religion. — The Evangelic Lutheran Church is the established church of Iceland. From the late 19th century, however, there has been full religious liberty, Sectarian bodies are few and inconsiderable in number, only the Roman Catholics and the Adventists having formed their own congregations. Iceland forms one bishopric with its see in Reykjavik.

Education. — There is compulsory elementary education between the ages 7 and 14 years, and practically everybody is able to read and write. In various parts of the country there are junior schools for children 13 to 1j years of age which provide courses of study and further instruction in the subjects taught in the elementary schools. There are also two state-owned coeducational high schools (*menntaskólar*), one in Reykjavik and one in Akureyri. The final examination or *stúdentspróf* (examen artium) entitles those who pass it to matriculation at the university. The country also possesses a number of special (technical) schools, most of which provide general as well as technical instruction.

The University of Iceland (Háskóli Islands) at Reykjavik was founded in 1911 and has five faculties; viz., theology, medicine and dental surgery, law and commerce, philosophy (dealing with the humanities — philosophy, Icelandic studies, languages, etc.) and engineering. Various research and experimental stations work in co-operation with the university. The university library is the second largest in the country, after the national library (Landsbókasafn fslands) founded in 1818. In 1951 the latter contained 185,400 volumes of printed books and more than 10,000 manuscripts.

Constitution. — After 1942 the althing was composed of not more than 52 members, 33 chosen from one- or two-member constituencies, 8 from the capital, and up to 11 supplementary members assigned to parties which had not gained seats in proportion to voting strength. The althing meets every year in Reykjavik and is usually divided into two houses, *efri* deild (upper house) and *neðri* deild (lower house), but on certain occasions both houses work together. Both houses have equal constitutional power.

The seat of the government is Reykjavik. The country is divided into 16 districts (*sýslur*), each of which is administered by a district magistrate (*sýslumaður*), and 8 towns, administered by town magistrates. As to justice, the ordinary judicial court has two instances. The first instance is the lower court, presided over by the magistrates. The second instance is the supreme court (*Hæstiréttur*) in Reykjavik, consisting of five judges. Juries are never employed in the trial of criminal cases.

Health. — In 1949 the birth rate was 27.8 per 1,000 and the death rate 7.9 per 1,000, the latter showing a marked improvement

on the previous figures. The surgeon general, residing in Reykjavik, has the general care of all matters of public health. The country is divided into 52 medical districts with as many government-paid doctors.

There were about 50 hospitals in Iceland in the 1950s, some extremely small; the largest, the national hospital, was in Reykjavik. There were two sanatoriums for tuberculosis patients and, in the neighbourhood of Reykjavik, a model rehabilitation centre for tuberculosis patients. In the same area there were also a mental institution and a leper hospital.

In 1936 a general national insurance scheme was instituted. This was later revised to include insurance against sickness, accident and unemployment, and pensions for the aged and disabled.

Industries. — Though farming is still the chief occupation of the population, it was formerly so in a much higher degree. In 1880 73.2% were engaged in farming compared with 30.0% in 1950. The farmhouses stand apart and isolated, each within the borders of the land belonging to it. They are never found in clusters or villages, but not infrequently two or three or (rarely) even more farmhouses are built together.

The farmers are largely occupied with cattle breeding, and more particularly sheep breeding. All farming in Iceland is based on the cultivation of grass. The hay from the manured homefield *(tun)* is almost exclusively used for cattle (cows) fodder, while horses and sheep are fed with the hay from the meadows (engi). Considerable quantities of potatoes and Swedish turnips are grown in the country. Government expenditure on agriculture increased greatly after 1900.

The decline in numbers of agricultural workers was a reflection of the concomitant development of Iceland's fisheries, which by 1950 were employing one-fifth of the population. The fishing fleet, expanded by the progressive introduction of trawlers and motor ships after 1920, comprised 614 vessels (56,856 gross registered tons) in 1952.

Cod and herring are the most important of all the kinds of fish caught in the Icelandic waters; and foreign trawlers are usually to be seen off Iceland, particularly off the northwest. Icelandic fishing vessels have sometimes visited the fishing grounds off Greenland and Bear Island and in the White sea. On the south and southwest coasts the chief cod fishing is carried on from January to May, but the season varies from one part of the country to another. Most of the catches made in the smaller boats go to quick-freeezing plants. The centre of the cod-fishing industry is Reykjavik, but it is carried on to a greater or less degree in practically all the towns and villages around the coast.

The herring fisheries are chiefly off the north coast, and their big season lasts from July to September, when the waters are crowded with ships from, among others, Norway, Sweden, Finland and the U.S.S.R. The centre of the herring fishing is Siglufjörður, where huge processing plants (a large number of them owned by the state) are situated. Similar factories are to be found in various other places in the north and east, the most important being at Raufarhofn on the northeastern coast. In autumn and winter considerable catches of herring are sometimes made off the southwest coast. The herring are sometimes salted, but otherwise they are processed to produce herring oil and herring meal. Some of the fish is frozen in order to be used for bait. Great Britain normally takes most of the'oil, continental Europe most of the salted herring, Israel and the U.S. most of the fish meal.

Foreign Trade. — Compared with the number of people the total foreign trade of Iceland is larger than that of most other countries. Having a limited range of products, Iceland must depend on foreign countries for a number of necessities. (*See* Table I.)

TABLE *I.*—*Foreign Trade*
(In 000,000 kr.)

Item	1938	1948	1950	1952	1954	1955
Imports	50.5	458.0	543.3	909.8	1,130.4	1,264.3
Exports	56.6	395.7	421.9	641.3	845.9	847.9

The most important articles imported are machinery, ships, oil and gasoline, grains and flour, timber, paper, metals, coal, automobiles, cement, salt, sugar and coffee. The chief articles exported are quick-frozen fish, fish on ice, cured saltfish, salted herrings, cod-liver oil, herring oil, whale oil, fish meal, herring meal, canned fish, guts, salted fish, roes and salted sheepskins. Main sources of imports in 1955 were: United States 23%, U.S.S.R. 14%, U.K. 11%, German Federal Republic 10%. Main destinations of exports in 1955 were: U.S.S.R. 18%, U.S. 12%, Italy 8%, Finland 7%.

Finance and Banking. — During the years 1946–52 Icelandic budgets were constantly in deficit, but that of 1953 had a small surplus. (*See* Table II.)

TABLE II.—*Budgets*
(In 000,000 kr)

Item	1/39	1948	1/50	1951	1952	1953
Revenue.	20.3	273.2	322.9	447.0	452.8	510.0
Expenditure	20.6	334.2	371.8	534.6	516.6	507.5

Iceland is in the Scandinavian monetary union. The unit is called króna (pl. krónur) and is divided into 100 aurar (sing. eyrir). The relation between króna and British and U.S. monetary units was at gold par exchange £1 = 18.16 kr.; $1 = 3.73 kr. The Icelandic króna followed the fluctuation of the Danish krone to 1920, but from the latter half of that year it was quoted independently. In 1955 the official rates of exchange were £1 = 45.70 kr. and $1 = 16.32 kr. Note circulation between the end of 1946 and the end of 1955 increased from 172,000,000 kr. to 305,000,000 kr. Gold and foreign exchange holdings were $9,500,000 in Dec. 1946, $3,100,000 in Dec. 1949 and $6,000,000 in Nov. 1955. The international metric system of weights and measures was introduced in Iceland by law in 1907.

Communications. — Formerly all land journeys were made on horseback and all transport in the interior on pack horses. In the last years of the 19th century the first carriageable roads were made, and thereafter road making progressed rapidly. Many bridges were constructed. After motorcars were introduced in 1913 their number increased rapidly, so that by Dec. 1954 there were 7,195 cars, 4,685 trucks, 315 buses and 312 motorcycles.

Regular automobile services are kept up between the capital and various places around the country. During summer motorcars are also regularly run between the northern and southern districts. Highways (1950) totalled 3,100 mi.

There are regular air services from Reykjavik to many places in the country. Numerous airfields were constructed but some of the aircraft used on the regular lines are flying boats. Postal communication, both inland and abroad, presents no difficulties, although the inland postal service is sometimes held up in winter by snow or bad weather. Great use is made of aircraft in maintaining the postal services. Coastal steamers go around the coasts, touching practically every port. In order to facilitate communications by sea, about 100 lighthouses were built. In 1906 a submarine cable was laid from the Shetland Islands to Seydisfjörður on the east coast. Telegraph and telephone stations were built all over the country. From 1917 Reykjavik had a wireless telegraph station, and in 1929 a regular broadcasting service was established.

ICELANDIC LANGUAGE. The Icelandic settlers came of Norwegian stock and in the early period their language must have been practically identical with that of western Norway. The oldest linguistic forms are found in 10th and 11th-century poetry, preserved in 13th-century records. Greenland was settled from Iceland, *c.* A.D. 900, but it is not known how the language there developed.

The Latin alphabet was adapted for Icelandic use by 1100. In the earliest manuscripts (c. 1150–1200), Old Icelandic can already be distinguished from Old Norwegian: among its significant features are retention of initial h before l, *n,* r, and regular operation of the so-called "younger" u-mutation (*e.g., land,* dat. pl. *lǫndum,* Norw. *landum*). By about 1300, e, o in endings became i, *u* respectively; *ǫ* fell together with *ø* (modern *ö*), *ǫ́* with *á, æ* with *æ;* short back vowels mere lengthened before 1 plus a labial or guttural (mod. Icelandic *hálfur,* Norwegian kalv). There were sporadic signs of changes fully effected later.

Important phonological changes in the transition period, c. 1300–1550, were: *é* became [jɛ], *vá* became *vó* (now usually vo); between final *r* and a preceding consonant (other than r) *u* was introduced (*maðr,* now *maður*); final k, *t* in weakly stressed syllables became g, *ð* (*mjǫk; mjög;* at: ab); there were certain consonantal assimilations and shortenings. Old distinctions of quantity were largely kept until the 16th century, but then gave way to accentual values. Analogical simplifications occurred in accidence, but too few to disrupt the inflectional system.

In the period 1100–1700, some earlier developments were completed and most sounds attained their present-day pronunciation: *á* to [au], *í* to [i:], *ó* to [ou], *æ* to [ai], *au* to [øy]; y, *ý,* ey fell together with i, *í,* ei; *ll* generally became [dl] in almost all positions, *nn* [dn] after long vowels and diphthongs; *fl,* fn became [bl, bn]. Amongst analogical changes in accidence were the transformation of masc. u-stems to *i*-stems (*fjörður,* acc. pl. *firði,* older *fjörðu*); the replacement of plural subjunctive endings, *-im, -ið,* -i, by indicative endings, *-um* (present and past), *-uð, -u* (past); tne use of *-i* (older *-a*) in the first person singular ending, past indicative weak verbs and present subjunctive all verbs. The dual pronouns, vid, *þið,* replaced *vér, þér* (we, you) in ordinary speech.

Dialects.—Dialectal differences are slight. The chief areas are the Southern (covering about three-quarters of the country) and Northern. Important differences are in the pronunciation of intervocalic *p,* t, k (half-voiced, Southern; voiceless, Northern); of *l,* m, n before *p, t,* k (unvoiced and following consonant unaspirated, Southern; voiced and following consonant aspirated, Northern: *stúlka,* [stu:lka, stu:lkʰa]); and of *hv-* ([χw], Southern; [kv], Northern). There is some dialectal variation in fanning and fishing terms.

Vocabulary.—Loan-words from Celtic and Latin (introduced especially after the Conversion) appear in the early language. In the 13th century, some Romance and German words were borrowed (*e.g., kurteiss, dans, læra*), but there was a strong tendency to translate new terms by native equivalents or compounds. A considerable number of Danish and German words were introduced in the period 1300–1550, although comparatively few remain in use. In the next two centuries, Icelandic was much influenced by Danish. A purist movement, which began towards 1800, has since become all-powerful. Internationally current technical and abstract terms have not generally been adopted, being rendered by direct translation (*framleiða:* producere), by the resuscitation of obsolete words in a special modern sense (*sími* "cord", used in (*tal*)*sími* "telephone"), and by the creation of new words (berkill "tu*berculo*sis"), generally with happy results.

Icelandic and Norwegian underwent dissimilar phonological developments, and Icelandic, unlike Norwegian, has remained extremely conservative in accidence, vocabulary and orthography; the two languages are no longer mutually intelligible. Icelandic is spoken in Iceland (with about 144,000 inhabitants) and by some 20,000 emigrants in North America.

See A. Noreen, Altislandische und *Altnorwegische* Grammatik (Halle, 1923); Halldór Hermannsson, Modern Icelandic (1919); Stefan Einarsson, Icelandic (1945). (P. G. F.)

ICELANDIC LITERATURE. Ever since the 10th century the Icelanders have been famous for their literature, first of all for poetry and later for prose. During many centuries their literature has been as rich and varied as that of any nation in Europe.

Iceland was not peopled by Scandinavians until late in the 9th century, but some of the poetry found in the Icelandic manuscripts must have been composed before that date, whether in Scandinavia, in the Scandinavian settlements of the British Isles, or even further afield.

Practically no early poetry written in a Scandinavian language is found in manuscripts other than the Icelandic, and the study of Icelandic poetry is thus the study of Scandinavian poetry.

Much of the oldest poetry is found in a manuscript called the Poetic Edda (see EDDA). This was written in Iceland during the second half of the 13th century, but was copied from older originals, probably written early in that century. Poetry of the kind found in this manuscript is sometimes called "Eddaic" in order to distinguish it from the "scaldic" poetry, which will be discussed below. The Poetic Edda consists of 45 leaves in quarto, and the poems in it fall naturally into two sections, which represent two distinct classes. The first half of the book consists of lays about pagan gods, and the second of lays about legendary heroes of the Germanic peoples.

Heroic Lays.—Many of the legends upon which the heroic lays are based originated in continental Germany, and even among the Goths of southeastern Europe. Heroes who figure in these lays appear also in the poetry of the Anglo-Saxons, in the *Nibelungen*lied and other mediaeval poetry of Germany. The heroic lays of the Edda are composed in various styles and belong to various ages. Perhaps the oldest is the Hambismdl (Words of Hamdir), which is the last in the book. It is preserved in a poor state and it is plain that it was not clearly remembered by the scribe who first wrote it down. In the *Hamðismál* a story is told of the historical Jormunrekk (Ermanaric), emperor of the Goths in eastern Europe (d. 375). Jormunrekk had married Svanhild, said to be the dadghter of Sigurd (Sigfrid) and of his wife, Gudrun. Believing that Svanhild had committed adultery with his own son, the emperor had caused her to be trodden to death by horses. The poem opens as Gudrún incites Hamdir and Sorli, her sons by a later marriage, to take vengeance for their half sister.

Entering the castle of Jormunrekk, the brothers fought against overwhelming odds. They cut off the arms and legs of the emperor, failing only to cut off his head. Hamdir and Sorli then fell dead upon a heap of Gothic corpses. rejoicing in their own valour and in the fame which would survive them. In no poem are the Germanic ideals of heroism expressed so clearly and forcefully as they are here.

It is not known when the *Hamðismál* received its present form, but several elements in it are very ancient. The story closely resembles one told by the Gothic historian Jordanes in the middle of the 6th century. Jordanes said that Jormunrekk was wounded by two brothers, Ammius and Sarus, because he had caused their sister, Sunilda, to be torn to pieces by wild horses. The account given by Jordanes contains more fiction than history, and he appears to be summarizing a poem. If so, the poem which Jordanes knew in the 6th century was one of the ancestors of the Hambismdl, written down in Iceland in the 13th century. It is possible that an early form of the *Hamðismál* was brought by a traveller from southeastern Europe to Scandinavia and adapted to the Scandinavian language. The story told in the *Hamðismál* changed little between the 6th and the 13th centuries, although it was combined with legends of Gudrún and of Sigurd, which belong to a later date than the legends of Jörmunrekk.

Another of the older lays is the *Atlakviða* (Lay of Atli, Attila),

which contains memories of events which took place in western Germany in the 5th century. In the year 437, the Burgundian tribe, then dwelling on the middle Rhine, had been overcome by a Hunnish army and the Burgundian king, Gundicarius, was killed. Atli (Attila) was not engaged in this campaign, but the poet saw it as a personal quarrel between him and Gunnar (Gundicarius). Atli is said to be married, at this time, to Gudrun, sister of Gunnar. He invites Gunnar and his brother, Hogni, to his castle with promises of gifts and then treacherously kills them. Gudrun takes revenge for her brothers by killing the sons whom she had borne to Atli and then stabbing Atli in his bed.

This story of Atli's death is not far removed from history. According to contemporary writers, he had married a woman, whose name Hildico shows that she was Germanic, and on the wedding night he died of a haemorrhage. Popular report soon had it that Hildico had murdered him. The story of Atli was rehandled by a later poet in the *Atlamál* (Words of Atli), which was probably composed among the Icelandic colony in Greenland.

A third legend was linked with those of Jormunrekk and the Burgundians. This was the German legend of Sigurd and Brynhild, which became one of the most popular in Scandinavia and Iceland, although it is not known how early it was introduced.

In the lays of the *Edda* the Burgundian princess, Gudrún, is married first to Sigurd, the spotless, valiant hero. Sigurd had formerly been betrothed to the warrior woman, Brynhild, but Grimhild, the mother of Gunnar and Gudrún had administered a magic potion, so that he forgot his betrothal and married Gudrun. Brynhild lived in a castle surrounded by flames and had sworne that she would marry none but the man who could ride through them. Gunnar failed to do this, but Sigurd succeeded in the disguise of Gunnar. Brynhild then married Gunnar and was heartbroken to discover that he was the lesser hero. She was stirred by loving hatred for Sigurd, as is most fully described in the *Sigurðar kviða en skamma* (Short Lay of Sigurd). Brynhild incited her husband, Gunnar, and his brothers to murder Sigurd, but when they had done this, she threw herself on the funeral pyre beside him.

The spiritual conflicts of Gudrún are described in several lays with even greater pathos. In the "First Lay of Gudrun" she is described weeping over his dead body, and in the "Second Lay of Gudrun" she looks back on her past life and dwells upon her sufferings. Her conflict was that of loyalties. She was bound by ties of blood to her brothers, who had murdered her beloved husband, and later she took revenge for these brothers upon her own sons and upon her second husband, Atli, who had murdered them.

Many modern critics hold that the lays of the *Edda* in which the spiritual conflicts of Gudrun and Brynhild are described belong to a later age than such austere poems as the *Hamðismál* and the *Atlakviða*. The lays about these heroines tend to be romantic and sentimental and seem to accord better with the tastes of the Christian middle ages than with those of the pagan dark ages. In their present form these lays are Icelandic, but they may well be derived from lost German poems of the 11th or even of the 12th century.

Nearly all heroic lays in the *Edda* are associated in one way or another with the story of Sigurd, although the heroes of three of them, the Helgi lays, have but distant relationship with Sigurd. These lays have another background and their scenes seem to be laid on the shores of the Baltic during the Viking age. One heroic lay in the *Edda*, the *Völundarkviða* (Lay of Wayland the Smith) is altogether divorced from the story of Sigurd. Its hero is the magic smith, Wayland, who seduces Bodvild, daughter of King Nidud. This story was well known in Anglo-Saxon England, for it is also told in the poem "Deor's Lament", and is depicted on panels of the Franks Casket, probably of the 8th century.

The *Poetic Edda* contains only a small proportion of the heroic poetry known in Iceland in the early middle ages. Much has been lost, but several fragments of ancient lays are found in sagas of the 13th and 14th centuries. Among the most important may be counted the "Battle of Goths and Huns," quoted in the *Heiðreks Saga*. The story is of a great battle between Goths, led by Angantýr, and Huns, led by Hlod. The scene appears to be southeastern Europe, in the region of the Black sea. The events celebrated have not been identified in history, but they may well have taken place in the 4th century, when the Gothic empire was invaded by Huns.

Other heroic lays of which fragments survive were concerned with Danish and Swedish heroes who lived between the 5th century and the 7th. Some of these heroes, such as Hrólf Kraki of Denmark and Adils of Sweden, were also known to the author of the Old English *Beowulf*.

Mythological Lays.—The first half of the *Poetic Edda* consists of lays about pagan gods and of wisdom attributed to them. Like the heroic lays, these are of various ages, but it is improbable that any of those which survive originated elsewhere than in Norway, Iceland and the Norse colonies of the British Isles. The most striking lay of this class, the *Völuspá* (Sibyl's Prophecy), is placed first in the *Edda*, and is preserved in another manuscript as well. It is supposed to be spoken by a sibyl, who tells the history of the world, of gods, men and monsters, from the beginning until the Ragnarok (Doom of the Gods), when the gods will fall, the sun turn black, smoke and fire will gush forth and the stars vanish.

Many passages in the *Völuspá* are obscure and it has been discussed more than any other Scandinavian poem. Most scholars would probably agree that it was composed in Iceland, for the scenery, which the poet described, is that of Iceland. The poet's background was pagan, but his thoughts were coloured by Christian legends of the end of the world. He probably worked about the year 1000, when the minds of Icelanders were turning from the old religion to the new.

An interesting story of the gods is told in the *Skirnismdl* (Words of Skirnir). Sitting in Hlidskjálf, the throne of Ódinn, the god Freyr gazed into the world of giants, where he saw the giant maiden, Gerd, whose beauty made him sick with love. Freyr sent his faithful messenger, Skirnir, riding into the world of giants to win the maiden for him. The journey of the messenger in darkness over misty hills is described in few but telling phrases. Skirnir seeks to win the maiden, first with offers of gifts and then with threats, until she gives way and agrees to make a tryst with Freyr in the grove Barri. Scholars have seen an ancient fertility myth in this story. Freyr is the god of fertility and sunshine; Skirnir is a ray of sunshine *(cf. skirr,* bright), and Gerd *(cf. garðr,* enclosure, field) is the cornfield held fast in the clutches of the frost giants, demons of winter. The *Skirnismdl* is one of the older mythological poems and probably originated in Norway.

The *Þrymskviða* contains a tale of Thór. His magic hammer had been stolen by the giant Thrym, who refused to give it back unless he could have the goddess Freyja as his bride. Since Freyja was enraged at the suggestion that she should be given to a giant, Thór himself was decked as a bride, and went to the house of the giant and recovered the hammer by this ruse. The humour of the *Prymskvida* is unique in early Scandinavian poetry.

The mythological poems so far mentioned are all narrative, but many of those contained in the *Edda* are didactic. The *Hdvamdl* (Words of the High One) consists of fragments of at least six poems, all said to be spoken by Ódinn. In the first section, the god speaks of relations between man and man and lays down rules of social conduct. The precepts are cynical and generally amoral, and evidently date from an age of lawlessness and treachery. This section of the *Hdvamdl* is altogether devoid of belief in the supernatural, or in life after death. No greater misfortune can befall than death, which nothing can survive except fame.

In other sections of the *Hdvamdl* Ódinn discourses on relations between men and women, and tells how the love of women may be lost or won with illustrations from his own experience. The last two sections are about runes and magic power. Ódinn describes how he hung fasting for nine nights on a windswept tree and thus discovered the runes. He speaks finally of magic songs, by whose force he can help his friends and destroy his enemies. The different poems of which the *Hdvamdl* is made up belong to different ages, but most of them were probably composed in Norway in the

9th and 10th centuries.

Another didactic poem, placed in an interesting setting, is the *Vafþrúðnismál* (Words of Vafthrúdnir). bdinn, as usual in disguise, comes to the house of the giant, Vafthrudnir, and the god and the giant enter a contest of wits, on which each wagers his head. They ask each other questions about gods, men and giants, until the god asks what Ódinn had whispered into the ear of his son, Baldr, when he was laid on the funeral pyre. No one knows the answer to this question except Ódinn himself, and so the giant forfeits his head. The *Grímnismál* (Words of Grimnir) is a didactic poem of the same kind, and another is the *Alvíssmál* (Words of the All-Knowing), which has rather a different form.

Some important mythological lays are found in manuscripts other than the *Edda*. Perhaps the most beautiful is the *Baldrs Draumar* (Baldr's Dreams), which was so skilfully translated into English by Thomas Gray as "The Descent of Odinn." The poet describes how the god Baldr dreamed baleful dreams, which threatened his life. Ódinn then rode to the grave of a prophetess and awakened her from death by the power of his magic songs, and forced her to tell the fate in store for Baldr. In the *Rígsþula* (Song of Rigr) the god Heimdall, who assumes the name Rigr, wanders through the world and begets three sons by three separate women. The first son is called Thræll, the second Karl and the third Jarl, and from these the three classes of men, thralls, freemen and chieftains, are descended. The name Rigr has been associated with the Irish *rí* (king) and it is not improbable that the poem was composed in Ireland, or by a Norseman who worked under Irish influence.

The **Eddaic** Verse Forms. — Three measures are commonly distinguished in Eddaic poetry, the *Fornyrbislag* (Old Story Measure), the *Málaháttr* (Speech Measure) and the *Ljóðaháttr* (Song Measure). Most of the narrative poems are in the *Fornyrbislag*, which consists of short lines of two beats bound by alliteration in pairs. The number of weakly stressed syllables may vary, but the total number of syllables in the line rarely falls below four. In these things the *Fornyrðislag* resembles the measure used by Anglo-Saxon and early German poets. But, unlike Anglo-Saxon and German poetry, the poems in the *Fornyrðislag* are generally arranged in strophes of eight lines, divided by a deep caesura into half-strophes of four lines. Poems which are considered among the oldest show much irregularity, both in the syllabic length of the line and in the length of the strophes, but the following half-strophe will serve as a typical example (alliterating syllables in italics):

Gengu *ia*rlar alsnotrir fram
þeir's harz hugar hdna lottu.

The *Málaháttr*, used in the *Atlamál*, differs little from the *Fornyrðislag*, although its lines generally have a greater number of weakly stressed syllables. The *Ljdbahdttr* is the most irregular of Eddaic forms and its origins are the most obscure. It is used chiefly in didactic poems and consists generally of strophes of six lines divided into half-strophes of three lines. The first two lines of the half-strophe contain two beats each and alliterate with each other; the third line is independent, alliterating only within itself. This line may contain two beats or three. The following half-strophe will serve as an example:

Deyr fé deyja frændr
deyr *sj*álfr it sama.

Scaldic Poetry. — Besides the Eddaic, the Norwegians and Icelanders of the 9th century to the 13th composed poetry of quite a different kind. This is distinguished as "scaldic" poetry (*cf.* Icelandic *skdld*, poet).

Scaldic poetry differs from the Eddaic in the first place in its form. It is not composed in the free variable measures of Eddaic lays and is quite unlike Anglo-Saxon and early German poetry. It is strictly syllabic and every syllable must be counted and weighed, and every line must end in a given form, trochaic, dactylic or monosyllabic as the case may be. Like the Eddaic lines, the scaldic ones are bound by alliteration in pairs and, besides this, most of them contain some form of internal rime or consonance. The strophe is usually of eight lines, divided into two halves by a caesura after the fourth. About 100 scaldic verse forms have been recorded, but the most popular, and probably the oldest, is the *Dróttkvætt* (Court Metre), which consists of strophes of eight lines, each of six syllables, ending in a trochee.

The scaldic poetry differs from the Eddaic, not only in form, but also in syntax and choice of expression. The word order is much freer than in Eddaic poetry and the scalds use many words never found in Eddaic poetry or in prose, besides periphrases, or kennings, of such complexity that their work often sounds like a riddle. They may denote a ship as "the horse of the sea" or "the bull of bow-sprits"; they call gold the "fire of the sea." Kennings are frequently doubled or trebled; *i.e.*, two or more are combined to denote one subject. Thus, the "fjord-elk" is the "ship," his "field" is the "sea" and its "fire" is "gold."

Little is known about the origins of scaldic verse forms and diction, but there are reasons to believe that they were devised in western Norway during the 9th century. If so, it is probable that the first scalds were influenced by the elaborate metrical forms and diction of the Irish poets of that period. During the 9th century, the Norwegians stood in close contact with Ireland.

The Eddaic poetry is all anonymous, but most of the scaldic is assigned to poets whose names are remembered. The oldest of the scalds whose verses survive was Bragi, nicknamed the Old, who probably worked in Norway in the second half of the 9th century. The chief of Bragi's surviving poems is a description of a painted shield given to him by a chieftain. Pictures of gods and legendary heroes were painted on the shield, and among them were the god Thór, struggling against the World Serpent, and Jormunrekk attacked in his castle by the brothers Hamdir and Sörli.

Much of the scaldic poetry was made in honour of the kings of Norway, nearly all of whom patronized poets. Harald Finehair (died c. 945), first king of all Norway, was eulogized by several poets, among whom were Thorbjorn Hornklofi and Thjódólf of Hvin. The first was the author of the *Haraldskvæði* (Lay of Harald), a remarkable poem, partly in Eddaic and partly in scaldic style. It is in the form of a dialogue between a valkyrie and a raven, who followed the king in search of the carrion which he had left on the battlefield, and sang his praises. An unnamed scald made a similar poem, the *Eiriksmdl*, as a memorial to Eirik Bloodaxe, who was killed in the British Isles soon after the middle of the 10th century, and another, Eyvind the Plagiarist, commemorated Haakon the Good (d. 961) in the same way.

Although the first scalds were Norwegians, it was the Icelanders who developed the art. The greatest of all was Egill Skalla-Grimsson (c. 910–80), who was born and died in Iceland, but lived much of his life in Norway and the British Isles. Among the best-known of his poems is the *Höfuðlausn* (Head Ransom), which he composed in York about the year 948. He had fallen into the hands of his enemy, Eirik Bloodaxe, then ruling in York, and saved his head by making this poem in honour of his enemy in a single night. The *Höfuðlausn* is in an unusual form with end-rime, which is probably due to the influence of hymns in Latin, which the poet had heard in England. Egill also made poetry in honour of Aethelstan, king of England (d. 939), but only scraps of it have survived.

Einar Skálaglamm, another Icelander, was the friend of Egill and chief poet of Haakon the Great (d. 995), in whose honour he made the *Vellekla* (Gold-dearth). Einar commemorated the achievements of Haakon and praised him for his loyalty to the pagan gods.

The Christian kings of Norway, Ólaf Tryggvason (d. 1000) and 61af the Saint (d. 1030), were praised by many Icelandic scalds. Hallfred, nicknamed the "Troublesome Poet," was the favourite of Ólaf Tryggvason and although his work has no great value as art, it is interesting because the poet describes his conversion to the Christian religion and the spiritual conflicts which went with it. Sigvat, the favourite of Ólaf the Saint, was a more notable poet. In his work he commemorated the chief events in Ólaf's life, from his adventures as a youthful viking to his death in the battle of Stiklastadir. Sigvat's work is simpler and easier to understand than that of most of the older scalds. Many sagas include lives of scalds and contain numerous verses which show that, in Iceland, scaldic poetry was admired as an accomplishment by rich and

poor alike.

Scaldic poetry, since it is ornate and difficult to understand, has been little appreciated in modem times. It is a rewarding subject for study, however. Scaldic poems, composed in the 10th and 11th centuries and remembered orally, were among the most valuable sources for the Icelandic historians of the late 12th and 13th centuries.

Histories, Law Codes and Religious Literature. — The Icelanders adopted the Christian religion in the year 1000 and this had far-reaching consequences. Their civilization was not greatly altered at first, but the conversion opened the way for new and powerful influences from Europe.

Details about some of the missionaries who worked in Iceland in the 11th century are recorded, and several of them came from the British Isles, while others were of German origin. Undoubtedly these missionaries taught the Icelanders to use the Latin alphabet. No manuscripts of this period survive, but the oldest preserved, dating from the middle of the 12th century, are written in a script based upon one used in England in the 11th century.

Icelanders soon began to study in the great schools of Europe. Perhaps the first to do this was fsleif (*c.* 1005–80), who was brought up in the convent of Herford in Westphalia and ordained priest. Soon after the middle of the 11th century, fsleif was consecrated bishop. He kept a school at Skálaholt, in the south of Iceland, which was for many centuries the chief bishopric and one of the main centres of learning.

fsleif was succeeded as bishop by his son Gizur (1082–1118), who was also educated at Herford. Historical literature was first written in his time. The oldest historian remembered was Sæmund Sigfússon (1056–1133). Sæmund went to school in France and was the author of a *History of the Kings of Norway*. This book is lost, but references made to it by writers of the later middle ages show that it was written in Latin, and was concerned especially with the chronology of the kings' reigns.

Ari Thorgilsson (*c.* 1067–1148) is regarded as the father of vernacular history. It is not known how many books Ari wrote, but there is a short history of Iceland, the *Libellus Islandorum,* which is signed by Ari. It was written shortly before 1133, although it exists today only in paper transcripts of the 17th century. Ari states in his prologue that he had also written an earlier version of this same work, which contained some account of the kings of Norway and other material not found in the existing book.

The *Landnámabók* (Book of Settlements) has long been associated with Ari's name. It consists of a detailed history of the settlement of Iceland. The settlement is treated district by district and the descendants of the chief settlers are traced. Ari probably compiled the *Landndmabdk,* or part of it, in its original form, but the existing versions date from the 13th and 14th centuries and were expanded after Ari's time.

It is not known how early Icelanders began to keep annals of contemporary events. The extant versions of them are not older than the 13th century, but since they contain records of an eclipse, visible in Iceland in 1131, and of a volcanic eruption in 1104, these extant versions of the annals probably derive from an original made early in the 12th century.

The first code of law, applied to the whole of Iceland. was drawn up by a certain Úlfljót about the year 930. This code was remembered by heart and recited by the law-speaker, the president of the national assembly, at regular intervals. In the year 1096, laws of tithe were introduced and perhaps written down at that time. In 1117 it was resolved that parts of the civil law should be written on parchment, and a few years later laws relating to ecclesiastical practices were also inscribed.

The oldest extant religious manuscripts in Icelandic, dating from about 1150, consist of homilies and lives of saints, which evidently formed the most extensive branch of the literature during the 12th century. Large collections of religious literature are also found in the manuscripts of the late 12th and early 13th centuries.

The Icelandic homilies are based largely upon those ascribed to the great apologists of Europe, such as Jerome, Bede, Gregory. Nevertheless, the Icelanders sometimes treated their models freely and added reflections of their own. Popular handbooks of theology, such as the *Lucidarius* of Honorius Augustodunensis, and the *Dialogues* of Gregory the Great, were also written in Icelandic versions during the 12th century.

Among the most popular religious books were lives of the apostles and of well-known European saints. The lives of the apostles were based largely upon apocryphal Acts and Gospels and partly upon canonical writings. Literature of this kind is little read today, and its importance is often overlooked, but its composition undoubtedly contributed much to the narrative art, in which the Icelanders of the 13th century were to excel.

The First Sagas. — In Icelandic the word "saga" is used for any kind of story or history, whether written or oral *(see* SAGA). In English, on the other hand, this word has a narrower sense and is generally applied to biographies of one hero or a group of heroes written in Iceland between the 12th and 15th centuries. Sagas are generally based upon native tradition, whether preserved orally or in writing. The heroes of sagas are most often kings of Nonvay, icelandic, or legendary Germanic heroes, said to have lived between the 4th and 8th centuries.

If the word "saga" is used in this restricted sense, the oldest saga known is the so-called *First Saga of St. Ólaf* of which some fragments are preserved. It was written about 1180, probably in the Benedictine monastery of Thingeyrar, in northern Iceland. It is cast in the form of a hagiographic narrative, and greatest emphasis is laid upon miracles worked through the agency of St. Ólaf. Stories about these miracles were preserved in oral tales, both in Norway and Iceland. In spite of its hagiographic tone, the *First Saga* has great value as history. The outline of Olaf's career was recorded in verses composed in scaldic form by contemporary poets and handed down orally.

The *First Saga* was used as a source, either directly or indirectly, by later biographers of St. Ólaf, by the author of the *Legendary Saga* (*c.* 1200), by Styrmir Kárason (c. 1220), and ultimately by Snorri Sturluson.

The monastery of Thingeyrar, which had been founded in 1133, played a great part in the cultural life of the Icelanders during the late 12th and early 13th centuries. About 1190, one of its inmates, Odd Snorrason, wrote a life of Ólaf Tryggvason, king of Norway (d. 1000). Odd was, no doubt, inspired to do this work by the *Saga of St. Ólaf.* Besides oral tales and scaldic poems about Ólaf Tryggvason, Odd used several written sources, including the histories of Sæmund and Ari. He wrote in Latin, but his work was translated into Icelandic soon afterward and was freely quoted by those who wrote about Ólaf Tryggvason in later times.

Ólaf Tryggvason was regarded widely as the apostle of Iceland, for it was at his instigation that the Icelanders had adopted Christianity. Odd's life of him was followed by another, whose author, Gunnlaug Leifsson (d. 1218), also belonged to Thingeyrar. Gunnlaug also wrote in Latin, but his work was translated into Icelandic. It was larger and more ambitious than Odd's life. but does not survive in its original form. Gunnlaug was a man of wide learning. He was also the author of a life of Jón Ögmundarson, bishop of northern Iceland (d. 1121), of a life of St. Ambrose, and of a metrical version in Icelandic of Geoffrey of Monmouth's *Prophecies of Merlin.*

The School of **Skálaholt.**—The work of the Thingeyrar monks was fanciful rather than critical or realistic. A more critical style of history had been established in the south of Iceland by Sæmund and Ari, and several notable works of history were written at Skblaholt or near by early in the 13th century. The most remarkable of these was the *Hungrvaka* (Hungerwaker), written about 1206, which is a short history of the bishops of Skálaholt from fsleif (d. 1080) to Klœng (d. 1176). The *Hungrvaka* is admired for its polished style and for its author's balanced judgment and objectivity. It appears to be designed as a prologue to the *Saga of St. Thorldk,* who was bishop of Skblaholt from 1178–93, and was regarded by many Icelanders as a saint. The *Saga of St. Thorldk* was written a few years earlier than the *Hungrvaka,* but stylistic peculiarities suggest that it was the work of the same author. Another work commonly ascribed to the

author of the *Hungrvaka* is the *Saga* of *Bishop Páll* (d. 1211), who succeeded his uncle, Thorlbk, as bishop of Skblaholt. This author was interested in the private lives of his heroes, rather than in their public acts or ecclesiastical policy. He was never extravagant in his praises nor overcredulous of miracles.

Histories of Kings of Norway.— During the latter years of the 12th century some short histories of kings of Norway were written in Norway itself and some of them were brought to Iceland and influenced Icelandic writers. One of these was the *Historia de antiquitate regum Norwagiensium,* which was written in Latin by a Norwegian monk, Theodoricus, about 1180, and was used as a source by Odd Snorrason. Another Norwegian work, which had greater influence. was the so-called *Agrip* (Summary of the History of the Kings), which was written in Norway in the vernacular about the end of the 12th century. The *Agrip* was brought to Iceland soon after it was written and exists only in an Icelandic manuscript of the early 13th century. In its original form it must have covered the history of the kings from the 9th century to the late 12th century, but the beginning and the end are missing. The *Fagrskinna* (Fine Skin) covered the same period as the *Ágrip,* but it is more detailed and its author has made greater use of older writings and of scaldic poetry. The *Fagrskinna* was also written in Norway, probably about 1230, but its author must have been an Icelander, for the sources which he used were chiefly those preserved in Iceland. The *Morkinskinna* (Rotten Skin) was probably written rather earlier than the *Fagrskinna,* and covers a shorter period of the history of the kings, from Magnús the Good (d. 1047) to the late 12th century. It was written in Iceland and based partly upon a lost history of the kings of the 12th century, the *Hryggjarstykki* (Backbone Piece), written by the Icelander Eirik Oddsson about 1170. The *Saga of the Orkney Earls (Orkneyinga Saga)* should also be included in this class. It was written by an Icelander in the first year of the 13th century, and covered the history of the Norwegian dependency, Orkney, from the 9th century to the latter years of the 12th. It survives only in later redactions.

A work of particular interest was the *Sverris Saga,* the life of King Sverrir of Norway (d. 1202). A part of it was written by Karl Jónsson (d. 1215), who was twice abbot of Thingeyrar, and spent several years in Norway as an attendant of King Sverrir. Karl wrote some chapters of this saga in Norway under the supervision of Sverrir himself and it was completed after he returned to Iceland, probably by others. There is no more intimate and detailed biography of a ruler of Norway.

Snorri **Sturluson (1179–1241).**—Snorri was the author of literature of many different kinds and played a prominent part in the political wrangles of his age. He was the son of a chieftain of western Iceland, but was brought up in the south by Jón Loptsson, a grandson of Sæmund Sigfusson. Among the works assigned to Snorri are several poems and the so-called *Prose Edda (see* EDDA), which is a handbook of prosody and poetic diction, probably written soon after 1220. Snorri illustrates his arguments with stories about pagan gods and ancient heroes, and it is these which give the *Prose Edda* its chief interest for modem readers. They have the charm of fairy tales and are told with admirable delicacy and taste.

Snorri twice visited Norway and much of his work consists of lives of its early kings. The first which he wrote was the *Saga of St. Ólaf.* This was based largely upon the lost life of that saint written by Styrmir Kbrason *(see* above), partly upon the work of Ari and other ancient books. and partly upon poems and tales transmitted orally. The chief difference between Snorri's account of St. Ólaf and those of his predecessors was that Snorri wrote neither as a hagiographer nor as an annalist. He depicted Ólaf as a living man, brave but not without faults, who began his career as a typical viking and developed gradually into a statesman, a saint and a martyr.

Snorri probably wrote his *Saga of St. Ólaf* within a few years of his return from Norway in 1220. He afterward combined it with lives of kings who had ruled Norway before and after Ólaf. The complete series is called the *Heimskringla* (Orb of the World). It begins with a short account of the Vnglingar, the ancient kings of the Swedes, from whom rulers of Norway were said to descend. The chief source of this first section is the poem, *Ynglingatal,* which dates from the 9th century. Several of the older kings of Norway are described in close detail and among the most interesting sections of the *Heimskringla* are those about Harald Finehair (d. c. 945), Haakon the Good (d. *c.* 963) and Ólaf Tryggvason (d. 1000). The *Heimskringla* ends with Magnús Erlingsson (d. 1184).

The value of Snorri's lives of the kings as sources of history has long been debated. It must suffice here to say that Snorri was an avid reader of vernacular history and he faithfully reported events about which he had read in older records, many of which are now lost. He also deduced more from the poetry of the scalds than most of his predecessors had done. In outline, Snorri's biographies of the kings may generally be accepted as true, but it was not his objective to write scientific history. His work was constructive; he portrayed his heroes imaginatively and brought them to life.

Many scholars hold that the *Egils Saga* was also written by Snorri, for both internal and external evidence support this opinion. The *Egils Saga* is the life of Egill Skalla-Grimsson, greatest of the scalds. It is among the most stirring and adventurous of sagas about Icelandic heroes.

Icelanders' Sagas.—The terms "Icelanders' Sagas" and "Family Sagas" are commonly applied to sagas about heroes who are supposed to have lived in Iceland in the 10th and 11th centuries. The best sagas of this class excel all others in artistic value; none present characters more vividly, nor show deeper sympathy and understanding of human tragedy.

Questions about the origins and historicity of sagas of this kind have been much discussed. While it is agreed that few, if any, of them were written before the 13th century, many have maintained that the Icelanders' Sagas are faithful records of the history of the 10th and 11th centuries. Consequently, it has been argued that these sagas were composed as early as the 11th century and handed down orally until they were written, almost without alteration, in the 13th century. Although this view was still widespread at mid-20th century. it has been rejected by most modem specialists, who see the individual hand of a literate author in each saga. Nevertheless, it is plain that sagas of this class owe much to tradition, to verses of contemporary poets handed down orally and to oral tales. They also owe much to written works, for their authors drew freely upon the books of Ari, upon the *Landnámabók* and early genealogies. Moreover, the author of one saga would frequently refer to an older one and quote its statements, either with or without acknowledgment.

The historicity of Icelanders' Sagas is difficult to check and few general statements are applicable. Not only the author's sources. but also his aims must be considered. While some of the older ones probably intended to write factual history, others relied rather on the imagination, and thus anticipated the historical novel of modem times.

The first Icelanders' Sagas were written about the beginning of the 13th century and were strongly influenced by the Kings' Sagas. Among the oldest may be counted the *Fóstbræðra Saga* (Saga of the Foster-brothers), whose heroes, Thorgeir and Thormód, were both attendants of St. Ólaf. Many chapters of it are based upon verses which are said to be the work of Thormód. Although somewhat crude in structure, this saga expresses clearly the northern ideals of loyalty and heroism. A great part of the story takes place in the Icelandic colony in Greenland in the 11th century. Both the *Eiriks Saga Rauða* (Saga of Eirik the Red) and the *Grœlendinga Saga* (Saga of the Greenlanders) are also placed in Greenland and contain adventurous tales about voyages to Wineland the Good, as the Norsemen called America.

Another of the older sagas is the *Hallfreðar Saga* (Saga of Hallfred), whose hero, Hallfred. was the favourite of Olaf Tryggvason. The *Hallfreðar Saga* is partly a love story and is smoother and more highly finished than the *Fóstbræðra Saga.* It was written at, or in the neighbourhood of, Thingeyrar, about 1220.

The scenes of several sagas are laid in the Eyjafjord and the northeast of Iceland and were probably written in that region. The most perfect is the *Víga-Glúms Saga* (Saga of Viga-Glum), written about 1230–40, a well-constructed and somewhat conventional story of a grasping peasant. Men of the same district are described

in the *Ljósvetninga Saga,* whose central figure, Gudmund the Mighty, is depicted as the wealthy, but cruel and cowardly, tyrant.

Although it is difficult to determine the ages of many sagas, it is possible to see how the art of saga-writing developed in the course of the 13th century. The *Gísla Saga* (Saga of Gisli) was probably written shortly before the middle of that century and is the story of a poet who lived in northwestern Iceland in outlawry, hunted by his enemies and penalized only because of his loyalty in avenging his foster brother. This saga contains some rich descriptions of nature and a large number of emotional verses, said to be composed by the hero.

The scene of the *Laxdœla Saga* (Saga of the Men of Laxárdal), evidently written a few years later than the *Gísla Saga,* is also western Iceland, and the story covers four or five generations. from the end of the 9th century to the 11th. The *Laxdœla Saga* is a tragedy. but it is finer and more delicately worked than the tragedies told in most sagas Women figure prominently and the most striking of them is Gudrun. Failing to marry the man she loves, Gudrun resorts to loving hatred and causes his death. Her story is plainly influenced by that of Sigurd and Brynhild. The author shows an unusual appreciation of visual beauty.

Many people described in the *Laxdœla Saga* appear also in the *Eyrbyggja Saga,* a work of different stamp. Its author has little sense of structure, but he is an able storyteller and depicts his characters intimately and vividly. He is also an antiquarian and throws valuable light upon popular practices and superstitions, recording many ancient poems.

The scenes of some short sagas are laid in eastern Iceland, a remote, isolated district. Among them is the *Vápnfirðinga Saga,* which takes place in Vapnafjord, and tells the tale of a family feud which passes through two generations. ending in reconciliation. The *Hrafnkels Saga Freysgoða* (Saga of Hrafnkell Freyr's Priest) takes place in a neighbouring district and is a masterpiece among the shorter sagas. Realistic as it is. the story is the author's creation and the saga contains little historical fact. It is improbable that it was written before 1270.

Among other short sagas of particular interest may be mentioned the *Bandamanna Saga* (Saga of the Confederates), which is a bitter, satirical tale, and the *Gunnlaugs Saga Ormstungu* (Saga of Gunnlaug Serpent Tongue), a love story strongly influenced by foreign romance. The *Hávarðar Saga Ísfirðings* (Saga of Hávard of fsafjord) is a spirited tale. which probably dates from the end of the 13th century. Icelandic literature of this period also includes many short stories, or *þættir,* of great value as literature, which describe one event or another in the life of a hero.

As the 13th century drew to its close, the taste for the fantastic and romantic grew stronger. One of the best-known of the sagas is the *Grettis Saga* (Saga of Grettir the Strong), which contains numerous motifs drawn from folklore, including stories about ghosts and trolls against whom the hero fights. In its present form this saga must date from about 1300, but it is based upon an older work about Grettir, probably written by Sturla Thordarson (d. 1284), nephew of Snorri Sturluson.

It is commonly agreed that the greatest of the Icelanders' Sagas is one of the youngest, the *Njáls Saga.* It has two heroes, Gunnar and Njáll. The first is the brave, guileless youth, like Sigurd of the legends, but the second is the wise and prudent man, endowed with prophetic gifts. Njáll faced the terrible death of burning with the resignation of a martyr, but he also had many of the qualities of the traditional Norse hero; he was loyal, upright and resolute The author of the *Njdls Saga* was influenced by a whole library of early literature. by older sagas as well as books on theology and law.

Sagas about Contemporary History. — Many works on contemporary history were wtitten in the 13th century and most of them were combined about the year 1300 in the *Sturlunga Saga* (Saga of the Sturlungar). This compilation includes the *Íslendinga Saga* (Saga of the Icelanders) of Sturla Thórdarson, which begins with the year 1183 and describes in minute detail the politics, intrigues and battles which took place during the greater part of the 13th century. Among other sagas included in the *Sturlunga* are those about Sturla, the father of Snorri (d. 1183), and about Gudmund the Good, the fanatical bishop of the northern Icelanders (d. 1237).

Heroic Sagas. — The growing taste for the fantastic was expressed in the latter years of the 13th century in the heroic sagas (Fornaldar Sogur), whose heroes were supposed to have lived in Scandinavia and in continental Germania before Iceland was peopled. The best-known of these sagas is the *Volsunga Saga* (Saga of the Volsungs), written about 1270, in which the story of Sigurd, the Burgundians and Jormunrekk is retold in prose. Its sources were Eddaic lays about the heroes. some of which are now lost. The *Heidreks Saga* is also based largely on heroic poetry, as in the *Hrdlfs Saga Kraka.* Although they have little value as art, sagas of this kind, since they are often based on lost poetry, have great antiquarian interest.

Translations from Latin. — A considerable quantity of profane literature was translated from Latin between the 12th and 14th centuries. The *Prophecies of Merlin,* mentioned above, were combined with a complete translation of Geoffrey of Monmouth's *Historia regum Britanniae,* the *Breta Sogur* (Tales of the Britons). In a manuscript of the 14th century the *Breta Sogur* is preceded by the *Trójumanna Saga* (Tale of the Trojans), a rendering of De *excidio Trojae* of Dares Phrygius. The *Alexanders Saga* (Saga of Alexander the Great) was a rendering in prose of a Latin poem of the 12th century written by Philip Gautier. The Icelandic version was made by the Abbot Brand Jonsson (d. 1264).

Romances. — These consist of translations and free adaptations of French and other European romances. This branch of literature originated in Norway early in the 13th century, but it soon took root and flourished in Iceland. The oldest work of this class is probably the *Tristrams Saga* (Saga of Tristram), which was mritten in Norway in the year 1226 at the behest of King Haakon. The source was the French poem of Thomas of Brittany. The *Karlamagnús Saga* (Saga of Charles the Great) is a collection of prose renderings of the French *chansons de geste,* whose heroes are Charles the Great and his men. A Norse version of the *Chanson de Roland* is included in this collection.

These romances are little read today, but in the 13th century they influenced the tastes of the Icelanders and the authors of historical sagas. This influence can be seen best in the *Laxdœla Saga, Gunnlaugs Saga* and *Grettis Saga.* The Icelandic romances are very numerous and exist in countless manuscripts, which give an indication of their popularity in Iceland from the 14th to the 18th century.

Post-Classical Literature. — The classical age of Icelandic literature might be said to end in the 14th century. Although literature has flowed richly at all periods during the history of Iceland, comparatively little of that composed between the 14th and the 19th centuries aroused interest outside Iceland itself. During the 14th century, much of the realism and detached objectivity which had characterized the literature during its best period is lost. Sagas and poetry of various kinds continued to be composed, but the fantastic, erotic and sentimental gained the upper hand.

The decline of taste may be attributed to several causes, partly to loss of political independence (1262) and partly to economic straits, resulting in famine and pestilence during the 14th and 15th centuries.

Although literature in the Classical style was no longer composed, interest in the great works of the 13th century persisted and the most valuable manuscripts of them date from the 14th century. when great collections were made. Among them may be mentioned the *Hauksbdk* (Hauk's Book), written early in the 14th century. containing texts of the *Landnámabók,* the *Völuspá* and the *Fóstbræðra Saga,* and the *Möðruvallabók* (Book of Mödruvellir), written about 1350, which contains texts of *Njáls Saga, Víga-Glúms Saga* and other important sagas of Icelandic heroes. The most beautiful of all Icelandic manuscripts is the *Flateyjarbdk* (Book of Flatey), written toward the end of the 14th century. This includes versions of the sagas of Ólaf Tryggvason and of Olaf the Saint. which are combined with texts of sagas about Icelandic and other heroes who were associated with these rulers. Many manuscripts of the classical literature date from the 15th, and some important ones were written as late as the 17th, or even the 18th century.

Post-Classical Sagas. — The prose literature of the 14th century includes several sagas about Icelandic heroes. Among them is the *Finnboga Saga* (Saga of Finnbogi the Strong), an adventurous tale about an Icelander of the 10th century, whose travels brought him to the emperor in Constantinople. The *Víglundar Saga* (Saga of Viglund) is a love story about an Icelandic hero, which is strongly influenced by continental romance. It contains some interesting love poetry in scaldic form. The *Krdka-Refs Saga* is of approximately the same age, and equally unrealistic, although it is one of the most successful of the humorous stories in Icelandic.

Sagas about bishops of Iceland had been written early in the 13th century and this branch of literature flourished vigorously in the 14th century. The *Arna Saga* consists of a detailed account of Arni Thorliksson, bishop of Skilaholt (1269–98). It contains much valuable history and was probably written by Arni's nephew, who succeeded him as bishop. The *Laurentius Saga* is no less interesting, and is a life of Laurentius Kálfsson, bishop of Holar 1324–31.

A number of heroic sagas, about men said to have lived before the settlement of Iceland, must be assigned to the 14th century. Some of them were based upon older traditions and others were largely invented. One of the more interesting is the *Eiríks Saga Víðförla* (Saga of Eirik the Far-traveller), whose hero reaches the *Óðáinsakr*, the land of eternal life, said to lie beyond the farthest India. Lives of foreign saints also flourished in the 14th century. Among the more notable was the *Life of St. Nicholas*, written by Abbot Berg Sokkason (d. 1345). Arni Laurentiusson, a monk of Thingeyrar (b. 1302), compiled a life of the English St. Dunstan. Somewhat later, probably in the 15th century, a short life of St. Oswald was written in Icelandic.

A large collection of *Ævintýri* or *exempla* was also compiled in the 14th century. These consist of tales of foreign origin, illustrating some moral precept. Many of them were said to have been told in Iceland first by Jón Halldórsson, the Norwegian bishop of Skalaholt (1322–39). Others were taken from the well-known *Disciplina Clericalis*, written early in the 12th century by the Christian Jew, Petrus Alphonsus.

Poetry. — After the 13th century no more is heard of Icelandic court poets, patronized by the Norse rulers. Nevertheless, a great deal of poetry was composed in Iceland between the 13th century and the Reformation and many new forms were devised. The most valuable of this poetry was the religious, composed in honour of the Virgin, the apostles, European and northern saints.

The best-known religious poem. of the 14th century is the *Lilja* (Lily), composed by Eysteinn Ásgrímsson (d. 1361), a monk of Thykkvabœr in south Iceland. Using a traditional scaldic measure *(hrynhent)*, Eysteinn surveys the story of the universe in 100 strophes. He passes through the creation, fall of Satan, the first sin, and the birth, life and passion of Christ.

Many poems of the 14th and 15th centuries were dedicated to the Virgin. They include the *Maríulykill* (Clavis Mariae), an experiment in metrical forms composed by Jón Pilsson (c. 1390–1471), and the anonymous *Maríugrátr* (Weeping of Mary). The life of St. Peter is celebrated in the *Pétrsdrápa* (Lay of Peter) and the *Heilagra manna drápa* (Lay of Saints) includes strophes in praise of St. Thomas of Canterbury, St. Edmund and others.

Rímur.—The term *rimur* (singular *ríma*) is used for narrative poetry in forms which developed in the 14th century and were used with undiminished vigour until the 19th century, The *rímur* consist of strophes of lines with end rhyme. Their metrical forms appear to derive from Latin hymns, but they inherit the alliterative system of early Icelandic poetry. The stories told in most of the *rimur* were taken from written texts of sagas and they are especially interesting in cases where the text of the saga itself has been lost. One of the oldest is the *Ólafsríma*, composed by Einar Gilsson (d. 1369), whose subject was the death and miracles of St. Ólaf. The *Griplur* were based upon a lost saga about an ancient hero, Hrómund Gripsson. Other *rimur* contained stories of the god Thór, the Volsungs and Grettir the Strong. Although the value of the *rimur* as literature is not great, they helped to maintain the interest in sagas and in early literature. They also saved scaldic diction from oblivion and are valuable as sources of linguistic history.

Ballads. — Ballads never attained such popularity in Iceland as they did in other European countries. Nevertheless, a number of ballads in Icelandic, dating from the 14th to 16th centuries, are preserved. Most of them are loose translations of Danish and Norwegian originals. The *Tristrams Kvœði* (Ballad of Tristram) is an exception, for it appears to be based upon the Norse saga of Tristram.

The Reformation. — The Reformation was enforced in Iceland by the Danish rulers in the 16th century. The chief political figure and chief poet of the period was Jón Arason, last Catholic bishop of Hblar, who was beheaded in 1550. In his life Jón showed that he was no less a viking than a martyr. Most of his surviving poetry is religious, including the *Píslargrátur*, the story of the Passion, based largely on St. John, the *Niðurstigningarvísur* (Verses on the Harrowing of Hell) and the *Ljómur* (Rays), which is reminiscent of the *Lilja* in structure.

The Reformation had various results for the development of learning and literature in Iceland and the first of them were not wholesome. Catholic poetry was discarded and attempts were made by the first Lutheran bishops to replace it with hymns poorly translated from Danish and German. Traditional rules of form and measure were ignored.

Lutheran teachers took pains to instruct the Icelandic people in the elements of dogma. Already in 1540, Odd Gottskálksson (d. 1556) had a translation of the New Testament in Icelandic printed in Denmark. In the following years several translations of sermons and books of instruction writen by German Lutherans were printed in Icelandic versions.

Bishop Gudbrand Thorliksson of Hblar (1571–1627) was the most energetic and the wisest of the Lutheran teachers and many translations were printed at Hólar under his guidance. Among these was the complete Bible. produced in 1584. The *Sálmabók*, published in 1589, consisted of hymns, mostly of foreign origin. In a remarkable prologue to this volume, Gudbrand showed his appreciation of the poetic traditions of Iceland, and he adhered to Icelandic conventions of alliteration and form. This respect for tradition is even more pronounced in the *Visnabdk*, verses on religious subjects published by Gudbrand in 1612.

The 17th Century. — By far the greatest poet of the 17th century mas Hallgrím Pétursson (1614–74), a clergyman who struggled for many years against poverty and ill-health. His *Passíusálmar* (Hymns on the Passion of Christ) is among the most popular books in Iceland today. The poet meditates on Christ's sufferings, drawing symbolical meaning from his wounds and words. Another interesting poet of this period was Stefán Ólafsson (c. 1620–87), remembered both for religious and profane work.

In Iceland as in other countries, interest in antiquity was stirred in the 17th century, and modern learning may be said to date from that period. Arngrim Jónsson, the Learned (1568–1648), called the attention of Danish and Swedish scholars to Icelandic traditions and to the treasures of Icelandic literature in a series of works in Latin, some of which contain abstracts of sagas now lost. Later in the century, Arni Magnússon (1663–1730) systematically collected the early Icelandic manuscripts. Part of his collection was burned in the fire of Copenhagen (1728), but the remainder passed to the University of Copenhagen, where it is kept.

Although an age of learning, the 17th century was also an age of superstition and witch-hunting. Striking evidence of this is found in the *Pislar Saga* of the clergyman Jón Magnússon (c. 1610–96), who described how he was persecuted by magicians. His complaints had led to the burning of two unfortunate victims in 1656. The *Pislar Saga*, in its lurid language, is an interesting example of the prose of the time.

The **18th Century.**—The best examples of the prose of the early 18th century are to be found in the *Húspostilla*, a collection of sermons written by Jón Vidalin (1666–1720), bishop of Skálaholt. Jón's style is forceful and his judgments forthright and severe.

Among important writers of the later 18th century may be mentioned Eggert Olafsson (1726–68), well-known both as a geog-

rapher and as a poet. Jón Steingrimsson (1728–91) is remembered for his autobiography and accounts of volcanic eruptions which he had experienced. Jón Thorláksson (1744–1819) was a poet and a scholar, and translated John Milton's Paradise Lost, as well as works of Friedrich Klopstock and Alexander Pope into Icelandic.

The greatest historian of the period was Finnur Jónsson (1704–89), bishop of Skilaholt, whose *Historia* ecclesistica Islandiae (1772–78), written in Latin, covers the history of Christianity in Iceland from the beginning to the author's time. It remains an authoritative work. Jón Espólín (1769–1836) was the author of *Árbœkur* fslands, a history of Iceland from 1262. His prose style was modelled on that of the classical period. (G. T.-P.)

MODERN LITERATURE

The later literature of Iceland was more flourishing than it had been since the 13th century. Lyrical poetry is by far the largest and most interesting portion of it. The first great poet of the 19th century was Bjarni Thórarensen (1786–1841), a judge and sheriff, who may be credited with the introduction of the Romantic movement into Iceland. The forms and diction of his poetry are strongly influenced by those of the Eddaic poets.

One of the favourite poets of Iceland is Jónas Hallgrimsson (1807–45), who succeeded best in his descriptions of nature. His touch is light and he has often been compared with Heinrich Heine. The influence of Jónas Hallgrimsson was still felt in the 20th century and his school was the reigning one up to the end of the 19th century, although then a change seemed to be in sight. The most successful poet of this school was Steingrimur Thorsteinsson (1831–1913). He is especially famous for his splendid descriptions of scenery (The Song of Gilsbakki), his love songs and his sarcastic epigrams. Equal in fame is Matthías Jochumsson (1835–1920), who, like Jónas Hallgrimsson, successfully revived the old metres of the classical Icelandic poets, whom he resembles in his majestic but sometimes too gorgeous language. He successfully treated subjects from Icelandic history, as in the *Grettisljóð*, a series of poems about the famous outlaw Grertir.

The great religious poet, Hallgrimur Pétursson, found a worthy successor in Valdimar Briem (1848–1930), whose Songs of the Bible are deservedly popular. An interesting position is occupied by Benedikt Grondal (1826–1907), whose travesties of old romantic stories are among the best satirical and humorous productions of Icelandic literature.

There was another school of poets influenced by Jónas Hallgrímsson but keeping alive the traditions of poetry maintained by Sigurður Breiðfjörð (1798–1846). In the middle of the 19th century this school mas best represented by Hjilmar Jónsson from Bóla (1796–1875), a poor farmer with little education but endowed with great poetic gifts. In the last decades of the 19th century this school produced two poets of a very high order, both distinctly original and Icelandic. One was Páll Ólafsson (1827–1905). His songs are mostly written in the mediaeval quatrains (ferskeytla) and are generally of a humorous and satirical character. The other was Porsteinn Erlingsson (1858–1914). His exquisite satirical songs, in an easy and elegant but still manly and splendid language, raised much discussion. Of his poems may be mentioned The Oath, a series of most beautiful ballads, with a tragical love story of the 17th century as the base, but with many happy satirical allusions to modern life. Near to this school, but standing apart, was Grimur Thomsen (1820–96).

In the beginning of the 1880s a new school arose among the Icelandic students in the University of Copenhagen who had attended the lectures of Georg Brandes. This school was quite different from the half-romantic one of Jónas Hallgrimsson; it was nearer to the national school of Páll Ólafsson and Porsteinn Erlingsson, but differed from these by introducing foreign elements hitherto unknown in Icelandic literature and — especially in the case of the prose writers — by imitating the style and manner of some of the great Norwegian novelists. Their influence brought Icelandic literature into new roads, and it is interesting to see how the tough Icelandic element gradually assimilated the foreign. Of the lyrical poets, Hannes Hafstein (1861–1922) was by far the most important. In his splendid ballad, *The* Death of *Skarphedinn,* and in his beautiful series of songs describing a voyage through some of the more picturesque parts of Iceland, he is entirely original; but in his love songs a strong foreign influence may be felt.

Among the many latei lyric poets Einar Benediktsson (1864–1940) and Stephan G. Stephansson (1853–1927), who lived in Canada, deserve mention, both rather heavy in style but rich in ideas and weighty in thought. Lighter and more elegant in style are Davíð Stefinsson (1895–) and Stefán frá Hvítadal (1887–1933). Tómas Guðmundsson (1901–) and Jón Helgason (1899–) deserve mention as lyrists.

The chief novelist of the 19th century was Jón Thoroddsen (1819–68). The influence of the realistic school became predominant. The most distinguished writer of that school was Gestur Pálsson (1852–91), whose short stories with their biting satire produced many imitators in Iceland. Jónas Jónasson (1856–1918), a clergyman of northern Iceland, in a series of novels and short stories gave accurate but somewhat dry descriptions of the more gloomy sides of Icelandic country life. Other interesting novelists were Einar H. Kvaran (1859–1938) and Gunnar Gunarsson (1889–). Guðmundur Friðjónsson (1869–1944), Jón Trausti (1873–1918) and Guðmundur G. Hagalín (1898–) portray folk life with skill. The most important novelist of the 20th century is undoubtedly Halldór Kiljan Laxness (1902–), whose novels Salka Valka and Independent People were translated into several languages and widely read abroad. In 1955 Laxness was awarded the Nobel prize for literature.

Among dramatists Jóhann Sigurjónsson (1880–1919) deserves mention for his powerful Eyvind of the Hills, which has been produced in many countries.

A great many gifted Icelanders of the 19th and 20th centuries devoted themselves to study and criticism of ancient Icelandic literature. Among these should be mentioned Jón Sigurðsson (1811–79) and Guðbrandur Vigfusson (1827–89), for many years reader in Icelandic at Oxford university. Finnur Jónsson (1858–1934) was professor of Icelandic in Copenhagen and the author of a detailed history of early Icelandic literature in Danish. A more humane approach to the early literature will be noticed in the works of Sigurður Nordal (1886–) and of Einar O. Sveinsson (1899–). (S. BL.; R. P. Co.)

BIBLIOGRAPHY.—The fullest bibliographies of early Icelandic literature are those of Halldór Hermannsson, published in *Islandica,* vol. i (1908), iii (1910), xiii (1920), xxiv (1935), xxvi (1937), and of J. Hannesson, *Islandica,* xxxvii (1955).

Studies of the early poetry include: H M. Chadwick, *The Heroic Age* (1912); *W.* P. Ker, *Epic and Romance* (1908); *A.* Olrik, *The Heroic Legends of Denmark,* trans. *by L.* M. Hollander (1919); A. Heusler, *Die altgermanische Dichtung* (1941).

Studies of the early prose: A. Heusler, *Die Anfange der islandischen Saga* (1914); K. Liestøl, *The Origin of the Icelandic Family Sagas* (1930); H Koht, *The Old Norse Sagas* (1931). On the later period *see* Jón Thorkelsson, *Om digtningen på Island i det 15. og 16. Århundrede* (1888); *M.* Schlauch, *Romance in Iceland* (1934); Páll E. Olason, *Menn og menntir siðskiptaaldarinnar á Islandi* (1919–26); S. Nordal, *Íslenzk Lestrarbdk 1400–1900* (1924).

ICELAND **MOSS,** a lichen (Cetraria islandica) of erect, loosely tufted habit, called moss because in common speech lichens were formerly known as mosses. It varies from deep brown to pale chestnut colour, rarely grayish-white. It grows to a height of from three to four inches, the branches being trough shaped to strap shaped, forking into flattened lobes fringed with short hairs bearing the male organs. The female organs are borne on the margins, usually at the tips of the lobes. It grows in alpine areas of mountains of the northern hemisphere, reaching the Alps in Europe, the Appalachians in North Carolina and Tennessee and the Rocky mountains in Colorado. It is common on the lava slopes and plains of Iceland, whence its name. A narrower variety grows in gravelly soils of the coastal plain of eastern and southern New

England.

A brown dye is sometimes extracted from it. The food processed from it in northern Europe is a light gray substance, resembling gelatin, with a slightly bitter taste. It contains about 70% lichenin or lichen starch, isomeric with common starch.

(C. W. DE.)

ICE MANUFACTURE: *see* REFRIGERATION.

ICENI, a race of ancient Britain who occupied the part of England now known as Norfolk and Suffolk. After the death of their king Prasutagus in A.D. 60 the Romans established their authority, and the Iceni were eventually conquered and became part of the Roman empire.

See BOADICEA.

ICE PLANT, the popular name for *Mesembryanthemum crystallinum* (family Aizoaceae), a hardy annual most effective for rockwork in mild climates. It is a low-growing, spreading, herbaceous plant with the fleshy stem and leaves covered with large glittering papillae which give it the appearance of being coated uith ice. It is a dry-country plant, a native of Greece and other parts of the Mediterranean region, the Canary Islands, south Africa and widely naturalized in California. *Mesembryanthemum* is a large genus (containing more than 1,000 species) of erect or prostrate fleshy herbs or low shrubs, mostly natives of south Africa, and rarely hardy in the British Isles or the northeastern United States, where they are mostly grown as greenhouse plants. They bear conspicuous white, yellow or red flowers with many petals inserted in the calyx tube. The thick fleshy leaves are variable in shape, and often have spiny rigid hairs on the margin. They are essentially sun-loving plants. The best-known member of the genus is *M. cordifolium variegatum,* with heart-shaped green and silvery leaves and bright rosy-purple flowers.

It is extensively used for edging flower beds and borders during the summer months. Besides the ice plant three other species grow on the coast of California, the sea fig or beach apple (*M. aequilaterum*), with thick, three-sided leaves; the small-leaved fig marigold (*M. nodiflorum*); and also the Hottentot fig (M. *edule*), all of south Africa. The latter has fleshy, edible fruit and is cultivated as a sand-dune binder along the coast near Los Angeles.

ICE SKATING, a means of self-propelled locomotion over ice on steel blades fastened to the bottoms of shoes. This article, after a general historical consideration of skating, skate design, rinks and ice shows, has separate sections on figure skating and speed skating and finally a section on skate sailing.

Early History. — From frequent allusions to skating in ancient Scandinavian literature, runic antiquaries and other historians assign to skating an antiquity dating back at least to the 8th century. The present-day skate may have had its origin in the primitive Norse snowshoe made of wood, but the earliest known skate is that of the bone runner. Made of cow bones and sometimes of the bones of reindeer, sheep or other large animals, these bones were ground down and shaped until they presented a flat traveling surface. They were bound to the feet with thongs. The earliest dated example is that found at Bjorko, Swed., a town which flourished between the 8th and 10th centuries. **A** specimen of an ancient skate 11 in. in length was exhibited in 1841 to the London Society of Antiquaries and described as "formed of the bone of some animal, made smooth on one side, with a hole at one extremity for a cord to fasten it to the shoe." This relic was found in the boggy soil in Moorfields. Samples of ancient bones giving evidence of having been used as skates may be seen in the British museum, in the museums of Cambridge, Edinburgh and York and also at Guildhall. Examples of the bone skate have also been found in Norway, Denmark, Scotland, Iceland, the Netherlands, Germany and Switzerland.

The modern Dutch word *schaats,* from which is derived the English word "skates," is at least as old as 1573. The earliest mention of the word in its present sense is found in Henry Hexham's *A Copious English and Netherduytch Dictionarie,* published in 1648, which refers to "Skates, nhich slide upon the ice in Holland." In the vocabulary of the Moravian educator Johann Comenius (1592–1670), *Orbis sensualium pictus* (1658), wooden skates shod with iron are called *Scrickshoes,* from the German, and in the print at the head of the section in that work they are represented as being quite long and with great curls of iron at the toes.

From the days of the Icelandic tales of the *Elder Edda* the early history of skating can be traced by means of casual reference to it in literature. Some contrivance for gliding over the ice was common in England in the 12th century, for William Fitzstephen's *Description of the City of London* states, "When the great fenne or moore (nhich watereth the walls of the citie on the North side) is frozen many young men play on the ice . . . some striding as wide as they may doe slide swiftlie; and some tye bones to their feete and under their heels, and shoving them. selves with a little picked staffe doe slide as swiftlie as a bird flyeth in the air or an arrow out of a cross-bow." Other references are found in the 14th-century Scandinavian saga *Fornmanna Sogur.* In *Historia de Gentibus Septentrionalibus* (1555) Archbishop Olaus Magnus wrote: "they race swiftly upon the slippery ice, having a plain polished iron or plain Deers or Sheep bones, mainly the shank bones that are naturally slippery by reason of their inbred fatness, and are a foot in length, fastened at the bottom of their feet." Among later writers who made mention of skating were Samuel Pepys, who first mentioned skating as an art, and John Evelyn, both of whom wrote in their separate diaries of watching ice skaters in St. James's park. London, on the same day, Dec 1, 1662. Commenting on the origin of skating, Charles Dickens wrote in an essay dated March 18, 1876, "It is curious to note that skating is almost unknown in Russia among the people, and is of entirely foreign and recent introduction." However, bone skates made from walrus teeth have been found in Siberia and are in the National Museum of Ethnology at Leiden, Neth.

Skating is widely recorded in art. One of the earliest known pictures of skating and a bladed skate is a woodcut dated 1448, illustrating the accident which befell St Lidwina, patron saint of skaters, in the year 1396. Pieter Brueghel the Elder, in the 16th century, pictured skaters in striking action in various works and other artists from many lands have immortalized skating. The world's first Christmas card, designed by 16-year-old William Maw Egley, Jr., apprentice to a London engraver, in 1842, included a skating scene. A number of countries have honoured skating with special postage stamp issues, among these being Germany, Hungary, the Netherlands, Rumania, Russia, Norway and Japan.

Skate Design. — It is not known when the metal runner was introduced, but early Dutch prints show the metal skate as having an extremely wide traveling surface. Until the middle of the 19th century the metal portion of the skate was fastened to a wooden base or footplate and the whole of the skate was fastened to the foot with leather thongs or straps. Improvement in skate design began in the 1800s with many ideas being patented, every effort being made by the inventor for security in attachment. One of the best developments was that of the Barney and Berry Co. of Springfield. Mass., which appeared in the early 1860s and which utilized screw clamps. fastening the skate to the welt of the sole and heel of the shoe. Another ingenious arrangement of this time was the Acme clamp skate from Halifax, N.S. The final and most satisfactory development in the securing of the skate to the shoe was simply to attach them permanently with screws, a method in continued use.

There were many experiments in the development of the blade of the skate, especially during the period 1830–80. Henry Boswell of Oxford designed an improved skate in 1837 which eliminated the projecting toe and had an elongated, rounded heel especially for figure skating. A major improvement was made in 1850 when E. W. Bushnell of Philadelphia introduced the all-steel skate, which eliminated the cumbersome wooden footplates and proved universally popular. The main developments in the figure skate after 1900 were the addition of sawlike teeth placed at the toe, enabling the skater to obtain better purchase in the ice when doing certain jumps, and the innovation of the "closed-toe" blade of one-piece steel, manufactured in 1914 by John E. Strauss of St. Paul, Minn. The Strauss design gave added strength to the skate and permitted

a much lighter-weight blade.

An average figure-skating blade is $\frac{5}{32}$ in. wide and is shaped with a curvature approximating that of a circle having a six-foot radius. The blade is hollow ground when sharpened, emphasizing the two edges of each skate. The hockey skate is also given a hollow grinding which allows better purchase in the ice. The speed skate uses a thinner blade and it is sharpened with a flat surface and a very long radius affording the racer a longer stroke. The popular length of the outdoor racing skate is 16 to 17 in., with the skate cups which hold the blade to the footpiece set low to the ice. For indoor racing the cups are heightened, the blade shortened to about 15 in. and the skates set far over to the left of the shoes to allow for the sharper turns.

Rinks. — The invention of refrigeration and the development of mechanically refrigerated ice rinks started the transformation of ice skating from a seasonal pastime to a major sport and launched the eminently practical skate on its way to theatrical history.

The world's first mechanically refrigerated rink was John Gamgee's "Glaciarium" in Kingsroad, Chelsea, London, built in 1876. It was a studio-type room with an ice surface 40 ft. by 24 ft., frozen by means of a mixture of glycerin and water running through copper pipes, chilled by ether. The first artificially frozen rink in the United States was installed in the old Madison Square Garden, New York city, in 1879 by Thomas L. Rankin and had a surface of 6.000 sq.ft. In 1889 a huge outdoor rink was built in Paris, running the full length of the Rue Pergolese. Other early rinks were opened in Glasgom, Frankfurt Berlin, Southampton, San Francisco. Baltimore and Pittsburgh. The popularity of these rinks grew steadily and in the second half of the 20th century there were more than 200 mechanically refriqerated ice arenas in the U.S., more than 200 in nine provinces of Canada, 28 in Great Britain and many others in practically every section of the world.

These ice arenas, many with large seating capacities, not only gave impetus to skating as a recreation and participant sport but they were also a major factor in establishing ice-show productions as leaders in spectator entertainment.

Ice Shows. — The professional skating spectacles, an outgrowth of the amateur ice carnivals, combined the colourful movement of huge casts of skaters with all the arts of the theatre — brilliant lighting, gorgeous costumes, special music and direction — and by the second half of the 20th century were established as among the most popular forms of entertainment. International tours were arranged, including the major cities of the world. One of the pioneer shows, the "Ice Follies," first produced in 1936 by Oscar Johnson, Edward Shipstad and Roy Shipstad, played to more than 40,000,000 people in 20 years. A trade publication, the *World* Ice *Skating Guide,* estimated that 11,000,000 people attended skating shows in Canada and the U.S. alone during one year in the mid-1950s, and paid more than $22,000,000 for admissions. Other prominent American shows of the 1950s were "Ice Capades," produced by John H. Harris; the "Hollywood Ice Review," produced by Arthur M. Wirtz; "Sonja Henie Ice Revue," produced by the Norwegian star. Sonja Henie; and "Holiday on Xce Shows," produced by Morris Chalfen, Emery Gilbert and George Tyson. The last were presented on ingenious mobile rinks, complete with refrigeration equipment, which could be transported anywhere in the world and set up indoors or out of doors. In a single year this company had seven separate full-scale productions playing in five continents at one time — North and South America, Europe, Asia and Africa.

Leading producers of skating spectacles in Great Britain were Sir Arthur Elvin, Gerald Palmer and Claude Langdon. Elaborate pantomimes with stories portrayed on ice were tremendously popular throughout Great Britain.

One of the earliest experiments in ice-show production, staged at the huge Hippodrome theatre in New York city in 1915, featured the German ice ballerina Charlotre (Oelschlagel) and an ice ballet imported from Berlin. Called "Flirting in St. Moritz," the show created a skating furore in New York and ran for 300 days, instigating the production of the first skating motion picture ever made, "The Frozen Warning," released in 1916 and starring Charlotte.

FIGURE SKATING

History. — Figure skating is one of the most scientific of all sports, and the most artistic division of skating. It is also the most difficult, requiring skill in plain skating, both forward and backward, a high degree of body control and assiduous practice. The first comprehensive written treatment of figure skating seems to be *A Treatise of Skating* by Capt. Robert Jones, published in London in 1772. Other early textbooks on the sport are *The Art of Skating* by Cyclos (George Anderson), published in 1830, and "The Skaters Manual," 1831.

Soon after the discovery that inside and outside edges and elementary figure-three turns could easily be done with the steel skate, it was found that turns could be made in the opposite direction or counter to the simple three turn. Combinations of various turns naturally developed, and these turns became increasingly more difficult; the style or the manner in which these turns were made was standardized, and when the course of standardization became general, competitions were organized. (See *School Figures,* below.)

Modern figure skating was influenced to a profound degree by the revolutionary style of the American Jackson Haines (1840–76). Haines, known as the "father of figure skating," gave skating a freedom of movement which it had not formerly possessed. He was born in New York city and first came into prominence in the 1860s. A ballet master, Haines combined dance movements with his skating, novelty in America where figure skating was executed in a stiff and rigid style, and gave exhibitions throughout the eastern states and Canada. After winning the American championship he left for a tour of Europe in 1865. His first appearances in England were not successful; Londoners, like New Yorkers, preferred their own cramped manner to the sensational routines of Haines. It was not until he went to Stockholm in 1866 that his art was fully appreciated and he began a triumphal tour across Europe. In Vienna he was an instantaneous success and there he taught the Viennese to waltz on ice, which resulted in the founding of the Vienna School of Skating. After 11 years abroad Haines planned to return to America but, traveling by sled from St. Petersburg to Stockholm, he contracted pneumonia and died in Finland in Jan. 1876.

The lack of appreciation of Haines in the U.S. and Great Britain was the result of the styles of skating then in vogue. Figures were accomplished by ungainly twisting of the body, together with much kicking of the nonskating leg.

At the continental winter resorts, in Great Britain and to some extent in Canada, a form of figure skating known as the "English" style was popular until the early 1900s. Various modifications of the style were known by other names but the essential features were identical. A branch of this form of skating was the hand-in-hand or "combined" style, in which more than one skater took part, usually four and sometimes six or eight. **A** member of the group was appointed "caller" and it was his duty to call out to the others moves which the group did simultaneously. Interesting patterns were thus performed.

Out of these various styles of skating there developed at the beginning of the 20th century the international style, which became popular and is followed the world over. Irving Brokaw, champion of America in 1906, brought the international method of skating back to the U.S. on his return from a European tour in 1908. Although but little remains of the previously mentioned forms of skating they cannot be easily dismissed, since the present form of skating has its foundations in their essentials and in those set down by Haines.

The development of figure skating from an obscure form of competition in the early 1900s to a major sport was largely the result of control organizations such as the Internationale Eislauf-Vereinigung (I.E.V.; International Skating union) of Europe, the National Skating Association of Great Britain (organized in 1879), the Cnited States Figure Skating association (U.S.F.S.A.; 1921), the Canadian Figure Skating association, and other amateur groups and clubs. The I.E.V., founded July 23, 1892, at Scheveningen. Neth., is the governing body over skating throughout the world. The principal aim of the control organization is to improve

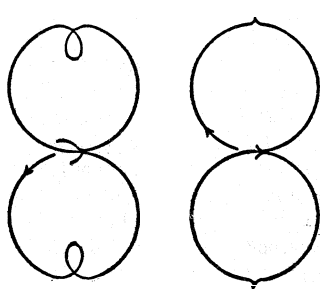
and advance figure skating, to provide standards. to prescribe tests and rules for the holding of competitions and generally to take all steps necessary to regulate figure skating through its membership clubs.

The Edinburgh Skating club, instituted in 1642, is the oldest skating club in the world. The Skating Club of London and the Glasgow Skating club were both formed in 1830. A steady increase of interest in the sport has been shown in the U.S. and Canada, especially since the 1930s. The U.S.F.S.A. had 120 member clubs in the second half of the 20th century. Organized in 1849, the Philadelphia Skating Club and Humane society is the oldest skating club in the U.S. Other early groups are the Skating Club of New York (1863) and the Skating Club of Boston (1912). The Canadian Figure Skating association had over 150 member clubs in the 1950s, including the historic Minto Skating Club of Ottawa and the Toronto Skating club.

Divisions.—What is broadly called figure skating is divided into various divisions; these are school figures, free skating, dancing, pairs and fours. In competition, the event for individuals consists of two sections, the prescribed school figures and free skating, or optional routine for a specified number of minutes.

School *Figures.*—The elements of school figures are simple curves or turns, which are done in the direction of motion, and the so-called forced turns, which are done against the direction of motion. There are four directions in which the skate may go: outside edge, both forward and backward, the inside edge, also forward and backward. Skated first on the right and then on the left skate to form full circles, these simple curves become the fundamental figure eights. A combination of these circles becomes the changes of edge. Following in difficulty are, threes, double threes, loops, brackets, counters and rockers. (*See* fig. 1.) Advanced figures are the so-called one-foot figures in which the full figure-eight form is done on the same skate instead of making a transitional change of feet at the point of start, as is done in the elementary figure eights.



REPRINTED FROM THE U.S.F.S.A. RULEBOOK WITH THE PERMISSION OF THE UNITED STATES FIGURE SKATING ASSOCIATION, HOLDERS OF THE COPYRIGHT

FIG. 2.—(1) LOOP-CHANGE-LOOP AND (2) BRACKET-CHANGE-BRACKET

There are 69 possible cornbinations of figures as officially designated by the I.E.V. Each figure is given a factor value from one to five, according to difficulty. The fundamental eights, for example (except the inside back eight), have factor values of one, while the back loop-change-loops and the back bracket-change-brackets have factor values of five. (See fig. 2)

Definite rules have been set down concerning the correct tracings of school figures on the ice. For example, both circles of the eight should be of equal size when divided by the transverse axis; there should be a symmetrical grouping of the individual parts of the figures about the axes; figures should be skated on the specified edge of the skate without changes of edge or flat edges, except, of course, when the figure calls for a change of edge. Three turns, brackets, rockers and counters should be made without changes of edge before or after the turns and the turns should be placed on the long axes.

There are also definite rules for the body positions of the skater while performing the figures. The body should be erect, without bending at the hips; there should be a moderate bending of the skating knee; the head should be held erect and the skater should not look at the ice. The free foot (nonskating leg) should have the toe of the foot turned downward and outward with the free knee slightly bent; the free foot is generally held behind the tracing foot. The arms should hang down easily but without raising the elbows or hands far from the body. Everything violent, angular or stiff is to be avoided. There should be no strong effort and the impression should be given that the skating is executed with ease.

Free Skating.—The second section of the singles events is free skating. Generally speaking it is a "free" adaption of the various parts of the circles and the turns which make up school figures, and is skated to music. The design of a free-skating program must be a varied one and should include spirals (exaggerated edges), dance steps, connecting moves, jumps and spins. Jumps are an important element in a program. They are leaps off the ice with from a half turn to triple turns in the air. Many of the jumps are named after their originators, for example, the Salchow, the Paulsen, the Boeckl, the Pat Low (also known as the W'alley) and the Lutz. Others are the three jump, the loop, the counter (named after school figures) and the flip. Spins are another element; some of these are the flat-foot spin, the toe scratch, the Haines and the arabesque, which is also called the camel spin. A pair skating program is very similar to the singles program in its content and construction. An important element in this branch, besides the jumps, spins and dance steps, is the lift. In this move the man lifts his woman partner in the air while skating. Many daring and exciting lifts have been devised. Fours consists of two men and two women, and is skated as pairs and as a group. Jumps, spins. lifts, pair and group moves comprise the program.

Dancing.—Although ice dancing has been known for many years, it became. after the 1930s, by far the most popular branch of the sport. Unlike ballroom dancing, in which steps may be improvised, ice dancing is skated in set patterns and with set steps which never vary. The steps are, as in free skating, based on parts of circles. The three turn is mostly used with an occasional bracket, rocker or counter.

Competitions.—Although the actual school figures to be skated in a singles competition are not known to the competitor until 15 minutes before the event, they are drawn by lot from a larger group, which is usually made known at some previous date. There must be an odd number of judges, no two of whom may be from the same club. city or country, depending upon whether the competition is local, national or international. When each skater has completed a particular figure, it is given a mark by each judge independently and represents his numerical opinion as to its value. The correctness of the shape of the figuie. the turn, triple repetition, the largeness of the figure and the form with which the figure is skated are the factors upon which judgment is made. The free-skating program is given two marks, one for content, or what the

skater has done, and the other for performance, or the manner in which the skating was done. The pairs, fours and dance competitions are judged in a similar manner except, of course, that there are no school figures skated.

The first amateur women's world champion was Madge Syers of England, who held the title for the years 1906–07. Gilbert Fuchs of Germany won the first world championship for men (1896). European skaters held a tight grasp on all the world's titles until Barbara Ann Scott of Canada triumphed in 1947, the first time a world figure-skating championship had left Europe. The men's world title went to America for the first time when Richard T. Button of the U.S. won the championship in 1948. Button was one of the great modern-day skaters and held all the major championships from 1948 1952. Tenley Albright, Newton Center, Mass., who won the Olympic title in 1956 and the world's in 1953 and 1955, was the first U.S. woman to win the Olympic championship. (For winners in Olympic competition see OLYMPIC GAMES.)

Great Britain dominated the dance championships of the world in the second half of the 20th century which such superb teams as Lawrence Demmy and Jean Westwood; Paul Thomas and Pamela Weight; and Courtney Jones and June Markham. Robert Paul and Barbara Wagner of Canada, always famous for magnificent pair skating teams, won the 1957 world pair title. Among the great pair skating combinations of the world was Montgomery Wilson and his sister, Constance Wilson Samuel, both of whom also held many major singles titles.

The most celebrated figure-skating champion of all time was Sonja Henie, who at ten years of age won the national championship of Norway. Henie was three times Olympic champion and ten times world champion. She turned professional in 1936 and skated in personal appearances before millions throughout the U.S., Canada, Europe and South America, producing many of her own shows, and she starred in 11 motion pictures.

SPEED **SKATING**

History. — Of the earliest skating races no records have been kept. That racing was a popular pastime in the Netherlands earlier than the 17th century is proved by numerous paintings depicting racing scenes. Women's races took place as early as 1805 at Leeuwarden. Keen interest in ice racing was evidenced in England from the early 1800s, especially in the fens or marshy section of the country. The first recorded skating match in England was that in which Youngs of Mepal beat Thomson of Wimblingdon, both men from the fens, in the year 1814. In Jan. 1823, according to the Annals of Sporting, the first amateur match took place between teams of six gentlemen from March and Chatteris, Drake of Chatteris finishing first. In the 1850s the celebrated Smart family entered the racing scene, with William ("Turkey") Smart defeating Larmen Register in 1854 and retaining the championship for more than a decade. His nephew, George ("Fish") Smart, won the championship in 1878 and held it until 1889, only to relinquish it to his younger brother, James. The first amateur championship of England was held in 1880 at Hendon by the newly formed National Skating association and won by F. Norman, a fens skater.

Speed skating was tremendously popular in northern sections of the United States and Canada. Charles June was considered the best U.S. skater for 1838 and many years thereafter, and his place of residence, Newburgh, N.Y., on the Hudson river, became the headquarters of U.S. ice racing. This city also is the birthplace of the Donoghue family, who may be called the Smarts of America. The most noted members of this family were T. Donoghue and his two sons, Tim and Joseph F. Donoghue, each in his day the fastest skater in the world.

J. F. Donoghue went to the Netherlands in 1889 to compete in the Amsterdam races and won the two-mile event, defeating among others the celebrated Russian flyer Alex von Panschin. In 1891 he again competed in the great international races at Amsterdam and on Jan. 6 and 7 won all four events on the program, earning him the title of champion of the world. J. F. Donoghue was the first American to skate one mile under three minutes, his time being 2 min. 59 sec.

The famous Norwegian figure skater Axel Paulsen was also one of the fastest racers of his day. He competed in some of the great American races and in 1884 he won most of the races he entered, first in New York, then in Milwaukee and Washington, D.C.

Norval Baptie, world champion 1905–07, was one of the most colourful skaters of all time. Born at Bathgate, N.D., Baptie was a champion racer, renowned exhibition skater on racing blades and on figure skates and a leading instructor of the sport.

The Stroke. — In speed skating the blade, when planted on the ice with weight upon it, describes a nearly straight line. When stroking, the last few feet only curve slightly outward as the skate leaves the ice. The length of stroke has tended to diminish since the days of the 12–18 yd. stride attributed to the old English champion William Smart on the fen "runners." The modern racing stroke rarely exceeds 10 yd., and is usually 6 or 7. Particular instances vary with conditions of ice, etc., but at St. Petersburg, in 1896, Eden's stroke in the 10,000-m. race averaged about 73 yd., that of Peder Oestlund at Davos, in 1900, the same (for one lap it was 8 yd.).

J. F. Donoghue's stroke in 1891 was computed at about 9 yd. Irving Jaffee, U.S., former Olympic champion, had a powerful 8-yd. stroke in some of his races. Clas Thunberg of Finland, world amateur champion 1923–25–28–29–31, had a tremendous $27\frac{1}{2}$-ft. stroke. He visited the U.S. in 1926 and in two races at Madison Square Garden in New York city was soundly beaten by Joe Moore, New York city, due in large measure to the fact that his stroke was far too long for the small indoor track and he could not negotiate the turns.

Later in the same year, on outdoor tracks, the "Flying Finn" set two U.S. records which had not been broken by the second half of the 20th century.

Courses. — The international system of ice racing involves a course with straight sides and curved ends of such a radius that no slackening of speed is necessary. The competitors race two at a time on a double track, and the time test is used. Each skater must keep his own course, to prevent either from using the other as pacemaker or windshield. The advantage of inner curve on a continental course is given alternately and a space left open between the tracks at one point for the skaters to cross. The official I.E.V. track measures 400 m.; the official U.S. outdoor track is 6 laps to the mile.

Form. — Competitive speed skating requires skill, strength, muscular co-ordination and great stamina. The body should be poised so that the centre of balance is in the hips. At racing pace the body should follow an imaginary straight line. The stroke should be kept as straight as possible, for swaying widely from side to side results in loss of momentum. To obtain the most effective stroke with minimum effort, the skater must lean forward from the waist and bend the knees. The force of the leg drive is directed forward, not upward; the push should be made toward the side, not backward; and the push is from the centre of the blade, not from the toe.

Records. — The official amateur world records are: 500 m., Yevgeni Grishin, U.S.S.R., 40.2 sec. (1956); 1,500 m., Grishin and Jurij Michailov, U.S.S.R., 2 min. 8.6 sec. (1956); 5,000 m., Boris Shilkov, U.S.S.R., 7 min. 48.7 sec. (1956); 10,000 m., Knut Johannesen, Norway, 15 min 46.6 sec. (1960).

For winners in Olympic competitions, see OLYMPIC GAMES.

The official U.S. amateur outdoor records were: 220 yd., R. Fitzgerald, 18.1 sec. (1943); 440 yd., C. Gorman (1937), R. Fitzgerald (1942), K. Bartholomew (1942), 35.4 sec.; 880 yd., R. Fitzgerald, 1 min. 14.2 sec. (1945); $\frac{3}{4}$ mi., C. Thunberg, 1 min. 55.2 sec. (1926); 1 mi., C. Thunberg, 2 min. 38.2 sec. (1926); 2 mi., E. Schroeder, 5 min. 38.8 sec. (1934); 3 mi., R. Robinson, 8 min. 19.6 sec. (1930); 5 mi., R. Robinson, 14 min. 30.4 sec. (1927).

The official British amateur outdoor records are: 220 yd., F. Tomlins, 18.2 sec. (1940); 440 yd., R. Wyman, 36.8 sec. (1933); 880 yd., C. W. Horn, 1 min. 31.8 sec. (1929); 1 mi., F. W. Dix, 2 min. 27.2 sec. (1912); $1\frac{1}{2}$ mi., N. A. Holwell, 4 min. 12.2 sec. (1952); 3 mi., C. W. Horn, 9 min. 52.8 sec. (1929).

SKATE SAILING

Skate sailing is the sport of moving over the ice on skates propelled by the wind. It is probable that skate sailing originated in the Scandinavian countries and was practised in some form or another almost immediately after the invention of the skate. One of the first skate-sailing organizations was the "Ice-Skate Sailing club" formed in Stockholm in 1901. The sport was taken up by members of the London Skating club in England in the 1890s and was introduced to North America in the early 1900s. The Skate Sailing Association of America, governing body over the sport in the United States. was organized in 1922.

The modern skate sail, generally rectangular or triangular in shape, has approximately 50 to 60 sq.ft. of area. The Skate Sailing Association of America recommends that the sail be perfectly flat and stretched to drumhead tightness. The spars and rigging should be moderately light, yet strong and as simple as possible so that they can be handled easily in cold, windy weather. In sailing, the skate sail is always carried on the windward shoulder, that is, between the sailor and the wind. The sail material can be a good grade of sheeting or unbleached muslin but for best results should be a nonporous, lightweight sailcloth or balloon silk. Long, tubular racing skates 16 to 18 in. in length are used.

Learning how to skate sail on the ice before and against the wind requires only a basic proficiency in skating, for the sail gives added stability and bears much of the sailor's weight. Speeds up to 55 m.p.h. are reported to have been recorded over measured courses.

ICE YACHTING. The sport of sailing and racing ice yachts, once a rich man's hobby involving boats costing several thousands of dollars and professional skippers and crews, became, in the second half of the 20th century, confined almost entirely to small, light but extremely fast boats, often built by their owners and costing from $500 to $1,500 apiece. By taking advantage of modern highways and car-top carriers and trailers, iceboatmen were able to widen the area and lengthen the season for iceboating. The most active regions in North America are Wisconsin, Illinois, Michigan, Ontario, southeastern New York, northern New Jersey, Connecticut and eastern Massachusetts. European areas where the sport is active include Sweden, the Netherlands and Germany —in general. the Baltic basin region.

The Dutch seem to have been the first iceboaters, although the Finns, Latvians and others living around the Baltic sea no doubt contrived some sort of "sailing sleigh." as the Austrians call it, at a very early date. **A** dram-ing of a Dutch iceboat dating from 1790 shows a regular sailing craft with a strong cross plank under the hull near the bow, a runner at each end and a sharp iron shoe at the stern, on the bottom of the boat's regular rudder.

Similar craft appeared in America along the banks of the Dutch-settled Hudson river. In 1790 Oliver Booth sailed an iceboat on the frozen river at Poughkeepsie. N.Y. Within a few years iceboats were sailing the frozen waters around Red Bank and Long Branch, N.J.

Immediately after the Civil War interest in iceboating increased rapidly. The Poughkeepsie Ice Yacht club was formed in 1861, followed within a few years by the New Hamburgh and Hudson River Ice Yacht clubs. The latter organization, located at Hyde Park. N.Y., flourished under the patronage of a large group of millionaire sportsmen. including Archibald Rogers and John E. Roosevelt. an uncle of Franklin D. Roosevelt, who was himself an officer of the club at one time. In 1900 the club fleet mustered over 50 yachts, including 6 giants of the first class with over 600 sq.ft. of sail apiece. The development of the sport at Long Branch and Red Bank followed the same pattern and the boats were similar to those on the Hudson.

When iceboating on the Hudson died out after 1902, activity shifted to these Jersey rivers and to the midwest. where the sport had become active and flourished in Kalamazoo, Mich., and Madison and Oshkosh, Wis. The boats in use were almost all of the basic Hudson river pattern. consisting of a single fore-and-aft spar, called the backbone, mounted just ahead of its midpoint on a broad. flexible wooden plank called the runner plank. which had a runner mounted at each end. The third running blade was pivoted through the after end of the backbone and controlled by a tiller. The helmsman and crew (only two men sailed these huge boats as a rule) clung precariously to a shallow, elliptical tray just ahead of the steering runner. The mast was stepped on the backbone, several feet ahead of the runner plank. The rig, almost without exception, was jib and mainsail. From 1879, when H. Relyea built the "Robert Scott" on the Hudson, until 1947, when Carl Bernard and Frank Tetzlaff constructed the "Mary B." at Madison, the only changes made in the design of this type of yacht were refinements of materials and rigging.

Some of the speeds recorded were notable. In 1885 Commodore James Weaver sailed the "Scud" at 107 m.p.h. on the Navesink river at Red Bank; in 1907 Commodore Elisha Price sailed the "Clarel" at 140 m.p.h. on the Shrewsbury river at Long Branch; in 1908 the "Wolverine" of Kalamazoo, Mich., sailed the fastest 20 mi, to windward and return recorded. covering the course from a standing start in 39 min. 4 sec. Clearly, in those days, the iceboat was the fastest vehicle man had yet produced.

Experiments show that the best speed the iceboat can accomplish is approximately four times the speed of the wind that is blowing at the time. This phenomenon is not easy to explain, but it must be borne in mind that (1) the boat is sailing across the wind and is not being pushed along by it and (2) by her very motion the boat creates an increase in the velocity of the wind she sails with. These principles were only vaguely known in the early days, and the traditional jib-and-mainsail rig with stern rudder was so firmly entrenched that experiments with other designs were usually unsuccessful. The forward thrust sometimes lifted the stern rudder from the ice, sending the whole boat into a spin. Perfect tuning of the boat and perfect handling by the sailor could minimize but never eliminate this built-in tendency to become unmanageable in strong winds.

About 1931 Starke Meyer of Milwaukee, Wis., became convinced that a boat with steering runner at the bow and runner plank aft, like a tricycle, would not spin. He reasoned that the downward and forward thrust of the mast. now located between steering runner and runner plank. could serve only to increase rudder traction. His first bow-steerer easily defeated all competition in her first season on the ice. It mas clear that the bow-steerer would not spin—that she was correctly balanced and directionally stable.

Smaller versions, mith a sail of only 75 sq.ft., showed they could sail safely and fast. By 1940 the design had crystallized and the 75-sq.ft. class enjoyed a rapid growth. By 1950 boats of this class were winning not only 75-sq.ft. class races, but also open and free-for-all events of all sorts. Other classes continued to exist, but very few boats mere built in them, and as the older large boats were discarded, they were not replaced.

Iceboats have always been classified for racing purposes by sail area. The classes of the Hudson River Ice Yacht club before 1900 were as follows: first class, over 600 sq.ft.; second class, 450 to 600 sq.ft.; third class. 300 to 450 sq.ft.; fourth class, 225 to 300 sq.ft.; fifth class, under 225 sq.ft. In 1935 the classes recognized by the Northwestern Ice Yachting association were as follows: class A, 250 to 350 sq.ft.; class B, 175 to 250 sq ft ; class C, 125 to 175 sq.ft.; class D, 75 to 125 sq.ft.; class E, up to 75 sq.ft.

In 1937 seven eastern clubs formed the Eastern Ice Yachting association, patterned after the Northnestern association (founded in Oshkosh, Wis., in 1912) and recognizing the same classes. Membership in both associations varies as their member clubs

prosper, but in general the Eastern association includes a group of clubs in the New York-New Jersey-Connecticut area, and the Northwestern association includes clubs from eastern Wisconsin, northern Illinois, Michigan and Ontario. Both the Northwestern and the Eastern associations conduct an annual championship regatta, to which member clubs may send their best boats in all recognized classes.

The growth of the "skeeter," or class E, at 75 sq.ft. was so rapid that by 1939 there was a need for an organization devoted to this class alone and the International Skeeter association was founded, with headquarters in Chicago. Activity was also brisk around Detroit, which fostered a great deal of experimentation and development in class E.

Most racing skeeters are single-seaters, precluding the possibility of carrying a passenger for pleasure sailing or for instruction. The need for a two-seater was felt strongly and crystallized in the founding in 1948 of a second one-design class, this time in the east. This new class was, appropriately, called the "Yankee," and had an orthodox two-seater as the accepted design. Yankees competed on even terms with single-seater racers, and in 1952, 1954, 1956 and 1957 the Eastern Ice Yachting association class E and open championships went to Homer Sieder's "Rebel," a Yankee one-design craft.

In 1951 the New Hamburgh Ice Yacht club, inactive for 25 years, turned over custody of the famous Ice Yacht Challenge Pennant of America to the Eastern Ice Yachting association. This trophy is open to any type or size boat and to any club in the world. An open invitation regatta was held at Greenwood Lake, N.J., Feb. 18, 1951, to which all known clubs in the world were invited. The most distant challenger was the Fox Lake (Ill.) Ice Yacht club, represented by Ed Rollberg's "Black Magic," which won a close series from Elmer Millenbach's "Renegade" of Detroit. Both easily defeated 15 eastern clubs. On March 1, 1953, Fox Lake lost the trophy to Pewaukee Ice Yacht club at Lake Geneva, Wis., which club successfully defended the flag for five years.

In the midwest, interest in the larger boats was kept alive by competition for two cups, by tradition open only to the boats of class A and larger, the Stuart cup, put up in 1903, and the Hearst Cup, put up in 1904 by William Randolph Hearst for competition in the 450-foot class (later opened to class A at 350).

Before World War II, European iceboating was very active and well organized under the European Ice Yachting union. Member nations included Sweden, Latvia, Estonia, Germany and Austria. Competitions were held annually in several classes, and a one-design class of 15 sq.m. sail area. Rigs were almost universally single-sail, or "cat"; the backbone was a hull, or fuselage, with pilot and passenger sitting upright, and steering done by a wheel. Although contact was never formally established across the Atlantic, correspondence and comparisons of ideas went on with the result that Americans, borrowing freely the efficient cat rig, fuselage backbone and safe, comfortable pilot's position, developed the modern fast racer when they made it into a bow-steering design. On the other hand, Europeans have steadfastly refused to use the bow-steerer.

After World War II some iceboating was again carried on in Germany. Sweden continued through the years.

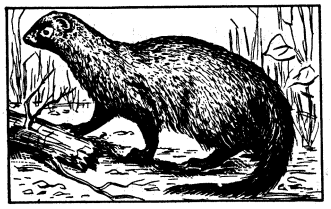
See F. M. Gardiner, *Wings on the Ice* (1938); *Yachting* (Nov.–Dec. 1942; Jan.–Feb. 1943; Jan.–Feb. 1944). (R. A. R.)

I-CH'ANG, a port of China on the north bank of the Yangtze river in western Hupeh province. Although a relatively small town, with about (1953 est.) 100,000 inhabitants, it plays an important economic role in the trade of Szechwan province and the Yangtze valley. In 1958 it was one of five municipalities in Hupeh under direct provincial administration, as well as being the seat of eight districts forming a special *ch'u* (region). Ten miles above the port begins the rugged country through which the Yangtze breaks in a series of four great limestone gorges and about 60 rapids and whirlpools, the grandeur of which has been a favourite theme of many Chinese poets, especially Li Po (*q.v.*). A short distance above I-ch'ang is the prospective site of a hydroelectric dam that has vast promise for the industrialization of central China. During flood stages 1,000-ton steamboats can navigate up to I-ch'ang where transshipment takes place between upriver and downriver traffic. Formerly, carriage upriver was entirely hauled by junks pulled over the rapids by gangs of men. After 1909 small, high-powered river steamers carried a large proportion of the commodities passing upstream, though much of the traffic remains junk-borne. A motor highway also reaches westward from Wu-han to I-ch'ang.

The city, captured in 1940, marked the farthest Japanese advance up the Yangtze valley in World War II. I-ch'ang, a treaty port (1876–1943), has a city wall between which and the sheltered anchorage stood the small foreign settlement. (H. J. Ws.)

ICHINOMIYA, a commercial town in Aichi prefecture in Japan, about 11 mi. N.N.W. of Nagoya. Pop. (1955) 157,025. There are approximately 1,000 factories which manufacture about 60% of the nation's woolen fabrics. The cotton-textile industry is also important. The town developed in the 7th century from the Masumida shrine. During the Edō period (1603–1867), Ichinomiya was an important stage on the Gifukaido highway. The suburbs form a part of the Owari horticultural zone. (R. B. H.)

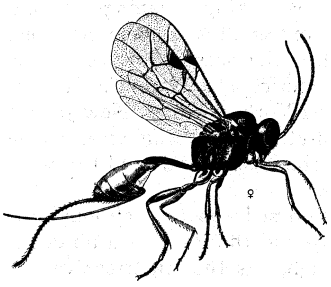
ICHNEUMON, the name applied to a large mongoose (*Herpestes ichneumon*) found throughout Africa and also in southern Spain. In size this species exceeds a domestic cat. It is covered with long, harsh, many-banded hairs, which results in a shaggy appearance and grayish-brown colour, darker on the head and along the middle of the back; its legs are reddish and its feet and tail black. It lives largely on rats and mice, birds and reptiles, and for this reason it is sometimes domesticated. *See* CARNIVORA: *Feloidea.* (J. E. HL.)



ICHNEUMON OR MONGOOSE OF AFRICA AND SOUTHERN SPAIN

ICHNEUMON FLY, common name for parasitic insects comprising the superfamily Ichneumonoidea, order Hymenoptera, from the genus *Ichneumon,* typical genus of the largest family of this group, Ichneumonidae. "Fly" in the common name is unfortunate since these insects are not flies at all (true flies, order Diptera, have only two wings whereas ichneumon flies have four) but are really parasitic wasps.

The Ichneumonoidea contains four families: Megalyridae, with less than 50 known species, mostly Australian; Stephanidae, with a few hundred known species, most of them native to tropical regions; and two very extensive families, Braconidae and Ichneumonidae, both widely distributed. and each with thousands of described species and even more thousands of undescribed ones. This superfamily includes most of the larger species of parasitic Hymenoptera, and also many that are very small; body lengths range from less than one-eighth inch to nearly two inches. The body, often brilliantly coloured, is usually comparatively narrow; the head is free and has long, slender antennae that very rarely have as few as 11 segments and often have more than 50. The compound eyes are large, and the forewings usually have rather complete venation. Some species, however, are wingless, at least in the female sex. The abdomen, sometimes petiolate (attached by a narrow "waist") and sometimes sessile, is, in the female, provided with an egg-depositing organ (ovipositor) which ranges in length from so short as to be unnoticed to several times as long as the body.



FROM CUSHMAN "JOURNAL OF AGRICULTURAL RESEARCH 1916

ICHNEUMON FLY (THERSILOCHUS CONOTRACHELI), A BENEFICIAL PARASITE

All species are parasitic, many on the caterpillars of moths and butterflies and larvae of sawflies and of wood-infesting beetles. Some of the smallest species are parasites on plant lice; a few on adult beetles, true bugs or spiders; and some are even parasites

of other ichneumon flies, these being called hyperparasites or secondary parasites.

The females deposit their eggs in or on the larvae or pupae (rarely eggs or adults) of the host species; the legless, maggot-like larvae that hatch from these eggs feed on the body fats and fluids of the host until fully grown. At this time the plump larvae usually spin silken cocoons, within which they pupate and from which the adult parasites eventually emerge. Those species parasitizing exposed hosts usually develop as internal parasites, whereas those attacking hosts concealed in wood burrows, plant stems, cocoons or leaf mines feed externally. In the case of the internal parasites the hosts feed and behave normally until shortly before the parasitic larvae have completed their development, but the hosts of the external feeders are paralyzed by the female parasites and do not regain activity. In most cases a single parasitic larva completes its development within or upon its host, but in some species many larvae develop in a single host. Twenty or more larvae of *Apanteles glomeratus,* a common and widely distributed parasite of cabbage butterfly caterpillars, complete development within a single caterpillar and then emerge to spin their cocoons beside the destroyed host.

Adults of ichneumon flies feed principally on honeydew secreted by aphids (*q.v.*) and certain related insects, or on host juices that exude from punctures made by the ovipositor. All species can, and under certain conditions do, reproduce without fertilization (parthenogenesis; *q.v.*). In most instances the progeny of such parthenogenetic reproduction are exclusively males, but certain species produce females regularly in parthenogenesis, the male sex being very rare or unknown.

Except for those that live as hyperparasites — and thus lower the numbers of other ichneumonids — ichneumon flies are generally beneficial and under certain conditions may play an important role in the control of plant pests. Some species have been transported from their original homes and colonized in new areas where their normal hosts became established and could not be controlled by sprays or other artificial treatment. See also INSECT.

ICHTHYOLOGY, that branch of zoology (*q.v.*) dealing with the study of fishes (*q.v.*). As a foundation for an understanding of the anatomy and physiology of fishes, one may start with the simple, diagrammatic lower chordate amphioxus (*q.v.*), then consider the characteristics of the subphylum Vertebrata (see VERTEBRATE) in general before approaching fishes as a special group.

Paleontology (*q.v.*) includes the study of fossil fishes (see OSTRACODERM). The lowest living fishes belong to the jawless Cyclostomata (see CYCLOSTOME). Higher in development of structures are the jawed selachians, or sharks and rays (see CHONDRICHTHYES), characterized by having a cartilaginous skeleton. The bony fishes first developed a combination cartilage-and-bone skeleton (see STURGEON; GAR PIKE; BOWFIN). Then the true bony fishes, or Teleostei (*q.v.*), appeared. The student may be interested in a particular fish or group of fishes, such as the herring. anchovy, char, salmon and trout, smelt, pike, electric eel, goldfish, catfish, eel, moray or *Muraena,* flying fish, sea horse, cod, barracuda, mullet, mackerel, swordfish, tuna or tunny, bass, drum, perch, sunfish, parrot fishes, angelfishes, goby, flatfish or flounder, sole, triggerfish (see FILEFISH), globefish or angler (*qq.v.*).

ICHTHYORNIS, a group of extinct birds known from the Upper Cretaceous deposits (from about 70,000,000 to 130,000,000 years ago) or the Great Plains area of the United States (Kansas and Texas), now classified in the order Ichthyornithiformes. These flying birds, with strongly developed wings, were one of O. C. Marsh's notable discoveries, the two best-known species being about the size of the domestic pigeon. Marsh identified parts of a maxilla and a lower jaw bearing teeth set in sockets as belonging to this group of birds, an allocation that has led to considerable discussion. It is generally accepted now that these jaw fragments are those of a reptile, probably a small species of mosasaur (an extinct marine lizard). Indications are that Ichthyornis, like its modern relatives, lacked teeth.

The brain showed greater development than that of another extinct bird, Hesperornis, but still was smaller than that of modern birds. The vertebrae differ from those of other birds in being biconcave. The breastbone (sternum) is large, with a strong keel, and the wing bones are long and well developed, with the shoulder girdle similar in general type to that of living birds of strong flight. The legs were moderately strong with short shank (tarsus), fairly long anterior toes and a small, slightly elevated hind toe. The tail had a well-developed terminal plate of bone (pygostyle).

The indication is that these were birds of active flight, probably with webbed feet, in general form like modern gulls and terns. This resemblance, however, is superficial as the species are primitive, and are to be placed in the superorder Ichthyornithes, apart from the Neognathae, the modern birds.

Seven species are recognized in the genus Ichthyornis, of which *Ichthyornis* dispar and I. *victor* are known from partial skeletons and the others from fragments. These form the family Ichthyornithidae. Apatornis *celer* from western Kansas, placed in the family Apatornithidae, completes the list, the two families forming the order Ichthyornithiformes.

Though only two groups of birds are known from the Cretaceous — the divers, like *Hesperornis,* and the strong flyers, also probably of aquatic habit, like Ichthyornis — it is probable that the bird life of that period was more diversified. The two known are both highly specialized so that they stand alone and cannot be considered as directly ancestral to any of the known groups of birds which have been found in fossil deposits of later age or which are living.

ICHTHYOSAUR, an extinct sharklike reptile of the Mesozoic era (about 70,000,000 to 200,000,000 years ago) that showed far-reaching adaptations toward life in the seas and held much the same position in the marine community as do the toothed whales of today. As is true of the whales, the ichthyosaurs descended from animals that lived on land; however, in the course of their adaptation to life in the water, their bodies became so highly modified that it is virtually impossible to recognize their ancestry.

SKELETON WITH OUTLINE OF BODY OF THE EXTINCT MARINE REPTILE STENOPTERYGIUS QUADRICISSUS, ICHTHYOSAUR FROM THE LOWER JURASSIC OF HOLZMADEN. GER.

Intact skeletons of ichthyosaurs are known from a number of famous localities in Europe and North America, but the most interesting specimens come from Boll-Holzmaden in southern Germany., where skeletons of Stenopterygius often occur with remains of the skin preserved (see fig.) and with embryos or eaten young in the abdominal cavity. Their mode of reproduction (bearing live young from eggs hatched in the body) and their food (belemnites — relatives of the cuttlefish — and fish), as well as their at least occasional cannibalistic behaviour, have been inferred from the contents of the abdominal cavity.

The ichthyosaur body was thoroughly streamlined, pointed in front and ending in a vertical, membranous tail fin which was the principal organ of propulsion; the lower lobe of the tail fin was supported by the backbone. Along the mid-line of the back was a

large membranous fin acting as a keel during propulsion. The fore and hind limbs were modified as lobelike steering paddles supported by greatly shortened and flattened limb bones and additional finger and toe bones. All these features suggest that the ichthyosaurs swam in a way similar to the sharks, by beating the tail fin from side to side and by steering with the fore and hind paddles or fins.

The relatively large skull tapered into a slender, elongated snout; the large eyes were within a ring of bony plates. The jaws were armed with a large number of sharp, conical teeth that were set in individual tooth sockets in the early ichthyosaurs (e g., *Mixo*saurus) and in continuous tooth grooves in the later ones; some forms became practically toothless. The backbone consisted of short vertebrae with biconcave vertebral bodies. In *Mixosaurus* the end of the tail region of the backbone was almost straight; in the later forms it was bent sharply downward, a matter closely tied to the size and efficiency of the tail fin. This evolutionary change from straight to bent tail end seems to have occurred to some extent during the growth process of individuals as demonstrated in specimens of young and old *Stenopterygius*.

Although most ichthyosaurs were of moderate size, even some of the earliest ones attained a length of 25 ft. Toward the end of the Mesozoic era just prior to their extinction, ichthyosaurs reached nearly world-wide distribution.

W. Williston, *Water Reptiles of the Past and Present* (1914); Bernhard Hauff, *Das Holzmadenbuch* (1953), containing superb photographs of ichthyosaurs. (R. ZL.)

ICHTHYOSIS (XERODERMA), a general thickening of the skin and marked accumulation of the epidermic elements, with atrophy of the sebaceous glands, giving rise to a hard, dry, scaly condition. This disease generally first appears in infancy and is probably congenital. It differs in intensity and in distribution, and is little amenable to treatment. (F. L. A.)

ICKES, HAROLD LE CLAIR (1874–1952), U.S. secretary of the interior under Pres. Franklin D. Roosevelt, was notable as a political reformer, conservationist and peppery controversialist and diarist. Born March 15, 1874. in Frankstown township, Pa., he was active in Chicago politics even before his graduation from The University of Chicago in 1897. After receiving his law degree in 1907, he entered the legal profession, frequently handling civil liberties cases without pay; he also fought for municipal reform and the curbing of public utilities. Nominally he was a Republican but he frequently bolted the party, most notably when he supported Theodore Roosevelt's Bull Moose candidacy in 1912 and Franklin D. Roosevelt's New Deal in 1932. Roosevelt, seeking a Republican progressive for his cabinet, turned almost by accident to Ickes after two prominent senators had declined the position. Ickes was 58 at the time, and has been described as "a rather thickset bespectacled vigorous man." He made the most of his position, becoming one of the most energetic members of the Roosevelt cabinet. As secretary of the interior he fought for the preservation of natural resources against what he considered to be unfair exploitation by private interests.

He was also in charge of the Public Works administration, which during the New Deal spent over $5,000,000,000 on federal and nonfederal public works, ranging from municipal buildings to the enormous federal dam projects in western states. Ickes, who was dubbed "Honest Harold," in 1933 went about the spending of the money so carefully that the projects were very slow getting under way. Consequently the program did not have the desired effect of putting large sums immediately into circulation to prime the economic pump and help pull the nation out of the depression. Late in the New Deal heavy expenditures for construction did significantly stimulate the economy and left the nation enriched with numerous useful permanent structures. During World War II Ickes added to his other duties the administration of petroleum, coal mines and fisheries. In presidential campaigns he became known as "Roosevelt's hatchet man" because of his colourful attacks upon the Republican candidates; between campaigns he feuded with almost equal vigour with several of his Democratic colleagues, and in his lively diary, published after his death (The Secret Diary of Harold L. Ickes, 3 vol.. 1953–54), recorded trenchant opinions of many others. He resigned Feb. 13, 1946, after a dispute with Pres. Harry S. Truman, and died in Washington, D.C., on Feb. 3, 1952. (FK. F.)

ICKNIELD WAY, the name, first recorded in the 10th century, of an unmetaled track which led from the eastern side of the Wash to the Berkshire downs and which was of great importance in prehistoric and early historic times. Beginning near Brancaster and following approximately a line marked by Swaffham. Thetford, Newmarket and Royston, it traverses the lower slopes of the Chilterns and crosses the Thames at Wallingford and at Goring. On Royston heath its several tracks span a width of a quarter of a mile. Because it was one of the four privileged roads in the late Anglo-Saxon period, its name came to be applied to other roads. The etymology of the name is uncertain. Sometimes it occurs in the form Ricknield street which arises from Middle English at there Ikenilde strete and which by wrong division of words became at the Rikenilde strete. (P. H. BR.)

ICON, generally any image or portrait figure. The word is specially applied to the representatives in the Eastern Church of sacred personages, which are either flat paintings or in very low relief, sculptured figures being forbidden. (See BYZANTINE ART.)

The term "iconography," once confined to the study of engravings, is now applied to the history of portrait images in Christian art, though it is also used with a qualifying adjective of Greek, Roman and other art.

ICONIUM (mod. KONYA, KONIA), a city of Asia Minor standing on the edge of the semidesert plateau of Lycaonia, backed on the west by the Pisidian mountains. The indigenous inhabitants were Phrygian in speech and culture. With the extension of Hellenic civilization in the time of the Seleucids, the place was gradually Hellenized and became a self-governing city, largely Greek in language, education and culture. It was probably among its Phrygian section that the Jewish community stirred up opposition to Paul on his first visit of A.D. 47 or 48. He returned in 50 and 53.

From 25 B.C. td the end of the 3rd century A.D. it was included in the Roman province of Galatia. In about A.D. 297 it was probably taken as the capital of the province Pisidia, and on the division of this province in about A.D. 371–72 it became the capital of the province Lycaonia. In later Byzantine times Iconium was the headquarters of the Anatolic theme (province). It was conquered by the Seljuk Turks about A.D. 1072, and in 1099 they chose it as their capital. See also KONIA; JALAL-UD-DIN RUMI. (WM. C. B.)

ICONOCLASTS, breakers of images, a name applied A.D. 726–842 to the opponents of the use of images in Christian worship. (See BYZANTINE EMPIRE.)

At the period of the Reformation (*q.v.*) the name was given to those who advocated the destruction of images in the churches.

ICONOSTASIS, the screen in a Greek, Russian or Armenian church, which encloses the sanctuary. It is generally of masonry, high enough to reach the spring of the vault, and extends into the body of the church as far as the easternmost nave pier. In its nave front there are usually three doors. The face of the screen is often decorated with many tiers of small arcades; each arch encloses the representation of a saint. In Russian churches only the hands, feet and faces of the painted representation or icon are exposed; the rest of the panel is covered with elaborate, engraved, embossed metalwork. In earlier times in Greece, however, the entire image was painted.

ICTERUS, a genus of birds belonging to the family Icteridae, intermediate between the finches (*q.v.*) and starlings (*q.v.*); many of them are called troupials; others are known as the American grackles (*q.v.*). One of the best-known species is Icterus *spurius*, the orchard oriole, an inhabitant of northern South and Central America and the United States. Very many species exist in the neotropical region, though a few migrate northward in summer. They are nearly all gregarious, many of them with loud and melodious notes, rendering them favourites in captivity. Some have a plumage wholly black, others are richly clad; the well-known Baltimore oriole, golden robin or hangnest

of the United States, *Icterus galbula,* has plumage of brightly contrasted black and orange, the tinctures of the armorial bearing of Lord Baltimore, the original grantee of Maryland. The most divergent form of Icteridae seems to be that known in the United States as the meadow lark (*q.v.*), *Sturnella magna,* while the bobolink (*q.v.*) or ricebird with its buntinglike bill is not much less aberrant. There are about 88 species in the family Icteridae, mostly in South America, of which only 10 genera and 21 species reach the United States. *See* BLACKBIRD, RED-WINGED; COWBIRD; ORIOLE.

BALTIMORE ORIOLES COMPLETING NEST THE CONSTRUCTION OF THEIR

ICTINUS, Greek architect of the 5th century B.C., was the architect of the Parthenon at Athens, of the Hall of the Mysteries at Eleusis and of the temple of Apollo Epicurius at Bassae, near Phigalia.

IDA (d. 559), first king of Bernicia. became king in 547, soon after the foundation of the kingdom by the Angles. He built the fortress of Bebbanburh (Bamborough), and after his death his kingdom, ahich did not extend south of the Tees, passed in turn to six of his sons. The surname of "flame bearer," sometimes applied to him, refers not to Ida but to his son Theodoric (d. 587).

IDA, classical name of a mountain range in northwest Asia Minor, at the head of the Gulf of Adramyttium (Edremit) and a short distance to the southeast of the site of ancient Troy. Its highest peak, about 5,000 ft., provides a view of the Marmara and Aegean seas, and from its heights, it is said, the gods witnessed the battle between the Greeks and Trojans. It was known as a classic shrine and is famous in mythology as the site where Paris passed judgment on the rival goddesses and as the scene of the rape of Ganymede. Its modem name is Kaz Dagi. Ida is also the classical name of a mountain traversing the island of Crete and site of a cave where Zeus was said to have been reared. The mountain is associated with the worship of Zeus, and relics of the classical Greek period, found there in cave excavations, substantiate the view that it was a shrine of the period. It is known as Psiloriti.

IDAHO, popularly known as the "Gem state," in the Pacific northwest of the United States, occupies most of the southern and northwestern part of the area enclosed by 42° and 49° N. and 113° 03' and 117° 16' W. To the north lies British Columbia, which Idaho borders for 45 mi. To the east are Montana and Wyoming; to the south, Utah and Nevada; and to the west, Oregon and Washington. Idaho extends nearly 315 mi. on its southern boundary and over 483 mi. from north to south, but an irregular northeastern mountain boundary limits Idaho's area to 83,557 sqmi. Thirteenth in size among the states of the United States, Idaho is about as large as England and Scotland combined or nearly twice as large as the New England states. The capital is Boise. Idaho became the 43rd state in the union in 1890. The state flower is the syringa. The state bird is the mountain bluebird.

The word Idaho as a name for the territory apparently originated in Washington, D.C., early in 1860 as a suggested name for Colorado; a dozen Indian language derivations for the name have been offered, but none of them has been substantiated.

PHYSICAL GEOGRAPHY

Physical Features.— Idaho's terrain is marked by startling diversity. Almost all physical features typical of the United States, except seacoast, may be found somewhere in Idaho: broad valleys and rugged mountains, arid plains and green prairies, sagebrush deserts and humid forests, spectacular canyons, great waterfalls, volcanic deposits and old limestone coast lines, major rivers and wandering streams that sink into the lava, gentle hills and glaciated peaks, sand dunes and hot springs, natural lakes and artificial reservoirs, range land and all types of farms: dry, irrigated and naturally watered.

All of Idaho is in the Columbia river basin, except the southeastern corner, which is drained by the Bear river flowing into the Great Salt lake basin. Most of the state is tributary to the Snake river and consists of a series of steep mountain masses and ranges running north and south. The highest peak is Mt. Borah (12,662 ft.), in the Lost river range. But across southern Idaho from east to west the broad valley of the Snake curves in a great geologic down warp that cuts across the bordering mountain ridges, which are buried in the valley. The valley surface—a series of geologically complex lake beds and lava flows—is furrowed by a number of almost unbelievably deep and narrow canyons. Within the canyons are spectacular waterfalls, the most notable being Shoshone falls (212 ft.) and Twin falls. Turning north, the Snake flows along Idaho's western boundary through Hell's canyon (*q.v.*)—the deepest gorge in North America—and then turns west to the Columbia. The Salmon river and Clearwater mountains, together with their attendant river canyons, form a barrier to transportation that has divided the state into sections. Most of northern Idaho is mountainous also, but elevations are lower. Three of the state's four large lakes, Coeur d'Alene, Pend Oreille and Priest, are in northern Idaho; the other, Bear lake, is in the southeast corner. Other natural attractions include Soda springs near Bear lake, and the magnificent Sawtooth range, with its multitude of alpine lakes, in the Sun valley area.

Climate.— Idaho's climate is as diverse as its physical features. Altitude, more than latitude, determines the climate: Lewiston, in north Idaho, is the warmest place in the state. Western prevailing winds from the Pacific are mild but are robbed of most of their moisture by the Cascade mountains before reaching Idaho. Mountain barriers on the east protect the state from cold waves that sweep down the Great Plains. Most of the mountain wilderness has cool summers and severe winters; the populated valleys, however, generally are mild in climate. Temperatures range from 108° to −45° F.; the mean annual temperature varies from about 36° F., with the coldest region centring in Custer county around the Sawtooth range, to 55° F. along the middle reaches of the Snake river. Annual rainfall varies even more than temperature, averaging 25 in. in the north and 8 in. on the dry plains of the south. Tornadoes are virtually unknown.

Soil.— Most Idaho soils are volcanic in origin, high in lime and potash but low in nitrogen and organic material. The deficiencies are easily overcome by plowing in alfalfa and clover. The windblown soils of the Palouse region, which straddles the Idaho-Washington boundary, are of special note, being fine and light and easy to till.

Vegetation.— Idaho's diversified climate produces a corresponding diversification in vegetation. Arid southern plains support only such plants as sagebrush, greasewood and salt grass. Greater precipitation in the north makes possible heavy evergreen forests of pine, cedar, fir and spruce, which extend southward into these higher altitudes where late-melting snow provides moisture. Deciduous forests are almost unknown, but a startling variety and profusion of colourful flowers—camas, columbine, mountain daisy, to name a few—may be found almost everywhere in the spring.

Animal Life.— Buffalo roamed the upper Snake river plains until 1840, but since then the deserts have been given over mainly to coyotes and hosts of jack rabbits. Beaver are historically important in Idaho because they attracted the trappers. Although relatively few in number, they are holding their own under careful state supervision. Weasels (ermine), mink and martens are fairly common. Badgers are plentiful, otters quite rare and wolverines on the brink of extinction. All of the following large mammals are found: elk, moose, white-tailed deer, mule deer, pronghorn, bighorn, black bears, grizzly bears and coyotes.

Ignoring common birds. there are ducks, geese, sage grouse, sharptails, pheasants, quail and doves. Hawks, owls, eagles, vultures, crows, ravens and magpies are common. The principal snakes include the Rocky mountain rubber boa, wandering garter, bull snake and prairie rattlesnake.

Parks and Recreation Areas.—There were 26 state parks and recreational areas, many historic as well as scenic, which constituted the state park system when a major development program was undertaken in 1958. Craters of the Moon National monument, established in 1924, is the product of Snake river lava flows as late as 200 to 1,000 years ago and is an awesome example of the result of volcanic activity.

Sun Valley.—This is a delightful valley located on Big Wood river, which drains a portion of the rugged Sawtooth mountains. The area was developed by Union Pacific railway officials because of the beautiful scenery, ample fine snow pack and calm weather. In about 20 years Sun Valley became world famous as a winter resort.

Primitive *Areas.*—In 1931 the state legislature passed the Primitive Area act, which reserved 1,250,000 ac. across the southern watershed of the Salmon river as a primitive area. Primitive conditions are expected to prevail because roads and buildings are prohibited.

Another area as large and nearly as primitive may be found on the Selway-Bitterroot drainage; there are several additional areas of this type. Idaho is one of the last frontiers in this respect.

HISTORY

What is now the state of Idaho was originally in Oregon country, claimed in turn by Spain, Russia, Great Britain and the United States, the last two settling, by treaty in 1846, on the 49th parallel as the northern U.S. border. Oregon territory (1848) included the present state of Idaho, as well as what is now Oregon, Washington and part of Montana. A half century of exploration and fur trade preceded white settlement which began in 1860. By the time Idaho reached the political maturity of statehood in 1890, there had begun a gradual shift from a primarily mining and stock-raising economy to a farming and lumbering one. Industrial development, confined almost entirely to mining in the 19th century, began to diversify after 1900 and to expand rapidly after 1940.

Explorers who came to Idaho at the beginning of the 19th century found practically the entire area occupied by Indian peoples of diverse language and seminomadic culture, notably the Shoshone and the Bannock in the south, and the Nez Perck, Pend d'Oreille and Kutenai in the north. Horses acquired from the Spaniards had given them mobility soon after 1700. Lewis and Clark from the United States, whose explorations through the Oregon country (1805–06) were the main basis for the U.S. claim, and the fur trader David Thompson from the British Northwest company (1808–12) established friendly relations with the Indians, and Thompson erected the first fort Kullyspell (Kalispell) house on Lake Pend Oreille in 1809. Other fur trappers soon entered Idaho. Andrew Henry of the Missouri Fur company crossed the continental divide into the valley of the upper Snake in order to escape from hostile Blackfeet warriors near the three forks of the Missouri and put up Ft. Henry, a temporary winter shelter, in 1810. John Jacob Astor's overland party from St. Louis to the Pacific crossed southern Idaho in 1811. The Astor enterprise failed, however, and was sold out to the Northwest company, for whom Donald Mackenzie organized the annual Snake river brigade that trapped in southern Idaho from 1818 to 1832. The U.S. gave up the region during the War of 1812, and Great Britain controlled it until the treaty of 1846.

A new era in the fur trade commenced in 1821, with reorganization of operations of the Hudson's Bay company (successor to the Northwest company) and with penetration of St. Louis mountain men under Jedediah Smith into the Snake country. Competition was sharp, and the British sent Peter Skene Ogden to trap the Snake country bare so that the mountain men would be kept away from rich beaver lands in British Columbia. Overexploitation, together with a style shift from fur to silk hats, reduced the fur industry to a small operation. At the end of the fur trade, the British company had two important Idaho posts—Ft. Hall (built in 1834 by Nathaniel J. Wyeth of Boston, but soon sold to the Hudson's Bay company) and Ft. Boise. The missions of Henry Harmon Spalding among the Nez Percé after 1836 and of Father Nicholas Point among the Coeur d'Alenes after 1842 grew out of the fur trade, which declined after 1840 with the coming of a large immigration through Idaho over the Oregon trail. A Mormon Salmon river mission at Ft. Lemhi (1855–58), followed in 1860 by Mormon settlement of Franklin and by a gold rush to northern Idaho, marked the transition from the wanderers of the fur trade to permanent white settlement.

Thousands of miners rushed to the Clearwater and Salmon river country after Elias Davidson Pierce's party discovered gold at Pierce on Sept. 30, 1860. Fabulous reports from Florence a year later brought in more than 10,000 prospectors. Important new discoveries in the summer of 1862 expanded the mining regions by hundreds of miles and thousands of men, and on March 4, 1863, Idaho territory was created to include all the new mines in what until then had been eastern Washington and western Dakota. (Until May 26, 1864, Idaho territory included all of Montana and practically all of Wyoming; final boundaries were not established until 1868.)

More than 32,000 miners, merchants, packers and farmers lived in the newly organized territory. Over one-half of them were in the Boise region, and another one-third in what soon was to be Montana. Continuation of the gold fever kept the mining population high in southwestern Idaho through the early years of the territorial period, and in 1864 Boise became the permanent territorial capital, as it later was of the state.

Quartz mining—both of gold and silver—became prominent in the Boise basin, Rocky Bar and Silver City in 1864 and at Atlanta and Warren shortly thereafter. A complex mining economy developed, with problems of capital and labour and with an advanced industrial technology. Quartz mining was relatively permanent in nature; farm and service communities grew up in irrigated valleys, and range cattle were driven in from California and Texas to form the basis for large Idaho herds.

Expansion of white occupation of Indian lands—particularly for cattle ranging—led to friction and hostility with the Indians. Three wars (Nez Percé, 1877; Bannock, 1878; and Sheepeater, 1879) resulted. Certain Nez Percé bands, forced to move onto the reservation in June 1877, became embroiled with white ranchers; the Indians crushed a U.S. army force at White Bird and then fought the battle of the Clearwater on nearly even terms with a force commanded by Gen. O. O. Howard. Deciding to join their friends the Crows of Montana, the Nez Perck made a hard journey over the mountains, only to have to beat off forces under Col. John Gibbon at the battle of Big Hole. Chief White Bird and many of the warriors eventually took refuge in Canada, but Chief Joseph finally made a deal with General Howard to return to the Idaho reservation—a bargain which the U.S. failed to keep.

In 1878 the Bannock Indians, disturbed by white intrusion into their lands on Camas prairie in southern Idaho, went on the warpath; after military defeat at South mountain, they wandered over much of eastern Oregon before returning across southern Idaho into Wyoming before capture. Finally the Sheepeaters, who inhabited the Salmon river mountain wilderness, were rounded up in 1879 after they had been accused (perhaps unjustly) of massacring a settlement of Chinese miners on remote Loon creek.

Improved transportation, so necessary for large-scale quartz and base-metal mining, came with the construction of railways. By 1880 the Utah and Northern had been completed across southeastern Idaho; the Oregon Short Line was completed through the Snake river valley in 1884; and the Northern Pacific crossed north Idaho at the same time. Thus it was possible to develop important lead-silver mines on Wood river and in the Coeur d'Alene mountains. Idaho grew rapidly with the new mining and railways, and the consequent expansion of irrigation, after 1880. Admission as a state came on July 3, 1890, after a scheme to divide the territory between Washington and Nevada had been rejected at the end of a long and bitter north-south sectional controversy.

Idaho was one of the most prominent of western silver states and voted Populist in its first national presidential election in 1892. The more radical Populist element of the Coeur d'Alene mining district, however, became involved in a long series of labour wars (1892–99) that culminated in the dynamiting of the Bunker Hill and Sullivan concentrator at Wardner, April 29, 1899. pression of the union, the Western Federation of Miners, followed during a two-year period of martial law. A shocking aftermath of the Coeur d'Alene labour war came six years later with the assassination of former Governor Frank Steunenberg by Harry Orchard, one of the disaffected miners. National leaders of the federation were arrested for conspiracy in the case. Newly elected Senator William E. Borah gained a national reputation as prosecutor during the resulting trial and acquittal of William D. Haywood, secretary of the federation and organizer of the Industrial Workers of the World (I.W.W.). Borah continued to be Idaho's most prominent political figure until his death in 1940.

At the beginning of the 20th century an important commercial lumber industry began to develop, especially in the valuable white-pine forests of northern Idaho. Ponderosa pine also was utilized commercially, and lumbering gained a position second only to agriculture in economic importance. Irrigation in Idaho expanded dramatically at the same time. Co-operative and private canal systems proved successful in the upper Snake river valley, settled primarily by Mormons moving northward from Utah. Canal companies in the Boise area, though, were unable to develop the major projects with success, and farmers' irrigation districts took over. In the Twin Falls region important projects carried on under the provision of the Carey act (1894) turned large tracts of sagebrush desert into fertile irrigated farms between 1902 and 1908; establishment of the Boise and the Minidoka projects under the United States reclamation service led to the construction of important dams with large reservoirs (Arrowrock, American Falls, Anderson Ranch, Palisades), so that by the second half of the 20th century roughly half of Idaho's potentially irrigable land had been reclaimed, and miles of farms existed where a desert had been before.

GOVERNMENT

Idaho's constitution, adopted Aug. 6, 1889, was detailed and codelike in nature; it therefore has required frequent amendment. A legislature meets every two years for 60 days, with special sessions at the call of the governor. There are 44 senators and 59 representatives, whose districts have close correspondence to the state's urban-rural population distribution. A supreme court, district courts, county probate courts and precinct justice's courts comprise the judiciary. A governor, lieutenant governor and six other elective officers, together with a large number of administrators, make up the executive branch. A reorganization in 1919 consolidated most state agencies into departments under the governor, but subsequent alterations again gave the state administration a more complex pattern.

The state operates on a biennia1 budget: departmental requests are screened by the state budget officer, who is advised by an interim prelegislative budget committee of the outgoing session; a report is released six weeks before the new legislative session convenes. The governor presents his final recommendations on the fifth legislative day. All funds are subject to legislative appropriation and to strict budgetary control; actual expenditures from the general fund are authorized by the state board of examiners, made up of the governor, secretary of state, auditor and attorney general, in accord with the pattern of actual anticipated state income.

Local government in Idaho is decentralized. More than half of the nearly 850 units which existed in the second half of the 20th century were special districts: cemetery, highway, irrigation, drainage, soil conservation, etc. More important were the 44 counties and 199 municipalities.

POPULATION

At the time Idaho was admitted as a state the population was 88,548; in 1910, 325,594; in 1940, 524,873; and in 1960, 667,191. In the second half of the 20th century the population was distributed primarily along the Snake river and near the western boundary of north Idaho. The state was still predominantly rural (48.0% urban in 1960), but the farm population gradually was decreasing and the cities growing. Less than 3.3% were foreign-born in 1950, and only about ½% were Indians. There was an interesting Basque concentration in the Boise area.

EDUCATION

In Idaho, education started in the several Indian missions. In the fall of 1860 Hannah Comish taught the children of Franklin in her log cabin. Several years later. similar efforts were made in the mining towns. The office of territorial superintendent of instruction was created in 1864. Thereafter, the usual formal integrated organization of school districts was effected. Administration of the various state educational programs, higher education, elementary and secondary schools, and vocational education was assigned to the state board of education, established in 1913; local school management, however, remained under local school boards. Reorganization of school districts, provided for by statute in 1947, resulted in a 40% decrease in the number of schools, and in the consolidation of 1,088 districts into 168 within a decade. Economies gained in consolidation, together with greatly increased state appropriations, made possible a rise in average salaries for teachers from $1.190 in 1942 to more than $4,000.

Schools of higher learning include the University of Idaho in Moscow (1889), the College of Idaho at Caldwell (1891), Idaho State college in Pocatello (1901), Northwest Nazarene college at Nampa (1913) and Magic Valley Christian college at Albion (1958). There are also two-year institutions: Boise junior college (1932). Ricks college at Rexburg (1888), and Lewis-Clark Normal school, a branch of the University of Idaho, at Lewiston (1955).

Idaho State college consists of a liberal arts college, a teachers college and a professional and graduate school. It was incorporated as the Academy of Idaho in 1901, and the name was changed to Idaho Technical institute in 1915, to the Southern Branch of the University of Idaho in 1927 and to the present name in 1947. The school of trade and industrial education is a nonacademic division of the college. The Gniversity of Idaho, the state university and land-grant college, includes the colleges of agriculture, letters and science, engineering, law, mines, forestry, education, and business administration, and a graduate school. The Lewis-Clark Normal school is a division of the state university, offering a two-year program for elementary-school teachers.

HEALTH AND WELFARE

The state department of health administers a mental health service, two state mental hospitals. a tuberculosis hospital, a maternal and child health program, a crippled children's service, a dental health program and a public health nursing service. Water pollution control, milk and food sanitation and health education are additional activities of the department. The state department of public assistance has social service and child neliare divisions, and the department of labor and the state mine inspector are charged with industrial safety programs. The state board of corrections administers the state penitentiary at Boise and undertakes rehabilitation of prisoners.

ECONOMY

The shift to an agricultural economy is shown by the fact that in the second half of the 20th century one-third of the men em-

ployed in Idaho were in agricultural occupations; one-quarter were in transportation and trade; of the remainder, one-tenth were in manufacturing, and almost that many in construction. Seasonal variation in employment was pronounced. Industrial wages reflected the relatively small size of most of the state's industries. Per capita income for the state rose from $1,436 in 1951 to more than $1,500 by 1960.

The total labour force in 1950 was 218,309, with 18,989 and 15,501 engaged in manufacturing and construction, respectively. Idaho ranked lowest among the mountain states in per capita income because of an unbalance between the primary occupations of agriculture, forestry and stock raising vis-à-vis manufacturing, mining and construction. Greater industrial development was warranted by the resources.

Agriculture. — Agricultural production produced more income in Idaho in the second half of the 20th century than any other source, field crops making up more than 95% of the total, truck crops and fruits comprising the remainder. The major grain crops are wheat, barley and oats. Other important crops include hay, potatoes, beet sugar, dry beans, dry peas, clover seed and field corn. Crops of lesser importance include hops, alfalfa seed, onions and sweet corn; and green peas, apples, prunes, peaches, pears and cherries are the economically important fruits in Idaho.

Industry. — The growing shift to industry is shown by the fact that after livestock (primarily cattle and sheep) and dairy products in the second half of the 20th century, industry followed agriculture in value, being followed in turn by lumbering and mining. Industry in Idaho grew rapidly in the decade before 1950 and continued to rise. Phosphate plants in the southeast and the national reactor testing station at Arco — where atomic electric power was pioneered from 1951 to 1955 — were the main industrial development after World War II. The phosphorus industry developed markedly after 1950, with four large companies producing a variety of products.

Transportation. — Four transcontinental railways serve Idaho: the Union Pacific, the Northern Pacific, the Great Northern, and the Chicago, Milwaukee, St. Paul and Pacific. Mountain barriers separating northern Idaho from the rest of the state delayed completion of a paved north-south highway until 1938. Construction on Idaho's more than 600 mi. of the interstate system of completely unimpeded, controlled access highways began in 1956. Air transportation is especially important in linking Idaho's widely separated centres of population and in penetrating the extensive wilderness areas of the state.

Beal, *A History of Southeastern Idaho (1942)*; and Floyd R. Barber and Dan W. Martin, *Idaho in the Pacific Northwest (1956).* Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures, together with the current history, are summarized annually in the *Britannica Book of the Year,* American edition.

(M. D. B.; M. W. W.)

IDAHO FALLS, a city of southeastern Idaho, U.S., and the seat of Bonneville county, originated as Eagle Rock, a community that grew up at Taylor's Ferry (1863), later Taylor's Bridge, over the Snake river. Serving heavy traffic on the Salt Lake-Montana road, the town prospered as a division point on the Utah and Northern railway (1879) but declined with removal of the railway shops to Pocatello in 1887. Reorganized as Idaho Falls in 1890, the community flourished again: irrigated farming grew rapidly, and an early sugar factory came in 1903. Other agricultural industrial plants were installed, and Idaho Falls became the marketing centre for upper Snake river valley potatoes. Municipal generators utilize the hydroelectric potential of the falls, and headquarters for the national atomic reactor testing station are there. Idaho Falls also has a Mormon temple, built in 1937. For comparative population figures see table in IDAHO: Population. (M. D. B.)

IDAS, in Greek legend, son of Aphareus of the royal house of Messene, brother of Lynceus. In Homer (*Iliad,* ix, 556 *et seq.*), he is called the strongest of men on earth. He carried off Marpessa, daughter of Evenus, as his wife, and dared to bend his bow against Apollo, who was also her suitor. Zeus intervened and left the choice to Marpessa, who declared in favour of Idas, fearing that the god might desert her when she grew old (Apollodorus i, 60–61).

The Apharetidae are best known for their fight with the Dioscuri. A quarrel had arisen about the division of a herd of cattle which the four had stolen. Idas claimed the whole and drove the cattle off to Messene. The Dioscuri overtook him and lay in wait in a hollow oak. But Lynceus, whose keenness of sight was proverbial, saw Castor through the trunk and warned his brother, who thereupon slew the mortal Castor; finally Polydeuces slew Lynceus, and Idas was struck by lightning (Apollodorus iii, 134–137; Pindar, *Nem.,* x, 60; Pausanias iv, 3, 1).

According to others, the Dioscuri had carried off the daughters of Leucippus, who had been betrothed to the Apharetidae (Ovid, *Fasti,* v, 699; Theocritus xxii, 137). The scene of the combat is placed near the grave of Aphareus at Messene, at Aphidne in Attica, or in Laconia; and there are other variations of detail in the accounts (see also Hyginus, *Fab.* 80). Idas and Lynceus were originally gods of light, probably the sun and moon, and the herd of cattle (for the possession of which they strove with the Dioscuri) represented the heavenly bodies. The annihilation of the Apharetidae in the legend indicates the subordinate position held by the Messenians after the loss of their independence and subjugation by Sparta, the Dioscuri being distinctly Spartan, as the Apharetidae were Messenian heroes. The grave of Idas and Lynceus was shown at Sparta, according to Pausanias (iii, 13), whose own opinion, however, is that they were buried in Messenia. On the chest of Cypselus, Marpessa is represented as following Idas from the temple of Apollo (by whom, according to some, she had been carried off), and there was a painting by Polygnotus of the rape of the Leucippidae in the temple of the Dioscuri at Athens.

IDDESLEIGH, STAFFORD HENRY NORTHCOTE, 1ST EARL OF (1818–1887), British statesman, was born in London, on Oct. 27, 1818. On leaving Balliol college, Oxford, he became in 1843 private secretary to Gladstone at the board of trade. He was afterward legal secretary to the board; and after acting as one of the secretaries to the Great Exhibition of 1851, co-operated with Sir Charles Trevelyan in framing the report which revolutionized the conditions of appointment to the civil service. He succeeded his grandfather as 8th baronet in 1851. He entered parliament in 1855 as Conservative M.P. for Dudley and was elected for Stamford in 1858, a seat which he exchanged in 1866 for North Devon. Steadily supporting his party, he became president of the board of trade in 1866, secretary of state for India in 1867 and chancellor of the exchequer in 1874. In the interval between these last two appointments he had been one of the commissioners for the settlement of the "Alabama" difficulty with the United States, and on Disraeli's elevation to the house of lords in 1876 he became leader of the Conservative party in the commons. As a finance minister he was largely dominated by the lines of policy laid down by Gladstone; but he distinguished himself by his dealings with the debt, especially his introduction of the new sinking fund (1876), by which he fixed the annual charge for the debt in such a way as to provide for a regular series of payments off the capital. His temper as leader was, however, too gentle to satisfy the more ardent spirits among his own followers, and party cabals led to Sir Stafford's transfer to the Lords in 1885, when Salisbury became prime minister. Taking the titles of earl of Iddesleigh and Viscount St. Cyres, he was included in the cabinet as first lord of the treasury. In Lord Salisbury's 1886 ministry he became secretary of state for foreign affairs, but the arrangement was not satisfactory, and his resignation had just been decided upon when on Jan. 12, 1887, he died suddenly at Salisbury's official residence in Downing street.

His second son, STAFFORD HENRY NORTHCOTE, 1st Baron Northcote (1846–1911) was appointed governor of Bombay (1899–1903), being created a peer in 1900. Lord Northcote was appointed governor general of the Commonwealth of Australia in 1903 and held this post till 1908. He married in 1873, Alice,

adopted daughter of the 1st Lord Mount Stephen.

IDDINGS, JOSEPH PAXSON (1857–1920), U.S. petrographer, who demonstrated the genetic relationships of igneous rocks formed during any one period of igneous activity within a region, was born in Baltimore, Md., on Jan. 21, 1857, and received his education at Yale, Columbia and Heidelberg universities. He was assistant geologist (1880–88) and geologist (1888–92) with the United States geological survey; in 1892 he became associate professor and, from 1895 to 1908, professor of petrology at The University of Chicago.

In his technical papers he emphasized the textural and chemical graduation of rocks and recognized the role of water in magmas. He concluded that physical conditions affect the essential mineral composition of rocks as well as their crystalline texture and that variations in crystallinity depend upon temperature and rate of cooling, and so contested the widely held opinion that granular rocks necessarily hardened at great depths and in very large masses.

Iddings worked with other petrographers on "Quantitative Classification of Igneous Rocks," published in the Journal of Geology (1902) and later as a book, and his important Igneous Rocks, in two volumes, appeared in 1909–13. His other publications include Rock Minerals (1906) and The Problem of Volcanism (1914). Iddings died at Brinklow, Md., on Sept. 8, 1920.

(M.A.F.; C. L. FE.; X.)

IDE, HENRY CLAY (1844–1921), U.S. diplomat and representative in the Samoan and Philippine Islands, was born at Barnet, Vt., on Sept. 18, 1844. Ide graduated from Dartmouth college, Hanover, N.H., in 1866, and later was a secondary-school principal at St. Johnsbury, Vt., and Arlington, Mass. Admitted to the Vermont bar in 1871, Ide was state's attorney in Caledonia county and served in the Vermont senate from 1882 to 1885.

In March 1891 he was appointed U.S. land commissioner in Samoa, where he won the praise of Robert Louis Stevenson for his "capacity, moderation, tact, and temper" before leaving Samoa in November of that year.

Under the joint appointment of the United States, Great Britain and Germany, he was chief justice of Samoa from 1893 to 1897.

From 1900 to 1906 Ide served in various official capacities in the Philippine Islands, including the offices of acting governor and governor general in 1905–06. He played an important role in framing new laws on civil procedure and internal revenue and in the reform of the currency of the Philippines.

In 1909 he was appointed U.S. envoy extraordinary and minister plenipotentiary to Spain. He held that position until 1913, when he returned to St. Johnsbury. Ide, who was a director of a number of banks and railway and manufacturing companies, died on June 13, 1921.

A Life of Henry Clay ***Ide*** (1935) was printed privately by the author, A. F. Stone.

IDEA. This word, brought into English from the Greek, was for some time most commonly used roughly in the technical sense (or senses) given to it by Plato in his theory of forms (see UNIVERSAL). But by the 17th century it had come to be used more or less in its modem sense of "thought," "conception," "concept"; sometimes of "belief"; sometimes of "intention" or "plan."

In the 17th and 18th centuries the word "idea" was in very general use as a technical term of philosophy, not with its Platonic meaning, but in a variety of senses mostly traceable to Locke, some of which were derived by him from Descartes. Locke introduces it first as "that term which, I think, serves best to stand for whatsoever is the object of the understanding when a man thinks" and later as signifying "the immediate object of perception, thought, or understanding." But this vague usage leads him into serious difficulties. In the first place, he holds that ideas are "in the mind"; so that, if ideas are said to be the objects of perception, he is faced with the problem of explaining how perception of things in our minds could lead us to knowledge of the "external" world. Secondly, he is led to overlook the important respects in which thinking and understanding must be distinguished from perception: he speaks indeed as if thinking and understanding really are essentially forms of perception, or as if all three consisted alike in "having ideas." George Berkeley retained the word "idea," with which he sometimes used "sensation" as a synonym, to stand for the objects of perception; he retained the view that ideas are "in the mind"; and he sought to evade the problem which Locke had failed to solve—the problem of founding our knowledge of the material world on perception of mind-dependent ideas—by refusing to draw any distinction between ideas and material objects. Material objects, he held, are "collections" of ideas, and hence they too can exist "only in the mind."

Hume introduced a distinction between ideas and impressions—the latter term being designed to cover "all our sensations, passions, and emotions," the former "the faint images of these in thinking and reasoning." In so doing, however, he did not much improve upon Locke: he still held that the objects of perception are "in the mind" and for the most part he retained in his account of thinking the fatally misleading analogy with perception. It was urged by an early critic, Thomas Reid, that most of the perplexities in which Locke, Berkeley and Hume had been entangled arose from initial confusions in the use of the word "idea," for which he thought Descartes ultimately responsible; and even though it can hardly be adequate to trace all difficulties to this one source, it can certainly be said that their uses of the term "idea" require very close and critical scrutiny, if their problems are to be resolved or even rightly understood.

See also IDEALISM; KNOWLEDGE, THEORY OF; and PSYCHOLOGY.

(G. J. WK.)

IDEAL means primarily that which is of the nature of an idea. It is, however, more commonly used to denote that which is perfect or supreme of its kind. See IDEA; IDEALISM.

IDEALISM is the name of a group of distinct but allied philosophical theories all of which agree (1) in denying that mind has originated from or may be reduced to matter and (2) in affirming that mind is a more fundamental feature of the universe than matter is. Some writers (*e.g.,* Marxists) define philosophical idealism as the view that mind is primary and matter secondary, but this would not clearly distinguish it from theism, the view that matter and finite minds were created and are sustained by an eternal, infinite and immaterial deity. It is thus convenient to adhere to the more common practice of regarding idealism as the philosophy which not only denies the truth of materialism and asserts the reality and importance of mind but also maintains either that matter does not exist at all or else that, if it does exist, it is more closely dependent on the existence of mind than it need be by the sole fact of having been created by God. Like theism, idealism is a religious philosophy, as any philosophy must be which regards the material world as somehow less real than the world of mind or spirit. But although idealists all seek to establish a view of the world that lays the foundations for a rational religion, they are not all committed to belief in a personal God or, indeed, to belief in God at all.

In what follows, the word "idealism" and its different meanings will be considered first. Then, since idealism is a group of modern philosophical views associated in its beginnings particularly with the arguments of George Berkeley, the survey is begun with a brief account of his system. The third section is a short account of phenomenalism, a theory about the material world that is briefly indicated in Berkeley's writings, but which was subsequently developed in ways that bring it into conflict with the religious aspects of idealism properly so called. Next, Immanuel Kant's transcendental idealism is discussed; and finally, after a fifth section on the absolute idealism of the 19th century, the article closes with a discussion of the main criticisms that have been brought against idealism.

Origin and Use of the Term.—The word "idealism" is derived from the' Greek word idea, which means, in untechnical language, a visible form or the look or appearance of something. This word became a technical term in the philosophy of Plato, who used it to mean a universal by contrast with particulars, or a standard, limit or ideal by comparison with the particular things which merely approached or approximated to it.

1. The word "idea," then, was first used in philosophy to mean Platonic ideas; *i.e.,* suprasensible universals or forms held to be

truly apprehended by the intellect and contrasted with particular things deceptively presented to the senses. In this sense Beauty Itself or Absolute Straightness are ideas in contrast with the particular things that may appear beautiful in one context and ugly in another, or with the more or less but never perfectly straight lines that we see or feel by our senses.

2. "Idea" was used in the 16th and 17th centuries for a form or shape impressed by a hard object upon some soft material, as when Descartes (in his *Rules for the Direction of the Understanding,* xii) wrote of "shapes or ideas" formed in the brain by things outside the body as if by the action of a seal on wax.

3. "Idea" was also used for a supposed representative *in the mind* (not in the brain, which is, of course, material) of an external object perceived by means of this representative. Descartes, in *Meditation III* contrasts such ideas, which, he says, "are, as it were, pictures of things," with activities of the mind such as acts of will and assertions. To perceive a man or the sky was, according to Descartes, directly to perceive such a representative idea in the mind, so that material things were never perceived except indirectly.

4. Not all of these picture ideas, however, are copies of something external to the mind, and according to Descartes we also have ideas such as that of a chimaera formed by combining at will ideas of colour and shape originally received from the senses. Such ideas were called ideas of the imagination.

John Locke, by frequent use in his *Essay Concerning Human Understanding* (1690) of the word "idea" in sense 3, gave wide currency to the theory that external objects cannot be directly known but must be known indirectly by means of representative ideas that are themselves directly perceived and exist only in the mind Locke and his followers were called "ideists" by contemporary critics, and the theory of representative ideas "the new way of ideas." In this philosophical usage, ideas are contrasted with material objects, are likened to pictures or images and are said to exist "in the mind." Usage 2, however, encourages the belief that they are somehow impressed *on* the mind as if by physical pressure, and usage 1, lingering alongside usage 3, made it possible to think of them also as objective existences just as independent of perception as Plato's ideas were. But the fact that ideas in sense 3 exist "in the mind" makes it easy to assimilate them to ideas of the imagination which no one supposes to exist except while they are actually being experienced.

Now the word '(idealism." as most commonly used by philosophers, is based upon the word "idea" in sense 3. It is true that Leibnitz, when he wrote in 1702 that "what is good in the hypotheses of Epicurus and Plato, of the greatest Materialists and the greatest Idealists, is combined in my view" (*Werke,* ed. by C. J. Gerhardt. iv, p 560), appears to have had sense 1 in mind; but when the word came into general philosophical use about the middle of the 18th century, idealism was taken as the view that there was no material world but only ideas existing in immaterial minds. Thus Denis Diderot wrote in 1j49 *(Oeuvres,* ed. by J. Assézat, vol i, p. 304). "We call *idealists* those philosophers who, knowing only their own existence and that of the sensations that follow one another within them, do not grant anything else . . . a system which. to the shame of the human mind and of philosophy, is the most difficult to oppose although the most absurd of all. . . . Whether we raise ourselves to the skies, whether we go down to the bottom of the abyss, we never get outside ourselves. now that is the result of the first of Berkeley's dialogues and the foundation of his whole system." It will be noticed that Diderot attributed to Berkeley not only the view that we have direct knowledge of ideas only, but also the view that it is impossible to have knowledge of anything beyond one's own existence and one's own ideas. This latter view is today called solipsism, but in the 18th century it was called idealism or egoism *(see* the *Encyclopédie, s.v.* "Égoistes"). It will be seen, then, that we must begin with Berkeley, to whose philosophy, which was little understood in his lifetime. the name "idealism" was given.

Immaterialism. — Berkeley called his philosophical system immaterialism. In denying the existence of matefial substance he held that the universe consists of God, the infinite spirit, of finite active spirits, including, of course, human beings; of passive, inert ideas, which exist only "in the mind" of spirits; of the relations between all these; and of nothing else. He believed that his denial of the existence of material substance enabled materialism, scepticism and atheism to be refuted and the cause of religion to be more firmly established than hitherto. That this system, if true, refuted materialism is obvious. That it refuted scepticism, Berkeley held, followed from the fact that we are each certain of our own existence and of the ideas in our minds. Scepticism arises from the inevitable disappointment at being unable to get knowledge of something beyond these ideas. Atheism is refuted "by this simple reflection on the repugnancy included in supposing the whole, or any part, even the most rude and shapeless of the visible world, to exist without a mind." In Berkeley's view, what exists independently of finite minds must exist in God's mind.

The first step in the arguments leading to these conclusions had been taken by Descartes and Locke when they said that ideas which cannot exist apart from a mind's awareness of them are the immediate objects of perception. These philosophers had held that, whereas ideas of colours, sounds, tastes and smells (the so-called ideas of secondary qualities) were not, ideas of shape, size and movement (the so-called ideas of primary qualities) were copies of physical features of independently existing material things. Put in its briefest terms, Berkeley's argument was that, once it is granted that what we immediately experience are ideas or sensations (he used both words) and that our knowledge of the world is based on what we immediately experience, then we can form no conception of anything besides or beyond ideas or sensations and the minds in which they exist. If our knowledge of things in nature is derived from experience, he argued, then it is derived from ideas and cannot reach to anything fundamentally different from them, apart from the minds in which they exist. The very being of ideas is their being experienced, for just as it would be absurd to say that a pain could exist unfelt, so it is absurd to say that an odour could exist unsmelled, that a sound could exist unheard, that a feel could exist unfelt, or that a colour could exist unseen. Berkeley added the further argument that the very notion of something existing unexperienced is contradictory since it implies that something not experienced is experienced. He was, however, as anxious to avoid scepticism as he was to refute materialism, and he therefore argued that his denial of material substance was not a denial of the familiar world in which men know one another and come across all sorts of physical bodies. Although material substance does not exist. trees and rocks and cherries do, and these are nothing but "collections" of ideas. Since they are collections of ideas we know them directly, without any dubious intermediaries, and hence we have no cause for doubt concerning them. And as they exist independently of human will and appear to us in a regular order. they must be results of the Divine will and exist in the Divine mind when not perceived by humans.

Berkeley was anxious to accommodate his immaterialism to the beliefs of ordinary men, and he therefore stressed the differences between ideas of sense and ideas of imagination, pointing out that the latter are more under the control of the will than are the former and are less vivid and regular. Arthur Collier, however, in his *Clavis universalis* (1713), which seems to have been written in complete independence of Berkeley, stressed the likeness between ideas of sense and of imagination. He asserted that in denying the independent existence of a material world he was saying that bodies exist in mind in the way in which "objects seen in a looking glass, by men light-headed. ecstatic. etc." exist only in mind In order to prove that the objects perceived by sense are in the mind in the same way as are the objects of the imagination, Collier appeals to the fact that an imagined object may appear just as external to the mind as a perceived object. He sharpens the paradox which Berkeley had blunted.

The arguments for immaterialism which have so far been considered are, with one exception, based on an examination of sense experience and assume that sense knowledge is immediate and, as such, indubitable. The exception is the argument that the very

notion of unexperienced material substance is self-contradictory. Now Collier put forward further arguments to show that matter was a self-contradictory conception. He held, for example. that it can be proved both that the external world is finite and that it is infinite in extent, both that it is finitely and that it is infinitely divisible. From this he concluded that there is no more ground for believing that there is an external world than for believing that there is a triangular square. Leibnitz, too, upheld a version of the immaterialist thesis Starting from the assumption that, if something complex or containing parts exists (as it does), then there must be ultimate elements which are simple and without parts, he asked whether these ultimate simples could possibly be material. Now anything material, he argued, is necessarily divisible into parts which are themselves divisible into further parts, and so on *in infinitum*. Hence, he concluded, nothing material could possibly be an ultimate element of the world, but since there must be ultimate elements, they are necessarily immaterial. These ultimate immaterial elements of the world he called monads. Not all monads were held by him to be minds, but they were all mindlike rather than material, and hence Leibnitz' monadism (as it is called) is a sort of immaterialism. Now arguments such as these do not start from Berkeley's assumption that sense experience is reliable and fundamental. On the contrary, they show, if successful, that the view of the world suggested by sense experience needs to be corrected by philosophical thinking. Immaterialism, then, may be supported by the appeal to experience in the manner generally adopted by Berkeley, or by arguments which purport to show that experience is misleading, in the manner of Leibnitz. Those who, like Berkeley, accept the fundamental reliability of sense experience are called empiricists. Those who, like Leibnitz, hold that sense experience is misleading by comparison with properly conducted philosophical argumentation, are called rationalists. Thus immaterialism has been supported both by empiricist and by rationalist arguments.

Phenomenalism. — Berkeley's idealism was intended not only as a defense of religion, but also, as he put it in the title of his *Treatise Concerning the Principles of Human Knowledge* (1710), as a step toward removing "the chief causes of error and difficulty in the sciences." The denial of material substance, he thought, put out of the way a notion that could only cause confusion. On Berkeley's view, to say that a physical object, a tree, for example, exists is to say that if someone looks he will see certain colours and shapes, that if someone touches he will feel certain hardnesses and temperatures, and so on. Thus Berkeley defined material objects in terms of actual and possible sensations, that is, in terms of what is or may be directly observed. He held that this principle of defining entirely in terms of observed or observable entities should be extended to the natural sciences and even to mathematics. In following out this plan he endeavoured to show that the only genuine causation is that exercised by minds with wills and that what goes by that name in the physical world is nothing but a regular sequence of ideas or sensations. He argued, too, that there is no absolute or empty space, but that space is definable in terms of touch and felt movement. Thus within Berkeley's philosophy there may be seen the beginnings of a radical philosophy of empiricism. Hume later in the 18th century and J. S. Mill and Ernst Mach in the 19th detached this element from the religious part of Berkeley's philosophy in order to develop what they regarded as a consistent form of empiricism. Berkeley's view that material things are collections of ideas was thus transformed by Mill into the definition of matter as a permanent possibility of sensation; and Mach made ingenious attempts to show that atoms and other unobservables of the natural sciences were "economical ways of symbolizing experience" *(The Analysis of Sensatzons,* 1886). The view that statements about physical objects and statements about the unobservables of natural science are reducible to statements about actual and possible sense experiences is called phenomenalism. It occupies a somewhat uneasy position between idealism and materialism, although it is, in its general bearing, more akin to the latter than to the former. But insofar as the ultimates to which phenomenalism refers are ideas, sensations, impressions or (to use a 20th-century expression) sense data, and insofar as these, as items of immediate experience, seem to be unthinkable apart from some percipient, there is an immaterialist look about phenomenalism which it inherits from its idealist ancestry. *(See* also PHENOMENALISM.*)*

Transcendental Idealism. — It has been shown that there are two forms of immaterialism and that there are two different types of argument purporting to establish it: there is the empiricist form, which starts from the premiss that there is immediate acquaintance with mind-dependent ideas and concludes that the notion of material substances beyond these ideas and causing them is redundant; and there is also the rationalist form, according to which material substances could not possibly exist, or at any rate could not be ultimate features of the world. The empiricist form is held to be a consequence of the policy of limiting one's view of the world to what sense experience reveals. The rationalist form is an attempt to prove by rational deduction that there is some logical absurdity in the very notion of material substance, so that it is impossible that material substances should exist or should be more than appearances of ultimate immaterial substances. In this second line of argument the court of appeal is not sense experience but rational conceivability. Now it was argued by Kant, in his *Critique of Pure Reason* (1781), that *a* consistent empiricism leads to skepticism, for in mere sense experience the percipient would be passively immersed first in one and then in another sight or feel or smell or sound or taste without there being any memory of past or recognition of new ones. To this disconnected sensible phantasmagoria he gave the name "manifold of sense"; and the phrase "perceptions without concepts are blind" *(Critique of Pure Reason,* 1st ed., p. 51) expresses his view that acquaintance with particular items of this manifold would not constitute knowledge. On the other hand, Kant argued, philosophical rationalism in its extreme form (he sometimes called it dogmatism) is nothing but an uncontrolled play of concepts or mere thoughts. From a mere concept or thought it is possible only to deduce another concept or thought, not to draw conclusions about what exists in the world. The rationalists erroneously thought that they could prove things about the nature of the substances in the world, or could prove that the world is or is not caused, or is infinitely or only finitely divisible, by arguments based only on the concept of substance, the concept of cause or the concept of infinity. This view is expressed in the phrase with which he balanced that already quoted: "thoughts without content are empty." Kant therefore argued that if there is to be genuine knowledge, the data of sense must fall within forms of space and time contributed by the mind itself and must be brought into some form of conceptual order by the activity of the understanding. It is only because the mind contributes the forms of space and time that we can be absolutely certain, as we are, that anything perceived must fall within one or both of them; and it is only because we impose conceptual forms such as those of substance and cause upon our sensations that we are quite sure that anything experienced must be in an ordered world of interacting things. If experience of a natural world is to be possible. the data of sense must be actively arranged (Kant's word is "synthesized") by the understanding in terms of concepts, principles or categories such as substance and cause. A sensation or idea on its own, for example, gives no knowledge at all and can only co-operate in doing so when it is regarded as belonging to some substance, whether it be a material thing or an embodied mind.

Kant believed. of course, that the ideas which are the raw material of our knowledge must somehow be due to realities existing independent of human minds; but he held that human knowledge cannot reach to them because it can only arise in the course of synthesizing the ideas of sense themselves. Things-in-themselves must remain forever unknown to us. He therefore called himself a formal or transcendental idealist, because the mind determines the form in which reality appears to us. "The mind does not derive its laws (a *priori*) from nature, but prescribes them to her" *(Prolegomena to Every Future Metaphysic* [1783], section *36).* Nevertheless Kant thought that he could refute both the idealism of Descartes and that of Berkeley. The former he called "prob-

lematic idealism," because Descartes merely held that the existence of matter could be doubted; and the latter "dogmatic idealism," because Berkeley maintained outright that matter does not exist. As Kant falsely believed that Berkeley's theory was that things in space are mere imaginations, his "refutation" of Berkeley need not detain us. His argument against problematic idealism was that the man who doubts the existence of objects in space outside him must be sure of his own existence but could not know of it unless he was aware of continuing physical things with which his own continually changing ideas could be contrasted. It will be seen, therefore, that Kant held both that the understanding is responsible for so ordering our sense experiences that they constitute the natural world (this is his transcendental idealism) and also that the embodied selves existing in the natural world are correlative with material objects of which they have as direct a knowledge as they have of themselves (this is his "empirical realism"; *cf. Crztique of Pure Reason,* 1st ed., p. 375). But how can the understanding both be a condition without which there could not be a natural world at all and also be a part of it belonging to embodied selves in space and time? Kant's answer was that experience is made possible by the synthesizing activity of a transcendental self of which we can know nothing except that it is a condition of our knowledge of the natural world and of ourselves as empirical selves within it. If Kant was right, the immaterialists made the mistake of supposing the sensible world depended upon empirical selves, whereas in fact there could be no experience of empirical selves any more than of the sensible world without the activity of a transcendental self.

According to this argument, therefore, there must be things-in-themselves and transcendental synthesizing activities, but any attempt to discover what sort of thing they are is doomed to inevitable failure. Kant recognized, nevertheless, that we do not remain content with this limitation but endeavour to extend our knowledge beyond the bounds of possible experience. He gave the name "reason" to the intellectual faculty with which we undertake this fruitless task. Prompted by reason, we speculate about the ultimate nature of the world, its source and its destiny, but in doing so we run into antinomies (*i.e.*, equally cogent arguments leading to incompatible conclusions). It was Kant's view that the traditional arguments for the existence of God inevitably call forth equally plausible counterarguments and hence cannot be relied upon as defenses of the religious viewpoint Theoretical reason, indeed, cannot even establish the freedom of the will, in spite of the importance of this notion for our moral life. On the other hand, however, Kant argued that reason has a practical use in which the moral law is revealed and with it the fact of freedom. Thus man's practical reason reveals him as a member of two worlds: the sensible world in which he is a natural being with desires that are subject to the law of causation; and an intelligible world in which he is spontaneous and free. (*See* also TRANSCENDENTALISM.)

Absolute Idealism. — Absolute idealism, which, along with positivism and materialism, was one of the most influential philosophies of the 19th century, is, in its essentials, the work of Hegel. It was largely due to his writings that the positivism and materialism that were so congenial to the new scientific outlook and to the developing industrial society had to face objections not only from the traditional religious teachers but also from philosophers who were free to speak their minds untrammeled by specific religious dogmas. In spite, therefore, of the difficulties to which his highly individual style and the scope of his writings give rise, the most characteristic traits of his idealist view must here be sketched in. The most convenient way of doing this will be to consider some ways in which he criticized and transformed Kant's transcendental idealism. He discussed Kant's views very fully in paragraphs 40–60 of his *Encyclopaedia of the Philosophical Sciences* (1817) and at the end of his *Lectures on the History of Philosophy.*

"Every philosophy" wrote Hegel in his *Science of Logic* (1812) "is essentially idealism"; but he did not mean by this that every philosophy was immaterialist. He said, indeed. that all that Berkeley's immaterialism amounted to was that the word "ideas" was applied to what previously had been called "things,' everything else being left just as it had been. Nor was he impressed by Kant's "refutation of idealism." for this merely rectified Berkeley's paradox by a return to the common sense that Berkeley had disturbed. By "idealism" Hegel meant "the proposition that the finite is ideal" — "ideal" being used to mean "not truly existing." In the passage in the *Science of Logic* from which these definitions are taken Hegel goes on to say that, in denying that the finite is real, idealism is at one with religion. Hegel argues that finite or limited being presupposes infinite unlimited being, within which the finite is a dependent element. The infinite contains the finite within it, for if the infinite were distinct from and external to the finite it would be limited by it and therefore not be infinite. Now Kant had said that the reason was the faculty by which we fruitlessly seek to transcend the limitations imposed by sense experience and the categories of the understanding. According to Hegel, however, this urge toward completeness shows that the reason is a superior, less limited faculty than the understanding, tending toward genuine philosophical knowledge of the infinite. He believed that Kant should not have remained satisfied with the notion of distinct faculties of sensibility, understanding and reason but should have seen that the sensibility is that part of experience that is most refractory to rational explanation and that the reason is the understanding freed from the restrictions of fixed and limited forms. According to Hegel there is a progress in knowledge from the vague blind stare of the senses, through the neatly distinguished categories of common sense and natural science, to the unified knowledge that is philosophy. The movement toward philosophical completeness necessarily leads away from mere sense experience. In this connection reference may be made to Kant's refutation of the ontological argument for the existence of God (*see* THEISM). According to this argument God, defined as the All-Perfect Being, must exist since existence is a perfection and a being without it would not be perfect. To this Kant objected that existence is not a predicate and therefore not a perfection and that it is impossible to deduce the existence of anything from a mere definition. This, of course, is a particular application of Kant's principle that thoughts without content are empty. Hegel, however, accepted the ontological argument, arguing that, although it does not follow from the thought of some finite thing, such as a hundred dollars. that that thing exists, the thought of an All-Perfect or Infinite Being is different and does imply existence. The principle behind this defense of the ontological argument is that the simple sort of verification that is appropriate when we are concerned with the existence of sensible objects is quite inappropriate for highly complex beings. It is absurd to think of verifying the existence of the Infinite Being in the way in which we verify the existence of a hundred dollars, and hence Kant's refutation rests on a confusion of categories. Hegel's defense of the ontological argument is thus a defense of the view that some thoughts are so coherent, comprehensive and compelling that the nonexistence of their object is unthinkable. He considered that if perceptions without concepts are blind, then the choice is between more or less adequate thoughts rather than between those that are supported by sense experience and those that are not.

Another way of approaching Hegel's absolute idealism is by reference to his criticisms of Kant's theory of the categories. In the section on transcendental idealism three categories only have been indicated, those of substance, cause and interaction; but Kant in fact held that there are 12 in all, which he arrived at by consideration of the forms of judgment distinguished in the traditional Aristotelian formal logic. Kant's general idea was that formal logic showed the forms of thought which the understanding uses in bringing order to the manifold of sense. On the one hand there is the manifold of sense, on the other 12 distinct categories. Hegel argued that the categories and that to which they apply should not be divorced from one another, and that the categories themselves should be considered in their relations to one another. If the categories and that to which they apply are inseparable, then an examination of the forms of thought is at the same time an exploration of the forms of being, and logic and metaphysics are one. And if the categories are not to be regarded as ultimate

items on a short list, then it may be possible for us to discover why it is that antinomies arise. They arise, Hegel held, from the limitation or abstract character of each form of thought considered on its own,

The aim, therefore, should be to show how our thinking becomes more and more adequate as, from the contradictions involved in the less satisfactory categories, we proceed toward those that are complex and comprehensive. This is the aim which Hegel claimed to fulfil in his *Science of Logic,* where, commencing with the most abstract category. "being." he passed through mathematical, physical, chemical and biological categories to the absolute idea. Just as the absolute idea contains within itself the truth of all the more abstract categories, so the later and more comprehensive systems of philosophy contain within themselves the truth of all the earlier and partial ones. "The latest philosophy contains therefore those which went before; it embraces in itself all the different stages of them; it is the product and result of those that preceded it. We can now, for example, be Platonists no longer" *(Lectures on the History of Philosophy).*

Absolute idealism, then, comprised the following main themes. It was held that the common-sense world of distinct things and embodied minds in space and time is not the world as it really is but merely the world as it appears in terms of uncriticized categories. It was held in the second place that the mathematical and physical categories are the least adequate for grasping the truth of things and that the world as a whole is best conceived in terms of self-conscious mind. It was held in the third place that thought does not consist in the imposition of ready-made forms upon merely given material, but is, in its most characteristic features, the relating of each particular experience with the infinite whole of which it is an expression. This was the general view which, in the latter part of the 19th century and in the beginning of the 20th, spread from Germany to Great Britain and the British empire, to the United States and. in rather different forms, to France and Italy too. The British writer who most consistently reproduced the central features of Hegel's absolute idealism was Bernard Bosanquet, especially in his *Logic* (1888) and *The Principle of Individuality and Value* (1912). In the former he traced the types of judgment and inference appropriate to the various stages of thought. from the rudimentary forms that are closest to mere sense experience to its highest systematic development. In the latter he showed the consequences of the view that no particular thing is real in isolation from the whole and that rational understanding and inference would be impossible unless the world were a system no part of which could be what it is apart from its relations to the other members. A somewhat more idiosyncratic version of absolute idealism is presented in the writings of F. H. Bradley. His *Ethical Studies* (1876) turned the Hegelian weapons against the utilitarian ethics and underlying empiricist assumptions of the time, while his influential *Appearance and Reality* (1893) was an attempt to show that, in spite of the appearances, the world is really "one comprehensive sentience." Josiah Royce's *The World and the Individual* (1901) was the most impressive American work in the tradition of absolute idealism. Mention should also be made of J. M. E. McTaggart's *The Nature of Existence* (2 vol., 1921–27), in which a subtly argued chain of reasoning is employed to establish the conclusion that the ultimate constituents of the world are a system of timeless selves who need no God to maintain the order that they observe. About the year rgoo absolute idealism had come to be by far the most active philosophical influence in the universities of the British empire and the United States, permeating the teaching of ethics, aesthetics and politics as well as the more fundamental disciplines of logic and metaphysics. Philosophy was thought to justify at any rate some of the religious hopes and to point the way to moral and political improvement.

Criticisms **of** Idealism. — By the middle of the 20th century philosophical idealism had lost its position of predominance and had few upholders in academic circles. The following paragraphs contain a summary of the types of argument that have led to this.

1. Immaterialism has never had wide support from philosophers, and both transcendental idealists and absolute idealists were chary of it. Now the first step in the empiricist form of immaterialism is the assertion that the objects immediately perceived are ideas or sensations which exist only "in the mind." This step has been challenged in two ways. In the first place it has been urged that immaterialists fail to distinguish between the object perceived (*e.g.,* a coloured patch) and the act of perceiving it and that it is the latter, not the former, that is really "in the mind." Those who use this argument, however. admit that the idea or sensation (for which the 20th-century name is "sense datum" or "sensum") only exists while it is being perceived and can only have those characteristics which it is perceived to have. They still have the problem, therefore, of determining the relationship of this entity to the material objects which, in any view, continue to exist when not perceived by any finite observer. The result is either a revised version of Locke's representationalism or else some form of phenomenalism. A second line of argument, therefore, takes the course of denying that there are such entities as sense data at all. Powerful support for this view is given by the reflection that if sense data have only those characteristics which they are perceived to have, then they must literally be vague or indefinite objects. For if someone sees a coloured patch with many speckles on it and yet does not see how many speckles there are, then according to the sense-datum theory he must be seeing a sense datum that has many speckles but has no definite number of them. Unless this paradox can be removed, upholders of sense data are in danger of maintaining the existence of entities with properties that seem to be logically impossible. If the analysis of perception in terms of ideas or sense data is untenable, then the arguments for immaterialism, as well as those for phenomenalism, cannot even get started.

2. The rationalist arguments for immaterialism and the arguments for the other types of idealism meet with criticisms of a type first clearly formulated by G. E. Moore. Idealists assert conclusions that conflict with common sense. Not only do they talk about transcendental selves and absolute ideas, but they deny that tables and embodied selves and other finite beings are real at all. But we do *say* that tables and people exist, and anyone who denied this would be *commonly* held to be saying what is false. Again, idealists have denied that time is real, and yet it certainly took time for this sentence to be written. Thus we have to choose between accepting the truth of statements that are universally understood and are universally held to be true, and accepting the truth of statements that are understood by very few and need a lot of philosophical argumentation in their support. The opponents of idealism argue that it is the first alternative that ought to be accepted, for, they say, it is ultimately only by means of the ordinary language which we are brought up to speak that anything at all can be explained to anybody. Someone who says that tables and people are not real is misusing the word "real," for it is commonly used just to indicate that it is tables and people that exist and such things as chimaeras and unicorns that do not. According to this argument, then, rationalist immaterialism and absolute idealism must be false because they deny the truth of commonsense statements that are certainly true if anything is true, and assert the truth of other statements whose meaning cannot be clearly explained in terms of the ordinary language in which everything explainable must ultimately be explained.

3. The absolute idealist holds that truth is a relationship of coherence between thoughts rather than a correspondence between thoughts and external realities. Against this empiricists argue that, important as coherence may be, it is secondary to the prime condition that statements are true by virtue of their stating what is the case. The idealist's objection to this, however, is that ascertaining what is the case (*i.e.,* verifying) is not a mere irrational seeing or touching, but is the testing of a theory and, since verification has its meaning and point only in the context of the theory that is being tested, it cannot take us beyond judgment, thought or inference (Brand Blanshard, *The Nature of Thought,* vol. ii, pp. 227–259, George Allen & Unwin Ltd., London, 1939; new impression, 1948).

4. The absolute idealist also maintains the view expressed by Hegel as "The truth is the whole." Understanding the world is discovering the place of subordinate things in subordinate wholes,

of subordinate wholes in less subordinate ones and, ultimately, of everything subordinate in the infinite whole. All our reasoning, it is held. rests on the assumption that everything is necessarily connected with everything else. The properties that things have they necessarily have, although we may not always see that this is so. It has been objected to this part of the idealist view that it is meaningless to say of any fact that it is necessarily as it is, since necessity is a property of elements of a symbolic system or of linguistic expressions: facts are the case, propositions may be necessarily true in the light of certain definitions and rules of inference. To this the idealist's reply is that necessity is a relationship between the elements of systems, so that the necessity of linguistic systems is one instance of a much wider notion. To understand anything, on his view, is to see it in its place in the various systems to which it belongs and is hence to grasp its necessity. "In what we take as the real world we can see the outlines of a necessary structure that is the counterpart of thought's ideal" (B. Blanshard, ibid. p. 516). See also MATERIALISM.

IDENTIFICATION: see FINGERPRINTS; EVIDENCE; INVESTIGATION, CRIMINAL.

IDENTITY, LAWS OF: see THOUGHT, LAWS OF.

IDEOGRAM, a pictorial symbol that conveys an idea or a meaning directly, as distinguished from a logogram (a word sign), syllabogram (a syllabic sign) or letter (an alphabetic sign), which represent sounds or linguistic elements. See PICTOGRAPHY; WRITING; LOGOGRAM AND SYLLABARY.

IDES, the name given in the Roman calendar to the 13th day of the month with the exception of March, May, July and October, the Ides in these months falling on the 15th day. See CALENDAR.

IDIOCY: see MENTAL DEFICIENCY.

IDOCRASE, a rock-forming mineral of variable composition also known as vesuvianite. Idocrase, a hydrous calcium aluminum silicate with some magnesium and iron, is transparent or translucent, has a vitreous lustre and is commonly brown or green. Transparent crystals of a good green or brown colour may be cut as gem stones. A compact green variety resembling jade is found at several localities in California and is known as californite. A sky-blue variety, cyprine, has traces of copper. Some varieties contain fluorine or boron. The crystals of idocrase have tetragonal symmetry, and the structural formula is $Ca_{10}(Mg,Fe)_2Al_4(Si_2O_7)_2(SiO_4)_5(OH)_4$. The crystal structure resembles in some ways that of garnet (*q.v.*). The crystals are four- or eight-sided prisms terminated by basal planes and pyramids. Idocrase occurs commonly as well-developed crystals, also as striated columnar aggregates. The specific gravity is about 3.4 and the hardness 6.5. Most varieties are optically uniaxial and negative. Viluite, a variety containing boron, is optically positive and may be biaxial.

Idocrase is found principally in crystalline limestones near their contacts with igneous rocks (see METAMORPHISM) and in beds of marble and calc-silicate granulite associated with gneiss and mica schist. It is also found in association with serpentinite and in chlorite schist and amphibolite. Minerals commonly occurring with it are calcite, garnet, diopside, wollastonite, phlogopite and amphibole.

Localities where fine crystals have been found are the Ala valley in the Piedmont; Monte Somma (Vesuvius); the Vilui river, Sib.; Christiansand, Nor.; and, in North America, at Auburn, Me.; Amity, N.Y.; Franklin, N.J.; and Litchfield, Que. (J. B. T.)

IDOL, literally an image (Gr. eidolon), particularly an image used as an object of worship. In philosophy, the word can mean a prejudice of some kind that hinders clear thought. It was used in this sense by Giordano Bruno and adopted from him by Francis Bacon (*q.v.*), who in a celebrated passage of his Novum Organum distinguished four kinds of idol, namely: (1) "idols of the tribe," prejudices more or less common to the whole human race; (2) "idols of the cave," prejudices peculiar to individuals; (3) "idols of the market place," prejudices encouraged by one's social group and mother tongue; and (4) "idols of the theatre," prejudices or false notions taught and encouraged by various schools of thought.

IDOLATRY, the worship of idols; *i.e.,* images or other objects believed to represent or be the abode of a superhuman personality. The term is often used generically to include such varied forms as litholatry, dendrolatry, pyrolatry, zoolatry and even necrolatry. In an age when the study of religion was practically confined to Judaism and Christianity, idolatry was regarded as a degeneration from an uncorrupt primeval faith, but the comparative and historical investigation of religion has shown it to be rather a stage of an upward movement. and that by no means the earliest.

According to Varro the Romans had no animal or human image of a god for 170 years after the founding of the city. Herodotus says that the Persians had no temples or idols before Artaxerxes I. Lucian bears similar testimony for Greece and as to idols for Egypt. Eusebius sums up the theory of antiquity in his statement "the oldest peoples had no idols."

Images of the gods indeed presuppose a definiteness of conception and powers of discrimination that could only be the result of history and reflection.

As the earlier stages in the development of the religious consciousness persist and are often manifest in idolatry, so in the higher stages, when men have attained loftier spiritual ideas, idolatry itself survives and is abundantly visible as a reactionary tendency.

The history of the Jewish people whom the prophets sought, for long in vain, to wean from worshipping images is an illustration; so, too, certain practices of modern popular Hinduism contrasted with the lofty teaching of the Indian sacred books.

In the New Testament the word εἰδωλολατρεία (idololatria), afterward shortened occasionally to εἰδωλατρεία (idolatria), occurs in all four times, viz., in 1 Cor. x, 14; Gal. v, 20; 1 Peter iv, 3; Col. iii, 5. In the last of these passages it is used to describe the sin of covetousness or "mammon worship." In the other places it indicates with the utmost generality all the rites and practices of those special forms of paganism with which Christianity first came into collision. It can only be understood by reference to the LXX, where εἴδωλον (like the word "idol" in the Authorized Version) occasionally translates indifferently no fewer than 16 words by which in the Old Testament the objects of what the later Jews called "strange worship" are denoted (see Encyclopaedia Biblica).

In the widest acceptation of the word, idolatry in any form is absolutely forbidden in the second commandment, which runs: "Thou shalt not make unto thee a graven image; [and] to no visible shape in heaven above, or in the earth beneath, or in the water under the earth, shalt thou bow down or render service." (See DECALOGUE.)

It is obvious that two religious votaries in an attitude of reverence before an image may be moved by very different ideas of what the image is and signifies, although their outward attitude is the same. The one may regard it as merely an image, picture or representation of a higher being, and in itself void of value or power. Its value is that of mere resemblance or some kind of acquired association. But the other may regard it as the tenement or vehicle of the god and fraught with divine influence. In modern Christendom the former is the attitude which the Roman Church officially inculcates toward sacred pictures and statues; they are intended to convey to the eyes of the faithful, especially to the illiterate among them, facts about Jesus, the

Virgin and the saints.

The other attitude is that into which simple-minded persons may easily lapse, as it is that which characterizes other religions, ancient or modern, which use images of any kind; and it is this attitude which may be conveniently called "idolatry" or image worship.

The invectives against idolatry of the early Jewish and Christian apologists, of Philo, Minucius, Tertullian, Arnobius, Lactantius and others, throw light on the question how an ancient pagan regarded his idols. One capital argument of the Christians was the absurdity of a man making an idol and then adoring or being afraid of the work of his own hands. Lactantius preserves the answer of the pagans so criticized (De *origine erroris,* ii, 2): we do not, they said, fear the images themselves but those beings after whose likeness they were fashioned and by whose names they were consecrated. And Augustine (De *civ.* dei, viii, 23) relates how, according to Hermes, the spirits entered "by invitation" so that the images became "bodies of the gods." Image worship is essentially a form or rather an outcome of animism, now known to represent a type of religion arising subsequently to its really primitive forms. An image fashioned like a god and having this advantage over a mere stock or stone, that it declares itself and reveals at a glance to what god it is sacred, is believed to attract and influence the god to choose it as his home and tenement. Religious ceremonial is much more hopeful and efficacious for a worshipper who thus has means of approaching the god he worships in visible and tangible form, and even of coercing it. Having the god thus at hand and bound up with the material object, the simple-minded worshipper can punish it if his prayers are left unanswered (cf. Tylor, Primitive Culture). Suetonius relates (Aug. 16) that Augustus, having lost some ships in a storm, punished Neptune by refusing to allow his image to be carried in procession at the games.

See RELIGION and ANIMISM with references to be found in those articles.

BIBLIOGRAPHY.—On the whole subject *see* "Images and Idols" in Hastings, *Encyclopaedia of Religion and Ethics,* vol. vii (1914), with extensive bibliography and references; also Sir Edward Burnett Tylor, *Printitive Culture,* 7th ed. (New York, 1924); L. R. Farnell, *Evolution of Religion* (1905).

IDOMENEUS, in Greek legend, son of Deucalion, grandson of Minos and Pasiphae, and king of Crete. He courted Helen and took a distinguished part in the Trojan War. According to the Odyssey, he returned home safely with all his countrymen who had survived the war. In later tradition, having been overtaken by a violent storm, he vowed to sacrifice to Poseidon the first living thing that met him when he reached home. This proved to be his son, whom he slew in accordance with his vow; whereupon a plague broke out and Idomeneus was driven out. He fled to the district of Sallentum in Calabria and subsequently to Colophon in Asia Minor, where he settled near the temple of the Clarian Apollo and was buried on Mt. Cercaphus. But the Cretans showed his grave at Cnossus, where he was worshiped as a hero with Meriones.

IDRIS I (MOHAMMED IDRIS EL-MAHDI ES-SENUSSI) (1890–), first king of the United Kingdom of Libya, was the grandson of Mohammed ben Ali ben es-Senussi (1791?–1859), an Algerian from Mostaganem who from 1843 onward lived in Cyrenaica and founded a powerful Moslem fraternity known as Senussiya. and the son of Senussi el-Mahdi (1845–1902).

Since Idris was a minor at the time of his father's death, the chieftainship passed to his cousin Ahmed esh-Sherif who fought against Italy in the Italian-Turkish war of 1911–12 and in World War I.

In 1917 Idris secured an agreement with the British and Italian governments, was recognized by the Senussi chiefs as Grand Senussi and in Nov. 1920 acknowledged Italian suzerainty over Cyrenaica. He was given the hereditary title of amir with jurisdiction over the oases of Kufra, Jaghbub, Jalo, Aujila and Jedabia. On the rise of fascism in Italy, he withdrew in Jan. 1923 to Egypt with his family. while his lieutenants continued to rule in the oases. In 1940, under an agreement with the British government, he organized an auxiliary military force which fought with the British 8th army.

In Nov. 1947 he returned to Cyrenaica and the following year was installed in the palace of the former Italian governor at Benghazi. On June 1, 1949, he was recognized by Great Britain as ruler of Cyrenaica.

In Dec. 1950 he was chosen by the national assembly representing Cyrenaica, Tripolitania and the Fezzan to be king of Libya when that state came into being.

On Dec. 24, 1951, Great Britain and France relinquished their administrative authority, and Idris proclaimed the independence of the new state. (K. SM.)

IDRISI (ABU 'ABDULLAH MOHAMMED IBN MOHAMMED ASH-SHARIF AL-IDRISI) (1100–*c.* 1166), Arab geographer, scientist and poet, was a descendant of the prophet Mohammed through Idris I of Morocco and the Banu Hammud, princes of Malaga. According to a very late authority Idrisi was born at Ceuta in A.H. 493 (A.D. 1099–1100). He studied at Córdoba and traveled widely in Spain, north Africa and Asia Minor. Roger II of Sicily (1101–05) treated him with great honour and entrusted him with the compilation of a treatise on the whole of the known world in which information from existing geographical works was collated with reports of travelers. After 15 years Idrisi completed early in 1154 the Nuzhat al-mushtdq *fi'khtirāq* al-dfdq ("Delight of him who wishes to traverse the regions of the world"), generally known as *Kitāb Rūjār* ("The Book of Roger"). He constructed a silver globe and planisphere, both of which have perished. The treatise was illustrated with maps and it can be shown that these were based upon the text, not the text upon the maps. He compiled another recension for William the Bad (1154–66) but it has been lost. A manuscript of a third version was found in the Hakimoglu Ali Pasha mosque in Istanbul in 1906; this is dedicated to an anonymous but not royal patron and omits the descriptive part of *The* Book of *Roger* but retains the itineraries and includes some new material. A manuscript of Idrisi's work on botany and materia medica also survives in Istanbul and a few of his verses have been preserved. It is unlikely that he remained in Sicily after the anti-Moslem riots of 1161 but it is not known when or where he died. No life of him has been traced in Arabic biographical literature and the account by Leo Africanus in De *viris illustribus apud Arabes* (Zurich, 1664) is of no value.

The Book of Roger is divided according to the seven climates of Greek geographers, beginning at the equator and extending northward as far as the latitude at which cold made the earth uninhabitable. Each climate is then subdivided by vertical lines into ten equal sections numbered from west to east. All divisions which do not coincide with these are ignored in the arrangement of the book. There is evidence of hasty compilation, and of misunderstanding of the written sources. Some legendary matter is included such as descriptions of the land of Gog and Magog, the wonders of Rome and the islands of St. Brandan; mathematical and descriptive errors are common. The maps seem to have been reduced by eye and areas well known to the author are shown as disproportionately large. The preface mentions written sources consulted by Roger which include Ptolemy and Orosius but no other European writers. Mas'udi and Ibn Hawqal are among the chief Arabic authorities Idrisi used but he appears not to have known Biruni or Maqdisi. Much of the information given was not derived from these sources and must have been taken from travelers' accounts and in Roger's own dominions from official records. The description of Sicily is the most detailed and is of great historical interest, for it includes much more than purely topographical information. Idrisi's place names are often difficult to identify because of corrupt manuscripts and the ambiguities of the script. In Italy, Greece, parts of France and even in Sicily some of them seem to have been taken from classical rather than Arabic maps or contemporary vernacular usage. In other parts of France and in northern Europe generally he gives versions of contemporary spoken forms. Ireland occupies the first and Britain the second section of the seventh climate. Some of his English place names are French in form. He knew something of the coast between Dartmouth and Grimsby, mentions Dover, London, probably Oxford and perhaps the Scilly Isles but he knows no British

river by name except the Thames and nothing of the interior or the west coast.

A garbled abridgment of his work was printed in Arabic (Rome. 1592), and in a Latin translation as *Geographia Nubiensis* (Paris, 1619), the title being due to a misunderstanding. His influence on European cartography and exploration was not important but it has been suggested that his delineation of Africa influenced the maps of Marino Sanudo and Pietro Vesconte. Like Ptolemy, Idrisi believed that Africa extended to the east and enclosed the Indian ocean on the south. It has also been suggested. without evidence. that his account of a voyage, apparently to Madeira and one of the Canaries. may have influenced the exploration of the Atlantic.

The most important manuscripts of *The Book of Roger* are in the Bibliothèque Nationale, Paris, and the Bodleian Library, Oxford The maps they contain were reproduced by Konrad Miller. *Mappae arabicae* (1926–31). The maps of the greater part of the British Isles were reproduced by D. M. Dunlop, "Scotland According to al-Idrisi," *Scottish Historical Review,* vol. xxvi (1947). There is no edition of the complete Arabic text. The French translation of A. Jaubert, 2 vol. (1836–40), is complete but very unsatisfactory. Sections of the text, especially those relating to Europe and north Africa, have been studied, and sometimes edited and translated in monographs and papers, many of which are in the academic journals of the countries concerned. For details of these *see* G. Sarton, *Introduction to the History of Science* (1927–48), vol. ii, pp. 410–412; C. Brockelmann, *Geschichte der arabischen Litterutur* (1898–1902) and the article "Idrisi" by C. F. Seybold in the *Encyclopaedia of Islam,* vol. ii (1930). The account of the British Isles was edited, translated and discussed by A. F. L. Beeston, "Idrisi's Account of the British Isles." *Bull. Schl orient. Stud. Lond. Univ.,* vol. xiii (1949–50).

On Idrisi's life and work generally, *see* especially M. Amari, *Storia dei musulmani di Sicilia,* 2nd ed. by C. A. Nallino, vol i, pp 49–51; vol. iii, pp. 460–468, 677–701 (1933–37). (C. F. Bm.)

IDUMAEA: *see* EDOM.

IDUN (IDUNA), in Norse mythology, is the wife of Bragi (*q.v.*), god of poetry. She guarded the apples which the gods must eat to preserve their youth. When she and her apples were seized by a giant, the gods quickly began to grow old. This story is mentioned in a Norwegian poem as early as the late 9th century.

(G. T.-P.)

IDYL or IDYLL, a short poem of a pastoral or rural character, in which something of the element of landscape is preserved or felt. The earliest commentators of antiquity used the term to designate a great variety of brief and homely poems, in which the description of natural objects was introduced, but the pastoral idea came into existence in connection with the Alexandrian school and particularly with Theocritus, Bion and Moschus, in the 3rd century B.C. It appears, however, that *eidyllion* was not, even then, used consciously as the name of a form of verse. but as a diminutive of *eidos,* and merely signified "a little piece in the style of" whatever adjective might follow. Thus the idyls of the pastoral poets were *eidylliu aipolkai,* "little pieces in the goatherd style." Ten of the so-called "Idyls" of Theocritus are extant, and these are the type from which the popular idea of this kind of poem is taken. The word was revived at the Renaissance. In 1658 the English critic, Edward Phillips, defined an "idyl" as "a kind of eclogue," but it was seldom used to describe a modern poem. The general use, or abuse, of the word in the second half of the 19th century, both in English and French, arises from the popularity of two works, by two eminent poets. The *Idylles héroiqztes* (1858) of Victor de Laprade and the *Idylls of the King* (1859) of Tennyson enjoyed a success in either country which led to a aide imitation of the title among those who had. perhaps, a very inexact idea of its meaning. On the whole, it is impossible to admit that the idyl has a place among definite literary forms.

IESI (anc. AESIS), a town and episcopal see of the Marche. Italy. province of Ancona, 17 mi. S.W. from Ancona town by rail. 318 ft. above sea level. The pop. (1951) 21,409. It lies on the left bank of the river Aesis (mod. Esino). It still retains its picturesque medieval town walls. S. Marco is an interesting 13th century church. The Palazzo del Comune is a fine, simple, early Renaissance building (1487–1503) by Francesco di Giorgio Martini. The courtyard with its loggie was built by Andrea Sansovino in 1519 The picture gallery contains some good pictures by Lorenzo Lotto The castle was built by Baccio Pontelli (1488). Iesi nas the birthplace of the emperor Frederic II (1194), and of the composer Giovanni Battista Pergolesi (1710–36). The silk spinning industry is of considerable importance The Aesis formed the boundary of Italy proper from about 250 B C to the time of Sulla (*c* 82 B C.); and, in Augustus' division of Italy, that between Umbria (the 6th region) and Picenum (the 5th).

See L Marinelli, "Le Mure di Iesi" in *Cronache d'Arte* iv (1928).

IF, a small island in the Mediterranean sea off the south coast of France, about 2 mi. S W. of Marseille. Its fortress prison, the Château d'If, was built by Francis I in the early 16th century and was made famous by Alexandre Dumas' novel, *Tlze Count of Monte Cristo.*

IFE, a town of the Western Region of Nigeria, Africa, lies at about 750 ft above sea level and 45 mi. E of Ibadan, in the rain forest area and within the main cocoa growing regions. Pop. (1953) 110,790 (Africans only). Formerly called Ile-Ife, it is one of the larger, and possibly the oldest, of the Yoruba towns. It has been described as the "holy city" of the Yoruba (*q* v.) and at its centre is the palace (afin) of the oni of Ife, the spiritual head of the Yoruba people. Apart from some modern two-story buildings, the houses are mostly of red mud with pan (metal) roofing.

In the palace compound (about two acres) is the Ife museum containing examples of Ife bronze and terra-cotta heads and figures. *Cire-perdue* bronze castings of uncertain date were first discovered by the archaeologist Leo Frobenius in 1910; further bronze heads were found in 1938 and terra-cotta figures in 1957. Another notable relic in the custody of the oni is the staff of Oranyan, an 18-ft. granite monolith in the shape of an elephant's tusk

At the north of the town stands Oduduwa college, named in honour of the reputed ancestor of the Yoruba.

Ife is linked by main road westward with Ibadan and Lagos, northnard with Oshogbo, Ilorin and the Northern Region, and eastward with Benin and the Eastern Region. The people are by tradition town-dwelling farmers and live mainly by farming the surrounding country. A substantial cocoa crop is also exported.

A local legend relates that Ile-Ife was the place where mankind was created. The Yoruba at least appear to have been established there at an early date Ife seems to have largely escaped the contacts made by Benin uith the first European explorers and was later less affected by the Fulani attacks and the civil wars of the 19th century than were the neighbouring Yoruba kingdoms of Oyo, Ibadan and Abeokuta. (W. H. I.)

IFFLAND, AUGUST WILHELM (1759–1814), German actor, dramatist and manager. was born in Hanover on April 19, 1759. At the age of 18 he broke nith parental authority and joined the Gotha court theatre to study acting under Konrad Ekhof's direction. In 1779 he went to Mannheim uhere he created the part of Franz Moor in Schiller's *Die Räuber.* In 1796, upon Goethe's invitation, he appeared as guest star on the Weimar court stage, charming his audiences with truthful and yet stylized portraits of pathetic and comic middle-class characters. His flights into tragedy (Lear, Wallenstein, Egmont) were less successful As an author Iffland achieved likewise fame in the field of domestic drama and sentimental comedy *(Verbrechen aus Ehrsucht, Die Jager, Der Spieler, Die Hagestolzen).* In 1798 he was appointed manager of the Berlin National theatre, and in 1811 director-general of all the royal theatres in Prussia. He died in Berlin on Sept. 22. 1814.

See his autobiography *Meine Theatralische Laufbahn* (republished 1885). (A. M. N.)

IGARA, a people closely resembling the Yoruba, inhabiting the provinces of Munshi and Nassarawa, northern Nigeria, and who speak a Yoruba dialect.

See Meek, *The Northern Tribes of Nigeria* (1925).

IGARKA, a port in the Krasnoyarsk *kray* of the Russian

S.F.S.R. It is located on the Yenisei river, 62 mi. N. of the Arctic circle and 418 mi. S. of the Kara sea. It is a station on the air route from Krasnoyarsk to Dickson Island, at the mouth of the Yenisei. The population, which varies considerably with the season, is approximately 12,000 in winter and 15,000–20,000 in summer, when migratory labour arrives to help load ships.

Igarka was founded in 1929 across the river from an old fishing village of the same name, to provide a seaport from which Siberian products might be shipped to other parts of the world. A natural harbour is formed in the Yenisei by a small island opposite the city, and since the river is 10 fathoms deep and 5 mi. wide here, ocean-going vessels can easily penetrate to Igarka, to which they are convoyed from the Kara sea by icebreakers. In addition, the river flows smoothly at that point, providing a suitable base for floating timber down the river after it has been processed in Igarka's sawmills.

Although the soil thaws only to a depth of two or three feet even in summer, marshes were drained for cultivation. The Soviet government established a Polar Agricultural station at Igarka which proved successful in growing grain and some vegetables as well as in maintaining dairy farms.

The name Igarka is commonly thought to have been derived from Yegor or Yegorka, the name of one of the first settlers in the old fishing village. The British, who sailed up the Yenisei in the 19th century, corrupted the word to Igarka. In 1929, when construction began on the new city, there were only 43 inhabitants of the old Igarka.

IGLESIAS POSSE, PABLO (1850–1925), Spanish politician was born at El Ferrol on Oct. 15, 1850. On the death of his father he was placed in a foundling asylum where after repeated attempts at escape he remained for some years. In 1871 he became secretary of the International Proletarian federation and in 1872 founded the Typographical societies of which he became president in 1885. He helped form the first Spanish Socialist group in 1879 and was elected to the house of deputies in 1910. In 1923, when Primo de Rivera overthrew the constitution and closed the doors of the cortes, he was chief of the Parliamentary socialist party. He became editor of *El Socialista,* the organ of the Spanish labour movement in 1886. For activities on behalf of the workers he served eight terms of imprisonment. He died in Madrid on Dec. 8, 1925.

See Meliá, Pabto *Iglesias* Posse. Rasgos *de su vida íntima* (1926).

IGNATIEV, NICHOLAS PAVLOVICH, COUNT (1832–1908), Russian diplomatist, was born at St. Petersburg (Leningrad) on Jan. 29, 1832. At 17 he became an officer of the Guards. His diplomatic career began at the Congress of Paris, after the Crimean War, where he took an active part as military attaché in the negotiations regarding the rectification of the Russian frontier on the Lower Danube. Two years later (1858) he was sent with a small escort on a dangerous mission to Khiva and Bokhara. The khan of Khiva laid a plan for detaining him as a hostage, but he returned safely, after concluding with the khan of Bokhara a treaty of friendship. He was Russian envoy at Peking nhen the Chinese government was terrified by the advance of the Anglo-French expedition of 1860 and the burning of the Summer palace; he used the occasion to secure for Russia not only the left bank of the Amur, the original object of the mission, but also a large extent of territory and seacoast south of that river. Ignatiev was ambassador at Constantinople from 1864 till 1877. Here his chief aim was to liberate from Turkish domination and bring under the influence of Russia the Christian nationalities in general and the Bulgarians in particular. His diplomacy led up to the Russo-Turkish war of 1877–78, at the close of which he negotiated with the Turkish plenipotentiaries the treaty of San Stefano. Ignatiev then retired in semidisgrace. After the accession of Alexander III in 1881, he was appointed minister of the interior to carry out a nationalist, reactionary policy, but was dismissed in 1882. He died on July 3, 1908.

IGNATIUS (Ἰγνάτιος), bishop of Antioch, a father of the Church. Our only trustworthy information is derived from the letters which he wrote to various churches on his last journey from Antioch to Rome, and from the short epistle of Polycarp to the Philippians. For the complicated controversy over the three recensions of the letters of Ignatius the reader is referred to the authorities quoted in the bibliography. The general consensus appears to be that the letters contained in the Medicean ms. at Florence, addressed to the Ephesians, Magnesians, Trallians, Romans, Philadelphians, Smyrnaeans and to Polycarp are genuine, and that they were written in the reign of Trajan. Harnack placed them in the latter years of Trajan or possibly 117–12j. Most scholars date them a few years earlier (110–117).

The letters of Ignatius unfortunately, unlike the Epistles of St. Paul, contain scant autobiographical material. We are told absolutely nothing about the history of his career. The fact that like St. Paul he describes himself as an ἔκτρωμα (Rom. 9), and that he speaks of himself as "the last of the Antiochene Christians" (*Trall.* 13; *Smyrn.* xi.), seems to suggest that he had been converted from paganism somewhat late in life and that the process of conversion had been abrupt and violent. He bore the surname of Theophorus, *i.e.,* "God-clad" or "bearing God." At the time when the Epistles were written he had just been sentenced to death, and was being sent in charge of a band of soldiers to Rome to fight the beasts in the amphitheatre The fact that he was condemned to the amphitheatre proves that he could not have been a Roman citizen. We lose sight of him at Troas, but the presumption is that he was martyred at Rome.

But if the Epistles tell us little of the life of Ignatius, they give us an excellent picture of the man himself, and are a mirror in which we see reflected certain ideals of the life and thought of the day. Ignatius, as Schaff says. "is the incarnation of three closely connected ideas: the glory of martyrdom, the omnipotence of episcopacy, and the hatred of heresy and schism."

Zeal for martyrdom in later days became a disease in the Church, but in the case of Ignatius it is the mark of a hero. The heroic note runs through all the Epistles; thus he says:

> I bid all men know that of my own free will I die for God, unless ye should hinder me . . . Let me be given to the wild beasts, for through them I can attain unto God. I am God's wheat, and I am ground by the wild beasts that I may be found the pure bread of Christ. Entice the wild beasts that they may become my sepulchre . . . ; come fire and cross and grapplings with wild beasts, wrenching of bones, hacking of limbs, crushings of my whole body; only be it mine to attain unto Jesus Christ (*Rom.* 4–5).

Ignatius constantly contends for the recognition of the authority of the ministers of the church. "Do nothing," he writes to the Magnesians, "without the bishop and the presbyters." The "three orders" are essential to the church; without them no church is worthy of the name (cf. Trall. 3). "It is not lawful apart from the bishop either to baptize or to hold a love-feast" (*Smyrn.* 8). Respect is due to the bishop as to God, to the presbyters as the council of God and the college of apostles, to the deacons as to Jesus Christ (Trall. 3). These terms must not, of course, be taken in their developed modern sense. The "bishop" of Ignatius seems to represent the modern pastor of a church. As Zahn has shown, Ignatius is not striving to introduce a special form of ministry, nor is he endeavouring to substitute one form for another. His particular interest is not so much in the form of ministry as in the unity of the church. Centrifugal forces were at work.

Ignatius was resisting this fatal tendency which threatened ruin to the faith. The only remedy for it in those days was to exalt the authority of the ministry and make it the centre of church life. It should be noted that (1) there is no trace of the later doctrine of apostolical succession; (2) the ministry is never sacerdotal in the letters of Ignatius As Lightfoot puts it: "The ecclesiastical order was enforced by him (Ignatius) almost solely as a security for doctrinal purity. The threefold ministry was the husk, the shell, which protected the precious kernel of the truth" (i. 40).

Ignatius fights most vehemently against the current forms of heresy The chief danger to the church came from the Docetists who denied the reality of the humanity of Christ and ascribed to him a phantom body Hence we find Ignatius laying the utmost stress on the fact that Christ "was *truly* born and ate and drank,

was *truly* persecuted under Pontius Pilate . . . was *truly* raised from the dead" *(Trall.* 9) "I know that He was in the flesh even after the resurrection, and when He came to Peter and his company, He said to them, 'Lay hold and handle me, and see that I am not an incorporeal spirit' " (*Smyrn.* 3). Equally emphatic is Ignatius's protest against a return to Judaism. "It is monstrous to talk of Jesus Christ and to practise Judaism, for Christianity did not believe in Judaism but Judaism in Christianity" *(Magn.* 10).

As far as Christology is concerned, there are two points to be noted: (1) Ignatius is the earliest writer outside the New Testament to describe Christ under the categories of current philosophy; *cf.* the famous passage in *Eph.* 7. "There is one only physician, of flesh and of spirit (σαρκικὸς καὶ πνευματικός), generate and ingenerate (γεννητὸς καὶ ἀγέννητος), God in man, true life in death, son of Mary and son of God, first passible and then impassible" (πρῶτον παθητὸς καὶ ἀπαθής). (2) Ignatius is also the first writer outside the New Testament to mention the Virgin Birth, upon which he lays the utmost stress. "Hidden from the prince of this world were the virginity of Mary and her child-bearing and likewise also the death of the Lord, three mysteries to be cried aloud, the which were wrought in the silence of God" (*Eph.* 19). Here, it will be observed, we have the nucleus of the later doctrine of the deception of Satan. In regard to the Eucharist also later ideas occur in Ignatius. It is termed a μυστήριον *(Trall.* 2), and the influence of the Greek mysteries is seen in such language as that used in *Eph.* 20, where Ignatius describes the Eucharistic bread as "the medicine of immortality and the antidote against death."

When Ignatius says, too, that "the heretics abstain from Eucharist because they do not allow that the Eucharist is the flesh of Christ," the words seem to imply that materialistic ideas were beginning to find an entrance into the church *(Smyrn* 6). Other points that call for special notice are: (1) Ignatius's rather extravagant angelology. In one place, for instance. he speaks of himself as being able to comprehend heavenly things and "the arrays of angels and the musterings of principalities" *(Trall.* j). (2) His view of the Old Testament. In one important passage Ignatius emphatically states his belief in the supremacy of Christ even over "the archives" of the faith, *i.e.,* the Old Testament: "As for me, my archives—my inviolable archives—are Jesus Christ, His cross, His death, His resurrection and faith through Him" *(Philadel.* 8).

See T. Zahn, *Ignatius von Antiochien* (Gotha, 1873); J. B. Lightfoot, *Apostolic Fathers,* part ii. (London, 2nd ed., 1889); F. X. Funk, *Die Echtheit der ignat. Briefe* (Tubingen, 1892); A. Harnack, *Chronologie der altchristlichen Litteratur* (Leipzig, 1897). There is a good bibliography in G. Kruger, *Early Christian Literature* (Eng. trans., 1897, pp. 28–29); Rackl, *Die Christologie des heil. Ignaz von Antiochien* (1914). *See* also APOSTOLIC FATHERS.

IGNIS FATUUS (Lat. *ignis,* "fire"; *fatuus,* "foolish"). The name applied to the pale flame, also called will-o'-the-wisp and jack-o'-lantern, sometimes seen flickering over marshy ground and, it is said, over churchyards. No entirely satisfactory explanation has been put forward but it is generally believed that the effect is due to the spontaneous ignition of gases (especially methane, CH_4 or phosphine, PH_3) produced by the disintegration of dead plant and, possibly, animal matter.

IGNORANCE. In the law among the English-speaking peoples, as in Roman law, ignorance of the law is, in general, no ground for avoiding the consequences of an act. As regards criminal offences, the maxim as to *ignorantia juris* admits of no exception, even in the case of a foreigner temporarily in England, who is likely to be ignorant of English law. In Roman law the harshness of the rule was mitigate8 in the case of women, soldiers and persons under the age of 2 j, unless they had good legal advice within reach *(Dig.* xxii. 6. g), while in England judges often inflict mitigated sentences when a criminal did not and could not reasonably be expected to know the law, especially if it be very recent. Ignorance of foreign law is ignorance of fact. A compromise of claims, doubtful in law, is good and cannot be upset by subsequent solving of the doubt *(Stewart* v. *Stewart* 6 Cl. and F. 911). Ignorance of a matter of fact may in general be alleged in avoidance of the consequences of acts and agreements, but such ignorance cannot be pleaded where it is the duty of a person to know, or where, having the means of knowledge at his disposal, he willfully or negligently fails to avail himself of it. (See CONTRACT.)

In logic, ignorance is that state of mind which for want of evidence is equally unable to affirm or deny one thing or another. Doubt, on the other hand, can neither affirm nor deny because the evidence seems equally strong for both. For *Ignoratio Elenchi* [irrelevant conclusion] *see* FALLACY.

IGOROT, a general name (meaning "mountaineer") for "non-Christian" peoples of the central Cordillera of north Luzon, Philippines; also used for specific ethnic groups within the region; *e.g.,* the Bontok. Some live in the tropical forests of the foothills, but most live in rugged grassland and pine forest zones from about the 3,500 to 8,000-ft. levels. Still imperfect censuses showed a total of about 250,000 at mid-20th century, with slowly rising numbers in most communities. Usually medium in height with brown skin and straight hair, the Igorot peoples are genetically composite, with varying frequencies of later Malayan and earlier Indonesian type characters, and an understratum of Negritoid.

Notorious in earlier days for their warmaking and head-hunting, they were partially pacified by the Spanish and the process was completed during the U.S. period; but local killings may still occur in remote areas.

Ethnologists distinguish about ten main ethnic groups, each with its own dialect and special types of houses, clothing, art design, social structure and other distinctions. These units in turn have subgroup variations, and indeed such differences show even between local communities, since formerly each settlement was likely to be politically separate and often feuding with its neighbours.

There are also two broad groupings of the Igorot as a whole: one, by far the larger, comprises the peoples of the higher country in the south, central and west zones, having intensive wet rice cultivation mostly in steplike terraces-up the mountainsides; the other, peoples of the lower rain forest areas in the east and north, growing dry rice in seasonally shifting gardens. The first group nearly all live in populous villages (the Nabaloi or Ibaloi, Kankanay, Lepanto or Northern Kankanay, Bontok, Southern Kalinga, Tinguian), but one ethnic unit (Ifugao) has small farmsteads of kinsmen dotted through the rice terraces. The second group are sparsely settled in hamlets or farmsteads around which new gardens are cleared as the soil is worked out (the Gaddang, Northern Kalinga, Isneg or Apayao); some Gaddang live in tree houses.

Cultural elements common to the Igorot area as a whole include use of iron and brass worked by local smiths from metal traded from the lowlands, weaving, beliefs relating to sacred trees and mountains, and animal sacrifice (pigs, chickens, dogs) for omen reading. Modern trade, peaceful travel on roads, Christian mission work, schools and other government activities, and urban influences especially from two mountain centres (Baguio, summer capital of the Philippines, with its gold mines, and the Mountain Province capital, Bontoc) are slowly bringing about assimilation of the Igorot to the general life of the Philippines.

IGUAÇU (IGUASSÚ; Spanish IGUAZÚ), a river which rises near the crest of the great coastal escarpment Serra do Mar in Paraná state, Braz., just east of Curitiba, and flows west for 745 mi. to join the ParanL river. It is thus part of the Plata river system *(see* PLATA, RÍO DE LA), and for the last 75 mi. of its course it forms the boundary between Brazil and Argentina. About 14 mi. above its mouth the river cascades over the famous Iguaqu falls. The Iguaçu river follows a meandering course westward across the Paraná plateau, but is frequently interrupted by rapids. It is only navigable for river boats for a short distance from Pôrto Amazonas to União da Vitória. Between prairie-covered uplands, the valley of the Iguaqu is filled with dense semideciduous forest, cleared

in part by pioneer farmers.

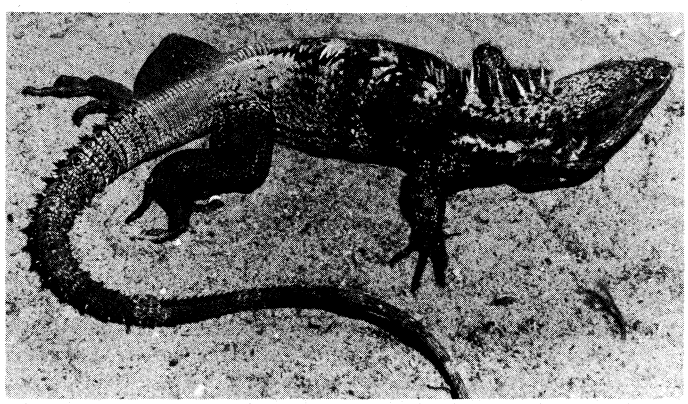
At Iguaqu falls the river drops about 269 ft. into a narrow gorge before emptying into the Paraná. The falls are about 2½ mi. wide, but the water is divided into hundreds of individual falls separated by rocky and heavily forested islands. National parks have been established on either side of the boundary by Argentina (1928) and Brazil (1939). Modern tourist hotels have been built at Foz do Iguaqu and Puerto Iguazú. The falls can be reached most easily by air. but many tourists prefer the river boat trip up the Paraná. The Brazilians have built a highway across Parana state to Foz do Iguaqu. About 30 to 40 ft. higher than Niagara falls, Iguaqu is often described as a potential hydroelectric power site but there are difficulties in the way of such development. First, the volume of water in the Iguaqu river varies greatly during the year, being highest in the southern hemisphere winter; it has been estimated that the rate of flow over the falls is about 62,000 cu.ft. per second for mean annual volume, which under extreme flood conditions may reach more than 450,000 cu.ft. per second. Second, such power development would require co-operation between Argentina and Brazil — traditionally un-co-operative with each other. Third, there is no potential market for power within range of transmission lines.

The name of the river and the falls is a Guarani word meaning "great water." The first Spanish explorers named the cataracts Salto de Santa María (Santa María falls), but the Indian name persisted. (P. E. J.)

IGUANA, the common name for lizards of the family Iguanidae, particularly the larger forms of the family. The same name or its corruption "goanna," is misapplied to the monitors (family Varanidae). With three exceptions all the genera (numbering about 65 and containing about 700 species) .belong to the new world; the exceptional genera are Brachylophus (nearing extinction) in the Fiji Islands and *Hoplurus* and Chalarodon in Madagascar. The Iguanidae can be regarded as the new world analogue of the old world Agamidae, which family it closely resembles in its structure and in the modifications which its members have undergone.

The only absolute distinction between the two families is in the position of the teeth; in the Agamidae they are fused to the crest of the jaw bones and in the Iguanidae attached to the inner slope below this crest. In many, however, the teeth are peculiar in being blade- or spear-shaped, with the upper cutting edges strongly serrated. Most iguanas are clothed with small scales and have a large dewlap, a pouch situated beneath the head and neck. Often a crest on the back and tail is composed of narrow, elongate scales which gradually diminish in size posteriorly. The tongue is short and cannot be thrust out.

Perhaps the best-known species is the common iguana (Iguana iguana), which occurs throughout tropical Central and South America. Reaching a length of as much as six feet (including the tail), this animal is much sought for as an article of diet; the flesh, white and tender, tastes somewhat like that of frogs' legs and is greatly esteemed by the Indians. The iguana is arboreal, its favourite haunts being trees overhanging water, into which it will unhesitatingly plunge if disturbed. Like most of the arboreal species, the ground colour is greenish, relieved in this particular case by brown bands. which form regular rings on the tail. The food consists largely of tender leaves and fruits but the lizards will also readily eat small birds and mammals. Another semi-arboreal genus of tropical America is Basiliscus, whose members exhibit some curious modifications. The body is compressed from side to side, the tail very long and whiplike, the hinder part of the head produced into a flat lobe like a cock's comb and the outer edges of the toes provided with a wide fringe of elongate scales; the males of all species have a crest along the back but in two species (B. *basiliscus* and B. *plumifrons*) this is enormously developed. being as deep as the body, supported by rays like the fins of a fish, and covered with very thin scales. In addition to these structural peculiarities they have the power, shared only by a few other forms of this family, of being able to run across the surface of water; if disturbed near the water they scutter across it on their hindlimbs, the body being held almost upright with the tail raised as a counterpoise and the forelimbs folded against their sides.



BY COURTESY OF JOHN E. WERLER, HOUSTON ZOOLOGICAL GARDENS

BLACK IGUANA (CTENOSAURA ACANTHURA), MANY OF WHICH ARE SOLD FOR FOOD IN MEXICAN MARKETS

Basiliscus often dives to the bottom as does Deiroptyx of Cuba, which rushes across the surface in the same way and in some quiet corner dives to the bottom, where it remains until the alarm has passed. Amblyvhynchus has achieved fame as the only marine lizard. Its aquatic nature has usually been exaggerated, however, and actually it seldom takes to the water. Large herds of these lizards used to frequent the rocky shores of the Galápagos Islands, feeding on the seaweeds between tidemarks. The ground iguana, *Cyclura,* one of the most primitive members of the family, was formerly found in the Galápagos but now is found on only a few islands of the West Indies. Ctenosaura species are the rather large black iguanas of Central America.

About ten genera of small iguanids are found in the U.S.; they are by far the most conspicuous lizards of the southwest. and include the desert iguana (crested lizard), the earless, zebra-tailed (gridiron-tailed), fringe-toed, collared, leopard and spiny lizards; the anoles, chuckwallas, utas and horned toads (*q.v.*).

The terrestrial species of the family are usually duller in colour than the arboreal ones and the body is, as a rule, depressed rather than compressed; this flattening has been carried to an extreme in the so-called horned toads (Phrynosoma) of the deserts of the United States and Mexico. As well as being flattened, they have, like many desert dwelling animals, developed an armour of spines, the largest of which occur on the back of the head and neck. This lizard greatly resembles the Australian moloch lizard, an agamid that under the influence of similar conditions has developed a very similar appearance. A unique characteristic of the homed toads is their ability to squirt a fine jet of blood from the eye; this extraordinary phenomenon, which has never been satisfactorily explained, only occurs under stress of great emotion, fright or anger. The lizard puffs itself up until the eyes bulge and then a very fine stream of blood is shot out of the eye, sometimes to a distance of ; ft. The special mechanism for this discharge is an agglomeration of blood vessels at the corner of the eye.

Another peculiarly modified genus is Anolis, which occurs throughout the warmer districts of both North and South America and which is particularly abundant among the West Indian islands. All of the lizards of this genus have the basal joints of their fingers and toes dilated and covered with transverse lamellae like those of the gecko (*q.v.*) and these adhesive pads, together with the powerful claws, render the animals excellent climbers. They have wonderful powers of changing colour, rivaling in this respect the true chameleons; in fact they are frequently called American chameleons. Anoles or anole would be a better term. The males often have enormously developed dewlaps which may be brilliantly coloured and can be expanded and contracted at will, like a fan.

Iguanids, except for a few species, reproduce by means of eggs laid in the ground. The few exceptions, iguanids living in cool, mountain climates, hatch their eggs within their bodies and bear

live young.

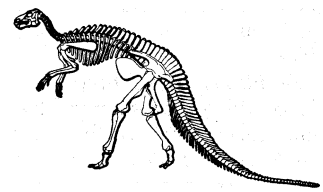
See K. P. Schmidt and R. F. Inger, Living Reptiles of the World (1957). (H. W. P.; X.)

IGUANODON, a large extinct amphibious reptile. Its remains were first discovered in the Wealden (Lower Cretaceous) estuarine deposits of Sussex by G. A. Mantell, who named it Iguanodon, in allusion to the resemblance between its teeth and those of the lizard *Iguana* of tropical America. In 1877 several nearly complete skeletons now in the Royal Museum of Natural History at Brussels were found in the Wealden rocks near Mons, Belgium. Another nearly complete skeleton, now in the British museum, was found by R. W. Hooley in the same rocks at Atherfield in the Isle of Wight. *Iguanodon* is interesting as being the first gigantic extinct reptile which it was attempted to restore by comparison with a modern lizard. Mantell's early restoration proved a failure, because it mas unknonn at the time that this reptile belonged to an extinct group, the Dinosauria (*q.v.*), in which the limbs did not have the sprawling posture found in modern reptiles, but were adapted for maintaining the body well off the ground when at rest. Like all the more active dinosaurs, it had comparatively large and heavy hind quarters, passing into a long tail; and footprints show that it walked only on its hind limbs, using the tail for balancing the fore-quarters.



BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

SKELETON (RECONSTRUCTED) OF THE IGUANODON, AN EXTINCT MAMMOTH REPTILE THAT RANGED SOUTHERN ENGLAND AND NORTHERN EUROPE DURING THE CRETACEOUS PERIOD

The typical species, *I. mantelli,* is from 16 to 20 ft. long, and must have measured about 13 ft. in height when standing upright. The largest known species seem to have been sometimes 33 ft. long. The head is relatively large, laterally compressed, and about twice as long as deep. Its long axis is bent downwards for cropping its vegetable food. The front of both jaws is toothless and must have been covered with a horny beak. The lower half of the beak is supported by a separate "predentary" bone. The edge of each jaw further back bears a single row of teeth, which differ from those of all existing reptiles in being often worn down to stumps by mastication. Under the teeth actually in use are numerous successional teeth. The neck and front half of the back are made flexible by ball-and-socket joints between the vertebrae. The front half of the tail is deep and laterally compressed, evidently for swimming. The small fore-limbs must have been very mobile, and the thumb in the five-fingered hand is reduced to a bony spur. The supporting bones of the hind-limbs are much like those of ostriches, though they differ in never being fused into one mass. The three toes of the heavy hind-foot are so much like those of birds that the fossilized footprints were originally mistaken for those of birds. The body lacks armour, but the skin was hardened with a close covering of small irregular tubercles. Footprints are common on the Wealden sandstones of Sussex, and several series have been observed without any trace of the forefeet and rarely a mark of the tail.

Nothing is satisfactorily known about the possible ancestors of Iguanodon, and few of its closely allied contemporaries have been discovered. The comparatively small *Hypsilophodon,* which occurs with it in the Wealden of the Isle of Wight, differs in having the teeth extending to the front of each jaw. The equally small Psittacosaurus, from rocks of nearly the same geological age in Mongolia, has the toothless front of the jaws shaped almost like the beak of a parrot. The successors of Iguanodon, the Trachodontidae, in the Upper Cretaceous, were more adapted for aquatic life, and their toothless beak was shaped almost like the end of the bill of a duck. The side of each jaw bore a powerful grinding dentition, several rows of teeth being in use at one time. Many of the trachodonts were peculiar in exhibiting a bony crest on the top of the head. (A. S. W.; X.)

IGUVIUM (mod. Gubbio, *q.v.*), a town of Umbria. among the mountains, about 23 mi. N.-N.E. of Perusia and connected with it by a by-road, which joined the Via Flaminia near the temple of Iuppiter Appenninus, at the modern Scheggia. It appears to have been important in pre-Roman times, both from its coins and from the celebrated tabulae *Iguvinae.*

Iguvium was in possession of a treaty with Rome. similar to that of the Camertes Umbri; and in 167 B.C. it was used as a place of safe custody for the Illyrian King Gentius and his sons. After the Social War, in which it took no part, it received full citizen rights and was included in the tribus Clustumina. Under the empire almost nothing was heard of it. Silius Italicus mentioned it as subject to fogs. A bishop of Iguvium is mentioned as early as A.D. 413. It was taken and destroyed by the Goths in 552, but rebuilt with the help of Narses. The Umbrian town had three gates only, and probably lay on the steep mountainside as the present town does, while the Roman city lay in the lower ground. There is the theatre, restored by Cn. Satrius Rufus in the time of Augustus. The diameter of the orchestra is 76½ ft. and of the whole 230 ft.; the stage is well preserved and so are parts of the external arcades of the auditorium. Not far off are ruins probably of ancient baths, and the concrete core of a large tomb with a vaulted chamber within.

Iguvine Tables.—The famous Iguvine (less correctly Eugubine) tables were discovered at Iguvium in 1444, bought by the municipality in 1456, and are still preserved in the town hall. They were originally nine in number, and two of the nine were taken to Venice in 1 j40 and never reappeared. The existing seven were first published in 1724.

Otfried Müller (Die *Etrusker,* 1828), pointed out that though their alphabet was akin to the Etruscan their language was Italic. Karl Lepsius, in his essay De *tabulis Eugubinis* (1833), finally determined the value of the Umbrian signs and the received order of the tables, pointing out that those in Latin alphabet were the latest. He published what may be called the editio *princeps* in 1841. The first edition, with a full commentary based on scientific principles, was that of S. T. Aufrecht and J. W. H. Kirchoff in 1849–51, and on this all subsequent interpretations were based (M. J. A. Bréal, Paris. 1875; F. Bücheler, *Umbrica,* Bonn, 1853, a reprint and enlargement of articles in Fleckeisen's Jahrbuch, 1875, pp. 127 and 313). See also UMBRIAN LANGUAGE.

IHARA (or IBARA) **SAIKAKU** (original name probably HIRAYAMA TŌGO) (1642–1693), Japanese poet and novelist, one of the most brilliant figures of the 17th-century literary revival, was born at Osaka in 1642. His early fame was occasioned chiefly by his amazing facility in composing haiku (see JAPANESE LITERATURE) and linked verse. In 1677 he turned out in the space of "a day and a night" 1.600 verses. Not surprisingly, these were not all of first quality, but to compose at the rate of one verse a minute for 24 hours was an achievement that few poets could match. He steadily increased the number of verses produced in a day, reaching 4.000 in 1680 and the incredible figure of 23,500 verses in 1684. This was somewhat over 16 a minute, and the performance earned him the nickname of the "20,000 poet." Saikaku continued to write verses at more normal speeds, but his style (essentially that of the Danrin school: headed by Nishiyama Soin, his master) was considered so bizarre that rival poets called it "Dutch" to indicate its extreme outlandishness.

Besides poetry Saikaku wrote some unsuccessful puppet plays and works of poetic criticism, but he is best known as a novelist. The style of Saikaku's novels is swift, allusive and elliptic, all qualities stemming from his training as a *haiku* poet. Their content reflects from many angles the Japanese society of the time. After many years of bitter warfare Japan was enjoying peace and prosperity. The merchant class had so risen in importance that its tastes now prevailed in the arts, and the licensed quarters catered to its whims. Many of Saikaku's novels are concerned with the voluptuary pleasures of these quarters. The first and most famous: Koshoku *Ichidai* Otoko ("The Man Who Spent His Life at Love-making," 1682), relates the amorous adventures of its hero, Yonosuke, from his precocious experiences at the age of 6 to his departure at 60 for an island of women. The popularity of this novel led Saikaku to write others in a similar vein, of which the best is Koshoku Gonin *Onna* ("Five Women Who Loved

Love," 1686), a work based on actual events.

Saikaku also wrote novels about the samurai. These are generally considered inferior to his amorous tales or to such accounts of tradesmen's life as *Nippon* Eitagura ("The Japanese Family Storehouse," 1688), a collection of stories on how to make (or lose) a fortune. Whatever the subject, Saikaku's satirical humour and his knack (derived from the haiku) of being able to seize the one detail that best evokes a person's character or his milieu are always conspicuous. Although Saikaku's works reveal a particular affinity for the lively spirit of Osaka, he wrote with facility about all Japan His Saikaku *Shokokubanashi* ("Saikaku's Tales of the Provinces," 1685), for example, records many stories picked up during his travels. His popularity was enormous everywhere and his influence on fiction continued for many years after his death.

IJAW, a people inhabiting the provinces of Owerri and Warri, southern Nigeria. No tribal organization exists; hereditary chiefs in the tonns have civil and religious functions, aided by councils of elders. Extended family groups live side by side. Marriage is permitted between near relations. When the bride-price is high, the wife cannot leave her husband and children belong to the iather; when it is small, divorce is possible and children belong to the mother. The brother inherits. They practise agriculture and arboriculture. are animists, have secret societies and age classes.

IJOLITE, in petrology an igneous rock composed essentially of nepheline and an alkali pyroxene, usually aegirine-augite. The rock was originally described from Iivaara in the parish of Kuusamo. northern Finland. Typically the pyroxene is well crystallized. the nepheline allotriomorphic. Accessory minerals include melanite, titanite, perofskite. apatite, cancrinite and calcite. The rock is the plutonic equivalent of the volcanic nephelinites and nepheline dolerites. Ijolites form characteristic members of carbonatite-alkali igneous complexes like those of Alno (Sweden). Fen (Norway), Khabozero (Kola peninsula—there carrying abundant wollastonite) and Iron hill (Colorado). The ijolites of Magnet cove (Arkansas), Ice river (British Columbia) and Sekukuniland (Transvaal) are among the better-known representatives found in rock collections. The rocks known as urtite (type locality Lujaur Urt, Kola peninsula) and melteigite (Melteig, Fen district, Norway) are essentially similar assemblages. In the former nepheline largely preponderates while melteigite is a melanocratic variant with excess pyroxene. (C. E. T.)

IJSSELMEER, a shallow fresh-water lake in the northern Netherlands formed (1932) by the IJsselmeer dam (Xfsluitdijk) between North Holland and Friesland. It takes its name from the IJssel, one of several rivers which flow into it. Much of the IJsselmeer was formerly the Zuider Zee. See ZUIDER ZEE.

IKHNATON (sometimes spelt AKHENATON), the name assumed by Amenhotep IV. of Egypt.

An adequate understanding of the origins and the history of the religious revolution carried through by this earliest known idealist is impossible without some knowledge of the historical and political situation of his generation. When he came to the throne (c. 1375 B.C.) there were plenty of men still living whose fathers had fought in the great wars of Thutmose III., who consolidated the conquests of his ancestors and united the contiguous regions of Asia and Africa into the first stable empire in history. His genius and his far reaching victories made him the first character of universal aspects, the first world hero. Such a towering personality inevitably affected the thought of the early world. The earliest gods of Egypt had been nature-gods. As the great Pharaonic State arose, the impressive figure of the sovereign profoundly influenced religion; the forms of the State passed over into human conceptions of the gods, and the Sun-god, the greatest of them all, was conceived as a pharaoh ruling the other divinities.

When therefore the power of the Pharaohs was extended to include a world empire, this greatly expanded arena of action deeply affected Egyptian conceptions of the Sun-god's realm. In the career of Thutmose III. the idea of universal power, of a world-empire was personalized and visibly bodied forth. This first great *human* personality of world wide aspects began to affect Egyptian ideas of *divine* personality. Men began to feel the thrill of universalism, expressed, it should be observed, in terms of *political* power. Other relations with the outside world beyond the limits of the Nile valley had not clearly disengaged for the Nile-dwellers the "world idea" as we may call it. For example, a net-work of commercial connections with surrounding countries had arisen centuries earlier and had resulted in a literature of adventure in far-off countries, as illustrated by such tales as the shipwrecked sailor or the story of the wandering hero. Sinuhe; but such knowledge of distant lands had done little toward bringing the great world without into the purview of Egyptian thinking. Neither did the universal power of natural laws, everywhere visibly active in uniform operation, suggest to these early men the world idea. Many a merchant had seen a stone fall in distant Babylon precisely as it did in Egyptian Thebes, but it had not occurred to him or to any man in that far-off age, that the same natural force reigned in these widely separated countries. It was universalism expressed in terms of *imperial* ***power*** which first caught the imagination of the thinking men of the Egyptian empire, and disclosed to them the universal sweep of the Sun-god's dominion as a physical fact. In the ancient East monotheism was but imperialism in religion

The Sun-god Aton.—As early as 1400 B.C. under the magnificent emperor, Amenhotep III., great-grandson of Thutmose III., the expanded conception of the Sun-god's power was gaining currency. In order to give this magnified Sun-god a new identity, not embarrassed by older and more limited conceptions, "Aton," an ancient name for the physical sun, was employed to designate him. When Amenhotep III. died (c. 1408 B.C.), his son and successor, Amenhotep IV., was closely associated with the new ideas. He assumed the office of the High Priest of Aton, with the same title, ('Great Seer," as that of the high priest of the old Sun-god Re at Heliopolis. It is clear therefore, that the new movement was closely connected with the old Solar theology and probably with its organized priesthood likewise.

The new and transformed Sun-god was obviously conceived as far more than the merely material sun. It is evident that the young Pharaoh was deifying the light of the sun or its vital heat, which he found accompanying all life. Light or heat plays an important part in the new faith, similar to that which we find it assuming in the early cosmogonic philosophies of the Greeks. In harmony with this conception the god is constantly stated to be everywhere active by means of his "rays." It is perfectly certain that in an age so early in the development of natural science the king could not have had the vaguest notion of the physico-chemical aspects of his assumption that all life issued from the rays of the sun, any more than had the Greeks in dealing with a similar thought. Yet the fundamental idea is surprisingly true, and as we shall see surprisingly fruitful.

With the international arena of his empire in view the Pharaoh devised a new symbol for the new god. It depicted the sun as a disk from which diverging rays radiated downward, each ray terminating in a human hand. As suggesting a power issuing from its celestial source and putting its hand upon the world and the affairs of men, it was a masterly symbol. It broke sharply with tradition, and for that very reason it was capable of practical introduction into the many countries making up the empire; for it could be understood by a foreigner at a glance, and this was far from being the case with any of the traditional symbols of the old Egyptian religion. To indicate the imperial power of Aton, however, Amenhotep IV. did employ an Egyptian device. He now enclosed the god's full name, as already introduced by the king's father, in two royal cartoucnes identical with those of the Pharaoh, thus suggesting for the god an earthly dominion like that of the Pharaoh.

Conflict Between Amon and Aton.—The king's zeal for the new cult was evident from the beginning. To Thebes, the imperial capital, he gave the new name, "City of the Brightness of Aton," its temple quarter was called, "Brightness of Aton

the Great," while the new Aton sanctuary itself was designated as "Gem-Aton," a term of unknown meaning. The priesthood of Amon who had long been the State god at Thebes, was a rich and influential body, and the high priest of Amon was head of a national sacerdotal organization including all the priesthoods of the country. Politically this Amonite priesthood had gained great power. A bitter conflict thus broke out, at first probably, chiefly between Amon and the intruder Aton, but eventually also between Aton and the older gods. The struggle eventually rendered Thebes intolerable to the young revolutionary. He broke with all the old priesthoods and began a drastic persecution to make Aton the sole god of the empire, not merely in the king's own thought, but in very fact. As far as their visible and external manifestations were concerned, this extermination of the old gods could be and was accomplished. Even the word "gods," the plural of the common noun "god," was carefully expunged from the monuments. In the tomb of Ramose, his father's old prime minister, a tomb still surviving in the Theban cemetery, Amenhotep IV.'s emissaries hewed out the word "gods" no less than nine times, clearly indicating their intentions, notwithstanding three untouched occurrences of the word which escaped their notice and which we still find in out-of-the-way corners of this marvellously sculptured tomb.

The persecution of Amon was especially severe and to-day the splendid monuments of Thebes are still dotted with unsightly holes where the hated god's name once stood. The young iconoclast was even involved in the expungement of his own father's name, Amenhotep, for it contained the name of the hostile god. Living as he probably was, in his father's splendid Theban palace, the wreckage of which is still visible, he finally brought himself to disfigure its sumptuous wall and ceiling decorations with unsightly blemishes where he blotted out his own father's name. With regard to his own name he was himself in the same embarrassing predicament, bearing as he also did, the illustrious throne name "Amenhotep," meaning "He in whom Amon is content." The king therefore cast off his old name, with all its traditional associations of power and splendor, and chose another of similar significance, "Ikhnaton," which means "Aton is satisfied," or "He in whom Aton is satisfied"

The New Capital, **Akhetaton.**—It is evident that this terrible revolution, violating all that was dearest and most sacred in Egyptian life and traditions, must have been a devastating experience for the young sovereign. Thebes became an impossible place of residence. His father's palace was disfigured by his own hand and the towering pylons and obelisks of Karnak and Luxor were a continual reminder of all that his fathers had contributed to the glory of Amon and the old gods. He therefore determined to forsake the capital and imperial residence of his ancestors. In each of the three great divisions of the empire, Egypt, Nubia and Asia, he built a city consecrated to Aton, and in the Egyptian Aton city he took up his own residence. He chose as its site a spacious bay in the Nile cliffs about 160 m. above the Delta and nearly 300 m. below Thebes. He called it "Xkhetaton," which means "Horizon of Aton" and it is known in modern times as Tell el-Amarna. The city thus established was designated as the real capital of the empire. In the sixth year of his reign and shortly after he had changed his name, we find the young king living in his new residence.

The evidence indicates that all that was devised and done in the new city and in the development and propagation of the Aton faith, was the work of the king himself. Everything bears the stamp of his individuality. The men about him must have been irresistibly swayed by his unbending will, for he was evidently not one to stop half way. But Ikhnaton understood enough of the old policy of the Pharaohs to know that he must hold his party by tangible rewards, and his leading followers enjoyed liberal bounty at his hands. Thus one of his priests of Aton and at the same time his master of the royal horse, named Eye, who had by good fortune happened to marry the childhood nurse of the king, states in his tomb inscriptions: "He doubles to me my favours in silver and gold." The commander of Ikhnaton's army likewise says: "He hath doubled to me my favours like the numbers of the sand. I am the head of the officials, at the head of the people; my lord has advanced me because I have carried out his teaching, and I hear his word without ceasing. My eyes behold thy beauty every day, O my lord, wise like Aton, satisfied with truth. How prosperous is he who hears thy teaching of life!" Although there probably was a nucleus of men who really appreciated the ideal aspects of the king's teaching, such inscriptions make it evident that many were not uninfluenced by "the loaves and the fishes."

A beautiful cliff-tomb hewn in the eastern cliffs by royal crafts' men at the king's command was the Pharaoh's most welcome demonstration of favour to each one of his followers. The walls of such a tomb chapel bore fresh and natural pictures from the life of the people in Akhetaton, the new capital, particularly incidents in the life of the dead man, and preferably his intercourse with the king. Thus the city of Akhetaton is now better known to us from its cemetery than from its ruins.

Throughout these tombs, both in relief and inscription, the nobles take delight in reiterating the intimate relation between Aton and the king. Over and over again they show the king and the queen standing together under the disk of Aton, whose enveloping rays terminating in hands, descend and embrace the king's figure. The nobles constantly pray to the god for the king, saying that he "came forth from thy rays," or "thou hast formed him out of thine own rays"; and interspersed through their prayers were numerous current phrases of the Aton faith, which had now become conventional, replacing those of the old orthodox religion which it must have been very awkward for them to cease using. On State occasions instead of the old stock phrases, with innumerable references to the traditional gods, every noble who would enjoy the king's favour was evidently obliged to display his familiarity with the Aton faith by a liberal use of these new allusions. The source of such phrases was really the king himself, and something of the "teaching" whence they were taken, so often attributed to him, is preserved in these "Amarna tombs," as we now commonly call them.

Hymn to Aton.—Among the fragments of the Aton faith which have survived in these tombs are two hymns to Aton, the longer and finer of which is worthy of being known in modern literature. It was probably written by the king himself. In the following translation the effort has been chiefly to furnish an accurate rendering. The headings of the strophes are insertions by the present writer, intended to make clear the arrangement of the subject matter, especially striking because it is identical with that in Psalm civ. of the Old Testament, which is many centuries later.

NIGHT

When thou settest in the western horizon of **the sky,**
The earth is in darkness like the dead;
They sleep in their chambers,
Their heads are wrapped up,
Their nostrils are stopped,
And none seeth the other,
While all their things are stolen,
Which are under their heads,
And they know it not.
Every lion cometh forth from his den,
All serpents, they sting.
Darkness . . .
The world is in silence,
He that made them resteth in his horizon.

DAY AND MAN

Bright is the earth when thou risest in the horizon.
When thou shinest as Aton by day
Thou drivest away the darkness.
When thou sendest forth thy rays,
The Two Lands (Egypt) are in daily festivity,
Awake and standing upon their feet
When thou hast raised them up.
Their limbs bathed, they take their clothing,
Their arms uplifted in adoration to thy dawning
(Then) in all the world they do their work.

DAY AND THE ANIMALS AND PLANTS

All cattle rest upon their pasturage,
The trees and the plants flourish,
The birds flutter in their marshes,

Their wings uplifted in adoration to thee.
All the sheep dance upon their feet,
All winged things fly,
They live when thou hast shone upon them.

DAY AND THE WATERS

The barques sail up-stream and down-stream alike.
Every highway is open because thou dawnest.
The fish in the river leap up before thee.
Thy rays are in the midst of the great green sea.

CREATION OF MAN

Creator of the germ in woman,
Maker of seed in man,
Giving life to the son in the body of his mother,
Soothing him that he may not weep,
Nurse (even) in the womb,
Giver of breath to animate every one that he maketh!
When he cometh forth from the womb . . . on the day of his birth,
Thou openest his mouth in speech,
Thou suppliest his necessities.

CREATION OF ANIMALS

When the fledgling in the egg chirps in the shell
Thou givest him breath therein to preserve him alive.
When thou hast brought him together (?)
To (the point of) bursting it in the egg,
He cometh forth from the egg
To chirp with all his might (?).
He goeth about upon his two feet
When he hath come forth therefrom.

THE WHOLE CREATION

How manifold are thy works!
They are hidden from before (us),
O sole God, whose powers no other possesseth.
Thou didst create the earth according to thy heart
While thou wast alone:
Men, all cattle, large and small,
All that are upon the earth,
That go about upon their feet;
(All) that are on high,
That fly with their wings.
The foreign countries, Syria and Kush,
The land of Egypt,
Thou settest every man into his place,
Thou suppliest their necessities.
Every one has his possessions,
And his days are reckoned.
The tongues are divers in speech,
Their forms likewise and their skins are distinguished.
(For) thou makest different the strangers.

We may conjecture that this hymn, partially reproduced above, was a fragment from the ritual of Aton as it was celebrated from day to day in the Aton temple at Amarna. Unhappily it was copied in but one tomb; in the others we have a miscellany of current quotations and stock phrases which made up the knowledge of the new faith as it had been apprehended by the scribes and painters who decorated these tombs. It is our misfortune that the fragments of the Aton faith, which have survived to us in the Amarna cemetery, our chief source, have thus filtered mechanically through the indifferent hands and the starved and listless minds of a few petty bureaucrats on the outskirts of a great religious and intellectual movement.

The New Universalism. — Nevertheless in this great hymn the new universalism of the empire finds full expression and the royal singer sweeps his eye from the far-off cataracts of the Nubian Nile to the remotest lands of Syria. He was looking beyond the nationalism which had prevailed for over 2,000 years, and he was consciously endeavouring to displace it by a world religion. Irrespective of race or nationality, he bases the universal sway of God upon his fatherly care of all men alike. He calls Aton "the father and the mother of all that he has made," and the hymn which we have just quoted above is very explicit in its insistence that Aton's fatherly care of all men entirely disregards diversity of speech or difference in colour. To the proud and exclusive Egyptian he points to the all-embracing bounty of the common father of humanity, even placing Syria and Nubia before Egypt as he catalogues the divisions of his empire.

Ikhnaton had gained the conception of a world-lord in two aspects: first, as the creator of the natural world; and second, as a benevolent father actively concerned for the daily maintenance of all his creatures, even the meanest. His hymns are the earliest known expression of deep emotion in the recognition of divine goodness and benevolence. Mingled with it is an almost ecstatic rapture in the thought of the all-enveloping light in which he saw revealed both the beauty and the goodness of the natural order. It reminds us of Him who bade us "consider the lilies." The picture of the lily-grown marshes, where, as another hymn tells us, the flowers are "drunken" in the intoxicating radiance of Aton, where the birds unfold their wings and lift them "in adoration of the living Aton," where the cattle dance with delight in the sunshine, and the fish in the river beyond leap up to greet the light, the universal light whose beams are even "in the midst of the great green sea"—all this discloses a discernment of the presence of God in nature, and an appreciation of the revelation of God in the visible world such as we find centuries later in the Hebrew psalms, and especially in our own poets since Wordsworth.

While the creative power and the benevolence of his god were very explicitly affirmed by Ikhnaton, our sources do not show us that he had risen from a discernment of the beneficence to a conception of the righteousness in the character of God, nor of his demand for this in the character of men. Nevertheless, there is in Ikhnaton's "teaching," as it is thus fragmentarily preserved in the hymns and tomb-inscriptions of his nobles, a constant emphasis upon "truth" such as is not found before nor since. The king always attached to his name the extraordinary phrase "living in truth," and that this phrase was not meaningless is evident as we discern the character of his daily life.

To him "living in truth" meant sincere acceptance of the daily facts of living in a simple and unconventional manner never before seen in the life of a sovereign and quite impossible of harmonization with the outward pomp and splendour of an oriental emperor. For him what *was* was right, and its propriety was evident by its very existence. Even in public he divested his daily round of those outward and formal observances which his royal ancestors had observed for 2,000 years. Thus, his family life was open and unconcealed before the people, even in intimate manifestations of family affection. He took the greatest delight in his children and appeared with them and the queen their mother on all possible occasions as if he had been but the humblest scribe in the Aton-temple. He had himself depicted on the monuments while enjoying the most familiar and unaffected intercourse with his family, and when he drove in his chariot to the temple to carry on its formal service, the queen and the daughters she had borne him likewise drove thither through the acclaiming multitudes and shared with the king the temple service. All that was natural was to him true, and he never failed practically to exemplify this belief, however radically he was obliged to disregard tradition.

Effect of the Revolution on Art. — These revolutionary changes in religion and in the position and character of the head of the State were not confined to theology, statecraft or palace proprieties. They unavoidably affected also the art of the time, and it was the intention of Ikhnaton to modify art in accordance with his regard for "truth." His chief sculptor, Bek, appended to his title the words, "whom his majesty himself taught." It is evident that the artists of Ikhnaton's court were taught by him to make the chisel and the brush tell the story of what they actually saw. The result was a simple and beautiful realism that saw more clearly than any art had ever seen before. They caught the instantaneous postures of animal life; the coursing hound, the fleeing game, the wild bull leaping in the marsh; for all these belonged to the "truth" in which Ikhnaton lived. The exalted divinity which for untold centuries had invested the Pharaoh's person with inviolable sacredness was stripped away without hesitation. Ikhnaton's artists represented him as they saw him, in attitudes of parental affection as he fondled his little daughters, or even as the object of the wifely solicitude of his queen as she stands in his presence in affectionate concern for his needs Such is the lovely scene on the back of the famous palace chair, preserved to us in the tomb of Tutankhamun. For the first time in

the history of art the subject of a great composition was a human relationship, and to depict it the artists of the day shook off the shackles of immemorial tradition. The monuments of Egypt and even the furniture and equipment of daily life bore what they had never borne before, a Pharaoh depicted in the natural and unaffected relations of life, and completely liberated from the rigid and conventional posture demanded by both the traditions of court propriety and by the venerable teachings of the State theology regarding the divinity of the sovereign. It is in this extraordinary art, which we commonly call the "Amarna school" or "Amarna art," that the revolution of Ikhnaton is most clearly disclosed as the earliest known age of spiritual emancipation.

Loss of the Empire.—A man wholly absorbed in a revolution like this found little time or inclination to devote any attention to the critical state of the empire. For three generations the royal house of Egypt had stood in close relations to the kings of Western Asia, and especially the kings of Mitanni on the Upper Euphrates had given their daughters in marriage to the Pharaoh. Supported by such alliances Ikhnaton failed to appreciate the gravity of the new movements which were transforming the political situation in Western Asia. In the north the expanding power of the Hittites gradually absorbed all the Pharaoh's vassal States in Syria; while in the south, *i.e.*, in Palestine, the incoming mercenary bands of nomads were steadily taking possession of Palestine, which the Pharaohs had held for centuries. It was this movement of nomadic hordes from the desert toward a settled life in the Palestinian towns, which carried the Hebrews into Palestine. At Akhetaton, the new and beautiful home of the Aton faith, the temple of Aton resounded with hymns to the new god of the empire, while the empire itself was no more,

The storm which had thus broken over Ikhnaton's Asiatic empire was not more disastrous than that which threatened him in Egypt; but there was no faltering in his steadfast policy. At his command temples of Aton had arisen all over a land which was now convulsed with revolution. Some years after Ikhnaton had disappeared, his son-in-law, Tutankhamun, left the following description of the hopeless situation of Egypt both at home and abroad: "The temples of the gods and goddesses were [desolated] from Elephantine [First Cataract] as far the marshes of the delta. . . . Their holy places were forsaken and had become overgrown tracts . . ., their sanctuaries were like that which has never been, and their houses were trodden roads. The land was in an evil pass, and as for the gods, they had forsaken this land. If people were sent to Syria to extend the borders of Egypt, they prospered not at all; if men prayed to a god for succour, he came not; . . . if men besought a goddess likewise, she came not at all."

***Opposition to* the New Religion.**—Ikhnaton had endeavoured to exterminate some of the most cherished beliefs of the people, especially those regarding the hereafter. Throughout the entire cemetery of his new capital not a single tomb contains the name of Osiris, upon whom every Egyptian, following the faith and practice of his ancestors, expected to depend for protection and guidance through the terrible fears and dangers that beset the dead in the world beyond the grave. This attempted banishment of Osiris must have aroused the fiercest opposition among the people. Eighteen hundred years after Ikhnaton's revolution, the Christian emperor, Theodosius, endeavoured to banish from Egypt the old pagan gods of the people, in an effort to introduce exclusively the God of the Christians. Long after the death of Theodosius the old gods of Egypt continued nevertheless to be worshiped by the people of Upper Egypt. What the power of the Roman emperor failed to accomplish could not of course be attained under much less favourable circumstances by Ikhnaton. The Aton-faith remained but the cherished theory of the idealist Ikhnaton and a little court circle surrounding his person; it never really became the religion of the people.

To the secret resentment and opposition of the people we must also add the dangerous activities of the dispossessed priesthoods, especially the politically powerful former priests of Amon, the old State god. Even more dangerous was the disaffection and discontent among the leaders of the army as they beheld the Egyptian empire in Asia falling to pieces for lack of effective military intervention. One of these leaders indeed, an officer named Haremhab who had long been a favoured partisan of Ikhnaton, not only contrived to win the support of the military class, but also gained the favor of the priests of Amon, who were of course looking for just such a man. Thus both the people and the priestly and military groups alike were united in plans for the overthrow of the hated dreamer in the palace of the Pharaohs, of whose thoughts they understood so little, and who incensed them with the teaching that both the Asiatics and the Egyptians were all children of the same kindly Father. In this dangerous situation, having no son to succeed him, he gave his eldest daughter in marriage to one of his favourites, and needing support, appointed his son-in-law as co-regent with himself. His position seems to have been complicated by family troubles in these closing days, and we find the name of his queen expunged from some of the family monuments at Amarna. He survived but a short time after arranging the co-regency and about 1358 B.C., in the 17th year of his reign, when he was probably not yet 30 years of age, he passed away.

It must be admitted that Ikhnaton pursued his aims with fatuous blindness and feverish fanaticism regardless of the destructive costs. There is something hectic and abnormal in this extraordinary man, suggesting a mind which may even have been diseased. Some question has been raised regarding the identity of the body found in his coffin; but it should be noted that the skull found with this body is one of the largest human crania ever found. However much we may censure him for the loss of his empire, however much we may condemn the fanaticism with which he pursued his aim, it must be recognized that there died with him a spirit such as the world had never seen before—a brave soul, undauntedly facing and opposing the momentum of century long tradition, in which it had never occurred to any mind before his to do anything but thoughtlessly acquiesce. He was the first of the long line of revolters against tradition and thoughtless acceptance of the past. He stepped out of the long line of conventionally colourless Pharaohs that he might disseminate ideas far beyond and above the capacity of his age to understand. He is looked upon not only as the world's first idealist and the world's first individual, but also as the earliest monotheist and the first prophet of internationalism—the most remarkable figure of the ancient world before the Hebrews.

IKI, an island of Japan. lying about 10 mi. off the northwest coast of Nagasaki prefecture of which it is part. Area, 53 sq.mi.; pop. (1955) 51,765. Most of the island is tableland and about 70% is under cultivation; cereals and tobacco are the important crops. Some of Kublai Khan's invading Mongols landed at Iki in the 13th century for the island lies in the Tsushima strait (eastern channel) on the direct route from Korea to Kyushu. Anchorages are at Gōnoura, Katsumoto and Ashibe. The chief town is Gōnoura. (R. B. H.)

ILCHESTER, a small agricultural town in the Yeovil rural district of Somerset, England, on the Ivel or Yeo river, 5 mi. N.W. of Yeovil Pop. (1951 est.) 731. Ilchester (Gifelcestre, *Ivel*cestre, Yevelchester, Ivelchester) was the Lendiniae of the Romans, the northern tribal capital of the Durotriges and the largest Roman town in Somerset. A royal mint was established by the time of Edgar (959–97j), and money was coined there until the reign of Henry III. In 1086 Ilchester was a royal borough with 107 burgesses and was granted a charter by Henry II. confirmed by John in 1203, giving it the same liberties as Winchester. It had a king's jail from before 1166 until 1843. From the 14th to the 19th centuries it was the centre of the county administration and the assizes and quarter sessions were held there. The town

was governed by a bailiff and 12 capital burgesses; the corporation, established in 1556. was abolished in 1886. From 1298 until 1832 Ilchester returned two members to parliament (among them Richard Brinsley Sheridan). It had two annual fairs, and its Wednesday market dated from Saxon times until the mid-19th century. In the middle ages there were seven parish churches in the town, St. Mary Major being the only one left; there were also a Dominican friary, an Augustinian nunnery, a lepers' hospital and an almshouse. Roger Bacon was born there *c.* 1214.

ILE-DE-FRANCE, an ancient region of France. The name "Francia," given under the Merovingians to the region between the Rhine and the Seine, was restricted under the Carolingians to the country bounded by the Aisne. the Oise and the Seine. In the 10th and 11th centuries it signified only the territory limited by the Seine, the Marne. the Reuvronne, the Oise and the Nonette. In the middle ages the word "isle" often designated countries more or less bounded by rivers, but we do not find it given specifically to France before 1387. In the 16th century the *gouvernement* of Ile-de-France was constituted under a governor or a lieutenant of the king. In the 18th century Ile-de-France was divided between the two *généralités* or *intendances* of Paris and Soissons. Under the Revolution the department of the Seine was formed from the territory of Ile-de-France, other sectors going to the departments of Seine-et-Oise, Seine-et-Marne, Oise and Aisne and smaller sectors to Loiret and Nièvre. The name Ile-de-France is also used for Mauritius (*q.v.*).

See P. Bernus, *Histoire de l'Ile de France* (1936); *A.* Leynitz, *L'Ile de France, sa géographie, sop histoire* (1948). (MI. M.)

ILERDA, CAMPAIGN OF (49 B.C.), the victory of Julius Caesar over Pompey's forces in Spain *(see* CAESAR. GAIUS JULIUS). When Caesar had forced Pompey to evacuate Italy, he decided not to follow him to Greece, but first to deal with Pompey's seven legions in Spain. In the spring of 49 B.C. he sent forward six legions from Gaul under Gaius Fabius. and joined them as soon as possible at Ilerda (Lerida) on the Sicoris (Segre) river, a tributary of the Ebro. Five Pompeian legions. together with many Spanish auxiliaries, commanded by L. Afranius and M. Petreius. concentrated against Caesar. They held Ilerda, which stood on a hill, and occupied a steep ridge (Gardeny) to the southwest. while below the city was a stone bridge over the river which was vital to their supplies. The river was subject to violent spring flooding. Caesar, who failed to provoke Afranius to battle, formed a camp near the enemy in order to hamper their foragers, but his attempt to seize a strong point between Ilerda and Gardeny was beaten back. When floods swept away his bridges, he was in a precarious position and short of supplies, although he managed to get one convoy safely across the river about 20 mi. to the north. Then he diverted part of the river just below Ilerda to make a ford near his camp; this forced the Pompeians to move two legions over the Sicoris to cover their communications against Caesar's superior cavalry. The tables thus being turned. Afranius retired toward the Ebro. Caesar, however, pursued him and headed him off: after a week of maneuvering the Pompeians. short of food and water, had to surrender. Caesar. having won a great victory with little loss, then showed his clemency: the enemy troops were disbanded, Afranius and Petreius were spared, and within two months all Spain was Caesar's.

See T. Rice Holmes, *The Roman Republic and the Founder of the Empire*, vol. ii (1923). (H. H. SD.)

ILESHA, a town of Western Region, Nigeria, lies on hills in the heart of the region and is the centre of an administrative division, bounded by the divisions of Ondo, Ife and Oshun. Pop. (1960) 82,427 (African pop.). The divisional council offices and the council hall (1934) are situated on Market square. Near this square are the Afin (king's palace), the central mosque and the principal park. The Wesley guild hospital was established in 1913.

Among the educational institutions are the women's training college; Ilesha grammar school, oldest secondary school of the town; and St. Margaret's secondary school. The main occupations are farming and trade; chief exports are cocoa and kola nuts; imports are consumer goods, such as cottons and hardware. Ilesha is linked by trunk roads with Ibadan and Lagos to the west, Oshogbo to the northwest and Benin to the southeast. The town has relics of its past as a warlike centre of the Yoruba people, such as the memorial to the warrior Ogedengbe, a native of Ilesha. who died in 1910. The inhabitants are of the Ijesha subgroup of the Yoruba; they are much interrelated and hold some land in common. They consider it a great advantage "to be an Ijesha who lives in Ilesha." (F. O. E.)

ILFORD, a municipal and parliamentary borough of Essex, England, 7 mi. E.N.E. of London bridge by road. Pop. (1961) 178,210. Area 13.2 sq.mi. Its popularity as a residential centre for London workers dates from the late 19th century (the population in 1901 was 41,279) and the borough (incorporated in 1926) now includes parts of Becontree and Hainault. Ilford returns two members to parliament. Photographic materials are manufactured.

Built where the Roman road from London to Colchester crossed the marshes. Ilford covers fertile land formerly used as a market garden for London. The name (Hile-ford in 1231) denotes the early site at a crossing of the Hyle river. non the Roding.

ILFRACOMBE, an urban district and holiday resort of Devonshire. England, on the southern shore of the Bristol channel, 52 mi. N.W. of Exeter by road, in the North Devon parliamentary division. Pop. (1961) 8,701. Area 8.8 sq.mi. The oldest part lines the winding valley breaking the steep coastal cliffs and forming the harbour between Capstone and Hillsborough (447 ft) hills. The town has spread over these hills on the edge of Exmoor, and tunnels lead to beaches at the foot of the cliffs The church of Holy Trinity, dating originally from the 12th century, is of various periods and has a beautiful wagon roof.

ILI, river of central Asia. in the Sinkiang-Uigur Autonomous Region of China and the Kazakh Soviet Socialist Republic of the Soviet Union. The length of the Ili from the confluence of its two headstreams, the Tekes and the Kunges, is 590 mi.; including the Tekes, it is 869 mi. The Tekes rises east of Lake Issyk-Kul on the north slopes of the Khan-Tengri mountain knot of the Tien-shan in the southeastern corner of Alma-Ata *oblast* of the Kazakh S.S.R. At first the Tekes flows eastward into Sinkiang until it meets the Kunges, which rises farther east in the Tien-shan. The combined stream, assuming the name Ili, then turns westward past Kulja (I-ning) and re-enters the Kazakh S.S.R.. where it flows past the town of Ili to Lake Balkhash (*q.v.*). In its upper reaches. the Ili is a mountain torrent with a steep gradient. Belon the confluence with the Kash, a right-hand tributary, the Ili emerges from the Tien-shan on the broad Ili valley, characterized by low swampy banks overgrown with reeds. The valley, enclosed by outlying spurs of the Tien-shan, ends at the Kapchagay gorge, 7 mi. below the town of Ili. where the Turkestan-Siberian (Turksib) railroad crosses the Ili. Beyond the Kapchagay gorge, which is the site of a proposed dam and hydroelectric station, the Ili flows through desert sands past the small settlement of Bakanas. forming a narrow delta on Lake Balkhash. Muskrats introduced among the reeds of the Ili delta before World War II have acclimatized and are being trapped for their pelts The Ili is fed mainly by the melting snows and glaciers of the Tien-shan and reaches its high-water stage in July and August, when the rate of flow rises to 100,000 cu.ft. per second (average annual rate of flow is 15,000 cu.ft. per second). The short tributaries that join the Ili along its middle course are used for irrigation. The main stream is navigable during the ice-free season from April to October.

The proposed Kapchagay project will create an 800-sq.mi. reservoir that will require the relocation of the town of Ili and of the Turksib railroad crossing. The reservoir project also was a factor in the realignment of the Urumchi-Alma Ata railroad from the Ili valley to the Dzungarian gate.

The Russians moved into the Ili valley in the conquest of central Asia in the mid-19th century and clashed repeatedly with the Chinese. who had reached the area earlier. From 1871 to 1881,

the Russians occupied the entire valley. including China's Kulja district. before the valley was divided between China and Russia along the present border.

In addition to being the designation of the river and of the Soviet town on the lower course. Ili is also the name of a former Chinese headquarters of the upper valley. This town was sacked in a Moslem rebellion in 1868 and was superseded by Rulja. The remains of old Chinese Ili are called Hui-yiian. (T. SD.)

ILION, a village of Herkiiner county, N.Y., U.S., 12 mi. S.E. of Utica (*q.v.*) on the Mohawk river (the New York State Barge canal); a part of the Utica-Rome standard metropolitan statistical area. Originally part of a Palatinate German settlement. Ilion was unimportant until 1825 when the Erie canal was built. In that decade Eliphalet Remington, Jr., perfected a rifle of such excellence that it was adopted by the U.S. army and several foreign governments. Remington factories thereafter became the principal support of Ilion and the villages around it. Searching for diversification, the company in 1873 introduced the first practical typewriter. Further diversification into office machinery and equipment led to the Univac electronic computer, developed in the 1950s.

The community was known successively as German Flats. Morgan's Landing and Remington Corners before it was incorporated as Ilion in 1852. For comparative population figures *see* table in NEW YORK: *Population.* (V. C. C.)

ILIPA, BATTLE OF (206 B.C.. or, less probably, 207), the final victory of the Roman general P. Cornelius Scipio (later surnamed Africanus) over the Carthaginian forces in Spain during the Second Punic War *(see* PUNIC WARS). Scipio! who had been campaigning against the Carthaginian armies in Spain since 210, met their combined forces under Hasdrubal Gisco and Mago near Ilipa (Alcalá del Rio, about 8 mi. N. of Seville). With 45.000 infantry and 3.000 cavalry, he had about 10.000 men less than the enemy. For several days the two armies faced each other in battle array, with their best troops in the centre, and their allies on the wings. Early one morning a Roman cavalry attack forced Hasdrubal Gisco to lead out his men in their normal formation. only to find too late that Scipio had put his Roman troops on the wings and his Spanish allies in the centre. A complicated maneuver followed. Scipio's centre advanced slowly, declining battle but "fixing" the enemy's centre; meanwhile his wings were extended. then they advanced in column and wheeled again into line, thus outflanking the enemy, whose resistance soon crumpled. By a rapid pursuit Scipio cut off the enemy's retreat. Few Carthaginians escaped. This victory was won by brilliant tactics, such as no Roman army could have performed a few years earlier; they were made possible only by Scipio's recent reforms and training. The battle smashed Carthaginian power in Spain once and for all, and this affected the whole course of the war against Hannibal.

See H. H. Scullard. *Scipio Africanus in the Serond Punic War* (1930). with bibliography; for 'the site, *Journal of Roman Studies,* vol. 26 (1936). (H. H. SD.)

ILKESTON, a market town and municipal borough in the Ilkeston parliamentary division of Derbyshire, Eng.. 10½ mi. N.E. of Derby and 7 mi. W. of Nottingham by road. Pop. (1951) 33.677. Area 4.7 sq.mi. It is a mining and manufacturing town standing on a hill overlooking the Erewash valley to the east. In the market place. used for a market on Saturdays and illuminated by fluorescent lighting, stands the church of St. Mary the Virgin, a Norman and Early English building with a fine 13th-century chancel screen. The town obtained a grant for a market and fair in 1252 and was incorporated in 1887. Coal mining and the making of iron and concrete pipes. hosiery, needles, plastics. clothing, various fabrics and coffee are its chief industries.

ILKLEY, a small town and urban district in the Ripon parliamentary division of the \Vest Riding of Yorkshire, Eng.. 17 mi. N.W. of Leeds by road, lying in mid-Wharfedale. bounded by the Wharfe river (north) and the crest of Ilkley moor (south). rich in legend. Pop. (1951) 17,284. Area 13.5 sq.mi. "Cup and ring" and "swastika" markings on the rocks of the moor, as well as stone circles in the vicinity, give ample evidence of prehistoric occupation. In 1919 Roman remains were excavated in the town and the 1st-century fort was possibly the Olicana of Ptolomy and the *Ravenna Cosmography.* Ilkley was originally a spa but is now residential. There is a large open-air swimming pool which attracts many visitors to this place which has become famous through the popular song beginning:

Wheer wer' ta bahn w'en **Aw** saw thee,
On Ilkla Moor baht 'at?

The ruins of Bolton abbey (*q.v.*) stand by the Wharfe, absut 6 mi. above Ilkley.

ILLAWARRA, a coastal district south of Sydney, New South Wales, Austr.. covering 2,234 sq.mi. (Illawarra is a corruption of the aboriginal name Alowrie meaning "from the sea to the mountain.") The district, which is cut off from the inland plateau by steep cliffs rising to 1,200 ft., comprises the industrial city of greater Wollongong and the fertile agricultural land to the south. More than 80% of the population is in the city of greater Wollongong, where the chief industries are steel manufacture and coal mining. The main rural industry is dairying, about 18,000,000 gal. of milk being produced annually. The climate is mellow, with generally warm winters, moderately hot summers and a sustained average annual rainfall of 48 in. The region contains many popular seaside holiday resorts.

ILLE-ET-VILAINE, a maritime *département* of northwestern France, formed in 1790 out of the eastern part of the old province of Brittany. Pop. (1954) 586.812. Area 2,700 sq.mi. It is bounded north by the English channel: the Bay of St, Michel and the *département* of Manche; east by Mayenne; south by Loire-Inférieure; and west by Morbihan and Côtes-du-Nord. The *département* consists of the basin of the upper Vilaine, with those of its tributaries (all navigable): the Ille from the north. the Seiche from the east and the Meu from the west, and the coastland north of the low watershed from the estuary of the Rance on the west to that of the Couesnon on the east. The Vilaine is navigable as far north as Rennes, which is connected by canal via the Ille with Evran on the Rance. The rich Marais de Dol, protected by dykes from the sea. occupies most of the north coastal plain. The coast is rocky and dangerous. The climate is oceanic, temperate and rainy, with fogs in spring and autumn. The soil, originally poor, has been improved by the use of artificial manure. Cereals are grown, chiefly wheat, buckwheat. oats and barley. Potatoes. beetroot. early vegetables, flax and hemp are also largely grown, and tobacco is cultivated in the arrondissement of St. Malo. Orchards are abundant. especially near Dol. Stock raising and dairying are important. Lead mines and quarries of slate, granite, etc.. are worked. There are boatbuilding yards, iron and copper foundries and forges and a widespread tanning industry. Sailcloth, rope, pottery. boots and shoes (Fougères), farming implements, paper and furniture are also made. The chief ports are St. Malo and St. Servan. Fishing is very active on the coast, and St. Malo, St. Servan and Cancale send fleets to the Newfoundland codbanks. There are also important oyster fisheries in the Bay of St. Michel, especially at Cancale. Dinard is the chief of a group of fashionable bathing resorts. Exports include agricultural products. butter, mine posts and dried fish; imports, livestock, coal, timber, building materials and wheat. The *département* is served by the Ouest-État railway. Ille-et-Vilaine is divided into the *arrondissements* of Fougères, St. Malo, Redon and Rennes, and it consists of 43 cantons and 361 communes. The chief town is Rennes, which is the seat of an archbishop and of a court of appeal, headquarters of the 10th army corps and the centre of an *académie* (educational division).

ILLEGITIMACY, the state of being of illegitimate birth (from Lat. *illegitimus,* "not in accordance with the law," hence born out of wedlock). All societies need to perpetuate themselves and are concerned with how they do so, generally approving or preferring procreation only within marriage. A socially recognized and regulated relationship between the sexes is in the interests of social order, and the systematic care and attention of both parents is best for the child. Illegitimacy is universally condemned. although the forms of punishment vary from place to place and from time to time in the same place. Not to condemn illegitimacy would be to attach no special significance to marriage. Recognizing the

great importance of marriage for social responsibility and stability, and the corresponding dangers of nonmarriage, the state makes marriage easy, the requirements being few and simple.

Limitations of the Data. — The amount of illegitimacy is unknown in most countries. In the United States a shifting number of states do not require a report on legitimacy status. The illegitimacy rate for the United States as a whole is but an estimate based on the data from those states reporting on illegitimacy, and is therefore subject to error. There is, moreover, a social stigma attaching to illegitimacy, which encourages false statements on birth certificates or even failure to record illegitimate births at all. The estimates of illegitimacy for the United States do not contain statistical adjustments for these contingencies.

Methods of Computing Rate. — There are two widely used methods of computing the illegitimacy rate. The more common method is the ratio of illegitimate births to 1,000 live births. This measure is useful for showing the proportion of all births that is illegitimate, but it may give a false picture of the illegitimacy problem. For example in the United States in 1949 the ratio of illegitimate births to 1.000 live births was 41.2, whereas in 1940 it had been 37.9, suggesting a relatively small increase in the interval. Actually there was a considerable increase which was obscured because there was an even greater increase in total births during the period. The explanation is as follows. There was a phenomenal increase in marriages during highly favourable economic conditions, and the proportion of U.S. women ever married reached a record high level. The increase in the proportion of women ever married was much greater in the decade 1940–50 than in the whole half-century prior to 1940. There were more families, and in addition the birth rate was higher. So the lower rate of illegitimacy reflected only the greater increase in total births. The estimated number of children born out of wedlock in 1953 was 160,800, or 79% more than the number (89,500) in 1940. This was an especially significant increase since the number of unmarried women in the country decreased.

A better measure of the illegitimacy problem for many purposes is the rate based on the number of illegitimate births per 1,000 unmarried women, 15–44 years old (the childbearing ages). The unmarried includes "never married." "widowed" and "divorced." On this basis the rate in the United States was 7.0 in 1938 and 17.0 in 1953, an increase of 143%.

Variation in Rates Within a Country. — The illegitimate births in a country are likely to be distributed unevenly throughout the population, with certain groups having more than their proportionate share. In the United States in 1953 a little more than two-fifths (40.4%) of illegitimate live births were to mothers in their teens, with 34,300 such births to girls 17 years old or younger. The probabilities of conception are greater in youth, which also has greater emotional immaturity. The percentage of illegitimate births in the United States in 1953 by age groups of mothers was as follows: under 15 years old, 2.1%; 15–19, 38.2%; 20–24, 30.3%; 25-29, 15.2%; 30–34, 8.3%; 35-39, 4.4%; 40 and over, 1.3%.

Illegitimacy rates vary by type of community. The rate per 1,000 unmarried women aged 15-44 years in the United States in 1947 was 10.5 for urban areas and 1j.3 for rural areas. However about a third of all women having babies in that year went outside their home areas for confinement. Unmarried mothers in rural areas are not so likely to move to an urban area for confinement as are married women. This has the effect of increasing the rural rate of illegitimacy. Unwed mothers who do migrate for their confinement are more likely to go to the big cities because the social agencies serving them are located there. Also the large city affords more opportunity for anonymity.

Illegitimacy rates also vary by race. The estimated number of illegitimate live births for nonwhites in the United States in 1953 (104,200) appreciably exceeded that for whites (56,600), although nonwhites were less than one-tenth as numerous as whites. If the ratio is calculated per 1,000 registered live births in each group, the ratio for the nonwhites in 1953 was 11.3 times that for whites. It is believed that illegitimacy is more fully reported by nonwhites than whites but this is probably a relatively minor factor in accounting for the difference in ratios. It is not to be inferred that the high ratio among nonwhites involves a racial or genetic factor and is therefore inevitable. On the contrary, the higher ratio among nonwhites in the United States represents differences in degree of cultural assimilation. the nonwhites not having fully acquired the cultural traditions of the dominant white society regarding marriage, largely because of economic handicaps.

The percentage of illegitimacy for nonwhites declined greatly from the estimated figure of 25% at the beginning of the 20th century. In small stable communities of the northern U.S. the illegitimacy ratio of nonwhites is very low. In the rural south illegitimacy is not regarded as an acute problem. The illegitimate child is usually accepted by the girl's mother and her people. If the unmarried mother must work, a relative may take over the responsibility of the child's care. The unmarried mother suffers little or no loss of status, nor are her chances of marriage lessened. The father of the child, even when known, is not prosecuted and generally is not even pressed to assume responsibility for mother and child. There are few or no data on representative samples of unmarried mothers which throw light on their socioeconomic and educational status and their personality traits. Only those mothers who come to the attention of social agencies are known, and they are largely from the lower class. In U.S. cities they are concentrated in such occupations as domestic servants, waitresses and other jobs with special opportunities for contact with men. Agency cases tend also to be mentally subnormal. In France in 1950 it was found that the chances for illegitimate children being born dead were 50% greater than for legitimate children, suggesting the biological or social inferiority of unmarried mothers.

Variations Among Countries. — There are wide differences among nations in the rate of illegitimacy, as the accompanying table indicates. Such variations cannot be understood without knowledge of many factors including the marital status and age composition of the female population and the cultural traditions of the respective countries. In Latin America, for example, there is a large native population to whom legal marriage is an alien concept. In such countries, common-law marriage (living together without benefit of clergy or civil ceremony) is often not legally recognized and the children born of such unions are considered illegitimate. In the United States in the 1950s about half the states still considered common-law marriage legal, although the trend had been to outlaw such marriage. Still another factor is war, when it results in a great surplus of women. In Germany in 1919 the first post-World War I census showed a surplus of 2,214,000 between 20 and 49 years of age. Social disorganization resulting from war or other causes encourages illegitimacy. For example from 1891 to 1926 New Zealand had a steady illegitimate birth rate of just a little more than 9 per 1,000 unmarried women at the reproductive ages; but in 1945 the rate was 11.6;. mainly, it is thought, because of war influences resulting in unusual movements of the population and the influx of servicemen to the more heavily

Illegitimate Births per 1,000 Live Births

populated centres. Comparisons between countries are affected also by the differences in completeness of birth registration and the extent of misrepresentation on the birth record to conceal illegitimacy of a birth. These are serious sources of error and may vary greatly from country to country.

Social Policy.— What happens to the unmarried mother and her illegitimate child? There are three principal stages in the history of social policy affecting illegitimacy in the United States. In colonial times the prevailing idea was to punish the mother by ostracizing her socially, as dramatized by Nathaniel Hawthorne in *The* Scarlet *Letter.* At a later time care for the mother was provided in maternity homes until the child was born, after which the child was separated from its mother. By the 1950s the policy was to permit the child to remain with the mother, unless there were special reasons to the contrary. In actuality the latter policy had worked out very differently in different countries. In the Cnited States the illegitimate child had more often been separated from its mother than in Scandinavia, where such a course of action had been frowned upon. The trend in social policy affecting illegitimacy during the first half of the 20th century was to lessen the social stigma attaching to the illegitimate child by removing legal disabilities and according equal rights with other children, beginning with the exclusion from the birth certificate of any record of illegitimacy. A large number of illegitimate children are legitimatized by the subsequent marriage of their parents; in Italy by 1950 about one-third of the children were so affected. The trend had also been to provide more effectively for the child's economic support by providing a closer check on paternity, and if paternity were established by law, to hold the legal father to a stricter accounting of his duties. Furthermore, there had been a tendency to extend to the illegitimate child and his guardian the same economic benefits granted by the state to legitimate children. In the United States the federal social security benefits entitled Aid to Dependent Children were available to illegitimate children.

The policies regarding illegitimate children have been especially liberal in the Scandinavian countries, and studies conducted in these countries produced no evidence that such a liberal policy promoted illegitimacy. On the other hand, in the late 1930s, the U.S.S.R. reversed the liberal policies that had been established after the Revolution of 1917 and denied the right of an unmarried mother to appeal to the court for the purpose of establishing fatherhood and claiming alimony for the upkeep of the child. It appears that despite variations in social policy, the trend of legislation affecting the illegitimate child had been liberal.

(M. F. N.)

ILLINOIS, the "Prairie state," is one of the north central group of the conterminous United States. It is bounded on the north by Wisconsin, east by Lake Michigan and Indiana, southeast and south by the Ohio river, which separates it from Kentucky, and southwest and west by the Mississippi river, which separates it from Missouri and Iowa. The enabling act of Congress providing for the organization of Illinois territory into a state extended its jurisdiction to the middle of Lake Michigan and the Mississippi river. The greatest length of Illinois is 382.1 mi. and the extreme width is 212.6 mi.; the total area of the state. exclusive of its Lake Michigan jurisdiction (1,526 sq.mi.), is 56,400 sq.mi., and the total land area is 55,930 sq.mi., giving it the rank of 24th in size among the states. It was admitted to the union on Dec. 3, 1818, the 21st state; the capital, since 1839, is Springfield. The official tree is the oak, of which 19 species grow in the state; the official flower is the violet; and the official bird is the cardinal (*Cardinalis cardinalis*). The state flag consists of a symbol based on the perched eagle, prairie boulder, shield, olive branch and scroll (bearing the state motto, "State Sovereignty, National Union") of the state seal on a white field edged with gold. The official state slogan is "Land of Lincoln."

PHYSICAL GEOGRAPHY

Physical Features.— Illinois is located with its southernmost point at 36° 58'; northernmost point, 42" 30'; easternmost point, 87" 30'; and its westernmost point, 91° 31'; except for its extreme southern point, it lies entirely in the prairie region. The southern end of the state is within the Coastal Plain belt at its northward extension along the Mississippi river. The surface is an inclined plane, sloping generally toward the south and southwest. The average elevation above mean sea level is 600 ft.; the highest elevation is Charles Mound (1.241 ft.), located on the Wisconsin-Illinois boundary in the northwestern corner of the state, in Jo Daviess county.

An elevation from 15 to 40 mi. wide, called the Illinois Ozarks, crosses the southern part of the state, from Grand Tower in Jackson county, on the Mississippi river, in the west to Shawneetown in Gallatin county, on the Ohio. in the east. The highest point in this southern range of hills is 1,065 ft. at Williams hill, in Pope county.

The drainage of Illinois is far better than its low elevations and comparatively level surface would indicate. There are nearly 500 streams in the state, grouped into two river systems; three-fourths of the waters flow into the Mississippi river, and the remaining one-fourth flow into the Wabash or Ohio rivers. The most important river is the Illinois, formed by the junction of the Des Plaines and Kankakee rivers in Grundy county; the Illinois river in its course of 273 mi. drains approximately 25,000 sq.mi. and in a few places broadens into wide, lake-like expanses, notably at Lake Peoria. The Kaskaskia, in the south, notorious for its variation of volume, and the Rock, in the north, are other important rivers emptying into the Mississippi; the Embarrass, Little Wabash. Saline and Cache in the east are important tributaries of the Wabash and Ohio rivers. Generally the Ohio river bottoms are so low and level that they are poorly drained. The Chicago river originally emptied into Lake Michigan, but by the construction in 1900 of a drainage canal, the direction of the river was reversed so that it now flows into the Mississippi.

Climate.— Illinois has a typical continental climate with a wide range in temperature and frequent short-period fluctuations in temperature, humidity, cloudiness and wind direction. Particularly in the winter, therefore, Illinois' geographical location results in temperatures that reflect both the northern and southern temperature belts of the United States. The north-south range in average temperature is 14" in January but only 5° in July. The mean annual temperature at Freeport, in the far northwest, is 48.4" F.; at Springfield, in central Illinois, 52.4"; at Cairo, the southernmost city, 59.8°. The mean annual temperature increases approximately 2° for every degree of latitude. The lowest temperature ever recorded was −35° F. on Jan. 22, 1930, at Mount Carroll, and the highest was 117° F., July 14, 1954, at East St. Louis, a maximum range of 152".

Precipitation ranges from 33 in. in the far north to 48 in. in the far south, 20–22 in. falling May–Sept. in most sections; but in the period Oct.–March there are only 11 in. in the extreme northwest and as high as 22 in. in the extreme south. Seasonal snowfall at Chicago has ranged from 10 to 66 in.; Cairo has had 48 in, in one winter, yet ⅓ of Cairo winters have less than 5 in. The average seasonal number of days with a snow cover of one inch or more is 80 in the extreme north but less than 20 in the extreme south; frost penetration in the soil ranges from about 36 in. in the extreme north to 6 in. in the extreme south. At Cairo, precipitation during winter is 25% of the annual total, while at Moline it is only 13%. Illinois is generally affected by most of the storm systems that move east or northeast through the central U.S.; precipitation is associated with air masses which have moved north from the Gulf of Mexico. Summer thunderstorms are occasionally severe with damaging winds or hail in local areas. Tornadoes are most likely during spring and early summer and are more numerous in the southwest, but may occur anywhere in the state. The heayily populated southern Illinois area probably has more severe tornadoes per unit of population than any other part of the U.S. The most disastrous tornado on record struck southern Illinois, March 18, 192.5, causing property loss estimated at $16,500,000, with 742 persons killed and 2,756 injured.

Soil.—The soil of Illinois is well known for its fertility. The surface soils are largely composed of drift deposits, varying from

2 to 100 ft. in depth; they are often overlaid with a dark-coloured loam 10 in. or more deep, and in a large portion of the state there is a subsoil of mottled clay; the clay pan in the central area of southern Illinois is not particularly productive. The soil of the prairies is darker and more granular than that of the forests, although most differences disappear with cultivation. The alluvial soil of the river bottoms is exceptionally fertile. and the American bottoms, extending along the Mississippi from Alton to Chester, have been cultivated for more than 200 years. Along the river bluffs there is a deposit of loess. well suited for orchards and vegetable production. The excellent drainage has always been advantageous to agricultural development. For the control of soil erosion. to preserve land resources and to perform similar conservation functions, 98.4% of all Illinois farms are in soil conservation districts, and all but one of the 102 counties (Du Page) are included in the state's 99 soil conservation districts.

Vegetation. — Illinois stretches about 380 mi. north and south in the centre of the North American continent and its vegetation is accordingly varied, ranging from the white pine and tamarack of the north to the bald cypress and tupelo gum of the south. Before the coming of the white man the area was an interspersion of tall prairie and eastern deciduous forest; the popular nickname "Prairie state" derives more from the fact that pioneers first encountered prairie there than from the actual amount of prairie, which is less extensive in Illinois than in many more westward states. Forest originally covered about 40% of the area; by the 1960s, through commercial use of timber and clearing of the land for agriculture, this had been reduced to about 10%, as compared with the 15% which agricultural experts consider desirable for best use of the land. With the establishment of the Shannee National forest in southern Illinois and an increasing interest in timber production, there was evident, in the second part of the 20th century, both an increase in acreage and a more intelligent use of forests and their products.

Animal Life. — Illinois once supported a great variety of animal life, now greatly depleted. Fur trading was an important commercial enterprise in the period of exploration and settlement, mink, muskrat, beaver and fox being significant; although some trapping is still carried on, it is of minor importance and the sporting value of fur animals has become relatively more important, especially since World War II. Three kinds of rabbits are native to the state: the white-tailed jack rabbit in the northwest, the swamp rabbit in the south and the cottontail throughout the state; they make up over one-third of the gamebag annually. Perhaps no mammals are enjoyed by more people than the gray and fox squirrels which inhabit town and city parks as well as woodlands. Deer have an interesting history: when white settlers first came they were common but not generally numerous, and as settlement increased their numbers increased, probably reaching a peak in the mid-19th century. Further clearing of land and more intensive agriculture eliminated their habitats and by 1910 native wild deer were virtually extinct. In 1933 the department of conservation placed four deer on a state game refuge. These and groups subsequently released gradually built up their number and in 1957 the first deer-hunting season since 1900 was inaugurated. The deer are concentrated in the southern and northwestern parts of the state. Quail increase from the northern to the southern part of the state, the majority being south of a line drawn from Rock Island southeastward through Peoria to the Indiana line. Pheasants are less numerous and are concentrated in northern Illinois. The state is in the heart of the Mississippi Flyway and is frequented by hundreds of thousands of waterfowl during the fall and spring migrations and in the winter. About 20 species of waterfowl are common in the state but only the wood duck nests there in appreciable numbers. Illinois has produced sizable catches of commercial fish for many years; the most important game fish is the largemouthed bass, common in all types of lakes and ponds.

State Parks and Memorials. — A consciousness of the value of the state's many historic sites and the need for recreational facilities. particularly for the great urban population, have led to the establishment of many state parks and memorials in Illinois. Places of interest in connection with Abraham Lincoln include Lincoln's New Salem State park, 20 mi. N.W. of Springfield, a reproduction of the village as it was in his time; the Lincoln Log Cabin State park, south of Charleston; and the Lincoln tomb, home and other memorials in Springfield. Stephen A. Douglas is commemorated by a monument on the site of his tomb in Chicago, and the sites of the seven Lincoln-Douglas debates (at Ottawa, Freeport, Jonesboro, Charleston. Galesburg, Quincy and Alton) are marked Other places of historic interest include Cahokia Mounds State park near East St. Louis and Dickson Mound State memorial on the Illinois river near Havana; Pere Marquette State park, at the junction of the Illinois and Mississippi rivers and Starved Rock State park, on the upper Illinois river, associated with the French period in Illinois history; Ft. Kaskaskia and Ft. Chartres State parks along the Mississippi below East St. Louis and Ft. Massac State park on the Ohio, all of which were French military strongholds of the 18th century; Nauvoo State park, on the Mississippi river north of Quincy, the site of the Mormon settlement; and the Ulysses S. Grant home in Galena, now a museum.

Among the state parks primarily of scenic and naturalistic interest are the Mississippi Palisades and Apple River Canyon parks in northwestern Illinois, the White Pines Forest, Buffalo Rock. Matthiessen, Illini and Gebhard Woods parks in north central Illinois, the Spitler Woods park near Decatur and the Giant City, Ferne Clyffe and Dixon Springs parks in southern Illinois. Among those with water areas (in some cases with facilities for camping and swimming) are Illinois Beach State park on Lake Michigan near Waukegan; Illinois and Michigan Canal State parkway along the old canal in Will. Grundy and La Salle counties; Kickapoo State park near Danville; Grand Marais State park near East St. Louis; and Fox Ridge State park near Charleston. Lake areas which are now state parks include Argyle lake in McDonough county, Beaver dam in Macoupin county, Lake Le-Aqua-Na in Stephenson county, Lake Murphysboro in Jackson county, Ramsey lake in Fayette county, Spring lake in Tazewell county and Weldon springs in De Witt county.

Chicago Portage, which preserves a portion of the famous portage discovered by Marquette and Jolliet, was designated as a national historic site in 1952; not owned by the federal government, it is under the jurisdiction of the Cook County Forest preserve.

HISTORY

French Exploration and Settlement. — The first Europeans to visit the region now known as Illinois were the French. In 1673, the Jesuit father Jacques Marquette, under orders to begin a mission to the Indians, and the explorer Louis Jolliet, who acted under orders of Jean Talon, intendant of Canada, ascended the Fox river, crossed the portage between it and the Wisconsin river and followed that stream to the Mississippi, which they descended to a point below the mouth of the Arkansas. On their return journey they ascended the Illinois river and crossed the portage to Lake Michigan; in 1675 Marquette founded a mission at the Indian town of Kaskaskia, near the present Utica, Ill. In 1679 the explorer René Robert Cavalier, sieur de la Salle. attempting to find the mouth of the Mississippi, ascended the St. Joseph river, crossed the portage separating it from the Kankakee, which he descended to the Illinois and built in the neighbourhood of Lake Peoria a fort which he called Ft. Crèvecoeur. La Salle reached the mouth of the Illinois Feb. 6. 1682. After such preliminary explorations, the French made permanent settlements, which had their origin in Jesuit missions and French trading posts. Chief of these were Kaskaskia, established near the mouth of the Kaskaskia river, about 1703; Cahokia. a few miles below present East St. Louis, Illinois, founded about 1699; and Ft. Chartres, on the Mississippi between Cahokia and Kaskaskia, founded in 1719 to be a link in a chain of fortifications intended to extend from the St. Lawrence to the Gulf of Mexico.

By the treaty of Paris, 1763, France ceded to Great Britain its claims to the country between the Ohio and Mississippi rivers, but because of the resistance of Pontiac, a chief of the Ottawas, who drew into conspiracy most of the tribes between the Ottawa river and the lower Mississippi, the English were not able to take possession until Capt. Thomas Stirling arrived at Ft. Chartres,

Oct. 10, 1765—the last place in North America to lower the French flag

British Rule.—British policy mas not favourable to the economic development of the newly acquired country, since it was feared that its prosperity might react against the trade and industry of Great Britain. But in 1769 this policy nas relaxed. and immigration began from the seaboard colonies, especially from Virginia In 1771 the people of the Illinois country demanded a form of self-government similar to that of Connecticut. The petition was rejected by Gen. Thomas Gage; and William Legge. 2nd earl of Dartmouth (1731–1801), secretary of state for the colonies and president of the board of trade and foreign plantations. drew up a plan of government for Illinois in which all officials were appointed by the cronn. This. however, was never operative for in 1774 the Quebec act (*q.v*) extended the boundaries of Quebec to the Ohio on the south and the Mississippi on the east. recognized French civil law and brought the Illinois country under an appointive governor and council. Most of the Illinois French were loyalists in the Revolutionary War; when the English instigated Indian attacks on the frontier, George Rogers Clark (*q.v.*), nho acted under orders of Patrick Henry, governor of Virginia, captured the British posts of Cahokia and Kaskaskia in 1778 and Vincennes in 1779. These conquests had much to do with the United States' securing the country west of the Alleghenies and north of the Ohio in the treaty of Paris. 1783.

Territorial Status and Statehood.—The Virginia house of delegates in 1778 extended the civil jurisdiction of Virginia to the northwest, and appointed Capt. John Todd (1750–82) of Kentucky governor of the entire territory north of the Ohio, organized as "the county of Illinois." This government. confined to the old French settlements. was short-lived and inefficient. In 1787 after Virginia and the other states relinquished their claims to the country west of the Alleghenies, the Northnest territory was organized by congress by the famous ordinance of 1787. Two years later St Clair county was formed out of the southwest part of the Illinois country. while the eastern portion and the settlements arbund Vincennes, Ind., were united into the county of Knox In 1795 the southern part of St. Clair county was organized into Randolph county, with Kaskaskia as the scat of administration. In 1800 the Illinois country nas included in the territory of Indiana, and in 1809 the western part of that territory, from Vincennes north to Canada. was organized as the territory of Illinois; it included. besides the present state, all of Wisconsin except the northern part of the Green Bay peninsula, a large part of Michigan and all of Minnesota east of the Mississippi In 1812, by permission of congress, a representative assembly was chosen, a territorial constitution was adopted and ,the territorial delegate in congress was elected directly by the people.

In 1818 Illinois became a state of the American union (see *Government,* belon). the enabling act fixing the line 42° 30' as the northern boundary. instead of that provided by the ordinance of 1787, nhich passed through the south bend of Lake Michigan. The reason given for this change was that if the Mississippi and Ohio rivers were the only outlets of Illinois trade, the interests of the state would become identified with those of the southern states; but if a Lake Michigan outlet were provided, closer relations would be established with the northern and middle states so that "additional security for the perpetuity of the Union" would be afforded.

Because there was conflict betneen French and English land claims, congress in 1804 established land offices at Kaskaskia and Vincennes to examine existing claims and to eliminate conflict with future grants; in 1812 new offices were established at Shawneetown and Edwardsville for the sale of public lands; and in 1816 more than 500 000 ac were sold. In 1818. honever. many citizens were in debt for their lands, and squatters invaded the rights of settlers Congress therefore reduced the price of land from $2 to $1 25 per acre and adopted the policy of pre-emption. preference being given to the claims of existing settlers. The Indians, honever. resisted measures looking toward the extinguishment of their claims to the country. Their dissatisfaction with treaties signed in 1795 and 1804 caused them to espouse the British cause in the War of 1812, and in 1812 they overpowered a body of soldiers and settlers who had abandoned Ft. Dearborn (*see* CHICAGO). For a number of years after the end of the conflict, the Indians mere comparatively peaceful; but in 1831 the delay of one band of Sauks and Foxes in withdrawing from lands in northern Illinois caused Gov. John Reynolds (1788–1865) to call out the militia. The following year the return of the Sauk leader Black Hawk resulted in war in northern Illinois and Wisconsin (the Black Hank War); and by 1833 the United States had acquired title to all the Indian land in Illinois.

The financial and industrial policy of the state was unfortunate. Money being scarce, the legislature in 1819 chartered a state bank nhich nas authorized to do business on the credit of the state. This bank never operated and a second was chartered in 1820. In a few years the bank failed. and the state in 1831 borrowed money to redeem the depreciated notes issued by the bank. A third state bank was chartered in 1835; two years later it suspended payment. and in 1843 the legislature provided for its liquidation. The state also undertook to establish a system of internal improvements, granting a loan for the construction of the Illinois and Michigan canal in 1836. and in 1837 appropriating $10.000.000 for the building of railroads and other improvements. The experiment proved unsuccessful; the state's credit declined and a heavy debt was incurred. and in 1840 the policy of aiding public improvements nas abandoned. Through the efforts of Gov. Thomas Ford (1800–50) a movement to repudiate the debt was defeated, and a plan was adopted by nhich the entire debt could be reduced nithout excessive taxation; by 1880 practically the entire debt was extinguished.

A notable incident in the history of the state was the immigration of the Mormons from Missouri about 1839. They succeeded in securing favours from the legislature, and their city of Nauvoo had courts and a military organization that were independent of state control. Political intrigue and claims of independence from the state. as well as charges of polygamy and lawless conduct, aroused such intense opposition that in 1844 a civil mar broke out in Hancock county resulting in the murder of the leader of the Mormons, Joseph Smith, and the removal of the Mormons from Illinois in 1846.

Slavery Question and the Civil War.—The slavery question was a problem of lasting political importance. Slaves had been brought into the Illinois country by the French, and Gov Arthur St. Clair (1736–1818) interpreted the article of the ordinance of 1787 forbidding slavery in the Northwest territory as a prohibition of the introduction of slaves into the territory, not an interference with existing conditions. Negroes were held as indentured servants. and such servitude was recognized in the Indiana code of 1803, the Illinois constitution of 1818 and statutes of 1819; indeed, slavery would have been recognized in the constitution of 1818 had it not been feared that recognition would have prevented the admission of the state to the union. In 1824 the voters rejected a legislative proposal calling for a constitutional convention; the aim, not expressed, was the legalization of slavery. But the resolution of the legislature was rejected. the leader of the opposition being Gov. Edward Coles (1786–1868), a Virginia slaveholder who had freed his slaves on coming to Illinois. The opposition to slavery. however, was at first economic. not philanthropic. In 1837 there was only one abolition society in the state, but chiefly through the agitation of Elijah P. Lovejoy (*q.v.*), abolition sentiment grew.

By 1840 the moral issue had become political and the Liberty party was organized. In 1818 it united with the Free-Soil party; but as the Whig party approved the policy of nonextension of slavery, these parties did not succeed. In 1854. however, the Liberty and Free-Soil parties united with some Whigs and those Democrats opposed to the Kansas-Nebraska bill; they secured a majority in the legislature and elected Lyman Trumbull to the U.S. senate. Two years later these elements were absorbed by the Republican party and elected candidates to state offices—the first time that the Democratic party had been defeated. its organization having been in control since the admission of Illinois to the union. Important in this political revolution was a change in the character

of the population. Until 1848 southerners predominated in the population. but after that year immigration from the northern states was greater than that from the south, and the number of foreigners also increased. The influence of immigration and sectionalism upon Illinois politics is well illustrated by the fact that the first six governors (1818–38) were born in the southern states, six of the eight U.S. senators of that period were also southern born and all of the representatives, with one exception, also came to Illinois from the southern states. After 1838 the eastern states began to be represented among the governors but until 1901 no governor was elected who was a native of Illinois.

The opposition to slavery continued to be political and economic rather than philanthropic. The constitution of 1848, which abolished slavery, also forbade the immigration of slaves into the state. The famous contest for the office of U.S. senator between Stephen A. Douglas (Democrat) and Abraham Lincoln (Republican) took place in 1858. Douglas was elected but the vote showed increasing northern sympathy, and two years later Lincoln, then candidate for the presidency, carried the state. The policy of Illinois in the early period of secession was one of marked loyalty to the union; even in the southern part of the state the majority of the people had no sympathy with proslavery men in their efforts to dissolve the union. The state contributed more than 250,000 men to the federal armies. From 1862 to 1864, however, there mas some opposition to a continuance of the war. The legislature of 1862 was Democratic, and for political purposes that body adopted resolutions against further conflict and recommended an armistice and a national convention to conclude peace. A constitutional convention that same year attempted to assume legislative powers; it wrote into the proposed constitution clauses preventing Negroes and mulattoes from immigrating into the state and from voting and holding office; and although the constitution as a nhole was rejected by the people, these clauses were ratified. A Democratic mass meeting, which met at Springfield in July 1863, adopted resolutions that condemned the suspension of the writ of habeas corpus. endorsed the doctrine of state sovereignty, demanded a national assembly to determine terms of peace and asked President Lincoln to withdraw the Emancipation Proclamation in order to permit the people of Illinois to fight only for "Union, the Constitution and the enforcement of the lams." Anti-war and pro-southern secret societies, including the Knights of the Golden Circle (*q.v.*), began to flourish, and so did exaggerated stories about their activities and strength. Capt. T. Henry Hines of the Confederate army led an elaborate attempt to liberate Confederate prisoners in Chicago (knonn as the Camp Douglas conspiracy) which mas thwarted by a discovery of the plans. In the elections of 1864 the Republicans and Union Democrats united, and after an exciting campaign they were successful. The new legislature was the first state legislature to ratify (Feb. 1, 1865) the 13th amendment.

Political Record. — From the close of the Civil War until the end of the 19th century the Republican party was generally dominant, but the trend of political development was not without interest.

In 1872 many prominent men joined the Liberal Republican party. among them Gov. John M. Palmer, Sen. Lyman Trumbull and Gustav Korner (1809–96), one of the most prominent representatives of Illinois' German population. Economic depression gave the Granger movement considerable popularity, and an outgrowth of the Granger organization was the Independent Reform party of 1874 which advocated retrenchment of expenses, the state regulation of railways and a tariff for revenue only. A Democratic Liberal party was organized in the same year, one of its leaders being Governor Palmer; consequently, no party had a majority in the legislature elected in 1874. In 1876 the Greenback party, the successor in Illinois of the Independent Reform party, secured a strong following; although its candidate for governor was endorsed by the Democrats, the Republicans regained control of the state administration.

In 1912, as a result of the Progressive secession, the Republican party lost control of the state for the first time in 16 years, the Democratic presidential electors winning by a vote of 405.038, as compared with 386,478 for the Progressives and 253,593 for the Republicans. By 1914 the normal Republican majority in Illinois reasserted itself. and two years later Pres. Woodrow Wilson lost the electoral vote of the state. At the same time the Republicans recaptured the governorship, which it held without interruption for the next 16 years. But in 1932 the people of the commonwealth cast their vote heavily for Franklin Delano Roosevelt and also elected a Democratic governor. Henry Horner. This political shift was confirmed in 1934 when 22 of the state's 27 seats in the house of representatives were filled by Democrats and again in 1936 and 1940 when President Roosevelt carried the state.

After 1944, when Roosevelt again carried the state but a Republican governor was elected, no pronounced trend developed. Harry S. Truman carried Illinois in 1948, and Paul Douglas and Adlai E. Stevenson, both Democrats, were elected U.S. senator and governor, respectively. But in 1950 a Republican G.S. senator. Everett McKinley Dirksen, was elected and in 1952 Dwight D. Eisenhower and a Republican governor, William G. Stratton, uere voted into office. In 1954 the Democratic senator Paul Douglas was returned to Washington while in 1956 Eisenhower carried the state for the Republicans. In 1960 Douglas was re-elected for a third term in the senate and the presidential vote uent to the Democratic candidate John F. Kennedy.

GOVERNMENT

Constitution and Apportionment. — On July 4, 1800, the Northwest territory was divided and the Illinois country was made a part of Indiana territory; Illinois territory was formed March 1, 1809, by dividing Indiana territory. The first legislative body of Illinois territory — the governor and three judges, all appointed by the president — met June 16, 1809, and passed a code of laws, keeping most of the laws previously in force; the first representative assembly passed a similar bill confirming the laws in force. On April 18, 1818, congress made provision for a state convention to form an Illinois state constitution and government; on Aug. 26 the delegates adopted a constitution which went into effect when Illinois was admitted as the 21st state on Dec. 3, 1818.

In 1848 a second constitution was adopted, and in July 1870 the electorate adopted a third. Agitation for a new constitution resulted in a constitutional convention which in 1922 submitted a new constitution to the voters who rejected it by 921,398 to 185,298. A proposal for a constitutional convention was passed by the legislature in 1933 but was defeated by the electorate in 1934, 23.5% for, 20% against and 56.5% not voting.

At that time, amendments to the constitution could be made either by a constitutional convention or by the affirmative vote of two-thirds of the members of each house of the legislature; the amendment then had to be ratified by a majority of the electors voting in the next general election. Prior to 1950, 19 amendments were submitted to the voters; of these, 7 were adopted. Many amendments were defeated because citizens who voted for candidates but neither for nor against a proposed amendment were in effect voting against the amendment, since a majority of those voting in the election had to approve the amendment. In the period 1908–50 no amendment carried in a general election.

Constitutional amendment mas made much simpler by the adoption of the Gateway amendment in 1950. The Gateway amendment provided that as many as three amendment propositions may be submitted to the voters at an election, instead of only one as formerly. Adoption requires a two-thirds majority of those voting on the amendment, or a simple majority of those voting in the election, whichever is less. Since the Gateway amendment was adopted, ten amendments have been voted on by the electorate, five being adopted and five failing.

The most important new constitutional amendment changed sections 6–8 of article iv, senatorial apportionment; as a result, for the first time in half a century the districts from which state senators and representatives were chosen received revision. Members of the legislature had been chosen by districts, 3 representatives and 1 senator from each of 51 districts; total membership in the legislature had been 204. The amendment adopted designated

58 senatorial and 59 representative districts, increasing the number of senators by 7 and the number of representatives by 24, for a total legislative membership of 235. Under the amendment the 101 downstate counties elect 34 rather than 32 senators, and Cook county (in which Chicago is located) elects 24 rather than 19; 30 representative districts were placed in Cook county (previously 19) and 29 (previously 32) were located downstate. The new senate district boundaries and apportionment were meant to be permanent; the representative districts were to be reapportioned on a population basis every ten years, beginning in 1963.

Legislature. — Regular sessions of the legislature meet on the first Wednesday after the first Monday in January in odd-numbered years. The term of senators is four years, that of representatives two years. The constitution of 1870 provided for minority representation in the election of representatives; by cumulative voting each voter may cast as many votes for one candidate as there are representatives to be chosen, or he may distribute his votes (giving three votes to one, or one-and-one-half votes to each of two, or one vote each to three candidates), the candidate or candidates receiving the highest number of votes being elected. Special legislation is prohibited when general laws are applicable, and special and local legislation is forbidden in any of 23 specified cases. The general assembly may pass an act over the governor's veto by a two-thirds vote of all members elected to each house. In practice, the governor's veto is not often overridden; if the governor's political party controls either of the two houses, it is all but impossible to secure legislation not desired by the governor.

Executive. — The constitution provides for an executive department consisting of a governor, lieutenant governor, secretary of state. auditor of public accounts. treasurer, attorney general and superintendent of public instruction; all except the treasurer may be re-elected to succeeding terms (Illinois has never elected a governor to three successive terms). The most far-reaching administrative change in state government occurred in 1917 with the enactment of the Consolidation act combining more than 100 state boards. divisions and commissions into nine departments. By 1960 the number of major departments had increased to 17, each directed by a departmental administrative officer appointed by the governor: aeronautics, agriculture, audits, conservation, finance, financial institutions, insurance, labour, military and naval, mines and minerals, personnel, public health, public safety, public welfare, public works and buildings, registration and education and revenue.

In addition, a number of boards and commissions are charged with varying responsibilities; the most significant include the budgetary, commerce, legislative audit, public aid and youth commission's.

Illinois enacted a civil service law in 1905 under which approximately two thirds of the state's employees were covered by 1960. The civil service commission is a division of the department of personnel; certain employees, including the scientific and academic staffs of the state universities and clerks in offices headed by elected officers, are exempted.

Judicial. — The judicial powers are vested in a supreme court, appellate courts, circuit courts, county courts, justices of the peace and police magistrates, and such courts as may be created by law in and for cities and incorporated towns. The supreme court is composed of seven members elected from districts for a term of nine years. The four appellate courts consist of one for Cook county (which has also two branch appellate courts, both the court and branches being presided over by three judges appointed by the supreme court) and three other districts, each with three judges appointed in a like manner. The state outside of Cook county is divided into 20 circuits, 3 of which have 4 judges each and 17 have 3 judges each, all elected for terms of six years. The constitution provides for separate courts in Cook county: a superior court consisting of 36 judges, a circuit court consisting of 20 judges all elected for six years, a criminal court, a county court and a probate court.

The city of Chicago has a municipal court composed of a chief justice and 36 judges. Each county has a county court consisting of one judge who serves for four years; in some counties there are probate courts, and juvenile courts are provided for in counties of more than 500,000 population. Each county elects a state's attorney for four years. Cities or other local units meeting certain requirements may establish city or municipal courts by referendum.

Local Government. — The local government of Illinois includes both county and township systems. The earliest American settlers came from the southern states and introduced the county system; but the increase of population from New England and the middle states led to a recognition of township organization in the constitution of 1848, and this form of government, at first prevalent only in the northern counties, is found in most of the middle and southern counties. Cook county, although it has a township system, is governed by a board of commissioners elected by the townships and the city of Chicago. Incorporated cities must have a population of at least 2,500. Requirements for suffrage are: age of 21 years or more, citizenship in the United States and residence in the state for 1 year, in the county 90 days and in the election precinct 30 days preceding the exercise of suffrage.

Relation to Corporations. — The relation of the state to corporations and industrial problems has been a subject of important legislation. The constitution declares that the state's rights of eminent domain shall never be so abridged as to prevent the legislature from taking the property and franchises of incorporated companies and subjecting them to the public necessity in a way similar to the treatment of individuals. In 1903 the legislature authorized the municipal ownership of public-service corporations. Railways organized or doing business in the state are required by the constitution to have a public office where books for public inspection are kept, showing the amount of stock, the owners and the amount of liabilities and assets. An antitrust law of 1893 exempted from the definition of trust combinations those which were formed by producers of agricultural products and livestock, but the United States supreme court in 2902 declared the statute unconstitutional as class legislation. The employment of children under 14 years of age in factories or mines, as well as working employees under 16 years of age for more than 48 hours a week, is forbidden by statute.

Finance. — The cost of state government, at the end of the fifth decade of the 20th century, exclusive of revolving funds and tax refunds, exceeded $900,000,000 annually; including revolving funds and tax refunds, total expenditures for the fiscal year ending June 30, 1959, reached $960,300,000. If revolving funds and tax refunds are excepted, there was an excess of receipts over expenditures of $74,000,000. The outstanding indebtedness of the state, on June 30, 1959, was about $150,000,000 for bonds issued to pay a bonus to soldiers from Illinois who served in World War II.

The revenue system employed by local units of government is based on the general property tax. There is local assessment of all real and personal property (except railroad property, which is state assessed). The basic revenue source of the state is the retailers' occupation or sales tax. Other state revenue sources include an indirect tax on corporations, motor vehicle licence and fuel fees, inheritance tax, beverage-liquor revenue tax, cigarette tax, pari-mutuel taxes, insurance fees and taxes, public utility gross receipts taxes as well as a number of miscellaneous fees and taxes. Faced with rising state expenditures in the second half of the 20th century and handicapped by an apparent constitutional prohibition of the graduated income tax and a reluctance to levy a general property tax, Illinois more frequently considered financing capital improvements through long-term bond issues.

The constitution also prohibits the state from lending its credit or making appropriations in aid of any corporation, association or individual, and from constructing internal improvements; counties, townships and other political units cannot incur indebtedness in excess of 5% of their assessed property evaluation. The legislature may not contract a debt of more than $250,000 except

*Populations are reported as constituted at date of each census. †Part of Champaign township annexed to Champaign city Jan. 22, 1920. Population of Champaign city, including this annexation, 16,256. ‡Lincolnwood. Name changed from Tessville in 1935. ‖Skokie. Returned in 1940 as Niles Center.

Note: Dash indicates place did not exist during reported census, or data not available.

to suppress treason, war or invasion unless approved by a vote of the people.

POPULATION

In the decade 1950–60, the over-all population of Illinois increased from 8,712,176 to 10,081,158 even though every county south of Springfield, except for counties surrounding the St. Louis, Mo. metropolitan area, and Effingham. Jackson and Massac counties, lost population. These losses were heavily concentrated in the extreme southern end of Illinois; Franklin. Gallatin, Saline, Pope, Hardin. Johnson, Pulaski and Alexander counties all had losses from 20% to 30%. The heaviest growth was in the Chicago suburbs, with Du Page county growing 102 8%, Lake up 64.0%, McHenry up 66.2%, Kendall up 44.8% and Will up 42.6%. A substantial portion of this suburban growth came from the city of Chicago, which lost 3.3% of its population. although as some moved out of Chicago, others moved in; particularly has the influx of southern Negroes been heavy. In that same decade a number of villages. some quite old, incorporated as cities. including Cahokia, Carpentersville, Morton Grove. Mount Prospect, Niles, Oak Lann, Rockdale and Westchester, as did the village of Park Forest (dating from 1940) and the newly established Rolling Meadows (see Table); all but Cahokia were in the Chicago metropolitan area.

The population of Illinois in 1810 was 12,282; in 1850 it was 851,470; in 1900, 4,821,550; in 1950, 8,712.176 and in 1960, 10,081,158. This last figure represents an increase of 16% over the population in 1950.

The population per square mile in 1960 was 178.7. as compared mith 154.5 in 1950, and with 49.7 for the U.S. in 1960. The urban population in 1960 which included. among other places, the thickly settled suburban area. or "urban fringe" adjacent to the 15 cities which had 50,000 inhabitants or more in 1960 amounted to 8,133,282 or 80 7% of the total.

The number of occupied dwelling units (or households) in 1950 was 2,585,691, as compared with 2.192.724 in 1940. The average population per household had declined from 3 6 in 1940 to 3.4 in 1950.

The population of the state was distributed by colour and nativity in 1950 as follons: 83.4% native white; 9.0% foreign-born white; and 7 6% nonwhite, practically all Negro. (Of the foreign-born white population in 1950, 14 2% was born in Poland, 12 3% in Germany and 10.7% in Italy.) There were 98.3 males per 100 females in the 1950 population. as compared nith 100 4 in 1940. Of the population 8.7% was 65 years old or over; and 55.4% of the population 14 years old and over was in the labour force.

Of the total number of employed males, 9.6% were engaged in agriculture, 6.7% in construction, 33 3% in manufacturing, 6.7% in transportation, 19.5% in wholesale and retail trade and 16.6% in service industries, including professional, business and personal services.

EDUCATION

Public education in Illinois had its genesis in the land of the Northwest territory reserved for educational purposes by the ordinance of 1787. The first school law. which provided for state taxation for public schools, was enacted in 1825. Only a few schools were established under this act since the section providing for taxation nas soon repealed. Free schools supported by the sale of land reserved for education and by local taxation were established as early as 1834.

A second state school law enacted in 1855 and providing for a state school tax is the foundation of the present Illinois public school system. The superintendent of public instruction was first elected in 1856. The Illinois constitution of 1870 required the legislature to provide a thorough and efficient system of public schools.

Elementary and High Schools. — The public schools are free to all betneen the ages of 6 and 21 and school attendance is compulsory for all children from 7 to 16 years of age. Between 1949 and 1959 enrollment increased by more than 500.000, to about 1,700,000; this additional school population resulted in nearly a 50% increase in the number of teachers employed.

Of the total public school funds about $\frac{3}{4}$ comes from local sources and about $\frac{1}{4}$ from state funds, exclusive of nonrevenue receipts and items of duplication. Average school expenditure per pupil (including local, state and federal as well as operations and equipment) has been rising steadily; it rose from approximately $375 in 1950 to about $600 in 1960. In the middle part of the 20th century there was an extensive consolidation of public school districts in Illinois. the number being reduced from almost 12.000 in 1945 to about 5,000 in 1950 and to about 1,700 by 1960. This consolidation was encouraged by state legislation authorizing county school surveys and limiting state financial aid to schools which could meet specific standards.

Public Universities. — In addition to the University of Illinois, the state provides for higher education at Southern Illinois university. Carbondale, and at four other state universities situated at Normal, Charleston, De Kalb and Macomb. The University of Illinois was founded in 1867 as the Illinois Industrial university, and received its present name in 1885; since 1870 it has been coeducational. The expansion of the university through the acquisition or organization of new colleges or schools began in 1896 when the Chicago College of Pharmacy became the University of Illinois school of pharmacy. Since that date important changes have been made. The university consists of colleges of agriculture, commerce, education, engineering, fine and applied arts, journalism. law, liberal arts and sciences, physical education, veterinary medicine and a graduate school; the school of social work; the institutes of aviation, government and public affairs. labour and public relations, all at Urbana; the colleges of dentistry, medicine, nursing. pharmacy and a graduate division, all at the Chicago professional campus: and an undergraduate division at Navy pier in Chicago which offers two years of work in commerce. engineering, liberal arts and sciences and physical education.

In the middle part of the 20th century the growth of Southern Illinois university, established in 1869. was rapid; in the fall quarter of 1960 the enrollment was well over 10,000, more than triple the resident student enrollment of 1953. The main campus is at Carbondale; the university also has a campus at Edwardsville and residence centres in Alton and East St. Louis. The professional schools and their date of establishment are agriculture (1955), applied science (1959), business (1956), communications (1955), fine arts (1955) and home economics (1957).

The four universities under the jurisdiction of the teachers college board are Northern Illinois university at De Kalb, established 1895; Western Illinois university at Macomb. established 1899; Eastern Illinois university at Charleston, established 1895; and Illinois State Normal university, at Normal. established 1857. Chicago Teachers college in Chicago (1869) is state supported and municipally controlled.

Private Colleges and Universities. — Illinois also has a number of distinguished private and church-related Institutions of higher learning. Among the privately endowed institutions are The University of Chicago (q.v.); Bradley university at Peoria (1896); George Williams college in Chicago (1884); Illinois Institute of Technology, Chicago. established in 1940 by merger of the Armour Institute of Technology, founded 1892, and Lewis institute, founded 1896; Rnox college at Galesburg (1836); National College of Education, Evanston (1886); Rockford college, Rockford (1847); Roosevelt university. Chicago (1945); School of the Art Institute of Chicago, Chicago (1866); and Wheaton college. Wheaton (1853). Roman Catholic colleges for women include Barat College of the Sacred Heart. Lake Forest (1904); College of St Francis, Joliet (1874); Mundelein. Chicago (1930); Rosary. River Forest (1848); and Saint Xavier. Chicago (1846). Maryknoll seminary at Glen Ellyn (1949) and St. Procopius at Lisle (1887) are Roman Catholic men's colleges; De Paul university (1898) and Loyola university (1870), both in Chicago, and Quincy college at Quincy (1860) are Roman Catholic coeducational institutions.

Institutions affiliated nith the Presbyterian Church are Blackburn college at Carlinville (1857), Illinois college at Jacksonville

(1829) (also affiliated with the Congregational Church), Lake Forest college at Lake Forest (1857). Millikin university at Decatur (1901), Monmouth college at Monmouth (1853) and McCormick Theological seminary in Chicago. Illinois Wesleyan at Bloomington (1850), MacMurray college at Jacksonville (1846) and Northwestern university at Evanston (1851) are hlethodist, as is Garrett Biblical institute, a seminary, at Evanston.

Other church-related institutions include Augustana college at Rock Island (1860), Carthage college at Carthage (1847) and Concordia Teachers college at River Forest (1864), all Lutheran; Aurora college at Aurora (1893), Advent Christian Church; Elmhurst, at Elmhurst (1865). Evangelical and Reformed Church; Greenville, at Greenville (1855), Free Methodist Church; North Central at Naperville (1861), Evangelical United Brethren; Northern Baptist Theological seminary at Chicago (1913), American Baptist convention; Olivet Nazarene at Kankakee (1907); The Principia college at Elsah (1898), for Christian Scientists; and Shimer college at Mount Carroll (1852), Episcopal. See also the various city articles.

Junior Colleges. — In addition to these four-year colleges Illinois in 1960 had 25 recognized junior colleges, 17 publicly controlled (of which 6 mere branches of the Chicago Junior college) and 8 private. Among the latter is Lincoln college, at Lincoln, founded by the Cumberland Presbyterian Church and chartered in 1865, the only college named for Abraham Lincoln in his lifetime.

HEALTH AND WELFARE

The Illinois department of public welfare supervises 26 institutions: 13 state hospitals for the mentally ill. 2 state schools for the mentally retarded, the Chicago Mental Health centre and 10 residential educational institutions. The hospitals for the mentally ill are located at Elgin, Kankakee. Jacksonville. Anna. East Moline, Peoria, Chicago, Alton, Manteno, Galesburg, Tinley Park, the Illinois Security hospital at hfenard and the Illinois State Psychiatric institute at Chicago. The two schools for the mentally retarded are at Lincoln and Dixon. In Jacksonville the state operates the Illinois School for the Deaf and the Illinois Braille and Sight Saving school; among the eight other educational and residential schools are the Illinois Soldiers' and Sailors' home at Quincy. the Soldiers' Widows' Home of Illinois at Wilmington, the Illinois Soldiers' and Sailors' Children's school at Normal and the Illinois Eye and Ear infirmary (in conjunction with the University of Illinois) at Chicago. The department of public welfare also operates 29 mental health clinics; an Institute for Juvenile Research operates 17 child guidance clinics.

The department of public safety administers the penal institutions: branches of the state penitentiary at Joliet-Stateville, Pontiac and Menard, the state farm for misdemeanants at Vandalia and the State Reformatory for Women near Dwight. In addition to these institutions for adult offenders the legislature in 1953 authorized the creation of the Illinois Youth commission to administer the handling of juvenile offenders. The Youth commission administers four institutions: the Illinois State Training School for Boys near St. Charles, the Illinois State Training School for Girls at Geneva, the Illinois Industrial School for Boys at Sheridan and the Reception and Diagnostic Center for Boys at Joliet; the commission also administers nine boys' forestry camps.

THE ECONOMY

Agriculture. — Among the more important changes which took place in Illinois agriculture during the 20 years preceding 1960 were the pronounced increase in size of farms and the accompanying decrease in number of farms. The average farm size reached 185 ac. compared to 147 ac. in 1939. This change required almost complete mechanization and constant increases in capacity of equipment. The number of Illinois farms declined 22% during this period, largely the product of consolidating farms, but due in small degree to moderate reductions in total farm land. Land in farms increased slightly in the late 1930s and early 1940s, but then started a gradual decline amounting to about 4% after 1945. Urban development and new highways took the greater part of this land. Areas adjacent to large metropolitan communities were most affected, as in Cook county where land in farms declined 35% following World War II. The number of tenants on farms increased from about 92,000 in 1930 to more than 100,000 in 1935, but since then has fallen steadily, to fewer than 92,000 in 1940, fewer than 70,000 in 1950 and fewer than 60.000 in 1960.

Cereals are the main crop and corn (maize) is the leading product. The largest corn crop on record up to 1960 was that of 1959, when 673,350,000 bu mere produced from 10.050.000 ac. Illinois is also an important soybean-producing state and produces important quantities of wheat, oats, rye. barley and sweet corn for canning Apples, peaches, strawberries, cherries, plums and other fruits are grown. The state also ranks high in the production of milk, chickens (including commercial broilers), eggs, cows and heifers two years old and over (milk cows) and ranks very high in the number of hogs. Sheep. horses and mules are of minor importance as compared with other states. Thirteen Illinois counties ranked among the 100 leading U.S. counties in the value of all farm products sold in 1954: McLean, De Kalb, La Salle. Iroquois, Livingston, Champaign, Henry, Bureau, Ogle, Kane. Vermilion, Whiteside and Lee.

Industry. — The growth of manufacturing in Illinois, largely because of the development of the state's exceptional transportation facilities, nas the most rapid and remarkable in the industrial history of the United States. In 1850 the state ranked 15th; in 1870. 6th; in 1880, 4th; and by 1900 had become 3rd, but by 1960 had dropped back to 4th behind New York, Ohio and Pennsylvania. In 1904 the value added by process of manufacture was $570,285,000. In 1919, just after World War I, it was $1,929,-125,000; in 1937 it reached $2,319,036,000; in 1947, $6,683,-083.000; and in 1957, $12,363,458.000.

Illinois ranks high in the meat-packing industry, producing about 10% of the U.S. total in 1954. Manufacture of iron and steel products and of products depending on iron and steel as raw material is first in importance among Illinois industries. representing more than 50% of all Illinois manufacturing. The iron for these industries is secured from the Lake Superior region, the limestone and much of the coal from mines within the state. The position of Illinois in the heart of the agricultural section and its easy access to a bountiful supply of iron caused the state to become the chief producer of agricultural implements. The most important industries in terms of value added by manufacturing are machinery, food and kindred products, electrical machinery, fabricated metal products. primary metal industries, printing and publishing, chemical and allied products, transportation equipment, instruments and related products and stone, clay and glass products.

Chicago. with its tributary manufacturing suburbs of Maywood, Harvey, Cicero, Blue Island, Chicago Heights and others in Illinois. and Hammond and Gary in Indiana, is the great manufacturing centre of the state. A lesser manufacturing area grew up in the railway network that centres at East St. Louis, Collinsville, Granite City and Edwardsville; a third centre is formed by Moline, East Moline, Rock Island and Davenport, Ia. Rockford is best known for its furniture manufactures, Kewanee for boilers, Elgin for watches, Decatur for its corn products industry, Moline, Peoria and Springfield for agricultural and road equipment and Peoria for its distilleries.

Mining. — In mining and allied interests Illinois occupies an important place. The state ranks among the top ten both in the number of persons engaged in the mining industries and in the value of products mined. In addition, large quantities of minerals are imported into the state for processing. Coal constitutes the chief mineral product. The Illinois coal field. as a part of the eastern interior field, extends into Indiana and western Kentucky. At least 70% of this field lies in Illinois from the latitude of Rock Island south to the Illinois Ozarks. It covers more than 55 counties and approximately 35,000 sq mi. of the land surface of the state. The number of mines and miners has been declining for nearly 40 years, the quality of the coal and the expansion in the use of other fuels being the basic cause for the decline. The peak year was 1918 nith 89,979,500 short tons being mined. Petroleum, the mineral second in importance, was long known to exist in the state

but was not seriously exploited until 1906, when the annual production reached 4,397,050 bbl. (42 gal.). The peak production year was 1940, a total of 147,647.000 bbl. being produced that year. In the second half of the 20th century annual production was about 80,000,000 bbl. from 32,000 producing wells. The producing area covers about 16,000 sq.mi. in the southern portion of the state. Clay products also are important. Limestone, dolomite, lime. cement, sand, gravel, tripoli, lead and zinc are other leading products. The quarrying industries are well distributed throughout the state and furnish not only stone for construction work but also limestone for agricultural purposes; the state is also a major producer of silica sand. Illinois has ranked as the leading state since 1842 in the production of fluorspar.

Finance.—All general banking laws must be submitted to the people for ratification. Northern Illinois is in the 7th federal reserve district, with headquarters in Chicago, and the southern part in the 8th, with headquarters in St. Louis. Although Chicago is the banking and financial centre of the state the rest of Illinois is well served by a full range of national and state banks and other financial institutions. The system of state banks created by the act of 1887 operated under the supervision of the auditor of public accounts until 1957. In that year state banks, credit unions and similar organizations were placed under the supervision of the newly created department of financial institutions.

Transportation.— Transportation facilities have been an important factor in the economic development of Illinois. The first settlers used the waterways, some coming by way of the Great Lakes while others used the Ohio river. The first improved transportation facilities were the turnpikes and canals, undertaken in whole or in part by the state. The task of connecting Lake Michigan and the Mississippi river was accomplished by the state's building the Illinois and Michigan canal to La Salle, at the head of the navigation on the Illinois river, a work begun in 1836 and completed in 1848. In 1890 the sanitary district of Chicago undertook the construction of a canal between Chicago and Lockport, where the new canal joined the Illinois and Michigan canal. This work was opened in 1900, providing a waterway with a depth of 20 ft. for navigation between the above places; but from Lockport to Utica, on the Illinois river, a distance of 62 mi., there was no adequate means of water transportation. A legislative act of 1919 provided for the issue of bonds to the amount of $20,000,000 for the construction of an 8-ft. channel, the Illinois waterway, connecting the points mentioned. The bond issue was insufficient to complete the waterway, and the federal government in 1930 completed the original Lockport-to-Utica portion and extended the improvement from Ctica to the mouth of the Illinois river. This improved waterway was opened to navigation in 1933. The federal government also had completed in 1907 the Illinois and Mississippi canal from Hennepin to the Mississippi river near Rock Island. Of these waterways, the Illinois and Michigan and the Illinois and Mississippi canals were little used by 1950. The Illinois waterway, however, experienced a substantial increase in tonnage. Fully opened to navigation in 1935, it carried a tonnage of 1,695,120 that year; annual tonnage reached 12,000,000 by 1950 and more than 24,000,000 by 1960. The completion of the St. Lawrence seaway greatly stimulated the expansion of the deep-water port of Chicago (*q.v.*).

Railways are a major means of transportation, although motor bus, truck and airlines have made heavy inroads into this field since 1930. With 11,349 mi. of railroads (steam, diesel and electric), Illinois in 1960 was second only to Texas. The most striking development in rail transportation in the 1940–60 era was the rapid replacement of steam locomotives with diesel electric locomotives. Between 1920 and 1960 little new mainline road was built and about 1,500 mi. of branch lines, including more than 150 mi. of electric railroad, were abandoned.

Civil aviation continued to develop in Illinois: in 1940 there were about 50 airports, 1,300 pilots, less than 1,000 private aircraft; in 1950 there were more than 150 certified airports, almost 10,000 registered pilots, more than 3,500 private aircraft; by 1960, there were about 125 public airports and more than 500 private landing strips, almost 14,000 registered pilots and almost 4,000 private aircraft. Through the department of aeronautics the state assists in developing public airports and conducts extensive air safety programs. Numerous airlines serve Illinois with scheduled service and a dozen Illinois cities are served by one or more airlines. In 1949 helicopter airmail service was inaugurated to suburbs in the Chicago metropolitan area; the Chicago Midway airport annually has had more departing and arriving aircraft than does any other U.S. airport.

The improvement of roads in the state of Illinois has been given marked attention. A state highway commission was created in 1905, and in 1914 state appropriations for hard roads were made from the proceeds of automobile licence fees. Actual construction was begun in 1914. Road building in Illinois is carried on under four distinct systems—the township, the county, the state and the city.

Acts of congress in 1916 and 1919, apportioning federal aid in behalf of roads, allotted Illinois $3,300.000 and $8,700,000, respectively. The question of issuing $60,000,000 in bonds based on automobile licence fees for the construction of 4,800 mi. of hard roads was submitted to the voters of the state in Nov. 1918 and was approved by them. A bond issue of $100,000,000 providing for the continuance of a state-wide system of hard-surface roads was approved by the people at the general election of 1924. In 1960 the state maintained about 14,500 mi. of highways of which about 13,000 were primary highways.

See also Index references under "Illinois" in the Index volume.

BIBLIOGRAPHY.—There is no comprehensive bibliography of the literature which relates to Illinois. Perhaps most useful is *A Handbook of Illinois History* by Paul M. Angle and Richard L. Beyer (1943).

The best general history of the state is the 5 vol. work edited by C. W. Alvord, *The Centennial History of Illinois* (1918–20). This work consists of: vol. i, C. W. Alvord, *The Illinois Country, 1673–1818;* vol. ii, T. C. Pease, *The Frontier State, 1818–1848;* vol. iii, A. C. Cole, *The Era of the Civil War, 1848–1870;* vol. iv, E. L. Bogart and C. Xl. Thompson, *The Industrial State, 1870–1893;* vol. v, E. L. Bogart and J. M. Mathews, *The Modern Commonwealth, 1893–1918.* An introductory volume to this work is Solon J. Buck, *Illinois itz 1818* (1917). Older standard histories which are still valuable are John Moses, *Illinois, Historical and Statistical,* 2 vol., 2nd ed. (1895); A. Davidson and B. Stuve, *Complete History of Illinois from 7673 to 1873* (1871); N. Bateman and P. Selby, *Historical Encyclopedia of Illinois* (1901). The best one-volume history is T. C. Pease, *The Story of Illinois,* rev. ed. (1949) and the Writers' Program, Illinois, *Illinois,* rev. ed. (1917) is also excellent. A picture history is James Monaghan, *This Is Illinois* (1919).

Much basic material about the state may be found in the *Journal of the Illinois State Historical Society* as well as its *Transactions* and *Occasional Publications;* the *Illinois Historical Collections;* and the University oi Illinois, *Studies in the Social Sciences.* The *Blue Book of the State of Illinois,* edited and published by the secretary of state every two years, is the best source of current information about state government and officials.

Information on the following special subjects may be found in the references named: banking: F. M. Huston, *Financing an Empire: History of Banking in Illinois, 4* vol. (1926); geography: D. C. Ridgley, *Geography of Illinois* (1921); constitution and government: E. Anthony, *Constitutional History of Illinois* (1891), N. F. Garvey, *The Government and Administration of Illinois* (1959), S. K. Gove *et al.* (eds.), *State and Local Government in Illinois: a Bibliography* (1953), D. W. Lusk, *Politics and Politicians of Illinois* (1886); labour: E. R. Beckner, *A History of Labor Legislation in Illinois* (1929), E. Staley, *History of the Illinois State Federation of Labor* (1930); slavery: N. D. Harris, *History of Negro Servitude in Illinois* (1904); southern Illinois: P. M. Angle, *Bloody Williamson* (1952), B. Brownell, *The Other Illinois* (1958), C. Colby, *A Pilot Study of Southern Illinois* (1956); transportation: C. J. Corliss, *Trails to Rails, a Story of Transportation Progress in Illinois* (1937), P. W. Gates. *The Illinois Central Railroad and Its Colonization Work,* Harvard Economic Studies, vol. 42 (1934).

Current statistics on production, employment, industry, etc., may be obtained irom the pertinent state departments; the principal figures, together with the current history, are summarized annually in the *Britannica Book of the Year,* American edition. (C. C. W.)

ILLINOIS, UNIVERSITY OF, an institution of higher learning in Urbana, Ill., was chartered as a land-grant college in Feb. 1867. See ILLINOIS: Education.

ILLITERACY. Illiteracy has usually been loosely defined in the past as inability to read and write. Since the discovery of methods of manufacturing paper and the invention of the printing press in the 15th century, illiteracy has declined at a more or

less constantly increasing rate. By the end of the first decade of the 20th century, it had been largely eliminated in most countries of western Europe, in the major part of North America and in a few other areas of the world. but it was still widespread in Asia and Africa.

Extent of **Illiteracy.**—In *World Illiteracy at Mid-Century*. a report covering all areas of the world published in 1957 by the Cnited Nations Educational, Scientific and Cultural organization (UNESCO), an effort was made to determine the extent of illiteracy among individuals 15 years of age and older; a summary of the findings appears in the table. When the data submitted did not cover the age specified. estimates were made through the use of general population data. Unfortunately the percentages reported are not comparable in all cases, due to the use of diverse sources of data and varying standards of lireracy, but the report provides the most comprehensive information available and the findings are highly significant.

Estimated Population and Extent of Illiteracy in the World at Mid-20th Century, by Coatinents and Regions

Continent and region	Estimated population (in 000,000)		Estimated extent of illiteracy	
	Total (all ages)	Adult (15 years old and over)	Per cent of adult illiteracy	Number of adult illiterates (in 000,000)
World total	2,496	1587	43–15	690–720
Africa	198		80–85	9 8 – 1
Northern Africa	65	1	85–90	'34–36
Tropical and Southern Africa	134	80	80–85	61–68
America	330	223	20–21	45–47
Northern America	168	126	3–4	4–5
Middle America	51	30	40–42	12–13
South America	111	67	42–44	28–29
Asia	1,376	830	60–65	510–540
Southwest Asia	62	37	75–80	28–30
South Central Asia	466	287	80–85	230–240
South East Asia	17.1	102	65–70	68–72
East Asia	677	404	45–50	180–200
Europe	393	293	7–9	22–25
Northern and Western Europe	133	102	1–2	1–2
Central Europe	128	96	2–3	2–3
Southern Europe	131	95	20–21	19–20
Oceania	13	9	10–11	1

Frqm *World Illiteracy at Mid-Century*, published by USESCO, Paris (1957): used by permission.

The striking fact revealed, even when minimal standards were generally used, is that from 43% to 45% of the adult population of the world. or approximately 700,000,000 persons, are wholly illiterate. About 75% of the world's illiterate population lives in Asia, about 14% or 15% in Africa, about 6 5% in the Americas and the remaining 4% or 5% in Europe, Oceania and the U.S S.R. The largest number of illiterates are found in south central and east Asia and the highest percentages occur in Africa and in south central and southwest Asia.

According to the UNESCO report, the countries and other areas of the world having the least illiteracy were: 1% to 2%, St. Helena (Africa), Greenland, Austria. Channel Islands, Denmark, Faeroe Island, Finland. Germany, Iceland, Ireland. Isle of Man, Liechtenstein, Netherlands. Norway, Saar. Sweden, Switzerland, United Kingdom. Australia and New Zealand; 2% to 3%, Japan, Czechoslovakia and Canada; 3% to 4%, United States. Bermuda. Belgium and France. The countries having the greatest extent of illiteracy (95% to 99%) were Angola. British Somaliland. Eritrea, Ethiopia. French Equatorial Africa. French Somaliland, French West Africa, Mozambique, Réunion. South-West Africa and Spanish West Africa. Aden Protectorate, Afghanistan, Bhutan, Muscat and Oman, Nepal, Portuguese Timor, Saudi Arabia, Trucial Oman and Yemen

Functional Literacy.— The use of "minimal" standards of literacy—at the lowest end of the scale, mere ability to read and write one's name—served a valuable purpose for many generations. In the course of time, however. it became apparent that limited ability to read and write does not qualify adults to use reading and writing effectively in meeting many of the practical needs of daily life. To designate the higher level of competence required, the term "functional literacy" was proposed and has been used widely since. During its early use a functionally literate person was defined as one who is able to read and write as well as children who have had four full years of schooling.

With the adoption of this concept countries began to discontinue the use of traditional literacy tests when taking censuses and secured instead statements concerning the extent of schooling, a practice begun by the United States in 1940. This plan is supported by research which shows that there is a reasonably close correspondence, on the average, between last school grade attended and reading competence. Estimates of illiteracy are considerably increased when a higher level of reading ability is adopted as a standard. Using the 1950 census as a basis. Ambrose Caliver of the U.S. office of education calculated the percentage of adults in the United States 25 years of age and above nho had received less than five years of schooling. His findings for the country as a whole showed that 11% of the adults in the United States were not functionally literate by that standard. The range of states was from 3.9% in Iowa to 28 7% in Louisiana. By the same standard about 55% of the population of the world 15 years of age and older is functionally illiterate.

Further adjustments in literacy standards may be desirable, for two reasons. First, such groups as army officials, directors of industrial and cominercial organizations and members of national literacy conferences have criticized fourth-grade standards as wholly inadequate to meet contemporary needs; for example, the U.S. census for 1940 showed only 4% of the population to be illiterate, yet during World War II the U.S. Armed Forces institute found it necessary to establish a literacy training program. These groups recommended as a minimum sixth- or eighth-grade, or even higher, standards. On the other hand a uniform level of literacy is not equally appropriate for all areas of the world. Thus a person may be defined as functionally literate "when he has acquired the knowledge and skills in reading and writing which enable him to engage effectively in all those activities in which literacy is normally assumed in his culture or group." (*The Teaching of Reading and Writing: An International Study*, by William S. Gray, page 24. UNESCO. Paris. 1956.)

Reduction of Illiteracy.— In the 20th century. and particularly after World War II, efforts to eliminate illiteracy were greatly accelerated. The movement was stimulated by the urgent need for broader understanding among citizens of newly established nations, particularly those where suffrage was being widely extended. and by the problems posed by technological and economic developments. National literacy campaigns were carried on with great vigour; those in Turkey, the U.S.S.R. and China were particularly notable. In some countries orthographic and other reforms mere introduced (*see*, for example, TURKISH LANGCAGE) and in almost all countries the system of elementary education was enlarged. Paralleling these developments new approaches to literacy training were developed among groups which had previously been deprived of such opportunities. Among the leaders in this effort were James Y. C. Yen of China, Lorenco Filho in Brazil, Jaime Torres Bodet in Mexico and Frank Laubach, an American-born missionary. In addition to its promotional activities, USESCO has conducted certain practical programs in collaboration with its member states. Two important ones are the International training centres: the Arab States Fundamental Education centre (ASFEC) in Egypt, serving the Arab states of the middle east and the Regional Training Centre for Teachers of Fundamental Education (CREFAL) in Mexico, serving all of Latin America.

The influence of the foregoing developments on methods of teaching adults to read has been very significant. Prior to 1950 highly specialized methods of two general types were used widely in achieving the limited goals sought. One type was synthetic in character and began by teaching the sounds of letters nhich were then used in the recognition of new nords. The other type was analytic in character and began by teaching whole words which were later used in identifying the sounds of letters. As the concept of functional literacy emerged. the view spread that good teaching should cultivate a thoughtful reading attitude, a clear grasp of meaning and interest in independent reading as well as the skills of word recognition.

When a world-wide study of methods of teaching adults to read

was made for USESCO between 1952 and 1955 it was found that they still differed nidely in character. They varied from the formal use of synthetic or analytic methods to broadly conceived programs of teaching which emphasized all the interests, attitudes and skills essential on the part of a good reader. A detailed study of the relative merits of the different methods used revealed the following facts: (1) that no single, highly specialized method secures superior results; (2) that the use of a given method promotes growth in whatever aspect of reading it emphasizes, such as skill in word recognition or a clear grasp of meaning: and (3) that best results are assured when the methods used emphasize all essential aspects of reading.

Stimulated by the results of the UNESCO study, and other reports, wide experimentation was undertaken in various parts of the world to develop improved programs of teaching. Resulting trends were well illustrated by the findings of a study of primers printed in 30 languages and used in six countries of the Americas The outstanding finding was not the diversity but the uniformity of methods Almost without exception the primers were eclectic in nature. even though based on different approaches. The essential principles of primer construction, as demonstrated by field testing, are the gradual introduction of new elements and provision for growth in ability to read independently, to understand what is read and to read fluently. Although methods of developing word recognition must of necessity vary nith the nature of the language involved, the foregoing report indicated progress toward the establishment of sound patterns of literacy teaching.

Reference should be made also to experimental use of television as an aid in reducing illiteracy. Beginning about 1958 the Foundation for World Literacy, sponsored by the Memphis (Tenn) Chamber of Commerce began the use of telecasts based on materials prepared by Laubach. Measures of the progress made during a year showed that those who learned with reasonable ease or had previously made some progress in learning to read profited from the instruction thus provided. Those who learned less rapidly were unable to keep up with the work and discontinued their efforts. The experiment showed that the use of television might be of great value in the fight against illiteracy, but much experimentation was needed in order to learn how it might be used most effectively either alone or in co-ordination with other modes of instruction

As the requirements for literacy have expanded, short-term course- nhich nere formerly given to meet "minimal" standards have been greatly modified and enriched Of great importance also is the fact that they are being extended to enable motivated and capable illiterate adults to gain admission to the regularly established educational institutions of a country, thus facilitating upward intellectual and cultural mobility.

ILLUMINATED MANUSCRIPTS. Illumination in art, is a term applied to the embellishment of written or printed text or design with colours or gold and, rarely, with silver. The old form of the verb "to illuminate" was "to enlumine," and 13th-century laymen nho practised the art were called "enlumineurs." While the term should be strictly applied to the brilliant book-ornamentation which was developed in the middle ages, it has been extended. by usage. to the illustration and decoration of early manuscripts in general.

The decisive changes in the history of the book are similarly turning points in the art of illumination. (*See* BOOKS) The production of precious illuminated manuscripts survived the introduction of printing by nearly a century. So far as is known, the art of decorating manuscripts did not create new forms through a development based on writing, but rather it took over pictures and ornaments from other forms of art. The written pages at first were simple and unadorned; even where the parchment was coloured and the writing in silver or gold; then simple enlarged initial letters and calligraphic ornament appeared. In the codices there were richly adorned title pages and brilliant displays of ornament in the canon tables of Gospel manuscripts. The form and position of the pictures vary exceedingly. Sometimes the illustrations are placed haphazard in the picture borders, in the text or as framed pictures in the text. They may also occupy full pages, or they may be in the form of a running band in the codex above or below the text or, in the roll, they may run in a continuous series of pictures from end to end.

Ancient. — The small amount surviving from the first great period in the history of illumination, which lasted until about the 4th century, consists of numerous fragments of papyrus rolls. Such fragments include the ancient Egyptian Book of *the Dead,* in which the illustrations are either dashing drawings or coloured pictures. The only illustrated rolls of the classical period are fragmentary examples found in Egyptian excavations, and knowledge of this period, as a whole, is very slight. The most ancient and important of these are the fragmentary copy of the *Iliad,* on vellum in the Ambrosiana library, Milan, with 58 pictures of various sizes, obviously the remains of a magnificent manuscript; the small Virgil at the Vatican (Lat. 3,22j; 4th century) with pictures set off in a simple frame and inserted in the text, all of which are considered to have been based on Augustan models; and another Virgil at the Vatican (Codex Romanus, Lat. 3,867).

Early Christian. — Christian illumination dates from the times of the few early profane illuminated manuscripts which are still extant. The number of ancient Christian illuminated manuscripts in Greek or in oriental languages is very small. (*See* BIBLE.)

Among illuminated theological or profane manuscripts which survive in the original, the most important is a medical treatise, the Dioscorides (early 6th century), in Vienna. Few of the manuscripts are dated and localized. Many manuscripts important to early Christian art are preserved only in medieval copies; even those actually written in early Christian times may be merely copies. This is why the Vienna Genesis (Vienna State library), made up of various series of illuminations, is closely allied to the Codex Rossanensis (Rossano, Italy) which belongs to another stage in the development of the style. The style was determined mainly by paintings of late antiquity based on Hellenistic models influenced by indigenous art (Coptic. Syrian and others).

Byzantine. — The development in Byzantium cannot be traced clearly until after the iconoclastic controversy. As art flourished again the works of the Byzantine Renaissance. as it is called, began to be produced. To this renaissance belong those codices which hand on works of late antique or early Christian times, partly in accurate copies, partly in free imitations (Joshua Roll, Kosmas Indikopleustes in the Vatican library), Psalters like that at Paris (Bibliothèque Nationale Manuscript Grec. 139). On the other hand, typical middle Byzantine art modeled its style on monumental art.

Although Constantinople decided the trend of artistic production, illumination was also cultivated outside the capital. As practised in the monasteries of Athos, its importance was far-reaching. From the 11th century a school of miniaturists developed in Russia, the works of which are, at first, scarcely to be distinguished from those of Byzantium. The menology at the Vatican is the only Byzantine manuscript in which each miniature is signed by the artist. The style in the later works, and especially in the productions of the monasteries, became dry, but it persisted through the Latin conquest (1204–61), and was capable of a rebirth after the restoration of the empire under the Palaeologues (1261).

Western.—Few early Christian illuminated manuscripts of western origin have survived. A comparison between the Quedlinberg Itala fragment at Berlin (State library) of this period and the Virgil of the Vatican (Lat. 3,225) proves that the scriptoria which produced the latter also executed Christian illuminated manuscripts. The affinity between the two is extraordinary. The style

is clear and simple in character; the pictorial conception gives evidence of naturalness and is without a trace of the Byzantine spirit.

The most important original manuscript is St. Augustine's Gospels at Corpus Christi. Cambridge (Nr. 286), which was probably executed in lower Italy. The Ashburnham Pentateuch at the Bibliothèque Nationale is of a different type; its 19 miniatures are stylistically and iconographically unique and indicate a connection with oriental models. These manuscripts bear witness to a survival of late antique and early Christian art in the vest. By comparison, the mass of the manuscripts produced in the monasteries of the Frank and Lombard kingdoms in the 7th and 8th centuries have quite a different character. Among the large number preserved only a few have figurative representations. Illuminated Bibles or Gospels are scarce. Ornament, in general. is restricted to initials and decorated pages, a method of embellishment based on the art of the scribe, not of the painter. Compared with the simplicity of the text in late antique manuscripts. it is a complete revolution. Part of the material originated in upper Italy and south France, apparently in the early 7th century. Later, the art was transplanted to central and northern France. The majority of the manuscripts, and especially those richest in decoration, came from north France in the latter half of the 8th century, *i.e.*, not until the Irish and Anglo-Saxon arts of illumination were already highly developed.

In Britain two fundamentally different tendencies must be distinguished, the Irish and the English. The development in England was determined by the Roman mission and by the close relations kept up between the Italo-Saxon churches and monasteries and Rome itself. In the 8th century, from which period a series of splendid manuscripts have survived, artists endeavoured to continue the early Christian figurative tradition in stiffly outlined forms, and at the same time displayed rich decorative splendour in the Irish fashion. The most important works of the Canterbury school are St. Augustine's Psalter with a portrait of David (British museum) and the Codex Aureus in Stockholm (Royal Library Manuscript A35).

Irish.—In spite of Ireland's numerous contacts with England, Irish illumination is unique. It is one of the most interesting phenomena in the whole range of medieval art. In the art of illumination it represents, perhaps, a climax never again reached. It is the more remarkable in that it suddenly appears fully developed, without any preliminary stages and with no source to which it can be traced. The three chief Irish works are the Book of Durrow (Dublin, Trinity college, A. 4, 5), the Book of Kells (ibid. A. 1, 6) and the Lindisfarne Gospels (British Museum Cotton. Nero D. IV). The Book of Durrow (c. 700) is pure Irish in style. The Book of Kells (for which the date 700 has been disputed in favour of a later period) shows traces of foreign ornamental ideas. The Lindisfarne Gospels (written soon after 700) have pictures of the evangelists that are not Irish in style, which implies the influence of the Italo-Saxon monasteries. Irish artists did not attempt naturalistic representation but made the figures of a picture as free as if they were calligraphic designs. so that it is often difficult to see what these plaited figures really mean. This antinaturalistic method of representation stands in sharp contrast to the whole range of classical antique art in all its derivations. Irish manuscripts show a richness of decoration unparalleled. so far as is known, up to that time. The various Gospels are preceded by whole pages with carpetlike designs and the initials at the beginning of the text grow and spread until they, too, cover the whole page.

Carolingian.—Simultaneously with the reform of writing, a project of Charlemagne, there arose a number of new schools of painting which aimed at restoring the connection with antique and early Christian art. The chief works probably were not created before the beginning of the 9th century. They include the Gospel book of Ada (?Charlemagne's sister) at Trier (Municipal Library Manuscript 22), after which all these works are called the Ada group; the group was produced at the Palatine school of Aix-la-Chapelle. These manuscripts include rich canon tables, pictures of the evangelists and of their symbols under large arcades, symbolic representations of the church, the fountain of life, etc. Obviously there is an ancient pictorial tradition, which can be traced on one side to Syria and on the other to Italy and England. The colouring is varied and splendid, the figures dramatic in movement, the faces fine and full of expression and the outlines of the figures rich in style. On the whole, the treatment, with its sharp and clear outlining of form, shows more of the spirit of drawing than of painting. All this points to models of high artistic importance.

In decided stylistic contrast to the Ada group are other manuscripts issuing from the Palatine school of Aix-la-Chapelle. Its chief work, the Gospel book of Charlemagne, is preserved among the crown treasures at Vienna. The treatment is altogether pictorial; the colouring is fine, simple and not too varied. The plain style of embellishment, with the greatness of conception in the figures and the soft pictorial treatment, point to early Christian models. This tendency is continued chiefly in the school of Reims, where a Gospel book at Epernay town library was made for Ebbo of Reims (816–35). There are significant changes of style however; the broad pictorial technique has made room for a hatched treatment, which has led to the supposition that the artist was accustomed to using a drawing pen. The style is that of the Utrecht Psalter, which has great affinity with later Anglo-Saxon work, and which subsequently exercised a strong influence on development in England. The Utrecht Psalter (Utrecht University library) is at once the most magnificent and the strangest production of Carolingian art. The composition with landscape like stage scenery is reminiscent of early Christian models. Without a doubt, the Utrecht Psalter has some connection with early Christian art. Nevertheless, it is essentially a creation of Carolingian times. The school of Tours was at its prime toward the middle of the 9th century under the lay abbot Count Vivian. The Gospel book destined for the emperor Lothaire is the most important work (Bibliothèque Nationale Lat. 266). The Tours manuscripts took from early Christian models a large number of Bible illustrations and introduced them into medieval art. A quite distinctive style marks the works of the Franco-Saxon school. It shows, unmistakably, a continuation of the Irish and Hiberno-Saxon school enriched by Carolingian elements. Its strength is based entirely on ornament and it is notable for having spread the art of the initial as developed in England and Ireland.

Anglo-Saxon.—Anglo-Saxon illumination began to flourish once more under King Edgar (c. 960). The new style, based on Carolingian art, suddenly made its appearance completely developed in the works of the Winchester school. It is one of the most original and attractive in the whole range of medieval art. The artist was not satisfied with normal movements of the neck or head, so the line of the neck is unnaturally prolonged and curved; the draperies appear as if driven by a gale of wind, and end in fluttering points; the seams are broken into numberless small folds. From the standpoint of correctness, fault might be found with these figures, but as the expression of immense spiritual force they excite wonder. Anglo-Saxon art, too, reaches its climax when it dispenses with painting in thick colours and contents itself with sketchlike drawings, which may be tinted with various light colours. The chief work of the early period is the Benedictional which Bishop Aethelwold (963–984) caused to be written by the scribe Godeman (British museum).

One of the most important seats of Anglo-Saxon art was at Canterbury. A copy of the Utrecht Psalter (British Museum Harley 603) is supposed to have been executed there. More than three hands worked at it. so it must have been made in a large scriptorium. The Anglo-Saxon style remained full of life until the middle of the 11th century. It was not confined to England; during the 10th century it crossed the channel to France, where the style appears in many works in such freshness and spontaneity that it seems likely that Anglo-Saxon artists had emigrated to there. Of this type is the Evangeliar (Boulogne library, No. 11) written at the Abbey of St. Bertin. In northern France, side by side with the illuminations influenced by the Anglo-Saxons, other manuscripts were created which are independent in style and full of intense expression.

Ottonian.—The Ottonian Renaissance flourished in Germany during the 11th century, about the same time as the Winchester school. Its political background was the renewal of the Holy Roman empire by Otto I. Within a few decades an almost inconceivable abundance of magnificent manuscripts was produced, which can be allotted to a number of different schools. These schools differ exceedingly in character, according to whether the artists used Carolingian or early Christian models. Middle Byzantine art, too, begins to exercise influence at this period. Most pictures in the Ottonian manuscripts spring from these sources. All the schools, however, were very creative in ornament. They used whole page illuminations with purple ground and richly formed initials of golden foliated branch work, similar to those found occasionally in Carolingian times, especially in the Metz school. In all schools of the Ottonian period, painting with thick colours prevails. In the works of the golden age of Ottonian art the intention to approach the illusionistic conception of the late antique is noticeable. But these endeavours were soon frustrated, and at the beginning of the 11th century decline set in. The painting became more medieval in character, the background of the pictures being divided up by ornamental and coloured stripes, for which the Byzantine gold background was occasionally substituted. The most prominent centres of artistic activity were the monasteries of Reichenau, situated on an island in Lake Constance, Trèves, Cologne, Hildesheim, Corvey, Fulda and Ratisbon.

Romanesque.—Illumination at the middle of the 11th century was at a turning point. Anglo-Saxon schools and the German Ottonian Renaissance were dying out, and so the connection with antique painting disappeared. From then onward in the whole of the west the style was based on linear, not pictorially treated, outline drawing, in which colour was used to tint the surfaces in the flat, with only slight modeling of forms. Art abandoned the last reminiscences of the illusionistic manner of the late antique, in which the picture was based on a reality either seen or visualized. The medieval style, which then established itself, dispensed with illusion, and gave the different components of the pictures, *i.e.*, the figures and whatever else was necessary to understand the action, but released them from contact with natural space. Even the background had a chiefly ornamental importance. The gold ground became more and more popular; borders and backgrounds consisting of a system of frames were also used. This manner of representation permitted the artist to pack the most complicated ideas into a picture and create the corresponding frame to hold the conceptions together. This tendency completely dominated the art of illustration. A counter movement was Byzantine art, which never altogether lost contact with the antique, preserving formulas from the illusionistic age. In the 12th and 13th centuries Byzantine influence penetrated farther and farther into Italy and obtained a strong hold in Germany.

In the west of Europe, especially in northern France, in Burgundy and in England, Byzantine influence may also be traced. Stained glass, with all its beauty of colour, is also based on outline drawing. rather than real modeling. It had an extremely strong influence on the method of painting, described above, in which numerous figurative representations were combined within a system of frames. In the 12th and, especially, the 13th centuries, many illuminated manuscripts show traces of having been imitated from stained glass.

Anglo-Norman.—Soon after 1100 Anglo-Norman scriptoria were at the height of their power. Their productions were chiefly enormous Bibles, separate books of the Bible with commentaries and especially the Psalter. The style abandoned the lightness of Anglo-Saxon times. It was based on stiff linear designs filled with opaque pigmepts of harsh colour. The figures mere, especially early in the 12th century, heavy and awkward. A little later the style became more spirited. The initial ornaments were astonishingly rich in invention and design, enlivened with numerous fantastic forms of men and animals in strange colours.

Bury St. Edmunds produced the first of the large Bibles so characteristic of the 12th century. Winchester again became, about the middle of the 12th century, the seat of an important school.

The wave of Byzantine art had reached England also and the deeply agitated style with its singular types was replaced by an almost classical conception of art. The chief work of this tendency is the M'inchester Psalter of the British museum. Well-proportioned forms of measured placidity and solemnity of movement are characteristic of these pictures. Of the greatest importance is the latest copy of the Utrecht Psalter (Bibliothbque Nationale Lat. 8846).

Continental.—Knowledge of the history of miniature in France is altogether much slighter than that of England. The quick rise and decline of an important scriptorium at Cîteaux, the founder of which mas Abbot Stephen Harding, is known. Numerous manuscripts with most peculiar decoration, especially initial letters of quite fantastic formation, emanate from Limoges and western France. The productions of monasteries in Belgium and northern France are extraordinarily numerous. Many of these are dated and indicate the names of the artists. In the eastern part of this territory, a style approaching the Rhenish predominated, while toward the west, where the narrowness of the straits provided a natural connection with England, the Anglo-Norman affinities already mentioned made their appearance.

In these districts, also, the presence of a strong Byzantine influence in the critical period around 1200 can be established.

In Germany the development of art, after the Ottonian Renaissance, varied in the different territories. In the southeast, the Middle Byzantine influence, already perceptible in the early 11th century, became permanent.

In the western and northern districts of Germany, Byzantine influence was not so powerful in the 12th century. One work, however, the famous Hortus Deliciarum of the abbess Merrad of Landsberg in Alsace was unique for the unusual illuminations it contained. (The original perished in 1870.) Pure pen drawing had become prevalent. On the lower Rhine, in north Germany and in Weingarten (Berthold Missal, Pierpont Morgan library, New York city) some miniatures were executed in opaque pigments. These are clear and calm in style, and at times they rise to monumental dignity, *e.g.*, in the Gospel book of Henry the Lion made at Helmarshausen, or the Hildesheim manuscripts of the 12th century (Hildesheim, Ratman Missal, etc.).

With the beginning of the 13th century Byzantine influence extended its power over almost all the country, and its style displays great restlessness. In the latter part of the 13th century the desire to create original forms and to express passionate feeling was so strong that the style was often positively distorted. The Byzantine tendency attains its zenith in the Gospel book of the town hall at Goslar, and the related miniatures in Halberstadt, executed in the first third of the 13th century. Immediately after the middle of the 13th century numerous fine works were produced especially in south Germany, where refined Byzantinesque style, mixed with the court style of Paris, predominated (Psalter, Munich Staatsbibliothek Lat. 3,900 and the Gospels of Aschaffenburg, Staatsbibliothek Manuscript 3).

Gothic.—In the first half of the 13th century there was a complete transformation of the fundamental ideas of book ornamentation. A refined and dainty style was cultivated which resulted in the contrast between miniatures in Gothic manuscripts and the art of monumental painting appearing sharper than ever before. Picture and text were more closely assimilated, and the historiated initial became predominant in Gothic manuscripts. When the miniature remained independent, it bore the character of a small medallion or of a quatrefoil. The initials, however, expanded more and more until they twined themselves all round the pages of text. Figures dispersed at random in the margin, called drolleries, although they represented any sort of conceivable object, introduced a new style of embellishment on which all development to 1500 was founded. Paris is regarded as the birthplace of the new style. Several manuscripts are designated as the property of Queen Blanche or of St. Louis, among them the Psalter of the Arsenal library in Paris. It is the first to show the substitution of medallions for the usual rectangular series of pictures. From other books it is still clearer that the illuminators kept very close to the example of stained glass windows, from

which they borrowed the complicated arrangement of the medallions.

Although a great advance was made by the manuscripts of the *Bible moralisée* and the allied manuscripts, the pure type of Gothic manuscript had not yet been produced. Many other miniatures, however, display a strongly dramatic and restless style, which has a certain affinity with contemporary German work rather than with French Gothic. A number of splendid manuscripts. which are supposed to emanate from Salisbury, are illustrated in this style. Early English examples include the magnificent pictures of the Apocalypse at Trinity college, Cambridge. A great new style. which was to oust all the previous tendencies in France and England, was created under the strong influence of monumental art in Paris about 1240. Its chief works are the Psalters written for St. Louis or other members of the royal family (Bibliothbque Nationale Lat. 10,525), and the liturgical manuscripts executed for the Ste. Chapelle, Paris. These works combine two qualities: first. the greatest simplicity of style, in that they work out the pure Gothic line; second, a marked attention to reality in ornament and in architectonic details, in costume, etc. It is very difficult to distinguish between French and English work of this period. In spite of numerous English traits the Psalter of the municipal library at Niirnberg and the Psalter of Queen Isabella, Edward II's wife, at Munich (Staatsbibliothek) probably originated from Paris. Queen Mary's Psalter at the British museum is, beyond dispute. an early 14th-century English masterpiece. In the work of the East Anglian school can be seen the gradual giving up of Gothic outline drawing for the sake of a broader pictorial treatment. Its most singular characteristic is extravagant richness of ornamentation displayed in the large border frames of the decorated pages, interlaced with figures of every shape and kind. In Parisian illumination the characteristic style of the miniaturists Honoré and Jean Pucelle show the change unmistakably. From this time the development of modern painting can be followed in the miniatures of the manuscripts. The fundamental revolution in style which took place during this period can only be explained on the assumption of Italian influence arising out of the close connection between Italian and French art. based, in its turn, on political and dynastic relations and the transference of the papal court to Xvignon. This may account for the fact that Pucelles' masterpieces, the breviary of Queen Jeanne of Navarre (formerly Tates Thompson collection), and the hours of Jeanne d'Evreur (Cloisters, Metropolitan museum, New York city) contain certain miniatures that can only be understood as imitating Italian pictures of the Trecento.

From the middle of the 14th century onward, the naturalistic tendency became more and more powerful. For this period the phrase. "the naturalism of head and hand," has been coined Its influence is seen most clearly in the dedication pictures, where the elements of portraiture in the persons represented, *e.g.*, Charles V, are unmistakable. In religious pictures, however, Gothic idealism continued until the beginning of the 15th century. The miniatures executed for Charles V are often set in quatrefoil frames, and gray monochrome (grisaille) is preferred to painting in colours. The decisive change in the direction of modernity may best be studied in the manuscripts illuminated for Charles V's brother, the duke of Berry. The name of André Beauneveu of Valenciennes is given for the Psalter at Paris (Bibliothbque Nationale Fr. 13,091), that of Jacquemart de Hèsdin for the prayer books at Paris (Bibliothbque Nationale Lat. 919) and Brussels (Bibliothèque Royale 11,060–61). In these manuscripts there is a change in the borders, the dainty sprays of ivy, which had hitherto sprouted loosely over the margins, now completely fill them up, and new motifs add to the wealth of ornament. In the miniatures the old Gothic tradition can be seen gradually being displaced by the tendencies of Italian art, with a rapid progress in naturalism. The new art reached its climax in the second decade of the 15th century in two manuscripts begun for the duke of Berry, which must be classed, beyond dispute, among the most magnificent illustrated books of all times. The unfinished prayer book at Chantilly (called, according to the inventory, Trks riches Heures du *duc de* Berry), was illuminated by Pol de Limbourg and his brothers. Pictures which are reminiscent of famous Italian mural paintings stand side by side with faithful representations of reality, as, *e.g.*, the calendar pictures with the views of the duke's castles or the genrelike February snow landscape. Another step forward was the prayer book begun for the duke of Berry, but after his death continued for Count William IV of Bavaria-Holland. In the pictures of William IV's time the Italian style has been completely replaced by a style so near to that of the brothers Van Eyck that some of the best pictures have been attributed to them. The miniatures of the two last-named manuscripts are invaluable to the history of painting.

Spanish and Italian. — Spanish and Italian illumination had only a slight share in the Renaissance movement on which Carolingian, Ottonian and Anglo-Saxon art was based. In Spain, as in Italy, tendencies prevailed, during this period, which can best be compared with the Franco-Saxon school. The Spanish manuscripts of the 9th to 11th centuries display a rich, but fantastic decoration in which early Christian and Moorish elements are mixed. The figures are antinaturalistic, reminding one of the Irish style. The most singular Spanish creation is the great series of illustrations to Beatus of Liebana's Commentaries on the Apocalypse which have survived in many copies from the 9th (?) to the 12th centuries (the oldest in the Pierpont Morgan library).

The character of Italian illumination varies extremely in the different Italian territories, according to their relations with east and west. A curious blend of contrasting tendencies is to be seen in the book ornamentation of the Benedictines at Monte Cassino in the 11th and 12th centuries. Here Hiberno-Saxon, Ottonian and Byzantine stylistic elements are intimately combined. Southern Italy made a specialty of Exultet Rolls, as they are called, *i.e* , long illuminated scrolls of parchment, which contained liturgical readings for use at Easter and which were unrolled by the officiant priest over the lectern of the pulpit. Various Italian monasteries produced from the 11th to the 13th centuries gigantic Bibles, some of which show a singular beauty of initial which was afterward imitated in the 15th century. The origin of these Bibles is partly to be sought in Tuscany, where, in the reign of the margravine Matilda, works of a pronounced original character were produced, *e.g.*, the Gospel book which Matilda presented in 1109 to the Abbey of Polirone (Pierpont Morgan library). During the 13th century, Italian illumination in the large university towns of northern Italy developed freely and in a manner quite its own. Legal textbooks. Bibles, etc., were executed and taken by the students all over Europe. Moreover, the 13th century produced a new type of book, the immense choir book, which was everywhere used at church services. In general, large miniatures are rare in Italian illuminated manuscripts. Most have only historiated initials, but these are drawn out to great length and spread out over the margins in branch and leaf work. Drolleries were added very early, so that one feels inclined to assume that they made their way to the north from Italy. All this, however, does not exhaust the importance of Italian miniature. Just as in mural and panel painting, Italy was foremost in diffusing the Byzantine style.

The immediate influence of the Crusades in causing an interpenetration of the western and Byzantine elements must not be overlooked. In the Latin kingdoms of the orient, there were executed for churches and princes magnificent manuscripts in which such a mixture of styles was inevitable, *e.g.*, the Psalter of Queen Melissenda of Jerusalem (British museum), the Missal of the Holy Sepulchre church at Jerusalem (Bibliothilque Nationale Lat. 12056), and many others. Similar works probably emanated from those districts of Italy which were particularly exposed to Byzantine influence. In this class may belong the missal at Madrid. A similar mixture of style is evident, in a much coarser form, in the epistolary, written in 1259 at Padua by Gaibana (cathedral treasure). About 1300 a large number of Byzantinesque illuminations were produced at Bologna, which are distinguished by copious border decoration, with figures in the pseudoclassic style. Splendid works of this kind are the Bibles at Paris (Bibliothbque Nationale Lat. 18) and at the British museum (Add. 18,720).

During the 14th century, throughout Italy's busy scriptoria, as at Naples, where French influence is noticeable, numerous manu-

scripts rich in miniatures were produced (Bible in the Berlin Kupferstich-Kabinett, Manuscript 78E3, once belonging to Leo X). Only rarely can miniatures be connected with the artists who painted on panel.

15th- and 16th-Century. — Ailany illuminated manuscripts of the later 15th and 16th centuries surpass in wealth of pictures and magnificent embellishment, even the works from the time of the duke of Berry. In the 16th century they were eventually supplanted by black and white. The splendid miniatures of the 15th and 16th centuries are, like those of the preceding period, chiefly destined for princes and great courtiers. Three large centres of production were prominent: Flanders (Ghent, Bruges); France (Paris. Tours); Italy (Florence, Ferrara and others). Illumination in this period acknowledged no restriction in its choice of subject. The Books of Hours, indeed, still played an important part. but, besides these, there were profane manuscripts of an incredible variety, among which the chronicles and the romances are prominent.

Flemish. — It can only rarely be proved that painters on panel of the generation after the Van Eycks had a hand in illumination. A number of miniaturists are known from their works or from documents; *e.g.,* Jean le Tavernier, Willem Vrelant, Loyset Lyédet, Philippe de Mazerolles, the Bening family. About the middle of the 16th century the activity of the Flemish scriptoria seems to have died out. It is important to note Simon Marmion, unsurpassed in landscape (Book of Hours, British Jluseum Add. 38.126). A master belonging to the circle of Roger van der Weyden is called, after the Romance of Girart de Roussillon, Jean le Tavernier. nho adorned the Conquêtes de Charlemagne executed for Philip the Good (Vienna Staatsbibliothek 2.539). His second masterpiece, the Chronicle of Hennegau, is at Brussels (Bibliothèque Royale Manuscript 9.066).

French. — The production of French manuscripts during the 1 jth century can best be judged by the *Heures* de Rohan (Bibliothkque Nationale), the *Heures* du *Marichal* de *Boucicaut* (Paris, Musée Jacquemart André), the Bedford Alissal (British museum) and the Salisbury breviary in Paris (Bibliothkque Nationale), nith its numberless miniatures. About the middle of the 15th century Jean Fouquet, the most important personality among the French miniaturists, made his appearance. He died about 1480 at Tours, where he had lived before and after his journey to Rome, between 1443–47. Attested works of his are parts of the *Antiquités Judaïques* at Paris, and the miniatures cut out from the *Heures d'Etienne Chevalier* at Chantilly. Fouquet's art, which otherwise shows affinities with Flemish naturalism, has a touch of the Renaissance.

German.-In Germany in the 15th century, illustration passed a humble existence in monasteries and scriptoria which engaged in large-scale manufacture of manuscripts (Diebold Lauber in Hagenau). In contrast with this mass production, there are the splendid manuscripts of the emperor Maximilian. The finest work is the superb border, executed by Dürer and other great German artists, in a copy of the prayer book printed by Schonsperger (Munich Staatsbibliothek and Besançon).

Italian. — In Italy the renaissance in the manuscripts began with the introduction of the *scrittura umanistica,* which returned to the model of the fine Italian manuscripts of the 11th and 12th centuries, from which was also taken the scroll work design in the frames enclosing the pages of text. Illumination did not really flourish until the middle of the 15th century, when a number of new studios, most of them associated with the luxurious courts, created a new style and new decorative forms. As in Flanders, the artists are seldom those who painted on panel, although. for example, the works of Simone Martini, Giovanni di Paolo and Andrea Mantegna are reflected in miniatures. In northern Italy, Milan and Verona were two of the centres. A masterpiece is the Book of Hours of Bona of Savoy, widow of Galeazzo Maria Sforza, duke of Milan, which afterward came into the possession of Charles V (British Museum Add. 34,924). In the Ferrara school, where a number of miniaturists worked for the ducal family of Este, Taddeo Crivelli takes the first place (Borso d'Este's Bible, 1455–62, Modena). The most important miniaturist under Borso's successor, Ercole I. is Martino da Modena (Ercole I's Breviary at Vienna). Miniature painting in central Italy was chiefly concentrated at Florence; Francesco d'Antonio del Cherico with Attavante degli Attavanti were the two chief miniaturists.

BLANCHE OF CASTILE AND SAINT LOUIS, KING OF FRANCE

Leaf from a *Bible Moralisée,* showing portraits of Blanche of Castile and her son, Saint Louis, king of France. This reproduction is from the original French manuscript, executed in the first quarter of the 13th century, now in the Pierpont Morgan library, New York

ILLUMINATED MANUSCRIPTS

AFTER A FACSIMILE BY SCHWENKE OF THE PELPLIN COPY OF THE GUTENBERG BIBLE, BY COURTESY OF THE NEW YORK PUBLIC LIBRARY

ILLUMINATED PAGE FROM THE GUTENBERG BIBLE

The Gutenberg Bible, traditionally accepted as the first book printed from movable type, was issued at Mainz, Germany, about 1454. The illustration shows page one of the Proverbs of Solomon. The pages are illuminated to give the effect of a hand-copied manuscript, as desired by the printers, who did not wish their invention discovered. The book was probably printed in 10 sections on 6 presses working simultaneously. Of nearly 300 copies, only 45 are known to be in existence to-day

ILLUMINATI, a short-lived movement of republican free thought founded on May day 1776 by Adam Weishaupt, professor of canon law at Ingolstadt and a former Jesuit. The members of this secret society called themselves "Perfectibilists." Their founder's aim was to replace Christianity by a religion of reason, as later did the revolutionaries of France and the positivist philosopher A. Comte in the 19th century. The order was organized along Jesuit lines and kept internal discipline and a system of mutual surveillance based on that model. It ran the full gamut of fads which are usually linked with secret bodies of this kind, including the assumption of classical names. From 1778 onward they began to make contact with various masonic lodges, where, under the impulse of A. von Knigge (*q.v.*), one of their chief converts, they often managed to gain a commanding position. The total numbers never exceeded 2.000.

The scheme itself had its attractions for literary men like Goethe and Herder, and even for the reigning dukes of Gotha and Weimar. Such notables were claimed as members although not actually so. Secret societies of this kind fitted in with the idea of benevolent despotism as a vehicle for the Enlightenment, as Goethe shows in Wilhelm Meister.

The movement suffered from internal dissension and was ultimately banned by an edict of the Bavarian government in 1785. This undermined other, genuine liberal forces that were now open to reprisals from the unprogressive authorities and the Roman Catholic Church alike.

See P. Tschackert in *A.* Hauck (ed.), *Realenzyklopädie fur protestantische Theologie und Kirche (1901).* (P. FO.)

ILLUSION, the experience and the result of misconstruing or misinterpreting some real sense stimulus or stimuli, as when a wax figure at Madame Tussaud's or similar exhibitions is mistaken for a real policeman, or when a piece of suitably modeled plasticine is mistaken for a sausage. Something is actually there to stimulate the senses, and the sense experience itself is produced in a normal manner, but, because of established habits of rapid association or the temporary "set" of the mind, the observer mistakes the thing for something different.

Many optical and other types of illusions are perfectly normal and can be experienced by large numbers of people at the same time. The familiar "magic" entertainments consisting of juggling and conjuring tricks are examples in which the conjurer employs special equipment and techniques designed to deceive the minds of his audience by directing their attention toward one action while another goes unnoticed (see CONJURING). The apparent bending of a pencil placed in a glass of water is an optical illusion caused by refraction of light as it passes from one medium to another, while many other illusions such as the apparent movement of motion pictures and many animated electric advertising signs are possible because of the physiological phenomenon known as persistence of vision.

The normality and indeed the inevitableness of so many illusions constitute one of the serious problems in any attempt to vindicate the validity of human knoll-ledge.

ILLUSTRATION. To illustrate means to elucidate, and illustration is the placing of informative pictorial material in books, magazines and papers. Though the terms illustration and illumination are not always distinguished clearly and the two words are sometimes used interchangeably, illumination strictly speaking applies to the decorative accompaniment of a text while illustration refers to that pictorial matter which clarifies or demonstrates a point in a text or adds vividness and concreteness to the characters and incidents of a story. (See ILLUMINATED MANUSCRIPTS.)

In most cases the illustrations to a text never become completely identified with it, and over a period of time the same story or treatise may be illustrated by a number of different artists, each contributing a different kind of elucidation. However, sometimes one artist's work will seem to be the definitive illustration of a story, no matter how many others attempt it—an example that comes readily to mind is the work of John Tenniel for Lewis Carroll's Alice's Adventures in Wonderland. Tenniel's illustrations seem far more satisfactory even than those designed by the author of the book.

There are other instances where the author himself was also the designer of illustrations that have become inseparable from the text. Among others that could be mentioned are Edward Lear's drawings for some of his limericks and nonsense verse and William Blake's illustrations for his prophetic books.

Ancient and Medieval Illustrations. — The history of illustration is as old as that of books themselves. Man's desire to have his literature illustrated has expressed itself independently of books. Many paintings, for example, are illustrations in the sense that they take their meaning from a literary text (which, however, is rarely provided for the viewer), and they can be fully understood only by those who are familiar with the literary sources. In the more usual sense of pictures intended to accompany a text not necessarily familiar, the earliest preserved illustrations date from the first known period of book production, the Middle Kingdom of Egypt (21st to 18th centuries B.C.), when large-scale workshops for the writing and illustrating of manuscripts were organized. Egyptian books were written on papyrus in roll form. The illustrations were similar in style to the wall paintings of the period, except that they were much more freely organized in space, usually with a single object or group of objects placed in an area left blank by the writer at the appropriate point in the text. Among the texts so illustrated were religious books, such as the Book of the Dead, scientific and literary works. The oldest surviving illustrated roll, the so-called Ramesseum papyrus (c. 1980 B.C.), is a ceremonial play.

The codex, the book of leaves bound together at one edge which is familiar to the modern world, was invented in the 1st century A.D., and for a time both roll and codex were used. The Greeks and Romans apparently made use of illustrated books. Their scientific texts seem to have been supplied most often with pictorial amplification. However, a number of illustrated epics (such as the Iliad and Odyssey) and plays have survived, and there is evidence that these were sufficiently available and popular to have become the models for wall paintings, vase decorations, metalwork and mosaic designs.

As the codex came into more widespread use, new forms were devised for illustrations. Instead of always being placed in the appropriate spot in the text, interrupting the writing, illustrations often were placed on separate pages left blank for the purpose and arranged so that the pictorial material faced the text to which it applied. Furthermore, many Byzantine, Celtic and western European manuscripts contained borders which surrounded pages of the text, and these borders frequently included illustrative pictures.

The Renaissance. — In the 14th century a new spirit entered book illustration. The monumental dignity of Byzantine manuscripts and the often fantastic storytelling of the middle ages gave way to an attempt to suggest reality. A notable early example is the *Très Riches Heures* of the duc de Berry, in which the occupations of the various seasons are depicted with a wealth of detail, a vivid sense of space and atmosphere and careful attention to the correct representation of man-made and natural objects.

Late medieval and early Renaissance scientific treatises were illustrated with great care and a real attempt was made to portray exactly the objects under consideration, but this was hindered by

the impossibility of accurately multiplying pictures. No matter how carefully an artist might draw a plant or an animal, his work was likely to be distorted beyond recognition by the scores of copyists — each copying drawings rather than drawing from life — who would reproduce the manuscript. Only with the invention of printing in the first half of the 15th century did it become possible for illustrations to be exactly reproduced once they had been rendered to the artist's satisfaction.

The Introduction of Printing. — Early printed books (the first to be illustrated was Ulrich Boner's *Der Edelsfein,* printed in 1461 by Albrecht Pfister in Bamberg, Ger.) used illustrations not so much for the sake of scientific accuracy as to produce books that would be attractive to the larger public that printing made possible. As with most manuscript illustrations, the idea of a picture was more important than the accuracy of its details — the same wood block illustration of a town might be labeled as the city of Ulm on one page of the *Nürnberg Chronicle* (1493) and as Damascus on another.

Of course with biblical and literary texts the illustrations had to match the story more closely, and the efforts of such artists as Albrecht Diirer, Albrecht Altdorfer and Lucas Cranach to produce meaningful, coherent accompaniments to these texts are justly famous.

While the first printed books, both in northern Europe and in Italy, used woodcuts, which could be printed at the same time as the text, it was not long before artists began to make intaglio illustrations, which required a separate printing operation. In spite of this difficulty, engraved and etched illustrations had become more common than woodcuts by the end of the 16th century and they remained in vogue for almost 200 years. The various intaglio techniques permitted a fineness of line and a subtlety of tonal values impossible to achieve in woodcuts, and Rubens, Rembrandt, Tiepolo, Fragonard and scores of other artists used these mediums in their illustrations.

Illustrators of the 16th and 17th centuries were particularly fond of creating fables in pictorial form. The so-called "emblem books" were full of illustrations depicting odd combinations of people, animals and objects whose meaning was explained in didactic poems printed under the pictures. This love of learned allegory was also displayed in the elaborate title page illustrations of the time, in which the meaning of the book or the interests of the author were suggested by a collection of clearly symbolic objects.

The illustrator also came to serve the scholar in the 18th century. In the elaborately illustrated archaeological and topographical studies of the period the large, carefully prepared engravings assumed as much importance as the text. Books of this kind had been published in the 17th century as well, but the earlier treatises were crude indeed compared with the fine 18th-century works.

Woodcut and Lithography. — Toward the end of the 18th century Thomas Bewick, an English engraver, developed a technique of engraving on wood in a finely controlled manner. The blocks he produced were capable of as subtle a range of tonal variation as any intaglio process and they had a distinct technical advantage in that they could be printed at the same time as the text and on the same press. Bewick's discovery gave rise to a school of exceedingly skilful engravers on wood who could reproduce drawings and even paintings with astonishing fidelity. As a result, in the 19th century intaglio illustrations practically ceased to be made.

Another important discovery of the late 18th century was the lithograph. which became particularly popular among painters who wished to be illustrators. Many designers of illustrations were distressed at the transformation of their drawings at the hands of commercial engravers. A few artists, like Bewick or Blake, were fortunate enough to be able to engrave their own designs, but most were at the mercy of such skilled engravers as the Dalziel brothers and John Swaine in England and Timothy Cole in the United States. Through the use of lithography the artist was able to produce a print which closely approximated a drawing in crayon or wash without the intervention of a professional engraver.

At the same time there was a significant increase in the size of the reading public and a concomitant reduction in the cost of books. As publishers sought more purchasers for their books, illustrations became important commercial assets. The first traces of this interest of publishers in popular illustrated editions appeared in the 15th century. By the 17th century it was possible for a successful engraver to amass great wealth and enjoy a considerable reputation. Only after the 1830s, however, were illustrated books generally available to the public at comparatively low prices.

In 1832 the *Penny Magazine* appeared, the first periodical regularly to use large numbers of illustrations designed to appeal to the popular taste. Soon a host of illustrated magazines and pictorial ne spapers were on the market — predecessors of the 20th century's *Life, Du, Paris-Match* and *The London Illustrated Weekly* and of the illustrated daily newspapers.

Photography and Photoengraving. — In 1844 Fox Talbot, the English pioneer photographer, used the newly developed technique to illustrate his book *The Pencil of Nature,* which showed the possibilities of photography for accurately and easily recording what an artist could transcribe only with considerable labour. Photography opened a whole new world, and it affected illustration in many ways. At first, individual photographs printed on paper were simply pasted into printed books. For larger editions, wood engravings or lithographs were made from photographs by commercial engravers and artists, and such copies of photographs were commonly used as illustrations in the 1850s and 1860s. Around 1851 a method was devised of transferring a drawing onto a wood block photographically, thus allowing the engraver to enlarge or reduce the drawing at will and enabling him to keep the original drawing on hand as a guide to his engraving. By the time this technique was in general use, in the 1870s, the technique of reproducing line drawings directly by photochemical means, without the intervention of the engraver's hand, had been perfected. Direct reproduction of photographs on a printing press through the use of halftone blocks, which came into use in the 1880s, made it possible to do away with hand engraving entirely. By World War I the craft of wood engraving was no longer of commercial significance. These developments led directly to the richly illustrated books, newspapers and magazines that became characteristic of the 20th century.

At the same time a significant reaction to these new processes took place. In the 1880s and 1890s a number of artists, led by William Morris in England and Maurice Denis in France: began to feel that the use of reproductive engraving had given rise to books lacking the unity and harmony of true works of art. To them, the finely engraved illustration seemed out of keeping with the weight and colour of the type used to print the text. Furthermore, the illustrations themselves tended to be overly literal and failed to provide an imaginative accompaniment for the text. These men and their followers in England and on the continent of Europe produced books that had a tremendous influence. Through their efforts, side by side with the popular illustrated books and periodicals, a series of privately printed, fine-art editions came into being which convinced a number of artists and publishers that illustrated books could be works of art of a high order.

Many artists, among them Aubrey Beardsley, Howard Pyle and T. T. Heine, used photoengraving to reproduce their drawings and were able to design their illustrations in such a way that the results were highly satisfactory artistically. Other artists — Denis; Pablo Picasso, Pierre Bonnard, Henri Matisse, Aristide Maillol and Georges Rouault, for example — preferred the older techniques of wood engraving; metal engraving, etching and lithography as giving them more control over the finished product.

20th-Century Illustration. — Finely illustrated books of this kind are exceedingly costly, and the culture of the 20th century would certainly have developed differently without the prevalence of cheap, accurate and attractive illustrations in school texts, magazines, newspapers, advertising illustrations: catalogues and books of all kinds. The illustrations in publications such as these are almost all produced (or reproduced) photographically. The photograph itself, in the hands of 20th-century workers, yielded masterpieces equal in importance to all but the finest earlier il-

lustrations. Furthermore, through photographic methods of full-colour reproduction, 20th-century publishers were able for the first time to illustrate books about the visual arts with facsimiles of paintings and drawings that were far less distorted than anything possible earlier.

This great diversity of illustration makes it almost impossible to consider any single style of illustration as the exclusive property of a single age. The artist illustrating a hook on botany or geometry will work very differently than he would if he were dealing with a novel or a play. Furthermore, the intentions of illustrators have changed over the years. The earliest illustrators were concerned with the depiction of an object, action or personage, and rarely attempted to evoke a sense of space or setting in their pictures. The artists of the Renaissance tried to represent space and form in such a way that the illustration on the page seemed to be a replica of nature. This continued to be an important concern of the sophisticated illustrator of the 16th, 17th and 18th centuries, who used it as the basis for the expression of his own imagination and emotional feelings about his subject, or as a tool in the representation of objects of scientific interest. The invention of photography made it possible for the painter-illustrator to concentrate on other aspects of his work, though he did not immediately take advantage of the opportunity. By the 20th century the photograph was seen as a powerful illustrative medium for the depiction of current happenings, for the accurate reproduction of scenes, for vivid portraiture and for the elucidation of scientific investigations. The painter and draftsman were left free to explore the realm of the imagination and the possibilities of new communicative techniques in the graphic arts. From a rare, costly, handmade object, the illustrated text became an essential part of western culture.

(A. M. FN.)

ILLYRIA, part of the Balkan peninsula extending along the eastern shore of the Adriatic from Fiume to Durazzo, and inland as far as the Danube and the Serbian Morava. It comprises modem Dalmatia, Bosnia and Hercegovina, and Montenegro, with the southern half of Croatia-Slavonia, part of western Serbia, the sanjak of Novibazar, and the extreme north of Albania. Its landward boundaries were never clearly defined. The name was an ethnological rather than a geographical term; the older Greek historians usually wrote of "the Illyrians" (οἱ Ἰλλύριοι), while the names Illyris (Ἰλλυρίς) or less commonly Illyria (Ἰλλυρία) were subsequently used of the indeterminate area inhabited by the Illyrian tribes, *i.e.,* a region extending eastward from the Adriatic between Liburnia on the north and Epirus on the south. The Latin name Illyricum was not synonymous with Illyria; it was a political name applied to various divisions of the Roman empire, the boundaries of which were frequently changed and often included an area far larger than Illyria properly so called.

Ethnology.— Herodotus and other Greek historians represent the Illyrians as a barbarous people who resembled the ruder tribes of Thrace. Both are described as tattooing their persons and offering human sacrifices to their gods. The women of Illyria seem to have occupied a high position socially and even to have exercised political power. Queens are mentioned among their rulers. Fuller and more trustworthy information can be obtained from archaeological evidence. In Bosnia the lake dwellings at Butmir, the cemeteries of Jezerine and Glasinac and other sites have yielded stone and horn implements, iron and bronze ornaments, weapons, etc., and objects of more recent date fashioned in silver, tin, amber and even glass. These illustrate various stages in the development of primitive Illyrian civilization, from the Neolithic age onward. The Hallstatt and La Tène cultures are especially well represented. Similar discoveries have been made in Dalmatia, as among the tumuli on the Sabbioncello promontory, and in Croatia-Slavonia. In Dalmatia there appears to have been a large Celtic element, and Celtic place names are common. The ancient Illyrian languages fall into two groups, the northern, closely connected with Venetic, and the southern, perhaps allied to Messapian and now probably represented by Albanian. (See ALBANIAN LANGUAGE.)

History.—Greek colonization on the Illyrian seaboard probably began late in the 7th century B.C. or early in the 6th century. The most important settlements were Epidamnus (Durazzo) and Salona (near Spalato). Researches at Salona (*see* SPLIT) have brought to light Greek inscriptions, Greek pottery, etc., dating from 600 B.C. But Greek influence seems never to have penetrated far into the interior, and even on the coast it was rapidly superseded by Latin civilization after the 3rd century B.C. Until then the Illyrian tribes appear to have lived in a state of intermittent warfare with their neighbours and one another. They are said by Herodotus (ix, 43) to have attacked the temple of Delphi. Brasidas with his small army of Spartans was assaulted by them on his march (424 B.C.) across Thessaly and Macedonia to attack the Athenian colonies in Thrace. The earlier history of the Macedonian kings is one constant struggle against the Illyrian tribes. The migrations of the Celts at the beginning of the 4th century disturbed the country between the Danube and the Adriatic. The necessities of defense seem to have united the Illyrians under a chief Bardylis (about 383 B.C.) and his son Clitus, but the great Philip crushed the Illyrians completely and annexed part of their country. During the next century they are heard of as pirates. Issuing from the secluded harbours of the coast, they ravaged the shores of Italy and Greece, and preyed on the commerce of the Adriatic. The Greeks applied to Rome for help. Teuta, the Illyrian queen, rejected the Roman demands for redress, and murdered the ambassadors; but the two Illyrian wars (229 and 219 B.C.) ended in the submission of the Illyrians, a considerable part of their territory being annexed by the conquerors. Illyria, however, remained a powerful kingdom with its capital of Skodra (Scutari in Albania), until 180 B.C., when the Dalmatians declared themselves independent. In 168 the Romans conquered and annexed the country. Dalmatia was invaded by a Roman army under Gaius Marcius Figulus in 156, but Figulus was driven back to the Roman frontier, and in Dalmatia the Illyrians were not finally subdued until 165 years afterward. In 119 L. Caecilius Metellus overran the country and received a triumph and the surname Dalmaticus. But in 51 a Dalmatian raid on Liburnia led to a renewal of hostilities; the Roman armies were often worsted, and though in 39 Asinius Pollio gained some successes it was not until Octavian took the field in person that the Dalmatians submitted in 33. They again revolted in 16 and 11, and in A.D. 6–9 joined the rebel Pannonians. In A.D. 9, however, Tiberius entirely subjugated them, and Dalmatia, Iapydia and Liburnia were united as the province of Illyricum.

Latin civilization spread rapidly, the cultivation of the vine was introduced, gold mining was carried on in Bosnia, and commercial cities arose along the coast. Illyria became one of the best recruiting grounds for the Roman legions; and in troubled times Illyrian soldiers fought their way up from the ranks to the imperial purple. Claudius, Aurelian, Probus, Diocletian and Maximian were all sons of Illyrian peasants. The importance of Illyricum caused its name to be extended to many neighbouring districts; in the 2nd century A.D. Illyricus Limes included Noricum, Pannonia, Moesia, Dacia and Thrace. The Via Egnatia, the great line of road which connected Rome with Constantinople and the east, led across Illyricum from Dyrrachium to Thessalonica. Either Diocletian or Constantine made Illyricum one of the four prefectures, each governed by a *praefectus praetorio,* into which the empire was divided. This prefecture included Pannonia, Noricum, Crete and the entire Balkan peninsula except Thrace, which was attached by Constantine to the prefecture of the east. From the partition of the empire in 285 until 379 Illyricum was included in the western empire, but thenceforward eastern Illyricum was annexed to the eastern empire; its frontier was almost identical with

the line of demarcation between Latin-speaking and Greek-speaking peoples, and roughly corresponded to the boundary which now severs Latin from Greek Christianity in the Balkan peninsula.

In 441 and 447 the country was ravaged by the Huns. In 481 Dalmatia was added to the Ostrogothic kingdom, which already included the more northerly parts of Illyricum. Bands of Slavonic invaders gradually established themselves in Illyria, where, unlike the earlier barbarian conquerors, they formed permanent settlements. Between 600 and 650 the main body of the immigrants (Croats and Serbs) occupied Illyria *(see* SERBIA: *History;* and SLAVS). The Croats settled in the western half of Illyria, the Serbs in the eastern; thus the former came under the influence of Italy and Roman Catholicism, the latter under the influence of Byzantium and the Greek Church Hence the distinction between them became a marked differenceof civilization and creed, which has always tended to keep the Illyrian Slavs politically disunited.

The Croats and Serbs rapidly absorbed most of the Latinized Illyrians. But the wealthy and powerful city-states on the coast were strong enough to maintain their independence and their distinctively Italian character. Other Roman provincials took refuge in the mountains of the interior; some Illyrian tribes remained unconquered among the mountains of Albania and were never Slavonized. With these exceptions Illyria became entirely Serbo-Croatian in population, language and culture. The name of Illyria disappeared from history, but was revived in the "Illyrian Provinces" of 1809 and the "Kingdom of Illyria" of 1816–49. For the political propaganda known as Illyrism, *see* CROATIA-SLAVONIA: *History.*

ILLYRIAN LANGUAGE was a language of the centum group of Indo-European languages. spoken in the Balkan peninsula through the early centuries of the Christian era. During the centuries before and after the beginning of the Christian era by far the greater part of western Europe, as well as large sections of the eastern part of the continent, was inhabited by peoples who spoke languages belonging to the great Indo-European family. Knowledge of these languages is derived primarily from their use in inscriptions and in literary texts. However, such evidence is almost completely lacking for the extensive region including modern Yugoslavia, Albania and parts of southeastern Austria and of southwestern Hungary, among others. This area, subject to early and scattered Greek colonization and later to incorporation into the Roman empire accompanied by intensive romanization. as well as to sporadic migrations and raids by the Celts and Germanic tribes, was known in later antiquity as the Roman province of Illyricum. Slavonic-speaking peoples do not appear there before the 7th century A.D.

Practically all that is known of the indigenous tongue of ancient Illyricum has been derived from an intensive study of its place names, and of the names of persons contained in the thousands of Latin inscriptions found there, insofar as these names are clearly not derivable from other identifiable languages. There are very few glosses which are specifically designated by ancient authors as Illyrian, *e.g., snbaia, sabaium* ("a beerlike beverage"). *cf.* Germanic **sapa-,* Eng. *sap;* and only one inscription which can surely be assigned to that language. Found near Scutari in northern Albania, it reads in transcription: *ana oëθë iser.* It is interpreted as being a dedication to a goddess Oethe, whose name is preceded by an epithet *ana* and followed by a word meaning "sacred" *(cf.* Gr. *hierds,* "sacred." from Indo-European **isero-*).

However. ancient tradition and modern scholarship agree in regarding as an Illyrian offshoot the language of the more than 300 inscriptions found in southeastern Italy and called Messapic. The linguistic evidence for this connection consists, first, in an impressive number of place names common to both areas; *e.g., Peuketioi* in both Illyricum and Apulia; and the *Galabrion* of the eastern Adriatic with the *Calabri* to the west; second, in some words occurring only in these two regions (*ana* as a divine epithet is common in Messapic); and. thirdly, in the fact that both areas exhibit a large measure of agreement in their reflexes of Proto-Indo-European phonemes.

From this evidence, meagre as it is, some statements can be made about the historical phonology and the morphology of what appears to have been a distinct Indo-European language. For example, names like *Acrabanis* make it probable that the Indo-European voiced aspirates became voiced stops in Illyrian, and that the Indo-European *ŏ* became *ă;* and *Vesclavesis* shows both that intervocalic *-s-* was preserved and that the language belonged to the centum group. These and other features contrast strongly with the contiguous Greek and Italic, and afford links with the northerly Germanic and Balto-Slavic idioms. Another indication that the Illyrian homeland may have lain in eastern Germany or Poland is afforded by a large number of place names common to both regions, *e.g., Setwia* in both Dalmatia and Silesia.

The little that is known of Illyrian, combined with certain archaeological facts and with the presence throughout western, central and southern Europe of names obviously Indo-European but not clearly attributable to any identifiable branch of the family. led earlier in the century to the hypothesis of a prehistoric diffusion of Illyrian-speaking Indo-Europeans over much of the continent. This theory, which for a time had many adherents, has been largely abandoned; and the term "Illyrian" is now usually restricted to the Balkan peninsula and immediately adjacent areas. *See* also ALBANIAN LANGUAGE; SERBO-CROATIAN LANGUAGE; VENETIC LANGUAGE.

ILMENAU, a town and summer resort of Germany, in the district of Suhl, at the north of the Thuringian forest, on the Ilm river, 30 mi. S. of Erfurt by rail. Pop. (1950) 18,538. Formerly a part of the county of Henneberg, Ilmenau came in 1631 into the possession of electoral Saxony, afterward passing to Saxe-Weimar. It was a favourite resort of Goethe, who wrote his *Iphigenie* there. It manufactures glass, porcelain, toys, chemicals, surgical instruments and turnery.

ILMENITE or TITANIC IRON ORE is a black metallic mineral named from the Ilmen mountains, U.S.S.R. Ilmenite is a source of titanium. Most titanium is used as the oxide in making pigments. The metal is used as a structural material in high-speed, long-range aircraft. Ilmenite is not used as an iron ore because of smelting difficulties. Ilmenite is usually in compact or granular masses or in grains as sand. It crystallizes in the hexagonal system and crystals are tabular or rhombohedra1 in habit. The hardness is 5.5 to 6.0 and the specific gravity 4.7; streak is black to bronnish red. The composition is $FeTiO_3$ with iron 36 8%, titanium 31.6%, oxygen 31.6%. The ratio between titanium and iron may vary considerably and magnesium or manganese may replace some of the iron. Ilmenite is often intergrown with magnetite, and associated minerals are hematite, apatite, rutile, sphene, zircon and monazite.

Ilmenite occurs in veins, lenticular bodies. large masses, beds, beach sands and river placers, and as an accessory mineral of igneous and metamorphic rocks. The deposits at Allard lake, Quebec, Tahawus, N Y., and in Norway are associated with anorthosite. norite or gabbro. Beach sands occur in Florida, India, Brazil, Australia and Japan. *See* also TITANIUM. (*A.* F. HR.)

ILOCANO, the third largest ethnolinguistic group in the Philippines, numbering over 2,500,000 in 1951. When discovered by the Spaniards in 1572 they occupied the narrow coastal plain of northwestern Luzon known as the Ilocos region. Their language is Malayo-Polynesian and closely related to that of the neighbouring Tinguian and other pagan peoples of the Mountain province, but their early Christianization and rapid acculturation led to population expansion and colonization of neighbouring provinces, and later to emigration to Mindanao and Hawaii.

The major Ilocano provinces, Ilocos Norte, Ilocos Sur and La Union, are among the most densely populated areas in the Philippines. Rice is the staple crop, grown on small fields and irrigated by rainfall during the rainy season. The great majority of rice fields are less than one hectare, and are mainly worked by their peasant proprietors. Vegetable plots supplement rice, and pigs,

goats and chickens are also raised. Fish provide a limited amount of protein and flavour to the diet.

Tobacco is currently an important cash crop, but many Ilocanos must supplement their agricultural income by wage work or handicraft activities, particularly during the dry season. Ilocano cotton textiles have a reputation throughout the Philippines.

Social status is correlated with ownership of land, and the scarcity of riceland has given it a very high value. The wealthier families reside generally in the provincial capitals or in other centres of population, while the poorer classes live in the barrios and hamlets. Marriages are generally arranged to maintain class lines, the husband's family providing the sabong or dowry of land.

The population is Roman Catholic, except for a strong minority who belong to the Philippine Independent Church, a schismatic group founded by Gregorio Aglipay during the revolt against Spain at the turn of the 20th century.

The Ilocanos have not only moved into new or frontier regions in the Cagayan valley and Mindanao but have also taken over large portions of Pangasinan. Nueva Ecija and Tarlac. In these regions they have been economically successful, so much so that they are sometimes called the "Yankees" of the Philippines. In each area they have also brought and maintained their own language and subculture, so that much of northern Luzon uses Ilocano as a lingua franca and imitates their way of life.

(F. R. E.)

ILOILO, a province and a chartered city, on the southeastern side of Panay Island (*q.v.*), west central Philippines. The province is mountainous in the west, hilly in the northeast, level and fertile in the centre and along coastal areas. Rainfall averages 80 in. with a short spring dry season. Area 2.048 sq.mi. Pop. (1960) 966.145. Iloilo is a major rice-producing province with many areas harvesting two crops a year. Important secondary crops are sugar, tobacco, coconuts, bananas and pineapples Important trading and rice-milling centres are Cabatuan and Janiuay on the main north-south highway; Pototan and Santa Barbara, which are also freight depots, on the Iloilo railroad; and Barotac Nuevo on the coast, northeast of Iloilo. The first Malay landing in Panay occurred in the 13th century near San Joaquin, 40 mi. S.W. of Iloilo city.

ILOILO city, the provincial capital, pop. (1960) 150,976, has a good port, protected by the offshore Guimaras Island and serving both interisland and international shipping. It grew rapidly as the major port for the great sugar exports of Negros but the construction of artificial ports on Negros caused a drop in Iloilo's freight. Passenger traffic remains high as thousands of labourers annually migrate through Iloilo to Negros' sugar plantations, returning with the new farming year. After the burning of the city in 1899, it was completely rebuilt and shows marked Spanish influence. The town is an educational centre with several private colleges in addition to a branch of the University of the Philippines. There are also several famous churches and two hospitals.

(R. E. HE.)

ILORIN, a town and capital of the province of that name in the Northern Region, Nigeria, Africa, lies 1,200 ft. above sea level overlooking the valley of the Niger, 50 mi. to the north, and clear of the forest belt in a region of farms. Pop. (1953) 40,994 (African pop. only). The town is of open plan, with shade trees and single-story red mud houses with thatched roofs, many having the traditional openwork walls. The amir's palace is modern concrete in simplified Moorish style, and before it is the canopied well of Mallam Alimi. There is a hospital, a modern junior secondary school and a modern trade and vocational training centre.

Ilorin stands on the north-south railway and at the junction of the east-west and north-south trunk roads. It has an airstrip used by local services. The town has no electricity or other poner and therefore no major industries. The principal local crafts are pottery, which is done by the women, the skill of throwing pots without a wheel being passed from mother to daughter, and hand weaving. The women use looms up to 22 in. while men work on j-in. looms. Dyeing is done by women, and there are some goldsmiths and ironsmiths. Most of the men are engaged in farming food crops, none of the Nigerian cash crops being grown in the district. The sale of farm produce is a monopoly of the women.

Ilorin has long been the subject of dispute between Northern and Western Nigeria. The bulk of the people are Yoruba, the principal race of the Western Region. and before the 19th century Ilorin was part of the old Yoruba kingdom of Oyo. It rebelled in 1817 and with the aid of Mallam Alimi of Sokoto became independent. A son of Alimi became amir and Ilorin has since formed part of Northern Nigeria. A former governor general, Sir John Macpherson, held that there was no case for alteration of the boundary, but there still persists a desire in the Western Region for the possession of Ilorin. Ilorin province has an area of 17,719 sq.mi. and a population (1953) of 530,723. (W. H. I.)

ILYUSHIN, SERGEI VLADIMIROVICH (1894–), an outstanding Russian aircraft designer. was born at Didyalevo, Vologda province. Russia, in 1894. Mobilized in the Russian army in 1914, he was transferred to the army air arm and received his pilot's certificate in 1917. He joined the Red army in 1919 and two years later was sent to the Moscow Air Force Engineering academy from which he graduated in 1926. He then began to design aircraft. In 1939 he designed the well-known IL-2 ("Shturmovik") armoured attack aircraft. Turning to the design of civil aircraft after World War II, he produced in 1946 the IL-12 twin-engined passenger aircraft and in 1957 the IL-18 ("Moscow") four-engined turboprop transport machine. Ilyushin reached the rank of lieutenant general in the Soviet army engineering technical service. He became a professor at the academy from which he had graduated and which in the meantime was named after N. E. Zhukovski. (D. CR.)

IMAGERY. Modern writers employ the word "image" differently, but a useful psychological definition is that of C. W. Bray. Images are "conscious memories which reproduce a previous perception, in whole or in part. in the absence of the original stimulus to the perception." Possibly every sense can produce its own type of image, the visual being the commonest and the most stirring; though it has been claimed that the organic sensations. including pain, and the muscular or kinesthetic sense may not call up conscious memories but actually, if faintly, reinstate immanent experiences.

It is usually easy to distinguish between a visual image and the actual percept. Failure to do so may involve disorders of conduct obvious to other people. But possibly the organic and kinesthetic senses provide us with actual experiences, which may easily pass into the real thing if the mind dwells upon them. In relatively rare instances in adults (probably not so rare in children) eidetic (visual) images may arise. They are not mistaken for percepts, but are more vivid and detailed than ordinary visual images. Such experiences are described by some portrait painters, and many people have them before falling asleep (hypnagogic). Dream images. too, are often of this type, and the intensity and character of images are both affected by drugs of various kinds.

Individual differences in imagery are so great that hardly any statement about them will not be disbelieved or even denied by some. Probably visual imagery is common and plays a great part in the mental life of ordinary people. Yet since thinking with words is needed for success in many types of written examinations, especially in philosophy, it is possible that study which leads to such success comes easier to the type of mind which turns away from concrete particulars and thinks in abstractions. Hence, since in the past psychologists have usually been recruited from the ranks of philosophy, their views concerning visual imagery are often faintly surprising to a nonpsychologist, who does not recognize his own mind in these descriptions.

Words, however, can come to the mind as images (visual, auditory, auditomotor) though their content is obviously itself more stereotyped; *e.g.*, the word "home" may be imaged in similar ways by thousands of people for nhom the visual image of "home" would be suffused uith intimate personal detail. "Imageless thinking" probably takes place in many professional thinkers. For them, "marginal utility" or "power politics" needs no specific picture. Yet some defenders of visual images hold that the abstract

thinking of the nonvisualizer might often be the better for a regular return to concrete examples, since it is apt to outstrip them. Occasional attempts to give examples of "democracy" might be good for all concerned. Experimental psychologists have worked in this region, but their aim has often been to assess or even to measure the utility, in thinking. of imagery; *i.e.*, its power of rendering the processes of judgment more effective. or of solving problems of a quasi-geometrical kind. Attempts have been made to deprive the experimental subject of the power of using imagery in solving a problem, or to pose one which might seem to offer special facilities to the visualizer. But it is doubtful whether such experiments cast much light except upon the artificial situations they were devised to explore. A visualizer may prefer to solve a geometrical problem in a nonvisual way (*e.g.*, by inner speech) because of the strain which visual imagery might entail, while his use of visual imagery in aesthetic enjoyment of memories or in judging whether he prefers one person, place or thing to another may be constant.

Since speech on the radio was deliberately contrived to call up visual imagery, it played a considerable part in most people's imaginations until the advent of television restored the balance of sight and sound.

It might be noted that one may open a book on, for example, Shakespeare's imagery without knowing if the writer is concerned with the poet's use of figures of speech, his power of suggesting imagery to the reader by descriptive writing. whether figurative or not, or the imagery (visual, auditory, kinesthetic, etc.) which the poet himself experiences.

Auditory imagery is probably much rarer, at least in an intensive form, this visual. Though many people can hear sounds in their "mind's ear," few can call up the full texture of an orchestra, though there are many instances (Beethoven. Mozart, Wagner, Elgar) in which this feat is recorded. Probably there is a great tendency for auditory imagery to arise in conjunction nith the muscular imagery necessary to sing, speak or whistle. It is common for people to assert that they cannot image easily, or at all, sounds (*eg.*, thunder, a waterfall) which they cannot make or at least imitate satisfactorily.

The associative powers of smells are famous, though usually it requires the actual percept of the odour, and not its image, to set off a train of vivid memories. It has been suggested that this special power of odours may be attributable to the fact that they are usually unanalyzable and therefore exist in their own right. If we see 50 Alps in the course of a holiday, their colour, shape and details are analyzed to some extent; but the smell of a wood fire or of melted ski wax may bring up a vivid Swiss memory with startling affective accomganiment.

Associated with this subject is that of synesthesia, uhen, to take a simple example, a percept (*e.g.*, of the sound of a violin) may evoke an image not of the instrument but of a colour or texture So a timbre, a pitch, a voice quality, even a musical key, may bring up images of colour. Alexander Scriabin and Nicolas Rimsky-Korsakov both used colours in composing music. There may also be associations between images of the different senses, or, if the auditory image (say of a voice) cannot be evoked, a visual image (*e.g.*, of gray velvet) may symbolize the voice. The musical criticisms of some modern writers are full of such derived adjectives (*e.g.*, "astringent" for a piano tone, "rich copper" for the sound of strings in a particular part of a symphony) though nothing but the critic's own introspection could decide if he mas working with concrete images, or merely with words which suggested them. While it is impossible to know if Rupert Brooke's "The Great Lover" is a list of the vivid images he enjoyed, Robert Graves in Poetic *Unreason* has given some account of his own imagery.

Imagery has often been described as fleeting and variable; hence, an unsure guide for thinking. Yet number forms, which are common, complicate such a simple belief. Their possessors either visualize numbers, or their positions, in patterns containing clock-faces, plans of malls in a garden or similar other remembered patterns of space. Assertions are not rare that number forms are useless or an obstacle to their possessor when calculating. Yet further investigation shows that while many find them useful others find them useless, and one distinguished mathematician used a number form which symbolized imaginary numbers and went up to 1,000,000,000,000. They are apt to remain relatively unaltered during life in many of their possessors, thus disproving the common generalization that all imagery is shifting and unstable. It is not irrelevant to remark that the use of the word "imagery" for all the "robust contents" of that part of our mental life which we call remembering, thinking and dreaming confuses a large number of discriminable events. Until more distinctions have been drawn between the processes involved in perceiving, imagining, judging, conceiving, thinking and expounding thoughts, many discussions of the uses of imagery are likely to be futile.

The details of creative imagination have been discussed by T. Ribot (*L'Imagination créatrice*) and by June E. Downey *(Creative Imagination)*. There are many connections, as yet not worked out, between creative imagination and the processes of dreaming. In fact, it is possible that Sigmund Freud's theory of the dreamwork could be profitably supplemented by determinations oi the extent to which the condensation, displacement oi emotion and regard for presentability which he describes are also operative in creative thinking. And since it is probably difficult to recall in exact detail any complicated object or scene which resembles another (both having been seen at different times by the same person), the possibility is not excluded that all recalling is in some degree creative.

Experiments upon thinking carried out by the Würzburg school resulted in the establishment of much evidence that one can think without discoverable imagery (imageless thought). "Undiscoverable," however, might mean "so dim as to be difficult to discern except by the trained introspectionist," and the thinking of such an introspectionist, himself a philosopher, when applied to abstract matters, might be far from typical. It seems probable that imageless thought exists, though it should be noted that one of its vehicles may be the conscious attitude (a blend of kinesthetic imagery and visceral sensation)—the last remnant of kinesthesis in a mind which had subsequently developed speech habits.

IMAGINATION: see IMAGERY; PSYCHOLOGY; *THINKING,* PSYCHOLOGY OF.

IMAM (Arabic, "leader" in the sense of a "pattern whose example is followed"). In the Koran it is used several times of leaders and (ii, 118) of Abraham, "Lo, I make thee a pattern for mankind." Imam thus became the name of the head of the Moslem community. His duty is to be the lieutenant, the caliph of the prophet, to guard the faith and maintain the government of the state. Around the origin and basis of his office all controversies as to the Moslem state centre. The Sunnites hold that it is for men to appoint; the Shi'ites, in general, that the appointment lies with God. through the Prophet or otherwise, and that He always has appointed. The Kharijites recognize no absolute need of an Imam; he is convenient and allowable. Another distinction between the Sunnites and the Shi'ites is that the Sunnites regard the Imam as liable to err, and to be obeyed even though he personally sins. provided he maintains the ordinances of Islam. But the Shi'ites believe that the divinely appointed Imam is also divinely illumined and preserved (*ma'sum*) from sin. The above is called the greater Imamate. The lesser Imamate is the leadership in the Friday prayers. This was originally performed by the Imam in the first sense, who not only led in prayers but delivered a sermon (*khutba*); but with the growth of the Moslem empire and the retirement of the caliph from public life, it was necessarily given over to deputies. who in Turkey were servants of the state, each in charge of his own parish; they performed the rites of circumcision. marriage and burial. In Persia among Shi'ites their position is more purely spiritual, and they are independent of the state. A few of their leaders are called mujtahids; *i.e.*, capable of giving an independent opinion on questions of religion and canon

law. A third use of the term Imam is as an honorary title. It is thus applied to leading theologians, *e.g.*, to Abu Hanifa, ash-Shafi'i, Malik ibn Anas, Ahmad ibn Hanbal (these are called "the four Imams"), Ghazali.

IMBECILE: see MENTAL DEFICIENCY.

IMBREX, in architecture, one of the raised, covering tiles placed over the joints between the flat tiles or pantiles in an ancient Greek or Roman roof. The pantiles were laid with the joints in each course, or row, exactly in line with the joints above and below, so that the imbrex tiles formed continuous ridges. There were two types. in one the tile was approximately semicircular, but in the more commonly used form and in the monumental marble examples the imbrex had vertical sides and an angular top. At the lower end of each row of imbrex tiles aas an antefix (*q.v.*) or decorative terminal. The plural is imbrices.

IMBROS or IMROZ, an island in the Aegean belonging to Turkey, at the southern end of the Thracian Chersonese peninsula. Herodotus (v, 26) mentions it as an abode of the historic Pelasgians (*q.v.*). It was, like Samothrace, a seat of the worship of the Cabeiri (q v.). There is much volcanic rock and parts of the island are very fertile. Wheat, oats, barley, olives and fruit are grown. The island was occupied by Greece during and after World War I. It uas also an important base for the British and Allied operations in the eastern Mediterranean at the same time. It was returned to Turkey by the treaty of Lausanne (1923). Its population is (1955) 6,243 and area 108 sq.mi.

IMHOTEP, a famous physician and sage of ancient Egypt, who afterward became the god of medicine.

Egyptian texts speak of Imhotep as a minister who lived in the reign of the pharaoh Zoser of the third dynasty (*c.* 2980 B.C.). He acquired a great reputation for his wisdom and learning and became first a demigod and, under the Ptolemies, the Egyptian god of medicine. By the Greeks Imhotep was called Imouthes, and by them was identified with Asklepios, the god of healing. Although certain Egyptologists regarded Imhotep as legendary, and doubted that he lived as an actual man in the reign of Zoser, later discoveries converted into certainty what aas ever a probability. There can no longer be the slightest doubt that Imhotep was a historical personage, and that, in common with other Egyptian nobles, he held civil as well as religious offices. He was vizier, architect, chief ritualist, sage and scribe under the ponerful king who built the celebrated "step pyramid" of Sakkara. There is no contemporary evidence that Imhotep was a physician, but his priestly duties were intimately concerned with magic, and in Egypt magic and medicine were inseparably related. Imhotep is referred to in certain literary texts as a sage of great renown, and he was born in the neighbourhood of Memphis, his parents being Kanufer and Khreduonkh. Under the Ptolemaic dynasties he was invested with all the attributes of deity and was regarded as the son of the Memphite god Ptah, ahose name is substituted for that of his earthly father, Kanufer. Imhotep had shrines as well as temples of his own in various parts of Egypt and of Nubia. It was believed that miraculous cures could be effected by his divine intervention, and his temples aere thronged with sufferers, many of whom have left records of their gratitude. Statues and figurines of Imhotep as god of medicine have been found in considerable numbers, and these attest his widespread popularity. The evidence afforded by Egyptian and Greek texts supports the view that Imhotep's reputation was respected in very early times and that he became at least a demigod not long after his death. His prestige increased with the lapse of centuries, and his temples in Greek times were the centres of medical teaching. His posthumous deification is paralleled by that of another Egyptian sage, Amenophis, the son of Hapu, who lived in the 18th dynasty. held civil and religious offices in the reign of Amenophis III and was deified under the Ptolemies and closely associated with Imhotep and aith medicine. (See W. R. Dawson, "Amenophis the Son of Hapu," *Aegyptus,* vol. vii, pp. 113–138 [1926].) Imhotep and Amenophis as deified mortals stand almost alone in Egyptian history, and both, during their lives, must have been men of outstanding merit to have earned such signal posthumous recognition.

(W. R. D.)

IMITATION is the reproduction or performance of an act the stimulus for which is the observation of a similar act of another animal or person. Essentially it involves a model set by the imitatee to which the attention and response of the imitator are directed. As a descriptive term it covers a wide range of social adaptation. Observers of mammalians in their native habitat report the duplication of the activities of the older by the younger members of the species, or of the young of each other in play. Experiments on like animals in the laboratory, such as having one animal watch another pull a string to release an escape door of a cage, or the performance of some other seemingly simple act, have produced contradictory results. Or if imitation was reported, it was described as of a low order, meaning it involved, at best, duplication of some element of the model, not the whole action. More carefully controlled studies, however, have given evidence for inferential imitation on the part of monkeys (C. J. Warden and T. A. Jackson, 1935).

Among human beings imitation has been used to describe behaviour ranging from ideomotor duplication of the leg reaction of a high jumper and such everyday experiences as yawning when others yawn, running when others run, laughing when others laugh and a whole host of unconsciously and passively learned reproductions of social conduct, to the deliberate and self-conscious adoption of the ideas and habits of others.

Studies of infants show that in the second half of the first year they will imitate the expressive movements of those about them; for example, raising of the arms, smiling and babbling. In the second year they begin imitating other people's reactions to objects. As the child grows up all kinds of models are set before him, most of them determined by his culture: physical posture, language, basic skills, prejudices and pleasures and the moral ideals and taboos. His copying these is determined chiefly by the manner in which his drives are socially and culturally directed and controlled in terms of reward and punishment. The duplication of responses set up by those in positions of authority and prestige are well known. Here suggestion (*q.v.*) as well as imitation is involved.

The facts of imitation, then, are well established. Difficulty ensues, however, when the question of explanation is raised. Uniformity or similarity of thoughts and acts among people does not necessarily mean that these are caused by the same or similar psychological motives or mechanisms. Deviations in the situations, in drives and in the learned ways of adaptation are often too complicated to permit of easy explanation by a descriptive term like imitation.

Many earlier psychologists took it for granted that imitation was caused by an instinct or, at least, by an inherited predisposition—the "pseudoinstinct" of W. McDougall (1908). Later writers have viewed the mechanisms of imitation as those of learning. It is usual, however, to distinguish between imitation caused by simple conditioning, that caused by common trial-and-error learning and that involving the higher thought processes (G. Murphy, L. B. Murphy and T. M. Newcomb, 1937). Almost all agree with the writer who said, "We learn to imitate" rather than "learn by imitation" (C. Bird, 1940). The conditioned-reflex theory of learning so modified as to include drive and final reward or punishment in the total process provides a lead to more careful analysis of the factors operating in various forms of imitation (N. E. Miller and J. Dollard, 1941).

Certainly as it stands, imitation is a descriptive not an explanatory concept. Yet, as such, it has considerable use in social psychology. But any consideration of imitation among human beings must take the following factors into account: (1) there is a common constitutional or organic likeness in drives and learn-

ing capacity which make for similar adult motivations and like responses; (2) there are a great many similar situations in which the developing individual is conditioned, through his nonculturalized but withal social relations as well as by means of culture itself; (3) social facilitation also plays a part, especially in the suggestion-imitation processes of prestige-bearing models and in the crowd-stimulus effect seen in mobs, panics, audiences, fashion and other forms of collective behaviour (*see* PSYCHOLOGY, HISTORY OF: *Social Psychology*); (4) finally, there is so-called conscious or deliberate imitation which rests upon the introjection of others' responses into one's own symbolic system and their reorganization, largely in self-other terms. This makes possible planned, self-conscious duplication of the ideas, attitudes and habits of others.

IMITATION OF CHRIST, THE (*Imitatio Christi*), the title of a famous mediaeval Christian devotional work, much used still by both Catholics and Protestants and usually ascribed to Thomas à Kempis. The prolonged controversy over the authorship of the work has been narrowed down to the issue, "either Thomas à Kempis, or an unknown author."

The following is a statement of the facts that may be received as certain:

1. It is the verdict of the most competent modern expert opinion that there is no palaeographical reason for suspecting that any known manuscript of the *Imitation* (or any part of it) is earlier than the first quarter of the 15th century. The earliest dated manuscript is of book I only (1424).

2. A Latin letter of a Dutch canon regular named Johann van Schoonhoven exhibits such a close connection with book I that plagiarism on the one side or the other is the only possible explanation. It is capable of demonstration that the author of the *Imitation* was the borrower, and that the opposite hypothesis is inadmissible. This letter can be shown to have been written after 1382. Therefore, book I was beyond controversy written between the years 1382 and 1424.

3. It is not here assumed that the four parts of the work formed a single work, or even that they are all by the same author; the date of the other three books cannot be fixed with the same certainty. But, on the one hand, before the beginning of the 15th century there is no trace whatever of their existence—a strong argument that they did not yet exist; and, on the other hand, after 1424 nearly each year produces its quota of manuscripts and other signs of the existence of these books become frequent. Moreover, as a matter of fact, the four treatises did commonly circulate together. The presumption is strong that books II, III and IV, like book I, were composed shortly before they were put into circulation.

It may then be taken as proved that the *Imitation* was composed between 1380 and 1425, and probably toward the end rather than the beginning of that period. Having ascertained the date, we must consider the birthplace.

4. A number of idioms and turns of expression throughout the book show that its author belonged to some branch of the Teutonic race.

5. Of the 400 manuscripts of the *Imitation*, 340 come from the Teutonic countries—another argument in favour of its Teutonic origin. Again, 100 of them, including the earliest, come from the Netherlands. This number is quite disproportionate to the relative size of the Netherlands, and so points to that country as the one in which the *Imitation* was first most widely circulated and presumably composed.

6 There is a considerable body of early evidence, traceable before 1450, that the author was a canon regular.

7. Several of the manuscripts were written in houses belonging to the Windesheim congregation of canons regular, or in close touch with it. Moreover, there is a specially intimate literary and spiritual relationship between the *Imitation* and writings that emanated from what has been called the "Windesheim circle."

8. There can be no question that in the Windesheim congregation itself there was already, during Thomas à Kempis' lifetime, a fixed tradition that he was the author of the *Imitation*. The most important witness to this tradition is Johann Busch, who passed a great part of his life in Windesheim, only a few miles from Mount St. Agnes, the monastery of which Thomas was an inmate. It would be hard to find a more authentic witness. Another witness is Hermann Rhyd, a German member of the Windesheim congregation, who also had personally known Thomas. Moreover, the tradition existed in Thomas & Kempis' own monastery shortly after his death, for John Mauburne became a canon in Mount St Agnes within a few years of Thomas' death, and he states more than once that Thomas wrote the *Imitation*.

9. The earliest biographer of Thomas à Kempis was an anonymous contemporary; the *Life* was printed in 1494, but it exists in a manuscript of 1488. The biographer says he got his information from the brethren at Mount St. Agnes, and he states in passing that book III was written by Thomas. Moreover, he appends a list of Thomas' writings, 38 in number, and 5–8 are the four books of the *Imitation*.

Internal arguments have been urged against Thomas' authorship. It has been said that his certainly authentic writings are so inferior that the *Imitation* could not have been written by the same author. It may be granted that Thomas was a prolific writer, that his writings vary very much in quality and that the *Imitation* surpasses all the rest, and that some are on a level very far below it; still, when at their best, some of the other works are not unworthy of the author of the *Imitation*.

It has been said that *The Imitation of Christ* has had a wider religious influence than any book except the Bible, and if the statement be limited to Christendom it is probably true. The *Imitation* has been translated into more than 50 languages, and is said to have run through more than 6,000 editions. The other statement, often made, that it sums up all that is best of earlier western mysticism, that in it "was gathered and concentered all that was elevating, passionate, profoundly pious in all the older mystics" (Milman), is an exaggeration. It depreciates unduly the elder mystics and fails to do justice to the originality of the *Imitation*. For its spiritual teaching is different from the mysticism of Augustine in the *Confessions*, or of Bernard in the *Sermons on the Song of Songs;* from the scholastic mysticism of the St. Victors or Bonaventura; and from the mysticism of the German school of J. Eckhart, H. Suso, J. Tauler and J. van Ruysbroek. Again, it is different from the later school of St. Teresa and St. John of the Cross, and from the introspective methods of what may be called the modern school of spirituality. The *Imitation* stands apart, unique, as the principal and most representative utterance of a special phase of religious thought—nonscholastic, non-Platonic, positive and merely religious in its scope—herein reflecting faithfully the spirit of the movement initiated by Gerhard Groot (*q.v.*), and carried forward by the circles in which Thomas à Kempis lived. In contrast with many mystical writings it is of limpid clearness, every sentence being easily understandable by all whose spiritual sense is in any degree awakened. No doubt it owes its universal power to this simplicity, to its freedom from intellectualism and its direct appeal to the religious sense and to the extraordinary religious genius of its author.

BIBLIOGRAPHY.—The best account in English of the controversy is that given by F. R. Cruise in his *Thomas à Kempis* (1887). Works produced before 1880 are in general, with the exception of those of Eusebius Amort, superannuated, and deal in large measure with points no longer of any living interest. A pamphlet by Cruise, *Who was the Author of the Imitation?* (1898), contains sufficient information on the subject for all ordinary needs; it has been translated into French and German, and may be regarded as the standard handbook.

The best Latin edition of the *Imitation* is that of Hirsche (1874), which follows closely the autograph of 1441 and reproduces the rhythmical character of the book. Of English translations the most interesting is that by John Wesley, under the title *The Christian's Pattern* (1735). (E. C. B.; X.)

IMMACULATE CONCEPTION, THE. This dogma of the Roman Catholic Church was defined as "of faith" by Pope Pius IX in the Bull *Ineffabilis Deus* (Dec. 8, 1854) in the following terms: "The doctrine which holds that the Blessed Virgin Mary, from the first instant of her conception, was, by a most singular grace and privilege of Almighty God, in view of the merits of Jesus Christ, the Redeemer of the human race, preserved from all stain of Original Sin, is a doctrine revealed by God, and therefore to be firmly and steadfastly believed by all the faithful." The definition imposed no new doctrine on Catholics but merely declared that what had always been believed by the faithful had its origin in revelation as found in Scripture and tradition. The traditional belief had been thoroughly investigated by a special papal commission, which finally reported that the doctrine could be defined and that the time was opportune. The Immaculate Conception is a privilege over and above that immunity from personal sin conceded to Mary. By it Mary, in view of her dignity

as Mother of God, was *immune* from original sin in which all descendants of Adam are conceived, and from which they are freed by baptism. Sanctifying grace was infused into her soul simultaneously with its creation by God. The testimony of Scripture (especially Genesis iii, 15; Luke i, 28) is only implicit, and the same is true of the fathers, but they make constant reference to Mary's unparalleled holiness and the contrast between her and the first Eve. The testimony of the faithful can be gathered from their devotion to Mary the all-holy and their celebration of a special feast from the early centuries. Some of the Scholastics impugned the feast because of an imperfect understanding of the doctrine, but their private judgment did not reflect the belief of the universal church. The Immaculate Conception should not be confused with the Virginal Conception and Virgin Birth which assert Mary's perpetual virginity.

Bachelet, vol. vii, col. 845–1218. Numerous references to sources and to periodical articles will be found in *Lexikon fur Theologie und Kirche,* under "Empfangnis Maria."

IMMANENCE, in philosophy and theology a term applied, in contradistinction to "transcendence," to the fact or condition of being entirely within something (from Lat. *in-manere,* to dwell in, remain). Its most important use is for the theological conception of God as existing in and throughout the created world, as opposed, for example, to deism (*q.v.*), which conceives Him as separate from and above the universe. This conception has been expressed in a great variety of forms *(see* PANTHEISM; THEISM).

IMMANUEL BEN SOLOMON (c. 1270–*c.* 1330), Hebrew poet, mas born in Rome, He was a contemporary and friend of Dante, and his verse shows the influence of the "divine poet." Immanuel's fame chiefly rests on his poems, especially the collection (in the manner of Harizi [*q.v.*]) entitled *Mehabberoth,* a series of 27 good-natured satires on Jewish life. Most popular is an additional section numbered 28 (often printed by itself) called *Hell and Paradise (ha-Tophet veha-Eden).*

See J. Chotzner, *Hebrew Humour,* pp. 82–102 (1905).

IMMERMANN, KARL LEBERECHT (1796–1840), German dramatist and novelist, was born on April 24, 1796 at Magdeburg, the son of a government official. His legal studies at Halle were interrupted by the call to arms and by the campaign of 1815, after which he returned to the university. He was *Referendar* in Magdeburg, and in 1819 *Assessor* at Miinster in Westphalia. There he made the acquaintance of Elise von Lützow, countess von Ahlefeldt, wife of the leader of the famous "free corps" *(see* LÜTZOW), and their relationship is reflected in several dramas written about this time. In 1823 Immermann was appointed judge at Magdeburg, and in 1827 was transferred to Dusseldorf. Thither the countess, whose marriage had in the meantime been dissolved, followed him, and shared his home until his marriage in 1839. In 1834 Immermann became manager of the Dusseldorf theatre where he accomplished great things in spite of lack of adequate funds. In 1836 he returned to his official duties. He died at Diisseldorf on Aug. 25, 1840.

Immermann's early plays are imitations, partly of A. von Kotzebue's, partly of the Romantic dramas of J. L. Tieck and A. Müllner, and are now forgotten. In 1826, however, appeared *Cardenio und Celinde,* a love tragedy ridiculed by count von Platen in his wittiest satire, *Der romantische Oedipus.* Between 1827 and 1832 Immermann wrote a series of historical tragedies. *Das Trauerspiel in Tirol,* on Andreas Hofer (1827), *Kaiser Friedrich* 11 (1828) and a trilogy from Russian history, *Alexis* (1832). His masterpiece is the poetic mystery, *Merlin* (1831), which, like its model, *Faust,* deals with the problems of spiritual life. Immermann's important dramaturgic experiments in Dusseldorf are described in detail in *Düsseldorfer Anfänge* (1840). As a novelist he clearly stands on the boundary line between romanticism and modern literature; his *Epigonen* (1836) might be described as one of the last romantic imitations of Goethe's *Wilhelm Meister,* while the satirical picture of contemporary life in his second novel, *Münchhausen* (1838–39), forms a major break with the older literature. In *Miinchhausen* is embedded the admirable story of village life, *Der Oberhof.* His last works were *Memorabilien* (1840–43), critical aesthetic observations, and an unfinished epic, *Tristan und Isolde* (1841).

IMMIGRATION: *see* MIGRATION; **POPULATION.**

IMMINGHAM, a seaport in Lindsey, Lincolnshire, Eng., on the south shore of the Humber estuary, 5 mi. N.W. of Grimsby. Pop. (1951) 2,803. The docks (with the graving dock) have a water area of 45 ac. with 9,097 ft. of quayage and berthage. The port was built there (1906–12) because the deep water (47–43 ft. depth) enables vessels to enter and leave unaided at all states of the tide. In 1953 over 3,000,000 tons of coal were exported. Iron and other ore are imported, largely for Scunthorpe's steel mills. Other cargoes handled include grain, timber, chemicals and oil. There are also passenger facilities and the R.A.F. maintain an air-sea rescue unit. The dockers have a reputation for quick turn-round of ships.

IMMOLATION, the ceremonial rites performed in the preparation of victims for sacrificial purposes. The human sacrifice or *sati* (suttee) of India consists of the immolation of a widow on the funeral pyre of her husband, and the Khond sacrifice of the meriah; the days preceding the sacrifice were devoted to increasing the sanctity of the victim by various processes of anointing and other ceremonies. *(See* SACRIFICE.)

IMMORTALITY. The term "immortal" has been used in a wide general sense for everlasting. as in such statements that the writings of Plato, the plays of Shakespeare, the music of Mozart, are immortal. But in its chief use the term "immortality" has had reference to a continuity of men's spiritual existence after the death of their bodies. This article is limited to that conception.

The earlier anthropologists, as E. B. Tylor and Sir James Frazer, assembled convincing evidence that the belief in a future life was widespread in the regions of primitive culture. Among most peoples the belief has continued through the centuries. But the nature of future existence has been conceived in very different ways. As Tylor showed, in the earliest known times there was little, often no, ethical relation between conduct on earth and the life beyond. M. Jastrow wrote of "the almost complete absence of all ethical considerations in connection with the dead" in ancient Babylonia and Assyria. Motoori, an 18th century Japanese thinker, said that "Hades is a land beneath the earth. whither, when they die, all men go, mean and noble, virtuous and wicked, without distinction." In some regions it came to be declared that warriors who died in battle went to a place of happiness. Later, there was a general development of the ethical idea that the afterlife would be one of rewards and punishments for conduct on earth. So in ancient Egypt at death the individual was represented as coming before judges as to that conduct. The Persian followers of Zarathustra accepted the notion of Chinvat, a bridge to be crossed after death, broad for the righteous, narrow for the wicked who fell from it into hell. In India, the steps upward—or downward—in the series of future incarnated lives have been (and still are) regarded as consequences of conduct and attitudes in the actual present life. The idea of future rewards and punishments dominated many Christians in the middle ages, and is held today by many Christians of all denominations. In contrast many contemporary secular thinkers maintain that the morally good is to be sought for itself, and evil shunned on its own account, irrespective of any belief in a future life.

That the belief in immortality has been widespread through history is no proof of its truth. It may be a superstition that arose

from dreams or other natural experiences. Thus, the question of its validity has been raised philosophically from the earliest times that men came to intelligent reflection. In the Hindu *Katha-Upanishad,* Naciketas says: "This doubt there is about a man departed—some say: He is; some: He does not exist. Of this would I know." The *Upanishads,* the basis of most philosophy in India, are predominantly a discussion of the nature of man and his ultimate destiny. Immortality was one of the chief problems of Plato's thought. With the contention that reality, as such, is fundamentally spiritual. he tried to prove immortality, maintaining that nothing could destroy the soul. Aristotle conceived reason as eternal, but did not defend personal immortality as he thought the soul could not exist disembodied. The Epicureans, from a materialistic standpoint, held that there is no consciousness after death. and thus it is not to be feared. The Stoics mostly considered that it is the rational universe as a whole that persists. Individual men, as Marcus Aurelius wrote, simply have their allotted periods in the drama of existence. However, Cicero *(see* below) finally accepted personal immortality. Augustine, following Neo-Platonism, regarded men's souls as being in essence eternal. The Moslem philosopher Avicenna declared the soul immortal, but his coreligionist, Averroes, keeping closer to Aristotle, accepted the eternity only of universal reason. Albertus Magnus defended immortality on the ground that the soul, in itself a cause, is an independent reality. John Duns Scotus contended that personal immortality cannot be proved or disproved by reason. Spinoza, taking God as ultimate reality as a whole maintained His eternity, but not the immortality of individual persons within Him. Leibniz contended that reality is constituted of spiritual monads. Men, as finite monads, not capable of origination by composition, are created by God. He could also annihilate them. However, in that he has planted in men a striving for spiritual perfection there may be faith that he will ensure their continued existence giving them the possibility to achieve it. Kant, admitting that the soul cannot cease by disintegration suggested that it might end by the loss of its own power. Immortality cannot be demonstrated by pure reason, but it may be believed as a postulate of morality. Holiness, "the perfect accordance of the will with the moral law," demands endless progress "only possible on the supposition of an endless duration of the existence and personality of the same rational being (which is called the immortality of the soul)." Joseph Butler. insisting that probability is the guide to life, urged, on ethical grounds similar to those of Kant, that immortality should be accepted as probable. Hegel's philosophy has been interpreted by one wing of his followers as pointing to a cessation of finite individualities in the absolute, and by another to their persistence as constituents of the absolute. A Schopenhauer conceived ultimate redemption from the misery of life as a lapse from conscious personality into the unconscious universal will. The foregoing illustrates the chief positions held in philosophical treatments. After 1925 there was little philosophical discussion of the problem. There was a widespread impression that no conclusions could be reached concerning it and its consideration might be avoided. William Ernest Hocking challenged this contemporary attitude as an "idleness of mind."

Any form of spiritual continuity has been rejected by some thinkers on the basis of an assumption that all is physical. Few philosophers in the occident or the orient have adopted a definite materialism. It was most widespread at mid-20th century among the adherents to Marxian communism. They find in it a ground for rejection of the belief in immortality, taken to be promulgated by priests and others to exploit the masses of the world. Some contemporary thinkers, discarding the term materialism for naturalism, treated man as part of nature. Though their position was metaphysically indefinite, they endeavoured to describe human psychical life without the admission of a spiritual soul or a spiritual deity. Gilbert Ryle describes the soul as a ghost. Corliss Lamont considers immortality an illusion, probably a delusion. The fundamental difficulty that should be regarded as definitely ruling out materialism and all forms of contemporary naturalism is that it is impossible to describe the difference between truths and errors in terms of physical processes. In dismissing the soul as a ghost, Ryle gives no satisfactory account of himself as the thinker of his own theories. Lamont similarly ignores the being who distinguishes between realities and illusions. The contention that we do not know *how* a spiritual mind and a material body may interact is met by the reply that we do not know *how* one material body may affect another. The ultimate problem in both is that of change. Changes have to be accepted; they cannot be explained in terms of the changeless. From the standpoints of science and philosophy the position in the 1950s was not fundamentally different from what it was for William James in 1905: that the relations of mind and body may be described in terms of the interactions of a spiritual being and a physical organism. But even if the soul is different from the body, they are so intimately related that it is extremely difficult to conceive of the continuance of a bodyless soul. This difficulty has been in part met, especially in the orient by the doctrine of reincarnation, and in the occident among Christians with the belief that the soul will have a spiritual body.

In contrast with materialism and naturalism is the theory that reality is ultimately one universal spirit and individual human beings only transitory manifestations of it. Though the one spirit is called eternal, human beings are not to expect personal immortality. The fundamental difficulty of this theory is that both truths and errors are manifestations of the one spirit, who alone is their ultimate thinker. The spirit, the absolute, is in a condition of self-contradiction. The conflicts of good and evil are within it. There is no escape from the difficulty by calling the contradictions and conflicts mere appearances, for the appearances must be in the absolute as they appear.

Discussions of immortality have frequently been obscured by the contention that what men seek is the "eternal." Rudolph Eucken spoke of immortality as experiencing the eternal "in the midst of time." William Ralph Inge interpreted it as a participation in eternal values, and seemed to have a contempt for the idea of a future life for individual minds. The two conceptions of eternity, (1) that it is a now inclusive of all the past, the present and the future; and (2) that it is something in itself timeless or transcending time, are products of abstract reflection. It cannot be said that men have any experience of either. For those other than the few philosophers and theologians who use these conceptions, immortality normally means temporal personal continuity. But within the now of this life and the future of a next one, the religious mind may have an enduring communion with an ever-living God that may give a satisfaction greater than that in values that may not persist. That may be what is sometimes called, indefinitely, an experience of the eternal.

It has frequently been argued that there is a universal desire for personal immortality—as though instinctive, involving its eventual satisfaction. But Sir William Osler, with wide experience of persons near to death, declared that one minority of them ardently desired a future life, another minority hoped for final extinction, and the majority appeared indifferent. The scientist Ilya Metchnikov, after a critical examination of the philosophical and religious arguments for immortality, argued that the discontent of men is due to their failure to obtain complete satisfaction of their natural impulses. If they could live to a ripe old age and attain that satisfaction they would accept death as the natural end of life. Such longevity and satisfaction may eventually be achieved by science, and then all desire for immortality would cease. But, as Shakespeare suggested in Hamlet's soliloquy, there may be a future life whether we desire it or not.

In some ancient literatures there are stories of reappearances of and communications with the dead. In modern times there have been attempts to investigate scientifically such alleged phenomena. Communications have been supposed to be received by writing on a planchette, by knocks made by a moving table, and through mediums; *i.e.,* persons accredited with special capacities for transmission of communications, usually in states of trance. After World War I, many in Britain who had lost loved ones in the war resorted to persons claiming to be mediums. Some support for this may have been in eminent persons, such as Oliver Lodge and Conan Doyle, avowing their acceptance of the validity of this kind of phenomena. Popular interest soon ceased, however, prob-

ably in the main because the messages supposed received had little, if any. significance The research into the alleged phenomena came to be limited chiefly to a few whose interest is more intellectual than emotional There were no signs of any similar popular interest in such mediums after World War II.

It is seriously doubted whether scientific methods can make human life as satisfactory as I. Metchnikov imagined. According to some scientists changing conditions may lead to the degradation and eventual cessation of terrestrial human life. Most followers of naturalism. like Metchnikov, do not take adequately into account the character of men's ethical aspirations. Some theists would maintain that nature is not intended to give men complete satisfaction. The ethical argument has always been recognized as one of the strongest in justification of belief in personal immortality. It is frustrating that mankind, having developed so far intellectually, aesthetically, morally and religiously, should end entirely nith death. Cicero expressed such a conviction in his *Tusculan Disputations:* "For we are not born or created idly or fortuitously; but doubtless there is some power which takes thought for the race of men. and which was not likely to create and foster what—when it had accomplished all its toils—would sink into everlasting misery in death." So Hastings Rashdall wrote in 1907: "Only if we suppose that the present life of human beings has an end which lies in part beyond the limits of the present natural order, in so far as that order is accessible to present human observation, can we find a rational meaning and explanation for human life as we know it; and by far the most natural and intelligible form of such a world-end is the belief in Immortality for the individual souls who have lived there."

There is a fundamental ethical implication in the belief in' a series of reincarnations—a belief common to all the indigenous religions of India—Hinduism, Jainism, Buddhism, and in part, Sikhism. That belief is inseparably associated with the so-called law of karma which is taken as axiomatic. According to that law, the consequences of one's attitudes and conduct follow as inevitably as effects follow causes in the physical world. The conditions into which an individual is born into this world depend on his conduct in previous lives. He looks forward to a sequence of future lives By his spiritual efforts in them he may progress toward ultimate bliss. Under the influence of philosophical thinkers different conceptions of that final goal have been developed. In popular religion, and in some philosophies like those of Ramanuja and Madhvacharya, the individual is believed to retain what in the occident is called his particular personality. He is to achieve infinity in harmonious relations with God and all others. In other philosophies, as in that of Sankara Acharya, the final goal is conceived as consciousness of complete identity with the One reality: in short. it is pantheistic as previously discussed. It may be asked how belief in reincarnation is justified. It seems to offer an explanation of the inequalities into which men are born. But it is also declared that in states of trance the religious devotee may recall experiences of past lives. It is impossible to discover if such claims are true. What is asserted to be from past lives may be due to a play of imagination with reference to otherwise forgotten or similar experiences in this life. The belief in reincarnation has been held by only a few occidental thinkers. There are suggestions of it in the works of Plato, and it was definitely accepted by the Cambridge philosopher, John MacTaggart Ellis MacTaggart.

The profoundly religious have a faith in immortality which is a firm conviction affecting their outlook on life. Though, in the use of the term *hope*, there may be at times the suggestion of a possible doubt, the faith is more than the acceptance of an intellectual hypothesis. It is a fact of history that the idea of immortality has been sustained within the religions. The one firm basis for the belief has been, and is, in religious experience, in the soul's immediate communion with God. He must know whether men are immortal, and may bring a conviction of it to individuals, *when they are truly ready to receive it.* If God creates selves at the beginning of their terrestrial lives. He may sustain in future lives either (1) all—universal immortality; or (2) only those who merit continuance—conditional immortality. This religious basis for belief in immortality is accepted by most Christian thinkers today, with the admission that adherents to other religions may experience it. However, traditionally orthodox theologians have maintained—and many still maintained in the second half of the 20th century—that certainty of a future life was given to men by Jesus. He promised the robber crucified with Him that he should go to paradise. More important, He manifested a future life by His resurrection and ascension. This view is bound up with doctrines as to Jesus Christ that philosophy can neither prove nor disprove, and with accounts of events as to the truth or falsity of which historians seem unable to give a certain decision It is interesting to note that the philosopher Alfred Edward Taylor accepted the traditional Christian view. He contended that all rests on belief that Jesus was God-incarnate. divine and human. "To whittle away either his divinity or his humanity is to surrender the very ground of all our hopes."

The contemporary neglect of philosophical consideration of human immortality has adverse effects on the philosophy of history. A door must be either open or shut. Those who do not definitely accept the belief in immortality think, act. and write as though they explicitly reject it, even if occasionally they admit doubts. The two attitudes involve important differences for philosophy of history. If there is an open door to future lives for individuals there may be significance in terrestrial history with reference to a nonterrestrial future. The religions maintain that there is. Their implied or expressed philosophies of history are affected by it. With the implication that there is no such open door, the significance of history is treated by many contemporary historians and philosophers as being entirely terrestrial. The Marxist theory of history is of that type. For philosophy of history the problem of human immortality needs to be seriously discussed.

Some modern humanists contend that belief in immortality takes attention from and reduces efforts for the goods of the present life. It did that in some periods in the past, and may still do so for a few individuals. Religious teachers now insist that God has put mankind into this life and the best is to be done for the fulfilment of its duties and the enjoyment of its possibilities. Faith in immortality has given men a wider vision. Some of the greatest sacrifices for mankind have been made by men with that faith.

IMMUNITY. By immunity is understood a state of lessened liability to injury by microorganisms and by certain complex poisons formed by animals and plants. An animal that recovers from a disease caused by a microorganism is at the time of recovery immune; the invading microorganism has been present in the body in force and, though it may not have been destroyed completely, is incapable for the time of doing further harm. Immunity is not, therefore, a constant state of freedom from the risk of disease but a state of defense which may rise to a peak in response to an attack and lapse at other times.

The type of immunity that excites most interest is the long-lasting immunity that follows attacks of certain diseases. It is rare that a person, however much exposed to infection, gets a second attack of those fevers—smallpox, chicken pox, measles, mumps—which are caused by viruses, or of typhoid fever and diphtheria, which are caused by bacteria. This immunity is specific: an attack of measles protects against measles but not against

chicken pox. The methods of this specific protection involve reactions with relatively simple constituents of the microorganisms that resemble reactions used in dealing with other foreign substances. These reactions are called immunity reactions, although they may have nothing to do with protection and the foreign substances involved may be harmless. (See articles on above diseases.)

The physics and chemistry of such reactions have been studied, free from the complicating secondary reactions that occur in a living animal, and the substances taking part can be isolated and measured. The terminology used in discussions of immunity is very largely that developed in the early studies of protection of animals against harmful substances; but the meanings of the words and modes of thought used in discussion of protection are largely derived in turn from these studies of simpler reactions. Without a preliminary study of these simpler reactions the words used in discussion of the specific methods of protection remain words with nothing concrete behind them.

IMMUNITY REACTIONS

The Precipitin Reaction. — The nature of these reactions is best illustrated by an example. If crystalline albumin prepared from hens' eggs is injected into a rabbit, a new or modified globulin begins to appear in the blood serum of the rabbit in about a week. If the injections are repeated the amount of such globulin increases. This globulin is called a "precipitin"; in solution it has the characteristic property of forming a precipitate when mixed with a solution of hen's egg albumin. The most remarkable feature of this reaction is its specificity. A solution of the precipitin forms a precipitate with albumin from the eggs of related birds; the amount of precipitate depends on the closeness of the relation. The amount formed with turkey's egg albumin is only about one-half, and that formed with duck's egg albumin one-sixth, of the amount formed with hen's egg albumin. No precipitate is iormed with other proteins, even with the albumin of a hen's blood serum. Other animals besides rabbits can be used and other proteins will stimulate the formation of precipitins when injected. Thus, injection of albumin from horse blood serum will lead to the iormation of a precipitin that will form a precipitate with horse serum albumin, a considerably smaller precipitate with ox serum albumin but none with any kind of egg albumin. (See SERUM THERAPY.)

Antigens and Antibodies. — These precipitins are typical examples of the substances called "antibodies" (in the strict sense of the word). The proteins that are injected are examples of "antigens"; that is, of foreign substances that, when introduced into the body of an animal, stimulate the formation of antibodies that react in some observable way with the antigen. The animals are said to be "immunized" with the antigen. To call this process immunization involves an extension and misuse of the meaning of the word. For egg albumin is not ab *initio* poisonous to a rabbit, while it may, as will be shown later, become harmful as a direct result of "immunization."

In carrying out reactions between antigen and antibody, the whole serum is used, as a rule, without any attempt to isolate the reacting antibody; a serum containing antibody is called an "antiserum."

Most antigens are proteins or contain proteins as an essential part. Proteins are split up by the digestive enzymes in the intestine into their constituent amino acids and lose all their specific characters. For this reason antigens are, as a rule, relatively ineffective if given by mouth: they must be injected. But in some instances small amounts of partially digested protein may be absorbed and may stimulate the formation of sufficient antibody to be detectable by the more delicate reactions.

The meanings of the words antigen and antibody have been extended to include substances which are not covered by the strict definition. At one time it was thought that no substances other than proteins would give rise to or react with antibodies. M. Heidelberger and O. T. Avery found in 1923 that the serums of animals immunized with pneumococci contained antibody that formed a precipitate with the gum that forms the capsules of pneumococci of the same type. Such gums have been called "partial antigens" because they react with antiserums, but were supposed to be incapable of provoking the formation of antibodies without the co-operation of proteins. It appears, however, that antibodies can be formed by injection of these gums absorbed on collodion particles, although the amount of antibody in the antiserums will be small. Antibodies which react specifically with fatty substances can be formed by injecting these fatty substances together with proteins. These polysaccharides and fatty substances, though poorly antigenic or nonantigenic in the strict sense of the word, are commonly spoken of as antigens in discussions of their reactions with antibodies.

The red blood corpuscles of blood groups A and B contain the specific A and B substances on which reactions of serums of groups B and A, respectively, with these corpuscles depend; these serums contain globulins which react with the red corpuscles, group B serum reacting with group A corpuscles and vice versa. These reactions are exactly comparable to the reactions between sheep's red blood corpuscles and serums obtained by immunizing rabbits with sheep's red corpuscles. The group specific substances of human red corpuscles are not, in normal life, used for immunizing other animals; the reacting globulins in the serums are not produced in response to immunization and are part of the genetic make-up of the individual. But these reacting substances are called group specific antigens and antibodies.

The Mechanism of the Precipitin Reaction. — Shortly after the precipitin reaction was discovered, it was shown that relatively crude chemical changes in a protein would change its specificity. During World War I Karl Landsteiner (*q.v.*) introduced a method of attaching chemical groups to proteins, forming azoproteins. The nature of such attached groups, which are called determinant groups, can be varied almost at will. These azoproteins can be used as antigens for immunizing rabbits. The antiserums obtained will form a precipitate with any protein to which the same chemical groups have been attached; they will also form smaller precipitates with proteins which contain determinant groups, closely resembling those contained in the original antigen in composition and structure; but they will form no precipitate with proteins containing determinant groups that do not closely resemble those of the original antigen. 'Enough is not yet known about the structure of the natural unmodified proteins for their specificity to be correlated with details of composition and structure; but the composition and structure of some of the gumlike antigens of bacteria are known. The capsules of the different types of pneumococci are made of gums of different compositions. Each of these type-specific gums forms a precipitate with the serum of an animal that has been immunized with pneumococci of the type from which the gum was derived. The specificity of these gums depends on the structure and composition of the gums exactly as specificity of the azoproteins depends on the composition and structure of their determinant groups. In some cases the antiserums formed by immunization with pneumococci of one type will form precipitates with gums derived from pneumococci of another type or with unrelated bacteria; these "cross reactions" are caused by common features in the compositions of the gums of the pneumococci used for immunization and of the other gums with which they form precipitates. It may be inferred that the specificity of all antigen-antibody reactions is determined by special composition and structure of certain groups in the antigen.

Specific Combination —By Landsteiner's method it was shown that the remarkable specificity of the reaction between antigen and antibody lies in the combination bet een antibody and the determinant groups of the antigen. For relatively simple substances that contain the determinant group will combine with the corresponding antibody though they will not form a precipitate; these substances which combine without forming a precipitate are called haptenes. This specific combination which is the essential stage depends on the composition and structure of certain groups in the antigen.

Precipitation. — A molecule of antigen may have several determinant groups and a molecule of antibody several combining sites. Large aggregates can be built up in which each molecule of antigen is linked to several molecules of antibody, whereas haptenes

with only one determinant group cannot link two antibody molecules together and therefore cannot build such aggregates. A change in the physical properties that reduces solubility in water follows this aggregation of antigen and antibody; like other insoluble substances the aggregates form precipitates.

More Complex Immunity Reactions.—A series of other specific reactions, which have a more obvious connection with immunity in the ordinary sense of the word, depends on a mechanism that is exactly similar to that of the precipitin reaction.

Agglutination.—In this type of reaction an antiserum causes a suspension of small particles coated with antigen to run together into clumps; this clumping is called agglutination and the reacting antibody is an agglutinin. Antiserums prepared by immunizing with a single substance, egg albumin for example, will agglutinate particles that have this substance on their surfaces. Most commonly the antiserums are produced by immunizing with a suspension of cells, such as bacteria or red blood corpuscles, which are relatively complex structures. In this case the substances that stimulate the formation of antibodies are constituents of the cells injected.

Complement.—Certain constituents of blood serum are grouped together under the name "complement." Until recently complement was known solely by its actions. It is absorbed by the complexes formed by most antigens and antibodies; for example, by the aggregates formed by a protein antigen and the corresponding precipitin or by cells and the corresponding agglutinin.

Lysis.—The complement absorbed has a further action on cells, such as red blood corpuscles and certain bacteria, that have combined with antibodies. The surface membranes of the cells are so changed that substances retained in normal cells can diffuse out and the cells may be broken up. This process is called lysis and the antibodies involved are then lysins.

The substances that act as complement are not specific in their action; the same complement will co-operate with the appropriate antibody in the lysis of bacteria and of the red blood corpuscles of various species of animals. Nor is the amount of complement in serum changed by immunization. The absorption of complement is the basis of such tests as the Wassermann reaction. Complement is absorbed by the compound formed by the syphilitic antibody and Wassermann antigen; the removal of this complement from the solution in which the reaction is carried out is demonstrated by the fact that it is no longer available for the lysis of red blood corpuscles that have been treated with an antiserum to the same red blood corpuscles.

Phagocytosis: Ofsonins.--The polymorphonuclear leucocytes of the blood, which are simple cells, can surround particles with which they come into contact and take them into their protoplasm; this is called phagocytosis. Bacteria and other cells, such as red blood corpuscles, are ingested in the same way but to a variable extent that depends on the nature of their surfaces. Cells that normally resist phagocytosis are ingested much more readily after they have been treated with the serum of an animal that has been immunized with the cells in question. This change is caused by the combination of antibody with antigen on the surface of the cell and by a subsequent change in the physical properties. Bacteria, treated with antiserum, are ingested more rapidly if a nonspecific constituent of serum which resembles complement is present. Sir Almroth Edward Wright (*q.v.*) called these substances, which make bacteria more suitable for ingestion by leucocytes, "opsonins" or "appetizers." The antiserum can be said to "opsonize" bacteria.

Anaphylaxis.—Injection of a small amount of a protein, such as egg albumin, of the order of one milligram or less into a guinea pig has no apparent effect. However, a second injection of the same protein after a latent period of about eight days will be followed within a minute by the first signs of a violent shock, of which the most conspicuous feature is contraction of the muscles that constrict the small air passages of the lungs, similar to that in human asthma. If the shock is sufficiently severe the guinea pig dies in less than half an hour. The amount required to sensitize guinea pigs is remarkably small; the limit is of the order of one ten-thousandth milligram and the amount commonly used is about one milligram. Sensitivity reaches its maximum in about three weeks after the sensitizing dose and remains sufficient for a second dose to produce a fatal shock for about six months; possibly the guinea pig remains somewhat sensitive for its whole life. A guinea pig may survive the shock produced by the second, shocking injection; if it does, then for a period of two weeks or more a further injection of the same protein will not produce another shock; the guinea pig is said to be desensitized.

This condition of hypersensitivity is called anaphylaxis. It can be produced in other animals, although larger doses are needed and the shock may take a different form. The hypersensitiveness is caused by the presence of antibodies, for an animal can be sensitized by injection of antiserum derived from another animal; hypersensitiveness induced in this way is called passive anaphylaxis. However, the shock that follows an injection of antigen into an animal that has been sensitized passively is not caused by reaction between antigen and antibody circulating in the blood. There is a latent period after the injection of the antiserum during which injection of a dose of antigen will not cause a shock; during this period antibodies become fixed to cells of the tissues. After the latent period, organs that have been isolated and freed from blood by transfusion will react by contracting on treatment with the antigen. This reaction, again, is specific: the contraction occurs only on addition of the antigen that was used for preparing the immune serum.

It might well be supposed that the aggregation of antigen and antibody on the surface of cells would be enough to account for anaphylactic shock. However, histamine produces symptoms very similar to those of anaphylactic shock; there is evidence that histamine or a substance resembling it is released from the tissues when antigen and antibody react and that it is this substance which produces reactions, such as the contraction of the muscles of the small air passages.

Neutralization of Toxins—The reactions hitherto considered have not involved protection against a harmful substance. There are, however, in the toxins of bacteria. of snakes and of some plants, examples of harmful agents that can be isolated as single chemical substances. An animal immunized with a toxin forms an antiserum (antitoxin) that will combine with and neutralize this toxin. A mixture of toxin with sufficient antitoxin is not poisonous; if antitoxin is injected into an animal before an injection of toxin, the animal is protected; if antitoxin is injected after toxin, it will to some extent mitigate the effects of the toxin. The action of antitoxin is not limited to combination and neutralization. Antitoxin and toxin when mixed in sufficiently strong concentrations form a precipitate comparable to those formed in precipitin reactions. The precipitate (toxin-antitoxin floccules) contains both toxin and antitoxin; it is nontoxic if the amount of antitoxin added is sufficient. Toxins are not destroyed by antitoxins and can, in some cases, be set free, in toxic form. from their combination with antibody. Diphtheria toxin has been liberated, unintentionally, from toxin-antitoxin floccules by shaking with a disinfectant that destroyed the antitoxin, with disastrous results when the mixture was used for immunizing human beings.

The Common Basis of Immunity Reactions.—All these reactions, like the precipitin reaction, are specific. By Landsteiner's method it has been shown that the specificity of agglutination, of opsonization and of anaphylaxis depends on the composition and structure of antigens used for immunization or sensitization. As in the precipitin reaction the essential stage is specific combination of antigen and antibody; it is followed by secondary manifestations which depend on the nature of the antigen and on its situation (on the surface of a cell or other particle), on the situation of the antibody (in solution on the surface of a particle or, again, on the surface of a tissue cell) and on the presence of co-operating nonspecific substances such as complement.

It is not necessary to postulate a series of different antibodies—precipitins, agglutinins, complement fixers, lysins, opsonins and sensitizing antibodies. Antibodies have been prepared in pure form which will not only precipitate but also agglutinate, fix complement and sensitize guinea pigs.

Antibodies: Properties and Formation.--Not only the

specific ability of antigens to combine with antibodies must be accounted for, but also the specific ability of the antibodies to combine with antigens. It must be supposed that the molecules of antibodies have combining sites specifically suited for combining with the corresponding determinant groups of the antigens.

Antibodies are globulins, and globulins belong to the type of substances called proteins. Proteins are built up of 21 different amino acids; they differ in the proportions of amino acids present in their molecules and in the ways in which these amino acids are arranged. There is nothing to suggest that antibodies have any constituents that are not found in other proteins. They are not distinguished from other serum globulins by special proportions of their constituent amino acids. The specific sites adapted to combine with antigens must be formed by special arrangements of these constituent amino acids.

When an animal is immunized 'the amount of globulin in its serum usually increases and the increase is greater than that which the antibody formed will account for. It seems, therefore, that the antigen stimulates the formation of serum globulin, some of the molecules of which have this special arrangement of their constituent amino acids. It is suggested that antigen is deposited in the cells in which serum proteins are synthesized; that the appropriate free amino acids are attracted by groups in the antigen in the pattern appropriate to make a combining site and are then joined together in this specific pattern. The antigen thus moulds the structure of serum globulins as they are synthesized.

Such hypotheses may explain the formation of antibodies shortly after the injection of antigen, but they do not account for the persistence of immunity, which is one of its most remarkable features. If antibodies derived from one animal are injected into the circulation of another of the same species, they disappear from the circulation in two or three weeks. The individual molecules of globulin, including antibody globulin that an animal itself makes, persist in the circulation for about 80 days. But antibodies may be detected in the serum for years after a disease or a course of immunization has ended. Anaphylaxis may persist for the whole life of a guinea pig. An animal that has once been immunized responds to a fresh injection of antigen by forming antibodies more rapidly and in larger amounts than after the first injection. The synthesis of antibody, or at least a heightened capacity to form antibody, must persist without any fresh introduction of antigen. It is this persistence which makes active immunity produced by inoculations so much more valuable than the passive immunity that follows injection of antiserum from another animal. It is difficult to see how the original antigen can persist in the tissues of the immunized animal and influence the synthesis of serum globulin for such a long time. Even such an inert structure as bone is continually renewed; other more active tissues are changed far more quickly. It might be expected that the whole of the antigen would be eliminated in the process. The whole structure of an animal must be renewed over and over again, while the stamp set by a course of immunization remains.

The Site of Formation. — Particles that are injected into the blood stream are taken up by the scavenger cells; it might be supposed that antibodies are formed here, where the antigens are fixed. It has been found that coloured antigens appear in the scavenger cells and these cells are said to shed protein into the circulation at the time when antibodies appear in the blood. However, the best evidence is in favour of the lymph glands as the main site at which antibodies are formed.

Incomplete Antibodies. — According to the definition given, antibodies should give some observable reaction with antigens. It has been realized for some time that globulins might occur in the serums of immunized animals that combined specifically with antigen, but did not produce the visible reaction that would be expected with the type of antigen used. These incomplete antibodies have come into special prominence because the serums of Rh-negative mothers who have Rh-positive babies may contain Rh antibodies, mainly of this type; these cannot be detected unless special techniques are used. They may pass through the placenta into the circulation of the unborn baby, break down the baby's red blood cells and cause severe anaemia,

DEFENSE

Defense against Invasion. — The entry of microorganisms into the bodies of the higher animals is checked by purely mechanical barriers. The horny layer of the skin has gaps only at the openings of sweat glands and hair follicles. The air breathed is filtered in the nose; a large proportion of the microorganisms it contains are caught in mucus and either passed down into the oesophagus or ejected through the nostrils. Even those that escape and get down into the air passages of the lungs are again caught in mucus on the walls and cleared out in the current set up by the cilia of the epithelium. The lining of the intestine is almost impermeable to microorganisms. In the stomach the concentration of hydrochloric acid is normally high enough to kill some microorganisms and check the growth of others. Bile salts inhibit the growth of some microorganisms in the upper part of the intestine. It is only in the large intestine that bacteria multiply freely.

There are other more subtle outer defenses of the body. Many species of bacteria disappear rapidly when spread on clean skin; typhoid bacilli, for example, cannot be recovered from the skin ten minutes after application. However, other bacteria, in particular staphylococci, which normally live on the skin, do rot disappear in this way. Tears, nasal secretion and many tissues contain a substance, lysozyme, which breaks down a mucinous substance that is an essential part of the structure of some bacteria and thereby kills them. This is not apparently the main agent responsible for the disinfection of the skin, but it may contribute to the protection of the eye.

Course after Invasion. — Cellular *Mechanism.*—When suspensions of particles, such as India ink, and certain dyes are injected into the veins of an animal they are deposited in various organs and may remain there in a recognizable form for weeks. These particles or dyes have been ingested by special scavenger cells which form the reticuloendothelial system. Apart from these cells of the reticuloendothelial system, there are the polymorphonuclear leucocytes of the blood, which do not ingest these dyes but play an important part in dealing with bacteria.

Nonspecific Bactericidal Action of Blood. — Attention has been focused on the two mechanisms of defense, the formation of specific antibodies and the phagocytosis of foreign particles. However, blood contains other substances, besides specific antibodies, that kill bacteria or check their growth. It is a common observation that blood serum "keeps" much better than other solutions of protein, such as egg albumin; that is to say, the growth of putrefactive organisms is checked in serum. The serum of some animals contains a substance, apparently not a specific antibody, that will kill anthrax bacilli. A rather similar substance can be extracted from polymorphonuclear leucocytes. During the early stages of fevers, before specific antibodies appear, this power of killing certain bacteria is much increased. The mechanism of this, which must be one of the most important weapons of defense, has been studied but little.

Weapons of the Invader. — Bacteria do not multiply in the body to such an extent that they interfere with its activities by sheer bulk. The size of such particles is not apparently injurious. The damage, whether local or general, is done by poisons (toxins) formed by the bacteria. It is customary to divide the toxins of bacteria into two classes, exotoxins and endotoxins. The exotoxins appear in the culture medium in which bacteria are grown. Diphtheria toxin, the exotoxin that has been most fully studied, is a protein with a molecular weight approximately equal to that of serum albumin. It is extremely poisonous: the minimal lethal dose for a guinea pig is about one ten-thousandth milligram. On a weight basis the minimal lethal dose for a man would be about one-thirtieth milligram; this may be compared with the fatal dose of aconitine, one of the most poisonous of the alkaloids. which is about one milligram. Animals that are immunized with the exotoxins form large amounts of antibody (antitoxin). The endotoxins include complex compounds of carbohydrates and fatty substances (glycolipides) that have been isolated from typhoid and dysentery bacilli. These endotoxins are very poisonous, but their minimal lethal doses are considerably higher than those of

exotoxins. Some bacteria, particularly *Streptococcus haemolyticus,* form substances called leucocidins which kill polymorphonuclear leucocytes. It appears that the harmful effects of viruses are entirely local and arise from their ability to establish themselves inside the actual cells of the tissues of the host's body. Bacteria have their defenses against the weapons of the host. Resistance to phagocytosis depends on the nature of the surface of bacteria. In the case of pneumococci this resistance is caused by the presence of the capsule. The most virulent strains of typhoid bacilli have a surface constituent, the Vi antigen; strains that have this Vi antigen are less readily ingested by phagocytes than those that have not. Antibodies which agglutinate, lyse or promote phagocytosis combine with the constituents of the surface of bacteria. These constituents, such as the gums that form the capsules of pneumococci, may be produced in excess and cast off into the surrounding fluid where they combine with antibodies and put them out of action. Such substances, though harmless in themselves, have been called "aggressins." Pneumonia is more commonly fatal when the amount of this capsular gum in the patient's blood is more than enough to neutralize all the circulating antibody. The virulence of bacteria may therefore depend on the poisonousness of their toxins, as in the case of the diphtheria bacillus, or on the presence of a defensive capsule and the formation of aggressins, as in the case of pneumococci.

Course after Invasion.— When nonvirulent bacteria are injected into the circulation of a rabbit they disappear rapidly from the blood, as lifeless and inert particles would do. If the bacteria are slightly virulent the number in the blood falls during the first five hours, then may rise for a time, as the bacteria multiply, but will fall to zero in a few days. The bacteria are cleared from the blood by both reticuloendothelial cells and polymorphonuclear leucocytes.

If the bacteria are highly virulent, the numbers in the blood fall at first but then increase rapidly until the rabbit dies. If the rabbit has been immunized or if it has been protected by the injection, beforehand, of serum from an immunized animal, the blood is eventually cleared of virulent bacteria, as it is when slightly virulent bacteria are injected.

The entry of bacteria directly into the blood stream must be a very rare event in normal life. When bacteria enter in other ways the object of the defense is to pin down the invader and fight a local battle. The first effect is the formation in injured tissues of a substance that dilates the local blood capillaries and increases the permeability of their walls. This increased permeability allows the constituents of the blood plasma, including nonspecific protective substances and any antibodies the plasma may contain, to flow out; polymorphonuclear leucocytes also are attracted through the walls of the capillaries, both by the substance that causes the increased permeability and, in the case of certain bacteria, by the substance formed by the bacteria themselves. The leucocytes ingest the bacteria if they can; the products of the breakdown of leucocytes that are killed attract more leucocytes to the spot. The bacteria are killed by the nonspecific bactericidal substances of the blood. In the meantime, the fibrinogen of the plasma that exudes from the capillaries coagulates round the area of invasion and walls it off. Later, other scavenger cells invade the area to carry on the work of the leucocytes. The barrier of fibrin is strengthened by the formation of fibrous tissue. The dilatation of the blood capillaries and the escape of blood plasma and leucocytes into the invaded area constitute inflammation; the killed leucocytes form pus.

If the invasion can be localized until appreciable amounts of antibodies are formed these are poured into the area and coat the bacteria. The bacteria are then agglutinated, immobilized and readily ingested by the phagocytes — polymorphonuclear leucocytes and other scavenger cells. Any pus formed and the remains of dead tissue are discharged or absorbed; the area then heals. If the invasion is not localized until the antibodies are formed, the bacteria spread into the surrounding tissues and into the blood stream and the battle is continued there.

If, however, the invaded animal has already been immunized with bacteria of the same species and type as the invaders, the first escape of plasma brings with it agglutinins and opsonins that assist the fixation and phagocytosis of the bacteria. The amount of antibody in the first plasma that escapes may be small and largely neutralized by the aggressins of the bacteria; but, as the animal has been immunized, it responds to the stimulus of the invasion by producing new antibody much more rapidly and in greater amounts than an animal that has not been immunized would do. The immunized animal maintains a small standing army of specific antibodies, but it can mobilize a large army quickly.

Although the invasion may be defeated, the invading bacteria are not necessarily all destroyed. Some may persist locally or, if the blood was invaded, in the liver and spleen. Some, particularly diphtheria and typhoid bacteria, may not only persist but also multiply and be discharged from the body. Persons with such persistent foci of virulent bacteria, calied carriers, may infect susceptible persons directly or through food and water.

Local Immunity.—After an animal has recovered from erysipelas. produced by a type of streptococcus, injection of streptococci of the same type into the area of skin that was affected will not produce a second attack, although it may produce erysipelas if injected into the skin elsewhere. The animal therefore appears to have a local immunity. It has been suggested that local fixed antibodies may be formed before antibodies appear in the circulation. However, all the evidence indicates that this local resistance springs from a persistent local mobilization of defense. particularly the accumulation of phagocytes. The local immunity is not specific.

A similar immunity follo s inflammation produced by chemical irritants and, after local infection by bacteria, the local resistance to wholly unrelated bacteria is increased.

Immunity to Virus Infections.— The most striking examples of long-lasting and complete immunity to disease are against diseases caused by viruses, and it is against virus diseases that the production of immunity by vaccination has been most successful. Because of difficulties of investigation, less is known about immunity to virus diseases and the mechanisms involved therein than about immunity to diseases caused by bacteria. It is known, however, that the essential manifestations of specific immunity to bacteria are reactions not to the bacteria as organized and living cells but to their constituent proteins, gums or fatty substances which are constituents of all living matter, including viruses; it is also knonn that phagocytosis deals not only with bacteria, virulent or avirulent, but also with inert lifeless particles. It would therefore be expected that these two methods of defense would be used against viruses. The presence of specific antibodies in the serum of immunized animals is shown by the protection of nonimmunized animals given by this serum against injected virus of the same species; the immune serum protects if it is mixed with the virus before injection or is injected into the animal beforehand. These protective antibodies combine with the virus particles. The main difference betaeen immunity to viruses and immunity to bacteria lies in the fact that an essential element in disease caused by a virus is the entry of the virus into susceptible cells; an adequate concentration of the antibody in or near these cells is needed in order to keep the virus out. (*See* also FILTERABLE VIRUSES; VACCINE THERAPY.)

The Importance of Antibodies in Defense.— If these concepts are correct. specific immunity depends on the presence of specific antibodies, their appearance in the circulation and the establishment of the machinery for the rapid formation of a large amount of antibody in response to a fresh stimulus. The most striking examples of the importance of antibodies are seen in newborn animals. They come into the world from sterile surroundings with no experience of even the less virulent organisms that they will encounter as soon as they are born. They have had no occasion to make antibodies to these organisms and it appears that their capacity to make antibodies is relatively undeveloped. They are, however, supplied with antibodies from the serum of their mothers. Antibody proteins similar to those in the plasma of the mother hen are found in the yoik of eggs, and they persist in the egg although other proteins of the yolk are used up to make the tissues of the chick. The placentas of rodents, apes and women allow anti-

bodies to pass from the blood of the mother to that of the foetus in the last stages of pregnancy. However, the placentas of ruminants, mares and pigs do not allow the passage of antibodies. The concentration of antibodies in the first milk of these animals is higher than in the plasma of the mother; these antibodies are not split up in the intestines of the newborn animal as they would be in the intestines of an adult or as other proteins are split in the intestines of the young animal; they are absorbed unchanged into the blood.

The great susceptibility of premature babies to infection is probably a result of the lack of antibodies which should be supplied by the mother during the last weeks of pregnancy. The importance of these antibodies can be shown more clearly in the case of ruminants. Newborn calves and foals have in their blood serum neither antibodies nor the fraction of globulin in which antibodies appear. Within a few hours after they have sucked their first milk both antibodies and the corresponding globulin appear. If the first milk is withheld neither antibodies nor the globulin fraction appear and the calves are very susceptible to common bacteria, particularly to *Bacillus coli.*

In the same way, antibodies appear in the serum of lambs only if they get the first milk, and lambs that do not get this milk are susceptible to lamb dysentery.

Such a transfer to an individual of antibodies made by another individual of the same or of another species is called passive immunization. If all goes well the newborn animal gets its quota of antibodies from its mother before it encounters any infection. To confer this passive immunity on older animals antiserums must be injected; if given by mouth the antibodies are split up in the intestine. Much depends on the relation of the time of injection to the time of attack by microorganisms. If the injection is made shortly beforehand it will, so long as the antibodies persist in the circulation, confer a high degree of immunity against disease. Thus, mice that have received an injection of antiserum against a type of pneumococcus will survive subsequent injection of 1,000,000 times the number of pneumococci of the same type, which would kill mice that had not been protected in this way.

When antiserums are used to treat human beings they are rarely injected before clinical symptoms appear; that is, before the microorganisms have invaded the host and have multiplied. Antiserums, other than those containing antibodies to exotoxins, then have little effect on the course of the disease. Investigations have been made on a large scale into the value of treating pneumonia with antiserums to pneumococci of the type with which the patients are infected. Only in the case of type I pneumonia caused by type I pneumococci was there any significant difference between the death rates of patients who were treated with serum and of those who were not so treated. It is the same with infections with a virus. In experiments on animals antiserum will not prevent disease unless it is injected before or with the virus. In the treatment of contacts of cases of measles by convalescent serums, which contain antibodies to the measles virus, it may be possible to forestall the multiplication of the virus and invasion of the body cells. If the serum is injected early in the incubation period, within four days of exposure to infection, measles does not usually develop. If the injection is delayed until the eighth day after exposure, it rarely prevents an attack but this attack is usually mild. Injections given still later have little or no effect on the course of the disease.

Treatment of diseases such as diphtheria and tetanus, in which the damage is mainly caused by exotoxins, may be successful after the symptoms have appeared. But again the antiserums are much more effective if given before or early in the course of a disease. With passive immunization this difficulty always arises: if the antiserum is given beforehand the antibodies may have disappeared from the circulation when they are needed for defense; if they are injected after a disease is diagnosed they may have little effect on its course.

When a person is immunized actively by an actual attack of a disease or by inoculation with bacteria or viruses, by bacterial toxins or by these agents modified in some way, the formation of antibodies may continue for years; when the amount of antibody circulating in the plasma has fallen to a low level the capacity rapidly to form antibody remains. A fresh infection can be met with antibody before the infective agent has time to multiply. The value of this active formation of antibodies, and of the capacity to form more antibody rapidly, is shown by the protective effects of inoculation with typhoid vaccine and with diphtheria toxin in some modified form.

In the case of diphtheria, the amount of circulating antitoxins and the capacity to respond by producing more is commonly kept up by repeated exposure to infection. But it rarely happens that people are exposed repeatedly to infection with typhoid or smallpox. The immunity that follows antityphoid inoculation and vaccination therefore wanes in the course of years. It is not possible to put a definite term to the duration of immunity. Individuals vary, and for a long time after the remaining antibodies have become insufficient to prevent disease the latent capacity to make fresh antibodies may be awakened early enough in the course of the disease to mitigate it considerably.

Attacks of some diseases, such as smallpox and typhoid, are almost always followed by lifelong protection. We might expect that inoculation with the organisms that give rise to these diseases, killed or attenuated in some way, or inoculation with a cross-reacting organism would confer protection for a considerable time. On the other hand, a person may suffer more than one attack of pneumonia, several attacks of influenza and innumerable colds. It would be surprising if inoculation against these diseases afforded anything more than a very transitory protection. Fuller investigations cast doubt on the claim that the incidence of pneumonia in South African mines was lowered by inoculation; other changes occurred at the same time that might have accounted for the fall in the incidence. In further trials little evidence of protection was found.

Natural Immunity. — Some species of animals are not harmed by toxins that are very poisonous to other animals, although the insusceptible animals have no special protective antibodies. Birds and cold-blooded animals, for example, are not poisoned by tetanus toxin. This insusceptibility appears comparable to the insusceptibility of hedgehogs to strychnine. Probably, because of some peculiarity of the composition of the constituents of the cells of these animals, the toxins are not able to combine them as they do in susceptible animals. But insusceptibility of this type seems to be exceptional.

The antibodies that young animals get from their mothers disappear during the first year of life. But through adult life, when these antibodies have gone, many species are still immune to some diseases and this immunity appears to be due to the presence of antibodies in their serum. Repeated exposure to diphtheria bacilli, without the development of recognizable disease, accounts for the presence of diphtheria antitoxin in the blood of human beings who have never been deliberately immunized with diphtheria toxin or toxoid and have not had diphtheria. But pigs and oxen may frequently have antibodies to typhoid and cholera bacilli, among other organisms, in their serums; and it is unlikely that they have been exposed to these organisms. These antibodies may be formed as a result of exposure to some other organisms that contain antigens identical with or similar to those in these bacilli. There are unquestioned examples of such cross reactions; the immunity to smallpox that follows vaccination is one of them. It is hardly conceivable. though, that such accidents could account for the immunity and for the antibodies in the serum found consistently in some species.

How could it arise that chickens have specific antibodies in their serums for three types of pneumococci? There is no doubt that the presence of the group specific agglutinins in human serums is determined by genetic factors; these agglutinins are not formed in response to the stimulus of foreign substances. It is possible that the presence of other antibodies may be part of the inborn constitution of certain species.

Serum, as already noted. may contain some substances that will break up anthrax bacilli but do not resemble antibodies. It appears that animals that are naturally immune to anthrax have a large amount of this substance in their serum, whereas susceptible ani-

mals have considerably less.

There is another kind of immunity that is familiar in everyday life and in experimental studies of the transmission of disease, but itself has been little studied. In most cases, experimental animals cannot be infected with certain human diseases, particularly the diseases, such as measles, caused by viruses. This immunity is not caused by the presence of antibodies in the serum. Bacteria are better adapted to one environment than another; for example, tubercle bacilli injected into the blood stream will settle down and infect one organ in one animal and another in another. The viruses, which actually enter the cells of the host, may be still more susceptible to the chemical composition of these cells and therefore be able to thrive in the cells of hosts belonging to a few species only.

THE INFLUENCE OF EXTRANEOUS FACTORS

Nutrition. — Malnutrition is commonly associated with a lowered resistance to disease, especially to tuberculosis. With the growth of the new knowledge of nutrition during the 20th century, attempts were made to pin the lowering of resistance to infections on to deficiency of one or other constituents of the diet. A clear distinction must be drawn between diseases (such as pneumonia) caused by infection and those (such as beriberi and rickets) caused by lack of some necessary constituents of the diet. in which there is no element of infection. This loss of resistance to infection has been ascribed to lack of various food constituents, particularly vitamin A. In experimental animals that are deprived of vitamin A the cells that line surfaces, such as those of the air passages, change to form a horny layer like the surface of skin. Such a horny layer has not the cilia which clear mucus and organisms entangled in it out of the air passages. Consequently, harmful 'microorganisms have an opportunity to establish themselves in the air passages: the outer defenses are breached. Because lack of vitamin A increases the risk of infection in this way it has been called the "anti-infective vitamin." It bears, however, no relation to the development of specific immunity; animals deprived of vitamin A can form antibodies as well as normal animals can. The change of surface cells can be seen on the surface of the eye, and it occurs there in human beings when the lack of vitamin A is extreme. But human subjects have been deprived almost completely of vitamin A for two years or more without the appearance of this local change or any evidence of an increased liability to colds, bronchitis or pneumonia. And pathologists are not convinced that the lack of vitamin A produces the change in the cells lining the air passages of human beings.

There is, however, evidence from experiments on human subjects that deprivation of vitamin A does lower the resistance to tuberculosis: in Denmark the supply of vitamin A was very low during the years 1915–1917, when the tuberculosis death rate rose; in 1918, when the death rate fell, the supply was well above the pre-war level.

Antibodies are proteins and must be made, in the end, from the constituent amino acids of the proteins of the food. It might be expected that animals that were not getting enough protein in their food would fail to make antibodies; this has been found by experiment. When an infection begins. in an animal already depleted of protein, a vicious circle is set up; for a diseased animal wastes protein and the depletion therefore becomes more severe.

In consequence, the formation of antibodies is defective; the animal is not able to throw off these infections and wastes more protein.

The effects of folic acid illustrate the importance of leucocytes in defense. The number of leucocytes in the blood of monkeys falls when they are fed on a diet which lacks vitamin M (proved to be folic acid); these monkeys become very susceptible to diseases, particularly to dysentery.

Vitamin C (ascorbic acid) is needed for the proper formation of fibrous tissue. In scurvy, the disease caused by lack of vitamin C, wounds heal slowly or not at all on account of defects in the fibrous tissue which should close them: breaches in the outer defenses remain open to invasion by microorganisms. Apart from this, the barrier of fibrous tissue formed round areas that bacteria have invaded is weak and incomplete; the invasion is not localized as in normal animals.

Several trials have been made of the effects of giving large supplements of vitamins for many months to people eating their usual diets. If the subjects of the experiments were already getting enough of the vitamins in their food, no benefit could be expected from their supplements. But, in most cases, the usual diet of some of the subjects would contain less of one or more of the vitamins than is considered necessary. The only constant difference found between the subjects who received the supplement of vitamin A, or a mixture containing vitamin A, and control subjects, who did not, was a slight reduction in the severity and duration of colds (but not in their frequency).

Cold and Injury. — Resistance may be lowered by cold or injury; the degree of injury needed to turn the scale in favour of the invader may be very slight. When foot-and-mouth virus is injected into the muscle of a guinea pig, blisters appear on the pads of the feet in three or four days. If one foot is protected from pressure by being wrapped in cotton wool, no blisters develop on this foot, although they appear on the unprotected feet. The virus of herpes, which commonly gives rise to blisters on the lips, often causes inflammation of the mouth in young children. The virus appears to lie latent in the tissues after this attack. The latent virus may cause blisters on the lips when resistance is lowered locally, by injuries such as burns, or generally, in association with colds and pneumonia: hence the name fever blisters. The name of the common "cold" may not be a misnomer. Infection with a virus, still virulent but kept in check by the local defenses, gets the upper hand and causes a fresh attack when these local defenses are weakened by cold.

Each cold is not necessarily caused by a fresh infection from another person.

HYPERSENSITIVE STATES OF HUMAN BEINGS

Skin Reactions. — If a small amount of antigen is injected into the skin of a subject who has been immunized with this same antigen, a patch of reddening followed by a weal appears round the point of injection in the course of 24 hr. to 48 hr. Such a response, for example, follows the injection of 0.02 ml. of horse serum into the skin of a person who has received a course of injections of diphtheria toxin-antitoxin floccules. The small amount of horse serum protein, present as antitoxin in the floccules, has immunized against horse serum. The reddening and formation of a weal is typical of all these skin reactions. These reactions can be produced in the skins of persons suffering from certain diseases; the most familiar instance is that produced in tuberculin tests. such as those of C. von Pirquet and C. Mantoux. A small amount of tuberculin, which contains antigenic constituents of tubercle bacilli, is injected into or under the skin; if infection with tubercle bacilli, whether active or dormant, is present, the injection is followed by a typical skin reaction.

With refinements of technique, precipitins can be demonstrated in the serum when the skin reactions are positive; for example, precipitins for tuberculin are found in the serums of persons who respond to the tuberculin test. These responses may therefore be supposed to be caused by reactions between antigen and antibody in the skin.

Reactions of this tuberculin type must be distinguished from those like the Béla Schick and G. F. Dick reactions. In the two latter reactions poisonous substances, the toxins of diphtheria bacillus and streptococcus. produce a response unless they are neutralized by antibody; the reaction appears if antibody is not present in sufficient amount.

Reactions of the tuberculin type are caused by local interaction of antibody and antigen; the reaction does not appear when antibody is not present.

Serum Sickness.—If anaphylaxis comparable to that which occurs in guinea pigs and dogs were at all common in human beings, treatment with serums derived from other species would have been out of the question. Fortunately. anything comparable to anaphylactic shock is extremely rare Serum sickness, which is the common response to a single injection of foreign serum, is

characterized by the onset, after about ten days, of urticaria, fever, pains on the joints and swelling near the site of injection. It is supposed that these symptoms are caused by reaction of antibodies, formed in response to the injections, with proteins of the foreign serum still remaining in the body.

Atopy, Hay Fever. — Certain people suffer from running of the nose and eyes after inhaling pollens of grasses. This "hay fever" is an example of a type of hypersensitivity which is characterized by the appearance of a set of symptoms after contact with some substances or a range of substances. These substances include pollens, horse dander and cutaneous debris of other species of animals, various foods and various drugs. The symptoms include, besides the running eyes and nose of hay fever, asthma, urticaria, gastrointestinal disturbances, eczema and local reactions at the site of application of some substances to the skin. Injection of a small amount of an extract from the substance that excites these symptoms (pollen, dander, etc.) into the skin of a sensitive person is promptly followed by reddening and a weal.

It is natural to regard these general and local reactions as comparable to the anaphylaxis and hypersensitiveness of the skin described earlier, and to attribute them to interaction of antibodies in the serum and antigens in the exciting substances. The serum of these subjects contains some kind of antibody, for if it is injected into the skin of normal persons it will usually sensitize the skin to the corresponding antigen. This hypothetical antibody has been called a reagin. We have seen that the amounts of antigen needed to sensitize an animal may be extremely small. The reagin may be formed in response to minute amounts of antigen absorbed from the intestine or from the respiratory passages.

When either these hypersensitive or normal persons are immunized by a series of injections of the exciting substance, a precipitin appears in the serum; such serums neutralize the sensitizing action of reagin. Two kinds of antibody are therefore formed by hypersensitive persons: the reagin which sensitizes and the normal precipitin which, if sufficient is present, combines with antigen and thereby neutralizes the sensitizing action of reagin. Reagin and normal precipitin differ in structure, for reagin is more readily destroyed by heat.

This hypersensitivity runs in families, although one member of a family may get hay fever when exposed to grass pollen and another get urticaria after eating certain foods. The abnormality of these hypersensitive persons seems to be twofold: they form antibodies in response to exposures to an antigen that would be insufficient to stimulate the formation of antibodies in normal persons; and the antibodies formed differ from normal antibodies. We have still to account for sensitivity to such relatively simple substances as formaldehyde and diphenylamine which, by themselves, would not serve as antigens. There is considerable evidence in favour of the theory that these substances form loose complexes with the proteins of the body and that these complexes serve as antigens and stimulate the production of reagins. (See also BACTERIAL AND INFECTIOUS DISEASES.) (J. R. MAR.)

PROPHYLACTIC PRODUCTION OF ACTIVE IMMUNITY

By means of artificial immunization man has attempted to improve on natural processes of immunization which occur whenever a human or animal population is exposed to certain infections. This natural phenomenon often fails to reach and immunize all of the susceptibles in the population, and unfortunately many of those exposed develop the disease in a severe or fatal form before immunity develops. Through artificial procedures it became increasingly possible to cause people to become immune to a certain disease at a desired time and age and to do so without causing them to be exposed to the hazards of the fully developed illness.

The advent of chemotherapy and the antibiotics did not decrease the importance of active immunization. It was still more important to prevent disease than to employ even a good method of treatment after a person became ill. People still died of infectious diseases in spite of the miracle drugs. The threat of bacteriological warfare which could cause wholesale disability was sufficient reason for continuing to immunize against those diseases for which prophylactic agents were available, and to seek for vaccines not yet available.

Artificial immunization may be brought about by the introduction into man or animals of a variety of agents designated as antigens. These antigens may be living or dead bacteria or other micro-organisms; chemically purified derivative of bacteria; toxins elaborated by bacteria; mixtures of toxin and the specific counteracting immune substance, antitoxin; or toxoids, which are toxins treated in such a manner that they are no longer poisonous, but still capable of stimulating immunity.

Living, unmodified micro-organisms are rarely used to immunize man because of the dangers associated with this practice. Before the discovery of smallpox vaccine in 1796 people were immunized against smallpox by injecting them with material taken from the skin eruption of persons ill with the disease. Some individuals inoculated in this way developed smallpox but, so great was the fear of this disease, many people preferred to take the smaller chance of dying from the inoculated disease rather than develop the more often fatal natural one. Probably, even in this case, there was some weakening of the virus through the handling it received before being injected. The route of inoculation was probably responsible for the lesser virulence of the inoculated material.

Bacteria or viruses which have been weakened or attenuated in some way are more useful as vaccines than fully virulent micro-organisms. A variety of procedures used for this purpose, including growing the organisms under conditions not optimum for their development, exposing them to physical and chemical agents, or adapting them to another animal so thoroughly that they become relatively nonvirulent for man. The latter procedure proved to be especially valuable. Yellow-fever vaccine, for example, was developed through application of this principle. The virus of this disease was first passed through many generations of mice, then through tissue culture and finally propagated in developing chick embryos. The virus by then was so altered that an amount of living virus equivalent to millions of infectious doses of the original, unattenuated virus could be injected into humans without causing yellow fever. Millions of people have been protected against yellow fever with this type of vaccine.

BCG (Bacillus Calmette-Guérin), the vaccine widely used against tuberculosis, is made from attenuated tubercle bacilli. In this case the bovine-type tubercle bacilli, originally virulent for man and animals, were rendered harmless by growing them for many generations on a potato-bile culture medium. It is generally agreed by authorities in the tuberculosis field that BCG is safe and that its use markedly lowers the incidence of infection.

Another type of vaccine, and possibly the most desirable, is one containing killed or inactivated micro-organisms. Vaccination against such diseases as typhoid fever, whooping cough, rabies and influenza is accomplished with killed vaccines. In the inactivation of the micro-organisms a great variety of physical and chemical agents are employed. Moderate heat and low concentrations of formalin and phenol are most commonly used. H. L. Hodes et al. first demonstrated that ultra-violet light is capable of inactivating the virus of rabies with less impairment of its immunogenic capacity than occurs when other physical or chemical agents are employed. An improved procedure, using ultra-violet light as the killing agent, was adopted for commercial production of some types of vaccine, especially antirabic vaccine. According to the Expert Committee on Rabies of the World Health organization, ultra-violet killed antirabic vaccine is superior to all others.

It appeared in the 1950s that future immunization would be carried out increasingly with purified antigens, freed from the extraneous materials which are inactive in the production of immunity but which sometimes may cause 'reactions in persons inoculated. These preparations, usually proteins or complex polysaccharides, are concentrated so as to have their immunizing power enhanced several thousand times as compared with an equivalent volume of the unpurified vaccine. A vaccine of this type, designed to immunize against several of the most prevalent types of pneumococci, the micro-organisms which cause pneumonia, became available for general use.

In some instances it is more important to stimulate protection against the toxin produced by a bacterium than against the organism itself since the symptoms of the disease may be due primarily to the toxin and not to the presence of the bacteria in the body. Inoculation with repeated graduated doses of toxin, beginning with amounts insufficient to cause local or systemic reactions, produces immunity to the toxin. This method was rarely used because it required too many injections and was also likely to give rise to undesirable reactions. However, it has been used in the Dick method of immunization against scarlet fever, because it has not been possible to produce a scarlet-fever toxoid with any degree of immunizing potency.

Mixtures of toxin and antitoxin, prepared in such a manner that there was a very slight excess of toxin, were the first prophylactics to be used in diphtheria immunization. They had the disadvantage, however, of sensitizing against horse serum. Furthermore, they were inferior in immunizing potency to toxoid and were almost entirely replaced by the latter.

Toxoid is usually made by exposing toxin to the action of formalin for several weeks. The resulting product seems to be identical with the original toxin in every respect except for the loss or reduction of its ability to produce poisonous effects in man or animals. Toxoids are widely used in immunization against diphtheria and tetanus and to a lesser extent as prophylactic agents against gas gangrene and staphylococcus infections (boils, carbuncles, septicaemia). Toxoids made from purified toxins are more potent and less likely to give rise to undesirable side reactions than those which were formerly available. In 1946 L. Pillemer and his associates announced that they had been able to produce purified crystalline tetanus toxin, from which it should be possible to produce even better toxoids. It was found possible to purify toxoids by various chemical methods. This is of considerable importance because of the increasing need of immunizing adults in whom undesirable reactions, following the injection of impure toxoids, are more likely to be severe.

Earlier attempts at immunization usually employed a single injection of antigen. In instances where a living vaccine is used; *i.e.,* in smallpox immunization, a single injection suffices because the organisms originally inoculated multiply manyfold. On the other hand, a single injection of vaccine consisting of killed bacteria or inactivated virus is usually only partially effective or offers complete protection for relatively short periods of time. The ideal method mould be to administer the vaccine in a large number of injections spread over a relatively long period of time. Practical considerations usually require that the number of injections for most diseases be limited to something like three or, at most, five.

With the small number of injections ordinarily employed, better immunity can be stimulated if the doses are given at considerable intervals. Originally, doses were spaced not more than seven to ten days apart for fear of encountering undesirable reactions of the anaphylactic type. Experience showed that the vaccines and toxoids in use were not likely to cause these undesirable reactions, and the tendency was to space the injections at greater and greater intervals. Three or four weeks is the usual spacing between injections but even better results can be obtained with intervals of three months or more.

The number of injections used and their spacing is determined to a large extent by whether the antigen contains an adjuvant. Potassium alum has been the most widely used adjuvant but there are others such as protamine aluminum phosphate or calcium phosphate. Perhaps the best adjuvant discovered by the 1950s was lanolin, but this substance could not be used in materials designed for human use. The mode of action of adjuvants is not fully understood but it appears that they may act in at least two mays. Antigens containing adjuvants are absorbed very slowly so that the effect is as if many repeated injections had been given. They also apparently stimulate the mechanism responsible for the production of immunity.

By adding alum to diphtheria toxoid it nas found that the percentage of individuals successfully immunized nith tno doses of this material was as great as when three doses of fluid toxoid (not containing alum) were used. It was claimed by several investigators that it is possible to immunize very young infants with whooping-cough vaccine containing alum whereas the same observers were unable to accomplish this end with vaccine lacking alum. Since about half the deaths from whooping cough occur in children under six months of age, this discovery offered new life-saving possibilities. On the other hand, alum was of no value in enhancing the potency of influenza vaccine. Unfortunately, adjuvants not only potentiate the desirable features of a vaccine or toxoid but may also enhance its capacity to produce undesirable side reactions. Further purification would remove foreign antigenic materials and thus would decrease the already low incidence of allergic reactions.

As stated above, ridding vaccines and toxoids of their potentialities for producing undesirable reactions became of greater importance because of the need of immunizing adolescents and adults. For example, when artificial immunization against diphtheria was first begun, it appeared that one course of injections would lead to lifelong immunity. It was not appreciated at that time that, because there was still a great deal of the disease in the community, the original artificial immunization was being bolstered continuously by the natural immunization process. Parallel with the reduced prevalence of diphtheria was a reduction in the opportunities for natural immunization to occur. Consequently it became recognized that reimmunization is necessary at some time subsequent to the primary immunization. Usually only a single injection is given as a "booster" dose and the amount of antigen used may be much smaller than that considered necessary in the primary immunization. In the U.S. it is believed that primary immunization should be done in early infancy with booster injections at about one year of age, at school entrance and at some later date such as graduation from grammar school.

In order to make it unnecessary for persons, especially children, to be subjected to numerous injections of vaccines and toxoids the practice of combining antigens became more prevalent. Diphtheria toxoid, tetanus toxoid and pertussis vaccine were combined with apparently excellent results. It mas formerly thought that immunization against diphtheria could not be successfully carried out at an earlier age than six months but this was found to be untrue. V. K. Volk's studies reported in 1947 seemed to indicate that there was a definite limit to the number of antigens that could be combined unless some way was found to forestall the high incidence of unwanted reactions that follow the use of combinations of four or five of the folloning antigens: diphtheria toxoid, tetanus toxoid, pertussis vaccine, typhoid vaccine and scarlet-fever toxin. It mas also evident that, unless markedly improved antigens were developed the dilution effect inherent in the combination would place a limit upon the number of component antigens.

Attempts to prevent an undue number of injections also took another course; *i.e.,* introduction of the antigens by some method not requiring its deposition in the tissues. Numerous investigators experimented with intranasal immunization by drops or by spraying the mucosa. Oral immunization was also tried by a number of research workers. G. Bousfield in 1945 suggested that diphtheria toxoid be incorporated in pastilles which could be sucked like hard candy, but indicated that this method could be used only for booster doses. In general, however, the results of studies along these lines were disappointing. It dppeared that the most fruitful course would be to continue attempts at further purification of the several antigens and the devising of techniques for combining them successfully.

Excellent results have been obtained through the use of prophylactics against diphtheria, tetanus, whooping cough, yellow fever and smallpox; good results in typhus. Rocky Mountain spotted fever, equine and Japanese encephalitis and typhoid, and poor or no results in bacillary dysentery, scrub typhus and influenza. In the case of the latter disease the reason for relative failure nas that new types of influenza virus, against which the vaccines mere not effective, kept cropping up every year or tno.

From the earliest work in this field it has been the practice to study immunizing materials extensively in laboratory animals

until adequate proof of their value could be adduced. These laboratory studies were usually followed by careful field studies in human populations, designed to evaluate the products further. Even after they came into general use, the various antigens used in artificial immunization continued to be on trial. Many vaccines and other immunogens failed to survive this rigorous sort of evaluation and sooner or later dropped out of use. Because vaccines and toxoids in use survived this vigorous process of elimination, they are, in general, admirably effective and are in large part responsible for the great reduction in the number of cases and deaths from such diseases as smallpox and diphtheria, diseases which heretofore ravaged so many communities.

IMMUNITY, in law, a term for exemption from liability, principally used in the legal sense in connection with exterritoriality (*q.v.*).

IMOLA, a town and episcopal see of Emilia, Italy (anc. Forum *Cornelii*), province of Bologna, 21 mi. S.E. of that town by rail, 140 ft. above sea level. Pop. (1951) 24,245. The cathedral of S. Cassiano possesses interesting reliquaries, and contains the tomb of Petrus Chrysologus, archbishop of Ravenna (d. 449), a native of Imola. S. Domenico has a fine Gothic portal and S. Maria in Regola an old campanile. The town also contains some fine palaces. The communal library has some manuscripts, including a psalter with miniatures, that once belonged to Sir Thomas More (1304).

IMPALLA: see PALLA.

IMPATIENS, a genus (family Balsaminaceae) of annual or biennial herbs, sometimes becoming shrubby, comprising about 350 or more species, chiefly natives of the mountains of tropical Asia and Africa, but also found widely distributed in the north temperate zone and in south Africa. The flowers, which are purple, yellow, pink or white and often showy, are spurred and irregular in form and borne in the leaf axils. *Impatiens nolitangere,* touch-me-not, an annual succulent herb with yellow flowers, is probably wild in moist mountainous districts in north Wales, Lancashire and Westmorland. I. *roylei,* a tall hardy succulent annual with rose-purple flowers, a Himalayan species, is common in England as a self-sown garden plant or garden escape. In North America they are often called jewel weed. Two of the commonest, the spotted touch-me-not (I. *biflora*), with orange-yellow flowers, mottled with brown, and the pale touch-me-not (I. *pallida*), with pale yellow flowers, are widely distributed across the continent.

I. *balsamina,* the common balsam of gardens, a well-known annual, is a native of India and China; it is one of the showiest of garden flowers and of comparatively easy cultivation. I. *sultani,* a handsome plant, with scarlet flowers, a native of Zanzibar, is grown in a greenhouse in winter, but used as a summer bedding plant outdoors.

IMPEACHMENT. The U.S. constitution provides that "The House of Representatives.. . shall have the sole Power of Impeachment" (art. i, sec. 2, cl. 5); "The Senate shall have the sole Power to try all Impeachments" (art. i, sec. 3, cl. 6).

"The President, Vice President and all civil Officers . . . shall be removed from Office on Impeachment for, and Conviction of, Treason. Bribery, or other high Crimes and Misdemeanors" (art. ii, sec. 4).

In Great Britain conviction on an impeachment may include fines and imprisonment. The U.S. constitution. however, provides that judgment on an impeachment shall extend no further than removal and disqualification from office. This difference has had a profound effect on the history of impeachment in the U.S.

Impeachment trials held in the United States senate are given below.

1. William Blount, senator from Tennessee, charged (1797) with conspiring and contriving to excite the Creek and Cherokee Indians against the king of Spain. The senate held that a senator was not a civil officer within the meaning of the constitution. The impeachment was dismissed, but Blount was expelled from the senate.

2. John Pickering, judge of the district court of New Hampshire, charged (1804) with drunkenness, tyrannous conduct and disregard for the terms of statutes. Convicted.

3. Samuel Chase, associate justice of the U.S. supreme court, charged (1805) with intemperate, arbitrary and unjudicial conduct in sedition-law trials. Acquitted.

4. James H. Peck, judge of the U.S. for the district of Missouri, charged (1830) with tyrannous treatment of counsel and arbitrary conduct. Acquitted.

5. West H. Humphrevs, judge of the district court of the U.S. for the eastern, middle and western districts of Tennessee, charged (1862) with supporting the secession movement. Convicted.

6. Andrew Johnson (*q.v.*), the only president ever impeached, charged (1868) with the attempted removal of the secretary of war, Edwin M. Stanton, contrary to statute, inducement of a general of the army to violate an act of congress and contempt and reproach of congress. Acquitted by the margin of a single vote.

7. William Belknap, former secretary of war, charged (1876) with accepting profits from his own appointee to an army trading post. The senate voted down Belknap's defense that he could not be impeached since he had already resigned. He was nonetheless acquitted.

8. Charles H. Swayne, judge of the northern district of Florida, charged (1905) with falsifying expense accounts, nonresidence and use of a private car belonging to a railroad in receivership. Acquitted.

9. Robert W. Archbald, judge of the U.S. commerce court, charged (1913) with using his official position for private gain and accepting loans from litigants. Convicted.

10. Harold Louderback, judge of the northern district of California, charged (1932) with favouritism in the appointment of receivers. Acquitted.

11. Halsted L. Ritter, judge of the southern district of Florida, charged (1936) with bankruptcy irregularities and income tax evasion. Convicted.

The principal criticism directed at the impeachment process is that it is cumbersome and anachronistic. An impeachment trial occupies the entire senate for from 16 days to six weeks, fills thousands of pages of testimony and involves conflicting and troublesome political pressures. Repeated attempts in congress to amend the procedure, however, proved uniformly unsuccessful. A partial explanation of the resistance to change is the fact that impeachment is regarded as an integral part of the American system of checks and balances.

Instead: a more practical solution has emerged. The resignation of the officer under inquiry has generally terminated the proceedings (despite the ruling in the Belknap case). For instance, in the case of District Judge George W. English (1926) the senate, after it had received the articles of impeachment from the house and had convened as a trial court, dismissed the impeachment upon notification of his resignation. A later example occurred when the house committee on the judiciary, after noting the removal by resignation of District Judge Albert W. Johnson (1946),

refused to recommend impeachment because a trial would have occupied the senate unduly "when that body is engaged in so many issues vital to the welfare of the nation."

England. — Impeachment in England is in the form of judicial parliamentary procedure against criminals, in which the house of commons are the prosecutors and the house of lords the judges. It differs from bills of attainder (*q.v.*) in being strictly judicial. When the house of commons has accepted a motion for impeachment, the mover is ordered to proceed to the bar of the house of lords. and there impeach the accused "in the name of the House of Commons, and of all the Commons of the United Kingdom." The charges are formulated in articles, to each of which the accused may deliver a written answer. The commons appoint managers to conduct the prosecution, but the whole house in committee attends the trial. The defendant may appear by counsel. The president of the house of lords is the lord high steward in the case of peers impeached for high treason; in other cases the lord chancellor. The hearing takes place as in an ordinary trial, the defense being allowed to call witnesses if necessary, and the prosecution having a right of reply. At the end of the case the president "puts to each peer, beginning with the junior baron, the questions upon the first article, whether the accused be guilty of the crimes charged therein. Each article is proceeded with separately in the same manner, the lord high steward giving his own opinion the last" (Sir T. E. May's Parliamentary Practice). Should the accused be found guilty, judgment follows if and only if the commons move for it. The commons thus retain the power of pardon in their own hands, and this right they have in several cases expressly claimed by resolution, declaring that it is not parliamentary for their lordships to give judgment "until the same be first demanded by this House." Spiritual peers occupy an anomalous position in the trial of peers, as not being themselves ennobled in blood; it is customary for them to withdraw before judgment is given, entering a protest "saving to themselves and their successors all such rights in judicature as they have by law, and by right ought to have." An impeachment, unlike other parliamentary proceedings, is not interrupted by prorogation, nor even by dissolution. Proceedings in the house of commons preliminary to an impeachment are subject to the ordinary rules, and in the Warren Hastings case an act was passed to prevent the preliminary proceedings from discontinuance by prorogation and dissolution.

A royal pardon cannot be pleaded in bar of an impeachment, though it is within the royal prerogative to pardon after the lords have pronounced judgment. The point was raised in the case of the earl of Danby in 1679, and the rule was finally settled by the Act of Settlement. Persons found guilty on impeachment may be reprieved or pardoned like other convicts. Impeachment will lie against all kinds of crimes and misdemeanours, and against offenders of all ranks. In the case of Simon de Beresford, tried before the house of lords in 1330, the house declared "that the judgment be not drawn into example or consequence in time to come, whereby the said peers may be charged hereafter to judge others than their peers," from which Sir William Blackstone and others have inferred that "a commoner cannot be impeached before the Lords for any capital offence, but only 'for high misdemeanours." In the case of Edward Fitzharris in 1681, the house of commons in answer to a resolution of the Lords suspending the impeachment, declared it to be their undoubted right "to impeach any peer or commoner for treason or any other crime or misdemeanour." And the house of lords has in practice recognized the right of the commons to impeach whomsoever they will. The procedure has, however. been reserved for great political offenders whom the ordinary powers of the law might fail to reach. It fell into desuetude. The last impeachments were those of Warren Hastings (1788–95) and Lord Melville (1806), but an unsuccessful attempt was made by Thomas C. Anstey to impeach Lord Palmerston in 1848.

IMPERIA, a city of Liguria, Italy, the capital of the province of Imperia, on the coast of the Ligurian sea, 46 mi. E. of Nice by rail and 70 mi. S.W. of Genoa, 115 ft. above sea level. Pop. (1957 est.) 32,132 (mun.). It consists of a picturesque old town on the heights and a modern town of villas on the lower slopes. The dome of the principal church, a large structure of 1780, was rebuilt in 1821. About 2 mi. N.E. on the same bay is Oneglia, with a fine church, S. Giovanni Battista (designed by Gaetano Amoretti), a hospital (1785) and a large prison. It suffered considerably from the earthquake of 1887. Both towns have small but safe harbours, and both are embowered amid olive groves. The district is famous for the quality of its oil. During World War II, Imperia's port and industrial section suffered damage.

Imperia, formerly Porto Maurizio, appears as Portus Maurici in the Maritime Itinerary. After being subject to the marquises of Turin (11th century) and of Clavesana, it was sold by Boniface of Clavesana in 1288 to Genoa in return for a yearly payment; in 1354 it became the seat of the Genoese vicar of the western Riviera, and thenceforth shared the fortunes of Genoa.

IMPERIAL CHAMBER (Reichskammergericlzt), the supreme judicial court of the Holy Roman empire, during the period between 1495 and the dissolution of the empire in 1806. From the early middle ages there had been a supreme court of justice for the empire—the Hofgericht, in which the emperor himself presided and a body of assessors found the judgments. The Hofgericht was connected with the person of the emperor; it ceased to act when he was abroad; it died with his death. Upon him it depended for its efficiency; and when, in the 15th century, the emperor ceased to command respect, his court lost the confidence of his subjects. After 1450 it ceased to sit.

Its place was taken by the Kammergericht, which appeared side by side with the Hofgericht from 1415 and after 1450 replaced it altogether. The king (or his deputy) still presided in the Kammergericht and it was still his personal court; but all the members of the new "chamber" were now officials—the consiliariz of the imperial aula (or Kammer, whence the name of the court). It was generally the legal members of the council who sat in the Kammergericht (see XULIC COUNCIL); and as they were generally doctors of civil law, the court which they composed tended to act according to that law, and thus contributed to the "reception" of Roman law into Germany toward the end of the 15th century.

Even the *Kammergericht,* however, fell into disuse in the later years of the reign of Frederick III; and the creation of a new and efficient court became a matter of pressing necessity, and was one of the most urgent of the reforms which were mooted in the reign of Maximilian I.

This new court was eventually created in 1495; and it bore the name of *Reichskammergericht,* or imperial chamber. It was distinguished from the old Kammergericht by the essential fact that it was not the personal court of the emperor but the official court of the empire (or Reich—whence its name). The emperor appointed the president; the empire nominated the assessors or judges. More exactly, the emperor nominated, according to the regular usage of later times, a certain number of the members—partly on his authority as emperor and partly as the sovereign of his hereditary states; the rest of the judges. who formed the majority, were nominated by the empire—partly by the electors and partly by the six ancient circles. There were originally 16 judges (afterward, as a rule. 18): half of these were to be doctors of Roman law, and half were to be knights; but after 1495 it became necessary that the latter should be learned in Roman law, even if they had not actually taken their doctorate. Thus the empire was at last possessed of a court—a court resting on the enactment of the diet and not on the emperor's will; a court paid by the empire and not by the emperor; a court resident in a fixed place (until 1693, Speyer. and afternard. from 1693 to 1806, Wetzlar) and not attached to the emperor's person.

The great result it served to achieve was the final "reception" of Roman law as the common law of Germany. That the imperial chamber should itself administer Roman law was an inevitable result of its composition; and it was equally inevitable that the composition and procedure of the supreme imperial court should be imitated in the various states which composed the empire, and that Roman law should thus become the local, as it was already the central, law of the land.

The province of the imperial chamber, as it came to be gradually defined by statute and use, extended to breaches of the public peace, cases of arbitrary distraint or imprisonment, pleas which concerned the treasury, violations of the emperor's decrees or the laws passed by the diet, disputes about property between imme-

diate tenants of the empire or the subjects of different rulers, and finally suits against immediate tenants of the empire—with the exception of criminal charges and matters relating to imperial fiefs, which went to the aulic council. The court also had cognizance in cases of refusal to do justice, and it acted as a court of appeal from territorial courts in civil, and, to a small extent, in criminal cases; but it had no authority as a court of appeal in all territories which enjoyed a *privilegium de non appellando* (such as, for example, the territories of the electors).

The business of the court, however, was badly done; the delay was interminable, largely a result of want of funds, which prevented the maintenance of the proper number of judges. In all its business it suffered from the competition of the aulic council (*q.v.*); for that body, having lost all executive competence after the 16th century, had also devoted itself exclusively to judicial work. Composed of the personal advisers of the emperor, the aulic council did justice on his behalf (the erection of a court to do justice for the empire having left the emperor still possessed of the right to do justice for himself through his *consiliarii*); and it may thus be said to be the descendant of the old *Kammergericht.*

The competition between the aulic council and the imperial chamber was finally regulated by the treaty of Westphalia, which stipulated that the court which first dealt with a case should alone have competence to pursue it.

See J. N. Harpprecht, *Staatsarchiv des Reichskammergerichts* (1757–85); G. Stobbe, *Reichshofgericht und Reichskammergericht* (Leipzig, 1878); R Schroder, *Lehrbuch der deutschen Rechtsgeschichte* (Leipzig, 1904). (E. B.)

IMPERIAL CHEMICAL INDUSTRIES LIMITED is the largest British chemical manufacturer and one of the largest industrial undertakings in the British Commonwealth. The situation that was to lead to the formation of I.C.I. developed during World War I. Although Great Britain had produced many of the pioneers of the chemical industry, the country lacked facilities at the outbreak of war to make the synthetic nitrate needed in the manufacture of explosives and fertilizers and could not produce many essential dyestuffs. By 1918 many technical deficiencies had been repaired, but the need for a strong chemical industry was clear. After the war, several explosives manufacturers banded together to form an organization which became Nobel Industries, Ltd. At about the same time, the dyestuffs industry was also being re-formed and several of the principal manufacturers had sunk their separate identities in the British Dyestuffs Corporation, Ltd. At the end of 1920, the four outstanding organizations in the British chemical industry were the British Dyestuffs Corporation, Ltd.; Brunner, Mond and Co., Ltd.; Nobel Industries. Ltd.; and the United Alkali Co., Ltd.

In other countries even larger corporations had arisen enjoying the advantages of large-scale enterprise. With their greater financial resources they could support research on the grand scale and maintain large technical service organizations for the benefit of their customers. In the light of such developments, the structure of the British chemical industry called for review. Sir Harry (later Lord) McGowan, the head of Nobel, and Sir Alfred Mond (later Lord Melchett) of the Brunner, Mond enterprise took action to bring together their own companies and the other two large groups, British Dyestuffs and United Alkali. Negotiations began in July 1926 and on Dec. 7, 1926, Imperial Chemical Industries, Ltd., came into being.

In more than 100 factories throughout England, Scotland, Wales and Northern Ireland, I.C.I.'s employees, numbering about 112,000, make about 12,000 products, ranging from heavy chemicals, blasting explosives and fertilizers to paints, plastics and synthetic fibres. Through its metals division, I.C.I. also enters into the nonferrous metals industry. Overseas, I.C.I. has manufacturing or selling organizations in almost every country. (GY. R.)

IMPERIAL CITIES or IMPERIAL TOWNS is the usual English translation of *Reichsstädte,* an expression of frequent occurrence in German history. These were cities and towns subject to no authority except that of the emperor, or German king; in other words, they were immediate. The earliest of them stood on the demesne land of their sovereign, and they often grew up around his palaces.

A distinction was thus made between a *Reichsstadt* and a *Landstadt,* the latter being dependent upon some prince, not upon the emperor direct.

The term *Freie Reichsstadt,* sometimes used in the same sense as *Reichsstadt,* is rightly only applicable to seven cities—Basle, Strasbourg, Speyer, Worms, Mainz, Cologne and Regensburg. Having freed themselves from the domination of their ecclesiastical lords, these called themselves *Freistadte* and in practice their position was indistinguishable from that of the *Reichsstadte.*

In the middle ages many other places won the coveted position of a *Reichsstadt.* Some gained it by gift and others by purchase; some won it by force of arms, others usurped it during times of anarchy, while a number secured it through the extinction of dominant families, like the Hohenstaufen. There were many more free towns in southern than in northern Germany, but their number was continually fluctuating, for their liberties were lost much more quickly than they were gained. Mainz was conquered and subjected to the archbishop in 1462.

Some free towns fell into the hands of various princes of the empire, and others placed themselves voluntarily under such protection. Some, like Donauworth in 1607, were deprived of their privileges by the emperor on account of real, or supposed, offenses, and others were separated from the empire by conquest. In 1648 Besançon passed into the possession of Spain; Basle had already thrown in its lot with the Swiss confederation, while Strasbourg, Colmar, Haguenau and other free towns were seized by Louis XIV.

Meanwhile the free towns had been winning valuable privileges in addition to those which they already possessed, and the more wealthy among them, like Lubeck and Augsburg, were practically *imperia in imperio,* waging war and making peace, and ruling their people without any outside interference. But they had also learned that union is strength. They formed alliances among themselves, both for offense and for defense, and these *Städtebünde* had an important influence on the course of German history in the 14th and 15th centuries. These leagues were frequently at war with the ecclesiastical and secular potentates of their districts and in general they were quite able to hold their own in these quarrels. The right of the free towns to be represented in the imperial diet was formally recognized in 1489 at the diet of Frankfurt, and about the same time they divided themselves into two groups, or benches, the Rhenish and the Swabian. By the peace of Westphalia in 1648 they were formally constituted as the third college of the diet and later as the third estate of the empire. A list drawn up in 1422 mentions 75 free cities and another drawn up in 1521 mentions 84, but at the time of the French Revolution the number had decreased to 51.

At this time there were 14 Rhenish free cities: Cologne, Aachen, Liibeck, Worms, Speyer, Frankfurt-on-Main, Goslar, Bremen, Hamburg, Muhlhausen, Nordhausen, Dortmund, Friedberg, and Wetzlar.

The Swabian free cities were: Regensburg, Augsburg, Nuremberg, Ulm, Esslingen, Reutlingen, Nordlingen, Rothenburg-ob-der-Tauber, Schwabisch-Hall, Rottweil, Uberlingen, Heilbronn, Memmingen, Gmund, Dinkelsbiihl, Lindau, Biberach, Ravensburg, Schweinfurt, Kempten, Windsheim, Kaufbeuren, Weil, Wangen, Isny, Pfullendorf, Offenburg, Leutkirch, Wimpfen, Weissenburg (Wissembourg), Giengen, Gengenbach, Zell, Buchhorn, Aalen, Buchau and Bopfingen. But a large proportion of these free cities, both Rhenish and Swabian, had as little claim to their exceptional positions as the pocket boroughs of Great Britain and Ireland had before the passing of the Reform bill of 1832.

By the peace of Lunéville in 1801 Cologne, Aachen, Worms and Speyer were taken by France, and by the decision of the imperial deputation of 1803 six cities only—Hamburg, Lubeck, Bremen, Augsburg, Frankfurt-on-Main and Nuremberg—were allowed to keep their *Reichsfreiheit,* or in other words to hold directly of the empire. This number was soon further reduced. On the dissolution of the empire in 1806 Augsburg and Nuremburg passed under the sovereignty of Bavaria, and Frankfurt was made the seat of a duchy for Karl Theodor von Dalberg, elector and archbishop of Mainz, who was appointed prince primate of

the Confederation of the Rhine. When the German confederation was established in 1815, Hamburg, Liibeck, Bremen and Frankfurt were recognized as free cities, and the first three continued to hold that position in the later. German empire; but Frankfurt-on-Main, in consequence of the part it took in the war of 1866, lost its independence and was annexed by Prussia.

In the earlier years of their existence the free cities were under the jurisdiction of an imperial officer, who was called the *Reichsvogt* or imperial advocate, or sometimes the *Reichsschultheiss* or imperial procurator. As time went on many of the cities purchased the right of filling these offices with their own nominees; and in several instances the imperial authority fell practically into desuetude except when it was stirred into action by peculiar circumstances.

The internal constitution of the free cities was organized after no common model, although several of them had a constitution drawn up in imitation of that of Cologne, which was one of the first to assert its independence (1288).

IMPERIAL CONFERENCE: ***see*** CONFERENCE.

IMPERIALISM. Imperialism is the policy of a state aiming at establishing control beyond its borders over people unwilling to accept such control. Because of this unwillingness imperialist policy always involves the use of power against its victims. It has therefore often been considered morally reprehensible, and the term has been employed in international propaganda to discredit an opponent's policy. This polemic use is facilitated by the fact that the imperialist nature of a policy is sometimes difficult to discover. For in foreign policy many means and methods can serve either imperialism or other purposes, depending upon the motivation of their user. The manifold and sometimes subtle or hidden political, financial, economic, technical and cultural activities of one state in another may aim at the creation of sympathy, friendship or influence, but they may also be techniques to gain control. Often only the result of a given policy can tell what the intention has been; and many imperialist policies, ending in failure, remain undetected. However, enough have been successful throughout the ages to show that, though the term as here defined dates back to only the last half of the 19th century, the phenomenon it describes is as old as civilization and that ancient and modern imperialism have in common not only the end but many means.

HISTORY

Ancient Times. — In eastern Asia, the Chinese empires of the Chou, Ch'in and Han dynasties (1766?–1123? B.C., 221–206 B.C., 206 B.C.–A.D. 221, respectively) and later the T'ang dynasty (618–906) extended over vast territories in the name of bringing the blessings of Chinese civilization to "barbarians." In northern India the dynasties of the Maurya (320–*c.* 185 B.C.) and later the Gupta (320–480) ruled over large empires without advancing any excuses and claimed suzerainty over tribes far beyond the borders of the empire.

The history of western Asia and the Mediterranean is an unending succession of empires, many building upon the ruins of preceding ones. About 25 centuries before Christ, Lugal-zaggisi united the Sumerians under his rule in Mesopotamia in what might have been the first Sumerian empire. It was followed around 2550 B.C. by the Semitic empire of Sargon of Akkad and thereafter by the second Sumerian empire lasting from the 22nd to the 21st centuries. The Babylonian empire came next. It was dominated by the personality of Hammurabi (*c.* 19th century B.C.) whose influence lasted into the Christian era, long after his empire had succumbed to the invasion of Indo-European tribes from eastern Europe.

The scene then shifted to the Nile where the Pharaohs established their empires from the 16th to the 13th centuries B.C. But in contrast to preceding rulers of empire, the Pharaohs could not expand their empire to coincide with the then known world. Failing to defeat the Hittites in northern Syria, they agreed upon peaceful coexistence, each guaranteeing the integrity of the other's empire.

The heritage of these two empires fell to the tyrannical empire of the Assyrians. It reached its apex around 660 B.C. and was soon thereafter, from the 6th to the 4th centuries, replaced by the Persian empire. Persian rule was in strong contrast to the Assyrian in its liberal treatment of subjected peoples, assuring it long duration.

It eventually gave way to the imperialism emanating from Greece. When Greek imperialism reached an apex under Alexander the Great (356–323 B.C.), a union of the eastern Mediterranean with western Asia was achieved. But the cosmopolis, in which all citizens of the world would live harmoniously together in equality, remained a dream of the great Alexander. It was realized when the Romans built their empire from Britain to Egypt and based it, ideologically, upon the Stoic and Christian concepts of the unity and brotherhood of man.

This idea of empire as a unifying force was never again realized after the fall of Rome. The nations arising from the ashes of the Roman empire in Europe, and in Asia on the common basis of Islamic civilization, pursued their own imperialisms. Imperialism became a divisive force among the peoples of the world.

Modern Times. — Some novel, mostly modern versions of old forces provided the impetus behind these modern imperialisms: nationalism (*q.v.*), industrialization, improved communications, discovery of new territories and even growing humanitarianism. People of all classes became involved in the drives for empire, though they acted on different motivations: merchants and missionaries, militarists and adventurers, nationalists and politicians.

Three periods stand out in the modern era in which competing imperialist policies of the nations led to the creation of vast empires, primarily of the colonial kind. Between the 15th century and the middle of the 18th, England, France, the Netherlands, Portugal and Spain built empires in the Americas, India and the East Indies. For almost a century thereafter relative calm in empire building reigned as the result of a strong reaction against imperialism. Then the decades between the middle of the 19th century and World War I were again characterized by intense imperialistic policies.

Russia, Italy, Germany, the United States and Japan were added as newcomers among the imperialistic states and indirect, especially financial, control became a preferred form of imperialism. For a decade after World War I the great expectations for a better world inspired by the League of Nations put the problem of imperialism once more in abeyance. Then Japan renewed its empire building with an attack in 1931 upon China, and under the leadership of the totalitarian states Japan, Fascist Italy, National-Socialist Germany and Communist Russia, a new period of imperialism was inaugurated.

THEORIES

Ancient Views. — Wherever imperialism existed, men have attempted to find its causes, usually either to denounce or to excuse, if not praise it. The Chinese Mencius, around 300 B.C., condemned imperialism as the result of man's unending greed and acquisitiveness, especially the insatiable ambitions and covetousness of princes, advised by selfish ministers and false counselors. The mass of the people, he felt, want to live in peace and are disturbed and injured by imperialistic wars. The country as a whole, he claimed. suffered because the maintenance of newly acquired territory was a burden and eventually a loss when it fell prey to the competing imperialism of another country. He saw no political, economic or moral justification for imperialism. In contrast to the idea, widely held in China, that admission to the empire was a blessing, Mencius granted that there may be a moral duty to liberate a people from its tyrannical rulers but that, once liberated, every people has a right to choose its own rulers.

In contrast to China, where ideologically war was deprecated and considered unnatural, secular Hindu philosophy in India had extreme views on the warlike nature of man. Life was considered an eternal and ruthless struggle, in which every state was the enemy of every other neighbouring state.

Quite logically, the ancient Hindu writers, Kautilya in his *Arthasastra* prominent among them, advocated the worst imperial-

istic power politics. They suggested that a state must strive for world domination, for only by beating its enemies into subjection can it have peace. A state must therefore be ready for war at all times, though if the aim can be achieved by cheaper means, such as diplomacy, alliances or the threat of force, they, rather than war, should be used.

Among the Persians the idea was widespread that in building their empire they were fulfilling a divine mission. And, perhaps more than most ancient empire builders, they translated this idea into reality by treating the conquered peoples with justice and fairness and granting them a certain degree of autonomy, though not neglecting to draw the greatest possible economic profit from them.

Among the Greeks ideas about empire building differed. In Sparta military prowess and the conquest of neighbouring territories were the ideals. But Sparta was satisfied essentially with military greatness and never became a colonizing power. In Athens political parties existed favouring and deprecating imperialistic wars. Thucydides (jth century B.C.) justified the expansion of Athens under Pericles by pleading security. Pericles himself, in the words of Thucydides, added that "to be within the circle of our influence is not dependence but privilege." To Plato and Aristotle, the self-sufficient city-state was the ideal. Aggressive war, Aristotle wrote, was justified only against people destined "by nature" to be slaves. Otherwise, he condemned the building of empires as endangering the morality of the citizens and also the freedom of the state which cannot remain liberal toward its own people while being tyrannical toward its vassals.

The Stoics, in the latter days of Greek imperialism, developed the ideal of world citizenship on an equalitarian basis and turned it eventually into humanitarianism. This concept never was applied in Greek political practice, but it became the ideological underpinning of the Roman empire where it fitted into the existing political and social reality.

Only later, when Stoic ideals gained a hold over important leaders of the empire did they exert a positive, directive effect upon the affairs of state. They finally fused with the Christian ideology and in the new form had a most fundamental effect deep into modern times.

Modern Views.—Considering the basic similarity in the patterns and the logic of imperialism throughout history, it is not surprising that in the thoughts of the ancients can be found the essence of all theories about the causes and value of imperialism. Modern thinkers have added refinements, elaborations, adaptations to modern conditions. and they have occasionally tried to support their views with evidence rather than dogma. but they have added little new knowledge. In their modern form, arguments about the causes and value of imperialism can be classified into four main groups.

The first group contains economic arguments and often turns around the question, does imperialism pay? Those who argue that it does and consequently advocate imperialist policies, from the English mercantilists to the German. Italian and Japanese totalitarians of the 20th century, point to the human and material resources and the outlets for goods, investment capital and surplus population provided by empire.

Their opponents. among them the physiocrats of France, Adam Smith, David Ricardo. J. A. Hobson, often admit that imperialism may benefit a small, favoured group but never the nation as a whole. Their reasoning ends in the advocacy of rectification of economic maladjustments in national economies and a liberalization of international economic relations so that in fact the benefits might be obtained which imperialism claims to but does not actually provide.

Marxist theoreticians have elaborated the economic aspects of imperialism in great detail. They interpret imperialism as a late stage of capitalism when the national capitalist economy has become monopolistic and is forced to conquer outlets for its overproduction and surplus capital in competition with the monopolistic economies of other capitalist states. This is the view held, for instance, by Nicolai Lenin and N. J. Bukharin to whom capitalism and imperialism are identical. Lenin argued further that the exploitation of "colonial slaves" moderated the oppression of the European workers and delayed their revolt. It would therefore hasten revolution in the developed countries to aid the emancipation of the colonial and semicolonial areas in the name of "nationalism." Marxist theory was thus reconciled with the nationalism of colonial peoples and both were made to serve the imperialist policies of the U S.S.R. Moderate Marxists, such as Karl Kautsky and Rudolf Hilferding, have argued that imperialism is merely a possible, not an inevitable, policy of a capitalist state. One of the chief weaknesses in these arguments is that historical evidence does not support them and that they fail to explain precapitalist imperialism and communist imperialism.

A second group of arguments relates imperialism to the nature of human beings and human groups, such as the state. Such different personalities as Niccolo Machiavelli, Sir Francis Bacon, Ludwig Gumplowicz, Adolf Hitler and Benito Mussolini, reasoning on different grounds, nevertheless arrive at similar conclusions. Imperialism to them is part of the natural struggle for survival. Nature has made men unequal, and those endowed with superior qualities are destined to rule all others. Nations must prove their strength and virility in combat and the subjection of weaker peoples. Like all organisms, states must pass through a period of growth (*i.e.*, expansion).

In Mussolini's words, "Fascism sees in the imperialistic spirit [*i.e.*, the tendency of nations to expand] a manifestation of their vitality." Critics of these viewpoints, for the most part biologists, political scientists and social psychologists, point out that in addition to being illogical in many cases, there is no evidence to support them and that they rest on mysticism rather than demonstrable fact.

The third group of arguments has to do with strategy and security. Nations are urged, proponents of this viewpoint say, to obtain bases. strategic materials, buffer states, "natural" frontiers, control of communication lines for reasons of security or to prevent other states from obtaining them.

Those who deny the value of imperialism for these purposes admit that they have been a motivating factor, but they point out that security is not achieved. On the contrary, expansion of a state's control over territories and peoples beyond its borders is likely to lead to friction, hence insecurity, because the safety belts and spheres of influence of competing nations are bound to overlap sooner or later. Related to the security argument is the argument that nations are imperialistic in the search for po er and prestige for their own sake.

The fourth group of arguments is based on moral grounds, sometimes with strong missionary implications. Imperialism is excused as the means of liberating peoples from tyrannical rule or of bringing them the blessings of a superior civilization. The white man's burden of the English, the civilizatory action of the French, the manifest destiny of the Americans, the greater east Asia coprosperity sphere of the Japanese, the Pan-Slavism of the Russians and the Pan-Germanism of the Germans, and the Liberation movements of the Communist Russians belong in this category.

These arguments have been used increasingly as growing liberalism and popular awareness of the price of imperialism combined with mass participation in the political process have caused a political and moral revulsion against imperialism.

The foes of imperialism have claimed that these moral arguments were merely a disguise to deceive people and gain their support for imperialist policies. But they can hardly deny that, driven by nationalist fervour and convinced of the righteousness of the moral mission, large sections among the population of imperialist states have supported, even demanded imperialist policies for no other gain than the psychological satisfactions they derive from them. The "devil theory" of imperialism, that only ruthless profiteers have engineered imperialism, is not borne out by the facts of history.

On the contrary, historical evidence, such as that assembled by Jacob Viner, Eugene Staley and William L. Langer, and theoretical analysis, such as that by Joseph A. Schumpeter and Lionel

Robbins, indicate that imperialism results from a complex of causes in which in varying degrees economic pressures. human aggressiveness and greed, search for security, drive for power and prestige, nationalist emotions, humanitarianism and many other factors are effective. Hence the difficulty of eliminating imperialism.

In the League of Nations and the United Nations attempts have been made to satisfy by peaceful means the legitimate aspirations of nations and to contain their illegitimate ones. Among the measures for these purposes are the collective security system, the mandate and the trusteeship system for dependent areas, the stimulation of cultural relations between nations, aid to underdeveloped countries and the improvement of health and welfare everywhere.

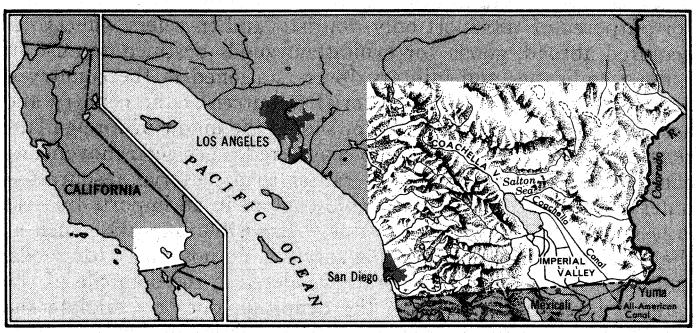
IMPERIAL PREFERENCE, the commercial system that arises when preferential rates (*i.e.,* duties levied at rates below the general level of the tariff, with free entry as a limiting case) are granted to each other by the constituent units of an empire; it may also include other sorts of preference, such as favourable consideration in the allocation of public contracts, indirect subsidies to shipping, preferential access to the capital market, etc.

Preferential arrangements of one kind or another have been enforced in the 20th century by most countries with dependent colonies, but in view of the great relative importance of the foreign trade of the British Commonwealth, the British imperial preference introduced in 1932 may be considered as the most important. The dominions granted preferences to Great Britain and to each other early in the 20th century; and when Great Britain imposed tariffs (*e.g.,* on certain key-industries goods in 1919 and 1921), the dominions were given preferences, which were however only of nominal value to them.

But when by the radical change in tariff policy in 1931 and 1932 Great Britain removed the ban on the taxation of food imports, the way was open for a systematic policy of imperial preference, based on the principle of "home producers first, empire producers second and foreign producers last," to come to a head at the Ottawa conference of 1932. The results were, after much hard bargaining, embodied in a series of bilateral agreements, which were to run for five years in the first instance (though they were allowed to run on after 1937 without formal renewal). These pledged that the United Kingdom was to allow the continued free entry of most empire goods and to impose new tariffs on certain food and metal imports from foreign countries; the dominions were to use their tariffs against United Kingdom produce in order only to protect efficient producers; and both sides were to maintain certain margins of preference. The political reasons for the agreements were strong, but the effect of the great depression and the search for "sheltered markets," as well as the spread of the protectionist spirit, culminating in the Hawley-Smoot Tariff act (1930) in the United States, may have been more important. Intraimperial trade increased after Ottawa, and empire trade as a proportion of an expanding world trade also increased in the 1930s. But other factors contributed to this; *e.g.,* the recovery of the prices of primary products and the existence of the sterling bloc.

During World War II and subsequently, exchange problems, commodity agreements and other factors had more effect than preferential tariffs. Some of the commonwealth suppliers of Great Britain benefited from the preferences, but not all countries achieved through it what they had hoped. Already some of the privileges had been waived to facilitate the signature of the Anglo-American trade agreement of 1938. Eventually the partners of the Ottawa agreements became signatories of the General Agreement on Tariffs and Trade (G.A.T.T.) in 1947, which was based on the most-favoured-nation principle and prohibited the extension of existing preferences. Indeed, in the several annual sessions of tariff negotiations through G.A.T.T. Great Britain and its partners agreed to some reductions of the preferential margins, without however abandoning the system. (L. Rs.)

IMPERIAL VALLEY, an intensively irrigated part of the Colorado desert, is located mainly in Imperial county in southeastern California, U.S., and extends slightly into Mexico. The valley is one portion of a huge trough in the earth's crust that includes, from southeast to northwest, the Gulf of California, the



LEFT. MAP SHOWING POSITION OF IMPERIAL VALLEY IN CALIFORNIA; RIGHT. DETAIL OF THE VALLEY

delta fan of the Colorado river (including the Imperial valley), the Salton sea and the Coachella valley. The Imperial valley extends northward about 50 mi. from just south of the California-Mexico border to the southerly end of the Salton sea. It is flanked on the east and west by slightly higher and gently sloping areas (east mesa and west mesa) which rise to barren hills and mountains.

All of the valley is below sea level—barely below at the Mexican border and 234 ft. below at the edge of the Salton sea. Were it not for the broad, damlike deposits of the delta fan of the Colorado river, the waters of the Gulf of California would invade and drown the Imperial valley, the Salton sea basin and much of the Coachella valley.

The Imperial valley has a hot desert climate, similar in many respects to that of the Sahara in Africa. The average temperature of the hottest month (July) is about 92° F.. and shade temperatures may at times reach 124° F. The coolest month (January) averages about 53° F., although cool-season temperatures may drop as low as 20° F. for a few hours in some years. Four months of the year average above 80° F., seven above 70° F. and only three average below 60° F. Rainfall is very meagre and uncertain from year to year; the average annual rainfall is about 3.5 in. The combination of high temperatures. abundant sunshine and numerous strong and drying winds makes the scant rainfall extremely ineffective.

Before 1900 the Imperial valley was a virtually uninhabited waste. The change from desert waste to green fields was accomplished by diverting water from the Colorado river to the deep, rich soils of the desert plain. This began nith the opening of the Imperial canal (about 50 mi. of which curved through Mexico) in May 1901. Disaster struck in 1905 and 1906 when Colorado river floodwaters destroyed diversion controls and the flow of the river poured northward into the Salton depression to create the Salton sea. Not until early 1907 nas control re-established. The area continued to face the possibility of new breaks. and not until the completion of Hoover dam (*q.v.*) in 1935 did major flood threat cease. In 1940 the All-American canal was completed and the valley became independent of the old Imperial canal. Chief products of the valley are beef cattle, sheep, lettuce, tomatoes, carrots, melons. sugar beets, alfalfa, barley, flax, cotton and dairy products. The chief cities and commercial centres are El Centro (*q.v.*) and Brawley.

By 1907 the Salton sea was about 40 mi. long and 13 mi. wide, covered over 500 sq.mi and had a surface 195 ft below sea level. Although it mas predicted that the sea, because of evaporation, would disappear by 1920, it continued to exist because of irrigation drainage water fed into it from the Imperial and Coachella valleys. In the middle part of the 20th century the greatly increased supply of drainage water caused the sea to rise again until in the early 1960s it covered nearly 300 sq.mi. and had a surface 234 ft. below sea level.

IMPORT DUTIES: see **TARIFFS.**

IMPORTING, the converse of exporting, is the process of bringing goods from abroad into one's own country for domestic consumption or transformation; it adds to the material resources of a country. Goods in direct transit that move through a country for purposes of transport only, tourists' and travelers' effects not acquired abroad, goods for exhibition, goods destined for use of foreign embassies and military forces stationed in the country—all these do not add to the material resources of the country and are not regarded as imports. Nor should the inflow of foreign currencies, securities and gold be so considered, since their movements change monetary and financial rather than material resources—unless, in the case of gold, the gold content in an imported object is less than 80% of its total value. ('Invisible imports," such as the purchase of foreign shipping services, do not deal with goods, and because services are generally rendered in the domicile of the caterer, their exclusion from the definition does not violate the reality as it would in the case of domestic marketing. This definition follows closely the concept underlying the standard international trade classification adopted by the United Nations. Importing, therefore, is part of the general process of marketing.

Importing Channels.— The import market structure is composed of three categories. In the first are import merchants, who buy from abroad on their own account, assume entire merchandising risks, carry goods in stock, engage in sorting, grading, cleaning, mixing and blending and do the physical importing. They generally specialize insofar as products and regions of supply are concerned. Indent houses belong to this group, but they buy from abroad only on orders from domestic customers. The second category comprises import agents, including import commission houses, commission merchants and resident agents or sales offices representing foreign supply. They sell to the domestic market on a commission basis for foreign exporters, usually with exclusive rights; they often attend to customs and details of shipments. Finally there are import brokers who, because of the need for knowledge of markets, grades, quality and trade practices, specialize in one or only a very few staples produced in many countries and by many individual producers (coffee, rubber, sugar, cocoa beans). They collaborate closely with export brokers abroad and normally act as intermediaries in bringing many domestic buyers (themselves not final consumers) and many foreign sellers together on specific lots either on the spot, already afloat or to be shipped from abroad. Unlike import agents, they are not at all associated with physical movements of goods or customs clearance.

This classification is made for analytical purposes only, for in actual practice the functions of the operators in these three categories greatly overlap and many of them carry on exporting as well as importing activities. Their relative importance varies according to product. International staples are handled in the first instance by import brokers and sometimes by import merchants who. together with import agents, generally deal with semi-manufactures and finished products. Some imports, consumer goods in particular, may even bypass the market structure through the use of correspondence, samples or catalogues and reach the final user by parcel post.

In underdeveloped countries where imports consist mainly of consumer goods, foreign firms traditionally have dominated the importing structure and will probably continue to play an important role as more and more capital goods are imported for national development. In industrialized countries the import agencies, generally operated by nationals, serve a good part of the domestic market well. They have to see to it that the foreign sources of supply are reliable as to design, quality, delivery dates and prompt delivery on reorder of identical products.

However, their services are not always satisfactory to large concerns in retailing, wholesaling and manufacturing. Modern merchandising methods require product differentiation and close co-ordination between production. sales promotion activity, inventory and changing consumer tastes in style, colour and pattern. Thus many large department stores and wholesalers establish purchasing agents abroad or send out traveling buyers in order to look after proper designing and uniform quality, to assure continuity of supply and to keep abreast of changes occurring constantly in foreign production. Other retail stores buy direct either through resident buying offices abroad that are under their own management or under indigenous management (commissionaires) or through branch offices or co-operative offices supported by groups of stores.

In some trades, manufacturing in particular, the problem of availability of supply (not to mention continuous supply at stable prices and in uniform quality) looms very large and has led many big corporations to acquire, develop and maintain full authority over foreign sources of supply (mining, rubber, bananas) with the express purpose of bringing the products back to their own country for processing or consumption. The same type of consideration underlies the "bulk purchase agreements" between national governments, such as that entered into by Great Britain from 1946 to 1951 to buy the exportable surpluses of various New Zealand and Australian farm products at prices negotiated annually.

In a socialist economy the market structure differs considerably. Importers, wholesalers and retailers there are, but they are part of the state trading machinery. Foreign trade is a state monopoly and importing as well as exporting may be as much a weapon of economic warfare as it is a method of trade development.

Importing Procedure.— Every important trading country has its omn laws governing imports with respect to documentation, packing, labeling, marking and customs clearance. (A separate set of regulations applies to personal baggage of nonresidents and returned residents.) The legal requirements are precise and deviation map result in financial losses, heavy penalties and in some cases even imprisonment. The most complicated among them is customs clearance, which consists of customs entry, appraisement and liquidation. For example, effective in the United States are 22 types of entry, each serving a particular purpose, and as many as five different bases of customs valuation (foreign value, export value. U.S. value, constructed value and American selling price). Procedures in other major trading countries are no less elaborate. Both the basis of valuation and the classification of the imported article for tariff purposes affect the amount of duty to be assessed. While the work of clearing import shipments may be relegated. as it is by many importers, to licensed customs brokers at reasonable costs, the uncertainty as to the amount of duty to be paid (especially on new products, novelties and specialties) remains and this partly explains the high margin in import pricing. Often appraisement entails delay in releasing the goods, and the delay might be prolonged if the importer appeals the decision of the appraiser to the customs court. Free ports, free-trade zones and foreign-trade zones help consignment and re-export trade; but when the goods landed there proceed to the hinterland, the same customs clearance procedure applies.

Complicated administrative regulations and procedures, costly to importers and consumers. may be regarded as an "invisible tariff," affecting, however, both duty-free and dutiable imports.

Importing and National Policy.—All trading nations have government boards, bureaus or ministries charged with the responsibility of assisting their own importers as well as exporters. In the United States, for example, the bureau of foreign and domestic commerce, with the help of the department of state foreign service personnel, provides importers with statistical aid relating to actual imports, reports on foreign producers as reliable sources of supply, indirect aid by means of information given to foreign producers and exporters, and surveys and analyses of domestic markets for imports. An import advisory committee to help importers functions in the office of international trade. And the Export-Import bank, a federal agency originally organized in 1934 to finance trade with the Soviet Union, has the task of assisting exporters and importers when adequate financing is not available to them from commercial banks and other private sources.

As profit-seeking businesses, importing firms strive to secure goods in domestic demand from the cheapest source in terms of total outlay for purchase price and transfer cost. In actual practice this freedom is variously prescribed in different countries. Some imports are banned for reasons of public health (certain food and drugs), public morals (obscene literature), public taste

(advertising matter) and fair trade practices (dumping, goods with infringing trade-marks). Although by no means uniform among countries, this type of embargo list is designed to protect public interests and tends to remain substantially unchanged in a country over long periods of time.

There is. however, great variation among countries in respect of a large group of control measures, each designed to attain a definite national policy objective and subject to modification as policy changes. The objective may be to raise revenue for the national treasury, to protect certain domestic industries, to give preference to products from certain areas, to restore equilibrium in the over-all balance of international payments, to maintain the international current account balanced with each particular trading partner, to reduce purchases that require "hard" or scarce currencies, to promote the import of essential producer and consumer goods against nonessential items, to safeguard state monopolies or to give effect to a domestic price- or income-support program which is susceptible to the depressing influences of imports.

Among the various instruments of control, the import tariff is the most widely used. either primarily for revenue or for protection purposes. A national tariff schedule is generally divided into the dutiable and the free list. Goods on the duty-free list are usually those that the country does not produce or prefers to import for political reasons (*e.g.,* Philippine sugar to the United States from 1916 to 1955). The dutiable list specifies three different levels of duty for all or some commodities: the highest is applicable to imports from countries that do not enjoy the most favoured nation treatment; the next. to those that do; and the lowest, to those accorded preferential treatment (the British imperial preference system). The duty rates are either ad valorem (*i.e* , a fixed percentage of the imported value to be determined) or specific amounts of money per unit of quantity or weight (gross, legal or net) or a combination of the two. In some countries, certain imports are also subject to excise taxes after they have been cleared through customs. Heavy duties and taxes, however, do not necessarily bar importation completely as long as the domestic market is willing to pay high enough prices for the goods in question.

Import quotas, import licensing and foreign exchange allocation are measures of quantitative restriction. There are many types of quotas relating to imports. The tariff rate quota provides for the entry of a specified quantity of the quota product at a reduced rate of duty during a given period and unlimited quantity above the quota at higher rates; the so-called mixed quota requires domestic manufacturers to use a minimum proportion of domestic materials in combination with imported materials. In contrast, the absolute quota fixes the quantity of total imports of the quota product during a given period. It may be global nith no discrimination against any one of the exporting countries or allocated to each one of them by unilateral action or by bilateral negotiation. Import licensing restricts importation of all or specified products by permit. and is often used in conjunction with allocated quotas or when the quotas are not publicly announced. Foreign exchange control usually accompanies foreign trade control; import restriction is exercised through allocation of exchange at official rates for certain imports and through limitation of the amount of exchange to be sold in the officially controlled "free" market.

Most of these measures, including the tariff, tend to favour certain producers and commercial firms at the consumers' expense, or to discriminate among the trading countries or both. Import control thus stands in contrast to public regulation of domestic marketing activities, which frequently takes consumers' interests as the point of departure.

IMPORTS. A term used to describe the commodities brought into a country by the operations of commerce. Considered economically, the imports into a country represent payments to the importing country for (1) exportation of goods; (2) services, such as the services of ships, or commercial or financial commissions; (3) interest and principal repayments on capital previously exported by the importing country; or (4) movements of gold and silver. After World War I. another source of imports arose out of the payment of indemnities, Germany being compelled to export to the Allies and thus causing them to receive imports. The repayment of the interallied debts set up a cause of imports, consisting of exports made by one ally to another.

The difference between the imports and exports of a country, as recorded by its customs houses, is called the balance of trade (see INTERNATIONAL PAYMENTS). The records made at the custom house can refer, of course, only to material commodities, but a country may at any time be importing services, the value of which cannot and is not recorded in the trade returns. To such imported services the term invisible imports is sometimes applied. The values at which imports are officially recorded by customs houses varies with different nations; in the case of the United Kingdom the imports are entered at what are called c.i f. values, that is, values representing the cost, insurance and freight; or when goods are consigned to the United Kingdom for sale, at the latest sale value of such goods. See also EXPORTS; TRADE, INTERNATIONAL.

IMPOSITION, in ecclesiastical usage, the "laying on" of hands by a bishop at the services of confirmation and ordination as a sign of a spiritual gift or conferring special service (Lat. *imponere,* to place or lay upon). The word also means the levying of a burdensome or unfair tax or duty. and of a penalty; also a trick or deception. In the printing trade the term is used for the arrangement of pages of type in the form.

IMPOST, a tax or tribute. and particularly a duty levied on imported or exported merchandise. In architecture, a molding, series of moldings, projecting band, carved ornament or projecting block, marking the spring of an arch. and placed at the top of the pier or section of wall that carries the arch. In Byzantine work the block sometimes placed between the capital of a column and the arches which it carries is known as an impost block. See DOSSERET.

IMPRESARIO, the contractor or promoter of an enterprise (from the Ital., *impresa,* an undertaking). specifically of concert and operatic ventures. The impresario was a person of musical judgment who negotiated tours of musicians. often abroad, when wider international fields were opened up at the end of the 19th century. Gabriel Astruc in Paris, Harold Holt in London and Arthur Judson in the United States were impresarios responsible for tours of this kind. With the 20th-century mechanical diffusion of music and its partial control by municipal or state organizations the impresario's role nas gradually taken over by the agent.

IMPRESSIONISM. The term impressionism, first used. derisively, by a journalist, was taken from Claude Monet's canvas representing the effect of the sun rising over the sea and entitled "Impression." The painting was shown at an exhibition (April–May 1874) organized by a group of young painters whose work had been rejected by the official Salon The word later spread throughout the entire world to refer to the first revolutionary movement of modern painting, of which the chief exponents were Manet, Degas, Monet, Pissarro, Sisley, Cézanne. Guillaumin and Berthe Morisot (*qq.v.*). Two periods are distinguishable in its development: a preparatory phase (1862–71), which. led by Manet, was hastened by the influence of two forerunners of Impressionism, Eugène Boudin and J. B. Jongkind (*qq.v.*), and by the introduction of Japanese prints to western attention; and, after Monet's and Pissarro's stay in England (1870–71), a phase of development. also called the Argenteuil phase because it centred around Monet uho was then living in that charming village on the outskirts of Paris. From 1880 onward the movement broke up and the last and eighth exhibition of the group, in 1886. confirmed its disintegration. Each of its founders developed his own individual technique, and other trends emerged.

Freed from academic fetters and artistic conventions, at one and the same time reacting against the romanticism of literary inspiration and the social tension of realism, Impressionism inaugurated independent painting based on the pure colours of the prism and the splitting-up of "tone" into its component colours. An expression of outdoor modern life, its chosen subjects were Paris and urban scenes, the coasts of the English channel and the North sea or the little village resorts on the banks of the Seine and Oise, made accessible by the railway. Influenced by what is spontaneously perceived, the Impressionists tried to convey the changing rhythm of appearances under the universal vibration of light, the rendering of which was the principal characteristic of their style. IMPRESSIONISM, MUSICAL. The word impressionism, borrowed from painting, was principally applied as a musical term to the music of Claude Debussy and later adopted to describe music of French associations of the post-Wagnerian period. An early use occurred in a letter of Renoir of Jan. 14, 1882, in which, referring to a conversation with Wagner, he wrote, "We spoke of the Impressionists of music." In 1887 the *Journal Officiel* criticized the "vague impressionism" of Debussy's *Printemps.* The term was used in a laudatory sense by Belgian critics in 1894 in reference to Debussy's String Quartet, which was played in the hall of an exhibition in Brussels of paintings by Renoir, Pissarro, Sisley, Gauguin and others. On the same occasion, Maurice Kufferath spoke of Debussy's "musical pointillism" and stated that his music suggested "the neo-Japanese canvases painted in Montmartre." The term mas later used by Jean d'Udine to describe the subtle orchestration of Debussy's *Nocturnes* and by Romain Rolland in writing of *Pelléas et Mélisande.* Though Debussy himself compared the original form of his *Nocturnes* to "a study in grey in painting" and frequently sought the musical equivalent of a visual image, so that his work shows a strong aesthetic affinity with that of contemporary painters, there was no conscious imitation of Impressionist methods in his music, nor in that of Emmanuel Chabrier, who possessed an important collection of Impressionist paintings.

Comparisons in technique, such as that between the broken chords in Debussy's *Reflets dans l'eau* and the reflection of clouds in water in Monet's "La Grenouillère" or between a bold use of solo instruments in the orchestration of Chabrier and the use of primary colours by the Impressionist painters, were therefore conjectural. In the first quarter of the 20th century the term was applied in a general sense to the works of many other composers (not all of them French) including Ravel, Delius, Scriabin and Stravinsky. Since an affinity with the aesthetic of the Impressionist painters in the work of such composers was remote) impressionism acquired a period sense, comparable to the use of the terms classical and romantic, and was used loosely to describe a variety of trends in post-Wagnerian music. (E. LR.)

IMPRESSMENT, the exercise of the authority of the state to "press" or compel the service of the subject for the defense of the realm.

In England impressment may be looked upon as an erratic, and often oppressive, way of enforcing the common obligation to serve in "the host" or in the *posse comitatus* (power of the county). In Scotland, where the feudal organization was very complete in the lowlands, and the tribal organization no less complete in the highlands, and where the state was weak, impressment was originally little known. After the union of the two parliaments in 1707, no distinction was made between the two divisions of Great Britain. In England the kings of the Plantagenet dynasty caused Welshmen to be pressed by the lords marchers and Irish kerns to be pressed by the lords deputy for their wars in France. Complaints were made by parliament of the oppressive use of this power as early as the reign of Edward III, but it continued to be exercised. A small sum called imprest money or coat and conduct money was given to the men when pressed to enable them to reach the appointed rendezvous. Soldiers were secured in this nay by Queen Elizabeth I, by Charles I and by the parliament itself in the Civil War. The famous new model army of Cromwell was largely raised by impressment. Parliament ordered the various county committees to select recruits of "years meet for their employment and well clothed." After the revolution of 1688 parliament occasionally made use of this resource. In 1779 a general press of all rogues and vagabonds in London to be drafted into the regiments was ordered. It is said that all who were not too lame to run away or too destitute to bribe the parish constable were swept into the net. As they were encouraged to desert by the undisguised connivance of the officers and men who were disgusted with their company, no further attempt to use the press for the army was made.

Armies on the continent were also made up in large part of men who had been impressed. They had been taken from jails, snatched from taverns while drunk or kidnapped in dark streets or alleys. "Press gangs," as the military or naval parties that impressed men were known, were as common in France and Prussia as they were in England. The fighting qualities of troops obtained in this manner were usually incredibly poor.

The impressment of sailors for the Royal Navy was regarded as a prerogative of the crown. From an act of Philip and Mary (1556) it appears that the watermen of the Thames claimed exemption from the press as a privileged body. They were declared liable, and the liability was clearly meant to extend to service as a soldier on shore. In the reign of Elizabeth I, an act was passed (1563) to define the liability of the sailors. It is known as "an act touching politick considerations for the maintenance of the navy." By its term all fishermen and mariners were protected from being compelled "to serve as any soldiers upon the land or upon the sea, otherwise than as a mariner, except it shall be to serve under any captain of some ship or vessel, for landing to do some special exploit which mariners have been used to do." The operation of the act was limited to ten years, but it was renewed repeatedly, and was at last indefinitely prolonged in the reign of Charles I (1631).

The justices of the peace in the coast districts, who were often themselves concerned in the shipping trade, were not always zealous in enforcing the press. The pressed sailors often deserted with the "imprest money" given them. Loud complaints were made by the naval officers of the bad quality of the men sent up to serve in the king's ships. On the other hand. the press gangs were accused of extorting money, and of making illegal arrests. In the reign of Queen Anne (1703) an act gave parish authorities power to apprentice boys to the sea and exempted such apprentices from the press for three years, and until the age of 18. It especially reaffirmed the part of the Vagrancy act of 1597 which left rogues and vagabonds subject to be pressed for the sea service. By an act of 1740, all men over 55 were exempted from the press, together with lads under 18, foreigners serving in British ships and landsmen who had gone to sea during their first two years. The act for "the better supplying of the cities of London and Westminster with fish" gave exemption to all masters of fishing boats, to four apprentices and one mariner to each boat and all landsmen for two years, except in case of actual invasion.

Subject to such limitations as these, all seafaring men and watermen on rivers, were liable to be pressed between the ages of 18 and 55, and might be pressed repeatedly for so long as their liability lasted. The rogue and vagabond element were at the mercy of the justices of the peace. The frightful epidemics that desolated the British navy till late in the 18th century were caused largely by infections brought by the prisoners drafted from the ill-kept jails of the time. Even merchant ships were stopped at sea and the sailors taken from them. On one occasion, in 1802, an East Indiaman on her way home was deprived of so many of her crew by a man-of-war in the Bay of Biscay that she was unable to resist a small French privateer and was carried off as a prize with a valuable cargo. In 1795 it was found necessary to impose on the

counties the obligation to provide a quota of men, at their own expense. The local authorities provided the recruits by offering high bounties. often to debtors confined in the prisons.

The impressment of seamen from United States vessels during the Napoleonic wars was one of the causes, though probably not the primary cause, of the War of 1812. The trouble stemmed from the British government's adherence to the generally accepted doctrine of inalienable allegiance: once a British subject always a British subject. The U S. government advanced a new, revolutionary concept that every man was free to change his allegiance at will Between 1790 and 1812 thousands of British seamen, some deserters from the Royal Navy, signed up on ships of the thriving U S merchant marine and claimed U S. citizenship. To cope with this problem the British insisted upon the right to board neutral ships on the high seas in search of deserters and British subjects liable to impressment. Because of the common language of the two countries and the abuses that grew up around the issuance and illegal sale of U S. citizenship papers. the difficulty of determining a man's citizenship was great Desperate for men to continue the fight against Napoleon, British boarding parties sometimes impressed bona fide U.S citizens.

After the conclusion of the Napoleonic wars in 1815, the power of the press was not again exercised. In 1835 an act was passed during Sir James Graham's tenure of office as first lord of the admiralty, by which men who had once been pressed and had served for a period of five years were to be exempt from future impressments. Sir James, however. emphatically reaffirmed the right of the crown to impress seamen. The introduction of engagements for a term of five years and then of long service produced a large body of voluntary recruits. With better pay and working conditions, service in the navy became so popular that the question had no longer any interest save a historical one In the 20th century compulsory service, both in the navy and army, once more became necessary, but it was then referred to by such terms as conscription, national service or selective service.

IMPROMPTU, a name used in the 19th century as the descriptive title of pieces for the piano, from the French, *impromptu,* unpremeditated or improvised. The style of the music is similar to that of other compositions of this period, nith such titles as fantaisie. caprice and bagatelle. In England, from the 16th century onward, music improvised by a performer, generally at the harpsichord or organ, in the form of a prelude to another composition. was known as a voluntary. The name impromptu first appeared in 1822 as the title of piano pieces by Jan Hugo Voříšek and Heinrich Marschner. In 1824 Liszt wrote an "Impromptu on Themes of Rossini and Spontini." These, and the impromptus by Chopin, Schumann and others, may have been intended to convey the impression of improvised pieces, but since they first appeared in their published form they were not actually extempore norks. This also applies to the first set of impromptus by Schubert, so called by his publisher. An improvised impromptu of this period is the 13-bar "Allegretto quasi andante" dedicated by Beethoven to a granddaughter of Charles Burney. No definite form is prescribed for the impromptu. which may resemble a prelude a set of variations or be freely conceived in the form of a fantasy. Among the impromptus of a later period are those of Gabriel Fauré and Alexander Scriabin.

IMPROVISATION (EXTEMPORIZATION) in music means composing and performing simultaneously; *i.e.,* literally making it up as you go along. Music originated as improvisation and is still extensively improvised in eastern traditions and in the modern western tradition of jazz (but this is an offshoot of African music nith a higher proportion of genuinely primitive inspiration than is usually realized).

In antiquity and in many eastern schools nith ancient traditions, elaborate modes (*i.e.,* forms of scale) developed for codifying melodic and rhythmic patterns. Different subjects, different emotions and even different localities are associated with different modes, between which any possibility of confusion is rigorously resisted. Knowing their modes well and preserving them jealously, musicians can improvise long compositions within the boundaries thus set. Important examples of this method of improvisation are encountered in the early history of European church music, including the Byzantine school of the so-called dark ages (*see* BYZANTINE MUSIC) and the astonishing Notre Dame school of music in medieval Paris. There the foundation was written down as plain chant and maintained according to strict and conservative rules; yet it nas the originally improvised additions to it which led to a written art of flexible melody subtly combined into "horizontal" harmony by counterpoint; *e.g.,* the Renaissance polyphony of Josquin, Byrd or Palestrina. (See also COUNTERPOINT; HARMONY; PLAINSONG.)

Outside this central tradition in western music, full "vertical" harmony was already being improvised within conservatively established modes (orally transmitted) by Welsh and other harpers of the Celtic fringe. The nearest surviving equivalent (though it is melodic rather than harmonic) is the highly developed and sophisticated Hindu tradition. Another and vast field in which improvisation has always played a vital part is folk music.

The delight taken by Renaissance organists, harpsichordists, lutanists, viol players and other instrumentalists in adapting plain vocal compositions to the idiosyncracies of their instruments by insinuating the most elaborate variations impromptu did more than anything else to develop the specifically instrumental idioms which have been the glory of western music since the 16th and 17th centuries.

Certain types of composition came into being through the same Spontaneous outpouring of invention. The prelude and the toccata ("touch-piece") were at first informal improvisations to loosen the fingers, check the tuning (*e.g.,* of a lute), establish the tonality and put both performer and audience at their ease. The chorale prelude started as improvisations on a hymn tune by church organists at suitable interludes in the service. The theme and variations grew out of that most sophisticated of early parlour games: improvising contrapuntal descants on a given plain chant, or free variations on a ground bass (divisions on a ground) or the like. A favourite 18th-century development of this, continued frequently in the 19th century and occasionally (*e.g.,* by French virtuoso organists) in the 20th, was improvising not merely variations but a formal fugue on a theme handed up by a member of the audience—not necessarily an accomplice of the performer. The art was quite genuine; and there were listeners who put it on record that the improvisations of John Bull and Frescobaldi, of Bach and Handel, of Mozart and Beethoven, of Liszt and Busoni impressed them as being almost as highly organized as, and in some ways even more moving than, the written-out compositions of these composers.

That impression may have been in part due to the excitement of hearing great music spontaneously shaped and no sooner shaped than lost again. Some allowance must also be made for the composer's bringing memory to the aid of invention in the spirit of that "offhand discourse which (all nature, no art)" Browning tells us in his poem "Englishman in Italy" that "the Dominican brother, these three weeks, was getting by heart." No one can genuinely improvise outside an existing tradition with which he is intimately familiar. But this is a condition which applies almost as strictly to composition in its ordinary, written form. A composer can only modify the existing tradition because he has the indispensable advantage of having gronn up inside it. The primary patterns out of which music is built up are archetypal in the sense that everyone inherits a predisposition to produce them and to understand them when other musicians produce them. It is because these archetypes not only well up from within the musician's consciousness, but, to a certain extent, organize themselves by their own autonomous nature that genuine improvisation can happen. (R. DO.)

IMPROVISATORE (Ital. *improvvisatore*), a word for a poet who recites verses which he composes on the spur of the moment. It became recognized as an English word in the middle of the 18th century and is used by Tobias Smollett in his Travels

(1766). The feminine form is *improvisatrice.* (*G. W. A.*)

IMRU'-AL-QAYS (AMRU-'L-KAIS; 6th century A.D.) Arabian poet and author of one of the Mu'allaqat (*q.v.*), nas regarded by Mohammed and others as the most distinguished poet of pre-Islamic times. He was of the kingly family of Kinda, and his mother was of the tribe of Taghlib. While he was still young, his father was killed by the Bani Asad (a rebel Bedouin tribe) and his life was devoted to the attempt to avenge his father's death. He wandered from tribe to tribe to gain assistance, but his attempts were always foiled by the persistent following of the messengers of Mundhir, king of Hira. By means of Harith of Ghassan he procured an introduction to the Byzantine emperor Justinian. After a long stay in Constantinople he was named phylarch of Palestine, and received a body of troops from Justin II. With these he started on his way to Arabia. The story that he was charged before the emperor with the seduction of a princess and that Justin sent him a poisoned cloak, which caused his death at Ancyra (Ankara), is generally regarded as legendary.

BIBLIOGRAPHY.—His poems mere published in W. Ahlmardt's *The Divans of the Six Ancient Arabic Poets* (1870) and in McG. de Slane's *Le Diwan d'Amro'lkais* (1837). *See* also G. Olinder, *The Kings of Kinda* (1927); R. A. Nicholson, *A Literary History of the Arabs* (1953).

INBREEDING is the mating of relatives. The consequences of inbreeding are slight unless the relationship is close. Hence the matings are not usually called inbreeding unless the mates are related at least as closely as half brother and sister or as individual and grandparent, although usage varies in this respect. In man, for example. matings of first cousins are often called inbreeding. and the term is even applied occasionally to the mating of second cousins.

Among species of plants which customarily reproduce by self-fertilization are some hardy and widespread ones like wheat, beans, barley. oats. cotton and the sorghums. Other species (*e.g.,* beets, alfalfa and many clovers) are equipped with special mechanisms to prevent self-fertilization and to insure cross-pollination. In still other species pollination is mainly by the wind and there is no special device either to favour or to hinder self-pollination. hlaize and many of the forest trees are examples (see POLLISATION). In the higher animals self-fertilization is impossible because the two sexes are not combined in the same individual. But among the lower animals, as among the plants, are many functional hermaphrodites (*q.v.*). In a few of these (*e.g.,* some tapeworms) self-fertilization is the rule. Many others (*e.g.,* oysters) have structures or devices to prevent self-fertilization or at least to make it rare.

Most breeders of farm animals regard inbreeding as dangerous, especially for the inexperienced, but a few have dared to inbreed when they thought their own animals were unusually good. Some of these have had conspicuous successes. From at least as far back as Bakewell's time, inbreeding has generally been considered the most effective way to "fix" type and to isolate "pure" (homozygous) lines.

consequences of **Inbreeding.**—The primary effect of inbreeding is to increase genetic purity; *i.e.,* to make the offspring homozygous for more pairs of genes than if the parents had been unrelated. Inbreeding does not create defective offspring. It is not harmful in itself; however, the increase in homozygosity permits more recessive genes to show their effects. These are generally less desirable than the effects of dominant genes. Therefore inbreeding usually increases the proportion of defective, weak, slow-growing or otherwise undesirable individuals. Yet inbred individuals vary much from this general rule and many of them are highly meritorious. The fundamental units of inheritance, the genes, are not themselves changed by inbreeding but are merely brought together in combinations which would be rarer under outbreeding (matings between nonrelatives). Families become more distinct from each other as the inbreeding proceeds. The members of an inbred family resemble each other genetically much more closely and outwardly somewhat more closely than members of an ordinary family do. The inbreeding permits them not only to be alike because they can inherit the same things from their sire or from their dam but also because one member can inherit from the sire the exactly same gene groupings as another inherits from the dam.

Measures of Inbreeding. — In ordinary speech inbreeding is measured only by describing verbally the relationship between the mates. In civil and canon law, inbreeding is measured in degrees by counting the number of generations intervening between the individuals which marry and the ancestor through which they are related. Since 1921 Wright's coefficienthas been available for expressing inbreeding intensity as a fraction of the initial heterozygosity ("mixture" of genes) which is expected to have been lost because of the inbreeding. Approximate values of this fraction in some of the more intense systems of inbreeding are as follows:

System of mating or relationship of mates	Inbred generation			Fraction of remaining heterozygosis lost per generation
	First	Second	Third	
Self-fertilization	.50	.75	.88	.50
Full brother-sister or parent-offspring	.2j	.38	.50	.19
Male and many half sisters (one-sire closed herd)	.12	.22	.30	.11
Two males and many females (two-sire closed herd)	.06	.12	.18	.06

Clearly, self fertilization is the most effective means of removing heterozygosity and creating a pure line.

Practical Uses of Inbreeding.—Inbreeding helps in purging a breed or other population from its recessive defects by bringing these to light in larger numbers. If the possessors of these defects can be culled, the population is freed from that undesirable heredity more rapidly than could be done without inbreeding.

Inbreeding makes family selection more effective. This it does in three ways. First, it makes the families drift apart, so that their averages become increasingly different. Second, it makes members of the same family more like each other genetically, so that what is true of the family average is more likely to be true of each member. Third, it permits increasing the family in numbers without mixing it with other families. In this way the family is still intact when it has declared its merit clearly. Probably much of the usefulness of inbreeding in the production of "hybrid corn" consists in its thus increasing the effectiveness of family selection.

Inbreeding is often used by livestock breeders to preserve the merits of a highly admired ancestor long after that ancestor is dead. This is generally called "line breeding." When the descendants of animal X are bred to each other the offspring tend to resemble X about as much as their parents did, whereas if they were mated to individuals unrelated to X their offspring would resemble him only about half as closely. Since all inbreeding except that necessary to hold high the relationship to the admired ancestor is avoided, line breeding is generally somewhat less intense than the inbreeding done when the primary intention is to make families distinct or to purge a stock of its defects.

Some inbreeding is done merely because the breeder thinks there are no animals as good as his, and that to mate his animals with unrelated stock would contaminate and dilute some inheritance which is especially meritorious. This was influential in originating many of the pure breeds.

Inbreeding in Nature. — Even among wild species which must cross-fertilize, some inbreeding may occur because of subdivision into small groups which rarely interchange breeding stock. Random mating within such isolated groups is inbreeding with respect to the whole species, since sooner or later all members of a subgroup become related to each other. This relationship continues to increase except as it is cancelled by immigration of individuals from other groups. Besides isolation by geographical barriers and by distance itself, there can be some isolation by having breeding seasons at different times of the year, by genes for partial sterility, and by other mechanisms. Some inbreeding due to isolation and to widely unequal reproductive rates between individuals certainly occurs in nature but whether it is an important factor in evolution, through permitting natural selection to operate on a family basis, is still uncertain (see HYBRIDISM; EVOLUTION, ORGANIC).

Inbreeding in man, except for a few striking cases such as among royalty in ancient Egypt, has generally been prohibited

(as incest) among civilized peoples and among primitive peoples was often prohibited by taboos. In civilized societies individuals more closely related than first cousins have generally been forbidden to marry. The marriage of first cousins has sometimes been forbidden, sometimes permitted freely, and sometimes permitted only on special dispensation. Biologically the last arrangement seems the most desirable, provided the dispensation is granted when the common ancestors were meritorious. The arguments against inbreeding have more validity in man than in animals because a few defectives occurring among domestic animals can be discarded without serious economic loss, whereas the production of even a few completely incompetent human beings may be a serious burden on a society which does not permit the deliberate elimination of such individuals. (See also EUGENICS; ANIMAL BREEDING; PLANT BREEDING.

INCA, a Peruvian tribe, speaking the Quichua dialect, who. at the time of the Spanish expedition under Francisco Pizarro in 1533, exercised paramount rule over a region extending west of the Atlantic slope of South America between Quito in Ecuador and the Maule river in Chile. They were a highland people and organized a renaissance of the earlier "civilization." characterized by megalithic, polygonal structures of stone, which appears to have prevailed in the uplands of Bolivia and Peru at an anterior date (known as the Tiahuanaco period). The earliest traditional records of the people are mythological. The ancestors of the tribe are supposed to have emerged from certain caverns in a hill (*Tamputocco*, "House of Windows"), in a region known as *Paccari-tampu* ("House of the Dawn"), under the leadership of four brothers, all bearing the title of *Ayar*. The chief was the eldest brother, named Manco, who was the high priest of the tribal god, the sun, whose emblem was a fetish in the form of a bird, kept concealed in a basket. This fetish possessed oracular powers and directed the migrations of its votaries. The other brothers were named Cachi ("Salt"), Uchu ("Pepper") and Auca ("Pleasure"). Their sister-wives, who bore the title of Mama ("Mother"), were named respectively, Occlo, Huaco, Cura and Raua.

INCA REPLICA OF A LLAMA WITH COPPER BODY AND HEAD AND NECK OF GOLD FOUND AT HUANACAURI HILL NEAR CUZCO, PERU

Under the direction of an oracle. these leaders conducted the tribe northward in search of empire. The leader, Manco, was equipped with a golden rod which, according to the prophecy, would sink into the ground when the predestined home was attained. In the course of the migration, the three younger brothers perished. Cachi was persuaded to return for certain fetishes which had been left behind in a sacred cave; but when he had entered the sanctuary his escort rolled a great rock against the entrance. Uchu, in the attempt to seize a mysterious stone statue encountered on the journey, was himself turned to stone. Auca, who was winged, was asked by Manco to fly to the top of a distant hill (afterward the site of the great sun temple in Cuzco), but he, on completing the feat, was transformed to stone. Nevertheless the tribe followed, the test of the golden rod was applied and Cuzco, the seat of the later Inca empire, was founded.

Most traditions give Manco's immediate successor as Sinchi Roca. It is probable that Manco is in the main a legendary character, dating back possibly to the Tiahuanaco period. Roca appears to have been the first ruler bearing the royal title of *Sapa Inca* ("Only Inca"), and it is probable that his accession heralded the epoch associated nith Inca domination. In fact he may be regarded as the first Inca "historical" ruler. The evolution of the Inca tribe into a ruling caste has brought about a certain confusion in the use of the word "Inca." Originally tribal. it became a term of rank, as applied to the members of the official hierarchy. At the same time, the phrase "the Inca" is used in connection with the supreme ruler, regarded as a god on earth and descendant of the old tribal god, the sun. *See* SOUTH AMERICA: *Archaeology; see* also Index references under "Inca" in vol. 24. WOODEN SEAT FOUND NEAR CUZCO

INCANTATION: *see* MAGIC.

INCENDIARPSM: *see* ARSON.

INCENDIARY MIXTURES are used to start fires, generally for military purposes but occasionally for arson or sabotage. They may be made from a variety of ingredients. Some mixtures ignite spontaneously when exposed to air; others take fire when the ingredients are brought together; still others require a fuse or first-fire mixture to heat them to the temperature where they will begin to burn. Many incendiary mixtures may be extinguished if smothered with sand or dirt.

Greek Fire.—Simple incendiary mixtures have been known since ancient times. The Romans made mixtures of pitch, sulfur and other flammables, poured them into pots and threw them, burning, upon enemy buildings and ships. The most famous of the early incendiary mixtures was Greek fire (*q.v.*) invented by Callinicus around 670 A.D., and used by the Byzantines to defeat an Arab fleet. The composition of Callinicus' mixture is not known for certain, because attempts were made to keep it secret and also because later writers applied the term Greek fire to many different kinds of incendiary mixtures and thus brought about unravelable confusion. Generally. the Greek fire of the middle ages contained petroleum and other flammables such as gums, resins and sulfur. The assertion that Greek fire contained quicklime that reacted with water and generated heat to ignite the petroleum is certainly incorrect because quicklime does not give off any flame when it is quenched.

Whatever the composition of the original Greek fire may have been, the name persisted down to the middle of the 19th century. During the American Civil War, Confederate agents burned Union transports on the Mississippi by throwing into the holds bottles containing a spontaneously flammable mixture which they called Greek fire; they set fire to buildings in New York city by similar means. Northern artillery upon occasion fired so-called Greek fire shells in attempts to burn Confederate positions and towns.

Thickened Gasoline.—An important advance in incendiary mixtures during the 20th century occurred when gasoline was thickened or solidified by the addition of materials such as rubber,

plastics and soaps. The thickening process changed the liquid gasoline into a sticky, jellylike solid which was much less volatile than ordinary gasoline and which burned with an intense heat. Early in World War II several countries used natural rubber as a thickener. As supplies of rubber gave out other thickeners were found. The U.S. army chemical corps made use of a plastic known as isobutyl methacrylate, and of napalm (*q.v.*), an aluminum soap of naphthenic and coconut fatty acids. The U.S. army used millions of pounds of thickened gasoline during World War II and the Korean War in incendiary bombs, fire bombs and flame throwers (*q.v.*). *See* also AIR WARFARE: *The B-29 Campaign.*

Phosphorus. — One of the oldest incendiary mixtures is a solution of phosphorus. The ability of phosphorus to ignite spontaneously in air was discovered coincidentally with the isolation of phosphorus in 1669. After substances capable of dissolving phosphorus were found, it was natural that phosphorus solutions be suggested as incendiary agents. A common solvent is carbon disulfide which evaporates rapidly and leaves behind a residue of spontaneously ignitable phosphorus. British patents were issued to John Macintosh in 1855 and to John Norton in 1863 for shells containing solutions of phosphorus and carbon disulfide. The U.S. army chemical corps standardized a mixture of phosphorus, carbon disulfide and rubber as a filling for glass grenades in World War II.

The German air force used a filling of phosphorus, benzene and rubber in incendiary bombs dropped on England. One of the most effective and most widely used types of artillery ammunition in World War II and the Korean War was the white phosphorus shell.

Metallic Incendiaries. — Thermit type mixtures contain a metal and an oxide of another metal. A number of combinations may be made using various metals and oxides. One of the most common is a mixture of powdered iron oxide and powdered or granulated aluminum, similar to thermit (*q.v.*) used in welding. This mixture is inert at ordinary temperatures but when heated to a certain point by means of a first-fire charge, the ingredients react, forming iron and aluminum oxide. Intense heat then develops, raising the temperature of the mass to more than 2,000° C., hot enough to melt iron to a liquid. Iron–aluminum oxide mixtures with their burning characteristics modified by addition of other materials have been used in incendiary bombs, grenades and artillery shells. In World War II the magnesium bomb was a metallic incendiary used in great quantities. It consisted of an aluminum–magnesium body filled with a compressed thermit mixture.

Other Types.—The above classes of incendiary mixtures are those that are most important from the viewpoint of history or because of the large quantities used in warfare. Many other mixtures are known. Sulfuric acid and potassium chlorate react vigorously when they come in contact, a property that has been applied in constructing delayed action sabotage devices. Potassium and sodium react violently with water, generating hydrogen which then takes fire from the heat of reaction. This fact has led to the development of sodium–oil and potassium–oil mixtures that burn on the surface of water. The reaction between chromic anhydride and alcohol has been used to ignite gasoline in glass grenades. In the final analysis, the range of incendiary mixtures is limited only by the ingenuity of chemists.

See also CHEMICAL WARFARE. (W. D. Ms.)

INCENSE, the perfume (fumigation) arising from certain resins and gum resins, barks, woods, dried flowers, fruits and seeds when burned, and also the substances so burned. In its literal meaning the word incense is one with the word perfume, the aroma given off with the smoke *(per fumum)* of any odoriferous substance when burned. But, in use, while the meaning of the word perfume has been extended so as to include everything sweet in smell. from smoking incense to the invisible fresh fragrance of fruits and exquisite scent of flowers, that of the word incense, in all the languages of modern Europe in which it occurs, has, by an opposite process of limitation, been gradually restricted almost exclusively to frankincense. *'(See* FRANKINCENSE.)

Probably nowhere can the actual historical progress from the primitive use of animal sacrifices to the later refinement of burning incense be more clearly traced than in the pages of the Old Testament; but in the monuments of ancient Egypt the authentic traces of the use of incense that still exist carry us back to a much earlier date. From Meroë to Memphis the commonest subject carved or painted in the interiors of the temples is that of some contemporary *phrah* or Pharaoh worshipping the presiding deity with oblations of gold and silver vessels, rich vestments. gems, the firstlings of the flock and herd, cakes, fruits, flowers, wine, anointing oil and incense. One of the best known of these representations is that carved on the memorial stone placed by Tuthmosis (Thothmes) IV (1533 B.C.) on the breast of the sphinx at Gizeh. The tablet represents Tuthmosis before his guardian deity, the sun-god Ra, pouring a libation of wine on one side and offering incense on the other. The ancient Egyptians used various substances as incense.

They worshipped Ra at sunrise with resin, at midday with myrrh and at sunset with an elaborate confection called *kuphi,* compounded of no fewer than 16 ingredients, among which were honey, wine, raisins, resin, myrrh and sweet calamus. While it was being mixed, holy writings were read to those engaged in the operation. According to Plutarch, apart from its mystic virtues arising from the magical combination of four times four, its sweet odour had a benign physiological effect on those who offered it *(De Iside et Osiride,* c, 52). The censer used was a hemispherical cup or bowl of bronze, supported by a long handle, fashioned at one end like an open hand, in which the bowl was, as it were, held, while the other end within which the pastils of incense were kept was shaped into the hawk's head crowned with a disk, as the symbol of Ra. In embalming their dead the Egyptians filled the cavity of the belly with every sort of spicery except frankincense (Herodotus, ii, 86), for it was regarded as specially consecrated to the worship of the gods. In the burnt offerings of male kine to Isis, the carcass of the steer, after evisceration, was filled with fine bread, honey, raisins, figs, frankincense, myrrh and other aromatics, and thus stuffed was roasted, being basted all the while by pouring over it large quantities of sweet oil, and then eaten with great festivity.

How important the consumption of frankincense in the worship of the gods became in Egypt is shown by two of its monuments, both of the greatest interest and value for the light they throw on the early history of the commerce of the Indian ocean. One is an inscription in the rocky valley of Hammamat, through which the desert road from the Red sea to the valley of Egypt opens on the green fields and palm groves of the Nile river near Coptos. It was cut on the rocks by an Egyptian nobleman named Hannu, who states that he was sent by Pharaoh Seankhkare, Mentuhotep IV, with a force gathered out of the Thebaid, from Coptos to the Red sea, there to take command of a naval expedition to the holy land of Punt (Puoni) "to bring back odoriferous gums." Punt is identified with the Somali country, later known to be the native country of the trees that yielded the bulk of the frankincense of commerce. The other bears the record of a second expedition to the same land of Punt, undertaken by the command of Queen Hatshepsut, 1600 B.C. It was preserved in the vividly chiselled and richly coloured decorations portraying the history of the reign of this famous Pharaoh on the walls of the "Stage temple" at Thebes. The temple was later ruined, but the entire series of gorgeous pictures recording the expedition to "the balsam land of Punt," from its leaving to its returning to Thebes, remained intact and undefaced.

These were the only authenticated instances of the export of incense trees from the Somali country until Col. Robert Playfair, then political agent at Aden. in 1860–62 collected and sent to Bombay the specimens from which Sir George Birdwood prepared his descriptions of them for the Linnean society in 1868. King Antigonus is said to have had a branch of the true frankincense tree sent to him.

Homer tells us that the Egyptians of his time were emphatically a nation of druggists *(Odyssey,* iv, 229, 230). This characteristic, in which, as in many others, they so remarkably resembled the

Hindus. the Egyptians maintained to modern times, and, though they changed their religion, the use of incense among them continued to be as familiar and formal as ever. The kohl or black powder, with which the modern. like the ancient, Egyptian ladies painted their eyelids, was nothing but the smeeth of charred frankincense, or other odoriferous resin brought with frankincense, and phials of water, from the well of Zem-zem, by the pilgrims returning from Mecca. They also melted frankincense as a depilatory and smeared their hands with a paste into the composition of which frankincense entered, for the purpose of communicating to them an attractive perfume. Herodotus (iv, 75) describes a similar artifice as practised by the women of Scythia (compare also Judith x, 3, 4). In cold weather the Egyptians warm their rooms by placing in them a brazier, chafing dish or standing dish filled with charcoal, whereon incense is burned; and in hot weather they refresh the rooms by occasionally swinging a hand censer by a chain through them — frankincense, benzoin and aloe wood being chiefly used for the purpose.

In the authorized version of the Bible, the word "incense" translates two wholly distinct Hebrew words. In various passages in the latter portion of Isaiah (xl–lxvi), in Jeremiah and in Chronicles it represents the Hebrew *lebōnah,* more usually rendered "frankincense"; elsewhere the original word is ketoreth (Exodus xxx, 8. 9; Leviticus x, 1; Numbers vii. 14, etc.), a derivative of the verb kitter (Pi.) or hiktir (Hiph.), which verb is used, not only in Exodus xxx, 7, but also in Leviticus i, 9, iii, 11, ix, 13, and many other passages to denote the process by which the "savour of satisfaction" in any burnt offering, whether of flesh or of incense, is produced. Sometimes in the authorized version (as in I Kings iii, 3; I Samuel ii, 28) it is incorrectly made to mean the burning of incense. The expression "incense (ketoreth) of rams" in Psalms lxvi, 15, and the allusion in Psalms cxli, 2, ought both to be understood, most probably, of ordinary burnt offerings. The "incense" (ketoreth)! or "incense of sweet scents" (ketoreth sammim), called, in Exodus xxx, 3j, "a confection after the art of the apothecary," or rather "a perfume after the art of the perfumer," which was to be regarded as most holy, and the imitation of which was prohibited under the severest penalties, was compounded of four "sweet scents" (sammim), namely stacte (*nataph*), onycha (sheheleth), galbanum (helbenah) and "pure" or "fine" frankincense (*lebōnah zaccah*), pounded together in equal proportions, with (perhaps) an admixture of salt (memullah). It was then to be "put before the testimony" in the "tent of meeting" (a transference of late ceremonial back to the years of sojourn in "the wilderness"). It was burned on the altar of incense by the priest every morning when the lamps were trimmed in the holy place, and every evening when they were lighted or "set up" (Exodus xxx, 7, 8). A handful of it was also burned once a pear in the holy of holies by the high priest on a pan of burning coals taken from the altar of burnt offering (Leviticus xvi, 12. 13). Pure frankincense (*lebōnah*) formed part of the meat offering (Leviticus ii, 16, vi, 1j), and was also presented along with the shew bread (Leviticus xxiv, 7) every Sabbath day (probably on two golden saucers; see Josh., Ant., iii, 10, 7). The religious significance of the use of incense, or at least of its use in the holy of holies. is distinctly set forth in Leviticus xvi. 12, 13.

The introduction of incense took place late in the history of the Jewish ritual (see J. Wellhausen, Geschichte *Israels,* i, 75 et seq. [1878]); but evidently the idea that the odour of a burnt offering (cf. the κνίσης ἡδὺς ἀϋτμή of Od., xii, 369) is pleasing to the deity, being at least the vehicle by which the sacrifice can be successfully conveyed to its destination, was a survival of a very early belief and underlies the biblical phrase "a savour of satisfaction" (Genesis viii, 21; Leviticus i, 9, and elsewhere; cf. Ephesians v, 2). It is probable that the development of a sensuous appreciation of pleasant perfumes, and knowledge of the sources from which these could be derived, expressed itself not only in domestic habits, sanitation, etc., but also in religious ceremonial: so that the custom of adding some kind of incense to animal sacrifices naturally arose. The final stage (not reached in the Levitical ritual) was the offering of incense pure and simple.

The "marbles" of Nineveh furnish frequent examples of the offering of incense to the sun-god and his consort (II Kings xxiii, 5). The kings of Assyria united in themselves the royal and priestly offices, and on the monuments they erected they are generally represented as offering incense and pouring out wine to the tree of life. According to Herodotus (i, 183), frankincense to the amount of 1,000 talents' weight was offered every year, during the feast of Bel, on the great altar of his temple in Babylon.

The monuments of Persepolis and the coins of the Sassanians show that the religious use of incense was as common in ancient Persia as in Babylonia and Assyria. Five times a day the priests of the Persians (Zoroastrians) burned incense on their sacred fire altars. Herodotus (iii, 97) states that the Arabs brought every year to Darius as tribute 1,000 talents of frankincense. The Parsees still preserve in western India the pure tradition of the ritual of incense as followed by their race from probably the most ancient times.

The Ramayana and *Mahabharata* afford evidence of the employment of incense by the Hindus. in the worship of the gods and the burning of the dead, from the remotest antiquity Its use was obviously continued by the Buddhists during the prevalence of their religion in India, for it is still used by them in Nepal, Tibet. Ceylon. Burma, China and Japan. These countries all received Buddhism from India. and a large proportion of the porcelain and earthenware articles imported from China and Japan into Europe consists of innumerable forms of censers. Jains all over India burn sticks of incense before their Jina. The commonest incense in ancient India was probably frankincense. The Indian frankincense tree is found chiefly where the Buddhist religion prevailed in ancient times. in Bihar and along the foot of the Himalayas and in western India. where it particularly flourishes in the neighbourhood of the Buddhist caves at Ajanta. Now, however, the incense in commonest use in India is benzoin. But the consumption of all manner of odoriferous resins, gum resins, roots, woods, dried leaves. flowers. fruits and seeds in India, in social as well as religious observances, is enormous. The incense sticks and pastils made at the Mohammedan city of Bijapur in the Maratha country are celebrated all over western India.

The Indian Moslems use incense at the ceremonies of circumcision, *bismillah* (teaching the child "the name of God"), virginity and marriage. At marriage they burn benzoin with nim seeds to keep off evil spirits, and prepare the bridecakes by putting a quantity of benzoin between layers of wheaten dough. closed all round, and frying them in clarified butter. For days the bride is fed on little else. In their funeral ceremonies, the moment the spirit has fled incense is burned before the corpse until it is carried out to be buried. The begging fakirs also go about with a lighted stick of incense in one hand, and holding out with the other an incense holder (literally, "incense chariot"), into which the coins of the pious are thrown. Large "incense trees" resembling the Christmas trees of the western world, formed of incense sticks and pastils and osselets and alight all over. are borne by the Shi'ah Moslems in the yearly procession of the Mohurrum, in commemoration of the martyrdom of the sons of Ali.

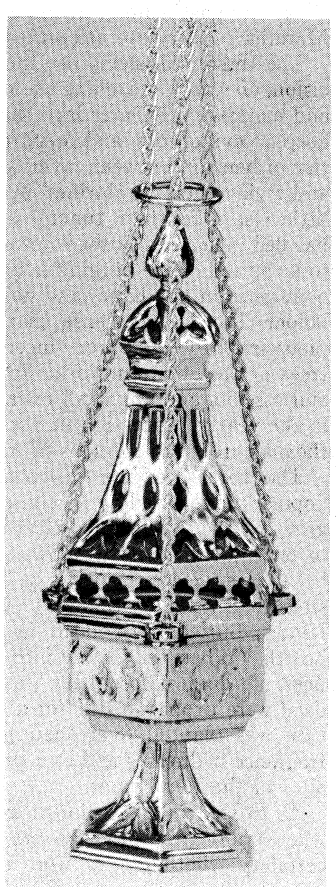
The worship of the *tulsi* plant, or holy basil, by the Hindus is popularly explained by its consecration to Vishnu and Krishna. It grows on the four-horned altar before the house, or in a pot placed in one of the front windows, and is worshipped every morning by all the female members of every Hindu household. It is possible that its adoration has survived from the times when the Hindus buried their dead in their houses, beneath the family hearth. When they came into a hot climate the fire of the sacrifices and domestic cookery was removed from the house; but the dead were probably still for a while buried in or near it, and the *tulsi* was planted over their graves. at once for the salubrious fragrance it diffuses and to represent the burning of incense of the altar of the family Lar.

As to the θύεα mentioned in Homer (Iliad, ix, 499, and elsewhere) and in Hesiod (Works *and* Days, 338), there is some uncertainty whether they were incense offerings at all, and if so, whether they were ever offered alone, and not always in conjunction with animal sacrifices. That the domestic use, however. of the fragrant wood θύον (arborvitae) was known in the Homeric

age is shown by the case of Calypso (Odyssey, v, 60), and the very similarity of the word θύον to θύος may be taken as almost conclusively proving that by that time the same wood was also employed for religious purposes. It is not probable that the sweet-smelling gums and resins of the countries of the Indian ocean began to be introduced into Greece before the 8th or 7th century B.C., and doubtless λίβανος or λιβανωτός first became an article of extensive commerce only after the Mediterranean trade with the east had been opened up by the Egyptian king Psammetichus (*c.* 663–609 B.C.). The new oriental word is frequently employed by Herodotus, and there are abundant references to the use of the thing among the writers of the golden age of Attic literature (see, for example, Aristophanes, *Plut.,* 1.114; Frogs, 871, 888; Clouds, 426; *Wasps,* 96, 861). Frankincense, however, though the most common, never became the only kind of incense offered to the gods among the Greeks. Thus the Orphic hymns are careful to specify, in connection with the several deities celebrated. a great variety of substances appropriate to the service of each; in the case of many of these the selection seems to have been determined not at all by their fragrance but by some occult considerations which it is now difficult to divine.

Among the Romans the use of religious fumigations long preceded the introduction of foreign substances for the purpose (see, for example. Ovid, Fast., i, 337 et seq., Et non *exiguo laurus adusta sono*). Later the use of frankincense (*mascula thura,* Virgil. Eclogues, viii, 6j) became very prevalent, not only in religious ceremonials, but also on various state occasions; such as in triumphs (Ovid, *Tristia,* iv, 2, 4), and also in connection with certain occurrences of domestic life. In private it was daily offered by the devout to the *Lar* familiaris (Plautus, *Aulularia,* prol. 23); and in public sacrifices it was not only sprinkled on the head of the victim by the pontifex before its slaughter, and afterward mingled with its blood, but was also thrown upon the flames over which it was roasted.

No perfectly satisfactory traces can be found of the use of incense in the ritual of the Christian church during the first four centuries. (Cf. L. M. O. Duchesne. Christian Worship [Eng. trans., 1904], ch. ii, "The Mass in the East," v, "The Books of the Latin Rite," and xii, "The Dedication of Churches.") Its use was foreign to synagogue services on which the worship of the primitive Christians is known to have been originally modeled; and its associations with heathen solemnities, and with the evil repute of those who were known as "thurificati." would still further militate against its employment. Various authors of the ante-Nicene period have expressed themselves as distinctly unfavourable to its religious, though not, of course, to its domestic, use. Thus Tertullian, while (De Cor. *Mil.,* 10) ready to acknowledge its utility in counteracting unpleasant smells ("si me odor alicujus loci offenderit, Arabiae aliquid incendo"). is careful to say that he scorns to offer it as an accompaniment to his heartfelt prayers (*Apol.,* 30; cf. 42). Athenagoras also (*Legat.,* 13) gives distinct expression to his sense of the needlessness of any such ritual ("the Creator and Father of the universe does not require blood, nor smoke, nor even the sweet smell of flowers and incense"); and Arnobius (*Adv. Gent.,* vii, 26) seeks to justify the Christian neglect of it by the fact, for nhich he vouches, that among the Romans themselves incense was unknown in the time of Numa, while the Etruscans had always continued to be strangers to it.



BY COURTESY OF JOHN P DALEIDEN CO.

INCENSE CENSER USED IN THE ROMAN CATHOLIC CHURCH

St. Cyril of Jerusalem, St. Augustine and the Apostolic Constitutions make no reference to any such feature either in the public or private worship of the Christians of that time. But in the Apostolic Canons (can. 3) the θυμίαμα is spoken of as one of the requisites of the eucharistic service. It is easy to perceive how it should inevitably have come in along with the whole circle of ideas involved in such words as "temple," "altar," "priest," which about this time came to be so generally applied in ecclesiastical connections. At a later date Roman Catholic theologians treated it as symbolically typifying the prayers of the faithful and the virtues of the saints. Ultimately the word incense was sometimes used symbolically of prayer; a usage anticipated in Revelation v, 8, viii, 3, 4 (cf. Origen. Contra *Celsum,* viii, 17, 20).

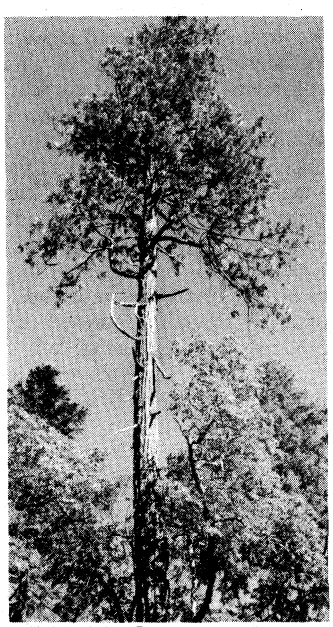
Incense in the **Church** of England. — The missal of the Roman Church, however, enjoins incensation before the introit, at the gospel and again at the offertory, and at the elevation. in every high mass; the use of incense also occurs at the exposition of the sacrament. at consecrations of churches and the like, in processions. in the office for the burial of the dead and at the exhibition of relics. On high festivals the altar is censed at vespers and lauds. There is reason to believe that. notwithstanding the order for the use of incense at every celebration, it was used in British churches only on high festivals. and then only in rich churches down to the period of the Reformation, and that the ritual of the mass remained unchanged until the death of Henry VIII (Jan. 28, 1547). On Whitsunday 1549 the first prayer book of Edward VI came into use under the first Act of Uniformity (2 and 3 Ed. VI, ch. 1), which required its exclusive use in public worship so as to supersede all other forms of service. Another act (3 and 4 Ed. VI, ch. 10) required the old service books to be delivered up to be destroyed. The first prayer book does not contain any direction to use or any mention of incense. It is a controverted question whether incense did or did not continue to be in ceremonial use under the first prayer book or during the rest of Edward VI's reign. No evidence has hitherto been discovered which justifies us in answering this question in the affirmative. The second prayer book of Edward VI (1552), published under the authority of the second Act of Uniformity (5 and 6 Ed. VI, ch. 1), contains no reference to incense. Edward VI died July 6, 1553. Queen Mary by statute (1 Mary, sess. 2, ch. 2) abolished the prayer book. repealed the Acts of Uniformity and restored "divine service and administration of sacraments as were most commonly used in England in the last year of Henry VIII." The ceremonial use of incense thus became again an undoubted part of the communion service in the Church of England. A proclamation issued (Dec. 6, 1553) directed the church wardens to obtain the proper ornaments for the churches; and the bishops in their visitations inquired whether censers had been furnished for use. Mary died Nov. 17, 1558. On June 24, 1559, the second prayer book of Edward VI (with a few alterations having no reference to incense) was again established, under the authority of the third Act of Uniformity (1 Eliz., ch. 2), as the exclusive service book for public service. There is no evidence of the ceremonial use of incense under Elizabeth's prayer book, or under the present prayer book of 1662 (established by the fourth Act of Uniformity. 13 and 14 Charles II. ch. 4) until the middle of the 19th century; and there is no doubt that as a ceremony of divine worship. whether at the Holy Communion or at other services, it was entirely disused. There are a good many instances recorded of what has been called a fumigatory use of frankincense in churches, but this use of incense — which was utilitarian and not symbolical — must be carefully distinguished from its ceremonial use. In the general revival of church ceremonial which accompanied and followed the Oxford movement incense was not forgotten, and its ceremonial use in the pre-Reformation method was adopted in a number of churches after 1850. Its use has been condemned as an illegal ceremony by the

ecclesiastical courts. In 1868 Sir Robert Phillimore (dean of the arches) pronounced the ceremonial use of incense to be illegal in the suit of *Martin* v. *Mackonochie* (2 A. and E.L.R. 116). The case was carried to the privy council on appeal, but there was no appeal on the question of incense. Again, in 1870, the ceremonial use of incense was condemned by Sir Robert Phillimore in the suit of *Sumner* v. *Wix* (3 A. and E.L.R. 58).

Notwithstanding these decisions, it was insisted by those who defended the revival of the ceremonial use of incense that it was a legal custom of the Church of England. The question was once more elaborately argued in May 1899 before an informal tribunal consisting of the archbishop of Canterbury (Frederick Temple) and the archbishop of York (William Maclagan), at Lambeth palace. On July 31, 1899, the archbishops decided that the liturgical use of incense was illegal. The Lambeth "opinion." as it was called, failed to convince the clergy against whom it was directed any better than the judgments of the ecclesiastical courts, but at first a considerable degree of obedience to the archbishops' view was shown. Various expedients were adopted, as, *e.g.*, the use of incense just before the beginning of service, by which it was sought to retain incense without infringing the law as laid down by the archbishops. There remained, nevertheless. a tendency on the part of the clergy who used incense, or desired to do so, to revert to the position they occupied before the Lambeth hearing—that is, to insist on the ceremonial use of incense as a part of the Catholic practice of the Church of England which it is the duty of the clergy to maintain. notwithstanding the decisions of ecclesiastical judges or the opinions of archbishops to the contrary.

Hastings, *Encyclopaedia of Religion and Ethics* (with many refs.); E. G. Atchley, *History of the Use of Incense in Divine Worship* (1909). *See* also PERFUMES.

INCENSE CEDAR *(Libocedrus decurrens)* is a handsome North American tree of the cypress family (Cupressaceae), native to high mountains from Oregon and Nevada to Lower California. It is a valuable timber tree, with cinnamon-red bark, frequently attaining a height of 150 ft., and sometimes a trunk diameter of 7 ft. The slender branches, with much-flattened branchlets and lustrous, cypresslike leaves, form a beautiful crown. The soft, durable, straight-grained, fragrant, resinous wood is utilized for pencil slats, fence posts, telephone poles and lumber.



RUTHERFORD PLATT

THE INCENSE CEDAR (LIBOCEDRUS DECURRENS)

The incense cedar is planted for ornament, as is. also the smaller South American species *(L. chilensis)*. Besides the foregoing, six other species of incense cedar are found, one each in Chile, New Caledonia, China and Japan and two in New Zealand. Of these. L. *uvifera* of Chile and *L. plumosa* of New Zealand are valuable timber trees.

INCEST, sexual intercourse between persons so related by kindred or affinity that legal marriage cannot take place between them *(see* MARRIAGE, LAW OF, especially the section *Canon Law).*

In England incest formerly was not generally treated as a crime. although, along with other offenses against morals. it was made punishable by death in 1650. After the Restoration it was. to use W. Blackstone's phrase, left to the "feeble coercion of the spiritual courts," but bills to make it a criminal offensewere at various times unsuccessfully introduced in parliament. In 1908, however, an act (the Punishment of Incest act, 1908) was passed under which sexual intercourse of a male with his granddaughter, daughter. sister or mother is made punishable with penal servitude for not less than three or more than seven years, or with imprisonment for not more than two years with or without hard labour. It is immaterial that the sexual intercourse was had with the consent of the female; indeed, by s. 2 a female who consents is on conviction liable to the same punishment as the male. The act also makes an attempt to commit the offense of incest a misdemeanor, punishable by imprisonment for not more than two years with or without hard labour. The terms "brother" and "sister" include half brother and half sister, whether the relationship is or is not traced through lawful wedlock. Formerly all proceedings under the act were held in *camera* (s. 5), but this provision was repealed by the Criminal Law Amendnient act, 1922. In *Rex* v. *Ball* (22 Cx. C.C. 366) it was held by the house of lords that evidence of previous intercourse was admissible to establish guilty passion and rebut innocent association. In the law of Scotland, it was, until the Criminal Procedure (Scotland) act, 1887, a crime nominally punishable with death, but the penalty usually inflicted was penal servitude for life. This sentence was actuallv pronounced on a man in 1855.

In the United States incest, though not an indictable offense at common law, has, generally speaking, been made a felony by statute and punishable by fine or imprisonment or both. It is also a punishable offense in some European countries, notably Germany, Austria and Italy. (W. DE B. H.)

INCH: *see* WEIGHTS AND MEASURES.

INCHBALD, ELIZABETH (1753–1821), English novelist, playwright and actress whose novel *A Simple Story* may have inspired Charlotte Brontë in writing *Jane Eyre,* was born at Standingfield, Suffolk, Oct. 15, 1753, the daughter of Joseph Simpson. At 18 she ran away to London to seek her fortune on the stage. Two months later she married Joseph Inchbald. an actor, and made her debut at Bristol as Cordelia to his Lear. They toured the provinces until his sudden death in 1779, after which she continued to act for ten years, also writing adaptations of plays and some original farces and comedies, the most successful being *I'll Tell You What* (1785). She was never a great actress, but her beauty, vivacity and blameless personal life won her great admiration. Her fame rests upon her two novels, *A Simple Story* (1791) and *Nature and Art* (1796); they are among the earliest examples of the novel of passion and enjoyed immediate success.

Mrs. Inchbald died at Kensington on Xug. 1, 1821.

BIBLIOGRAPHY.—J. Boaden, *Memoirs of Mrs. Inchbald,* 2 vol. (1833); Fanny Kemble, *Records of a Girlhood* (1878); W. Bell Scott, preface to *A Simple Story* (1880); S. R. Littlewood, *Elizabeth Inchbald aad her Circle* (1921).

INCHCAPE, JAMES LYLE MACKAY, 1ST EARL (1852–1932), British shipowner, was born at Arbroath. Forfarshire, on Sept. 11, 1852, and educated there and at Elgin. In 1874 he went to India to join the firm of Mackinnon, hfackenzie and company, Calcutta, of which he ultimately became senior partner; he was a member of the legislative council of the viceroy (1891–93) and a member of the Council of India from 1897 to 1911.

In 1902, consequent upon the Boxer rebellion: Mackay negotiated a commercial treaty with China. In 1911 he was raised to the peerage as Baron Inchcape of Strathnaver. As a representative of the shipping industry Inchcape took a leading part in all its affairs both during World War I and after, being president of the Chamber of Shipping of the United Kingdom (1893, 1918, 1919) and president of the Shipping federation (1926). He served on most of the government commissions of inquiry both in India and England. He was a member of the Geddes committee on national expenditure (1921) and chairman of the Indian retrenchment committee (1922). In 1924 he was created viscount and grand commander of the order of the Star of India. The positions of chairman of the P. and O. Steam Navigation company and director of the National Provincial bank and Suez Canal company were other important positions which he occupied. In 1928 Lord Inchcape lost his daughter, Elsie Mackay, in an attempted transatlantic flight. He was created an earl June 3, 1929. He died at Monaco, May 23, 1932.

INCHIQUIN, MURROUGH O'BRIEN, 1ST EARL OF (c. 1614–1674), Irish soldier and statesman, was the son of Dermod O'Brien, 5th Baron Inchiquin (d. 1624). He belonged to a great family which traced its descent to Brian Boroimhe, king of Ireland, and which was always to the forefront in Irish public life. The first baron of Inchiquin was another Murrough O'Brien (d. 1551) who, after having made his submission to Henry VIII, was created baron of Inchiquin and earl of Thomond in 1543. When Murrough died in Nov. 1551 his earldom passed to his nephew Donogh, son of Conor O'Brien (d. 1539), the last independent prince of Thomond (see THOMOND, EARL AND MARQUESS OF), leaving only his barony to be inherited by his son Dermod (d. 1557), the ancestor of the later barons of Inchiquin.

Murrough O'Brien, who became 6th baron of Inchiquin in 1624, took an active part in suppressing the Irish rebellion which broke out in 1643, and during the Civil War the English parliament made him president of Munster. Early in 1648, however, he declared for Charles I, and for about two years he sought to uphold the royalist cause in Ireland. He then emigrated. In 1654 Charles II made him an earl. He died on Sept. 9, 1674.

His son WILLIAM, 2ND EARL OF INCHIQUIN (c. 1638–1692), served under his father in France and Spain, and for six years was governor of Tangier. He was a partisan of William III in Ireland, and in 1690 he became governor of Jamaica, where he died in Jan. 1692. In 1800 his descendant Murrough, the 5th earl (d. 1808), was created marquess of Thomond, but on the death of James, the 3rd marquess, in July 1855 both the marquessate and the earldom became extinct.

INCIDENTAL MUSIC, a type of music so called because it is incidental or subservient to the action of a play, film, radio or television program, being intended to reflect or enhance a dramatic situation, rather than to form an integral part of it. The best of such music, originally written to form part of a dramatic performance, has acquired a life of its own, and can be played and heard without reference to the work for which it was intended, although it is, in a sense, "programme music" (*q.v.*), *i.e.*, music written to express a literary idea, rather than a purely musical one.

The place of music in drama is closely bound up with the origins of both drama and opera (*qq.v.*). It is not really possible to describe the music in Greek drama or in oriental drama, with its ritual associations, as "incidental," although the songs in Menander's comedies seem to have been forerunners, as do the flute accompaniments to speeches in Roman plays. In any case, our knowledge of this music can only be inferred from stage directions and it is difficult to determine how far it was regarded as essential, or whether it always took the same form. The gradual emergence of drama from the liturgy of the church in the late middle ages was marked by a development of a more truly "incidental" music. But it was not until the 16th century that the use of music in the theatre began to approximate to modern practice. In Italy attention was concentrated on opera and oratorio, and in England on the spoken drama: thus it was in England that incidental music developed. It took the form of songs within the plays themselves, interludes between acts and instrumental music accompanying the interpolated dumb shows or masques or even off-stage (indicated by the frequent stage direction "music within") as a means of heightening dramatic effect. Early examples of such music are the comic songs in Nicholas Udall's *Ralph* Roister Doister (c. 1553), the dumbshom music in Gorboduc (1562) and the music between the acts in *Gammer Gurton's* Needle (c. 1559).

Incidental music was used in a variety of ways by Shakespeare. The use of songs serves many dramatic purposes and instrumental music not only forms an accompaniment to the masque scenes (as in *Timon* of Athens, *Much* Ado about Nothing and Tlze *Tempest*), and to the dances which sometimes ended the plays, but also heightens the dramatic tension (as in the casket scene in the *Merchant* of Venice), and introduces supernatural characters (as in *Cymbe*line, *Pericles* and As You Like It). Knowledge of this music is derived both from Shakespeare's own stage directions (*e.g.*, "Music! ho") and from the inventories of Elizabethan theatres, which show the types and number of instruments used and make possible a reconstruction of the manner of performance. Settings of Shakespeare's songs were made by such contemporary composers as Robert Johnson, Thomas Morley and John Wilson.

In the Restoration theatre elaborate scores of incidental music were written by Purcell for adaptations of A *Midsummer Night's* Dream and *The* Tempest, for John Dryden's King Arthur and for The Indian Queen by Dryden and Robert Howard. Purcell also wrote incidental music for about 40 other plays, by Thomas Durfey, Beaumont and Fletcher, John Dryden, Thomas Shadwell, William Congreve and others.

In France Lully, in association with Molière, wrote a series of *comédies-ballets,* forming interludes in the plays for the *Plaisirs* du Roi (Louis XIV). The king and princes of the blood themselves took part in the performances of these ballets which fell into two categories: majestic ballets such as that in Les *Amants magnifiques* and comic ballets such as those in Monsieur de Pourceaugnac and Le Bourgeois *Gentilhomme*. Since vocal items were introduced into these ballet interludes the former was held to have anticipated the French opera and the latter the *opéra-comique*.

In the 18th century there was relatively little incidental music, though Handel wrote music for Ben Jonson's *The* Alchemist (1732) and Mozart for T. P. von Gebler's *Thamos,* Konig in *Aegypten* (1779). Where opera and drama were performed in the same subsidized theatre, as at the 19th-century German and Austrian courts, the orchestra was also available for dramatic productions with the result that incidental music was written by Beethoven for Goethe's *Egmont* (1810), by hfendelssohn for A *Midsummer* Night's Dream (1843) and by Schumann for Byron's *Manfred* (1852). These scores, like those by Bizet for Daudet's *L'Arlésienne,* Grieg for Ibsen's Peer Gynt and Fauré for Maeterlinck's *Pelléas* et *Mélisande,* were later played independently of the plays for which they were written and which they sometimes outlived.

Among later associations of playwrights and composers of incidental music are those of Paul Claudel and Darius Milhaud, Virgil Thomson and Ernest Hemingway and Benjamin Britten and W. H. Auden.

Toward the middle of the 20th century developments in motion-picture productions and in radio and television programs created an enormous demand for incidental music. Much of it was ephemeral, but some of the scores by composers who experimented with new forms of film and broadcast music, among them T'aughan Williams and Prokofiev, survived in their own right. These new opportunities in film and radio for incidental music increasingly supplied the main sources of income for many composers. Motion pictures and radio also made use of experiments with electronic music in Germany, Italy and France. These types of incidental music branched out in two directions. They either tended to become more accurate and telling in expression, as when films or radio programs represented the joint efforts of composer and producer; or they tended to become debased, as when background music was selected from libraries of recorded music, written not so much to be heard during the performance as to be overheard.

(E. LR.)

INCINERATOR, a term which came into use during the first half of the 20th century, replacing "destructor" in England and "crematory" in the United States, to describe a plant designed to burn solid wastes (refuse). An incinerator is comprised of a furnace into which the refuse is charged and ignited, a secondary combustion chamber in which burning at a high temperature is continued to complete the combustion process, flues to convey the gases of combustion to a chimney and thence to the atmosphere. Incinerator plants also include facilities for unloading and storing the refuse for short periods to permit uniform charging of the furnaces, and a building, if necessary, to house the incinerator appurtenances. Incineration of community refuse is not a complete disposal process as the remaining ash (about 10% by volume) must be disposed of (see REFUSE DISPOSAL).

The growth of large cities was primarily responsible for the development of refuse incinerators since it was not practical from nuisance, public health and aesthetic viewpoints to permit refuse dumps in their midst. The burning of refuse provided an efficient means of inoffensively reducing the bulk of refuse to a readily

transportable and often usable ash. To accomplish the burning in a sanitary and effective manner it was necessary to develop specialized furnaces and other equipment as well as buildings laid out to facilitate delivery, storage, handling and salvage of the refuse and ash.

Although many refinements of equipment have been developed during the 20th century the basic components of a municipal incinerator remain the same.

Incineration Costs.—Incineration has always been costly as compared with other methods of disposal, so it is usually resorted to as a final choice dictated by necessity. In the United States, capital costs for pit-and-crane incinerators have been found to range from $3,000 to $4.500 per ton of rated capacity. Of a complete municipal incinerator, about 40% of the cost is for the furnaces and their appurtenances and about 60% for the access roads and ramps, storage bins, building and chimney. Operating costs range from $3 to $6 per ton of refuse burned.

Nature of Refuse.—Town or community refuse is considered the useless, unused or unwanted solid wastes resulting from the normal course of community activity. It consists primarily of food wastes (garbage), rubbish (paper, wood, glass, metal, leather, plastic, etc.) and ashes.

The composition of refuse received at an incinerator plant may vary widely with the season of the year and with local conditions, such as the presence of various industries: Pre-World War II analysis of English refuse indicated its composition to average 48% noncombustibles (including fine dust) and 52% combustibles, such as rags, garbage, paper and cinders. Later analyses on a limited basis showed a higher vegetable content. The average over-all yield of town refuse in England is about 1,800–1,900 lb. per 1,000 population per day. In the United States, an analysis of refuse in a city where natural gas was used extensively could be expected to show 80% by weight of combustible material (paper, rags, wood, garbage), 13% of noncombustibles (metals, glass) and only 7% ash. Normally, community incinerators in the United States and Canada are designed to handle 2.500 lb. of refuse per 1,000 population per day. A higher design figure is needed where a heavy industrial refuse contribution is encountered.

For plant design purposes the combustible component of refuse may be considered the same as cellulose ($C_6H_{10}O_5$). Actually, refuse contains a small percentage of carbohydrates and fats but these do not influence the design significantly. The calorific or heat value of refuse has been found to vary from 3,000 to 5,000 B.T.U. per pound in England.

Incinerators constructed by the city of New York utilized a calorific design value of 4,000 B.T.U. per pound (7,000 to 9,000 B.T.U. per pound of dry combustible solids).

Engineering Design.—The combustion equipment in an incinerator plant is similar to the furnace system in a power plant, except that it must be designed to receive a heterogeneous fuel rather than a uniform fuel such as coal or oil. In order to determine the amount of air and, if necessary, auxiliary fuel needed to consume the combustible refuse and evaporate the water present, it is necessary to compare the heat value of the refuse with the heat required to maintain the proper combustion temperature. Through use of the basic combustion formula (cellulose + oxygen → carbon dioxide + water) and the molecular weights of the combustible refuse, the amount of oxygen and thus the air required to sustain combustion is found. The total moisture in the refuse and in the combustion air, the water formed during the combustion process and heat losses through furnace doors and refractories are calculated to determine minimum heat requirements to raise the gases of combustion to at least 1,300° F. The heat available from the refuse is then calculated to determine the excess heat value available or additional heat required for proper combustion.

Facilities for Receiving Refuse.—Refuse is usually delivered to an incinerator in trucks. It may then be fed directly into a furnace or undergo a separation process to remove salvable material before the remainder is incinerated. In England, the relative economics of direct salvage of components of the refuse v. the production of steam from burning it was an issue for many years. Successful plants of both systems were built, the controlling feature being local conditions. However, subsequent to World War II, very few plants in Great Britain were designed on the direct incineration principle. In the Cnited States, because of the high cost of separating refuse and the poor market potential for salvage, direct incineration is practiced almost exclusively.

Incinerator plants are referred to as "floor dump" plants or "pit-and-crane" plants depending on whether the refuse is dumped on the charging floor and pushed into the charging opening to the furnace or dumped into a pit first for storage and subsequently fed into the furnace with a bucket crane. Smaller plants operated eight hours a day are usually of the floor dump type since the storage area required for the refuse received is not great; such plants require smaller capital outlay and can be operated more economically on a limited basis. Cities of more than 100,000 population almost always build pit-and-crane plants since it is more economical for such plants to operate on a 16- to 24-hr. basis.

The refuse is collected and delivered to the plant during the eight-hour working day. The storage pits of a modern plant are usually designed to hold 70% to 100% of the plant's 24-hr. burning capacity.

Furnaces.—The furnace chamber of an incinerator, sometimes called the primary or ignition chamber, must be designed to promote the rapid desiccation of the raw refuse, leaving only volatile gases to be burned in the secondary chamber and ashes to fall into the ash pit.

A mixing chamber, placed immediately following the combustion chamber and equipped with baffles or restricted passageways, promotes mixing and burning of volatile gases to prevent odours. The gases in the mixing chambers should be at a temperature of at least 1,300° F., and usually the temperature is from 1,600° to 1,800° in modern incinerators. A secondary combustion or expansion chamber is provided to permit expansion of the combustion gases, complete the burning process and permit particulate matter (fly ash) to settle out.

The sizes of these chambers are governed by the volume of the gas produced in the combustion process. After the amount of refuse that must be burned per hour is established, grate areas, chamber volumes and size and placement of air ports are determined. U.S. designs which take into account air pollution requirements employ a grate loading factor of about 50 lb. per square foot per hour.

Similarly, a furnace volume of 12.5 cu.ft. per ton of rated capacity is deemed reasonable and a combined volume of the secondary combustion chambers and flues of 80 cu.ft. per ton of rated capacity is indicated for municipal plants (rated capacity of a plant is the amount of refuse in tons that can be burned over a 24-hr. period).

Grates.—The function of a grate is to support the refuse without leakage of the combustibles and to provide a free flow of air to support combustion. The design of furnace grates has undergone considerable change because community refuse no longer consists primarily of garbage with its high moisture content and because high labour costs have necessitated automation.

Prior to World War II practically all incinerators constructed in the United States were hand stoked. Within a few years after the war, automatic and semiautomatic mechanical grates were being installed in practically all new plants. Mechanical grates developed during this period were of four basic types: rectangular, cylindrical, traveling grate and rotary kiln.

The rectangular type (fig. [D]) is provided with alternately moving stoker bars that agitate the burning refuse and keep noncombustible materials moving toward the front of the furnace, where they pass through a dumping grate.

In the cylindrical incinerator (fig. [B]), refuse is dropped onto a circular grate over a rotating perforated cone through which cdmbustion air is passed. Ravel arms, attached to the cone, stir the burning mixture and move unburned material toward dumping grates at the outer edges.

Higher production rates can be achieved in incinerators equipped with traveling grate stokers (fig. [A]), for these permit continuous charging of refuse and removal of residue. In this type, the more inflammable refuse is largely consumed on the ignition

BASIC INCINERATOR DESIGNS

(A) Traveling grate: (B) cylindrical; (C) rotary kiln; (D) rectangular

stoker; the remainder then drops onto the burning stoker, which runs about 25% faster than the ignition stoker so as to spread the less inflammable materials thinner over the grate surface.

Continuous charging and residue removal also is possible in the rotary kiln incinerator (fig. [C]), in which refuse is dumped onto an inclined grate and thence into a rotary kiln, which provides greater agitation and more intimate mixing with combustion air.

Flues.—A flue is the connection between the secondary combustion chamber and the chimney. In large plants, when more than one furnace is employed, the flues are interconnected so that one chimney can serve two or more units. Flues are designed to facilitate removal of particulate matter from the combustion gases as they flow to the chimney.

Chimneys.—The chimneys (or stacks, as they are usually referred to in the United States and Canada) are the means of conveying the gases of combustion to the atmosphere. Their dimensions must be chosen so as to obtain proper draft for the incinerator and to dispense the gases over a wide area. A large municipal plant may have a chimney as high as 200 ft., depending on the velocity and volume of flue gases, the height of nearby buildings and the nature of the terrain.

Preheaters.—If an incinerator handles a large percentage of refuse of high moisture content, a recuperative type of preheater is placed before the flues to furnish preheated air to the forced draft fan supplying air to the stoker. In the United States, community refuse is composed primarily of readily burnable material and preheaters are not used in many incinerators. Auxiliary oil or gas burners in the furnace may be provided in lieu of preheaters in order to maintain combustion chamber temperatures for short periods when the refuse contains a high percentage of moisture.

Draft Facilities.—The air needed for combustion is provided by forced, by induced or by natural draft. The first two require fans; the third requires a chimney of adequate height and cross-sectional area. The quantity of air required varies from 4 lb. per pound of mixed refuse with 54% moisture to more than 10 lb. per pound of highly combustible rubbish having a moisture content of 15%. In the latter instance almost half of the air requirement is needed to cool gaseous products of combustion to prevent thermal damage to the furnace refractories. Dampers to regulate furnace draft are usually placed between the combustion chamber and the secondary chamber or between the secondary chamber and the flues.

Ash Hoppers.—The ash hoppers are designed to receive the residue or ash from the furnace grate. Hoppers usually are of steel construction and lined with vitrified paving brick. Usually the ash is cooled by water quenching in the hoppers and dumped directly into a truck or transported through a water bath on an endless belt conveyor to an ash storage hopper or to an ash truck.

Instruments.—The instruments necessary for operation of the plant usually include recording pyrometers connected to thermocouples placed in the combustion chamber and chimney, gauges to record draft at the base of the chimney and forced draft pressure beneath the grates, a recording meter for wind direction and a smoke density meter mounted in the chimney. A carbon dioxide recorder for determining the percentage of CO_2 in the flue gases is also recommended. The instruments usually are mounted on the stoking floor for easy observation by the operator.

Fly Ash Control.—The problem of controlling particulate matter (fly ash) in the combustion gases to prevent a nuisance condition from the plant chimney discharge in the vicinity of the incinerator has continued to plague designers. The expense of installing. maintaining and operating the necessary fly ash control equipment has been the principal deterrent to achieving desired standards. Two basic methods of fly ash control are used in modern incinerators: entrapment with water sprays (or baffles) and gravity settlement. Fly ash emission was effectively controlled in one type of incinerator by utilizing extremely large flues along with a series of wall baffles to settle out and trap the fly ash under natural draft conditions. Another incinerator design accomplished fly ash removal by using forced draft to force the flue gases through stainless steel baffles equipped with water sprays; the water trapped the particulate matter in the gases and carried it via drains to a lagoon where the ash was allowed to settle out.

Waste Heat Utilization.—Much attention has been paid to the possible utilization of the heat generated by the incineration process for steam or power production. In Great Britain many such plants were built in the early half of the 20th century. It was found in the Birmingham plants, for example, that 2 lb. of steam were obtained from each 1 lb. of refuse burned. Glasgow had a successful scheme of power production wherein the electrical authority purchased excess power from the incinerating plant to help meet demand periods during the week. The incinerating plant ran for 5½ days each week and thus its power production fitted in with the demand for electricity, which fell off on Saturday afternoon and Sunday.

Generation of steam for heating or other purposes is also found profitable in certain locations. The Miami, Fla., plant is designed to provide steam for a nearby hospital. Generally, in the United States and Canada heat produced from the refuse is wasted to the atmosphere because it has been found that the equipment required to produce steam and electricity cannot be installed and operated economically in competition with regular power supply sources.

Institutional and Household Incinerators.—On-site disposal of combustible refuse is an economical method for many industries, multiple apartment dwellings and many large retail commercial establishtnents as well as, in certain instances, for householders. There are thousands of such plants in the larger cities and they usually form an important part of the over-all disposal system. The basic furnace design for such units is similar to that required for their larger municipal counterparts.

There is usually incorporated in the design of apartment house incinerators special charging features for the convenience of their users. Such units are often "flue fed"—that is, a chute extends to the upper story of the building and rubbish placed into an opening in the chute drops directly into the furnace. These units have often been the source of nuisances, however, where insufficient attention is given their operation.

Because such units have been found to be a significant source of air pollution, much attention has been given to improvement of their design.

Household incinerator units are not recommended by refuse disposal authorities in lieu of use of a community-wide collection system, but have found application in rural areas. When garbage is included in the refuse burned, some odour can be detected in the gases discharged into the flue when a single-cell unit is used. Such units usually are equipped with a gas burner to assist in the combustion of refuse such as garbage.

It has been the practice in many communities to encourage the burning of refuse in "backyard incinerators." These are some-

times specially built single-cell burning units, but usually are converted oil drums or wire baskets. To call them incinerators is a misnomer. Usually such practice is necessitated by inadequate or incomplete refuse collection systems.

In Los Angeles, Calif., for example, the collection of combustible rubbish was instituted in 1957 because it was shown that the practice of burning combustible rubbish by householders was a significant contributing factor to that city's severe air pollution problem. At the time the municipal collection system was instituted and backyard burning banned, there were 1,500,000 household rubbish burners in the city. (Lo. W.)

INCLEDON, CHARLES BENJAMIN (1763–1826), English singer, son of a doctor in Cornwall. was the principal English tenor of his day. He sang both in opera and in oratorio, but his chief popularity lay in his delivery of ballads. such as "Sally in Our Alley," "Black-Eyed Susan," "The Arethusa" and others of a similarly bold and manly type. On retiring in 1822 from the operatic stage, he travelled through the provinces with an entertainment called "The Wandering Melodist." He died at Worcester on Feb. 11, 1826.

INCLINOMETER. Two classes of instruments are used for measuring the dip or inclination of the earth's magnetic field to the horizontal, the dip circle (*q.v.*) and the induction inclinometer or earth inductor. The principle on which induction inclinometers depend is that if a coil of insulated wire is spun about a diameter there will be an alternating current induced in the coil, unless the axis about which it turns is parallel to the lines of force of the earth's field. Hence, if the axis about which such a coil spins is adjusted until a sensitive galvanometer connected to the coil through a commutator, by which the alternating current is converted into a direct current, is'undeflected: then the axis must be parallel to the lines of force of the earth's field, and hence the inclination of the axis to the horizontal is the dip.

INCLOSURE or ENCLOSURE: *see* COMMONS.

IN COENA DOMINI, a papal bull, so called from its opening words. first issued in 1363 and republished annually about Eastertide. It was a statement of ecclesiastical censure against heresies, schisms. sacrilege, infringement of papal and ecclesiastical privileges, attacks on person and property, piracy, forgery and other crimes. Because of the opposition of the sovereigns of Europe, both Protestant and Catholic, who regarded the bull as an infringement of their rights, its publication was discontinued by Pope Clement XIV in 1770. It is considered to have been formally abrogated by Pius IX in the constitution *Apostolicae Sedis.* It received its final form from Pope Crban VIII in 162;.

See J. Prior, "In Coena Domini" in the *Catholic Encyclopaedia;* M. O'Riordan, "Apostolicae Sedis," *ibid.*

INCOME: ECONOMIC DEFINITION. Income has been defined as: (1) "the wealth measured in money which is at the disposal of an individual or a community, per year or other unit of time"; (2) "the inflow of satisfactions from economic goods, estimated in money" (Seligman); (3) "those incomings which are in the form of money. including 'payments in kind.'"

These definitions have some ambiguity. In general, the term is confined to those "satisfactions a-hich are capable of being parted with, or are usually parted with. for money." For example. the satisfaction or economic value derived from living in one's on-n house is commonly expressible as an annual rental. and this is usually included in income, but an analogous satisfaction from contemplating one's pictures or using one's furniture is not. Again. periodicity is essential. and a year is the common basis, though the flow may be quite uneven. in fact. and even accruing unevenly over the year. Services performed for oneself which, if performed for others. would bring in an income are not usually included; *e.g.,* painting one's own house. or a wife's domestic services. This is extended to exclude other mutual services within a group; *e.g.,* a club or co-operative society. There is a field of difficult distinction from capital; *e.g.,* a series of profits from transactions which, taken singly. are regarded as capital transactions (sales of houses, lands or securities) may constitute an income in certain circumstances. And "net income" involves considerations of long-period wastage in the producing agent—a coal mine, or 99 years' lease or a building. The term "national income" is subject to numerous special conventions.

INCOME BONDS, bonds bearing a stipulated interest rate but upon which no interest is paid unless there is sufficient income for this purpose after all other fixed charges have been met. The nonpayment of interest on an income bond when the earnings are not sufficient for this purpose does not constitute a default and does not give the bondholder the right to sue. Income bonds are almost invariably brought about during reorganizations of businesses, whereupon they may be accepted by holders of old defaulted bonds or offered for sale to the general public to raise cash.

Income bonds may be secured as to principal by a mortgage, in which case the mortgage would be junior to the others; or by collateral: or may be strictly of the debenture type. The interest may be either cumulative or noncumulative. It is usually the practice to use available income to pay a portion of the interest if there is not enough to pay the full rate. Because of the uncertainty of interest payments income bonds generally rank very low as investments and are usually regarded as just above the preferred stock of the corporation.

They are often bought at a low price by unprincipled persons and sold at par or above to uninformed buyers upon the false representation that the name "income bonds" means bonds upon which an income is guaranteed, than which nothing could be further from the truth.

INCOME TAX. An income tax, under usual terminology, is a tax imposed upon net incomes, that is. on total incomes less expenses incurred in earning them. An income tax may apply to individuals (personal income tax), corporations (corporation income tax) or both. The personal income tax typically applies only to income in excess of a certain figure. and thus low-income groups are freed from the tax. Income tax rates may be proportional at all income levels, but are more commonly progressive, the rate rising as the size of the income rises. Progression is particularly common with personal income taxes. An income tax may be applied in blanket fashion to all income (or to all except certain specially treated items), as in the United States, or it may consist of a series of schedules applying to various forms of income, as in Great Britain and some countries of continental Europe.

An income tax in the typical form is distinguished from a gross income tax. which applies to the entire gross income of individuals, corporations or both, without deduction of expenses of gaining the income, or other items.

After World War I, the income tax became the most important source of tax revenue in many countries, particularly the Gnited States. Great Britain and most nations of the British Commonwealth and the countries of northern Europe. In the 1953 fiscal year. Great Britain obtained about 50% of its total revenue from the various income taxes: the United States. 78% (personal 47%, corporate 31%); Canada, 60%; Australia, 60%; and New Zealand, 35%. In western Europe the percentage was highest in Luxembourg, 66%; the Netherlands, 52%; and Sweden, 50%; other figures include west Germany (federal and *Länder*), 36%; Finland, 26%; Belgium, 42%; Norway, 32%; Denmark, 43%; Switzerland (federal and cantons), 48%; France, 29%; Italy, 15%; Austria. 33%; Portugal. 31%; Spain: 43%.

This article is divided into three sections, as follows: *Historical Development of Income Taxation; Practical Aspects of Income Tuxation;* and *Economics.*

HISTORICAL DEVELOPMENT OF INCOME TAXATION

Income taxation developed slowly, with many reverses. The merits of income taxation were recognized centuries ago, but fear that administration would be difficult or impossible—a fear supported by evidence in many instances in which the tax was tried—

delayed its widespread use. But the development of democratic government gave important impetus to the income tax movement. as did increased awareness of the disadvantages of other forms of taxation in terms of accepted standards of society and the growing need for revenue as government expenditures increased. Introduction of the tax was facilitated by increased importance of exchange and the earning of money incomes, more adequate record keeping and use of banking facilities and improved standards of tax administration. The income tax can effectively constitute a major source of government revenue only in a society with a high state of economic and political development and education.

Great Britain. — Credit for the establishment of the first major successful income tax in the world is usually given to Great Britain. The British tax was first introduced in 1799 by William Pitt, to aid in the financing of the war against France. Exemptions and progressive rates were provided, with a standard rate of 10%. The tax was repealed in 1802, but reimposed in 1803 when war resumed. This tax, which involved the use of income schedules and deduction at source, was repealed in 1816 after the battle of Waterloo. In 1842 the tax was revived by Sir Robert Peel. initially for a three-year period. The levy was extended a number of times, and became accepted as' a more or less permanent tax in 1860, when tariff reductions made its revenue essential. The tax was gradually reduced from the 1 shilling 4 pence in the pound figure of 1860, but was raised during the South African War of 1899–1902 to 1*s*.3*d*.

These earlier taxes, with minor exceptions, had been levied with proportional rates. In 1909, however. graduated rates were permanently established, through the introduction of the surtax. The standard rate reached 6s. during World R a r I. was reduced during the 1920s and raised to a level of 10*s*. during World War II. The figure was cut to 9s. in 1946, raised to 9*s*.6*d*. during the Korean war and cut to 8*s*.6*d*. in 1955. The exemptions were reduced somewhat during World War II and raised after 1945. A separate tax on profits, primarily on those distributed as dividends, was introduced for the first time in 1937, largely replaced by an excess-profits tax during World War II and reinstated, at relatively high rates. in 1946. The profits tax was increased in 1955 and 1956 as a part of an anti-inflationary and exchange-control program.

United States. — Limited attempts to use income taxes were made by four states early in the 19th century. But administration was weak, and the yield was very low. While additional states attempted to use the tax prior to 1900, the first successful state use came with the Wisconsin tax in 1911. Other states then followed. Expansion of state use, however, was retarded after 1940 by the high federal tax.

The first federal income tax was imposed in 1862, to meet Civil War expenditures. The rate. at first 3%, was later raised. made progressive for a time and then returned to a proportional 10% figure in 1865. Exemptions were provided. Despite the lack of adequate enforcement machinery. the tax yielded substantial revenue. But complaints of evasion and the dislike of many groups for the principle of the tax led congress to allow it to expire in 1872.

During the succeeding decades the tax remained a political issue, support coming primarily from farm and labour groups. Finally, in 1894, a proportional 2% tax was imposed, in part to offset revenue losses from tariff reductions In a reversal of the Civil War tax decision. the 1894 tax mas held to be unconstitutional by the supreme court on the grounds that certain portions of it were direct taxes, and therefore were invalid because the tax was not apportioned according to population as required by the constitution. An immediate attempt was made to sanction income taxation by constitutional amendment; this culminated in the 16th amendment. which became effective in 1913. Meanwhile, in 1909, a levy had been successfully imposed upon corporation profits in the technical form of an excise tax.

In 1913, immediately after the 16th amendment became effective, congress enacted a personal income tax, with a normal rate of 1% on incomes in excess of $3,000 for a single person and $4,000 for a married person, and surtax rates on taxable incomes in excess of $20,000 ranged from 1% to 6%. The corporate rate was 1%.

The development of the tax after 1913 can be summarized briefly, in terms of the following major trends:

1. Sharp increases during World War I. In 1918 the normal rate was made progressive, with a range from 6% to 12%, and the progression of the surtax greatly sharpened. the rate rising from 1% to 65%. The combined normal and surtax rate on income in excess of $1,000,000 was 77%, the highest rate used in any country to that date. Exemptions were also lowered.

2. Gradual reductions in rate and increases in exemptions during the 1920s. The exemption reached $1,500 for single persons and $3,500 for married persons, with $400 for other dependents, by 1925. The normal tax was lowered to a range of from ½% to 4%, and the top surtax rate to 20%.

3. Increases during the 1930s. In an effort to reduce budget deficits, the exemption for married couples was lowered to $2,500, and the basic rate raised to 4% in 1932; progression was sharply increased in an effort to place more of the burden on the higher income groups. Later in the period the surtax rates were raised to a maximum of 75%.

4. Drastic increases during World War II. At the beginning of World War II, the tax was converted almost overnight from a "rich man's tax" to one which reached down to the great majority of workers. The exemption, after several reductions, was set at a flat $500 per person, including the taxpayer, and the surtax rate made to apply to all taxable income, the initial tax rate reaching 23%. The maximum combined normal and surtax rate reached 94%. The normal and surtax rates were eventually consolidated into a single rate. The number of returns, which had been 6,000,000 in 1937, reached 50,000,000 in 1945, or 38% of the population.

In 1943 a significant change was made in methods of collection by the establishment of the withholding system on wages and salaries.

5. Modifications, 1945–56. In the postwar period, continuing high expenditures prevented sharp reductions in income tax, and the general level, while fluctuating somewhat, remained much closer to the wartime figures than to those of the 1930s. Several modifications were made, however, in the structure of the tax.

Rates were reduced in 1946, to a basic figure of 19% and a maximum of 86.45%. In 1948 the exemption figure was raised to $600, rates were reduced again (basic, to 16.6%) and the splitting of income between husband and wife was universally permitted. This rule greatly reduced the operation of progression for married couples. After 1950, as a result of the Korean war, rates were raised again, to a high of 22.2% basic and 92% maximum. In 1953 the rate increase was eliminated and the basic rate table, with rates ranging from 20% to 91%, restored. In 1954 a number of other modifications were made, primarily in the direction of easing the, severity of various rules relating to dependents, to working wives, to depreciation and other questions. A step was also taken to reduce double taxation of dividend income.

The corporation income tax followed a pattern somewhat similar to the personal tax. The rate, originally 1%, reached a high level of 13.5% in 1926, was reduced to 12% in 1928 and raised again in the 1930s. During the latter period limited rate progression was introduced, primarily to lessen the adverse effects of the tax on the growth of small businesses. In 1936, for example, the beginning rate was 8%, the maximum rate 15%. The subjecting of dividend income of individuals to both the normal and surtax rates of the income tax in 1936 established double taxation of corporate dividend income; a proposal to apply the corporate tax only to undistributed profits was rejected by congress in favour of a supplementary tax on such profits in addition to the regular levy. This tax led to great protests and was abandoned in 1937.

During World War II the corporate income tax was raised drastically, the maximum rate figure reaching 40%. The structure of the tax was greatly simplified in 1936 with the establishment of a two-rate structure, a 23% rate applying to all corporate income and a surtax rate of 19% on income in excess of $25,000. The basic rate was raised to 28% in 1951 and to 30% in 1952, the maximum effective rate becoming 52%. These rate increases were extended several times by congress.

While expanded state use of income taxes was restricted after 1940 by the high federal tax, there was a tendency toward greater

use of income taxes (restricted usually to wages and salaries) by the cities, especially in Pennsylvania and Ohio.

Canada. — In Canada income taxation commenced at the municipal level. with substantial development of such taxes at the time of confederation (1867). First provincial use came in 1876, although only two provinces levied the' tax prior to 1923. Five others followed during the 1920s and 1930s, but all provinces temporarily surrendered their right to impose this tax in 1941 in exchange for federal tax rental payments.

Quebec did not renew its tax rental agreement after World War II and imposed its own personal income tax beginning in 1954. Other provinces continued under the rental system. Municipal income taxation also came to an end in 1941.

The first dominion income tax was introduced in 1917, to aid in the financing of World War I, and increased after the war, in contrast with the usual pattern, to eliminate continuing deficits. After 1925 rates were reduced on several occasions and there was some belief that the tax would be repealed. However, after 1932, deficits led to increases in the tax. World War II brought drastic increases in rates and reductions in exemptions. After the end of the war the tax was reduced sharply, the prewar exemptions being re-established (in contrast with United States policy). In 1947 a tax credit for dividend income was granted. Rates were raised in 1952 because of the increased defense spending, and subsequently reduced again.

Corporation income taxation was introduced in 1916 in the form of a special war tax on excess profits; this was supplemented by a tax on all corporate profits in 1917. The rate was raised immediately after the end of the war, reduced during the late 1920s, raised during the depression and very sharply during World War II. Rates were lowered after the end of the war, but' increased somewhat after 1950.

Other Countries. — In the countries of continental Europe, the income tax developed slowly during the 19th century. Income taxes of limited significance were imposed in Belgium as early as 1828, and a general income tax was levied by the Swiss canton of Basle-Stadt in 1840. Austria imposed a general income tax in 1849, and Italy in 1864. Germany entered the field in 1894. Spain imposed an income tax of limited significance in 1900. France was one of the last major countries to enter the field, imposing the tax in 1914. Most of the Swiss cantons did not impose income taxes until the World War I period, and the confederation levied the tax only in 1940. The general trend in most countries has been toward a gradual strengthening of the income tax, the rate levels, however, being greatly increased in periods of war and often not falling back after the end of the wars to prewar levels.

PRACTICAL ASPECTS OF INCOME TAXATION

UNITED STATES

In 1956 the United States applied a single income tax to all taxable personal income, with a corporation income tax imposed upon the entire net profit of corporations.

Returns. — Personal income tax returns were required to be filed by all residents whose gross income exceeded $600, and by nonresidents in certain instances.

There were two primary return forms: 1040A, on which the tax liability was figured by the internal revenue service, was available only to those with wage income subject to withholding of under $5,000 per year (including not over $100 of other specified incomes). Form 1040 required calculation of tax liability by the taxpayer. either by the use of a table (permissive only if the income was under $5,000), or by application of the actual tax rates. Normal filing date was April 1 j.

Married couples might file separate or joint returns, but the latter was almost always preferable because it provided automatic splitting of income between the two persons.

Gross Income. — The law did not define income, but the regulations indicated the types of items which had to be included in gross income. These included all incomes in the usual sense, including gross receipts of operators of business firms, professional men and farmers. Receipts which involved merely a change in the form of nealth with no increase in value did not constitute income. Increases in the value of property were taxed only when realized through sale of the property and received special treatment.

Items of income specifically excluded include certain armed forces pay, most veterans' benefits, social security benefits, gifts and inheritances. casualty insurance benefits received, life insurance benefits upon death and interest on state and municipal bonds. Partial exclusion was permitted for sick leave pay, annuity income (under a complicated formula) and corporate dividends (the first $50 received).

Business Deductions and Adjusted Gross Income. — In general. various expenses of gaining the income, known as business deductions. could be subtracted from gross income to determine adjusted gross income. These were of primary importance for operators of business firms, professional men operating their own practices, farmers, etc. All business and trade expenses, in the usual sense of the term, were deductible, including depreciation on capital equipment and interest on borrowed money. Depreciation deductions had to conform with regulations relating to length of life of the property and allocation formulas.

For an employee, business deductions were restricted to expenses of travel (including meals and lodging while away from home) in the services of the employer. Expenses of going to and from work were not deductible.

Nonbusiness Deductions. — From adjusted gross income the taxpayer could deduct certain personal expenses, which were designated as nonbusiness deductions. These included:

1. Contributions to religious, charitable. educational and similar organizations, up to 20% of adjusted gross income, with an additional 10% for certain types of contributions.
2. All state and local taxes paid (including sales taxes separately quoted by the vendor) with minor exceptions, such as special assessment levies. No federal taxes were deductible as nonbusiness deductions.
3. Casualty and theft losses in excess of insurance compensation.
4. Medical and dental expenses in excess of 3% of adjusted gross income, subject to certain maximums ($10,000 for a married couple. for example).
5. Interest payments, with minor exceptions.
6. Expenses for the care of children, by a woman or widower, when necessary to permit employment of the person.
7. Certain expenses related to employment, such as union dues. and expenses of certain tools, supplies, special clothing, professional journals, etc.

The taxpayer bad the option of taking the standard deduction, equal to 10% of adjusted gross income up to a maximum of $1,000, in place of itemizing deductions. About 75% of all taxpayers used this option.

Exemptions. — A taxpayer was allowed a $600 exemption for himself, for his spouse and for each dependent, as defined by law. To qualify as a dependent. the person had to have received more than half of his support from the taxpayer (with special rules when several persons provide joint support of a dependent), have received less than $600 per year gross income (except for students and persons under 19) and be related, as defined.

Tax Rates. — The tax liability was determined by applying the tax rates to the sum of taxable income, or by using the tax tables (in the case of incomes under $5,000 only). Separate rate tables were applicable to single persons, married taxpayers and unmarried heads of households, the latter receiving partial benefit of the income-splitting provisions.

As of 1956 the basic rate was 20%, applying to the first $2,000 of taxable income for a single person, and the first $4,000 for a married couple. The rate rose to 227, for the portion of income in excess of $4,000 (married couple) up to $8,000; to 26% in the third income bracket: and ultimately to 91% on the excess over $400,000. The effective rate on the entire amount of a particular taxable income was much lower than the marginal rate, which applied only to the excess of income over the previous bracket figure.

Dividend and Other Credits.—The taxpayer was entitled to a credit against the figure of tax due, of an amount equal to 4% of corporate dividends received in excess of the $50 exclusion, and for certain tax payments to foreign countries.

Withholding.—With minor exceptions, all employers were required to withhold tax on a current basis from employees' pay cheques and transmit the sums to the government. Thus when the taxpayer filed his return at the end of the year he merely paid the difference due, or received a refund if overpayment had been made. Withholding was not applied to other incomes.

Persons not covered by withholding and those subject to withholding but earning in excess of a certain sum were required to file declarations of estimated income and pay tax on a quarterly basis during the current year.

Capital Gains and Losses.—Capital gains from the sale of property held more than six months were taxable either at a flat rate of 25% or through inclusion of one-half of the gain with other income, at the option of the taxpayer. Gains on property held less than six months were fully taxable. Special provisions were made for owner-occupied residences, which in effect exempted the gain from the sale of a home if one of equivalent or greater value was purchased or built within a given time interval. Capital losses could be deducted only from capital gains or from other income in limited amounts.

The Corporation Income Tax.—The corporation income tax applied to the net profit of corporations, calculated in the usual accounting manner, apart from certain special rules relating to depreciation. Bond interest was fully deductible. Contributions to charity were deductible up to 5% of net income. No exemption was provided for small businesses. As with the personal income tax, losses incurred in one year might be carried back two years and forward five years against earnings of those years. The rate structure, as of 1956, contained a basic rate of 30%, applying to all taxable income, and a surtax of 22% on income in excess of $25,000.

Administration.— The tax is administered by the internal revenue service. Returns are filed with the office of the district director of internal revenue. All returns are subject to routine office audit, and larger returns, plus all about which there is any doubt. receive more thorough field audit. Except in cases of fraud, examination of returns is subject to a three-year statute of limitations.

General regulations are issued by the internal revenue service in amplification of the code, and rulings are issued on specific cases arising; these are summarized in the semimonthly Internal *Revenue Bulletin.* Appeals from the rulings may be taken by the taxpayer to the tax court.

State Income Taxes.—Thirty-one states imposed personal income taxes in 1956. The rates were low by comparison with the federal rates, exceeding 7% only in four states, with a top figure of 15%. Progression was usually limited, and terminated at a low figure. Business and personal deductions were similar to those of the federal tax, but exemptions were typically higher. Some of the taxes applied only to income of residents of the state, and others only to income earned in the state regardless of residence. Most states, however, combined the two bases, taxing residents on all income and nonresidents on income earned in the state. The amount of double taxation was lessened, however, by reciprocal provisions in the laws of most states.

Thirty-one states imposed corporation income taxes, as of 1956. The rates ranged from 1% to 8%, with limited progression in a few instances. Formulas have been established for the allocation of interstate income.

GREAT BRITAIN

The British income tax system in 1957 consisted of three distinct but co-ordinated elements: (1) the income tax, levied at a standard rate; (2) the surtax, applied only to incomes in excess of a certain figure; and (3) the profits tax. imposed primarily on distributed profits. In the fiscal year ending in 1955, the income tax yielded £1,893,000,000; the surtax, £135,000,000; and the profits tax, £249,000,000.

The Income Tax.—The income tax was applied not only to the income of individuals, but also, in effect. to undistributed profits of corporations. Husband and wife had to aggregate their income for tax purposes. Exclusions from income included capital gains (defined more narrowly than in the United States); benefits in kind which are not convertible into money income, as for example lodging for a servant; interest on National Savings certificates; certain armed forces benefits; and benefits under the national insurance scheme (for unemployment, sickness, etc.).

The tax was levied under five different schedules (but at uniform rates):

Schedule A: income from the ownership of real property, including the rental value of owner-occupied homes. The tax was assessed on the "net annual value," the amount at which the property is or could be rented, less repairs and other expenses. By the mid-1950s the net annual value figures had not been completely reassessed since 1936, the figures of that year generally remaining in use. Actual rentals in excess of the assessed figure are included in Schedule D income.

Schedule B: income from certain types of land, now of minor importance.

Schedule C: interest from certain government securities, collected at the source.

Schedule D: profits of trades, businesses, professions and farming; and interest. Normal accounting rules were employed in determining net income, except with respect to depreciation. Specific schedules of depreciation allowances for tax purposes were established, with, in many instances, a high allowance in the initial year, partly to compensate for rising cost of capital equipment, partly to give a direct stimulus to investment. From 1954 to 1956 the initial allowances, termed investment allowances, were granted in addition to the depreciation allowed over the subsequent years of life of the equipment, which was equal to original cost.

Schedule E: wages and salaries. Deduction of certain expenses of employees in the performance of their duties was permitted. The tax on wages and salaries was subject to the PAYE (pay-as-you-earn) system, involving current collection from the employer and deduction from the pay cheques. The system of determining the an-fount deductible was much more complicated than in the U.S. as it was designed to ensure that the exactly correct amount, instead of an approximate amount, would have been deducted by the end of the year.

Withholding was applied to other incomes where possible.

The system of personal deductions and exemptions differed substantially from that of the U.S. and Canada:

1. Relief was given for earned income (labour income) by allowing deduction of $\frac{2}{9}$ of such income, up to a maximum figure, in 1957, of £4,005, and of $\frac{1}{9}$, up to £9,945.

2. Personal allowances (exemptions), as of 1956, were: £140 for a single person. £240 for a married couple, and amounts for each child dependent on age: under 11, £100; 11–16. £125; and over 16, £150. Special rules are provided for other dependents.

3. A portion of amounts paid as life insurance premiums were deductible. No other items were deductible.

The standard rate, as of 1957, was 8*s*.6*d*. on the pound. Progression was introduced in two ways:

1. Lower incomes were taxed at rates reduced below the standard figure; as of 1956, 2*s*.3*d*. rate on the first £60, 4*s*.9*d*. on the next £1 jo and 6*s*.9*d*. on the next £150. Standard rate was applied only to the excess.

2. The surtax, technically a separate tax, applied to all income in excess of £2,000. The combined normal and surtax rates reached, in 1956, the maximum figure of 18*s*.6*d*. on income in excess of 615,000.

With relatively low exemptions and a standard rate of nearly 50%, the tax burden on the typical wage earner was very much heavier than that in the United States. While the maximum rates were not fundamentally different from those in the U.S., they were reached at a much lower income level, and were thus much more significant.

Corporations were subject to the standard income tax rate on their entire income, but the portion on dividends paid was sub-

tracted from the dividend and was treated by the stockholder as prepayment or withholding of tax on the dividend, in the same manner as withholding of tax on wages. There mas. therefore, no double taxation of dividend income by the income tax.

Profits Tax. — Distinct from the income tax was the profits tax, applied only to corporations. The tax was applied to net profit, after deduction of bond interest, in the same manner as the income tax. Companies with incomes of less than £2,000 a year were exempt, and a reduction in tax was provided for those with income between £2,000 and £12,000. The standard rate was 27½% on distributed profits and 2½% on undistributed profits (the latter being taxed at the low figure because it was subject to the income tax). The profits tax created an element of double taxation of dividend income.

CANADA

The Canadian income tax system has been influenced by both the U.S. and British taxes, although in general structure it resembles the former more than the latter.

The Personal Income **Tax.**—The tax in 1956 was applied to income from all sources, excluding capital gains (more narrowly defined than in the U.S.), armed forces pay (subject to separate assessment), most veterans' benefits, gifts and bequests, life insurance proceeds at death, casualty insurance proceeds, unemployment benefits, family allowances and. in part, annuities.

Net income was determined by deducting the expenses of gaining the income: for business firms and the professions, usual business expenses, including depreciation on a prescribed basis (the diminishing balance system); for employees, expenses involved in travel away from home in connection with employment, and union dues. Contributions by both employees and employers into approved pension systems were deductible.

Taxable income was obtained by subtracting from net income the following deductions: contributions (up to 10% of net income); medical expenses (in excess of 3% of net income); personal exemptions of $1,000 each for taxpayer and for spouse. $400 for each dependent over 16 and $150 for each dependent under 16 (the lower figure offsetting the exclusion of family allowances from taxable income).

Joint returns might be filed if the wife earned less than $1,000; if she earned more, she was required to file a separate return. No splitting of income for tax purposes was permitted.

The rate on the first $1,000 of taxable income in 1956 was 13%, and on the second $1,000, 15%. The marginal rate reached 33% at $10,000, 52% at $30,000 and a maximum of 78% on income in excess of $400,000. An additional 4% tax was applied to investment income in excess of $2,500 and an additional 2% tax on all income up to $3,000 for social security purposes.

A credit of 20% of the amount of the dividends received from Canadian corporations was deductible in determining tax due. and thus double taxation of dividend income was greatly reduced.

Tax on wage and salary income was collected through a withholding system.

Corporation Income Tax. — The dominion corporation income tax was very similar to the United States tax, applying to the entire net profit of the corporation whether distributed or not. The basic rate in 1956 was 20% on the first $20,000 of net income, with a combined rate of 49% (including 2% for social security purposes) applying to the portion in excess of $20,000.

OTHER COUNTRIES

Australia. — Income taxation in Australia was employed only by the commonwealth government. The concept of income was basically the same as in the U.S., except that capital gains were not taxable. Usual business deductions were permitted, as well as certain personal expenses, including those for medical care, gifts to charities but not churches. insurance premiums and tuition fees. Special deductions were permitted for persons living in high cost areas. These as well as deductions for dependents, took the form of deductions from tax rather than from income, and thus did not reduce the tax rate class into which the income fell. The allowance in 1956 was £A130 for a married couple, LA78 for the first child under 16 and LA52 for subsequent children. No income splitting was permitted. Property income was taxed more severely than other income.

The rate structure was highly progressive, by a formula system which eliminated wide brackets. The initial rate was only 1*d* in the pound. but the maximum rate of 13*s*.4*d*. was reached at the income level of £A16,000. Collection by withholding was employed.

Corporate income was subject to a tax on net profit, with a slight degree of progression; the principal rate was 35%. Small corporations were taxed as though they were partnerships. There was no mitigation of double taxation of dividends.

New Zealand. — The New Zealand income tax applied to income defined in the usual manner, excluding capital gains and excluding dividends, which were, however, taken into consideration in determining the tax rate applicable. Dividends themselves were taxed only at the corporate level. Usual business deductions were permitted, but personal deductions were limited to a very few items. Exemptions of £N.Z.375 for a single person, £N.Z.500 for a married couple and £N.Z.75 for other dependents were allowed in 1956. Rates were progressive; in 1956 they commenced at 3*s*. on the first £N.Z.100 of taxable income and rose to 12*s*. on income in excess of £N.Z.4,000. In some years flat rebates independent of the amount of tax paid, where the amount equaled the rebate, were given. Corporations were taxed on their entire incomes, at somewhat progressive rates.

South Africa. — The Union income tax was a two-stage tax, with a normal tax rate which commenced at 6¼% and a supertax at 10%, both rates being progressive. The rate was higher for unmarried persons, commencing at 7¼% instead of 6¼%. Incomes of husband and wife were aggregated. **A** system of rebates from calculated normal tax was provided, with a greater sum for married than for single persons. and a figure for each minor child (whether supported or not) four times that for other dependents.

The provinces also levied income taxes, in the form of percentage additions to the Union tax.

France. — The personal income tax system was twofold. A uniform 18% tax applied to all types of income (replacing a schedular tax applied at different rates to various forms of income. imposed prior to 1948). and a surtax with progressive rates applied to higher incomes (to only about 2,000,000 taxpayers out of 30,000,000). With both taxes, low incomes were excluded, and exemptions were allowed for dependents. Earned income and income of farmers, craftsmen and some other groups received special treatment. From 1948 the proportional tax on workers' income was payable by the employer (as a flat 5% of his payroll) and not deductible from wages. A vanishing exemption (applicable only to income below a certain figure) was provided, and the tax itself reduced according to the number of children. Income splitting was provided not only between husband and wife, but between parents and children as well. Small business firms and farmers were, in effect. taxed upon an estimated profit figure rather than a calculated figure of profits.

The corporation income tax, introduced in 1948, applied to all corporate profits; the rate in 1956 was 38%. A partnership had the option of being treated as a corporation.

Italy. — The Italian income tax system consisted of two parts, a proportional schedular tax on various forms of income, and a progressive tax on total income. The schedular tax was imposed at different rates on various forms of income. Three flat-rate taxes applied, respectively, to income from land, from buildings and from other sources. The third group was classified into three categories. investment income, profits from operation of business and wage and salary income. The wage income mas treated most leniently, from the standpoint of both rates and exemptions. These taxes applied to both individuals and corporations.

In addition to these proportional taxes, a complementary personal income tax was imposed at progressive rates. Personal exemptions were provided. The yield of this tax was limited.

Only after 1951 were all taxpayers required to file a return on an annual basis; prior to that time tax was paid primarily on the basis of estimates.

West Germany.— Technically the income taxes in nest Germany were imposed by the *Lander,* although the federal government shared in the revenue, and the taxes were uniform throughout the republic. The personal income tax resembled that of the United States. being imposed on all income regardless of source. the rate being the same on all types of income. The tax rate was sharply progressive, to a maximum figure of 95%. Exemptions were provided for dependents.

A corporation income tax was imposed on the net profit of all corporations, at a proportional rate (50% to 60% after 1950). Reduced rates mere applied to certain types of businesses.

Others.—Belgium imposed schedular taxes on various types of income, at different rates. There were three such levies: on income from land and buildings; on interest and dividends; and on labour income. There were two supplementary taxes, the first on both individuals and corporations, at a progressive rate, nith exemptions similar to those of the tax on labour income; the second a steeply graduated tax on personal incomes only.

In the Netherlands, special income taxes were imposed on wages and dividend payments, which constituted credits against basic income tax liability, and thus constituted a form of withholding. A basic tax at progressive rates applied to all income. Exemptions were provided for dependents. An income tax on all business establishments was imposed for local tax purposes. and a corporation income tax was applied to all corporate profits.

Personal and corporate income taxes were major revenue sources in the Scandinavian countries. In some instances local income taxes were levied as supplements to the national tax. In Snitzerland the primary income tax was that imposed by the cantons, but from 1940 the confederation imposed a tax, at progressive rates, uniform on all types of personal Income.

ECONOMICS

THE ROLE OF THE INCOME TAX IN THE TAX STRUCTURE

The role of the income tax in the tax structure and the effects which it has upon the economy have become questions of major significance, as the tax has grown in importance.

Income taxes have been introduced primarily to raise revenue in a manner which conforms most closely with the ability-to-pay doctrine of taxation. Typically in the literature of public finance, and in less explicit form in popular thinking and discussions of legislative bodies. the principle that persons should pay tax on the basis of their ability is widely accepted. In turn, net income. after certain adjustments, is regarded as the best measure of ability, since it is the principal determinant of a person's economic well-being—the level of consumption and savings which he can enjoy. Adjustments can be made in net income in determining taxable income to reflect certain circumstances, such as size of the family, which influence the standard of living which the family can enjoy from a given net income.

The importance of income taxation is also due in part to the fact that the burden of such taxes can be made progressive relative to income. There is wide acceptance of the principle that taxpaying ability rises faster than income, and thus that persons with high incomes should pay not merely more taxes, but a higher percentage of their income in taxes, than persons with lower incomes. Only by a direct tax on income can this result be accomplished readily. Closely related has been the goal of lessening inequality of real income. Under the philosophy that income distribution tends to be excessively unequal relative to the standards regarded by society as desirable, the income tax has been regarded as an effective instrument of producing greater equality.

The willingness of countries to employ the income tax has been greatly increased by its high revenue yield (under favourable circumstances) and by the belief that such a tax does not seriously affect economic behaviour and thus does not significantly reduce total national product or alter its composition to the detriment of the welfare of society. This belief is not necessarily entirely valid, as noted in a subsequent section.

Objections to Income Taxation.— Acceptance of the principle of income taxation is by no means universal. Most of the attack upon the tax centres upon the use of progressive rates, rather than upon the principle of taxation of income as such. It is charged that there can be no possible scientific standards for determining the desirable degree of progression. Thus, progression tends to become excessive and seriously weakens the incentives of persons to work, to take more responsible positions, to develop and expand businesses. to invest in securities. etc.

In part, however, the attack is made against the income basis itself. It is maintained that administration of an income tax is inherently difficult because of the impossibility of checking reported figures of earnings and deductions. As a consequence, it is charged, substantial evasion results and great incentive is given for dishonesty. This argument receives particular emphasis in countries in which record keeping, accounting methods and standards of administration are not highly developed, and has been a major factor discouraging such countries from using income taxes of any magnitude.

The income basis is also condemned on the grounds that its use results in double taxation of the portion of income saved, since both the savings and the earnings from them are taxed, to the detriment of capital formation and economic development. This argument is regarded as spurious by defenders of the tax.

Finally, it is charged that excessive reliance on income taxation tends to penalize persons who have not yet accumulated wealth, compared with those who have.

PROBLEMS RELATING TO THE STRUCTURE OF AN INCOME TAX

If a particular income tax is to meet the threefold requirements, under generally accepted standards, of (1) equity relative to ability to pay, (2) avoidance of adverse effects on the economy and (3) administrative feasibility, certain problems must be solved in the establishment of the tax. These can be summarized briefly:

Definition of Income.— In principle, income, as a measure of economic well-being, can most appropriately be defined as the sum of (1) the person's consumption during the period, plus (2) the net increase in the person's wealth. The second item may, of course, be a negative figure. It is this sum which constitutes the gain obtained by the person from economic activity during the period. But the difficulties of calculating these two magnitudes and of taxing persons on unrealized increases in wealth have led in practice to a different approach to the definition. Income is usually defined or described, therefore, in terms of the flow of wealth to the person during the period.

There are two important consequences of the use of the flow definition. In the first place, in the U.S. persons are usually not taxed on the value of income arising in cases in which no market transaction is involved, as, for example, the gain from the use of durable consumption goods previously acquired, the rental value of their own homes: etc. As a consequence, persons are given some artificial tax incentives to buy homes instead of renting them,

to perform tasks for themselves instead of working for money income and paying others for the work, etc.

In the second place. the definition of income as flow during the period results in the taxation of capital gains — increases in the value of assets held--only when the gains are realized when the property is sold, instead of uhen they accrue. Since taxation at progressive rates in the year of realization of the gain would, in some instances, be inequitable, special favourable treatment is usually provided for capital gains, compared with that given other income. The recurrent flow concept of income has led Great Britain and most British Commonwealth nations to exclude capital gains from taxable income completely. In countries in which the gains are partially taxable there has been constant demand for complete exemption, partly on the basis of the argument that such a policy would stimulate investment.

The favourable treatment or complete exemption of capital gains has provided great incentive to taxpayers to convert other income into the form of capital gains whenever possible; this in turn has led to progressive narrowing of the definition of such gains for tax purposes.

Specific Exclusion of Certain Types of Income. — There is a strong presumption in favour of taxing all income regardless of the source, to avoid inequities and administrative problems in delineating various types of income. But arguments can be advanced for excluding certain types on grounds of general economic or social policy, or to avoid administrative complications. Bequests and gifts, for example, are universally excluded, because of their irregularity and consequent tax penalty under progressive rates, and the significance for taxpaying ability of the relationship of the donee to the donor. Small gifts are difficult to check. Pay to persons in the armed forces and veterans' benefits are often excluded on grounds of general governmental policy. Incomes from some types of economic activity may be excluded in order to stimulate the conduct of such activity.

Business v. Personal Expenses. — If an income tax is to rest upon net income, provision must be made for deduction of those expenses involved in gaining the income, generally known as business expenses. But even as a matter of principle it is difficult to distinguish precisely betueen such expenses and those for personal consumption purposes, and it is even more difficult to ensure correct application of the rules which are established. The greatest problems of principle arise in cases in which purchases are made for both business and consumption use (purchase of a car by a farmer or doctor) and with expenditures for education. Typically income tax laws have not recognized the latter as expenses of gaining the income, to the possible detriment of the maintenance of the supply of labour in fields requiring extensive training. Apart from the matter of principle is the very serious problem of preventing taxpayers from listing personal expenses as business expenses.

Time-Period Problems. — Income is essentially a more or less continuous stream through the years in which a person is earning a livelihood. But for tax purposes the stream must be segmented into periods, usually annual ones. Thus rules must be established to control the allocation of income and expenditures to particular periods. The item which has given rise to greatest time-period assignment difficulties has been depreciation charges on capital equipment. Typically, businesses are not permitted to charge capital purchases as current expenses for tax purposes. but are permitted to depreciate the purchase price over a period of time. Governments have set up rather arbitrary rules relating to such allocation. with consequent problems of interpretation and complaints from business firms.

The depreciation question has been complicated in the mid-20th century by the sharp rise in the cost of capital equipment for replacement purposes. Demands that depreciation be permitted on the basis of replacement cost rather than the original cost of the equipment have been denied in most instances, although some countries have made special provisions to ease the problem for the firms created by higher replacement cost.

Because of the use of exemptions and progressive rates. the segmentation of the income stream results in an inequitable burden on those persons whose incomes fluctuate sharply from year to year. Over a ten-year period a person who earns a uniform $10,000 per year will pay much less tax than a person who earns $100,000 in one year and nothing in the other nine years. This penalty can be avoided by a system which allows the averaging of income over a period of years. But except in limited instances, as, for example, with capital gains, with business losses (which typically may be carried forward or backward against business profits of other years) and with incomes of certain specified occupations (farmers and fishermen in Canada, for example), governments have been reluctant to permit averaging because of the added administrative complications.

Personal Deductions and Exemptions. — It is generally recognized that the suitability of income as a measure of taxpaying capacity can be improved by adjusting the figure in terms of certain circumstances nhich affect the standard of living which can be attained with a given money income.

The most important adjustment permitted is that for dependents, including the taxpayer himself. This allowance serves two primary functions: families with very low incomes are excluded completely from the tax; and the height of the tax on other families is adjusted in terms of the family size.

The exemption may be a flat amount per dependent, or adjusted according to the dependent's status, a larger sum often being given for the taxpayer and spouse than for others. In theory the amount of the exemption should be based upon an estimate of the sum necessary for a minimum living standard, but in practice it has been dictated by revenue expediency.

It is obvious that certain types of expenditures, such as those for medical care, directly reduce tax capacity, and many countries have authorized deductions for items of this type, as noted in previous sections. But the fear of eroding the tax base and opening avenues for evasion has tended to minimize the granting of such deductions.

The Taxpaying Unit. — A question of major importance is that of the taxpaying unit. The unit may be each individual separately, the husband and wife, or the entire family, including children. The treatment of each individual as a separate taxpayer ignores the basic nature of the family as a spending unit. In practice, husband and wife are usually permitted or required to file joint returns. A requirement for pooling of the income of the husband and wife has the unfortunate effect of causing marriage to increase total tax liability if both partners are earning substantial incomes.

An alternative. of allowing the division of income between husband and wife for tax purposes regardless of who earns it, as permitted in the United States, is the most equitable in many ways, but it does place a heavy tax premium on marriage. The usual practice of treating children merely as dependents encourages the splitting of property income with the children; only France has sought to meet this problem by treating children as partial partners in the entire family income.

The Problem of Corporation Income. — One of the most controversial aspects of developing a satisfactory income tax structure is the treatment of income earned by corporations. If only individual persons are subject to tax, the portion of corporate income not paid out as dividends is not subject to current income tax. To prevent this, special levies on corporations are typically employed. In some instances. particularly in Great Britain in the past, these have been regarded purely and simply as devices to reach the undistributed profits. But in many countries, and particularly in the U.S., the taxes on corporation income have gone far beyond merely reaching the undistributed profits, and have applied to all corporation net income, uhether held or distributed. The effect is to place a double burden on corporate income paid out as dividends, so long as the initial tax burden rests on the corporations and is not passed on to their customers in the form of higher prices. This policy has been in part based upon the idea that the corporation as such, as a separate legal entity, is a suitable object for taxation, independently of any tax on the stockholders, and in part on the fact that such a tax raises a large amount of revenue with relatively little complaint and is

perhaps less objectionable than most alternative sources. Since 1945, however. several countries. including the U.S. and Canada, have taken partial steps in the direction of lessening the double burden on dividends, typically by reducing the net impact of the personal income tax on dividends. An alternate approach. under which the corporate tax would be limited to the portion of profits held in the company. has not met with favour, although it has important merits.

ECONOMIC SIGNIFICANCE

There are three primary aspects of the economic significance of the income tax: the incidence. or pattern of distribution of burden; the effects on economic development; and the significance of the tax for fiscal policy.

The Distribution of the Income Tax Burden. — It has been traditionally assumed that the burden of an income tax rests upon the persons upon whom it is levied. So far as wages and other individual incomes are concerned, it is argued that the tax does not enable the persons to obtain higher incomes than they would otherwise receive, because the tax does not affect the supply of or demand for the particular goods or services used in production. With respect to business firms, it is assumed that the tax will not lead to a change in supply or price, since the reduction of the net earnings by a given percentage will not alter the levels of output and price which allow the firm to make the most profit.

In the mid-20th century these assumptions have been questioned. When labour unions develop in an industry, the income tax may be a factor leading them to demand and obtain higher wages than otherwise. and thus a portion of the tax burden will be shifted off of their members. Likewise. particularly in view of the fact that the income tax applies to all net profit and not merely to excess profit, business firms may in fact shift at least a portion of the income tax imposed upon them. Especially in nonpurely competitive markets, the tax may serve as a stimulus to movement closer to the price which mould allow the maximum profits for the firms as a group, but was not previously obtainable, given the relationships among the firms. Others have argued that the tax will reduce the volume of investment and thus the output of goods by lowering the net return on capital, and cause shifting of the burden.

The state of knowledge in the mid-1950s did not permit any exact statement of the extent of the shifting, but it was obvious that the traditional assumptions were too restricted. To the extent that shifting of the tax does occur, obviously the distribution of burden of the tax will differ from that which is intended.

The Effects on Economic Development. — Particular emphasis was given after 1940 to the possible adverse effects of the income tax on the level of national product and the rate of economic development. There are several aspects of this question:

1. Effect on the supply of labour. It has commonly been charged, especially during and after World War II, that the income tax tends to reduce the total supply of labour-hours available and, particularly, the supply of highly trained executives, professional men. etc. It is argued that the tax lessens persons' willingness to work because the government takes an increasing percentage of their incomes as they earn more. The tax may discourage overtime work: and encourage absenteeism and the taking of longer vacations. The tax may make persons unwilling to undertake the training necessary for more skilled jobs and to accept more responsible positions, by reducing the net financial gain.

While isolated illustrations can be found to demonstrate these effects, and wartime tax rates apparently had a noticeable effect on overtime work and absenteeism in some instances, there was little evidence in the mid-1950s that income taxes were significantly reducing the labour supply, even at the higher income levels. Increased income taxes will cause some persons to work more rather than less to maintain old levels of living, particularly if the basic rate, rather than the marginal rates, is raised. Other motives besides purely financial gain obviously play a major role in encouraging persons to take more responsible jobs.

2. Effects upon investment and economic development. The income tax has been charged with retarding business development and investment. The tax lessens the supply of money capital in the hands of individuals and may reduce their willingness to invest in business; it curtails the amounts of money which the firms themselves have for expansion and their willingness to undertake the risks of loss.

Despite many complaints about these effects. business expansion progressed at an extremely rapid rate in most countries after 1945; the deterring effects of the taxes were much less obvious than might be expected. In part, the taxes merely operated in the same manner as restrictive credit policy, holding expansion down to levels permitted by availability of resources. In part, as demonstrated by several studies of the question, the favourable tax treatment of capital gains reduced the adverse effects of the high tax rates by shifting some investors from other outlets to those involving the financing of business expansion by purchase of common stock. However, over a period of time, the restrictive effect of high personal and corporate taxes on investment might become much more marked.

The Income Tax and Fiscal Policy. — From the standpoint of fiscal policy, that is, the attempt to gain greater economic stability by adjustment of government revenues and expenditures, the income tax has an important advantage. Because of its exemptions and progressive rates, its yield tends to fall drastically in depressions and rise more rapidly than the national income in inflationary periods. Thus, it cushions the fall of purchasing power and spending in depressions and curtails them in inflationary periods. This instability in yield, however, appears as a definite disadvantage to those persons who believe that any use of fiscal policy is unwise and that the budget should be balanced at all times. It is also a disadvantage to subordinate units of government, such as states and cities, which often have limited borrowing capacities and are not in a position to conduct deliberate fiscal policy. If the income tax does seriously retard investment, it would aggravate the problem of maintaining long-range full employment.

INCONVERTIBLE PAPER CURRENCY: *see* BANKING; MONEY.

INCORPORATION, in law, the embodying or formation of a legal corporation, brought about either by a general rule contained in such laws (*e.g.,* as the Companies acts) or by a special act of sovereign power (*e.g.,* an incorporating statute or charter). The word is used also in the sense of uniting; *e.g.,* a mill may incorporate by reference other papers, which may be then taken as part of the will as much as if they were set out at length in it. This term is used similarly in the U.S. and Great Britain.

INCREASING RETURNS. In economics, a term used to describe a condition of production in which the application to land of additional capital and labour produces a greater proportionate return. This phenomenon is especially common in the fields of transportation, mining, manufacturing and electrical generation. For example, the investment of $5,000 in capital and labour to develop a power site at a waterfall might result in a net loss to the investor; a $50,000 investment might bring in revenue sufficient to cover costs but yield no net profit; while an investment of $500,000 might yield a net return of 10% per year.

In agriculture, the tendency for returns per unit of investment to grow as investment per acre increases disappears as cultivation grows intensive. (See DIMINISHING RETURNS; ECONOMICS.)

INCREMENT VALUE DUTY. A duty called by this name was first imposed by the parliament of the United Kingdom in 1910, the tax being one of the highly controversial measures contained in the Finance act, 1909–10. The rate of duty was £1 for every complete £5 of the "increment value" of any land accruing (a) on a sale, or on a lease (other than a mining lease, and other

than a lease for a term not exceeding 14 years); (b) on a succession on the death of the owner; (c) on a valuation made every 1 jth year in the case of land held by permanent corporations. Increment value was defined as the amount by which the site value of the land as defined in the act should exceed the original site value as ascertained under the provisions of the act as to valuation. The administration of the tax was entrusted to the commissioners of inland revenue, who were directed "as soon as may be after the passing of the act" to cause a valuation to be made of all land in the United Kingdom, showing (a) the "site value," and (b) the total value of the land. The "site value" was to be the value of the land exclusive of buildings and other improvements, which were taken into account in estimating the total value. The "original site value" was the value of the land without improvements on April **30,** 1909. The duty was not imposed in respect to agricultural land while the land had no higher value than its market value for agricultural purposes; or in respect to houses of a limited annual value when occupied by the owner; or in the case of agricultural land not exceeding 50 ac. in area and £75 per acre in value, when cultivated by the owner. One-half of the proceeds of the duty was appropriated for the benefit of local authorities in the United Kingdom in such manner as parliament might determine. The increment value duty did not fulfil the hopes of the promoters of the legislation, and was, together with the other land values duties, *i.e.*, the reversion duty and the undeveloped land duty, repealed by section 57 of the Finance act, 1920.

(J. S. S.)

INCUBATORS. Boxes or rooms of special construction designed for the maintenance of a constant internal temperature. usually blood heat or above room temperature. Common uses of such contrivances are in bacteriology, in the poultry industry and for the rearing of prematurely-born infants.

BACTERIOLOGICAL INCUBATORS

An incubator uhich will remain with 0.5° C. (.9° F.) of the adjusted temperature gives sufficiently accurate heat regulation for all ordinary bacteriological purposes. Bacteriological incubators, unlike bird incubators, do not require a continuous circulation of air, nor is it necessary to provide any arrangement to moisten the contained air. The type in ordinary use is in the form of a rectangular box fitted with a double door in front and surrounded on all the other sides by insulated walls; one or more shelves are fitted for the accommodation of flasks, racks of tubes, culture dishes, etc.

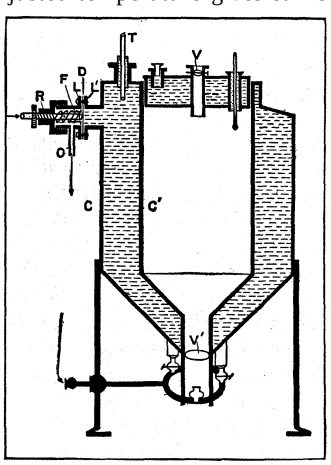

FIG. 1.— D'ARSONVAL INCUBATOR

D'Arsonval Incubator.— Some of the older incubatorswere cylindrical in form, that of Arsène d'Arsonval being the best known. This apparatus (fig. 1) consisted essentially of a cylindrical water jacketed chamber c. The water jacket was heated by gas and there was a gas regulator controlled by the expansion of the water in the jacket. The water expanding by heat rose in the tube T; this increased head of pressure acted upon a rubber diaphragm D which was forced outward thus obstructing the gas flow into the regulator. A great disadvantage of the cylindrical incubator was its inconvenient shape; there was also difficulty of access to the contents as compared with the modern types.

Hearson Incubators.— In the models heated by an oil lamp, or by gas, the incubation chamber is surrounded by a water tank (fig. 2, A) and the lowest part of this is traversed by an in-going (L) and an out-going flue. The mode of regulation of the temperature is by means of a thermostatic capsule which operates the movements of a cap (F) over the main flue (V), and it is identical in its chief features with the method employed in the chicken incubator. The capsule (S) is situated in the upper part of the incubation chamber. When gas is used for heating the incubator, the regulator controls the flow of gas to the burner rather than the heated air.

Electricity replaced these forms of heat early in the 20th century, except in rural regions lacking a power station. With electricity there is less fire hazard, the controlling mechanism is less elaborate and the variation in temperature within the incubator may be held within narrow limits. The electric incubators (fig. *3*) usually have no water tanks in the walls, but have improved insulation.

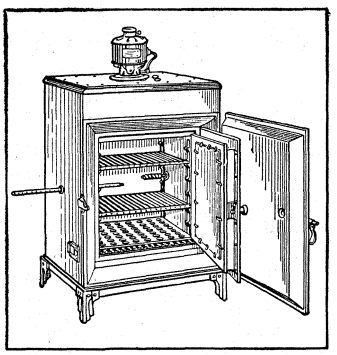
FIG. 2.— HEARSON'S BACTERIOLOGICAL INCUBATOR (HEATED BY A PETROLEUM LAMP)



COURTESY OF CENTRAL SCIENTIFIC CO.

FIG. 3.— DEKHOTINSKY INCUBATOR (WITH AIR CIRCULATION AND HEATED BY ELECTRICITY)

An inner glass door permits examining the contents of the incubator without opening the chamber, and the outer door is double and insulated like the walls. An electric motor placed on top of the incubator drives a fan for circulating the air within the incubator and prevents variation of the temperature at different parts of the chamber.

Pathogenic, or disease producing bacteria are usually kept at blood heat (37° C.; 98.6" *F.).* Fungi and protozoa may be grown at temperatures from 18° to 30° C. (62° to 86° F.). In many parts of the world the temperature of the hot season exceeds these values and means must be provided for cooling the incubator in order to maintain a constant temperature.

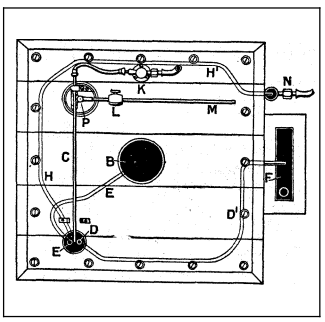


FIG. 4.— HEARSON'S COOL BIOLOGICAL INCUBATOR

Hearson, however, constructed a "cool biological incubator," in which by an ingenious device the expansion or contraction of the thermostatic capsule deflects a horizontal pipe (C) on the roof (fig. 4), through which runs cold water from an ordinary tap, in one of two directions. If it is deflected so as to open into the tube (D), the cold water passes into the tank (F), where it is warmed by a gas flame, and thence it passes into the water jacket of the incubator. If it is deflected so as to open into the pipe (E), it then runs through the ice tank (B), containing broken ice, before passing through the water jacket of the incubator. If it pours into neither of these pipes it then simply passes out through the pipe (H) to the waste pipe (N). By this device the temperature of the incubator can be kept constant at any desired point, even though it may be about 30° to 40° C. (54° to 72° F.) below that of the external air. A refrigerating unit may be used in place of ice for cooling the circulating fluids, or coils containing the refrigerant may be built into the walls of the incubator.

Incubator **Rooms.**—When large numbers of cultures must be used, it is often preferable to insulate the walls of a small room, or suite of rooms, and maintain the entire room and its contents

at a given temperature. Shelves or racks are used to support the cultures. The heat may be supplied by electric heaters, steam or hot water. In warm climates the room may also have pipes for circulating cold water, or other refrigerant, to hold the desired temperature when the outside temperature may be higher. Means to provide a constant humidity, by evaporating or absorbing water vapour in the room may also be provided.

INFANT INCUBATORS

Tarnier's Incubator. — The first incubator for rearing children who are too weak to survive under normal conditions, or who are prematurely born, was that of Dr. E. S. Tarnier. It was constructed in 1880 and was first used at the Paris Maternity Hospital. Its form is that of a rectangular box measuring 6 j × 30 × 50 centimetres (fig. 5). It is divided into an upper and lower chamber; the former contains the infant, while the latter serves as a heating chamber, and in reality is simply a modified water tank. The partition (P) which divides the incubator into two chambers does not extend the whole length of it, so that the upper and lower chambers are in communication with each other at one end of the apparatus. It is through this passage that the heated air from the lower chamber passes into the upper one containing the infant. The narrow bottom chamber (C) serves to prevent loss of heat from the base of the water bottles. The outside air is admitted into the lower chamber at the opposite end, through an aperture (A). and passing over a series of bottles (B) containing warm water, becomes heated. The air is rendered adequately moist by means of a wetted sponge (S) which is placed at the entrance of the lower chamber into the upper. The warmed and moistened air is determined in its direction by the position of the outlet aperture (0), which is situated above and just behind the head of the infant. It contains a helix valve (H) and the rotation of this is an indication that the air is circulating within the incubator.

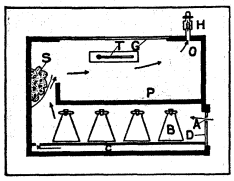

FIG. 5.—TARNIER'S INCUBATOR

The child is kept under observation by means of a sliding glass door (G) situated in the upper or roof wall of the incubator. Immediately beneath this, and attached to one of the side walls, is a thermometer (T) which records the temperature of the air in the infant chamber; the temperature to be determined by the condition of the child; the smaller and weaker it is, the higher the temperature must be.

Hearson's Thermostatic Nurse. — This consists fundamentally of an application of the arrangements for heating and moistening the air and for regulating the temperature of Hearson's chick incubator to Dr. Tarnier's human incubator. As in this latter form, there are two chambers (fig. 6), an upper (A) and a lower (B), connected with each other in the same way as in Tarnier's apparatus The upper chamber contains the infant, but the lomer is not a heating but a moistening chamber. The external air- passes through apertures in the bottom chamber (M), through the inner cylinder of the water tray (O) and through a sheet of wet canvas to the chamber proper. A basket with perforated walls rests on supports (D). The infant is placed in the basket and may be observed through a glass door in the top of the incubator.

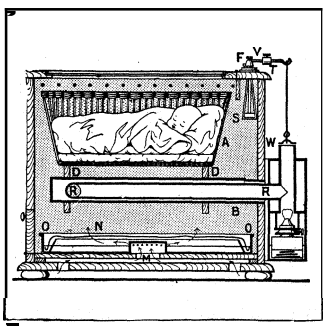

FIG. SONS "THERMOSTATIC

As in bacteriological incubators, electricity has displaced other forms of heat and in addition the humidity is regulated automatically by a humidistat which may be preset to any desired humidity. This is important, as very premature infants require a higher relative humidity than do those born nearly at term. It is desirable to reduce the humidity gradually to that of the nursery before the infant is removed from the incubator. Premature infants of six and one-half months have been reared successfully in the Humidicrib (fig. 7). Such infants usually are kept in the incubator for two to three months at 27° to 37° C. (80° to 98° F.).

The top of the Humidicrib may be raised when the infant is put in the incubator. The sliding panels permit access for ordinary care. An opening is provided in the left side to admit oxygen should the condition of the infant require it. A switch provides light for temporary observation. The main switch and controls for temperature and relative humidity are located on the right end, as well as a door to give access to the automatic heating and humidifying equipment. Air filters at the lower front and in back, provide fresh air and are removable for cleaning. The crib is entirely automatic except for filling the water reservoir.

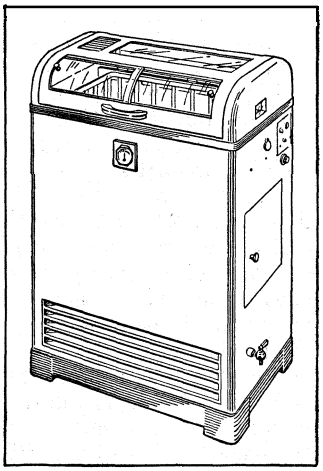

FIG. 7.—HUMIDICRIB WITH AUTOMATICALLY CONTROLLED HUMIDITY AND TEMPERATURE

FUNDAMENTALS OF DESIGN

While many organisms that require a constant temperature environment are kept in bacteriological incubators, experiments to determine the effect of changing temperature on the rate of life processes, such as growth, must be made with more exact and flexible control of the temperature.

Types.—Incubators in general use are water or air baths. The temperature of a large water bath is disturbed less when the cultures are changed, because of the high latent heat capacity of the water. The culture containers may be placed directly in the bath, or in an air chamber near the centre of the bath. Some form of water circulator, or stirrer. is essential.

Most incubators are air baths (fig. 3). When a variation of one or two degrees within the different parts of the incubator is unimportant, no circulation of air is needed. Better uniformity may be obtained with a gravity air circulation by means of adjustable openings at the top and bottom of the incubator. Circulating the air with an electric fan establishes a more uniform temperature in the incubator. Water jacketed incubators (fig. 1) are, in a sense, intermediate between the air and water bath types. When made in the more convenient rectangular shape, the temperature is held well and any cooling from opening the box is quickly replaced by the heat in the walls The water evaporation must be replaced, and the boxes are heavy. Improved wall construction has largely displaced this type of incubator.

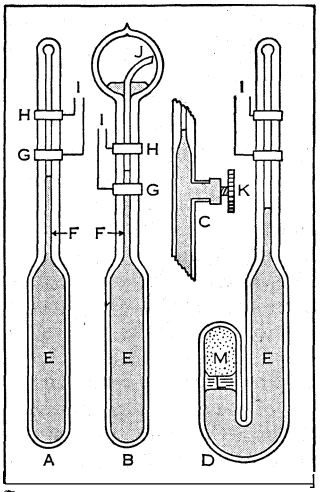

FIG. 8.—MERCURY THERMOREGULATORS

Insulating Materials. — The most elementary incubators are made with a single wall of wood, fibreboard or hardened asbestos board. The high rate of heat flow through the walls precludes close control of the temperature. To obtain better insulation the wall and door usually have an air space between two supports and the air space may be filled with cork, asbestos or glass fibre, glass foam or other insulating material.

Thermal Exchange. — An object warmer than its surroundings looses heat at a rate depending on the extent of the difference. To keep the incubator at a constant temperature above its surroundings, heat must be added to the incubator. Or. if the box is to be kept cooler than the room, heat must be taken away from

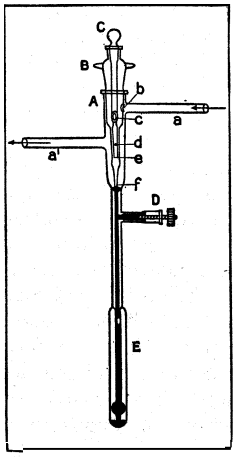
It as fast as it becomes heated from the warmer room. The amount transferred may be determined experimentally, or calculated from the size of the box and the thermal conductivities of the materials used in making the incubator. (See HEAT; THERMOMETRY.)

Fluctuations in room temperature require heating or cooling mechanisms with sufficient capacity and a sensitive controlling element. When large changes must be met, it is better to use several heating units separately controlled. rather than one large one. Otherwise the warming may lag behind, or overshoot the proper temperature. A satisfactory method is to use a continuous heater to keep the incubator almost up to temperature and to use a smaller intermittent heater to maintain the temperature. If the surrounding room does not remain moderately constant, it may not be possible to hold the incubator within a small variation.

Heat may be removed from the box by running cold water, or by some form of refrigeration (*q.v.*). The cooling coil may be placed near or within the incubator. Or, the refrigerator may cool a tank of brine or other refrigerant which is circulated through coils in the walls of the incubator. The natural flow of heat may be utilized by building a row of incubator chambers with common walls, heating one end and cooling the other end. Those in-between will have intermediate temperatures. The group should be placed in a basement room not subject to rapid temperature fluctuations.

Gas, gasoline, kerosene or electricity are used to supply heat. The hot combustion gases from gas or kerosene may be led around, or through the walls of the box. The flame may be regulated by controlling the fuel supply; the flow of the heated air may be regulated with a damper or louvers, or both means may be combined. Electric heating coils are placed in the lower part of the chamber, or in the walls.

The precision of the incubator depends on how nearly the loss or gain in heat is balanced by adding or removing heat. Good design is necessary. For the usual care of bactekial cultures a variation of a degree may not be important, but incubators for physiological experiments may need to be held to at least a tenth of a degree. The smaller the variation to be tolerated, the better must be the insulation and the controlling thermoregulator.



BY COURTESY OF GREINER & FRIEDRICHS

FIG. 9.—NOVY'S THERMOREGULATOR

THERMOREGULATORS

Most materials expand with heat and this change in size is used to regulate the flow of heat by operating a switch or valve. Expanding capsules (fig. 2, S) were used first. They tended to wear out, or leak and have been supplanted by mercury or bimetallic thermoregulators. Mercury has a large thermal expansion and is a convenient liquid to use. Since it corrodes most metals, it is used in glass containers.

Mercury Regulators. — A considerable volume of mercury is placed in a bulb (E, fig. 8) connected with a capillary tube (F). A small change in temperature expands or contracts the mercury slightly and causes a proportionately larger movement of the mercury in the narrow capillary. Control to a tenth of a degree is possible.

When the incubator is to be used at a fixed temperature, two electrical contacts (G, H) are sealed into the capillary. As the mercury rises contact is made with (G), on reaching (H) the circuit is completed and current applied to the mires (I) will flow through the connecting mercury. As the regulator cools the mercury recedes, the current is interrupted and the heating cycle restarted. The setting is made by adding enough mercury to reach the contact (H) when at the desired temperature and the tube is then sealed. An adjustable regulator is left open so that the mercury may be added or removed, or the mercury volume changed by a screw plunger (K, fig. 8; D, fig. 9). Possible loss from spilling is prevented in the sealed, adjustable regulator (fig. 8). A bulb is fused onto the top of the regulator and the capillary is extended toward the side of the bulb (J). The device is adjusted by heating until the excess mercury spills over into the bulb. To set to a lower temperature, the bulb is tilted until the tip of the capillary dips into the mercury; the regulator is warmed until the mercury in the capillary reaches that in the bulb and allowed to cool and draw mercury into the larger bulb.

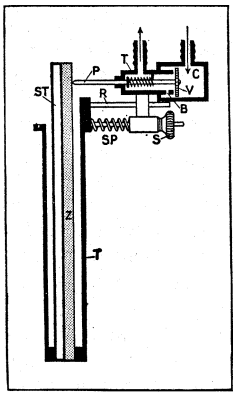


FIG. 10.— DR. ROUX'S THERMOSTAT (STRAIGHT BAR)

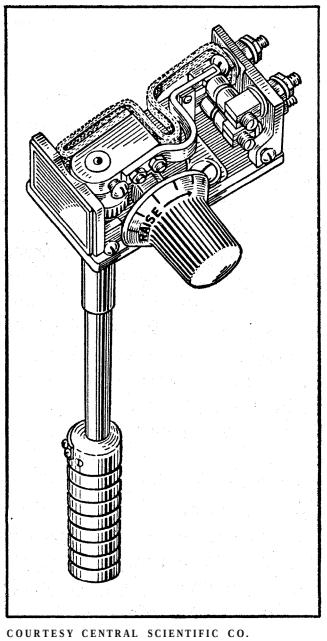
Mercury is heavy and expensive and the use of large amounts is avoided sometimes by partly filling the bulb with toluene or some other liquid with a high thermal expansion. Another modification (fig. 8) has a turned up bulb with a layer of liquid (L) over the mercury. Vapour (M) from the liquid fills the remaining space. The liquid, with a boiling point somewhat above the operating temperature, vaporizes, and as the volume of the vapour changes more rapidly with temperature than the liquid, the system is more sensitive. The liquid-vapour systems usually are used only with water bath incubators.

The expanding mercury may control the flow of gas as in Novy's thermoregulator (fig. 9), which consists of a toluene-mercury bulb (E), a volume regulating screw (D), gas ports (a, a') and two ground-glass stoppers (B, C). By turning the glass stoppers the sizes of the openings (b, c, d) may be changed to regulate the gas flow from a to a'.

The early mercury thermoregulators were used to control the current to the heaters, and breaking such large amounts of current soon fouled the mercury surface. This sparking and fouling was lessened by sealing some inert gas above the mercury, or by putting an insulating oil on the mercury. This lessened the oxidation but only prolonged the intervals between cleaning and replacing the mercury. The solution of this difficulty occurred when relays and electronic switches were developed that required very small amounts of current. In the meantime metallic thermoregulators were improved.



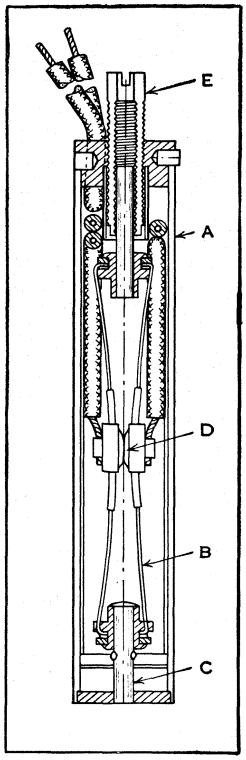
COURTESY CENTRAL SCIENTIFIC CO.

FIG. 11.—DE KHOTINSKY'S SPIRAL BIMETALLIC THERMOREGULATOR

Bimetallic Regulators. — If two strips of metals with different thermal expansions are riveted or welded together, the combination when heated will curve toward the side of the metal with the lesser expansion. As used in a regulator, (fig. 10) one end (T) is fixed and the other end may move a valve (V) and pin (P) to control the gas flow from (C). When used with electricity, one wire is connected to the case and the other to an adjustable contact in place of the pin. The regulators are set by moving the valve unit by a screw (S) nearer toward, or farther from the end of the moving bar. Many metals may be used. Steel (ST) has a very low coefficient of expansion and zinc (Z) a high one, which makes a useful combination. Wilhelm Roux obtained more movement by making the bimetallic pair in the shape of a U.

Arcing or sparking occurs as the contacts open unless the current is small. This pits the contacts and reduces the sensitivity of the regulator. The best contacts are of silver, platinum or their alloys. Placing a condenser of suitable capacity across the contacts greatly reduces damage to the contacts.

De Khotinsky Thermostat. — By bending the welded strip of metals into the form of a spiral (fig. 11) Capt. A. de Khotinsky (1850–1933) obtained greater movement and increased sensitivity. One end of the spiral is fixed to the setting mechanism on the frame and the other end is fastened to a rod which extends back through the spiral and the housing and turns the switch bar. One or two pairs of contacts are used. As the temperature changes the difference in expansion between the two metals causes the spiral to revolve, which turns the rod and opens or closes the switch. The regulator is set to the desired temperature by turning the knob which rotates the spiral to correspond with its position at that temperature. Control at the spiral is possible within about one-quarter of a degree. (*Cf.* fig. 3.)



COURTESY FENWAL, INC.

FIG. 12.—FENWAL CARTRIDGE THERMOSWITCH

Fenwal Cartridge. — The wall of this thermoswitch (fig. 12) consists of a material with a high coefficient of expansion (A). A nonexpanding member (B) is anchored to it at (C). With increased heat (A) slowly elongates and pulls apart the contacts (D) to break the electrical circuit. It is set by turning the screa (E). It will control loads of one kilowatt and is stated to be sensitive to one-tenth degree F.

Thermocouple **Regulators.**—When a junction of suitable dissimilar metals is heated, an electrical current is generated in the thermocouple. (*See* THERMOMETRY.) The current can be measured with a voltmeter or potentiometer calibrated to read in temperature. When a small metal disk is put on the pointer of the meter and two coils mounted on a movable lever which may be set on the scale, then as the disk moves between the coils the frequency of an oscillating current from an electronic tube is changed. the tube draws less current and operates a solenoid switch to control the heater current. The electronic control is sensitive to Iess than a degree. (*See* ELECTRON TUBE; MAGSETISM.)

Controls.—With small currents in the thermoregulator circuits the contacts are not damaged, even over long periods. Direct current is preferable and is obtained by using a transformer (*q.v.*) to reduce the supply voltage to about 6 volts, which is then changed into direct current, often by a built-in rectifier. Sensitive relays are available which operate on about 10 milliamperes. The relay is provided with a mercury tube or heavy contact switch for the control of the heater current. With steam heat, hot or cold water the relay operates a shutoff valve in the pipe line.

A nonmechanical sensitive controlling method uses the small current in the thermoregulator circuit to monitor an electronic tube of the *Thyratron* type so that the heater current passes through the tube in proportion to the control current.

Rs.)

INCUNABULA, a Latin neuter-plural meaning "swaddling-clothes," a "cradle," "birthplace," and so the beginning of anything, now curiously specialized to denote books printed in the 15th century. Its use in this sense may have originated with the title of the first separately published list of 15th century books, Cornelius a Beughem's *Incunabula typographiae* (Amsterdam, 1688). The word is generally recognized all over Europe and has produced vernacular forms such as the French *incunables*, German *Inkunabeln* (Wiegendrucke), Italian *incunaboli*, and the anglicized form incunables is now frequently used. Despite the rapid development of printing in some centres as compared with others, the attractions of a round date have caused the word to be applied to all books produced before the close of the year 1500 and to these alone. The earliest important catalogues of them were (i.) Panzer's *Annales typographici ab artzs inventae origine ad annum MD.*, printed in five volumes at Nuremberg in 1793 and subsequently in 1803 carried on to 1536 in six additional volumes; (ii) Hain's *Repertorium bibliographicum in quo libri omnes ab arte typographica inventa usque ad annum MD. typis expressi ordine alphabetico vel simpliciter enumerantur vel adcuratius, recensentur* (Stuttgart, 1826–38). In Panzer's *Annales* the first principle of division is that of the alphabetical order of the Latin names of towns in which incunabula were printed, the books being arranged under the towns by the years of publication. In Hain's *Repertorium* the books are arranged under their authors' names, and in 1891 an invaluable index of printers was added by Konrad Burger. In 1898 Robert Proctor published an *Index to the Early Printed Books in the British Museum: from the invention of printing to the year MD., with notes of those in the Bodlezan Library.* In this work the books were arranged as far as possible chronologically under their printers, the printers chronologically under the towns in which they worked, and the towns and countries chronologically in the order in which printing was introduced into them, the total number of books registered being nearly 10,000 After Proctor's premature death in 1903, the trustees of the British Museum ordered a full dress catalogue of its incunabula to be prepared, and of this five volumes have been issued, comprising Germany (including Austria and German speaking Switzerland), Rome and Venice. In France Mlle. Pellechet in 1897 began a *Catalogue général des incunables des bibliothkques publiques de France,* which was continued by M Louis Polain but stopped in the middle of G. In Germany after 21 years of preparation the first volume of a *Gesamtkatalog der Wiegendrucke* was published in 192j.

In any attempt to estimate the extent to which the incunabula still in existence represent the total output of the 15th century presses a sharp distinction must be drawn between the weightier and the more ephemeral literature Owing to the great religious and intellectual upheaval in the 16th century much of the literature previously current went out of date, while the cumbrous early editions of books still read were superseded by handier ones. Before this happened the heavier works had found their way into countless libraries and here they reposed peacefully, only sharing the fate of the libraries themselves when these were pillaged, or, by a happier fortune, amalgamated with other collections in a larger library. The considerable number of copies of many books for whose preservation no special reason can be found encourages a belief that the proportion of serious works now completely lost is remarkably low, except in the case of books of devotion whose honourable destiny was to be worn to pieces by devout fingers On the other hand, of the lighter literature in book-form, the cheap romances and catchpenny literature of all kinds, the destruction has been very great. Most of the broadsides and single sheets generally which have escaped have done so only by virtue of the 16th century custom of using waste of this kind as a substitute for wooden boards to stiffen bindings. Excluding these broadsides, etc.. the total output of the 15th century presses in book form is not likely to have exceeded 40.000 editions. As to the size of the editions we know that the earliest printers at Rome favoured 22j copies, those at Venice 300. By the end of the century these numbers had increased, but the soft metal in use then for types probably wore badly enough to keep down the size of editions, and an average of 500 copies. giving a possible total of 20 million books put on the European market during the 15th century, is probably as near an estimate as can be made.

Types as Evidence — Very many incunabula contain no information as to when, where or by whom they were printed, but the individuality of most of the early types as compared with modern ones has enabled typographical detectives (of whom Robert Proctor, who died in 1903, was by far the greatest) to track most of them down. To facilitate this work many volumes of facsimiles have been published, the most important being K. Burger's *Monumenta Germaniae* et Italiae *Typographica* (1892, etc.). J. W. Holtrop's Monuments *typographiques* des Pays-Bas (1868), O. Thierry-Poux's Premiers *monuments* de *l'imprimerie* en France au *XVe* sibcle (1890), K. Haebler's *Typographie ibérique* du *quinzième* sibcle (1901) and Gordon Duff's Early English Printing (1896), the publications of the Type Facsimile Society (1700, etc.) and the *Woolley* Facsimiles, a collection of 500 photographs, privately printed by George Dunn.

In his Index to the Early Printed Books at the British Museum Proctor enumerated and described all the known types used by each printer, and his descriptions have been usefully extended and made more precise by Dr. Haebler in his Typenrepertorium der Wiegendrucke (1905, etc.). With the aid of these descriptions and of the facsimiles already mentioned it is usually possible to assign a newly discovered book with some certainty to the press from which it was issued and to fix within narrow limits the date at which it was finished.

The total number still extant of incunabula printed in England is about 360, of which Caxton produced nearly 100. Of the 10,000 different incunabula which the British Museum and Bodleian Library owned between them in 1898, about 4,100 are Italian, 3,400 German, 1,000 French, 700 from the Netherlands, 400 from Switzerland, 150 from Spain and Portugal, 50 from other parts of the continent of Europe and 200 English, the proportion of these last to the total known being about doubled by the special zeal for collecting them. The celebration in 1640 of the second centenary (as it was considered) of the invention of printing may be taken as the date from which incunabula began to be collected for their own sake. apart from their literary interest, and the publication of Beughem's Incunabula typographiae in 1688 marks the increased attention paid to them. But up to the end of the 17th century Caxton's could still be bought for a few shillings. The third centenary of the invention of printing in 1740 again stimulated enthusiasm, and by the end of the 18th century the really early books were eagerly competed for. Interest in books of the last 10 or 15 years of the century is a much more modern development, but with the considerable literature which has grown up round the subject is not likely to be easily checked.

The chief collections of incunabula are those of the Bibliothèque Nationale at Paris; Royal library, Munich; and British museum, London. Other important collections are at the University library, Cambridge; the John Rylands library, Manchester; the Pierpont Morgan library, New York; the Annmary Brown Memorial, Providence. R.I.; the Henry E. Huntington library. San Marino, Calif.; and the Library of Congress at Washington. See also BOOK COLLECTING. (A. W. P.)

INDENTURE, a law term for a special form of deed executed between two or more parties, and having counterparts or copies equal to the number of parties. These copies were all drawn on one piece of vellum or paper divided by a toothed or "indented" line. The copies when separated along this waved line could then be identified as "tallies" when brought together. Deeds executed by one party only had a smooth or "polled" edge, whence the name "deed poll." By the Real Property act, 1845, s. 5, all deeds purporting to be "indentures" have the effect of an "indenture." even though the indented line be absent. The name "chirograph" was also early applied to such a form of deed, and the word itself was often written along the indented line (see further DEED). The term "indenture" is now used generally of any sealed agreement between two or more parties, and specifically of a contract of apprenticeship, whence the phrase "to take up one's indentures," on completion of the term, and also of a contract by labourers to serve in a foreign country or colony (see CONTRACT LABOUR). In the United States indenture is used generally as a term meaning a conveyance.

INDEPENDENCE, a city of Missouri, U.S., 10 mi. E. of Kansas City (*q.v.*) and 3 mi. S. of the Missouri river; the county seat of Jackson county. Independence is within the Kansas City standard metropolitan statistical area and co-operates with Kansas City in area planning. Pop. (1960) 62.328; for comparative population figures see table in MISSOURI: *Population.*

Best known since his presidency as the home of Harry S. Truman, Independence was once the only city of consequence west of the Mississippi. It was settled in 1827; Mormon settlers arrived in 1831 and were driven out in 1833 (see LATTER-DAY SAINTS, CHURCH OF JESUS CHRIST OF: History). From the early 1820s until 1848, Independence was the starting and outfitting point for the Santa Fe trail (q *v.*) and the Oregon and California trails. It was chartered as a city in 1849.

The Harry S. Truman library, a research centre on the presidency, including a museum was dedicated in 1957. A colonial-style courthouse. rebuilt in 1932 when Truman was presiding judge, is on the square in the centre of the city. The restored log courthouse (1827) houses the welfare office; the old jail, built in 1859, is a museum and county historical society headquarters. World headquarters of the Reorganized Church of Jesus Christ of Latter Day Saints are in Independence; and in 1907 the Mormons of Salt Lake City moved their central states mission there. More than 60 industries make a variety of products. Independence is also a residential suburb of Kansas City. (S. C. G.)

INDEPENDENCE, DECLARATION OF: *see* DECLARATION OF INDEPENDENCE.

INDEPENDENCE DAY, U.S., or Fourth of July. the anniversary of the adoption by the Continental congress, July 4, 1776, of the Declaration of Independence, proclaiming the severance of the allegiance of the American colonies to Great Britain, is the greatest secular holiday of the United States, observed in all the states, territories and dependencies.

The congressional delegates from Virginia introduced in the Continental congress, June 7, 1776, a resolution that "that . . . body declare the United Colonies free and independent States, absolved from allegiance to or dependence on the Crown or Parliament of Great Britain. . . ." On June 10 a committee of five, headed by Thomas Jefferson, was appointed to prepare a declaration suitable to the occasion in the event that the Virginia resolution w s adopted.

Congress approved the resolution July 2; the declaration composed by Jefferson and amended by his committee was adopted July 4 and was publicly read in the yard of the state house July 8.

The first anniversary of the declaration was observed only in Philadelphia, Pa., by the adjournment of congress, a ceremonial dinner, bonfires, the ringing of bells and fireworks. In 1788, after the requisite number of states had adopted the constitution, Philadelphia celebrated July 4 by elaborate festivities, including a grand procession which incorporated five symbolic groups: independence; French alliance; definitive treaty of peace; convention of the states; and constitution.

Boston, Mass., first observed the day in 1783, and thereafter this celebration replaced that of the Boston Massacre, March 5. The custom spread to other cities and states, where the day was marked by parades. patriotic oratory, military displays and fireworks. As the toll of deaths and injuries mounted annually, many communities in the 20th century passed laws prohibiting the sale of fireworks. Civic minded groups worked to link the ideals of democracy and citizenship to the patriotic spirit of the day. Games and athletic contests, picnics, patriotic programs and pageants, and community fireworks displayed by experts became characteristic of the day. (J. K. So.)

INDEPENDENCIA, a small province in southwestern Dominican Republic. Area, 719 sq.mi.; pop. (1960) 27,475. It largely comprises the arid basin between the Sierra de Neiba to the north and the Sierra de Bahoruco on the south. Lake Enriquillo, a large salt lake near the centre where flamingos and alligators breed, lies 144 ft. below sea level. The province produces small amounts of irrigated sugar cane, rice and bananas. It was created from the western section of Bahoruco province in 1948 as part of a plan to develop the area bordering Haiti. The provincial capital,

Jimani, founded 1949 on the west shore of the lake, is a small frontier town. (D. R. D.)

INDETERMINATE EQUATIONS: *see* DIOPHANTINE EQUATIONS.

INDEX, a list of the matter discussed in a book or set of books, showing the pages where each subject is to be found; or, in a more general sense, an indicator of the position of information on any given subject. Such a list may contain the names of persons, places, specific subjects or ideas discussed. An alphabetical arrangement of an index is usually found to be more convenient for consultation than one divided into several parts under large subjects.

Indexes are a valuable key to the material they are concerned with, and for many books they are essential. They have been found in volumes printed as early as the 15th century; the growth of indexing from a short table of contents to an extensive subject index is traced in H. B. Wheatley's *What Is an Index?* (1878). In modern books the table of contents and the index are distinguished, the table of contents being printed at the beginning of the book and the index at the back. Indexes to sets of books, such as the complete works of an author or an encyclopaedia, may be printed in separate volumes. The Index to *Encyclopædia Britannica* is an example; the introduction to it sets forth some principles that apply to other indexes as well.

Periodical Indexes.—Almost a~~periodicals have an index covering the entire volume, issued with the last number. A useful type of periodical index is for many volumes of a set, especially when the publication has not been analyzed in one of the indexing mediums. *Gentlemen's Magazine,* for example, has a *General Index* in 2 volumes covering the years from 1731 to 1818; *Poole's Index to Periodicals* did not begin indexing the *Gentleman's Magazine* until 1868. Daniel C. Haskell has compiled a *Check List of Cumulative Indexes to Individual Periodicals in the New York Public Library* (1942) that lists about 4,500 different indexes.

In 1848 William F. Poole published the first index to English periodicals, *An Alphabetical Index to Subjects Treated in the Reviews and Other Periodicals to Which No Indexes Have Been Published.* In 1876 Poole proposed a co-operative plan for indexing current periodicals. This resulted in the publication in 1891 of the first two volumes of *Poole's Index to Periodicals,* covering 1802–81. This was followed by five supplements, each covering five years.

The H. W. Wilson Co. has published indexes for many years, beginning in 1900 with the *Readers' Guide to Periodical Literature,* which analyzes over 100 of the popular current periodicals. This was followed in 1913 by the *International Index to Periodicals,* now indexing about 175 of the more scholarly journals too specialized for inclusion in the *Readers' Guide.* Readers asked for more specialized indexes, with the result that the *Industrial Arts Index* was begun in 1913, the *Agricultural Index* in 1916, the *Education Index* in 1929, the *Art Index* in 1930, *Library Literature* in 1936, and the *Bibliographic Index* in 1938.

Other **Indexes.**—Newspaper indexes are valuable, but few have been compiled because of the magnitude of the work. The best-known ones are the Palmer's *Index to the London Times* from 1790 to 1906. followed by the *Official Index to the Times* (begun in 1906), and the *New York Times Index* (begun in 1913). An index to one newspaper can serve as an index to other papers, since general news items appear in all the papers of the country at about the same time.

The *Great Books of the Western World,* edited by Robert Maynard Hutchins and published in 1952 in 54 volumes, contains 443 works of 74 authors. In volumes 2 and 3, entitled *The Great Ideas, a Syntopicon,* are 163,000 references arranged under 3,000 topics contained in the *Great Books.* It is the greatest index ever made of ideas found in the classics.

See also BIBLIOGRAPHY: *Enumerative (or Systematic) Bibliography.*

Making an Index.—The making of an index is an art that requires certain skills, such as accuracy, keenness in acquiring the point of view of the author. good judgment and conciseness, as well as knowledge of certain accepted rules for compiling such an index. For a brief discussion of basic considerations and procedures see *A Manual of Style,* published by The University of Chicago Press.

The rapid increase in the volume and complexity of the literature to be indexed has forced a serious consideration of the contribution that automation can make to indexing operations. "Mechanized indexing" is a generic term that includes a wide variety of mechanical and electronic devices and the indexing systems which they use.

Hand-sorted marginal-punched cards. the Peek-a-Boo system developed at the U.S. bureau of standards and Calvin Mooers' Zatocoding are effective for small files of material. Much experimentation has been conducted in adapting standard computer equipment, the IBM series, the Remington Rand UNIVAC, and similar machines, to the indexing of large collections of material. The most efficient devices. however, are those designed specifically for indexing operations such as the Minicard system of the Eastman Kodak Co., and the Filmorex developed in France by Jacques Semain, both of which employ microfilm as the storage medium. The Searching Selector developed at the school of library science of Western Reserve university is the most flexible yet devised and can use punched cards, microfilm or magnetic tape.

The advantages of mechanization are the ability to index large volumes of material so that it can be searched at extremely high speeds, the ability of the machine to correlate a great number of characteristics of the literature to be searched in a variety of complex ways and the capacity to perform other repetitive indexing operations that a machine can do more efficiently than man.

See also Robert L. Collison, *Indexes and Indexing* (1959); Martha T. Wheeler, *Indexing* (jth ed. rev., 1957), which is a pamphlet published by the New York State Library and an excellent brief treatment. (W. V. N.)

INDEX LIBRORUM PROHIBITORUM, the official list of books authoritatively forbidden to members of the Roman Catholic Church, together with the general rules of canon law which declare certain classes of books forbidden *ipso jure; i.e.,* without specific mention. The exact origin of this legislation cannot be assigned with certainty. The apostle Paul approved the burning of bad books by the newly converted Christians of Ephesus (Acts xix, 19). Early ecclesiastical condemnations of books are the *Muratorian Canon* (2nd century), giving the canon of the New Testament and condemning apocryphal books, the condemnation of Arius and his book, *Thalia,* by the Council of Nicaea (325) and the *Decretum Gelasii* promulgated by Pope Gelasius in 496. Though vigilance against the contamination of faith and morals through bad books had been constant throughout the earlier centuries, it became still more necessary after the invention of printing. The principal later editions of the *Index* are those of 1559, 1564, 1596, 1664, 1670, 1681, 1752, 1758, 1819, 1835, 1877, 1881, 1900, 1917, 1922, 1929, 1930, 1938 and 1940. For the historical development, consult the works listed in the bibliography.

The *Index* includes the rules of the code of canon law on forbidden books, but not those which prescribe previous censorship of certain books as a requisite for their licit publication. Books published without this previous examination and approval are not necessarily forbidden, though some of them will fall under the fifth classification given below. Books which are forbidden *ipso jure* are:

(1) Editions of the original text and of ancient Catholic versions of Sacred Scripture, published by non-Catholics; also all translations of Sacred Scripture into any language, made or published by non-Catholics; this prohibition does not apply to persons who are studying theology or Sacred Scripture; (2) books which deiend heresy or schism, or which in any way attempt to subvert the very foundations of religion; ancient and obsolete heresies are not embraced in this prohibition; (3) books which purposely attack religion or sound morals; (4) books by non-Catholics which treat professedly of religion, unless it is certain that they contain nothing against the Catholic faith; (5) books of Sacred Scripture or annotations and commentaries thereof, and books and booklets of prayer, devotion or instruction which tell of new apparitions, revelations, visions. prophecies, miracles, or which introduce new devotions, if any of these were published without observing the special requirements of canon law; (6) books which attack or ridicule any of the Catholic dogmas. which deiend errors proscribed by the Holy See, which disparage divine worship. or strive to overthrow ecclesiastical discipline, or purposely insult the ecclesiastical hierarchy or the clerical or religious state; (7) books which teach or approve of any sort of superstition, fortunetelling,

divination, magic, spiritism or other such practices; (8) books which hold duelling, suicide or divorce licit, or which, treating of Masonic sects and other such societies, contend that they are useful and not harmful to the church and civil society; (9) books which purposely treat of, narrate or teach lascivious or obscene matter; scientific books, written with a serious purpose, are not considered obscene; (10) editions of liturgical books approved by the Holy See, in which anything has been changed so that they do not agree with the authentic editions; (11) books containing indulgences which are spurious or which have been proscribed or revoked; (12) pictures of Christ, His Mother or angels and saints if they are foreign to the mind and decrees of the church.

In 1949 the Holy Office declared that all books, papers, etc., which champion the doctrine or action of Communists, are equally forbidden, without special mention, under the terms of the existing law.

The procedure prescribed by Benedict XIV in 1753 remained unchanged when, in 1917, the Holy Office took over the entire charge of the prohibition of books from the congregation of the *Index*. Books are first examined by one of the *qualificatores* or by one of the consultors, then discussed and voted on by all the consultors; the verdict is given by the cardinals of the Holy Office and then submitted to the pope, who makes the final decision. Individual bishops can forbid a book only for their own territory, subject to recourse to the Holy See. condemnations apply to future editions and translations into any language and forbid the reading, keeping, sale, translation or communication of the book. Cardinals, bishops and ordinaries are exempt from the law. Other persons must obtain permission from the Holy See, or, with certain restrictions, from the ordinary. The law is subject to a rather liberal rule of interpretation in accordance with the general principle that laws which restrict liberty are to be narrowed rather than enlarged in their application (canon 19). The penalty of excommunication *ipso facto* is incurred only in a few strictly limited cases (canon 2318).

The *Index* of 1940 (pp. xxiv + 508) contained: a preface by Cardinal Merry del Val reproduced from the 1929 edition, the canons of the code of canon law (effective May 19, 1918) on the prohibition of books, a decree of the Holy Office (May 3, 1927) on sensual and sensual-mystic literature, a page of *Praenotanda* or prenotes and the authentic list of forbidden books. These are listed alphabetically by author and title, usually with the date and source of the condemnation. An asterisk designates a book which was condemned *donec corrigatur; i.e.*, only until it be satisfactorily amended; a cross (†) distinguishes those condemned by apostolic letter from those condemned only by a decree of a Roman congregation.

BIBLIOGRAPHY.—*Codex Iuris Canonici,* canons 1384–1405 (1918); Joseph Hilgers, *Der Index der verbotenen Bucher* (1904) and articles "Index of Prohibited Books" and "Censorship of Books" in the *Catholic Encyclopedia;* Arthur Vermeersch, *De prohibitione et censura librorum* (1906); A. Boudinhon, *La Nouvelle législation de l'Index* (2nd ed., 1926); Joseph M. Pernicone, *The Ecclesiastical Prohibition of Books* (1932); Edwin F. Healy, *Moral Guidance* (1942). (*T. L.* B.)

INDEX NUMBERS. The phrase index number is sometimes applied to any series in which a chosen term is written as 100 and the other terms expressed as percentages of it. The earlier and more general use is, however, consonant with the following definitions: "An index number [is] a number adapted by its variations to indicate the increase or decrease of a magnitude not susceptible of accurate measurement" (Edgeworth, *Economic Journal,* 1923, p. 379); "index numbers are used to measure the change in some quantity which we cannot observe directly, which we know to have a definite influence on many other quantities which we can so observe, tending to increase all or diminish all, while this influence is concealed by the action of many causes affecting the separate quantities in different ways" (Bowley, *Elements of Statistics,* 1920, p. 196). Thus index numbers are applied to the measurement of the *general* movement of prices, cost of living, wages, production, consumption, employment, etc.

The data from which index numbers are formed consist of records of particular quantities at two or more dates or places and information about the relative importance of these quantities in a general measurement. In constructing an index number to measure the movement of any defined magnitude it is necessary to decide on the choice of the separate quantities, on their relative importance, on the period or place to be taken as base, and on the formula of compilation. Thus, in the *Statist* index number the objective is the measurement of the change of wholesale prices in the United Kingdom; 45 commodities are selected and regarded as of equal importance, the period 1867–77 is taken as base, the average price in that period of each commodity is equated to 100, the terms in each series of prices are expressed as percentages of that average ("price-relatives"), and the simple average of the 45 relatives in any year forms the index number for that year.

A distinction is drawn, but not by all writers, between two classes of index numbers: (a) where, as in the definitions quoted above, the object is to measure the movements of a magnitude without specific reference to any pre-determined application, *e.g.*, the purchasing power of money in general ("indice monétaire") as conceived by Jevons, *The Variation of Prices and the Value of Currency since 1782* (1865); (*b*) where the measurement is to be applied to a defined group, *e.g.*, the changes in the cost of a quantitative standard, such as is used in a cost of living index ("indice budgétaire"). Many index numbers, however, are intermediate between these classes, and much of the analysis of the form and content of the numbers is appropriate to both. Thus, in all cases of price measurement, only those commodities can be included which are measurable in a defined and unchanged unit, and for which the price can be ascertained, and (unless the geometric mean is used) a base period in which each price is equated to 100 must always be selected.

PURCHASING POWER

(*a*) In the measurement of the purchasing power of money in general it is argued that the prices of all commodities, not subject to regulation or monopoly, are equally significant. Theoretically the problem is one of pure sampling, and the precision of the result in any year is directly proportional to the square root of the number of independent terms included and inversely proportional to the mean dispersion of these terms from their average in that year. In practice, the terms are not completely independent, for the prices of related commodities influence one another, and the precision is thus reduced. Also, the greater the interval from the base year, the greater tends to be the dispersion and the smaller the precision. In periods when prices are changing rapidly, as in the years 1914 to 1923, the dispersion is usually considerable and the measurement loses accuracy.

There are three types of averages applicable to price-relatives: their arithmetic mean as described above for the *Statist* index number; the geometric mean of the same numbers, that is the nth root of their product if there are n commodities; and the harmonic mean, which is the reciprocal of the arithmetic mean of the reciprocals. Thus, for two commodities whose prices were 6d. and 10d. in the base year, and 1s. and 2s. 1d. in any other year, the price-relatives are 200 and 250, their A.M. is 225, their G.M. is $\sqrt{(200\times250)}=223{\cdot}6$, their H.M. is $1\div\frac{1}{2}(\frac{1}{200}+\frac{1}{250})=222.2$. If the latter year is taken as 100, the relatives in the original base year are 50 and 40, the A.M. is 45, and $45:100=100:222{\cdot}2$. The H.M. of the "forward" relatives gives the same measurement as the A.M. of the "backward" relatives; or, if the comparison is between two places the H.M. of the relatives when the first is taken as base gives the same measurement as the A.M. when the second is so taken.

A general change in the relation of currency to its use tends to affect all prices in the same proportion, and "if other disturbing causes may be considered proportional to the ratio of change of price they produce in one or more commodities, then all the individual variations of prices will be correctly balanced off against each other in the Geometric Mean" (Jevons, *Investigations in Currency and Finance,* 1884, pp. 121–122; *see* also Bowley, *Economic Journal,* 1921, p. 202). The Geometric Mean is therefore considered appropriate to this problem. It has the advantage that it gives less importance to extreme measurements than does the Arithmetic Mean. It has the further advantage that the comparison by its use of any two years is independent of the choice of the base year (*see* below).

CHANGE IN A FIXED AGGREGATE

(b) The method generally used in the more objective problem of measuring the change of cost of a fixed aggregate of goods is as follows: the quantities of defined commodities which are produced or consumed in a year, or exported or imported, or are purchased in a week by a family, are estimated and the prices per unit are

ascertained in a base year or period and also in the year to which the measurement is to refer. This budget of quantities is valued at the base year prices and again at the prices of the year in question; the latter total expressed as a percentage of the first gives the required index number. The computation is often effected by writing down the relative expenditure (quantity × price) on each commodity in the base year, applying to each the percentage that its price in the second year forms of that in the first, and adding the products. This sum (divided by the total of the base year's relative expenditures) gives the same index number as before. Cost of living index numbers are computed by this method. In this form the index number appears as a "weighted average," where the weights are the relative expenditures and the things weighted are the price-relatives. From the theory of weighted averages it is known that considerable roughness in the weights has little effect on the result. It may also be regarded as an average of price-relatives which form a sample of a larger group than that included, and therefore—as under (a)—its precision depends on the square root of the number of independent relatives and, inversely, on their dispersion about their average.

The weakness of this method is that, when we make a comparison between two years or two places, the relative expenditures generally differ and each scheme of expenditure appears to have an equal claim to be included. This difficulty may be met theoretically by computing the index twice, first with the expenditures in year or place A and then with those in B and averaging the result. For comparison between places this method is applied; but it is seldom that the necessary "weights" can be obtained for more than one year, and till there is a further census of production or a new collection of working class budgets the double computation cannot be made. Further, if the weights are available for three years or places, A, B and C, the index for B in reference to A multiplied by that for C in reference to B does not by any weighted average formula give that for C in reference to A (÷100), as it should. This so-called "condition transitive" is not satisfied by any formula that is symmetrical with regard to weights. The algebra of the method is as follows:—

Write ${}_aQ_1$, ${}_aQ_2$ . . . and ${}_aP_1$, ${}_aP_2$ . . . for quantities and prices in **A,** and ${}_bQ_1$, ${}_bQ_2$. . . , ${}_bP_1$, ${}_bP_2$ . . . in B. The "forward" index number is $I_a = 100\Sigma_aQ_1 \cdot {}_bP_1 \div \Sigma_aQ_1 \cdot {}_aP_1$ and the "backward" index number is $I_b = 100\Sigma_bQ_1 \cdot {}_bP_1 \div \Sigma_bQ_1 \cdot {}_aP_1$. The Geometric Mean $\sqrt{I_a \times I_b}$ is Prof. Irving Fisher's "Ideal index number" (The Making of Index *Numbers,* 1922, p. 220). The arithmetic average, $\frac{1}{2}(I_a + I_b)$ and the form $I_2 = 100\Sigma\frac{1}{2}({}_aQ_1 + {}_bQ_1) \cdot {}_bP_1 \div \Sigma\frac{1}{2}({}_aQ_1 + {}_bQ_1) \cdot {}_aP_1$, may be conveniently used. The three forms of average may be expected to give nearly identical results. I_2, in which the quantities at the two dstes are averaged, is perhaps the simplest in idea. Each average lies between I_a and I_b, and is greater than I_a if an increase of prices of a commodity above the general increase from year A to a later year B is correlated with a relative decrease of the quantity purchased, as may be expected if there is a possibility of substitution of one commodity for another without any general change of standard (Bowley, Statistical *Journal,* 1919, pp. 343 *seq.*).

In their measurement of the change of import or export index prices from year A to the consecutive year B, the Board of Trade uses the formula I_b and for comparison with the next year C the formula $100 \times \frac{\Sigma_bQ_1 \cdot {}_bP_1}{\Sigma_bQ_1 \cdot {}_aP_1} \times \frac{\Sigma_cQ_1 \cdot {}_cP_1}{\Sigma_cQ_1 \cdot {}_bP_1}$ which does not- equal $100\,\frac{\Sigma_cQ_1 \cdot {}_cP_1}{\Sigma_cQ_1 \cdot {}_aP_1}$ obtained by direct re-valuation of the C quantities by the A prices and, if there is a very rapid change of quantities and prices, may differ considerably from it. This is an example of the "step-by-step" or "chain" method of index numbers. Note that from A to B, $100\,\frac{\Sigma_bQ_1 \cdot {}_aP_1}{\Sigma_aQ_1 \cdot {}_aP_1}$ is an index number of quantity of trade (prices constant), and $100\,\frac{\Sigma_bQ_1 \cdot {}_bP_1}{\Sigma_aQ_1 \cdot {}_aP_1}$ is the index number of value of trade. The product of these measurements of price and quantity is the index of value (×100).

Since no form of index number satisfies all the conditions which can properly be laid down (see *e.g.,* Gini, in Metron, 1924, pp. 81 and 134), we must select in each case the form most suited for the particular purpose in hand (regard being had to the data available) and it follows that we can only expect precision when different relevant forms give approximately the same result, for which the conditions are that the dispersion of prices from their average should be small and the number of constituent elements should be considerable. See COST OF LIVING; PRICES, STATISTICS OF. (A. L. B.)

INDEX SYSTEM: see OFFICE MACHINES AND APPLIANCES.

INDIA, a great subcontinent of Asia, with an area of 1,127,345 sq.mi. and a population (1951) of 436,424,429, of the same order of magnitude in area and population as the whole of Europe without the U.S.S.R. and inhabited by many different races speaking about 200 distinct languages. (The figures include India, Pakistan, Kashmir, Nepal. Bhutan and the Portuguese and former French possessions in India.) India was for many years under British rule (*see* below, History); but the transfer of power on Aug. 15, 1947, created two new dominions of the British Commonwealth, the larger retaining the name India with its capital at New Delhi (capital of undivided India since 1912), the latter becoming Pakistan (*q.v.;* capital Rawalpindi). On Jan. 26, 1950, the Dominion (or Union) of India became an independent sovereign republic which, as a full member of the Commonwealth of Nations. recognized the king of England as the head of that commonwealth but not as emperor of India and replaced his governor-general with a president elected by the Indian parliament; Bharat was taken as the official Hindi name of India.

The Indians can scarcely be said to have a word of their own by which to express their common country. In Sanskrit it would be called Bharata-varsha, from Bharata, a legendary monarch of the Lunar line; but Sanskrit is no more the vernacular of India than Latin is of Europe. The name Hindustan, which was at one time adopted by European geographers, applies properly only to that portion of the peninsula lying north of the Vindhya mountains, or yet more strictly to the upper basin of the Ganges, where Hindi is the spoken language. India, a word derived through the Greeks from the Persicized form of the Sanskrit *sindhu,* "river," pre-eminently the Indus, became familiar only after the British connection. To the establishment by the British of a single administration and to the adoption of English as the only common language of educated Indians was due the emergence of the conception of India as a political unit, not, like Europe, a mere geographic term.

The basis of the transfer of power could not be found in this unity; so, when British control went, partition was inevitable. In dealing with India it is impossible at this stage fully to separate earlier data, stalistical or general, according to the subsequent division. Where confusion might otherwise occur it will be necessary to use either "undivided India" or "the Indian subcontinent" in referring to the territory of the former Indian empire; and "India" for the newly created republic, the population of which. according to the 1951 census, was 357,241,494 over an area of 1,177,061 sq.mi. (excluding Jammu and Kashmir, but including the former French possessions.)

GEOGRAPHY

The Indian subcontinent is the middle of the three irregularly shaped peninsulas which jut out southward from the mainland of Asia. Its form is that of a great triangle, with its base resting upon the Himalayan range and its apex running far into the ocean. It extends from the 8th to the 37th degree of north latitude; that is to say, from the hottest tropical regions to far within the temperate zone. The length of India from north to south and its greatest breadth from east to west are both about 1,900 mi.; but the triangle tapers with a pear-shaped curve to a point at Cape Comorin, its southern extremity.

Burma (*q.v.*), which by British conquest formed part of India after 1885, was in 1937 separated from India. The island of Ceylon (*q.v.*), lying at the foot of India, came under British rule in 1795. Thenceforward it was first administered by the government of Madras until 1798, when its control was transferred to

the governor-general of India; but in 1802 it became a crown colony under the sole authority of the British colonial office. On Feb. 4, 1948, it attained to full self-government as a member of the Commonwealth of Nations. Aden (*q.v.*), at the mouth of the Red sea, with Perim and protectorates over the adjacent mainland and the island of Sokotra, was included within the British Indian empire until April 1, 1937, when it became a crown colony. The Andaman and Nicobar Islands in the Bay of Bengal and the Laccadives in the Arabian sea are administered from India.

On the coast of the peninsula itself, small Portuguese settlements break the continuous line of Indian territory. Similar French territories (see PONDICHERRY) were ceded to India in 1954. The subcontinent is shut off from the rest of Asia on the north by a vast mountainous region, known in the aggregate as the Himalaya, amid which lie the kingdom of Nepal and the Indian-protected principalities of Sikkim and Bhutan, with the great tableland of Tibet behind. From the rest of the world it is severed by tropical oceans. The territory included within these boundaries is rich in varieties of scenery and climate, from the highest mountains in the world to vast river deltas raised only a few inches above the level of the sea. India as a subcontinent is divided into three well-defined tracts.

Himalaya. — The first of the three regions is the Himalaya mountains and their offshoots to the southward, comprising a system of stupendous ranges, the loftiest in the uorld. They extend in the shape of a scimitar, with its edge facing southward, for a distance of 1,500 mi. along the northern frontiers of West Pakistan and India. At the northeastern angle the Dihang river, the connecting link between the Tsanpo of Tibet and the Brahmaputra of Assam, bursts through the main range. At the opposite or northwestern angle the Indus in like manner pierces the Himalaya and turns southward through the Punjab. Ancient trade routes exist, by means of which merchandise from the Punjab finds its way over heights of 18.000 ft. into Sinkiang and Tibet. The Muztagh (Snowy mountain), the Karakoram (Black mountain) and the Changchenmo are the most famous of these passes.

The Himalaya not only form a double wall north of the subcontinent but at their eastern and western extremities send out ranges to the south, which protect its northeastern and northwestern frontiers. On the northeast, those offshoots form a barrier between Assam and the tribal areas of upper Burma. On the opposite or northwestern frontier the mountains run down the entire length of the Afghan border from the Himalaya to the sea. As they proceed southward, their best-marked ranges are in turn known as the Safed Koh, the Sulaiman and the Hala mountains. These massive barriers have peaks of great height, culminating in the Takht-i-Sulaiman, or Throne of Solomon, 11,290 ft. above the level of the sea. But the mountain wall is pierced at the corner where it strikes southward from the Himalaya by an opening through which the Kabul river flous. An adjacent opening, the Khyber pass, the Peiwar (Kurram) pass to the south of it, the Gomal pass near Dera Ismail Khan, the Tochi pass between the two last-named and the Bolan pass via Quetta still farther south furnish the gateways from Afghanistan. The Hala, Brahui and Pab mountains, forming the southern offshoots in western Baluchistan, have a much smaller elevation.

River Plains. — The wide plains watered by the Himalayan rivers form the second of the three regions. They extend from the Bay of Bengal on the east to the Afghan frontier and the Arabian sea on the west, and they contain India's richest and most densely populated areas. The vast level tract which thus covers northern India is watered by three distinct river systems. One of these systems takes its rise in the hollow trough beyond the Himalaya and issues through their western ranges upon the Punjab as the Sutlej and Indus. The second of the three river systems also takes its rise beyond the double wall of the Himalaya, not very far from the sources of the Indus and the Sutlej. It turns, however, almost due east instead of west, enters India at the eastern extremity of the Himalaya and becomes the Brahmaputra. These rivers collect the drainage of the northern slopes of the Himalaya and convey it, by long and tortuous although opposite routes, into India. The third river system of northern India receives the drainage of their southern slopes and eventually unites into the mighty stream of the Ganges.

Southern Tableland. — The third division of India comprises the Deccan (*q.v.*), the three-sided tableland which covers the southern or more strictly peninsular portion of India. This tract comprises Madhya Pradesh (formerly Central Provinces and Berar). Madras. Bombay, Hyderabad, Mysore and others.

Vindhyas.—The northern side of this tableland rests on confused ranges, running with a general direction of east to west and known in the aggregate as the Vindhya mountains. Guarding the flanks of this tumbled mass stand two peaks sacred to the mysteries of the Jain religion. Mt. Abu on the extreme west and Mt. Parasnath on the extreme east, with a succession of ranges stretching 800 mi. between. The various ranges of the Vindhyas, from 1,500 to more than 4.000 ft. high, form, as it were, the northern wall and buttresses which support the central tableland. Though pierced by road and railway, they stood in former times as a barrier of mountain and jungle between northern and southern India and formed one of the main obstructions to welding the whole into an empire.

Ghats. — The other two sides of the elevated southern triangle are known as the Eastern and Western Ghats. These start southward from the extremities of the Vindhya system and run along the eastern and western coasts of India. The Eastern Ghats stretch in fragmentary spurs and ranges down the Madras and Andhra coasts, here and there receding inland and leaving broad level tracts between their base and the coast. The Western Ghats form the great sea wall of the Bombay state, with only a narrow strip between them and the shore. The Eastern Ghats have an average elevation of 1,500 ft. The Western Ghats ascend more abruptly from the sea to an average height of about 3,000 ft. with peaks up to 4,700 along the Bombay coast, rising to 7,000 and even 8,640 (Dodabetta peak) in the upheaved angle which they unite with the Eastern Ghats to form toward their southern extremity. The inner triangular plateau thus enclosed lies from 1,000 to 3.000 ft. above the level of the sea. But it is dotted with peaks and seamed with ranges exceeding 4.000 ft. in height. Its best-known hills are the Nilgiris, with the summer resort of Madras, Ootacamund, 7,000 ft above the sea.

On the eastern side of India, the Ghats are traversed by a number of broad and easy passages from the Madras and Andhra coasts. Through these openings the rainfall of the southern half of the inner plateau reaches the sea. The drainage from the northern, or Vindhyan, edge of the three-sided tableland falls into the Ganges. The Narbada and Tapti carry the rainfall of the southern slopes of the Vindhyas and of the Satpura hills, in almost parallel lines, into the Gulf of Cambay. But from Surat to the farthest south, the Western Ghats form a lofty unbroken barrier between the waters of the central plateau and the Indian ocean. The drainage has therefore to make its way across India to the eastward, now turning sharply round projecting ranges, now tumbling down ravines or rushing along the valleys, until it finally falls into the Bay of Bengal. In this way the three great rivers of the Andhra-hladras region (viz., the Godavari, the Kistna and the Cauvery) rise in the mountains overhanging the western coast and traverse the whole breadth of the central tableland before they reach the sea on the eastern shores of India.

Of the three regions thus briefly surveyed, the first, or the Himalaya, lies for the most part beyond the political frontier, but a knouledge of it supplies the key to the ethnology and history of India. The second region, or the great river plains in the north, formed the theatre of the ancient race movements which shaped the civilization and the political destinies of the whole Indian peninsula. The third region, or the triangular tableland in the south, differs markedly in its population, languages and traditions from either of the other two divisions. (ME.; E. HD.)

GEOLOGY

Geologically, also, the Indian subcontinent consists of three elements — the Himalaya, the Indo-Gangetic plain and the Deccan peninsula. The relations of the Himalaya to the peninsula and the essential differences between them are dealt with in the article

ASIA, and a more detailed description of the geology of the Himalaya is given there. The following account deals only with the Indo-Gangetic plain and the peninsula.

Indo-Gangetic Plain. — The Indo-Gangetic depression is the foredeep of the Himalaya, lying between the folded belt which forms the mountain range and the rigid foreland constituted by the peninsula. It bears the same relation to the Himalaya as the Pacific deeps bear to the island arcs near which they lie, but in those the level is lower and both foreland and foredeep lie beneath the sea. There can be no doubt, however, that the Himalayan foredeep itself extends far below sea level, though since its formation it has been filled up by deposit. In the eastern section of the plain the deposit is chiefly alluvial material brought down from the hills; in the western section wind-blown material plays an important part. Everywhere, except in the neighbourhood of the hills, the deposit is fine-grained, consisting of sands and muds, though kunkur concretions may sometimes give a pebbly appearance.

No boring has ever reached the base of the alluvium or has even shown any downward increase in the coarseness of the material. In a boring at Calcutta a bed of peat with wood, about 360 ft. below sea level, clearly points to subsidence. A boring at Lucknow reached nearly 1,000 ft. below sea level without any indication of an approach to the bottom of the deposit. Sir Sidney Burrard found that the deflections of the plumb line and anomalies of gravity suggest that the loose material filling the Indo-Gangetic depression extends to a depth of 40,000 ft. He thought so great a depth scarcely probable. But the foredeeps of much less massive mountain arcs reach 20,000 ft. and more, and in comparison with these Sir Sidney's estimate seems not improbable for the Himalayan foredeep.

Peninsular India. — The geological history of the Indian peninsula has been so different from that of Europe that the classification of the strata which is natural in Europe cannot be used in India, and an almost entirely different terminology becomes necessary. The grouping, originally proposed by Sir Thomas Holland and later commonlv adopted, is as follows:

Aryan group	Tertiary and recent Cretaceous and Deccan trap Gondwana system
Dravidian group	(absent in the peninsula)
Purana group	Vindhyan system Cuddapah system
Vedic, or Archaean, group	Dharwar system Gneisses and granites

The term Archaean is here used in the restricted sense in which it is often employed, denoting only the crystalline and schistose rocks of pre-Cambrian age. The Purana group consists of normal sedimentary deposits which rest unconformably upon the Archaean but which, from the total absence of fossils, are believed to be pre-Cambrian also, like the Algonkian of North America or the Torridonian of Scotland. The Dravidian group, which is absent in the peninsula but present in the Himalaya, corresponds approximately with the Palaeozoic up to the Upper Carboniferous. The Gondwana system includes the oldest fossiliferous beds of the peninsula and ranges from the Upper Carboniferous to the Upper Jurassic.

The pre-Gondwana rocks (Archaean and Purana groups) form the foundation of the whole peninsula. Southeast of a line drawn from Goa to Allahabad they occupy most of the surface, the areas covered by the later beds being relatively small. Northwest of this line they are concealed over a wide space by the great outflows of the Deccan trap, but they reappear at the surface in Bandelkhand and Gujarat. In southern India appearances suggest that there was an ancient gneissic series, including granitic and other intrusive masses, into which has been infolded a later series of sedimentary and volcanic beds, now for the most part converted into schists. The schistose series is the Dharwar system, nhich runs in long narrow bands through the gneiss from south-southeast to north-northwest. There has certainly been strong folding in this direction, but the Mysore geologists think that the Dharwar system is the older and that the gneissic rocks have been intruded into it.' Farther north, however, where the Dharwar rocks have been less altered and retain their original bedding, they seem to be later than the main body of the gneiss, though intrusions of later date penetrate both. The gneissic series is in fact a complex of various ages. and it has not yet been possible to separate it completely into its several parts.

Rocks of Dharwar type and probably of Dharwar age occur also in the Aravalli hills, in Madhya Pradesh and in western Bengal. The famous "marble rocks" of Jubbulpore, for example, are referred to this system. It is interesting to note that while in southern India the trend of the Dharwar folds is from south-southeast to north-northwest, in the Aravalli hills it is from southwest to northeast.

The Dharwar rocks form the most highly metalliferous system in India. In southern India all the most productive gold-bearing quartz veins, including those of the Kolar gold field. lie within it; while in Madhya Pradesh and Bengal it includes valuable manganiferous deposits. Iron ore of high quality also occurs at several localities but is usually too distant from the coal fields to be profitably worked.

The rocks of the Purana group have not been subjected to the intense folding which has affected the Dharwar system and have suffered little from metamorphism. They are mostly sedimentary deposits, such as sandstones, shales and limestones, and rest quite unconformably and often horizontally upon the older rocks. But in spite of their unaltered condition no fossils have been found in them and for this reason they are supposed to be pre-Cambrian in age. In southern India the group occurs in the Cuddapah basin and between Belgaum and Kaladgi. It covers a wide area in Madhya Pradesh and it forms most of the northern border of the peninsular massif overlooking the Indo-Gangetic plain. Some failure to conform has been recognized in the group and various local subdivisions have been made; but in the absence of fossils the correlation of rocks in widely separated areas is necessarily open to doubt. Two points of general interest may be noted. In the first place, although both the Cuddapah and the Vindhyan systems are often undisturbed, yet in places the former has been strongly folded: along the eastern margin of the Cuddapah basin, for example, the Cuddapah beds show strong overfolding and overthrusting toward the east, the trend of the folds being from north to south. If these beds are correctly referred to the pre-Cambrian there were certainly two great periods of mountain building in pre-Cambrian times, separated by a long interval, the first one being post-Dharwar and pre-Cuddapah and the second post-Cuddapah and pre-Vindhyan.

The second point of general interest is that all the most famous diamond deposits, such as those of Karnul in southern India and of Pannah in Bandelkhand, belong to the upper Vindhyan system. The diamonds usually occur in sandstone or conglomerate and have evidently been carried by water in the same way as other pebbles. No diamond-bearing igneous rock like that of Kimberley has been found, and the original source from which the diamonds have been derived is unknown, though certain igneous rocks have been suspected.

The Gondwana System. — The Gondwana system is the most important and interesting set of beds in India. Outside the peninsula, for example in Assam, coal is found chiefly in the Eocene, but in the peninsula all the principal coal seams lie in the Lower Gondwana series. The Gondwana beds occur in strips which are let into the foundation of older rock by faults. These strips, which may be continuous or broken, show a close connection with the lines of existing rivers and probably by their comparative softness determined the courses which the rivers took. There is, for example, a series of Gondwana patches along the Damodar and a more continuous strip roughly parallel to the Mahanadi. These two strips unite into a broad triangular area traversed by the Son. Another strip is associated with the Godavari.

The Gondwana system consists chiefly of sandstones, shales and clays, with seams of coal in the lower division. For the most part the deposits are entirely of terrestrial origin, but in Cutch and at several places along the Coromandel coast marine beds are interstratified toward the top. The fossils found in these marine

bands are of Upper Jurassic age. In general, however, plants are the predominant fossils. with reptiles! crustacea and freshwater fish locally. The Lower Gondwana is characterized by ferns of the *Glossopteris* type and by Equisetaceae, the Upper Gondwana by the prevalence of Cycadaceae. The lowest subdivision of the Gondwana system is known as the Talcher series and near its base is a remarkable clay with striated boulders) now universally admitted to be of glacial origin. In its lithology, fauna and flora the Gondwana system of India is remarkably like the Karroo system of South Africa, and it was this resemblance that led Eduard Suess and Georg von Neumayr to the conception of "Gondwanaland." It should, however: be pointed out in passing that the *Glossopteris* flora has a much wider distribution than was originally supposed and extends into northern Asia and the U.S.S.R.

The chief interest of the Indian Cretaceous lies in the evidence that it affoids for a former connection between India and South Africa. The marine Cretaceous of the Indian peninsula belongs entirely to the Upper division of the system. A number of detached outcrops occur along the valley of the Sarbada from the town of Bagh in Madhya Bharat, past Baroda, to Wadhwan in Saurashtra. In the south of India there is a Cretaceous area of zoo or 300 sq.mi. in Trichinopoly district and smaller patches near Pondicherry and Viruddhachalam. By far the greater number of species which have been obtained from the Narbada Cretaceous occur also in Europe, but only about a third of them have been found in southern India. On the other hand: only about a sixth of the numerous species which have been found in the south Indian Cretaceous occur in Europe. Moreover, there are Cretaceous beds in Assam and nearly all the species found there are southern Indian forms. Finally, many of the Assam and south Indian species occur also in South Africa. Hence it has been concluded. that in Upper Cretaceous times the Narbada area lay in a northern sea which stretched into Europe, while Assam and the southeast border of India lay in a southern sea which extended to South Africa. Between these seas a land mass stretched from Africa to India.

The Deccan Trap.—The Deccan trap is an extensive series of basaltic laval flows, with a total thickness of several thousand feet, which covers an area of about 250,000 sq.mi. in the northwestern quadrant of the peninsula. Along the west coast it reaches the sea without any diminution in thickness from about 21° N. to 16° N., and since the lavas are certainly subaerial it is clear that at the time of their eruption the land must have extended much farther to the west than it does now. The flat-topped hills and deep-cut valleys characteristic of the Deccan trap area are well shown on the route to Bombay, either from Calcutta or Madras. In spite of the great extent of these lavas there is very little indication of volcanoes, and it is believed that the eruptions took place from fissures, with little explosive action. The duration of the eruptions cannot be determined with certainty. Probably they began during the later part of the Cretaceous period but may have continued into the Eocene.

The Tertiary beds of the peninsula are insignificant. Near the west coast there are a few small outcrops in Travancore. Gujarat and the Kathiawar peninsula (Saurashtra) and a more complete sequence in Cutch. On the east coast the Cuddalore series, ranging in age from Eocene to Pliocene, occurs in patches from Orissa to the southern extremity of the peninsula.

The most interesting of the recent deposits in India is laterite (*q.v.*), which caps many of the hills and plateaus of the Deccan trap area and is also found extensively at a lower level both upon the western and the eastern border of the peninsula. It is a surface formation caused by the weathering characteristic of regions where temperature and humidity are high enough.

Laterite owes its prominence to the fact that, though comparatively soft when first quarried, it hardens on exposure and after hardening often resists erosion more strongly than the rocks on which it rests.

(P. LA.)

Wadia, *Geology of India, for Students*, 3rd ed. (London, New York, 1953). A general geological map of India, scale 1 in. = 32 mi., is published by the Geological Survey.

CLIMATE

Regional Climate.—The subcontinent of India, with its lofty mountain ranges behind and its extensive seaboard exposed to the violence of the winds of two oceans, forms an exceptionally valuable field for the study of meteorological phenomena.

From the gorge of the Indus to that of the Brahmaputra, a distance of 1,400 mi., the Himalaya form an unbroken watershed. The average elevation of the Himalaya crest may be taken at not less than 19,000 ft. and therefore equal to the height of the lower half of the atmosphere; and indeed few of the passes are below 16,000 or 17,000 ft.

Across this mountain barrier there appears to be a constant flow of air, more active in the daytime than at night, northward to the arid plateau of Tibet.

At the foot of the great mountain barrier, which it separates from the more ancient land that now forms the highlands of the peninsula, a broad plain, for the most part alluvial, stretches from sea to sea. In the midwest of this plain is a dry region occupied partly by the alluvial deposits of the Indus and its tributaries and the saline swamps of Cutch. partly by the rolling sands and rocky surface of the desert of western Rajasthan and the more fertile tracts to the eastward watered by the Luni. Over the greater part of this region rain is of rare occurrence; and not infrequently more than a year passes without a drop falling on the parched surface. On its eastern margin, however, in the neiphbourhood of the Aravalli hills, and again in the northern Punjab, rain is more frequent, occurring both in the southwest monsoon and also at the opposite season in the cold weather.

The alluvial plain which lies north of the desert area and is traversed by the Indus and its tributaries passes into that of the Gangetic valley without visible interruption. Up or down this plain, at opposite seasons, sweep the rain-bearing monsoon winds, in a direction at right angles to that of their nominal course. Nearly the whole surface of the Gangetic plain is under cultivation, and it ranks among the most productive as well as the most densely populated regions of the world. The rainfall diminishes from 100 in. in its southeast corner to less than 30 in. at Agra and Delhi, and there is an average difference of from 15 to 25 in. between the northern and southern borders of the plain.

From the Bengal delta at its eastern extremity, two alluvial plains stretch up between the hills which connect the Himalayan system with that of Burma. The first, or the valley of Assam and the Brahmaputra, is long and narrow, bordered on the north by the Himalaya, on the south by the lower plateau of the Garo, Khasi and Naga hills. The other, short and broad and in great part occupied by swamps, separates the Garo, Khasi and Naga hills from those of Tripura and the Lushai country. The climate of these plains is damp and equable, and the rainfall is prolonged and generally heavy, especially on the southern slopes of the hills.

The peninsula area of India, cut off from the encircling ranges by the broad Indo-Gangetic plain, is divided into two unequal parts by the Vindhyas, an amalgam of several hill systems running almost continuously across the country from west by south to east by north, just south of the Tropic of Cancer. The waters to the north of this watershed drain chiefly into the Narbada and the Ganges, those to the south into the Tapti, the Mahanadi, the Godavari and some smaller streams. Together with the two parallel valleys of the Narbada and Tapti, which drain the flanks of its western half, this mass of hills gives, at opposite seasons of the year, a decided easterly and westerly direction to the winds of that part of India and condenses a tolerably copious rainfull during the southwest monsoon.

The peninsula south of the Vindhyas consists chiefly of the triangular plateau of the Deccan, terminating abruptly on the west in the Sahyadri range (Western Ghats) and shelving to the east (Eastern Ghats). This plateau is swept by the southwest monsoon, but not until it has surmounted the western barrier of the Ghats; and hence the rainfall is, as a rule, light at Poona and places similarly situated under the lee of the range and but moderate over the more easterly parts of the plateau. The rains, however, are prolonged about three or four weeks later than in tracts to the north of the Vindhyas, since they are also brought by the easterly

winds which blow from the Bay of Bengal in October and the early part of November, when the recurved southerly mind ceases to blow up the Gangetic valley and sets toward the southeast coast.

At the junction of the Eastern and Western Ghats rises the bold triangular plateau of the Nilgiris, and to the south of them come the Anamalais, the Palnis and the hills of Travancore. These ranges are separated from the Nilgiris by a broad depression or pass known as the Palghat gap, about 25 mi. wide, the highest point of which is only 1,500 ft. above the sea. This gap affords a passage to the winds which elsewhere are barred by the hills of the Ghat chain. The country to the east of the gap receives the rainfall of the southwest monsoon. In the strip of low country that fringes the peninsula below the Ghats the rainfall is heavy.

The Seasons.—Within the Indian subcontinent almost any extreme of climate that is known to the tropics or the temperate zone can be found. It is influenced from outside by two adjoining areas. On the north the Himalaya range and the plateau of Afghanistan give it a continental climate; on the south the ocean gives it an oceanic climate. The continental type of weather prevails over almost the whole of India from December to May, and the oceanic type from June to November, thus giving rise to the two great divisions of the year, the dry season, of northeast monsoon, and the rainy season, or southwest monsoon. India thus becomes the type of a tropical monsoon climate.

The Indian year may be divided into four seasons: (1) the cold season, including the months of January and February; (2) the hot season, comprising the months of March, April and May; (3) the southwest monsoon period, including the months of June, July, August, September and October. and (4) the retreating monsoon period, including the months of November and December. The temperature is nearly constant in southern India the whole year round, but in northern India the variation is very large.

In the cold season the mean temperature averages about 30° F. lower in the Punjab than in southern India. In the Punjab, the Uttar Pradesh and northern India generally the climate from November to February resembles that of the Riviera, with a brilliant cloudless sky and cool dry weather. The hot season begins about the middle of March, when there is a steady rise in temperature, until the break of the rains in June. In May the highest temperatures are found in the East Punjab, Delhi and Rajasthan.

The southwest monsoon currents usually set in during the first fortnight of June on the Bombay and Bengal coasts (though they linger on their way upcountry) and give more or less general rain in every part of India during the next three months. But the distribution of the rainfall is very uneven. Overlooking the Bay of Bengal, where the mountains catch the masses of vapour as it rises off the sea, the rainfall is enormous At Cherrapunji in the Khasi hills the rainfall averages 428 in. a year. The Bombay monsoon leaves with very little rain a strip 100 to 200 mi. in width in the western Deccan parallel with the Ghats, and it is this part of the Deccan, together with the Mysore tableland and the Carnatic, that is most subject to drought. Similarly the Bengal monsoon passes by the Coromandel coast and the Carnatic with an occasional shower, taking a larger volume inland and abundant rain to Assam and Cachar. The same current also supplies with rain the broad band across India, which includes the Vindhyas, Chota Nagpur, the greater part of Madhya Pradesh and central India, Orissa and Bengal. Rainfall rapidly diminishes to the northwest from that belt. A branch of the Bombay current blows pretty steadily through Rajasthan to the Punjab, carrying some rain to that area now divided between Pakistan and India. But the greater part of the northwest (which lies in Pakistan) is served as a rule by cyclonic storms between the two currents. In September the force of the monsoon begins rapidly to decline, and in its rear springs up the gentle steady northeast monsoon, which gradually extends over the Bay of Bengal. A wind similar in character, but rather more easterly in direction, simultaneously takes possession of the Arabian sea. The most unhealthful season immediately follows the rains, when malaria is prevalent, especially in the north. Later the sharp contrast between day and night temperatures at the outset and end of the cold weather in the north, encourages pulmonary diseases. (ME.; X.)

See W G Kendrew, *Climates of the Continents*, 4th ed. (London, New York, 1953); H F Blanford, *The Climate and Weather of India, Ceylon and Burmah* (London, 1889).

FLORA

The Indian subcontinent has no botanical features peculiar to itself; its flora is compounded out of those of the adjoining countries. In the mountainous region in the extreme northwest many European and Siberian forms occur. while the northeast displays the influence of western China. The south of the peninsula and Ceylon show distinct affinity with Malaya and to a certain extent with east Africa. Burma, while akin to India, has a strong Malayan bias. The nhole area is divisible into three primary botanical sections: (1) Himalayan, (2) western and (3) eastern. These, however, are by no means homologous and are susceptible of further subdivision. They are best considered under the following six main botanical regions.

The Western Himalayan Region.—The region consists of the western portion of the Himalaya from Chitral to Kumaon and covers a vast depth from north to south, embracing a series of parallel snow-clad ranges. Toward the south the vallevs are narrow and tortuous; northward they are more open and tend to form elevated tablelands which merge into the great Tibetan plateau. The predominant families are Gramineae. Leguminosae, Cyperaceae, Labiatae. Ranunculaceae, Orchidaceae. Cruciferae, Rosaceae and Scrophulariaceae, showing a definite western influence, more especially at the higher levels. In the south subtropical trees and shrubs intrude, such as *Boswellia* and *Holoptelea*. The oaks are few and among them is the European holm oak (*Quercus ilex*). Of conifers are found the *Cedrus deodara, Pinus longifolia, Pinus excelsa, Abies pindrow, Cupressus torulosa, Juniperus macropoda* and in the drier localities *Pinus geradiana*

The Eastern Himalayan **Region.**—The remainder of the Himalayan range falls into the next region, which is narrower from north to south and has a lower average level. Tropical forms there are more numerous and there is a definite Chinese influence The dominating families are Orchidaceae, Gramineae, Leguminosae, Compositae, Cyperaceae, Urticaceae (in the wide sense). Scrophulnriaceae, Rosaceae, Rubiaceae and Euphorbiaceae A number of oaks and *Castanopsis* and a large number of rhododendrons characterize the region as do also many species of *Prmula* and *Meconopsis*. The deodar hardly occurs at all and few of the conifers of the last region; they are replaced by *Abies webbiana, Picea morinda, Larix griffithii, Tsuga brunoniana* and two species of *Juniperus*. Tree magnolias are conspicuous and the tropical influence is emphasized by the presence of numerous species of *Impatiens* and orchids.

The Indus Plain Region.—The Punjab, Sind, Rajasthan west of the Aravalli hills, Cutch and northern Gujarat make up the region Over the greater part arid conditions prevail with a very low rainfall and a scanty vegetation which approaches extinction in the Indian desert. Tree growth is comparatively rare and stunted; the vegetation is mainly herbaceous and is burnt or dried up in the hot season Thorny species are conspicuously numerous. The dominant families are Gramineae. Leguminosae, Compositae, Cyperaceae Scrophulariaceae, Labiatae, Boraginaceae, Malvaceae, Euphorbiaceae and Convolvulaceae. Characteristic among the shrubs and undershrubs are *Fagonza arebica,* thorny species of *Capparis* and *Zizyphus* and *Calotropis*. There are two indigenous palms, *Phoenix sylvestris* and *Nannorrhops ritchieana,* and one bamboo, *Dendrocalamus strictus*.

The Gangetic Plain Region.—Extending from the Aravalli hills eastward to the Bay of Bengal, the region comprises all the tract from the Himalayan foothills to the low country of Orissa. There are considerable variations in the vegetation of its different parts, all of nhich are far more humid than the last region. The dominant families are Graminae, Leguminosae, Cyperaceae, Compositae, Scrophulariaceae, Malvaceae. Xcanthaceae, Euphorbiaceae, Convolvulaceae and Labiatae. The deltas of the Ganges and the Brahmaputra consist of a number of islands uhich support a dense evergreen forest of trees and shrubs in which the mangroves predominate. A valuable timber tree, the sal *(Shorea robustu),*

is almost confined to that region.

The **Malabar** Region. — The region occupies a wet zone of mountainous country with a narrow strip of low land between it and the west coast running from Gujarat to Travancore. Its highest peaks attain to a little short of 9,000 ft. in elevation. The vegetation generally is very luxuriant and mainly evergreen and approaches the Malayan type. Dense evergreen forests with thick cane *(Calamus)* brakes and bamboo thickets are characteristic. On the higher hills are found wide expanses of grassy downs dotted with patches of evergreen woods, the remnants of former extensive forests left clinging to the sides of ravines and depressions. In the moderately wet areas below 2,000 ft., the teak, *Tectona grandis,* attains to very large dimensions, growing mixed with a number of other large and valuable timber trees—*Dalbergia, Pterocarpus, Terminalia, Lagerstroemia*—and with *Bambusa arundinacea.* In the wetter forests at moderate elevations Anonaceae, *Garcinia,* Dipterocarpaceae, *Mesua ferrea, Calophyllum, Cullenia,* many Rubiaceous trees, shrubs and herbs, Euphorbiaceae. *Ficus, Artocarpus* and Zingiberaceae occur as does also a single conifer, *Podocarpus latifolius,* and a number of palms and numerous ferns. In the low-lying swampy localities *Pandanus* and several Araceae are noticeable. At higher elevations many Acanthaceous shrubs: particularly of the genus *Strobilanthes,* are prominent and among the trees species of *Elaeocarpus,* many *Eugenias* and a tree Composite — Vernonia *monosis.* Epiphytic orchids are fairly numerous and tree ferns appear here and there. Among the grasses of the downs at elevations of more than 6,000 ft. are numerous herbs and undershrubs of *Impatiens,* Leguminosae, Umbelliferae, Rubiaceae, Compositae, terrestrial orchids, Liliaceae. Commelinaceae and patches of the bracken fern.

The Deccan Region. — The whole of the peninsula south of the Ganges valley and east of the Western Ghats is comprised in the region. With the exception of a belt of dry-evergreen, low jungle along part of the east coast? characterized by species of *Capparis, Pterospermum, Eugenia, Ixora, Mimusops, Diospyros* and *Strychnos,* the vegetation is mainly deciduous and much of it is thorny. Leguminosae occupy a conspicuous place; other prominent families, besides the ubiquitous Gramineae, are Tiliaceae, Rhamnaceae, Rubiaceae, Asclepiadaceae, Convolvulaceae and Euphorbiaceae, with large areas occupied almost exclusively by one or other of the two common bamboos, *Bambusa arundinacea* and *Dendrocalamus strictus.* On dry rocky hillocks *Givotia rottleriformis, Sterculia urens, Gyrocarpus jacquinii, Cochlospermum gossypium, Cassia fistula* and *Euphorbia antiquorum* claim attention. Along the coast and in the semidesert sandy tract in the extreme south the Palmyra palm, *Borassus flabellifer,* forms dense groves and thickets; similar aggregations of another palm, *Phoenix sylvestris,* occur inland. The true sandal ood, *Santalum album,* is found in the south central part.

The chief cultivated plants of India include rice, wheat, many pulses and grains; castor, sesame and peanut oilseeds; fruit trees such as the mango, citrus fruits and coconut, palmyra and arecanut palms; and apples, pears, peaches, apricots, walnuts in the Himalayan valleys. Tea plantations cover large areas in the north as well as in the south Indian mountains; and in the latter are also extensive coffee, rubber, cardamom and pepper gardens. Rubber is also grown in the north. In several damp localities cinchona is successfully grown. (c. E. C. F.j

See H. G. Champion, *A Preliminary Survey of the Forest Types of India and Burma* (Delhi, *1936)*; C. Chakravarti, *The Common Indian Plants* (Calcutta, *1938)*; *J. F. Dastur, Useful Plants of India and Pakistan* (Bombay, 1951).

FAUNA

Mammals. — The lion *(Felis leo)* was not uncommon within historical times in Hindustan proper and the Punjab. A peculiar variety, often described incorrectly as maneless. is preserved in the Gir, or rocky hill-desert and forest of Saurashtra. It is protected by law and its stock was improved by the import of east African lions for breeding purposes.

The tiger *(Felis tigris)* is found in every part of the country, from the slopes of the Himalaya to the Sundarbans swamps. The average length of a tiger from nose to tip of tail is g ft. to 10 ft. for males, and 8 ft. to 9 ft. for tigresses, but a tiger of 12 ft. 4 in. has been shot. The advance of cultivation. even more than the incessant attacks of sportsmen, reduced numbers, but extermination remained unlikely. The malarial Tarai fringing the Himalaya, the uninhabitable swamps of the Gangetic delta and the wide jungles of the central plateau are the chief home of the tiger. His favourite food appears to be deer, antelope and wild hog. When these abound, he will disregard domestic cattle. Indeed, the Indians are disposed to consider him as in some sort their protector since he saves their crops from destruction by the wild animals on which he feeds. But he may develop a taste for human blood, and the confirmed man-eater, generally an old beast disabled from overtaking his usual prey, seems to accumulate victims from instinct rather than for food. A favourite mode of shooting the tiger is from elevated platforms (machans).

The leopard or panther *(Felis pardus)* is everywhere far more common than the tiger and at least equally destructive of life and property. Its greatest length is about 7 ft. 6 in. A black variety, as beautiful as it is rare, is sometimes found in the extreme south of the peninsula, as also in Java. The cheetah, or hunting leopard *(Acinonyx jubatus),* found only on the Deccan, is trained for hunting antelope. The' cheetah's limbs are long, its hair rough and its claws blunt and only partially retractile. Other cats are the ounce, or snow leopard *(Felis uncia),* the clouded leopard *(Felis nebulosa),* the marbled tiger cat *(Felis marmorata),* the jungle cat *(Felis chaus)* and the viverrine cat *(Felis viverrina).*

Wolves *(Canzs lupus)* abound in open country preying on sheep, but are said to run down or ambush antelopes and hares. The Indian wolf has a dingy reddish-white fur, some of the hairs being tipped with black. By some naturalists it is regarded as a distinct species, *Canis pallipes.* Three distinct varieties, the white, red and black wolf, are found in the Tibetan Himalaya. The Indian fox *(Vulpes bengalensis)* is comparatively rare. but the jackal (*Canis aureus*) abounds. The wild dog, or dhole *(Cuon dukhunensis),* is found in all the wilder jungles. Its characteristic is that it hunts in packs, sometimes comprising 30 dogs, and is mute. Among other dogs are the pariah, which is merely a mongrel, running wild and half starved; the poligar dog. an immense creature peculiar to the south; the greyhound. used for coursing; and the mastiff of Tibet and Bhutan. The striped hyena *(Hyaena striata* or *hyaena)* is common, being found wherever the wolf is absent. Like the wolf, it is very destructive.

Of bears, the common black or sloth bear *(Melursus labiatus)* is common wherever rocky hills and forests occur. It is distinguished by a white horseshoe mark on its breast. Its food consists of ants. honey and fruit. When disturbed, it will attack man, and it is a dangerous antagonist for it always strikes at the face. The Himalayan or Tibetan sun bear (*Ursus malayanus*) is found along the north, from the Punjab to Assam. During the summer it remains high up in the mountains. near the limit of snow, but in the winter it descends to 5,000 ft. and even lower.

The elephant (*Elephas indicus*) is now, at any rate, an inhabitant not of the plains but of the hills; and even on the hills it is found usually among the higher ridges and plateaus and not in the valleys. From the peninsula of India the elephant was gradually exterminated, being found now only in the primaeval forests of Coorg, Mysore and Travancore and in Orissa. It still exists in places along the Tarai, or submontane fringe of the Himalaya. The main source of supply is the northeast transition zone from Assam to Burma. Two varieties are there distinguished, the gunda, or tusker, and the makna, or hine, which has no tusks. The maximum height is probably 12 ft. The elephant must be hunted on foot. A law regulates the licensing of hunting.

Of the rhinoceros, three distinct varieties are enumerated, two with a single and one with a double horn. Most familiar is *Rhinoceros unicornis,* commonly found in the Brahmaputra valley. It has one horn and is covered with massive folds of naked skin. It sometimes attains a height of 6 ft.; its long horn is much prized by natives for medicinal purposes. The Javan rhinoceros *(Rhinoceros sondaicus).* found in the Sundarbans, also has but one horn and mainly differs from *Rhinoceros unicornis* in being smaller and having less prominent "shields." The Sumatran rhinoceros *(Rhi-*

noceros or *Ceratorhinus sumatrensis*), found from Chittagong southward, has two horns and a bristly coat.

The wild hog (*Sus cristatus*) is well known. It frequents cultivated situations and is the most mischievous enemy of the villager. A rare animal, called the pygmy hog (*Sus salvanius*), exists in the Tarai of Nepal and Sikkim and has been shot in Assam. Its height is only 10 in. and its weight does not exceed 12 lb. The wild ass (*Equus hemionus*) is confined to the sandy deserts of Sind and Cutch, where it is almost unapproachable.

Many wild species of the sheep and goat tribe are to be found in the Himalayan ranges. The *Ovis ammon* and *Ovis poli* are Tibetan rather than Indian species. The urial and the skapu are kindred species of wild sheep (*Ovis vignei*), found respectively in Ladakh and the Sulaiman ranges. The former comes down to 2,000 ft. above the sea. the latter is never seen below 12,000 ft. The bharal, or blue wild sheep (*Pseudois nahura*), and the markhor and tahr (both wild goats) also inhabit the Himalaya. A variety of the ibex is also found there, as well as in the highest ranges of south India. The serow (*Naemorhedus sumatraensis*), allied to the chamois, inhabits the northern mountains.

The antelope tribe is represented by comparatively few species, as compared with the great number peculiar to Africa. The antelope proper (*Antilope*), the "black buck" of sportsmen, is very generally distributed. Its special habitat is salt plains, as on the coast line of Gujarat and Orissa, where herds of 50 does may be seen, accompanied by a single buck. The doe is of a light fawn colour and has no horns. The colour of the buck is a deep brown-black above. sharply marked off from the white of the belly. His spiral horns, twisted for three or four turns like a corkscrew, often reach a length of 30 in. The flesh is dry and unsavoury but is permitted meat for Hindus, even of the Brahman caste. The nilgai, or blue cow (*Boselaphus tragocamelus*), is also widely distributed, but especially abounds in Hindustan proper and Gujarat. As with the antelope, the male alone has the dark blue colour. The nilgai is held peculiarly sacred by Hindus from its fancied kinship to the cow. The four-horned antelope (*Tetraceros quadricornis*) and the gazelle (*Gazella bennetti*), the chikara or "ravine deer" of sportsmen, are also found in India.

The sambar or jarau (*Cervus aristotelis*) is found on the forest-clad hills in all parts. It is deep brown, with hair on its neck almost like a mane; and it stands nearly 5 ft. high, with spreading antlers nearly 3 ft. in length. Next in size is the swamp deer or barasingha, signifying "12 points" (*Rucervus duvaucelli*), common in lower Bengal and Assam. The chital or spotted (axis) deer (*Cervus axis*) is generally admitted to be the most beautiful inhabitant of the Indian jungles. Other species include the hog deer (*Cervus porcinus*), the barking deer or muntjac (*Cervulus muntjac*) and the chevrotain or mouse deer (*Tragulus meminna* or *kanchil*). The musk deer (*Moschus moschiferus*) is confined to Tibet. The gaur (*Bos gaurus*), the "bison" of sportsmen, is found in the hill jungles, in the Western Ghats, in central India and in Assam. This animal sometimes attains a height of 20 hands (about 7 ft.), measuring from the hump above the shoulder. Its short curved horns and skull are enormously massive. Its colour is dark chestnut or coffee brown. From the difficult nature of its habitat and from the ferocity with which it charges an enemy, the pursuit of the bison is no less dangerous and exciting than that of the tiger or the elephant. Akin to the gaur, though not identical, is the gayal, or mithun (*Bos frontalis*), confined to the hills of Assam, where it was domesticated for sacrificial purposes by the aboriginal tribes. The wild buffalo (*Bos bubalus*) differs from the tame only in being larger and fiercer. The finest specimens come from Assam. The horns of the bull are thicker than those of the cow, but the horns of the cow are larger; in the domestic kind they are often of irregular form. A head has been known to measure 13 ft. 6 in. in circumference and 6 ft. 6 in. between the tips. The greatest height is 6 ft. 6 in. at the shoulder. The colour is a slaty black; the hide is immensely thick, nith scanty hairs. The domestic variety is the ungainly "water buffalo," familiar as a draught animal throughout the subcontinent. During the heat of the day it likes to stand in water with only its nostrils showing. The cow gives nutritious if, to western palates, oddly flavoured milk.

The rat and mouse family is only too numerous. The loathsome bandicoot (*Nesokia bandicota*), which sometimes measures 2 ft. in length, including its tail. and weighs three pounds. burrows under houses and is very destructive to plants, fruit and even poultry. More interesting is the tree mouse (*Dendromus*). about 7 in. long. which makes its nest in palms and bamboos. The field rats (*Mus mettada*) occasionally multiply so exceedingly as to diminish the out-turn of the local harvest.

Birds.—The ornithology of India is not considered so rich in specimens of gorgeous and variegated plumage as that of other tropical regions. The parrot tribe is the most remarkable for beauty. Four vultures are found. including the common scavengers (*Gyps indicus* and *Pseudogyps bengalensis*). The eagles comprise many species, but none to surpass the golden eagle of Europe. Of falcons. there are the peregrine (*Falco peregrinus*), the shaheen or royal falcon (*Falco peregrinator*) and the lagar (*Falco jugger*), which are all trained by the Indians for hawking; of hawks, the shikra (*Astur badius*), the goshawk (*Astur palumbarius*) and the sparrow hawk (*Accipiter nisus*). Ringfishers of various kinds and herons are sought for their plumage. The mynah (*Acridotheres tristis*), a member of the starling family, lives contentedly in a cage and talks well. Snipe (*Gallinago caelestis*), pigeons, partridges, quail. plover, duck, teal, sheldrake, widgeon—all of many varieties—make up the list of small game. The red jungle fowl (*Gallus ferrugineus*), supposed to be the ancestor of domestic poultry, is not good eating; and the same may be said of the peacock (*Pavo cristatus*).

Reptiles.—Serpents intrude into gardens and dwellings, especially in the rainy season. The cobra de capello, the name given by the Portuguese to *Naja tripudians* from the appearance of a hood produced by the expanded skin about the neck, is the most dreaded. The Russelian snake (*Vipera russelli*), about 4 ft. in length, is pale yellowish-brown, beautifully variegated with large oval spots of deep brown with a white edging; its bite is fatal, as is that of the krait (*Bungarus coeruleus*). Salt-water snakes in India are poisonous; fresh-water forms are innocuous.

Other reptiles include two species of crocodile (*Crocodilus porosus* and *C. palustris*) and the gavial (*Gavialis gangeticus*), all more ugly than destructive. Lizards and scorpions abound.

Fish.—Among edible Indian fish, the Cyprinidae, or carp, and the Siluridae, or catfishes, are best represented. From the angler's point of view, by far the finest fish is the mahseer (*Barbus mosal*), a species of barbel, found in all hill streams, whether in Assam, the Punjab or the south. One of the richest and most delicious of Indian fishes is the hilsa (*Clupea ilisha*). Fish are eaten as nearly fresh as may be, for the practice of curing or refrigerating them is rather exceptional.

Insects.—Mosquitoes are innumerable, as are moths and ants of the most destructive kind, especially the white ant and "fish insect," together with others equally noxious and disagreeable. Useful insects are the bee, the silkworm and the insect that produces lac. Clouds of locusts which leave no green thing behind occasionally appear. There are many beautiful butterflies.

See K. *N*. Bahl, *Indian Zoological Memoirs* (Lucknow, 1926 ff.); Indian Zoological Survey, *Annual Report* (Calcutta, 1917 ff.); S. *A*. Ali, *Book of Indian Birds*, 5th ed. (London, 1955).

HISTORY

Prehistoric India.—The history of India, in so far as it is attested by literary documents, begins shortly after the invasion of northwestern India by those Aryan tribes who established in the subcontinent a unifying civilization and a tradition of culture which, in spite of profound modifications and changes, maintained through the ages an unbroken continuity. The nature of our sources does not permit any accurate dating of this event, but a general consensus of opinion, based on such evidence as is available, places it about the middle of the 2nd millennium B.C. or in the centuries immediately following. The country invaded by the Aryans mas already occupied by numerous and various populations, some of whom possessed a material culture superior to that of the invaders. Of this early prehistoric period some information can be derived from the study of linguistics and ethnogra-

phy, while in the case of the northwest the work of modern archaeology revealed rich civilizations hidden for millennia beneath the soil.

Two important pre-Aryan linguistic families have preserved themselves against the Aryan inundation: the Munda, or Kolarian, and the Dravidian. It is interesting that these linguistic families too, no less than the Aryan, can be shown to be of extra-Indian origin. their introduction to India having taken place at a period prior to the invasion of the Aryans which it is not possible to specify. The Kolarian languages exhibit unmistakable signs of affinity with Mon, Khmer and a large group of other languages which are found in southeast Asia, and it is clear that their presence in India is due to a migration of peoples from the east at an early time. On the other hand, the Dravidian languages, like the Aryan, appear to have been introduced from the northwest; and the isolated Dravidian language Brahui still remains in Baluchistan as a pointer in this direction. Striking resemblances in vocabulary between Dravidian and the Finno-Ugrian languages confirm this northwestern origin. In the extreme northwest the isolated Burushaski represents yet another extraneous element of unknown origin; and the traces of others may have perished in the course of time.

The conclusions of ethnography correlate themselves only vaguely with the conclusions of linguistics, since populations have mixed with each other and changed in their environment during the ages. Nevertheless, the gradual change of colour from light to dark as we move south fits in well with a pattern of invasion which gradually pushed the original populations before it. In isolated mountain regions of the south there exist small groups of tribes who have maintained their identity from pre-Dravidian times. In general it may be said that the ethnographer's material takes him back to periods long antedating the linguistic invasions which we have been led to assume.

The investigations of archaeologists revealed traces of man in India from early Palaeolithic times onward, but the materials are not numerous enough to establish. on the European model, any sequence of cultures or any approximate dating. It is only when we come nearer historic times, and that in northwest India, that the results of archaeology can be used to any great extent for historical purposes.

Excavations beginning in 1922 at Harappa and Mohenjo-Daro brought to light the existence of a hitherto unsuspected civilization, antedating the Aryan period and not inferior in achievement to the contemporary civilization of Mesopotamia. Like the latter, the Indus civilization, as it is called from the site of its two great cities, is essentially an urban civilization; and in this respect it differs markedly from what we know of the Vedic Aryans. It is also clear from the finds that it was a civilization devoted extensively to trade and commerce, and there is evidence from both sides of lively intercourse of this kind between the Indus and Mesopotamia. It is from this contact that it has been found possible to date the civilization approximately, since numbers of objects of Indus origin have been unearthed in datable strata of the Mesopotamian cities. According to this evidence and from calculations based on the excavation of the Indus cities themselves, the flowing period of this civilization may be placed around 2300–2200 B.C.; and if, as the evidence seems to indicate, we allow a period of about 600 years for the whole course of occupation, the rough dates 2500–1900 B.C. may be provisionally established as the period of the Indus civilization.

Excavations revealed the cities as being populous and closely packed communities built round a citadel which served at the same time as the centre of government and religion and as a defense against enemies in time of war. Centralized arrangements for grain storage existed, and the water supply and drainage systems nere carefully and even elaborately organized. The material in nhich the cities were constructed were burnt red brick, and this stood the test of time well enough for the essential features of many structures to be still clear at the time of the excavations. Many indications point to the fact that the climate of the region was different from what it is now and wetter; and there is evidence of the presence of animals (tigers, etc.) which are not now found in the area. Of the many material remains some reach a high standard of artistic excellence and can be compared with anything found in contemporary civilizations. From artistic representations it is possible to form some idea of the religion of the people. In this the worship of a mother-goddess, as so frequently elsewhere, plays a prominent part; and as her consort there appears a deity who has some of the characteristics of the later Rudra-Siva.

Most interesting among the finds, but unfortunately not utilizable, is a fully developed system of writing. This appears mainly in impressions on seals and consequently includes no extended passages of text. If such existed they were on perishable material and have therefore not been preserved. In the absence of any bilingual passage (it is possible, in view of the connections with Mesopotamia, that such may one day be found), it has not been possible to decipher the script, which would enable us to identify the creators of this civilization. Of the many theories propounded none can be regarded as established, and the only thing that can be said with certainty is that they were different from the Vedic Aryans, whose civilization as revealed in the texts differs widely from theirs in almost every respect.

In addition to the civilization above described, other cultures either immediately preceding or immediately following were discovered. Of these cultures, which are named after the places where they were first revealed. the Amri culture precedes Harappa and Mohenjo-Daro and the Jhukar and Jhangar cultures follow in that order Less developed than the Indus civilization proper and without a system of writing, they appear, from material evidence to have connections with Iran. But anything that would connect these cultures with the Aryans is lacking, just as in the case of the great Indus civilization.

ANCIENT HISTORY

The invasion of India by Aryan tribes from the northwest inaugurates the historical period proper. The oldest literary document of India was composed in the period immediately following this event, when the invading tribes were still battling in the Punjab and the adjacent regions for possession of the land. The date of these events can be reached only by approximate calculations. The close linguistic connection between Vedic Sanskrit and the ancient Iranian language of the *Avesta* argues against too long a period of separation; and the literary and linguistic evolution of Sanskrit between the earliest hymns of the *Rig-Veda* and the period of Buddha and Mahavira (which can be dated *c.* 500 B.C.) indicates a considerable period, but definitely not the millennia in which the age of the *Vedas* is sometimes reckoned. A period of 600 years or at most 700 years from the earliest compositions of the *Veda* to the end of the Vedic period, about 500 B.C., is most commonly assumed. Behind this and at least some centuries earlier, since the early documents do not speak of it, lies the invasion. or rather the series of invasions, c. 1500 B.C. onward. The original home of the Aryans appears to have been southern Russia. from which they spread out in several directions. At a date roughly contemporary with that postulated for the beginning of the invasion of India, we find another group of Aryans in the near east ruling in the country of the Mitanni, where they were eventually absorbed into the native population. The Indo-Aryans and Iranians on the other hand moved eastward across the steppes, whence they proceeded to found their two great nations in India and Iran.

It has been pointed out that when the Aryans entered India they found it in the possession of peoples whose material civilization was in many respects superior to their own. The superiority of the invaders lay in political and military organization and in the technique of warfare. The *Rig-Veda* abounds in allusions to the bitter warfare between the invaders and the previous occupants of the country. Particularly numerous are the references to cities (pur) destroyed, the significance of which term was not fully appreciated until excavations unearthed the great Indus cities. At the same time. it is still not possible to say whether it was the Aryans who destroyed the Indus cities, or whether the cities destroyed had succeeded those of the Indus. The Aryans

themselves were a pastoral and agricultural people living mainly in villages and made no attempt to occupy the cities that they overcame; it was only centuries later, with the advance of civilization and prosperity, that the great historical cities of northern India began to arise.

The geographical horizon of the early Vedic period as depicted in the hymns of the Rig-Veda is fairly narrowly delimited. The centre is the Punjab, the land of the five rivers. To the west the frontier rivers (Gomal, Kurram, etc.) are known, and to the east Aryan tribes are found settled on the Sarasvati, a region which later counts as the most sacred land of Brahmanism. Mention of a battle fought on the banks of the Yamuna against non-Aryan tribes indicates the easternmost point of Aryan expansion at that period. Over that country the consolidation of Aryan power was first completed, and it is served as a base for the rapid occupation of the greater part of northern India in the succeeding centuries.

The later Vedic period, during which this process was achieved, may be placed between the 10th and 6th centuries B.C. The latest hymns of the Rig-Veda and also its final redaction date from the beginning of this epoch. The three other *Vedas*, Sama-, *Yajur-* and Atharva-, follow closely in time. After them there arose a large body of explanatory and commentatorial literature, the *Brahmanas,* devoted to the explanation of the sacred literature. Toward the close of the period the Aranyakas and, in particular, the *Upanishads* indicate a new philosophical approach and herald the beginnings of the intellectual revolution to come. None of this literature is devoted to history; and, though many rulers and their kingdoms are mentioned casually, it is rarely possible to fix their place in time. More information can be gathered from them about social and material conditions that prevailed in pre-Buddhist India The famous Purusasukta, one of the latest hymns of the Rig-Veda, proclaims for the first time the basic principles of the caste system—the division of society into the four "colours" (Varna), Brahmana, Kshatriya, Vaisya and Sudra The growth and increasing complication of this system is already apparent in the later Vedic texts and is progressively accentuated as the centuries go by.

Apart from the contemporary literature some information may be gathered from the great epic *Mahabharata* and the *Puranas.* The tradition of the former was founded in Vedic times, but since it was not established in its present form till 1,000 years later, it is not reliable as a detailed chronicle of events. The Puranas contain dynastic lists dealing with the major early kingdoms, which on the whole appear to be founded on sound tradition. Moreover, the early Buddhist literature—particularly the *Jatakas*—contains many references to kings of the late Vedic period whose historicity seems to be established.

The general picture that emerges from all this material is that of the continued expansion of Aryan pomer; of the establishment of a series of permanent kingdoms or states which retain their identity throughout the period and later; and of a gradual shift of the centre of gravity toward the east. After the Rig-Veda the region of the Punjab fades into the background. The centre of Aryan power becomes the land of the Kurus with their capital (*hastināpura*) near Delhi, with whom are closely associated the neighbouring Panchalas. It was there that the Brahman religion was finally consolidated, and it was there also that classical Sanskrit, which was to become the national language of India for 2,000 years, was evolved. It was the centre of an empire of the Kurus that was the chief political pomer in the early part of the period, its greatness being reflected after many centuries in the *Maha*bhauata. Some of its rulers are mentioned in contemporary literature, and a list is provided by the Puranas. Like its successors, the empire crumbled and vanished, so that a proverb current in the later Vedic period asked "What became of the descendants of Pariksit?"

Aryan expansion from that centre proceeded in two main directions and is reflected in the much wider geographical nomenclature of the later Vedic texts. The advance was steadily continued down the Ganges valley, and stable kingdoms arose in Kosala, Videha, Kasi and other centres. Magadha remained longer outside the Aryan pale, but a powerful dynasty was installed there by the end of the period. This expansion was associated with a shift of power to the east. and the later Vedic texts indicate that kingdoms of Kosala and Videha had replaced the Kurus and Panchalas as the most important centres of political power. Another road of expansion led southmest to Avanti (capital Ujjayini, modern Ujjain) and thence to the ports of the west coast, where trade with the near east was early established. It is probable that writing was first introduced into India by this route toward the close of the Vedic period. To the south the Xsmakas, Vidarbhas and allied tribes crossed the Vindhya and established Aryan rule in Maharashtra at an early date.

Kosala and Magadha.—Toward the close of the 6th century B.C. the Vedic period reaches its close in the face of the rise of new religions and ideologies which transformed the intellectual climate of the country. Gautama Buddha (563–483) and Vardhamana Mahavira (540–468) stand out among many teachers and reformers as the founders of religions which have survived to this day (see BUDDHA AND BUDDHISM; JAINS). Because of the interest that believers took in the lives of these two leaders, the history of India is for a short time illuminated by more than usual information.

The various states (*mahajanapadas*) which had been established in late Vedic times are enumerated in the Buddhist literature, and at that period there appears a tendency for the smaller to be incorporated in the greater. The most important states of the time were the eastern monarchies of Kosala and Magadha, which were not only the political centre of India at the time, but also the home of the new religious and intellectual ferment which was affecting the country. To the southwest lay the kingdom of the Vatsas ruled by Udayana, later to become famous in Indian legend; and to the southwest again Avanti was ruled by Pradyota the Fierce, a powerful and ruthless king. To the northwest the Kuru and Panchala countries maintained their identity; and on the extreme northwest of the Indo-Aryan territory lay the kingdom of Gandhara, soon to be incorporated, together with Sind, into the Persian empire. To the north of the hfagadhan and Kosalan kingdoms lay a series of aristocratic republics (Licchavis, Sakyas, etc.), from among which the founders of the new religions sprang.

The kingdom of Kosala (capital Sravasti). at that time ruled by Prasenajit, roughly a contemporary of Buddha, had already incorporated the older kingdom of Kasi, which in Vedic times had existed as an independent and power kingdom. To the north the expansive tendencies of the Kosalan kings tended to reduce the neighbouring republican tribes to the state of vassals. More important in the long run was the neighbouring kingdom of Magadha, whose expansion, already evident at that period. was destined to create the most extensive empire that ever held sway in ancient India. About 600 B.C. a new dynasty in that kingdom had been founded by Sisunaga; and a successor of his, Bimbisara (c. 550–490), held sway in the time of Buddha. He is represented as busily engaged in extending the frontiers of his kingdom, his most important acquisition being the annexation of the kingdom of Anga to the east. Bimbisara was followed by his son Ajatasatru; who .attained the throne by murdering him. Ajatasatru pursued his father's policy of expansion with the conquest of Videha and adjoining territories to the north. On the other hand, a war against Kosala seems to have been undecisive. Ajatasatru also founded a royal residence at Pataliputra (modern Patna). which was to become the premier city of northern India for centuries afterward. For the next century information from Buddhist and Jaina sources is almost completely lacking. From the *Puranas* we learn that the dynasty founded by Sisunaga continued to rule in Magadha; and we may be certain that this was a period of imperialist expansion, since when light again appears in the middle of the 4th century Magadha has outclassed all its rivals and emerges as the premier pomer of northern India. At that time the old dynasty was overthrown, and a usurper. Nanda, occupied the throne. At the time of Alexander's invasion of India (327–325) the major portion of the Ganges valley was under Nanda's dominion; and the occupation of considerable territories in the south appears attested by native tradition. The Magadhan army

consisted of 200,000 soldiers and a corresponding number of elephants, horses and chariots.

The Mauryas.—The dynasty of Nanda was short-lived. In 320 Chandragupta Maurya (*q.v.*), assisted by the Brahman Vishnugupta, or Chanakya, and by allies from the northwest of India, overthrew the sons of Nanda and established himself in Pataliputra. Once established, Chandragupta proceeded to expand the empire in every direction. The territories of the northwest conquered by Alexander were occupied by him; and in 305 Seleucus Nicator found it advisable to cede to him all the Indian territories up to Afghanistan in return for a treaty and a gift of 500 elephants. Chandragupta died *c.* 297 and was succeeded by his son Bindusara, about whom little is known though it is clear from the result that he was successful in the expansion and consolidation of the empire.

Bindusara's son Asoka (*q.v.*) (274–237) was the greatest and most celebrated of all Indian rulers. Of Asoka's reign we are well informed in his own edicts, which are engraved in stone in various parts of his vast empire, particularly in the frontier regions, so that an accurate idea of its boundaries can be gained. It is clear that the whole of India except the Tamil south was under the direct control of the Mauryan empire. Asoka himself undertook only one campaign of conquest, that of Kalinga (Orissa and the region to the south); afterward. distressed by the slaughter and misery involved, he renounced further ideas of conquest and devoted himself to the promotion of righteousness. He became an earnest adherent of Buddhism; and in his reign, if not at his instigation, a great council was held in Pataliputra to establish the tenets of the Buddhist religion and the organization of its members. Buddhist missionary activity dates from that period, and Asoka's own son Mahendra is credited with the conversion of Ceylon.

The Mauryan empire did not long survive Asoka. A number of his successors are mentioned in the Puranas and Buddhist literature, but it is not clear whether they reigned successively over the whole empire or over parts of it as it began to disintegrate. Finally, c. 185, Pushyamitra, commander in chief of the last Maurya, assassinated his master and founded the dynasty of the Sungas (185–72 B.C). Pushyamitra was an opponent of the Buddhists, and a growing Brahmanical reaction dates from that time. His empire seems to have been considerable, though not on the Mauryan scale; but it was progressively weakened under his successors. The last Sunga met the same fate as the last Maurya, and after him a short-lived Kanva dynasty held sway in the north until about 28 B.C. From then till the rise of the Guptas no power of importance arose among the native kingdoms of northern India.

Foreign Invasions, 180 **B.C.—A.D.** 200.—The fall of the Mauryan empire was followed by two major developments in the political history of India. On the one hand, there arose in the Deccan a new imperial power, the Andhras, known also by their family name of Satakarni, or Satavahana. Northern India, on the other hand, was subjected to a series of invasions from the west—by Greeks, Sakas. Parthians and Kushans—which constituted the major political pattern for the next three centuries.

The empire of the Andhras, or Satavahanas, arose on the ruins of the Maurya empire and provided a unitary rule for the greater part of the Deccan for nearly three centuries. The earlier rulers were engaged in conflict with the Sungas and Kanvas, and the destruction of the latter dynasty is attributed to them. The period of their greatest power and influence came later, in the 2nd century **A.D.**, when under the rulers Gautamiputra Satakarni (c. **A.D.** 100–130) and Vasishthiputra Pulamayi (c. 130–155) they were successful in guarding the Deccan against foreign invasion. The last great Andhra ruler was Yajnasri (c. 166–195). By the 3rd century the Andhra empire was replaced in the Deccan by a series of minor kingdoms, Ikshvakus, Salankayanas, etc.

The Andhras were noted as patrons of Prakrit literature, and it was under them that the Maharashtri Prakrit was elevated to the status of a literary language. An anthology attributed to the Andhra king Hala is all that now remains of this literature. The Brhatkatha of Gunadhya, written in a different Prakrit (Paisaci) was also a production of the Andhra period. In the religious field Buddhism prospered under the Andhras, and Nagarjuna, the great propagator of Mahayana Buddhism, flourished under their patronage.

Contemporary with the early Andhras, the kingdom of Kalinga came into prominence for a short time during the reign of Kharavela, who in a famous inscription left a detailed account of his reign. The kingdom, at that time a home of Jainism, was clearly powerful enough to compete with the Andhras and to overrun the weakened states of northern India; but after Kharavela complete darkness descended upon it, and it must be assumed that the growing power of the Andhras led to its eclipse.

The fall of the Maurya empire was followed immediately by the first of a series of foreign invasions from the northwest. Such invasions were not new. The empire of the Achaemenids had embraced the provinces of Gandhara and Sind; and, after destroying the Persian empire, Alexander had invaded India to subdue those provinces which owed allegiance to the Persian kings. But these invasions had not penetrated farther than the northwestern corner of India, and the greater part of the country had been left untouched, whereas the invasions which followed penetrated deeply into northern India and prevented the emergence of any formidable native power in the region as long as they lasted.

The first of the new invaders were Greeks from the kingdom of Bactria, which had established itself in the eastern part of Alexander's empire. In 183 B.C. Demetrius, the Greek king of Bactria, crossed into India and carried all before him. He occupied the country as far as Pataliputra, which he besieged; and had he not been recalled by treachery at home he might have achieved what Alexander failed to achieve. As it was, Pushyamitra gradually asserted himself against the Greeks in northern and central India, and Greek rule was confined to the region of the Punjab. There their most famous ruler was Menander, whose name is perpetuated in a Buddhist work (*Milindapanha*) in which a teacher expounds the doctrines of his faith to the Greek king. After Menander's death (c. 145) the Greek kingdom lasted into the early part of the following century but was gradually weakened by the onslaughts of the Sakas, or Scythians. The Greek invasions were not without effect in the cultural field. In sculpture there arose in Gandhara a school operating almost entirely under western inspiration. In science Indian astronomy is notably indebted to the Greeks, from whom it has borrowed some of its technical terms. But on the whole the influence was short-lived, and in the long run little remained.

The Sakas, moving from their central Asian home, brought about the do nfall of the Greek kingdom of Bactria and followed the Greeks in the invasion of India. About 80 B.c.. under their ruler Maues. or Moga, they appeared in control of the Punjab; and under his successor they were firmly established in Muttra. Closely associated with the Sakas were the Parthians (in Sanskrit, Pahlava). aho eventually established some kind of suzerainty over them. Their most powerful ruler in India, Gondophares, achieved fame in Christian legend, since it was under his rule that the apostle Thomas is said to have gone to convert India.

A later group of Sakas established itself in Ujjayini. and it is possible that the Saka era (A.D. 78 *ff.*; see CHRONOLOGY) was founded on that event. Inscriptions record Ysamotika and Cashtana as early rulers of this dynasty, and they still bear Iranian names; later they were progressively Indianized, and by **A.D.** 150 Rudradaman, in a famous inscription, speaks as a purely Hindu monarch. The dynasty lasted till the close of the 4th century, when it was destroyed by the Guptas.

The most powerful of all the invaders of the period were the Kushans, a people known to the Indian tradition as Tukhara (Tokharians) (see YUE-CHI). Their early wanderings in central Asia are recorded by the Chinese historians; they appear on the Indian scene when the first Kushan dynasty under Kujula Kadphises (Kozulokadphises) and Vima Kadphises (Ooemokadphises) established itself on the borders of India in the latter part of the 1st century A.D Their greatest figure is Kanishka, founder c. 130 of the second Kushan dynasty. Inscriptions shon that the whole of northern India. at least as far as Benares, was subject to Kan-

ishka; and in addition to this his empire included considerable stretches of central Asia. He was a great patron of Buddhism, and the fact that his empire combined the central Asian area with India contributed as much as any other single factor to the spread of that religion throughout Asia. Kanishka's recorded successors are Huvishka and Vasudeva, after whom, early in the 3rd century, the Kushans recede into obscurity.

The Guptas and Classical India. — The 3rd century may be taken as the beginning of the classical age of Indian civilization. The series of foreign invasions in the preceding period had in no may interfered with the cultural life of the country. On the contrary it had been one of the most creative periods in Indian history. and during that time literature. art, science and philosophy had gradually evolved the form that they were to retain, in the main, through the succeeding centuries. The foreign rulers were on the whole eager to adopt and patronize the native culture and by doing so contributed materially to its advancement.

After a period in which no major power appeared on the scene and of which the political history remains comparatively obscure, a new and successful attempt at empire-building was begun in the 4th century by the Guptas, a dynasty originating in the same part of India as the imperial Mauryas. The accession of Chandragupta I (320) marked the beginning of their greatness; and from that date the Gupta era was founded. The great conqueror of that dynasty was Chandragupta's son Samudragupta (c. 340–380). The details of his career were engraved by his minister Harishena on an Asokan pillar at Allahabad. from which he is seen as the main founder of the Gupta empire.

The campaigns of Samudragupta soon resulted in the incorporation of the major part of northern India in the Gupta empire. In the east the kingdoms of Nepal and Assam and in the northwest the trihes of the Punjab paid him tribute. To the south Samudragupta undertook an ambitious campaign down the east coast. advancing as far as Kanchi to defeat the early Pallava king Vishnugopa. The son and successor of Samudragupta, Chandragupta II Vikramaditya, further expanded the empire by the conquest of the Saka kingdom of Ujjayini and the surrounding territories (Malava, Aparanta). Under him the Gupta empire reached the zenith of its power and splendour. His reign coincides also with the golden age of Sanskrit literature. Indian tradition relates that nine literary notables, including the poet Kalidasa. resided at the court of Vikramaditya.

The Guptas, unlike the Mauryas, did not seriously attempt to incorporate southern India in their dominions. The successful campaign of Samudragupta was more in the nature of a raid than an organized plan of conquest. The chief power in the Deccan at the time was the Vakataka kingdom. with whom the Gupta kings found it politic to maintain friendly relations. These relations were strengthened by matrimonial alliances, and the agreement between the two powers seems to have continued throughout the period.

At the very end of the long reign of Kumaragupta I (c. 414–45j) we hear of serious trouble in the northwest, and for the first time the Ephthalites, or White Huns, appear on the Indian scene. *(See* HEPHTHALITES.) Under Skandagupta (455–470) the empire was successfully defended against the impending dangers and the Ephthalite invasions postponed for nearly 50 years.

After Skandagupta the imperial period of the Guptas came to an end, though the family continued to rule with lessened authority for some centuries. At first the empire was split up, with a western centre at Ujjayini and an eastern at Pataliputra. At the same time new dynasties began to arise. In the west a general of the Guptas established at Valabhi the Maitraka dynasty, which was to reign with distinction for several centuries; in the north, at Kanauj, the Maukhari dynasty grew into a formidable power.

In these circumstances the Ephthalites finally succeeded in making a successful invasion and conquering a considerable part of northern India. In 510 Toramana overcame all opposition and penetrated deeply into India.. His son Mihiragula (*c.* 512–528) maintained this supremacy, until toward the end of his reign a successful campaign by the Gupta Baladitya drove the Ephthalites from eastern India. Soon after (533) in western India Yasodharman, a prince of obscure origin, was successful in re-establishing Hindu supremacy.

In the following century a successful, though short-lived attempt at empire-building was undertaken by Harsha (Harshavardhana) of Thanesvar (606–647). In a series of campaigns he established himself as the dominant ruler of northern India; but against the powerful Chalukya kingdom of the south he was unable to make any impression. Harsha was a great patron of letters and himself an author of Sanskrit dramas. At his court lived Bana, one of the most famous of Sanskrit authors, and it is to his pen that we owe an account of the youth and early career of Harsha. Harsha was also favourably inclined toward Buddhism, and it mas during his reign that the Chinese pilgrim Hsüan Tsang visited India. The account that Hsüan Tsang left of his travels is one of the most valuable documents for the history and civilization of the time.

Dynastic Rivalries, 650–1200. — After the death of Harsha northern India was again divided into a large number of separate states. An attempt by Yasovarman of Kanauj, early in the 8th century, to build a northern Indian empire was shattered on his defeat (736) by Lalitaditya of Kashmir. Gradually two main powers arose in the north. In Rengal the Pala dynasty established itself in the middle of the 8th century and reigned till the 12th. The Palas were noted as supporters and protectors of Buddhism at a time when in the rest of India it was giving way to Hinduism. They were followed by the Senas, who after a short but culturally brilliant period of rule were uprooted by the Mohammedans. In the western portion of northern India a new series of rulers — the Rajputs — came into prominence then. Their origin remains somewhat obscure, as does that of the Gurjara tribe, which appeared then for the first time in Indian history and provided in the Gurjara-Pratihara dynasty the leading power of the period. Tradition relates that the four leading Rajput families, Paramara, Chahamana. Pratihara and Chaulukya, originated in a sacrificial fire at Mount Abu; modern historians, with little direct evidence, have seen in them the descendants of the various foreign invaders of India.

By the 8th century the power of the Gurjara-Pratiharas was consolidated under Nagabhata, and he was successful in repelling (740) the further advance of the Mohammedan invaders, who in 712 had occupied Sind. The supremacy of the Gurjara-Pratiharas in northern India continued for two centuries, and during that period they maintained a successful front against further Mohammedan encroachment. They were also in recurring conflict with their main Indian rivals, the Palas of Bengal and the Rashtrakutas of the Deccan. In the latter part of the 10th century the Gurjara supremacy was destroyed, and northern India was again split up into a multitude of small and warring principalities. Among these dynasties mention may be made of the Chaulukyas of Gujarat (c. 950–1300), the Paramaras of Malava (Bhoja, 1010–55), the Chandellas and Kalachuris of central India and the Chahamanas of Rajputana. In those circumstances the task of the Mohammedan invaders was made easier especially because the native powers, who had little inkiing of what was in store for them, were more interested in pursuing their own private quarrels than in combining against the invader. In 1001 Mahmud of Ghazni (see below) made himself master of the Punjab and from that centre carried on a series of devastating raids against northern and western India. The final debacle did not come until nearly two centuries later. In 1192 Prthviraja, the Chahamana ruler of Delhi, was defeated and slain in a decisive battle; and in a few years from that date the whole of northern India was engulfed by the Mohammedan flood.

In the south the period saw the consolidation of two main centres of political power, one centred in the Deccan and covering the Maratha (Mahratta) and Kanarese areas. the other in the south centred in the Tamil country. After the end of the rule of the Vakatakas the Deccan came again under unitary rule by the rise of the early Chalukyas (*q.v.*) (*c.* 550–757). Pulakesin I established his capital at Vatapi (Badami). where it remained, and under him the Chalukyas acquired the status of a great power. The most powerful ruler of this dynasty, Pulakesin II (608–642),

extended his territory in all directions and in doing so came into conflict with both Harsha in the north and with the Pallavas in the south. From the latter he acquired territory on the east coast around the mouth of the Krishna and Godavari, where a junior branch of the family continued to rule for several centuries (Chalukyas of Vengi). Successful during most of his reign, he was finally defeated and slain in conflict with the Pallavas. In spite of this the Chalukya kingdom continued to flourish under his descendants, until power was wrested from them by the Rashtrakuta family (757–973). The Rashtrakutas organized their state on strongly militaristic lines, and their history consists mainly of aggressive campaigns against their northern and southern neighbours. In these they were predominantly successful, and in northern India in particular their attacks contributed not a little toward the weakening of those states in face of the coming Mohammedan invasion. Toward the end of the 10th century the Chalukya family again won mastery of the Deccan. and its second phase of rule, centred this time at Kalyani (Hyderabad state), continued for about 200 years (973–1190). After the fall of this dynasty a series of smaller kingdoms — the chief of whom were the Yadavas of Deogir (1187–1312) (see DAULATABAD), the Hoysalas of Dorasamudra (Dvarasamudra; 1191–1317) and the Kakatiyas of Warangal (till 142 j) — partitioned their territories. As in the north, no great imperial power remained in the Deccan to meet the Mohammedan attack.

In the extreme south the three Tamil kingdoms — Chola, Pandya and Chera — which had for long maintained an independent existence together with an indigenous Dravidian culture, were overshadowed by the Pallavas, a dynasty of northern origin. The Pallavas are first noticed in the 3rd or 4th century, in Prakrit inscriptions, in Kanchi, where they were established as successors of the Satavahanas: but it was not until the latter part of the 6th century, under Simhavishnu. that they acquired the status of a great power. Under Mahendravarman I (600–630) and Narasimhavarman I (630–660) the Pallavas reached the height of their power and prosperity. In the south they were without rivals, and to the north they maintained a successful front against the contemporary Chalukya power. Under their rule northern culture penetrated in a greater degree to the south; and in particular the Saiva and Vaishnava religions attained in that period the predominant position in the Tamil country which they still held at mid-20th century.

The Pallava power continued till toward the close of the 9th century. when it was replaced by a new empire of the Cholas (*q.v.*). One of the three ancient Tamil dynasties, the Cholas had long subsisted as vassals of the Pallavas. but during that period they were able not only to assert their independence of the Pallavas, but also to replace them as the new imperial power of the south, with such success that they achieved for a time a dominion wider than anything seen under the Pallavas. Under the kings Rajaraja (985–1014) and his son Rajendra (1014–44) the Cholas reached the height of their power. They not only controlled the whole of southern India and Ceylon but also were able to send a military expedition as far as the Ganges and to defeat the Pala king of Bengal. They were moreover the greatest naval power of the time, and under Rajendra a successful naval expedition was dispatched to Malaya and Indonesia.

Toward the close of the 12th century the Chola supremacy became seriously weakened and under Rulottunga III (c. 1180–1216) the rival Pandya dynasty asserted its independence. With the accession of Sundara Pandya (1251) the Pandyas replaced the Cholas as the premier dynasty of the south, but their triumph was short-lived because early in the next century (1310) the Moslem invader appeared in southern India and inaugurated a new epoch. (T. Bw.)

THE MOHAMMEDAN PERIOD

The Arab conquest of Sind in A.D. 712 was merely an episode in the history of Arab expansion for, although Hajaj, the viceroy of the eastern provinces of the caliphate. was an imperialist. Sind was not rich enough nor sufficiently well placed strategically to serve as a base from which the Arabs could extend their rule over the rest of India. Moreover, the difficult nature of their line of communications through Baluchistan and the decline of the central government prevented the dispatch of adequate reinforcements. In India. as in Europe, the 8th century witnessed the end of the wave of Arab expansion; and it was not until Islam had been firmly established in the area corresponding to modern Afghanistan that the Moslem conquest of India became possible.

Mahmud of Ghazni.—With the decline of the effective power of the Abbasid caliphate independent Moslem dynasties had arisen in Persia, Afghanistan and Turkistan. So far as India was concerned the most important of these was the Yamini, or Ghaznevid, dynasty founded by Turkish slaves in the mountainous regions surrounding Ghazni. It was under their ruler Subuktigin (977–997) that they first began to raid into northern India. At that time large tracts of the Punjab and the Kabul valley between the Chenab river and Lamaghan acknowledged the rule of the Hindushahiyyas under Raja Jaipal; but he proved no match for Subuktigin, who wrested from him the country between Lamaghan and Peshawar. The most famous of the Ghaznevids was Mahmud (*q.v.*) (998–1030), whose empire at its greatest extent stretched from the frontiers of Mesopotamia to the river Ganges and from Transoxiana to the deserts of Rajputana. Authorities differ as to the extent of his expeditions into India and also as to their number, which is varied between 12 and 1 j. As a result of these expeditions he destroyed the power of the Hindushahiyyas, annexing all their territories between Lamaghan and the Chenab; captured the famous fort of Nagarkot in the Kangra valley and the stronghold of the heretical Carmathians of hlultan; and seized Bhatinda, which guarded the route to the Ganges valley. Mahmud was therefore an Indian ruler only in a very limited sense, for his Indian conquests were confined to the Punjab, which became a frontier province of his extensive empire. But his plundering incursions carried him as far afield as the Jumma-Ganges Doab and the coast of Kathiawar. The most famous of his expeditions was that across the desert from hlultan to the temple of Somnath, which housed a huge Hindu idol in the form of a *lingam,* or phallus, that was mashed daily in water brought by runners from the Ganges. It was served by 1,000 Brahmans and 600 musicians, dancers and attendants. who mere supported by the offerings of innumerable pilgrims and by the revenues of 10,000 villages owned by the temple. Mahmud with iconoclastic fury razed the place to the ground, and no fewer than 50,000 Hindu devotees are said to have laid down their lives in defense of their deity. Mahmud was a zealous upholder of Islam, an ardent warrior against idolaters and a stern persecutor of heretics. particularly those who were politically as well as doctrinally dangerous. So far as India is concerned the importance of his career is that by his systematic policy of plunder and massacre he shattered the economic strength of northern India and paved the way for its final subjugation by later Moslem invaders.

Delhi and the Sultanates.—Mahmud's descendants were driven from Ghazni by a rival Moslem power, the Shansabanis of Ghur, and forced to take refuge in the Punjab. Mohammed of Ghur, the ablest of the Shansabani sultans, departed from the policy of predatory incursions and resolved to conquer northern India. The expulsion of the Ghaznevids from Lahore in 1186 was followed by several years of narfare, culminating in the defeat of the Hindu forces of Rai Prithiraj of Delhi at the final battle of Taraori in 1192, after which northern India almost as far as the gates of Delhi was annexed. The work of conquest was completed by Mohammed's generals, who subjugated the Gangetic Doab and overran Bihar and Bengal. After Mohammed's assassination by Moslem heretics in 1206, his general, Kutb ud-Din Aibak, founded the dynasty knonn as the Slave kings of Delhi (*q.v.*). Thus was established the sultanate of Delhi, which lasted until Babur laid the foundations of the Mogul empire in 1526. During that period Hindustan was ruled by five successive dynasties: (1) the Slave dynasty (1206–90); (2) the Khaljis (1290–1320); (3) the Tughlaks (1320–1413); (4) the so-called Sayyids (1414–51); and (5) the Lodis (1451–1526).

Of the 33 sultans of Delhi. few deserve to be remembered. The work of Aibak was completed by Iltutmish (1211–36), who ruth-

lessly crushed internal revolts, reannexed Bengal, conquered Sind and, toward the end of his reign, advanced through Malwa to the Narbada river. His death was the signal for dissensions which, together with Mongol raids across the northwest frontier, prevented the consolidation of Moslem power; and it was not until the reign of Balban (1266–86) that the sultanate became powerful again. Balban's time was fully occupied with the suppression of rebellion, which gave him little opportunity for entertaining ideas of fresh conquests. It must be remembered that throughout the 13th century the Moslem hold on Hindustan was extremely precarious. In fact, it was a military occupation effective only in the neighbourhood of Moslem garrisons and military forces. Because of the numerical inferiority of the invaders and the vastness of the country large areas had necessarily to be left in the hands of Hindu chiefs, who probably were the dominant factor in the situation.

Balban's successors were worthless, and power passed to the Khaljis, the ablest of whom was Ala ud-Din (1296–1316). His short reign was characterized by oppressive regulations designed to crush the Hindu chiefs and prevent rebellion. His demand for one-half of the gross produce of the land as revenue impoverished the peasantry, and he has therefore been condemned as a ruthless tyrant; but the necessity for consolidation called for stern measures. He not only restored order but conquered the Hindu kingdom of Gujarat and stormed the Rajput fortresses of Ranthambhor and Chitor. It is recorded that before the sack of Chitor its defenders performed the horrible rite of *jauhar* and immolated their wives and daughters to save them from dishonour. The Khalji period is important because it marks the beginning of Moslem penetration across the Narbada into the Deccan and southern India. At that time the chief Hindu powers to the south of the Narbada were the Yadavas of Deogir, the Kakatiyas of Warangal, the Hoysalas between the Krishna and the Cauvery and the Pandyas of Madura and the far south *(see* above). No united front was presented to the invader and Ala ud-Din's general, the eunuch Malik Kafur, easily penetrated to the extreme south of the peninsula, plundering the principal cities and temples. There was a fundamental difference between the Deccan policy of the Khaljis and that of their successors, the Tughlaks. Khalji policy was not one of occupation, whereas the Tughlaks aimed at permanent conquest.

Under Mohammed ibn Tughlak (1325–51) the sultanate attained its greatest extent and in the year 1330 stretched from Madura to the borders of Kashmir. Mohammed's removal of the capital from Delhi to Deogir and his attempt to rule over the whole of India from the Deccan was doomed to failure, for no strongly centralized government was possible until the development of communications in the second half of the 19th century. Mohammed has been eulogized as a cultured dreamer and denounced as a bloodthirsty tyrant. An attempt to whitewash his character has been made by those who refuse to accept the contemporary evidence of travellers like Ibn Batuta and historians like Zia ud-Din Barni; but he appears to have been guilty of revolting cruelties which would be unpardonable in any age. Toward the end of his reign the sultanate began to decline. Madura broke away as early as 1334. By 1341 Bengal had been lost. In 1347 the whole of the Deccan, except Khandesh in the Tapti valley, was formed into an independent Moslem kingdom under the Bahmanis. His successor, Feroz Shah (1351–88), made little attempt to recover these possessions; and after his death Malwa, Jaunpur and Gujarat refused to acknowledge the suzerainty of Delhi, and the whole of northern India relapsed into anarchy. This was the state of affairs when Timur (Tamerlane) crossed the Indus toward the end of 1398. His invasion, which lasted until March 1399, was merely a large-scale raid, and his depredations and ruthless massacres were confined to the vicinity of his Line of march through the Punjab to Delhi. Its chief result was to intensify the existing anarchy. From Timur's visitation to the establishment of the Lodi dynasty in 1451 no regular government existed, since the authority of the so-called Sayyids was confined to a small area around Delhi.

The Lodis were Afghans, or Pathans, with a tribal conception of sovereignty, the sultan being merely the most powerful of the tribal leaders. Bahlul, their first ruler, fully realized his position, but the attempt of his successors, Sikandar and Ibrahim, to revert to the autocratic methods of Balban and Ala ud-Din Khalji estranged their followers and produced rebellions which weakened the sultanate and paved the way for the Mogul conquest of Hindustan. Moreover, northern India was hopelessly divided, since independent Moslem states had arisen in Sind, Multan, Gujarat, Malwa, Khandesh and Bengal. Another outstanding feature of the 15th century was the growing strength of the Rajputs in the deserts of Rajputana, where they had taken refuge after their defeat in the days of Mohammed of Ghur. In the Deccan the Bahmani kingdom had resolved itself into five independent Moslem sultanates: (1) the Nizam Shahis of Ahmadnagar; (2) the Adil Shahis of Bijapur; (3) the Kutb Shahis of Golconda; (4) the Barid Shahis of Bidar; and (5) the Imad Shahis of Berar. To the south of the Krishna and Tungabhadra rivers stretched the mighty Hindu empire of Vijayanagar. Founded on the ruins of Chola power, it reached its greatest extent under Krishna Deva Raya (1509–29); and it was not until 1565 that the Moslem kingdoms of the Deccan combined to overthrow this last stronghold of Hinduism.

The Mogul Empire.—Baber (Babur; *q.v.*), the founder of the Mogul, or Mughal, dynasty, was descended from Timur and Jenghiz Khan, the two great scourges of Asia. He records in his famous Memoirs that his chief ambition was to recover the vast territories which had once formed part of Timur's mighty empire. In this he was thwarted by Shaibani Khan, ruler of the Uzbeg tribes of Turkistan. Ousted from his ancestral dominions in central Asia, he was eventually forced to take refuge in the mountain fastnesses of Kabul, which served as a convenient base for his attacks upon India. In April 1526, after a series of preliminary raids, he routed the forces of Ibrahim Lodi on the historic field of Panipat, where the fate of India has so often been decided. This victory has long been regarded as resulting from the extensive employment of artillery, but there is neither textual nor circumstantial evidence to support this contention. In the following year at Khanua he overwhelmed the Rajput confederacy under Rana Sanga of Mewar; and by 1529 he had overrun Bihar. At his death in 1530 he controlled the greater part of northern India. His son Humayun succeeded to a troublesome charge, for the Afghan chiefs had been only temporarily crushed and it cannot be said that Baber had consolidated his power in Hindustan. Moreover, Humayun, an opium addict, lacked the energy necessary for the completion of Raber's task. After years of desultory warfare he was defeated by an extremely able Afghan rebel named Sher Shah and was forced to seek asylum in Persia in 1544. Sher Shah proved himself a capable general and an able administrator during his short reign of five years, but under his successors anarchy supervened and gave Humayun the opportunity to attempt the reconquest of his lost dominions. Humayun succeeded in recapturing Delhi and Agra in 1555 but died in the following year. His importance lies in the fact that he mas the father of Akbar, who, at the second battle of Panipat, in 1556, defeated the forces of a Hindu usurper called Hemu and re-established his dynasty in Hindustan. Panipat may therefore be termed a decisive battle, for there had been no Mogul empire before Akbar, only the attempt to create one.

Akbar (*q.v.*) (1556–1605) was undoubtedly the greatest of the Mogul emperors. For the first five years of his reign his kingdom was restricted to the Punjab, Ajmere. Gwalior, the basin of the Ganges and Jumna and the country between the Gumti and the foothills of the Himalaya. A further 15 years of incessant warfare resulted in the annexation of the whole of northern India with the exception of lower Sind Between 1586 and 1601 he extended his rule over Kashmir, Baluchistan, Kandahar, Khandesh, Berar and parts of Ahmednagar and Orissa. At his death in 1605 his empire comprised 15 provinces, or *subas,* and stretched from Ahmednagar in the Deccan to Kabul and Kashmir in the north.

As far as his Hindu subjects were concerned. Akbar's policy was one of conciliation, for he realized that it was impossible

for him to rule as a strictly orthodox Moslem sovereign whose duty it was to spread the Islamic faith. He therefore abolished the *jizya* (the hated poll tax on non-Moslems) and the taxes which had previously been levied on Hindu pilgrims. For the same reason he sought to obtain the active support of the Rajput chiefs and enlisted Hindus in his armies and in the imperial service. At the same time his conception of sovereignty was autocratic, and this led him to crush the *ulema,* a religious body of Moslem doctors and scholars ahich constituted a check upon his powers. Although genuinely interested in the study of comparative religion and inclined to toleration, his religious policy appears to have been to a very great extent secondary to dynastic and political considerations. A further basic principle of his administration was to demand no more than one-third of the gross produce from the peasant. for he was convinced that the stability of his empire depended upon an equitable system of assessing and collecting the land revenue. The structure of the central government which he evolved. the elaborate checks upon the powers of the provincial governors, and his military organization testify to his administrative ability. It was only when his successors departed from the main principles of his rule that the empire began to decline.

His son Jahangir (1605–27) neglected the administration and was subservient to a selfish *junta* controlled by his favourite wife, Nur Jahan. The extravagant expenditure of the court was a serious drain on the financial resources of the country. and Jahangir was forced to make use of the accumulated cash reserves of his father. It was during his reign that the Persians recovered Kandahar. Important European evidence on the prevailing conditions is contained in the *Remonstrantie* of the Dutch factor Francisco Pelsaert and in the *Journal* of Sir Thomas Roe, the first English ambassador to the court of the Great Mogul. Jahangir is chiefly remembered for his self-revealing *Memoirs,* from which it appears that he was a drunken despot subject to outbursts of fiendish cruelty.

He was succeeded by his son, Shah Jahan, who had an almost insatiable passion for building. Iiot content with erecting a new capital city at Shahjahanabad he enriched the world's store of beauty by many other buildings, outstanding among which are the Moti Masjid and the Taj Mahal, both at Agra. His reign was also a period of great literary activity while the arts of painting and calligraphy were not neglected. That the splendour of the Mogul court reached its zenith under Shah Jahan must not blind one to the fact that he set in motion influences which finally led to the decline of the empire. His expeditions against Balkh and Badakhshan and his attempts to recover Kandahar brought the empire to the verge of bankruptcy. Moreover, unlike Akbar, he displayed a religious bigotry surpassed only by his more orthodox successor, Aurangzeb. In 1657 Shah Jahan fell ill, and in the civil war that ensued between his sons Aurangzeb defeated Dara Shikuh at the battle of Samugarh in 1658, after nhich he assumed the imperial title and imprisoned his father in the fort at Agra until his death in 1666.

The political and religious intolerance of Aurangzeb (*q.v.*) (1658–1707) was the chief cause of the decline of the empire. Puritanically orthodox and extremely bigoted, he departed from Akbar's conciliatory policy toward the subject Hindu population. It is significant that during the war of succession he claimed the throne as the champion of orthodox Islam against the heretical principles and practices of his brother Dara Shikuh. As soon as he assumed power, the *kalima,* or Mohammedan confession of faith, was removed from all gold and silver coins lest it should be trampled underfoot or otherwise defiled by unbelievers. Censors of morals were appointed to suppress unorthodox practices. Courtiers were forbidden to salute in the Hindu fashion. Hindus were excluded from public office, their schools and temples destroyed and the detested poll tax was reimposed. Aurangzeb subjected the Sikhs of the Punjab to persecution and put their religious leader, or *guru,* to death because he refused to embrace Islam. This transformed the Sikhs from a sect of quietists into a brotherhood of fanatical soldiers opposed to Moslem rule. The result was that the Rajputs, Jats and Sikhs of the north and the Marathas of the Deccan under their famous leader Sivaji raised the standard of revolt.

Aurangzeb's revenue policy led to a steady impoverishment of the agricultural classes, for the pressure on the peasant was increased by raising the revenue demand to one-half of the gross produce. The writings of contemporary European travellers contain frequent references to absconding peasants and untilled soil which lead one to infer that the mass of the population must have lived dangerously near the subsistence level. The general result of all this was a decay in all branches of the administration accompanied by a corresponding economic decline.

It is true that during Aurangzeb's reign the empire attained its greatest extent and, after the annexation of Bijapur and Golconda, stretched from the Hindu Kush to the Coromandel coast. But his policy of expansion in the Deccan and his attempt to rivet his authority on the whole of India was a military and political miscalculation since consolidation did not keep pace with conquest. When he died in 1707, he had failed to crush the Marathas (Mahrattas) of the Deccan and his authority was disputed throughout the length and breadth of his dominions.

CONJURORS PLAYING FLUTES TO CHARM THE COBRAS

The successors of Aurangzeb were wretched puppets controlled by favourites and court factions. Between the death of Bahadur Shah in 1712 and the accession of Mohammed Shah in 1719, five puppets were successively installed on the throne of Delhi. During the reign of Mohammed Shah (1719–48) able adventurers rose to power and provincial governors laid the foundations of independent dynasties. Nizam ul-Mulk, the Mogul viceroy in the Deccan, founded the state of Hyderabad. From a Moslem adventurer, Ali Vardi Khan, descended the nawabs of Bengal, while the kings of Oudh sprang from Saadat Ali Khan, the Mogul governor of that province. It was during this reign that the Marathas of the Deccan overran Malwa, Gujarat, Bundelkhand and parts of Rajputana and made repeated incursions into Bihar and Bengal. In 1737 they even defeated an imperial army outside the walls of Delhi. Eventually the emperor was forced to come to terms. To make matters worse, northern India was invaded by Nadir Shah of Persia, who in 1739 defeated the emperor's forces at Karnal, about 20 mi. N. of the historic field of Panipat. A popular uprising in Delhi in which several hundred Persian soldiers lost their lives was the signal for an indiscriminate massacre of the inhabitants of that city, after which, in the words of the contemporary chronicler "the streets remained strewn with corpses, as the walks of a garden with dead flowers and leaves." Nadir Shah made no attempt to annex northern India to his empire and was satisfied with the acquisition of vast booty, which included the famous Peacock throne of Shah Jahan and the Koh-i-Nor diamond. Apart from this, the chief result of Nadir's expedition was to intensify the existing anarchy and accelerate the decline of the empire. Foreign invasion was not so much a cause of the downfall of the Mogul empire as symptomatic of a decline that had already taken place.

After the death of Mohammed Shah the Marathas overran almost the whole of northern India from the river Narbada to Peshawar in the vicinity of the Khyber pass. They were gradually driven southward from the Punjab by Ahmad Shah Durrani, who had risen to power as ruler of the turbulent Afghan tribes of Kabul and Kandahar. Between 1747 and 1769 he led no less than ten invasions into Hindustan. The Marathas had to face a formidable coalition of the northern Moslem chiefs, who joined forces with the Afghan invader. They also had to fight without the assistance of the Rajputs and other Hindu powers, whom their revolting cruelties and extortionate demands had estranged. Eventually they were crushingly defeated by Ahmad Shah Durrani at the third battle of Panipat in 1761. This victory had

far-reaching consequences. It enabled the nizam to recover his power in the Deccan and probably saved the state of Hyderabad from extinction. It proved to the Indian world that neither the Marathas nor the Mogul emperor could protect them from foreign aggression. Internal dissensions now seriously impaired the strength of the Marathas and power passed from the peshwa, or titular head of the confederacy, to the generals — Sindhia of Gwalior. Holkar of Indore, the gaikwar of Baroda and the raja of Berar, or Nagpur. But the real importance of the Maratha defeat was that it granted the British the respite needed for the consolidation of their power in Bengal.

EUROPEAN SETTLEMENTS

Portuguese Enterprise. — The quest for India by sea was begun by Portugal, the smallest nation on the Atlantic seaboard and the first of the European states to become consolidated. After more than 50 years of preliminary exploration by intrepid Portuguese mariners, Vasco da Gama rounded the Cape of Good Hope and anchored off Calicut on May 20, 1498, the voyage from Lisbon having taken 10 months and 12 days. Friendly relations were established with the zamorin, or Hindu raja, of Calicut; but Cabral, the leader of the second expedition which reached India in 1500, quarrelled with the zamorin and sought trading concessions from his rival, the raja of Cochin, with the result that Cochin, with its excellent harbour, became the first trading headquarters of the Portuguese in India. The first Portuguese viceroy was Francisco de Almeida (1505–09), a firm believer in the importance of sea power, who gained command of the sea in Indian waters by the destruction of the Turco-Egyptian fleet in 1509. It is important to note that the absence of timber on the shores of the Red sea, which prevented this fleet from being rebuilt, was one of the principal causes of the growth of Portuguese power in the east. Almeida's successor, Alphonso d'Albuquerque (*q.v.*) (1509–15), believed that it was also essential to build fortresses on land and aimed at establishing a coastal empire based on the retention of important strategical positions. Since the carrying trade of the Indian ocean was in the hands of Arab merchants, he attempted to intercept this trade at its base. With this object he seized the island of Socotra and built a fortress at Ormuz which enabled him to control the mouth of the Red sea and the entrance to the Persian gulf. Realizing that a fortified base was essential for supremacy at sea, he captured Goa and thus obtained command of the trade with the Malabar ports. Because of its central position Goa became the capital of the Portuguese possessions in India. The conquest of Malacca in 1511 enabled him to control the valuable spice trade of the Malay archipelago. It was fortunate for the Portuguese that, during the critical years when they were establishing their power on the Malabar coast, the rivalry between the Moslem kingdoms of the Deccan and the Hindu empire of Vijayanagar prevented any effective resistance to their schemes.

The Portuguese empire reached its greatest extent in the middle of the 16th century. Its existence depended upon the command of the sea in Indian waters. With the arrival of more powerful Dutch and English fleets in the first half of the 17th century Portuguese power rapidly declined, and Portugal lost its monopoly of eastern trade.

Dutch Enterprise. — The closing of Lisbon to Dutch vessels toward the end of the 16th century adversely affected their carrying trade, especially the pepper trade, and prompted them to trade directly with the spice islands of the archipelago. Their first expedition under Cornelis Houtman reached Bantam in Java in 1595, one year and three months after leaving the Netherlands. A realization of the weakness of a system of separate voyages led to the formation in March 1602 of the United East India Company of the Netherlands. This powerful concern, with inscribed funds totalling £540,000, was granted a monopoly of trade and was emponered to maintain fleets and armed forces. The Dutch concentrated on establishing themselves in the archipelago; and their first governor-general. Pieter Both (1609–14), established factories or trading posts at Bantam and Jacatra (*i.e.*, Jakarta. or Batavia) The most important of their governors-general was Jan Coen (1617–22), who was to the Dutch in the 17th century what Albuquerque had been to the Portuguese in the 16th. Intensely prejudiced against the English. Coen protested to the home authorities when his hands were tied by the Anglo-Dutch treaty of 1619 that amalgamated the two companies for a period of 20 years. In 1623 Herman van Speult, the Dutch governor of Amboina, executed 12 Englishmen whom he considered guilty of conspiracy. This lamentable occurrence, known as the massacre of Amboina, had important results, for from that date the English confined their activities to the mainland of India. After this the Dutch were not seriously challenged in the archipelago until Lord Minto's conquest of Java in 1811. Even in India the Dutch were the real successors of the Portuguese and established factories on the Coromandel coast, in Gujarat and in Bengal. The death blow to Dutch interests in India proper was Robert Clive's capture of Chinsura in Bengal in 1759.

The English East India Company. — On Dec. 31, 1600, Queen Elizabeth granted a charter to the "Governor and Company of Merchants of London trading with the East Indies." Compared with the Dutch company already in the field this company was an insignificant body of private traders with inscribed funds amounting to only £30,133. For the first 12 years of its existence it was run as a regulated company, gradually developing after 1612, into a joint-stock concern.

The first two voyages, following the Dutch example, proceeded to the archipelago for pepper and spices. It was during the third voyage that the "Hector," commanded by William Hawkins, reached Surat on the Gujarat coast. Thence Hawkins travelled to the Mogul court at Agra. where for a time he became the boon companion of Jahangir but failed to obtain trading concessions. In 1611 the ships of Sir Henry Middleton reached Surat but met with a hostile reception. the result of Portuguese intrigues. In the following year Thomas Best anchored off the mouth of the Tapti, where he defeated a much superior Portuguese fleet. thereby increasing the prestige of his compatriots. Eventually, in 1613, an imperial firman granted permission for the establishment of a permanent English factory at Surat. The Portuguese persisted in their hostile attitude but in 1614 were again defeated. by four English vessels under Nicholas Dowton. One of Dowton's ships, the "Hope," which left India in March 1615. was the first English vessel to return to England with a cargo from India In September of the same year Sir Thomas Roe arrived in India as the first English ambassador to the court of the Mogul emperor, where he created a good impression and obtained important privileges for his countrymen. By 1619 English trading posts had been established at Surat, Agra, Ahmedabad and Broach. Surat became the company's headquarters, with a president and council who controlled the other factories.

The island of Bombay formed part of the dowry of Catherine of Braganza when she married Charles II of England in 1661 Seven years later Charles handed it over to the company, reserving an annual quitrent of £10 as a mark of sovereignty. This payment appears to have lapsed in 1730. It was Gerald Aungier, governor there from 1670 to 1677, who first realized that Bombay was a more suitable base for English enterprise on the west coast than Surat, which suffered from the Iack of a good harbour and was exposed to Maratha raids. Despite its foul climate, to Aungier it was "a city which by God's assistance is intended to be built." He laid the foundations of English justice, fixed the land revenue and established the first English mint in India. For its defense was raised the first European regiment in India, the Bombay Fusiliers. It was not. however. until 1687 that Bombay replaced Surat as the company's headquarters on that coast.

The first English settlement on the Coromandel coast was at Masulipatam in 1611. In 1626 a subsidiary settlement was formed at Armagaon. In return for a substantial annual payment. permission was obtained in 1639 from the local Hindu ruler to build a fortified factory at Madraspatam. There in the following year Francis Day built Fort St. George, which developed into the company's headquarters on that coast. When the Moguls overran the area, the company's status remained unchanged except that hlogul sovereignty nas acknowledged on its coins. Settlements were formed at Porto Novo and Cuddalore in 1681.

Because of the unhealthful climate of Cuttack in Orissa, where they had settled in 1633, the English moved to Hugli in Bengal and obtained permission to build a factory there in 1651. To protect themselves from the exactions of local rulers it was decided in 1681 to fortify the settlement. After an attack by the local Mogul governor, Job Charnock (who was in charge of the settlement) deemed it advisable to abandon the place for Sutanati lower down the river Sutanati was temporarily abandoned in 1689 in favour of Chittagong; but in 1690 Charnock returned to Sutanati, where he laid the foundations of modern Calcutta (*q.v.*). The settlement was fortified in 1696 and renamed Fort William in honour of William III. In 1700 all the Bengal factories were placed under the control of a president, Sir Charles Eyre becoming the first president and governor of Fort William in Bengal.

Between 1600 and 1750 the company had to contend with serious difficulties both at home and abroad. Not only had it to withstand the attacks of rival European nations but, in England, its monopoly of eastern trade was the subject of much hostile criticism. which led to the formation of rival trading associations and to attacks by pirates or interlopers, for whose depredations the Indian coastal powers held the company responsible. Moreover, the anarchy which accompanied the decline of the Mogul empire placed the company's settlements at the mercy of semi-independent provincial governors and encouraged the Marathas to attack Surat. In 1698 the enemies of the 'company in England, with the consent of parliament, formed themselves into a rival company known as the "English Company trading to the East Indies." After much bickering the two companies came to an agreement in 1702 by which they were amalgamated into the "United Company of Merchants of England trading to the East Indies." This was the company which obtained territorial sovereignty in India and retained its possessions until the crown assumed control in 1858. Despite all these difficulties, in the first half of the 18th century the volume of India's overseas trade, which was chiefly an export trade. increased enormously. The most important exports were cotton and silk piece goods, cotton yarn and raw silk. An important change in its export trade was the decline of the spice trade, occasioned by the European demand for sweet in preference to spiced dishes and by the use of winter fodder for cattle to ensure a supply of fresh meat throughout the year. Bullion, particularly silver, was the principal import into India; next in importance came broadcloth, lead, copper, tin and quicksilver.

The French Company. — It was not until 1664, In the reign of Louis XIV, that the Compagnie des Indes Orientales was formed. Between 1666 and 1690 French settlements were established at Surat, Pondicherry, Masulipatam, Chandernagore, Balasore and Kasimbazar; to these were added Calicut in 1701 and Mahé in 1721. Unfortunately the company became entangled in John Law's financial schemes and suffered severely when the crash came in 1720. After this it was reorganized as the Perpetual Company of the Indies. By 1744 the chief European rivals for the trade of India were the English. Dutch and French. There were other European companies in the field, such as the Ostend company formally chartered in 1722, the Banish company re-established in 1729 and the Swedish company of 1731, but they cannot be regarded as serious competitors.

When news reached India in 1744 that England and France had become involved in the War of the Austrian Succession, an unsuccessful attempt was made by Joseph Dupleix, the French governor of Pondicherry, to secure French interests in the east by a treaty of neutrality between the two companies. The arrival of an English squadron under Commodore Curtis Barnett, which swept French shipping from the seas and captured their China fleet. forced Dupleix to summon the comte Mahé de la Bourdonnais from Mauritius to his assistance. The death of Barnett and the timorous tactics of his successor gave the French command of the sea long enough to enable them to capture Madras. It was not until the arrival of Adm. Ednard Boscauen with reinforcements, in April 1748, that the English recovered their power at sea. By the treaty of Aix-la-Chapelle (1748) Madras was restored to the English in exchange for Louisbourg, the capital of Cape Breton Island.

After 1748 an unofficial war gradually developed in southern India between the English and French companies. The death of Nizam ul-Mulk in 1748 was the signal for a struggle between his descendants for the viceroyalty of the Deccan, and the death of Anwar ud-Din produced a similar struggle for the nawabship of the Carnatic. While the French supported Muzaffar Jang for the viceroyalty of the Deccan and Chanda Sahib for the nawabship of the Carnatic, the English espoused the causes of Nasir Jang and Mohammed Ali. To relieve the pressure on Mohammed Ali, who was beleaguered in Trichinopoly. the English sent Robert Clive, one of their servants, to attack Arcot. Clive's capture of Arcot in 1751 and his successful defense of it against the forces of Chanda Sahib and his French allies proved the turning point in the struggle. Stringer Lawrence's defeat of the French before Trichinopoly and the capitulation of the French forces, together with Dupleix's failure to reverse this decision, mearit the ruin of French schemes for controlling the Carnatic.

Muzaffar Jang, the French candidate for the viceroyalty of the Deccan, had been escorted to Hyderabad and Aurangabad by a French army under Charles de Bussy, the ablest officer in the service of the French. On the assassination of Muzaffar Jang, Bussy championed the cause of another claimant, Salabat Jang. who, in Oct. 1751, granted to Dupleix and after him to the French nation, free of all tribute, the southern provinces of Arcot, Trichinopoly and Madura. This grant was rendered worthless by the English victories in the Carnatic. Bussy's expedition into the Deccan proved a fatal division of forces and a dissipation of military strength. The failure of Dupleix's ambitious plans for a French empire in India led to his recall in Aug. 1754, and, with the arrival of his successor, Charles Robert Godeheu, a provisional treaty was arranged which terminated the unofficial war between the two companies. The final struggle between the French and English was postponed until the outbreak of the Seven Years War, in the course of which Eyre Coote defeated the French general Thomas de Lally at Wandewash on Jan. 22, 1760. Pondicherry surrendered to a combined land and sea force in Jan. 1761.

BRITISH ASCENDANCY

Clive and Bengal.—The privileges enjoyed by English merchants in Bengal were based on an imperial firman of 1717; but in practice this often proved valueless against the extortionate demands of semi-independent provincial governors and local officials. With the decline of Mogul power the nawabs of Bengal became practically independent of the central government. In 1756 the nawab Suraj ud-Daulah attacked and captured the English settlement at Calcutta. He incarcerated 146 English prisoners in the notorious Black Hole, a small military prison 18 ft. by 14 ft. 10 in. in size; and in the morning only 23 persons emerged alive. The chief reason for Suraj ud-Daulah's attack was the fear of foreign aggression—a fear which had its origin in recent events in the Carnatic and the Deccan. There was also much truth in his contention that the English had fortified their settlements in Bengal without his permission and had abused the trading privileges granted by the imperial firman of 1717.

To avenge this outrage Robert Clive (*q.v.*) and Adm. Charles Watson sailed to the Hooghly with a force from Madras. Clive easiiy recaptured Calcutta and forced Suraj ud-Daulah to sign a treaty confirming all the privileges which the English had formerly enjoyed. But it soon became obvious that the nawab had no intention of keeping his word and that he was intriguing with the French. Clive therefore decided to replace him with Mir Jafar, a person more favourably inclined to the English company. In this he was supported by the famous Hindu bankers, the Seths, whom Suraj ud-Daulah had threatened with circumcision. On June 23, 1757, Suraj ud-Daulah's forces were easily defeated at the battle of Plassey. This victory was of supreme importance in the growth of British power in India, for, by making the British the de facto rulers of Bengal. it placed at their disposal one of the wealthiest parts of India, the resources of which were used

to destroy the French power in the Carnatic. All European opposition in Bengal ceased with the repulse of a Dutch naval expedition to the Hugli and the capture of the Dutch settlement of Chinsura in 1759. In the following year Clive returned to England. His policy had been to strengthen the British position in Bengal and rule through a puppet nawab. His successor, Henry Vansittart, replaced Mir Jafar with Mir Kasim but made the mistake of strengthening the new nawab, who, from the beginning, asserted his authority and quarrelled with the company over the question of the abuses connected with the internal trading of its servants. It cannot be denied that the company's servants and their native agents had been guilty of gross abuses and oppression. Mir Kasim has therefore been depicted by Indian writers as a great patriot solicitous for the welfare of his subjects. The important point to remember is that he was aiming at complete independence of foreign control and at reversing the decision of Plassey. Vansittart failed to realize this and adopted a conciliatory policy which encouraged the nawab in his designs. Exasperated by the attitude of Vansittart's colleagues who were opposed to the governor's policy, Mir Kasim perpetrated the horrible massacre of Patna, in 1763, when 150 Englishmen were put to death in cold blood, a far more deliberate crime than the Black Hole of Calcutta. The defeat and flight of Mir Kasim was followed by the restoration of the more pliant Mir Jafar. A final attempt to oust the British from Bengal was made by Shah Alam, the titular Mogul emperor, and his nawab-wazir, Shuja ud-Daulah, the ruler of Oudh, but they were crushingly defeated by Maj. Hector Munro at the battle of Buxar in 1764. This victory completed the work of Plassey. Henceforward the British were the unchallenged rulers of Bengal. This was the position when, in 1765, Clive returned to India as governor of Bengal for the second time. By the treaty of Allahabad (1765) he restored Oudh to Shuja ud-Daulah, with the exception of the two districts of Kora and Allahabad, which were handed over to the emperor for his support. By a special agreement with the emperor the company was granted the *diwani,* or right to collect and administer the revenues of Bengal, Bihar and Orissa, in return for a promise to pay the emperor an annual tribute of 26 lakhs of rupees. Clive's foreign policy thus aimed at converting Oudh into a buffer state to protect the company's possessions from Maratha attacks. Clive left India in 1767 and for the next five years Bengal was governed by mediocrities.

Warren Hastin@.— When Warren Hastings became governor of Bengal in 1772, the Mogul empire had resolved itself into conflicting factions. In the struggles of the nizam of Hyderabad, of Hyder Ali of Mysore and of the Maratha confederacy there was no idea of a balance of power in the European sense. Territorial aggrandizement and paramountcy in the Indian peninsula were the declared aims of the Marathas. Thus, the foreign policy of Hastings was to maintain intact the British possessions in India, threatened as they were during his term of office (1772–85) by the Marathas, by a formidable coalition of the country powers round the nizam of Hyderabad and by the arrival of a French armament in Indian waters.

By the treaty of Benares (1773) Hastings reversed Clive's policy. Because the emperor by this time had deserted the British for the Marathas, in whose hands he had become a puppet, Hastings refused to continue the payment of the tribute since this would have been tantamount to furnishing the Marathas with financial aid to facilitate their attacks on Bengal. For the same reason he reclaimed the districts of Kora and Allahabad, which were sold to the ruler of Oudh. In order to strengthen the northwestern frontiers of Oudh he assisted Shuja ud-Daulah to conquer the Rohilla country. Because Clive's alliance with Oudh had been a financial drain, Hastings entered into a subsidiary alliance with that state whereby its ruler subsidized a British force for its protection, His relations with Oudh and his Rohilla policy aimed at strengthening an important buffer state upon whose security the safety of Bengal depended. Similar motives influenced him in an unsuccessful attempt to form a subsidiary alliance with the Maratha state of Berar, or Nagpur, which commanded the land route between Bengal and Madras. Had he been given a free hand he would have protected the British possessions by a chain of allies stretching from the Jumna to Gujarat. He would also have allowed the Indian states to ally themselves with the crown of Great Britain but was overruled. The remarkable thing is that he was able to accomplish so much during his 13 years of office for he was severely handicapped by the Regulating act of 1773, which, although making him the first governor-general of Bengal, placed him at the mercy of a bare majority on his council. The Regulating act also allowed the subordinate presidencies of Bombay and Madras to act on their own initiative in cases of imminent necessity or where they had received direct orders from the home authorities. Bombay's interference in Maratha affairs, which had been encouraged by the court of directors in England, led to war with the Marathas; and the situation was retrieved only by the prompt action of Hastings, who dispatched Gen. Thomas Goddard against them. After the defeat of the Marathas by Goddard and the storming of Mahadaji Sindhia's rock-fortress of Gwalior by Capt. William Popham peace was concluded by the treaty of Salbai in 1782.

While the Maratha war was taking place, Hyder Ali of Mysore, who had been estranged by the policy of the Madras council, invaded the Carnatic in 1781 and threatened Madras. Once more Hastings rose to the occasion and sent Eyre Coote by sea to Madras. After much bitter fighting the war was brought to an end by the treaty of Mangalore (1784), which stipulated a mutual restoration of conquests. During this war the situation had been further complicated by the arrival of a French naval force under the famous admiral Pierre André de Suffren (*q.v.*), who, between Feb. 1782 and June 1783, fought five more or less indecisive conflicts with the English squadron under Adm. Sir Edward Hughes. Although he was unable to destroy the French squadron Hughes was able to thwart their efforts to obtain command of the sea. Peace between England and France in Europe led to a cessation of these naval encounters. While his masters in England had lost the American colonies, Hastings had preserved their Indian empire intact.

Cornwallis, Shore and **Wellesley.**—The most important problem of internal administration, apart from the preservation of law and order, was the assessment and collection of the land revenue. The efforts of Warren Hastings had been merely experimental. To estimate the fertility of the soil required a detailed survey, for which the company's servants were unfitted. Moreover, the local Indian revenue officials conspired together to keep the British in ignorance of the real assets of Bengal. In 1793 Lord Cornwallis, against the advice of his ablest revenue officer, Sir John Shore, and without a survey, ordered a permanent settlement of the land revenues of Bengal. The demand from the *zamindars,* or landholders, was fixed in perpetuity, and they were declared to be the hereditary proprietors of their holdings. This was a grave error since the same advantages could have been secured by a temporary settlement for a long term of years without the disadvantage of unalterably fixing the revenue demand. Fortunately this system was not extended to the rest of India.

Cornwallis also attempted to reform the administration of justice. Although Hastings had made serious efforts to grapple with this problem, the administration of criminal justice was notoriously defective. Cornwallis, who distrusted Indians, placed it entirely under European supervision. The civil courts were also reorganized. In the districts of Bengal he vested the collection of the revenues and the administration of justice in separate officers, thus making the collectors purely fiscal agents. Cornwallis' reforms were defective in many respects: no means existed whereby the new laws could be brought to the notice of an illiterate peasantry; the courts were not numerous enough to cope with the cases brought before them, and accused persons were confined in prison for long periods pending trial; in the long run his mistrust of Indians in the administration of justice proved to be a fundamental error; and his separation of the revenue and judicial functions proved unworkable and too expensive.

His principal achievement was the reorganization of the Indian civil service on a footing worthy of its task. This was accomplished by prohibiting the collectors from engaging in private

trade and by paying them adequate salaries, thus placing them above corruption.

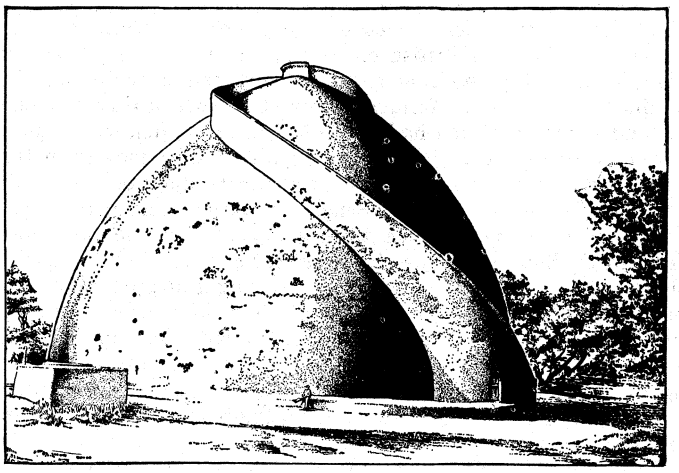
From the earliest days of the British connection with India there were two opposing forces at work, a forward tendency and a policy which sought to restrict or prevent expansion. In accordance with Pitt's India act of 1784, both Lord Cornwallis and his successor, Sir John Shore, pursued a policy of nonintervention in the affairs of the native states. To this there were two exceptions. Cornwallis found it impossible to avoid a conflict aith Tipu Sultan (Tippoo Sahib) of Mysore, who in 1790 made an unprovoked attack upon a British ally, the ruler of Travancore. After initial reverses Cornwallis, in 1792, advanced to the walls of Seringapatam and dictated terms by which Tipu was deprived of one-half of his territories and compelled to pay a huge indemnity. Neither can it be contended that the policy of Cornwallis and Shore toward Oudh was one of nonintervention. for they recognized that some control of this buffer state was essential. Shore even found it necessary to depose its ruler, Wazir Ali, because he was hostile to British interests. Elsewhere Shore's policy was one of unenterprising neutrality, and his refusal to protect Hyderabad from Maratha incursions resulted in the defeat of the nizam at Kharda in 1795. The system of neutrality prescribed by the home authorities lowered British prestige and increased the influence of French adventurers at the Indian courts. Lord Wellesley therefore found the British without allies when he arrived as governor-general in May 1798: both Daulat Rao Sindhia and the nizam had entrusted their best battalions to French officers; Tipu Sultan was intriguing on all sides against the British; Oudh was in no condition to serve as a buffer state; and the Carnatic and Tanjore had lapsed into anarchy. He also found the army badly organized and the financial condition of the company distressing.

As a result of Tipu's intrigues a small French force from Mauritius reached Mysore in 1799. A Jacobin club was formed, a tree of liberty planted and Tipu was hailed as "Citoyen Tipou". Eventually Wellesley declared war, and after a short campaign of three months Tipu was defeated and slain in May 1799. Wellesley decided to form a small central kingdom of Mysore and to restore the ancient Hindu dynasty. What was left was divided between the British and their allies. From that time Mysore was really under British control. Between 1799 and 1801 Tanjore, Surat and the Carnatic were placed under British administration. Because of the weakness of Oudh as a buffer state its ruler was compelled, in 1801, to surrender Rohilkhand, Farrukhabad, Mainpuri, Etawah, Cawnpore, Fategarh, Allahabad, Azimgarh, Basti and Gorakhpur. Thenceforward it was entirely surrounded by British territory, except on the Nepalese frontier, and ceased to be a buffer state.

Wellesley was the first governor-general to realize that the time had come for the British to stand forth as the paramount power. To accomplish this it was essential to control or crush the Marathas. His efforts at forming separate subsidiary alliances with each member of the Maratha confederacy ended in failure. Dissensions among the Marathas and the flight of the peshwa to British territory gave him the opportunity he sought. By the treaty of Bassein (1802) the peshwa entered into a subsidiary alliance and accepted British arbitration in his disputes with the other country powers. This naturally proved unacceptable to the other members of the confederacy and made war inevitable. In southern India the forces of Sindhia and Berar were crushed by Lord Wellesley's brother, Gen. Arthur Wellesley (later duke of Wellington), at Assaye and Argaon in 1803. In the same year Gen. Gerard Lake defeated Sindhia's forces in northern India at Aligarh and Laswari. As a result of these victories the British annexed Cuttack and all of Sindhia's territories in the Upper Doab. Wellesley was recalled before he was able to crush the forces of Holkar.

Minto and the Marquess of **Hastings.**—For a few years after Wellesley's departure British prestige was once more lowered by the resumption of a policy of nonintervention; but French intrigues in Persia forced Lord Minto (1807–13; later 1st earl of Minto) to adopt a more active foreign policy. After the treaty of Finkenstein (1807) by which Napoleon promised to force Russia to restore Georgia to Persia, French influence became paramount at the Persian court. This prompted Minto to send John Malcolm on a mission to Persia, Mountstuart Elphinstone to the Afghan Shah Shuja at Peshawar and Charles Metcalfe to Ranjit Singh, the Sikh ruler of Lahore. It was Napoleon's sacrifice of Persian interests at Tilsit in 1807, not Minto's diplomatic measures, that brought about the decline of French influence at Tehran. Elsewhere more concrete results were obtained. An expedition to the French islands in 1810 led to the capture of Bourbon and Mauritius; and in the following year Java was taken from the Dutch.

Establishment of British Paramountcy.— From 1813 to 1823 the company's territories were governed by the marquess of Hastings. Like Wellesley before him, he found that the policy of nonintervention prescribed by the authorities in England had broken down and that the country was being plundered by well-organized bands of brigands. He was first called upon to deal with the Gurkhas of the Himalayan state of Nepal, whose continual raids across an ill-defined frontier into British territory compelled him to declare war. The incompetence of the British officers chosen and the stubborn resistance of the Gurkhas prolonged the campaign from Nov. 1814 to March 1816. The situation was retrieved in the final stages by Sir David Ochterlony; and the Nepal durbar, after the capture of Fort Malaun, came to terms. By the treaty of Segauli (1816) the Gurkhas were forced to cede Garhwal and Kumaon together with most of the Tarai. They also agreed to withdraw from Sikkim and to accept a British resident at Katmandu.



BANKIPORE, INDIA. A GREAT GRANARY BUILT IN 1780 TO BE FILLED WITH GRAIN TO GUARD AGAINST FAMINE. STAIRWAY LEADS TO TOP: GRAIN TAKEN OUT AT BOTTOM

This accomplished, the governor-general turned his attention to the extirpation of the Pindari robber bands, who. urged on by the Marathas, had begun to plunder the company's territories. Eventually the home authorities gave a reluctant consent to military operations, and in 1818 the Pindaris were destroyed by a huge force of 20.000 men and 300 guns, the largest force that the British had been able to command in India up to that date. The Pindari war developed into a struggle with the Marathas. For this Hasting was fully prepared and, in the final Maratha war (1817–19), British arms were everywhere successful. As a result of this war the military power of the Maratha states was completely shattered and the territories of Holkar and the raja of Berar greatly reduced in size. Holkar was forced to cede Ajmer, the strategical key to Rajputana. The peshwa was deposed and forced to reside as a pensioner at Bithur near Cawnpore. Thus, by the suppression of the Pindaris, the defeat of the Marathas and the inclusion of the Rajput and other states within the pale of British protection, the British became the paramount power in the Indian peninsula. Except on the northwest frontier all the Indian states accepted the British ascendancy and from that time began to look to the British for rights and privileges.

Burmese aggressions on the northeast frontier led to war with Burma from 1824 to 1826. After a badly managed campaign the British dictated terms in the treaty of Yandabu, by which the Burmese agreed to accept a British resident, pay an indemnity of £1,000,000, surrender Assam, Arakan and the coastal strip of Tenasserim and abstain from all interference in Cachar, Jaintia and Manipur.

British Social Policy. — Amid the wars attending the establishment of British power in India there had been little time for social reform, although such practices as slavery, infanticide and suttee (*sati*) were extremely prevalent. Even though it was decided. in 1833, to emancipate all slaves in British territory, it was not until 1843 that slavery lost its legal status in British India. As early as 1795, as a result of the efforts of Jonathan Duncan, the company's resident at Benares, female infanticide was declared to be murder, but it was a difficult order to enforce and, as late as 1870, it was necessary to verify the existence of female children some years after birth. Suttee, or the burning of Hindu widows on the funeral pyres of their husbands, was sanctioned by the Hindu religion. This horrible rite was also tolerated by the British because it was feared that its suppression would provoke widespread disturbances. Despite the protests of Christian missionaries. of isolated British officials and of the Indian reformer Ram Mohan Roy, nothing effective had been done before the administration of Lord William Bentinck, by which time a strong demand for its abolition had arisen in England. Bentinck, therefore, arrived in India in 1828, armed with instructions from the court of directors to consider measures for its abolition. In 1829 it was declared illegal in the Bengal presidency, and persons assisting a voluntary sacrifice were guilty of culpable homicide. To Lord Dalhousie must be given the credit for its abolition in the Indian states. The honour of suppressing thuggee (thagi), a semi-religious cult and an organized system of murder, must be shared between Bentinck and Captain William Sleeman. It was not until an approver, named Feringhia, saved his life by betraying its secrets to Sleeman that the various gangs were hunted down. Between 1831 and 1837, 3,266 thugs were disposed of in one way or another.

Until the third decade of the 19th century no attempt was made to impose a European culture on India. The British conception of empire was confined to the establishment of law and order, the foundation of an administrative system, the dispensing of justice and the collection of revenue. There gradually developed a deeper sense of responsibility for the welfare of the inhabitants of India. As early as 1792 Charles Grant, supported by William Wilberforce and Zachary Macaulay, fellow members of the Clapham sect, had advocated the regeneration of India by the introduction of a knowledge of the Christian religion, the English language and western science For many years they were voices crying in the wilderness, for the company's policy was one of strict neutrality as far as Hindu and Moslem religious observances were concerned. As late as 1833 the government of Madras was responsible for the administration of 7,500 Hindu shrines. This was denounced by public opinion in England as tantamount to the encouragement of idolatry. With the growth of the humanitarian and evangelical movements the support of missionary enterprise increased, and one of the main achievements of the Whigs in 1833 was that missionaries were allowed to proceed to India without a licence. From 1813 to 1835 there was a period of controversy between the Orientalists and the Anglicists. Thomas Babington Macaulay, who became in 1833 the first legal member of the governor-general's council, supported the Anglicists in a famous minute which was largely responsible for the fact that English became the principal medium of instruction and western literature and science the chief subjects of study. In 1837 great encouragement was given to western learning by the supersession of Persian as the language of the law courts. The administration of Bentinck (1828–35) therefore stands out as a great landmark, for the study of the English language unlocked the door to a study of modern scientific knowledge and brought Indians into closer contact with the liberal and democratic ideas of the west.

Frontier Wars and Annexations — Soon after the arrival of Lord Auckland as governor-general in 1836 the British became alarmed at the growth of Russian influence in Persia. At that time the British sphere of influence in northern India extended to the river Sutlej. Between British India and Afghanistan lay the independent states of the Punjab under its Sikh ruler, Ranjit Singh, and Sind under the Talpur amirs. Shah Shuja, the Sadozai ruler of Afghanistan with whom Minto had concluded a treaty, had been ousted from his dominions and forced to take refuge in British territory. Auckland found Afghanistan divided into three states: Dost Mohammed Barakzai had extended his rule over Kabul, Ghazni and Jalalabad; Kandahar was independent under Dost Mohammed's brothers; and Herat was governed by Kamran Mirza, a Sadozai.

In the 1830s Russophobia was at its height. Urged on by Count Simonich, the Russian envoy at Tehran, the shah had laid siege to Herat, which in those days was regarded as the gate to India. In June 1836 Auckland was warned by the foreign office in London of these intrigues and that Dost Mohammed was in active correspondence with Persia. To ascertain the exact state of affairs Auckland dispatched Alexander Burnes ostensibly on a commercial mission to Kabul. Friendly relations could have been established had Auckland been prepared to help Dost Mohammed recover Peshawar, which had been lost to the Sikhs. This Auckland could not promise since he was anxious to conciliate Ranjit Singh. Burnes, who was tied by his instructions, was therefore outmanoeuvred by the Russian agent P. Vitkevich and recalled. Auckland, influenced by his private secretaries and other irresponsible advisers, decided to replace Dost Mohammed by the more pliant Shah Shuja. To this the government in England agreed. One of the chief reasons for Auckland's decision to invade Afghanistan was to relieve Herat, yet, when news arrived that the shah had abandoned the siege, he persisted in his efforts to oust Dost Mohammed from Kabul. At first the British were successful. Shah Shuja was restored and Dost Mohammed took his place in India. Eventually there was a general rising of the Afghan tribes against the British. The principal reasons for this were the unpopularity of Shah Shuja, hatred of foreign domination and the licentious conduct of British troops at Kabul. Both Burnes and Sir William Macnaughten, the British envoy, were assassinated and the troops besieged in Kabul. Gen. William Elphinstone and his military advisers eventually decided to retreat to India, but the force was practically annihilated before reaching Jalalabad. Out of 4,000 troops and 12,000 camp followers only W. Brydon, Maj. Lisant of the 37th native infantry, a merchant named Barnes and a few Indians reached Jalalabad. The restoration of the British position in Afghanistan was the work of Lord Ellenborough. who succeeded Auckland in Feb. 1842. After British honour had been satisfied by the avenging armies of Generals George Pollock and William Nott, Dost Mohammed was allowed to return to Kabul as ruler. The first war with the Afghans was a melancholy piece of folly which left a legacy of hatred and poisoned Anglo-Afghan relations for many years.

The reverses sustained by the company's troops in Afghanistan were not calculated to raise British prestige on the northwest frontier. Moreover, Auckland's treatment of the amirs of Sind had made them distrustful of British motives. In 1832 the British had pledged themselves to protect the territories of the Hyderabad and Khairpur amirs. In contravention of these treaties Sind had been used as a base for the British advance into Afghanistan, and Auckland in 1839 had forced the amirs to subscribe to a subsidiary treaty which practically deprived them of their independence. The policy adopted by Ellenborough was not less highhanded and eventually provoked the amirs into attacking the British residency. In 1843 they were defeated by Sir Charles Napier at the battles of Miani and Dabo and their country annexed. The annexation of Sind may have been expedient both politically and strategically; on moral grounds it was indefensible.

It was left to Ellenborough's successor, Sir Henry Hardinge (1844–48), to deal with the situation in the Punjab. After the death of Ranjit Singh in 1839, the Punjab had become the scene

of widespread lawlessness and domestic contentions. The only effective power was the Sikh army, which in 1845 comprised 88,662 men supported by a powerful artillery. Suspecting the British of contemplating the annexation of its country and eager for war. the Sikh army in Dec. 1845 crossed the Sutlej and invaded British territory, whereupon Hardinge declared war. The Sikhs were defeated in desperate struggles at Mudki, Ferozeshah, Aliwal and Sobraon, after which they were forced to surrender all territory on the British side of the Sutlej together with the Jullundur Doab, to pay an indemnity and to limit the strength of their armed forces. In 1846 Gulab Singh, a Dogra raja, was placed in possession of all the hill country between the Indus and the Ravi, including Kashmir, Ladakh, Gilgit and Chamba. The administration of the Punjab was entrusted to a council of regency presided over by Sir Henry Lawrence with a team of brilliant colleagues. the chief of whom were John Lawrence. Herbert Edwardes and John Nicholson. These arrangements did not prove acceptable to the Sikhs; and Lord Dalhousie, who succeeded Hardinge in 1848. was faced with a second war six months after his arrival in the country. The indecisive battle of Chillianwalla was followed by the destruction of the Sikh army at Gujrat, whereupon Dalhousie annexed the Punjab to British India. After nearly a century of incessant warfare the British political and geographical frontiers had become conterminous.

Dalhousie's period of office was marked by extensive annexations, and as a stage in the growth of British power in India it is comparable only with those of Wellesley and the marquess of Hastings. Soon after the defeat of the Sikhs his attention was directed to the northeast frontier, where Anglo-Burmese relations had steadily deteriorated since the conclusion of the treaty of Yandabu in 1826. The arrogant insolence of the Burmese and Dalhousie's failure to obtain satisfaction for acts of oppression on British merchants eventually compelled him to declare war in 1852. After a short well-organized campaign, Dalhousie, contrary to the instructions of the court of directors, contented himself with the annexation of Pegu or Lower Burma, which gave the British complete control of the Burmese coast line and enabled them to develop the port of Rangoon.

In India itself he complied nith the directors' instructions and, in accordance with what has been aptly termed the doctrine of lapse, annexed any tributary or dependent Hindu state whose ruler had died without a natural successor or without having previously adopted an heir with the sanction of the paramount power. In pursuance of this policy the following Hindu states became British territory: Satara (1848); Jaitpur, to the north of Jhansi (1849); Sambalpur (1849); Jhansi (1853); and Nagpur (1854). Tears of chronic misgovernment under a succession of dissolute rulers prompted Dalhousie to annex Oudh in 1856. This was the only case of annexation not in accordance with the doctrine of lapse or the result of conquest.

The Mutiny.—Dalhousie's successor, Lord Charles Canning, reached India in 1856. A year later the sepoys of the Bengal army mutinied An analysis of the factors underlying this revolt brings to light social. religious, economic, political and military causes. To regard it merely as a sepoy mutiny is to underestimate the increasing pace of westernization after the establishment of British paramountcy in 1818. Despite numerous invasions the structure of Hindu society had persisted; and it looked at first as if the British, like previous conquerors, had merely superimposed a political structure on the underlying Hindu social system. It soon became apparent, however, that Hindu society was being affected by the introduction of western ideas. Missionaries nere challenging the religious beliefs of the Hindus. The humanitarian movement had led to reforms which went deeper than the political superstructure. Dalhousie had made efforts for the emancipation of women and had introduced a bill to remove all legal obstacles to the remarriage of Hindu widows. Converts to Christianity were to share with their Hindu brethren in the property of the family estate. There was a widespread belief that the British aimed at breaking down the caste system. The introduction of western methods of education was a direct challenge to orthodoxy, both Hindu and Moslem. The mutiny therefore was not so much a revolt against foreign political domination as a protest against westernization, the pace of which had been accelerated in the years immediately preceding its outbreak. These changes threatened the supremacy of the Brahmans, who were the upholders of orthodox Hinduism. Many of them had been dispossessed of their revenues or had lost lucrative positions. Everywhere the old Indian aristocracy was being replaced by British officials; and recent land-revenue settlements in Allahabad and Oudh had favoured the peasants at the aristocracy's expense. Dalhousie had instituted an inquiry into the titles of landholders and it had been discovered that many of their claims rested on patents of doubtful authenticity. More than 20.000 estates had been confiscated in the five years tefore the mutiny. The annexations of Dalhousie, especially the annexation of Oudh, had produced a discontented nobility and a disbanded soldiery.

The mutiny broke out in the Bengal army because it was only in the military sphere that Indians were organized. From 1764 onward there had been frequent sepoy mutinies. The conquest of Sind and the Punjab produced great discontent since the sepoy no longer received extra allowances for service in provinces which had become British territory. Four Bengal regiments warned for service in Sind refused to march until these extra allowances were restored. There mere also serious defects in the administration of the army. The growing centralization of military authority at headquarters and Bentinck's abolition of corporal punishment in the native army had deprived commanding officers of adequate powers of punishment, for it was not until after the suppression of the mutiny that summary courts martial were instituted. There had been recruited high-caste sepoys, whose caste prejudices interfered with their military duties. Until the General Enlistment act of 1856 sepoys could refuse to proceed on foreign service. At the close of Dalhousie's administration the distribution of European troops was unstrategic. Only three regiments garrisoned the 900 mi. between Calcutta and Meerut. To make matters worse European troops were hopelessly outnumbered. In fairness to Dalhousie it must be stated that his appeals to rectify this grave error had been pigeonholed in London. The pretext for revolt was the introduction of the new Enfield rifle; to load it the cartridges had to be lubricated and to have their ends bitten off by the sepoys. There appears to be some foundation for the popular belief that the grease used for this purpose was a mixture of pigs' and cows' lard, an insult to both Moslems and Hindus.

Geographically the mutiny was practically confined to Upper and Central India and did not spread to Bombay and Madras. Thanks to the efforts of Herbert Edwardes, John Nicholson and John Lawrence the Punjab remained loyal. With the exception of the Mogul emperor and his sons and Nana Sahib, the adopted son of the deposed peshaa. none of the important Indian princes joined the mutineers. The extension of the revolt was gradual and resulted from gross British incompetence in the early stages when sterner and prompter action might have prevented it. But Canning was incapable of rapid decisions. and mediocrity was the prevailing note on his council. (For the military history of the mutiny *see* INDIAN MUTINY, THE.)

BRITISH IMPERIAL ADMINISTRATION

After the fall of Delhi, Bahadur Shah, the last puppet Mogul emperor, was tried for complicity in the revolt and condemned to exile. The crown took over the government of India from the East India company and a secretary of state, assisted by a council of experts, took the place of the board of control dating from William Pitt's India act of 1784. Lord Canning became the first Viceroy and Governor-general. The assumption of direct government by the crown was the occasion for a royal proclamation. To the peoples of India the queen proclaimed her deep personal concern for their welfare. The hour of victory was not to be an opportunity for repressive legislation An assurance was given that neither race nor religion should debar Indians from employment in the government of the country. Henceforth fitness was to be the criterion of eligibility. To the princes the crown relinquished the right, recently enforced by Dalhousie, of resuming

their territories on the failure of natural heirs. One of the most important questions after the mutiny was the reorganization of the military forces in India. It was eventually decided to amalgamate the British forces with the British army under the nominal control of the crown, thus ensuring that the Indian army should be an imperial force and not a local militia.

The second half of the 19th century was a period of consolidation and conciliation. It was an age of moral and material progress, of commercial development and constitutional experiments, of administrative and legal reforms. It witnessed a centralization under the crown made possible by the rapid development of communications, with the result that the secretary of state's powers increased at the expense of those of the governor-general. It also witnessed the fixed resolve of educated Indians to secure a larger share in the government of their country. Of outstanding importance were the legal codes. The Indian penal code, first drafted by Macaulay as early as 1834, became law in 1860. Codes of criminal and civil procedure were enacted in 1861. The same year saw the unification of the judicial system by the amalgamation of the supreme court and the adalats (courts) of the company into high courts. In 1861, for the first time, provision was made for the nomination of unofficial members to the governor-general's legislative council. The working of the executive council was also remodelled by the introduction of the portfolio system of business.

The mutiny left the government of India saddled with an enormous debt. By 1864 the efforts of James Wilson and his successor, Samuel Laing, had converted the debt into a surplus by means of large economies in military and civil expenditure and by introducing an income tax and other imposts. The year 1871 saw the beginnings of financial decentralization. which made the provincial governments more responsible for their own finances. This was gradually extended until, in 1882, the provinces received a share of the revenues instead of a fixed grant from the central treasury. During the viceroyalty of Lord Lytton (1876-80), Sir John Strachey, his finance minister, abolished the internal customs line, a huge cactus hedge interspersed with stone walls and ditches extending from Attock to Berar. This had been erected to prevent the untaxed salt of Rajputana and the lightly taxed salt of southern and western India from entering British territory. By granting compensation to the Indian states the British were able to control the sources of supply and remove this fiscal anachronism. In accordance with the doctrines of free trade, Strachey remitted the import duties on many articles. In 1882 the general customs tariff, with the exception of salt, liquor, tobacco and kerosene oil, was abolished. This lasted until 1894 when the progressive decline in the exchange value of the rupee made additional taxation imperative. A general duty of 5% was therefore imposed on imports. In the interests of the Lancashire manufacturers a countervailing excise duty was placed on Indian manufactured cotton cloth—a measure which rankled with growing bitterness in the Indian mind until abolished in 1926.

Before 1858 no attempt had been made to grapple with the problem of recurrent famines by introducing ? system of famine relief and there had been little expenditure of public funds. The modern idea that famine relief is the responsibility of the state was not recognized until India passed under the crown. The Famine commission of 1867 under Sir George Campbell laid the foundations of a more humane policy and enunciated the principle of preventing deaths from starvation. In the Bihar famine of 1873–74 village inspection, the basis of modern organization against famine, was carried out for the first time. The idea of insurance against famine originated with Sir John Strachey, who in 1874 contended that famines were normal periodic calamities against which it was necessary to make financial provision. During the southern Indian famine of 1876–78 the Temple, or reduced, ration, named after Sir Richard Temple, was adopted in Madras and Bombay but was abandoned after three months as insufficient. The Famine commission of 1878–80, presided over by Sir Richard Strachey, Sir John's elder brother, recommended that a definite system of procedure should be embodied in a famine code to be put into operation by the local governments subject to the financial control of the central government. A commission in 1898 under Sir James Lyall confirmed these principles but advocated in addition a more liberal famine wage and an extension of gratuitous relief. Unfortunately before these proposals had been incorporated in the provincial codes the great famine of 1899–1900 occurred. The Famine commission of 1901 recommended an efficient system of intelligence in order to obtain earlier estimates of anticipated crop failure and placed special emphasis on the importance of moral strategy since moral depression led to physical deterioration.

Of all the viceroys between 1858 and the end of the century Lord Ripon (1880–84) did most to make the British connection acceptable to educated Indian opinion. Appointed by a Liberal ministry in England, he sponsored a factory act, the first of its kind in India, and repealed the Vernacular Press act of 1878, which had muzzled the Indian press. In 1882 he decided to foster local self-government as a measure of political education even at the cost of administrative efficiency. But his rule is chiefly remembered for the famous Ilbert bill of 1883 by which he sought, as a minor administrative reform, to permit senior Indian judges to try criminal cases in which Englishmen were involved. Furious opposition from the unofficial English element in Bengal and Bihar resulted in the measure's being considerably modified. The importance of the controversy is that it intensified racial antagonism.

Foreign Policy.—The death of Dost Mohammed in 1863 was the signal for fratricidal conflicts in Afghanistan, and it was not until 1868 that his son Sher Ali succeeded in crushing all rival claimants. The policy of the government of India under Sir John Lawrence (1864–69) was one of abstention from interference in Afghan affairs and no attempt was made to recognize Sher Ali until his power had been firmly established. The desire for a closer alliance prompted Sher Ali in 1869 to meet Lawrence's successor, Lord Mayo (1869–72), at the conference of Amballa, the results of which have been much overrated by historians. The advance of Russia in central Asia led to a further conference at Simla in 1873, but Sher Ali failed to obtain dynastic pledges and had to content himself with vague promises of support. From this date Russian influence gained ground at Kabul. Sher Ali was further estranged by the Seistan arbitral award of 1872, which in his opinion favoured Persia. and by the British occupation of Quetta in 1876, which he regarded as a knife pointed at him. Caution therefore marked the policy of the government of India toward Afghanistan until the arrival of Lord Lytton in 1876. The Peshawar conference of 1877 was a final attempt to reconcile Sher Ali, but it was wrecked by the efforts of Lytton and his advisers in England to force British residents on the amir. Russia's reply was the mission of Stolyetov to Kabul. The refusal of Sher Ali to allow a British mission under Sir Neville Chamberlain to cross the frontier at Ali Masjid furnished Lytton with his famous *casus belli* for the Second Afghan War (1878–80). .On two occasions, in 1839 and in 1878, Russian intrigues had led to a British invasion of Afghanistan. The proper solution would have been to bring pressure to bear on Russia in Europe, for strained relations between India and Afghanistan were obviously to the advantage of Russia. British military operations were successful and Sher Ali fled the country. By the treaty of Gandamak (1879) his son Yakub Khan was recognized as amir and the British position around Quetta in Baluchistan was acknowledged. The assassination of Sir Louis Cavagnari, the British resident, in Sept. 1879, was followed by the reoccupation of Kabul by a force under Gen. Sir Frederick Roberts. In July 1880 Abdur-Rahman Khan, the nephew of Sher Ali, was recognized as amir of Kabul in return for his acknowledgement of the British right to control his foreign relations. Three years later this promise was renewed by Lord Ripon, who also bestowed on Abdur-Rahman an annual subsidy of 12 lakhs of rupees to be spent on the defense of his northern frontiers. In promising to protect Afghanistan against unprovoked aggression the British pledged themselves to defend a country of unknown limits. The Russian occupation of Merv in 1884 gave the necessary impetus to negotiations which ended in the appointment of an Anglo-Russian commission for the delimitation and demarcation of the northern boundary of Afghanistan. Although the Panjdeh incident of 1885, when an Afghan

force suffered heavy losses in an engagement with Russian troops, brought Britain and Russia to the verge of war, the process of demarcation was completed by the year 1888. The last frontier dispute in which Russia was concerned was settled by the Pamir agreement of 1895. Thus, in the closing years of the 19th century, the recognition of a definite frontier between Russia and Afghanistan led to a decided improvement in Anglo-Russian relations. The boundary between India and Afghanistan was delimited by the Durand agreement of 1893. British penetration into the tribal areas of the northwest frontier of India provoked the Pathan tribesmen to revolt in 1897. The Tirah expedition of 1898 was followed by a temporary cessation of hostilities. On the northeast frontier strained relations with Burma led to the Third Burmese War of 1885, which ended with the acquisition of Upper Burma. By the convention of Peking in 1886, China recognized British rule in Burma and arrangements were made for the delimitation of the frontier between Burma and China.

Lord Curzon as Viceroy (1899–1905).—Lord Curzon's attention was first directed to the problem presented by the tribes of the northwest frontier, largely an aftermath of the forward policy adopted by his predecessors. His policy has been aptly summarized as one of withdrawal and concentration. Regular troops were recalled from isolated garrisons in tribal territory and the defense of these forward areas entrusted to a tribal militia supported by British movable columns. In 1901, to increase the control of the government of India over frontier administration, he created the North-West Frontier province, which he placed under a chief commissioner assisted by officers of the political department and other specially recruited officials. Curzon's foreign policy aimed at the exclusion of Russian influence from areas of vital importance to the protection of India. Convinced of the necessity of maintaining British political and commercial supremacy in the Persian gulf, he frustrated Russian schemes for a coaling station at Bandar Abbas and for a railway terminus at Kuwait and also the French attempt to obtain a naval base on the coast of Oman. Similar motives influenced him in sending an expedition into Tibet in 1904 under Col. Francis Younghusband. Since the dalai lama had come under the influence of a Russian Buddhist named Dordzhiyev, Curzon considered it essential that British influence should be recognized in such a manner at Lhasa as to make it impossible for any other power to exercise pressure on the Tibetan government inconsistent with the interests of British India. It appears that his fears of Russian penetration into Tibet were not well founded. The Younghusband expedition, which slaughtered 700 badly armed Tibetans, was an inglorious episode in British history and served no useful purpose.

His internal administration was characterized by far-reaching reforms. The Punjab Land Alienation act protected the peasant against moneylenders. Co-operative credit societies and agricultural banks were instituted. An agricultural department was formed to improve farming and cattle breeding, and a department of commerce and industry was founded to encourage trade. The administration of the Indian police was reformed and a criminal investigation department created. In addition, commissions were appointed to inquire into education, irrigation and famine administration. His interest in Indian culture resulted in the Ancient Monuments Preservation act of 1904 and the appointment of Sir John Marshall as director-general of archaeology. Unfortunately Curzon lacked tact; and his unguarded utterances, especially his Calcutta convocation speech, and his attitude to the Indian princes were, to say the least, regrettable. His attitude of mental superiority combined with unpopular proposals for the partition of Bengal were largely responsible for the unrest and the outbreak of grave political crime with which his successors were confronted. As in the days of Dalhousie, the pace of reform had been too rapid. His viceroyalty may be said to mark the end of benevolent autocracy.

The Indian Nationalist Movement.— In its early stages this movement took the form of constitutional agitation which aimed at securing for Indians a greater share in the administration of the country. At first there was no desire to dispense with the British connection, but the reluctance of the government of India to grant reforms produced a distrust of British motives which led in the 20th century to a revolutionary movement demanding self-government and freedom from foreign control. A Hindu religious renaissance in the second half of the 19th century, by focusing attention on India's great cultural heritage, fostered national consciousness and racial pride. Prominent among the religious reformers were Keshub Chunder Sen (*q.v.*) (1833–84), who broadened the basis of the Brahma Samaj; Dayanand Saraswati (1824–83), founder of the Arya Samaj; and Ramakrishna (1834–88), whose work was continued by his more famous disciple Swami Vivekananda. But the most important factor underlying the growth of the nationalist movement was the influence of British rule. The establishment of British paramountcy and the development of communications facilitated centralization and tended to greater unification. English became the *lingua franca* of educated Indians and brought them into contact with European liberalism and political philosophy and with the ideas of nationalism and patriotism prevalent in the west. It enabled them to study the works of Edmund Burke, John Stuart Mill and other political philosophers and to read the lives of Giuseppe Garibaldi. Giuseppe Mazzini and Lajos Kossuth. They saw the part played by nationalism in the Italian *risorgimento* and how it had helped to unify Germany. The awakening of Japan and the defeat of Russia by an oriental poser was looked upon as symptomatic of general occidental decadence. Beneath the constitutional agitation lay a stratum of bitter economic discontent, and unemployment among educated Indians produced a vehement demand for a more rapid indianization of the administration. Racial discrimination against Indians. especially in South Africa, the controversy about the Ilbert bill of 1883 and the partition of Bengal in 1905 all played their part and led to the Swadeshi movement. which advocated the use of Indian-made goods. This developed into an agitation for the boycott of British goods resembling the boycott of American goods in China.

In imitation of western methods Indians formed societies for the discussion of political affairs. This was the purpose of the Indian association formed by Surendranath Banerjea in 1876. It was not until 1885, however, that the first Indian national congress met at Bombay. Its founder was Allan Hume, an Englishman who had consistently advocated the introduction of a more representative form of government; and it was hoped that it would develop into a sort of Indian parliament for the discussion of grievances. The first congress was attended by 72 delegates, chiefly lawyers, schoolmasters and newspaper editors. Of these only two were Moslems. The second congress in 1886 was composed of 440 delegates, but because of the influence of Sir Sayyid Ahmad only 33 Moslems attended. In reply to Lord Dufferin's description of the congress as a microscopic minority. 1.248 delegates attended the annual meeting in 1888. The last decade of the 19th century witnessed a change in the character of Indian nationalism, and by 1907 the moderate party led by Banerjea and Krishna Gokhale had given way to a virulently anti-British party under a Maratha Brahman journalist Bal Gangahdar Tilak and a Bengali named Arabindo Ghose, who had taken a first class in the Classical tripos at Cambridge. The anarchist movement was first organized by the Brahmans of Poona and owed much to inflammatory articles advocating the assassination of British officials which appeared in Tilak's paper, the *Kesari*. Centres of conspiracy were also formed in London, Paris and San Francisco, Calif. From Bombay the movement spread to Bengal, where, under Barindra Ghose and his brother Arabindo. recruits were trained both mentally and physically for revolution. The English secondary schools and colleges of Bengal were the most fruitful recruiting centres. Eventually. in 1908, as a result of the discovery of bombs, dynamite and correspondence. 35 conspirators were arrested, of whom 15 nere found guilty. An approver was shot dead in jail, the public prosecutor was assassinated in Calcutta and a deputy-superintendent of police murdered while leaving the high court. From this it is clear that the most important problem of Lord Minto's viceroyalty (1905–10) was the suppression of political conspiracy.

The **Morley-Minto** Reforms.— In an attempt to meet Indian

political aspirations, important constitutional reforms were carried out in concert between Lord Minto and Lord Morley, the secretary of state for India. In 1907 Morley appointed two Indians, Sayyid Husain Bilgrami and Krishna Gupta (afterward Sir), as members of his council in London. By the Indian Councils act of 1909 the governor-general's legislative council and the provincial legislative councils were considerably enlarged and their powers increased to enable them to adopt resolutions on matters of administrative and financial policy. In the provinces the official members were outnumbered, but an official majority was still retained at the centre. Because of Moslem agitation the principle of communal representation was formally incorporated in the constitution. For the first time an Indian was appointed to the governor-general's executive council. Unfortunately these reforms did not go far enough. Because of the restricted franchise, the reformed councils were not based on any system of direct popular representation. The percentage of lawyers among the nonofficial elected members was too great; and the official bloc was always strong enough to dominate the voting power in all councils. In fact, they were merely advisory bodies and lacked ministerial responsibility, the essence of the parliamentary system. Neither did these reforms, as Morley had expected, check the rising tide of unrest in India.

From 1909 to 1914.—Between 1909 and 1914 the terrorist movement spread from Bombay and Bengal to Bihar, the United Provinces, Madras and the Punjab. In July 1909 Sir Curzon Wyllie, political aide-de-camp at the India office. was assassinated by an Indian at the Imperial institute in London. Five months later an unsuccessful attempt was made to assassinate Lord and Lady Minto at Ahmedabad. In December of the same year Arthur Jackson, the district magistrate of Nasik, was shot dead at a farewell party given in his honour. In 1910 a secret society was unmasked at Satara. Robert Ashe. the district magistrate of Tinnevelly in Madras, was killed in June 1911. In Dec. 1911 occurred the Delhi bomb outrage. in which Lord Hardinge of Penhurst, who had succeeded Minto in Nov. 1910, was seriously wounded. The archconspirator behind the Ghadr (mutiny) movement in the Punjab was one Hardayal, who had proceeded to Oxford university with a state scholarship which he surrendered in order to return to India to preach sedition. Hardayal was later arrested in the U.S. but, escaping from custody, fled first to Switzerland and then to Berlin, Ger., leaving his unfortunate dupes in India to pay the penalty for their crimes.

It must not be imagined that these acts of violence were typical of the Indian attitude toward British rule. Among the moderates, at least, there was for some time after the Morley-Minto reforms a better feeling; and at the 1910 congress, for the first time, an address of welcome was presented to the new viceroy. The visit of the king-emperor to India in 1911 and the revocation of the partition of Bengal temporarily checked the growing unrest. For a time the new system of communal electorates strengthened Moslem loyalty, but this attitude gradually changed as a result of the apparent indifference of the British government to Moslem interests, which were endangered by the Italo-Turkish and Balkan wars. A motion proposed in the imperial legislative council on Jan. 24, 1911, demanding the discontinuance of separate representation for Moslems, served only to exacerbate Hindu-Moslem relations. By 1913 the attitude of the Moslem league, which had been formed in 1906 as a counterpoise to congress, became so hostile that the Aga Khan resigned the presidency. The treatment of Indian immigrants in the self-governing dominions and colonies intensified the growing resentment against western supremacy. The leader of the Indian movement of passive resistance in South Africa was Mohandas Raramchand Gandhi, soon to become famous for the adoption of a similar plan of campaign in India itself.

Despite all this unrest the opening years of the 20th century witnessed a great increase and a striking change in the trend of India's ioreign trade. Cn the eve of World War I, although Great Britain still had the bulk of this trade, the C.S. and Japan had become more serious rivals.

World War I.—Although the government of India was automatically involved in World War I by the royal declaration, Indians of all classes and shades of political opinion, with the exception of a minority of extremists, gave positive proof of their support of the Allied cause. The martial classes Aocked to the recruiting centres; the Indian princes offered their imperial service troops; Nepal placed its Gurkhas at the disposal of the empire; and even Tibet offered to provide a contingent of 1,000 soldiers. Amir Habibullah of Afghanistan remained loyal to his engagements, despite the fact that his country was much disturbed by the presence of German and Turkish emissaries. Notwithstanding the fact that the military forces in India had been raised purely for local defense, the loyal response of the country made possible the dispatch of troops to all theatres of war with the result that for some time India was so denuded of troops that only 15,000 were available for its immediate defense. These were later reinforced by contingents from the territorial regiments of Great Britain. About 80,000 British and 230,000 Indian troops were sent overseas from India in the first few months of the war. Indian sepoys were called upon to endure the European winter campaign of 1914–15 and distinguished themselves at the battles of Neuve Chapelle and Loos. In Nov. 1915 it was decided to withdraw the bulk of Indian troops from France for service in the middle east and other theatres of war. They fought throughout the badly managed Mesopotamian campaign; served with Viscount Allenby in Palestine and with Jan Christiaan Smuts in East Africa; bore their full share of the fighting in Gallipoli and Salonika. Egypt and the Cameroons; were used to protect Aden and the Abadan pipe line in the Persian gulf; and saw service in Kurdistan. Trans-Caspia, North China and on the northwest and northeast frontiers of India. India's total contribution to the war effort was 1,302,000 men; casualties amounted to 106.594, including 36.696 deaths from all causes. Out of the total number of combatants Bengal, with a population of 45,000,000 provided only 7,000. The much less densely populated Punjab was the chief recruiting centre and provided roughly 300,000 fighting men, Moslems, Sikhs, Dogras and Jats. of whom more than one-half were Moslems. Of the total number of combatants recruited throughout British India, three-quarters came from the Punjab and the United Provinces. India's financial contribution was no less remarkable. At its own request it bore the expense of its overseas forces and, in addition, made a free gift of £100,000,000 to the imperial exchequer. By means of war loans in 1917 and 1918 a sum of £73,000,000 was raised. India's immense wealth of raw material was placed at the service of the empire and, by 1918, it had supplied stores and equipment to the value of £80,000,000.

It would be a mistake, however, to infer that the internal situation was free from anxiety since the government of India had to contend with the Ghadr conspiracy in the Punjab and with the terrorist movement in Bengal. Every effort was made by Germany to take advantage of this. On the outbreak of war an Indian Tamil, Chempakaraman Pillai, who had formed the International Pro-Indian committee at Zurich. Switz., left Switzerland for Berlin, Ger., where he and Hardayal were employed by the German foreign office to disseminate anti-British propaganda. The chief centres of German propaganda were Bangkok and Batavia. which were under the direction of the consul general for Germany at Shanghai, himself acting under instructions from the German embassy in Washington, D.C. The refusal of the Canadian authorities to allow Sikhs, who failed to comply with the immigration regulations, to land in Vancouver, B.C., was skilfully exploited by the Ghadr party in the United States and Canada. The return of these discontented Sikhs to India led to serious unrest in the Punjab, and in Feb. 1915 an abortive attempt was made, in conjunction with the Bengal revolutionaries, to overthrow British rule. Efforts by the Germans to co-operate with these conspirators and to land arms and ammunition met with no success since they had overestimated the organizing ability of their Indian confederates and underrated the vigilance of the British authorities.

The entrance of Turkey into the war was followed by efforts to undermine the loyalty of Indian Moslems. Discontent ex-

pressed itself in the Khilafat movement, the members of which regarded the sultan of Turkey as the legal caliph. The arrival of a Turco-German mission in Kabul gave rise to exaggerated rumours which prompted some of the younger members of the Khilafat party to cross the frontier and join forces with certain discontented mullahs in Afghanistan and the tribal tracts of the northwest frontier. Although a small punitive expedition had to be undertaken against the Mohmand tribes to the northeast of Peshawar, the danger of a rising of the powerful Afridis was averted when the British, in Feb. 1915, decided to double their allowances. In Aug. 1916 Turkish emissaries visited the frontier with money for the notoriously anti-British Haji Sahib of Turangzai. one of whose evil counsellors was Mohammed Ali, a graduate of Cambridge and a lecturer in the amir's college at Kabul. Great pressure was also brought to bear on the amir Habibullah to declare war, but he refused to break his engagements with the government of India.

During World War I the conception of India as a self-governing dominion within the empire took a firmer hold than ever before on the politically minded classes. In his presidential address to the national congress of 1915 Sir Satyendra P. (afterward Lord) Sinha spoke with pride of the fact that India's contribution to the war effort had not fallen behind that of other parts of the empire: although, in his opinion. India was not ripe for self-government, he was convinced that this should be the final aim of British rule. Events proved that this pronouncement did not go far enough to meet the aspirations of educated Indians; and Lord Chelmsford, who succeeded Lord Hardinge as governor-general in 1916, was confronted with a widespread agitation for home rule sponsored by Mrs. Annie Besant and B. G. Tilak, who had been released from detention. A home rule league was established in Sept. 1916, and Mrs. Besant's paper, ***New*** India, became the medium for an intensive campaign. In October of the same year 19 members of the governor-general's legislative council published a memorandum in which they complained of the inadequacy of the Morley-Minto reforms and claimed that India's loyalty during the war had earned for it the right to parliamentary institutions. In November proposals for extensive constitutional reform were made by joint representatives of the congress and the Moslem league. This Hindu-Moslem rapprochement, known as the Lucknow pact, recognized the principle of communal electorates as far as Moslems were concerned and was hailed somewhat prematurely by M A. Jinnah, a prominent Moslem leader, as the birth of a united Indian nation. The policy of the national congress for 1916 was a triumph for the principles of the Home Rule party, and political independence was advocated by both moderates and extremists. A resolution was passed that a proclamation conferring self-government on India should be immediately issued by the British government. Widespread agitation continued throughout 1917 and forced the British government to turn its attention to Indian affairs. Eventually on Aug. 20, 1917, E. S. Montagu, the secretary of state for India, declared in the house of commons that "the policy of His Majesty's Government, with which the Government of India are in complete accord, is that of the increasing association of Indians in every branch of the administration and the gradual development of self-governing institutions with a view to the progressive realisation of responsible government in India as an integral part of the British Empire." The announcement went on to emphasize that the stages in this development had to be gradual and that the pace would be determined by the British government. Indians naturally interpreted this as a promise of equality with the self-governing dominions. Moslems, however, regarded it as a victory for the Hindu majority and saw in it a threat to communal representation. From this time onward Hindu-Moslem rivalry developed apace and expressed itself in violent communal outbreaks. The visit of the secretary of state to India to hold consultations with the viceroy resulted in the publication of the famous Montagu-Chelmsford report of 1918.

The **Punjab** Rebellion, 1919.—In order to cope with revolutionary conspiracy, the ramifications of which had been disclosed by the publication of the report of the Sedition committee presided over by Sir Sidney Rowlatt, it was proposed to endow the government of India with emergency powers. The draft bills, published in Jan. 1919, provided for the internment of persons suspected of subversive activities and for the trial of political offenders by judges unassisted by juries since it was feared that juries would be intimidated by deliberate terrorism. The agitation which ensued saw the emergence of Gandhi as a factor in Indian politics and the organizing of a movement of passive resistance, known as Satyagraha, the use of which in South Africa had first brought him into prominence. Now too for the first time the masses began to be affected. When the Rowlatt act was passed in March 1919 Gandhi announced that as a protest March 30 should be observed as a hartal, or day of abstention from business. Events soon proved that his doctrine of ahimsa, or nonviolence, was not appreciated by the Indian mob, and his preaching of passive resistance led to violent outrages in Delhi, Gujarat and the Punjab. The railway station at Delhi, focus of all the railway traffic of northern India, was stormed by the mob, and British troops and police officers were assaulted. In the firing which followed eight persons were killed. Because of the subversive activities of Kichlu, a Kashmiri Moslem who had taken a degree at a German university, and a Hindu assistant surgeon named Satya Pal, the Punjab had been seriously disturbed since the middle of 1918. Not dissuaded by what had happened in Delhi, Gandhi ordered another hartal for April 6. Posters appeared in Lahore and Amritsar announcing this date as the day of *ghadr*, or mutiny, and urging the populace to "kill and die." Proclamations by the Punjab authorities forbidding public meetings were openly defied, and riots took place throughout the province. Emissaries were sent to the border tribes and Afghanistan, but fortunately war with Afghanistan did not coincide with the Punjab disturbances. Chaos reigned in Amritsar between April 10 and April 12. The mob murdered five Europeans and attempted to murder two Englishwomen (a missionary and a doctor). It set fire to the Anglican church and to the mission school while the teachers and pupils were at work; looted two English banks and put to death three British managers; set fire to the railway goods station and murdered a British official on duty (an attack on the passenger station was repulsed); attacked and gutted the central telegraph office; set fire to the town hall; and finally attacked the Calcutta mail train. Similar outbreaks occurred at the same time in Lahore. At Kasur, 25 mi. from Lahore, the mob, on April 12, held up the trains and murdered two British warrant officers. Turning their attention to government buildings, the rioters attacked the treasury and burned the civil courts. The whole outbreak appears to have been a well-organized attack on communications, with the result that Sir Michael O'Dwyer, the lieutenant governor. was forced to rely on radio. At Amritsar, on April 13, took place what has been termed the Amritsar massacre, when Brig. Gen. Reginald Dyer's troops fired on a mob which had collected in the Jallianwalla Bagh in defiance of the prohibition, killing 379 and wounding 1,208. His action was approved by the Punjab government but condemned by the secretary of state for India, the army council and the Hunter commission. The house of lords, however, justified his conduct on the ground that he had saved British rule in the Punjab. As a result of this unfortunate affair racial feeling in India became more bitter than at any other time since the mutiny, and many moderate "home rule" enthusiasts changed over to a more extreme nationalism.

The Third Afghan War.—On Feb. 20, 1919, Habibullah Khan was assassinated in his camp near Jalalabad and his brother Nasrullah Khan was proclaimed as amir in his stead. A few days later Amanullah Khan. a son of the late amir, who controlled the arsenal and treasury at Kabul, was accepted as ruler by the army and the Young Afghan party, and Nasrullah was imprisoned because of his guilt in instigating the murder of his brother. The assassination of Habibullah had not been entirely unexpected in Afghanistan since his policy of neutrality from 1914 to 1918 had incensed the mullahs and other powerful sections of the population who blamed him for not having gone to the assistance of Turkey. Anxious to placate the mullahs and allay this discon-

tent, Amanullah, at a durbar in Kabul on April 13, declared Afghanistan to be free from foreign control. On May 4, unable to resist the popular demand for war against Britain as the chief enemy of Turkey, he proclaimed a jehad, or holy war, and pamphlets calling upon the tribesmen to rise u-ere distributed by the Afghan postmaster at Peshawar. An attempted rising in Peshawar, in co-operation with the Indian revolutionary party, was foiled by the vigilance of the local frontier officials. On May 3 Afghan troops crossed the frontier near Landi Khana and occupied the village of Bagh, whereupon British reinforcements were rushed through the Khyber pass to Landi Kotal. The Afghans were driven from Bagh on May 11, and within eight days of mobilization British troops had advanced through the Khyber into Afghanistan and occupied Dakka. The only Afghan success during the campaign was the penetration of Nadir Khan to Thal in the Kurram valley. After Jalalabad and Kabul had been bombed the amir on May 31 asked for an armistice. A preliminary treaty was signed at Rawalpindi on Aug. 8, 1919, and ratified by a formal treaty on Nov. 22, 1921. In the future Afghanistan was to be free to control its own foreign affairs, but the government of India withdrew the privilege enjoyed by Afghanistan of importing arms and ammunition through India and discontinued the subsidy which had been paid since the viceroyalty of Lord Ripon. Amanullah persisted in regarding his defeat as a victory and erected a monument at Kabul depicting the British Lion with one leg chained. The cessation of hostilities with Afghanistan did not bring peace to the northwest frontier, and from 1919 to 1920 punitive operations had to be undertaken against the fierce Mahsud tribes inhabiting the heart of Waziristan.

The Act **of** 1919.—The main trend in Indian history after the conclusion of World War I was the development of self-governing institutions and the rapid growth of the nationalist movement under the leadership of Gandhi. The Government of India act of 1919 was based in the main on the principles adumbrated in the Montagu-Chelmsfotd report. Before 1919 the chief characteristics of British rule in India, from the administrative, financial and legislative points of view, had been the concentration of authority at the centre; the control of the executive over legislative functions; and the responsibility of the British parliament for the whole of Indian government. Under the reformed constitution, authority, instead of being concentrated at the centre, was to be in large measure devolved on the provinces; the opportunities of the central legislative for influencing the government of India were to be increased; and the control formerly exercised by parliament was to be modified by handing over certain subjects of provincial administration to Indian ministers responsible to the provincial legislatures.

At the centre the first reform was to increase the number of Indian members on the governor-general's executive council from one to three. The central legislature was entirely remodelled and made bicameral by the creation of a new body called the council of state composed of 60 members, not more than 20 of whom were to be officials (that is, persons in the full-time civil or military service of the crown). There was to be a majority of elected members, but the franchise was extremely limited in order to give this new body the character of an upper chamber. The legislative assembly (that is, the old imperial legislative council) consisted of 145 members, 104 of whom were elected. Of the elected members 52 were returned for general constituencies, 30 for Moslems. 9 for Europeans, 7 for landowners, 4 for commerce artd 2 for Sikhs. The franchise was on the same lines as for the provincial councils with a somewhat higher electoral qualification. The durdtion of the council of state was to be five years; that of the legislative assembly, three. It is important to note that this was the first time that the official majority was withdrawn from the central legislature. A bill rejected by the assembly could be certified by the governor-general as essential to the peace or good government of the country. The same applied to the grant of supplies or new taxation proposals.

At first there were eight major provinces under governors; viz., Madras, Bombay, Bengal, the Punjab, the United Provinces, the Central Provinces, Bihar and Orissa, and Assam. The North-West Frontier Province, Baluchistan, Delhi, Coorg, Ajmer-Merwara and the Andaman and Nicobar Islands were left in charge of chief commissioners or agents of the central government. Burma became a governor's province in 1923, as did the North-West Frontier Province in 1932. Reserved for the administration of the central government n-ere military matters and foreign affairs, tariffs and customs, railways, posts and telegraphs, income tax, currency and coinage, the public debt, commerce and shipping and civil and criminal law. The subjects allocated to the provincial governments included local self-government, medical administration and public health, education, public works, irrigation, land revenue, famine relief, agriculture, forests and police.

By an ingenious device unofficially known as dyarchy the provincial executive was divided into two parts: a governor and executive council responsible for what were termed "reserved subjects"; and ministers chosen by the governor from the elected members of the provincial legislature to whom were entrusted the "transferred subjects." Reserved subjects included irrigation, land revenue, famine relief, administration of justice, development of mineral resources. police, control of newspapers and printing presses, criminal tribes and prisons. The transferred subjects under the control of Indian ministers included local self-government, medical administration and vital statistics, public works, education, agriculture, the civil veterinary department, fisheries, co-operative societies, forests, excise and industries. In this way Indians were to take charge of great departments of provincial administration as leaders of elected majorities in the legislatures.

The provincial legislatures were unicameral, the legislative councils varying in size from province to province. In all cases they were considerably enlarged and were nearly twice the size of the 1909 councils. The franchise was extended mainly by lowering the property qualification, which resulted in an electorate of about 5,500,000. Since a large proportion of the voters were illiterate use was made of ballot boxes of different colours; or pictorial symbols, such as tigers and umbrellas, were used on ballot papers. Communal electorates were 'maintained for Moslems. Sikhs, Anglo-Indians and Europeans. In Madras seats were reserved for non-Brahmans and Christians. It will be noted that the device known as dyarchy, or double government, was confined to the provinces and was intended to train Indians for responsible government. There was no dyarchy at the centre, where the governor-general continued to be directly responsible to the secretary of state for India and the British parliament. Provincial legislatures were thus set the difficult task of discharging two different functions at the same time: in one sphere (the transferred subjects) they were to exercise control over policy; in the other (the reserved subjects), while free to criticize, they were to have no responsibility. There was therefore a tendency in the years that followed for these councils to regard the government as a whole and to think of the ministers as if they were executive councillors. There was also a tendency to magnify the functions of the reserved field.

The Government of India act of 1919 received the royal assent on Dec. 23. 1919. Elections were held in Nov. 1920, and in the first week of Jan. 1921 the new provincial executives came into office. The central legislature at Delhi was opened in state by the duke of Connaught on Feb. 9, 1921. On the previous day he had opened the new chamber of princes, thus placing on a permanent footing the previous system of informal conferences. Provision was made in the act for the appointment of a parliamentary commission after a period of ten years to inquire into the working of the new constitution and into the possibilities of further constitutional advance.

Khilafat and **Swarajists.**—The idea behind the Montagu-Chelmsford reforms had been to allay political agitation and to inspire Indians with a spirit of co-operation and a sense of responsibility. Many factors combined to defeat this object. The new constitution did not prove acceptable to the Congress party, which boycotted the first elections in 1920; thus only about one-third of the total electorate went to the polls, and the abstention of the extremists left the moderates in a majority on the new

councils. India was also seething with racial and religious discontent. The memory of Amritsar still rankled in the minds of both Hindus and Moslems. India's position as a member of the League of Nations and the presence of its representatives at the imperial conferences led to an increasing demand for dominion status since Indians resented their position of inferiority and their failure to obtain redress ior the disabilities suffered by their compatriots in South Africa. Resentment was also caused by the attitude adopted by European colonists in East Africa, who were advocating the restriction of Indian immigration on the ground that it was antagonistic to the best interests of the African natives. All this was accentuated by the treatment of Indian indentured labourers in Fiji. Considerable unrest was also caused by the publication in Oct. 1920 of the Esher committee's report, the recommendations of which were tactlessly aimed at subordinating the Indian army to the needs of imperial strategy. Indians naturally regarded this as an attempt to deprive India of the control of its military forces, which were to be used for what was termed imperial aggression in the middle east.

The Khilafat movement, which aimed at the preservation of the Turkish empire and of the sovereignty of the sultan as caliph, was another source of anxiety to the government of India. The demand by influential sections of British and U.S. opinion that the Turks should be expelled from Constantinople and the failure of the Khilafat deputation to obtain satisfaction from David Lloyd George produced great discontent among Indian Moslems and prompted two agitators, the brothers Mohammed and Shaukat Ali, to proclaim that it was the duty of all true Moslems to leave India for countries where Islam was respected. In obedience to this call many thousands of Moslems sold their goods and joined the, *hijrat* (flight) movement from India to Afghanistan. It was calculated that in the month of Aug. 1920 more than 18,000 people, the *muhajrin,* as they were called, moved in the direction of Afghanistan. The limited resources of Afghanistan compelled the Afghan government to forbid their entry into the country, with the result that the road from Peshawar through the Khyber pass was strewn with the graves of old men, women and children who had succumbed to the hardships of the journey. The failure of this movement was a severe setback to Khilafatist agitation.

The death of Tilak in Aug. 1920 left Gandhi undisputed leader of the nationalist party. In a letter to Lord Chelmsford he announced his adoption of a policy of non-co-operation as a remedy against a government for which he retained "neither respect nor affection." This was the situation facing Lord Reading when he succeeded Lord Chelmsford as viceroy in April 1921. Gandhi had no sooner taken charge of the nationalist party than he formed an entente with the leaders of the Khilafat movement. Hindu and Moslem grievances were now combined in subversive agitation, which produced the Moplah rebellion of 1921–22 and caused bloodshed and disorder for more than two years in every province in India.

The Moplahs of Malabar, fanatical Moslems of Arab descent, broke out into rebellion in Aug. 1921. The aim of these people was to establish an independent Khilafat kingdom in Malabar. A reign of terror ensued in which thousands of innocent Hindus were either massacred or forcibly converted to Islam. Since the topography of the country favoured guerrilla warfare the rebellion was not suppressed until Feb. 1922. The chief result of this abortive insurrection was to shatter the Hindu-Moslem entente and to exacerbate communal relations It is recorded that 450 lives were lost and 5,000 persons injured in communal disturbances between 1922 and 1927. The Khilafat agitation gradually petered out after the failure of the *hijrat* movement, but the chief reason for its decline was the establishment of a strong secular Turkish republic and the abolition of the caliphate in 1924.

Serious rioting resulting from Gandhi's policy of non-co-operation marred the occasion of the landing of the prince of Wales at Bombay in Nov. 1921. On Feb. 4, 1922, mob violence was responsible for the murder of 21 police officers at the village of Chauri Chaura in the United Provinces. Eight days after this tragedy Gandhi, realizing his responsibility for the massacre, suspended his campaign of civil disobedience. On March 10 he was arrested, tried for sedition and sentenced to six years' imprisonment. In 1922 the peace of the Punjab was seriously disturbed as a result of the efforts of the Akalis, a reforming sect of Sikhs, to redeem certain shrines and temples from the maladministration of their *mahants,* or hereditary incumbents, in order to apply the revenues for the spiritual benefit oi the Sikh community. Unfortunately the movement, laudable enough in itself, was exploited for political purposes by extremists, and troops had to be employed to suppress disturbances. It was not until the passing of the Sikh Shrines' act of 1925 that more sober views began to assert themselves.

At the end of 1923 the Swarajists, a Congress home-rule party under the leadership of Pandit Motilal Nehru and Chitta Ranjan Das, contested the elections to the legislatures, their aim being to wreck the constitution from within by consistent obstruction. Although large numbers of Swarajists were returned to the legislative assembly and to all provincial councils. it was only in the Central Provinces that they obtained an absolute majority which made the working of dyarchy impossible. In Bengal the support of certain independent members, chiefly Moslems, gave them a majority, and their refusal to vote ministerial salaries led to the suspension of the transferred subjects. Elsewhere dyarchy continued to function, especially in Madras where the opposition to Brahman supremacy united to form the Justice party.

Indianization of the Services.—The growth of the nationalist movement naturally led to the demand for a more rapid indianization of the civil and military services. Although the principle of indianization had been adopted as early as 1833 and had been incorporated in the royal proclamation of 1858, the British showed a reluctance to admit Indians into the higher ranks of the civil service. As late as Aug. 1922 Lloyd George. in his "steel-frame" speech, declared that he could see no period when India would be able to dispense with the guidance and assistance of a British element in its civil service. This was followed in June 1923 by the appointment of a royal commission under the chairmanship of Viscount Lee of Fareham to examine the position of the superior civil service in India. The report of this commission, published in May 1924, contained proposals for a large increase in the recruitment of Indians; but, although it recommended that the Indian civil service should be half Indian after 1j years and the Indian police likewise after 25 years, the proposed pace of indianization did not prove acceptable to Indian opinion. Whereas Indians had been slowly and reluctantly admitted into the higher ranks of the civil service, they had been rigidly excluded from the commissioned ranks of the army; and it was not until 1918 that they became eligible for the king's commission. In the same year ten places were reserved for Indians in the Royal Military academy at Sandhurst, Eng. The year 1923 saw the introduction of a cautious experiment known as the "eight units scheme" which aimed at building up a small force (five infantry battalions, two cavalry regiments and one pioneer unit) entirely officered by Indians. In 1927 the number of reservations at Sandhurst was raised to 20 and Indians also became eligible for admission to Woolwich and Cranwell, both in England. It was not until 1934, however, that an Indian Sandhurst was opened at Dehra Dun.

Political Assassination, 1923–32.—The year 1923 witnessed a recrudescence of terrorist activity with a new and bolder technique. Terrorists entered the Congress party, were elected to its committees and forced their resolutions upon its conferences. Bombs of a more powerful type were manufactured and leaflets were issued proclaiming that the Bengal Revolutionary council had decided to assassinate police officers and any persons assisting them. The old method of obtaining funds by the robbery of wealthy Indians was discarded in favour of skilfully planned attacks on post offices and railway cash offices by gangs of armed dacoits. In 1924 an Englishman was murdered in Calcutta by mistake for Sir Charles Tegart, the commissioner of police. To combat this type of crime, special measures were introduced by the Bengal Criminal Law Amendment act of 1925, which led to the internment of 150 ringleaders and to a temporary cessation

of outrages. It was calculated that in Bengal, out of a total population of 50,000,000, not more than 2,000 men and women were in the inner circle of the anarchist movement. Checked in Bengal, the terrorists transferred their activities to the United Provinces and the Punjab. In Dec. 1928 two police officers were murdered in Lahore. In April 1929 bombs were thrown into the legislative assembly at Delhi; and in December of the same year an unsuccessful attempt was made to wreck the viceroy's train. Because of the improved situation in Bengal all interned terrorists were released in Jan. 1929, and in the following year the Bengal Criminal Law Amendment act was allowed to lapse. This was the signal for a revival of terrorism in the province. In April 1930 there occurred the most daring raid that had yet been attempted; a gang of about 100 Bengali youths dressed in uniform attacked the police armoury, the European club and the telegraph office at Chittagong. There were 30 outrages besides this in 1930, including the assassination of the inspector general of police and of the inspector general of prisons and an unsuccessful attempt to assassinate the governor of the Punjab. Attempts were also made in July 1931 and in Feb. 1932 on the lives of the acting governor of Bombay and the governor of Bengal. Between 1931 and 1932 in Bengal three district magistrates and one district judge were assassinated and several senior officials of the civil service wounded. The Congress party contended that these murders were the outcome of repressive legislation. but others pointed out that an amnesty had always been the signal for further outrages. The formation on the northwest frontier of a revolutionary party known as the Red Shirts under the leadership of Abdul-Ghaffar Khan, a Pathan of Utmanzai, was followed by grave disturbances in Peshawar, Bannu, Mardan and Kohat in April 1930. In the same month Abdul-Ghaffar was arrested, but as a result of Gandhi's intercession with the viceroy he was released in March 1931. In August of the same year the Red Shirt movement was officially affiliated to the Congress party; but because of his subvereive activities Abdul-Ghaffar was once more arrested in Dec. 1931.

In addition to the recrudescence of anarchical crime, the government of India under Lord Irwin, who had succeeded Lord Reading in April 1926, was confronted with the rapid growth of communal antagonism and with a civil disobedience movement under the leadership of Gandhi, who had been released from prison because of ill health. Although Lord Irwin showed a marked sympathy with the cause of Indian self-determination and attempted by means of conferences to bring the leaders of the two religions into agreement, his efforts proved unavailing and communal bitterness remained an outstanding feature of the Indian situation from this time onward. When the third elections were held in Nov. 1926, appeals were made to electors in many cases on communal lines. Relations between Hindus and Moslems were exacerbated by the anti-Moslem attitude of the Mahasabha, an extremely orthodox Hindu organization, and by the rejection of communal electorates in the Nehru constitution drawn up by an entirely Indian body under the chairmanship of Pandit Motilal Nehru in 1928.

The Simon Commission. — It will be remembered that the act of 1919 provided for an inquiry into the working of the new constitution after a period of ten years. In response to Indian wishes this inquiry was expedited by two years, and the appointment of a statutory commission was announced on Nov. 8, 1927. Appointed by a Conservative government in England, it consisted of seven persons, all members of the British parliament, under the chairmanship of Sir John Simon. Two visits were paid to India: Feb. 3–March 31, 1928; and Oct. 11, 1928–April 13, 1929. The noninclusion of Indians offended the strong sentiment of national self-respect that prevailed in India, and at first the commission was boycotted even by moderate nationalists like Sir Tej Bahadur Sapru. When the members of the commission landed at Bombay on Feb. 3, 1928, they were greeted with hostile demonstrations which included a *hartal,* or suspension of business. During their second visit, however, they found committees from both the central and provincial legislatures prepared to co-operate in the examination of witnesses. In the same year the Nehru report was published advocating the immediate grant of "full responsible government on the model of the constitutions of the self-governing dominions"; but extremists under the influence of Motilal's son. Jawaharlal Nehru, declared that they would be satisfied with nothing short of *purna swaraj;* that is, complete national independence. At the Calcutta congress of Dec. 1928 a resolution was passed giving the British until the end of 1929 to accept the Nehru constitution, their refusal to be followed by a civil disobedience campaign. The disturbed condition of India prompted Lord Irwin to proceed to London for consultation with the Labour government, which had come into office. On Oct. 31, 1929, after his return to India, he was authorized to make two important announcements:

1. "In view of the doubts which have been expressed both in Great Britain and India regarding the interpretation to be placed on the intentions of the British Government in enacting the statute of 1919, I am authorized on behalf of His Majesty's Government to state clearly that, in their judgment, it is implicit in the Declaration of 1917 that the natural issue of India's constitutional progress as there contemplated is the attainment of Dominion status."
2. To disperse the distrust concerning British intentions, which had been aggravated by the exclusion of Indians from the statutory commission, he also declared that, after the report of the Simon commission, there should be a round table conference in London to uhich Indians would be invited in order to express their views before proposals for the future government of India were laid before the British parliament.

These pronouncements were accepted by the moderates, but the Lahore congress of Dec. 1929 passed resolutions in favour of complete independence and authorized immediate preparations for a campaign of civil disobedience. The signal for this campaign was given by Gandhi when he set out on his ceremonial march from Ahmedabad to the sea coast and on April 6, 1930, broke the law by manufacturing salt on the beach at Dandi. Widespread disturbances followed, from which Moslems as a body held aloof. One feature of the movement was the unexpected assistance of women, some of whom emerged from purdah to join the Congress demonstrations and assist in the picketing of liquor shops. Details of the terrorist outrages have already been given. Both Gandhi and Jawaharlal Nehru were arrested.

In June 1930 the Simon report was published. Its main recommendations were that dyarchy should be replaced by full responsible government in the provinces, the governors still retaining special powers in an emergency; that the existence of racial and religious differences necessitated the retention of communal electorates; and that any constitutional reconstruction should take into consideration not only the provinces of British India but also the Indian states. Since the report contained no mention of dominion status and expressed doubts about the suitability of a parliamentary system of government in India it met with a hostile reception.

The Round Table Conferences. — Between 1930 and 1932 three conferences were held in London to enable representatives of the various Indian communities and of the three British political parties to consider proposals for the future constitution of India. Because of the refusal of Congress to co-operate the first conference (Nov. 1930–Jan. 1931) was representative only of a minority of politically minded Indians. Nevertheless, the success of this conference, at which the general principle of an all-India federation was accepted, was a severe blow to the influence of Congress and was an important factor underlying what is called the Irwin-Gandhi pact of March 1931, whereby the government of India agreed to release all political prisoners provided Congress would suspend the civil disobedience campaign. This was followed by a temporary improvement in the Indian situation, and Gandhi attended the second London conference (Sept. 7–Dec. 1, 1931) as the sole spokesman of Congress. For many reasons he was unable to make any constructive contribution to the deliberations of the conference and failed to bring about any solution of the communal problem. On his return to India early in 1932 he again fomented civil disobedience and was promptly arrested by Lord Willingdon. who had taken over the viceroyalty in April 1931. Because of the difficulties revealed at the second conference a franchise committee under Lord Lothian, a federal

finance committee under Lord Eustace Percy and an Indian states inquiry committee under J. C. C. Davidson proceeded to India for further investigation of these problems. For the same reason, in Aug. 1932, the British prime minister, Ramsay MacDonald, made his communal award by which the existing system of communal electorates was preserved and the depressed classes recognized as a minority community. This did not prove acceptable to Gandhi, who was in prison at Poona; and in deference to his wishes the caste Hindus and the depressed classes accepted a scheme known as the Poona pact, by which a larger number of seats was reserved for the depressed classes. After a third conference (Nov. 17–Dec. 24, 1932) which chiefly concerned itself with a consideration of the reports of the Lothian, Percy and Davidson committees, the British government elaborated its draft proposals, which were examined by a joint select committee of lords and commons assisted by specially selected Indians. From these discussions emerged the Government of India bill of 1935.

The Act of 1935.—The three main principles underlying the new constitution were an all-India federation, provincial autonomy and responsibility with safeguards. The federation was not to come into operation until the rulers of Indian states representing not less than half of the aggregate population of the states signified their desire to accede. Each state had to sign a separate instrument of accession, but for the provinces entry into the federation was compulsory. Power to amend the constitution was vested in the British parliament, and a federal court was to be established to determine disputes between the constituent units of the federation. For the central government a system of dyarchy was devised whereby all departments, with the exception of foreign affairs and defense, were to be in charge of ministers responsible to the federal legislature consisting of a council of state and a house of assembly. The council of state was to be composed of 156 representatives of British India directly elected on a population basis, with the exception of six seats reserved for nomination by the governor-general; and not more than 104 representatives of the Indian states appointed by the rulers of the states concerned. The house of assembly, which was to be reelected every five years, was to consist of not more than 125 nominees of the states and 250 representatives of British India elected by the provincial legislatures. Communal representation was to be retained both at the centre and in the provinces. Because the federal legislature never came into operation, the central constitution continued to be that of the 1919 act.

British India was to be divided into 11 governor's provinces (Madras, Bombay, Bengal, United Provinces, Central Provinces, Punjab, Bihar, Assam, North-West Frontier Province, Orissa and Sind). Burma was separated from India, and Aden placed under the colonial office. Responsibility of the executive to the legislature was to be the basic principle of government in the provinces; the governor's special powers were to be exercised only in an emergency. British Baluchistan, Delhi. Ajmer-Menvara, Coorg and the Andaman and Nicobar Islands were to be administered by chief commissioners responsible to the governor-general. Except in the Central Provinces, Punjab, North-West Frontier Province, Orissa and Sind, the provincial legislature was to be bicameral. Provincial autonomy was established April 1, 1937.

The proposals for an all-India federation were bitterly assailed by Congress politicians on the ground that there was no true basis for a federation since the Indian states did not approximate to the provinces of British India in the establishment of responsible government, civil liberties and method of election to the federal legislature. Great exception was also taken to the reservation in the hands of the viceroy of powers over defense and foreign affairs. Moslems fought shy of the federation because it would strengthen the Hindu predominance in the central legislature. Although the states had at first supported the proposals for a federation their attitude gradually changed as they came to realize the sacrifice of sovereignty required of them.

At the first general elections in Jan. and Feb. 1937 the Congress party secured large majorities in all provinces except Bengal, the Punjab, Sind and Assam but refused to accept office unless provincial governors pledged themselves not to use their special powers of interference or to set aside the advice of their ministers. Since the governors declined to compromise their statutory powers it was not until June 1937, when Lord Linlithgow announced his intention of striving for "the full and final establishment in India of the principles of parliamentary government," that Congress ministries were formed and the minority cabinets, which had bridged the gap, disappeared. During their period of office from July 1937 to Sept. 1939 communal tension increased because of the grievances of Moslems under Congress rule in Bihar and the United Provinces. This was aggravated by the claim of Congress to represent Moslems as well as Hindus, a claim vigorously opposed by the Moslem league under Jinnah. As a result of Congress agitation for constitutional reforms in the Indian states serious disturbances broke out in Mysore, Hyderabad, Kashmir and Travancore. The new provincial governments were also confronted with agrarian unrest and with industrial disputes, the result of Communist propaganda. But useful social and agrarian legislation was introduced. Relief was given to certain classes of agricultural tenants, the burden of peasant indebtedness was reduced and an attempt was made to enforce prohibition.

World War II.—When war broke out in Sept. 1939 India was declared a belligerent by the governor-general without even the pretence of consultation with the central legislature or the provincial governments. The result was that Congress, although expressing its condemnation of nazi aggression, refused to associate itself with the war effort unless India were declared an independent nation. The governor-general therefore announced that dominion status was already envisaged by the British government as the goal of its policy and that at the end of the war it was prepared to modify the act of 1935 in consultation with the leaders of the various Indian communities and parties. At the same time he proposed to establish an advisory council representative of all major Indian interests in order to associate Indian public opinion with the prosecution of the war. This assurance did not satisfy Congress, and in Nov. 1939 all Congress ministers resigned on the ground that the British government had failed to make an acceptable declaration of its war aims. The governors of the provinces concerned therefore assumed powers in accordance with section 93 of the act of 1935.

India's contribution to the war effort, though impeded by the refusal of Congress to co-operate, was magnificent. In 1939 the Indian army consisted of about 200,000 regular soldiers. By 1945 the government of India had recruited on a voluntary basis more than 2,000,000 Indians, the largest voluntary recruitment ever recorded in history. Indian troops served with distinction in all theatres. They played a major part in the first Allied victory of the war, the conquest of Italian East Africa. Out of the 1,000,000 troops engaged in the final Allied victory of the war, the defeat of the Japanese in Burma, 700,000 were provided by the Indian army. India's total casualties during the war were 179,935, of whom 24,338 were killed or died of wounds, 11,754 were reported missing. 64,354 were wounded and 79,489 were prisoners of war. But India's most important contribution was economic and the development of the industrial system enabled India not only to produce the bulk of military supplies needed at home but also to equip the imperial armies in Africa and the middle east. Many hitherto neglected resources were exploited, and the war saw a remarkable revival of the old Indian industry of shipbuilding. The net expenditure on defense rose from £34,500,000 in 1939 to £300,000,000 in 1945. One result of the Allied calls on its resources was to transform India from a debtor to a creditor nation with accumulated sterling balances at the end of 1945 amounting to about £1,250,000,000.

On several occasions during the war attempts were made to put an end to the political deadlock. On Jan. 10, 1940, Lord Linlithgow announced that the object of the government of India was the development of full dominion status in accordance with the Statute of Westminster. But in March of the same year the Moslem league under Jinnah's leadership condemned the act of 1935 as unacceptable to Moslems, whose aim was the establishment of an autonomous Moslem state embracing the areas where Moslems formed a majority of the population.

Once more in Aug. 1940 the viceroy repeated his statement that dominion status was the goal of British rule in India and announced that the British government wished India to enjoy that position under a constitution framed primarily by Indians as soon as possible after the end of hostilities. At the same time Indian political leaders were invited to serve as heads of departments on the viceroy's executive council. The reply of Congress to this proposal was that India should be granted immediate independence and that the task of drafting a constitution should be committed to an assembly elected by universal suffrage.

In Dec. 1941 Japan entered the war and in the opening months of 1942 occupied Singapore, Malaya and the Andaman Islands, overran Burma and threatened India with invasion. In spite of all this the political deadlock remained. On March 11, 1942, Winston Churchill. the British prime minister, announced that it had been decided to send Sir Stafford Cripps. a member of the war cabinet, to India with proposals for a settlement of the Indian constitutional problem. It was proposed to create a new Indian union as a fully independent dominion. As soon as the war ended, a new constitution was to be framed by a body consisting of elected representatives of British India and nominees of the Indian states. Membership in the proposed union was not to be compulsory, and dissenting provinces were to be free to form separate unions. Until the new constitution of the Indian union came into being the British government was to be responsible for the defense of India with the help of an Indian government composed of members of all parties and with the full co-operation of the Indian people. These proposals were rejected by Congress because they did not comply with its demands for the immediate establishment of a fully independent national government and by the Moslem league because they did not meet its wishes for an independent Moslem state. On Aug. 8, 1942, Congress passed a resolution calling upon the British to "quit India" immediately, failure to comply to be the signal for mass civil disobedience. This was followed by widespread disorders in the autumn of 1942, which were suppressed by the end of the year uith the arrest of the Congress leaders. Meanwhile, in 1941, Subhas Chandra Bose, a left-wing nationalist extremist, had escaped to Berlin, where he was made the focus of an anti-British, anti-American Indian "freedom movement." In 1943–45, successively in Singapore, Rangoon and Bangkok, he headed a "provisional government of free India" which in July 1943 set up the "Indian National army (I.N.A.)," composed of Indian prisoners of war and deserters and Indian residents in overrun British territories, to fight with the Japanese on the Burma front. The extent and effectiveness of I.N.A. participation, though this certainly took place at times in some strength, has not been finally assessed. Bose died after an air crash in 1945.

In 1943 and 1944 more than 1,500,000 people died in India as a direct result of famine and the epidemics that followed in its wake. The Bengal famine of 1943 was caused by the failure of the main rice crop harvested in the winter of 1942. This, unfortunately, was aggravated by the loss of Burma rice caused by the war with Japan and by a failure to ensure an equitable distribution of the available supplies. In Oct. 1943 Lord Linlithgow was succeeded as viceroy by Lord Wavell.

INDIAN INDEPENDENCE

With the end of World War II and the return of a Labour government to power in England it was announced that elections would take place to the central and provincial legislatures in India and that as soon as possible afterward a constitution-making body would be convened. In Feb. 1946 it was decided to send a British cabinet mission to India to discuss with the viceroy and Indian political leaders the constitutional future of the country.

When the mission reached India in March, responsible ministries were functioning in all provinces for the first time since 1939. Since the main political parties failed to reach an agreement, the mission was forced to produce its own scheme. Until an elected constituent assembly had decided on India's future constitution, it was proposed to set up an interim government in which all portfolios would be held by Indians. The demand for a separate Moslem state of Pakistan was rejected as incompatible with the requirements of Indian defense. Eventually the Congress party agreed to form an interim government, which came into office on Sept. 2 with Nehru as vice-president to the viceroy. This was followed by Hindu-Moslem clashes in which about 7,000 persons were killed. When the constituent assembly met on Dec. 9, 1946, it was boycotted by the Moslem league and the Indian states. On Feb. 20. 1947, the British government announced its intention of transferring power into Indian hands by a date not later than June 1948. At this juncture Lord Wavell resigned and was succeeded on March 23, 1947, by Viscount Mountbatten, who after a series of consultations with Indian political leaders announced that the only solution was the division of India into two separate states. An Indian independence bill became law on July 18, 1947. Its effect was to set up on Aug. 15, 1947, two completely independent states in India, the Dominion of Pakistan and the Dominion of India, their eventual boundaries in the Punjab and Bengal to be determined by a commission presided over by Sir Cyril Radcliffe. Partition mas the signal for mass migrations accompanied by hideous massacres, but by the end of Sept. 1947 the fury of the slaughter had died down. Gandhi's supposed responsibility for the partition of India was given as the reason for his assassination on Jan. 30, 1948, by a member of the Hindu Mahasabha.

On June 21, 1948, Mountbatten was succeeded as governor-general of India by Chakravarti Rajagopalachari, a distinguished Madrasi Brahman and a minister in the interim government.

India's desire to reach more than dominion status was soon formally expressed; and the draft constitution of Feb. 1948 proposed that it should be a federal republic. The London commonwealth prime ministers' conference of April 1949 agreed that India could adopt this republican constitution yet remain within the British Commonwealth (as the Indians had decided to do in 1948). The constitution itself came into effect on Jan. 26, 1950. The first president of the new republic was the former chairman of the constituent assembly, Rajendra Prasad. a devoted Gandhian. Nehru, who had become prime minister of the dominion in 1947, continued in office under the republic. During 1948–50 the outstanding feature of internal affairs was the modification of the provincial structure. The governors' provinces (or "states," as all the federated units were now to be called) remained more or less as in British days—except, of course, for the partitioned Punjab and Bengal. But the continued separate existence of about 570 princely states, ranging in area from that of France to that of the City of London, was clearly out of the question. With the passage of the 1947 independence act British paramountcy over these states lapsed. Together, they contained nearly half the country's area and nearly one-third of its population; and the immense task of making them part and parcel of the ne nation was entrusted to the deputy prime minister, Vallabhbhai Patel.

The big south Indian state of Mysore was considered capable of continued provincial autonomy, and its maharaja remained at its head as *rajpramukh* (*q.v.*) or constitutional "prince president." Many of the smaller states, however, were grouped into more manageable "unions," each under a *rajpramukh;* one such union, Saurashtra, absorbed no fewer than 222 states in the Kathiawar peninsula. Other principalities were taken over by the central government and administered, either singly or in convenient groups, through chief commissioners. The remainder, mostly those interspersed with the districts of governors' provinces, were merged with those provinces. The refusal of the Moslem nizam of Hyderabad to accede his mainly Hindu-populated state led to its occupation by Indian troops in Sept. 1948; following his enforced accession he was left at the head of his people as *rajpramukh.* In 1952–54 there was increasing pressure from some quarters for the redrafting of internal boundaries on a linguistic basis: in Oct. 1953 Andhra state, composed of the Telugu-speaking districts of northeastern Madras, was inaugurated.

The government at first resisted the establishment of further linguistic states, but the commission appointed in 1953 to examine the-whole question of state reorganization recommended in

Sept. 1955 a drastic redrafting of boundaries largely on this basis. This the government accepted in Jan. *1956*, proposing, however, to divide Bombay state into Gujarati- and Marathi-speaking provinces, leaving aside as a nationally administered "city-state" Bombay city, 20% of whose population comprised wealthy Gujaratis, 50% working-class Marathas. This last proposal caused serious riots in the city.

India's relations with Pakistan were marred from the outset by a dispute for the possession of Kashmir (*q.v.*), which, in spite of the attempts of a Gnited Nations commission to arrange a settlement, remained partitioned de *facto* into two states. On May 14, 1954, President Prasad extended the Indian constitution to Kashmir. Another cause of friction was Pakistan's refusal to follow India in devaluing the rupee in terms of the dollar; in consequence Pakistan stopped jute supplies to India and India suspended coal exports to Pakistan. The deadlock was ended on Feb. *25*, 1951, by a trade agreement. In Aug. 1953 Nehru and Mohammad Ali, the Pakistan prime minister, reached accord about a Kashmir plebiscite; but in 1954 relations were again troubled by Pakistan's military aid negotiations with the U.S. and by a dispute about the control of the Punjab river waters. On Oct. *21*, 1954, the long-standing dispute with France about the latter's settlements on the Indian coast was ended by an amicable agreement for their merger into India. This was carried out on Nov. *1*, and on Jan. 6, 1955, the four settlements were reorganized as the chief commissioner's state of Pondicherry (*q.v.*). Portugal continued to insist upon its sovereign rights in Goa, Damão and Diu, despite agitations by "nationalists" and mass frontier crossings. On Dec. *18, 1961*, however, Indian troops invaded the three enclaves, and the following day the Portuguese forces surrendered.

The 1952 general elections, the biggest ever undertaken by any country, confirmed Nehru and Congress in power. But the Communists, especially successful in Madras and Travancore-Cochin, emerged as the principal opposition. Even after China's aggression in Korea, its assertion of sovereignty in Tibet and its support of Vietminh in Indochina, Indian public opinion did not seem to consider Communist expansion to be a serious threat. Guided by Nehru in foreign policy, India declared its "noninvolvement" with either the Soviet bloc or the west and trusted to negotiation to settle international difficulties. Nehru offered friendship to all, based on his *panch sila* or "five points" (see NEHRU, JAWAHARLAL). This position was confirmed by his speeches at the Asian-African conference at Bandung, Indonesia, in April *1955* and maintained in the face of a successful tour of India by the Soviet leaders N. A. Bulganin and N. S. Khrushchev in Nov.–Dec. *1955*.

ETHNOLOGY

Races.—It is generally accept'ed that in remote antiquity India was occupied by a Negroid people of low culture, ethnically related to the aborigines of Ceylon, Sumatra and possibly even Australia. At a still prehistoric stage, it is believed that an inflow of what are loosely called Dravidian races made its way through Baluchistan from western Asia and slowly penetrated India to the far south. Another prehistoric movement, more restricted in its scope, was an infiltration of Mongoloid races from the northeast. The fusion of these elements with the indigenes had probably gone far when the invasions through the northwest passes began.

From that period successive waves swept through and were largely absorbed among the older inhabitants. Seven racial types can be traced with some confidence; for them Sir H. Risley's names are provisionally retained though some are now mere labels.

1. The aboriginal, or pre-Dravidian, type, surviving in the short, platyrrhine men of certain scattered primitive tribes of the hills and jungles, such as the Santals, Bhils, Kurumba, etc.

2. The Dravidian type, extending from Ceylon, all over the southern peninsula. up to the Gangetic valley.

3. Indo-Aryans in Rajasthan and Punjab.

4. The Aryo-Dravidian, or Hindustani, type in the Gangetic valley, the product of the absorption into a mainly Dravidian population of colonies from the more definitely Indo-Aryan country farther west.

5. The Scytho-Dravidian type, running east of the Indus, down through Gujarat and the western part of Bombay and represented chiefly by the Marathas.

6. The Mongoloid type, in Assam and the foothills of the eastern Himalayas, clearly originating in China and Tibet.

7. The Mongolo-Dravidian type, probably a blend of Dravidian and Mongoloid elements, with a strain of Indo-Aryan blood in the higher groups, of which the Bengalis are representatives.

The discoveries at Mohenjo-Daro in Sind include the skeletal remains of a dolichocephalic (longheaded) people, who, in Sir John Marshall's opinion, "may reasonably be assumed to have belonged to the great longheaded race of southern Asia and Europe to which the name 'Mediterranean' is commonly applied." One skull approximating to the brachycephalic (roundheaded) type, which seems to possess the same characteristics as the pronouncedly brachycephalic statues, was found.

These remains are of the Chalcolithic period and subsequent to the abandonment of the latest city (c. *2500* B.C.). Two skulls found buried deep in alluvial deposits near Bombay are perhaps *2,000* years old and were regarded by Sir Arthur Keith as of the small size and narrow shape now prevalent in India. Two of the skulls discovered at Aditanallur in a prehistoric burial site are conspicuously prognathous (with prominent jaws), and others are markedly longheaded, a feature still noticeable in south India.

In early Indian literature mention is made of people having the complexion of a charred stake, flattened features and very short stature, a type quite common in the present population.

The Andamanese (*see* ANDAMAN ISLANDS) are typical Negritos and may be considered to be a pure race. It is possible that this Negrito element may at one time have existed on the Indian subcontinent, but it has left no traces in the present population. More widely spread is a stock marked by short stature, longish heads, broad noses, very dark skins and curly, even frizzly, hair and lips inclined to be everted. This class includes in its numbers the jungle tribes of southern India and of Chota Nagpur, the lower castes in western Bengal and to a slight extent the lowest castes in upper India. This element appears to be related to the Veddas of Ceylon, the Sakai of Malaya and the Australoids.

An important element, conspicuous in southern but found in western India as well, is longheaded, with medium to fine noses, shortish, with darkish skin and fine wavy hair. The lips are thin. This element resembles in many respects, the Mediterranean stock. The dominant element in the northern, especially the northwestern, area is tall. longheaded, with fine noses, fair skins (allowing for the effects of exposure to the sun) and in many instances light-coloured eyes. The lips are thin. It is a type represented among the higher castes of Bengal, and the Nambutiri Brahmans of Malabar, the Nayars, the Coorgs and the Todas also must be regarded as of this stock. In the mountain regions on the west and in Baluchistan is found a roundheaded stock, fairly tall, with fine features, wavy hair, ranging from dark brown to fair, and occasional lightish eyes, which seems to be affined to the Alpine stock. A somewhat similar roundheaded element can be traced along the west coast but is darker in skin, hair and eyes.

Many groups in central, northern and eastern Bengal have Mongoloid features, and the Savaras on the east coast in the state of Andhra have the Mongolian eyefold. While these main elements may be distinguished in the Indian population, miscegenation has taken place in varying intensity under different conditions all over the continent from prehistoric times.

The dissociation of language and race is complete in many parts of India so that terms such as Aryan or Dravidian have no significance when attached indiscriminately.

Languages. — The linguistic survey of India made at the 1951 census suffered from two radical defects. First, an attempt fully to affiliate dialects to their parent languages was made in only four states; in four others only the more obviously assimilable dialect returns were combined with parent language data; and in the rest of India, in contrast with the 1931 survey, no affiliation was made. Thus no fewer than 782 "languages" were listed. Secondly, in northwest India there was wholesale falsification of returns because of agitation by certain Hindu political factions that people should return Hindi instead of Punjabi as their mother tongue. Therefore only a combined all-India total could be given for the important Hindi-Urdu-Hindustani group and Punjabi.

The 1951 data for languages "specialized" in the constitution (*i.e.*, the *lingua franca* and the greater regional languages) were as follows:

Hindi, Urdu, Hindustani, Punjabi	149,944,311	Bengali	25,121,674
Telugu	32,999,916	Gujarati	16,310,771
Marathi	27,049,522	Kannada (Kanarese)	14,471,764
Tamil	26,546,764	Malapalam	13,380,109
		Oriya	13,153,909
		Assamese	4,988,226

Kashmiri (5,086 speakers outside Kashmir, where no census was taken) and Sanskrit (555 speakers) are also specified in the constitution.

In addition 23 tribal languages were spoken by 100,000 or more people each; 24 other Indian tongues were used by 100,000 or more people each; and 720 languages and dialects were spoken by less than 100,000 people each. (ME.; X.)

SOCIAL INSTITUTIONS

Caste. — So far as Hinduism is concerned, the intermixing of the racial types described above left one definite ethnical legacy in caste; for it is apparently from the difference in civilization and political power resulting from the imposition of successive strata of conquerors over the conquered that the Hindu system of caste arose. The census report of 1911 defined a caste as "an endogamous group or collection of such groups bearing a common name and having the same traditional occupation. who are so linked together by these and other ties, such as the tradition of a common origin and the possession of the same tutelary deity, and the same social status; ceremonial observances and family priests, that they regard themselves, and are regarded by others, as forming a single homogeneous community." Not only is the caste usually endogamous, but within it there are a number of smaller circles, each of which is also endogamous. Caste has come to be the chief factor in the life of the ordinary Hindu, regulating his acts from the cradle to the grave; and its influence extends to the Mohammedan masses who are descended from the more recent converts to Islam. (*See* CASTE [INDIAN].)

Aryan Settlement. — The evidence as to the social system of the early Vedic Aryas is singularly vague. They were settled in the Punjab between the Indus and the Sarasvati, but had also occupied lands on the Jumna and even on the upper Ganges. This area was of very varying fertility. Probably the central Punjab was then, as later, a barren steppe; but the riverain tracts, the Kurukshetra and the sub-Himalayan belt were doubtless fertile, well-wooded and possibly densely forested. We may thus expect to find pastoral types in the steppes and agricultural in the cultivable areas. We have no good reason to assume that the Aryas found these lands unpeopled; on the contrary the pre-Aryans of the north were probably quite as advanced as the Dravidians. who seem to have been settled in villages from an early period. Even in the Rig-Veda we find mention of measured fields and of ploughlands. The village (*grama*) sometimes contained a fort (*pur*), doubtless a tower, and might be of considerable size. Grain was certainly stored; so the villagers cannot always have been nomadic; but hints are given that the village-folk were in places a body of herdsmen, wandering in search of pasture under the guidance of the god Pushan. Of the social economy of the settled villages we learn little. At its head was the village leader, but he seems to have been the chief of its militia, often connected with the *senani*, or "leader of the host," which would be quite compatible with the exercise of civil or fiscal functions.

Of village councils we hear nothing, although assemblies (sabha *samiti*) of the people met to advise the king; but in the epics they disappear.

The village body included such artisans as the *rathakara*, "chariotmaker," carpenter! smith and others, but they are not described as members of it. Only once do we read of a *gramyavadin*, seemingly a village judge. Indeed, we find no term to define a "village-owner" in any way equivalent to the modern usage. On the other hand the king's relation to the soil is equally indefinite. That he was not formally its superior owner is clear, yet he could grant villages or assign his fiscal rights over them to favourites, though such gifts to Brahmans were reproved. And later the idea developed that he was legal owner of the soil, and that his grantees were landlords. Doubtless the feuds between nobles and people arose out of these nebulous relations.

When we turn to the Vedic organization of the tribes the darkness deepens. The *vish* was the people as opposed to the *kshatra*, "nobility," but originally the word doubtless meant "settlement" or merely "dwelling." and the head of it was the *vishpati*, its "lord"; but again the king is *vishpati* as "lord of the people." The *vish* did not, however, include all the *jana*, a term which means "man" and collectively "people," or "tribe." It seems to have denoted the "host" collectively as well as units of it; but whether those units were clans or cantons is not explained, and we have no mention of either tribal chiefs or headmen of cantons. We cannot, however, be very wrong if we picture the Aryan hosts as composed of tribal rather than territorial levies under their own "kings" (*vishpatis*), obeying the *senani* or *senapati* with village leaders under them.

Villages, Gotras and Families. — The process whereby the Aryan village developed into the modern village community is nowhere described, but it is not difficult to form some idea of it. First of its factors must have been a change in inheritance laws which now gave each son an equal share in the paternal land. This stereotyped the sept, or *gotra*. Meaning at first merely a "herd," or "cowstall," this word assumed later a new significance. A change of *gotra*, once quite possible, became unthinkable, and marriage within it was disallowed. The older system had prohibited it only within three or four degrees on either side and even so permitted a union with the daughter of a paternal uncle; but some instinctive dread of inbreeding seems to have extended the exogamous principle not only to the whole *gotra*, necessitating its immutability, but to the descendants of three more kinships. the mother's and the grandparents'. The result was a solidifying, as it were, of the proprietary body which held a village or a number of villages, whether grouped or dispersed. This principle was applied with equal stringency to nonlandholding castes of all degrees, though it was often relaxed so as to exclude only one or two kinships beside the paternal *gotra*, and in extreme cases it might be further relaxed by splitting even that *gotra* in two, after a long period of time had reduced the perils of inbreeding to zero. The original *gotra* indeed seems to have been an artificial unit, at least among the Brahmans, whose *gotras*, named after the semimythical sages (*rishis*), may well have included their disciples as well as their own issue. Not until the epic period do we find one of the *Upanishads* enunciating the rule that spiritual succession must descend from father to son, thus closing the *gotra* to new blood. It is, however, important to note that in the south the exogamous instinct still permits cross-cousin marriage.

The village community no doubt has been and still is a real commonwealth. But if we ask how it has enforced its collective will, we shall find it rarely evolving a constitution written or unwritten. Sporadically, in the south of India some interesting inscriptions of the 10th century tell us of village committees. under royal control, on which the members sat in rotation determined by lot and on which a low-caste man was eligible if he had undergone expiation. But elsewhere investigation fails to trace any ordered forms of village rule. The convention of the village owners; often called its *panchayat*, or "council of five." includes in fact all its members. Its headmen rarely possess definite authority. Yet it has achieved much: it has enabled provinces devastated by war to reconstruct their rural economy; it has

helped vaster areas, ruined by repeated famines, to recover their prosperity; it has repeopled regions left desolate by massacres like those of Timur. But it has failed to set up any working system of self-government on which could be grafted a legal structure.

No doubt the Indian village varies in the types of its tenures. In the north its lands may be held on the precise shares heritable by descent, the tenure favoured by the Rajputs. Or it may be that in the fragmentation of the holdings ancestral right is no longer the measure of actual occupatiori which has been allowed to individual coparceners according to their energy and enterprise; so that the industrious, having brought much of the common waste under the plough, have bequeathed to their descendants, on its final partition. an indefeasible right to the lion's share of what is left of it. Much has been done to consolidate holdings, by enforced mutual exchange of scattered ones. but only under state action. In the south of India a more individualistic system was observed to exist by the earliest British administrators. There they found the village not strictly regarded by its former rulers as collectively responsible for the payment of its land tax, and consisting of individual holdings. The village community therefore was held to be less often existent; and the *ryotwari,* or system whereby each holder paid his own land tax to the government. was favoured. The repercussion., of these economic phases in Indian society have been marked. The refusal to endure primogeniture fragmented wealth too rapidly and above all impoverished the smaller gentry who were compelled to adopt widow-remarriage as an economy. The denial of all testamentary power to the father weakened social discipline. Hindu law and custom often almost entail property on all the sons alike, abolishing incentives to effort in the cadets.

Indian society must not be regarded as aristocratic but as an infinite series of democratic strata lying one above another. Within the *gotra,* now the *got* or whatever its modern synonym may be. all men are equal. But the dictum at once calls for qualification. Within the *got* individuals shall not excel, but groups may; and so where a *got* holds a big cluster of villages and hamlets. one or two bigger, older or more prosperous than the rest mill set up a claim to be superior to the rest. This superiority will be manifested by a denial of brides to a hitherto equal clan, more extravagance at births. weddings, funerals and so on. But as the cost of placing daughters hypergamously or even isogamously is prohibitive, they will be made away with or so neglected that their chances of life are far below those of boys. Hence there is a loss of almost a moiety of the best-bred strata in the finest *gots,* an unparalleled sacrifice on the altar of snobbery. But the repercussions spread further. The *gotra* must always have been an unprogressive body, its pace being that of its slowest members, and the *got* has inherited its retardation and has rarely if ever created a council of canton or tribe. It has had a keen spirit of tribal self-esteem. It has done nothing to advance self-administration in the village or over it.

So far what has been said applies peculiarly to the Hindu castes, including the Sikhs and Mohammedanized tribes which hold the plains of northern India. In the south, caste is tenser, but there is less apparent tendency to subdivide socially. On the other hand two great factions—the right-hand, which is headed by the Brahmans and includes curiously the Pariahs; and the left-hand. headed by the Panchalars, the "five-castes." workers in stone, metal. etc., and including the Pullars or Pullans—have been formed.

How the feud between these factions originated is unknown. The causes of collision were trivial and apparently for the most part of a purely sumptuary character. The Pullans are agricultural serfs, little. if at all, above the Pariahs. Offspring of a Brahman woman by a Shudra, Devendra, they say created the work for the Tamil peasantry. which hints at a pre-Tamil origin. A stocky, sturdy black man eating meat (but not beef, and so superior to the Pariahs). the Pullan specializes in the cultivation of wet riceland. but is excelled by his womanfolk. Some old sumptuary law forbade a Pullan woman to be clothed above the waist, and when Christian converts broke this rule disturbances ensued. Divided into numerous endogamous and innumerable exogamous groups, they trace descent through females and bury their dead. Yet they adopted some Hindu gods and even claim descent from Indra. In a faction fight they form the vanguard, as do the Pariahs on the other side. Yet, low in the caste as they are, the Pullans evince a consiilerable power of self-organization. They have caste-couricils. which punish theft and adultery, and discipline is enforced by flogging (of both sexes) or expulsion.

In northern India it may be said that caste self-government is confined to the artisan castes, with occasional guild committees among the traders. But no general assemblies ever seem to have existed. The traders settle commercial disputes in townships and their associations may also decide matrimonial questions, but the latter form the main if not the sole matter which interests the artisan *panchayats* or juries. These are presided over by elders, usually hereditary. and sometimes have an appellate system. Because of the dispersion of such castes, the jurisdictional area may be large and it is often contermirious with an old fiscal area.

To sum up, the social organization of India presents a wide range of complexity from the simple tribe, an endogamous group with its exogamous subdivisions, or from the local group, be it village or simple hunting group, with local exogamy, divided into family groups (the debris or the rudiments of a clan system), to an organized polity wherein the castes are ranged in order of purity, which is determined by factors deep in the history of the people, some economic, others racial, others purely political. Clearly, there was in ancient India an advanced urban organization, the influence of which upon the social history, upon the development of caste, upon the economic and industrial life of India has not yet been explored. The family, be it joint or divided, is ultimately in India, as elsewhere, the primal unit in the social organization within which are built up the dispositions which, universalized within the society, become its institutions. Kinship —whether matrilineal: as in Malabar, or, as more generally, patrilineal—is with the *got,* or clan system, reckoned unilaterally; but with the system of cousin marriage, still, as in the early days, typical of southern India, from the highest to the lowest groups, the true bilaterality of the family appears. In this vast area marriage rites have been developed to great variety. The caste system exhibits even now, with a vigorous endogamy strong with religious and social sanctions, the principle of separatism, of emphasis on the differences between groups, and it finds scope for perennial application. *(See* CASTE [INDIAN]; also CLAN; COUSIN MARRIAGE; FAMILY; HINDUISM; HYPERGAMY; LEVIRATE; POLYGYNY; SORORATE; TRIBE.)

RELIGIONS

According to the census of undivided India taken in 1941, the numbers of adherents of the principal religions were as follows: Hindus *254,930,506*: Moslems 92,058,096; Christians *6,316,*549; Sikhs 5,691,447; Jains 1,449,286; Buddhists 232,003; and animists and others 25,873,846 The Sikhs were found mainly in the Punjab and adjacent states (their homeland was almost bisected by the partition); more than two-fifths of the Jains were in Bombay and its states, including Baroda; and all but *28,620* of the Parsees were in Bombay. The other religions were widely distributed *(see* below). At the 1951 census the following was the position (first figure is for republic of India, figure in parentheses for Pakistan): Hindus *303,186,986* (9,770,000); Sikhs *6,219,134;* Jains 1,618,406; Buddhists *180,767 (319,630);* Zoroastrians (Parsee and Irani) 111,791 (5,356); Moslems 35,400,117 (64,959,000); Christians 8,157,765 (541,000).

The oldest of these religions is animism, which represents the beginnings of religion in India and is still professed by the more primitive tribes, such as Santals, Bhils and Gonds. The transition from this crude form of religion to popular Hinduism is comparatively easy. The most obvious characteristics of the ordinary Hindu are that he worships a plurality of gods, looks upon the cow as a sacred animal, regards certain rivers and pools as holy and accepts Brahmanical supremacy and the caste system; and when it is a question whether one of the animistic tribes has or has not entered the fold of Hinduism, these seem to be the proper tests to apply.

On the other hand there are various offshoots from orthodox Hinduism, the distinguishing feature of which, in their earlier history at least, is the obliteration of caste distinctions and the rejection of the Brahmanical hierarchy. It is doubtful if Buddhism, and still more so if Jainism and Sikhism, all of which are commonly recognized as distinct religions, ever differed from Hinduism to a greater extent than did the tenets of the earlier followers of Chaitanya in Bengal or those of the Lingayats in Mysore; and these three religions are therefore presented here only in their relation to the general development of Hinduism, their particular features being discussed in separate articles.

HINDUISM AND ITS OFFSHOOTS

Pre-Vedic Animism.— In the beliefs of the most backward tribes of India, observers have detected animism, definable concisely as a worship of spirits including impersonal forces But it is doubtful if Indian animism ever had any real conception of an impersonal force. It lacked quite completely a vivid idea of personality. The Santal, who still believes that if he takes a false oath on a piece of tiger skin he will be devoured by a tiger, does not seem to attribute any impersonal power to the relic, but to regard it as a convenient substitute for the live tiger which mill eat him if he calls upon him to do so in his oath and then commits perjury: So inchoate is the concept of personality that his primitive mind fails to draw much distinction between inanimate things and living beings. It is equally incapable of realizing death. Accustomed to obey his living village chiefs, he continues to placate them when dead. but worships neither their ashes nor their memorial stones nor their spirits. The last are not deified or even ranked as specially endowed *bongas,* the so-called spirits who in human shape marry Santal men and maidens, cause disease and mischance when so bidden by witches and display gratitude in tangible form by material acts. The Santals seem to have no words of their own for ghosts or spirits and their native god is Marang Buru, the "great mountain," whose personality can only be described by using a borrowed term, *deo,* the Sanskrit *deva,* and whose main function appears to be the instruction of maidens in witchcraft. But the Santals cannot be safely regarded as typical pre-Aryans. They dwell in the eastern outskirts of the Chota Nagpur plateau and are hunters in the forest, not assiduous cultivators. In more favoured localities the Dravidians may have attained a much higher civilization. Still less can we be certain that the conceptions of impersonal forces, of the soul and of a future life were unknown to them before the Aryan conquests.

Vedic Theology.— The *Vedas* however display much loftier conceptions. The cosmogony of the *Rig-Veda* fluctuates between two theories, one regarding the universe as the work of a great architect, the other as the result of natural generation. In the first Indra measured out the six regions, made the expanse of earth and the dome of heaven. He and other gods built a cosmic house of timber, framed on posts but rafterless; and why the sky does not fall is a marvel. Savitri made fast the earth with hands, Vishnu fixed it with pegs and Brihaspati supports its ends. In a frame Indra fixed the air, and the morning light enters by the portals of the east. But the generation theory is more complex. Dawn, Ushas, born of Night, generates the Sun and morning sacrifice. But parentage is more easily assigned to place than it is to time; so Heaven and Earth, containing all, are universal parents. Dyaus, the sky, is father; the Dawn is his daughter. Generically again, he who is the chief, the most prominent of a group, is their parent. Vayu, the wind, fathers the storm-gods; Rudra, the Maruts (*q.v.*) or Rudras; Soma, all plants; and Sarasvati, all rivers. But abstractions are already used figuratively so that the gods are "sons" of immortality and of skill: Agni is son of night; Pusan, of freedom; and Indra, of truth. This concept recalls the Semitic idiom. On the other hand, in the latest canto of the *Rig-Veda* the world is primitively imaged as a giant from whose members sprang the universe, as Indra and Agni from his mouth (which also became the Brahmana); the Rajanya, "warrior," from his arms; and the Vaishya, "commonalty," from his thighs. His head became the sky; his navel, the air; and his feet (which also produced the Shudra), the earth. Moreover, the gods are also moral, all are true and "not deceitful," friendly to honesty and righteousness. In this aspect Varuna (*q.v.*) is foremost. The Vedic gods however lack individuality and clearness of outline. Already in the *Rig-Veda* they are said to be 33 in number, a figure constantly increased. And these gods are graded, classed as celestial (those who dwell above the firmament), aerial and terrestrial.

But when we inquire into each god's special functions we find a singular vagueness, a puzzling overlapping of jurisdictions. It is as if the Vedic Aryans had been formed of a confederacy of tribes, each affecting a god of its own, not differing much one from another, often bearing the same names with function adapted now to pastoral, now to cultivating, clans, but generally warlike; and as if these gods had been transferable from tribe to tribe as treaties united their followers. Most of the gods have at least some solar attributes. None has a monopoly. If Varuna upholds physical and moral order, so does Mitra. If Varuna is invoked as universal king *(sumraj),* so are Mitra, Indra and even Agni. as though aspirants to the supreme monarchy over the Aryan hosts grasped and lost political power. Though the Vedic gods remain interdependent (Varuna and Surya subordinate to Indra; Indra, Mitra, Varuna and Rudra, to Savitri; and Varuna with the Asvins, to Vishnu), every god is praised in turn, even the exalted Varuna being mostly invoked in conjunction with at least one colleague while verses to pairs, triads and groups are frequent. The Vedic pantheon resembles the Aryan polity in that it never arrived at an uncontested monarchy. But the *Rzg-Veda* closes with some notable hymns which treat the origin of the world as a philosophical problem; and the sun, as a golden embryo, is given the new name of Prajapati (hitherto a mere epithet of Savitri), "lord of creatures." Foreshadowing or reflecting some monotheistic innovation, Parjapati is the All, soon to become the anthropomorphic personification of the desire (*kama*), which is the first seed. Such in outline is the story of the *Rig-Veda's* development, but it does not exhaust all its slowly achieved conceptions. We must at least add to them the toothless Pushan, the "prosperer," an indistinct individuality, hardly yet anthropomorphic, who watches over paths and guides the dead on the last road. Naturally such a concept is capable of almost infinite expansion, and Pushan was later to become a sun-god and Aditya, "the preserver of all things," and then to fade into oblivion. The Adityas, sons of Aditi, a group of some six or more gods whose names are variously given, included not only Mitra and Varuna (Indra was added later) but such minor deities as Aryaman, Bhaga. Daksa and Amsu; later they too will be sun-gods and include Vishnu. Aditi denoted bondlessness and may be regarded as the only abstraction personified as a goddess in the *Vedas.* Aditi is the great mistress of the devout, but motherhood is her ,essential trait. Her epithet is *pastya,* "housewife." She cannot. honever, be safely regarded as "Mother of the Gods" in the *Rig-T'eda,* her recognition as such not appearing till the epic period Her lesser sons are as indistinct as herself, Bhaga besought to be Bhagavan, "bountiful." and Amsha also connoting "bounty"; Aryaman, "comrade"; and Daksa, "dexterity"; yet the first must be of great antiquity, *bogŭ* being "god" in old Slavonic, while Aryaman is Avestan. In Vedic worship goddesses are fairly numerous but quite subordinate even when wives of the high gods like Indrani. They bear simple names, Ushas (*q.v.*), Night, Earth, Speech, Parendi, or Puramdhi, a goddess of plenty like Dhishana. Ila, or Ida, "abundance" of milk, later "cow." Not until we come to the *Brakmanas* (*q.v.*) do the wives of the gods have a place in the cult assigned to them apart from their husbands. Lower deities like the *Apsarasas* and Gandharvas (*q.v.*) deified priests and heroes like Manu (*q.v.*), animals, especially horses, kine (the cow is not to be slain), birds such as Garuda, inanimate objects from rivers and hills down to weapons and tools, but not the phallus, abound. Opposed to the benevolent deities is a host of demons: *asuras* ("gods" in the *Rig-Veda* like the Avestan *ahura)* and *dasus,* possessed of occult power, the term *dasu* being at first applied to the dark aborigines, then to demons of the air and finally to slaves (on the other hand *vritras* were at first demons and later human foes); *rakskasas* and others.

In the *Rig-Veda* we find belief in a future life, delectable for penitents, heroes and donors of sacrificial gifts; and, though burial is mentioned in the earliest hymns, cremation of the dead was preferred because the soul could ascend to heaven with the smoke. Yama was a god of the dead but hardly their judge since they had to pass between two fires which burned the wicked and let the good go by. Belief in metempsychosis does not appear at all in the *Vedas* but is mentioned in a *Brahnzana* and accepted in the *Upanishads* and in all later Hindu sacred writings and has influenced nearly all Hindu thought. An essential part of this belief is the doctrine of *karma* (*q.v.*), developed in Jainism and Buddhism, whereby a man's actions in one life determine his position in the next. Though this interpretation of *karma* was originally atheistic, the old Vedic ritual was not abandoned: and the *Sutras* which were now written were intended to aid the student, being classified indices of its increasing perplexities, more or less unintelligible by themselves and requiring a commentary to explain them. They reflect ritualism and polytheism which are retained without misgivings as to their contradictions by the *karma* theory.

Sectarianism. — The significance of the *Mahabharata* and the *Ramayana,* the first epics, is discussed in the article SANSKRIT LANGUAGE AND LITERATURE. The next great batch of religious writing was the *Upanishads,* or secret doctrine. These were probably put together by Kshatriyas, but they are assigned to Brahmanical schools and some like the *Chhandogya Upanishad* bear the very names of their *Brahmanas.* The essential teaching of the *Upanishads* is that knowledge gives release. Dating from about 500 B.C. they took form in the lands of the Ganges and the Jumna, and they are followed by versified condensations of little later date. But these introduce Vishnu and Shiva as symbols of Brahma; and Isha, or Ishvara, appears as the Supreme in the *Isha Upanishad,* while in the *Saetashvatara* Shiva is introduced under his older title of Rudra and. for the first time in Hindu literature, *bhakti,* or devotional feeling, is spoken of as being due to him. In these treatises also first occurs the term Vedanta as a name of the Upanishad philosophy.

Hence. by the middle of the 6th century, we find a network of Hindu schools, already in full working order and represented by the prose *Upanishads,* the *Karma Mimamsa,* etc.

Probably in the 4th or 3rd century B.C. appear the Sankhya and Yoga (*q.v.*) systems. The former admitted Sudras; the latter, outcasts as well; the one derived from the *Upanishads* in the main; the latter: uitimately from popular magic and hypnotism. The Lokayata, or materialistic school, was probably also in existence. To these must be added Jainism and Buddhism *(see* BUDDHA AND BUDDHISM; JAINS), both founded by Kshatriyas.

The great movement toward theism may be said to have begun about 200 B.C. In the conditions which then prevailed it could hardly have had a more unpromising outlook, and to add to its misfortunes its earliest writings perished. *Upanishads* continued to be written but its principal manual disappeared, only the sectarian writings such as the *Sannyasa, Yoga* and *Shiva Upanishads* surviving. It seems indeed to have been an epoch when works which struck at particularism were deliberately destroyed. The original version of the laws of *Manu,* the *Dharmasutra,* was replaced by the *Dharmashastra* in verse. Probably some early versions of the Sankhpa and Yoga systems also existed, but both disappeared as did the fundamental texts of the *Vaishesika, Nyaya* and *Charvaka.* The Vaishnavas took over the great epics and changed their character.

Vishnu and Shivs.-Among the twice-born we must recognize two great divisions: the orthodox faithful to the Vedic pantheon and ritual; and the sectarians exalting one god to the neglect of the rest and in his cult using a ritual and liturgy of non-Vedic origin chiefly by temple and image. The sectarian position was greatly strengthened by the *Bhagavadgita,* the earliest and greatest of the didactic epics. In its present form it cannot be earlier than the 1st or 2nd century A.D., but its original may go back to the 4th century B.C. Suddenly in the added matter of the great epics we find the doctrine of divine incarnation. It is useless to ask nhence it came or to point to gods in the *Brahmanas* taking temporarily the forms of animals. fish or dwarf. The Vaishnavas go much further. They identify Vishnu with the Brahman-Atman of the *Upanishads* and with Krishna, to whom is given the title of Bhagavan (whence the name of the poem "The Lord's Song"). Vishnu's selection is inexplicable. He was one of the great trio but Brahma was the more likely to be chosen as chief of the gods, as the Supreme. Krishna, man, a partial incarnation of Vishnu in the second stage of the epic, is promoted as a full incarnation of Vishnu-Brahman. The change is not merely revolutionary but unexplained. The theology of the poem is thus a theism, but still imperfect. The song is coloured, as it were, with some pantheistic passages. Sankhya, Yoga and the *Upanishads* are all dragged in without any attempt to reconcile their differences. It recognizes no animal sacrifice but it tightens up the bonds of caste and establishes the regular worship of ancestors. If the Dharmashastras as we have them are those to which it refers. the ideal is laid down that every man ought to pass through the four *asramas* and that not even a virgin widow may remarry. Scholars who hold that the song was contaminated by the pantheism of the *Upanishads* in the 2nd century A.D. have much on their side. Rut how did it in the 2nd century B.C. appear as a purely theistic tract glorifying Krishna? It began as a sectarian thesis; it became the very cream of orthodoxy.

This by no means exhausts the Vaishnava material in the didactic epic. It mas followed by a flood of writings, notably by the *Marayaniya* section of the *Mokshadharma.* This seems to present a later period in the history of Vaishnavism and adds *inter alia* the doctrine of *vyuha,* or expansion, according to which Vishnu exists in four forms, denoting the steps of his ascent to Brahma. The second of these forms is Samkarshana, "withdrawn," because Vishnu, identified with primaeval matter, was drawn from his mother's womb and placed in Rohini. But Vasudeva is Krishna; Balarama or Samkarshana. Krishna's brother; Pradyumna, his son; and Aniruddha, one of his grandsons. The *Narayaniya* has ten incarnations of Vishnu, whereas the *Anugita* mentions only six, adding four to the original two but othentise making no advance whatsoever. The *Narayaniya* also has a tale of Narada, the saint, taking a long journey to the north where he came to the White Island in the Sea of Milk, wherein white men worshipped Narayana; *i.e.,* Vishnu. Here we have seemingly allusions to Christianity. But as yet there is nothing to suggest any worship of the child Krishna or any association of Krishna with the Gopis, "cowherdesses." The story of his rescue from the wrath of Kamsa is still untold and Radha is not mentioned.

In the didactic epic, Shiva follows Vishnu, but at a long interval. His new theology is clearly in its inception an imitation. Its name, Pasupata, is formed from *Pasu pati*, "lord of flocks," once an epithet of Rudra. Shiv worshippers today revere the phallus (*e.g.,* the Lingayats, *q.v.*), but though it appears on pre-Christian monuments no mention of it occurs in literature before this period.

Buddhism was developing similar traits. This can be stated with confidence if we regard the literature which has been preserved. The Mahayana is the acute Hinduizing of Buddhism, and in it Buddha is conceived of as the Supreme, boundless in power and wisdom and surrounded by Bodhisattvas just attaining Buddhahood. The textbook of this school was the *Lalita Vistara,* originally the Buddha biography of the Sarvastivadins but taken over and rewritten. In it the old Hindu self-torture reappears. In his efforts to save men Analokitesvara, "looking down from above," can save from danger.

With Jainism there was a good deal of literary activity between 200 B.C. and A.D. 500, but much of it was lost or altered. The main writers were connected with Pataliputra and the norks of one were used by both the Jain sects. They also adapted the *Ramayana.* All this shows how the sects were inclined to mingle with the Hindus.

Saktism.—About AD. *550* we see the dawn of the Saktas though they may have been known earlier. In this system the god is neutral or inactive — apparently because he must be so if he is to remain beyond the sway of the law of *karma* — *and* his spouse, the goddess, embodies his energy *(saktia).* The oldest goddess

of this type is Durga, the virgin goddess of the Vindhyas. Her alliance as Uma with Shiva is later and she is no longer regarded as a virgin. Here we have palpably a fruitful field for new philosophers, sects and almost religions, and we begin to get onto historical ground Shankara in the first half of the 9th century took up the teaching. A series of works is attributed to him; but all of it is probably not from his pen. He certainly. however, wrote commentaries, or *vhashyas,* on the *Vedanta-Sutras,* the *Bkagavadgita* and many *Upanishads.* Shankara distinguishes between the supreme truth and that of experience. Besides the supreme or para-Brahman is a lower (*apara*) one. the world-soul and personal god. All our lower knowledge, our personal experience and conception of ourselves as distinct'personalities is ignorance rather than knowledge. Liberation comes when a man rises to true knowledge. which is finally granted by the grace of God and for which a man may prepare himself by the study of the Veda and the discipline of the Vedanta. Hence, when a man became a *sunnyasi* of the Advaita Vedanta, he gave up all the duties of the ordinary Hindu, laying aside even the sacred thread. Naturally its illusion and doctrine of double truth led its opponents to term it covert Buddhism. By Shankara's day the *Upanishads,* the *Bhagavadgita* and the *Vedanta-Sutras* nere recognized as fundamental for the Vedanta Later they were called the Triple Canon. Shankara re-regulated its orders, dividing them into ten, whence their name of Dasnamis. He founded Sringeri in Mysore as his chief monastery, where he himself nas the head, Govardhan in Puri. Sarada (Saraswati as patroness of sciences) in Dwarka, and Joshi at Badrinath And he was able to reform the Bhagavatas, a Ramaite sect in the south. and the Shaivas of Kashmir. Many other writers followed The Puranas, whose history is as old as it is obscure, had virtually all come into existence by the end of this period and two of them betray Sakta influence

The Vaishnavas of the Bhagavata school also accepted the Advaita Vedanta and the five gods. but still more serious was their identification of Shiva with Vishnu in the Skanda *Upanishad.* Today in the Tamil country the ritual is that of the Pancharatra Samhitas said to be unorthodox as inconsistent with Vedic usage, but we cannot be certain when they were written..

The Samhitas mark first the appearance of Sakta principles among the Vaishnavas; indeed. the theology of the chief one is a development of the Naraniya episode with the considerable addition of Saktism. The basis of their philosophy is the theistic Yoga, but it is manipulated so that it is hardly recognizable. Vishnu and his Sakti are one in the primary creation, which is followed by 36,000 secondary ones, in which a Sankhyan evolution appears. Their description is that of an attempt to combine most of what has gone before into a single but disconnected system. Even magic is commended. The Sri-Vaishnavas have a sect mark, two white curving lines with a vertical red one between them, the red representing Vishnu's Sakti. The Samhitas ordain that this symbol shall also be branded on the body. The cult is open to all four castes but not to outcasts. But besides the Sri-Vaishnava several other sects arose, notably the Narsimha (Narsingh) sect, which worships the man-lion incarnation of Vishnu, especially in the south, and had two *Upanishads* of its own. The Shaivas had a bewildering number of sects and schools such as the Kapalikas, or skull-men, perpetrating human sacrifice and full of Sakta ideas.

The sect of Durga, reorganized with a new theology, a more varied cult and a fresh literature, appears as the Sakta sect. Its writings still await scholarly investigation but many of them were in existence by 600. Its system is fundamentally an unlimited array of magic rites drawn from the practices of the most ignorant classes; and it has been credited with ritual usually ascribed to secret sects. It was divided into the left-handed, or those who pushed such usages to an extreme, and the right-handed, as reformed possibly by Shankara.

Bhakti — Between 900 and 1350 there was a new movement in Hindu literature — that of Bhakti. The earlier singers of the Tamil country, the Alwars, in their lyrics introduced great changes in the Sri-Vaishnava temples and paved the way for Ramanuja, whose influence reacted on all the sects.

So, too, the chauntries of the Shaiva gave their cults a great uplift and made possible the creation of the Tamil Shaiva Siddhanta. The two great books are the *Sri-Bhashya* of Ramanuja and the *Bhagavata Purana,* whence sprang two streams of Bhakti, the one meditative, the other explosively emotional. While the Sankhya and Yoga schools stood still, all the others continued their literary activity in which Bhaskaracharya, author of the *Bhaskara-Chashya,* attacks Shankara and in turn is assailed by Udayana in the Kusummanjali, between 850 and 980, while Madhva, founder of the Madhva sect, left Dvaita commentaries on ten principal *Upanishads.* The *Bhagavata Purana* seems to have sprung from the Bhagavata community and from its influences were born a number of new sects. It has several distinctive features. It devotes itself to Krishna's boyhood and youth and to the Gopis, or cow-maidens; but even yet Radha does not appear. her place being foreshadowed by a favourite gopi. Further. Bhakti now attains its highest point of mystical expression, and it must have arisen among Vaishnava ascetics. It is a surging emotion which leads to tears and laughter, to sudden fainting fits and long trances of unconsciousness. But it has one fatal feature in its sensuous description of Krishna's dalliance with the Gopis. Hindus are by no means in accord as to its age or authorship, but, since Alberuni mentions it, it can hardly have been written after 900 and must be due to a community of singers in the Tamil country. The sects due to the *Blzagavata Purana's* influence are numerous. They included the now possibly extinct Raseshvaras, or Mercurials, who acquired a divine body by the use of mercury and then by Yoga an intuition of the Supreme; the aspirant is then liberated in this life. Another inchoate sect is that of the Gorakhnathis — closely related to the Kapalikas — with an unorganized laity. They have temples all over India from the Gorkatri in Peshawar, in Nepal, right down to the south. Its adherents, mainly called Kanphatas, Yogis, or split-eared. are its strongest part. Both Tantric Hinduism and Tantric Buddhism glorify Goraksha Nath and his companion saints; yet Goraksha himself probably flourished about 1200; and with his name is associated a new type of Yoga, the Hatha-yoga, destined to attain the *samadhi,* "supreme concentration of mind," by strange bodily postures, breathing exercises and attention. In the later books on this cult is added Raja-yoga, a more intellectual discipline. The book by Goraksha on the Hatha-yoga seems to be lost.

On the other hand. some of the older sects have disappeared; *e.g.,* the Rama sect which rewrote the *Ramayana,* adding Sakta elements to it so that Sita's illusory self is carried off by Ravana and when Rama speaks as a man he is explained to be under the influence of *maya,* "illusion." This elevates the pair to the position of the Supreme.

Syncretism **and** Monotheism. — The earliest influences of the Moslem invasions were naturally confined to Sind, the Punjab and Hindustan. They were often unorthodox, the purer forms of the faith being too intent on the establishment of their own sternly monotheistic creed to win acceptance from Hindus. Not much before 1400 did Sufism begin to make headway in India and most of the institutions which have survived from that period are due to it. The Mohammedans certainly destroyed Hindu temples, which they called Jain, but more for the sake of their materials than for any other purpose. With the reign of Akbar began a new movement; namely, the attempt to create a new world-religion which should unite the warring elements. This religion borrowed from all. It was never strictly defined since Akbar was suspect to his Moslem subjects, but he was at least tolerant, which the later Aurangzeb was not. It would be as difficult to deny that his austere faith was one of the principal causes of the fall of the Mogul empire as it would be to dispute its influence on Hindu monotheism. Weak as we have seen the movement toward theism to have been, it found support from Islamic example. It was the same with idolatry. To this movement must be ascribed the teachings of Namdeva and Trilochan in the Maratha land, of Sadana and Beni in the north and of Ramananda, who lived from about 1400 to 1470. He was followed by his disciple Pipa and by Kabir. Ramananda seems to have been under Ramanuja's influence; yet he worshipped Rama and Sita and their attendants alone. He probably derived his doctrine from the Ramaites of the south, but

he came to the north and among his personal followers were an outcast, a Mohammedan and a woman; yet he attempted no reform of caste restraints though he mitigated some in the matter of food. The most numerous of the ascetics founded by him are the Bairagis, "passionless." or Avadhuta, "liberated." equalled today in numbers only by Shankara's Dasnamis. But he founded no regular sect. Indeed, sectarianism was in process of decay. Ramananda still affected images. but Kabir denounced them and worshipped God (Ram) alone. Many of his sayings were included in the Sikh Granth (*q.v.*).

Of the ten sects founded by his followers during the next three centuries, the Sikhs (*q.v.*) are undoubtedly the most important. Their religion, which rejects caste and Brahminist dominance was founded by Nanak in 1469. His tenth successor as *guru* in the 18th century transformed the Sikhs into a military community because of persecution. More widely travelled than any other Indian community — Malaya, Hong Kong, Shanghai, Vancouver and Hankow know them well — the Sikhs are fine craftsmen, good soldiers, able administrators and resolute politicians. (See also **HINDUISM.**)

MOSLEMS AND CHRISTIANS

Moslems. — The bewildering diversity of religious beliefs collected under the name of Hinduism has no counterpart among the Mohammedans, who are limited as to their main tenets by the teaching of a single book, the Koran. The two main sects are Sunnis and Shiahs. In India the Sunnis greatly preponderate, but they usually share with the Shiahs their veneration for Hasan and Husain and strictly observe the Moharram. However, an orthodox reformer Mirza Ghulam Ahmad (1839–1908) started at Qadian (Punjab) the sect known as Ahmadiyahs. or Qadianis. Its missionary enterprise made it better known in the west than its importance in India warranted, but it has had as adherents leading Moslem personalities and even has its onn mosque at Putney in England. Partition left Qadian in Indian territory, though close to the Pakistan border; and Lahore has the headquarters of an offshoot of the sect, politically passive but energetic in disseminating Islamic liberal ideas.

The Mohammedans of the subcontinent may be divided into two classes: (1) pure Mohammedans from the Mogul and Pathan conquering races; and (2) Mohammedan converts. who differ little racially from the surrounding Hindu population from which they originally sprang. The pure Mohammedans may again be subdivided into four sections: (1) Moguls, or the descendants of the great conquering race, including Persians; (2) Afghans or Pathans, in the Punjab and in the Rohilkhand division of the Uttar Pradesh; (3) Saiyads, who claim to be lineally descended from the Prophet; and (4) Sheikhs, which is a name sometimes adopted by converts. The remainder are unspecified. In Bengal the vast majority of the Mohammedans in their devotion to hereditary occupations are scarcely to be distinguished from Hindu castes. In the Punjab, besides the Pathan immigrants from across the frentier, Islam has taken a strong hold on the Jats. Rajputs and Gujars. Western India and Pakistan have three peculiar classes of Mohammedans. each of which is specially devoted to maritime trade: (1) the Memons, chiefly in Sind; (2) the Borahs. mainly in Gujarat; and (3) the Khojahs, of whom half live on the island of Bomhay. In southern India are found the two peculiar races of the Moplahs and the Labbays, both of which are-seated along the coast and follow a seafaring life. Descended from the Arab traders who settled there in very early times, and recruited partly by voluntary adhesions and partly by forcible conversions during the persecutions of Hyder Ali and Tippoo Sultan, they have been prone to fanatical outbreaks.

For the partition of 1947 the classification of Islamic elements in India was thus made from 1941 census figures: northwestern area (Punjab, Korth-West Frontier Province, Sind, British Baluchistan) 60.02%; northeastern area (Bengal, Assam) 51.697,; rest of British India 10.6%. To effect partition there had to be a division of the Punjab and Bengal.

Christians. — The Christian community of 1941 in undivided India included 6,040,665 Indian members. Of these about two-fifths were Roman Catholics, with metropolitan see in Bombay. More than half of the Indian Christians are found in Madras and the adjoining states. a tribute to the labours of St. Francis Xavier and the Protestant missionary Christian Friedrich Schwartz. "Christians of St Thomas" in Malabar, Travancore and Cochin are the most ancient Christian community in the south. They are, however. now much divided and comprise two Roman Catholic "uniat" churches, two Jacobite (Monophysite) bodies, an autonomous reformed group and a Nestorian group. After these come the Latin Roman Catholics, who trace their origin to the teaching of St. Francis Xavier and the Madura Jesuits. The Anglicans originated in the Church of England chaplaincies to the East India company, but their hierarchy (with metropolis at Calcutta) dates only from the early 19th century, as do the Protestant churches, whose progress after that time was considerable. Taking Indian Christians alone, their numbers increased from 1,246,288 in 1872 to the above-mentioned figure in 1941, and the rate of increase was even greater than these figures would show, because they include the Christians of St. Thomas, whose numbers are practically constant. The classes most receptive to Christianity have been those outside the Hindu system, or whom Hinduism regarded as degraded. Conversions from Islam have been relatively scarce.

Under the Indian Church Measure act. 1927, the Anglican body — the Church of India. Burma and Ceylon — became independent of its parent body, the Church of England, in 1930. The Church of South India was formed by a union of Anglicans, Methodists, Presbyterians, Dutch Reformed and Congregationalists in 1947. The Anglicans ceased thereby to be members of the Anglican communion. although attempts were later made to regularize relations between the two churches. A bishop administers "continuing" Anglicans in Xndhra and Madras. (ME.; H. **A. R.**; X.)

ECONOMICS

Nearly three-quarters of the total population of India ordinarily derive their living from occupations connected with the land. The fertility of the land. except where it is protected by irrigation, largely depends on the adequacy and timeliness of the monsoon rains. Should they fail, vast areas remain unsown or yield no harvest; masses of people. chiefly agricultural labourers and petty cultivators, are thrown out of employment; and famine results.

The second powerful force which affects the economic situation in India is the constant demand of the outer world for its raw produce, coupled with its own industrial weakness in converting that produce into manufactured articles, From earliest times India was noted for its spices, precious stones and delicate textiles; in return, it imported gold and silver in untold quantities and absorbed them. Spices are no longer a necessity in western diet; the diamond mines of Golconda have been worked out; and the famous cashmeres and muslins have been ousted. as have cottage industries everywhere, by loom-made substitutes. Before World War II, India's exports included coal, jute and jute products, hides and skins, lac, manganese. mica, tea, oilseeds and vegetable oils. spices, cotton and manufactured cotton. The war increased the export of many of these items; and during the German occupation of continental Europe. the British Commonwealth and the United States became the chief recipients. Among India's imports were machinery, chemicals, glassware, hardware, oils, rubber manufactures, textiles and automobiles.

NATURAL RESOURCES

Agriculture. — The cultivation of the soil occupies the Indian people in a sense which it is difficult for the foreigner to realize. The operations of rural life are familiar to every class. Everywhere. the same untiring labour is found, but inherited experience had taught the cultivators to adapt their simple methods to different conditions. Irrigation, apart from the great network of government canals, is practised wherever possible from wells of all types and depths, from tanks and evanescent streamlets. Manure is applied to the more valuable crops wherever it is available. although the land as a rule is starved by the much more insistent demand for manure as fuel. The rotation of crops is an ideal that is widely recognized, but poverty makes the use of periodic fallows unattainable.

On the other hand, the regularity of the seasons allows two, and on highly manured soils even three, harvests in the year, though comparatively rarely on the same fields; and there is much natural fertility. For inexhaustible productiveness and for retentiveness of moisture in a dry year, no soil could surpass the "black cotton soil"; but at the other end of the scale vast areas of the driest sandy land are coaxed to yield a scrannel harvest of poor millets and thin pulses.

Despite the innate conservatism of the peasantry and in the face of a very inadequate provision of staff and funds, the departments of agriculture, which were organized early in the 20th century, achieved a variety of important results. In the forefront of their work was the introduction of improved varieties of plants. The area sown in 1923–24 with improved varieties popularized in this way exceeded 5,000,000 ac. and had risen to 23,000,000 ac. by 1942. The Research institute at Pusa (*q.v.*) had remarkable success in its work with wheat, particularly in the introduction of types which are immune from rust; very valuable work was also done on sugar at Coimbatore. Experiments there led eventually to the establishment of the sugar-cane industry in Uttar Pradesh and Bihar.

Irrigation.—In the age-long contest against the tyranny of a semitropical climate, irrigation has played the dominant part, not only as a preventive of scarcity due to drought, but as an everyday adjunct to the productivity of the soil. In 1939–40 the area actually sown (some of it more than once) in British India was 244,500,000 ac., of which nearly 56,000,000 were irrigated. About half the irrigated area was supplied with canals; the rest, largely from wells and tanks. The canal system is one of the greatest achievements of the British. It embraces the great Ganges canals in northern India, with more than 1,200 mi. of main channels and 6,500 mi. of distributaries; the vast network of the Punjab canals; and the elaborate delta systems of Madras, besides extensive works in Sind and Deccan. Some of these draw on rivers fed by the Himalayan snows; others are channels for inundation and thus of less assured permanency; others again, chiefly in Madras, are supplied by storage works. The substitution of a permanent supply for the uncertainties of an inundation supply is in the forefront of the modern projects. Among these the greatest, and, indeed, one of the largest in the world, is the Sukkur barrage in Sind. At the point where the combined five rivers of the Punjab enter Sind through a narrow gorge, the flow is stemmed by a barrage 4,725 ft. long between abutments. The inundation system of Sind is served, and a vast new area brought under irrigation, by seven canals which take off from the barrage and which will ultimately water 6,000,000 ac.

Second only to the Sukkur scheme in magnitude is the Sutlej valley project, also mainly in Pakistan. It consists of four weirs, with ten main canals taking off from above them and irrigating more than 5,000,000 ac., which are partly waste and partly served inadequately by inundation channels. Outside the Indus basin there is no scope for works of equal magnitude, but a great scheme was completed for the irrigation of Oudh, by a canal fed from the Sarda river. This project had been under contemplation for 50 years but was in abeyance because of the opposition of the Oudh landowners. The area irrigated is 1,700,000 ac. In Madras even older schemes first planned by Sir Arthur T. Cotton were revived, for great storage reservoirs in the Cauvery, Bhavani, Tangabhadra and Kistna rivers. The Cauvery-Mettur system was inaugurated in 1934. With a capacity of 93,500,000 cu.ft., it was then the largest single block masonry reservoir in the world.

For the plan of 1950, which combined irrigation with the development of hydroelectricity, see Finance, below.

Co-operation.——To the improvement of Indian agriculture few obstacles are as grave as the chronic indebtedness of the peasantry. Legislation to combat this by restricting the alienation of rights in land has long been active; but a much more effective remedy was the establishment of rural credit banks on the Raiffeisen plan. It was initiated by an act of 1904, when registrars of co-operative societies were appointed for the different provinces, to draft model rules, register, inspect and audit the accounts of co-operative banks and also to carry on propaganda and education in co-operative principles. In 1912 an amending act was passed as the result of eight years' experience; this act also extended the official encouragement to co-operation in other fields. The number of registered societies in 1949–50 was 173,090, with a total membership of about 12,600,000; the capital employed was Rs. 233.1 crores (about £174,825,000). The great majority of the societies were village banks; but there were a large number of "central banks" situated in towns, which gathered in deposits, supplied funds to the rural banks in their neighbourhood and acted as links between them. There were also "apex" banks for most of the states.

Cereals.—Of the total cropped area in undivided British India one-third was occupied by rice, which is the dominant crop of the staple food in Bengal, Bihar and Orissa, as well as in parts of Madras and Uttar Pradesh, the so-called Patna rice coming mainly from the latter.

In area the next most important crops are the great variety of millets and pulses. The millets are probably the most prolific grain in the world and the best adapted to the vicissitudes of a tropical climate, requiring practically no irrigation.

Gram is the predominant variety and occupied more than 11,000,000 ac. in Uttar Pradesh and Punjab alone; but lentils and the smaller pulses are more universal. They are not an export commodity.

The wheat area sown was estimated at 34,862,000 ac. in 1940–41 and at 22,769,000 ac. for India in 1951–52 and 10,651,000 ac. for Pakistan in 1953–54; and the production, at 11,205,600 short tons in 1940–41 and at 5,679,000 for India (1951–52) and 3,683,000 for Pakistan (1953–54). More than two-thirds of the wheat crop is ordinarily grown in Uttar Pradesh and Punjab. The canal colonies of the Punjab turned northern India into the chief granary of the subcontinent.

Barley, maize and fodder crops cover about 59,000,000 ac.

Cotton.—Undivided India was the world's second largest producer of cotton, following the U.S. Partition changed this position, roughly half the area under cotton going to Pakistan. Bombay, Hyderabad, Madhya Pradesh, Madras and Uttar Pradesh all have important cotton tracts producing distinct types with widely varying yields. The total area in 1947–48 was about 10,900,000 ac., giving 2,100,000 bales (400 lb. each). About 5,100,000 ac. were under improved varieties. Raw cotton exports were 187,000 bales from India and 1,095,000 bales from Pakistan in 1951–52 (1 bale = 392 lb.).

Oilseeds, Sugar and Jute.—A crop of importance universally grown is the mixed group which yields oilseeds. Oil is an essential to the Indian toilet and to Indian cookery and as an illurninant. Chief varieties are peanuts, sesamum, rape or mustard and linseed. Export values in 1949–50 were £12,000,000.

Sugar cane covers 3,300,000 ac., most of which is in Uttar Pradesh and Bihar. The total yield in raw sugar was 4,493,000 tons in 1946–47. The world's supply of jute is derived almost wholly from the two Bengals, but partition gave 70% to East Bengal (Pakistan). India's jute crop in 1947–48 covered 646,000 ac., yielding 1,027 lb. per acre and producing 1,658,000 bales (400 lb. each). In 1952–53 Pakistan produced 6,823,000 400-lb. bales on 1,907,000 ac.

Tea.—The cultivation of tea in India replaced indigo as the chief article for European capital, more particularly in Assam. The real tea (Thea *viridis*), a plant akin to the camellia, grows wild in Assam, being commonly found throughout the hilly tract between the valleys of the Brahmaputra and the Barak. There it sometimes attains the dimensions of a large tree; and from that, as well as from other indications, it has been plausibly inferred that Assam is the original home of the plant, which was thence introduced at a prehistoric date into China. In 1949–50 the area under tea was 771,000 ac., yielding 585,030,000 lb. in India; in 1953–54, 75,000 ac. yielded 57,700,000 lb. in Pakistan.

Coffee.—Thecultivation of coffee is confined to southern India. The coffee tract includes almost the whole of Coorg, the districts of Kadur and Hassan in Mysore, the Nilgiri hills and the Wynaad. The cultivation has also extended to the Shevaroy hills in Salem district and to the Palni hills in Madura. Although local tradi-

tion dates its introduction in the 18th century, coffee was not grown systematically until 1840. After 1860 it spread with great rapidity along the whole line of the Western Ghats, clearing auay the primaeval forest and opening a new era of prosperity to the labouring classes. The export of coffee annually is about 3.000 tons. The area cultivated in 1950–51 was 224,215 ac. Local consumption of coffee is encouraged by the setting up of coffeehouses by the Coffee board.

Cinchona.—The cultivation of cinchona was introduced into India in the year 1860 under the auspices of the government through the efforts of Sir Clements Markham, and a stock of plants nas prepared and distributed to planters in the Nilgiris and in Coorg. At the same time governmental plantations were established in the Nilgiri hills and at Darjeeling. A considerable amount of the bark from private plantations is bought by the government and treated at the government factories.

Miscellaneous Crops.—Vegetables occupy an important place in the Indian dietary and are grown everywhere. Besides the ordinary European species which can mostly be grown in the cold season. the favourites are the eggplant (brinjal), garlic, yams and a great variety of cucurbitaceous plants. Among cultivated fruits the commonest are the mango, plantain, guava tamarind, jack, pomegranate, pineapple, papaw, custard apple and several varieties of fig, melon. orange, lime and citron. The mangoes of Bombay and the oranges of Nagpur and the Khasi hills enjoy a high reputation, while the guavas of Madras make an excellent preserve. Spices form another essential element in the Indian diet; turmeric and chillies are in universal use and are cultivated everywhere. Ginger, coriander aniseed, black cumin and fenugreek come next in importance. Pepper is confined mostly to the Malabar coast, and cardamoms are hardly less localized. But betel leaf, used in making the various delicacies grouped under the name pan, is grown pretty generally; it is a difficult crop to grow. The betel nut. or areca palm, is found in the deltaic districts of Bengal and the highlands of northern India. Other palms include the coconut, which flourishes on the uestern coast of south India; and the bastard date, which supplies the jaggery sugar of commerce and the intoxicating liquor known as *tari* or toddy.

Cattle.—Throughout the whole of India horned cattle are the only beasts used for plowing. The well-known humped species of cattle predominates everywhere, being divided into many varieties. The livestock estimate of 1937 returned 188,000,000 cattle in what was then British India; but, because of unfavourable conditions of climate and soil, insufficiency of grazing ground and want of selection in breeding, the general condition of the cattle was miserably poor. There are, however, some fine breeds in existence. In Mysore the *amrit* mahal, a breed said to have been introduced by Hyder Ali for military purposes, was kept up by the state. In the Madras districts of Nellore and Kurnool the indigenous breed was greatly improved, and in Madhya Pradesh there is a peculiar .breed of trotting bullocks in great demand for wheeled carriages. The large and handsome oxen of Gujarat in Bombay are excellently adapted for drawing heavy loads in a sandy soil. Cattle-breeding farms were set up by the government in different parts of the country; and invaluable work was done by the veterinary service in the discovery and use of a serum prophylactic against the devastations of rinderpest The worst cattle are to be found always in the deltaic tracts, but there their place is to a large extent taken by buffaloes. These last are more hardy than ordinary cattle; their character is maintained by crossing the cows with wild bulls. and their milk yields the best ***ghi***, or clarified butter. (See also Fauna.) The breed of horses is little better than that of the milch kine. In Bengal and in Madras it may be broadly said that horses are not bred. But horses are still required for the Indian cavalry and the police; and in order to maintain the supply a civil veterinary department was founded in 1892. Horse breeding is carried on chiefly in Uttar Pradesh, and there are a number of stallions in the various provinces. Formerly Norfolk trotters held the first place in point of number. but their place was taken by English thoroughbreds, Arabs and especially Australians. For the supply of ordnance, baggage and transport mules a large number of donkey stallions were imported by the government.

Forestry.—Up to 1850 the destruction of forests by timber cutters, by charcoal burners and above all by shifting cultivation was allowed to go on everywhere unchecked. But as the pressure of population on the soil became denser and the construction of railways increased the demand for fuel, the question of forest conservation forced itself into notice, while its importance also as affectingthe general meteorology of a country was being learned from bitter experience in Europe. In 1865 an act of the legislature was passed (no. vii of 1865).

Sound principles of forest administration after that date were gradually extended. Indiscriminate timber cutting was prohibited; the burning of the jungle by the hill tribes was confined within bounds; large areas were surveyed and demarcated; plantations were laid out; and, generally, forest conservation became a reality. In 1894 the government divided forests into four classes: (1) forests, the preservation of which was essential on climatic or physical grounds; (2) forests which supplied valuable timber for commercial purposes; (3) minor forests; and (4) pasture lands. In the first class the special purpose of the forests, such as the protection of the plains from devastation by torrents and the conservation of the rainfall for the service of the great canals, came before any smaller interests. The second class included tracts of teak, sal or deodar timber and the like, where private or village rights of user were few. In those forests, while every reasonable facility was afforded to the people concerned for the satisfaction of their needs, restrictions were imposed, and the system of shifting cultivation was permitted, under due regulation, only where forest tribes, depended on it for their sustenance. In the third class there were minor forests which produced inferior or smaller timber. These were managed mainly in the interests of the surrounding population and supplied grazing or fuel to them at moderate rates. The fourth class included pastures and grazing grounds. In these, even more than in the third class, the interests of the local community were made to stand first. The state forests, under the control of the forest department, amounted to about 89,019 sq.mi. in 1946–47, or more than 7% of the total area of the republic. In 1951 the total forest area of the republic was about 265,700 sq.mi., of which about 69% was exploitable. Pakistan's total forest area in 1953 was only 5,800,000 ac.

A large part of the reserved forests, where the control of the forest department is most complete, consists of valuable timber, in which the first place is held by teak on the southwest coast of India and inland from the Ghats as far as the middle of Madhya Pradesh. There it meets the sal, which, however, is more especially found in the sub-Himalayan tracts of Uttar Pradesh and East Bengal and Assam. In the Himalaya themselves the deodar and other conifers form the bulk of the timber while in the lower ranges, such as the Khasi hills in Assam, various pines are prominent. In the northeast of Assam the Ficus *elastica*, a species of India-rubber tree, is found. The sandalwood flourishes all along the southern portion of the Ghats, especially about Mysore and Coorg; and in the same regions, as well as in upper India, the blackwood occurs. A valuable tree. known as the *padouk*, is restricted almost entirely to the Andaman Islands. There are many other timber trees that are in general demand in different parts of India. The annual yield of timber and fuel from the Indian forests is more than 293,655,000 cu.ft. Many by-products of the forests are now being exploited on commercial lines; and the great Forest Research institute at Dehra Dun is busy on silvicultural work and wood technology.

Mineral Resources.—The chief underground wealth of India, apart from salt which will be discussed separately, is derived (in order of its value) from coal, manganese, gold, petroleum, iron, mica, copper and ileminite, the first two being by far the most important.

Coal was first mined at Raniganj in 1820. It exists in varying quantity under a very extensive area, being found almost everywhere except in Bombay and Mysore. The finest coal, however, and the largest output by far come from the seams in Chota Nagpur and the adjoining districts of West Bengal. There are also considerable mines in Madhya Pradesh and the contiguous district

of Rewah. Vindhya Pradesh, and an important field in Hyderabad. Production reached a yearly average of 20,160,000 short tons in World War I and had risen to more than 31,360,000 by 1938. The total output in 1955 mas 38,832,000 metric tons.

The oil fields of India are in Assam, and the total output in 1951 was only 260,400 tons, petroleum products being mostly imported.

Manganese ore is found in large quantities in Madhya Pradesh and Orissa, as well as in scattered parts of Madras, Bombay and elsewhere. Output rose from 504,466 tons in 191j to 1,120,000 in 1937. The export in 1951–52 was 1,143,356 metric tons of high-grade ore (30% manganese).

The mining of gold is practically confined to the Kolar gold fields in Mysore, the amounts obtained by sand washing in scattered areas elsewhere being negligible. The mines were worked under leases from the Mysore government, which secured to the state a royalty of 5% of the production. In 1956 it was decided to nationalize them.

The main iron deposits are in Bihar, Mysore and Orissa. It is the contiguity of iron ore and coal that determined the site of the great Tata works at Jamshedpur, Bihar, in the midst of what was formerly a primitive jungle. Production of iron ore increased from 448,000 tons in 1914–18 to more than 3,080,000 tons in 1937–38. In 1955, 1,920,000 metric tons of pig iron and 1,728,000 tons of crude steel were produced. A state steelworks at Bhilai, central India, was to be opened in 1959 with Soviet equipment.

The subcontinent has valuable chrome mines and is an important producer; in 1937 output was 70,405 tons, double the output of 1914–18; and in 1950 the output of chromic oxide was estimated at 16,729 tons for India and in 1953, 23,390 tons for Pakistan. Copper production in 1914–18 averaged 8,960 tons and increased to 379,680 tons by 1938; the copper refined in 1955 was about 7,400 metric tons, although the government aimed at increasing this to about 20,000 tons.

Mica has long been obtained in Bihar, chiefly in the Hazaribagh district, and there is a ruby-coloured variety which is held in great estimation; in Madras also a mica industry has grown up. Plumbago is found in Madras; corundum, in southern India.

Despite its legendary wealth, which is really due to the accumulations of ages, India cannot be said to be naturally rich in precious stones. Under the Mohammedan rule diamonds were a distinct source of state revenue, and the name of Golconda has passed into literature; but that city, once the Moslem capital of the Deccan, was the home of diamond cutters rather than the source of supply. By the 20th century the only place where the search for diamonds was pursued as a regular industry was the state of Panna in Bundelkhand. The stones are found by digging down through several strata of gravelly soil and washing the earth. In 1956 the government decided to nationalize and develop the Panna workings, as well as some of the copper industry. Pearls are found off the southern coast of Madras, on the shores of Gujarat and in the Mergui archipelago.

MANUFACTURING INDUSTRIES

Textiles. — Textiles constitute the major nonagricultural industry of the subcontinent, if we reckon by the number of persons employed. Of these textiles cotton is the most important, followed by jute and then by silk and wool. In 1947, out of about 2,235,188 workers in factories of all sorts, 995,411 were employed in textile mills and 17,481 in cotton gins and presses. In World War II Indian supplies of textiles had amounted to $360,000,000 by June 1942 and increased rapidly thereafter.

Cotton. — The first cotton mill in India was opened in 1851, and the industry received a powerful stimulus during the U.S. Civil War. The staple, however, is short; and with the cultivation of better varieties lacking, no competition was possible with cottons of the U.S. type, and trade was confined to the home and far eastern markets. Before 1914 Indian mills supplied a little less than 30% of the total Indian consumption of mill-woven cloth. From 1922 onward, in the competition between Indian and Japanese mills, it was the hand-loom weavers who suffered most. In some districts they were compelled to abandon their hereditary calling; in others, where the level of skill and enterprise was higher, they gave up cotton weaving for silk or textures with gold or silver thread interwoven. The industry as a whole showed a surprising degree of vitality; fly shuttles, which increase a weaver's output from 20% to 100%, were adopted widely, and so also were simple machines for winding and warping, owned and used co-operatively. Indeed, the growth of the industry notwithstanding the Japanese rivalry may be judged from the following figures: in 1914 it included 271 cotton mills, with 6,788,895 spindles, 104,179 looms and 260,276 workers; by 1941 there were 390 mills, 9,961,178 spindles, 198,574 looms and 459,509 workers; in the same period output of cotton yarn rose from 268,000,000 to 1,303,000,000 yd.; net imports fell from a pre-1914 average of 192,000,000 to 38,000,000 yd.; mill-made cloth increased from 1,164,000,000 to 4,269,000,000 yd., supplying 52% of India's consumption, imports falling from 3,100,000,000 to 556,000,000 yd. In 1943, 35% of India's cotton textiles production (excluding hand-loom), amounting to about 5,000,000,000 yd. yearly, was earmarked for war supply. The output of army clothing in 1943 was more than 8,000,000 garments per month. In 1955 the republic of India produced 744,800 metric tons of cotton yarn and 4,681,000,000 m. of fabrics; and Pakistan, 414,000,000 m. of fabrics.

Jute. — In the manufacture of jute the supremacy of Bengal became firmly established. Nearly two-thirds of the jute crop is ordinarily worked up in the Bengal mills; so that Bengal produces about tuice as great a bulk of jute manufactured goods (gunny bags, hessian cloth, cordings, etc.) as all the rest of the world, Sixty jute mills which existed in Bengal before 1914–18 had increased by 1938–39 to 100. Partition, however, affected the industry adversely; all the jute mills went to India whereas 70% of the jute acreage remained in Pakistan. The situation was made the more unsatisfactory by the different rates of exchange prevalent after Sept. 1949. (See PAKISTAN.) In 1952–53, 1,717,000 ac. in East Pakistan yielded 6,823,000 400-lb. bales of jute. In 1951–52 Indian mills produced 931,400 tons of jute hessian, sacking, cordage, etc.

Silk —The silk industry in India experienced many vicissitudes. Under the East India company large quantities of mulberry silk were produced chiefly in West Bengal and exported to Europe; and Malda, Murshidabad and other places in that state have long been famous for their silk manufactures. Other kinds of silk are native to certain parts of India, but the chief of the wild silks is the tussore silk, which is found in the jungles almost throughout India. Large quantities of comparatively coarse silk are made from silk so produced.

Other than Bengal, the main silk centres are in Mysore, Madras, Kashmir (all mulberry fed), Assam, Bihar and Madhya Pradesh (nonmulberry).

Wool.—The demand of the Indian population for woollen fabrics is very small in comparison with that for cotton, and although the manufacture of blankets is carried on in many parts of India, the chief part of the indigenous woollen industry was originally concerned- with shawls. Kashmir shawls were at one time famous, but the industry is practicallv extinct. The chief seat of the woollen industry is the Punjab,-where a considerable number of weavers, thrown out of work by the decline of the shawl industry, have taken to carpetmaking. The chief centre of this industry is Amritsar. The output of the woollen mills at Cawnpore and elsewhere was chiefly used for the army and the police. (ME.; X.)

Metallurgy and Heavy Industries. — Many industries beside textiles made progress between World Wars I and II, including engineering, railroad workshops, cement, hides and skins, rubber, electric insulators, paint and enamel, chemicals, etc.; and World War II led to an increased demand for India's manufactures, which were moreover stimulated by a big drop in imports as well as by the government's decision to expand armament production greatly. Production of steel was minute and of pig iron only a few thousand tons prior to 1914–18; in 1938–39, however, 1,764,560 tons of pig iron, 1,094,688 tons of steel ingots and 1,048,208 tons of finished steel were produced. In World War II, again, pig iron output increased to the point where not only was

the domestic demand fully met but there was a surplus for export to the United Nations. In May 1942 the output of finished steel was already 50% above the prewar production level. The prewar production of ordinary steel was substantially increased and the industry also began to produce a large variety of special steels for shells, armour plate, machine guns, high-explosive shells, machine tools, surgical instruments, steel mill rolls, shipbuilding, steel billets for telegraph wires, barbed wire and alloys for steel helmets, armour-piercing bullets, etc. Acid for hard steel for gun chargings, gun-carriage mountings, axles, railroad wheels, etc., was developed. India thus was able, barring certain exceptional types of steel, to meet all its own requirements. Total output of all heavy chemicals was about 78,400 tons in 1940. *(See* also *Mineral Resources,* above.)

The Chatfield Committee on Defense (see **Defense,** below), whose recommendations were published in Sept. 1939, included plans for extensive mechanization of the army and expansion of the ordnance factories. Further armament expansion followed the creation of the Eastern Supply Group council. For the first two and one-half years of World War II, India was responsible for supplying nearly all the war materials for the middle east. By July 1943 Indian industry (excluding government-owned factories) had executed war orders to the value of $1,917,000,000. Output rose steadily year by year and was many times any comparable figure of World War I, while an enormously larger range of products was involved. amounting to nearly 20,000 different articles. India supplied 80,000 medical instruments of indigenous production to the U.S.S R. in 1943.

The output of India's ordnance factories was in 1943 many times the prewar quantity. The production of rifles had increased 6 times, of machine guns 8 times, of bayonets 10 times, of small arms ammunition 4 times, of gun ammunition 24 times and of guns and carriages 9 times. The manufacture of armoured fighting vehicles in India progressed steadily after the Indian steel industry succeeded in producing an armoured plate of the required specification at an early stage of the war. In 1941 an aircraft factory in India turned out the first indigenously assembled aeroplane and thus marked the beginnings of an aircraft industry in India; the factory was primarily engaged in the servicing and repair of aircraft.

Before World War II there was no shipbuilding in India; thereafter Indian shipbuilding yards began working to capacity on the construction of ships for antisubmarine and general patrol duties, minesweepers, motor launches and other craft. The number of vessels launched in Indian shipyards during 1942 was two and one-half times the combined total of 1940 and 1941. More than 4,000 seagoing vessels of all types were repaired in Indian shipyards during the first two and one-half years of the war. In the 1950s small-scale shipbuilding was being developed at Karachi, Pakistan, with German aid, while a French firm was helping to develop existing shipbuilding facilities at Visakhapatnam, India.

Pottery and Hardware.— Pottery is made in almost every village, from the small vessels required in cooking to the large jars used for storing grain and occasionally as floats to ferry persons across a swollen stream. Sind, West Pakistan, has pottery of two kinds: encaustic tiles and vessels for domestic use. In both cases the colours are the same—turquoise blue, copper green, dark purple or golden brown, under an exquisitely transparent glaze. The tiles. which are evidently of the same origin as those of Persia and Turkey, are chiefly to be found in the ruined mosques and tombs of the old Moslem dynasties. Artistic pottery is made at Hyderabad. Karachi, Tatta and Hala and also at Multan and Lahore in the Punjab. The Madura pottery deserves mention from the elegance of its form and the richness of its colour. Uttar Pradesh has, among other specialties, an elegant black ware worked with designs in white metal.

The village brazier, like the village smith, manufactures the necessary vessels for domestic use. Chief among these vessels is the *lota,* or globular bowl, universally used in ceremonial ablutions. Benares enjoys the first reputation for work in brass and copper. In the south, Madura and Tanjore have a similar frame, and in the west, Ahmedabad, Poona and Nasik. Silver is sometimes mixed with the brass, and in rarer cases gold. The brass or rather bell-metal ware of Murshibad, known as khagrai, has more than a local reputation because of the large admixture of silver.

Miscellaneous Industries.— Other industries of the subcontinent naturally include rice mills, timber mills, leatherworks (India produced more than 4,000,000 pairs of army boots a year in World War 11), oil mills, iron and brass foundries, tile factories, printing presses, lac factories, silk mills and paper mills. There is a large trade in wood carving, the material being generally Indian ebony in northern India, sandalwood in southern India.

TRADE

Local Trade.— Local trade is conducted either at the permanent bazaars of great towns, at weekly markets held in certain villages, at annual gatherings primarily held for religious purposes or by means of travelling brokers and agents. The cultivator, who is the chief producer and the chief customer, knows little of the great towns and expects the dealer to come to his door. Each village has at least one resident trader, who usually combines in his own person the functions of moneylender, grain dealer and cloth seller. The moneylender deals chiefly in grain and in specie. In those districts where the staples of export are largely grown, the cultivators commonly sell their crops to travelling brokers, who resell to larger dealers, and so on until the commodities reach the hands of the agents of the great shipping houses. The wholesale trade thus rests ultimately with a comparatively small number of persons, who have agencies, or rather corresponding firms, at the great central marts.

Buying and selling in their aspects most characteristic of India are to be seen at the fairs which are held periodically in most districts. Crowds of petty traders attend, bringing all those miscellaneous articles that can be packed into a pedlar's wallet; and the neighbouring villagers look forward to the occasion to satisfy alike their curiosity and their needs.

Foreign Trade.— The trade of India with foreign countries is ordinarily conducted partly by sea and partly across the land frontiers; but the frontier trade, though capable of much extension, is only a small fraction of the whole. The sea-borne trade is carried on chiefly through the great ports. Calcutta serves the fertile valley of the Ganges and Brahmaputra; Bombay serves the cotton trade of western India; Madras with its artificial harbour serves southern India. Pakistan is less well served—by the major port of Karachi in the west, by Chittagong (before partition a small river port) and by the new Chalna-Mangla-Khulna anchorage scheme in the east. The land trade is carried on with Iran, Afghanistan, Nepal, Tibet and western China.

Between 1913 and 1939 there were significant changes in the trend of the overseas trade. There was a reduction in the volume of imports, most marked in cotton goods and other textiles; but from this decline, in spite of protective duties, iron and steel were exempt, the increase in Indian production being no greater than the increase in Indian demand; and there was a very great increase in the imports of machinery and millwork. Other imports which were greatly increased were mineral oil and motorcars. The volume of exports was at as high a level as before World War I; but the character was considerably altered. Less grain was being exported and more tea; much less raw jute and a great deal more manufactured; the export of raw cotton increased, and so did that of cloth, particularly coloured piece goods, but the export of yarn greatly declined.

India, in fact, became much more self-sufficing with regard to manufactures and less disposed to export food and raw materials except where, as in the case of cotton, high prices and increased production made export especially profitable. The causes of this change were partly to be found in higher freights and higher import duties; partly also in the changed condition of world trade as a whole, regarded as an interchange of manufactures for foodstuffs and raw materials, in consequence of which the Indian peasantry received only a small increase in price for most of what they sold but had to pay a great deal more for what they bought. But it was also partly because of Indian progress in manufacturing equipment and industrial organization.

Tariffs and Protection. — From 1894 there was a general standard customs duty of 5% ad valorem, with certain exemptions and certain exceptions; it was levied entirely for revenue purposes. Cotton goods were taxed at 3.5%, whether imported or uoven in Indian mills. During World War I financial exigencies drove up the standard rate to 7.5%; and in the postwar slump it rose further to 11%, with 20% on certain luxury articles. Then came the constitution of 1919, with its pronouncement in favour of allowing India to choose its own fiscal policy. It was speedily followed by the appointment in 1921 of the Indian Fiscal commission, which reported for "rapid industrialization by means of discriminating protection." Coinciding as this did with a prominent tenet in the nationalist creed, the recommendation was quickly put into practice, and an Indian tariff board was appointed in 1923 to deal with applications for protection. The first and most important of these was from the steel industry; and in the event the Tata enterprise was protected by a heavy tariff supplemented for several years by subsidies. The tariff schedule became a complicated document, divided into nonprotective duties and other duties ranging from 2½% to 30% ad valorem. The distinction was subtle, seeing that some of the "nonprotective" duties were as high as 25% (rough sugar) and 75% (cigars). The board decided against a general protective duty on coal. Besides the import duties, there were some low export dues on jute, hides and rice. The objectionable excise formerly levied on cotton goods manufactured in the country was removed in 1925, and the 11% duty on imported cloth became undisguisedly protective (see further under Finance, below, section Revenue).

In 1921 British exporters, who had formerly supplied the bulk of India's manufactured goods, were the chief sufferers since India's industries were built up behind tariff walls. For example, the Indian import of Lancashire cotton goods had averaged 2,j50,-000,000 yd. per annum before 1914, but by 1939 it had dropped to 205,000,000 yd., or less than one-twelfth of the total of a quarter of a century earlier. Other British exports to India declined similarly. Behind the tariff wall India built up a great steel industry; and the Tata steelworks (an Indian enterprise) became the largest single unit manufacturing steel in the British Commonwealth. The net effect was to reduce India's imports of British goods in quantity from 63% of its total imports in 1914 to 30% in 1938 and in value from an average of Rs. 915,801,000 ($274,740,300) in the years 1909–14 to Rs. 519,575,128 ($155,-872.538) in 1939. In 1938–39 Britain took 34% of all India's exports, to the value of Rs. 555,113,000, or $166,533,900. Britain, therefore, was buying more goods from India than it was selling to India. India had obtained economic independence as far as trade was concerned. In 1950 a new fiscal commission recommended important extensions of the policy of protection. A permanent statutory commission was appointed to replace the tariff board after Nov. 4, 1951. The Pakistan Tariff commission was set up in 1950. (X.)

GOVERNMENT AND ADMINISTRATION

The Union of India which came into being on Aug. 15, 1947, by partition of the former Indian empire, had in 1951 a total area of 1,176,864 sq.mi. and a population of 356,879,394. To begin with, the union operated under an adaptation of the Government of India act, 1935, pending the adoption of a new constitution which was then in process of drafting. This constitution was completed and approved by the Indian parliament on Nov. 26, 1949. Under it on Jan. 26, 1950, the Union of India became an Indian sovereign republic; but by an affirmation at the commonwealth ministers' conference in London in April 1949, India continued its "full membership of the Commonwealth of Nations and her acceptance of the King as the symbol of the free association of its independent member nations and as such the head of the Commonwealth." The last governor-general of India, before administering the oath of office to the new president, read a proclamation announcing that "India. that is Bharat, shall be a Union of States, comprising within the Union the territories which were hitherto the Governors' Provinces, the Indian States and the Chief Commissioners' Provinces." In the period following the transfer of power an extensive process of integration of the numerous Indian states, which represented about 45% of the area of undivided India and varied in siee from small landholdings to large countries, had either merged these states in the former governors' provinces or had formed them in groups of states, a few of the larger ones retaining their individual entity. The composition of the union of states (as the total was called) was as follows:

Part A: Assam, Bihar, Bombay, Madhya Pradesh (formerly Central Provinces), Madras, Orissa, East Punjab, Uttar Pradesh (formerly United Provinces), West Bengal.

Part B: Hyderabad. Madhya Bharat (west part of former Central India), Mysore, Patiala and East Punjab States union, Rajasthan, Saurashtra, Travancore, Cochin (Jammu and Kashmir under reference to the United Nations in dispute with Pakistan).

Part C: Ajmer, Bhopal, Bilaspur. Coorg, Delhi, Himachal Pradesh, Kutch, Tripura, Vindhya Pradesh (east part of former Central India).

Part A comprised the former British governors' provinces; Part B, Indian states and groupings of Indian states; and Part C, areas known as chief commissioners' provinces under the central government. In addition, the territories of the Andaman and Nicobar Islands also came under the central government's control.

In 1956 the government accepted the report of a commission which recommended the complete redrafting of the boundaries of states (with the abolition of some and the inauguration of others) on a basis of language, ethnic affinity and administrative convenience. The report was culminated in the States Reorganisation act, no. 37, which came into force on Nov. 1, 1956.

Constitution. — The constitution was passed by the constituent assembly on Nov. 26, 1949. It had been drafted by a committee presided over by B. R. Ambedkar, law member of the government of India and formerly leader of the "scheduled castes" ("untouchables"). Presiding over the assembly was Rajendra Prasad, destined to become the first president of the republic under the constitution. Based largely on the Government of India act, 1935, and on the constitutions of Great Britain and the United States of America, it contained 395 articles — an addition of 80 articles made by the assembly to Ambedkar's draft as first presented on Feb. 21, 1948. It provided for the setting up of parliament, the creation of an independent judiciary with wide powers and the guarantee of fundamental rights. The preamble says: "We, the people of India, having solemnly resolved to constitute India into a Sovereign Democratic Republic and to secure to all its citizens: justice, social? economic and political; liberty of thought, expression, belief, faith and worship; equality of status and opportunity; and to promote among them all fraternity assuring the dignity of the individual and the unity of the nation; in our constituent assembly this 26th November, 1949, do hereby adopt, enact, and give to ourselves this constitution."

The executive head of the republic is a president. elected by an electoral college of members of the Indian parliament and state legislative assemblies. His term of office is five years, but he is eligible for re-election. He must be a citizen of India, more than 35 years of age and qualified for election to the house of the people (the lower house of the bicameral central legislature). There is a vice-president, who is elected by both houses of parliament and who, in addition to being a citizen of India and more than 35 years of age, must be qualified for election to the council of states (upper house), of which he is ex officio chairman. The president acts on the advice of his council of ministers, over which the prime minister presides. The council is responsible to the house of the people. Ministers, following the practice of the former central legislature, can speak in either of the two houses but can vote only in the one of which they are members. The council of states (upper house) has not more than 250 members, a third of whom retire every two years, the election being by the states legislatures. The house of the people has not more than 500 members elected directly by the people on adult franchise at the rate of 1 representative to every 500,000 people. The duration of the life of the house of the people is five years. From it alone can money bills emanate. The official and national language is Hindi in the Devanagari script, though English was to be used for official purposes for 15 years after the inauguration of the constitution. "Untouchability" was abolished, and its practice in any form forbidden by law.

The constitution reversed the trends, shown in the later stages of British rule, to give the provinces greater powers at the expense

of the centre, with consequent difficulties in the way of co-ordinating effort on important financial and economic issues. The constitution therefore gave the central government definite powers to obviate that dapger. It also contains powers for the president to take over the administration of any state where an emergency exists. The republic is a federation of 26 units deriving their power from the centre. In fulfilment of the resolve to secure fundamental rights the constitution declared that the state shall not deny to any person equality before the law or the equal protection of laws within the territory of India; nor shall it discriminate on grounds of religion, race, caste, sex or place of birth. Equality of opportunity for all citizens in matters relating to employment under the state was prescribed. All titles were abolished, and no citizen of India henceforth could accept any title from any foreign state. Citizens of India all acquired the right to freedom of speech, of assembly, of association, of movement and of residence, to acquisition of property and to the practice of professions or trade. Traffic in human beings and forced labour was prohibited. Freedom of religion was assured.

The classification of the states has already been noted. The relations between the centre and the states in respect of legislation were determined by article 246; this gave parliament exclusive powers to make laws in respect of matters set out in what is called the Union list and also with respect to matters in the Concurrent list, which contains subjects with which both the centre and the states are competent to deal. The State list contains matters on which the legislatures of states of the Part A or Part B category have exclusive power to make laws.

The principle of universal suffrage was tempered by the reservation of seats in the lower houses of the union and states for scheduled castes and tribes; and authority given to the president to nominate not more than two Anglo-Indians to the lower house of the union if he is of opinion that their community is not adequately represented there. These special provisions were given a time limit of ten years. Governors are nominated by the president as constitutional heads of their states, advised by cabinets of ministers headed by a chief minister and responsible to the state legislatures. The governors' term, as before, is for five years.

The unicameral system of legislature was made applicable to all states except a few large ones, but even there the lower house has power to abolish the upper house by a resolution passed by a two-thirds majority. The lower house in the state legislatures is known as the legislative assembly and is to function for five years unless dissolved earlier. Representation in the lower house is on the basis of 1 member for every 75,000 of the population of the state, elected on adult suffrage. The total strength of a legislative assembly is to be not more than 500 nor less than 60. Each of the states has a high court, the appellate jurisdiction of which applies to all ordinary cases up to a certain limit.

Secession from the union is not permitted under the constitution. Single citizenship for the whole of India was prescribed, and there is no dual citizenship. Other principles recognized by the constitution are the abolition of landlordism (*zamindari*), the prevention of cow slaughter, the introduction of prohibition and the right of every citizen to admission to any educational institution maintained by the state or receiving state aid, whatever his religion, race, caste or language. Trade, commerce and intercourse throughout the union are free; but parliament has the right to impose such restrictions as may be rkquired in the public interest, and states may also impose on goods imported from other states any tax to which similar goods manufactured or produced in that state are subject. Restrictions were imposed on the powers of states to levy sales tax and purchase tax. For five years from the commencement of the constitution parliament was given power to make laws in regard to the following as if they were in the Concurrent list: (1) trade and commerce within a state; (2) production, supply and distribution of cotton and woollen textiles. raw cotton and cottonseed; **(3)** paper; (4) foodstuffs; (5) coal; (6) iron and steel; (7) mica.

For the constitutional development of India under British rule see History, above. (See also PAKISTAN.) Within the separate states the administrative unit is the district. Under British rule three or more districts (except in Madras) were formed into divisions, over each of which was set a commissioner. This grade was abolished in some states after the transfer of power. The districts were partitioned out into lesser tracts, which are strictly units of administration, though subordinate ones. Generally the subdivision,—called variously tehsil (tahsil), taluka (taluk) or peta in different states—became the ultimate unit, with none below. The thana, or police division, continued to exist, mainly for police purposes. The old pargana, or fiscal division, had now only historic interest; the 24 parganas, a district of West Bengal and the Santal Parganas in Bihar were reminders of it. The village remained as the agricultural unit and preserved its independence for revenue purposes in most areas.

The Indian States.—The relations subsisting between the Indian states and the British government were the outcome of an evolutionary process. The mutiny, the passing of the East India company and the grant of sanads of adoption to the rulers in 1862 obliterated the peril of annexation, breached the barriers of isolation and inaugurated for the states a new era of union under the crown. Queen Victoria's proclamation of 1858 announced to the "Native Princes of India" that all treaties and engagements made with them would be scrupulously observed and that their rights, dignity and honour would be respected.

Under British rule there were nearly 600 states, covering more than one-third of the whole territory of the Indian empire and one-quarter of the population. Their rulers had what were called treaty relations with the British crown as the paramount power. Under the Government of India act of 1935 it was proposed to create a federation of India under a government responsible to a federal legislature composed of representatives of the states and of British India; but this had not been achieved before the outbreak of World War II. In the period immediately preceding the final phases of the transfer of pomer in 1947, the uncertainty regarding the position of the states inspired an attempt to set up an extraconstitutional organ in the form of a chamber of princes (narendra mandal). When at length the transfer of power was effected in Aug. 1947, paramountcy was returned to the Indian states; but it was plainly intended that they should accede to one or the other of the two new governments, accession being mainly determined by the geographical situation of the states. This was a comparatively simple matter in regard to Pakistan, to which states such as Kalat, Dir, Chitral, Swat and Bahawalpur, by reason of their proximity, naturally acceded.

There remained in suspense for a short time the small state of Junagadh (*q.v.*); surrounded by Hindu states in Kathiawar but ruled by a Moslem, who eventually Ieft the state, it came under the government of India and was merged in Saurashtra. Then, too, Hyderabad (*q.v.*), with a predominantly Hindu population and ruled by a Moslem who was the premier Indian prince, showed hesitation regarding its destiny; negotiations for accession to India proved abortive for some time until Indian troops took what was described as police action and the nizam came to an agreement for accession to India.

Kashmir, where the predominantly Moslem population of about 4,000,000 was under the rule of a Dogra (Hindu) prince, also hesitated, but when Moslem tribesmen from over the frontier invaded Kashmir, the ruler applied for accession to India and abdication, which was accepted by the then governor-general on the understanding that the destiny of Kashmir would eventually be settled by the will of the people. From this a grave dispute arose, which was referred to the United Nations by India. Hostilities broke out between India and Pakistan until a cease-fire was arranged on Jan. 1, 1949, and a commission of the United Nations was appointed to investigate. Later Sir Owen Dixon, a judge of the Australian court, was appointed representative of the United Nations to propose a solution. After lengthy conversations with the prime ministers of India and Pakistan Sir Owen had to report failure, and the dispute persisted, despite all efforts, into the late 1950s.

Meanwhile, the government of India, recognizing the need for absorbing many of the petty states into the adjacent provinces and for grouping others so as to provide a sounder financial ad-

ministration, took steps along the lines that had been tentatively contemplated by the British. By dint of considerable forcefulness and expedition this merging of the states was accomplished, with a few states left for a further process of tidying up.

Under British rule the Indian princes were left in almost complete charge of their states, in fulfilment of the proclamation of Queen Victoria of 1858. Interference occurred only where gross misgovernment appeared, and this power of interference was exercised with considerable reluctance. By the new integration the princes were relieved of responsibility not only for defense and foreign affairs (as under the British regime) but also for the day-to-day administration of their states; forms of responsible government were introduced. and the senior ruler in each group, where grouping was concerned, became the equivalent to the governor of that group under the title of *rajpramukh* (*q.v.*).

Moreover. the new Indian government carried out a reform, which the British government had consistently favoured, by fixing a civil list for the former rulers of the states, whether they continued as *rajpramukhs* or became merely hereditary noblemen.

Where mergers occurred, the state territory in effect became part of the normal administrative demarcation of the province (now known as state) concerned. The rulers retained their hereditary rights of succession and the titles to which they were accustomed.

The underlying intention of this integration was to establish in the states democratic systems of government, toward which British influence through the various political officers attached to the states had been gently pressing. This creation of ministries and legislatures was not immediate. Interim ministries were set up to conduct the administration of unions of states; and in three unions (namely, Saurashtra, Travancore-Cochin and hladhya Bharat) legislatures were actually functioning very soon and their ministries made responsible to the legislatures. Representative governments were established in Mysore, in Hyderabad and, subject to the outcome of the dispute already mentioned. in Jammu and Kashmir. Certain areas. being centrally administered and coming under Part C, had advisory councils with a majority of elected representatives to assist the chief commissioners representing the central government. Two of the first of the new unions to have this form of constitution were Himachal Pradesh and Cutch. By the mid-1950s the government of all states, whether Part **A,** B or C, was more or less uniform, and the idea that those under part B were unions of princely states had become largely superseded.

In the merger of the former Indian states with provinces (now known as states) transfer of power to the people was automatic in that the merged states became part of the administrative units governed by the provinces or the centre as the case might be.

Judicial Service.—On the transfer of power the federal court (established in Oct. 1937) became the supreme court. Appeals to the judicial committee of the privy council in London ceased in respect of civil matters in Feb. 1948 and altogether in Oct. 1949. Article 124 of the constitution provided for a supreme court consisting of a chief justice and not more than seven other judges all appointed by the president and sitting in Delhi. Each state has a high court, the judges of which are also appointed by the president (article 214). Below these courts come district and sessions judges who perform the ordinary judicial work of the country, civil and criminal. Their jurisdictions coincide for the most part with the magisterial and fiscal boundaries. Except in Madras, however, where districts are large, a single civil and sessions judge sometimes exercises jurisdiction over more than one district. In some states, judicial and executive functions mere still to a certain extent combined in the same hands but the constitution prescribed the separation of the "judiciary from the executive in the public services of the state." (E. HD.)

The Police.—The police system was established by an act of 1561. It provides a regular force in each district, under a superintendent subordinate for general purposes to the district magistrate. The unit of work is the thana, or police station: some thanas have jurisdictions as big as some English counties and staffs of not more than 12 men. Control of the police rests in the government of each state. The central government has a central bureau of intelligence and investigation.

The regular force depends necessarily on the village watchmen, overworked and underpaid Dogberries, for information and help in their investigations; and they suffer from the steady failure of the general public to give them adequate support in the discharge of their duties. The old canker of corruption and abuse of power among the rank and file of the force mas greatly reduced and the morale of the force vastly improved. The force well stood the strain of the loss of British officers on the transfer of power.

The average population of jails in British India in 1938 was a little more than 122,000, a figure uhich, in its relation to the total population, is striking testimony to the general law-abiding disposition of the Indian people. Discipline was well maintained, though separate confinement had been abolished; and various industries especially carpet weaving, were profitably pursued.

A committee of inquiry laid stress on the reformative side of the prison system; and considerable progress was made by use of the Borstal system and similar treatment. It used to be the rule to transport to the Andamans convicts with more than six years to serve.

FINANCE

Currency and Exchange.—The foundation of the currency system is the rupee (16 annas or 192 pies), a coin weighing 180 gr. and containing 165 gr. of pure silver. The subsidiary coinage comprises pieces of silver. nickel and bronze; all being legal tender up to one rupee only, except the eight-anna piece, which, like the rupee itself, is legal tender without limit. Beside these is a paper currency, at first of slow and lingering growth, in the form of government currency notes; the favourite notes are for Rs. 1, 5, 10 and 100, but there are also others for Rs. 2.5, 20, 50, 500, 1,000 and 10,000. The note circulation as a whole is backed as to more than one-half by a reserve of gold and silver and as to the balance by government securities, with a margin for seasonal expansion based on trade bills up to a strictly defined amount.

The exchange value of the rupee (*q.v.*) follows the ordinary economic law and depends on India's trade balance with the outer world. The operation of this law, however, assumes a fairly constant adjustment of the volumes of currency to the requirement of trade. If there were no restriction on the output of rupees, the gold value of the coin would tend to fluctuate with the gold value of silver. Up to 1873, although the Indian mints were open, the rupee continued steady at an exchange value of two shillings; then the price of silver began to tumble until the rupee dropped almost to one shilling, and in 189.3 it was decided to close the mint to free coinage and establish a "managed" currency, with the rupee as a token coin.

By the start of World War I the rupee had been given by law a parity of 16*d*., and the government bought silver and coined rupees to meet the requirements of the country. So long as silver was under 43*d*. an ounce there was a profit on the operation, which was placed to the gold standard reserve. Against this reserve the government of India could sell sterling drafts (technically known as "reserve councils"), if the exchange value of the rupee threatened to fall. On the other hand, if it were rising, the secretary of state could increase his normal sales of rupee drafts on India (technically known as "councils"). Should this fail to check the rising exchange, it was generally possible to count on a free importation of private gold which would either pass into circulation or be presented to the government for the purchase of rupees. In 1914 the gold standard reserve stood at £26,000,000, the paper currency reserve had £24,000,000 in gold or gold securities and the note circulation had risen to Rs. 66 crores (£44,000,000). With the war, however, the government had therefore to disburse a rupee currency in very large amounts and was compelled to increase the note issue without a corresponding increase of rupees held against the notes. The notes were convertible and their encashment drained away the reserve stock of rupees. The time drew near when either inconvertibility must be declared or silver obtained in large quantities for coinage.

The political effects of inconvertibility were regarded with

grave anxiety; but in 1918 the U.S. came to India's aid, by passing the Pittman act and selling 200,000,000 oz of its silver dollar reserve to the government of India. From July 1918 onward US. silver was coined into rupees and by Dec. 1918 the convertibility of the note issue was secured. Within a few months the output of the mints was represented by the enormous quantity of 1,390,000 000 new rupees (£93,000,000) as currency.

Throughout this struggle another anxiety grew apace. in the risk of being unable to maintain the rupee as a token coin at its statutory parity with sterling. Sterling was depreciating and silver was rapidly appreciating. As the conversion of the rupee into bullion became profitable when silver touched 43d., the rapid rise beyond that figure led to a wholesale melting down of rupees for clandestine export; and the government was forced to protect itself by hurriedly pushing up the parity of the rupee until it stood at as. 4d. in Dec. 1919, while for a short time private remittances brought more than as. 10d.

In 1920 a committee of currency and banking experts in London recommended that the rupee should be correlated to gold and not to sterling and that it should be given a new statutory ratio equivalent to one-tenth of the gold contained in a sovereign. Accordingly. in Sept. 1920 the Indian Coinage act established the new ratio. But there was now a rush of remittances to England, and the former surplus of exports gave place during the second half of 1920 to a large adverse trade balance. which had to be liquidated by bills on London. Exchange persistently dropped from 2s. 6d. the rupee to below 1s. 4d. in the early part of 1921. and the price of silver receded to 32d. the ounce. At last. on the report of a royal commission in 1926, a gold bullion standard was established, under which the rupee was fixed by law at the equivalent of 1s. 6d. gold, its fluctuations being confined between the upper and lower gold points corresponding to that ratio. The maintenance of this ratio was. the commission advised. to be the duty of a reserve bank, obliged to buy and sell gold without limit at rates fixed to accord nith the gold parity of the rupee. The sovereign and half-sovereign were to be no longer legal tender; and thus the old attempts to introduce a gold circulation were finally condemned. Action on those recommendations was taken by the government of India as far as lay in its power. but it had to abandon the scheme of creating a new reserve bank. Meanwhile, the improvement in general economic conditions strengthened the new legal value of the rupee. In 1925–26 the daily telegraphic transfer rates betneen Calcutta and London averaged 1s. 6.08d.; and in 1926–27 the average was 1s. 5.902d.

The efforts made to preserve the convertibility of the currency notes were rewarded by a rapid expansion of their popularity. The circulation (Rs. 66 crores[1]) of March 1914 had trebled by Aug. 1926, when it touched Rs. 200 crores, notwithstanding the practical disappearance of the Rs. 2.5 and the Rs. 200 notes. In 1920 the whole system was improved by the Paper Currency Amendment act, which allowed an unlimited note issue provided a metallic basis of 50% was observed, required the gold backing to be held in India and introduced the principle of a certain definite expansion of the note issue during the busy season against trade bills of a durance not exceeding 90 days. Before the note circulation became firmly established. several attempts were made to lighten the task of supplying India with silver currency by the employment of gold. Among them was the opening of a branch of the British mint at Bombay, intended to coin sovereigns and Rs. 1j gold pieces, which, however disappeared immediately into the hoards of the people. Nearly 3,500,000 gold coins were minted at Bombay in 1918–19, and work was then abandoned.

The close of World War I was marked by a great outburst of speculation. The aggregate authorized capital of new joint-stock companies floated in the year 1919–20 alone was Rs. 281 crores, uhereas the paid-up capital of all registered companies in existence in 1914 was only Rs. 75 crores. Subsequent liquidations were heavy. The most important of the new projects which failed to realize expectations was the Tata Industrial bank, founded to finance new industries on much the same lines as those followed by the "D banks."

[1] One crore = 100 lakhs; 1 lakh = 100,000 rupees, written Rs. 1,00,000.

Exchange subsequently remained stable at the 1s. 6d. rate. The world depression in 1930 created difficulties for the government of India. but these ended nhen Britain left the gold standard in Sept. 1931 and the rupee was linked to sterling. India then benefited by the sale of large quantities of hoarded gold. A steadily favourable balance of trade maintained the rupee's value. In 1935 the Reserve Bank of India (see below) superseded the government's currency department by means of its issue department; and the combined assets of the gold standard reserve and of the currency department mere transferred to it. On the outbreak of World War II in Sept. 1939, restrictions on exchange operations were inaugurated. The rupee continued to maintain its strength nith ease during the conflict and without control would certainly have risen in value in terms of foreign currencies. It was revalued in Sept. 1949 to keep step nith the devaluation of the pound sterling, to which it therefore remained in the same relation as before; viz., 1s. 6d. As Pakistan did not follow suit (until 1955) the exchange with its rupee became 2s. 2d.

International Balances. — India's public debt at the time of World War II consisted of (1) loans raised in India; i.e., rupee loans; and (2) loans raised on the London market; i e sterling loans. On March 31. 1939, the end of the last prewar fiscal year, the sterling debt was £348 700,000, or $1,394 800,000 (conversion being at the rate of $4 to £1 and 30 cents to R. 1). The interest rate on the various sterling loans varied from 5% to 2.5%, and the total interest paid on the sterling debt in the fiscal year 1938–39 was £12,468,000, or $49 872 900. Later virtually the whole of the sterling debt was repatriated by the cancellation of sterling loans and their replacement by rupee loans. So rapid was repatriation that by Jan. 21, 1943, the sterling debt had been reduced to £12,250,000, or $49,000,000. In Sept. 1943 the sterling debt. therefore, was slightly less than the amount of interest paid on the sterling debt in 1938–39. Sterling balances continued to accumulate in the Reserve Bank of India through Britain's heavy purchases of war supplies.

India's sterling debt was mostly incurred for the creation of such enterprises as the government-owned railways (42,000 mi.) and the irrigation schemes that had added 55,076,625 ac to the fertile land of British India by 1944. Revenue from these sources so exceeded the interest payable on the debts as to cover more than the annual charge for India's total debt; that is to say, India acquired by these loans permanent assets yielding a return relieving the taxpayer of interest on debt Industrial and commercial enterprises passed steadily from British to Indian hands

A severe strain was imposed on India's economy by World War II and subsequently by partition. The financial arrangements under the Chatfield scheme were revised under the pressure of war conditions. For the period between April 1, 1940, and March 31, 1946. India bore a total of £13,097,000,000, while the British government bore £13,018,000,000 in respect of India's defense. In addition to expenditure on services and stores of a purely military nature. ministries in Great Britain made purchases of raw materials and food from India on their own account. The effect of this expenditure nas to increase the flow of exports from India with no corresponding flow of imports, thus contributing further to the sterling balances which India held jointly with Pakistan at the time of the transfer of power in 1947. In the course of the next few years these sterling balances were reduced by releases to India and Pakistan so that. according to the Bulletin of the Reserve Bank of India for Aug. 1949 they amounted to £596,333,000. Since under the Reserve Bank of India act not less than approximately £313,000,000 had to be held in sterling securities in support of the note issue. the real figure of the sterling balances by 1949 was about £283,000,000.

The size of foreign investment in India in relation to total investment is large according to the census conducted by the Reserve Bank of India in 1950. The market value of long-term private and foreign investment was £389 000,000, British investment being valued at £282,000 000 and U.S. investment at £22,000,000. The chief element in this foreign investment is "direct investment," in which control of operation is associated with ownership of capital. Its amount is estimated to be £323,000,000.

The government exercises power of control over the admission of new foreign enterprises for the purpose of preventing overinvestment in crowded sectors of the economy. The control of capital issues applies only to joint-stock companies with a capital of £37,500. The manufacture of munitions is reserved to the government. Enterprises of national importance, such as civil aviation and shipping, are open to participation by private enterprise with the government in semipublic corporations. The full current earnings of all foreign enterprises can be freely admitted abroad under existing regulations. (See also Trade, above).

Banking. — The considerable development of banking business which occurred in the years between World Wars I and II started with the formation in 1921 of the Imperial Bank of India by the amalgamation of the three presidency banks of Bengal. Bombay and Madras. But in 1934 the legislative assembly passed the Reserve Bank of India act. and on April 1, 1935. the Reserve bank came into existence. This took over the nork of the currency department of the government (see above) and also the clearing-house functions of the Imperial bank. It had a share capital of Rs. j crores fully paid up and a reserve fund of Rs. 5 crores provided by the government by means of government rupee securities. The scheduled (memberj banks were required to deposit percentages of their liabilities with it. The Reserve bank's first major test was successfully passed when it sanctioned special credits to southern Indian banks on the failure of an important local one in 1938. The Imperial bank could act as the Reserve bank's agent in all places where it had branches in 1934 so long as there were no Reserve bank branches.

Another type of business is done by the exchange banks, which finance practically ail India's export trade and had before 1939 begun increasingly to finance internal trade also. Their total deposits rose from Rs. 1,050 lakhs in 1900 to Rs. 17,900 lakhs in 1945.

The Reserve Bank of India was nationalized on Jan. 1, 1949. The shares of the Reserve bank were transferred to the central government, compensation being paid to persons registered as shareholders immediately before Jan. 1, 1949.

The Banking Companies act. 1949, consolidated and amended the law relating to banking companies. It regulates all banking companies and covers all states of India. to the extent to which the dominion legislature has power to legislate for states in respect of banking. It provides for the licences to banks to be issued by the Reserve bank: lays down the minimum requirements relating to the paid-up capital and reserves of a bank incorporated in India; scheduled banks continued to be required to keep minimum reserves with the Reserve bank arid to submit weekly returns under the Reserve Bank of India act, 1934; and interlocking directorates and the employment of managing agents are prohibited among banking companies.

The total of balance kept by the scheduled banks with the Reserve bank in Nov. 1949 was Rs. 8.063 lakhs.

Planning. — The republican government of India in 1950 drew up a plan for economic development covering a period of six years at a total cost of Rs. 322 crores, of which Rs. 184 crores was earmarked for most urgent projects. The plan included three important multipurpose projects on which work was already in progress for the advancement of agriculture. The Damodar valley project (Rs. 50 crores), the Hirakud dam (Rs. 30 crures) and the Bhakra Nangal project (Rs. 76 crores). The Damodar scheme in Bihar was desiened to harness the Damodar river to provide irrigation, power channels and navigation and to open up to full development the richest mineral base in India. The Hirakud dam was to control the floods of the Mahanadi valley in the south and supply irrigation for the crops and power for cottage industries In the north Bhakra (East Punjab) dams were erected across the river Sutlej and provided power for the cities of the north of India. including Ken Delhi.

Under these three projects 6,000,000 ac. of new land were to be brought under irrigation by 1956–57 and electricity-generating capacity increased by 708,000 kw The government's plan dealt also with the extension of cultivation on reclaimed land the use of fertilizers and improvement of railway communications The plan was directed at the centre by a planning commission which advised the central government. financial control being exercised by the ministry of finance and for some important schemes by the economic committee of the cabinet. Parliamentary control was exercised by the standing finance committee, nhose approval was necessary for all schemes involving nonrecurring expenditure of more than Rs. 5 lakhs, or recurring expenditure of more than Rs. 1 lakh.

The execution of the plan was expected to make possible net private investment to the order of Rs. 160 crores. a figure which it was hoped to increase to Rs. 260 crores at the end of the six years. Government investment in India was estimated to be Rs. 307 crores. and private investment 160 Rs. crores in 1951–52. The revenues of the central and state governments were estimated tor the six years from 1951 to 1957 at an annual average of £128,000,000 pr a total of £772,000,000. A further five-year plan, to begin in 1957, nas laid before parliament in May 1956. It gave priority to increased production of steel, heavy chemicals. machinery and heavy engineering products.

Revenue. — In India powers of taxation are possessed by three authorities: (1) the government of India; (2) state governments; and (3) corporations or municipal boards.

The government of India taxes income and takes excise duties on the production and manufacture of certain articles (*e.g.*, kerosene, matches, motor spirit, silver, steel ingots, sugar. tobacco, tires. vegetable products, cloth, coffee and tea) and customs duties on imports generally and on particular articles of export. State governments levy taxes on the sale of goods, the sale of motor spirit and the consumption of electricity. Municipalities levy octroi duties or terminal taxes on certain goods entering their jurisdiction and also impose water rates, etc.

Before the 1919 constitution, the resources of the state used to be divided, by a sort of variable contract, between the central government and the provincial governments. Part of the 1919 reform was the complete severance of the central from the provincial finances: from 1533 up to 1921 they had been amalgamated; from the budget for 1921–22 onward they were separated. Under this arrangement the provinces by World War II had received and disposed of more than £60,000,000 of receipts, representing their collections of land and irrigation revenue: excise, stamps and forest income. It was spent by them on their administrative business, justice, education, public works, police and jails, public health, etc. In other words, the local governments received the yield of the sources which they administered and were responsible for the expenditure of the provincial departments, both reserved and transferred. In order to enable local governments to discharge their new functions. they were given powers of taxation, scheduled so as not to invade the sphere earmarked for the requirements of the central government. They were authorized to raise loans, either through the central government or independently; and some of the provinces borrowed for works of improvement such as irrigation and city development schemes. At the outset, the central government found itself no longer in control of funds sufficient for its own business. The customs, salt, opium and net railway receipts, income tax, etc., when they ceased to be supplemented as before by a share of the provincial land revenue, stamps and excise receipts, etc., proved inadequate to meet the demands of defense, the public debt and the other central liabilities. It was thus necessary to impose a levy on the provinces, admittedly as a temporary measure pending the inevitable expansion of the central revenues. The provincial legislatures fastened on the arrangement as the main cause of their own financial stringency and magnified a not unreasonable expedient into an intolerable grievance, under cover of which there was a tendency to evade the imposition of taxation that might have balanced their own budgets. From 1928, however, the levy ceased. Meanwhile, local governments claimed, in addition to their own separate revenues, a share of the taxation upon income collected a-ithin their boundaries; and some concession on this point was yielded as an exception to the general rule of separate resources.

The municipalities of India in 1946–47 had the disposal of an annual revenue of £17,000,000 excluding abnormal iteins and bor-

rowings; and the district and local boards had a normal revenue of about £13,000,000. Both classes of bodies had been endowed by the 1919 constitution with a financial independence commensurate in its degree with that of the provinces. The six port trusts had statutory powers for their own business and controlled an income of approximately £8,000,000, Bombay and Calcutta in particular having raised considerable loans, which rank in the Indian market second only to government securities.

For tariffs see Trade, above.

Land *Assessment.*—Since the land revenue is the oldest and formerly by far the most important element in the state's income, some description of the machinery for assessing it seems desirable, especially since it is unique to India and since no field of government policy was more hotly canvassed.

That the state should appropriate to itself a direct share in the produce of the soil is a fundamental maxim of Indian finance recognized from time immemorial. In the old Hindu village community, the land was not held by private owners but by occupiers under the petty corporation; the revenue was due not from individuals, but from the community represented by its headman. The aggregate harvest of the village fields was thrown into a common fund, and before the general distribution the head man was bound to set aside the share of the state. No other system of taxation could be theoretically more just, or in practice less obnoxious to the people. Under the Mogul empire, as organized by Akbar, the share of the state was fixed at one-third of the gross produce of the soil; and a regular army of tax collectors was permitted to intervene between the cultivator and the supreme government.

Shah Jahan and Aurangzeb extracted a larger land revenue than the British. When the government mas first undertaken by the East India company, no attempt was made to understand the social system upon which the land revenue nas based. The joint responsibility of the village community for the revenue was overlooked, and the convenience of collecting it from some individual or group was magnified. The conception of private property in the soil, with which the early British authorities were familiar at home, was grafted from a rural policy to which it was wholly alien. As a result, the office of zamindar—originally a mere farmer or lessee of the revenue under the Mohammedan regime—mas transmuted into that of landowner; and zamindars were created, where they did not exist. from men or families who, for some reason, were prominent in the areas of their residence.

The annual government demand was made the first liability on the land; subject thereto, the registered landholder was given powers of sale or mortgage scarcely more restricted than those of a tenant in fee simple. At the same time the possible hardships, as regards the cultivator, of this absolute right of property vested in the owner were anticipated by the recognition of occupancy rights of fixity of tenure, under certain conditions. Legal rights were substituted for unwritten customs; and the new landowners were endowed with a credit which they had never before possessed, by allowing them a certain share of the unearned increment. Against the misuse of this credit the British government had consistently to struggle.

The means by which the land revenue was assessed was known as settlement, and the assessor was styled a settlement officer. In Bengal the assessment was accomplished once and for all, but throughout the greater part of the rest of India the process was continually going on. The details varied in the different provinces; but, broadly speaking, a settlement may be described as the ascertainment of the agricultural capacity of the land. The settlement officer estimated the character of the soil. the kind of crop, the opportunities for irrigation, the means of communication and their probable development in the future and all other circumstances tending to affect the value of the produce. With these facts before him, he proceeded to assess the government demand upon the land according to certain general principles, which varied in the several provinces. The result was the settlement report, which recorded, as in a Domesday book, the entire mass of agricultural statistics concerning the district.

Lower Bengal and a few adjoining districts of the United Provinces and of Madras had a permanent settlement, the land revenue having been fixed in perpetuity by Lord Cornwallis in 1793. The zamindars of that time became practically landlords, with rights of transfer and inheritance, subject to the payment of a rent charge in perpetuity. But no detailed record of tenant-right was inserted in the settlement papers, and the cultivators lost rather than gained in security of tenure. The peasantry found no protection in the law courts until 1859, when an act was passed which restricted the landlord's powers of enhancement. Later the Bengal Tenancy act of 1885, to be amended by an act of 1908, created various classes of privileged tenants, including one class known as "settled ryots," in which the qualifying condition was holding land, not necessarily the same land, for 12 years continuously in one village. Outside the privileged classes of tenants the act gave valuable protection to tenants-at-will: and the original vices of the Bengali system were partly overcome though the growing division of rights in the land is an abiding economic calamity.

The prevailing system throughout the Madras presidency was the ryotwari, which took the cultivator or peasant proprietor as its rent-paying unit.

The representatives of several ancient lines of powerful chiefs in the extreme south and in the north of the presidency had their estates guaranteed to them on payment of a *peshkash,* or permanent tribute, and were saved by the custom of primogeniture from having to subdivide them. Throughout the rest of Madras there were no zamindars either in name or fact. The influence of Sir Thomas Munro led to the adoption of the *ryotwari* system, which came to be associated with his name. According to his system, assessment was made with the cultivating proprietor upon the land taken up for cultivation year by year. Neither zamindar nor village officer intervenes between the cultivator and the state, which took directly upon its shoulders all the landlord's responsibility.

Nothing can be more complete in theory and mare difficult of exposition than a Madras *ryotwari* settlement. First, the entire area of the district, whether cultivated or uncultivated. and of each field within the district was accurately measured. The next step was to calculate the estimated produce of each field, having regard to every kind of both natural and artificial advantage. Lastly) a rate was fixed upon every field, which may be regarded as roughly equal to one-third of the gross, and one-half of the net, produce. The rates thus ascertained were fixed for a term of 30 years; but during that period the aggregate rent roll of a district was liable to be affected by several considerations, which were discussed and decided by the collector at the *jamabandi,* or court, held every year for definitely ascertaining the amount of revenue to be paid by each ryot for the current season.

In the early days of British rule no system whatever prevailed throughout the Bombay presidency; and even at the time of World War II there were tracts where something of the old confusion survived. The modern "survey tenure" as it is called, dates from 1838. Each field was measured, and assessment placed upon it according to the quality of the soil without any attempt to fix the actual average produce. This assessment held good for a term of 30 years.

In the other provinces variations of the *zamindari* and *ryotwari* systems were found. In the United Provinces and the Punjab the ascertainment of the actual rents paid was the necessary preliminary to the land revenue demand. In the Central Provinces, where the landlords (*malguzras*) derived their title from the revenue settlements made under British rule, the rents were actually fixed by the settlement officer for varying periods. In addition, nearly every province had its own laws regulating the subject of tenancy. In Uttar Pradesh, Bihar and West Bengal *zamindari* was abolished under the republic.

The principles of the land revenue settlement and administration were reviewed by the government of India in a famous resolution prepared under Lord Curzon's direction and presented to parliament in 1902. It gave a full description and justification of the system and its consequences. In the previous year, the Famine commission had come to the general conclusion that "except in Bombay, where it is full, the incidence of land revenue is

low to moderate in ordinary years. and it should in no way per se be the cause of indebtedness." Later there was an active movement to have the principles of valuation and assessment fixed by law instead of being left to usage. In areas ivhere enhancements in the land revenue were decided to be, in whole or in part. attributable to the benefits of state irrigation, an appropriate part of the field was transferred to the state irrigation department. Otherwise. that department charged by a rate on the land for the water it supplied. attempts to meter the flow and charge accordingly having met with imperfect success.

Income Tax.—Income tax was first imposed in 1860 to cope with the effects of the mutiny of 1857. The system underwent many vicissitudes but in an act of 1886 the schedule was consolidated. A tax was imposed on all incomes derived from sources other than agriculture—an exemption which still held good at mid-20th century. The tax remained at a low figure until World War I, when the schedule was revised upward. During World War II receipts from income corporation and excess profits taxes contributed an increasingly large proportion of the revenue, rising from 20.2% in 1940–41 to 57.2% in 1945–46. In 1950–51 it was estimated to be 44.9%. The range of the tax rate on incomes of Rs. 3,600 and upward was for 1950–51 from 1.8% to 77%. The excess profits tax imposed during World War II was abolished after March 31, 1946.

Salt.—Before the successive reductions of the salt duty in 1903, 1905 and 1907, next to land. salt contributed the largest share to the Indian revenue. In March 1947 the government of undivided India abolished the duty; but it had to be reimposed after the loss of Rs. g.j crores of revenue. Later, plans were put into effect to develop the industry. On April 23, 1948, it was announced that licences would no longer be needed by producers of salt.

Excise.—Excise duties vary greatly in different provinces, and flow from a special form of government monopoly. The articles taxed are intoxicants and drugs; and the avowed object of government is to check consumption as well as to raise revenue. No duty whatever is levied upon tobacco in any part of India. The plant is universally grown by the cultivators for their own smoking, and the impossibility of accurate excise supervision caused the government to abandon the impost.

The right to manufacture and the right to retail spirits and beer are monopolies of government permitted to individuals only upon terms and under strict supervision. In Madras and Bombay the governments under the republic abolished excise on the sale of liquor and instituted prohibition.

Of excisable drugs the most important are opium, bhang, ganja and charas. Opium is sold through private retailers at a monopoly price. Its importance as a source of revenue steadily diminished, however, the area under poppy cultivation having shrunk from 207,000 ac. in 1918 to 4,800 ac. in 1940, and being still further reduced later. Opium used to be largely auctioned for private export to China and elsewhere. But the attempts at social reform in China and the intervention of the League of Nations led to a profound modification of the system. and cultivation was regulated with a view to the extinction of the export trade. A certain amount of opium is also sold to state governments for local consumption in India; and attempts were made to develop the market for the medicinal products of the drug.

Bhang, ganja and charas are three different narcotic drugs prepared from the hemp plant. The plant grows wild in many parts of India; but the cultivation of it for ganja is practically confined to a limited area in the Rajshahi district of East Bengal (Pakistan), and charas is mainly imported from central Asia. In regard to ganja and charas, cultivation of the plants is severely restricted and a direct quantitative duty is levied on the drugs on issue from the warehouse in the province of consumption; while as regards bhang, cultivation of the hemp for its production is prohibited or taxed. and collection of the drug from wild plants permitted only under licence, a moderate quantitative duty being levied in addition to vend fees.

Other sources of revenue are stamps, levied on judicial proceedings and commercial documents; registration of mortgages and other instruments; and provincial rates, chiefly in West Bengai and Uttar Pradesh for public works or rural police.

DEFENSE

In undivided India defense forces consisted mainly of the army in India, the Royal Indian navy and the Royal Indian air force.

Army.—At the time of partition, the army in India had existed for nearly 300 years. It derived from the small forces which the East India company maintained for the local protection of its factories; but as time went on it took more organized form. At first it consisted of European troops only; then it was divided into three presidency armies, each having royal troops, company's European troops and company's Indian troops. Thus, the Indian army began. In 1860 the queen's and the company's European troops were absorbed into the British army in India, the Indian troops becoming at the same time part of her majesty's forces.

The change of the name of the Indian troops to the Indian army was incidental to Lord Kitchener's reorganization of 1903. Of the details of the reorganization it is not necessary to say more than that it divided the army in India (British troops and Indian army) into three commands, northern, eastern and ti-estern, roughly corresponding to the old Punjab, Bombay and Bengal commands. In 1907 the command system was abolished and India was divided into two armies, northern and southern.

In World War I both army commands took the field and were not replaced. In that war the Indian troops served on many fronts with great distinction, notably in France, at Gallipoli, in east Africa, in Palestine and in Mesopotamia. In the early days of the war the strain of the first German advance impelled the British government to withdraw many of the British regiments from India and to replace them by territorial units. The first territorials thus to arrive in India landed in Bombay in Nov. 1914; and. since in the first convoy was the territorial battalion of the Dorsetshire regiment, arrangements were made for it to be the first to disembark in order to carry on regimental tradition, because the first British regiment to land in India was the 39th foot —later 1st battalion of the Dorsetshire regiment—which arrived in Madras in 1754 and thus got the title of *Primus* in *Indis.*

Later: after serving in India, most of these territorials went eventually to other fields of the war, and their places were taken by garrison battalions formed in the United Kingdom from veterans who had already seen active service.

The Indian army had two main categories of officers, one holding the king's commission and the other the viceroy's, the latter being exclusively Indian and promoted from the ranks. In Jan. 1918 Indians were made eligible for the king's commission, and the accepted policy of indianization of the king's commission ranks was accelerated in 1924 by the selection of 8 units, subsequently extended to 16, for closure to any further posting of British officers. The scheme was eventually proved to be inadequate, and in 1932 the Indian military academy was established at Debra Dun, for it had been found that for various reasons the number of Indians who could be passed through Sandhurst was insufficient. In 1945 it was announced that the grant of permanent commissions in the Royal Indian navy and Indian army would in future be restricted to Indians as it had already been in the Royal Indian air force.

The regiments of the Indian army had long traditions of service in all parts of the world; in fact, during the Crimean War in 1854 Indian troops were sent to garrison Malta and Gibraltar to release British units for the front.

Special orders were instituted for recognition of gallantry in the field; the highest was the Indian order of merit instituted by Queen Victoria in 1837 Its standards were as high as those which 17 years later were to qualify for the order of the Victoria cross. At the time it was intended that all soldiers and sailors of the empire alike should be able to earn the Victoria cross; but the government of India of the day, jealous, it was thought, for the prestige of the Indian order of merit, did not agree and pointed out that to that order was attached an annual monetary reward similar to that given with the Victoria cross. As time went on the cause of this limitation was forgotten, and in 1911 at the

royal durbar at Delhi the king-emperor announced its removal as one of the boons forthcoming at that ceremony. The first award of the Victoria cross under this decision was made in 1914, to Naik Khudadad Khan of the 129th Baluchis. In World War II, 31 Victoria crosses were won by the Indian army, 10 of them by Gurkhas. The first Victoria cross in that war to be won by an Indian was awarded in 1941 to 2nd Lieut. Premindra Singh Bhagat, a former Dehra Dun cadet, for gallantry in Abyssinia. The Indian distinguished service medal was another distinction for soldiers of the Indian army; and the order of British India, established in 1937, went to Indian officers for long and faithful service. From 1815 onward the Indian army, by treaty with the kingdom of Nepal, recruited regiments of Gurkhas, the number reaching ten.

Because of the geographical and political situation of India the government's military expenditure was a heavy item in the budget, and this was naturally increased by war conditions. The need for keeping the army in India on a modernized footing permitted the setting up of a committee under Lord Chatfield in Sept. 1938; and as a result of this inquiry the annual grant of £1,500,000 (which had been paid to the government of India since 1933 in aid of Indian defense expenditure) was increased to £2,000,000 and a capital grant made for the re-equipment of certain British and Indian units in India and for the provision of aircraft to certain squadrons of the royal air force in India. It was further agreed that four British battalions should be transferred from the Indian to the imperial establishment. The number of British troops in India was reduced by about 25%. The committee's view was that the forces maintained by India could bear only a small share in the wider responsibilities of defense, and in the recommending of the increase in the payment by the British government it was laid down that the margin for external defense should be one-tenth of the military forces maintained in India. During World War II, because of the part played by India in the operations in the middle east and in Africa and in the subsequent attempted invasion by Japan, the Indian army was greatly expanded and reached a total strength of 2,250,000.

Transfer of power in r947 brought about partition of the Indian army. the Royal Indian navy and the Royal Indian air force, though both dominions retained British commanders in chief, India until Jan. 1 j, 1949, and Pakistan until Jan. 1, 1951.

The allocation of units of the former Indian army to the new dominions was made on the basis of the composition of the units. The majority of regiments already largely composed of Moslem soldiers were allotted to Pakistan, the rest to India. Moslem subunits of regiments predominantly Hindu and so assigned to India were left in Pakistan and vice versa.

This allocation gave India the following numbers of units, Pakistan's quota being noted in parentheses: infantry 15 (8); armoured corps 12 (6); artillery 19 (9); engineers 61 (34). The future of the ten Gurkha regiments of the Indian army was determined by a tripartite agreement between the United Kingdom, India and the independent kingdom of Nepal: four regiments (2nd, 6th, 7th and 10th Gurkhas) entered the British army under the king of England; the remaining six regiments became part of the new Indian army. The prevailing religions of Nepal being Hinduism and Buddhism, there was no question of allotment of any Gurkha regiment to Pakistan. The service of Gurkha soldiers either in the Indian army or in the British army was to continue to be voluntary.

Navy. — The East India company, under its charter, maintained an armed naval force, and in 1829 the company founded an Indian navy. After the mutiny this service was abolished for reasons of economy; and an Indian marine service was formed which developed, in 1892, into the Royal Indian marine. In 1914 this force consisted of six armed transports manned by British officers and native crews. During World War I the ships were employed in patrolling the Red sea and the Persian gulf, and the Royal Indian marine took charge of the inland water transport in Mesopotamia until the end of 1916.

Constitutional progress in India led to the desire for a full-fledged Indian navy, and in 1934 the council of state and assembly passed a bill authorizing its establishment. On Oct. 2, 1934, the Royal Indian navy was inaugurated at Bombay, the Royal Indian marine ceasing to exist. A flag officer of the royal navy was placed in command and training establishments were instituted. On the outbreak of war in 1939 a large program of construction was initiated, giving considerable stimulus to shipbuilding in India. During World War II, ships of the Royal Indian navy operated over wide theatres from the Atlantic ocean to the China sea, mainly in the escort of convoys, mine sweepers. antisubmarine operations and patrolling, and its personnel had grown from 1,400 before the mar to 20,000 men at the end of 1943. In 1955 the republic of India had two cruisers, six destroyers and four vessels of the frigate and escort type. The establishment was 1,000 officers and 10,000 ratings.

Air Force. — The royal air force in undivided India, under the control of the air vice-marshal, originally comprised six squadrons organized in three wings of two squadrons each; and its establishment was 218 officers and 1,757 British and 138 Indian other ranks. The aircraft depot and the various aircraft parks were directly under R.A.F. headquarters in India.

An Indian air force was formed at Karachi in 1933 with one flight and had grown to ten fully equipped squadrons by 1943. It served with distinction during World War II. In 1943 the personnel was 30,000. On partition India received seven fighter squadrons and one transport squadron.

Republican Changes. — On India's becoming a sovereign republic the designation of "royal" was dropped from the titles of the various regiments possessing it, as also from the Indian navy and Indian air force. India had already instituted its own awards for gallantry to replace the British awards. These were the Param Vir Chakra, to rank next and immediately after the Victoria cross and awarded for the most conspicuous gallantry; the Maha Vir Chakra, next to and immediately after the distinguished service order; and the Vir Chakra, next to and immediately after the military cross. The name "viceroy's commissioned officers" was changed to "junior commissioned officers."

COMMUNICATIONS

Railways. — The railways of the subcontinent serve at least three different purposes: (1) the ordinary business of carrying passengers and commerce; (2) safeguarding of the internal and external peace of the country; and (3) protection against famine by facilitating the movement of grain. For this reason the interest on capital cannot, in the case of all the lines, be judged by a purely commercial standard; but for India as a whole the return on the capital expended is normally between 5½% and 6%. In the early days of railway enterprise the agency of private companies guaranteed by the state was exclusively employed, and nearly all the great trunk lines were built under this system. In 1870 a new policy of railway development by the direct agency of the state was inaugurated; and the government of India was often criticized for lack of enterprise, undue complexity and vacillation in its railway policy. But the tide later ran strongly in the direction of taking the main lines under state control as the leases of their working companies fell in, or as the purchase powers under their original concessions matured. By World War II, 41,134 mi. of railroad had been constructed, comprising 21,255 mi. of broad-gauge (5½ ft.), 15,757 of metre-gauge and 4,122 of narrow-gauge, nearly all absorbed by the state or about to be absorbed. These conveyed passengers (an average of 622,000,000 in a year) at less than one-third of a penny per mile as the average third-class fare, and goods at a little more than a half-penny per ton per mile.

World War II imposed a tremendous strain on the Indian railways which they withstood well. Traffic increased tremendously with movements of troops and war supplies and also when for a period loss of control of the Bay of Bengal diverted much traffic from sea to land. Quantities of Indian locomotives, track and personnel were sent to Iran to open a new war supply route to the U.S.S.R.

Partition affected three railway systems: the North-Western, the Bengal-Assam and the Jodhpur railways. The North-Western

railway, with a mileage of 6,881 mi. before partition, was divided so that 5,026 mi. went to Pakistan and 1,855 mi. to India. Of the Bengal-Assam railway. 352 mi. of broad-gauge, 17 mi. of narrow-gauge and 1,573 mi. metre-gauge fell within India, leaving 1,613 mi. in Pakistan. The Sind section of the Jodhpur-Hyderabad railway (319 mi. metre-gauge) fell entirely within Pakistan. The total mileage of railways in India in 1952–53 was 34,275 mi. Among the lines constructed after partition was an addition to the Oudh, Tirhut arid Assam section of the North-Eastern railway of 145 mi., linking Assam with West Bengal and thus obviating the need for crossing Pakistani territory in that area. The majority of the railways in the republic were nationalized and regrouped in 1952 into six regional systems.

Civil Aviation. — Civil air transport first came to India in the international field when, in 1929–30, the British, French and Dutch extended their empire air services to and across India. In undivided India plans for the operation of a state service between Karachi and Calcutta were made but abandoned for financial reasons. The first effective step for the operation of internal air services in India was taken by the Tata Sons, Ltd., in organizing an air service from Karachi to Madras in 1932. On the introduction of the empire air mail scheme the government of India, in association with the government of Ceylon, participated. Between 1937 and 1939 three companies came into existence, but on the outbreak of World War II a drastic change was made in these arrangements: the empire air mail scheme was suspended and its resources diverted to the needs of war; and all transport operations in India were placed on a war footing. Plans for postwar reconstruction of civil aviation were drawn up by Sir Frederick Tymms and generally approved by the government of India; but with the partition in Aug. 1947 the air-route pattern underwent a change and, moreover, some of the companies operating found themselves in financial embarrassment. On June 30, 1948, there were 23 Indian air companies with an authorized capital of Rs. 42.2 crores. Nine of them operated 38 scheduled air services, internal and international, on 23 routes employing 191 aircraft, 229 pilots and 140 other air-crew personnel. In 1953 these nine companies were grouped in two state-owned corporations — Indian Airlines and Air-India International.

Posts and Telegraphs. — In addition to its primary duties, this department has served miscellaneous functions. It acts as the people's savings bank; it allows the people to do their shopping at all distances through the system known as the V(alue) and P(ayable) P(ost); it collects customs charges on dutiable articles coming to India by post; it has a life insurance department; it pays the pensions of retired officials of the Indian army; and it sells quinine. In 1946–47 there were 26,130 post offices; the number of postal articles handled was 2,263,000,000, and 9,300,000 articles were sent by V.P.P. Money orders issued amounted to Rs. 52,000,000. The number of village postmen was 19,000, and the total strength of the establishment was 170,000; boxes numbered 57,000. The telegraph lines totalled 653,340 mi. Radio telegrams totalled 51,439, but of this only 5,000 were sent, the rest were received. There were 551,000 mi. of telephone wire and 2,870 exchanges, including departmental, nondepartmental and branch exchanges. The total number of telephones connected was 123,000 and lines 105,000. In 1954 the republic had 210,314 telephones (Pakistan had 27,886).

Broadcasting. — The Indian Broadcasting company was licensed in 1927 but went into liquidation in 1930, after which the government of India took control of broadcasting. After the partition of India, regional stations at Peshawar, Lahore and Dacca were handed over to Pakistan. All-India Radio is attached to the department of information and broadcasting. Its headquarters are at New Delhi and its stations are situated at Delhi, Lucknow, Patna, Calcutta, Cuttack, Madras, Tiruchirapalli and Bombay, Shillong-Gauhati, Nagpur, Vijayawada, Baroda, Allahabad and Jullunder. The programs are broadcast in 13 Indian languages and in English. From Broadcasting house in New Delhi (completed in 1943) 22,980 news bulletins are issued in the year. Broadcasts are provided in the external services in English. Hindustani, Tamil and Gujarati for Indians overseas; radiating from Delhi but distinct from the Delhi regional programs, they also provide 24 news bulletins a day in 12 languages — 9 foreign and 3 Indian. The number of radio receiving sets in 1954 was 680,000 in India and 99,000 in Pakistan — a marked increase on the total figure for 1937, which was 50.680.

WELFARE

Public **Health.**—The sanitary welfare of the subcontinent is extremely backward, largely because of the climate, general poverty and the pressure of the population. For the years 1931–35 the average ratio of births was 34.4 per 1,000 of population, and the ratio of deaths 23.5, fully one-fifth of the mortality being among infants of less than a year old.

In years of bad epidemics, the death roll runs much higher; the ratio, for example, was 62.46 in 1918, the disastrous influenza year; and plague carried off 12,000,000 in a single decade. Cholera is endemic in some areas, malaria in almost all; hookworm and kala-azar are widespread. Medical relief hardly exists outside the towns, except at the dispensaries established by the government and now controlled by local authorities. Yet improvement was slowly effected. In the past, every important fair or seat of pilgrimage was a focus of disease and death to many thousands. This was later brought under control; and great strides were made in providing the cities and larger urban areas with a supply of pure drinking water and with proper sewage or conservancy. Elementary hygiene was also introduced into the teaching in schools; and interest was taken in child welfare.

In 1943 the government of India appointed a health survey and development committee under the chairmanship of Sir Joseph Bhore. Its report made important recommendations with the object of providing each individual in the country with adequate medical care irrespective of his ability to pay for such services; of making medical aid available to rural as well as to urban areas; and of securing the active co-operation of the people in the development of the program. A long-term plan was drawn up by the committee; and the new government of India in 1947 accepted all the recommendations in principle and started implementation of the report by the establishment of medical scholarships, the creation of an all-India medical institute and the examination of the state governments' five-year medical and public-health development schemes accordingly. In the year 1946–47, according to the economic adviser's report of 1949, there were in India about 3,500 hospitals and dispensaries of varying quality, at which 51,000,000 patients were treated, though the total number of beds available was only about 53,500.

Labour Organization and Legislation. — Trade unionism on British lines made its first appearance in Madras during World War I. The pioneer society, the Madras Labour union, was a fairly solid organization of the cotton-mill operatives, which quickly found imitators. The great rise of prices and the industrial boom of 1919 furnished the most favourable conditions for a rapid advance. notably in Bombay. The cotton operatives in particular showed unsuspected staying power and not only secured advances during the boom but also, in 1925, won a more remarkable victory in resisting successfully a reduction of wages during the slump. An act intended to recognize trade unionism and to encourage it on sound lines came into force on June 1, 1927, and the movement became a permanent and growing element in Indian industrial life.

India was represented at the International Labour conference at Washington. D.C., which was followed by an "All India Industrial Welfare congress" held in Bombay in April 1922. Important labour legislation was enacted in the same year. The Factories act of 1922 raised the age of admission for children from 9 to 12, for full-time work from 14 to 15, prohibited night work for women- and enacted for all workers a maximum day's work of 11 hours and a maximum week of 60 hours. The Mines act of 1923 forbade the employment of children and young persons below ground, while still permitting that of women, and limited the week's work to 60 hours above ground and 54 hours below. The Workmen's Compensation act of the same year allowed compensation for death or accident for 3,000,000 industrial workers. Fac-

tory law in India was completely overhauled by the Factories act of 1934, amended in 1936, 1940 and 1941. The act classified factories into seasonal and perennial. Seasonal factories are those engaged in processing such seasonal activities as cotton ginning or tea manufacture. The 1922 act's maximum hours of work had applied only to seasonal factories; in others a maximum of 10 hours per day and 54 hours per meek was allowed. The act of 1934 covered factory "spreadover" hours, artificial cooling and humidification, welfare (water, shelter, rest, first aid. reservation of rooms for men, uomen and children), holidays. overtime. certificates of fitness for children and security. Under the Factories act of 1948 (a consolidating measure) minimum requirements regarding the health. safety and general welfare of the workers were prescribed. The object was to remove a weakness in the act of 1934 which left, it was thought. too much to the rule-making powers of the state (then provincial) governments. The act which came into force on April 1, 1949, covered all industrial establishments employing 10 or more workers and using power and those employing 20 or more workers and not using power. It abolished the distinction between perennial and seasonal factories.

EDUCATION

At no period of its history has India been an altogether unenlightened country. Inscriptions on stone and copper, the palm-leaf records of the temples and in later days the widespread manufacture of paper all alike indicate not only the general knowledge but also the common use of the art of writing.

From the earliest times the caste of Brahmans has preserved, by oral tradition as well as in manuscripts, a literature unrivalled in its antiquity and in the intellectual subtlety of its contents.

The Mohammedan invaders introduced the profession of the historian, which reached a high degree of excellence, even as compared with contemporary Europe. Through all changes of government vernacular instruction in its simplest form has always been given, at least to the children of the higher castes, in every large village.

British India. — During the early days of the East India company's rule the promotion of education was not recognized as a duty of a government either in India or in England. Warren Hastings did indeed found the Calcutta *madrasa* for Mohammedan teaching, and the establishment of the Sanskrit college at Benares in 1791 was associated with the name of another servant of the company, Jonathan Duncan. But Wellesley's schemes of imperial dominion did not extend beyond the establishment of a college for English officials. On the Rs. 1,00,000 grant which was prescribed. the first of its kind, for the encouragement of education by the Charter act of 1813, no general scheme of public instruction could be built. But the Sanskrit college in Calcutta was founded in 1824, the medical college by Lord William Bentinck in 1835 and the Hooghly *madrasa* by a wealthy Indian gentleman in 1835; the Agra college had been established in 1823.

Meanwhile. the missionaries made the field of vernacular education their own. Discouraged by the official authorities and ever liable to banishment or deportation, they not only devoted themselves with courage to their special work of evangelization but also were the first to study the vernacular dialects spoken by the common people. Just as two centuries earlier the Jesuits at Madura, in the extreme south, composed works in Tamil, which are still acknowledged as classical, so did the Baptist mission at Serampore, near Calcutta, first raise Bengali to the rank of a literary language. The interest of the missionaries in education had two distinct aspects. They studied the vernacular, in order to reach the people by their preaching and to translate the Bible; and they taught English, as the channel of nonsectarian learning.

A fresh wind began to blow from England with the Charter act of 1833. The work of the missionaries received official licence; and in 1835 Bentinck decided that "the great object of the British government ought to be the promotion of European literature and science among the natives of India." This was the last word on a long-drawn controversy between a school which arrived at the extension of oriental learning in India in its own languages and the school which urged the teaching of elementary knowledge in the vernacular tongues and of the higher branches in English. The scale had been turned by Macaulay's minute in support of the latter view; and the low state into which Hindu morality and culture had sunk at the time was felt to be adequate justification for the decision. It settled the aim of the British governmental system of education in India, and Sir Charles Wood's dispatch of 1854 determined the methods and machinery. From that date onward education meant a network of schools, colleges and examinations ultimately controlled by the government.

Many of the institutions were maintained directly from public funds and staffed by teachers who were public officials. Another class was maintained by local authorities, subject to close control by the government. A third class under private (*e.g.*, missionary) management depended on the government for grants-in-aid or for "recognition"; and both grants and recognition implied strict compliance with governmental regulation. At the same time the government in its anxiety to hold an even balance between the different sects and creeds in India kept carefully aloof from the teaching of religion.

The British government thus, while honestly giving its best in teachers and what it believed to be its best in curricula, exposed itself to the odium of what were for long three grave defects in the system.

1. By making its own type of education the qualification for government service, it tended to concentrate the energies of the youth of India on the search for public offices, rather than on learning for its own sake or on that general development of the intelligence which would serve the industrial growth of the country.

2. The mass of students who clamoured for a purely literary education as the doorway to official employment was so great that the vast majority of them absorbed only a shallow and mechanical smattering of knowledge; and, since to those who failed in securing government service this education proved of no commercial value. a class of unemployable and half-educated lads grew up, who became ready vehicles for political unrest and in some cases for revolutionary crime.

3. Purely secular instruction which virtually ignored the vernacular languages involved neglect of the indigenous ethos and culture of India and became in time largely responsible for the reaction against western civilization.

To these defects the government was far from blind, and the educational policy of the British in the 20th century was a constant endeavour to mitigate them. Lord Curzon had the whole system overhauled and improved. The universities were liberalized, the colleges set on the way to becoming residential institutions and the assistance to elementary schools largely extended; while technical and agricultural schools were reformed. Lord Minto got a special ministry of education established; and the financial prosperity of Lord Hardinge's viceroyalty enabled him to make generous grants to the provinces for education and to wage war on illiteracy.

But the root of the matter was attacked when a special commission was appointed. under the chairmanship of Sir Michael Sadler, to inquire into the weaknesses of the Calcutta university and incidentally of university education generally. It reported in 1919 and condemned in emphatic language the whole conduct of secondary and university education.

The commission advised radical reforms. The universities should be centralized, unitary, residential teaching bodies with a government of their oun. Tuition of a preparatory type should be removed to a new grade of intermediate colleges where the curriculum u-ould be varied and would lead up to examinations not under university control. though qualifying for entrance to a university and having an independent value as a certificate of general education. Students would thus enter the universities at a later age and at a stage represented by the old "intermediate" examination, thus relieving the universities of a part of their unuieldy host of undergraduates. These recommendations were generally welcomed. and most of the former universities (including the Hindu university at Benares, which owed much to Mrs.

Annie Besant) reconstituted themselves accordingly, while new universities of the teaching and residential type sprang up at Dacca, Aligarh (Moslem), Lucknow, Patna, Nagpur and Delhi. In 1926 legislative provision was made for incorporating a university at Agra to relieve the external work at Allahabad, and in the same year a new Andhra university was inaugurated in Madras. In 1939 the number of students at university and professional colleges was 145,000, of whom 7% were women. By 1951 there were 34 universities in the republic with over 350,000 students (and 6 in Pakistan with about 55,000 students).

Secondary education advanced apace, and in high and middle schools of a nontechnical type the enrolment in 1939 was 2,659,000 pupils, including about 14% females. But shortage of funds interfered with the establishment of "intermediate" institutions advised in the Sadler report, as well as with the improvement of the mass of high schools.

The pace of development in primary education was also seriously retarded by financial difficulties; but by 1939 the number of children at primary schools had risen to 11,445,000, inclusive of more than 2,849,000 girls. Although it was recognized that here was the only nursery for an intelligent electorate in the future, the difficulties were many: the traditions confining education to certain castes, communal troubles, bad communications, the dearth of competent teachers and above all the poverty of the rural parent, who could not spare his sons from the ranks of the breadwinners and had no belief whatever in educating his daughters. To these permanent obstacles must be attributed the fact that, according to the census of 1941, only 195 in every 1,000 men and 55 in every 1,000 women in undivided India could read and write. In face of these figures it was not surprising that the legislatures had frequently turned to the remedy of compulsion. Acts asserting the compulsion principle were passed in several provinces, but the translation of principle into practice was still incomplete. Meanwhile the decentralization of the control of primary education offered a prospect of greater elasticity, especially in adapting the school curriculum to rural needs.

Female education was long the despair of reformers. Social prejudices and the subordinate and largely dependent position of women were antagonistic to it, and there was the greatest difficulty in obtaining, except in the Christian community, qualified women teachers. The Brahmo Samaj and a few enlightened groups and individuals persevered in the education of their womenfolk: but progress was deplorably limited and slow. With the awakening of national feeling, however, some advance became apparent. By 1926 there were a little more than 1,000,000 females receiving college and school education in the whole of British India. By 1939 this figure had risen to 3,270,000. By 1951–52 about 25,000,000 children were at school in India (and about 4,000,000 in Pakistan).

The Republic. — The general educational policy of the government of India is comprised in the report of the central advisory board of education. This report, popularly known as the Sargent report, because Sir John Sargent was deputed from England as educational commissioner to prepare it for the government of undivided India, was adopted by the government after partition as the basis of its educational policy. It aims at introducing as speedily as possible a system of universal compulsory education free of charges for all boys and girls between the ages of 6 and 14. The report estimated that 40 years were required to achieve 100% literacy, but in the new India an all-India educational conference in Jan. 1948 recommended a reduction of that period to 16 years by means of two 5-year plans and one 6-year. Shortage of funds seriously impeded the implementation of the Sargent recommendations in the 1950s. (ME.; G. MA.; E. HD.)

INDIA, FRENCH, a general name for the former French possessions in India. When India received its independence in 1947, they comprised Pondicherry (112 sq.mi.), Karikal (52 sq.mi.) and Yanaon (Yanam) (6 sq.mi.) on the Coromandel coast; Mahé (23 sq.mi.) on the Malabar coast; Chandernagore (4 sq.mi.) in Bengal; and certain dependent loges, or plots, in the vicinity of former French factories.

Pondicherry was purchased in 1683 and Chandernagore permanently occupied in 1688. Mahé was acquired in 1721, Karikal in 1739 and Yanaon in 1750. They were captured by the English during the Anglo-French struggles in the second half of the 18th century and in the Napoleonic Wars but were restored to France in 1815 (see INDIA: History).

The dependent loges were ceded to the Indian union in Oct. 1947.

In May 1948 the French and Indian governments agreed to allow the populations of the French settlements to decide whether they should join India.

In 1948 the population, according to the census, was as follows: Pondicherry, 317,163; Karikal, 70,541; Mahé, 18,293; Yanaon, 5,853; and Chandernagore, 44.800.

Elections in Pondicherry, Karikal and Yanaon in Oct. 1948 resulted in a victory for those who favoured the retention of the connection with France; polling in Mahé had to be postponed because of rioting. As a result of municipal elections held on June 19, 1949, the inhabitants of Chandernagore opted for inclusion in the Indian union.

The remaining states of Pondicherry, Karikal, Yanaon and Mahé were transferred to Indian sovereignty Nov. 1, 1954, under an agreement signed by the French and Indian governments after a congress of representatives had voted in favour of union with India.

It was announced on Jan. 6, 1955, that the four settlements would constitute a single state of India under the name of the state of Pondicherry. The new state of Pondicherry had a population (1951 est.) of 330 688.

The chief town and seat of administration is Pondicherry (pop. [1955 est.] 62,716).

INDIAN, LATIN-AMERICAN. Of the 16,000,000 or more people who, according to estimates of A. L. Kroeber and J. H. Steward, inhabited the western hemisphere at the time of European discovery, about 15,000,000 lived in what is now Latin America. Heavy concentrations were in Mexico and adjacent parts of Central America with perhaps 5,000,000, and the Andean area of western South America with at least 6,000,000. Today these same areas tend to have proportionally large Indian populations. Thus while of the population of the U.S., only about 0.4% are Indians, in Ecuador, Bolivia, Peru and Guatemala the percentage of persons recognized as and called Indians runs from 40% to 50% and higher. There are large areas in Mexico, Guatemala and the Andes where the vast majority of the people are Indian in ancestry and maintain Indian languages and cultures. In much of Latin America the aboriginal population therefore has been of great importance historically and represents in modern times a highly significant segment of life. Nor are the Indians disappearing in Latin America. (The same is true of North America.) Although many individuals join the ranks of caboclos, *criollos*, mestizos, Ladinos — as the Europeanized classes are variously called — and although some Indian communities substitute European languages and many European ways for their own, the population of "Indian" Indians may actually increase as such "losses" are compensated for by the population growth that modern medicine permits. As colonial-type class systems break before modern communications and democratic ideas, the Indians may be expected to maintain and increase their importance in the economy and politics of many Latin-American nations.

ABORIGINAL LANGUAGES AND TRIBES

It is generally agreed that Indians began to migrate across

Bering strait 15,000 to 20,000 years ago, and continued to come in small numbers until about 4,000 years ago. Presumably they began from earliest times to spread over the whole hemisphere, and by 10,000 years ago there were migrant hunters in South America. (*See* ARCHAEOLOGY: *The New* World: Early Man.) When about 4,000 years ago agriculture, based mainly on maize and manioc, developed in the new world, and village life and city-states grew, extreme cultural variation resulted. In addition to differences based on ecological variations, there mere those of cultural intensity or complexity, difference~between nomadic tribes, for example, and urban civilizations. Movements of people and wars and conquests continued throughout history, so that—as pieced together from archaeological evidences and linguistic and ethnological distributions, as well as from what documentary evidences there are—the picture is one not only of extreme mobility but of a patchwork. Mysteries like those of the Basques or the gypsies in Europe are common in aboriginal America. Despite this, and the relatively small amount of research so far done on South American archaeology and languages, anthropologists have brought remarkable order to the data.

About 1,700 mutually unintelligible languages appear to have been spoken by the Indians of the area. In the 20th century these languages have been ordered somewhat independently by Norman McQuown, by Joseph Greenberg and by Morris Swadesh. (*See* also AMERICAN ABORIGINAL LANGUAGES for description and discussion of their history and characteristics.) The accompanying table includes all languages about which linguists have substantial knowledge, classified mainly according to Greenberg. The number of independent groupings tends to be reduced with increasing research.

A "tribe" may be identified with a particular language, but it is an error to confuse languages with social units, especially where settled agricultural populations of a variety of language groups have been joined politically, or where single widespread language groups are socially distinct. Thus, in Guatemala, the Quiché-speaking villages have nothing more in common with one another than with neighbouring Cakchiquel-speaking or Zutuhil-speaking villages. One cannot therefore speak of "the Quichés" as though they were a tribe like the Yahgan or the Siriono. Generally only the marginal nonagricultural areas of South America, and some of the tropical forest groups, were organized in tribes identified by the linguistic name.

ABORIGINAL CULTURAL GROUPINGS

The variety of cultures has been grouped meaningfully into areas as follows:

The Greater Southwest.—This region includes northern Mexico and the southwest area of the U.S. It would all have been part of Latin America if most of it had not been annexed by the United States. Because so little of it is now a part of Latin America, it need only be mentioned that at the time of the conquest it included a wide variety of tribal groups—the Navahos, the Pueblos, the Huichols and so forth. Many of these still exist, maintaining their distinctive cultures. Those which are in Mexico are included in the table.

Mesoamerica to the south included about 3,000,000 people in central and southern Mexico, the Yucatan peninsula, El Salvador, Guatemala and parts of Honduras, Nicaragua and Costa Rica. Among the many tribes of the region at least two, the Aztecs of Mexico and the Maya of Central America, developed what we think of as high civilizations. Both had hieroglyphic writing, complex political and religious systems and great art and science. (*See* AZTEC.)

The classic Maya practised slash-and-burn agriculture; the cornfields cleared in the jungle were abandoned when they lost fertility and new patches were cleared. This system of shifting cultivation, involving gradual shifts in habitation, discouraged the development of true cities. Instead, the Maya built huge, monumental city ceremonial centres. populated largely by priests, around which the rest of the people were distributed for many miles in every direction. Classic Maya society was not oriented toward war; conquest, tribute taking and a warrior class were foreign to their way of life. The Maya priests, who had the highest status in the society, developed art, architecture and calendrical systems to a high degree of sophistication.

The Aztecs, flowering much later, based their civilization on intensive maize agriculture, which made possible the development of cities. The society which centred around these cities and their temples was rigidly stratified; at the bottom of the social pyramid were the commoners and at its apex, the priests. The temple cult was fundamental to Aztec life. Since the rites of the temple required frequent sacrifices of war prisoners, warfare was common, and the warrior had high prestige. The outlying peoples were forced to bring tribute to the Aztec rulers, but were never welded into an integrated empire.

The Tropical Forests and Southern Andes.—Numbering somewhat over 2,000,000, these forest peoples were scattered over a tremendous rain forest area, primarily the vast Amazon river drainage, and spilling over into the southern Andes. They lived in semipermanent villages, around which they carried on slash-and-burn cultivation of such crops as bitter manioc, yams, arrowroot, beans, squash and taro; the villages were moved every generation or so when the soil around ceased to be productive. Hunting and fishing were also important activities. Characteristically, each village was an independent unit, with no political allegiance to any other. Within the village, the main unit was the extended family or lineage. Where the village consisted of a single such family group, the village head mas merely the family head; some multifamily villages had a hereditary chief, of limited powers, who was often also a shaman. Religious activities were often centred in the shaman, whose main functions as medicine man were to cure sickness, to prognosticate and to perform magic. Warfare was carried on to obtain human trophies and victims for cannibalistic feasts—not for conquest.

The tribes of the southern Andes, inhabitants of the northern edge of Chile and a small slice of northwest Argentina, were much like the peoples of the tropical forest, except that they had taken over many techniques from the more "civilized" peoples of the central Andes. They lived in widely separated villages, fortified for defense since warfare was continual in the area, and practised intensive farming of corn, beans, quinoa and potatoes. They also raised llamas and guinea pigs, and wove cloth of wool and cotton.

The Circumcaribbean and Subandean Regions.—The peoples of northern South and Central America and the Antilles numbered a little over 1,000,000 village-dwelling farmers. Although intensive agriculture was the main basis of the economy, along the coasts and in the Antilles the ocean was an important source of livelihood. The technology of these peoples included many items—like pottery, woven basketry, hammocks, thatch houses—characteristic of the tropical forests, and others—such as the use of metals, salt, the raising of guinea pigs—which were typical of the people of the high Andes. They produced enough material goods to allow local specialization and trade in such items as metals, salt, cloth and beads. They lived in permanent villages, which usually consisted of several extended family or lineage groups. Bonds between these kin groups were reinforced by strong political controls as society was characteristically divided into somewhat fluid classes. A group of hereditary chiefs constituted the upper class; nobility in general seems to have developed from an earlier class of warriors. Shaman priests performed religious rites in local temples, celebrating the powers of tribal gods. Many of the tribes entered into multicommunity states through federation and conquest, but none of these ever became completely consolidated like the state of the Inca in the high Andes. The subandean peoples differ from this general pattern largely in their greater approximation to central Andean culture; *i.e.*, in such items as copper smelting and construction of roads, stone houses. forts and bridges.

The Central Andes.—This region is fully comparable to Mesoamerica in complexity and general cultural achievement. A population of more than 4,500,000 lived in this thin strip of high mountain country, stretching from Colombia 2,000 mi. S. along the Andes to Ecuador. Intensive farming and herding supported the densest population and the largest and most permanent communities in South America. This population was integrated by a most efficient

Provisional Classification of Aboriginal Languages of Latin America

administrative system, and produced some remarkable technological achievements. The attainment of agricultural surpluses coupled with the construction of an elaborate system of roads and communications permitted the growth of truly urban centres. A strong centralized government developed uhich replaced traditional tribal custom by a complex code of laws and regulations enforced through a judicial system.

Religion was organized around a state temple cult, served by a graded priesthood. Social classes became hereditary. self-perpetuating castes; high-caste nobles took part in government and religious affairs while commoners tilled the soil or engaged in manufactures. Warfare was an implement of imperialist conquest rather than a source of slaves and ritual victims.

Marginal Regions. — In greatest contrast are the marginal peoples, a term referring to clumps of tribes widely scattered over different areas of South America. They include small tribal groups in the Chaco and in the interior forests of Brazil, shellfish gatherers of Chile. hunters of Patagonia and Tierra del Fuego. Their cultures differed greatly one from another; nhat they had in common was that they were all peoples of simple technology and rudimentary social organization; all told. they numbered about 750,000 people. They lived chiefly by hunting and gathering. although some of the northern groups practised a limited and not very efficient agriculture. Mostly these were nomadic bands, made up of a single kinship group or of several unrelated families or clans. Lineage groups were rarely larger than 60 persons ; chiefs or formal government were usually lacking. With subsistence depending on the availability of wild foods, their life was materially meagre. Their cultures were able to develop only those elaborations possible under conditions of nomadism and simple technology; these were chiefly in the fields of personal adornment, dances, songs and games. Religion generally laid great stress on shamanism and magic. Warfare was unorganized and typically defensive.

It is worth noting again that these various areas differed frorn one another not only in

the way of life of their peoples, but in the density of their populations. At one extreme, the marginal tribes of southern Argentina and Chile had exceedingly sparse populations — less than nine persons per 100 sq.km. — and naturally so, because of their nomadism and their subsistence on widely scattered wild foods. At the other extreme, the two areas of high civilization — Mesoamerica and the central Andes — had relatively dense populations, supported by intensive agriculture. Population density in the central Andes was about 720 persons per 100 sq.km. and in Mesoamerica 300. In between were the tropical forest areas, with a density of something like 10 to 50 persons per 100 sq.km., and the circumcaribbean area with a wide range including West Indian islands with densities over 500. Density of population, then, was closely correlated with cultural complexity, and with the development of political systems integrating larger numbers of people.

THE INDIANS TODAY

Although there are still areas in the interior of South America where Indians are hostile and virtually isolated, almost all Indians have been greatly affected by European contact and settlement; there are large areas in which Indians are no longer identifiable as such. Nevertheless it is no less true that Indians and Indian culture have been remarkably resistant to erosion. Many Indian techniques, especially in agriculture, food and household arts, were adopted by Europeans as soon as they settled in the new environment. Likewise, the Indians quickly accepted many items of European technology and merged the new religious and governmental systems with their own. In virtually all of Latin America, Indian and European cultural elements (and African wherever African Negroes had been imported) blended freely. Most of the interchange came in the first years of conquest and colonization, after which there was a long period of consolidation in which the cultural mixture became well established. In recent decades, with the improvement in communications, there appears to have begun a second great adjustment of Indians to the novelties of the world outside.

Perhaps it should be said not so much that Indian culture has been resistant as that Indians have adjusted to new circumstances within their own systems of values. One assumes then that where adjustment required major changes in values, the Indians either did not adjust or else they stopped being Indians. At least the approximately 7,000,000 Indians counted in censuses generally live by the values of their traditional cultures. There are other millions who share Latin-American culture, but these also identify themselves not as Indians but as nationals of the countries in which they live.

The fate of Indian communities in Latin America depended less on the nature of the conquest and colonization (which was fairly uniform) than on differences in aboriginal settlement and culture. Where Indians were populous and highly organized (as in Mesoamerica and the Andes) the Spaniards simply replaced the native religious and political central organization with their own bureaucracy; the Indians were exploited, as Indians, and retained their identity and large numbers. These are the areas that Elman Service calls Indo-America, including central and southern Mexico, Guatemala, the highlands of Colombia, Bolivia, Peru and Ecuador. At the other extreme the aboriginal marginal areas had sparse Indian populations of mobile independent tribes who generally were subjugated one by one and administered only with difficulty. As in North America, these tribes tended to maintain their identity and their ways of life, but as small islands in a sea of European culture (Service's Euro-America). Most of the erosion therefore occurred only in the tropical forest and circumcaribbean areas. There the Indians were settled in villages where Europeans could easily maintain contact and control; but since the Indians were relatively few in numbers and lived in somewhat independent communities, they lost many of their members to the European society, which became mixed European-Indian. Compared with those of Indo-America and of Euro-America, the Indians of this mestizo America have been losing their identity. But even there (except in the West Indies) they are far from being on the verge of disappearance; about 1,200,000 Indians — 17% of the population of mestizo America — are considered and consider themselves Indians.

It would be rash to predict the disappearance of Indian identity and cultures. But perhaps for the first time in history there began in the second half of the 20th century a serious attempt to bring to the Indians the benefits of modern medicine and technology, to build highways so that they could move their goods by truck and to offer genuine opportunity to learn new techniques, including those of literacy and business institutions. Whether Indian communities which voluntarily accepted novelties (without building the resistances often engendered by attempts to apply pressure) would lose their community integrity and culture together with their isolation remained a question. The sympathetic "Indianist" movement is furthest advanced in Mexico, where the evidence tends to show that new "adjustments" can be made without necessarily changing Indian values or destroying community identity; but any conclusion had to await future developments. INDIAN, NORTH AMERICAN. The European discoverers of the new world had at the outset only limited access to the two American continents and could not, therefore, form any judgment as to the extent and variety of the human settlement which had occurred prior to their coming upon the scene. Not until three centuries and more had gone by would all the regions of the western hemisphere be explored and the aboriginal inhabitants noted. For all practical purposes, it can be said that all geographical regions and all climatic zones of both continents were occupied. Human population had accommodated itself to sea level and to the ultramontane conditions of the high Andes, and from arctic to tropic temperatures. Moreover, this population, at the time of its greatest diffusion over the two continents, was divided into nearly 400 major tribal groups, with countless subdivisions. The social organizations developed within these groups ranged from the simplest atomistic nomadic societies to complicated religious and economic hierarchies. The languages spoken presented a bewildering variety and complexity. The accommodation was not limited to physical adjustments of the body, but was reflected in the extent to which the animal, vegetal and mineral resources of the various regions were utilized. This utilization included the diversion of water from natural stream beds to irrigate dry lands; the mining and processing of certain ores, such as gold, silver, and copper; the domestication of an astonishing number of food and fibre plants; the manufacture of textiles and ceramics; and the development of calendric systems involving accurate knowledge of the movements of heavenly bodies. No supportable evidence has been offered that the discoveries or inventions involved in these processes were imported from the old world.

Asiatic Origin. — It is generally agreed among students of man's prehistory that the first inhabitants of the western hemisphere did not originate there. The earliest remains of man thus far found in the Americas are essentially modern in type. They display none of the archaic or primitive characteristics of the man creatures found in Java (*Pithecanthropus erectus*) or China (*Sinanthropus pekinensis*) or the later Neanderthal man found widely in Europe and Africa. It is agreed also that America was never inhabited by anthropoids which could have given rise to a parent human stock. Granting that the point of origin was somewhere outside the hemisphere, it follows rationally that Asia

is the most likely place of beginning. The level of technological advancement could not have been too high at the time of the first migrations into the new world, and this fact must rule out long sea voyages or other hazards. The break between the American and Asiatic continents at Bering strait is so slight (a matter of 45 mi., with islands lying at the midway point) as to make it, in the opinion of authorities, the only practical route. The view is also held that the migration was not a single incident, but that waves of men continuing over a long period of time were responsible for the peopling of the continents. At least partial confirmation of this hypothetical route of migration is seen in the fact that various mammals invaded North America during Pleistocene (Ice Age) times, and their remains have been found in Alaska, in the high mountain plateaus in the west, on the Great Plains and as far south as Mexico, but rarely in eastern Canada. Similarities in cultural traits, on which further comment will be made, serve further to strengthen this view of an Asiatic-American link.

Glacial Age.—The probabilities as to when this migration took place are broadly framed within the terms of glacial advance and recession across the top of North America. The so-called Ice Age consisted of four intervals of maximum glaciation and three intervening nonglacial periods, or possibly two pairs of maximum glaciated periods with a long, middle, ice-free interval, in a total time span of about 250,000 years. The exact boundaries of these glacial patterns cannot be plotted in all areas; neither can the timing be stated too precisely. Geologists believe, however, that the central plain of Alaska (south of the Brooks range and east of the Coast range), and also the lowlands bordering the Bering sea and the Arctic ocean, were at no time glaciated. The great ice barriers formed, instead, on the Pacific slope of the Coast range and poured through mountain passes for some distance. A second (Keewatin) ice sheet spread eastward from the Hudson bay area and, during the last maximum, joined with the Pacific (Cordilleran) glacier across southern Canada and the northern part of the United States. The problem of chronology, then, is to determine during what years the last maximum glaciation endured and during what intervals openings or corridors between the two ice sheets were available for southward travel. Generally it is agreed that an ice-free land route extended along the arctic coast to the Mackenzie river and southward into what is now the United States as long ago as 20,000 years. This route may also have been open for a brief period about 40,000 years ago. The next prior ice-free period would have occurred during the Sangamon interglacial epoch about 75,000 years ago. The relation of sea level to land is another factor which may have a bearing on the time and manner of migration between the two continents. At the time of the last maximum glaciation, sea level in the vicinity of Bering strait was probably lowered by as much as 240 ft., as water was converted into ice. A certain amount of sinking of the land under the tremendous weight of ice was coincident with the dropping water level. As temperatures warmed and ice returned to water. both the land and the sea level began rising, but not at the same rate. Enormous quantities of water would be needed to make an appreciable difference in the level of the sea, while pressures within the earth would respond promptly to lessening weight. This leaves the possibility that a bridge of dry land actually existed during several millenia following the last glacial epoch. Modern coast survey charts reveal that much of the bottom between the continents does not exceed 20 fathoms (120 ft.). The pattern of glaciation on the Asiatic side of Bering strait is not clear in detail, but there seems to be a certain degree of correspondence between the phases as these developed east and west of the strait. It seems likely, then, that an open land route, extending from central Asia into central North America, existed 20,000 years ago. At a later time the Yukon river valley offered an ice-free route, and still later (10,000–8,000 years ago), the Liard and Peace river systems were available for transmontane travel. The Pacific coast slope was probably available for travel at about the same time. Some migrations may also have occurred by way of the Aleutian Islands, but this would have taken place at a considerably later date.

New World Contrasts.—The data offered by physical anthropology do not preclude the possibility that as long ago as the last (Sangamon) interglacial period there were in the old world human types capable of carrying out long intercontinental treks, if such did not involve sea voyages. It dues not follow from this that migration into the new world did take place at so remote a time, but neither should the possibility be ruled out in view of an increasing number of discoveries of human occupation which are difficult to explain in terms of postglacial time. The problem of assigning dates to occupation sites and to human artifacts in the Americas has been complicated by certain apparent basic inconsistencies between European and American prehistory. In Europe the so-called Neolithic (New Stone) Age did not occur until about 8,000 B.C., whereas in the western hemisphere, if geological evidence can be accepted, man was producing equivalent stone tools and implements as many as 12,000 years before that time. In Europe, also, the comparatively primitive Neanderthal men continued until rather late, perhaps 25,000 years ago, and the assumption has persisted that men predating such a period must be at least as primitive. No skeletal material had been found by mid-20th century in conjunction with the earliest occupation sites in the Americas, but the view had become widely accepted that Neanderthal is not the progenitor of modern man in either Europe or America. According to this view, it is quite possible that men of essentially modem anatomical structure could have migrated into the new world as long ago as the Sangamon interglacial period.

Folsom Culture.—The chronological data derived from European palaeontology formerly dominated American age estimates. Beginning in 1926, however, a series of discoveries of human artifacts associated with the bones of extinct species of mammals and with identifiable geological age elements began to alter the time reference material for American prehistory. The situation was still far from clear at mid-century, since the causes and dates of disappearance of such mammals as the mammoth, archaic bison and horse and a score of others was yet to be worked out. The first important discovery was made in northeastern New Mexico near the little town of Folsom, the name of which became associated with a specific type of projectile point, three types of implements and two kinds of stone knives. Facial fluting of the projectile points and one type of knife, together with very careful chipping of the outer edges, are the characteristic identifying marks. A more generalized type of artifact is likely to be larger and to lack the additional chipping of the working edges. It is the workmanship displayed in the manufacture of these stone points and of another series designated as Yuma that resulted in a rather thorough re-examination of the comparative archaeology of the old and new worlds. By European systems of classification, the Folsom and Yuma points belonged in the Neolithic series; yet the geologic evidence of the site at which the original Folsom material was found indicated a greater antiquity than the European Neolithic. The dramatic touch which, as much as anything else, brought notoriety to the Folsom discovery was the apparent lodgment of one of the projectile points between the ribs of an extinct species of bison. In later finds, the fossilized bones of the American camel, extinct and living forms of musk ox, the giant sloth and the native horse, as well as species whose descendants are found today, are associated with the human material. After the original Folsom discovery, similar sites were located between the towns of Portales and Clovis, S.M., and at the Lindenmeier ranch near Fort Collins, in northern Colorado. At each of these sites the deposits were located under a dark soil stratum which was formed during a wet cycle, indicative of the climatic conditions prevailing near the close of the Pleistocene, or late glacial, period. Following the initial discoveries of the Folsom culture complex, a number of other sites were identified as containing comparable material, while earlier discoveries which previously had not been classified mere recognized as belonging to the same general type. Most of the Folsom material was recovered in a region bounded by the Rocky mountains, from Alberta and Saskatchewan in Canada to southern New Mexico; on the east by the western boundary of the Dakotas, western Nebraska, Kansas,

Oklahoma and Texas, where it turns eastward to the Mississippi river. Some scattered evidences are reported west of the Rockies in the Great Basin in Utah and Nevada, and one site appears to occur in southeastern California.

The so-called Yuma projectile point was found also in Colorado for the first time, and takes its name from the county of that name where the discovery was first made. The craftsmanship displayed is also of a high order, the chief identifying characteristic being a long, slender blade with finely chipped diagonal grooves. The geology of the established sites indicates that Folsom and Yuma occurred contemporaneously over at least part of their range, but the Yuma people may have survived until more recently.

Older Strata. — The Folsom material probably is not the earliest record of human occupation in the new world. Near Albuquerque, N.M., a cave in the Sandia mountains was excavated beginning in 1939 and resulted in uncovering three levels of occupation. The top layer contained artifacts belonging to the modern Pueblo culture, though the material was in fact pre-Columbian. At the bottom of this first layer occurred a hard calcium carbonate deposit. Once this intact crust was removed, the excavators found a second level of habitation, containing Folsom artifacts, along with the bones of bison, mammoth, giant sloth, camel, native horse and wolf. A stratum of yellow ochre occurred, devoid of cultural material, and at first this was thought to be the true floor of the cave. Additional digging, however, disclosed a third layer containing man-made implements, together with bones of bison. camel, mammoth, mastodon and horse. Hearth places outlined in small stones brought from outside the cave were found at this layer, with charcoal and fragments of burned bones. The Sandia type of point is cruder than Folsom work; yet it has a characteristic general outline and a notch always on one side of the base. The association of materials in horizontal strata indicates a greater age for the Sandia material, though it is not possible to determine how much older than Folsom. The yellow ochre was probably deposited at a time when moist. cool conditions prevailed in the area, again suggesting a period falling at the end of the Pleistocene, or Ice Age.

Food Gatherers. — The Sandia discovery is not the only evidence of occupation by man prior to Folsom. Near Abilene in north central Texas, occupation levels at various depths ranging from 4 to 30 ft. beneath the surface were uncovered. The lowest (Abilene complex) level produced charcoal and crude tools, including scrapers, axes and leaf-shaped points somewhat comparable with the Sandia points. The bed on which this material was deposited is thought to date from the middle of the last glacial stage, or later. At a higher level occur implements and projectiles of a type to which the name Clear Fork was given. Resemblances to Folsom types are seen in this material. The top stratum, as at Sandia, contains remains of pre-Columbian Indians of the Texas area. The Abilene. Sandia and Folsom material are all suggestive of a hunting economy. and it is usually assumed that the men crossing over from Asia were hunters pursuing game and constantly searching for a more plentiful supply. Certainly the weapons and implements of this early man confirm this picture. In at least one instance, however, material was recovered from deposits of some antiquity which indicates that the people were seed gatherers and grinders rather than hunters. This is the so-called Cochise culture, the original site of which was discovered near Douglas, Ariz. The area was thoroughly explored and a record of occupation covering a very long period was reconstructed.

While an exact date could not be given at mid-20th century for the original entry of man into the new world, certain archaeological sites had been tentatively dated and these provided some clues to the possible antiquity of human occupation. As already indicated, a thoroughfare extending from southeast Asia and continuing through Alaska and out to the great central plain of North America was probably available to man 20,000 years ago; a similar corridor may have been open 20,000 years earlier. Speculation beyond that point seemed unwarranted. The Lindenmeier (Folsom) site in northern Colorado had been given a date of 10,000 to 25,000 years, with archaeologists favouring one or the other extreme. The Sandia site, assuming it to be older than Folsom, might well be placed at or near the upper range of the 10,000–25,000-year span. The Abilene culture was correlated with Sandia, while Cochise appeared to be at least 10,000 years old.

With the announcement in 1947 of successful tests to measure quantitatively the residual amounts of radiocarbon present in nonliving organic materials, a wholly new method of arriving at age determinations became possible. Subsequently the technique was applied to organic substances recovered from various archaeological sites, in collaboration with a committee composed of anthropologists and geologists.

THE PEOPLE

Physical Types. — The American Indian appears not to represent a homogeneous racial stock, though it has been customary so to describe him. This can be explained perhaps by the fact that certain outward characteristics seemed to be fairly uniformly present among the living Indians with whom Europeans came into contact. Thus, the reddish-brown skin, straight black hair, dark brown eyes, high cheekbones and scant beard and body hair generally observed among the various Indian tribes came to be accepted by the casual observer as the Indian type par excellence. Skeletal material from the earliest levels of occupation has been largely lacking and absence of comparative data tended to prolong the view of uniformity. Also, as there came to light skeletal material such as the Lagoa Santa skulls in Brazil, the Punin skull in Ecuador and the so-called Minnesota man, it was analyzed more with a view to determining what information it might provide with regard to the antiquity of the race than its place in a system of classification. In course of time all students came to remark one pronounced distinction between the earliest and later crania: the earliest are invariably longheaded (dolichocephalic), while the skulls which date from about the time of the development of agriculture or slightly before are broad (brachycephalic). It is thought that two waves of longheaded people moved into the new world, and that the earliest of the two might be termed a hyperdolichocephalic, or extra-longheaded specimen. It is even suggested that a line drawn between San Francisco, Calif., and the Gulf of Mexico would divide this earlier, or extra-longheaded, man from the later and less longheaded arrival; and moreover, such a line would divide seed gatherers and grinders such as characterized the Cochise culture of southeastern Arizona from the predominantly hunting culture typified, presumably, by Folsom remains. This may oversimplify the underlying situation, but it serves to emphasize the lack of homogeneity in this earliest material.

It is likely that the peopling of the American continents was accomplished over a long period of time, in successive waves of migration. Moreover, these succeeding waves were doubtless composed of people of different points of origin, quite likely of different language stocks, and certainly of nonhomogeneous physical types. In the first wave or series of waves moving over a considerable period of time, groups of people crossed into the new world, bringing with them such cultural elements as the bow, harpoon, atlatl (spear thrower), clubs, spears, perhaps daggers of stone and bone, chipped and flaked stone implements, bone awls, twisted cords and twined or woven baskets and nets, cooking with heated stones in vessels of bark, wood or skin, and the domesticated dog. In physical type, these first people represented a blend of three racial strains, all longheaded: (1) one resembling the stock called "Mediterranean"; (2) a more primitive form with heavy brow ridges, broad face and wide nose, usually identified as "Australoid"; and (3) a Negroid strain. The mixing of these types occurred before the movement into the new world got under way, and the migration occurred before people of Mongoloid features reached northeast Asia. The latter people are predominantly roundheaded, with relatively low head height, and flat nosed. These features are not found among skeletal remains identified with the earliest occupation levels. Eventually, a second wave of migration, composed of a Mongoloid people, crowded the earlier longheads into the peripheral areas of the new

TABLE I.—Aboriginal Indian Population, North of Mexico

Area	Date	Estimated Population
North Atlantic: (New England, New York, New Jersey, Pennsylvania)	1600	55,600
South Atlantic: (Delaware, Maryland, Virginia, West Virginia, the Carolinas, except Cherokee country)	1600	52,200
Gulf states: (Georgia, Florida, Alabama, Mississippi, Louisiana, Arkansas, Tennessee, Cherokee country)	1650	114,400
Central states: (Ohio valley from Alleghenies to Mississippi, Chippewa in Canada)	1650	75,300
The Plains (Canada to Gulf):		
Northern	1780	100,800
Southern	1690	41,000
Columbia River basin: (Washington, most of Oregon, northern half of Idaho)	1780	80,200
California	1769	260,000
Central mountain: [Nevada, Utah, parts of surrounding states)	1845	19,300
New Mexico and Arizona	1680	72,000
British America: (Eastern Canada, central Canada, British Columbia)	1600–1780	190,950
Alaska	1740	72,600
Greenland	1721	10,000
Total		1,153,450

Source: James Mooney, "The Aboriginal Population of America North of Mexico," Smithsonian Miscellaneous Collection, Vol. 80, No. 7 (1928).

Analysis of these figures according to modern political divisions yields roughly the following subtotals as of dates given above:

United States (except Alaska)	849,000
Alaska	73,000
British America	221,000
Greenland	10,000

world.

In reconstructing the prehistory of the American Indians, the roundheads are identified with the development of the high material cultures, indicating a greater capacity for invention and adaptation or perhaps indicating only that these later comers brought with them technologies which had not yet been developed at the time of the first migrations. The Eskimo people were the last to move into the new world, most estimates placing the time of their migration at about 2,000 years ago. In spite of their close resemblance to the Mongoloid type (narrow, flat nose, smoothness over the brow ridge and epicanthus fold at the inner eye), the Eskimos are essentially longheaded. This probably resulted from crossing with the earlier dolichocephalic Indian strains which preceded the Eskimos into the arctic area.

Population. — Estimates of the aboriginal population are inevitably based on information supplied by explorers. traders, missionaries and other early reporters. Any so-called estimate of the population as of the time of Christopher Columbus can be only a fictitious figure. Moreover: estimates based on first contacts are only as good as the reporter's observations are trustworthy. A more serious impediment to a completely accurate count is that some tribes, by the time the explorers. traders or missionaries caught up with them, had already been depopulated by epidemics reaching them from tribes in contact with Europeans or by enemy tribes obtaining more efficient killing weapons ahead of them. The estimates supplied by James Mooney in Table I, it should be noted, are given an approximate dating.

A. L. Kroeber submitted an almost identical total for the area north of Mexico, though he subgrouped the material to accord with subsistence areas rather than geographic boundaries. In addition, he ranked the areas according to population densities, expressed in numbers of persons per square kilometre: California area 43.40; northwest coast 28.30; southwestern United States 10.70; Columbia-Fraser river area 7.15; eastern area 6.95; arctic coast 4.02; Great Basin 2.47; and northern area 1.35. While the agricultural areas of the east and southwest contained the greater population (about 405,000 in all), Kroeber believed the predominantly fishing economy of the Pacific coast (Bering strait to southern California) had greater relative density of population, His estimates were: Pacific coast 25.2 persons per square kilometre; agricultural areas 10.1; remaining area north of Mexico 2.2.

Estimates of population for the entire hemisphere have fluctuated between wide ranges, running as high as 50,000,000 to 75,000,000 for the period A.D. 1200. Kroeber estimated the total at 8,400,000, divided about equally between the two continents, with 200,000 in the West Indies.

Language. — The wide distribution of a few major languages is thought to be a development of comparatively late times in human history; contrariwise, it is believed that in ancient times a great number of languages flourished, each confined to a limited geographical area and to a small population. Such a condition describes to a large extent the linguistic situation among the American Indians. The first identification of American languages and relationships between languages was accomplished by comparing vocabularies, and while this method may have resulted in overlooking many resemblances which later were discovered when grammatical structures were examined, nevertheless, the work of J. W. Powell, who first published a complete classification of the languages of the United States and Canada, remained the foundation work. His system of nomenclature, adding the adjective termination "-an^x or "-in" to a tribal name! was still followed at mid-20th century. All related Sioux languages, for example, are grouped under "Siouan," the Shoshone languages under "Shoshonean," etc. Powell's classification and distribution map, as published in 1891, contained 58 language stocks, of which 3 (Beothukan, Esselenian and Karankawan) were already extinct, and 2 others (Adaizan and Palaihnihanj were subsequently combined with other stocks. This left a net of 53 living linguistic stocks in the Powell classification. Other students identified 29 linguistic stocks for Mexico and Central America, and 84 for South America.

These, it should be noted, are not separate languages; each is actually a language family with from 1 to as many as 50 component languages.

Subsequent workers in the area north of Mexico (Roland B. Dixon and Kroeber for California) began to study the morphology of the Indian languages and to discover relationships where none had appeared before. Edward Sapir then found that methods developed in the study of Indo-European languages could be applied equally to the unwritten American languages. Such linguistic phenomena as borrowing from other languages, grammatical developments, dialectic blending and social differentiation of speech all operated in the primitive language as in more sophisticated tongues. Sapir in 1929 suggested a regrouping of Powell's so-odd language stocks into six major divisions according to type. This involved shifting some stocks under new headings, creating some descriptive titles and demonstrating relationships not previously recognized. Sapir's principal contributions consisted of: (1) proposing the Nadene stock, to combine Athabaskan, Haida and Tlingit, each of which had been classified separately by Powell; (2) extension of the term Hokan (first used by Dixon and Kroeber for certain California languages) to include the Coahuiltecan languages of Texas and a Central American group; (3) the Uto-Aztekan division, in which were brought together Piman, Shoshonean and Nahuatl; and (4) the Algonkin-Ritwan stock, grouping the extensive Algonkin languages with the Wiyot and Yurok of California.

The six linguistic groups proposed by Sapir, with brief descriptions of the salient features of each, are as follows:

1. *Eskimo-Aleut;* Polysynthetic and inflective; suffixes employed, but never prefixes; verb modified principally as regards mode and person and to distinguish between the transitive and intransitive actions.

2. *Algonkin-Wakashan:* Also polysynthetic; Algonkin employs inflection; suffixes, prefixes to a lesser extent; weak development of case; noun and verb stems markedly subject to suffixing with instrumental, adverbial and specifying elements.

3. *Nadene:* Strongly characterized as "tone" language, in which pitch of the voice is used to shade meanings. Monosyllabic elements, prevailingly nominal and having fixed order with reference to each other, are combined into loose word forms; emphasizes voice and aspect rather than tense; distinguishes carefully between active and static verb forms.

4. *Penutian:* More tightly knit than preceding three, analogies with Indo-European languages; uses suffixes more formally; many types of inner stem changes; true nominal cases.

5. *Hokan-Siouan:* Prevailingly agglutinative; tendency to use prefixes rather than suffixes for formal elements; distinguishes active **and**

static verbs.

6. *Aztec-Tanoan:* Moderately polysynthetic; many formal elements suffixed;sharp distinction between noun and verb; free use of reduplication, compounding of stems and nominal incorporation; many postpositions; pronominal elements differentiated by subject and object, but not for transitive and intransitive constructions.

Table II contains Powell's classification by linguistic stocks; Sapir's organization of the same material by major types; and C. F. Voegelin's arrangement of the languages north of Mexico still spoken. The latter writer estimates that more than half (slightly less than 150) of the aboriginal languages survived.
